Matrix Theory

Linear algebra for 21-242 at Carnegie Mellon

21-242

A proof-based treatment of linear algebra written alongside 21-242 Matrix Theory. It follows the course closely and covers a good deal more; anything outside the course is marked.

Reading this book

Proofs are preceded, where it helps, by what they use, the techniques they rely on, hints, and a sketch. The web version reveals these one at a time.

Proofs and exercises carry a difficulty:

ROUTINE	Follows directly from the definitions; a few lines.
STANDARD	Typical homework level; needs one real idea.
HARD	Upper end of course level; several ideas or a delicate argument.
CHALLENGE	Harder than the course expects. Skip it if you are targeting course-level problems.

Material marked BEYOND 21-242 goes past what the course covers and can be skipped.

Chapter 1

Vector spaces

Fields, the vector space axioms, span, subspaces, linear independence, bases, and coordinates.

1.1 Fields

In $\mathbb{R}$ we can add, subtract, multiply, and divide by any nonzero number. In $\mathbb{R}^2$ we can add two vectors and scale a vector by a real number, but there is no useful way to multiply or divide two vectors. Linear algebra keeps these roles apart. Vectors only need to be added and scaled, while the numbers that do the scaling, the scalars, need the full arithmetic of $\mathbb{R}$. Before we define vector spaces in Section 1.2, this section makes "full arithmetic" precise. The resulting notion, a field, is all we will ever ask of our scalars, so the theory applies verbatim over $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, and number systems as unfamiliar as $\mathbb{F}_2$, where $1 + 1 = 0$.

1.1.1 The field axioms

Intuition (What we need from scalars). The basic computational problem of linear algebra is solving systems of linear equations. Take the smallest case: one equation $ax + c = d$ in one unknown, with $a \neq 0$. Over $\mathbb{R}$ we subtract c and divide by a without a second thought. Spelled out, subtracting c means adding $-c$ to both sides and simplifying the left side with

$$(ax + c) + (-c) = ax + (c + (-c)) = ax + 0 = ax,$$

and dividing by a means multiplying by a^{-1} and simplifying with

$$a^{-1}(ax) = \big(a^{-1}a\big)x = 1x = x.$$

Gauss–Jordan elimination (Section 3.3) solves systems of any size with the same moves: it adds a multiple of one equation to another and divides by nonzero pivots. So we want two operations that can be undone, that can be regrouped and reordered freely, that have neutral elements 0 and 1, and that are linked by distributivity, so that multiplying a sum means multiplying each term. The field axioms are exactly this list.

Definition 1.1.1 (Field). A **field** is a set F together with two operations, **addition** $+ : F \times F \to F$ and **multiplication** $\cdot : F \times F \to F$, that satisfy the following **field axioms**.

- *Commutativity.* For all $a, b \in F$, $a + b = b + a$ and $ab = ba$.
- *Associativity.* For all $a, b, c \in F$, $(a + b) + c = a + (b + c)$ and $(ab)c = a(bc)$.
- *Distributivity.* For all $a, b, c \in F$, $a(b + c) = ab + ac$.
- *Additive identity.* There is an element $0 \in F$ such that $a + 0 = a$ for all $a \in F$.
- *Multiplicative identity.* There is an element $1 \in F$ with $1 \neq 0$ such that $a \cdot 1 = a$ for all $a \in F$.
- *Additive inverses.* For every $a \in F$ there is some $b \in F$ with $a + b = 0$.
- *Multiplicative inverses.* For every $a \in F$ with $a \neq 0$ there is some $b \in F$ with $ab = 1$.

The elements of F are called **scalars**. We write ab for $a \cdot b$.

Remark 1.1.2. Since $+$ and $\cdot$ are functions $F \times F \to F$, sums and products of elements of F lie in F. When we check that a candidate set is a field, this closure has to be checked along with the axioms.

We stated the identity, inverse, and distributive axioms on one side only. Commutativity supplies the other side: $0 + a = a$, $1a = a$, $b + a = 0$ and $ba = 1$ for the inverses b above, and

$$(a + b)c = c(a + b) = ca + cb = ac + bc.$$

We use these mirrored forms freely and cite them by the axiom they come from.

Finally, read the quantifiers carefully. The identity axioms say that *some* element 0 satisfies $a + 0 = a$ for every a, and similarly for 1. The axioms after them then refer to "0" and "1" as if these were determined. If a field could contain two different additive identities, the condition $a \neq 0$ would be ambiguous. Theorem 1.1.9 shows that this cannot happen, and the proof of its part (a) uses only commutativity and the identity axioms, so the argument is not circular.

Example 1.1.3 ($\mathbb{Q}$ and $\mathbb{R}$). $\mathbb{R}$, with its usual addition and multiplication, is a field; we take the arithmetic of real numbers as known. So is $\mathbb{Q}$: sums, products, and negatives of rational numbers are rational, $1/q$ is rational for every nonzero rational q, and identities such as $a(b + c) = ab + ac$ hold in $\mathbb{Q}$ because they hold in $\mathbb{R}$. (Proposition 1.1.33 makes this last argument general.)

Example 1.1.4 (The field with two elements). Let $\mathbb{F}_2 = \{0, 1\}$, with

$$0 + 0 = 1 + 1 = 0, \quad 0 + 1 = 1 + 0 = 1, \quad 1 \cdot 1 = 1, \quad 0 \cdot 0 = 0 \cdot 1 = 1 \cdot 0 = 0.$$

These are the parity rules for integers if we read 0 as "even" and 1 as "odd": odd plus odd is even, odd times odd is odd, and so on. Both operations are commutative by inspection, 0 and 1 are identities with $0 \neq 1$, the additive inverse of 0 is 0 and that of 1 is 1 (as $1 + 1 = 0$), and 1 is its own multiplicative inverse. Associativity and distributivity can be checked case by case, or deduced from Lemma 1.1.21 below, since $\mathbb{F}_2$ is $\mathbb{Z}/2\mathbb{Z}$.

So a field's arithmetic can look quite unlike that of $\mathbb{R}$. An argument about general fields that silently assumes $1 + 1 \neq 0$ is not valid in $\mathbb{F}_2$.

Non-example 1.1.5 ($\mathbb{Z}$). The integers satisfy every field axiom except the existence of multiplicative inverses. That one fails for $a = 2$: for every $b \in \mathbb{Z}$ the product $2b$ is even, so $2b \neq 1$. Correspondingly, the equation $2x = 1$ has no solution in $\mathbb{Z}$.

Non-example 1.1.6 (Componentwise multiplication on $\mathbb{R}^2$). Give $\mathbb{R}^2$ the componentwise operations

$$(a, b) + (c, d) = (a + c, b + d), \quad (a, b)(c, d) = (ac, bd).$$

Every axiom except multiplicative inverses holds, because each holds in each coordinate separately; the identities are $(0, 0)$ and $(1, 1)$. But $(1, 0) \neq (0, 0)$ has no inverse, since $(1, 0)(c, d) = (c, 0) \neq (1, 1)$ for every (c, d). So the obvious way to multiply vectors in $\mathbb{R}^2$ does not give a field. Section 1.1.4 gives $\mathbb{R}^2$ a less obvious multiplication that does.

Intuition (What each axiom is for). Here is what goes wrong when one axiom is dropped.

- Without multiplicative inverses we cannot divide by pivots. In $\mathbb{Z}$, the equation $2x = 1$ has no solution.
- Without additive inverses we cannot subtract one equation from another. In $\{0, 1, 2, \ldots\}$, the equation $x + 1 = 0$ has no solution.
- Without associativity, multiplying $ax = b$ by a^{-1} gives $a^{-1}(ax) = a^{-1}b$, and we could not regroup the left side as $\left(a^{-1}a\right)x = x$.
- Without commutativity of multiplication, $ax = b$ and $xa = b$ are different equations. Square matrices multiply like this (Section 2.4).
- Without distributivity, nothing links $+$ to $\cdot$, since it is the only axiom that mentions both. Even $0a = 0$ (Proposition 1.1.15) can fail: Exercise 1.1.55 builds a structure satisfying every other axiom in which $0 \cdot 0 \neq 0$.
- Without $1 \neq 0$, the one-element set $\{0\}$ with $0 + 0 = 0 \cdot 0 = 0$ would be a field. It would also be the only new example, since $1 = 0$ forces $F = \{0\}$ (Exercise 1.1.39).

1.1.2 Consequences of the axioms

From now on, F denotes a field. All we know about F is the axioms, so facts that are second nature in $\mathbb{R}$, such as $0a = 0$ and $(-a)(-b) = ab$, need proofs. In exchange, each such proof establishes the fact in every field at once.

Technique 1.1.7 (Proving from axioms). When objects are defined by axioms, as fields are here and vector spaces will be in Section 1.2, the only facts available are the axioms and what has already been proved from them. A fact that is obvious for real numbers is not available until it is proved, because a general field need not look like $\mathbb{R}$.

The move is to write the argument as a chain of equalities that changes one thing at a time, and to justify each link by the axiom or earlier result it uses. Watch for steps that move a term past another (commutativity) or regroup (associativity): in $\mathbb{R}$ we make these without noticing.

Reach for it whenever the hypotheses are an axiom system and the claim is an identity or an elementary property. If you are stuck, ask which axioms can connect the objects in the claim. For example, distributivity is the only axiom that involves both $+$ and $\cdot$, so any fact relating 0 (an additive object) to multiplication must go through it. The canonical example is $0a = 0$ (Proposition 1.1.15).

Used in. Theorem 1.1.9, Proposition 1.1.13, Proposition 1.1.15, Proposition 1.1.16, Proposition 1.1.17, Proposition 1.1.30, Proposition 1.1.33, Exercise 1.1.38, Exercise 1.1.39, Exercise 1.1.58, Proposition 1.2.5, Proposition 1.2.10, Proposition 1.2.22, Proposition 1.2.27, Proposition 1.2.28, Proposition 1.2.30, Proposition 1.2.32, Proposition 1.2.33, Proposition 1.2.34, Proposition 1.2.35, Exercise 1.2.54, Exercise 1.2.55, Exercise 1.2.56, Exercise 1.7.14, Problem 1.2, Lemma 2.1.22, Proposition 4.6.2, Theorem 4.6.22, Proposition 6.1.4.

Uniqueness

The identity and inverse axioms assert that certain elements exist, not that they are unique. Uniqueness is what entitles us to speak of *the* zero of F and *the* inverse of a.

Technique 1.1.8 (Uniqueness via two candidates). To show that at most one object has a property P, suppose x and x' both have P and prove $x = x'$. Usually one evaluates a single well-chosen expression in two ways, once using that x has P and once using that x' has P.

Reach for it whenever a claim says "the", "unique", or "exactly one". Existence and uniqueness are separate claims: prove existence by producing an object, and uniqueness by this technique. The canonical example is the uniqueness of 0 in Theorem 1.1.9, where the expression is $0 + 0'$.

Used in. Theorem 1.1.9, Exercise 1.1.11, Corollary 1.1.14, Proposition 1.1.16, Exercise 1.1.37, Exercise 1.1.46, Exercise 1.1.47, Proposition 1.2.27, Proposition 1.2.28, Proposition 1.2.30, Proposition 1.2.34, Exercise 1.2.43, Exercise 1.2.52, Proposition 1.6.16, Exercise 1.7.6, Exercise 1.7.7, Exercise 1.7.11, Problem 1.3, Problem 1.17, Proposition 2.1.4, Theorem 2.2.1, Proposition 2.3.10, Proposition 2.3.17, Proposition 2.4.3, Theorem 2.5.10, Exercise 2.5.37, Exercise 2.5.49, Exercise 2.6.42, Exercise 2.6.43, Theorem 3.3.17, Corollary 3.3.18, Proposition 3.4.27, Problem 3.2, Problem 3.17, Exercise 4.3.44, Proposition 4.4.31, Proposition 4.5.16, Proposition 4.6.7, Theorem 4.6.30, Theorem 4.7.22, Proposition 4.7.32, Proposition 5.2.5, Proposition 5.3.17, Theorem 6.4.6, Theorem 6.4.24, Theorem 6.4.38, Proposition 6.5.27, Theorem 6.6.3, Proposition 6.6.9, Theorem 7.1.14, Corollary 7.1.17, Proposition 7.1.29, Theorem 7.1.45, Exercise 7.1.51, Theorem 7.6.2, Notation 8.3.10, Theorem 8.3.23, Theorem A.1.14, Proposition A.2.4, Theorem A.3.10, Proposition B.1.2, Exercise 2.6.49, Exercise 4.6.39, Exercise 4.6.54, Exercise 6.6.37, Exercise 7.1.58, Exercise A.2.9.

Theorem 1.1.9 (Uniqueness of identities and inverses). Let F be a field.

(a) F has exactly one additive identity and exactly one multiplicative identity.

(b) Every $a \in F$ has exactly one additive inverse, and every nonzero $a \in F$ has exactly one multiplicative inverse.

Proof. ROUTINE

Uses. Definition 1.1.1 (Field)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Proving from axioms (Technique 1.1.7)
Hint 1. Suppose 0 and $0'$ are both additive identities. Find one expression that involves both.
Hint 2. Evaluate $0 + 0'$ twice: once using that $0'$ is an identity, once using that 0 is.
Hint 3. For inverses, suppose $a + b = 0$ and $a + b' = 0$. Start from $b = b + 0$, replace 0 by $a + b'$, and regroup.
Sketch. Each identity absorbs the other: $0 = 0 + 0' = 0' + 0 = 0'$. If b and b' are additive inverses of a, insert $0 = a + b'$ into $b = b + 0$ and regroup to get $(b + a) + b' = 0 + b' = b'$. The multiplicative statements are the same arguments with $\cdot$ and 1 in place of $+$ and 0.

(a) Suppose 0 and $0'$ both satisfy the additive identity axiom. Then

$$\begin{aligned} 0 &= 0 + 0' && (\text{as } \ 0' \ \text{ is an additive identity}) \\ &= 0' + 0 && (\text{commutativity}) \\ &= 0' && (\text{as } \ 0 \ \text{ is an additive identity}). \end{aligned}$$

The same argument, with 1 and $1'$ in place of 0 and $0'$ and multiplication in place of addition, shows that the multiplicative identity is unique. Realize that we used only commutativity and the identity axioms. So from here on "0" and "1" are unambiguous, and the remaining axioms say what they were meant to say.

(b) Let $a \in F$, and suppose $a + b = 0$ and $a + b' = 0$. Then

$$\begin{aligned} b &= b + 0 && (\text{additive identity}) \\ &= b + (a + b') && (\text{as } \ a + b' = 0\ ) \\ &= (b + a) + b' && (\text{associativity}) \\ &= 0 + b' && (\text{as } \ b + a = a + b = 0\ ) \\ &= b' && (\text{additive identity}), \end{aligned}$$

as desired. If $a \neq 0$ and $ab = ab' = 1$, the same chain with multiplication in place of addition and 1 in place of 0 gives $b = b'$. □

Notation 1.1.10. By Theorem 1.1.9 we may write $-a$ for the additive inverse of a, and a^{-1} for the multiplicative inverse of $a \neq 0$. **Subtraction** and **division** are defined by

$$a - b = a + (-b), \quad \frac{a}{b} = ab^{-1} \quad (b \neq 0).$$

For a positive integer n, a^n is the product of n copies of a, and $a^0 = 1$.

Exercise 1.1.11. ROUTINE Show that $-0 = 0$, and that $-(a+b) = (-a)+(-b)$ for all $a, b \in F$.

Solution on page 1024

Remark 1.1.12. Regrouping arguments like the solution of Exercise 1.1.11 get long, so we record a convenience. Associativity implies that all ways of parenthesizing a sum $a_1 + a_2 + \cdots + a_n$ give the same element: by strong induction on n, each of them equals $(\cdots((a_1 + a_2) + a_3) + \cdots) + a_n$. Commutativity then implies that the order of the terms does not matter either, since any reordering is a sequence of swaps of adjacent terms. The same holds for products. From now on we drop such parentheses and reorder sums and products freely.

Arithmetic in a field

We now return to the problem that motivated the definition.

Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$). Let $a, b \in F$.

(a) The equation $a + x = b$ has exactly one solution $x \in F$, namely $x = b - a$.

(b) If $a \neq 0$, the equation $ax = b$ has exactly one solution $x \in F$, namely $x = b/a$.

Proof. ROUTINE

Uses. Definition 1.1.1 (Field), Notation 1.1.10
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Existence and uniqueness are separate claims. For existence, substitute the proposed solution.
Hint 2. For uniqueness, take any solution x of $a + x = b$, add $-a$ to both sides on the left, and regroup to isolate x.
Sketch. Substituting $x = b - a$ and regrouping gives $a + (b - a) = (a + (-a)) + b = b$. Conversely, if $a + x = b$, then $x = ((-a) + a) + x = (-a) + (a + x) = (-a) + b = b - a$. Part (b) is the same argument with a^{-1} and 1 in place of $-a$ and 0.

(a) First, $x = b - a$ is a solution:

$$\begin{aligned} a + (b - a) &= a + ((-a) + b) && \text{(definition of subtraction, commutativity)} \\ &= (a + (-a)) + b && \text{(associativity)} \\ &= 0 + b = b && \text{(additive inverse, additive identity).} \end{aligned}$$

Conversely, suppose $a + x = b$. Then

$$\begin{aligned} x &= 0 + x && \text{(additive identity)} \\ &= ((-a) + a) + x && \text{(additive inverse)} \\ &= (-a) + (a + x) && \text{(associativity)} \\ &= (-a) + b = b - a && \text{(as } a + x = b \text{, commutativity),} \end{aligned}$$

so $b - a$ is the only solution.

(b) Suppose $a \neq 0$, so that a^{-1} exists. Then $x = b/a = ba^{-1}$ is a solution, since by commutativity, associativity, and the inverse and identity axioms,

$$a\big(ba^{-1}\big) = a\big(a^{-1}b\big) = \big(aa^{-1}\big)b = 1b = b.$$

Conversely, if $ax = b$, the same axioms give

$$x = 1x = \big(a^{-1}a\big)x = a^{-1}(ax) = a^{-1}b = b/a,$$

so b/a is the only solution. □

Part (b) is what the section set out to guarantee: in any field, a linear equation in one unknown with a nonzero coefficient has exactly one solution. The uniqueness half is often used in the following form.

Corollary 1.1.14 (Cancellation). Let $a, b, c \in F$. If $a + b = a + c$, then $b = c$. If $ab = ac$ and $a \neq 0$, then $b = c$.

Proof. ROUTINE

Uses. Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Both b and c solve one equation of the kind in Proposition 1.1.13. Which one?
Hint 2. They both solve $a + x = d$, where $d = a + b$. Apply the uniqueness in part (a) of Proposition 1.1.13.
Sketch. b and c are two solutions of $a + x = a + b$, which has only one solution. Likewise b and c both solve $ax = ab$ when $a \neq 0$.

Suppose $a + b = a + c$. Then b and c are both solutions of the equation $a + x = a + b$, which has exactly one solution by part (a) of Proposition 1.1.13. Hence $b = c$. If $ab = ac$ with $a \neq 0$, then b and c both solve $ax = ab$, and part (b) of Proposition 1.1.13 gives $b = c$. □

Intuition. No axiom says anything about a product with 0. The only fact we have about 0 is additive, namely $0 + 0 = 0$, and distributivity is the only axiom that converts additive facts into multiplicative ones. So multiply $0 + 0 = 0$ by a and see what distributivity says.

Proposition 1.1.15 (Multiplying by zero). For every $a \in F$, $0a = a0 = 0$.

Proof. ROUTINE

Uses. Definition 1.1.1 (Field), Corollary 1.1.14 (Cancellation)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Which axiom could say anything about a product involving 0? Only one axiom mentions both $+$ and $\cdot$.
Hint 2. Multiply both sides of $0 + 0 = 0$ by a and expand with distributivity.
Hint 3. You get $a0 + a0 = a0$. Compare it with $a0 + 0 = a0$ and cancel.
Sketch. Distributivity turns $0 + 0 = 0$ into $a0 + a0 = a0 = a0 + 0$. Cancelling $a0$ (Corollary 1.1.14) gives $a0 = 0$, and commutativity gives $0a = 0$.

Let $a \in F$. Then

$$\begin{aligned} a0 + a0 &= a(0 + 0) && \text{(distributivity)} \\ &= a0 && \text{(additive identity)} \\ &= a0 + 0 && \text{(additive identity).} \end{aligned}$$

Cancelling $a0$ from both sides (Corollary 1.1.14) gives $a0 = 0$. By commutativity, $0a = a0 = 0$. □

The proof converted the additive fact $0 + 0 = 0$ into the multiplicative fact $a0 + a0 = a0$. The same trick shows that $0\mathbf{v} = \mathbf{0}$ for vectors in Section 1.2.

Intuition. Every sign rule below comes from one observation: to show that an element equals $-x$, it is enough to show that it is *an* additive inverse of x, since there is only one. In particular $(-1)a$ is an additive inverse of a, and once $-a = (-1)a$ is known, signs are just factors of -1 that can be moved around.

Proposition 1.1.16 (Sign rules). For all $a, b \in F$:

(a) $-(-a) = a$;

(b) $(-1)a = -a$;

(c) $(-a)b = -(ab) = a(-b)$;

(d) $(-a)(-b) = ab$.

Proof. ROUTINE

Uses. Theorem 1.1.9 (Uniqueness of identities and inverses), Proposition 1.1.15 (Multiplying by zero), Definition 1.1.1 (Field)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Proving from axioms (Technique 1.1.7)

Hint 1. To show that an element equals $-x$, show that it is an additive inverse of x and quote Theorem 1.1.9.
Hint 2. For (b), compute $a + (-1)a$ by writing $a = 1a$ and using distributivity and Proposition 1.1.15.
Hint 3. For (c) and (d), rewrite each negative as (-1) times something using (b), and move the factors -1 around with associativity and commutativity.
Sketch. a is an additive inverse of $-a$, which gives (a). Distributivity and $0a = 0$ give $a + (-1)a = (1 + (-1))a = 0$, which gives (b). Then (c) is (b) plus associativity and commutativity, and (d) is (c) twice followed by (a).

(a) Since $(-a) + a = a + (-a) = 0$, the element a is an additive inverse of $-a$. By Theorem 1.1.9, $a = -(-a)$.

(b) We compute

$$\begin{aligned} a + (-1)a &= 1a + (-1)a && \text{(multiplicative identity)} \\ &= (1 + (-1))a && \text{(distributivity)} \\ &= 0a && \text{(additive inverse)} \\ &= 0, \end{aligned}$$

where the last step is Proposition 1.1.15. So $(-1)a$ is an additive inverse of a, and $(-1)a = -a$ by Theorem 1.1.9.

(c) By (b), associativity, and (b) again, $(-a)b = ((-1)a)b = (-1)(ab) = -(ab)$. Using commutativity and what we just proved, $a(-b) = (-b)a = -(ba) = -(ab)$.

(d) By (c) twice and then (a), $(-a)(-b) = -(a(-b)) = -(-(ab)) = ab$. □

In particular $(-1)(-1) = 1$, and $(a - b)c = ac - bc$ by distributivity and (c). One more consequence is used constantly, for instance whenever we factor an expression and set each factor equal to zero.

Proposition 1.1.17 (No zero divisors). If $a, b \in F$ and $ab = 0$, then $a = 0$ or $b = 0$. Equivalently, a product of nonzero elements of F is nonzero.

Proof. ROUTINE
Uses. Definition 1.1.1 (Field), Proposition 1.1.15 (Multiplying by zero)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. To prove "$a = 0$ or $b = 0$", assume one of them is nonzero and prove that the other is zero.
Hint 2. If $a \neq 0$, then a^{-1} exists. Multiply $ab = 0$ by it.
Sketch. If $a \neq 0$, then $b = 1b = (a^{-1}a)b = a^{-1}(ab) = a^{-1}0 = 0$.

Suppose $ab = 0$. If $a = 0$ we are done, so suppose $a \neq 0$. Then a^{-1} exists, and

$$\begin{aligned} b &= 1b && \text{(multiplicative identity)} \\ &= (a^{-1}a)b && \text{(multiplicative inverse)} \\ &= a^{-1}(ab) && \text{(associativity)} \\ &= a^{-1}0 && (\text{as } ab = 0) \\ &= 0, \end{aligned}$$

where the last step is Proposition 1.1.15. So $a = 0$ or $b = 0$. □

The integers also have no zero divisors, so this property alone does not make a field. In Section 1.1.3 we meet number systems that have zero divisors, and there the uniqueness in part (b) of Proposition 1.1.13 fails.

Exercise 1.1.18. ROUTINE Find all $x \in F$ with $x^2 = x$.

Solution on page 1024

1.1.3 The fields $\mathbb{F}_p$

$\mathbb{F}_2$ is the first of an infinite family of finite fields, built from arithmetic with remainders.

Definition 1.1.19 (Integers modulo n). Let $n \geq 2$ be an integer. For $x \in \mathbb{Z}$, write $x \bmod n$ for the remainder of x on division by n, that is, the unique $r \in \{0, 1, \ldots, n-1\}$ such that $n \mid x - r$. The **integers modulo** n are the set $\mathbb{Z}/n\mathbb{Z} = \{0, 1, \ldots, n-1\}$ with the operations

$$a +_n b = (a + b) \bmod n, \quad a \cdot_n b = (ab) \bmod n.$$

This is clock arithmetic: in $\mathbb{Z}/12\mathbb{Z}$, $9 +_{12} 5 = 2$ and $5 \cdot_{12} 5 = 1$. Outside of proofs we drop the subscripts and write $a + b$ and ab, once it is clear which n we work with.

All the field axioms except multiplicative inverses hold in $\mathbb{Z}/n\mathbb{Z}$ for every n. Structures like this are common enough to have a name.

Definition 1.1.20 (Commutative ring). A **commutative ring** is a set with an addition and a multiplication that satisfy all the field axioms, except possibly the existence of multiplicative inverses and the condition $1 \neq 0$.

So every field is a commutative ring. The integers and componentwise $\mathbb{R}^2$ (Non-example 1.1.6) are commutative rings that are not fields, and so are polynomials with coefficients in a field (Section 7.1).

Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$). Let $n \geq 2$.

(a) For all $x, y \in \mathbb{Z}$, $(x \bmod n) +_n (y \bmod n) = (x + y) \bmod n$ and $(x \bmod n) \cdot_n (y \bmod n) = (xy) \bmod n$.

(b) $\mathbb{Z}/n\mathbb{Z}$ is a commutative ring with identities 0 and 1. The additive inverse of $a \neq 0$ is $n - a$.

Proof. STANDARD

Uses. Definition 1.1.19 (Integers modulo n), Definition 1.1.20 (Commutative ring), the division algorithm: $x \bmod n = y \bmod n$ if and only if $n \mid x - y$

Hint 1. Every axiom except inverses is either an identity, like associativity, or asks for an identity element. The identities hold in $\mathbb{Z}$; you need a way to carry them over to $\mathbb{Z}/n\mathbb{Z}$.

Hint 2. For (a), x and $x \bmod n$ differ by a multiple of n. What does that say about $(x + y)$ versus $(x \bmod n) + (y \bmod n)$?

Hint 3. For (b), use (a) to write both sides of each identity in $\mathbb{Z}/n\mathbb{Z}$ as the remainder of the corresponding side of the same identity in $\mathbb{Z}$.

Sketch. Since x and $x \bmod n$ differ by a multiple of n, so do $x + y$ and $(x \bmod n) + (y \bmod n)$, and likewise for products; this is (a). By (a), each side of an identity such as associativity in $\mathbb{Z}/n\mathbb{Z}$ is the remainder of the corresponding side in $\mathbb{Z}$, where the identity holds. The identities are 0 and 1, and $a +_n (n - a) = 0$.

Throughout we use the fact, from the division algorithm, that $x \bmod n = y \bmod n$ if and only if $n \mid x - y$. In particular $n \mid x - (x \bmod n)$ for every $x \in \mathbb{Z}$.

(a) Let $x, y \in \mathbb{Z}$, and write $x' = x \bmod n$ and $y' = y \bmod n$. Then

$$(x + y) - (x' + y') = (x - x') + (y - y')$$

is a sum of multiples of n, so $(x' + y') \bmod n = (x + y) \bmod n$. That is, $x' +_n y' = (x + y) \bmod n$. Similarly,

$$xy - x'y' = (x - x')y + x'(y - y')$$

is a multiple of n, so $x' \cdot_n y' = (xy) \bmod n$.

(b) Every element of $\mathbb{Z}/n\mathbb{Z}$ is its own remainder, $a \bmod n = a$, so (a) applies to elements of $\mathbb{Z}/n\mathbb{Z}$ directly. Let $a, b, c \in \mathbb{Z}/n\mathbb{Z}$. For associativity of addition, (a) gives

$$(a +_n b) +_n c = ((a + b) \bmod n) +_n (c \bmod n) = ((a + b) + c) \bmod n,$$

and likewise $a +_n (b +_n c) = (a + (b + c)) \bmod n$. These agree because $(a + b) + c = a + (b + c)$ in $\mathbb{Z}$. Associativity of $\cdot_n$, and commutativity of both operations, follow in the same way from the corresponding laws in $\mathbb{Z}$. For distributivity, by (a) twice,

$$a \cdot_n (b +_n c) = (a(b + c)) \bmod n = (ab + ac) \bmod n = (a \cdot_n b) +_n (a \cdot_n c).$$

Next, $a +_n 0 = a \bmod n = a$ and $a \cdot_n 1 = a \bmod n = a$, and $0 \neq 1$ because $n \geq 2$. Finally, $0 +_n 0 = 0$, and for $1 \leq a \leq n-1$ the integer $n - a$ lies in $\mathbb{Z}/n\mathbb{Z}$ and $a +_n (n-a) = n \bmod n = 0$. So every axiom of a commutative ring holds. □

Remark 1.1.22. Look back at which results of Section 1.1.2 used multiplicative inverses. Uniqueness of the identities and of additive inverses (Theorem 1.1.9), part (a) of Proposition 1.1.13, additive cancellation, Proposition 1.1.15, and Proposition 1.1.16 did not, so they hold in every commutative ring with the same proofs. We will use this in Section 7.3, where determinants have polynomial entries. Proposition 1.1.17 and multiplicative cancellation did use inverses, and Non-example 1.1.23 shows that they can fail.

Compare the multiplication tables of $\mathbb{Z}/5\mathbb{Z}$ and $\mathbb{Z}/6\mathbb{Z}$.

$\cdot$	0	1	2	3	4
0	0	0	0	0	0
1	0	1	2	3	4
2	0	2	4	1	3
3	0	3	1	4	2
4	0	4	3	2	1

Table 1.1.1. Multiplication in $\mathbb{Z}/5\mathbb{Z}$. Every nonzero row contains each element exactly once, in particular a 1 (highlighted), so every nonzero element has an inverse.

$\cdot$	0	1	2	3	4	5
0	0	0	0	0	0	0
1	0	1	2	3	4	5
2	0	2	4	0	2	4
3	0	3	0	3	0	3
4	0	4	2	0	4	2
5	0	5	4	3	2	1

Table 1.1.2. Multiplication in $\mathbb{Z}/6\mathbb{Z}$. The rows of 2, 3, and 4 contain 0 in a nonzero column (highlighted) and never contain 1.

Non-example 1.1.23 ($\mathbb{Z}/6\mathbb{Z}$). In $\mathbb{Z}/6\mathbb{Z}$ we have $2 \cdot 3 = 6 \bmod 6 = 0$ with $2 \neq 0$ and $3 \neq 0$. Fields have no zero divisors (Proposition 1.1.17), so $\mathbb{Z}/6\mathbb{Z}$ is not a field. The failure is visible in Table 1.1.2: the row of 2 is $0, 2, 4, 0, 2, 4$, which never contains 1, so 2 has no inverse. Linear equations misbehave accordingly: $2x = 1$ has no solution, and $2x = 4$ has two, $x = 2$ and $x = 5$.

Intuition. By Lemma 1.1.21, the only question is which nonzero a have inverses, that is, which rows of the multiplication table contain a 1. If $n = rs$ with $1 < r, s < n$, then $rs = 0$ in $\mathbb{Z}/n\mathbb{Z}$, a zero divisor, which no field has. If n is prime, we give two proofs that every nonzero a is invertible. The first constructs a^{-1} from Bézout's identity. The second never finds a^{-1}: it shows that the row of a has no repeated entries, and then counting forces every element, 1 included, to appear in it.

Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime). Let $n \geq 2$ be an integer. Then $\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime.

Proof (via Bézout's identity). STANDARD

Uses. Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Proposition 1.1.17 (No zero divisors), Bézout's identity: if $\gcd(a, n) = 1$, then $ax + ny = 1$ for some $x, y \in \mathbb{Z}$
Hint 1. By Lemma 1.1.21, only multiplicative inverses are in question. If $n = rs$ with $1 < r, s < n$, look at $r \cdot_n s$.
Hint 2. For $n = p$ prime, an inverse of a is an integer b with $p \mid ab - 1$, that is, $ab + py = 1$ for some integer y. Which theorem produces such integers?
Hint 3. Bézout's identity applies because $\gcd(a, p) = 1$. Reduce the resulting x modulo p.
Sketch. If $n = rs$ with $1 < r, s < n$, then $r \cdot_n s = 0$ is a product of nonzero elements, impossible in a field. If $n = p$ is prime and $0 < a < p$, then $\gcd(a, p) = 1$, so $ax + py = 1$ for some integers x, y, and $x \bmod p$ is an inverse of a by part (a) of Lemma 1.1.21.

By Lemma 1.1.21, $\mathbb{Z}/n\mathbb{Z}$ satisfies every field axiom except possibly the existence of multiplicative inverses. So it is a field if and only if every nonzero element has a multiplicative inverse.

(⇒) We prove the contrapositive. Suppose n is not prime. Since $n \geq 2$, we can write $n = rs$ with integers $1 < r, s < n$. Then r and s are nonzero elements of $\mathbb{Z}/n\mathbb{Z}$ with $r \cdot_n s = n \bmod n = 0$. A field has no zero divisors (Proposition 1.1.17), so $\mathbb{Z}/n\mathbb{Z}$ is not a field.

(⇐) Suppose $n = p$ is prime, and let $a \in \{1, \ldots, p - 1\}$. The only positive divisors of p are 1 and p, and $p \nmid a$ because $0 < a < p$, so $\gcd(a, p) = 1$. By Bézout's identity there are integers x, y with $ax + py = 1$. Let $b = x \bmod p$. By part (a) of Lemma 1.1.21,

$$a \cdot_p b = (a \bmod p) \cdot_p (x \bmod p) = (ax) \bmod p = (1 - py) \bmod p = 1,$$

where the last step holds because $1 - py$ and 1 differ by a multiple of p. So b is a multiplicative inverse of a, as desired. □

Proof (by counting). STANDARD

Uses. Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Proposition 1.1.17 (No zero divisors), Euclid's lemma: if p is prime and $p \mid ac$, then $p \mid a$ or $p \mid c$, an injective function from a finite set to itself is surjective
Hint 1. Fix $a \neq 0$ and look at its row in the multiplication table, that is, the function $x \mapsto a \cdot_p x$. You want 1 to appear in it.
Hint 2. Show that the row has no repeated entries: if $a \cdot_p x = a \cdot_p y$, then $p \mid a(x - y)$. Use Euclid's lemma.
Hint 3. A row with p entries taken from a set of p elements, with no repeats, contains every element.
Sketch. The direction (⇒) is as in the first proof. For p prime and $a \neq 0$, the map $x \mapsto a \cdot_p x$ on $\mathbb{Z}/p\mathbb{Z}$ is injective, since $p \mid a(x - y)$ and $p \nmid a$ force $p \mid x - y$, hence $x = y$. An injective map from a finite set to itself is surjective, so $a \cdot_p b = 1$ for some b.

The direction (⇒) is proved as in the first proof. For (⇐), let p be prime and $a \in \{1, \ldots, p - 1\}$, and define $m : \mathbb{Z}/p\mathbb{Z} \to \mathbb{Z}/p\mathbb{Z}$ by $m(x) = a \cdot_p x$. We will show that m is injective. Suppose $m(x) = m(y)$, that is, $(ax) \bmod p = (ay) \bmod p$. Then $p \mid ax - ay = a(x - y)$. Since p is prime and $p \nmid a$, Euclid's lemma gives $p \mid x - y$. But $x, y \in \{0, \ldots, p - 1\}$, so $|x - y| < p$, and the only multiple of p strictly between $-p$ and p is 0. Hence $x = y$.

So m is an injective function from the finite set $\mathbb{Z}/p\mathbb{Z}$ to itself. Its image then has p elements, so it is all of $\mathbb{Z}/p\mathbb{Z}$, and in particular $1 = m(b) = a \cdot_p b$ for some b. That is, b is a multiplicative inverse of a. □

The two proofs differ in what they produce. The first computes a^{-1}, and running the Euclidean algorithm to find Bézout's x is how one inverts elements of $\mathbb{F}_p$ in practice. The second only proves that a^{-1} exists, but it uses just two facts about $\mathbb{Z}/p\mathbb{Z}$: it is finite, and $ax = ay$ with $a \neq 0$ forces $x = y$. On a finite set, a function to itself is injective if and only if it is surjective, so a multiplication that can be cancelled can also be undone. The same principle returns in Section 4.2 with dimension in place of the number of elements: a linear map from a finite-dimensional space to itself is injective if and only if it is surjective.

Notation 1.1.25 ($\mathbb{F}_p$). For a prime p, the field $\mathbb{Z}/p\mathbb{Z}$ is denoted $\mathbb{F}_p$. Later chapters use a bare $\mathbb{F}$ to mean $\mathbb{R}$ or $\mathbb{C}$; $\mathbb{F}_p$ always carries its subscript, so the two uses never clash.

Example 1.1.26 (Arithmetic in $\mathbb{F}_5$). From Table 1.1.1, the inverses in $\mathbb{F}_5$ are $1^{-1} = 1$, $2^{-1} = 3$, $3^{-1} = 2$, and $4^{-1} = 4$. To solve $3x + 4 = 1$ in $\mathbb{F}_5$, follow Proposition 1.1.13: first $3x = 1 - 4 = -3 = 2$, and then $x = 3^{-1} \cdot 2 = 2 \cdot 2 = 4$. Check: $3 \cdot 4 + 4 = 16 \bmod 5 = 1$.

Exercise 1.1.27. ROUTINE Find the multiplicative inverse of every nonzero element of $\mathbb{F}_7$. Then solve $3x + 5 = 2$ in $\mathbb{F}_7$.

Solution on page 1024

ASIDE: *Characteristic*

In $\mathbb{F}_p$, adding 1 to itself p times gives 0, while in $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$ no number of 1's adds up to 0. For a positive integer m and $a \in F$, write $m \cdot a$ for $a + a + \cdots + a$ (m terms). This is repeated addition, not multiplication by an element of F.

Definition 1.1.28 (Characteristic). The **characteristic** of a field F, written $\operatorname{char} F$, is the least positive integer m such that $m \cdot 1 = 0$, or 0 if there is no such m.

So $\operatorname{char} \mathbb{F}_p = p$ and $\operatorname{char} \mathbb{Q} = \operatorname{char} \mathbb{R} = \operatorname{char} \mathbb{C} = 0$. A nonzero characteristic is always prime (Exercise 1.1.48). If $\operatorname{char} F = p > 0$, then $p \cdot a = (p \cdot 1)a = 0$ for every $a \in F$, by distributivity.

The case that matters most later is characteristic 2, where $1 + 1 = 0$. There $-a = a$ for every a, and we cannot divide by $1 + 1$. Some later arguments do divide by $1 + 1$: the converse of "alternating implies antisymmetric" for determinants (Section 5.1), and the passage between quadratic forms and symmetric matrices (Section 12.2). Those results assume $1 + 1 \neq 0$, and $\mathbb{F}_2$ is where to look for counterexamples when the assumption is dropped.

1.1.4 The complex numbers

Componentwise multiplication does not make $\mathbb{R}^2$ a field (Non-example 1.1.6), but a different multiplication does. We give only what the next few chapters need: the definition and the field axioms. Conjugation, the modulus, polar form, and roots of unity are developed in Section B.1.

Definition 1.1.29 (Complex numbers). The **complex numbers** are the set $\mathbb{C} = \mathbb{R}^2$, whose element (a, b) we write as $a + bi$, with the operations

$$(a + bi) + (c + di) = (a + c) + (b + d)i,$$
$$(a + bi)(c + di) = (ac - bd) + (ad + bc)i.$$

The **real part** of $a + bi$ is a and its **imaginary part** is b. We identify the real number a with $a + 0i$, and write bi for $0 + bi$ and i for $0 + 1i$.

Intuition. The multiplication rule is forced. Suppose we want a field that contains $\mathbb{R}$ and an element i with $i^2 = -1$. Then the field axioms leave no choice:

$$(a + bi)(c + di) = ac + adi + bci + bdi^2 = (ac - bd) + (ad + bc)i.$$

So the definition is the only candidate, and what remains is to check that it satisfies the axioms. In particular $i^2 = (0 \cdot 0 - 1 \cdot 1) + (0 \cdot 1 + 1 \cdot 0)i = -1$.

The identification of $a \in \mathbb{R}$ with $a + 0i$ respects the operations: $(a + 0i) + (c + 0i) = (a + c) + 0i$ and $(a + 0i)(c + 0i) = ac + 0i$. Also $a(c + di) = ac + adi$, so multiplying by a real number scales both coordinates.

Proposition 1.1.30 ($\mathbb{C}$ is a field). $\mathbb{C}$ is a field, with identities $0 = 0 + 0i$ and $1 = 1 + 0i$. The additive inverse of $a + bi$ is $-a - bi$, and if $a + bi \neq 0$, then

$$(a + bi)^{-1} = \frac{a}{a^2 + b^2} - \frac{b}{a^2 + b^2}i.$$

Proof, part 1 of 2: the algebraic laws. ROUTINE

> *Uses.* Definition 1.1.29 (Complex numbers), the field axioms of $\mathbb{R}$
> *Techniques.* Proving from axioms (Technique 1.1.7)
> *Hint 1.* Write $z = a + bi$, $w = c + di$, and $u = e + fi$ with real $a, \ldots, f$, and compute both sides of each law from Definition 1.1.29.
> *Hint 2.* Addition is coordinatewise, so its laws hold coordinate by coordinate. For multiplication, expand both sides and compare real parts and imaginary parts separately.
> *Sketch.* Addition is coordinatewise addition in $\mathbb{R}^2$, so its laws come from those of $\mathbb{R}$. For each multiplicative law, expand both sides with the definition; the real parts agree, and so do the imaginary parts, by the field axioms of $\mathbb{R}$.

Let $z = a + bi$, $w = c + di$, and $u = e + fi$, where $a, b, c, d, e, f \in \mathbb{R}$. Addition in $\mathbb{C}$ is coordinatewise addition in $\mathbb{R}^2$, so it is commutative and associative because addition in $\mathbb{R}$ is.

For commutativity of multiplication, $wz = (ca - db) + (cb + da)i$, which equals $zw = (ac - bd) + (ad + bc)i$ by commutativity in $\mathbb{R}$. For associativity, expanding with the definition gives

$$\begin{aligned}(zw)u &= ((ac - bd)e - (ad + bc)f) + ((ac - bd)f + (ad + bc)e)i \\ &= (ace - adf - bcf - bde) + (acf + ade + bce - bdf)i,\end{aligned}$$

and

$$\begin{aligned}z(wu) &= (a(ce - df) - b(cf + de)) + (a(cf + de) + b(ce - df))i \\ &= (ace - adf - bcf - bde) + (acf + ade + bce - bdf)i,\end{aligned}$$

so $(zw)u = z(wu)$. For distributivity,

$$\begin{aligned}z(w + u) &= (a(c + e) - b(d + f)) + (a(d + f) + b(c + e))i \\ &= ((ac - bd) + (ae - bf)) + ((ad + bc) + (af + be))i \\ &= zw + zu.\end{aligned}$$

> *Intuition.* The remaining axioms ask for identities and inverses, and only the multiplicative inverse needs an idea. For $z = a + bi$, multiplying by $a - bi$ produces a real number,
>
> $$(a + bi)(a - bi) = \left(a^2 + b^2\right) + (-ab + ba)i = a^2 + b^2,$$
>
> and a nonzero real number can be divided by. Dividing $a - bi$ by $a^2 + b^2$ gives the inverse in the statement.

Proof, part 2 of 2: identities and inverses. ROUTINE

> *Uses.* Definition 1.1.29 (Complex numbers), $x^2 + y^2 > 0$ for real $(x, y) \neq (0, 0)$
> *Hint 1.* Check directly that $0 + 0i$ and $1 + 0i$ are identities and that $-a - bi$ is an additive inverse of $a + bi$.
> *Hint 2.* For the multiplicative inverse, first explain why $a^2 + b^2 \neq 0$ when $a + bi \neq 0$. Then multiply $a + bi$ by the proposed inverse.
> *Sketch.* The identities and additive inverses are immediate from the definition. If $a + bi \neq 0$, then $a^2 + b^2 > 0$, and multiplying out shows that $(a - bi)/\left(a^2 + b^2\right)$ is an inverse.

For $z = a + bi$ we have $z + (0 + 0i) = z$ and $z(1 + 0i) = (a \cdot 1 - b \cdot 0) + (a \cdot 0 + b \cdot 1)i = z$, and $0 + 0i \neq 1 + 0i$. Also $(a + bi) + (-a - bi) = 0 + 0i$.

Now suppose $z \neq 0$, that is, $(a, b) \neq (0, 0)$. Then $D = a^2 + b^2 > 0$, since squares of real numbers are nonnegative and at least one of a^2 and b^2 is positive. Let $w = a/D - (b/D)i$. Then

$$zw = \left(a \cdot \frac{a}{D} - b \cdot \frac{-b}{D}\right) + \left(a \cdot \frac{-b}{D} + b \cdot \frac{a}{D}\right)i = \frac{a^2 + b^2}{D} + 0i = 1,$$

so w is a multiplicative inverse of z. □

From now on we compute in $\mathbb{C}$ with the field axioms and $i^2 = -1$, as in the intuition above; the product formula never needs to be memorized.

Example 1.1.31 (Complex arithmetic). $(2+3i)(1-i) = 2-2i+3i-3i^2 = 5+i$. By Proposition 1.1.30, $(1+2i)^{-1} = (1-2i)/5$, so the unique solution of $(1+2i)z = 3-i$ (Proposition 1.1.13) is

$$z = \frac{(3-i)(1-2i)}{5} = \frac{3-6i-i+2i^2}{5} = \frac{1-7i}{5}.$$

The number $a-bi$ in the proof is the complex conjugate of $a+bi$, and $\sqrt{a^2+b^2}$ is the modulus of $a+bi$. Both reappear in Chapter 6, where inner products over $\mathbb{C}$ need them.

1.1.5 Subfields

The operations of $\mathbb{C}$, restricted to the real numbers $a+0i$, are the operations of $\mathbb{R}$, and the operations of $\mathbb{R}$ restricted to $\mathbb{Q}$ are those of $\mathbb{Q}$. Fields sitting inside other fields like this come up whenever we compare the same vectors over two fields, for instance over $\mathbb{R}$ and over $\mathbb{C}$ (Section 1.5).

Definition 1.1.32 (Subfield). Let F be a field. A subset $K \subseteq F$ is a **subfield** of F if $0, 1 \in K$ and K is closed under the operations of F: for all $a, b \in K$, we have $a+b \in K$, $ab \in K$, $-a \in K$, and $a^{-1} \in K$ if $a \neq 0$.

Proposition 1.1.33 (A subfield is a field). A subfield K of a field F is a field under the operations of F restricted to K.

Proof. ROUTINE

Uses. Definition 1.1.32 (Subfield), Definition 1.1.1 (Field)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Sort the axioms into those of the form "for all elements, an identity holds" and those of the form "there exists an element".
Hint 2. The first kind hold in K because they hold in F. For the second kind, the element whose existence is claimed must lie in K, and that is what the closure conditions provide.
Sketch. Closure under $+$ and $\cdot$ makes them operations on K. Identities that hold for all elements of F hold for all elements of K. The identities $0, 1$ and the inverses required by the existence axioms lie in K by assumption.

Since K is closed under $+$ and $\cdot$, these restrict to operations $K \times K \to K$. Commutativity, associativity, and distributivity hold for all elements of F, so in particular for all elements of K. We have $0, 1 \in K$, the equations $a+0 = a$ and $a \cdot 1 = a$ hold for $a \in K$ because they hold in F, and $0 \neq 1$. Finally, for $a \in K$ we have $-a \in K$ with $a + (-a) = 0$, and if $a \neq 0$ then $a^{-1} \in K$ with $aa^{-1} = 1$. So every field axiom holds in K. □

Example 1.1.34 (Subfields and non-subfields). $\mathbb{Q}$ is a subfield of $\mathbb{R}$, and $\mathbb{R}$, viewed as the set of $a+0i$, is a subfield of $\mathbb{C}$; the identification above shows the closure conditions, with $(a+0i)^{-1} = a^{-1} + 0i$. On the other hand, $\{0, 1\}$ is not a subfield of $\mathbb{R}$, since $1+1 = 2 \notin \{0, 1\}$, even though $\{0, 1\}$ with the operations of $\mathbb{F}_2$ is a field: a subfield must use the operations of the bigger field. Similarly $\mathbb{Z}$ is not a subfield of $\mathbb{Q}$, since $2^{-1} = 1/2 \notin \mathbb{Z}$.

Exercises

Exercise 1.1.35. ROUTINE Solve the system

$$x + 2y = 3, \quad 3x + 4y = 1$$

(a) over $\mathbb{F}_7$, and (b) over $\mathbb{F}_2$, reading each integer as its remainder modulo 2.

Solution on page 1025

Exercise 1.1.36. ROUTINE Write each of the following in the form $a+bi$ with $a, b \in \mathbb{R}$: (a) $(3-2i)(1+4i)$; (b) $(2+i)^{-1}$; (c) $(1+i)/(1-i)$; (d) $(1+i)^8$.

Solution on page 1025

Exercise 1.1.37. ROUTINE Let $a, b \in F$ be nonzero. Show that $a^{-1} \neq 0$ and $\left(a^{-1}\right)^{-1} = a$, and that $ab \neq 0$ and $(ab)^{-1} = a^{-1}b^{-1}$.

Solution on page 1025

Exercise 1.1.38. ROUTINE Let $a, b, c, d \in F$ with $b \neq 0$ and $d \neq 0$. Show that

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}, \quad \frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd},$$

and that $a/b = c/d$ if and only if $ad = bc$.

Solution on page 1026

Exercise 1.1.39. ROUTINE Let F be a set with operations $+$ and $\cdot$ satisfying all the field axioms except that $1 \neq 0$ is not required, and suppose that in fact $1 = 0$. Show that F has exactly one element.

Solution on page 1026

Exercise 1.1.40. ROUTINE Prove or disprove: in every field, if $a^2 = b^2$, then $a = b$ or $a = -b$.

Solution on page 1026

Exercise 1.1.41. ROUTINE Prove or disprove: for every prime p, the equation $x^2 + 1 = 0$ has a solution in $\mathbb{F}_p$.

Solution on page 1026

Exercise 1.1.42. ROUTINE Find the error in the following argument.

Claim. In every field, the equation $x^2 = 1$ has exactly two solutions.

Proof. We have $x^2 - 1 = (x - 1)(x + 1)$, so by Proposition 1.1.17, $x^2 = 1$ holds if and only if $x = 1$ or $x = -1$. These are the two solutions.

Solution on page 1027

Exercise 1.1.43. ROUTINE Let $a, b \in F$, and define $f : F \to F$ by $f(x) = ax + b$. Show that f is a bijection if and only if $a \neq 0$, and find f^{-1} in that case.

Solution on page 1027

Exercise 1.1.44. STANDARD

(a) Show that the only complex numbers z with $z^2 = -1$ are i and $-i$.

(b) Find all $z \in \mathbb{C}$ with $z^2 = i$.

Solution on page 1027

Exercise 1.1.45. STANDARD Find the error in the following argument.

Claim. $\mathbb{Z}/n\mathbb{Z}$ is a field for every $n \geq 2$.

Proof. By Lemma 1.1.21, only multiplicative inverses need checking. Let $a \neq 0$ in $\mathbb{Z}/n\mathbb{Z}$, and define $m(x) = ax$. If $m(x) = m(y)$, then $ax = ay$, so $x = y$ by cancellation (Corollary 1.1.14). So m is an injective function from a finite set to itself, hence surjective, and $ax = 1$ for some x.

Solution on page 1027

Exercise 1.1.46. STANDARD

(a) Let F be a field with exactly three elements, $F = \{0, 1, c\}$. Show that

$$1 + 1 = c, \quad 1 + c = 0, \quad c + c = 1, \quad c \cdot c = 1.$$

Conclude that the addition and multiplication tables of F are those of $\mathbb{F}_3$ with c in place of 2.

(b) Find all fields F in which $x^3 = x$ for every $x \in F$.

Solution on page 1028

Exercise 1.1.47. STANDARD Show that the following are equivalent for a field F:

(i) $1 + 1 = 0$;

(ii) $a = -a$ for every $a \in F$;

(iii) the map $F \to F$, $x \mapsto x^2$, is injective.

Solution on page 1028

Exercise 1.1.48. STANDARD Show that the characteristic of a field is either 0 or a prime number.

Solution on page 1029

Exercise 1.1.49. STANDARD Let $\mathbb{Q}(\sqrt{2}) = \left\{a + b\sqrt{2} \;\middle|\; a, b \in \mathbb{Q}\right\}$. Show that $\mathbb{Q}(\sqrt{2})$ is a subfield of $\mathbb{R}$.

Solution on page 1029

Exercise 1.1.50. STANDARD Let F be a field with $1 + 1 \neq 0$. Write $2 = 1 + 1$ and $4 = 2 \cdot 2$, and let $a, b, c \in F$ with $a \neq 0$.

(a) Show that $ax^2 + bx + c = 0$ has a solution $x \in F$ if and only if $b^2 - 4ac = d^2$ for some $d \in F$, and that in that case the solutions are $x = (-b \pm d)/(2a)$.

(b) Show that (a) fails without the hypothesis $1 + 1 \neq 0$: find $a, b, c \in \mathbb{F}_2$ with $a \neq 0$ such that $b^2 - 4ac$ is a square but $ax^2 + bx + c$ has no root in $\mathbb{F}_2$.

Solution on page 1029

Exercise 1.1.51. STANDARD Let p be prime and let $a \in \mathbb{F}_p$ be nonzero.

(a) Show that the products $a \cdot 1, a \cdot 2, \ldots, a \cdot (p-1)$ are the elements $1, 2, \ldots, p-1$ of $\mathbb{F}_p$ in some order.

(b) Deduce that $a^{p-1} = 1$ in $\mathbb{F}_p$. (This is Fermat's little theorem.)

Solution on page 1030

Exercise 1.1.52. STANDARD Let p be an odd prime. How many elements of $\mathbb{F}_p$ are squares, that is, of the form x^2 for some $x \in \mathbb{F}_p$?

Solution on page 1030

Exercise 1.1.53. HARD Prove or disprove: the set $K = \left\{a + b\sqrt[3]{2} \;\middle|\; a, b \in \mathbb{Q}\right\}$ is a subfield of $\mathbb{R}$.

Solution on page 1030

Exercise 1.1.54. HARD Fix $c \in \mathbb{R}$ and give $\mathbb{R}^2$ the componentwise addition and the multiplication

$$(a, b)(a', b') = (aa' + cbb', ab' + ba').$$

(For $c = -1$ this is $\mathbb{C}$.) For which c is $\mathbb{R}^2$ with these operations a field?

Solution on page 1031

Exercise 1.1.55. HARD Construct a set with operations $+$ and $\cdot$ that satisfy every field axiom except distributivity, in which $0 \cdot 0 \neq 0$. (So distributivity cannot be removed from the proof of Proposition 1.1.15.)

Solution on page 1031

Exercise 1.1.56. HARD BEYOND 21-242 $\mathbb{Z}/4\mathbb{Z}$ is not a field, but there is a field with four elements. Let $\mathbb{F}_4 = \{0, 1, \alpha, \beta\}$, four distinct symbols, with the following operations. Addition: 0 is an identity, $x + x = 0$ for every x, and the sum of two different elements of $\{1, \alpha, \beta\}$ is the third. Multiplication: $0x = x0 = 0$, $1x = x1 = x$, $\alpha^2 = \beta$, $\beta^2 = \alpha$, and $\alpha\beta = \beta\alpha = 1$.

(a) Show that $\mathbb{F}_4$ is a field.

(b) Show that $\operatorname{char} \mathbb{F}_4 = 2$, and explain why $\mathbb{F}_4$ is not $\mathbb{Z}/4\mathbb{Z}$ with its elements renamed.

Solution on page 1032

Exercise 1.1.57. HARD Let F be a finite field. Show that the sum of all the elements of F is 0, unless F has exactly two elements.

Solution on page 1033

Exercise 1.1.58. CHALLENGE Show that commutativity of addition follows from the other field axioms. That is, suppose F has operations $+$ and $\cdot$ satisfying every field axiom except possibly $a + b = b + a$, and show that $a + b = b + a$ for all $a, b \in F$.

Solution on page 1033

1.2 Vector spaces

Section 1.1 made precise what we ask of scalars. This section does the same for vectors. In $\mathbb{R}^2$ we can add two vectors and scale a vector by a real number, and these operations obey a short list of rules. A vector space is a set with an addition and a scalar multiplication that obey the same rules, with scalars taken from any field. Tuples, matrices, functions, and polynomials all form vector spaces, and a fact proved from the rules alone holds in each of them.

1.2.1 The axioms

The definition lists the rules that addition and scaling obey in $\mathbb{R}^2$, and nothing more. We number them (A1)–(A8) and cite them by number.

Definition 1.2.1 (Vector space). Let F be a field. A **vector space over** F is a set V together with two operations, **vector addition** $+ : V \times V \to V$ and **scalar multiplication** $\cdot : F \times V \to V$, that satisfy the following **vector space axioms**. We write $a\mathbf{v}$ for $a \cdot \mathbf{v}$.

- (A1) *Commutativity.* For all $\mathbf{v}, \mathbf{w} \in V$, $\mathbf{v} + \mathbf{w} = \mathbf{w} + \mathbf{v}$.
- (A2) *Associativity.* For all $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$, $(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w})$.
- (A3) *Additive identity.* There is an element $\mathbf{0} \in V$ such that $\mathbf{v} + \mathbf{0} = \mathbf{v}$ for all $\mathbf{v} \in V$.
- (A4) *Additive inverses.* For every $\mathbf{v} \in V$ there is some $\mathbf{w} \in V$ with $\mathbf{v} + \mathbf{w} = \mathbf{0}$.
- (A5) *Multiplicative identity.* For all $\mathbf{v} \in V$, $1\mathbf{v} = \mathbf{v}$, where 1 is the multiplicative identity of F.
- (A6) *Associativity of scaling.* For all $a, b \in F$ and $\mathbf{v} \in V$, $(ab)\mathbf{v} = a(b\mathbf{v})$.
- (A7) *Distributivity over vector addition.* For all $a \in F$ and $\mathbf{v}, \mathbf{w} \in V$, $a(\mathbf{v} + \mathbf{w}) = a\mathbf{v} + a\mathbf{w}$.
- (A8) *Distributivity over scalar addition.* For all $a, b \in F$ and $\mathbf{v} \in V$, $(a + b)\mathbf{v} = a\mathbf{v} + b\mathbf{v}$.

The elements of V are called **vectors**, and $\mathbf{0}$ is called the **zero vector**. We also say that V is an F-**vector space**. A vector space over $\mathbb{R}$ is a **real vector space**, and a vector space over $\mathbb{C}$ is a **complex vector space**.

Remark 1.2.2 (Reading the axioms). Closure is part of the definition. Since $+$ and $\cdot$ are functions into V, sums and scalar multiples of vectors lie in V. When we test whether a candidate is a vector space, closure comes first: if a sum leaves the set, there is no addition on the set whose axioms could be checked (Non-example 1.2.21).

The symbols are overloaded. In (A8), the $+$ on the left adds scalars and the $+$ on the right adds vectors. In (A6), ab is a product in F, while the other two products are scalar multiplications. Bold type separates the scalar $0 \in F$ from the vector $\mathbf{0} \in V$. No axiom multiplies two vectors or adds a scalar to a vector, because neither operation exists.

Quantifier order matters. (A3) has the form "there is $\mathbf{0}$ such that for all $\mathbf{v}$": one vector serves every $\mathbf{v}$ at once. The statement with the quantifiers swapped, that each $\mathbf{v}$ has some $\mathbf{z}$ with $\mathbf{v} + \mathbf{z} = \mathbf{v}$, is weaker; part (c) of Example 1.2.25 satisfies it and fails (A3). In (A4) the order is "for every $\mathbf{v}$ there is $\mathbf{w}$", so the inverse $\mathbf{w}$ may depend on $\mathbf{v}$. Also, (A4) mentions $\mathbf{0}$, the vector promised by (A3). If two different vectors satisfied (A3), then (A4) would be ambiguous. Proposition 1.2.27 rules this out, and its proof uses only (A1) and (A3), so there is no circularity.

The field is part of the data. The same set with the same addition can be a vector space over one field and not over another (Example 1.2.20). When the field matters, we say explicitly that V is a vector space over F.

1.2.2 Examples

To show that a candidate is a vector space, we specify the two operations, check closure, and check the eight axioms. In the standard examples below, the operations act one coordinate (or one input) at a time, and each axiom reduces to the field axiom of the same name.

Example 1.2.3 (The zero space). Let $V = \{\mathbf{0}\}$ be a set with one element, with $\mathbf{0} + \mathbf{0} = \mathbf{0}$ and $a\mathbf{0} = \mathbf{0}$ for all $a \in F$. Each axiom is either an equation between elements of V, which holds because V has only one element, or asks for an element of V, which $\mathbf{0}$ supplies. So $\{\mathbf{0}\}$ is a vector space over every field, called the **zero space**. By (A3), every vector space has at least one element, so the zero space is as small as a vector space can be.

Tuples and matrices

Definition 1.2.4 (The space F^n). Let $n \geq 1$. The set F^n consists of all columns

$$\mathbf{x} = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

with $x_1, \ldots, x_n \in F$, called the **coordinates** of $\mathbf{x}$. Two columns are equal when all their coordinates are equal. The operations are coordinatewise:

$$\begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} + \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix} = \begin{pmatrix} x_1 + y_1 \\ \vdots \\ x_n + y_n \end{pmatrix}, \quad a\begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} ax_1 \\ \vdots \\ ax_n \end{pmatrix}.$$

In running text we write $(x_1, \ldots, x_n)$ for the column with coordinates $x_1, \ldots, x_n$.

Proposition 1.2.5 (F^n is a vector space). F^n is a vector space over F. The column $(0, \ldots, 0)$ is a zero vector, and $(-x_1, \ldots, -x_n)$ is an additive inverse of $(x_1, \ldots, x_n)$.

Proof. ROUTINE

> *Uses.* Definition 1.2.4 (The space F^n), Definition 1.1.1 (Field)
> *Techniques.* Proving from axioms (Technique 1.1.7)
> *Hint 1.* Two columns are equal exactly when their i-th coordinates are equal for every i. So compute the i-th coordinate of each side of each axiom.
> *Hint 2.* Coordinatewise, each axiom becomes a field axiom. For example, the i-th coordinate of (A7) reads $a(x_i + y_i) = ax_i + ay_i$.
> *Sketch.* Sums and multiples of columns with entries in F have entries in F. Comparing i-th coordinates, each of (A1)–(A8) becomes the field axiom of the same name applied to x_i, y_i, z_i, with $(0, \dots, 0)$ and $(-x_1, \dots, -x_n)$ supplying (A3) and (A4).

The coordinates of $\mathbf{x} + \mathbf{y}$ and $a\mathbf{x}$ are sums and products in F, so they lie in F, and the operations map into F^n. Let $\mathbf{x} = (x_1, \dots, x_n)$, $\mathbf{y} = (y_1, \dots, y_n)$, and $\mathbf{z} = (z_1, \dots, z_n)$ be in F^n, let $a, b \in F$, and fix $i \in \{1, \dots, n\}$. Two columns are equal when their i-th coordinates agree for every i. By the definition of the operations, the i-th coordinates of the two sides of each axiom are as follows, and they agree by the field axiom named on the right:

(A1)	$x_i + y_i = y_i + x_i$	commutativity,
(A2)	$(x_i + y_i) + z_i = x_i + (y_i + z_i)$	associativity,
(A3)	$x_i + 0 = x_i$	additive identity,
(A4)	$x_i + (-x_i) = 0$	additive inverses,
(A5)	$1x_i = x_i$	multiplicative identity,
(A6)	$(ab)x_i = a(bx_i)$	associativity,
(A7)	$a(x_i + y_i) = ax_i + ay_i$	distributivity,
(A8)	$(a + b)x_i = ax_i + bx_i$	distributivity.

In (A3) we compare $\mathbf{x} + (0, \dots, 0)$ with $\mathbf{x}$, and in (A4) we compare $\mathbf{x} + (-x_1, \dots, -x_n)$ with $(0, \dots, 0)$. So all eight axioms hold. □

Example 1.2.6 (Small fields). $\mathbb{F}_2^3$ has $2^3 = 8$ elements, and in it $(1, 1, 0) + (0, 1, 1) = (1, 0, 1)$, because $1 + 1 = 0$ in $\mathbb{F}_2$. For the same reason, $\mathbf{v} + \mathbf{v} = \mathbf{0}$ for every $\mathbf{v} \in \mathbb{F}_2^n$. In $\mathbb{C}^2$, $i(1, i) = (i, -1)$ and $(1 + i)(1, -i) = (1 + i, 1 - i)$.

For $n = 1$, F^1 is F with its own addition and multiplication. So every field is a vector space over itself.

Definition 1.2.7 (Matrices). Let $m, n \geq 1$. An $m \times n$ **matrix** over F is a rectangular array

$$A = \begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{m1} & \cdots & a_{mn} \end{pmatrix}$$

of elements $a_{ij} \in F$, the **entries** of A. The entry a_{ij} sits in row i and column j, and we also write $A = (a_{ij})$. Two matrices are equal when all their entries are equal. The set of $m \times n$ matrices over F is denoted $F^{m \times n}$, and its operations are entrywise:

$$(a_{ij}) + (b_{ij}) = (a_{ij} + b_{ij}), \quad c(a_{ij}) = (ca_{ij}).$$

A matrix is mn entries arranged in a rectangle, and the operations ignore the arrangement. So the proof of Proposition 1.2.5, run entry by entry, shows that $F^{m \times n}$ is a vector space over F (Remark 1.2.11 below makes this precise). Its zero vector is the **zero matrix**, all of whose entries are 0. The rectangular shape starts to matter when matrices are multiplied (Section 2.4). An $n \times 1$ matrix is a column, so $F^{n \times 1}$ is F^n. For example, in $\mathbb{R}^{2 \times 3}$,

$$2\begin{pmatrix}1 & 0 & -1\\ 3 & 2 & 0\end{pmatrix}+\begin{pmatrix}0 & 4 & 1\\ -1 & 1 & 1\end{pmatrix}=\begin{pmatrix}2 & 4 & -1\\ 5 & 5 & 1\end{pmatrix}.$$

Exercise 1.2.8. ROUTINE

(a) In $\mathbb{F}_3^3$, find $\mathbf{x}$ with $2\mathbf{x}+(1,2,0)=(2,0,1)$.

(b) In $\mathbb{F}_5^{2\times 2}$, find X with $3X+A=B$, where $A=\begin{pmatrix}1 & 2\\ 3 & 4\end{pmatrix}$ and $B=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$.

(c) In $\mathbb{C}^2$, find $\mathbf{v}$ with $(1+i)\mathbf{v}+(1,0)=(0,2i)$.

Solution on page 1033

Functions

Matrices, functions, and polynomials keep their usual names A, f, p even when we treat them as vectors, and so do numbers in the few examples whose vectors are numbers. Bold letters are reserved for vectors of a general vector space and of F^n. The zero vector is written $\mathbf{0}$, whether it is the zero matrix, the zero function, or the zero polynomial; only when the vectors are numbers do we write it as a number.

Definition 1.2.9 (Function spaces). Let X be a set. The set F^X consists of all functions $f : X \to F$. For $f, g \in F^X$ and $a \in F$, the functions $f+g$ and af are defined pointwise:

$$(f+g)(t)=f(t)+g(t),\quad (af)(t)=af(t)\quad (t\in X).$$

Proposition 1.2.10 (F^X is a vector space). F^X is a vector space over F. The zero function $\mathbf{0}$, given by $\mathbf{0}(t)=0$ for all $t\in X$, is a zero vector, and the function $t\mapsto -f(t)$ is an additive inverse of f.

Proof. ROUTINE

Uses. Definition 1.2.9 (Function spaces), Definition 1.1.1 (Field), Proposition 1.2.5 (F^n is a vector space)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Two functions $X\to F$ are equal exactly when they take the same value at every $t\in X$.
Hint 2. Evaluate both sides of each axiom at t. This is the proof of Proposition 1.2.5, with the value $f(t)$ in place of the coordinate x_i.
Sketch. Pointwise operations give functions $X\to F$ again. Evaluating both sides of each axiom at $t\in X$ turns it into the field axiom of the same name for the values $f(t), g(t), h(t)$, and the zero function and $t\mapsto -f(t)$ supply (A3) and (A4).

For $f, g\in F^X$ and $a\in F$, the rules above assign an element of F to each $t\in X$, so $f+g$ and af are functions $X\to F$, that is, elements of F^X. Two functions $X\to F$ are equal when they agree at every $t\in X$. Let $f, g, h\in F^X$, $a, b\in F$, and $t\in X$. Evaluating both sides of each axiom at t gives

(A1) $f(t)+g(t)=g(t)+f(t)$,
(A2) $(f(t)+g(t))+h(t)=f(t)+(g(t)+h(t))$,
(A3) $f(t)+0=f(t)$,
(A4) $f(t)+(-f(t))=0$,
(A5) $1f(t)=f(t)$,
(A6) $(ab)f(t)=a(bf(t))$,
(A7) $a(f(t)+g(t))=af(t)+ag(t)$,
(A8) $(a+b)f(t)=af(t)+bf(t)$,

where in (A3) the second summand is $\mathbf{0}(t)=0$, and in (A4) it is the value at t of $t\mapsto -f(t)$. Each line is a field axiom, as in the proof of Proposition 1.2.5. Since t was arbitrary, both sides of each axiom are the same function. □

Remark 1.2.11 (Tuples and matrices are functions). A column $(x_1, \ldots, x_n)$ carries the same information as the function $\{1, \ldots, n\} \to F$, $i \mapsto x_i$, and adding or scaling columns coordinatewise is adding or scaling these functions pointwise. So F^n is F^X for $X = \{1, \ldots, n\}$, under another name. In the same way, $F^{m\times n}$ is F^X for $X = \{1, \ldots, m\} \times \{1, \ldots, n\}$, a matrix being the function $(i, j) \mapsto a_{ij}$. In particular, Proposition 1.2.10 shows that $F^{m\times n}$ is a vector space. Other choices of X give the space $\mathbb{R}^{\mathbb{R}}$ of all functions $\mathbb{R} \to \mathbb{R}$, and the space of sequences $(x_0, x_1, x_2, \ldots)$ in F, which is F^X for $X = \{0, 1, 2, \ldots\}$.

Many vector spaces of interest sit inside some F^X and use its operations. Then only closure needs a real argument.

Example 1.2.12 (Continuous functions). Let $C[0, 1]$ be the set of continuous functions $[0, 1] \to \mathbb{R}$, with the operations of $\mathbb{R}^{[0,1]}$. Sums and constant multiples of continuous functions are continuous, so the operations map into $C[0, 1]$. The equations in (A1), (A2), and (A5)–(A8) hold for all elements of $\mathbb{R}^{[0,1]}$, so in particular for continuous ones. The zero function is continuous, which gives (A3), and if f is continuous then so is $-f$, which gives (A4). So $C[0, 1]$ is a real vector space.

The same argument applies to

$$\left\{ f \in C[0, 1] \;\middle|\; \int_0^1 f(t)\,\mathrm{d}t = 0 \right\},$$

since $\int_0^1 (f + g) = \int_0^1 f + \int_0^1 g$ and $\int_0^1 af = a\int_0^1 f$: sums and multiples of functions with integral 0 have integral 0, and so do $\mathbf{0}$ and $-f$. On the other hand, the functions with integral 1 do not form a vector space under these operations: if $\int_0^1 f = \int_0^1 g = 1$, then $\int_0^1 (f + g) = 2$, so addition is not an operation on that set.

The pattern of this example, a subset of a known vector space that contains $\mathbf{0}$ and is closed under the operations, is common enough that Section 1.4 turns it into a criterion.

Polynomials

In school, a polynomial is an expression $a_0 + a_1 x + \cdots + a_d x^d$. As a definition this is not quite right: 5 and $5 + 0x$ are different expressions, and we want them to be the same polynomial. What determines a polynomial is its list of coefficients, all but finitely many of which are 0. So we define a polynomial to be that list, and recover the expressions afterwards.

Definition 1.2.13 (Polynomials). A **polynomial** over F is a sequence $p = (a_0, a_1, a_2, \ldots)$ of elements of F such that only finitely many a_k are nonzero. The a_k are the **coefficients** of p, and two polynomials are equal when all their coefficients are equal. The set of polynomials over F is denoted $F[x]$. Its operations are coefficientwise:

$$(a_0, a_1, \ldots) + (b_0, b_1, \ldots) = (a_0 + b_0, a_1 + b_1, \ldots), \quad c(a_0, a_1, \ldots) = (ca_0, ca_1, \ldots).$$

Proposition 1.2.14 ($F[x]$ is a vector space). $F[x]$ is a vector space over F. Its zero vector is the **zero polynomial** $\mathbf{0} = (0, 0, \ldots)$.

Proof. ROUTINE

Uses. Definition 1.2.13 (Polynomials), Proposition 1.2.10 (F^X is a vector space), Remark 1.2.11 (Tuples and matrices are functions), Proposition 1.1.15 (Multiplying by zero)

Hint 1. A sequence is a function on $\{0, 1, 2, \ldots\}$, and the operations of $F[x]$ are those of F^X for $X = \{0, 1, 2, \ldots\}$. Argue as for $C[0, 1]$ in Example 1.2.12.

Hint 2. The only real work is closure. If $a_k = 0$ for $k > m$ and $b_k = 0$ for $k > n$, which coefficients of the sum must vanish?

Sketch. $F[x]$ is the set of finitely supported elements of F^X, $X = \{0, 1, 2, \ldots\}$, with the same operations. Sums and multiples of finitely supported sequences are finitely supported, as are the zero sequence and $(-a_k)$; the equational axioms are inherited from F^X.

A sequence $(a_0, a_1, \ldots)$ is the function $k \mapsto a_k$ on $X = \{0, 1, 2, \ldots\}$, and the operations of $F[x]$ are those of F^X. So $F[x] \subseteq F^X$, and we argue as in Example 1.2.12.

Closure. Let $p = (a_k)$ and $q = (b_k)$ be polynomials, and choose m and n with $a_k = 0$ for $k > m$ and $b_k = 0$ for $k > n$. For $k > \max(m, n)$ we have $a_k + b_k = 0 + 0 = 0$ and $ca_k = c0 = 0$ (Proposition 1.1.15). So $p + q$ and cp have only finitely many nonzero coefficients.

The axioms. The equations in (A1), (A2), and (A5)–(A8) hold for all elements of F^X by Proposition 1.2.10, so in particular for polynomials. The zero sequence has no nonzero coefficients, so it lies in $F[x]$ and gives (A3). For $p = (a_k)$, the sequence $q = (-a_0, -a_1, \ldots)$ has its nonzero coefficients in the same positions as p (as $-a_k = 0$ only when $a_k = 0$), so $q \in F[x]$, and $p + q = \mathbf{0}$ gives (A4). □

Notation 1.2.15. For $k \geq 0$, x^k denotes the polynomial whose k-th coefficient is 1 and whose other coefficients are 0. We also write 1 for x^0 and x for x^1. If $a_k = 0$ for all $k > d$, then

$$(a_0, a_1, a_2, \ldots) = a_0 + a_1 x + \cdots + a_d x^d = \sum_{k=0}^{d} a_k x^k,$$

where the right side is computed with the operations of $F[x]$: its j-th coefficient is a_j for $j \leq d$ and 0 for $j > d$.

So the familiar expressions are honest sums of vectors in $F[x]$, and the problem with 5 and $5 + 0x$ disappears: both are the sequence $(5, 0, 0, \ldots)$. A polynomial can be written with any d that is at least as large as the index of its last nonzero coefficient. To decide whether two expressions are the same polynomial, compare coefficients. We multiply polynomials in Section 7.1; here only the vector space operations matter.

Definition 1.2.16 (Degree). Let $p = \sum_{k=0}^{d} a_k x^k \in F[x]$. If $p \neq \mathbf{0}$, the **degree** $\deg p$ is the largest k with $a_k \neq 0$, and $a_{\deg p}$ is the **leading coefficient** of p. The zero polynomial has degree $\deg \mathbf{0} = -\infty$, with the convention that $-\infty < n$ for every integer n. For $n \geq 0$,

$$F[x]_{\leq n} = \{p \in F[x] \mid \deg p \leq n\}$$

is the set of polynomials $a_0 + a_1 x + \cdots + a_n x^n$ with $a_0, \ldots, a_n \in F$ (any of which may be 0).

Definition 1.2.17 (Evaluation). Let $p = \sum_{k=0}^{d} a_k x^k \in F[x]$ and $c \in F$. The **value** of p at c is

$$p(c) = \sum_{k=0}^{d} a_k c^k \in F.$$

The function $F \to F$, $c \mapsto p(c)$, is the **polynomial function** of p.

The value does not depend on which d we use to write p, since the extra terms are $0 \cdot c^k = 0$. For example, over $\mathbb{R}$, $\deg(3 - x^2) = 2$ and $(3 - x^2)(2) = -1$.

Proposition 1.2.18 (Degree and evaluation versus the operations). Let $p, q \in F[x]$ and $a, c \in F$.

(a) $\deg(p + q) \leq \max(\deg p, \deg q)$, with equality if $\deg p \neq \deg q$.

(b) If $a \neq 0$, then $\deg(ap) = \deg p$.

(c) $(p + q)(c) = p(c) + q(c)$ and $(ap)(c) = ap(c)$.

Proof. ROUTINE

Uses. Definition 1.2.16 (Degree), Definition 1.2.17 (Evaluation), Proposition 1.1.17 (No zero divisors), Definition 1.1.1 (Field)

Hint 1. Write $p = (a_k)$ and $q = (b_k)$. For (a), which coefficients of $p + q$ are forced to vanish? If $\deg p > \deg q$, look at the coefficient of $p + q$ in position $\deg p$.

Hint 2. For (b), when is aa_k zero? For (c), write p and q with the same d and expand.
Sketch. (a) Beyond $\max(\deg p, \deg q)$ both coefficient sequences vanish, so the sum's does; if $\deg p > \deg q$, the coefficient of $p+q$ in position $\deg p$ is $a_{\deg p} + 0 \neq 0$. (b) $aa_k = 0$ if and only if $a_k = 0$. (c) Distributivity and reordering of finite sums.

Write $p = (a_k)$ and $q = (b_k)$.

(a) Let $n = \max(\deg p, \deg q)$. For every integer $k > n$ we have $a_k = b_k = 0$, so the k-th coefficient $a_k + b_k$ of $p+q$ is 0. Hence $\deg(p+q) \leq n$; this includes the case $p+q = \mathbf{0}$, and the case $n = -\infty$, where $p = q = \mathbf{0}$. Now suppose $\deg p \neq \deg q$; by symmetry we may assume $\deg p > \deg q$. Then $p \neq \mathbf{0}$, and with $m = \deg p$ we have $b_m = 0$ because $m > \deg q$. So the m-th coefficient of $p+q$ is $a_m + 0 = a_m \neq 0$, and $\deg(p+q) \geq m$. With the first part, $\deg(p+q) = m = \max(\deg p, \deg q)$.

(b) The k-th coefficient of ap is aa_k. Since $a \neq 0$, Proposition 1.1.17 gives $aa_k = 0$ if and only if $a_k = 0$. So ap and p have their nonzero coefficients in the same positions, and in particular the same degree.

(c) Choose d with $a_k = b_k = 0$ for all $k > d$. Then, by distributivity and by reordering the finite sum,

$$(p+q)(c) = \sum_{k=0}^{d} (a_k + b_k)c^k = \sum_{k=0}^{d} a_k c^k + \sum_{k=0}^{d} b_k c^k = p(c) + q(c),$$

and $(ap)(c) = \sum_{k=0}^{d} (aa_k)c^k = a\sum_{k=0}^{d} a_k c^k = ap(c)$. □

Parts (a) and (b) say that sums and nonzero multiples of polynomials of degree at most n again have degree at most n (and $0p = \mathbf{0}$ has degree $-\infty$). So $F[x]_{\leq n}$ is closed under the operations of $F[x]$, and it is a vector space by the argument of Example 1.2.12. Part (c) says that taking polynomial functions is compatible with the operations of $F[x]$ and of F^F.

ASIDE: *Polynomials versus polynomial functions*

Different polynomials can have the same polynomial function. Over $\mathbb{F}_2$, the polynomial $f = x^2 + x$ has coefficients $(0, 1, 1, 0, \ldots)$, so $f \neq \mathbf{0}$ and $\deg f = 2$. But $f(0) = 0$ and $f(1) = 1 + 1 = 0$, so the polynomial function of f is the zero function $\mathbb{F}_2 \to \mathbb{F}_2$, the same as that of $\mathbf{0}$. Similarly, for every prime p, the polynomial $x^p - x \in \mathbb{F}_p[x]$ is nonzero but vanishes at every element of $\mathbb{F}_p$ (Exercise 1.2.51).

This is one reason to define polynomials by their coefficients. If a polynomial were its function, then $x^2 + x$ and $\mathbf{0}$ would be the same polynomial over $\mathbb{F}_2$, and degree would not be well defined. Later we will also substitute matrices and linear maps into polynomials (Section 7.2), which a function $F \to F$ cannot accommodate.

Over an infinite field such as $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, nothing is lost by thinking of functions. A nonzero polynomial of degree d has at most d roots (Section 7.1). So if p and q have the same polynomial function, then $(p-q)(c) = p(c) - q(c) = 0$ for every $c \in F$ (Proposition 1.2.18(c)); a nonzero $p - q$ would have infinitely many roots, so $p - q = \mathbf{0}$. This is why some books, LADR among them, can define polynomials over $\mathbb{R}$ and $\mathbb{C}$ as functions.

Changing the field

The field is part of the data of a vector space, and shrinking the field is always allowed.

Proposition 1.2.19 (Restriction of scalars). Let K be a subfield of F, and let V be a vector space over F. Then V, with the same addition and with scalar multiplication restricted to $K \times V$, is a vector space over K.

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space), Definition 1.1.32 (Subfield), Proposition 1.1.33 (A subfield is a field), Theorem 1.1.9 (Uniqueness of identities and inverses)
Hint 1. Sort the axioms into those about addition alone, those that hold "for all scalars", and (A5).
Hint 2. For (A5), you need to know that the multiplicative identity of the field K is the 1 of F.

Sketch. (A1)–(A4) only involve addition, which is unchanged. (A6)–(A8) hold for all scalars in F, hence for those in K, whose sums and products are computed as in F. The identity of K is the 1 of F, by uniqueness of identities in the field K, so (A5) holds.

The restricted scalar multiplication is a function $K \times V \to V$. Axioms (A1)–(A4) involve only the addition of V, which has not changed. Axioms (A6)–(A8) hold for all $a, b \in F$, so in particular for all $a, b \in K$; here $a + b$ and ab mean the same elements whether computed in K or in F, because K carries the operations of F. For (A5), K is a field (Proposition 1.1.33), and $1 \in K$ by Definition 1.1.32. Since $a \cdot 1 = a$ for every $a \in K$, the element 1 is a multiplicative identity of K, so it is the multiplicative identity of K by Theorem 1.1.9. As $1\mathbf{v} = \mathbf{v}$ for all $\mathbf{v} \in V$, (A5) holds over K. □

Example 1.2.20 (Real and rational scalars). $\mathbb{C}$ is a vector space over itself (Example 1.2.6), hence over its subfield $\mathbb{R}$. For $a \in \mathbb{R}$, $a(x + yi) = ax + ayi$, so as a real vector space $\mathbb{C}$ is $\mathbb{R}^2$ with the pair (x, y) written as $x + yi$. Likewise $\mathbb{C}^n$ is a real vector space.

$\mathbb{R}$ is a vector space over $\mathbb{Q}$, with scalar multiplication the usual product. The change of field changes the geometry. Over $\mathbb{R}$, every real number is a scalar multiple of 1. Over $\mathbb{Q}$, $\sqrt{2}$ is not a rational multiple of 1, so 1 and $\sqrt{2}$ point in different directions. Section 1.5 makes this precise.

In the other direction, $\mathbb{Q}$ with the usual product is not a vector space over $\mathbb{R}$: $\sqrt{2} \cdot 1 \notin \mathbb{Q}$, so the product is not a function $\mathbb{R} \times \mathbb{Q} \to \mathbb{Q}$. For the same reason, $\mathbb{R}$ with the usual product is not a vector space over $\mathbb{C}$. Whether some other scalar multiplication works is a different question (Exercise 1.2.47).

1.2.3 Non-examples and repairs

To show that a candidate is not a vector space, one failure suffices: a sum or multiple that leaves the set, or a specific choice of vectors and scalars for which an axiom fails. The candidates below fail in different ways, and the first can be repaired by changing its operations.

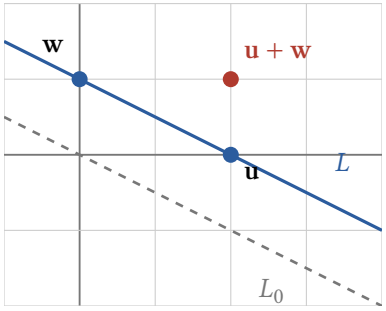

Figure 1.2.1. The line L: $x + 2y = 2$ (solid) and the line L_0: $x + 2y = 0$ through the origin (dashed). The vectors $\mathbf{u} = (2, 0)$ and $\mathbf{w} = (0, 1)$ lie on L, but their sum $(2, 1)$ does not.

Non-example 1.2.21 (A line not through the origin). Let $L = \{(x, y) \in \mathbb{R}^2 \mid x + 2y = 2\}$, with the operations of $\mathbb{R}^2$. This is not a real vector space, and the first problem is that the operations of $\mathbb{R}^2$ are not operations on L. The vectors $\mathbf{u} = (2, 0)$ and $\mathbf{w} = (0, 1)$ lie on L, but $\mathbf{u} + \mathbf{w} = (2, 1)$ does not, since $2 + 2 \cdot 1 = 4$ (Figure 1.2.1). Similarly $0\mathbf{u} = (0, 0) \notin L$.

Even setting closure aside, (A3) fails. Notice what showing this requires. Observing that $(0, 0) \notin L$ is not enough on its own, because the zero vector of a structure on L need not be $(0, 0)$ (see Example 1.2.23). We must show that no $\mathbf{z} \in L$ satisfies $\mathbf{v} + \mathbf{z} = \mathbf{v}$ for all $\mathbf{v} \in L$. Here that is quick: if $\mathbf{v} + \mathbf{z} = \mathbf{v}$ in $\mathbb{R}^2$ for even one $\mathbf{v}$, then subtracting $\mathbf{v}$ coordinatewise gives $\mathbf{z} = (0, 0)$, which is not in L.

Intuition. L is the line L_0 through the origin, shifted by $\mathbf{p} = (2, 0)$: every point of L is $\mathbf{p} + \mathbf{v}$ for exactly one $\mathbf{v} \in L_0$ (Figure 1.2.1). The line L_0 is closed under the operations of $\mathbb{R}^2$, so the only defect of L is where

its origin is. To repair L, we can add and scale as if $\mathbf{p}$ were the origin. The cleanest way to carry this out is to copy the operations of a known vector space across a bijection.

Proposition 1.2.22 (Transport of structure). Let V be a vector space over F, let W be a set, and let $\varphi : V \to W$ be a bijection. Define operations on W by

$$\mathbf{w}_1 \oplus \mathbf{w}_2 = \varphi\big(\varphi^{-1}(\mathbf{w}_1) + \varphi^{-1}(\mathbf{w}_2)\big), \quad a \odot \mathbf{w} = \varphi\big(a\varphi^{-1}(\mathbf{w})\big).$$

Then W with $\oplus$ and $\odot$ is a vector space over F in which $\varphi(\mathbf{0})$ is a zero vector, and for all $\mathbf{v}, \mathbf{v}' \in V$ and $a \in F$,

$$\varphi(\mathbf{v} + \mathbf{v}') = \varphi(\mathbf{v}) \oplus \varphi(\mathbf{v}'), \quad \varphi(a\mathbf{v}) = a \odot \varphi(\mathbf{v}). \tag{1.2.1}$$

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space), a bijection φ has an inverse φ^{-1} with $\varphi^{-1}(\varphi(\mathbf{v})) = \mathbf{v}$ and $\varphi\big(\varphi^{-1}(\mathbf{w})\big) = \mathbf{w}$
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. First prove (1.2.1) directly from the definitions. Then every element of W has the form $\varphi(\mathbf{v})$.
Hint 2. With (1.2.1), each side of an axiom in W, written for elements $\varphi(\mathbf{v})$, becomes φ applied to the corresponding side of the same axiom in V.
Sketch. The definitions give $\varphi(\mathbf{v}) \oplus \varphi(\mathbf{v}') = \varphi(\mathbf{v} + \mathbf{v}')$ and $a \odot \varphi(\mathbf{v}) = \varphi(a\mathbf{v})$. Since φ is surjective, it suffices to check each axiom on elements $\varphi(\mathbf{v})$; pushing $\oplus$ and $\odot$ inside φ turns it into φ applied to the same axiom in V. The zero vector is $\varphi(\mathbf{0})$, and $\varphi(\mathbf{v}')$ is an inverse of $\varphi(\mathbf{v})$ whenever $\mathbf{v} + \mathbf{v}' = \mathbf{0}$.

The operations take values in W because φ does. Substituting $\mathbf{w}_1 = \varphi(\mathbf{v})$, $\mathbf{w}_2 = \varphi(\mathbf{v}')$, and $\mathbf{w} = \varphi(\mathbf{v})$ into the definitions and using $\varphi^{-1}(\varphi(\mathbf{v})) = \mathbf{v}$ gives (1.2.1). Since φ is surjective, every element of W is $\varphi(\mathbf{v})$ for some $\mathbf{v} \in V$, so it suffices to verify each axiom for elements of this form. Let $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$ and $a, b \in F$. Each of the following chains uses (1.2.1) to move the operations inside φ, applies the axiom of V named on the right, and moves the operations back out:

$$\begin{aligned}
\varphi(\mathbf{v}) \oplus \varphi(\mathbf{w}) &= \varphi(\mathbf{v} + \mathbf{w}) = \varphi(\mathbf{w} + \mathbf{v}) \\
&= \varphi(\mathbf{w}) \oplus \varphi(\mathbf{v}) && \text{(A1)}, \\
(\varphi(\mathbf{u}) \oplus \varphi(\mathbf{v})) \oplus \varphi(\mathbf{w}) &= \varphi((\mathbf{u} + \mathbf{v}) + \mathbf{w}) = \varphi(\mathbf{u} + (\mathbf{v} + \mathbf{w})) \\
&= \varphi(\mathbf{u}) \oplus (\varphi(\mathbf{v}) \oplus \varphi(\mathbf{w})) && \text{(A2)}, \\
1 \odot \varphi(\mathbf{v}) &= \varphi(1\mathbf{v}) = \varphi(\mathbf{v}) && \text{(A5)}, \\
(ab) \odot \varphi(\mathbf{v}) &= \varphi((ab)\mathbf{v}) = \varphi(a(b\mathbf{v})) = a \odot (b \odot \varphi(\mathbf{v})) && \text{(A6)}, \\
a \odot (\varphi(\mathbf{v}) \oplus \varphi(\mathbf{w})) &= \varphi(a(\mathbf{v} + \mathbf{w})) = \varphi(a\mathbf{v} + a\mathbf{w}) \\
&= (a \odot \varphi(\mathbf{v})) \oplus (a \odot \varphi(\mathbf{w})) && \text{(A7)}, \\
(a + b) \odot \varphi(\mathbf{v}) &= \varphi((a + b)\mathbf{v}) = \varphi(a\mathbf{v} + b\mathbf{v}) \\
&= (a \odot \varphi(\mathbf{v})) \oplus (b \odot \varphi(\mathbf{v})) && \text{(A8)}.
\end{aligned}$$

For (A3), $\varphi(\mathbf{v}) \oplus \varphi(\mathbf{0}) = \varphi(\mathbf{v} + \mathbf{0}) = \varphi(\mathbf{v})$ for every $\mathbf{v}$, so $\varphi(\mathbf{0})$ is a zero vector of W. For (A4), given $\mathbf{v}$, choose $\mathbf{v}'$ with $\mathbf{v} + \mathbf{v}' = \mathbf{0}$; then $\varphi(\mathbf{v}) \oplus \varphi(\mathbf{v}') = \varphi(\mathbf{0})$. □

The map φ is a dictionary: it renames each vector of V, and W inherits the arithmetic of V under the new names. In the language of Section 4.5, (1.2.1) says that φ is an isomorphism from V to W with its new operations.

Example 1.2.23 (Repairing the line). Parametrize L by $\varphi : \mathbb{R} \to L$, $\varphi(t) = (2 - 2t, t)$. This is a bijection: each $(x, y) \in L$ has $x = 2 - 2y$, so $(x, y) = \varphi(y)$, and $\varphi^{-1}(x, y) = y$. Transport the structure of $\mathbb{R}$, a real vector space by Example 1.2.6, along φ. By Proposition 1.2.22, L becomes a real vector space with

$$(x, y) \oplus (x', y') = \varphi(y + y') = (2 - 2(y + y'), y + y'),$$

$$a \odot (x, y) = \varphi(ay) = (2 - 2ay, ay).$$

Its zero vector is $\varphi(0) = (2, 0) = \mathbf{p}$, and an additive inverse of (x, y) is $\varphi(-y) = (2 + 2y, -y)$.

These formulas can be written without φ. For $\mathbf{u} = (x, y)$ and $\mathbf{u}' = (x', y')$ in L we have $x = 2 - 2y$ and $x' = 2 - 2y'$, and substituting shows

$$\mathbf{u} \oplus \mathbf{u}' = \mathbf{u} + \mathbf{u}' - \mathbf{p}, \quad a \odot \mathbf{u} = \mathbf{p} + a(\mathbf{u} - \mathbf{p}),$$

where the right sides use the operations of $\mathbb{R}^2$. For instance, the first coordinate of $\mathbf{u} + \mathbf{u}' - \mathbf{p}$ is $x + x' - 2 = 2 - 2(y + y')$. So $\oplus$ and $\odot$ are the operations of $\mathbb{R}^2$ recentered at $\mathbf{p}$: subtract $\mathbf{p}$, compute as usual, and add $\mathbf{p}$ back. Any other point of L could serve as the origin instead and gives another valid structure; the line itself has no preferred origin. Such sets are studied as affine spaces in Section 4.7.

Exercise 1.2.24. ROUTINE Find the error in the following argument, and show that its conclusion is false.

Claim. No operations make the interval $(1, 2) = \{t \in \mathbb{R} \mid 1 < t < 2\}$ a real vector space.

Proof. Every vector space contains a zero vector, and the zero vector of a set of real numbers is 0. Since $0 \notin (1, 2)$, the interval cannot be a vector space.

Solution on page 1034

The next example changes one operation of $\mathbb{R}^2$ at a time. Each variant fails the axioms listed and satisfies the others, which shows what those axioms are for.

Example 1.2.25 (Changing one operation on $\mathbb{R}^2$).

(a) *Usual addition,* $a \odot (x, y) = (ax, 0)$. Axioms (A1)–(A4) are those of $\mathbb{R}^2$. Axioms (A6)–(A8) hold, because both sides agree in the first coordinate as in $\mathbb{R}^2$ and both have second coordinate 0. But (A5) fails: $1 \odot (0, 1) = (0, 0) \neq (0, 1)$. So (A5) does not follow from the other axioms; it is what stops scalar multiplication from discarding part of a vector. (The extreme case $a \odot \mathbf{v} = \mathbf{0}$ for all a and $\mathbf{v}$ also satisfies every axiom except (A5).)

(b) *Usual addition,* $a \odot (x, y) = (ax, y)$. Now (A5), (A6), and (A7) hold; for instance $(ab) \odot (x, y) = (abx, y) = a \odot (bx, y)$. But (A8) fails:

$$(1 + 1) \odot (0, 1) = (0, 1), \quad \text{while} \quad 1 \odot (0, 1) + 1 \odot (0, 1) = (0, 2).$$

Together with (A5), (A8) forces $2 \odot \mathbf{v} = \mathbf{v} + \mathbf{v}$, so scalar multiplication cannot leave a coordinate untouched.

(c) *Midpoint addition,* $(x, y) \oplus (x', y') = ((x + x')/2, (y + y')/2)$, *usual scalar multiplication.* (A1) holds, but (A2) fails: with $\mathbf{u} = \mathbf{v} = (0, 0)$ and $\mathbf{w} = (4, 0)$,

$$(\mathbf{u} \oplus \mathbf{v}) \oplus \mathbf{w} = (2, 0), \quad \text{while} \quad \mathbf{u} \oplus (\mathbf{v} \oplus \mathbf{w}) = (1, 0).$$

(A3) fails too, and this failure shows the quantifier order at work (Remark 1.2.2). We have $\mathbf{v} \oplus \mathbf{z} = \mathbf{v}$ exactly when $\mathbf{z} = \mathbf{v}$. So every $\mathbf{v}$ has a vector that acts like zero for it, namely $\mathbf{v}$ itself, but no single $\mathbf{z}$ works for every $\mathbf{v}$. Without a zero vector, (A4) cannot even be stated. Finally, (A8) fails: $(1 + 1)(1, 0) = (2, 0)$, while $(1, 0) \oplus (1, 0) = (1, 0)$. Axioms (A5)–(A7) hold.

The last non-example has operations that stay inside the set and satisfy most of the axioms.

Non-example 1.2.26 (Addition modulo 1). For $t \in \mathbb{R}$, write $t \bmod 1 = t - \lfloor t \rfloor \in [0, 1)$ for the fractional part of t. Then $s \bmod 1 = t \bmod 1$ exactly when $s - t \in \mathbb{Z}$. Let $V = [0, 1)$ with

$$s \oplus t = (s + t) \bmod 1, \quad a \odot t = (at) \bmod 1 \quad (a \in \mathbb{R}).$$

For instance $0.7 \oplus 0.5 = 0.2$. Think of V as a circle of circumference 1, on which adding means walking around the circle. Both operations land in V.

Replacing a real number by its fractional part changes it by an integer, and numbers that differ by an integer have the same fractional part. So, as in Lemma 1.1.21, both sides of (A2) equal $(s+t+u) \bmod 1$, and (A1) holds because $s+t = t+s$. The number 0 is a zero vector, an inverse of $t \neq 0$ is $1-t$, and 0 is its own inverse. (A5) holds since $1 \odot t = t \bmod 1 = t$ for $t \in [0,1)$. (A8) holds since $(a+b)t = at+bt$ differs from $(a \odot t) + (b \odot t)$ by an integer, so the fractional part of the latter, which is $(a \odot t) \oplus (b \odot t)$, equals that of the former, which is $(a+b) \odot t$. But (A7) fails: with $a = 1/2$ and $s = t = 1/2$,

$$\frac{1}{2} \odot \left(\frac{1}{2} \oplus \frac{1}{2}\right) = \frac{1}{2} \odot 0 = 0, \quad \text{while} \quad \left(\frac{1}{2} \odot \frac{1}{2}\right) \oplus \left(\frac{1}{2} \odot \frac{1}{2}\right) = \frac{1}{4} \oplus \frac{1}{4} = \frac{1}{2}.$$

(A6) fails as well: with $a = 1/2$, $b = 2$, and $t = 1/2$, we get $(ab) \odot t = 1 \odot t = 1/2$, while $a \odot (b \odot t) = a \odot 0 = 0$.

One might hope that a cleverer scalar multiplication repairs this. It cannot, and the reason (Example 1.2.40) is a consequence of the axioms that involves only the addition.

1.2.4 Consequences of the axioms

From now on, V is a vector space over a field F. The axioms are all we know about V, so as with fields, we prove each elementary fact from them (Technique 1.1.7). Each fact then holds in every example of the previous subsections.

Uniqueness

(A3) and (A4) assert existence only. As for fields, uniqueness is proved by comparing two candidates (Technique 1.1.8).

Proposition 1.2.27 (Uniqueness of the zero vector). A vector space has exactly one zero vector. That is, if $\mathbf{0}, \mathbf{0}' \in V$ both satisfy (A3), then $\mathbf{0} = \mathbf{0}'$.

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Proving from axioms (Technique 1.1.7)
Hint 1. Suppose $\mathbf{0}$ and $\mathbf{0}'$ both satisfy (A3). Find one expression that involves both.
Hint 2. Evaluate $\mathbf{0} + \mathbf{0}'$ twice: once using that $\mathbf{0}'$ satisfies (A3), and once, after (A1), using that $\mathbf{0}$ does.
Sketch. Each absorbs the other: $\mathbf{0} = \mathbf{0} + \mathbf{0}' = \mathbf{0}' + \mathbf{0} = \mathbf{0}'$.

Suppose $\mathbf{0}$ and $\mathbf{0}'$ both satisfy (A3). Then

$$\begin{aligned} \mathbf{0} &= \mathbf{0} + \mathbf{0}' && (\text{as } \mathbf{0}' \text{ satisfies (A3)}) \\ &= \mathbf{0}' + \mathbf{0} && (\text{A1}) \\ &= \mathbf{0}' && (\text{as } \mathbf{0} \text{ satisfies (A3)}), \end{aligned}$$

as desired. □

The proof used only (A1) and (A3), so (A4) refers to a definite vector. When several vector spaces are in play, we write $\mathbf{0}_V$ for the zero vector of V. The proof is word for word that of Theorem 1.1.9(a), because (A1)–(A4) are the additive axioms of a field with vectors in place of scalars.

"Exactly one additive inverse" is two claims. Existence is (A4). Uniqueness becomes precise once we name two candidates.

Proposition 1.2.28 (Uniqueness of additive inverses). Every vector has exactly one additive inverse. That is, if $\mathbf{v}, \mathbf{w}, \mathbf{w}' \in V$ satisfy $\mathbf{v} + \mathbf{w} = \mathbf{0}$ and $\mathbf{v} + \mathbf{w}' = \mathbf{0}$, then $\mathbf{w} = \mathbf{w}'$.

Proof. ROUTINE

> *Uses.* Definition 1.2.1 (Vector space), Proposition 1.2.27 (Uniqueness of the zero vector)
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8), Proving from axioms (Technique 1.1.7)
> *Hint 1.* Start from $\mathbf{w} = \mathbf{w} + \mathbf{0}$ and replace $\mathbf{0}$ by something involving $\mathbf{w}'$.
> *Hint 2.* Replace $\mathbf{0}$ by $\mathbf{v} + \mathbf{w}'$, then regroup so that $\mathbf{w}$ meets $\mathbf{v}$.
> *Sketch.* Insert $\mathbf{0} = \mathbf{v} + \mathbf{w}'$ into $\mathbf{w} = \mathbf{w} + \mathbf{0}$ and regroup: $\mathbf{w} = (\mathbf{w} + \mathbf{v}) + \mathbf{w}' = \mathbf{0} + \mathbf{w}' = \mathbf{w}'$.

Suppose $\mathbf{v} + \mathbf{w} = \mathbf{0}$ and $\mathbf{v} + \mathbf{w}' = \mathbf{0}$. Then

$$\begin{aligned} \mathbf{w} &= \mathbf{w} + \mathbf{0} && \text{(A3)} \\ &= \mathbf{w} + (\mathbf{v} + \mathbf{w}') && (\text{as } \mathbf{v} + \mathbf{w}' = \mathbf{0}) \\ &= (\mathbf{w} + \mathbf{v}) + \mathbf{w}' && \text{(A2)} \\ &= \mathbf{0} + \mathbf{w}' && (\text{as } \mathbf{w} + \mathbf{v} = \mathbf{v} + \mathbf{w} = \mathbf{0} \text{ by (A1)}) \\ &= \mathbf{w}' && \text{(A1 and A3),} \end{aligned}$$

as desired. □

Notation 1.2.29. The additive inverse of $\mathbf{v}$ is written $-\mathbf{v}$, and **subtraction** is defined by $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-\mathbf{v})$.

The additive facts about fields carry over with the same proofs, and we record the ones we use.

Proposition 1.2.30 (Additive arithmetic). Let $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$.

(a) The equation $\mathbf{u} + \mathbf{x} = \mathbf{w}$ has exactly one solution $\mathbf{x} \in V$, namely $\mathbf{x} = \mathbf{w} - \mathbf{u}$.

(b) If $\mathbf{u} + \mathbf{v} = \mathbf{u} + \mathbf{w}$, then $\mathbf{v} = \mathbf{w}$.

(c) $-(-\mathbf{v}) = \mathbf{v}$, and $-\mathbf{0} = \mathbf{0}$.

Proof. ROUTINE

> *Uses.* Definition 1.2.1 (Vector space), Proposition 1.2.28 (Uniqueness of additive inverses), Notation 1.2.29, Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$)
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8), Proving from axioms (Technique 1.1.7)
> *Hint 1.* For (a), check that $\mathbf{w} - \mathbf{u}$ is a solution. For uniqueness, add $-\mathbf{u}$ on the left of $\mathbf{u} + \mathbf{x}$ and regroup.
> *Hint 2.* (b) is (a) with $\mathbf{w}$ replaced by $\mathbf{u} + \mathbf{v}$. For (c), to show a vector equals $-\mathbf{y}$, show it is an additive inverse of $\mathbf{y}$.
> *Sketch.* This is Proposition 1.1.13(a) and its consequences, whose proofs used only the additive axioms. $\mathbf{u} + (\mathbf{w} - \mathbf{u}) = (\mathbf{u} + (-\mathbf{u})) + \mathbf{w} = \mathbf{w}$, and any solution satisfies $\mathbf{x} = (-\mathbf{u} + \mathbf{u}) + \mathbf{x} = -\mathbf{u} + \mathbf{w}$. For (c), $\mathbf{v}$ is an inverse of $-\mathbf{v}$, and $\mathbf{0} + \mathbf{0} = \mathbf{0}$.

(a) First, $\mathbf{w} - \mathbf{u}$ is a solution:

$$\begin{aligned} \mathbf{u} + (\mathbf{w} + (-\mathbf{u})) &= \mathbf{u} + ((-\mathbf{u}) + \mathbf{w}) && \text{(A1)} \\ &= (\mathbf{u} + (-\mathbf{u})) + \mathbf{w} && \text{(A2)} \\ &= \mathbf{0} + \mathbf{w} = \mathbf{w} && \text{(A4, then A1 and A3).} \end{aligned}$$

Conversely, suppose $\mathbf{u} + \mathbf{x} = \mathbf{w}$. Then

$$\begin{aligned} \mathbf{x} &= \mathbf{0} + \mathbf{x} && \text{(A1 and A3)} \\ &= ((-\mathbf{u}) + \mathbf{u}) + \mathbf{x} && \text{(A4 and A1)} \\ &= (-\mathbf{u}) + (\mathbf{u} + \mathbf{x}) && \text{(A2)} \\ &= (-\mathbf{u}) + \mathbf{w} = \mathbf{w} - \mathbf{u} && \text{(hypothesis, then A1),} \end{aligned}$$

so $\mathbf{w} - \mathbf{u}$ is the only solution.

(b) Both $\mathbf{v}$ and $\mathbf{w}$ solve $\mathbf{u} + \mathbf{x} = \mathbf{u} + \mathbf{v}$, which has only one solution by (a). So $\mathbf{v} = \mathbf{w}$.

(c) By (A1) and (A4), $(-\mathbf{v}) + \mathbf{v} = \mathbf{v} + (-\mathbf{v}) = \mathbf{0}$, so $\mathbf{v}$ is an additive inverse of $-\mathbf{v}$, and $\mathbf{v} = -(-\mathbf{v})$ by Proposition 1.2.28. Since $\mathbf{0} + \mathbf{0} = \mathbf{0}$ by (A3), $\mathbf{0}$ is an additive inverse of $\mathbf{0}$, so $-\mathbf{0} = \mathbf{0}$. □

Remark 1.2.31. A set with an operation satisfying (A1)–(A4) is called an **abelian group** (Section 14.1). Everything in this subsection is a fact about abelian groups: scalars have not appeared yet, and the same statements hold in $(F, +)$.

Scalars and vectors together

Intuition. Every fact so far used only (A1)–(A4). A fact relating the additive objects 0 or $\mathbf{0}$ to scalar multiplication must use (A7) or (A8), the only axioms that involve addition and scalar multiplication together. For the scalar 0, the additive fact to start from is $0 + 0 = 0$ in F, and (A8) carries it over to vectors, just as distributivity did for $0a = 0$ in a field (Proposition 1.1.15).

Proposition 1.2.32 (The scalar zero). For every $\mathbf{v} \in V$, $0\mathbf{v} = \mathbf{0}$.

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space), Proposition 1.2.30 (Additive arithmetic)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Which axiom can turn the scalar equation $0 + 0 = 0$ into a statement about vectors?
Hint 2. Apply (A8) to $(0 + 0)\mathbf{v}$. You get $0\mathbf{v} + 0\mathbf{v} = 0\mathbf{v}$. Compare with $0\mathbf{v} + \mathbf{0} = 0\mathbf{v}$ and cancel.
Sketch. (A8) turns $0 + 0 = 0$ into $0\mathbf{v} + 0\mathbf{v} = 0\mathbf{v} = 0\mathbf{v} + \mathbf{0}$, and cancelling $0\mathbf{v}$ (Proposition 1.2.30(b)) gives $0\mathbf{v} = \mathbf{0}$.

Let $\mathbf{v} \in V$. Then

$$\begin{aligned} 0\mathbf{v} + 0\mathbf{v} &= (0 + 0)\mathbf{v} && \text{(A8)} \\ &= 0\mathbf{v} && (\text{as } \ 0 + 0 = 0 \ \text{ in } \ F\,) \\ &= 0\mathbf{v} + \mathbf{0} && \text{(A3).} \end{aligned}$$

Cancelling $0\mathbf{v}$ from both sides (Proposition 1.2.30(b)) gives $0\mathbf{v} = \mathbf{0}$. □

The companion statement is about the zero *vector* multiplied by any scalar. It is a different statement, and its first proof below uses the other distributive law. The second proof reduces it to Proposition 1.2.32.

Proposition 1.2.33 (The zero vector). For every $a \in F$, $a\mathbf{0} = \mathbf{0}$.

Proof (via (A7)). ROUTINE

Uses. Definition 1.2.1 (Vector space), Proposition 1.2.30 (Additive arithmetic)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Imitate the proof of Proposition 1.2.32, starting from the vector equation $\mathbf{0} + \mathbf{0} = \mathbf{0}$.
Hint 2. Apply (A7) to $a(\mathbf{0} + \mathbf{0})$ and cancel $a\mathbf{0}$.
Sketch. (A7) turns $\mathbf{0} + \mathbf{0} = \mathbf{0}$ into $a\mathbf{0} + a\mathbf{0} = a\mathbf{0} = a\mathbf{0} + \mathbf{0}$; cancel $a\mathbf{0}$.

Let $a \in F$. Then

$$\begin{aligned} a\mathbf{0} + a\mathbf{0} &= a(\mathbf{0} + \mathbf{0}) && \text{(A7)} \\ &= a\mathbf{0} && \text{(A3)} \\ &= a\mathbf{0} + \mathbf{0} && \text{(A3),} \end{aligned}$$

and cancelling $a\mathbf{0}$ (Proposition 1.2.30(b)) gives $a\mathbf{0} = \mathbf{0}$. □

Proof (from $0\mathbf{v} = \mathbf{0}$). ROUTINE

Uses. Proposition 1.2.32 (The scalar zero), Proposition 1.1.15 (Multiplying by zero), Definition 1.2.1 (Vector space)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Proposition 1.2.32 says every vector times the scalar 0 is $\mathbf{0}$. Apply it to the vector $\mathbf{0}$ to rewrite $\mathbf{0}$.
Hint 2. Write $a\mathbf{0} = a(0\mathbf{0})$ and use (A6) to move the scalar 0 next to a.
Sketch. $a\mathbf{0} = a(0\mathbf{0}) = (a0)\mathbf{0} = 0\mathbf{0} = \mathbf{0}$, by Proposition 1.2.32, (A6), $a0 = 0$ in F, and Proposition 1.2.32 again.

Let $a \in F$. By Proposition 1.2.32 applied to the vector $\mathbf{0}$, we have $\mathbf{0} = 0\mathbf{0}$. Using this, then (A6), then $a0 = 0$ in F (Proposition 1.1.15), and finally Proposition 1.2.32 once more,

$$a\mathbf{0} = a(0\mathbf{0}) = (a0)\mathbf{0} = 0\mathbf{0} = \mathbf{0}.$$ □

The first proof is the template of Proposition 1.2.32 with the other distributive law. The second uses no distributive law directly: it writes $\mathbf{0}$ as $0\mathbf{0}$ and moves the scalar 0 through (A6), so the work is done by the field ($a0 = 0$) and by the earlier result, through which (A8) enters. Reducing a new claim to one already proved is often shorter than starting again from the axioms.

Intuition. To show that a vector equals $-\mathbf{v}$, it suffices to show that it is *an* additive inverse of $\mathbf{v}$, by Proposition 1.2.28. For $(-1)\mathbf{v}$, write $\mathbf{v} = 1\mathbf{v}$ and combine the two terms with (A8).

Proposition 1.2.34 (Negatives and the scalar -1). For all $a \in F$ and $\mathbf{v} \in V$:

(a) $(-1)\mathbf{v} = -\mathbf{v}$;

(b) $(-a)\mathbf{v} = -(a\mathbf{v}) = a(-\mathbf{v})$.

Proof. ROUTINE

Uses. Proposition 1.2.28 (Uniqueness of additive inverses), Proposition 1.2.32 (The scalar zero), Proposition 1.1.16 (Sign rules), Definition 1.2.1 (Vector space)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Proving from axioms (Technique 1.1.7)
Hint 1. For (a), compute $\mathbf{v} + (-1)\mathbf{v}$. Write $\mathbf{v}$ as $1\mathbf{v}$ first.
Hint 2. (A8) gives $(1 + (-1))\mathbf{v} = 0\mathbf{v}$, and Proposition 1.2.32 finishes. Conclude with Proposition 1.2.28.
Hint 3. For (b), write $-a = (-1)a$ (Proposition 1.1.16) and move the factor -1 with (A6).
Sketch. $\mathbf{v} + (-1)\mathbf{v} = 1\mathbf{v} + (-1)\mathbf{v} = (1 + (-1))\mathbf{v} = 0\mathbf{v} = \mathbf{0}$, so $(-1)\mathbf{v} = -\mathbf{v}$ by uniqueness of inverses. Then $(-a)\mathbf{v} = ((-1)a)\mathbf{v} = (-1)(a\mathbf{v}) = -(a\mathbf{v})$, and $a(-\mathbf{v}) = a((-1)\mathbf{v}) = (a(-1))\mathbf{v} = (-a)\mathbf{v}$.

(a) We compute

$$\begin{aligned} \mathbf{v} + (-1)\mathbf{v} &= 1\mathbf{v} + (-1)\mathbf{v} && \text{(A5)} \\ &= (1 + (-1))\mathbf{v} && \text{(A8)} \\ &= 0\mathbf{v} = \mathbf{0}, \end{aligned}$$

where the last step is Proposition 1.2.32. So $(-1)\mathbf{v}$ is an additive inverse of $\mathbf{v}$, and $(-1)\mathbf{v} = -\mathbf{v}$ by Proposition 1.2.28.

(b) By Proposition 1.1.16, $-a = (-1)a = a(-1)$. Using (A6) and (a),

$$(-a)\mathbf{v} = ((-1)a)\mathbf{v} = (-1)(a\mathbf{v}) = -(a\mathbf{v}),$$

and

$$a(-\mathbf{v}) = a((-1)\mathbf{v}) = (a(-1))\mathbf{v} = (-a)\mathbf{v}.$$ □

In particular $a(\mathbf{v} - \mathbf{w}) = a\mathbf{v} + a(-\mathbf{w}) = a\mathbf{v} - a\mathbf{w}$ by (A7) and (b), and similarly $(a - b)\mathbf{v} = a\mathbf{v} - b\mathbf{v}$ by (A8) and (b).

Intuition. In a field, $ab = 0$ forces $a = 0$ or $b = 0$ (Proposition 1.1.17), and the proof multiplied by a^{-1}. The vector version has the same proof. It is the first place where the multiplicative inverses of F matter for vectors.

Proposition 1.2.35 (Zero products). Let $a \in F$ and $\mathbf{v} \in V$. If $a\mathbf{v} = \mathbf{0}$, then $a = 0$ or $\mathbf{v} = \mathbf{0}$. Consequently, $a\mathbf{v} = \mathbf{0}$ if and only if $a = 0$ or $\mathbf{v} = \mathbf{0}$.

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space), Proposition 1.2.33 (The zero vector), Proposition 1.2.32 (The scalar zero), Definition 1.1.1 (Field)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. To prove "$a = 0$ or $\mathbf{v} = \mathbf{0}$", assume $a \neq 0$ and prove $\mathbf{v} = \mathbf{0}$.

Hint 2. If $a \neq 0$, then a^{-1} exists. Write $\mathbf{v} = 1\mathbf{v} = (a^{-1}a)\mathbf{v}$ and use (A6).
Sketch. If $a \neq 0$, then $\mathbf{v} = 1\mathbf{v} = (a^{-1}a)\mathbf{v} = a^{-1}(a\mathbf{v}) = a^{-1}\mathbf{0} = \mathbf{0}$. The converse is Proposition 1.2.32 and Proposition 1.2.33.

Suppose $a\mathbf{v} = \mathbf{0}$. If $a = 0$ we are done, so suppose $a \neq 0$. Then a^{-1} exists, and

$$\begin{aligned} \mathbf{v} &= 1\mathbf{v} && \text{(A5)} \\ &= (a^{-1}a)\mathbf{v} && \text{(multiplicative inverse in } F\text{)} \\ &= a^{-1}(a\mathbf{v}) && \text{(A6)} \\ &= a^{-1}\mathbf{0} && \text{(as } a\mathbf{v} = \mathbf{0}\text{)} \\ &= \mathbf{0}, \end{aligned}$$

where the last step is Proposition 1.2.33. Conversely, if $a = 0$ then $a\mathbf{v} = \mathbf{0}$ by Proposition 1.2.32, and if $\mathbf{v} = \mathbf{0}$ then $a\mathbf{v} = \mathbf{0}$ by Proposition 1.2.33. □

Corollary 1.2.36 (Cancelling scalars and vectors). Let $a, b \in F$ and $\mathbf{v}, \mathbf{w} \in V$.

(a) If $a\mathbf{v} = a\mathbf{w}$ and $a \neq 0$, then $\mathbf{v} = \mathbf{w}$.

(b) If $a\mathbf{v} = b\mathbf{v}$ and $\mathbf{v} \neq \mathbf{0}$, then $a = b$.

Proof. ROUTINE

Uses. Proposition 1.2.35 (Zero products), Proposition 1.2.34 (Negatives and the scalar -1), Proposition 1.2.30 (Additive arithmetic)
Hint 1. Move everything to one side: $a\mathbf{v} = a\mathbf{w}$ is equivalent to $a\mathbf{v} - a\mathbf{w} = \mathbf{0}$. Factor.
Hint 2. $a\mathbf{v} - a\mathbf{w} = a(\mathbf{v} - \mathbf{w})$ and $a\mathbf{v} - b\mathbf{v} = (a - b)\mathbf{v}$. Now use Proposition 1.2.35.
Sketch. $a(\mathbf{v} - \mathbf{w}) = a\mathbf{v} - a\mathbf{w} = \mathbf{0}$ with $a \neq 0$ forces $\mathbf{v} - \mathbf{w} = \mathbf{0}$; and $(a - b)\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$ forces $a - b = 0$.

(a) By (A7) and Proposition 1.2.34(b), $a(\mathbf{v} - \mathbf{w}) = a\mathbf{v} + a(-\mathbf{w}) = a\mathbf{v} - a\mathbf{w}$, which is $\mathbf{0}$ because $a\mathbf{v} = a\mathbf{w}$. Since $a \neq 0$, Proposition 1.2.35 gives $\mathbf{v} - \mathbf{w} = \mathbf{0}$. Hence, by (A3), (A4) with (A1), (A2), and (A1) with (A3),

$$\mathbf{v} = \mathbf{v} + ((-\mathbf{w}) + \mathbf{w}) = (\mathbf{v} - \mathbf{w}) + \mathbf{w} = \mathbf{0} + \mathbf{w} = \mathbf{w}.$$

(b) By (A8) and Proposition 1.2.34(b), $(a - b)\mathbf{v} = a\mathbf{v} + (-b)\mathbf{v} = a\mathbf{v} - b\mathbf{v} = \mathbf{0}$. Since $\mathbf{v} \neq \mathbf{0}$, Proposition 1.2.35 gives $a - b = 0$, so $a = b$. □

Part (b) says that if $\mathbf{v} \neq \mathbf{0}$, the multiples $a\mathbf{v}$ for different scalars a are different vectors. So a vector space other than $\{\mathbf{0}\}$ has at least as many elements as F (Exercise 1.2.42).

Exercise 1.2.37. ROUTINE Let $a \in F$ and $\mathbf{u}, \mathbf{w} \in V$.

(a) Suppose $a \neq 0$. Show that the equation $a\mathbf{x} + \mathbf{u} = \mathbf{w}$ has exactly one solution $\mathbf{x} \in V$, and find it.

(b) Suppose $a = 0$. For which $\mathbf{u}$ and $\mathbf{w}$ does the equation have a solution, and how many?

Solution on page 1034

Testing claims on small cases

Facts that are second nature in $\mathbb{R}^2$ can fail in other vector spaces, and the quickest way to find out is to compute in a small one.

Technique 1.2.38 (Try small cases and small fields). Before proving a general claim, test it on the smallest examples available: the zero space, F^1 and F^2, and small fields, especially $\mathbb{F}_2$, where $1 + 1 = 0$. Small cases are where counterexamples live. When the claim survives them, the computation often shows why it is true and which hypothesis a proof must use.

Reach for it when a claim feels obvious from experience with $\mathbb{R}^2$, and whenever a hypothesis such as $1 + 1 \neq 0$ or $V \neq \{\mathbf{0}\}$ might be needed. The canonical example is Example 1.2.39: $\mathbf{v} = -\mathbf{v}$ forces $\mathbf{v} = \mathbf{0}$ over $\mathbb{R}$, but not over $\mathbb{F}_2$.

Used in. Exercise 1.2.49, Exercise 1.3.30, Exercise 1.3.43, Exercise 1.4.42, Exercise 1.7.6, Exercise 1.7.13, Exercise 1.7.15, Exercise 2.8.5, Problem 2.8, Problem 2.14, Problem 2.20, Problem 3.6, Problem 4.17, Exercise 5.6.10, Exercise 5.6.15, Exercise 1.3.46, Exercise 1.4.32, Exercise 1.5.36, Exercise 7.1.53, Exercise 7.5.31, Exercise 7.6.41.

Example 1.2.39 (When does $\mathbf{v} = -\mathbf{v}$ force $\mathbf{v} = \mathbf{0}$?). Over $\mathbb{R}$, a vector equal to its own negative is $\mathbf{0}$. Over $\mathbb{F}_2$ this fails: in $\mathbb{F}_2^2$, $(1,0) + (1,0) = (1+1,0) = (0,0)$, so $(1,0) = -(1,0)$, although $(1,0) \neq \mathbf{0}$. So the answer depends on the field, and the computation suggests why. By Proposition 1.2.28, $\mathbf{v} = -\mathbf{v}$ holds exactly when $\mathbf{v} + \mathbf{v} = \mathbf{0}$, and by (A5) and (A8),

$$\mathbf{v} + \mathbf{v} = 1\mathbf{v} + 1\mathbf{v} = (1+1)\mathbf{v}.$$

If $1 + 1 \neq 0$ in F, then $(1+1)\mathbf{v} = \mathbf{0}$ forces $\mathbf{v} = \mathbf{0}$ by Proposition 1.2.35. If $1 + 1 = 0$ in F, then $\mathbf{v} + \mathbf{v} = 0\mathbf{v} = \mathbf{0}$ for every $\mathbf{v}$, so every vector is its own negative. The test over $\mathbb{F}_2$ produced both the counterexample and the hypothesis $1 + 1 \neq 0$ under which the claim holds (compare Aside (Characteristic)).

Example 1.2.40 (Addition modulo 1, again). We show that no scalar multiplication makes $V = [0,1)$ a real vector space with the addition $\oplus$ of Non-example 1.2.26. In every real vector space, $\mathbf{v} + \mathbf{v} = \mathbf{0}$ forces $\mathbf{v} = \mathbf{0}$, by Example 1.2.39, because $1 + 1 = 2 \neq 0$ in $\mathbb{R}$. But in V,

$$\frac{1}{2} \oplus \frac{1}{2} = 1 \bmod 1 = 0,$$

and $1/2$ is not the zero vector 0 (the zero vector is unique, Proposition 1.2.27, and 0 satisfies (A3) for $\oplus$). The argument uses only consequences of the axioms that every candidate scalar multiplication must satisfy, so it rules them all out at once.

This is a different way to show that something is not a vector space. Instead of finding an axiom that fails for given operations, find a consequence of the axioms that involves only the part we cannot change, here the addition, and check that it fails.

Exercises

Exercise 1.2.41. ROUTINE Let $p, q \in F[x]$ be nonzero. Prove or disprove each statement.

(a) $\deg(p+q) = \max(\deg p, \deg q)$.

(b) If $\deg(p+q) < \deg p$, then $\deg p = \deg q$, and the leading coefficients of p and q add to 0.

(c) The set of polynomials in $\mathbb{R}[x]$ of degree exactly 2, with the operations of $\mathbb{R}[x]$, is a real vector space.

Solution on page 1035

Exercise 1.2.42. ROUTINE Suppose $V \neq \{\mathbf{0}\}$. Show that V has at least as many elements as F. In particular, a vector space over an infinite field is either $\{\mathbf{0}\}$ or infinite, and if V is finite, then so is F.

Solution on page 1035

Exercise 1.2.43. STANDARD

(a) Find the error in the following argument.

Claim. If $\mathbf{u}, \mathbf{v} \in V$ and $\mathbf{u} + \mathbf{v} = \mathbf{u}$, then $\mathbf{v} = \mathbf{0}$.

Proof. By Proposition 1.2.27, $\mathbf{0}$ is the only vector $\mathbf{z}$ with $\mathbf{u} + \mathbf{z} = \mathbf{u}$. Since $\mathbf{u} + \mathbf{v} = \mathbf{u}$, we get $\mathbf{v} = \mathbf{0}$.

(b) Prove the claim correctly.

(c) Give an example of a set with an addition satisfying (A1)–(A3), in which $\mathbf{u} + \mathbf{v} = \mathbf{u}$ for some $\mathbf{u}$ and some $\mathbf{v}$ that is not the identity element of (A3).

Solution on page 1035

Exercise 1.2.44. STANDARD

(a) For which fields F is there a vector space over F with exactly two elements?

(b) Show that no vector space over $\mathbb{F}_2$ has exactly three elements, and no vector space over $\mathbb{F}_3$ has exactly four.

Solution on page 1035

Exercise 1.2.45. STANDARD For a positive integer n and $\mathbf{v} \in V$, write $n * \mathbf{v} = \mathbf{v} + \cdots + \mathbf{v}$ (n terms), and similarly $n * 1 = 1 + \cdots + 1 \in F$ (written $n \cdot 1$ in Definition 1.1.28; we use $*$ here because juxtaposition already means scalar multiplication). Suppose $V \neq \{\mathbf{0}\}$. Show that the following are equivalent:

(i) $n * 1 = 0$ in F;

(ii) $n * \mathbf{v} = \mathbf{0}$ for every $\mathbf{v} \in V$;

(iii) $n * \mathbf{v} = \mathbf{0}$ for some $\mathbf{v} \neq \mathbf{0}$ in V.

Deduce that $\operatorname{char} F$ (Definition 1.1.28) can be read off from the addition of V: it is the least $n \geq 1$ with $n * \mathbf{v} = \mathbf{0}$ for all $\mathbf{v} \in V$, or 0 if there is none.

Solution on page 1036

Exercise 1.2.46. STANDARD

(a) Is there a scalar multiplication that makes $\mathbb{Z}$, with its usual addition, a vector space over $\mathbb{F}_p$?

(b) Is there a field F and a scalar multiplication that make $\mathbb{Z}/4\mathbb{Z}$, with its usual addition, a vector space over F?

Solution on page 1036

Exercise 1.2.47. STANDARD Is there a scalar multiplication $\odot : \mathbb{C} \times \mathbb{R} \to \mathbb{R}$ that makes $\mathbb{R}$, with its usual addition, a complex vector space, and that agrees with the usual product for real scalars, that is, $a \odot x = ax$ for $a \in \mathbb{R}$?

Solution on page 1037

Exercise 1.2.48. STANDARD Keep the usual addition on $\mathbb{C}^2$. For $a = x + yi \in \mathbb{C}$ with $x, y \in \mathbb{R}$, write $\bar{a} = x - yi$, $|a| = \sqrt{x^2 + y^2}$, and $\operatorname{Re} a = x$. Which of the following scalar multiplications make $\mathbb{C}^2$ a complex vector space?

(a) $a \odot \mathbf{v} = \bar{a}\mathbf{v}$.

(b) $a \odot \mathbf{v} = |a|\mathbf{v}$.

(c) $a \odot \mathbf{v} = (\operatorname{Re} a)\mathbf{v}$.

Solution on page 1037

Exercise 1.2.49. STANDARD Let F be a field. On F^2, keep the usual addition and define $a \odot (x, y) = (ax, a^2 y)$. For which fields F is this a vector space over F?

Solution on page 1037

Exercise 1.2.50. STANDARD Let $P = \{(x, y) \in \mathbb{R}^2 \mid y = x^2\}$ be the parabola. Find operations that make P a real vector space in which $(1, 1) \oplus (2, 4) = (3, 9)$. In your structure, find the zero vector, the additive inverse of $(2, 4)$, and $3 \odot (-1, 1)$.

Solution on page 1038

Exercise 1.2.51. STANDARD

(a) Find all $f \in \mathbb{F}_2[x]_{\leq 3}$ whose polynomial function $\mathbb{F}_2 \to \mathbb{F}_2$ is the zero function. How many polynomials does $\mathbb{F}_2[x]_{\leq 3}$ contain, and how many functions $\mathbb{F}_2 \to \mathbb{F}_2$ are there? When do two polynomials in $\mathbb{F}_2[x]_{\leq 3}$ have the same polynomial function?

(b) Let p be a prime. Show that $x^p - x \in \mathbb{F}_p[x]$ is a nonzero polynomial whose polynomial function is zero.

Solution on page 1038

Exercise 1.2.52. STANDARD Let V be a vector space over $\mathbb{Q}$.

(a) Show that for every integer $n \geq 1$ and $\mathbf{w} \in V$, the scalar multiple $n\mathbf{w}$ equals $\mathbf{w} + \cdots + \mathbf{w}$ (n terms).

(b) Let $q = m/n$ with $m, n \in \mathbb{Z}$ and $n \geq 1$. Show that $q\mathbf{v}$ is the only vector $\mathbf{w} \in V$ with $n\mathbf{w} = m\mathbf{v}$.

(c) Deduce that the scalar multiplication of a $\mathbb{Q}$-vector space is determined by its addition: if $\odot$ and $\odot'$ both make $(V, +)$ a vector space over $\mathbb{Q}$, then $q \odot \mathbf{v} = q \odot' \mathbf{v}$ for all q and $\mathbf{v}$.

Solution on page 1038

Exercise 1.2.53. HARD Let $V = (-1, 1)$, and define $u \oplus v = (u + v)/(1 + uv)$. (In units where the speed of light is 1, this is how velocities along a line add in special relativity.)

(a) Show that $u \oplus v \in V$ for $u, v \in V$.

(b) Find a scalar multiplication $\odot$ that makes $(V, \oplus, \odot)$ a real vector space. Compute $2 \odot v$ and $(1/2) \odot v$ explicitly, and identify the zero vector and the additive inverse of v.

Solution on page 1039

Exercise 1.2.54. HARD

(a) Find the error in the following argument.

Claim. (A4) follows from the other axioms.

Proof. Let $\mathbf{v} \in V$. By (A5), (A8), and Proposition 1.2.32,

$$\mathbf{v} + (-1)\mathbf{v} = 1\mathbf{v} + (-1)\mathbf{v} = (1 + (-1))\mathbf{v} = 0\mathbf{v} = \mathbf{0}.$$

So $(-1)\mathbf{v}$ is an additive inverse of $\mathbf{v}$.

(b) Show that the claim is false: construct a set with operations that satisfy every axiom except (A4).

Solution on page 1040

Exercise 1.2.55. HARD Suppose V, with operations $+$ and $\cdot$, satisfies every vector space axiom except possibly (A5). Let

$$W = \{\mathbf{v} \in V \mid 1\mathbf{v} = \mathbf{v}\}, \quad N = \{\mathbf{v} \in V \mid a\mathbf{v} = \mathbf{0} \text{ for all } a \in F\}.$$

(a) Show that every $\mathbf{v} \in V$ can be written as $\mathbf{v} = \mathbf{w} + \mathbf{n}$ with $\mathbf{w} \in W$ and $\mathbf{n} \in N$, in exactly one way.

(b) Show that W, with the operations of V, is a vector space over F.

(c) Show that (A5) holds if and only if $N = \{\mathbf{0}\}$.

Solution on page 1040

Exercise 1.2.56. HARD Suppose V, with operations $+$ and $\cdot$, satisfies (A2)–(A8), but not necessarily (A1). (Note that (A3) and (A4) only say $\mathbf{v}+\mathbf{0}=\mathbf{v}$ and $\mathbf{v}+\mathbf{w}=\mathbf{0}$, with $\mathbf{0}$ and $\mathbf{w}$ on the right. Without (A1) we cannot prove that the zero vector is unique, so fix one element $\mathbf{0}$ satisfying (A3) for which (A4) holds, and let $\mathbf{0}$ always mean this element.) Show that $\mathbf{u}+\mathbf{v}=\mathbf{v}+\mathbf{u}$ for all $\mathbf{u},\mathbf{v}\in V$.

Solution on page 1041

Exercise 1.2.57. CHALLENGE Let $f:\mathbb{R}\to\mathbb{R}$ be a function, and on $V=\mathbb{R}$ with its usual addition define $a\odot x=f(a)x$.

(a) Show that $(V,+,\odot)$ is a real vector space if and only if $f(1)=1$, $f(a+b)=f(a)+f(b)$, and $f(ab)=f(a)f(b)$ for all $a,b\in\mathbb{R}$.

(b) Show that the only such f is the identity. So the usual product is the only scalar multiplication of this form.

Solution on page 1042

1.3 Lists, linear combinations, and span

A vector space has two operations, and each of them combines at most two vectors. Applying them over and over to finitely many vectors $\mathbf{v}_1,\ldots,\mathbf{v}_k$ produces sums $a_1\mathbf{v}_1+\cdots+a_k\mathbf{v}_k$, and every expression built from the $\mathbf{v}_i$ with the two operations can be brought into this form (Lemma 1.3.9). Two questions about these sums run through the rest of the book: which vectors they produce, and in how many ways. This section answers the first question with the span; the second leads to linear independence in Section 1.5. We begin by making "finitely many vectors $\mathbf{v}_1,\ldots,\mathbf{v}_k$" precise, in a form where the order is fixed and repetitions are allowed.

1.3.1 Lists

Definition 1.3.1 (List). Let V be a set and let $k\geq 0$ be an integer. A **list of length** k in V is a function $\{1,\ldots,k\}\to V$. Writing $\mathbf{v}_i$ for its value at i, we write the list as

$$\mathbf{v}_1,\mathbf{v}_2,\ldots,\mathbf{v}_k,$$

without parentheses, and call $\mathbf{v}_i$ its i**-th entry**. Two lists are equal when they have the same length and the same i-th entry for every i. Lists are named by calligraphic letters, as in $\mathcal{L}=\mathbf{v}_1,\ldots,\mathbf{v}_k$, and $|\mathcal{L}|=k$ is the **length** of $\mathcal{L}$. For $k=0$ the domain is empty, and there is exactly one function from the empty set to V. It is the **empty list**, written $()$.

So a list is a finite sequence. Defining it as a function settles what equality of lists means, and it makes the empty list an ordinary list rather than an exception. A list of length one is written $\mathbf{v}$, and a list of length two $\mathbf{v},\mathbf{w}$. Columns in F^n keep their parentheses, so $(1,0),(0,1)$ is a list of length two in $\mathbb{R}^2$, and $(1,0)$ alone is a list of length one.

Example 1.3.2 (Lists versus sets). In $\mathbb{R}^2$, the lists $(1,0),(0,1)$ and $(0,1),(1,0)$ are different, since their first entries differ, while the sets $\{(1,0),(0,1)\}$ and $\{(0,1),(1,0)\}$ are equal. In any vector space, $\mathbf{0},\mathbf{0},\mathbf{0}$ is a list of length 3. It is different from the list $\mathbf{0}$ of length 1 and from the empty list $()$, although $\{\mathbf{0},\mathbf{0},\mathbf{0}\}=\{\mathbf{0}\}$ as sets.

We work with lists because a linear combination gives each entry its own coefficient. In the list $\mathbf{v},\mathbf{v}$, the vector $\mathbf{v}$ receives two coefficients, and $1\mathbf{v}+(-1)\mathbf{v}$ produces $\mathbf{0}$ in a way that the set $\{\mathbf{v}\}$ cannot record. This kind of redundancy is what linear independence detects (Section 1.5), and the order of a list will fix the order of coordinates (Section 1.6).

Notation 1.3.3. Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in V.

- We write $\mathbf{v} \in \mathcal{L}$ if $\mathbf{v} = \mathbf{v}_i$ for some i. For a subset $S \subseteq V$, we write $\mathcal{L} \subseteq S$ if every entry of $\mathcal{L}$ lies in S.
- For a list $\mathcal{M} = \mathbf{w}_1, ..., \mathbf{w}_m$, the **concatenation** $\mathcal{L}, \mathcal{M}$ is the list $\mathbf{v}_1, ..., \mathbf{v}_k, \mathbf{w}_1, ..., \mathbf{w}_m$ of length $k + m$. In particular, $\mathcal{L}, \mathbf{w}$ is $\mathcal{L}$ with $\mathbf{w}$ appended.
- A **sublist** of $\mathcal{L}$ is a list $\mathbf{v}_{i_1}, ..., \mathbf{v}_{i_m}$ with $1 \le i_1 < \cdots < i_m \le k$. It is obtained by deleting some entries and keeping the rest in order. A **reordering** of $\mathcal{L}$ is a list $\mathbf{v}_{\sigma(1)}, ..., \mathbf{v}_{\sigma(k)}$, where σ is a bijection from $\{1, ..., k\}$ to itself.

1.3.2 Linear combinations

From now on, V is a vector space over a field F.

Definition 1.3.4 (Linear combination). Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in V. A **linear combination** of $\mathcal{L}$ is an expression

$$a_1\mathbf{v}_1 + a_2\mathbf{v}_2 + \cdots + a_k\mathbf{v}_k, \quad \text{also written} \quad \sum_{i=1}^{k} a_i\mathbf{v}_i,$$

where $a_1, ..., a_k \in F$ are its **coefficients**. Two linear combinations of $\mathcal{L}$ are the same exactly when their coefficients are the same. Carrying out the operations of V in the expression produces a vector of V, and we say that the linear combination **represents** that vector. The empty list has exactly one linear combination, the empty sum, and it represents $\mathbf{0}$.

To carry out the operations, compute each term $a_i\mathbf{v}_i$ and add the terms from left to right:

$$\sum_{i=1}^{0} a_i\mathbf{v}_i = \mathbf{0}, \quad \sum_{i=1}^{k} a_i\mathbf{v}_i = \left(\sum_{i=1}^{k-1} a_i\mathbf{v}_i\right) + a_k\mathbf{v}_k \quad (k \ge 1). \tag{1.3.1}$$

By (A1) and (A2), neither the order nor the grouping of the terms affects the result; the argument is the one for sums in a field (Section 1.1.2). The empty sum must be $\mathbf{0}$ if the recursion is to give $\sum_{i=1}^{1} a_i\mathbf{v}_i = a_1\mathbf{v}_1$.

The definition separates two things that everyday usage runs together: the expression, which is determined by its coefficients once $\mathcal{L}$ is fixed, and the vector it represents. Formally, a linear combination of $\mathcal{L}$ is just its list of coefficients $a_1, ..., a_k$. When we write $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$, the equation says that the linear combination on the right represents $\mathbf{w}$. We also say "$\mathbf{w}$ is a linear combination of $\mathcal{L}$" to mean that some linear combination of $\mathcal{L}$ represents $\mathbf{w}$. This phrase is standard and harmless, as long as we keep track of which object is meant. The next example shows why the distinction matters.

Example 1.3.5 (One vector, many representations). In $\mathbb{R}^2$, let $\mathcal{L}_1 = (0,0), (1,-1), (-\pi, \pi)$. The linear combinations

$$0(0,0) + 1(1,-1) + 0(-\pi,\pi) \quad \text{and} \quad \sqrt{87}(0,0) + 0(1,-1) + \left(-\frac{1}{\pi}\right)(-\pi,\pi)$$

are different, because their coefficients differ, but both represent $(1,-1)$. So "the linear combination equal to $(1,-1)$" does not name a single linear combination of $\mathcal{L}_1$. By contrast, in F^2 the vector (x,y) is represented by exactly one linear combination of $(1,0), (0,1)$: the combination $a(1,0) + b(0,1)$ represents (a,b), which is (x,y) only if $a = x$ and $b = y$. Lists with this uniqueness property are the linearly independent ones (Section 1.5).

Exercise 1.3.6. ROUTINE For the list $\mathcal{L}_1$ of Example 1.3.5, find all linear combinations of $\mathcal{L}_1$ that represent $(1,-1)$, and all that represent $\mathbf{0}$. How are the two families related?

Solution on page 1042

Example 1.3.7 (Standard lists). For $1 \le i \le n$, let $\mathbf{e}_i \in F^n$ be the column with 1 in position i and 0 elsewhere. For every $\mathbf{x} = (x_1, \dots, x_n) \in F^n$,

$$\mathbf{x} = x_1\mathbf{e}_1 + x_2\mathbf{e}_2 + \cdots + x_n\mathbf{e}_n,$$

because by the coordinatewise operations, the i-th coordinate of the right side is $x_1 \cdot 0 + \cdots + x_i \cdot 1 + \cdots + x_n \cdot 0 = x_i$. So every vector of F^n is a linear combination of $\mathbf{e}_1, \dots, \mathbf{e}_n$, the standard basis of F^n (Definition 1.6.8).

In $F[x]$, Notation 1.2.15 says that the polynomial with coefficients $(a_0, \dots, a_d, 0, 0, \dots)$ is represented by the linear combination $a_0 \cdot 1 + a_1 x + \cdots + a_d x^d$ of the list $1, x, \dots, x^d$. The coefficients of the polynomial and those of the linear combination coincide.

Example 1.3.8 (Is a vector a linear combination?). Is $(1, 2, 3) \in \mathbb{R}^3$ a linear combination of $(1, 1, 0), (0, 1, 1)$? An arbitrary linear combination represents

$$a(1, 1, 0) + b(0, 1, 1) = (a, a + b, b).$$

For this to be $(1, 2, 3)$, we need $a = 1$, $b = 3$, and $a + b = 2$. The first two equations force $a + b = 4$, so no linear combination works, and the answer is no. In contrast, $(1, 4, 3) = 1(1, 1, 0) + 3(0, 1, 1)$.

The answer depends on the field. Read in $\mathbb{F}_2^3$, the same coordinates give the vector $(1, 0, 1)$, and the equations become $a = 1$, $b = 1$, and $a + b = 0$. These hold, since $1 + 1 = 0$ in $\mathbb{F}_2$. Indeed, $(1, 1, 0) + (0, 1, 1) = (1, 2, 1) = (1, 0, 1)$ in $\mathbb{F}_2^3$.

In general, deciding whether $\mathbf{w}$ is a linear combination of $\mathbf{v}_1, \dots, \mathbf{v}_k$ means deciding whether the equation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{w}$ can be solved for the coefficients. In F^n this is a system of linear equations, and Section 3.1 develops the general method (Technique 3.1.9).

Computing with linear combinations relies on the following rules.

Lemma 1.3.9 (Arithmetic of linear combinations). Let $\mathcal{L} = \mathbf{v}_1, \dots, \mathbf{v}_k$ be a list in V, and let $a_1, \dots, a_k, b_1, \dots, b_k, c \in F$. Then

(a) $\sum_{i=1}^k a_i\mathbf{v}_i + \sum_{i=1}^k b_i\mathbf{v}_i = \sum_{i=1}^k (a_i + b_i)\mathbf{v}_i$;

(b) $c\sum_{i=1}^k a_i\mathbf{v}_i = \sum_{i=1}^k (ca_i)\mathbf{v}_i$;

(c) $\sum_{i=1}^k 0\mathbf{v}_i = \mathbf{0}$.

Here each sum denotes the vector that the linear combination represents.

Proof. ROUTINE

Uses. (1.3.1), Definition 1.2.1 (Vector space), Proposition 1.2.32 (The scalar zero), Proposition 1.2.33 (The zero vector), induction on k

Hint 1. Use induction on k, splitting off the last term of each sum as in (1.3.1).

Hint 2. In the inductive step of (a), regroup $(\mathbf{x} + a\mathbf{v}) + (\mathbf{y} + b\mathbf{v})$ as $(\mathbf{x} + \mathbf{y}) + (a\mathbf{v} + b\mathbf{v})$ and apply (A8) to the second part. For (b), apply (A7) and then (A6).

Sketch. Induction on k. For $k = 0$ every sum is $\mathbf{0}$, and $\mathbf{0} + \mathbf{0} = \mathbf{0}$, $c\mathbf{0} = \mathbf{0}$. In the inductive step, write each sum as the sum of its first k terms plus its last term. Then (a) follows by regrouping with (A1) and (A2) and applying (A8) to the last terms, (b) follows from (A7) and (A6), and (c) from $0\mathbf{v}_{k+1} = \mathbf{0}$.

For a list of scalars $a = a_1, a_2, \dots$, write $S_k(a) = \sum_{i=1}^k a_i\mathbf{v}_i$, and write $a + b$ and ca for the lists with entries $a_i + b_i$ and ca_i. By (1.3.1), $S_0(a) = \mathbf{0}$ and $S_{k+1}(a) = S_k(a) + a_{k+1}\mathbf{v}_{k+1}$. We use induction on k.

For $k = 0$ all the sums are empty. Then (a) reads $\mathbf{0} + \mathbf{0} = \mathbf{0}$, which is (A3); (b) reads $c\mathbf{0} = \mathbf{0}$, which is Proposition 1.2.33; and (c) reads $\mathbf{0} = \mathbf{0}$.

Now suppose that (a)–(c) hold for lists of length k, and consider a list of length $k + 1$. For (a),

$$\begin{aligned} S_{k+1}(a) + S_{k+1}(b) &= (S_k(a) + a_{k+1}\mathbf{v}_{k+1}) + (S_k(b) + b_{k+1}\mathbf{v}_{k+1}) \\ &= (S_k(a) + S_k(b)) + (a_{k+1}\mathbf{v}_{k+1} + b_{k+1}\mathbf{v}_{k+1}) \quad \text{(A1, A2)} \end{aligned}$$

$$= S_k(a+b) + (a_{k+1} + b_{k+1})\mathbf{v}_{k+1} \qquad \text{(induction, A8)}$$
$$= S_{k+1}(a+b).$$

For (b),

$$cS_{k+1}(a) = cS_k(a) + c(a_{k+1}\mathbf{v}_{k+1}) \qquad \text{(A7)}$$
$$= S_k(ca) + (ca_{k+1})\mathbf{v}_{k+1} = S_{k+1}(ca) \qquad \text{(induction, A6).}$$

For (c), $S_{k+1}(0) = S_k(0) + 0\mathbf{v}_{k+1} = \mathbf{0} + \mathbf{0} = \mathbf{0}$, by the inductive hypothesis, Proposition 1.2.32, and (A3). □

Together with $-\mathbf{v} = (-1)\mathbf{v}$ (Proposition 1.2.34), the lemma rewrites any expression built from $\mathbf{v}_1, ..., \mathbf{v}_k$ with addition, subtraction, and scalar multiplication as a single linear combination of $\mathbf{v}_1, ..., \mathbf{v}_k$. For example, reading $\mathbf{v}_1 + 3\mathbf{v}_2$ and $\mathbf{v}_1$ as the linear combinations of $\mathbf{v}_1, \mathbf{v}_2$ with coefficients $1, 3$ and $1, 0$,

$$2(\mathbf{v}_1 + 3\mathbf{v}_2) - \mathbf{v}_1 = (2\mathbf{v}_1 + 6\mathbf{v}_2) + ((-1)\mathbf{v}_1 + 0\mathbf{v}_2) = \mathbf{v}_1 + 6\mathbf{v}_2.$$

1.3.3 Span

Definition 1.3.10 (Span). The **span** of a list $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ in V is the set of vectors represented by linear combinations of $\mathcal{L}$:

$$\operatorname{span}(\mathcal{L}) = \{a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k \mid a_1, ..., a_k \in F\} \subseteq V.$$

We also write $\operatorname{span}(\mathbf{v}_1, ..., \mathbf{v}_k)$ for $\operatorname{span}(\mathcal{L})$. In particular, $\operatorname{span}(()) = \{\mathbf{0}\}$, since the only linear combination of the empty list represents $\mathbf{0}$.

So $\mathbf{w} \in \operatorname{span}(\mathcal{L})$ means that there are scalars $a_1, ..., a_k$ with $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. To show that $\mathbf{w}$ is in the span, exhibit the scalars. To show that it is not, show that no choice of scalars works. Usually this means finding a property that every vector of the span has and $\mathbf{w}$ lacks. In Example 1.3.8, every vector $(a, a+b, b)$ of the span has middle coordinate equal to the sum of the outer two, and $(1, 2, 3)$ does not.

Example 1.3.11 (Small spans). *One vector.* $\operatorname{span}(\mathbf{v}) = \{a\mathbf{v} \mid a \in F\}$ is the set of multiples of $\mathbf{v}$. In $\mathbb{R}^2$ with $\mathbf{v} \neq \mathbf{0}$, it is the line through $\mathbf{0}$ and $\mathbf{v}$. In $\mathbb{F}_2^n$ it is $\{\mathbf{0}, \mathbf{v}\}$, since the only scalars are 0 and 1.

Zero. $\operatorname{span}(\mathbf{0}) = \{a\mathbf{0} \mid a \in F\} = \{\mathbf{0}\}$ by Proposition 1.2.33. So the lists $()$, $\mathbf{0}$, and $\mathbf{0}, \mathbf{0}$ are different, but they have the same span.

Standard lists. By Example 1.3.7, $\operatorname{span}(\mathbf{e}_1, ..., \mathbf{e}_n) = F^n$. Similarly $\operatorname{span}\left(1, x, ..., x^d\right) = F[x]_{\leq d}$: a linear combination $a_0 + a_1x + \cdots + a_dx^d$ has no nonzero coefficients beyond position d, so it has degree at most d, and conversely Definition 1.2.16 describes $F[x]_{\leq d}$ as the set of such combinations.

Functions. In $\mathbb{R}^{\mathbb{R}}$, the identity $\sin(t+c) = \cos c \sin t + \sin c \cos t$ shows that every shift $t \mapsto \sin(t+c)$ of the sine function lies in $\operatorname{span}(\sin, \cos)$. The constant function 1 does not: if $1 = a\sin + b\cos$ as functions, then evaluating at $t = 0$ and at $t = \pi$ gives $1 = b$ and $1 = -b$, a contradiction.

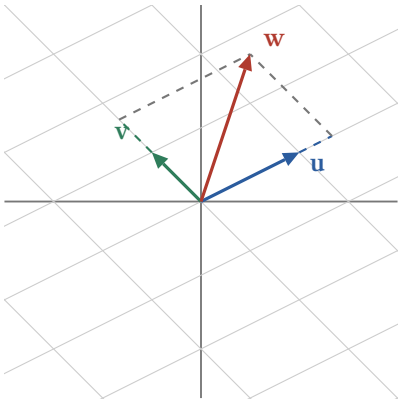

Figure 1.3.1. The faint lines are the combinations $a\mathbf{u} + b\mathbf{v}$ of $\mathbf{u} = (2, 1)$ and $\mathbf{v} = (-1, 1)$ in which a or b is an integer. Every vector of $\mathbb{R}^2$ appears to be a combination of $\mathbf{u}$ and $\mathbf{v}$; for instance, $\mathbf{w} = (1, 3) = \frac{4}{3}\mathbf{u} + \frac{5}{3}\mathbf{v}$.

Figure 1.3.1 suggests that two vectors pointing in different directions span the whole plane; Exercise 1.3.37 makes this precise.

Definition 1.3.12 (Spanning list). A list $\mathcal{L}$ in V **spans** V, and is a **spanning list** of V, if $\operatorname{span}(\mathcal{L}) = V$.

By Example 1.3.11, $\mathbf{e}_1, \ldots, \mathbf{e}_n$ spans F^n, the list $1, x, \ldots, x^d$ spans $F[x]_{\leq d}$, and the empty list spans the zero space $\{\mathbf{0}\}$. A spanning list may contain entries that are not needed: $(1, 0), (0, 1), (1, 1)$ also spans $\mathbb{R}^2$. Spanning lists without such entries are the bases of Section 1.6.

Double containment

Describing a span explicitly means proving that two sets are equal: the span, whose elements are the vectors that some linear combination represents, and a set described in another way, typically by equations. Such proofs follow a fixed pattern, built from two moves.

Technique 1.3.13 (Fix an arbitrary element and chase it). To prove $A \subseteq B$, let x be an arbitrary element of A. Unpack the definition of A until x is described concretely, manipulate that description until it matches the definition of B, and conclude that $x \in B$. Since x was arbitrary, $A \subseteq B$.

Reach for it for every containment between sets defined by properties. Once both definitions are written out, the proof has a fixed shape: the first line is "let $x \in A$", the next uses the definition of A, and the last uses the definition of B. For spans, unpacking produces scalars ("let $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, say $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$"), and repacking means exhibiting scalars. The canonical example is each half of Example 1.3.15.
Used in. Example 1.3.15, Exercise 1.3.16, Proposition 1.3.18, Proposition 1.4.14, Proposition 1.4.16, Proposition 1.4.22, Proposition 1.4.24, Exercise 1.7.5, Proposition 2.5.4, Proposition 2.5.5, Exercise 2.5.33, Proposition 2.6.8, Theorem 2.6.11, Proposition 2.6.15, Proposition 2.7.7, Problem 2.1, Proposition 4.2.3, Proposition 4.5.5, Theorem 4.5.17, Theorem 4.6.5, Proposition 4.7.3, Proposition 4.7.10, Proposition 6.3.9, Proposition 7.2.30, Proposition A.1.5, Theorem A.1.12, Exercise A.1.26, Exercise 2.6.36, Exercise 2.6.39, Exercise 2.6.51, Exercise 2.6.52.

Technique 1.3.14 (Double containment). To prove that two sets A and B are equal, prove $A \subseteq B$ and $B \subseteq A$ separately, each by Technique 1.3.13.

Reach for it whenever a claim says that two sets are equal. The two containments usually need different ideas, and one is often much easier than the other. For a span, "$\operatorname{span}(\mathcal{L}) \subseteq B$" is a computation with an arbitrary linear combination, while "$B \subseteq \operatorname{span}(\mathcal{L})$" requires constructing coefficients for each element of B. A common mistake is to prove one containment carefully and forget the other (Exercise 1.3.30). The canonical example is Example 1.3.15.

Used in. Example 1.3.15, Exercise 1.3.16, Corollary 1.3.19, Exercise 1.3.26, Exercise 1.3.30, Exercise 1.3.32, Exercise 1.3.33, Exercise 1.3.36, Corollary 1.4.17, Exercise 1.4.37, Exercise 1.7.5, Exercise 1.7.15, Proposition 2.1.16, Corollary 2.6.31, Exercise 2.6.51, Proposition 3.1.19, Exercise 3.1.41, Exercise 3.1.45, Proposition 3.2.30, Exercise 3.2.46, Problem 3.1, Proposition 4.4.2, Proposition 4.6.11, Lemma 4.6.14, Proposition 4.7.3, Exercise 6.2.42, Proposition 6.3.9, Exercise 6.3.11, Theorem 6.4.15, Corollary 6.4.25, Theorem 6.4.26, Exercise 6.4.47, Proposition 6.5.9, Proposition 6.6.23, Proposition A.1.5, Lemma A.3.5, Exercise 1.4.35, Exercise 1.4.36, Exercise 1.4.44, Exercise 2.6.39, Exercise 4.6.40, Exercise A.2.10, Exercise A.3.20.

Example 1.3.15 (A span that is a line). In $\mathbb{R}^2$, let $\mathcal{L}_1 = (0,0), (1,-1), (-\pi,\pi)$ as in Example 1.3.5, and let

$$W = \{(c_1, c_2) \in \mathbb{R}^2 \mid c_2 = -c_1\}.$$

Then $\operatorname{span}(\mathcal{L}_1) = W$. In particular, $(2,0) \notin \operatorname{span}(\mathcal{L}_1)$, since $0 \neq -2$.

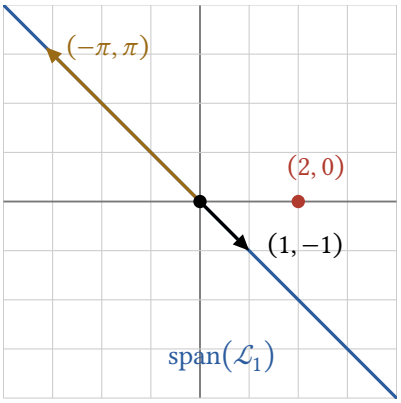
Proof. ROUTINE

Uses. Definition 1.3.10 (Span), Definition 1.3.4 (Linear combination), Definition 1.2.4 (The space F^n)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Write out both definitions. What does an element of $\operatorname{span}(\mathcal{L}_1)$ look like, and what condition defines W?
Hint 2. For $\operatorname{span}(\mathcal{L}_1) \subseteq W$, compute an arbitrary linear combination coordinatewise. For $W \subseteq \operatorname{span}(\mathcal{L}_1)$, you need coefficients for $(c_1, -c_1)$, and one entry of $\mathcal{L}_1$ suffices.
Sketch. Every linear combination of $\mathcal{L}_1$ represents $(a_2 - \pi a_3, -(a_2 - \pi a_3))$, which lies in W. Conversely, $(c_1, -c_1) = 0(0,0) + c_1(1,-1) + 0(-\pi,\pi)$.

We proceed by double containment.

$\operatorname{span}(\mathcal{L}_1) \subseteq W$. Let $\mathbf{w} \in \operatorname{span}(\mathcal{L}_1)$. Then some linear combination of $\mathcal{L}_1$ represents $\mathbf{w}$, so for some $a_1, a_2, a_3 \in \mathbb{R}$,

$$\mathbf{w} = a_1(0,0) + a_2(1,-1) + a_3(-\pi,\pi) = (a_2 - \pi a_3, -a_2 + \pi a_3).$$



The second coordinate of $\mathbf{w}$ is $-a_2 + \pi a_3 = -(a_2 - \pi a_3)$, the negative of the first, so $\mathbf{w} \in W$.

$W \subseteq \operatorname{span}(\mathcal{L}_1)$. Let $(c_1, c_2) \in W$. By the definition of W, $c_2 = -c_1$, so

$$(c_1, c_2) = (c_1, -c_1) = 0(0,0) + c_1(1,-1) + 0(-\pi,\pi).$$

This linear combination of $\mathcal{L}_1$ represents (c_1, c_2), so $(c_1, c_2) \in \operatorname{span}(\mathcal{L}_1)$, as desired. □

The two containments needed different kinds of argument. The first was a computation that applies to every linear combination at once. The second needed one well-chosen linear combination for each element of W, and it used only the entry $(1,-1)$. The other two entries of $\mathcal{L}_1$ contribute nothing to the span, and Example 1.3.21 explains why without computing anything.

The span of $\mathcal{L}_1$ is the line $c_2 = -c_1$, and $(2, 0)$ is not on it. In the interactive version, $(-\pi, \pi)$ is replaced by $(-3, 3)$, which has the same span. Drag an entry off the line: the span becomes all of $\mathbb{R}^2$, and the explorer shows coefficients that represent $\mathbf{w} = (2, 0)$. (Interactive in the web version.)

Exercise 1.3.16. ROUTINE Show that

$$\operatorname{span}((1, 0, -1), (0, 1, -1)) = \{(x, y, z) \in \mathbb{R}^3 \mid x + y + z = 0\}.$$

Solution on page 1043

1.3.4 Comparing spans

A span is usually an infinite set, so comparing two spans element by element means checking infinitely many vectors. The results of this subsection reduce such a comparison to finitely many checks.

Proposition 1.3.17 (A list lies in its span). Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V. Then $\mathbf{0} \in \operatorname{span}(\mathcal{L})$, and $\mathbf{v}_j \in \operatorname{span}(\mathcal{L})$ for each j. That is, $\mathcal{L} \subseteq \operatorname{span}(\mathcal{L})$.

Proof. ROUTINE

Uses. Definition 1.3.10 (Span), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.2.32 (The scalar zero)
Hint 1. Membership in a span is shown by exhibiting coefficients.
Hint 2. Use the coefficients $0, \ldots, 0$ for $\mathbf{0}$. For $\mathbf{v}_j$, use the coefficient 1 on $\mathbf{v}_j$ and 0 on every other entry.
Sketch. $\mathbf{0} = 0\mathbf{v}_1 + \cdots + 0\mathbf{v}_k$, and $\mathbf{v}_j$ is represented by the combination with coefficient 1 in position j and 0 elsewhere, since $0\mathbf{v}_i = \mathbf{0}$ and $1\mathbf{v}_j = \mathbf{v}_j$.

By Lemma 1.3.9(c), the linear combination with all coefficients 0 represents $\mathbf{0}$, so $\mathbf{0} \in \operatorname{span}(\mathcal{L})$. Now fix j, and consider the linear combination with $a_j = 1$ and $a_i = 0$ for $i \neq j$. Its terms are $1\mathbf{v}_j = \mathbf{v}_j$, by (A5), and $0\mathbf{v}_i = \mathbf{0}$ for $i \neq j$, by Proposition 1.2.32. Adding copies of $\mathbf{0}$ changes nothing, by (A3), so this linear combination represents $\mathbf{v}_j$, and $\mathbf{v}_j \in \operatorname{span}(\mathcal{L})$. □

Intuition (Recipes of recipes). Think of a linear combination of $\mathcal{L}$ as a recipe that says how much of each $\mathbf{v}_i$ to use. Suppose that every entry of $\mathcal{M} = \mathbf{w}_1, \ldots, \mathbf{w}_m$ has a recipe in terms of $\mathcal{L}$. A linear combination of $\mathcal{M}$ is then a recipe whose ingredients are themselves recipes, and expanding it gives a recipe in terms of $\mathcal{L}$. For instance, if $\mathbf{w}_1 = \mathbf{v}_1 + \mathbf{v}_2$ and $\mathbf{w}_2 = \mathbf{v}_1 - \mathbf{v}_2$, then

$$3\mathbf{w}_1 + 2\mathbf{w}_2 = (3\mathbf{v}_1 + 3\mathbf{v}_2) + (2\mathbf{v}_1 - 2\mathbf{v}_2) = 5\mathbf{v}_1 + \mathbf{v}_2.$$

So as soon as the finitely many entries of $\mathcal{M}$ lie in $\operatorname{span}(\mathcal{L})$, every vector of $\operatorname{span}(\mathcal{M})$ does.

Proposition 1.3.18 (Comparing spans). Let $\mathcal{L}$ and $\mathcal{M}$ be lists in V. Then $\operatorname{span}(\mathcal{M}) \subseteq \operatorname{span}(\mathcal{L})$ if and only if $\mathcal{M} \subseteq \operatorname{span}(\mathcal{L})$.

Proof. STANDARD

Uses. Proposition 1.3.17 (A list lies in its span), Lemma 1.3.9 (Arithmetic of linear combinations), Definition 1.3.10 (Span), induction on m
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. One direction follows at once from Proposition 1.3.17. For the other, let $\mathbf{u} \in \operatorname{span}(\mathcal{M})$ and write $\mathbf{u} = \sum_j c_j \mathbf{w}_j$.
Hint 2. Replace each $\mathbf{w}_j$ by a linear combination of $\mathcal{L}$ that represents it, say $\mathbf{w}_j = \sum_i b_{ij}\mathbf{v}_i$. Then use Lemma 1.3.9 to collect the coefficient of each $\mathbf{v}_i$.
Sketch. ($\Rightarrow$) $\mathcal{M} \subseteq \operatorname{span}(\mathcal{M}) \subseteq \operatorname{span}(\mathcal{L})$. ($\Leftarrow$) If $\mathbf{w}_j = \sum_i b_{ij}\mathbf{v}_i$, then by Lemma 1.3.9, $\sum_j c_j \mathbf{w}_j = \sum_j \sum_i (c_j b_{ij})\mathbf{v}_i = \sum_i \bigl(\sum_j c_j b_{ij}\bigr)\mathbf{v}_i$, which is a linear combination of $\mathcal{L}$.

Write $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ and $\mathcal{M} = \mathbf{w}_1, \ldots, \mathbf{w}_m$.

($\Rightarrow$) By Proposition 1.3.17, $\mathcal{M} \subseteq \operatorname{span}(\mathcal{M})$, and $\operatorname{span}(\mathcal{M}) \subseteq \operatorname{span}(\mathcal{L})$ by assumption.

($\Leftarrow$) Suppose that $\mathcal{M} \subseteq \operatorname{span}(\mathcal{L})$. For each j, choose scalars $b_{1j}, \ldots, b_{kj}$ with

$$\mathbf{w}_j = \sum_{i=1}^{k} b_{ij}\mathbf{v}_i.$$

Let $\mathbf{u} \in \operatorname{span}(\mathcal{M})$, say $\mathbf{u} = \sum_{j=1}^{m} c_j \mathbf{w}_j$ with $c_1, \ldots, c_m \in F$. By Lemma 1.3.9(b), $c_j \mathbf{w}_j = \sum_{i=1}^{k} (c_j b_{ij})\mathbf{v}_i$ for each j. Adding these m vectors one at a time with Lemma 1.3.9(a), that is, by induction on m, gives

$$\mathbf{u} = \sum_{j=1}^{m} \sum_{i=1}^{k} (c_j b_{ij})\mathbf{v}_i = \sum_{i=1}^{k} \left(\sum_{j=1}^{m} c_j b_{ij} \right) \mathbf{v}_i.$$

(For $m = 0$ both sides are $\mathbf{0}$, by Lemma 1.3.9(c).) So $\mathbf{u}$ is represented by the linear combination of $\mathcal{L}$ with coefficients $d_i = \sum_j c_j b_{ij}$, and $\mathbf{u} \in \operatorname{span}(\mathcal{L})$. Since $\mathbf{u}$ was arbitrary, $\operatorname{span}(\mathcal{M}) \subseteq \operatorname{span}(\mathcal{L})$, as desired. □

The forward direction is Proposition 1.3.17. The backward direction is the useful one: to show that one span contains another, it suffices to check the finitely many entries of one list. Section 1.4 gives a second proof. There we show that $\operatorname{span}(\mathcal{L})$ is the smallest subspace of V containing the entries of $\mathcal{L}$ (Proposition 1.4.14), and the backward direction follows at once.

Corollary 1.3.19 (Equal spans). Let $\mathcal{L}$ and $\mathcal{M}$ be lists in V. Then $\operatorname{span}(\mathcal{L}) = \operatorname{span}(\mathcal{M})$ if and only if $\mathcal{L} \subseteq \operatorname{span}(\mathcal{M})$ and $\mathcal{M} \subseteq \operatorname{span}(\mathcal{L})$.

Proof. ROUTINE

Uses. Proposition 1.3.18 (Comparing spans)
Techniques. Double containment (Technique 1.3.14)
Hint 1. Split the equality of sets into two containments.
Hint 2. Apply Proposition 1.3.18 to each containment.
Sketch. $\operatorname{span}(\mathcal{L}) \subseteq \operatorname{span}(\mathcal{M})$ if and only if $\mathcal{L} \subseteq \operatorname{span}(\mathcal{M})$, and $\operatorname{span}(\mathcal{M}) \subseteq \operatorname{span}(\mathcal{L})$ if and only if $\mathcal{M} \subseteq \operatorname{span}(\mathcal{L})$.

The sets $\operatorname{span}(\mathcal{L})$ and $\operatorname{span}(\mathcal{M})$ are equal exactly when each contains the other. By Proposition 1.3.18, $\operatorname{span}(\mathcal{L}) \subseteq \operatorname{span}(\mathcal{M})$ holds exactly when $\mathcal{L} \subseteq \operatorname{span}(\mathcal{M})$, and $\operatorname{span}(\mathcal{M}) \subseteq \operatorname{span}(\mathcal{L})$ holds exactly when $\mathcal{M} \subseteq \operatorname{span}(\mathcal{L})$. □

Corollary 1.3.20 (Operations that preserve the span). Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V.

(a) Every reordering of $\mathcal{L}$ has the same span as $\mathcal{L}$.

(b) If $\mathcal{L}'$ is a sublist of $\mathcal{L}$, then $\operatorname{span}(\mathcal{L}') \subseteq \operatorname{span}(\mathcal{L})$.

(c) For $\mathbf{w} \in V$, $\operatorname{span}(\mathcal{L}, \mathbf{w}) = \operatorname{span}(\mathcal{L})$ if and only if $\mathbf{w} \in \operatorname{span}(\mathcal{L})$. In particular, appending $\mathbf{0}$ or a second copy of an entry of $\mathcal{L}$ does not change the span.

(d) Let $i \neq j$, and let $a, c \in F$ with $c \neq 0$. Replacing $\mathbf{v}_j$ by $c\mathbf{v}_j$, or by $\mathbf{v}_j + a\mathbf{v}_i$, does not change the span.

Proof. ROUTINE

Uses. Corollary 1.3.19 (Equal spans), Proposition 1.3.18 (Comparing spans), Proposition 1.3.17 (A list lies in its span), Notation 1.3.3
Hint 1. Each part compares the spans of two lists. By Corollary 1.3.19, it suffices to check that the entries of each list lie in the span of the other, and Proposition 1.3.17 handles the entries the two lists share.
Hint 2. For (d), write $\mathbf{v}_j$ in terms of the new entries: $\mathbf{v}_j = c^{-1}(c\mathbf{v}_j)$, and $\mathbf{v}_j = (\mathbf{v}_j + a\mathbf{v}_i) + (-a)\mathbf{v}_i$.
Sketch. (a) The two lists have the same entries. (b) $\mathcal{L}' \subseteq \mathcal{L} \subseteq \operatorname{span}(\mathcal{L})$. (c) If $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, then every entry of $\mathcal{L}, \mathbf{w}$ lies in $\operatorname{span}(\mathcal{L})$, and $\mathcal{L}$ is a sublist of $\mathcal{L}, \mathbf{w}$; conversely $\mathbf{w} \in \operatorname{span}(\mathcal{L}, \mathbf{w})$. (d) The new entry is a linear combination of $\mathcal{L}$, and $\mathbf{v}_j$ is a linear combination of the new list because $c \neq 0$ and $i \neq j$.

(a) A reordering $\mathcal{L}'$ of $\mathcal{L}$ has the same entries as $\mathcal{L}$. By Proposition 1.3.17, $\mathcal{L}' \subseteq \operatorname{span}(\mathcal{L})$ and $\mathcal{L} \subseteq \operatorname{span}(\mathcal{L}')$, so the spans are equal by Corollary 1.3.19.

(b) Every entry of $\mathcal{L}'$ is an entry of $\mathcal{L}$, so $\mathcal{L}' \subseteq \operatorname{span}(\mathcal{L})$ by Proposition 1.3.17, and $\operatorname{span}(\mathcal{L}') \subseteq \operatorname{span}(\mathcal{L})$ by Proposition 1.3.18.

(c) Suppose that $\mathbf{w} \in \operatorname{span}(\mathcal{L})$. The entries of $\mathcal{L}, \mathbf{w}$ are the $\mathbf{v}_i$, which lie in $\operatorname{span}(\mathcal{L})$ by Proposition 1.3.17, and $\mathbf{w}$, which lies there by assumption. So $\operatorname{span}(\mathcal{L}, \mathbf{w}) \subseteq \operatorname{span}(\mathcal{L})$ by Proposition 1.3.18. Conversely, $\mathcal{L}$ is a sublist of $\mathcal{L}, \mathbf{w}$, so $\operatorname{span}(\mathcal{L}) \subseteq \operatorname{span}(\mathcal{L}, \mathbf{w})$ by (b). Now suppose instead that $\operatorname{span}(\mathcal{L}, \mathbf{w}) = \operatorname{span}(\mathcal{L})$. Then $\mathbf{w} \in \operatorname{span}(\mathcal{L}, \mathbf{w}) = \operatorname{span}(\mathcal{L})$ by Proposition 1.3.17. The last statement of (c) follows, since $\mathbf{0}$ and the entries of $\mathcal{L}$ lie in $\operatorname{span}(\mathcal{L})$ by Proposition 1.3.17.

(d) Let $\mathcal{L}'$ be $\mathcal{L}$ with $\mathbf{v}_j$ replaced by $\mathbf{v}'_j$, where $\mathbf{v}'_j = c\mathbf{v}_j$ or $\mathbf{v}'_j = \mathbf{v}_j + a\mathbf{v}_i$. The entries of $\mathcal{L}'$ other than $\mathbf{v}'_j$ are entries of $\mathcal{L}$, and $\mathbf{v}'_j$ is a linear combination of $\mathcal{L}$: the one with coefficient c on $\mathbf{v}_j$ and 0 elsewhere, or the one with coefficient 1 on $\mathbf{v}_j$, a on $\mathbf{v}_i$, and 0 elsewhere (this uses $i \neq j$). So $\mathcal{L}' \subseteq \operatorname{span}(\mathcal{L})$. In the other direction, the entries of $\mathcal{L}$ other than $\mathbf{v}_j$ are entries of $\mathcal{L}'$, and

$$\mathbf{v}_j = c^{-1}(c\mathbf{v}_j) \quad \text{or} \quad \mathbf{v}_j = (\mathbf{v}_j + a\mathbf{v}_i) + (-a)\mathbf{v}_i,$$

by (A6) and (A5), or by (A2), (A8), Proposition 1.2.32, and (A3). Since $c \neq 0$, and since $\mathbf{v}_i$ is still an entry of $\mathcal{L}'$ (as $i \neq j$), these are linear combinations of $\mathcal{L}'$. So $\mathcal{L} \subseteq \operatorname{span}(\mathcal{L}')$, and Corollary 1.3.19 finishes the proof. □

Combining (a) and (c): the entry $\mathbf{v}_j$ can be deleted from $\mathcal{L}$ without changing the span exactly when $\mathbf{v}_j$ lies in the span of the remaining entries. (Reorder so that $\mathbf{v}_j$ comes last, and apply (c).) Parts (a) and (d) are the three moves of row reduction, applied to the entries of a list: swap two entries, scale an entry by a nonzero scalar, and add a multiple of one entry to another. Section 3.3 performs them on the rows of a matrix. Both hypotheses in (d) are needed: scaling by $c = 0$, or replacing $\mathbf{v}_j$ by $\mathbf{v}_j + (-1)\mathbf{v}_j$, turns $\mathbf{v}_j$ into $\mathbf{0}$, and in $\mathbb{R}^2$ this shrinks $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) = \mathbb{R}^2$ to the line $\operatorname{span}(\mathbf{e}_1)$.

Example 1.3.21 (A span that is a line, again). In $\mathcal{L}_1 = (0,0), (1,-1), (-\pi, \pi)$, the third entry is $-\pi(1,-1)$ and the first is $\mathbf{0}$. By Corollary 1.3.20(c), together with (a) to move entries to the end, we may delete $(-\pi, \pi)$, since it lies in $\operatorname{span}((0,0),(1,-1))$, and then delete $(0,0)$. Hence

$$\operatorname{span}(\mathcal{L}_1) = \operatorname{span}((1,-1)) = \{c(1,-1) \mid c \in \mathbb{R}\} = \{(c,-c) \mid c \in \mathbb{R}\},$$

which is the set W of Example 1.3.15. Two observations about entries have replaced the double containment.

Example 1.3.22 (Equal spans, and a small field). Let $\mathcal{L} = (1,1,0), (0,1,1)$ and $\mathcal{M} = (1,2,1), (1,0,-1)$ in F^3. We transform $\mathcal{L}$ into $\mathcal{M}$ with the moves of Corollary 1.3.20(d):

$$(1,1,0),(0,1,1) \quad \rightsquigarrow \quad (1,2,1),(0,1,1) \quad \rightsquigarrow \quad (1,2,1),(0,-2,-2) \quad \rightsquigarrow \quad (1,2,1),(1,0,-1).$$

The first move adds the second entry to the first, the second scales the second entry by -2, and the third adds the first entry to the second. Each move preserves the span, provided that $-2 \neq 0$ in F, which holds exactly when $1 + 1 \neq 0$. So over $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, or $\mathbb{F}_3$, $\operatorname{span}(\mathcal{L}) = \operatorname{span}(\mathcal{M})$.

Over $\mathbb{F}_2$ the conclusion is false. There $(1,2,1) = (1,0,-1) = (1,0,1)$, so $\mathcal{M}$ is the list $(1,0,1),(1,0,1)$, and $\operatorname{span}(\mathcal{M}) = \operatorname{span}((1,0,1)) = \{\mathbf{0},(1,0,1)\}$ by Corollary 1.3.20(c) and Example 1.3.11. This set does not contain the vector $(1,1,0)$ of $\operatorname{span}(\mathcal{L})$. The move that fails is the scaling by $-2 = 0$. Testing the claim over $\mathbb{F}_2$ (Technique 1.2.38) is how one notices that the hypothesis $c \neq 0$ in (d) is doing real work.

Remark 1.3.23 (What the span forgets). By Corollary 1.3.20, the span of a list depends neither on the order of the entries, nor on repetitions, nor on entries that lie in the span of the others. In particular, it depends only on the set of entries (Exercise 1.3.24), and lists of different lengths can have the same span. The span also does not record how many linear combinations represent each of its vectors. Section 1.5 shows that some entry of a list lies in the span of the other entries exactly when some vector of its span has more than one representation.

Exercise 1.3.24. ROUTINE Let $\mathcal{L}$ and $\mathcal{M}$ be lists in V with the same set of entries; that is, $\mathbf{v} \in \mathcal{L}$ if and only if $\mathbf{v} \in \mathcal{M}$. Show that $\operatorname{span}(\mathcal{L}) = \operatorname{span}(\mathcal{M})$.

Solution on page 1043

Exercise 1.3.25. ROUTINE Let $\mathbf{v}_1,\ldots,\mathbf{v}_k \in V$, and let $\mathbf{w}_j = \mathbf{v}_1 + \cdots + \mathbf{v}_j$ for $1 \leq j \leq k$. Show that $\operatorname{span}(\mathbf{w}_1,\ldots,\mathbf{w}_k) = \operatorname{span}(\mathbf{v}_1,\ldots,\mathbf{v}_k)$.

Solution on page 1043

ASIDE: *Spans of infinite sets* BEYOND 21-242

Every linear combination has finitely many terms. A vector space only adds two vectors at a time, and an infinite sum would need a notion of convergence, which a general vector space does not have. For an arbitrary subset $S \subseteq V$, possibly infinite, one defines $\operatorname{span}(S)$ as the set of vectors represented by linear combinations of finite lists in S; the empty list is allowed, so $\operatorname{span}(\varnothing) = \{\mathbf{0}\}$. For a finite set S, this is the span of any list whose set of entries is S (Exercise 1.3.24). For example, $\operatorname{span}(\{1, x, x^2, \ldots\}) = F[x]$, since each polynomial is a linear combination of $1, x, \ldots, x^d$ for some d, while no finite list spans $F[x]$ (Section 1.6). Spanning sets of this kind are the subject of Section 15.1.

Exercises

Exercise 1.3.26. ROUTINE Let $\mathcal{L} = (1,2,0),(0,1,1)$ in $\mathbb{R}^3$.

(a) Show that $\operatorname{span}(\mathcal{L}) = \{(x,y,z) \in \mathbb{R}^3 \mid y = 2x + z\}$.

(b) Decide whether $(1,1,1)$ and $(2,5,1)$ lie in $\operatorname{span}(\mathcal{L})$. For each one that does, find a linear combination of $\mathcal{L}$ that represents it.

Solution on page 1043

Exercise 1.3.27. ROUTINE Let $\mathcal{L} = (1,1,0),(0,1,2)$ in $\mathbb{F}_3^3$.

(a) List the elements of $\operatorname{span}(\mathcal{L})$, and decide whether $(1,0,1)$ and $(1,1,1)$ belong to it.

(b) Let $\mathcal{M} = (1,1,0),(0,1,2),(1,2,2)$. Show that $\operatorname{span}(\mathcal{M}) = \operatorname{span}(\mathcal{L})$. How many linear combinations of $\mathcal{M}$ are there, and how many of them represent $(1,0,1)$?

Solution on page 1044

Exercise 1.3.28. ROUTINE

(a) Find all lists $\mathcal{L}$ in V with $\operatorname{span}(\mathcal{L}) = \{\mathbf{0}\}$. Which lists span the zero space?

(b) Let $\mathbf{v},\mathbf{w} \in V$. Show that $\operatorname{span}(\mathbf{v}) = \operatorname{span}(\mathbf{w})$ if and only if $\mathbf{w} = c\mathbf{v}$ for some nonzero $c \in F$.

Solution on page 1044

Exercise 1.3.29. ROUTINE

(a) Find the error in the following argument.

Claim. Let $\mathbf{v}_1, \mathbf{v}_2 \in V$ and $a_1, a_2, b_1, b_2 \in F$. If $a_1\mathbf{v}_1 + a_2\mathbf{v}_2 = b_1\mathbf{v}_1 + b_2\mathbf{v}_2$, then $a_1 = b_1$ and $a_2 = b_2$.

Proof. Two linear combinations of $\mathbf{v}_1, \mathbf{v}_2$ are the same exactly when they have the same coefficients (Definition 1.3.4). The two sides of the hypothesis are equal, so their coefficients are equal.

(b) Show that the claim is false in general, and that it is true for $\mathbf{v}_1 = (1, 0)$ and $\mathbf{v}_2 = (0, 1)$ in F^2.

Solution on page 1045

Exercise 1.3.30. STANDARD

(a) Find the gap in the following argument.

Claim. $\operatorname{span}((1, 1), (1, -1)) = \mathbb{R}^2$.

Proof. Let $\mathbf{w} \in \operatorname{span}((1, 1), (1, -1))$, say $\mathbf{w} = a(1, 1) + b(1, -1) = (a + b, a - b)$. Both coordinates are real numbers, so $\mathbf{w} \in \mathbb{R}^2$. Hence $\operatorname{span}((1, 1), (1, -1)) = \mathbb{R}^2$.

(b) Prove the claim.

(c) Is $\operatorname{span}((1, 1), (1, -1)) = \mathbb{F}_2^2$ in $\mathbb{F}_2^2$? Is $\operatorname{span}((1, 1), (1, -1)) = \mathbb{F}_3^2$ in $\mathbb{F}_3^2$?

Solution on page 1045

Exercise 1.3.31. STANDARD Work in the real vector space $\mathbb{R}^{\mathbb{R}}$ of functions $\mathbb{R} \to \mathbb{R}$.

(a) Show that the function $t \mapsto \cos^2 t$ lies in $\operatorname{span}(1, c_2)$, where $c_2(t) = \cos 2t$.

(b) Show that $\sin \notin \operatorname{span}(1, \cos)$.

(c) Does the function $t \mapsto \sin^2 t$ lie in $\operatorname{span}(1, \cos)$?

Solution on page 1046

Exercise 1.3.32. STANDARD Let $W = \{p \in \mathbb{R}[x]_{\leq 3} \mid p(1) = 0\}$. Find a list of length 3 that spans W, and prove that it does.

Solution on page 1046

Exercise 1.3.33. STANDARD

(a) Let $p_0, p_1, \ldots, p_n \in F[x]$ with $\deg p_k = k$ for each k. Show that $\operatorname{span}(p_0, \ldots, p_n) = F[x]_{\leq n}$.

(b) Write x^2 as a linear combination of $1, x - 1, x^2 - 2x + 1$ in $\mathbb{R}[x]$.

Solution on page 1046

Exercise 1.3.34. STANDARD Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V, and let $\mathbf{w} \in \operatorname{span}(\mathcal{L})$ with $\mathbf{w} \notin \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$. Show that

$$\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1}, \mathbf{w}) = \operatorname{span}(\mathcal{L}).$$

In other words, $\mathbf{w}$ can be exchanged for $\mathbf{v}_k$ without changing the span.

Solution on page 1047

Exercise 1.3.35. STANDARD Let $\mathcal{L}$ and $\mathcal{M}$ be lists in V, and let $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$. Prove or disprove each statement.

(a) $\operatorname{span}(\mathcal{L}) \cup \operatorname{span}(\mathcal{M}) = \operatorname{span}(\mathcal{L}, \mathcal{M})$.

(b) $\operatorname{span}(\mathcal{L}) \cap \operatorname{span}(\mathcal{M}) = \operatorname{span}(\mathcal{N})$, where $\mathcal{N}$ is a list of the vectors that are entries of both $\mathcal{L}$ and $\mathcal{M}$.

(c) If $\operatorname{span}(\mathcal{L}) = \operatorname{span}(\mathcal{M})$, then $|\mathcal{L}| = |\mathcal{M}|$.

(d) If $\mathbf{u} \in \operatorname{span}(\mathbf{v}, \mathbf{w})$ and $\mathbf{v} \in \operatorname{span}(\mathbf{u}, \mathbf{w})$, then $\mathbf{w} \in \operatorname{span}(\mathbf{u}, \mathbf{v})$.

(e) If $\mathbf{u} \in \operatorname{span}(\mathbf{v}, \mathbf{w})$ and $\mathbf{u} \notin \operatorname{span}(\mathbf{w})$, then $\mathbf{v} \in \operatorname{span}(\mathbf{u}, \mathbf{w})$.

Solution on page 1047

Exercise 1.3.36. STANDARD Let $\mathcal{L}$ and $\mathcal{M}$ be lists in V. Show that

$$\operatorname{span}(\mathcal{L}, \mathcal{M}) = \{\mathbf{u} + \mathbf{w} \mid \mathbf{u} \in \operatorname{span}(\mathcal{L}), \mathbf{w} \in \operatorname{span}(\mathcal{M})\}.$$

Solution on page 1048

Exercise 1.3.37. STANDARD Let $\mathbf{u} = (a, b)$ and $\mathbf{v} = (c, d)$ be vectors in F^2.

(a) Show that $\mathbf{u}, \mathbf{v}$ spans F^2 if and only if $ad - bc \neq 0$.

(b) Suppose $\mathbf{u} \neq \mathbf{0}$. Show that $\mathbf{u}, \mathbf{v}$ spans F^2 if and only if $\mathbf{v} \notin \operatorname{span}(\mathbf{u})$.

Solution on page 1048

Exercise 1.3.38. STANDARD Let F be a finite field with q elements.

(a) Show that no list of length 1 spans F^2.

(b) Show that exactly $\big(q^2 - 1\big)\big(q^2 - q\big)$ lists of length 2 span F^2.

(c) For $q = 2$, how many lists of length 3 span $\mathbb{F}_2^2$?

Solution on page 1049

Exercise 1.3.39. STANDARD Let F be a finite field with q elements, and let $\mathcal{L}$ be a list of length k in V.

(a) Show that $\operatorname{span}(\mathcal{L})$ has at most q^k elements.

(b) Deduce that no list of length less than n spans F^n.

Solution on page 1049

Exercise 1.3.40. HARD Let F be a finite field with q elements, and let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in V. For $\mathbf{w} \in V$, let $N(\mathbf{w})$ be the number of linear combinations of $\mathcal{L}$ that represent $\mathbf{w}$.

(a) Show that $N(\mathbf{w}) = N(\mathbf{0})$ for every $\mathbf{w} \in \operatorname{span}(\mathcal{L})$.

(b) Deduce that $q^k = |\operatorname{span}(\mathcal{L})| \cdot N(\mathbf{0})$. In particular, $|\operatorname{span}(\mathcal{L})|$ divides q^k.

(c) If $F = \mathbb{F}_p$ with p prime, show that $\operatorname{span}(\mathcal{L})$ has p^r elements for some integer $0 \leq r \leq k$.

Solution on page 1049

Exercise 1.3.41. STANDARD Let $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$, and let $D = \operatorname{span}(\mathbf{u} - \mathbf{v}, \mathbf{v} - \mathbf{w})$.

(a) Show that $D = \operatorname{span}(\mathbf{u} - \mathbf{v}, \mathbf{v} - \mathbf{w}, \mathbf{w} - \mathbf{u})$ and $D \subseteq \operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w})$.

(b) Prove or disprove: $D = \operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w})$.

(c) Show that $D = \operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w})$ if and only if $\mathbf{u} \in D$.

Solution on page 1050

Exercise 1.3.42. HARD Let $n \geq 2$, let $\mathbf{s} = (1, 1, \ldots, 1) \in F^n$, and let $\mathbf{u}_i = \mathbf{s} - \mathbf{e}_i$ be the vector with 0 in position i and 1 elsewhere. For a positive integer m, write $m * 1 = 1 + \cdots + 1$ (m terms) in F, as in Exercise 1.2.45. Show that $\mathbf{u}_1, \ldots, \mathbf{u}_n$ spans F^n if and only if $(n-1) * 1 \neq 0$ in F.

Solution on page 1050

Exercise 1.3.43. HARD Let $n \geq 3$. Let $\mathcal{W}_2$ be a list of all vectors in F^n with exactly two coordinates equal to 1 and all others 0, and define $\mathcal{W}_3$ similarly with three coordinates equal to 1.

(a) Show that if $1 + 1 \neq 0$ in F, then $\mathcal{W}_2$ spans F^n.

(b) Over $\mathbb{F}_2$, show that $\operatorname{span}(\mathcal{W}_2) = \{\mathbf{x} \in \mathbb{F}_2^n \mid x_1 + \cdots + x_n = 0\}$.

(c) Over $\mathbb{F}_2$, show that $\mathcal{W}_3$ spans $\mathbb{F}_2^n$ when $n \geq 4$. What is $\operatorname{span}(\mathcal{W}_3)$ when $n = 3$?

Solution on page 1051

Exercise 1.3.44. STANDARD Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$ (Example 1.2.20). Show that $\sqrt{3} \notin \operatorname{span}\left(1, \sqrt{2}\right)$. You may use that $\sqrt{2}$, $\sqrt{3}$, and $\sqrt{6}$ are irrational.

Solution on page 1052

Exercise 1.3.45. HARD BEYOND 21-242 Show that no finite list spans $\mathbb{R}$ as a vector space over $\mathbb{Q}$. (Use countability.)

Solution on page 1052

Exercise 1.3.46. CHALLENGE A row of $n \geq 1$ lamps, each on or off, is recorded as a vector $\mathbf{x} \in \mathbb{F}_2^n$, with $x_i = 1$ when lamp i is on. Pressing lamp i switches lamp i and its neighbors $i-1$ and $i+1$ (those that exist). That is, it adds $\mathbf{t}_i = \mathbf{e}_{i-1} + \mathbf{e}_i + \mathbf{e}_{i+1}$ to $\mathbf{x}$, where $\mathbf{e}_0 = \mathbf{e}_{n+1} = \mathbf{0}$.

(a) Show that every configuration can be switched entirely off by pressing lamps if and only if $\mathbf{t}_1, \ldots, \mathbf{t}_n$ spans $\mathbb{F}_2^n$.

(b) Show that this happens if and only if n is not of the form $3m + 2$.

Solution on page 1052

1.4 Subspaces

Several of the vector spaces in Section 1.2 live inside a larger one and use its operations: $C[0,1]$ inside $\mathbb{R}^{[0,1]}$, and $F[x]_{\leq n}$ inside $F[x]$. So does every span. The span of a list in V is a subset of V, and by Lemma 1.3.9, sums and scalar multiples of linear combinations of the list are again linear combinations of it. This section names such subsets and gives a quick test for recognizing them. The lecture defines subspaces later (L11–12), alongside dimension. We meet them now because the span is their prototype, and because the kernel and the image of a linear map (Section 2.6) are subspaces the moment they are defined.

1.4.1 The subspace criterion

Throughout, V is a vector space over a field F.

Definition 1.4.1 (Subspace). A subset $W \subseteq V$ is a **subspace** of V if W is a vector space over F under the operations of V, restricted to W. That is, for $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$, the sum $\mathbf{w} + \mathbf{w}'$ and the scalar multiple $a\mathbf{w}$ are computed in V. A subspace $W \neq V$ is a **proper** subspace.

So a subspace is a vector space in its own right, and its operations are not new: we add and scale elements of W exactly as we do in V. In particular, sums and scalar multiples of elements of W must lie in W, because closure is part of being a vector space (Remark 1.2.2).

Non-example 1.4.2 (A line that misses the origin). In $\mathbb{R}^2$, the line $L = \{(c_1, c_2) \mid c_1 + c_2 = 1\}$ is not a subspace. The operations of $\mathbb{R}^2$ are not even operations on L: the vectors $(1, 0)$ and $(0, 1)$ lie on L, but their sum $(1, 1)$ does not, since $1 + 1 \neq 1$. Non-example 1.2.21 made the same observation for the line $x + 2y = 2$. By contrast, the line $\{(r, r) \mid r \in \mathbb{R}\}$ through the origin is a subspace (Example 1.4.8).

Checking all eight axioms for every candidate would be tedious, and most of the work is redundant.

> *Intuition (What has to be checked).* Suppose $W \subseteq V$ is closed under the operations of V. Six of the axioms, (A1), (A2), and (A5)–(A8), are identities that hold *for all* vectors and scalars. An identity that holds for all vectors of V holds in particular for all vectors of W, so these six come for free. The other two axioms assert that something *exists*: (A3) a zero vector, and (A4) an additive inverse of each vector. These are where a subset can fail, because the vector that exists in V might not lie in W. Scalar multiplication produces both of them: $0\mathbf{w} = \mathbf{0}$ and $(-1)\mathbf{w} = -\mathbf{w}$ (Proposition 1.2.32, Proposition 1.2.34). For the first we need some $\mathbf{w} \in W$ to start from, so W must be nonempty. We used the same reasoning for subfields (Proposition 1.1.33) and for $C[0, 1]$ (Example 1.2.12).

The lecture packages this as a criterion with two equivalent tests. The first speaks about linear combinations, which suits spans; the second is the one we check in practice.

> **Theorem 1.4.3** (Subspace criterion). Let $W \subseteq V$. The following are equivalent.
>
> (I) W is a subspace of V.
>
> (II) $W \neq \emptyset$, and W is **stable under linear combinations**: for every $k \geq 1$, all $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$, and all $a_1, \ldots, a_k \in F$, the vector $a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k$ lies in W.
>
> (III) $\mathbf{0} \in W$, and W is **closed under addition and scalar multiplication**: $\mathbf{w} + \mathbf{w}' \in W$ and $a\mathbf{w} \in W$ for all $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$.
>
> Here $\mathbf{0}$ is the zero vector of V.

Proof. ROUTINE

> *Uses.* Definition 1.4.1 (Subspace), Definition 1.2.1 (Vector space), Proposition 1.2.32 (The scalar zero), Proposition 1.2.34 (Negatives and the scalar -1), (1.3.1), induction on k
> *Techniques.* Proving TFAE (Technique 2.7.1)
> *Hint 1.* Sort the axioms (A1)–(A8) into identities that hold "for all" vectors and scalars, and statements that something exists. Which kind can fail for a subset that is closed under the operations?
> *Hint 2.* For (I) ⇒ (III), the subspace W has a zero vector of its own, but (III) asks for the zero vector of V. Multiply the zero vector of W by the scalar 0.
> *Hint 3.* For (III) ⇒ (II), induct on k and split off the last term. For (II) ⇒ (I), produce the zero vector and negatives inside W as $0\mathbf{w}_0$ and $(-1)\mathbf{w}$.
> *Sketch.* (I) ⇒ (III): the operations of W land in W, and $\mathbf{0} = 0 \cdot \mathbf{0}_W \in W$. (III) ⇒ (II): induction on k, writing a combination of length $k + 1$ as one of length k plus a single term. (II) ⇒ (I): sums and multiples are combinations of length 2 and 1, so the operations restrict to W; the identities (A1), (A2), (A5)–(A8) are inherited from V; and $\mathbf{0} = 0\mathbf{w}_0$ and $-\mathbf{w} = (-1)\mathbf{w}$ lie in W and supply (A3) and (A4).

We prove (I) ⇒ (III) ⇒ (II) ⇒ (I).

(I) ⇒ (III). Suppose W is a subspace. Since W is a vector space under the operations of V, these operations map $W \times W$ and $F \times W$ into W; that is, W is closed under addition and scalar multiplication. By (A3) for the vector space W, there is a zero vector $\mathbf{0}_W \in W$. By closure under scalar multiplication, $0 \cdot \mathbf{0}_W \in W$, and $0 \cdot \mathbf{0}_W = \mathbf{0}$ by Proposition 1.2.32, applied in V. Hence $\mathbf{0} \in W$.

(III) ⇒ (II). Since $\mathbf{0} \in W$, $W \neq \emptyset$. We show by induction on $k \geq 1$ that $a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k \in W$ for all $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$ and $a_1, \ldots, a_k \in F$. For $k = 1$ this is closure under scalar multiplication. Suppose it holds for some $k \geq 1$, and let $\mathbf{w}_1, \ldots, \mathbf{w}_{k+1} \in W$ and $a_1, \ldots, a_{k+1} \in F$. By (1.3.1),

$$\sum_{i=1}^{k+1} a_i\mathbf{w}_i = \left(\sum_{i=1}^{k} a_i\mathbf{w}_i\right) + a_{k+1}\mathbf{w}_{k+1}.$$

The first summand lies in W by the inductive hypothesis, and the second by closure under scalar multiplication. So their sum lies in W, by closure under addition.

(II) ⇒ (I). Let $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$. Then $\mathbf{w} + \mathbf{w}' = 1\mathbf{w} + 1\mathbf{w}'$ by (A5), and $a\mathbf{w}$ are linear combinations of elements of W, of lengths 2 and 1, so they lie in W by (II). Hence the operations of V restrict to functions $W \times W \to W$ and $F \times W \to W$. Axioms (A1), (A2), and (A5)–(A8) are identities that hold for all vectors of V and all scalars, so in particular for all vectors of W. It remains to check (A3) and (A4).

(A3). Since $W \neq \emptyset$, we may choose some $\mathbf{w}_0 \in W$. By (II), $0\mathbf{w}_0 \in W$, and $0\mathbf{w}_0 = \mathbf{0}$ by Proposition 1.2.32. So $\mathbf{0} \in W$, and $\mathbf{w} + \mathbf{0} = \mathbf{w}$ for every $\mathbf{w} \in W$, because this holds in V.

(A4). Let $\mathbf{w} \in W$. By (II), $(-1)\mathbf{w} \in W$, and $\mathbf{w} + (-1)\mathbf{w} = \mathbf{w} + (-\mathbf{w}) = \mathbf{0}$ by Proposition 1.2.34, where $\mathbf{0}$ is the zero vector of W just found.

So W satisfies all eight axioms, and W is a subspace of V. □

Remark 1.4.4 (The zero vector of a subspace). Let W be a subspace of V. The proof of (I) ⇒ (III) showed that $\mathbf{0} \in W$. Since $\mathbf{w} + \mathbf{0} = \mathbf{w}$ for every $\mathbf{w} \in W$, the vector $\mathbf{0}$ is a zero vector of the vector space W, so it is *the* zero vector of W (Proposition 1.2.27, applied in W). That is, $\mathbf{0}_W = \mathbf{0}_V$. Similarly, the additive inverse of $\mathbf{w}$ in W is the vector $-\mathbf{w}$ of V, by Proposition 1.2.28. So the vectors whose existence (A3) and (A4) promise are also inherited from V, and from now on we write $\mathbf{0}$ for the zero vector of every subspace of V.

Remark 1.4.5 (Why nonemptiness matters). The empty set is closed under addition and scalar multiplication, because there are no elements to test: "for all $\mathbf{w}, \mathbf{w}' \in \emptyset$" is vacuously true. Likewise, it is stable under linear combinations of lists of length $k \geq 1$. But $\emptyset$ is not a vector space, since (A3) requires an element. So the conditions $W \neq \emptyset$ in (II) and $\mathbf{0} \in W$ in (III) cannot be dropped, and the proof shows where they enter: nonemptiness was used exactly once, to produce the zero vector of W as $0\mathbf{w}_0$.

In practice, check $\mathbf{0} \in W$. It proves nonemptiness, and it is also the fastest test in the other direction: a set that does not contain $\mathbf{0}$ is not a subspace, whatever else it does. If (II) also allowed $k = 0$, the empty linear combination, which represents $\mathbf{0}$ (Definition 1.3.4), would force $\mathbf{0} \in W$, and the condition $W \neq \emptyset$ would be automatic. Exercise 1.4.15 states the criterion in this form.

> **Exercise 1.4.6.** ROUTINE Show that $W \subseteq V$ is a subspace of V if and only if $\mathbf{0} \in W$ and $a\mathbf{w} + \mathbf{w}' \in W$ for all $\mathbf{w}, \mathbf{w}' \in W$ and all $a \in F$.

Solution on page 1053

This one-line form is convenient when W is defined by a condition that is visibly compatible with linear combinations, as for kernels in Section 2.6.

1.4.2 Examples

To show that a subset is a subspace, we check (III). To show that it is not, one failure suffices: $\mathbf{0} \notin W$, or particular vectors and scalars whose sum or scalar multiple leaves W.

Example 1.4.7 (Trivial subspaces). $\{\mathbf{0}\}$ and V are subspaces of V. For V itself there is nothing to check. The set $\{\mathbf{0}\}$ contains $\mathbf{0}$, and $\mathbf{0} + \mathbf{0} = \mathbf{0}$ and $a\mathbf{0} = \mathbf{0}$ by (A3) and Proposition 1.2.33. With the operations of V, $\{\mathbf{0}\}$ is the zero space (Example 1.2.3). By (III), every subspace of V contains it.

Example 1.4.8 (One equation in F^n). Let $a_1, \dots, a_n \in F$, and let

$$H = \{\mathbf{x} \in F^n \mid a_1x_1 + \cdots + a_nx_n = 0\}.$$

Then H is a subspace of F^n. It contains $\mathbf{0}$, since $a_1 0 + \cdots + a_n 0 = 0$. If $\mathbf{x}, \mathbf{y} \in H$ and $c \in F$, then by the coordinatewise operations, distributivity, and regrouping,

$$\sum_{i=1}^{n} a_i(x_i + y_i) = \sum_{i=1}^{n} a_i x_i + \sum_{i=1}^{n} a_i y_i = 0 + 0 = 0,$$
$$\sum_{i=1}^{n} a_i(cx_i) = c \sum_{i=1}^{n} a_i x_i = c \cdot 0 = 0,$$

so $\mathbf{x} + \mathbf{y} \in H$ and $c\mathbf{x} \in H$. For $n = 2$ and the equation $x_1 - x_2 = 0$ over $\mathbb{R}$, H is the line $\{(r, r) \mid r \in \mathbb{R}\}$. In $\mathbb{R}^3$, the equation $x_1 + x_2 + x_3 = 0$ gives a plane through $\mathbf{0}$.

With a nonzero right-hand side, the solution set of $a_1x_1 + \cdots + a_nx_n = b$ is never a subspace, since it does not contain $\mathbf{0}$: the left side at $\mathbf{0}$ is $0 \neq b$. The solution set of a homogeneous system of m equations is the set of vectors that lie in m subspaces of the form H at once, one for each equation; it is a subspace by Proposition 1.4.16 below. Corollary 3.1.16 reaches the same conclusion by recognizing it as a kernel.

Example 1.4.9 (Polynomials). For $n \geq 0$, $F[x]_{\leq n}$ is a subspace of $F[x]$. It contains $\mathbf{0}$, whose degree is $-\infty$, and by Proposition 1.2.18(a) and (b), sums and nonzero multiples of polynomials of degree at most n have degree at most n; the multiple $0p = \mathbf{0}$ does too.

Fix $c \in F$. The polynomials that vanish at c form a subspace $\{p \in F[x] \mid p(c) = 0\}$ of $F[x]$. Indeed $\mathbf{0}(c) = 0$, and if $p(c) = q(c) = 0$ and $a \in F$, then $(p + q)(c) = p(c) + q(c) = 0$ and $(ap)(c) = ap(c) = 0$ by Proposition 1.2.18(c).

The polynomials of degree exactly n do not form a subspace, since $\mathbf{0}$ has degree $-\infty$. Neither do the polynomials with $p(c) = 1$, since $\mathbf{0}(c) = 0$.

Example 1.4.10 (Functions). Let X be a set and $t_0 \in X$. The functions vanishing at t_0 form a subspace of F^X: the zero function vanishes at t_0, and if $f(t_0) = g(t_0) = 0$, then $(f + g)(t_0) = 0 + 0 = 0$ and $(af)(t_0) = a \cdot 0 = 0$ by the pointwise operations. The functions with $f(t_0) = 1$ do not, since the zero function is not among them.

In $\mathbb{R}^{\mathbb{R}}$, the **even** functions $E = \{f \mid f(-t) = f(t) \text{ for all } t\}$ and the **odd** functions $O = \{f \mid f(-t) = -f(t) \text{ for all } t\}$ form subspaces. For O: the zero function is odd, as $0 = -0$. If $f, g \in O$ and $a \in \mathbb{R}$, then for every t,

$$(f + g)(-t) = f(-t) + g(-t) = -f(t) - g(t) = -(f + g)(t), \quad (af)(-t) = af(-t) = -(af)(t).$$

The argument for E is the same without the signs. Finally, $C[0, 1]$ is a subspace of $\mathbb{R}^{[0,1]}$ (Example 1.2.12), and so are the continuous functions with integral 0.

Example 1.4.11 (Matrices). In $F^{n\times n}$, the **symmetric** matrices, those with $a_{ij} = a_{ji}$ for all i, j, form a subspace S, and so do the **trace-zero** matrices, those with $a_{11} + \cdots + a_{nn} = 0$. For $n = 2$,

$$S = \left\{ \begin{pmatrix} a & b \\ b & d \end{pmatrix} \,\middle|\, a, b, d \in F \right\}, \quad T = \left\{ \begin{pmatrix} a & b \\ c & -a \end{pmatrix} \,\middle|\, a, b, c \in F \right\}.$$

Both are cut out by equations among the entries that the zero matrix satisfies, and that survive entrywise sums and scalar multiples: if $a_{ij} = a_{ji}$ and $b_{ij} = b_{ji}$, then $a_{ij} + b_{ij} = a_{ji} + b_{ji}$ and $ca_{ij} = ca_{ji}$, and the trace-zero condition is the equation of Example 1.4.8 in the n^2 entries. In the language of Section 2.4, S consists of the A with $A^{\mathsf{T}} = A$, and T of the A with $\operatorname{tr} A = 0$.

Example 1.4.12 (The subspaces of $\mathbb{F}_2^2$). Over $\mathbb{F}_2$, the only scalars are 0 and 1, and $0\mathbf{w} = \mathbf{0}$, $1\mathbf{w} = \mathbf{w}$. So a subset of an $\mathbb{F}_2$-vector space that contains $\mathbf{0}$ is automatically closed under scalar multiplication, and the subspaces are exactly the subsets that contain $\mathbf{0}$ and are closed under addition.

The space $\mathbb{F}_2^2$ has four elements, $\mathbf{0}$, $\mathbf{e}_1 = (1,0)$, $\mathbf{e}_2 = (0,1)$, and $\mathbf{e}_1 + \mathbf{e}_2 = (1,1)$. Each vector satisfies $\mathbf{v} + \mathbf{v} = \mathbf{0}$, and the sum of any two different nonzero vectors is the third one. So a subset containing $\mathbf{0}$ and at most one nonzero vector $\mathbf{v}$ is closed under addition, since $\mathbf{v} + \mathbf{v} = \mathbf{0}$ and $\mathbf{v} + \mathbf{0} = \mathbf{v}$. A subset containing two different nonzero vectors contains their sum, hence all three nonzero vectors, and it is all of $\mathbb{F}_2^2$. Hence $\mathbb{F}_2^2$ has exactly five subspaces:

$$\{\mathbf{0}\}, \quad \{\mathbf{0}, (1,0)\}, \quad \{\mathbf{0}, (0,1)\}, \quad \{\mathbf{0}, (1,1)\}, \quad \mathbb{F}_2^2.$$

The middle three are the spans of the nonzero vectors (Example 1.3.11), the analogues of lines through the origin. Section 1.4.6 shows that every F^2 looks like this.

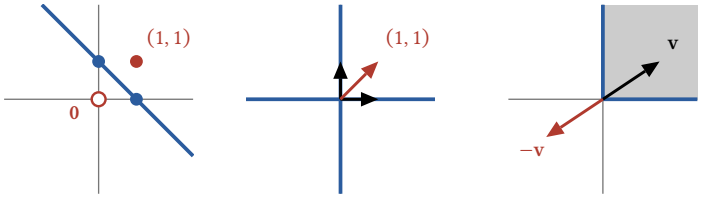


Figure 1.4.1. Three subsets of $\mathbb{R}^2$ that fail to be subspaces, each in a different way. Left: the line $c_1 + c_2 = 1$ misses $\mathbf{0}$; it also contains $(1,0)$ and $(0,1)$ but not their sum. Middle: the union of the axes contains $\mathbf{0}$ and every multiple of its vectors, but not $(1,0) + (0,1)$. Right: the closed first quadrant contains $\mathbf{0}$ and all sums of its vectors, but not $(-1)\mathbf{v}$.

Non-example 1.4.13 (Three ways to fail). Each of the following subsets of $\mathbb{R}^2$ violates a different condition of (III) (Figure 1.4.1).

(a) The line $L = \{(c_1, c_2) \mid c_1 + c_2 = 1\}$ does not contain $\mathbf{0}$. (It fails the other two conditions as well.)

(b) The union of the axes, $A = \{(x, y) \mid xy = 0\}$, contains $\mathbf{0}$ and is closed under scalar multiplication: if $xy = 0$, then $(ax)(ay) = a^2xy = 0$. But $(1,0)$ and $(0,1)$ lie in A, while their sum $(1,1)$ does not.

(c) The first quadrant $Q = \{(x, y) \mid x \geq 0, y \geq 0\}$ contains $\mathbf{0}$ and is closed under addition, since sums of nonnegative numbers are nonnegative. But $(1,0) \in Q$, while $(-1)(1,0) = (-1,0) \notin Q$.

The empty set satisfies both closure conditions and fails only $\mathbf{0} \in W$ (Remark 1.4.5). Together with (b) and (c), this shows that none of the three conditions in (III) follows from the other two.

The set A in (b) is the union of two subspaces, the two axes. We return to it in Section 1.4.4.

1.4.3 The span is the smallest subspace

Intuition. Let U be a subspace of V that contains the entries of a list $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$. By (II) of Theorem 1.4.3, U contains every linear combination of $\mathbf{v}_1, \ldots, \mathbf{v}_k$, so $\operatorname{span}(\mathcal{L}) \subseteq U$. If $\operatorname{span}(\mathcal{L})$ is itself a subspace, it is therefore the smallest subspace containing the entries of $\mathcal{L}$: it lies inside every other one. And it is a subspace, because sums and scalar multiples of linear combinations of $\mathcal{L}$ are linear combinations of $\mathcal{L}$. So the span can be described from the inside, as the set of all linear combinations, or from the outside, as the least subspace that the entries of $\mathcal{L}$ force on us.

Proposition 1.4.14 (The span is the smallest subspace containing a list). Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V.

(a) $\operatorname{span}(\mathcal{L})$ is a subspace of V, and $\mathcal{L} \subseteq \operatorname{span}(\mathcal{L})$.

(b) If U is a subspace of V and $\mathcal{L} \subseteq U$, then $\operatorname{span}(\mathcal{L}) \subseteq U$.

Proof. ROUTINE

Uses. Theorem 1.4.3 (Subspace criterion), Proposition 1.3.17 (A list lies in its span), Lemma 1.3.9 (Arithmetic of linear combinations), Definition 1.3.10 (Span)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For (a), check (III) of Theorem 1.4.3. What is the sum of two linear combinations of $\mathcal{L}$?
Hint 2. For (b), an element of $\operatorname{span}(\mathcal{L})$ is a linear combination of vectors that lie in U. Which condition of Theorem 1.4.3 speaks about linear combinations? Treat the empty list separately.
Sketch. (a) $\mathbf{0}$ and the entries of $\mathcal{L}$ lie in $\operatorname{span}(\mathcal{L})$ by Proposition 1.3.17, and by Lemma 1.3.9, $\sum a_i\mathbf{v}_i + \sum b_i\mathbf{v}_i = \sum(a_i + b_i)\mathbf{v}_i$ and $c\sum a_i\mathbf{v}_i = \sum(ca_i)\mathbf{v}_i$. (b) The subspace U satisfies (II) of Theorem 1.4.3 and contains $\mathbf{v}_1, \ldots, \mathbf{v}_k$, so it contains every linear combination of them; if $k = 0$, $\operatorname{span}(\mathcal{L}) = \{\mathbf{0}\} \subseteq U$.

(a) We check (III) of Theorem 1.4.3. By Proposition 1.3.17, $\mathbf{0} \in \operatorname{span}(\mathcal{L})$, and also $\mathcal{L} \subseteq \operatorname{span}(\mathcal{L})$. Let $\mathbf{u}, \mathbf{w} \in \operatorname{span}(\mathcal{L})$ and $c \in F$, say $\mathbf{u} = \sum_{i=1}^{k} a_i\mathbf{v}_i$ and $\mathbf{w} = \sum_{i=1}^{k} b_i\mathbf{v}_i$. By Lemma 1.3.9,

$$\mathbf{u} + \mathbf{w} = \sum_{i=1}^{k}(a_i + b_i)\mathbf{v}_i \quad \text{and} \quad c\mathbf{u} = \sum_{i=1}^{k}(ca_i)\mathbf{v}_i,$$

which are linear combinations of $\mathcal{L}$. So $\mathbf{u} + \mathbf{w}$ and $c\mathbf{u}$ lie in $\operatorname{span}(\mathcal{L})$, and $\operatorname{span}(\mathcal{L})$ is a subspace.

(b) Let U be a subspace with $\mathcal{L} \subseteq U$, and let $\mathbf{w} \in \operatorname{span}(\mathcal{L})$. If $k = 0$, then $\mathbf{w} = \mathbf{0}$, which lies in U by (III) of Theorem 1.4.3. If $k \geq 1$, then $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$ for some scalars a_i, where each $\mathbf{v}_i$ lies in U. By (II) of Theorem 1.4.3, $\mathbf{w} \in U$. Hence $\operatorname{span}(\mathcal{L}) \subseteq U$. □

In particular, $\operatorname{span}(\mathcal{L})$ is a vector space in its own right, and $\mathcal{L}$ spans it. Part (b) gives the second proof of Proposition 1.3.18 promised in Section 1.3.4. If $\mathcal{M} \subseteq \operatorname{span}(\mathcal{L})$, then $\operatorname{span}(\mathcal{L})$ is a subspace, by (a), that contains the entries of $\mathcal{M}$, so it contains $\operatorname{span}(\mathcal{M})$, by (b). The first proof expanded every linear combination of $\mathcal{M}$ into one of $\mathcal{L}$ and collected coefficients. The second needs only that $\operatorname{span}(\mathcal{L})$ is closed under sums and scalar multiples; Theorem 1.4.3 upgrades this to closure under all linear combinations, by an induction done once and for all.

Part (b) also changes how we prove that a span lies in a given subspace: it suffices to check the finitely many entries of the list. For instance, the plane $P = \{\mathbf{x} \in \mathbb{R}^3 \mid x_1 + x_2 + x_3 = 0\}$ is a subspace (Example 1.4.8) that contains $(1, 0, -1)$ and $(0, 1, -1)$, so it contains their span. In Exercise 1.3.16 the same containment took a computation with an arbitrary linear combination.

Exercise 1.4.15. ROUTINE Show that a subset $W \subseteq V$ is a subspace of V if and only if $\operatorname{span}(\mathcal{L}) \subseteq W$ for every list $\mathcal{L}$ in W, the empty list included.

Solution on page 1053

1.4.4 Intersections and unions

Given two subspaces, we would like to build new ones from them. Intersections always work; unions almost never do.

Proposition 1.4.16 (Intersections of subspaces). Let $(U_i)_{i \in I}$ be a family of subspaces of V, indexed by any set I. Then

$$\bigcap_{i \in I} U_i = \{\mathbf{v} \in V \mid \mathbf{v} \in U_i \text{ for every } i \in I\}$$

is a subspace of V.

Proof. ROUTINE

Uses. Theorem 1.4.3 (Subspace criterion)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Check the three conditions of (III) in Theorem 1.4.3 for the intersection.
Hint 2. A vector lies in the intersection exactly when it lies in every U_i, and each U_i satisfies (III) on its own.
Sketch. $\mathbf{0}$ lies in every U_i. If $\mathbf{u}, \mathbf{w}$ lie in every U_i, then so do $\mathbf{u}+\mathbf{w}$ and $a\mathbf{u}$, since each U_i is closed under the operations.

Write $X = \bigcap_{i \in I} U_i$. We check (III) of Theorem 1.4.3. Each U_i is a subspace, so $\mathbf{0} \in U_i$ for every i, and $\mathbf{0} \in X$. Let $\mathbf{u}, \mathbf{w} \in X$ and $a \in F$, and fix $i \in I$. Then $\mathbf{u}, \mathbf{w} \in U_i$, and since U_i is closed under addition and scalar multiplication, $\mathbf{u}+\mathbf{w} \in U_i$ and $a\mathbf{u} \in U_i$. As i was arbitrary, $\mathbf{u}+\mathbf{w} \in X$ and $a\mathbf{u} \in X$. So X is a subspace. □

The family may be infinite, or even empty; for $I = \emptyset$ the condition "for every $i \in I$" is vacuous, the intersection is V, and the proof still applies. The polynomials of degree at most n that vanish at c form a subspace, as the intersection of two subspaces from Example 1.4.9, and the solution set of a homogeneous system is the intersection of the subspaces H of Example 1.4.8, one for each equation.

Intersections give a second description of the span, from the outside.

Corollary 1.4.17 (The span as an intersection). Let $\mathcal{L}$ be a list in V. Then $\operatorname{span}(\mathcal{L})$ is the intersection of all subspaces of V that contain the entries of $\mathcal{L}$.

Proof. ROUTINE

Uses. Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 1.4.16 (Intersections of subspaces)
Techniques. Double containment (Technique 1.3.14)
Hint 1. Let X be the intersection. Is $\operatorname{span}(\mathcal{L})$ one of the subspaces being intersected?
Hint 2. Each subspace in the family contains $\operatorname{span}(\mathcal{L})$, by Proposition 1.4.14(b).
Sketch. Since $\operatorname{span}(\mathcal{L})$ belongs to the family, $X \subseteq \operatorname{span}(\mathcal{L})$. Since every member contains $\operatorname{span}(\mathcal{L})$, $\operatorname{span}(\mathcal{L}) \subseteq X$.

Let X be the intersection of all subspaces U of V with $\mathcal{L} \subseteq U$. We proceed by double containment. By Proposition 1.4.14(a), $\operatorname{span}(\mathcal{L})$ is a member of the family, so $X \subseteq \operatorname{span}(\mathcal{L})$. By Proposition 1.4.14(b), every member U satisfies $\operatorname{span}(\mathcal{L}) \subseteq U$, so $\operatorname{span}(\mathcal{L}) \subseteq X$. □

The description in Definition 1.3.10 builds the span by listing its elements, and it is the one we compute with. The description in Corollary 1.4.17 uses no linear combinations at all, and so it makes sense for any subset $S \subseteq V$, finite or not: by Proposition 1.4.16, the intersection of all subspaces containing S is a subspace, and it is the smallest one containing S.

Unions

Now take two subspaces U and W. The union $U \cup W$ contains $\mathbf{0}$, and it is closed under scalar multiplication, since a multiple of a vector of U lies in U and a multiple of a vector of W lies in W. Addition is the problem. The union of the two axes of $\mathbb{R}^2$ (Figure 1.4.1, middle) is not closed under addition: a vector on one axis plus a vector on the other lies on neither. Reading off exactly why this example fails is a move worth naming.

Technique 1.4.18 (Finding counterexamples and minimal examples). To disprove a claim about all objects of some kind, a single object for which it fails is enough. Look for one by shrinking everything: the smallest space, the fewest vectors, the simplest field (Technique 1.2.38). Then read the counterexample. Ask which features made it work; often they point to the exact hypothesis under which the claim does hold, and the counterexample, run on general objects, turns into a proof.

Reach for it whenever a claim seems plausible but no proof suggests itself, and in every "prove or disprove". The canonical example is the claim that the union of two subspaces is a subspace. It fails for the two axes of $\mathbb{R}^2$, since $(1,0)+(0,1)$ lies on neither (Non-example 1.4.13). The failure used only one vector of the first subspace outside the second and one vector of the second outside the first. So nested subspaces escape the counterexample, and Proposition 1.4.20 shows that only they do.

Used in. Proposition 1.4.20, Exercise 1.4.37, Exercise 1.5.34, Exercise 1.6.35, Exercise 1.7.12, Exercise 1.7.15, Problem 1.10, Exercise 2.7.22, Exercise 2.8.14, Exercise 2.8.15, Problem 2.10, Problem 2.14, Problem 2.20, Problem 3.7, Problem 3.8, Exercise 4.1.41, Exercise 4.1.48, Exercise 4.2.38, Exercise 4.3.29, Exercise 4.3.34, Exercise 4.3.36, Exercise 4.4.34, Exercise 4.5.39, Exercise 4.5.46, Exercise 4.6.6, Exercise 4.6.51, Exercise 4.7.51, Exercise 4.8.5, Exercise 4.8.6, Exercise 4.8.11, Problem 5.4, Exercise 6.5.44, Exercise 6.7.15, Problem 6.6, Problem 6.7, Exercise 7.2.43, Exercise 7.2.53, Exercise 7.2.54, Exercise 7.3.38, Exercise 7.4.38, Exercise 7.5.33, Exercise 7.6.43, Exercise 7.7.4, Exercise 7.7.5, Exercise 7.7.6, Exercise 7.7.8, Problem 7.5, Exercise 8.3.29, Exercise 8.3.38, Exercise B.1.38, Exercise 1.4.26, Exercise 1.4.27, Exercise 1.4.40, Exercise 1.5.16, Exercise 2.4.44, Exercise 2.5.34, Exercise 2.5.35, Exercise 2.6.36, Exercise 2.6.37, Exercise 2.6.38, Exercise 2.6.40, Exercise 2.6.50, Exercise 2.6.52, Exercise 2.7.21, Exercise 2.7.27, Exercise 4.2.45, Exercise 4.3.32, Exercise 4.3.35, Exercise 5.5.38, Exercise 5.5.49, Exercise 6.2.34, Exercise 6.3.46, Exercise 6.3.47, Exercise 6.3.55, Exercise 6.4.48, Exercise 6.4.50, Exercise 6.4.63, Exercise 6.5.35, Exercise 6.6.36, Exercise 7.1.53, Exercise 7.5.37, Exercise 8.2.34, Exercise A.1.15, Exercise A.1.25, Exercise A.2.13, Exercise A.3.14, Exercise A.3.17, Exercise A.3.18.

The key step in the counterexample is that a vector on one axis plus a vector off that axis lands off that axis. This holds for every subspace.

Lemma 1.4.19 (Adding a vector outside a subspace). Let U be a subspace of V, let $\mathbf{u} \in U$, and let $\mathbf{v} \in V$ with $\mathbf{v} \notin U$. Then $\mathbf{u} + \mathbf{v} \notin U$.

Proof. ROUTINE

Uses. Theorem 1.4.3 (Subspace criterion), Proposition 1.2.34 (Negatives and the scalar -1)
Hint 1. Suppose $\mathbf{u} + \mathbf{v} \in U$. Can you recover $\mathbf{v}$ from two vectors of U?
Hint 2. $\mathbf{v} = (\mathbf{u} + \mathbf{v}) + (-1)\mathbf{u}$, a linear combination of two vectors of U.
Sketch. If $\mathbf{u} + \mathbf{v} \in U$, then $\mathbf{v} = (\mathbf{u} + \mathbf{v}) + (-1)\mathbf{u}$ lies in U by closure, a contradiction.

Suppose, to the contrary, that $\mathbf{u} + \mathbf{v} \in U$. By Proposition 1.2.34 and the axioms,

$$(\mathbf{u} + \mathbf{v}) + (-1)\mathbf{u} = (\mathbf{v} + \mathbf{u}) + (-\mathbf{u}) = \mathbf{v} + (\mathbf{u} + (-\mathbf{u})) = \mathbf{v}.$$

The left side is a linear combination of $\mathbf{u} + \mathbf{v}$ and $\mathbf{u}$, which lie in U, so $\mathbf{v} \in U$ by (II) of Theorem 1.4.3. This contradicts $\mathbf{v} \notin U$. □

Proposition 1.4.20 (Unions of two subspaces). Let U and W be subspaces of V. Then $U \cup W$ is a subspace of V if and only if $U \subseteq W$ or $W \subseteq U$.

Intuition. The backward direction is immediate, since $U \cup W$ is then W or U. The forward direction concludes "$U \subseteq W$ or $W \subseteq U$", and there are two natural ways to prove a disjunction. One is to assume that the first alternative fails and deduce the second: a vector $\mathbf{u} \in U$ outside W is a lever, and adding it to each vector of W forces that vector into U. The other is the contrapositive: assume both alternatives fail, and build the counterexample of the two axes from one witness on each side.

Proof (assume one alternative fails). STANDARD

Uses. Theorem 1.4.3 (Subspace criterion), Lemma 1.4.19 (Adding a vector outside a subspace)
Hint 1. The backward direction is immediate: if $U \subseteq W$, then $U \cup W = W$.
Hint 2. For the forward direction, assume $U \not\subseteq W$ and prove $W \subseteq U$. Fix $\mathbf{u} \in U$ with $\mathbf{u} \notin W$.
Hint 3. For $\mathbf{w} \in W$, the sum $\mathbf{u} + \mathbf{w}$ lies in $U \cup W$. Which of the two can it lie in? Use Lemma 1.4.19.
Sketch. ($\Leftarrow$) $U \cup W$ is W or U. ($\Rightarrow$) Suppose $U \cup W$ is a subspace and $U \not\subseteq W$; fix $\mathbf{u} \in U \setminus W$. For $\mathbf{w} \in W$, $\mathbf{u} + \mathbf{w} \in U \cup W$ by closure, and $\mathbf{u} + \mathbf{w} \notin W$ by Lemma 1.4.19 (applied to W, with $\mathbf{w} \in W$ and $\mathbf{u} \notin W$). So $\mathbf{u} + \mathbf{w} \in U$, and $\mathbf{w} = (\mathbf{u} + \mathbf{w}) - \mathbf{u} \in U$. Hence $W \subseteq U$.

($\Leftarrow$) If $U \subseteq W$, then $U \cup W = W$, and if $W \subseteq U$, then $U \cup W = U$. Either way, $U \cup W$ is a subspace.

($\Rightarrow$) Suppose $U \cup W$ is a subspace. If $U \subseteq W$, we are done. Otherwise, fix a vector $\mathbf{u} \in U$ with $\mathbf{u} \notin W$; we show $W \subseteq U$. Let $\mathbf{w} \in W$. Both $\mathbf{u}$ and $\mathbf{w}$ lie in the subspace $U \cup W$, so $\mathbf{u} + \mathbf{w} \in U \cup W$. By Lemma 1.4.19, applied to the subspace W, the vector $\mathbf{w} \in W$, and the vector $\mathbf{u} \notin W$, we have $\mathbf{w} + \mathbf{u} \notin W$. Hence $\mathbf{u} + \mathbf{w} \in U$. Since $\mathbf{u} \in U$ as well, $\mathbf{w} = (\mathbf{u} + \mathbf{w}) + (-1)\mathbf{u} \in U$ by (II) of Theorem 1.4.3. As $\mathbf{w}$ was arbitrary, $W \subseteq U$. □

Proof (generalize the counterexample). STANDARD

> *Uses.* Theorem 1.4.3 (Subspace criterion), Lemma 1.4.19 (Adding a vector outside a subspace)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* The backward direction is immediate. For the forward direction, prove the contrapositive: if neither subspace contains the other, then $U \cup W$ is not closed under addition.
> *Hint 2.* Imitate the two axes: take $\mathbf{u} \in U$ outside W and $\mathbf{w} \in W$ outside U, and locate $\mathbf{u} + \mathbf{w}$.
> *Sketch.* If $U \not\subseteq W$ and $W \not\subseteq U$, pick $\mathbf{u} \in U \setminus W$ and $\mathbf{w} \in W \setminus U$. By Lemma 1.4.19, applied once to U and once to W, $\mathbf{u} + \mathbf{w}$ lies in neither U nor W. So $U \cup W$ is not closed under addition.

The backward direction is as in the first proof. For the forward direction, we prove the contrapositive. Suppose $U \not\subseteq W$ and $W \not\subseteq U$, and pick $\mathbf{u} \in U$ with $\mathbf{u} \notin W$ and $\mathbf{w} \in W$ with $\mathbf{w} \notin U$. By Lemma 1.4.19 applied to U, with $\mathbf{u} \in U$ and $\mathbf{w} \notin U$, we get $\mathbf{u} + \mathbf{w} \notin U$. By Lemma 1.4.19 applied to W, with $\mathbf{w} \in W$ and $\mathbf{u} \notin W$, we get $\mathbf{w} + \mathbf{u} \notin W$. So $\mathbf{u}$ and $\mathbf{w}$ lie in $U \cup W$, but $\mathbf{u} + \mathbf{w}$ does not. Hence $U \cup W$ is not closed under addition, and it is not a subspace by Theorem 1.4.3. □

The second proof is the counterexample of the two axes, with U and W in place of the axes and the two witnesses in place of $(1, 0)$ and $(0, 1)$. The first proof shows a different habit: to prove "P or Q", assume P fails and use the failure. Here the failure of $U \subseteq W$ supplied a single vector $\mathbf{u}$, and that one vector moved every vector of W into U.

Exercise 1.4.21. ROUTINE Let U and W be subspaces of V with $U \cup W = V$. Show that $U = V$ or $W = V$.

Solution on page 1054

Unions of chains

A union of subspaces can still be a subspace when the subspaces are nested. Closure under addition involves only two vectors at a time, so only two members of the family at a time, and for nested subspaces Proposition 1.4.20 applies to each pair.

Proposition 1.4.22 (Unions of chains). Let $(U_i)_{i \in I}$ be a family of subspaces of V, indexed by a nonempty set I, such that for all $i, j \in I$, $U_i \subseteq U_j$ or $U_j \subseteq U_i$. Then $\bigcup_{i \in I} U_i$ is a subspace of V. In particular, if $U_1 \subseteq U_2 \subseteq U_3 \subseteq \cdots$ are subspaces of V, then $\bigcup_{n \geq 1} U_n$ is a subspace of V.

Proof. ROUTINE

> *Uses.* Theorem 1.4.3 (Subspace criterion)
> *Techniques.* Fix an arbitrary element and chase it (Technique 1.3.13)
> *Hint 1.* Check (III) of Theorem 1.4.3. Two vectors of the union lie in two members of the family.
> *Hint 2.* If $\mathbf{u} \in U_i$ and $\mathbf{w} \in U_j$, one of U_i, U_j contains both vectors.
> *Sketch.* $\mathbf{0}$ lies in any member. If $\mathbf{u} \in U_i$ and $\mathbf{w} \in U_j$, say with $U_i \subseteq U_j$, then $\mathbf{u} + \mathbf{w} \in U_j$. Multiples of $\mathbf{u}$ stay in U_i. For an increasing sequence, $U_m \subseteq U_n$ whenever $m \leq n$, so any two members are nested.

Write $X = \bigcup_{i \in I} U_i$. We check (III) of Theorem 1.4.3. Since I is nonempty, there is some $i_0 \in I$, and $\mathbf{0} \in U_{i_0} \subseteq X$. Let $\mathbf{u}, \mathbf{w} \in X$ and $a \in F$, say $\mathbf{u} \in U_i$ and $\mathbf{w} \in U_j$. Then $a\mathbf{u} \in U_i \subseteq X$. By hypothesis, $U_i \subseteq U_j$ or $U_j \subseteq U_i$; exchanging the names of $\mathbf{u}$ and $\mathbf{w}$ if necessary, we may assume $U_i \subseteq U_j$. Then $\mathbf{u}$ and $\mathbf{w}$ both lie in the subspace U_j, so $\mathbf{u} + \mathbf{w} \in U_j \subseteq X$. So X is a subspace.

For an increasing sequence $U_1 \subseteq U_2 \subseteq \cdots$, we have $U_m \subseteq U_n$ whenever $m \leq n$, by induction on $n - m$, so any two members are nested and the first part applies. □

Example 1.4.23 ($F[x]$ as a union of a chain). The subspaces $F[x]_{\leq 0} \subseteq F[x]_{\leq 1} \subseteq F[x]_{\leq 2} \subseteq \cdots$ of Example 1.4.9 form an increasing sequence, and their union is all of $F[x]$, since every polynomial has a degree, which is $-\infty$ or some $n \geq 0$. Each $F[x]_{\leq n}$ is a proper subspace, as $x^{n+1} \notin F[x]_{\leq n}$. So $F[x]$ is the union of infinitely many proper subspaces. By Exercise 1.4.21, two proper subspaces never suffice, and over an infinite field no finite number does (Exercise 1.4.43).

1.4.5 Sums of subspaces

Since $U \cup W$ is usually not a subspace, we ask instead for the smallest subspace that contains both U and W. Any subspace containing U and W contains every sum $\mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in U$ and $\mathbf{w} \in W$, and these sums already form a subspace.

Proposition 1.4.24 (The sum of two subspaces). Let U and W be subspaces of V, and let

$$U + W = \{\mathbf{u} + \mathbf{w} \mid \mathbf{u} \in U, \mathbf{w} \in W\}.$$

(a) $U + W$ is a subspace of V that contains U and W.

(b) If X is a subspace of V with $U \subseteq X$ and $W \subseteq X$, then $U + W \subseteq X$.

Proof. ROUTINE

Uses. Theorem 1.4.3 (Subspace criterion), Definition 1.2.1 (Vector space)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For (a), check (III) of Theorem 1.4.3. Regroup $(\mathbf{u} + \mathbf{w}) + (\mathbf{u}' + \mathbf{w}')$ so that the vectors of U are together.
Hint 2. To see $U \subseteq U + W$, write $\mathbf{u} = \mathbf{u} + \mathbf{0}$. For (b), use that X is closed under addition.
Sketch. (a) $\mathbf{0} = \mathbf{0} + \mathbf{0}$; $(\mathbf{u} + \mathbf{w}) + (\mathbf{u}' + \mathbf{w}') = (\mathbf{u} + \mathbf{u}') + (\mathbf{w} + \mathbf{w}')$ and $a(\mathbf{u} + \mathbf{w}) = a\mathbf{u} + a\mathbf{w}$; and $\mathbf{u} = \mathbf{u} + \mathbf{0}$, $\mathbf{w} = \mathbf{0} + \mathbf{w}$. (b) If $\mathbf{u}, \mathbf{w} \in X$, then $\mathbf{u} + \mathbf{w} \in X$.

(a) We check (III) of Theorem 1.4.3. Since $\mathbf{0} \in U$ and $\mathbf{0} \in W$, $\mathbf{0} = \mathbf{0} + \mathbf{0} \in U + W$. Let $\mathbf{u} + \mathbf{w}$ and $\mathbf{u}' + \mathbf{w}'$ be elements of $U + W$, with $\mathbf{u}, \mathbf{u}' \in U$ and $\mathbf{w}, \mathbf{w}' \in W$, and let $a \in F$. By (A1) and (A2),

$$(\mathbf{u} + \mathbf{w}) + (\mathbf{u}' + \mathbf{w}') = (\mathbf{u} + \mathbf{u}') + (\mathbf{w} + \mathbf{w}'),$$

with $\mathbf{u} + \mathbf{u}' \in U$ and $\mathbf{w} + \mathbf{w}' \in W$, and by (A7), $a(\mathbf{u} + \mathbf{w}) = a\mathbf{u} + a\mathbf{w}$, with $a\mathbf{u} \in U$ and $a\mathbf{w} \in W$. So both lie in $U + W$, and $U + W$ is a subspace. Finally, for $\mathbf{u} \in U$ we have $\mathbf{u} = \mathbf{u} + \mathbf{0} \in U + W$, and for $\mathbf{w} \in W$ we have $\mathbf{w} = \mathbf{0} + \mathbf{w} \in U + W$, by (A3) and (A1).

(b) Let $\mathbf{u} + \mathbf{w} \in U + W$, with $\mathbf{u} \in U \subseteq X$ and $\mathbf{w} \in W \subseteq X$. Since X is closed under addition, $\mathbf{u} + \mathbf{w} \in X$. □

So $U + W$ is the smallest subspace containing $U \cup W$, and $U \cup W \subseteq U + W$ with equality exactly when one of U, W contains the other (Proposition 1.4.20). Sums of spans are spans: $\operatorname{span}(\mathcal{L}) + \operatorname{span}(\mathcal{M}) = \operatorname{span}(\mathcal{L}, \mathcal{M})$ by Exercise 1.3.36. For example, in F^3 the sum of the x_1-axis $\operatorname{span}(\mathbf{e}_1)$ and the x_2-axis $\operatorname{span}(\mathbf{e}_2)$ is $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$, the plane $x_3 = 0$, while their union is just the two axes. Sums of more than two subspaces, the case where every vector of $U + W$ has only one decomposition $\mathbf{u} + \mathbf{w}$, and the dimension of $U + W$ are the subject of Section 4.4.

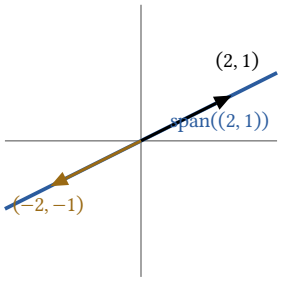
1.4.6 Subspaces of the plane

In $\mathbb{R}^2$ we have met three kinds of subspace: $\{\mathbf{0}\}$, lines through the origin, and $\mathbb{R}^2$ itself. There are no others, over any field.

Intuition. A subspace that contains one nonzero vector contains the whole line through it, and a subspace that contains two vectors pointing in different directions contains the whole plane. There is no room in between. The proof makes this precise with Proposition 1.4.14(b), which turns "contains these vectors" into "contains their span", and with Exercise 1.3.37, which says when two vectors span F^2.

Theorem 1.4.25 (The subspaces of F^2). The subspaces of F^2 are $\{\mathbf{0}\}$, the lines $\operatorname{span}(\mathbf{v})$ with $\mathbf{v} \neq \mathbf{0}$, and F^2. Two such lines $\operatorname{span}(\mathbf{v})$ and $\operatorname{span}(\mathbf{v}')$ are equal if and only if $\mathbf{v}' = c\mathbf{v}$ for some $c \neq 0$.

Proof. STANDARD



Uses. Proposition 1.4.14 (The span is the smallest subspace containing a list), Exercise 1.3.37, Exercise 1.3.28, Example 1.4.7 (Trivial subspaces)
Hint 1. Each of the listed sets is a subspace. For the converse, let U be a subspace and split into cases according to how much of F^2 it contains.

Hint 2. If $U \neq \{\mathbf{0}\}$, pick $\mathbf{v} \in U$ with $\mathbf{v} \neq \mathbf{0}$. Then $\operatorname{span}(\mathbf{v}) \subseteq U$. If this is not all of U, pick $\mathbf{w} \in U$ outside $\operatorname{span}(\mathbf{v})$.
Hint 3. By Exercise 1.3.37(b), $\mathbf{v}, \mathbf{w}$ spans F^2. Now apply Proposition 1.4.14(b) again.
Sketch. The listed sets are subspaces by Example 1.4.7 and Proposition 1.4.14(a). Let U be a subspace other than $\{\mathbf{0}\}$, and pick $\mathbf{v} \neq \mathbf{0}$ in U, so $\operatorname{span}(\mathbf{v}) \subseteq U$. Either $U = \operatorname{span}(\mathbf{v})$, or there is $\mathbf{w} \in U \setminus \operatorname{span}(\mathbf{v})$, and then $F^2 = \operatorname{span}(\mathbf{v}, \mathbf{w}) \subseteq U$ by Exercise 1.3.37(b). The statement about equal lines is Exercise 1.3.28(b).

The sets $\{\mathbf{0}\}$ and F^2 are subspaces (Example 1.4.7), and so is every span (Proposition 1.4.14(a)). Conversely, let U be a subspace of F^2. If $U = \{\mathbf{0}\}$, we are done. Otherwise, choose $\mathbf{v} \in U$ with $\mathbf{v} \neq \mathbf{0}$. By Proposition 1.4.14(b), $\operatorname{span}(\mathbf{v}) \subseteq U$. If $U = \operatorname{span}(\mathbf{v})$, then U is a line. Otherwise, choose $\mathbf{w} \in U$ with $\mathbf{w} \notin \operatorname{span}(\mathbf{v})$. Since $\mathbf{v} \neq \mathbf{0}$ and $\mathbf{w} \notin \operatorname{span}(\mathbf{v})$, the list $\mathbf{v}, \mathbf{w}$ spans F^2 by Exercise 1.3.37(b). Both entries lie in U, so by Proposition 1.4.14(b),

$$F^2 = \operatorname{span}(\mathbf{v}, \mathbf{w}) \subseteq U,$$

and $U = F^2$. The criterion for two lines to be equal is Exercise 1.3.28(b). □

Both vectors lie on the line $\operatorname{span}((2, 1))$, so their span is that line. In the interactive version, drag the second vector off the line: the span jumps from the line to all of $\mathbb{R}^2$, with nothing in between. (Interactive in the web version.)

Over $\mathbb{R}$, the lines $\operatorname{span}(\mathbf{v})$ are the lines through the origin. Over $\mathbb{F}_2$ each line has two elements, and the theorem recovers the five subspaces of Example 1.4.12. Over a field with q elements, F^2 has $q + 1$ lines (Exercise 1.4.33).

The proof was a count in disguise: U contains no direction, one direction, or two. Section 4.1 makes this count precise. Every subspace U of F^n has a dimension between 0 and n, with $U = F^n$ only for dimension n (Proposition 4.1.21). In particular, the subspaces of $\mathbb{R}^3$ are $\{\mathbf{0}\}$, the lines and the planes through $\mathbf{0}$, and $\mathbb{R}^3$.

Exercises

Exercise 1.4.26. ROUTINE Decide which of the following are subspaces, and justify each answer.

(a) $\{\mathbf{x} \in \mathbb{R}^3 \mid x_1 = 2x_3\}$.

(b) $\{\mathbf{x} \in \mathbb{R}^3 \mid x_1 + x_2 + x_3 = 1\}$.

(c) $\{\mathbf{x} \in \mathbb{R}^3 \mid x_1 x_2 = 0\}$.

(d) $\{\mathbf{x} \in \mathbb{R}^3 \mid x_1 \leq x_2\}$.

(e) $\{\mathbf{x} \in \mathbb{R}^3 \mid x_1^2 + x_2^2 = 0\}$, and the subset of $\mathbb{C}^3$ defined by the same equation.

Solution on page 1054

Exercise 1.4.27. ROUTINE Decide which of the following are subspaces, and justify each answer. Write $p = \sum_k a_k x^k$ for polynomials.

(a) $\left\{f \in \mathbb{R}^{\mathbb{R}} \;\middle|\; f(0) = f(1)\right\}$.

(b) $\left\{f \in \mathbb{R}^{\mathbb{R}} \;\middle|\; f(1) = f(0)^2\right\}$.

(c) The bounded functions in $\mathbb{R}^{\mathbb{R}}$, those f for which there is M with $|f(t)| \leq M$ for all t.

(d) $\{p \in \mathbb{R}[x] \mid p(1)p(2) = 0\}$.

(e) $\{p \in \mathbb{R}[x] \mid a_k = 0 \text{ for every odd } k\}$.

(f) $\left\{A \in F^{2\times 2} \;\middle|\; a_{11}a_{22} = a_{12}a_{21}\right\}$.

Solution on page 1054

Exercise 1.4.28. STANDARD By Proposition 1.2.19, $\mathbb{C}^2$ is a vector space over $\mathbb{C}$ and also over $\mathbb{R}$, with the same addition. For $z = a + bi$ with $a, b \in \mathbb{R}$, write $\overline{z} = a - bi$.

(a) Show that every subspace of $\mathbb{C}^2$ over $\mathbb{C}$ is also a subspace of $\mathbb{C}^2$ over $\mathbb{R}$.

(b) For each of the sets $\mathbb{R}^2 = \{(a, b) \mid a, b \in \mathbb{R}\}$ and $D = \{(z, \overline{z}) \mid z \in \mathbb{C}\}$, decide whether it is a subspace of $\mathbb{C}^2$ over $\mathbb{R}$, and whether it is a subspace over $\mathbb{C}$.

Solution on page 1055

Exercise 1.4.29. ROUTINE Find the error in the following argument.

Claim. The set $P = \{t \in \mathbb{R} \mid t > 0\}$ is a subspace of the real vector space $\mathbb{R}$.

Proof. For $s, t \in P$ and $c \in \mathbb{R}$, define $s \oplus t = st$ and $c \odot t = t^c$. With these operations, P is a real vector space, with zero vector 1. Hence P is a subspace of $\mathbb{R}$.

(You may take for granted that P is a real vector space under $\oplus$ and $\odot$.)

Solution on page 1055

Exercise 1.4.30. ROUTINE Find the error in the following argument.

Claim. If U and W are subspaces of V, then $U \cup W$ is a subspace of V.

Proof. Since $\mathbf{0} \in U$, we have $\mathbf{0} \in U \cup W$. Let $\mathbf{v} \in U \cup W$ and $a \in F$. Then $\mathbf{v}$ lies in U or in W, and in either case $a\mathbf{v}$ lies in the same subspace, hence in $U \cup W$. Finally, let $\mathbf{v}, \mathbf{w} \in U \cup W$. Each of them lies in U or in W, and U and W are closed under addition, so $\mathbf{v} + \mathbf{w} \in U$ or $\mathbf{v} + \mathbf{w} \in W$. Hence $\mathbf{v} + \mathbf{w} \in U \cup W$.

Solution on page 1055

Exercise 1.4.31. STANDARD

(a) Let p be a prime, and let V be a vector space over $\mathbb{F}_p$. Show that a nonempty subset $W \subseteq V$ that is closed under addition is a subspace.

(b) Show that (a) fails over $\mathbb{Q}$: find a nonempty subset of $\mathbb{Q}^2$ that is closed under addition and under $\mathbf{v} \mapsto -\mathbf{v}$, but is not a subspace of the $\mathbb{Q}$-vector space $\mathbb{Q}^2$.

Solution on page 1056

Exercise 1.4.32. STANDARD For which primes p is $S_p = \left\{(x, y) \in \mathbb{F}_p^2 \;\middle|\; x^2 = y^2\right\}$ a subspace of $\mathbb{F}_p^2$?

Solution on page 1056

Exercise 1.4.33. STANDARD

(a) List all subspaces of $\mathbb{F}_3^2$, writing each line as a set of three vectors.

(b) Let F be a finite field with q elements. Show that F^2 has exactly $q+1$ lines $\operatorname{span}(\mathbf{v})$, $\mathbf{v} \neq \mathbf{0}$, and hence exactly $q+3$ subspaces.

Solution on page 1056

Exercise 1.4.34. STANDARD Let $\sigma : F^2 \to F^2$ swap the coordinates, $\sigma(x, y) = (y, x)$. Find all subspaces U of F^2 such that $\sigma(\mathbf{u}) \in U$ for every $\mathbf{u} \in U$. The answer depends on whether $1 + 1 = 0$ in F.

Solution on page 1057

Exercise 1.4.35. STANDARD Let E and O be the subspaces of even and odd functions in $\mathbb{R}^{\mathbb{R}}$ (Example 1.4.10).

(a) Show that $E \cap O = \{\mathbf{0}\}$ and $E + O = \mathbb{R}^{\mathbb{R}}$.

(b) Over $\mathbb{F}_2$, call $f : \mathbb{F}_2 \to \mathbb{F}_2$ even if $f(-t) = f(t)$ for all t, and odd if $f(-t) = -f(t)$ for all t. Show that every such f is both even and odd. Which steps of (a) fail over $\mathbb{F}_2$?

Solution on page 1057

Exercise 1.4.36. STANDARD Let $n \geq 2$. In $F^{n\times n}$, let S be the symmetric matrices, N the strictly upper triangular matrices ($a_{ij} = 0$ whenever $i \geq j$), and K the skew-symmetric matrices ($a_{ij} = -a_{ji}$ for all i, j).

(a) Show that N and K are subspaces, that $S \cap N = \{\mathbf{0}\}$, and that $S + N = F^{n\times n}$. This holds over every field.

(b) Show that $S + K = F^{n\times n}$ if and only if $1 + 1 \neq 0$ in F.

Solution on page 1058

Exercise 1.4.37. STANDARD Let U, W, and X be subspaces of V. Prove or disprove each statement.

(a) If $U + W = U + X$, then $W = X$.

(b) $U \cap (W + X) = (U \cap W) + (U \cap X)$.

(c) If $W \subseteq U$, then $U \cap (W + X) = W + (U \cap X)$.

Solution on page 1058

Exercise 1.4.38. STANDARD Let U be a proper subspace of V. Show that the only subspace of V that contains every vector outside U is V itself.

Solution on page 1059

Exercise 1.4.39. STANDARD

(a) Let U be a subspace of $F[x]$ that contains a polynomial of degree k for every $k \geq 0$. Show that $U = F[x]$.

(b) Find a proper subspace of $F[x]$ that contains polynomials of infinitely many different degrees.

Solution on page 1059

Exercise 1.4.40. HARD A function $f : \mathbb{R} \to \mathbb{R}$ has **period** $p > 0$ if $f(t + p) = f(t)$ for all $t \in \mathbb{R}$, and f is **periodic** if it has some period.

(a) Show that the functions with period 1 form a subspace of $\mathbb{R}^{\mathbb{R}}$.

(b) Is the set of all periodic functions a subspace of $\mathbb{R}^{\mathbb{R}}$?

Solution on page 1059

Exercise 1.4.41. HARD Let $n \geq 2$. Call a subspace U of F^n *symmetric* if permuting the coordinates of any vector of U gives a vector of U. Let $\mathbf{s} = (1, 1, ..., 1)$ and $Z = \{\mathbf{x} \in F^n \mid x_1 + \cdots + x_n = 0\}$.

(a) Show that the symmetric subspaces of F^n are exactly $\{\mathbf{0}\}$, $\text{span}(\mathbf{s})$, Z, and F^n.

(b) When is $\text{span}(\mathbf{s}) \subseteq Z$?

Solution on page 1060

Exercise 1.4.42. HARD

(a) Show that $\mathbb{F}_2^2$ is the union of three subspaces, none of which contains the other two.

(b) Suppose F has at least three elements, and let U_1, U_2, U_3 be subspaces of V whose union is a subspace. Show that one of the U_i contains the other two.

Solution on page 1061

Exercise 1.4.43. CHALLENGE BEYOND 21-242 Let V be a vector space over F, and let $U_1, ..., U_n$ be proper subspaces of V, where $n \geq 1$.

(a) Show that if F has at least n elements, then $U_1 \cup \cdots \cup U_n \neq V$.

(b) Deduce that over an infinite field, no vector space is a union of finitely many proper subspaces.

(c) Show that (a) is sharp: if F has q elements, then F^2 is a union of $q + 1$ proper subspaces.

Solution on page 1061

Exercise 1.4.44. ROUTINE

(a) Find the smallest subspace of $\mathbb{R}^3$ containing $(1, 1, 0)$ and $(1, -1, 0)$, and describe it by one equation.

(b) Find the smallest subspace of $\mathbb{R}[x]$ containing $1 + x^2$ and $1 - x^2$.

Solution on page 1062

1.5 Linear independence

A linear combination of a list represents one vector, but one vector can be represented by many linear combinations. Section 1.3 asked which vectors the linear combinations of a list represent, and the span answered it. This section asks in how many ways. In Example 1.3.5, the vector $(1, -1)$ has two different representations by the list $(0, 0), (1, -1), (-\pi, \pi)$, while every vector of F^2 has exactly one representation by $(1, 0), (0, 1)$. Lists of the second kind are called linearly independent. A linearly independent list that also spans V names every vector of V by a unique list of coefficients, and these coefficients are the coordinates of Section 1.6.

1.5.1 Unique representations

Throughout, V is a vector space over a field F.

Definition 1.5.1 (Linear independence). A list $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ in V is **linearly independent** if every vector of $\text{span}(\mathcal{L})$ is represented by exactly one linear combination of $\mathcal{L}$. Otherwise $\mathcal{L}$ is **linearly**

dependent. We also say that the vectors $\mathbf{v}_1, ..., \mathbf{v}_k$ are linearly independent (or dependent), and we often drop the word "linearly".

Every vector of $\operatorname{span}(\mathcal{L})$ is represented by at least one linear combination of $\mathcal{L}$, by Definition 1.3.10, so independence asks for at most one. In terms of coefficients, $\mathcal{L}$ is linearly independent when, for all scalars $a_1, ..., a_k$ and $b_1, ..., b_k$,

$$\sum_{i=1}^{k} a_i \mathbf{v}_i = \sum_{i=1}^{k} b_i \mathbf{v}_i \quad \text{implies} \quad a_1 = b_1, \ ..., \ a_k = b_k.$$

This is the claim of Exercise 1.3.29, which holds for some lists and fails for others. Order and repetitions are part of a list, and independence is a property of the list, not of its set of entries: we will see that a list with a repeated entry is never independent (Proposition 1.5.15).

Example 1.5.2 (The lists $\mathcal{L}_0$ and $\mathcal{L}_1$). In $\mathbb{R}^2$, let $\mathcal{L}_0 = (1,0), (0,1)$ and $\mathcal{L}_1 = (0,0), (1,-1), (-\pi, \pi)$.

$\mathcal{L}_0$ is linearly independent. The linear combination with coefficients a_1, a_2 represents $a_1(1,0) + a_2(0,1) = (a_1, a_2)$. So if the linear combinations with coefficients a_1, a_2 and b_1, b_2 both represent (c_1, c_2), then $(a_1, a_2) = (c_1, c_2) = (b_1, b_2)$, that is, $a_1 = c_1 = b_1$ and $a_2 = c_2 = b_2$. The two linear combinations were the same all along. The same computation shows that $\mathbf{e}_1, ..., \mathbf{e}_n$ is linearly independent in F^n, since the linear combination with coefficients $a_1, ..., a_n$ represents $(a_1, ..., a_n)$ (Example 1.3.7).

$\mathcal{L}_1$ is linearly dependent. By Example 1.3.15, $\operatorname{span}(\mathcal{L}_1)$ consists of the vectors $(c, -c)$ with $c \in \mathbb{R}$. Each of them has the two representations

$$0(0,0) + c(1,-1) + 0(-\pi, \pi) \quad \text{and} \quad \sqrt{87}(0,0) + 0(1,-1) + \left(-\frac{c}{\pi}\right)(-\pi, \pi),$$

which are different linear combinations, as their first coefficients differ. So no vector of $\operatorname{span}(\mathcal{L}_1)$ has a unique representation.

Intuition (Independence as the absence of redundancy). The two representations of $(c, -c)$ by $\mathcal{L}_1$ show where the redundancy lies. Any coefficient can be placed on $(0,0)$ at no cost, and since $(-\pi, \pi) = -\pi(1,-1)$, an amount of $(1,-1)$ can be traded for a multiple of $(-\pi, \pi)$. An independent list allows no such trade. From the vector that a linear combination represents we can recover every coefficient, so no entry can be made up for by the others. Theorem 1.5.5 and Lemma 1.5.10 turn these two readings, "the coefficients can be recovered" and "no entry is made up for by the others", into criteria we can check.

1.5.2 Testing at zero

Checking Definition 1.5.1 directly means checking every vector of the span, usually infinitely many. One vector suffices.

Intuition. Two representations of the same vector $\mathbf{w}$ differ by a representation of $\mathbf{0}$: subtracting coefficients gives a linear combination that represents $\mathbf{w} - \mathbf{w} = \mathbf{0}$. In the other direction, adding the coefficients of a representation of $\mathbf{0}$ to those of a representation of $\mathbf{w}$ gives another representation of $\mathbf{w}$ (Exercise 1.3.6). So every vector of the span has as many representations as $\mathbf{0}$ has, and $\mathbf{0}$ is the vector to test. It always has the representation with all coefficients 0; the question is whether it has any other.

Definition 1.5.3 (Linear relation). A **linear relation** of a list $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ is a linear combination of $\mathcal{L}$ that represents $\mathbf{0}$, that is, a list of scalars $a_1, ..., a_k$ with

$$a_1 \mathbf{v}_1 + \cdots + a_k \mathbf{v}_k = \mathbf{0}.$$

The **trivial relation** is the one with $a_1 = \cdots = a_k = 0$; it represents $\mathbf{0}$ by Lemma 1.3.9(c). A linear relation with at least one nonzero coefficient is **nontrivial**, and is also called a **dependence relation** of $\mathcal{L}$.

The empty list has one linear combination, the empty one, which represents $\mathbf{0}$ and has no nonzero coefficient. So its only linear relation is the trivial one.

The lecture proves the equivalence below by proving one direction in a contrapositive form. The move deserves a name.

Technique 1.5.4 (Contrapositive). An implication "P implies Q" is logically equivalent to its contrapositive, "not Q implies not P". Prove the contrapositive when "not Q" gives you more to work with than P does. The typical case is a conclusion Q asserting that something holds *for every* object, or that some object is *unique*. Then "not Q" hands you a specific object, a counterexample or a second candidate, and you can compute with it.

Reach for it when the hypothesis is hard to use directly and the conclusion is a "for all" or a uniqueness statement. The canonical example is (II) ⇒ (I) in Theorem 1.5.5. Statement (I) asserts uniqueness for every vector of the span. Its negation provides one vector with two different representations, and subtracting them shows that (II) fails.

Used in. Theorem 1.5.5, Corollary 1.5.13, Corollary 1.5.17, Problem 1.1, Problem 1.3, Corollary 2.5.11, Proposition 2.6.14, Proposition 3.4.15, Proposition 3.4.16, Corollary 4.1.13, Theorem 4.7.22, Theorem 5.4.7, Corollary 7.1.23, Exercise 1.5.41, Exercise A.1.24.

Theorem 1.5.5 (Independence is decided at zero). Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V. The following are equivalent.

(I) $\mathcal{L}$ is linearly independent.

(II) $\mathcal{L}$ has no nontrivial linear relation: if $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$, then $a_1 = \cdots = a_k = 0$.

Proof. ROUTINE

Uses. Definition 1.5.1 (Linear independence), Definition 1.5.3 (Linear relation), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.2.34 (Negatives and the scalar -1)

Techniques. Contrapositive (Technique 1.5.4)

Hint 1. (I) ⇒ (II) is a special case of the definition. Which vector of the span is in question, and which representation does it always have?

Hint 2. For (II) ⇒ (I), prove the contrapositive. If $\mathcal{L}$ is dependent, some $\mathbf{w} \in \operatorname{span}(\mathcal{L})$ has two different representations.

Hint 3. Subtract the two representations: compute $\mathbf{w} + (-1)\mathbf{w}$ with Lemma 1.3.9. Why is one of the resulting coefficients nonzero?

Sketch. (I) ⇒ (II): $\mathbf{0} \in \operatorname{span}(\mathcal{L})$, and the trivial relation represents it, so by uniqueness it is the only linear combination representing $\mathbf{0}$. (II) ⇒ (I), by contrapositive: if $\sum a_i\mathbf{v}_i$ and $\sum b_i\mathbf{v}_i$ are different representations of $\mathbf{w}$, then $\sum(a_i - b_i)\mathbf{v}_i = \mathbf{w} - \mathbf{w} = \mathbf{0}$, and $a_j \neq b_j$ for some j, so this relation is nontrivial.

(I) ⇒ (II). Suppose that $\mathcal{L}$ is linearly independent. The trivial relation represents $\mathbf{0}$, so $\mathbf{0} \in \operatorname{span}(\mathcal{L})$, and by (I) no other linear combination of $\mathcal{L}$ represents $\mathbf{0}$. That is, every linear relation of $\mathcal{L}$ is trivial.

(II) ⇒ (I). We prove the contrapositive: if $\mathcal{L}$ is linearly dependent, then $\mathcal{L}$ has a nontrivial linear relation. Suppose that $\mathcal{L}$ is linearly dependent. Then some $\mathbf{w} \in \operatorname{span}(\mathcal{L})$ is represented by two different linear combinations of $\mathcal{L}$, say with coefficients $a_1, \ldots, a_k$ and $b_1, \ldots, b_k$. By (A4) and Proposition 1.2.34, then Lemma 1.3.9(b) with $c = -1$, and Lemma 1.3.9(a),

$$\begin{aligned}\mathbf{0} = \mathbf{w} + (-1)\mathbf{w} &= \sum_{i=1}^{k} a_i\mathbf{v}_i + (-1)\sum_{i=1}^{k} b_i\mathbf{v}_i \\ &= \sum_{i=1}^{k} a_i\mathbf{v}_i + \sum_{i=1}^{k}(-b_i)\mathbf{v}_i = \sum_{i=1}^{k}(a_i - b_i)\mathbf{v}_i.\end{aligned}$$

The two linear combinations are different, so $a_j \neq b_j$ for some j, and then $a_j - b_j \neq 0$. So the scalars $a_1 - b_1, ..., a_k - b_k$ form a nontrivial linear relation of $\mathcal{L}$, and (II) fails. □

In practice, to show that $\mathcal{L}$ is independent, suppose that $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ and deduce that every a_i is 0. To show that $\mathcal{L}$ is dependent, exhibit one nontrivial relation. A relation is a certificate: anyone can check it by computing a single linear combination, without knowing how it was found.

A single relation also produces many representations. If $c_1, ..., c_k$ is a dependence relation and $b_1, ..., b_k$ represents $\mathbf{w}$, then for every $t \in F$ the coefficients $b_1 + tc_1, ..., b_k + tc_k$ represent $\mathbf{w} + t\mathbf{0} = \mathbf{w}$, by Lemma 1.3.9. Different values of t give different linear combinations, because $c_j \neq 0$ for some j. So over an infinite field, a dependent list represents each vector of its span in infinitely many ways, and over a finite field with q elements in at least q ways.

Example 1.5.6 (A list whose independence depends on the field). Consider $\mathcal{L} = (1, 2), (2, 1)$ in F^2, where $2 = 1 + 1$ in F. Suppose that $a(1, 2) + b(2, 1) = \mathbf{0}$, that is,

$$a + 2b = 0 \quad \text{and} \quad 2a + b = 0.$$

Subtracting twice the first equation from the second gives $b - 4b = 0$, that is, $-3b = 0$, where $3 = 1 + 1 + 1$.

If $3 \neq 0$ in F, as in $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, $\mathbb{F}_2$, and $\mathbb{F}_5$, then $-3 \neq 0$ and $b = 0$ (Proposition 1.1.17), and then $a = -2b = 0$. So the only linear relation is trivial, and $\mathcal{L}$ is linearly independent by Theorem 1.5.5. (Over $\mathbb{F}_2$ the list is just $(1, 0), (0, 1)$.)

If $3 = 0$, as in $\mathbb{F}_3$, both equations hold for $a = b = 1$, since $1 + 2 = 3 = 0$. So $(1, 2) + (2, 1) = \mathbf{0}$ in $\mathbb{F}_3^2$ is a dependence relation, and $\mathcal{L}$ is linearly dependent. In fact $(2, 1) = 2(1, 2)$ in $\mathbb{F}_3^2$, since $2 \cdot 2 = 4 = 1$.

Example 1.5.7 (Monomials). In $F[x]$, the list $1, x, x^2, ..., x^n$ is linearly independent. By Notation 1.2.15, the linear combination $a_0 + a_1x + \cdots + a_nx^n$ represents the polynomial with coefficients $(a_0, a_1, ..., a_n, 0, 0, ...)$, and by Definition 1.2.13 this is the zero polynomial only if $a_0 = a_1 = \cdots = a_n = 0$. So the only linear relation is trivial. This holds over every field, $\mathbb{F}_2$ included, because polynomials are compared coefficient by coefficient (Aside (Polynomials versus polynomial functions)).

> **Exercise 1.5.8.** ROUTINE Let $\mathbf{v}, \mathbf{w} \in V$ be linearly independent. Show that $\mathbf{v} + \mathbf{w}, \mathbf{v} - \mathbf{w}$ is linearly independent if and only if $1 + 1 \neq 0$ in F.

Solution on page 1062

1.5.3 The linear dependence lemma

Theorem 1.5.5 detects dependence through a relation. The next result reads off from a relation which entry is redundant.

> *Intuition.* A dependence relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ can be solved for any entry whose coefficient is nonzero, and this writes that entry as a linear combination of the others. To control which entries appear on the other side, solve for the *last* entry with a nonzero coefficient. All later entries have coefficient 0, so only earlier entries remain.
>
> Here is a picture. Build $\text{span}(\mathcal{L})$ by adding the entries one at a time: first $\text{span}(\mathbf{v}_1)$, then $\text{span}(\mathbf{v}_1, \mathbf{v}_2)$, and so on. At each step the span either grows or stays the same, and it stays the same exactly when the new entry already lies in the span of the earlier ones (Corollary 1.3.20(c)). The lemma says that for a dependent list, some step does not make the span grow.

The proof chooses an index that is as large as possible. This is the first of many proofs built on an extreme choice.

Technique 1.5.9 (Extremal choice and minimal counterexamples). When a proof needs an object with special properties, choose one that is extreme in some respect: the largest index with a nonzero coefficient, a polynomial of largest degree, a dependence relation with the fewest nonzero coefficients, a smallest counterexample. Extremality is a hypothesis you get for free. "The largest j with $a_j \neq 0$" also says that every later coefficient is 0. "A relation with the fewest nonzero coefficients" also says that every relation with fewer nonzero coefficients is trivial.

It combines with contradiction. To show that no object has some property, suppose that some do, take an extreme one, and use it to build another object with the property that is more extreme still. This contradicts the choice.

Reach for it when a relation or a sum has many terms and the argument would be easy if most of them vanished. The canonical example is the linear dependence lemma (Lemma 1.5.10), which solves for the largest index with a nonzero coefficient. The same choice, of a largest degree, proves Proposition 1.5.24, and the contradiction form appears in Exercise 1.5.44.

Used in. Lemma 1.5.10, Proposition 1.5.24, Example 1.5.27, Exercise 1.5.44, Exercise 1.5.45, Theorem 1.6.10, Exercise 1.7.8, Exercise 1.7.9, Problem 1.4, Problem 1.15, Exercise 3.6.13, Problem 3.18, Lemma 4.1.2, Theorem 4.1.10, Proposition 4.1.21, Exercise 4.1.56, Theorem 4.4.7, Exercise 4.6.55, Theorem 4.7.34, Problem 6.13, Theorem 7.1.32, Theorem 7.1.45, Theorem 7.2.21, Proposition 7.2.35, Proposition 7.2.37, Exercise 7.2.51, Theorem 7.6.2, Theorem 7.6.7, Theorem 7.6.31, Problem 7.1, Theorem 8.2.5, Exercise 8.2.44, Exercise 8.2.46, Notation 8.3.10, Exercise A.1.30, Theorem A.2.1, Proposition A.2.4, Exercise A.2.10, Theorem A.4.4, Theorem A.4.7, Exercise A.4.8, Exercise 4.2.51, Exercise 5.5.39, Exercise 6.4.61, Exercise 7.4.53, Exercise 7.6.49, Exercise 7.6.56.

Lemma 1.5.10 (Linear dependence lemma). Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a linearly dependent list in V. Then there is an index $j \in \{1, \ldots, k\}$ with

$$\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}).$$

Moreover, for every such j, deleting $\mathbf{v}_j$ from $\mathcal{L}$ does not change the span:

$$\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}, \mathbf{v}_{j+1}, \ldots, \mathbf{v}_k) = \operatorname{span}(\mathcal{L}).$$

For $j = 1$ the condition reads $\mathbf{v}_1 \in \operatorname{span}(()) = \{\mathbf{0}\}$, that is, $\mathbf{v}_1 = \mathbf{0}$.

Proof. STANDARD

Uses. Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.2.32 (The scalar zero), Proposition 1.2.28 (Uniqueness of additive inverses), Proposition 1.2.34 (Negatives and the scalar -1), Corollary 1.3.20 (Operations that preserve the span)

Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)

Hint 1. By Theorem 1.5.5, $\mathcal{L}$ has a nontrivial relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. Solve it for one entry. Which choice of entry leaves only earlier entries on the other side?

Hint 2. Let j be the largest index with $a_j \neq 0$. The terms after j vanish; move the others to the other side and divide by a_j.

Hint 3. For the second statement, $\mathbf{v}_j$ lies in the span of the list with $\mathbf{v}_j$ deleted. Use Corollary 1.3.20(a), (b), and (c).

Sketch. Take a nontrivial relation and the largest j with $a_j \neq 0$. Then $a_1\mathbf{v}_1 + \cdots + a_j\mathbf{v}_j = \mathbf{0}$, so $\mathbf{v}_j = \sum_{i<j}(-a_i/a_j)\mathbf{v}_i$. If $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$ and $\mathcal{L}'$ is $\mathcal{L}$ without $\mathbf{v}_j$, then $\mathbf{v}_j \in \operatorname{span}(\mathcal{L}')$, so appending $\mathbf{v}_j$ to $\mathcal{L}'$ does not change the span (Corollary 1.3.20(c)); and $\mathcal{L}', \mathbf{v}_j$ is a reordering of $\mathcal{L}$.

Since $\mathcal{L}$ is dependent, (II) of Theorem 1.5.5 fails: there are scalars $a_1, \ldots, a_k$, not all 0, with $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. Let j be the largest index with $a_j \neq 0$. For $i > j$ we have $a_i = 0$, so $a_i\mathbf{v}_i = \mathbf{0}$ by Proposition 1.2.32, and dropping these terms gives

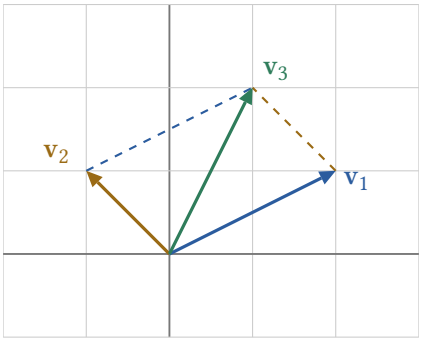
$$(a_1\mathbf{v}_1 + \cdots + a_{j-1}\mathbf{v}_{j-1}) + a_j\mathbf{v}_j = \mathbf{0}.$$

By Proposition 1.2.28, $a_j\mathbf{v}_j$ is the additive inverse of the sum in parentheses. By Proposition 1.2.34 and Lemma 1.3.9(b), that inverse is (-1) times the sum, so

$$a_j\mathbf{v}_j = (-a_1)\mathbf{v}_1 + \cdots + \big(-a_{j-1}\big)\mathbf{v}_{j-1}.$$

Since $a_j \neq 0$, we may multiply both sides by a_j^{-1}. By (A6) and (A5) on the left, and Lemma 1.3.9(b) on the right,

$$\mathbf{v}_j = \sum_{i=1}^{j-1}\left(-\frac{a_i}{a_j}\right)\mathbf{v}_i \in \operatorname{span}\big(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}\big).$$



(If $j = 1$, the sum is empty and the equation says $\mathbf{v}_1 = \mathbf{0}$.)

Now let j be any index with $\mathbf{v}_j \in \operatorname{span}\big(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}\big)$, and let $\mathcal{L}'$ be the list obtained from $\mathcal{L}$ by deleting $\mathbf{v}_j$. The list $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$ is a sublist of $\mathcal{L}'$, so $\mathbf{v}_j \in \operatorname{span}(\mathcal{L}')$ by Corollary 1.3.20(b). By Corollary 1.3.20(c), $\operatorname{span}\big(\mathcal{L}', \mathbf{v}_j\big) = \operatorname{span}(\mathcal{L}')$. The list $\mathcal{L}', \mathbf{v}_j$ is a reordering of $\mathcal{L}$, so its span is $\operatorname{span}(\mathcal{L})$ by Corollary 1.3.20(a). Hence $\operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{L})$. □

The proof did not search for j. It read j off a dependence relation: any relation gives an index, the largest one with a nonzero coefficient. Different relations can give different indices, and the lemma guarantees only that *some* j works, not that a particular one does.

Example 1.5.11 (Which entries are redundant). Take $\mathcal{L}_1 = (0,0), (1,-1), (-\pi, \pi)$ in $\mathbb{R}^2$ again, and write $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ for its entries. The relation $1\mathbf{v}_1 + 0\mathbf{v}_2 + 0\mathbf{v}_3 = \mathbf{0}$ has largest nonzero index 1, and indeed $\mathbf{v}_1 = \mathbf{0} \in \operatorname{span}(())$. The relation $0\mathbf{v}_1 + \pi\mathbf{v}_2 + 1\mathbf{v}_3 = \mathbf{0}$ gives $j = 3$, and indeed $\mathbf{v}_3 = -\pi\mathbf{v}_2$. No relation gives $j = 2$, because $(1,-1) \notin \operatorname{span}((0,0)) = \{\mathbf{0}\}$. Deleting $\mathbf{v}_1$ and then, in the remaining list $(1,-1), (-\pi, \pi)$, deleting the last entry, the lemma recovers $\operatorname{span}\big(\mathcal{L}_1\big) = \operatorname{span}((1,-1))$, the computation of Example 1.3.21.

The last entry of a dependent list need not be redundant. In $\mathbb{R}^2$, the list $(1,0), (2,0), (0,1)$ is dependent, since $2(1,0) + (-1)(2,0) + 0(0,1) = \mathbf{0}$, but $(0,1)$ does not lie in $\operatorname{span}((1,0), (2,0))$, which is the first axis. Here $j = 2$ is the only index that works.

The list $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3 = (2,1), (-1,1), (1,2)$ is dependent: $\mathbf{v}_1 + \mathbf{v}_2 - \mathbf{v}_3 = \mathbf{0}$. So $\mathbf{v}_3 \in \operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$, and by Lemma 1.5.10 deleting $\mathbf{v}_3$ leaves the span unchanged. In the interactive version, the explorer reports a dependence relation and the representations of $\mathbf{w} = (0,3)$. Delete one vector and drag the other two onto a common line to see when two vectors are dependent (Proposition 1.5.15). With three vectors in $\mathbb{R}^2$, no position makes the list independent; Section 4.1 explains why. (Interactive in the web version.)

Exercise 1.5.12. ROUTINE In $\mathbb{R}^3$, let $\mathcal{L}$ be the list

$$\mathbf{v}_1, \ldots, \mathbf{v}_5 = (1,1,0), (2,2,0), (0,1,1), (1,2,1), (0,0,1).$$

Find every j with $\mathbf{v}_j \in \operatorname{span}\big(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}\big)$, and for each such j, a dependence relation whose largest index with a nonzero coefficient is j.

Solution on page 1063

The lemma has a converse. If some entry lies in the span of the earlier ones, solving for it backwards produces a relation in which that entry has coefficient -1. So the condition of the lemma characterizes dependence.

Corollary 1.5.13 (Independence, one entry at a time). A list $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ in V is linearly independent if and only if

$$\mathbf{v}_j \notin \operatorname{span}(\mathbf{v}_1, ..., \mathbf{v}_{j-1}) \quad \text{for every } j \in \{1, ..., k\}.$$

Proof. ROUTINE

Uses. Lemma 1.5.10 (Linear dependence lemma), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.34 (Negatives and the scalar -1), Proposition 1.2.32 (The scalar zero)
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. One direction is the contrapositive of Lemma 1.5.10.
Hint 2. For the other, suppose $\mathbf{v}_j = b_1\mathbf{v}_1 + \cdots + b_{j-1}\mathbf{v}_{j-1}$. Write down a linear relation of $\mathcal{L}$ in which $\mathbf{v}_j$ has coefficient -1.
Sketch. ($\Leftarrow$) If $\mathcal{L}$ were dependent, Lemma 1.5.10 would give a j violating the condition. ($\Rightarrow$) If $\mathbf{v}_j = \sum_{i<j} b_i\mathbf{v}_i$, then the coefficients $b_1, ..., b_{j-1}, -1, 0, ..., 0$ form a nontrivial relation, so $\mathcal{L}$ is dependent.

($\Leftarrow$) This is the contrapositive of Lemma 1.5.10: if $\mathcal{L}$ is dependent, then $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, ..., \mathbf{v}_{j-1})$ for some j.

($\Rightarrow$) We prove the contrapositive. Suppose that $\mathbf{v}_j = b_1\mathbf{v}_1 + \cdots + b_{j-1}\mathbf{v}_{j-1}$ for some j and some scalars b_i. Consider the linear combination of $\mathcal{L}$ with coefficients $b_1, ..., b_{j-1}$ on the first $j-1$ entries, -1 on $\mathbf{v}_j$, and 0 on the entries after $\mathbf{v}_j$. By Proposition 1.2.34, Proposition 1.2.32, and (A4), it represents

$$\big(b_1\mathbf{v}_1 + \cdots + b_{j-1}\mathbf{v}_{j-1}\big) + (-1)\mathbf{v}_j = \mathbf{v}_j + \big(-\mathbf{v}_j\big) = \mathbf{0}.$$

Its coefficient on $\mathbf{v}_j$ is $-1 \neq 0$, so it is a nontrivial relation, and $\mathcal{L}$ is dependent by Theorem 1.5.5. □

Condition (II) of Theorem 1.5.5 does not refer to the order of the entries, so a reordering of an independent list is independent (Proposition 1.5.18(a)). Applying Corollary 1.5.13 to a reordering in which a chosen entry comes last gives the symmetric form: $\mathcal{L}$ is linearly dependent if and only if some entry lies in the span of the other entries. In that form, the entry is the one that the intuition at the start of the section called "made up for by the others".

The corollary also says what happens when an independent list is lengthened by one vector.

Proposition 1.5.14 (Appending a vector). Let $\mathcal{L}$ be a linearly independent list in V, and let $\mathbf{w} \in V$. Then $\mathcal{L}, \mathbf{w}$ is linearly independent if and only if $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$.

Proof. ROUTINE

Uses. Corollary 1.5.13 (Independence, one entry at a time), Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations)
Hint 1. For ($\Rightarrow$), the last entry of $\mathcal{L}, \mathbf{w}$ is $\mathbf{w}$. Apply Corollary 1.5.13.
Hint 2. For ($\Leftarrow$), take a relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k + b\mathbf{w} = \mathbf{0}$, and split into the cases $b \neq 0$ and $b = 0$.
Sketch. If $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, the last entry of $\mathcal{L}, \mathbf{w}$ lies in the span of the earlier ones. Conversely, in a relation $\sum a_i\mathbf{v}_i + b\mathbf{w} = \mathbf{0}$, a nonzero b would give $\mathbf{w} = \sum(-a_i/b)\mathbf{v}_i \in \operatorname{span}(\mathcal{L})$; so $b = 0$, and then all $a_i = 0$ by independence of $\mathcal{L}$.

Write $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$.

($\Rightarrow$) If $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, then the last entry of $\mathcal{L}, \mathbf{w}$ lies in the span of the entries before it, so $\mathcal{L}, \mathbf{w}$ is dependent by Corollary 1.5.13.

($\Leftarrow$) Suppose that $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, and let $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k + b\mathbf{w} = \mathbf{0}$. If $b \neq 0$, then, as in the proof of Lemma 1.5.10,

$$\mathbf{w} = \sum_{i=1}^{k} \Big(-\frac{a_i}{b}\Big)\mathbf{v}_i \in \operatorname{span}(\mathcal{L}),$$

a contradiction. So $b = 0$, and $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. Since $\mathcal{L}$ is independent, all $a_i = 0$ by Theorem 1.5.5. So the relation is trivial, and $\mathcal{L}, \mathbf{w}$ is independent. □

So an independent list that does not span V can always be lengthened, keeping it independent: append any vector outside its span. Repeating this is how independent lists are extended to bases in Section 4.1 (Theorem 4.1.16). Whether the process stops is a real question. In $F[x]$ it never does: $x^{n+1} \notin \operatorname{span}(1, x, \ldots, x^n)$, since every polynomial in that span has degree at most n (Example 1.3.11), so appending the next power of x never stops.

1.5.4 First consequences

Proposition 1.5.15 (Short lists, zeros, and repeats). Let V be a vector space over F.

(a) The empty list () is linearly independent.

(b) A list $\mathbf{v}$ of length one is linearly independent if and only if $\mathbf{v} \neq \mathbf{0}$.

(c) A list containing $\mathbf{0}$ is linearly dependent. A list with a repeated entry, $\mathbf{v}_i = \mathbf{v}_j$ for some $i \neq j$, is linearly dependent.

(d) A list $\mathbf{v}, \mathbf{w}$ of length two is linearly dependent if and only if one of $\mathbf{v}$, $\mathbf{w}$ is a scalar multiple of the other.

Proof. ROUTINE

Uses. Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.35 (Zero products), Proposition 1.2.32 (The scalar zero), Proposition 1.2.33 (The zero vector), Proposition 1.2.34 (Negatives and the scalar -1)
Hint 1. Use (II) of Theorem 1.5.5 throughout. For dependence, write down a nontrivial relation; for independence, start from an arbitrary relation.
Hint 2. For (b) and the forward direction of (d), the key fact is that $a\mathbf{v} = \mathbf{0}$ forces $a = 0$ or $\mathbf{v} = \mathbf{0}$ (Proposition 1.2.35).
Hint 3. In (d), given $a\mathbf{v} + b\mathbf{w} = \mathbf{0}$ with $(a, b) \neq (0, 0)$, split into the cases $a \neq 0$ and $a = 0$.
Sketch. (a) The only relation of () is trivial. (b) $1\mathbf{0} = \mathbf{0}$ is nontrivial; if $\mathbf{v} \neq \mathbf{0}$, then $a\mathbf{v} = \mathbf{0}$ forces $a = 0$. (c) $1\mathbf{0} = \mathbf{0}$ and $\mathbf{v}_i - \mathbf{v}_j = \mathbf{0}$, padded with zero coefficients. (d) $\mathbf{v} = c\mathbf{w}$ gives the relation $\mathbf{v} - c\mathbf{w} = \mathbf{0}$; conversely, from $a\mathbf{v} + b\mathbf{w} = \mathbf{0}$ with $a \neq 0$ we get $\mathbf{v} = (-b/a)\mathbf{w}$, and with $a = 0$ we get $b\mathbf{w} = \mathbf{0}$, $b \neq 0$, so $\mathbf{w} = \mathbf{0} = 0\mathbf{v}$.

We use (II) of Theorem 1.5.5.

(a) The only linear relation of () is the empty one, which is trivial.

(b) If $\mathbf{v} = \mathbf{0}$, then $1\mathbf{v} = \mathbf{0}$ by Proposition 1.2.33, a nontrivial relation. If $\mathbf{v} \neq \mathbf{0}$ and $a\mathbf{v} = \mathbf{0}$, then $a = 0$ by Proposition 1.2.35, so the only relation is trivial.

(c) If $\mathbf{v}_j = \mathbf{0}$, the linear combination with coefficient 1 on $\mathbf{v}_j$ and 0 elsewhere represents $1\mathbf{0} = \mathbf{0}$, by Proposition 1.2.33 and Proposition 1.2.32; it is a nontrivial relation. If $\mathbf{v}_i = \mathbf{v}_j$ with $i \neq j$, the linear combination with coefficient 1 on $\mathbf{v}_i$, -1 on $\mathbf{v}_j$, and 0 elsewhere represents $\mathbf{v}_i + (-\mathbf{v}_i) = \mathbf{0}$, by Proposition 1.2.34; it is nontrivial as well.

(d) If $\mathbf{v} = c\mathbf{w}$, then $1\mathbf{v} + (-c)\mathbf{w} = c\mathbf{w} + (-c\mathbf{w}) = \mathbf{0}$ is a nontrivial relation; similarly if $\mathbf{w} = c\mathbf{v}$. Conversely, suppose that $a\mathbf{v} + b\mathbf{w} = \mathbf{0}$ with a and b not both 0. If $a \neq 0$, then $\mathbf{v} = (-b/a)\mathbf{w}$, by the argument in the proof of Lemma 1.5.10. If $a = 0$, then $b \neq 0$ and $b\mathbf{w} = \mathbf{0}$, so $\mathbf{w} = \mathbf{0} = 0\mathbf{v}$ by Proposition 1.2.35 and Proposition 1.2.32. Either way, one vector is a multiple of the other. □

In (d), "one of them is a multiple of the other" cannot be strengthened to "each is a multiple of the other". If $\mathbf{v} \neq \mathbf{0}$, the list $\mathbf{v}, \mathbf{0}$ is dependent, and $\mathbf{0} = 0\mathbf{v}$, but $\mathbf{v}$ is not a multiple of $\mathbf{0}$. In $\mathbb{R}^2$, (d) says that two vectors are dependent exactly when they lie on a common line through the origin. Part (c) shows once more that independence belongs to lists: the list $\mathbf{v}, \mathbf{v}$ is dependent, although its set of entries is $\{\mathbf{v}\}$.

Exercise 1.5.16. ROUTINE Find the error in the following argument.

Claim. Let $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3 \in V$, and suppose that none of them is a scalar multiple of another. Then $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ is linearly independent.

Proof. Suppose that $a_1\mathbf{v}_1 + a_2\mathbf{v}_2 + a_3\mathbf{v}_3 = \mathbf{0}$ and that some $a_i \neq 0$, say $a_1 \neq 0$. Then $\mathbf{v}_1 = (-a_2/a_1)\mathbf{v}_2 + (-a_3/a_1)\mathbf{v}_3$, so $\mathbf{v}_1$ is a scalar multiple of $\mathbf{v}_2$ or of $\mathbf{v}_3$, a contradiction. So all $a_i = 0$.

Solution on page 1063

Corollary 1.5.17 (Sublists). Every sublist of a linearly independent list is linearly independent. Equivalently, if some sublist of a list $\mathcal{L}$ is linearly dependent, then $\mathcal{L}$ is linearly dependent.

Proof. ROUTINE

Uses. Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.32 (The scalar zero), Notation 1.3.3
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. Use (II) of Theorem 1.5.5. A relation of the sublist uses only some of the entries of $\mathcal{L}$.
Hint 2. Extend the coefficients of a relation of the sublist by 0 on the entries of $\mathcal{L}$ that were deleted.
Sketch. A relation $\sum_r c_r\mathbf{v}_{i_r} = \mathbf{0}$ of the sublist, padded with zero coefficients on the deleted entries, is a relation of $\mathcal{L}$, so all its coefficients are 0. The second statement is the contrapositive of the first.

Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be linearly independent, and let $\mathcal{L}' = \mathbf{v}_{i_1}, ..., \mathbf{v}_{i_m}$ be a sublist, with $i_1 < \cdots < i_m$. Suppose that $c_1\mathbf{v}_{i_1} + \cdots + c_m\mathbf{v}_{i_m} = \mathbf{0}$. Define $a_i = c_r$ if $i = i_r$, and $a_i = 0$ if i is not one of $i_1, ..., i_m$. In $\sum_{i=1}^{k} a_i\mathbf{v}_i$, the terms with $i = i_r$ are $c_r\mathbf{v}_{i_r}$, in the same order as in the relation, and the other terms are $0\mathbf{v}_i = \mathbf{0}$ by Proposition 1.2.32. So

$$\sum_{i=1}^{k} a_i\mathbf{v}_i = \sum_{r=1}^{m} c_r\mathbf{v}_{i_r} = \mathbf{0}.$$

Since $\mathcal{L}$ is independent, every $a_i = 0$ by Theorem 1.5.5; in particular $c_r = a_{i_r} = 0$ for every r. So $\mathcal{L}'$ has only the trivial relation, and it is independent.

The second statement is the contrapositive of the first. □

The corollary goes in one direction only. A dependent list can have independent sublists, such as $(1, 0), (0, 1)$ inside the dependent list $(1, 0), (0, 1), (1, 1)$. The corollary also gives a second proof of Proposition 1.5.15(c): a list containing $\mathbf{0}$ has the dependent sublist $\mathbf{0}$, and a list with $\mathbf{v}_i = \mathbf{v}_j$ for $i < j$ has the dependent sublist $\mathbf{v}_i, \mathbf{v}_j$, by Proposition 1.5.15(b) and (d).

The span of a list is unchanged by the moves of Corollary 1.3.20(a) and (d). These moves preserve independence too, and they are the moves of row reduction (Section 3.3).

Proposition 1.5.18 (Operations that preserve independence). Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in V, and let $\mathcal{L}'$ be obtained from $\mathcal{L}$ by one of the following operations:

(a) reordering the entries;

(b) replacing $\mathbf{v}_j$ by $c\mathbf{v}_j$, where $c \neq 0$;

(c) replacing $\mathbf{v}_j$ by $\mathbf{v}_j + a\mathbf{v}_i$, where $i \neq j$ and $a \in F$.

Then $\text{span}(\mathcal{L}') = \text{span}(\mathcal{L})$, and $\mathcal{L}'$ is linearly independent if and only if $\mathcal{L}$ is.

Proof. ROUTINE

Uses. Corollary 1.3.20 (Operations that preserve the span), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.1.17 (No zero divisors), Lemma 1.3.9 (Arithmetic of linear combinations)
Hint 1. The spans are handled by Corollary 1.3.20. For independence, it suffices to show that if $\mathcal{L}$ is independent then so is $\mathcal{L}'$: each operation can be undone by an operation of the same kind.
Hint 2. Take a relation of $\mathcal{L}'$, expand the modified entry, and collect coefficients to get a relation of $\mathcal{L}$. Then read off what independence of $\mathcal{L}$ says.

Sketch. Spans: Corollary 1.3.20(a) and (d). Each operation is undone by one of the same kind: reorder back, scale by c^{-1}, add $-a\mathbf{v}_i$. So it suffices to show that $\mathcal{L}$ independent implies $\mathcal{L}'$ independent. A relation of $\mathcal{L}'$ becomes a relation of $\mathcal{L}$ with coefficient $b_j c$ on $\mathbf{v}_j$ in (b), and with coefficients $b_i + ab_j$ on $\mathbf{v}_i$ and b_j on $\mathbf{v}_j$ in (c). Independence of $\mathcal{L}$ makes these 0, which forces every $b_l = 0$.

The spans agree by Corollary 1.3.20(a) and (d). Each operation can be undone by an operation of the same kind: a reordering by the reverse reordering, the scaling by c by the scaling by c^{-1}, and the replacement of $\mathbf{v}_j$ by $\mathbf{v}_j + a\mathbf{v}_i$ by the replacement of the new j-th entry by itself plus $(-a)\mathbf{v}_i$, which is allowed since $\mathbf{v}_i$ is still an entry of $\mathcal{L}'$ (as $i \neq j$). So it suffices to show that if $\mathcal{L}$ is independent, then so is $\mathcal{L}'$. Suppose that $\mathcal{L}$ is independent, and take a linear relation of $\mathcal{L}'$. We use (II) of Theorem 1.5.5.

(a) The coefficients of the relation, attached to the entries of $\mathcal{L}$ in their original positions, give a linear combination of $\mathcal{L}$ with the same terms in a different order. By (A1) and (A2) it also represents $\mathbf{0}$, so all its coefficients are 0.

(b) Let the relation be $\sum_{l \neq j} b_l \mathbf{v}_l + b_j(c\mathbf{v}_j) = \mathbf{0}$. By (A6), $b_j(c\mathbf{v}_j) = (b_j c)\mathbf{v}_j$, so this is the linear combination of $\mathcal{L}$ with coefficient $b_j c$ on $\mathbf{v}_j$ and b_l on $\mathbf{v}_l$ for $l \neq j$. By independence of $\mathcal{L}$, $b_l = 0$ for $l \neq j$ and $b_j c = 0$. Since $c \neq 0$, $b_j = 0$ by Proposition 1.1.17.

(c) Let the relation be $\sum_{l \neq j} b_l \mathbf{v}_l + b_j(\mathbf{v}_j + a\mathbf{v}_i) = \mathbf{0}$. By (A7), (A6), and Lemma 1.3.9, the left side is the linear combination of $\mathcal{L}$ with coefficient $b_i + b_j a$ on $\mathbf{v}_i$, b_j on $\mathbf{v}_j$, and b_l on $\mathbf{v}_l$ for $l \neq i, j$. By independence of $\mathcal{L}$, all of these are 0. So $b_j = 0$, then $b_i = b_i + b_j a = 0$, and $b_l = 0$ for the remaining l. □

Both hypotheses are needed, as they were for the span: replacing $\mathbf{v}_j$ by $0\mathbf{v}_j$, or by $\mathbf{v}_j + (-1)\mathbf{v}_j$, puts $\mathbf{0}$ into the list.

1.5.5 Changing the field

A linear relation is a statement about scalars, so whether a list is independent depends on which scalars are allowed. In Example 1.5.6 the same coordinates gave an independent list in $\mathbb{R}^2$ and a dependent one in $\mathbb{F}_3^2$, but these are different vector spaces. More striking is a single set of vectors, viewed over two fields.

Example 1.5.19 (The same vectors over two fields).

(a) $\mathbb{C}$ is a vector space over $\mathbb{C}$ and, by restricting scalars, over $\mathbb{R}$ (Example 1.2.20). Over $\mathbb{C}$, the list $1, i$ is dependent, since $i \cdot 1 + (-1) \cdot i = 0$. Over $\mathbb{R}$ it is independent: if $a \cdot 1 + b \cdot i = 0$ with $a, b \in \mathbb{R}$, then $a + bi = 0$, so $a = b = 0$ by Definition 1.1.29.

(b) Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$. The list $1, \sqrt{2}$ is independent over $\mathbb{Q}$: if $a + b\sqrt{2} = 0$ with $a, b \in \mathbb{Q}$ and $b \neq 0$, then $\sqrt{2} = -a/b$ would be rational; so $b = 0$, and then $a = 0$. Over $\mathbb{R}$ the same list is dependent, since $\sqrt{2} \cdot 1 + (-1)\sqrt{2} = 0$.

(c) In $\mathbb{C}^2$, the list $(1, i), (i, -1)$ is dependent over $\mathbb{C}$, since $(i, -1) = i(1, i)$. Over $\mathbb{R}$ it is independent: for $a, b \in \mathbb{R}$,

$$a(1, i) + b(i, -1) = (a + bi, -b + ai),$$

and this is $\mathbf{0}$ only if $a + bi = 0$, that is, $a = b = 0$.

In each case the list was independent over the smaller field and dependent over the larger one. The opposite never happens.

Proposition 1.5.20 (Fewer scalars, fewer relations). Let K be a subfield of F, and regard V as a vector space over K as well (Proposition 1.2.19). If a list in V is linearly independent over F, then it is linearly independent over K.

Proof. ROUTINE

Uses. Proposition 1.2.19 (Restriction of scalars), Theorem 1.5.5 (Independence is decided at zero)

Hint 1. Compare the linear relations over K with those over F.
Hint 2. Scalar multiplication over K is that of F, restricted to K.
Sketch. A linear relation over K has coefficients in $K \subseteq F$ and is computed with the same operations, so it is a linear relation over F, hence trivial.

Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be independent over F, and let $a_1, ..., a_k \in K$ with $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. The scalar multiplication of the K-vector space V is that of F restricted to K, and the addition is the same, so $a_1, ..., a_k$ is also a linear relation of $\mathcal{L}$ over F. By Theorem 1.5.5, all $a_i = 0$. So $\mathcal{L}$ is independent over K. □

The converse fails, as Example 1.5.19 shows. In each of those examples, though, the vectors themselves involved the larger field: i, $\sqrt{2}$, and $(i, -1)$. For vectors whose coordinates lie in the smaller field, the extra scalars bring no new relations.

Intuition. Let $\mathcal{L}$ be a list of real vectors. Viewed in $\mathbb{C}^m$, it has more candidate relations, with complex coefficients. But a complex relation splits into its real and imaginary parts, and because the entries of $\mathcal{L}$ are real, each part is a real relation by itself.

Proposition 1.5.21 (Real lists in $\mathbb{C}^m$). Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in $\mathbb{R}^m$. Then $\mathcal{L}$ is linearly independent in the real vector space $\mathbb{R}^m$ if and only if it is linearly independent in the complex vector space $\mathbb{C}^m$.

Proof. STANDARD

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.1.29 (Complex numbers), Definition 1.2.4 (The space F^n)
Hint 1. One direction holds because every real relation is a complex relation.
Hint 2. For the other, write each complex coefficient as $c_j = a_j + b_j i$ with $a_j, b_j \in \mathbb{R}$, and look at one coordinate of the relation at a time.
Hint 3. In the t-th coordinate, $\sum_j c_j v_{jt} = \sum_j a_j v_{jt} + \left(\sum_j b_j v_{jt}\right)i$ with both sums real. When is a complex number 0?
Sketch. (⇐) A real relation is a complex one. (⇒) If $\sum c_j\mathbf{v}_j = \mathbf{0}$ with $c_j = a_j + b_j i$, then in each coordinate t the real and imaginary parts give $\sum a_j v_{jt} = 0$ and $\sum b_j v_{jt} = 0$, since the v_{jt} are real. So $\sum a_j\mathbf{v}_j = \sum b_j\mathbf{v}_j = \mathbf{0}$ in $\mathbb{R}^m$, and independence over $\mathbb{R}$ gives $a_j = b_j = 0$.

The operations of $\mathbb{C}^m$, applied to real vectors and real scalars, agree with those of $\mathbb{R}^m$, since $\mathbb{R}$ is a subfield of $\mathbb{C}$. Write $v_{jt} \in \mathbb{R}$ for the t-th coordinate of $\mathbf{v}_j$.

(⇐) Suppose that $\mathcal{L}$ is independent in $\mathbb{C}^m$, and let $a_1, ..., a_k \in \mathbb{R}$ with $\sum_j a_j\mathbf{v}_j = \mathbf{0}$ in $\mathbb{R}^m$. This equation also holds in $\mathbb{C}^m$, with the real numbers a_j regarded as complex scalars, so all $a_j = 0$ by Theorem 1.5.5.

(⇒) Suppose that $\mathcal{L}$ is independent in $\mathbb{R}^m$, and let $c_1, ..., c_k \in \mathbb{C}$ with $\sum_j c_j\mathbf{v}_j = \mathbf{0}$ in $\mathbb{C}^m$. Write $c_j = a_j + b_j i$ with $a_j, b_j \in \mathbb{R}$. Fix a coordinate $t \in \{1, ..., m\}$. Since each v_{jt} is real, $c_j v_{jt} = a_j v_{jt} + \left(b_j v_{jt}\right)i$, and the t-th coordinate of the relation reads

$$0 = \sum_{j=1}^{k} c_j v_{jt} = \left(\sum_{j=1}^{k} a_j v_{jt}\right) + \left(\sum_{j=1}^{k} b_j v_{jt}\right)i,$$

where both sums in parentheses are real numbers. By Definition 1.1.29, a complex number $x + yi$ with $x, y \in \mathbb{R}$ is 0 only if $x = y = 0$. So both sums vanish for every t, which says that

$$a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0} \quad \text{and} \quad b_1\mathbf{v}_1 + \cdots + b_k\mathbf{v}_k = \mathbf{0} \quad \text{in } \mathbb{R}^m.$$

Since $\mathcal{L}$ is independent in $\mathbb{R}^m$, all a_j and b_j are 0, so all $c_j = 0$. By Theorem 1.5.5, $\mathcal{L}$ is independent in $\mathbb{C}^m$. □

Exercise 1.5.22. ROUTINE Decide whether $(1, 1 + i), (1 - i, 2)$ is linearly independent in $\mathbb{C}^2$ over $\mathbb{C}$, and over $\mathbb{R}$. Does this contradict Proposition 1.5.21?

Solution on page 1063

Remark 1.5.23 (Rational and real scalars). The analogue of Proposition 1.5.21 holds for $\mathbb{Q} \subseteq \mathbb{R}$: a list in $\mathbb{Q}^m$ is independent over $\mathbb{Q}$ if and only if it is independent over $\mathbb{R}$. It holds for every subfield K of a field E

(Exercise 1.5.42). The proof above does not carry over directly. It split each complex coefficient into two real ones, which works because every complex number is a real linear combination of 1 and i. No finite list of real numbers spans $\mathbb{R}$ over $\mathbb{Q}$ (Exercise 1.3.45), so there is no such splitting of real coefficients into rational ones. The proof in Exercise 1.5.42 uses only the finitely many real numbers that occur as coefficients in one relation.

1.5.6 Polynomials and functions

In a space of functions, a linear relation is an identity that holds at *every* point. So to prove independence we may evaluate at any points we like, or compare other data that the functions determine, such as their behavior for large t. For polynomials, which are coefficient sequences rather than functions, the data to compare are the coefficients.

> *Intuition.* Among polynomials of different degrees, the one of largest degree has a leading term that the others cannot cancel. So a nontrivial combination of them has a nonzero top coefficient. Choosing the largest degree is the extremal move of Technique 1.5.9.

Proposition 1.5.24 (Distinct degrees). Let $p_1, \dots, p_k \in F[x]$ be nonzero polynomials with distinct degrees. Then $p_1, \dots, p_k$ is linearly independent.

Proof. STANDARD

> *Uses.* Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.13 (Polynomials), Definition 1.2.16 (Degree), Proposition 1.1.17 (No zero divisors)
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9)
> *Hint 1.* Suppose that a nontrivial combination $a_1p_1 + \cdots + a_kp_k$ is the zero polynomial. Among the indices with $a_i \neq 0$, choose one for which $\deg p_i$ is as large as possible.
> *Hint 2.* Compute the coefficient of the combination in position $d = \deg p_i$. Which terms can contribute to it?
> *Sketch.* Suppose $\sum a_ip_i = \mathbf{0}$ with some $a_i \neq 0$. Among those i, take the one with the largest degree d. Every other a_lp_l is $\mathbf{0}$ or has degree less than d, so the coefficient of the sum in position d is a_i times the leading coefficient of p_i, which is nonzero. Contradiction.

Suppose, to the contrary, that $a_1p_1 + \cdots + a_kp_k = \mathbf{0}$ with not all $a_i = 0$. Among the indices i with $a_i \neq 0$, choose one for which $d = \deg p_i$ is largest; since the degrees are distinct, it is unique. Let $c \neq 0$ be the leading coefficient of p_i. The operations of $F[x]$ are coefficientwise (Definition 1.2.13), so the coefficient of the sum in position d is the sum of the coefficients of the a_lp_l in position d. For $l = i$ this is a_ic. For $l \neq i$ with $a_l \neq 0$, we have $\deg p_l < d$ by the choice of i, so the coefficient of p_l in position d is 0, and so is that of a_lp_l. For l with $a_l = 0$, $a_lp_l = \mathbf{0}$. So the coefficient of $a_1p_1 + \cdots + a_kp_k$ in position d is a_ic, which is nonzero by Proposition 1.1.17. This contradicts $a_1p_1 + \cdots + a_kp_k = \mathbf{0}$. By Theorem 1.5.5, the list is independent. □

For example, $1, 1+x, 1+x+x^2$ and $1, x-1, x^2-2x+1$ are linearly independent in $F[x]$ over every field. The hypothesis matters: x^2+x, x^2-x, x has two entries of degree 2, and it is dependent, since $(x^2+x) - (x^2-x) + (-2)x = \mathbf{0}$.

Example 1.5.25 (Polynomials versus polynomial functions). Over $\mathbb{F}_2$, the list x, x^2 is linearly independent in $\mathbb{F}_2[x]$, by Proposition 1.5.24. Their polynomial functions $\mathbb{F}_2 \to \mathbb{F}_2$ are $c \mapsto c$ and $c \mapsto c^2$, and these are the same function, since $0^2 = 0$ and $1^2 = 1$. So in the vector space $\mathbb{F}_2^{\mathbb{F}_2}$ the two functions form a list with a repeated entry, which is dependent (Proposition 1.5.15(c)). The same "polynomials" are independent in one vector space and dependent in another, as Aside (Polynomials versus polynomial functions) warned.

Over an infinite field this cannot happen. If $a_1, \dots, a_k$ is a linear relation among the polynomial functions of $p_1, \dots, p_k$, then the polynomial $q = a_1p_1 + \cdots + a_kp_k$ satisfies $q(c) = 0$ for every $c \in F$ (Proposition 1.2.18(c)). A nonzero polynomial has only finitely many roots (Proposition 7.1.22), so $q = \mathbf{0}$, and $a_1, \dots, a_k$ is a linear relation among the polynomials themselves.

Example 1.5.26 (Trigonometric functions). In $\mathbb{R}^{\mathbb{R}}$, the list $\sin, \cos$ is linearly independent. Suppose that $a \sin + b \cos = \mathbf{0}$, the zero function. Then $a \sin t + b \cos t = 0$ for every $t \in \mathbb{R}$. At $t = 0$ this reads $b = 0$, and at $t = \pi/2$ it reads $a = 0$.

On the other hand, $1, \sin^2, \cos^2$ (where $\sin^2$ is the function $t \mapsto (\sin t)^2$) is dependent, since $\sin^2 t + \cos^2 t - 1 = 0$ for every t.

The method used for $\sin, \cos$ works in general. Evaluating a relation at a point t_0 gives one linear equation for the coefficients, so evaluating at as many points as there are coefficients gives a system of equations. If the only solution is 0, the functions are independent. If the system has nonzero solutions, nothing follows: a combination that vanishes at a few points need not vanish everywhere. To prove dependence, one needs an identity valid at *every* point, such as $\sin^2 + \cos^2 = 1$.

Example 1.5.27 (Exponential functions). BEYOND 21-242 In $\mathbb{R}^{\mathbb{R}}$, let $f_k(t) = e^{kt}$ for $k = 1, 2, 3$. Then f_1, f_2, f_3 is linearly independent. (The proofs use calculus.)

> *Intuition.* Evaluating at three points works, but it produces equations with entries such as e^2 and e^6 that hide what is going on. Two features of exponentials give cleaner proofs. Differentiation sends each f_k to a multiple of itself, $f_k' = k f_k$, with a different factor for each k; combining a relation with its derivative eliminates one term at a time. And as $t \to \infty$, the term with the largest exponent dominates all the others.

Proof (differentiate to eliminate terms). STANDARD

> *Uses.* Theorem 1.5.5 (Independence is decided at zero), the derivative of e^{kt} is ke^{kt}
> *Techniques.* Apply an operator to a relation to kill terms (Technique 4.1.25)
> *Hint 1.* Suppose $ae^t + be^{2t} + ce^{3t} = 0$ for all t. Differentiate this identity. Which combination of the identity and its derivative has no e^t term?
> *Hint 2.* Subtract the identity from its derivative. Repeat the idea on the result to eliminate the e^{2t} term, then evaluate at $t = 0$.
> *Sketch.* From $ae^t + be^{2t} + ce^{3t} = 0$, subtracting the identity from its derivative gives $be^{2t} + 2ce^{3t} = 0$; doing the same with factor 2 gives $2ce^{3t} = 0$. Evaluating at $t = 0$ in reverse order gives $c = 0$, $b = 0$, $a = 0$.

Suppose that $af_1 + bf_2 + cf_3 = \mathbf{0}$, that is,

$$ae^t + be^{2t} + ce^{3t} = 0 \quad \text{for all } t \in \mathbb{R}.$$

Both sides are differentiable functions of t, and the derivative of the zero function is 0, so

$$ae^t + 2be^{2t} + 3ce^{3t} = 0 \quad \text{for all } t.$$

Subtracting the first identity from the second eliminates the term with e^t:

$$be^{2t} + 2ce^{3t} = 0 \quad \text{for all } t.$$

Differentiating this gives $2be^{2t} + 6ce^{3t} = 0$, and subtracting twice the previous identity eliminates the term with e^{2t}: $2ce^{3t} = 0$ for all t. At $t = 0$ this gives $2c = 0$, so $c = 0$. Then $be^{2t} + 2ce^{3t} = 0$ at $t = 0$ gives $b = 0$, and the first identity at $t = 0$ gives $a + b + c = 0$, so $a = 0$. By Theorem 1.5.5, f_1, f_2, f_3 is independent. □

Proof (the dominant term). STANDARD

> *Uses.* Theorem 1.5.5 (Independence is decided at zero), $e^{-st} \to 0$ as $t \to \infty$, for $s > 0$
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9)
> *Hint 1.* Suppose $ae^t + be^{2t} + ce^{3t} = 0$ for all t. Which term grows fastest as $t \to \infty$?
> *Hint 2.* Divide the identity by e^{3t} and let $t \to \infty$.
> *Sketch.* Dividing by e^{3t} gives $ae^{-2t} + be^{-t} + c = 0$ for all t; letting $t \to \infty$ gives $c = 0$. Then divide $ae^t + be^{2t} = 0$ by e^{2t} to get $b = 0$, and $ae^t = 0$ gives $a = 0$.

Suppose that $ae^t + be^{2t} + ce^{3t} = 0$ for all $t \in \mathbb{R}$. Multiplying by e^{-3t},

$$ae^{-2t} + be^{-t} + c = 0 \quad \text{for all } t.$$

As $t \to \infty$, $e^{-2t} \to 0$ and $e^{-t} \to 0$, so the left side tends to c. It is 0 for every t, so $c = 0$. Now $ae^t + be^{2t} = 0$ for all t; multiplying by e^{-2t} and letting $t \to \infty$ in the same way gives $b = 0$. Finally $ae^t = 0$ at $t = 0$ gives $a = 0$. □

The first proof uses only that differentiation multiplies each f_k by a different factor. It adapts to sequences, with a shift in place of the derivative (Exercise 1.5.44), and Section 4.1 names the move: apply an operator to a relation to eliminate terms (Technique 4.1.25). The second proof is the analytic counterpart of Proposition 1.5.24: there the largest degree dominated, here the largest exponent. Both extend to any number of distinct exponents (Exercise 1.5.45).

ASIDE: *Independent sets* BEYOND 21-242

A subset $S \subseteq V$, possibly infinite, is called linearly independent if every list of distinct elements of S is linearly independent. Distinctness is needed because a list with a repeated entry is never independent. For a finite set S, this agrees with independence of any list that runs through the elements of S once each (Proposition 1.5.18(a), Corollary 1.5.17). For example, $\{1, x, x^2, \ldots\}$ is linearly independent in $F[x]$, since a list of distinct monomials is a reordering of a sublist of some $1, x, \ldots, x^n$ (Example 1.5.7). By Exercise 1.5.45, the set of functions $t \mapsto e^{\lambda t}$, $\lambda \in \mathbb{R}$, is an uncountable independent subset of $\mathbb{R}^{\mathbb{R}}$. Independent sets and spanning sets (Aside (Spans of infinite sets)) lead to bases of infinite-dimensional spaces (Section 15.1).

Exercises

Exercise 1.5.28. ROUTINE Decide whether each list in $\mathbb{R}^3$ is linearly independent. For each dependent list, find a dependence relation and every j with $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$.

(a) $(1, 2, 3), (4, 5, 6), (7, 8, 9)$.

(b) $(1, 1, 1), (0, 1, 1), (0, 0, 1)$.

(c) $(1, -1, 0), (0, 1, -1), (-1, 0, 1)$.

Solution on page 1064

Exercise 1.5.29. ROUTINE For which primes p is $(1, 1, 1), (1, 2, 3), (1, 4, 9)$ linearly independent in $\mathbb{F}_p^3$? Is it linearly independent in $\mathbb{Q}^3$?

Solution on page 1064

Exercise 1.5.30. ROUTINE

(a) Find the error in the following argument.

Claim. If $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is linearly dependent, then $\mathbf{v}_k \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$.

Proof. Take a nontrivial relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$, and let j be the largest index with $a_j \neq 0$. Since k is the largest index, $j = k$. Solving for $\mathbf{v}_k$ as in Lemma 1.5.10 gives $\mathbf{v}_k \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$.

(b) Show that the claim does hold when $\mathbf{v}_1, \ldots, \mathbf{v}_{k-1}$ is linearly independent.

Solution on page 1064

Exercise 1.5.31. ROUTINE Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V, and let $S_j = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$ for $0 \leq j \leq k$, so that $S_0 = \{\mathbf{0}\}$. Show that $\mathcal{L}$ is linearly independent if and only if

$$S_0 \subsetneq S_1 \subsetneq \cdots \subsetneq S_k,$$

that is, every entry makes the span strictly larger.

Solution on page 1065

Exercise 1.5.32. STANDARD Decide whether each list is linearly independent.

(a) In $\mathbb{R}^{\mathbb{R}}$: the functions 1, $t \mapsto \cos 2t$, and $t \mapsto \cos^2 t$.

(b) In $\mathbb{R}^{\mathbb{R}}$: the functions $t \mapsto \sin t$, $t \mapsto \sin 2t$, and $t \mapsto \sin 3t$.

(c) The functions $t \mapsto t$ and $t \mapsto |t|$, first in $\mathbb{R}^{\mathbb{R}}$ and then in $\mathbb{R}^{[0,\infty)}$.

Solution on page 1065

Exercise 1.5.33. STANDARD Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be linearly independent, let $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$, and fix j. Let $\mathcal{L}'$ be $\mathcal{L}$ with $\mathbf{v}_j$ replaced by $\mathbf{w}$. Show that $\mathcal{L}'$ is linearly independent if and only if $a_j \neq 0$, and that in this case $\operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{L})$.

Solution on page 1065

Exercise 1.5.34. STANDARD Let $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$, and let $\mathcal{L}, \mathcal{M}$ be lists in V. Prove or disprove each statement.

(a) If $\mathbf{u}, \mathbf{v}$ and $\mathbf{v}, \mathbf{w}$ are linearly independent, then so is $\mathbf{u}, \mathbf{w}$.

(b) If $\mathbf{u}, \mathbf{v}, \mathbf{w}$ is linearly dependent, then $\mathbf{w} \in \operatorname{span}(\mathbf{u}, \mathbf{v})$.

(c) If $\mathcal{L}$ and $\mathcal{M}$ are linearly independent, then so is the concatenation $\mathcal{L}, \mathcal{M}$.

(d) If $\mathbf{v}_1, ..., \mathbf{v}_k$ is linearly independent, then $\mathbf{v}_1, ..., \mathbf{v}_k, \mathbf{v}_1 + \cdots + \mathbf{v}_k$ is linearly dependent.

(e) If $\mathbf{u}, \mathbf{v}$ is linearly independent and $\mathbf{w} \notin \operatorname{span}(\mathbf{u}) \cup \operatorname{span}(\mathbf{v})$, then $\mathbf{u}, \mathbf{v}, \mathbf{w}$ is linearly independent.

Solution on page 1066

Exercise 1.5.35. STANDARD In $F[x]$, let

$$p_1 = x^2 - 3x + 2, \quad p_2 = x^2 - 2x, \quad p_3 = x^2 - x,$$

where $3 = 1 + 1 + 1$ and $2 = 1 + 1$ in F. Show that p_1, p_2, p_3 is linearly independent if and only if $1 + 1 \neq 0$ in F.

Solution on page 1066

Exercise 1.5.36. STANDARD Let $n \geq 2$, and let $\mathbf{v}_1, ..., \mathbf{v}_n$ be linearly independent in V. Let

$$\mathbf{w}_i = \mathbf{v}_i + \mathbf{v}_{i+1} \quad (1 \leq i < n), \quad \mathbf{w}_n = \mathbf{v}_n + \mathbf{v}_1.$$

Find all n and all fields F for which $\mathbf{w}_1, ..., \mathbf{w}_n$ is linearly independent.

Solution on page 1067

Exercise 1.5.37. STANDARD Let V be a vector space over $\mathbb{C}$, regarded also as a vector space over $\mathbb{R}$ (Proposition 1.2.19). Show that $\mathbf{v}_1, ..., \mathbf{v}_k$ is linearly independent over $\mathbb{C}$ if and only if

$$\mathbf{v}_1, i\mathbf{v}_1, \mathbf{v}_2, i\mathbf{v}_2, ..., \mathbf{v}_k, i\mathbf{v}_k$$

is linearly independent over $\mathbb{R}$.

Solution on page 1067

Exercise 1.5.38. STANDARD Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in $\mathbb{R}^m$. Show that $\mathcal{L}$ spans the real vector space $\mathbb{R}^m$ if and only if it spans the complex vector space $\mathbb{C}^m$.

Solution on page 1068

Exercise 1.5.39. STANDARD Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$. Show that $\ln 2, \ln 3, \ln 5$ is linearly independent. (Use unique factorization of positive integers into primes.)

Solution on page 1068

Exercise 1.5.40. HARD Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$. Show that $1, \sqrt{2}, \sqrt{3}, \sqrt{6}$ is linearly independent. You may use Exercise 1.3.44: $\sqrt{3} \notin \operatorname{span}\left(1, \sqrt{2}\right)$ over $\mathbb{Q}$.

Solution on page 1069

Exercise 1.5.41. HARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_k \in \mathbb{Q}^m$ have integer coordinates, let p be a prime, and let $\overline{\mathbf{v}}_j \in \mathbb{F}_p^m$ be the vector whose coordinates are those of $\mathbf{v}_j$ reduced modulo p.

(a) Show that if $\overline{\mathbf{v}}_1, \ldots, \overline{\mathbf{v}}_k$ is linearly independent in $\mathbb{F}_p^m$, then $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is linearly independent in $\mathbb{Q}^m$.

(b) Show that the converse of (a) is false.

Solution on page 1069

Exercise 1.5.42. HARD Let K be a subfield of a field E, for instance $\mathbb{Q} \subseteq \mathbb{R}$, and let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in K^m. Show that $\mathcal{L}$ is linearly independent in the K-vector space K^m if and only if it is linearly independent in the E-vector space E^m. This exercise uses Theorem 1.6.10 from Section 1.6.

Solution on page 1070

Exercise 1.5.43. HARD Let F be a finite field with q elements.

(a) Show that a list $\mathcal{L}$ of length k in V is linearly independent if and only if $\operatorname{span}(\mathcal{L})$ has exactly q^k elements.

(b) Show that the number of linearly independent lists of length k in F^n is

$$(q^n - 1)(q^n - q)\left(q^n - q^2\right)\cdots\left(q^n - q^{k-1}\right).$$

(c) How many lists of length 3 in $\mathbb{F}_2^3$ are linearly independent? How many of length 4?

Solution on page 1071

Exercise 1.5.44. HARD Let $X = \{0, 1, 2, \ldots\}$, so that F^X is the space of sequences $(x_0, x_1, x_2, \ldots)$ in F (Remark 1.2.11). For $\lambda \in F$, let $\mathbf{s}_\lambda = \left(1, \lambda, \lambda^2, \lambda^3, \ldots\right)$. Show that if $\lambda_1, \ldots, \lambda_k \in F$ are distinct, then $\mathbf{s}_{\lambda_1}, \ldots, \mathbf{s}_{\lambda_k}$ is linearly independent.

Solution on page 1071

Exercise 1.5.45. HARD BEYOND 21-242 Let $\lambda_1, \ldots, \lambda_k \in \mathbb{R}$ be distinct. Show that the functions $t \mapsto e^{\lambda_1 t}, \ldots, t \mapsto e^{\lambda_k t}$ are linearly independent in $\mathbb{R}^{\mathbb{R}}$.

Solution on page 1072

Exercise 1.5.46. HARD A town has n residents, numbered $1, \ldots, n$, and k clubs $C_1, \ldots, C_k \subseteq \{1, \ldots, n\}$. Every club has an odd number of members, and for $i \neq j$ the clubs C_i and C_j have an even number of members in common. (In particular, no club is listed twice.) For a club C, let $\mathbf{x}_C \in \mathbb{F}_2^n$ have t-th coordinate 1 if $t \in C$ and 0 otherwise. Show that $\mathbf{x}_{C_1}, \ldots, \mathbf{x}_{C_k}$ is linearly independent in $\mathbb{F}_2^n$.

Solution on page 1072

Exercise 1.5.47. HARD Let $a_1 < a_2 < \cdots < a_n$ be real numbers, and let $f_i(t) = |t - a_i|$. Show that the functions $1, t \mapsto t, f_1, \ldots, f_n$ are linearly independent in $\mathbb{R}^{\mathbb{R}}$. (No calculus is needed.)

Solution on page 1073

Exercise 1.5.48. CHALLENGE Let $\lambda \geq 1$ and $m \geq 2$ be integers, and let $A_1, ..., A_m$ be distinct subsets of $\{1, ..., n\}$ such that $|A_i \cap A_j| = \lambda$ for all $i \neq j$. For a subset A, let $\mathbf{x}_A \in \mathbb{R}^n$ have t-th coordinate 1 if $t \in A$ and 0 otherwise. Show that $\mathbf{x}_{A_1}, ..., \mathbf{x}_{A_m}$ is linearly independent in $\mathbb{R}^n$.

Solution on page 1073

1.6 Bases and coordinates

In F^n a vector is its list of entries: $\mathbf{x} = (x_1, ..., x_n)$ is the linear combination $x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n$, and no other linear combination of $\mathbf{e}_1, ..., \mathbf{e}_n$ represents it. A basis of a vector space V is a list that does for V what $\mathbf{e}_1, ..., \mathbf{e}_n$ does for F^n: every vector of V is represented by exactly one of its linear combinations. The coefficients of that combination are the coordinates of the vector. They name each vector of V by a column in F^n, and they turn computations in V into computations with columns. This section defines bases, shows that every spanning list contains one, and develops coordinates.

1.6.1 Bases

Throughout, V is a vector space over a field F.

Definition 1.6.1 (Basis). A list $\mathcal{B}$ in V is a **basis** of V if every vector of V is represented by exactly one linear combination of $\mathcal{B}$. The plural of basis is **bases**.

So $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ is a basis when, for every $\mathbf{v} \in V$, the equation

$$a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n = \mathbf{v}$$

has exactly one solution $(a_1, ..., a_n)$. "Exactly one" is two claims: at least one solution, and at most one. The first is a statement about the span of $\mathcal{B}$, and the second is the uniqueness that defines linear independence.

Proposition 1.6.2 (Bases are independent spanning lists). A list $\mathcal{B}$ in V is a basis of V if and only if $\mathcal{B}$ spans V and $\mathcal{B}$ is linearly independent.

Proof. ROUTINE

Uses. Definition 1.6.1 (Basis), Definition 1.3.12 (Spanning list), Definition 1.5.1 (Linear independence), Definition 1.3.10 (Span)

Hint 1. Split "exactly one linear combination represents $\mathbf{v}$" into "at least one" and "at most one". Which of the two properties of $\mathcal{B}$ is each of them?

Hint 2. Definition 1.5.1 asks for uniqueness only for vectors of $\operatorname{span}(\mathcal{B})$. If $\mathcal{B}$ spans V, which vectors are those?

Sketch. "At least one representation for every $\mathbf{v} \in V$" says $\operatorname{span}(\mathcal{B}) = V$. Given that, "at most one representation for every $\mathbf{v} \in V$" is the same as "exactly one for every vector of $\operatorname{span}(\mathcal{B})$", which is linear independence.

(⇒) Suppose that $\mathcal{B}$ is a basis of V. Every $\mathbf{v} \in V$ is represented by some linear combination of $\mathcal{B}$, so $V \subseteq \operatorname{span}(\mathcal{B})$. The span consists of vectors of V, so $\operatorname{span}(\mathcal{B}) = V$. Every vector of $\operatorname{span}(\mathcal{B}) = V$ is then represented by exactly one linear combination of $\mathcal{B}$, which is Definition 1.5.1.

(⇐) Suppose that $\mathcal{B}$ spans V and is linearly independent, and let $\mathbf{v} \in V$. Since $\mathbf{v} \in V = \operatorname{span}(\mathcal{B})$, some linear combination of $\mathcal{B}$ represents $\mathbf{v}$, and by independence no other one does. □

The lecture defines a basis by unique representation and records the proposition as an equivalent form. The proposition splits the work of checking a basis into two familiar tasks: show that every vector is a linear combination of $\mathcal{B}$ (spanning), and show that $a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n = \mathbf{0}$ forces every $a_i = 0$ (independence, by Theorem 1.5.5). The definition suggests doing both at once: solve $a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n = \mathbf{v}$ for an arbitrary

v. If the computation shows that the a_i *must* be given by certain formulas, and these formulas do give a solution, then the solution exists and is unique.

Example 1.6.3 (First bases).

(a) In $\mathbb{R}^2$, consider $(1,1),(1,-1)$. For $(x,y)\in\mathbb{R}^2$, the equation $a(1,1)+b(1,-1)=(x,y)$ reads $a+b=x$ and $a-b=y$. Adding and subtracting, any solution has $a=(x+y)/2$ and $b=(x-y)/2$, and these values are a solution. So each (x,y) is represented by exactly one linear combination, and $(1,1),(1,-1)$ is a basis of $\mathbb{R}^2$. The same computation works over any field with $1+1\neq 0$. Over $\mathbb{F}_2$ the list is not a basis: there $(1,-1)=(1,1)$, and a list with a repeated entry is dependent (Proposition 1.5.15).

(b) Let $P=\{(x,y,z)\in\mathbb{R}^3 \mid x+y+z=0\}$. The list $(1,0,-1),(0,1,-1)$ spans P (Exercise 1.3.16). It is independent, because $a(1,0,-1)+b(0,1,-1)=(a,b,-a-b)$ is $\mathbf{0}$ only if $a=b=0$. So it is a basis of the plane P, a vector space in its own right (Definition 1.4.1).

(c) The zero space $\{\mathbf{0}\}$ has the empty list () as a basis: () spans $\{\mathbf{0}\}$ and is independent (Definition 1.3.10, Proposition 1.5.15). It is the only basis, since every nonempty list in $\{\mathbf{0}\}$ contains $\mathbf{0}$ and is therefore dependent.

Non-example 1.6.4 (One property without the other).

(a) In $\mathbb{R}^3$, the list $(1,0,1),(0,1,1)$ is linearly independent, because $a(1,0,1)+b(0,1,1)=(a,b,a+b)$, which is $\mathbf{0}$ only if $a=b=0$. It does not span $\mathbb{R}^3$: every vector $(a,b,a+b)$ of its span has third coordinate equal to the sum of the first two, and $(0,0,1)$ does not. So the vector $(0,0,1)$ has no representation at all.

(b) In $\mathbb{R}^2$, the list $(1,0),(0,1),(1,1)$ spans $\mathbb{R}^2$, as its sublist $(1,0),(0,1)$ already does. It is dependent, since $(1,0)+(0,1)-(1,1)=\mathbf{0}$. So every vector has many representations: $(1,1)=1(1,0)+1(0,1)+0(1,1)=0(1,0)+0(0,1)+1(1,1)$.

Whether a list is a basis depends on the field, since both spanning and independence do.

Example 1.6.5 ($\mathbb{C}$ over $\mathbb{R}$ and over $\mathbb{C}$). Regard $\mathbb{C}$ as a vector space over $\mathbb{R}$ (Example 1.2.20). The list $1,i$ spans it, since every complex number is $a+bi=a\cdot 1+b\cdot i$ with $a,b\in\mathbb{R}$, and it is independent over $\mathbb{R}$ (Example 1.5.19). So $1,i$ is a basis of $\mathbb{C}$ over $\mathbb{R}$. Over $\mathbb{C}$ the same list is dependent, as $i\cdot 1+(-1)\cdot i=0$, so it is not a basis of $\mathbb{C}$ over $\mathbb{C}$. Instead, the list 1 is: every $z\in\mathbb{C}$ is $z\cdot 1$ for exactly one complex scalar, namely z. So the same set has bases of length 2 over $\mathbb{R}$ and of length 1 over $\mathbb{C}$.

Exercise 1.6.6. ROUTINE Let $W=\{p\in\mathbb{R}[x]_{\leq 3} \mid p(1)=0\}$. Show that $x-1,x^2-1,x^3-1$ is a basis of W.

Solution on page 1074

1.6.2 Standard bases

The spaces F^n, $F^{m\times n}$, and $F[x]_{\leq n}$ each come with a basis in which the coefficients of a vector are the numbers used to write it down.

Proposition 1.6.7 (Standard bases).

(a) In F^n, the list $\mathbf{e}_1,\ldots,\mathbf{e}_n$ is a basis, where $\mathbf{e}_i$ has 1 in position i and 0 elsewhere.

(b) In $F^{m\times n}$, let U_{ij} be the matrix with 1 in position (i,j) and 0 elsewhere. The mn matrices U_{ij}, listed row by row as

$$U_{11},U_{12},\ldots,U_{1n},U_{21},\ldots,U_{2n},\ldots,U_{m1},\ldots,U_{mn},$$

form a basis.

(c) In $F[x]_{\leq n}$, the list $1,x,x^2,\ldots,x^n$ is a basis.

Proof. ROUTINE

Uses. Definition 1.6.1 (Basis), Definition 1.2.4 (The space F^n), Definition 1.2.7 (Matrices), Notation 1.2.15, Example 1.3.7 (Standard lists)
Hint 1. Use Definition 1.6.1 directly: compute the vector represented by an arbitrary linear combination, and compare with the vector you want to represent.
Hint 2. The combination $c_1\mathbf{e}_1 + \cdots + c_n\mathbf{e}_n$ is the column $(c_1, \ldots, c_n)$. What are the analogous statements for $\sum c_{ij}U_{ij}$ and $c_0 + c_1x + \cdots + c_nx^n$?
Sketch. In each case the combination with coefficients c is the vector whose entries (or coefficients) are the c's: $\sum c_i\mathbf{e}_i = (c_1, \ldots, c_n)$, $\sum c_{ij}U_{ij}$ has (i,j) entry c_{ij}, and $\sum c_kx^k$ has k-th coefficient c_k. So the combination represents a given vector exactly when its coefficients are that vector's entries.

(a) By the coordinatewise operations, the linear combination with coefficients $c_1, \ldots, c_n$ represents $c_1\mathbf{e}_1 + \cdots + c_n\mathbf{e}_n = (c_1, \ldots, c_n)$ (Example 1.3.7). This equals $\mathbf{x} = (x_1, \ldots, x_n)$ if and only if $c_i = x_i$ for every i. So every $\mathbf{x} \in F^n$ is represented by exactly one linear combination.

(b) By the entrywise operations, the (k,l) entry of $\sum_{i,j} c_{ij}U_{ij}$ is $\sum_{i,j} c_{ij}\left(U_{ij}\right)_{kl} = c_{kl}$, since $\left(U_{ij}\right)_{kl}$ is 1 for $(i,j) = (k,l)$ and 0 otherwise. So the linear combination with coefficients c_{ij} represents $A = \left(a_{ij}\right)$ if and only if $c_{ij} = a_{ij}$ for all i, j.

(c) By Notation 1.2.15, $c_0 + c_1x + \cdots + c_nx^n$ is the polynomial with coefficients $(c_0, \ldots, c_n, 0, 0, \ldots)$. A polynomial $p \in F[x]_{\leq n}$ has the form $(a_0, \ldots, a_n, 0, 0, \ldots)$, and the two are equal if and only if $c_k = a_k$ for $0 \leq k \leq n$.□

Definition 1.6.8 (Standard bases). The bases of Proposition 1.6.7 are the **standard bases** of F^n, $F^{m\times n}$, and $F[x]_{\leq n}$. The vector $\mathbf{e}_i$ is the i-th **standard basis vector** of F^n, and the U_{ij} are the **matrix units** of $F^{m\times n}$.

The notation $\mathbf{e}_i$ does not record n, which is always clear from the context: $\mathbf{e}_1 = (1,0)$ in F^2 and $\mathbf{e}_1 = (1,0,0)$ in F^3. For matrix units we avoid the name E_{ij}, which Section 3.2 reserves for elementary matrices. Once matrices can be multiplied, $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ (Lemma 2.4.24). A column is an $n \times 1$ matrix, and the matrix units of $F^{n\times 1}$ are the $U_{i1} = \mathbf{e}_i$, so (b) contains (a).

The standard bases have lengths n, mn, and $n+1$, and these numbers will turn out to be the dimensions of the three spaces: we will see in Section 4.1 that all bases of a vector space have the same length (Theorem 4.1.4). The space F^n has many other bases, as Example 1.6.3(a) shows already for $n = 2$. The standard basis is the one in which coefficients can be read off without computation.

1.6.3 Every spanning list contains a basis

A spanning list fails to be a basis only by being dependent. The linear dependence lemma finds an entry whose deletion does not change the span, so we can delete it and still have a spanning list. Repeating this, the list gets shorter at each step, so the process stops, and it can only stop at an independent list. To turn "repeat until it stops" into a proof, we induct on the length of the list.

Technique 1.6.9 (Induction on the length of a list). Many statements are about all lists in V, or about linear combinations of every length. To prove one, induct on the length k. The base case is usually the empty list, where the claim tends to be immediate: $\operatorname{span}(()) = \{\mathbf{0}\}$, the empty list is independent, and the empty sum is $\mathbf{0}$. In the inductive step, take a list of length $k+1$, produce from it a list of length k (by deleting a well-chosen entry, or by splitting off the last term of a sum), apply the inductive hypothesis to the shorter list, and carry the conclusion back to the original list.

Two things need care. First, the inductive hypothesis must cover *every* list of length k, since the shorter list is produced by the argument and is not known in advance. Second, if the statement has hypotheses (for instance, that the list spans V), the shorter list must satisfy them too. Deleting an arbitrary entry of a spanning list can destroy spanning, which is why the deleted entry has to be chosen (Exercise 1.6.30).

Reach for it when removing one entry or one term reduces a claim to the same claim for a shorter list. The canonical example is Theorem 1.6.10, which deletes an entry supplied by Lemma 1.5.10. The arithmetic of linear combinations (Lemma 1.3.9) was proved by splitting off the last term, and so is Proposition 1.6.19(c) below. Later, the exchange lemma (Lemma 4.1.2) and Gram–Schmidt (Algorithm 6.4.14) are built the same way.

Used in. Theorem 1.6.10, Proposition 1.6.19, Exercise 1.6.30, Exercise 1.7.10, Exercise 1.7.11, Problem 1.17, Theorem 2.1.3, Lemma 4.1.2, Theorem 4.1.16, Corollary 4.1.35, Proposition 4.7.30, Exercise 4.7.61, Corollary 6.2.13, Corollary 6.3.6, Theorem 6.4.15, Proposition 7.1.22, Proposition 7.1.27, Exercise 2.6.50, Exercise 6.4.62, Exercise 6.6.19.

The lecture proves a slightly more general statement, about lists that need not span V. Any list spans its own span, so the general statement says that every list can be thinned to an independent list without losing any of its span.

Theorem 1.6.10 (Every spanning list contains a basis). Every list $\mathcal{L}$ in V has a linearly independent sublist $\mathcal{L}'$ with $\operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{L})$, and such an $\mathcal{L}'$ is a basis of $\operatorname{span}(\mathcal{L})$. In particular, if $\mathcal{L}$ spans V, then some sublist of $\mathcal{L}$ is a basis of V.

Once an independent sublist $\mathcal{L}'$ with the same span is found, the rest is formal. The entries of $\mathcal{L}'$ lie in the subspace $\operatorname{span}(\mathcal{L})$ (Proposition 1.4.14), $\mathcal{L}'$ spans it, and $\mathcal{L}'$ is independent there, because linear relations are computed with the same operations in V and in the subspace. So $\mathcal{L}'$ is a basis of $\operatorname{span}(\mathcal{L})$ by Proposition 1.6.2, and if $\mathcal{L}$ spans V, then $\operatorname{span}(\mathcal{L}) = V$. We give three proofs that $\mathcal{L}'$ exists. The first is the lecture's induction; the second and third show what that induction is doing in two other forms.

Proof (induction on the length). STANDARD

Uses. Lemma 1.5.10 (Linear dependence lemma), Proposition 1.5.15 (Short lists, zeros, and repeats), Notation 1.3.3
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Induct on $k = |\mathcal{L}|$. What is the empty list's span, and is the empty list independent?
Hint 2. In the inductive step, if $\mathcal{L}$ is independent there is nothing to do. Otherwise, which entry can be deleted without changing the span?
Hint 3. Delete the entry given by Lemma 1.5.10 and apply the inductive hypothesis to the shorter list. Why is a sublist of the shorter list also a sublist of $\mathcal{L}$?
Sketch. Induct on $|\mathcal{L}|$. The empty list is independent. For a list of length $k+1$: if it is independent, take $\mathcal{L}' = \mathcal{L}$; if not, Lemma 1.5.10 gives an entry whose deletion keeps the span, and the inductive hypothesis, applied to the resulting list of length k, gives an independent sublist with the same span, which is also a sublist of $\mathcal{L}$.

We prove by induction on $k \geq 0$ that every list of length k in V has a linearly independent sublist with the same span.

Base case. If $k = 0$, then $\mathcal{L} = ()$, which is independent (Proposition 1.5.15(a)). Take $\mathcal{L}' = \mathcal{L}$.

Inductive step. Suppose that every list of length k in V has an independent sublist with the same span, and let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_{k+1}$. If $\mathcal{L}$ is independent, take $\mathcal{L}' = \mathcal{L}$. Otherwise, by Lemma 1.5.10 there is an index j such that the list

$$\mathcal{L}_j = \mathbf{v}_1, \ldots, \mathbf{v}_{j-1}, \mathbf{v}_{j+1}, \ldots, \mathbf{v}_{k+1}$$

satisfies $\operatorname{span}\left(\mathcal{L}_j\right) = \operatorname{span}(\mathcal{L})$. The list $\mathcal{L}_j$ has length k, so by the inductive hypothesis it has an independent sublist $\mathcal{L}'$ with $\operatorname{span}(\mathcal{L}') = \operatorname{span}\left(\mathcal{L}_j\right) = \operatorname{span}(\mathcal{L})$. Deleting entries from $\mathcal{L}_j$ amounts to deleting entries from $\mathcal{L}$, so $\mathcal{L}'$ is a sublist of $\mathcal{L}$ (Notation 1.3.3), as desired. □

Intuition (What the induction is doing). Unwinding the induction, the proof deletes redundant entries one at a time until none is left. The induction guarantees that this stops, because each deletion shortens the list. Another way to guarantee it is to look directly at the end result: a shortest sublist with the same span. Such a sublist exists because lengths are nonnegative integers, and it cannot be dependent,

since the dependence lemma would shorten it further. This is the extremal form of the same argument (Technique 1.5.9).

Proof (a shortest sublist). STANDARD

Uses. Lemma 1.5.10 (Linear dependence lemma), Notation 1.3.3
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Among all sublists of $\mathcal{L}$ with the same span as $\mathcal{L}$, choose one of the smallest length. Why is there at least one such sublist?
Hint 2. If the chosen sublist were dependent, what would Lemma 1.5.10 produce?
Sketch. The sublists of $\mathcal{L}$ with span $\operatorname{span}(\mathcal{L})$ include $\mathcal{L}$, so there is one, $\mathcal{L}'$, of smallest length. If $\mathcal{L}'$ were dependent, deleting the entry given by Lemma 1.5.10 would give a shorter sublist of $\mathcal{L}$ with the same span, contradicting minimality.

Let S be the set of sublists of $\mathcal{L}$ whose span is $\operatorname{span}(\mathcal{L})$. It is nonempty, since $\mathcal{L} \in S$. The lengths of the members of S are nonnegative integers, so some $\mathcal{L}' \in S$ has the smallest length. Suppose, to the contrary, that $\mathcal{L}'$ is dependent. By Lemma 1.5.10, deleting a suitable entry of $\mathcal{L}'$ gives a list $\mathcal{L}''$ with $\operatorname{span}(\mathcal{L}'') = \operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{L})$. As a sublist of a sublist of $\mathcal{L}$, $\mathcal{L}''$ is a sublist of $\mathcal{L}$, so $\mathcal{L}'' \in S$, and it is shorter than $\mathcal{L}'$. This contradicts the choice of $\mathcal{L}'$. So $\mathcal{L}'$ is independent. □

Both proofs make a choice they cannot control: which redundant entry to delete, or which shortest sublist to take. The third proof makes no choices. It reads the list from left to right and keeps exactly the entries that are not in the span of the entries before them. This procedure, **sifting**, can be carried out by hand or by a computer, and its output is determined by $\mathcal{L}$. In Section 4.2 the entries it keeps reappear as the pivot columns of a matrix.

Proof (sifting). STANDARD

Uses. Corollary 1.5.13 (Independence, one entry at a time), Corollary 1.3.20 (Operations that preserve the span), Corollary 1.3.19 (Equal spans), Proposition 1.3.17 (A list lies in its span)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Let $\mathcal{L}'$ consist of the entries $\mathbf{v}_j$ with $\mathbf{v}_j \notin \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$. Independence of $\mathcal{L}'$ should come from Corollary 1.5.13.
Hint 2. For each j, compare $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$ with the span of the entries of $\mathcal{L}'$ among $\mathbf{v}_1, \ldots, \mathbf{v}_j$. Prove that they are equal by induction on j.
Hint 3. In the inductive step, split into the cases where $\mathbf{v}_j$ is kept and where it is deleted. In the second case, Corollary 1.3.20(c) applies.
Sketch. Keep $\mathbf{v}_j$ exactly when $\mathbf{v}_j \notin S_{j-1} = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$. By induction on j, the kept entries among the first j span S_j: a kept entry is added to both sides, and a deleted entry lies in S_{j-1}, so $S_j = S_{j-1}$. Taking $j = k$ gives the span. Each kept entry lies outside S_{j-1}, which is the span of the earlier kept entries, so the kept list is independent by Corollary 1.5.13.

Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$, and write $S_j = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$ for $0 \le j \le k$, so $S_0 = \{\mathbf{0}\}$. Call $\mathbf{v}_j$ *kept* if $\mathbf{v}_j \notin S_{j-1}$ and *deleted* otherwise. Let $\mathcal{L}'$ be the sublist of kept entries, and for $0 \le j \le k$ let $\mathcal{K}_j$ be the sublist of kept entries among $\mathbf{v}_1, \ldots, \mathbf{v}_j$.

We show by induction on j that $\operatorname{span}(\mathcal{K}_j) = S_j$. For $j = 0$ both sides are $\{\mathbf{0}\}$. Let $j \ge 1$ and assume $\operatorname{span}(\mathcal{K}_{j-1}) = S_{j-1}$.

- If $\mathbf{v}_j$ is kept, then $\mathcal{K}_j = \mathcal{K}_{j-1}, \mathbf{v}_j$. The entries of $\mathcal{K}_j$ are entries of $\mathbf{v}_1, \ldots, \mathbf{v}_j$, so they lie in S_j (Proposition 1.3.17). Conversely, $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$ lie in $S_{j-1} = \operatorname{span}(\mathcal{K}_{j-1}) \subseteq \operatorname{span}(\mathcal{K}_j)$, and $\mathbf{v}_j$ is an entry of $\mathcal{K}_j$. By Corollary 1.3.19, $\operatorname{span}(\mathcal{K}_j) = S_j$.
- If $\mathbf{v}_j$ is deleted, then $\mathcal{K}_j = \mathcal{K}_{j-1}$ and $\mathbf{v}_j \in S_{j-1}$, so $S_j = S_{j-1}$ by Corollary 1.3.20(c). Hence $\operatorname{span}(\mathcal{K}_j) = \operatorname{span}(\mathcal{K}_{j-1}) = S_{j-1} = S_j$.

For $j = k$ this gives $\operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{K}_k) = S_k = \operatorname{span}(\mathcal{L})$.

For independence, let $\mathbf{v}_j$ be a kept entry. The entries of $\mathcal{L}'$ that come before it form $\mathcal{K}_{j-1}$, whose span is S_{j-1}, and $\mathbf{v}_j \notin S_{j-1}$ by definition. So no entry of $\mathcal{L}'$ lies in the span of the entries of $\mathcal{L}'$ before it, and $\mathcal{L}'$ is independent by Corollary 1.5.13. □

Example 1.6.11 (Sifting a list of polynomials). In $\mathbb{R}[x]_{\le 2}$, let

$$\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_5 = 1 + x, \quad 2 + 2x, \quad x - x^2, \quad 1 + x^2, \quad x^2.$$

We sift. The entry $\mathbf{v}_1 = 1 + x$ is nonzero, so it is kept. Next, $\mathbf{v}_2 = 2\mathbf{v}_1$ lies in $\operatorname{span}(\mathbf{v}_1)$ and is deleted. Every vector of $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2) = \operatorname{span}(1 + x)$ has degree at most 1, so $\mathbf{v}_3 = x - x^2$ is kept. Then $\mathbf{v}_4 = 1 + x^2 = (1 + x) - \big(x - x^2\big)$ is deleted. Finally, a linear combination

$$a(1 + x) + b\big(x - x^2\big) = a + (a + b)x - bx^2$$

equals x^2 only if $a = 0$, $b = -1$, and $a + b = 0$, which is impossible. So $\mathbf{v}_5 = x^2$ is kept, and sifting produces

$$\mathcal{L}' = 1 + x, \quad x - x^2, \quad x^2,$$

a basis of $\operatorname{span}(\mathcal{L})$. Here $\operatorname{span}(\mathcal{L})$ is all of $\mathbb{R}[x]_{\leq 2}$, because x^2, $x = \big(x - x^2\big) + x^2$, and $1 = (1 + x) - x$ lie in $\operatorname{span}(\mathcal{L}')$ (Proposition 1.3.18). So $\mathcal{L}'$ is a basis of $\mathbb{R}[x]_{\leq 2}$.

Other sublists of $\mathcal{L}$ are bases too. For instance, $2 + 2x, 1 + x^2, x^2$ is independent and spans $\mathbb{R}[x]_{\leq 2}$, as one checks in the same way. So a spanning list usually contains several bases, and sifting picks a particular one, determined by the order of the entries: it keeps an entry exactly when the entries before it do not already account for it.

Exercise 1.6.12. ROUTINE Let $\mathcal{L} = (1, 0), (1, 1), (2, 2), (0, 1)$ in $\mathbb{R}^2$. Find all sublists of $\mathcal{L}$ that are bases of $\mathbb{R}^2$.

Solution on page 1074

Minimal spanning lists and maximal independent lists

The first proof deletes entries until no entry can be deleted without shrinking the span. The next result says that this stopping condition characterizes bases, and that so does the mirror-image condition for independent lists, to which no vector can be appended.

Proposition 1.6.13 (Bases are minimal spanning lists and maximal independent lists). Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a list in V. The following are equivalent.

(i) $\mathcal{B}$ is a basis of V.
(ii) $\mathcal{B}$ spans V, and for every j, the list obtained by deleting $\mathbf{v}_j$ from $\mathcal{B}$ does not span V.
(iii) $\mathcal{B}$ is linearly independent, and for every $\mathbf{w} \in V$, the list $\mathcal{B}, \mathbf{w}$ is linearly dependent.

Proof. STANDARD

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Lemma 1.5.10 (Linear dependence lemma), Proposition 1.5.14 (Appending a vector), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. Prove (i) ⇔ (ii) and (i) ⇔ (iii). In each, one half of the definition of a basis is common to both statements.
Hint 2. For (ii) ⇒ (i), suppose $\mathcal{B}$ were dependent and apply Lemma 1.5.10. For (i) ⇒ (ii), if deleting $\mathbf{v}_j$ leaves a spanning list, write $\mathbf{v}_j$ as a combination of the others.
Hint 3. For (iii), use Proposition 1.5.14: for independent $\mathcal{B}$, the list $\mathcal{B}, \mathbf{w}$ is independent exactly when $\mathbf{w} \notin \operatorname{span}(\mathcal{B})$.
Sketch. (i) ⇒ (ii): if the list without $\mathbf{v}_j$ spans V, then $\mathbf{v}_j = \sum_{i \neq j} b_i \mathbf{v}_i$, and the coefficients b_i and -1 form a dependence relation of $\mathcal{B}$. (ii) ⇒ (i): if $\mathcal{B}$ were dependent, Lemma 1.5.10 would delete an entry without changing the span V. (i) ⇔ (iii): for independent $\mathcal{B}$, by Proposition 1.5.14, $\mathcal{B}, \mathbf{w}$ is dependent for every $\mathbf{w}$ exactly when every $\mathbf{w}$ lies in $\operatorname{span}(\mathcal{B})$, that is, when $\mathcal{B}$ spans V.

Throughout we use Proposition 1.6.2: (i) says that $\mathcal{B}$ spans V and is independent. Write $\mathcal{B}_j$ for $\mathcal{B}$ with $\mathbf{v}_j$ deleted.

(i) ⇒ (ii). Suppose that $\mathcal{B}$ is a basis, and suppose that $\mathcal{B}_j$ spans V for some j. Then $\mathbf{v}_j \in \operatorname{span}\big(\mathcal{B}_j\big)$, say $\mathbf{v}_j = \sum_{i \neq j} b_i \mathbf{v}_i$. The linear combination of $\mathcal{B}$ with coefficient b_i on $\mathbf{v}_i$ for $i \neq j$ and -1 on $\mathbf{v}_j$ represents $\mathbf{v}_j - \mathbf{v}_j = \mathbf{0}$, and it is nontrivial. This contradicts the independence of $\mathcal{B}$ (Theorem 1.5.5). So no $\mathcal{B}_j$ spans V.

(ii) ⇒ (i). Suppose (ii). Then $\mathcal{B}$ spans V, and it remains to show that $\mathcal{B}$ is independent. If it were dependent, Lemma 1.5.10 would give an index j with $\operatorname{span}\big(\mathcal{B}_j\big) = \operatorname{span}(\mathcal{B}) = V$, contradicting (ii).

(i) ⇔ (iii). Both statements include the independence of $\mathcal{B}$, so assume it. By Proposition 1.5.14, for $\mathbf{w} \in V$ the list $\mathcal{B}, \mathbf{w}$ is dependent if and only if $\mathbf{w} \in \operatorname{span}(\mathcal{B})$. So $\mathcal{B}, \mathbf{w}$ is dependent for every $\mathbf{w} \in V$ if and only if $V \subseteq \operatorname{span}(\mathcal{B})$, that is, if and only if $\mathcal{B}$ spans V. □

In (ii), deleting one entry suffices: if some sublist of $\mathcal{B}$ shorter than $\mathcal{B}$ spans V, then so does any $\mathcal{B}_j$ containing it, since enlarging a list can only enlarge its span (Corollary 1.3.20(b)). So (ii) says that $\mathcal{B}$ is a spanning list from which nothing can be removed, and (iii) says that $\mathcal{B}$ is an independent list to which nothing can be added. These are statements about removing and adding entries, not about lengths. In Section 4.1 they become statements about lengths: every independent list is at most as long as every spanning list (Lemma 4.1.2).

1.6.4 Coordinates

Choosing a basis of V amounts to choosing a coordinate system for V. The lecture marks the next definition as important, and it is the reason bases are worth having: every vector of V gets a name in F^n, and the name determines the vector.

Definition 1.6.14 (Coordinates). Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of V, and let $\mathbf{v} \in V$. Let $a_1, ..., a_n$ be the coefficients of the unique linear combination of $\mathcal{B}$ that represents $\mathbf{v}$, so that $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. The **coordinate vector** of $\mathbf{v}$ with respect to $\mathcal{B}$, or the **$\mathcal{B}$-coordinates** of $\mathbf{v}$, is

$$[\mathbf{v}]_{\mathcal{B}} = \begin{pmatrix} a_1 \\ \vdots \\ a_n \end{pmatrix} \in F^n,$$

and a_i is the **i-th coordinate** of $\mathbf{v}$ with respect to $\mathcal{B}$. The function $V \to F^n$, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$, is the **coordinate map** of $\mathcal{B}$.

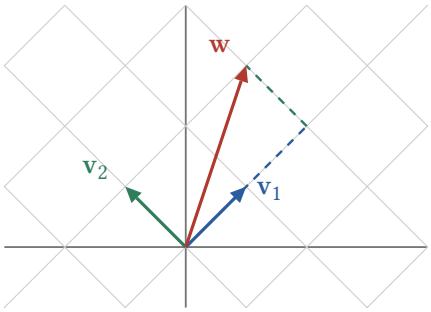
For $n = 0$, that is, for the basis () of $\{\mathbf{0}\}$, we use the convention that $F^0 = \{\mathbf{0}\}$ consists of the empty column, so that $[\mathbf{0}]_{()} = \mathbf{0}$. With it, everything below holds for $n = 0$ as well.

The definition makes sense because $\mathcal{B}$ is a basis: some linear combination represents $\mathbf{v}$ since $\mathcal{B}$ spans, and only one does since $\mathcal{B}$ is independent. Read in reverse, it says that for every column $(a_1, ..., a_n) \in F^n$,

$$[\mathbf{v}]_{\mathcal{B}} = (a_1, ..., a_n) \quad \text{if and only if} \quad \mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n. \tag{1.6.1}$$

The forward direction is the definition. For the backward direction, if the combination with coefficients $a_1, ..., a_n$ represents $\mathbf{v}$, then it is *the* combination representing $\mathbf{v}$, by uniqueness. This is how coordinates are computed in practice: to find $[\mathbf{v}]_{\mathcal{B}}$, find any linear combination of $\mathcal{B}$ that represents $\mathbf{v}$. For instance, $[\mathbf{v}_j]_{\mathcal{B}} = \mathbf{e}_j$, since $\mathbf{v}_j$ is the combination with coefficient 1 on $\mathbf{v}_j$ and 0 elsewhere, and $[\mathbf{0}]_{\mathcal{B}} = \mathbf{0}$.

In the standard bases, coordinates are the familiar numbers. By the proof of Proposition 1.6.7, the coordinate vector of $\mathbf{x} \in F^n$ in the standard basis is $\mathbf{x}$ itself. That of $A \in F^{m \times n}$ is



$$(a_{11}, a_{12}, ..., a_{1n}, a_{21}, ..., a_{mn}) \in F^{mn},$$

the entries of A read row by row. That of $a_0 + a_1x + \cdots + a_nx^n$ is $(a_0, a_1, ..., a_n) \in F^{n+1}$, the list of its coefficients; note the shift, as the i-th coordinate of a polynomial is its coefficient a_{i-1}. For other bases, coordinates take some work to compute, and they carry information that the entries do not show directly.

Example 1.6.15 (Coordinates in the plane). In $\mathbb{R}^2$, let $\mathcal{B} = \mathbf{v}_1, \mathbf{v}_2 = (1, 1), (-1, 1)$. Solving $a(1, 1) + b(-1, 1) = (x, y)$, that is, $a - b = x$ and $a + b = y$, gives the unique solution $a = (x + y)/2$, $b = (y - x)/2$. So $\mathcal{B}$ is a basis, and

$$[(x, y)]_{\mathcal{B}} = \begin{pmatrix} (x + y)/2 \\ (y - x)/2 \end{pmatrix}.$$

For $\mathbf{w} = (1, 3)$ this gives $[\mathbf{w}]_{\mathcal{B}} = (2, 1)$: indeed $\mathbf{w} = 2\mathbf{v}_1 + \mathbf{v}_2$. The standard coordinates $(1, 3)$ say how to reach $\mathbf{w}$ along the horizontal and vertical grid lines: one step right, three steps up. The $\mathcal{B}$-coordinates say how to reach it along the tilted grid of lines parallel to $\mathbf{v}_1$ and $\mathbf{v}_2$: two steps along $\mathbf{v}_1$, then one along $\mathbf{v}_2$.

The basis $\mathbf{v}_1, \mathbf{v}_2 = (1, 1), (-1, 1)$ and $\mathbf{w} = (1, 3) = 2\mathbf{v}_1 + \mathbf{v}_2$, so $[\mathbf{w}]_{\mathcal{B}} = (2, 1)$. In the interactive version, the coefficients that the explorer reports for $\mathbf{w}$ are its $\mathcal{B}$-coordinates; drag $\mathbf{w}$ to see them change. Drag $\mathbf{v}_2$ onto the line through $\mathbf{v}_1$: the list becomes dependent, $\mathbf{w}$ gets many representations or none, and coordinates no longer make sense. (Interactive in the web version.)

The order of the entries of $\mathcal{B}$ matters. The list $\mathbf{v}_2, \mathbf{v}_1$ is also a basis, and in it the coordinates of $\mathbf{w}$ are $(1, 2)$. This is one reason bases are lists rather than sets.

Coordinates name every vector of V, and different vectors get different names. The lecture records this as an observation.

Proposition 1.6.16 (The coordinate map is a bijection). Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V. The coordinate map $V \to F^n$, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$, is a bijection. Its inverse is

$$F^n \to V, \quad (a_1, \ldots, a_n) \mapsto a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n.$$

Proof. ROUTINE

Uses. Definition 1.6.14 (Coordinates), (1.6.1)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Call the proposed inverse Φ. A function with a two-sided inverse is a bijection. Check $\Phi([\mathbf{v}]_{\mathcal{B}}) = \mathbf{v}$ and $[\Phi(\mathbf{a})]_{\mathcal{B}} = \mathbf{a}$.
Hint 2. The first identity is the definition of $[\mathbf{v}]_{\mathcal{B}}$. For the second, which linear combination of $\mathcal{B}$ represents $\Phi(\mathbf{a})$?
Sketch. Let $\Phi(a_1, \ldots, a_n) = \sum a_i\mathbf{v}_i$. By definition, $[\mathbf{v}]_{\mathcal{B}}$ lists coefficients representing $\mathbf{v}$, so $\Phi([\mathbf{v}]_{\mathcal{B}}) = \mathbf{v}$. The combination with coefficients a_i represents $\Phi(\mathbf{a})$, so by uniqueness $[\Phi(\mathbf{a})]_{\mathcal{B}} = \mathbf{a}$ ((1.6.1)). So the two maps are inverse to each other.

Let $\Phi : F^n \to V$ be the map $(a_1, \ldots, a_n) \mapsto a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. For $\mathbf{v} \in V$ with $[\mathbf{v}]_{\mathcal{B}} = (a_1, \ldots, a_n)$, we have $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$ by Definition 1.6.14, that is, $\Phi([\mathbf{v}]_{\mathcal{B}}) = \mathbf{v}$. For $\mathbf{a} = (a_1, \ldots, a_n) \in F^n$, the combination with coefficients $a_1, \ldots, a_n$ represents $\Phi(\mathbf{a})$, so $[\Phi(\mathbf{a})]_{\mathcal{B}} = \mathbf{a}$ by (1.6.1). So Φ is a two-sided inverse of the coordinate map, and both maps are bijections. □

For a fixed basis the correspondence is perfect, but it depends heavily on the basis, as the lecture's example shows.

Example 1.6.17 (One polynomial, two bases). In $\mathbb{R}[x]_{\leq 2}$, let $\mathcal{B} = 1, x, x^2$ be the standard basis and let $\mathcal{C} = 1, 1 + x, 1 + x + x^2$. To see that $\mathcal{C}$ is a basis, solve

$$a \cdot 1 + b(1 + x) + c\big(1 + x + x^2\big) = (a + b + c) + (b + c)x + cx^2 = p_0 + p_1x + p_2x^2.$$

Comparing coefficients, $c = p_2$, then $b = p_1 - p_2$, then $a = p_0 - p_1$, and these values do solve the equation. So every polynomial of degree at most 2 is represented by exactly one linear combination of $\mathcal{C}$, and

$$[p_0 + p_1x + p_2x^2]_{\mathcal{C}} = \begin{pmatrix} p_0 - p_1 \\ p_1 - p_2 \\ p_2 \end{pmatrix}, \quad \text{while} \quad [p_0 + p_1x + p_2x^2]_{\mathcal{B}} = \begin{pmatrix} p_0 \\ p_1 \\ p_2 \end{pmatrix}.$$

For $p = x + x^2$,

$$[x + x^2]_{\mathcal{B}} = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}, \quad [x + x^2]_{\mathcal{C}} = \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix},$$

and indeed $x + x^2 = -1 + 0(1 + x) + \left(1 + x + x^2\right)$. The same vector has different coordinates in different bases, and the column $(0, 1, 1)$ names $x + x^2$ in $\mathcal{B}$ but names $(1 + x) + \left(1 + x + x^2\right) = 2 + 2x + x^2$ in $\mathcal{C}$. How $[\mathbf{v}]_{\mathcal{B}}$ and $[\mathbf{v}]_{\mathcal{C}}$ are related for two bases is the subject of Section 4.5.

Over $\mathbb{R}$, the basis $1, i$ of $\mathbb{C}$ (Example 1.6.5) gives $[a + bi]_{(1,i)} = (a, b)$. This is the identification of $\mathbb{C}$ with the plane $\mathbb{R}^2$, and Proposition 1.6.16 makes it a bijection.

Exercise 1.6.18. ROUTINE Let $\mathcal{T} = 1, x - 1, x^2 - 2x + 1$ in $F[x]_{\leq 2}$.

(a) Show that $\mathcal{T}$ is a basis of $F[x]_{\leq 2}$.

(b) Show that $\left[a + bx + cx^2\right]_{\mathcal{T}} = (a + b + c, b + 2c, c)$.

(c) Explain why the first coordinate of $[p]_{\mathcal{T}}$ is $p(1)$ for every $p \in F[x]_{\leq 2}$.

Solution on page 1075

Coordinates respect linear combinations

The coordinate map is a bijection, and it is compatible with the vector space operations: adding in V and then taking coordinates gives the same column as taking coordinates and then adding in F^n. This is what makes coordinates useful for computation.

Proposition 1.6.19 (Coordinates respect linear combinations). Let $\mathcal{B}$ be a basis of V of length n.

(a) For all $\mathbf{x}, \mathbf{y} \in V$, $[\mathbf{x} + \mathbf{y}]_{\mathcal{B}} = [\mathbf{x}]_{\mathcal{B}} + [\mathbf{y}]_{\mathcal{B}}$.

(b) For all $c \in F$ and $\mathbf{x} \in V$, $[c\mathbf{x}]_{\mathcal{B}} = c[\mathbf{x}]_{\mathcal{B}}$.

(c) For all $k \geq 0$, all $\mathbf{x}_1, \ldots, \mathbf{x}_k \in V$, and all $c_1, \ldots, c_k \in F$,

$$[c_1\mathbf{x}_1 + \cdots + c_k\mathbf{x}_k]_{\mathcal{B}} = c_1[\mathbf{x}_1]_{\mathcal{B}} + \cdots + c_k[\mathbf{x}_k]_{\mathcal{B}}.$$

On each left side the operations are those of V, and on each right side those of F^n.

Proof. ROUTINE

Uses. Definition 1.6.14 (Coordinates), (1.6.1), Lemma 1.3.9 (Arithmetic of linear combinations), Definition 1.2.4 (The space F^n), (1.3.1)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. By (1.6.1), to show $[\mathbf{w}]_{\mathcal{B}} = (d_1, \ldots, d_n)$ it suffices to exhibit $\mathbf{w}$ as $\sum d_i\mathbf{v}_i$.
Hint 2. For (a), write $\mathbf{x} = \sum a_i\mathbf{v}_i$ and $\mathbf{y} = \sum b_i\mathbf{v}_i$, and combine the two sums with Lemma 1.3.9. Do (b) the same way.
Hint 3. For (c), induct on k. Split off the last term $c_k\mathbf{x}_k$ and apply (a), (b), and the inductive hypothesis.
Sketch. If $[\mathbf{x}]_{\mathcal{B}} = (a_i)$ and $[\mathbf{y}]_{\mathcal{B}} = (b_i)$, then $\mathbf{x} + \mathbf{y} = \sum(a_i + b_i)\mathbf{v}_i$ and $c\mathbf{x} = \sum(ca_i)\mathbf{v}_i$ by Lemma 1.3.9, so by (1.6.1) the coordinates are $(a_i + b_i)$ and (ca_i), which are $[\mathbf{x}]_{\mathcal{B}} + [\mathbf{y}]_{\mathcal{B}}$ and $c[\mathbf{x}]_{\mathcal{B}}$. For (c), induct on k: the empty sum is $\mathbf{0}$ with coordinates $\mathbf{0}$, and $[\mathbf{u} + c_k\mathbf{x}_k]_{\mathcal{B}} = [\mathbf{u}]_{\mathcal{B}} + c_k[\mathbf{x}_k]_{\mathcal{B}}$ by (a) and (b).

Write $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$.

(a) Let $[\mathbf{x}]_{\mathcal{B}} = (a_1, \ldots, a_n)$ and $[\mathbf{y}]_{\mathcal{B}} = (b_1, \ldots, b_n)$, so that $\mathbf{x} = \sum_i a_i\mathbf{v}_i$ and $\mathbf{y} = \sum_i b_i\mathbf{v}_i$. By Lemma 1.3.9(a),

$$\mathbf{x}+\mathbf{y}=\sum_{i=1}^{n}a_i\mathbf{v}_i+\sum_{i=1}^{n}b_i\mathbf{v}_i=\sum_{i=1}^{n}(a_i+b_i)\mathbf{v}_i.$$

So the combination with coefficients $a_1+b_1,\dots,a_n+b_n$ represents $\mathbf{x}+\mathbf{y}$, and by (1.6.1),

$$[\mathbf{x}+\mathbf{y}]_{\mathcal{B}}=\begin{pmatrix}a_1+b_1\\ \vdots\\ a_n+b_n\end{pmatrix}=\begin{pmatrix}a_1\\ \vdots\\ a_n\end{pmatrix}+\begin{pmatrix}b_1\\ \vdots\\ b_n\end{pmatrix}=[\mathbf{x}]_{\mathcal{B}}+[\mathbf{y}]_{\mathcal{B}},$$

where the middle equality is the definition of addition in F^n (Definition 1.2.4).

(b) With $[\mathbf{x}]_{\mathcal{B}}=(a_1,\dots,a_n)$ as before, Lemma 1.3.9(b) gives $c\mathbf{x}=\sum_i(ca_i)\mathbf{v}_i$. So $[c\mathbf{x}]_{\mathcal{B}}=(ca_1,\dots,ca_n)=c[\mathbf{x}]_{\mathcal{B}}$, by (1.6.1) and the definition of scalar multiplication in F^n.

(c) We induct on k. For $k=0$ both sides are empty sums: the left side is $[\mathbf{0}]_{\mathcal{B}}=\mathbf{0}$, and the right side is $\mathbf{0}\in F^n$. Suppose that (c) holds for combinations of length k, and let $\mathbf{u}=c_1\mathbf{x}_1+\cdots+c_k\mathbf{x}_k$. By (1.3.1), then (a), then (b) and the inductive hypothesis,

$$\begin{aligned}[c_1\mathbf{x}_1+\cdots+c_{k+1}\mathbf{x}_{k+1}]_{\mathcal{B}}&=[\mathbf{u}+c_{k+1}\mathbf{x}_{k+1}]_{\mathcal{B}}=[\mathbf{u}]_{\mathcal{B}}+[c_{k+1}\mathbf{x}_{k+1}]_{\mathcal{B}}\\&=\big(c_1[\mathbf{x}_1]_{\mathcal{B}}+\cdots+c_k[\mathbf{x}_k]_{\mathcal{B}}\big)+c_{k+1}[\mathbf{x}_{k+1}]_{\mathcal{B}},\end{aligned}$$

as desired. □

The lecture calls (c) the "Mega-Prop": the coordinate map *respects linear combinations*. Functions between vector spaces with this property are the linear maps of Section 2.1 (Definition 2.1.1), and the induction in (c) shows in general that (a) and (b) are enough to check (Theorem 2.1.3). So the coordinate map of a basis is a linear map, and by Proposition 1.6.16 it is a bijection. Such a map is an isomorphism (Section 4.5): once a basis of length n is chosen, V and F^n are the same vector space with different names for the vectors.

The practical consequence is that every question about linear combinations in V can be asked in F^n instead.

Proposition 1.6.20 (Coordinates translate questions about V into F^n). Let $\mathcal{B}$ be a basis of V of length n, and let $\mathbf{x}_1,\dots,\mathbf{x}_k,\mathbf{w}\in V$. For all $c_1,\dots,c_k\in F$,

$$c_1\mathbf{x}_1+\cdots+c_k\mathbf{x}_k=\mathbf{w}\quad\text{ if and only if }\quad c_1[\mathbf{x}_1]_{\mathcal{B}}+\cdots+c_k[\mathbf{x}_k]_{\mathcal{B}}=[\mathbf{w}]_{\mathcal{B}}.$$

Consequently:

(a) $\mathbf{x}_1,\dots,\mathbf{x}_k$ is linearly independent in V if and only if $[\mathbf{x}_1]_{\mathcal{B}},\dots,[\mathbf{x}_k]_{\mathcal{B}}$ is linearly independent in F^n;

(b) $\mathbf{w}\in\operatorname{span}(\mathbf{x}_1,\dots,\mathbf{x}_k)$ if and only if $[\mathbf{w}]_{\mathcal{B}}\in\operatorname{span}\big([\mathbf{x}_1]_{\mathcal{B}},\dots,[\mathbf{x}_k]_{\mathcal{B}}\big)$;

(c) $\mathbf{x}_1,\dots,\mathbf{x}_k$ spans V if and only if $[\mathbf{x}_1]_{\mathcal{B}},\dots,[\mathbf{x}_k]_{\mathcal{B}}$ spans F^n. In particular, $\mathbf{x}_1,\dots,\mathbf{x}_k$ is a basis of V if and only if $[\mathbf{x}_1]_{\mathcal{B}},\dots,[\mathbf{x}_k]_{\mathcal{B}}$ is a basis of F^n.

Proof. ROUTINE

Uses. Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 1.6.16 (The coordinate map is a bijection), Theorem 1.5.5 (Independence is decided at zero), Definition 1.3.10 (Span), Proposition 1.6.2 (Bases are independent spanning lists)

Hint 1. For the displayed equivalence, apply the coordinate map to the left equation, and use that it is injective for the converse.

Hint 2. Then (a) is the case $\mathbf{w}=\mathbf{0}$, and (b) is a restatement. For (c), every vector of F^n is $[\mathbf{w}]_{\mathcal{B}}$ for some $\mathbf{w}\in V$.

Sketch. By Proposition 1.6.19(c), $[\sum c_i\mathbf{x}_i]_{\mathcal{B}}=\sum c_i[\mathbf{x}_i]_{\mathcal{B}}$, and the coordinate map is injective, so $\sum c_i\mathbf{x}_i=\mathbf{w}$ exactly when the coordinates agree. So the two lists have the same linear relations (take $\mathbf{w}=\mathbf{0}$), and $\mathbf{w}$ is in one span exactly when $[\mathbf{w}]_{\mathcal{B}}$ is in the other. Since the coordinate map is surjective, (b) for all $\mathbf{w}$ gives (c).

By Proposition 1.6.19(c), $[c_1\mathbf{x}_1 + \cdots + c_k\mathbf{x}_k]_{\mathcal{B}} = c_1[\mathbf{x}_1]_{\mathcal{B}} + \cdots + c_k[\mathbf{x}_k]_{\mathcal{B}}$. The coordinate map is injective (Proposition 1.6.16), so two vectors of V are equal if and only if their coordinate vectors are. Applying this to $\sum_i c_i\mathbf{x}_i$ and $\mathbf{w}$ proves the displayed equivalence.

(a) Since $[\mathbf{0}]_{\mathcal{B}} = \mathbf{0}$, the case $\mathbf{w} = \mathbf{0}$ says that the two lists have exactly the same linear relations. So one has only the trivial relation if and only if the other does, and (a) follows from Theorem 1.5.5.

(b) By the displayed equivalence, some $c_1, \ldots, c_k$ satisfy the left equation if and only if they satisfy the right one.

(c) Suppose that the $\mathbf{x}_i$ span V, and let $\mathbf{y} \in F^n$. The coordinate map is surjective, so $\mathbf{y} = [\mathbf{w}]_{\mathcal{B}}$ for some $\mathbf{w} \in V$. Since $\mathbf{w} \in \operatorname{span}(\mathbf{x}_1, \ldots, \mathbf{x}_k)$, (b) gives $\mathbf{y} \in \operatorname{span}\big([\mathbf{x}_1]_{\mathcal{B}}, \ldots, [\mathbf{x}_k]_{\mathcal{B}}\big)$. Conversely, if the coordinate vectors span F^n, then for every $\mathbf{w} \in V$, $[\mathbf{w}]_{\mathcal{B}}$ lies in their span, so $\mathbf{w} \in \operatorname{span}(\mathbf{x}_1, \ldots, \mathbf{x}_k)$ by (b). The last statement follows from (a), (c), and Proposition 1.6.2. □

Example 1.6.21 (Testing polynomials through their coordinates). In $F[x]_{\leq 2}$, consider $1 + x + x^2$, $1 + 2x + 3x^2$, $1 + 4x + 9x^2$. Their coordinate vectors in the standard basis are $(1,1,1), (1,2,3), (1,4,9)$. In Exercise 1.5.29 we reduced a linear relation among these columns to $2c = 0$, using steps that are valid over every field, so the columns are independent when $1 + 1 \neq 0$. When $1 + 1 = 0$, the last two columns are both $(1,0,1)$, so they are dependent. By Proposition 1.6.20(a), the three polynomials are linearly independent if and only if $1 + 1 \neq 0$ in F. Nothing about polynomials was used beyond their coordinates. In the same way, questions about matrices in $F^{m\times n}$ become questions about columns in F^{mn}, and Section 3.1 solves such questions systematically.

> **Exercise 1.6.22.** ROUTINE Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ and $\mathcal{C} = \mathbf{w}_1, \ldots, \mathbf{w}_n$ be bases of V such that $[\mathbf{v}]_{\mathcal{B}} = [\mathbf{v}]_{\mathcal{C}}$ for every $\mathbf{v} \in V$. Show that $\mathcal{B} = \mathcal{C}$.

Solution on page 1075

1.6.5 Finite and infinite dimension

Theorem 1.6.10 produces a basis from any spanning list. It applies exactly to the spaces that have a spanning list.

> **Definition 1.6.23** (Finite-dimensional). A vector space V is **finite-dimensional** if some list in V spans V. Otherwise V is **infinite-dimensional**.

The name anticipates Section 4.1, where the dimension of a finite-dimensional space is defined as the common length of its bases (Definition 4.1.5). Every space in Section 1.6.2 is finite-dimensional, as are $\{\mathbf{0}\}$ (spanned by ()), $\mathbb{C}$ over $\mathbb{R}$, and the span of any list.

> **Corollary 1.6.24** (Bases exist in finite dimensions). Every finite-dimensional vector space has a basis. More precisely, every spanning list of V contains a basis of V as a sublist.

Proof. ROUTINE

> *Uses.* Definition 1.6.23 (Finite-dimensional), Theorem 1.6.10 (Every spanning list contains a basis)
> *Hint 1.* What does the definition of finite-dimensional provide?
> *Hint 2.* Apply Theorem 1.6.10 to it.
> *Sketch.* A finite-dimensional space has a spanning list, and by Theorem 1.6.10 that list has a sublist which is a basis.

If V is finite-dimensional, some list $\mathcal{L}$ spans V. By Theorem 1.6.10, some sublist of $\mathcal{L}$ is a basis of V. The same argument applies to every spanning list of V. □

Not every vector space is finite-dimensional. The basic example is $F[x]$, and the reason is the degree.

Proposition 1.6.25 (No finite list spans $F[x]$). For every list $p_1, ..., p_k$ in $F[x]$, $\operatorname{span}(p_1, ..., p_k) \neq F[x]$. So $F[x]$ is infinite-dimensional.

Proof. ROUTINE

Uses. Example 1.4.9 (Polynomials), Proposition 1.4.14 (The span is the smallest subspace containing a list), Definition 1.2.16 (Degree)
Hint 1. Every linear combination of $p_1, ..., p_k$ has degree at most the largest of the degrees $\deg p_i$. Find a polynomial of larger degree.
Hint 2. Let d be the largest of $0, \deg p_1, ..., \deg p_k$. Then every p_i lies in the subspace $F[x]_{\leq d}$. What does Proposition 1.4.14 say about the span?
Sketch. With $d = \max(0, \deg p_1, ..., \deg p_k)$, all p_i lie in the subspace $F[x]_{\leq d}$, hence so does their span (Proposition 1.4.14). But $x^{d+1} \notin F[x]_{\leq d}$.

Let d be the largest of the integers $0, \deg p_1, ..., \deg p_k$, where an entry $\deg p_i = -\infty$ (for $p_i = \mathbf{0}$) does not affect the maximum, and $d = 0$ if $k = 0$. Then $p_1, ..., p_k \in F[x]_{\leq d}$, which is a subspace of $F[x]$ (Example 1.4.9). By Proposition 1.4.14(b), $\operatorname{span}(p_1, ..., p_k) \subseteq F[x]_{\leq d}$. The polynomial x^{d+1} has degree $d + 1 > d$, so it is not in $F[x]_{\leq d}$, and hence not in $\operatorname{span}(p_1, ..., p_k)$. So no list spans $F[x]$, and $F[x]$ is infinite-dimensional by Definition 1.6.23. □

So $F[x]$ has no basis in our sense, since a basis is a finite list that spans. Other infinite-dimensional spaces are $\mathbb{R}$ over $\mathbb{Q}$ (Exercise 1.3.45) and the space of finitely supported functions on an infinite set. Function spaces such as $\mathbb{R}^{\mathbb{R}}$ and $C[0, 1]$ are infinite-dimensional too, but proving it is easier with the tools of Section 4.1, which show that a subspace of a finite-dimensional space is finite-dimensional (Proposition 4.1.21).

Remark 1.6.26 (Thinning down and growing up). Proposition 1.6.13 suggests two ways to reach a basis. *Thinning down:* start with a spanning list and delete redundant entries, as in Theorem 1.6.10. *Growing up:* start with an independent list and, as long as it does not span V, append a vector outside its span, which keeps it independent by Proposition 1.5.14. By Proposition 1.6.13, either process can only stop at a basis.

The difference is that thinning always stops, because a list has only finitely many entries to delete, while growing need not stop. In $F[x]$ it never stops, whatever vectors are appended, because no list spans $F[x]$ (Proposition 1.6.25). For instance, starting from the empty list and appending 1, then x, then x^2, and so on, every stage $1, x, ..., x^n$ is independent (Example 1.5.7), and there is always a next power of x outside its span. In a finite-dimensional space growing does stop, because an independent list can never be longer than a spanning list (Lemma 4.1.2). That is how Section 4.1 proves that every independent list extends to a basis (Theorem 4.1.16). In infinite dimensions, making "grow forever" produce a basis needs set theory, which the next aside describes.

ASIDE: *Bases of infinite-dimensional spaces* BEYOND 21-242

Allowing bases to be infinite subsets fixes the problem. A subset $B \subseteq V$ is called a **basis** (or **Hamel basis**) of V if every vector of V is represented by exactly one linear combination of finitely many distinct elements of B, up to terms with coefficient 0. Equivalently, B is linearly independent (Aside (Independent sets)) and spans V (Aside (Spans of infinite sets)). The set $\{1, x, x^2, ...\}$ is a basis of $F[x]$ in this sense, and the coordinates of a polynomial with respect to it are its coefficient sequence, which is how Definition 1.2.13 defined $F[x]$ in the first place. Every vector space has a basis in this sense, but the proof uses Zorn's lemma and gives no way to write one down for $\mathbb{R}$ over $\mathbb{Q}$ or for $\mathbb{R}^{\mathbb{R}}$ (Section 15.1).

Exercises

Exercise 1.6.27. ROUTINE Decide whether each list is a basis of the given space, and justify your answer.

(a) $(1,2,0),(0,1,2),(2,0,1)$ in F^3. (The answer depends on F.)

(b) $1+x^2, x-x^2, 2+x+x^2$ in $\mathbb{R}[x]_{\leq 2}$.

(c) $U_{11}, U_{12}+U_{21}, U_{22}$ in $\mathbb{R}^{2\times 2}$.

Solution on page 1075

Exercise 1.6.28. ROUTINE

(a) Show that $\mathcal{B} = (1,1,1),(0,1,1),(0,0,1)$ is a basis of F^3, find $[(x,y,z)]_{\mathcal{B}}$, and find the vector $\mathbf{v} \in F^3$ with $[\mathbf{v}]_{\mathcal{B}} = (1,2,3)$.

(b) In $F^{2\times 2}$, let

$$\mathcal{C} = U_{11}, \quad U_{11}+U_{12}, \quad U_{11}+U_{12}+U_{21}, \quad U_{11}+U_{12}+U_{21}+U_{22}.$$

Show that $\mathcal{C}$ is a basis and find $[A]_{\mathcal{C}}$ for $A = \begin{pmatrix} p & q \\ r & s \end{pmatrix}$.

Solution on page 1076

Exercise 1.6.29. ROUTINE For which $c \in \mathbb{R}$ is $1+x^2, x+x^2, 1+x+cx^2$ a basis of $\mathbb{R}[x]_{\leq 2}$? Work with coordinate vectors.

Solution on page 1076

Exercise 1.6.30. ROUTINE

(a) Find the error in the following argument.

Claim. Every spanning list of V contains a basis of V.

Proof. We induct on the length k of the spanning list $\mathcal{L}$. If $k = 0$, then $\mathcal{L} = ()$ spans V, so $V = \{\mathbf{0}\}$, and $()$ is a basis of V. Suppose the claim holds for spanning lists of length k, and let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_{k+1}$ span V. If $\mathcal{L}$ is independent, it is a basis. Otherwise, delete its last entry. The list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ has length k, so by the inductive hypothesis it contains a basis of V, which is also a sublist of $\mathcal{L}$.

(b) Repair the argument.

Solution on page 1077

Exercise 1.6.31. ROUTINE The list $\mathcal{L} = (1,0),(0,1),(1,1)$ spans $\mathbb{R}^2$. A student defines $[\mathbf{v}]_{\mathcal{L}} \in \mathbb{R}^3$ to be "the coefficients of a linear combination of $\mathcal{L}$ that represents $\mathbf{v}$", and concludes that $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{L}}$ is a function $\mathbb{R}^2 \to \mathbb{R}^3$ satisfying $[\mathbf{x}+\mathbf{y}]_{\mathcal{L}} = [\mathbf{x}]_{\mathcal{L}} + [\mathbf{y}]_{\mathcal{L}}$, by the proof of Proposition 1.6.19.

(a) What is wrong with the definition, and which step of the proof of Proposition 1.6.19(a) fails for $\mathcal{L}$?

(b) Let $c : \mathbb{R}^2 \to \mathbb{R}^3$ be any function such that $c(\mathbf{v})$ is the list of coefficients of some linear combination of $\mathcal{L}$ representing $\mathbf{v}$, for every $\mathbf{v}$. Show that c is injective but not surjective.

Solution on page 1077

Exercise 1.6.32. STANDARD Let $n \geq 1$, and let $S \subseteq F^{n\times n}$ be the subspace of symmetric matrices, those with $a_{ji} = a_{ij}$ for all i, j (Example 1.4.11). Let K be the set of $A \in F^{n\times n}$ with $a_{ji} = -a_{ij}$ for all i, j.

(a) Find a basis of S of length $n(n+1)/2$.

(b) Suppose that $1+1 \neq 0$ in F. Find a basis of K of length $n(n-1)/2$.

(c) What are K and a basis of K when $F = \mathbb{F}_2$?

Solution on page 1078

Exercise 1.6.33. STANDARD Let $Z \subseteq F^{3\times 3}$ be the set of matrices in which every row and every column sums to 0. For $k, l \in \{1, 2\}$, let

$$Z_{kl} = U_{kl} - U_{k3} - U_{3l} + U_{33}.$$

Show that $\mathcal{Z} = Z_{11}, Z_{12}, Z_{21}, Z_{22}$ is a basis of Z, and that for $A \in Z$,

$$[A]_{\mathcal{Z}} = (a_{11}, a_{12}, a_{21}, a_{22}).$$

Solution on page 1078

Exercise 1.6.34. STANDARD Let $n \geq 1$, and let $p_0, ..., p_n \in F[x]_{\leq n}$.

(a) Show that if $\deg p_k = k$ for each k, then $p_0, ..., p_n$ is a basis of $F[x]_{\leq n}$.

(b) Show that if no p_k has degree n, then $p_0, ..., p_n$ is not a basis of $F[x]_{\leq n}$.

(c) Find a basis of $F[x]_{\leq n}$ all of whose entries have degree n.

Solution on page 1079

Exercise 1.6.35. STANDARD Prove or disprove each statement.

(a) If $\mathcal{B}$ is a basis of V and U is a subspace of V, then some sublist of $\mathcal{B}$ is a basis of U.

(b) If $\mathcal{B}$ and $\mathcal{C}$ are bases of V and $V \neq \{\mathbf{0}\}$, then the concatenation $\mathcal{B}, \mathcal{C}$ is not a basis of V.

(c) If $\mathbf{v}_1, ..., \mathbf{v}_n$ is a basis of V and $c_1, ..., c_n \in F$ are nonzero, then $c_1\mathbf{v}_1, ..., c_n\mathbf{v}_n$ is a basis of V.

(d) If $\mathcal{L}$ is a list in V such that every vector of V is represented by at most one linear combination of $\mathcal{L}$, then $\mathcal{L}$ is a basis of V.

(e) If $\mathcal{L}$ spans V, then exactly one sublist of $\mathcal{L}$ is a basis of V.

Solution on page 1079

Exercise 1.6.36. STANDARD Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of V, let $\mathbf{w} \in V$ with $[\mathbf{w}]_{\mathcal{B}} = (a_1, ..., a_n)$, and fix j. Let $\mathcal{B}'$ be the list obtained from $\mathcal{B}$ by replacing $\mathbf{v}_j$ with $\mathbf{w}$.

(a) Show that $\mathcal{B}'$ is a basis of V if and only if $a_j \neq 0$.

(b) Deduce that if $\mathbf{w} \neq \mathbf{0}$, then $\mathbf{w}$ can replace some entry of $\mathcal{B}$ so that the result is still a basis.

Solution on page 1080

Exercise 1.6.37. STANDARD Let $f : V \to F^n$ be a bijection that respects linear combinations:

$$f(c_1\mathbf{x}_1 + \cdots + c_k\mathbf{x}_k) = c_1 f(\mathbf{x}_1) + \cdots + c_k f(\mathbf{x}_k)$$

for all $k \geq 0$, all $\mathbf{x}_i \in V$, and all $c_i \in F$. Show that there is exactly one basis $\mathcal{C}$ of V such that $f(\mathbf{v}) = [\mathbf{v}]_{\mathcal{C}}$ for every $\mathbf{v} \in V$. In other words, the coordinate maps of bases are exactly the bijections $V \to F^n$ that respect linear combinations.

Solution on page 1080

Exercise 1.6.38. STANDARD Let F be a finite field with q elements, and let $n \geq 1$.

(a) Show that a list in F^n is a basis of F^n if and only if it is linearly independent and has length n.

(b) How many bases does F^n have? List all bases of $\mathbb{F}_2^2$.

Solution on page 1081

Exercise 1.6.39. HARD Let $X = \{0, 1, 2, \ldots\}$, so that $\mathbb{R}^X$ is the space of real sequences $\mathbf{s} = (s_0, s_1, s_2, \ldots)$, and let

$$V = \left\{ \mathbf{s} \in \mathbb{R}^X \;\middle|\; s_{k+2} = s_{k+1} + s_k \text{ for all } k \geq 0 \right\}.$$

(a) Show that V is a subspace of $\mathbb{R}^X$, and that if $\mathbf{s} \in V$ and $s_0 = s_1 = 0$, then $\mathbf{s} = \mathbf{0}$.

(b) Let $\mathbf{g}, \mathbf{f} \in V$ be the sequences with $g_0 = 1, g_1 = 0$ and $f_0 = 0, f_1 = 1$. (So $\mathbf{f} = (0, 1, 1, 2, 3, 5, \ldots)$ is the Fibonacci sequence.) Show that $\mathbf{g}, \mathbf{f}$ is a basis of V, and that $[\mathbf{s}]_{(\mathbf{g},\mathbf{f})} = (s_0, s_1)$.

(c) Let $\varphi = \left(1 + \sqrt{5}\right)/2$ and $\psi = \left(1 - \sqrt{5}\right)/2$, the roots of $t^2 = t + 1$. Show that the geometric sequences $\mathbf{a} = \left(\varphi^k\right)_{k \geq 0}$ and $\mathbf{b} = \left(\psi^k\right)_{k \geq 0}$ form a basis of V. By finding $[\mathbf{f}]_{(\mathbf{a},\mathbf{b})}$, prove that

$$f_k = \frac{\varphi^k - \psi^k}{\sqrt{5}} \quad \text{for all } k \geq 0.$$

Solution on page 1081

Exercise 1.6.40. HARD Let $S \subseteq F^{3\times 3}$ be the set of matrices whose three row sums and three column sums are all equal; for $A \in S$, write $s(A)$ for this common value. Let $Z \subseteq S$ and $\mathcal{Z} = Z_{11}, Z_{12}, Z_{21}, Z_{22}$ be as in Exercise 1.6.33, the case $s(A) = 0$.

(a) Show that S is a subspace of $F^{3\times 3}$, that $I, Z_{11}, Z_{12}, Z_{21}, Z_{22}$ is a basis of S, where $I = U_{11} + U_{22} + U_{33}$, and that for $A \in S$ with $s = s(A)$,

$$[A]_{(I,\mathcal{Z})} = (s, \quad a_{11} - s, \quad a_{12}, \quad a_{21}, \quad a_{22} - s).$$

(b) Let J be the matrix all of whose entries are 1. Find $[J]_{(I,\mathcal{Z})}$, and determine for which fields $J \in Z$.

(c) A **permutation matrix** has exactly one entry 1 in each row and each column, and 0 elsewhere. Show that the six 3×3 permutation matrices span S, and find a dependence relation among them.

Solution on page 1082

Exercise 1.6.41. HARD Let K be a subfield of a field E, and let V be a vector space over E; regard E and V as vector spaces over K by restricting scalars (Proposition 1.2.19). Suppose that $\alpha_1, \ldots, \alpha_m$ is a basis of E over K and $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis of V over E.

(a) Show that the mn vectors $\alpha_i \mathbf{v}_j$, listed as

$$\alpha_1\mathbf{v}_1, \ldots, \alpha_m\mathbf{v}_1, \quad \alpha_1\mathbf{v}_2, \ldots, \alpha_m\mathbf{v}_2, \quad \ldots, \quad \alpha_1\mathbf{v}_n, \ldots, \alpha_m\mathbf{v}_n,$$

form a basis of V over K.

(b) Write down the resulting basis of $\mathbb{C}^2$ over $\mathbb{R}$, and the coordinates of $(1 + 2i, 3 - i)$ in it.

Solution on page 1083

Exercise 1.6.42. CHALLENGE Let $n \geq 1$, and let $V = \mathbb{F}_2^X$ be the space of all functions $X \to \mathbb{F}_2$, where $X = \mathbb{F}_2^n$. For a subset $S \subseteq \{1, \ldots, n\}$, let $m_S \in V$ be the function

$$m_S(y_1, \ldots, y_n) = \prod_{i \in S} y_i,$$

with $m_\varnothing = 1$ (the constant function). Show that the 2^n functions m_S, listed in any order, form a basis of V. Deduce that every function $\mathbb{F}_2^n \to \mathbb{F}_2$ can be written in exactly one way as a sum of distinct products $y_{i_1} y_{i_2} \cdots y_{i_r}$ with $i_1 < \cdots < i_r$ (allowing the empty product 1).

Solution on page 1084

1.7 Proof patterns

Most proofs in this chapter are short, and most of their steps were forced. Once a claim is written out with its definitions unpacked and its quantifiers in order, its shape usually decides the first move. This section sorts the chapter's proofs by the question they answer. For each question it compares the moves that answer it, on examples from the chapter, and says when a move is the wrong tool. The exercises at the end practice one move at a time, and the chapter's problem set (Problems for Chapter 1) mixes them.

1.7.1 Showing that two sets are equal

The default is double containment (Technique 1.3.14), with each containment proved by chasing a generic element (Technique 1.3.13). The two halves are rarely alike. In Example 1.3.15, the containment $\operatorname{span}(\mathcal{L}_1) \subseteq W$ was a computation that handled every linear combination at once, while $W \subseteq \operatorname{span}(\mathcal{L}_1)$ needed a linear combination built for each element of W. Expect one half to be a check and the other a construction, and look for the construction first, since that is where proofs get stuck.

When the sets carry structure, finitely many checks can replace a containment.

- If both sets are spans, compare entries: $\operatorname{span}(\mathcal{L}) = \operatorname{span}(\mathcal{M})$ exactly when each list lies in the span of the other (Corollary 1.3.19).
- If one set is a subspace U, then $\operatorname{span}(\mathcal{L}) \subseteq U$ as soon as the entries of $\mathcal{L}$ lie in U (Proposition 1.4.14(b)).
- If one set is defined as the smallest subspace with some property, use the property instead of the elements, as in the proof of Corollary 1.4.17.

Example 1.7.1 (One equality, two ways). Let $P = \{\mathbf{x} \in \mathbb{R}^3 \mid x_1 + x_2 + x_3 = 0\}$. Exercise 1.3.16 proved $\operatorname{span}((1,0,-1),(0,1,-1)) = P$ by chasing an element through each containment. With the structure in view, one half needs no computation: P is a subspace (Example 1.4.8) that contains $(1,0,-1)$ and $(0,1,-1)$, so it contains their span by Proposition 1.4.14(b). The other half is the construction, and with the tools of this chapter it cannot be avoided. For $(x,y,z) \in P$ we have $z = -x - y$, so

$$(x,y,z) = x(1,0,-1) + y(0,1,-1).$$

In the same way, Example 1.3.21 replaced both halves of Example 1.3.15 by two observations about entries.

Chasing elements is the wrong tool for showing that two sets *differ*. Then one element of one set outside the other is enough, and the way to find it is a property that every element of one set has. Every vector $(a, a+b, b)$ of $\operatorname{span}((1,1,0),(0,1,1))$ has middle coordinate equal to the sum of the other two, and $(1,2,3)$ does not (Example 1.3.8). For finite sets there is a third option: a containment together with equal sizes gives equality. Over a finite field this decides when a list is a basis of F^n (Exercise 1.6.38). From Section 4.1 on, dimension plays the role of size over every field (Proposition 4.1.21).

Exercise 1.7.5 practices the choice between these tools, and Exercise 1.3.30 shows what is lost when one half is forgotten.

1.7.2 Showing that something is unique

Every "the" in this chapter, such as the zero vector or the coordinate vector, rests on a uniqueness proof. There were two ways to give one.

The first is uniqueness via two candidates (Technique 1.1.8): take two candidates and show that they are equal, as for identities and inverses (Theorem 1.1.9, Proposition 1.2.27, Proposition 1.2.28). With vectors, the comparison is usually a subtraction, and the difference of two candidates solves the homogeneous version of the problem. Two representations of $\mathbf{w}$ differ by a representation of $\mathbf{0}$, which is how (II) $\Rightarrow$ (I) of Theorem 1.5.5 went, and two solutions of $a\mathbf{x} = \mathbf{w}$ differ by a solution of $a\mathbf{x} = \mathbf{0}$ (Corollary 1.2.36). So

uniqueness reduces to the statement that the homogeneous problem has only the zero solution, a question about one fixed vector. Section 3.1 builds on this reduction (Technique 3.1.18).

The second is to derive the formula: suppose x is a solution, deduce that it must equal a specific expression, and check that this expression is a solution. This proves existence and uniqueness at once, and it computes the object. Proposition 1.1.13 was proved this way.

Example 1.7.2 (A basis, two ways). Is $(1,1),(1,-1)$ a basis of $\mathbb{R}^2$? Following Proposition 1.6.2, we can check two things separately. Spanning needs coefficients for each (x,y), which still have to be found (they turn out to be $(x+y)/2$ and $(x-y)/2$), and independence needs $a+b=a-b=0$ to force $a=b=0$, which it does (add and subtract the equations). Deriving the formula instead: if $a(1,1)+b(1,-1)=(x,y)$, then $a+b=x$ and $a-b=y$, so

$$a=\frac{x+y}{2},\quad b=\frac{x-y}{2},$$

and these values are a solution. So every (x,y) has exactly one representation, and we have its coordinates as a bonus (Example 1.6.3). Both routes divide by 2, and both fail over $\mathbb{F}_2$, where the list repeats an entry.

The formula is shorter here, but it needs equations that can be solved in general. For the polynomials of Exercise 1.6.6, no formula was needed: spanning came from Exercise 1.3.32 and independence from degrees (Proposition 1.5.24).

Before proving that something is unique, check that it is. The index j of Lemma 1.5.10 is not unique (Example 1.5.11), and a vector does not determine its coefficients with respect to a spanning list that is dependent (Exercise 1.6.31). Uniqueness also says nothing about existence: a list in which every vector has at most one representation need not span (Exercise 1.6.35). Practice: Exercise 1.7.6, Exercise 1.7.7, and Exercise 1.2.43.

1.7.3 Showing that a list is independent, or dependent

Dependence is shown by a certificate: one nontrivial relation, which anyone can check by computing a single linear combination (Theorem 1.5.5). Independence is a statement about *all* relations, and the chapter proved it in several ways.

- *The test at zero.* Assume $a_1\mathbf{v}_1+\cdots+a_k\mathbf{v}_k=\mathbf{0}$ and solve for the coefficients (Example 1.5.6).
- *One entry at a time.* Show that each entry lies outside the span of the entries before it (Corollary 1.5.13, Proposition 1.5.14). Usually some property is shared by the whole span of the earlier entries and fails for the new entry, such as having degree at most n.
- *An extreme term.* Look at the largest degree (Proposition 1.5.24) or the fastest-growing function (Example 1.5.27, second proof), which nothing else in a relation can cancel.
- *Evaluation and operators,* for functions: evaluate a relation at well-chosen points (Example 1.5.26), or apply an operation such as differentiation that eliminates terms (Example 1.5.27, first proof).
- *Transfer.* Pass to coordinates (Proposition 1.6.20), apply the moves of Proposition 1.5.18, recognize the list as a sublist of a list already known to be independent (Corollary 1.5.17), or change the field: independence over F gives independence over a subfield (Proposition 1.5.20), and for lists of real vectors, independence over $\mathbb{R}$ gives independence over $\mathbb{C}$ (Proposition 1.5.21).

Example 1.7.3 (Three tools on one list). Let $p_1=1+x$, $p_2=x+x^2$, and $p_3=1+x^2$ in $F[x]$.

The test at zero. The combination $ap_1+bp_2+cp_3=(a+c)+(a+b)x+(b+c)x^2$ is $\mathbf{0}$ exactly when $a+c=a+b=b+c=0$. The first two equations give $b=c=-a$, and then the third reads $-(1+1)a=0$. So if $1+1\neq 0$, the only relation is trivial and the list is independent; if $1+1=0$, then $a=b=c=1$ is a dependence relation.

One entry at a time. $p_1 \neq \mathbf{0}$. Every vector of $\operatorname{span}(p_1)$ has degree at most 1, so $p_2 \notin \operatorname{span}(p_1)$. The vectors of $\operatorname{span}(p_1, p_2)$ are $a + (a+b)x + bx^2$, and this is p_3 exactly when $a = b = 1$ and $a + b = 0$, which is possible only when $1 + 1 = 0$. Same answer, with more information: over $\mathbb{F}_2$, p_3 is the first entry in the span of the earlier ones, $p_3 = p_1 + p_2$.

An extreme term. Proposition 1.5.24 does not apply, since p_2 and p_3 both have degree 2. Its hypothesis is doing real work: the leading terms of p_2 and p_3 can cancel, and over $\mathbb{F}_2$ the relation $p_1 + p_2 + p_3 = \mathbf{0}$ cancels them. When a tool's hypothesis fails, fall back on the test at zero.

Two tempting shortcuts are invalid. For functions on an infinite set, evaluating at finitely many points can prove independence but not dependence, since a combination that vanishes at a few points need not vanish everywhere (Section 1.5.6). And a list in which no entry is a multiple of another can still be dependent (Exercise 1.5.16). Practice: Exercise 1.7.8, Exercise 1.7.9, and Exercise 1.7.12.

1.7.4 Proving a statement about every list

Claims about lists of every length, or about linear combinations of every length, are proved by induction on the length of the list (Technique 1.6.9), usually with the empty list as the base case. The arithmetic of linear combinations (Lemma 1.3.9), (III) ⇒ (II) of Theorem 1.4.3, and Proposition 1.6.19(c) split off the last term of a sum. Theorem 1.6.10 deletes a well-chosen entry.

That theorem has three proofs, and they are one idea in three forms: delete redundant entries until none is left. The induction deletes one entry and hands the shorter list to the inductive hypothesis. The extremal proof takes a shortest sublist with the same span and shows that the dependence lemma could not shorten it further. Sifting reads the list once, from left to right, and keeps exactly the entries that the earlier ones do not account for. When only existence is needed, the extremal form is the shortest. When something must be carried along from step to step, as the coefficients are in Proposition 1.6.19(c), the induction is the natural form. When the output itself matters, sifting is the one to use, because it produces a definite sublist; its kept entries return as pivot columns (Section 4.2).

Two things go wrong in inductions on length. The shorter list must satisfy the hypotheses of the statement: deleting the last entry of a spanning list need not leave a spanning list, which is why the entry to delete is supplied by Lemma 1.5.10 (Exercise 1.6.30). And the inductive step must work from the base case on, not only for long lists (Exercise 1.7.10). Finally, induction proves things about all finite lists, but it does not show that a process of adding vectors stops. Thinning a spanning list stops because its length drops at every step, while growing an independent list need not stop, and in $F[x]$ it never does (Remark 1.6.26). Practice: Exercise 1.7.10 and Exercise 1.7.11.

1.7.5 Proving a statement with "or"

Several results of the chapter conclude "P or Q", among them Proposition 1.1.17, Proposition 1.2.35, and Proposition 1.4.20, and each of these has a proof by the same move.

> **Technique 1.7.4** (Proving a disjunction). To prove "P or Q", assume that P fails and prove Q. The failure of P is a hypothesis you can use, and it usually hands you an object: an inverse a^{-1} when $a \neq 0$, or a vector of U outside W when $U \not\subseteq W$. If one alternative is easier to negate usefully, negate that one. The other route is the contrapositive: assume that both alternatives fail and derive the negation of the hypothesis (or a contradiction). It hands you two objects at once, which helps when the argument needs both.
>
> Reach for it whenever a conclusion reads "... or ...". The canonical example is Proposition 1.4.20, which has one proof of each kind.
>
> *Used in.* Exercise 1.7.13.

In Proposition 1.1.17 and Proposition 1.2.35, the conclusion is "$a = 0$ or ...", and assuming $a \neq 0$ supplies a^{-1}, which cancels a. In the first proof of Proposition 1.4.20, the failure of $U \subseteq W$ supplies one vector $\mathbf{u} \in U$ outside W, and adding $\mathbf{u}$ to each vector of W pushes that vector into U. The second proof negates both alternatives and uses the two witnesses to rebuild the counterexample of the two axes.

The invalid version of this move is a case split on two objects at once: "$\mathbf{v}$ lies in U or in W, and so does $\mathbf{w}$, so $\mathbf{v} + \mathbf{w}$ lies in U or in W". The split forgets the mixed case, $\mathbf{v} \in U$ and $\mathbf{w} \in W$, which is where the claim fails (Exercise 1.4.30). Practice: Exercise 1.7.13.

1.7.6 Disproving a claim, and proving that no object exists

To disprove "every X has property P", one X without P suffices (Technique 1.4.18), and the smallest examples are the place to look (Technique 1.2.38): the zero space, F^1 and F^2, lists of length one or two, and the field $\mathbb{F}_2$. Most of the chapter's counterexamples were of this size: $\mathbf{v} = -\mathbf{v}$ in $\mathbb{F}_2^2$ (Example 1.2.39), the scaling move of Corollary 1.3.20(d) with the scalar -2, which is 0 in $\mathbb{F}_2$ (Example 1.3.22), the two axes of $\mathbb{R}^2$ (Non-example 1.4.13), and $x^2 = 1$ in $\mathbb{F}_2$ (Exercise 1.1.42). "Small" means the smallest case in which the claim says something. The claim that a list with no entry a multiple of another is independent is true for two vectors, so its counterexample needs three (Exercise 1.5.16).

Showing that *no* object of some kind exists is a different task, and one failure is not enough. In Example 1.2.25, each candidate operation on $\mathbb{R}^2$ was refuted by one instance of one failing axiom. But to show that *no* scalar multiplication makes $[0, 1)$ with addition modulo 1 a real vector space (Example 1.2.40), testing candidates one at a time cannot finish. Instead we found a consequence of the axioms that involves only the addition, which is the part held fixed, and showed that this addition violates it. The same need to rule out every candidate appeared on a smaller scale in Non-example 1.2.21: to show that the line $x + 2y = 2$ has no zero vector under the operations of $\mathbb{R}^2$, it was not enough to note that $(0, 0)$ is not on the line; every candidate $\mathbf{z}$ had to be excluded. Practice: Exercise 1.7.15 and Exercise 1.7.14.

1.7.7 Reading the chapter's proofs

Most of the chapter's proofs were found by reading the definitions slowly. Here is what to look at first.

The definitions and the quantifiers. Unpack every definition in the claim and keep the quantifiers in order. Then the shape is visible. "For all" calls for a generic element, "there exists" for a construction, "unique" for two candidates, and "or" for negating one alternative. For instance, independence says that every vector of the span has *at most one* representation. Its negation hands us a vector with two representations, and subtracting them gives a relation. That is the proof of (II) ⇒ (I) in Theorem 1.5.5, found by negating the definition. The subspace criterion came from sorting (A1)–(A8) by their quantifiers: identities that hold for all vectors are inherited by any subset closed under the operations, and the existence statements (A3) and (A4) are where a subset can fail (the intuition before Theorem 1.4.3). The same sorting proved Proposition 1.1.33 and Proposition 1.2.19. When a fact has to connect two operations, list the axioms that mention both: distributivity for $0a = 0$ (Proposition 1.1.15), and (A7) and (A8) for vectors.

The extreme choice. A dependence relation can be solved for any entry whose coefficient is nonzero. The dependence lemma wants only earlier entries on the other side, so the proof solves for the *last* entry with a nonzero coefficient (Lemma 1.5.10). Solving for the *first* one instead puts that entry in the span of the later entries (Exercise 1.7.8). The same move, a largest index or degree, runs Proposition 1.5.24 and the second proof in Example 1.5.27, and a shortest sublist runs the second proof of Theorem 1.6.10. Extremality is a hypothesis we get for free: "the largest j with $a_j \neq 0$" also says that every later coefficient is 0.

The degenerate cases. The empty list, the zero space, and the index $j = 1$ are where the conventions get tested: $\text{span}(()) = \{\mathbf{0}\}$, the empty list is independent and is the basis of $\{\mathbf{0}\}$, and $j = 1$ in Lemma 1.5.10 means $\mathbf{v}_1 = \mathbf{0}$. The subspace criterion needs its nonemptiness condition exactly once, to produce $\mathbf{0}$ (Remark 1.4.5).

The counterexample, read closely. The natural first guess is that $U \cup W$ is a subspace whenever U and W are. The two axes of $\mathbb{R}^2$ refute it. Reading the counterexample, it used only one vector of the first axis outside the second and one vector of the second outside the first, whose sum lies on neither (Lemma 1.4.19). So the failure needs each subspace to stick out of the other. That suggests the corrected statement, Proposition 1.4.20, and its second proof is the counterexample run on general U and W. The same reading turned the counterexample over $\mathbb{F}_2$ in Example 1.2.39 into the hypothesis $1 + 1 \neq 0$: the computation $\mathbf{v} + \mathbf{v} = (1 + 1)\mathbf{v}$ located the scalar that has to be invertible.

1.7.8 Common errors

Each of these appears somewhere in the chapter, most of them as find-the-error exercises.

- *Unions.* "$U \cup W$ is closed under addition because U and W are." The case split forgets the mixed case (Exercise 1.4.30). The repair is Proposition 1.4.20, and the smallest subspace containing both is $U + W$ (Proposition 1.4.24).
- $\mathbf{0}$ *in a span versus* $\mathbf{0}$ *in a list.* $\mathbf{0}$ lies in every span, including $\operatorname{span}(()) = \{\mathbf{0}\}$, and this says nothing about independence. A list that *contains* $\mathbf{0}$ is always dependent (Proposition 1.5.15(c)), while the empty list is independent. Relatedly, the zero vector of a structure is whatever satisfies (A3) for its addition, not the number 0 or the vector $(0, 0)$ (Exercise 1.2.24, Example 1.2.23). A subspace, on the other hand, always has the zero vector of the ambient space (Remark 1.4.4), which is the point of Exercise 1.4.29.
- *Lists versus sets.* The list $\mathbf{v}, \mathbf{v}$ is dependent, although its set of entries is $\{\mathbf{v}\}$. The span forgets order and repetition (Remark 1.3.23). Independence does not forget repetition, and coordinates do not forget order: reordering a basis reorders the coordinates. A vector determines its coefficients only with respect to an independent list (Exercise 1.3.29, Exercise 1.6.31).
- *Pairwise is not enough.* A list of three vectors, none a multiple of another, can be dependent (Exercise 1.5.16). Two independent lists can have a dependent concatenation (Exercise 1.7.12).
- *The wrong redundant entry.* The last entry of a dependent list need not lie in the span of the others (Exercise 1.5.30), and an induction that deletes an arbitrary entry of a spanning list breaks (Exercise 1.6.30).
- *Half of a double containment.* Showing that a span lies in V proves nothing about whether the list spans V (Exercise 1.3.30).
- *Hidden division.* An argument that divides by $1 + 1$, assumes $1 \neq -1$, or cancels a zero divisor fails over $\mathbb{F}_2$ or $\mathbb{Z}/n\mathbb{Z}$ (Exercise 1.1.42, Exercise 1.1.45, Example 1.3.22).
- *Local versus global.* The zero vector is unique among vectors that satisfy $\mathbf{v} + \mathbf{z} = \mathbf{v}$ for *every* $\mathbf{v}$; a vector that works for one $\mathbf{v}$ needs a separate argument (Exercise 1.2.43). Deriving (A4) from $(-1)\mathbf{v}$ is circular, because the proof of $0\mathbf{v} = \mathbf{0}$ used (A4) (Exercise 1.2.54).

Exercises

Exercise 1.7.5. ROUTINE For each equality, decide which containments are finite checks and which need a construction, and prove the equality.

(a) $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3) = \operatorname{span}(\mathbf{v}_1 - \mathbf{v}_2, \mathbf{v}_2 - \mathbf{v}_3, \mathbf{v}_3)$, for any $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3 \in V$.

(b) $\{p \in F[x]_{\leq 2} \mid p(0) = p(1)\} = \operatorname{span}(1, x^2 - x)$.

Solution on page 1084

Exercise 1.7.6. ROUTINE Let $\mathbf{u}, \mathbf{w} \in V$, and consider the equation $\mathbf{m} - \mathbf{u} = \mathbf{w} - \mathbf{m}$ for an unknown $\mathbf{m} \in V$.

(a) Suppose $1 + 1 \neq 0$ in F. Show that the equation has exactly one solution, and find it.

(b) Suppose $F = \mathbb{F}_2$. Show that the equation has a solution only if $\mathbf{u} = \mathbf{w}$, and that in that case every $\mathbf{m} \in V$ is a solution.

Solution on page 1085

Exercise 1.7.7. STANDARD Let $n \geq 2$, and let $\mathbf{v}_1, ..., \mathbf{v}_n$ be a linearly dependent list in V such that every sublist of length $n-1$ is linearly independent.

(a) Show that every dependence relation $c_1, ..., c_n$ of the list has all $c_i \neq 0$.

(b) Show that any two dependence relations are proportional: if $c_1, ..., c_n$ and $d_1, ..., d_n$ are dependence relations, then $d_i = \lambda c_i$ for all i, for some $\lambda \in F$.

(c) Find such a list of length 3 in $\mathbb{R}^2$, and all of its linear relations.

Solution on page 1086

Exercise 1.7.8. ROUTINE Let $\mathbf{v}_1, ..., \mathbf{v}_k$ be a list in V. Show that it is linearly independent if and only if

$$\mathbf{v}_j \notin \operatorname{span}(\mathbf{v}_{j+1}, ..., \mathbf{v}_k) \quad \text{for every } j \in \{1, ..., k\}.$$

For the backward direction, argue directly with an extremal choice of index, without reordering the list and quoting Corollary 1.5.13.

Solution on page 1086

Exercise 1.7.9. STANDARD Let X be a set, let $f_1, ..., f_n \in F^X$, and let $t_1, ..., t_n \in X$ be points such that

$$f_i(t_i) \neq 0 \text{ for every } i, \quad \text{and} \quad f_i(t_j) = 0 \text{ whenever } j < i.$$

(a) Show that $f_1, ..., f_n$ is linearly independent.

(b) For $i \geq 0$, let $r_i \in \mathbb{R}^{\mathbb{R}}$ be the ramp $r_i(t) = \max(0, t - i)$. Show that $1, r_0, r_1, ..., r_{n-1}$ is linearly independent in $\mathbb{R}^{\mathbb{R}}$ for every $n \geq 1$, where 1 is the constant function.

Solution on page 1087

Exercise 1.7.10. ROUTINE Find the error in the following argument, and show that its claim is false. Then show that the argument does prove the following statement: if every two of the nonzero vectors $\mathbf{v}_1, ..., \mathbf{v}_k$ lie on a common line, then all of them do.

Claim. Any nonzero vectors $\mathbf{v}_1, ..., \mathbf{v}_k \in V$, with $k \geq 1$, lie on a common line: there is a vector $\mathbf{u}$ with $\mathbf{v}_1, ..., \mathbf{v}_k \in \operatorname{span}(\mathbf{u})$.

Proof. Induction on k. For $k = 1$, take $\mathbf{u} = \mathbf{v}_1$. Suppose the claim holds for all lists of length k, and let $\mathbf{v}_1, ..., \mathbf{v}_{k+1}$ be nonzero. Applying the inductive hypothesis to $\mathbf{v}_1, ..., \mathbf{v}_k$ gives $\mathbf{u}$ with $\mathbf{v}_1, ..., \mathbf{v}_k \in \operatorname{span}(\mathbf{u})$, and applying it to $\mathbf{v}_2, ..., \mathbf{v}_{k+1}$ gives $\mathbf{u}'$ with $\mathbf{v}_2, ..., \mathbf{v}_{k+1} \in \operatorname{span}(\mathbf{u}')$. The vector $\mathbf{v}_2$ lies on both lines and is nonzero, so $\operatorname{span}(\mathbf{u}) = \operatorname{span}(\mathbf{v}_2) = \operatorname{span}(\mathbf{u}')$. Hence all of $\mathbf{v}_1, ..., \mathbf{v}_{k+1}$ lie in $\operatorname{span}(\mathbf{u})$.

Solution on page 1087

Exercise 1.7.11. STANDARD Let V be a vector space over $\mathbb{F}_2$ and $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ a list in V. Let $Z(\mathcal{L})$ be the number of subsets $I \subseteq \{1, ..., k\}$ with $\sum_{i \in I} \mathbf{v}_i = \mathbf{0}$, where the empty set counts, with the empty sum $\mathbf{0}$.

(a) Let $\mathbf{w} \in V$. Show that $Z(\mathcal{L}, \mathbf{w}) = Z(\mathcal{L})$ if $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, and $Z(\mathcal{L}, \mathbf{w}) = 2Z(\mathcal{L})$ if $\mathbf{w} \in \operatorname{span}(\mathcal{L})$.

(b) Deduce that $Z(\mathcal{L}) = 2^d$, where d is the number of entries that sifting deletes from $\mathcal{L}$ (the third proof of Theorem 1.6.10). In particular, $Z(\mathcal{L}) = 1$ if and only if $\mathcal{L}$ is linearly independent.

Solution on page 1088

Exercise 1.7.12. STANDARD

(a) Disprove: if $\mathcal{L}$ and $\mathcal{M}$ are linearly independent lists in V, then the concatenation $\mathcal{L}, \mathcal{M}$ is linearly independent. Use the smallest counterexample you can find.

(b) What do $\operatorname{span}(\mathcal{L})$ and $\operatorname{span}(\mathcal{M})$ have in common in your counterexample? Use the answer to formulate a corrected statement.

(c) Prove: if $\mathcal{L}$ and $\mathcal{M}$ are linearly independent, then $\mathcal{L}, \mathcal{M}$ is linearly independent if and only if $\operatorname{span}(\mathcal{L}) \cap \operatorname{span}(\mathcal{M}) = \{\mathbf{0}\}$.

Solution on page 1088

Exercise 1.7.13. ROUTINE Let U be a subspace of V, and let $\mathbf{v}, \mathbf{w} \in V$ with $\mathbf{v} \notin U$.

(a) Suppose $1 + 1 \neq 0$ in F. Show that $\mathbf{v} + \mathbf{w} \notin U$ or $\mathbf{v} - \mathbf{w} \notin U$.

(b) Show that (a) fails over $\mathbb{F}_2$.

Solution on page 1089

Exercise 1.7.14. STANDARD Show that there is no field F, and no scalar multiplication $F \times \mathbb{Z} \to \mathbb{Z}$, that make $\mathbb{Z}$ with its usual addition a vector space over F. (Exercise 1.2.46 treated the fields $\mathbb{F}_p$.)

Solution on page 1089

Exercise 1.7.15. ROUTINE Prove or disprove: every subspace of F^2 is the solution set $\{(x, y) \in F^2 \mid ax + by = 0\}$ of a single equation, for some $a, b \in F$. If the claim is false, find the subspaces for which it holds, and prove that it holds for them.

Solution on page 1090

Problems for Chapter 1

These problems combine the sections of Chapter 1. The first four are review prompts of the kind found on an exam review sheet: state the result, prove it without looking, and then answer a follow-up question that the text did not ask. The rest are ordered roughly by difficulty. Problems of kind "competition" are harder than anything the course expects.

Review: state and prove

Problem 1.1. STANDARD

(a) State the criterion for $\mathbb{Z}/n\mathbb{Z}$ to be a field, and prove it.

(b) One of the two proofs in Section 1.1.3 computes inverses. Use it to find 17^{-1} in $\mathbb{F}_{101}$, and then solve $17x + 3 = 5$ in $\mathbb{F}_{101}$.

Solution on page 1090

Problem 1.2. STANDARD Two of the vector space axioms, (A7) and (A8), involve both operations.

(a) Using only (A1)–(A7), and not (A8), prove that $a(\mathbf{v} - \mathbf{w}) = a\mathbf{v} - a\mathbf{w}$ for all $a \in F$ and $\mathbf{v}, \mathbf{w} \in V$.

(b) Prove that $(a - b)\mathbf{v} = a\mathbf{v} - b\mathbf{v}$ for all $a, b \in F$ and $\mathbf{v} \in V$. Which axioms does your proof use?

(c) Show that the identity in (b) can fail for a structure that satisfies every axiom except (A8).

Solution on page 1091

Problem 1.3. STANDARD Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ be a list in V.

(a) State the definition of linear independence and the test at zero (Theorem 1.5.5), and prove that they are equivalent.

(b) Suppose that *some* vector $\mathbf{w} \in \operatorname{span}(\mathcal{L})$ is represented by exactly one linear combination of $\mathcal{L}$. Show that $\mathcal{L}$ is linearly independent.

(c) Suppose instead that some $\mathbf{w} \in V$ is represented by *no* linear combination of $\mathcal{L}$. Can you conclude that $\mathcal{L}$ is independent? That it is dependent?

Solution on page 1092

Problem 1.4. STANDARD

(a) State the linear dependence lemma, including the statement about deleting an entry, and prove it.

(b) In the proof, j was the *largest* index with $a_j \neq 0$ in a nontrivial relation. Let i instead be the *smallest* such index. What does the relation say about $\mathbf{v}_i$?

(c) For the list $(1,0), (0,1), (0,2)$ in $\mathbb{R}^2$, find all j with $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, ..., \mathbf{v}_{j-1})$, and all i with $\mathbf{v}_i \in \operatorname{span}(\mathbf{v}_{i+1}, ..., \mathbf{v}_3)$.

Solution on page 1093

Synthesis problems

Problem 1.5. ROUTINE Work in $\mathbb{F}_5^2$.

(a) List the lines $\operatorname{span}(\mathbf{v})$, $\mathbf{v} \neq \mathbf{0}$, of $\mathbb{F}_5^2$ by giving one nonzero vector on each. Which line contains $(2,3)$?

(b) Show that $\mathcal{B} = (1,2), (1,3)$ is a basis of $\mathbb{F}_5^2$, and find $[(x,y)]_{\mathcal{B}}$ and $[(2,3)]_{\mathcal{B}}$.

(c) How many bases of $\mathbb{F}_5^2$ have their first entry on the line $\operatorname{span}((1,2))$?

Solution on page 1093

Problem 1.6. ROUTINE In $F[x]_{\leq 3}$, let $U = \{p \mid p(1) = 0\}$ and $W = \{p \mid p(-1) = 0\}$.

(a) Suppose $1 + 1 \neq 0$ in F. Find a basis of $U \cap W$, and show that $U + W = F[x]_{\leq 3}$.

(b) Describe U, W, $U \cap W$, and $U + W$ when $F = \mathbb{F}_2$.

Solution on page 1094

Problem 1.7. ROUTINE In $\mathbb{R}^{\mathbb{R}}$, let $V = \operatorname{span}(1, \cos, \sin)$, where 1 is the constant function.

(a) Show that $1, \cos, \sin$ is a basis of V.

(b) Find the coordinates, with respect to this basis, of the functions $t \mapsto \cos(t + \pi/3)$, $t \mapsto \sin^2(t/2)$, and $t \mapsto (\cos(t/2) + \sin(t/2))^2$.

(c) Is the function $t \mapsto \cos^2 t$ in V?

Solution on page 1095

Problem 1.8. STANDARD Let K be a subfield of F with $K \neq F$, and let $n \geq 1$. Regard K^n as a subset of F^n.

(a) Show that K^n is a subspace of F^n regarded as a vector space over K (Proposition 1.2.19), but not a subspace of the F-vector space F^n.

(b) Show that the only subspace of the F-vector space F^n that is contained in K^n is $\{\mathbf{0}\}$.

(c) Let U be a subspace of the F-vector space F^n. Show that $U \cap K^n$ is a subspace of the K-vector space K^n. For $F = \mathbb{C}$, $K = \mathbb{R}$, and $n = 2$, find subspaces U of $\mathbb{C}^2$, other than $\{\mathbf{0}\}$ and $\mathbb{C}^2$, with $U \cap \mathbb{R}^2 = \{\mathbf{0}\}$ and with $U \cap \mathbb{R}^2 \neq \{\mathbf{0}\}$.

Solution on page 1095

Problem 1.9. STANDARD Let $P = (0, \infty)$ with the operations $x \oplus y = xy$ and $a \odot x = x^a$ for $a \in \mathbb{R}$. This is the real vector space obtained by transporting the structure of $\mathbb{R}$ along $\exp : \mathbb{R} \to (0, \infty)$ (Proposition 1.2.22), and you may take that for granted.

(a) What is the zero vector of P? Decide whether each of the lists $1, 2$, then $2, 4$, then $2, 3$ is linearly independent in P.

(b) Regard P as a vector space over $\mathbb{Q}$ (Proposition 1.2.19). Show that $2, 3$ is linearly independent over $\mathbb{Q}$, while $2, 3, 6$ and $2, 4$ are not.

(c) Show that $5 \notin \operatorname{span}(2, 3)$ over $\mathbb{Q}$.

Solution on page 1096

Problem 1.10. STANDARD Let U and W be subspaces of V, and let $\mathcal{L}$ be a list in V. Prove or disprove each statement.

(a) If $\mathbf{u} \in U$, $\mathbf{u} \notin W$, $\mathbf{w} \in W$, and $\mathbf{w} \notin U$, then $\mathbf{u}, \mathbf{w}$ is linearly independent.

(b) Under the same hypotheses, $\mathbf{u} + \mathbf{w}, \mathbf{u} - \mathbf{w}$ is linearly independent.

(c) The set of $\mathbf{v} \in V$ for which $\mathcal{L}, \mathbf{v}$ is linearly dependent is a subspace of V.

(d) If V is a complex vector space and $\mathcal{L}$ spans V, then $\mathcal{L}$ spans V regarded as a real vector space.

(e) If $\operatorname{span}(\mathcal{L}) \cap U = \{\mathbf{0}\}$, then $\mathcal{L}$ is linearly independent.

(f) If every entry of $\mathcal{L}$ lies in $U \cup W$, then $\operatorname{span}(\mathcal{L}) \subseteq U + W$.

Solution on page 1096

Problem 1.11. STANDARD Let U and W be subspaces of V with bases $\mathcal{L} = \mathbf{u}_1, \ldots, \mathbf{u}_k$ and $\mathcal{M} = \mathbf{w}_1, \ldots, \mathbf{w}_m$, and sift the concatenation $\mathcal{L}, \mathcal{M}$ (the third proof of Theorem 1.6.10).

Claim. Every entry of $\mathcal{M}$ that sifting deletes lies in $U \cap W$.

Proof. Let $\mathbf{w}_j$ be deleted. It lies in W, since it is an entry of $\mathcal{M}$. It was deleted because it lies in the span of the entries before it, and these are the entries of $\mathcal{L}$, so $\mathbf{w}_j \in \operatorname{span}(\mathcal{L}) = U$. Hence $\mathbf{w}_j \in U \cap W$.

(a) Find the error, and show that the claim is false.

(b) Show that sifting deletes no entry of $\mathcal{L}$, and that the kept entries form a basis of $U + W$.

(c) Show that if $\mathbf{w}_j$ is deleted, then $\mathbf{w}_j - \mathbf{y}$ is a nonzero vector of $U \cap W$ for some $\mathbf{y} \in \operatorname{span}(\mathbf{w}_1, \ldots, \mathbf{w}_{j-1})$.

Solution on page 1097

Problem 1.12. HARD Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$, let $t = \sqrt[3]{2}$, and let

$$K = \operatorname{span}(1, t, t^2) = \{a + bt + ct^2 \mid a, b, c \in \mathbb{Q}\}.$$

You may use that no rational number has cube 2.

(a) Show that $1, t, t^2$ is linearly independent over $\mathbb{Q}$.

(b) Show that K is closed under multiplication.

(c) For $\alpha = a + bt + ct^2 \in K$, let $\beta = \big(a^2 - 2bc\big) + \big(2c^2 - ab\big)t + \big(b^2 - ac\big)t^2$. Show that $\alpha\beta = a^3 + 2b^3 + 4c^3 - 6abc$. Deduce that K is a subfield of $\mathbb{R}$. (Compare Exercise 1.1.53, where the span of $1, t$ alone was not.)

Solution on page 1097

Problem 1.13. HARD Let F be a finite field with q elements. Call a subspace of F^3 a *line* if it is $\operatorname{span}(\mathbf{v})$ for some $\mathbf{v} \neq \mathbf{0}$, and a *plane* if it is $\operatorname{span}(\mathbf{v}, \mathbf{w})$ for some linearly independent $\mathbf{v}, \mathbf{w}$. You may use Exercise 1.5.43: a linearly independent list of length k in a vector space over F has a span with exactly q^k elements, and F^n contains exactly $(q^n - 1)(q^n - q)\cdots\big(q^n - q^{k-1}\big)$ independent lists of length k.

(a) Show that every subspace of F^3 is $\{\mathbf{0}\}$, a line, a plane, or F^3, and that no subspace is of two of these kinds.

(b) Count the lines and the planes of F^3, and the subspaces of F^3. Check your count against $\mathbb{F}_2^3$, which has 16 subspaces.

Solution on page 1098

Problem 1.14. HARD Let F be a finite field with q elements, and let $n \geq 1$.

(a) Let U be a proper subspace of F^n. Show that U has at most q^{n-1} elements.

(b) Deduce that if $S \subseteq F^n$ has more than q^{n-1} elements, then every list whose entries run through the elements of S spans F^n.

(c) Show that (b) is sharp: find a set S with exactly q^{n-1} elements whose span is not F^n.

Solution on page 1099

Problem 1.15. HARD Let $n \geq 1$. In $\mathbb{R}^{\mathbb{R}}$, let $V_n = \operatorname{span}\big(1, t, t^2, \ldots, t^n\big)$, where t^k denotes the function $t \mapsto t^k$. For $0 \leq k \leq n$, let

$$b_k(t) = t^k(1 - t)^{n-k}.$$

(a) Show that $b_0, \ldots, b_n$ lie in V_n.

(b) Show that $b_0, \ldots, b_n$ is linearly independent. (Consider the smallest k with a nonzero coefficient, and let $t \to 0$.)

(c) Show that $b_0, \ldots, b_n$ spans V_n, so it is a basis of V_n.

(d) Find the coordinates of the constant function 1 and of $t \mapsto t$ in this basis.

Solution on page 1100

Problem 1.16. HARD Let F be a finite field. Write $m * 1 = 1 + \cdots + 1$ (m terms) for integers $m \geq 1$, and $0 * 1 = 0$. (Definition 1.1.28 writes $m \cdot 1$; we use $*$ because juxtaposition already means multiplication in F.)

(a) Show that $p = \operatorname{char} F$ is a prime. (You may use Exercise 1.1.48.)

(b) Let $K = \{0 * 1, 1 * 1, \ldots, (p-1) * 1\}$. Show that K has exactly p elements and is a subfield of F.

(c) Deduce that F has exactly p^n elements for some $n \geq 1$. In particular, there is no field with 6 elements.

Solution on page 1101

Problem 1.17. HARD Let X be a set and let $f_1, \ldots, f_n \in F^X$ with $n \geq 1$. Show that $f_1, \ldots, f_n$ is linearly independent if and only if there are points $t_1, \ldots, t_n \in X$ such that the only scalars $a_1, \ldots, a_n$ with

$$a_1 f_1(t_j) + \cdots + a_n f_n(t_j) = 0 \quad \text{for } j = 1, \ldots, n$$

are $a_1 = \cdots = a_n = 0$. That is, the independence of n functions can always be certified by evaluating at n well-chosen points.

Solution on page 1101

Problem 1.18. CHALLENGE Find all fields F such that every function $F \to F$ is the polynomial function (Definition 1.2.17) of some $p \in F[x]$. For each such field, show that every function $F \to F$ is the polynomial function of exactly one polynomial of degree less than $|F|$. You may use that a nonzero polynomial of degree d has at most d roots (Proposition 7.1.22).

Solution on page 1102

Problem 1.19. CHALLENGE Let $n \geq 1$. Find the largest k for which there is a list of k vectors in $\mathbb{F}_2^n$ in which every sublist of length at most 3 is linearly independent.

Solution on page 1103

Chapter 2

Linear maps and matrices

Linear maps, their matrices, matrix multiplication as composition, inverses, kernels and images, and the Fundamental Theorems.

2.1 Linear maps

In Section 1.6 we attached to each vector $\mathbf{v}$ of a space V with basis $\mathcal{B}$ its coordinate vector $[\mathbf{v}]_{\mathcal{B}} \in F^n$, and we saw that coordinates respect linear combinations: $[c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k]_{\mathcal{B}} = c_1[\mathbf{v}_1]_{\mathcal{B}} + \cdots + c_k[\mathbf{v}_k]_{\mathcal{B}}$ (Proposition 1.6.19). Forming a combination in V and then taking coordinates gives the same answer as taking coordinates first and forming the combination in F^n. A vector space has no structure besides addition and scalar multiplication, so the functions worth studying between vector spaces are the ones with this property. They are the linear maps, and from here on they are the main objects of the book.

2.1.1 Definition and first properties

Definition 2.1.1 (Linear map). Let V and W be vector spaces over the same field F. A function $T : V \to W$ is a **linear map**, or **linear transformation**, if it **respects linear combinations**: for every $k \geq 1$, all $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$, and all $a_1, \ldots, a_k \in F$,

$$T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k) = a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k).$$

A linear map from V to itself is also called a **linear operator**, or just an **operator**, on V.

Notation 2.1.2. $\mathrm{L}(V, W)$ denotes the set of linear maps $V \to W$, and $\mathrm{L}(V) = \mathrm{L}(V, V)$ the set of operators on V. Other texts write $T\mathbf{v}$ for $T(\mathbf{v})$; we keep the parentheses in this section. When the field matters, we say that T is F-**linear**.

Realize that the two sides of the defining equation are computed in different spaces. On the left, the linear combination is formed in V and then T is applied to the result. On the right, T is applied to each $\mathbf{v}_i$ first and the combination is formed in W, with the same coefficients. Linearity says that the order does not matter: applying T commutes with forming linear combinations.

Intuition. The definition asks about combinations of every length k, which is unpleasant to check directly. But a linear combination is built one operation at a time from scalar multiples and sums. So a function that respects scalar multiplication and addition separately should respect every linear combination: split off the last term $a_k\mathbf{v}_k$ using addition, pull out its coefficient using scalar multiplication, and

handle the shorter combination that remains in the same way. This is an induction on k. Conversely, $a\mathbf{v}$ and $\mathbf{u}+\mathbf{v}$ are themselves linear combinations, of lengths 1 and 2.

Theorem 2.1.3 (Checking linearity). Let V and W be vector spaces over F, and let $T : V \to W$ be a function. The following are equivalent.

(i) T is linear.

(ii) T is **additive** and **homogeneous**: $T(\mathbf{u}+\mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v})$ and $T(a\mathbf{v}) = aT(\mathbf{v})$ for all $\mathbf{u}, \mathbf{v} \in V$ and all $a \in F$.

(iii) For all $\mathbf{u}, \mathbf{v} \in V$ and all $a \in F$, $T(a\mathbf{u}+\mathbf{v}) = aT(\mathbf{u}) + T(\mathbf{v})$.

Proof. ROUTINE

Uses. Definition 2.1.1 (Linear map), Definition 1.2.1 (Vector space)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Sums and scalar multiples are linear combinations of length 2 and 1, so (i) ⇒ (iii) and (iii) ⇒ (ii) come down to choosing special cases. For (ii) ⇒ (i), induct on the length k.
Hint 2. For (iii) ⇒ (ii), first take $a = 1$ and $\mathbf{u} = \mathbf{v} = \mathbf{0}$ to learn that $T(\mathbf{0}) = \mathbf{0}$. Then $a = 1$ gives additivity and $\mathbf{v} = \mathbf{0}$ gives homogeneity.
Hint 3. For the induction step, write $a_1\mathbf{v}_1 + \cdots + a_{k+1}\mathbf{v}_{k+1}$ as $\mathbf{u} + a_{k+1}\mathbf{v}_{k+1}$ with $\mathbf{u} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. Apply additivity, then homogeneity to the last term and the induction hypothesis to $T(\mathbf{u})$.
Sketch. (i) ⇒ (iii) is the definition with $k = 2$ and coefficients $a, 1$. In (iii), the choice $a = 1$, $\mathbf{u} = \mathbf{v} = \mathbf{0}$ gives $T(\mathbf{0}) = T(\mathbf{0}) + T(\mathbf{0})$, so $T(\mathbf{0}) = \mathbf{0}$; then $a = 1$ gives additivity and $\mathbf{v} = \mathbf{0}$ gives homogeneity. For (ii) ⇒ (i), induct on k: the case $k = 1$ is homogeneity, and additivity splits a combination of length $k+1$ into one of length k plus a single term.

We prove (i) ⇒ (iii) ⇒ (ii) ⇒ (i).

(i) ⇒ (iii). Let $\mathbf{u}, \mathbf{v} \in V$ and $a \in F$. The definition of linearity with $k = 2$, $\mathbf{v}_1 = \mathbf{u}$, $\mathbf{v}_2 = \mathbf{v}$, $a_1 = a$, and $a_2 = 1$ gives $T(a\mathbf{u} + 1\mathbf{v}) = aT(\mathbf{u}) + 1T(\mathbf{v})$. Since $1\mathbf{x} = \mathbf{x}$ for every vector $\mathbf{x}$, in V and in W, this is (iii).

(iii) ⇒ (ii). Taking $a = 1$ and $\mathbf{u} = \mathbf{v} = \mathbf{0}$ in (iii) gives

$$T(\mathbf{0}) = T(1 \cdot \mathbf{0} + \mathbf{0}) = 1 \cdot T(\mathbf{0}) + T(\mathbf{0}) = T(\mathbf{0}) + T(\mathbf{0}).$$

Adding $-T(\mathbf{0})$ to both sides and regrouping, $\mathbf{0} = T(\mathbf{0})$. Now let $\mathbf{u}, \mathbf{v} \in V$ and $a \in F$. With $a = 1$, (iii) reads $T(\mathbf{u}+\mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v})$, which is additivity. With $\mathbf{v} = \mathbf{0}$, it reads

$$T(a\mathbf{u}) = T(a\mathbf{u} + \mathbf{0}) = aT(\mathbf{u}) + T(\mathbf{0}) = aT(\mathbf{u}),$$

which is homogeneity.

(ii) ⇒ (i). We show by induction on $k \geq 1$ that $T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k) = a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k)$ for all $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$ and $a_1, \ldots, a_k \in F$. For $k = 1$ this is homogeneity. Suppose it holds for some $k \geq 1$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_{k+1} \in V$ and $a_1, \ldots, a_{k+1} \in F$. Put $\mathbf{u} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. Then

$$\begin{aligned} T(a_1\mathbf{v}_1 + \cdots + a_{k+1}\mathbf{v}_{k+1}) &= T(\mathbf{u} + a_{k+1}\mathbf{v}_{k+1}) \\ &= T(\mathbf{u}) + T(a_{k+1}\mathbf{v}_{k+1}) \\ &= a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k) + a_{k+1}T(\mathbf{v}_{k+1}), \end{aligned}$$

as desired. The second step is additivity, and the third applies the induction hypothesis to $T(\mathbf{u})$ and homogeneity to the last term. □

From now on we verify linearity through (ii) or (iii), and we use (i) whenever we apply a linear map to a linear combination. Neither half of (ii) implies the other: complex conjugation is additive but not homogeneous over $\mathbb{C}$ (Non-example 2.1.14), and Exercise 2.1.38 gives a homogeneous map that is not additive.

Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives). Let $T \in \mathrm{L}(V, W)$. Then $T(\mathbf{0}_V) = \mathbf{0}_W$, and for all $\mathbf{u}, \mathbf{v} \in V$,

$$T(-\mathbf{v}) = -T(\mathbf{v}) \quad \text{and} \quad T(\mathbf{u}-\mathbf{v}) = T(\mathbf{u}) - T(\mathbf{v}).$$

Proof (via homogeneity). ROUTINE

Uses. Theorem 2.1.3 (Checking linearity), Proposition 1.2.32 (The scalar zero), Proposition 1.2.34 (Negatives and the scalar -1)
Hint 1. Write $\mathbf{0}_V$ as a scalar multiple of some vector, so that homogeneity applies.
Hint 2. $\mathbf{0}_V = 0 \cdot \mathbf{0}_V$, and $0\mathbf{w} = \mathbf{0}_W$ for every $\mathbf{w} \in W$. For negatives, $-\mathbf{v} = (-1)\mathbf{v}$.
Sketch. $T(\mathbf{0}) = T(0 \cdot \mathbf{0}) = 0 \cdot T(\mathbf{0}) = \mathbf{0}$, using $0\mathbf{x} = \mathbf{0}$ in V and then in W. Similarly $T(-\mathbf{v}) = T((-1)\mathbf{v}) = (-1)T(\mathbf{v}) = -T(\mathbf{v})$, and the last identity follows by additivity.

By Proposition 1.2.32, $0\mathbf{x} = \mathbf{0}$ for every vector $\mathbf{x}$, in V and in W. So by homogeneity,

$$T(\mathbf{0}_V) = T(0 \cdot \mathbf{0}_V) = 0 \cdot T(\mathbf{0}_V) = \mathbf{0}_W.$$

By Proposition 1.2.34, $-\mathbf{x} = (-1)\mathbf{x}$ in V and in W, so homogeneity gives $T(-\mathbf{v}) = T((-1)\mathbf{v}) = (-1)T(\mathbf{v}) = -T(\mathbf{v})$. Finally, by additivity, $T(\mathbf{u}-\mathbf{v}) = T(\mathbf{u}+(-\mathbf{v})) = T(\mathbf{u}) + T(-\mathbf{v}) = T(\mathbf{u}) - T(\mathbf{v})$. □

Proof (via additivity). ROUTINE

Uses. Theorem 2.1.3 (Checking linearity), Definition 1.2.1 (Vector space), Proposition 1.2.28 (Uniqueness of additive inverses)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Write $\mathbf{0}_V$ as a sum, so that additivity applies.
Hint 2. $T(\mathbf{0}) = T(\mathbf{0}+\mathbf{0}) = T(\mathbf{0}) + T(\mathbf{0})$. Now cancel. For negatives, show that $T(-\mathbf{v})$ is an additive inverse of $T(\mathbf{v})$.
Sketch. $T(\mathbf{0}) = T(\mathbf{0}+\mathbf{0}) = T(\mathbf{0}) + T(\mathbf{0})$, and adding $-T(\mathbf{0})$ gives $\mathbf{0} = T(\mathbf{0})$. Then $T(\mathbf{v}) + T(-\mathbf{v}) = T(\mathbf{v}-\mathbf{v}) = T(\mathbf{0}) = \mathbf{0}$, so $T(-\mathbf{v}) = -T(\mathbf{v})$ by uniqueness of additive inverses.

By additivity, $T(\mathbf{0}_V) = T(\mathbf{0}_V + \mathbf{0}_V) = T(\mathbf{0}_V) + T(\mathbf{0}_V)$. Writing $\mathbf{w} = T(\mathbf{0}_V)$, we have $\mathbf{w} = \mathbf{w} + \mathbf{w}$, so

$$\mathbf{0}_W = \mathbf{w} + (-\mathbf{w}) = (\mathbf{w}+\mathbf{w}) + (-\mathbf{w}) = \mathbf{w} + (\mathbf{w} + (-\mathbf{w})) = \mathbf{w} + \mathbf{0}_W = \mathbf{w}.$$

Next, for $\mathbf{v} \in V$, additivity gives $T(\mathbf{v}) + T(-\mathbf{v}) = T(\mathbf{v} + (-\mathbf{v})) = T(\mathbf{0}_V) = \mathbf{0}_W$. So $T(-\mathbf{v})$ is an additive inverse of $T(\mathbf{v})$, and by Proposition 1.2.28 it equals $-T(\mathbf{v})$. The identity $T(\mathbf{u}-\mathbf{v}) = T(\mathbf{u}) - T(\mathbf{v})$ follows from additivity as in the first proof. □

The first proof used only homogeneity and the second only additivity. So a function satisfying either condition alone sends $\mathbf{0}$ to $\mathbf{0}$; we use this for additive maps in Exercise 2.1.36 and Exercise 2.1.37. In practice Proposition 2.1.4 is a quick test in the contrapositive: a function with $T(\mathbf{0}) \neq \mathbf{0}$ is not linear. It is only a necessary condition. The map $\mathbb{R}^2 \to \mathbb{R}$, $(x, y) \mapsto xy$, sends $\mathbf{0}$ to 0, but it sends $(1, 1)$ to 1 and $2(1, 1) = (2, 2)$ to $4 \neq 2 \cdot 1$, so it is not homogeneous.

Exercise 2.1.5. ROUTINE Let W be a vector space over F, and regard F as a vector space over itself.

(a) Show that for every $\mathbf{w} \in W$, the map $F \to W$, $x \mapsto x\mathbf{w}$, is linear.

(b) Show that every $T \in \mathrm{L}(F, W)$ has this form, with $\mathbf{w} = T(1)$. In particular, the linear maps $F \to F$ are exactly the maps $x \mapsto ax$ with $a \in F$.

Solution on page 1104

2.1.2 Examples

Many familiar operations are linear maps. In each example below, linearity is checked with Theorem 2.1.3.

Example 2.1.6 (Zero, identity, and scaling maps). Let V and W be vector spaces over F.

- The **zero map** $V \to W$, $\mathbf{v} \mapsto \mathbf{0}_W$, is linear, since both sides of (iii) in Theorem 2.1.3 are $\mathbf{0}_W$ (by Proposition 1.2.33). We denote it by 0; the context tells it apart from $0 \in F$ and $\mathbf{0}_W$.
- The **identity map** $\mathrm{id}_V : V \to V$, $\mathbf{v} \mapsto \mathbf{v}$, is linear, since both sides of (iii) are $a\mathbf{u} + \mathbf{v}$.
- For $\lambda \in F$, the **scaling map** $V \to V$, $\mathbf{v} \mapsto \lambda\mathbf{v}$, is linear:

$$\lambda(a\mathbf{u} + \mathbf{v}) = (\lambda a)\mathbf{u} + \lambda\mathbf{v} = (a\lambda)\mathbf{u} + \lambda\mathbf{v} = a(\lambda\mathbf{u}) + \lambda\mathbf{v}.$$

  The middle step is the commutativity of multiplication in F.

Example 2.1.7 (Maps $F^n \to F^m$ given by linear formulas). Let $A \in F^{m\times n}$ (Definition 1.2.7) have entries a_{ij}, and define $T_A : F^n \to F^m$ by

$$T_A(x_1, \ldots, x_n) = (a_{11}x_1 + \cdots + a_{1n}x_n, \ldots, a_{m1}x_1 + \cdots + a_{mn}x_n).$$

That is, the i-th coordinate of $T_A(\mathbf{x})$ is $\sum_{j=1}^{n} a_{ij}x_j$. This map is linear. For $\mathbf{x}, \mathbf{y} \in F^n$ and $c \in F$, the i-th coordinate of $T_A(c\mathbf{x} + \mathbf{y})$ is

$$\sum_{j=1}^{n} a_{ij}(cx_j + y_j) = c\sum_{j=1}^{n} a_{ij}x_j + \sum_{j=1}^{n} a_{ij}y_j,$$

which is the i-th coordinate of $cT_A(\mathbf{x}) + T_A(\mathbf{y})$. For example, $T : \mathbb{R}^3 \to \mathbb{R}^2$, $T(x, y, z) = (2x - y + 3z, x + 5z)$, is T_A with

$$A = \begin{pmatrix} 2 & -1 & 3 \\ 1 & 0 & 5 \end{pmatrix}.$$

Over $\mathbb{F}_2$, the map $(x, y, z) \mapsto (x + y, y + z)$ is T_A with $A = \left(\begin{smallmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{smallmatrix}\right)$. The coordinate projections $(x_1, \ldots, x_n) \mapsto x_i$ are special cases too.

In Section 2.3 we write $T_A(\mathbf{x})$ as a matrix–vector product $A\mathbf{x}$ (Definition 2.3.8, Definition 2.3.15) and show that every linear map $F^n \to F^m$ is T_A for some A (Proposition 2.3.17).

Example 2.1.8 (Coordinates). Let $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V. The coordinate map $V \to F^n$, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ (Definition 1.6.14), is linear; this is Proposition 1.6.19. In the other direction, for any list $\mathbf{v}_1, \ldots, \mathbf{v}_n$ in V, basis or not, the map

$$F^n \to V, \quad (a_1, \ldots, a_n) \mapsto a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n,$$

is linear, because $\sum_i (ca_i + d_i)\mathbf{v}_i = c\sum_i a_i\mathbf{v}_i + \sum_i d_i\mathbf{v}_i$ by the vector space axioms. For the basis $\mathcal{B}$, the two maps undo each other: $[a_1\mathbf{b}_1 + \cdots + a_n\mathbf{b}_n]_{\mathcal{B}} = (a_1, \ldots, a_n)$ by the definition of coordinates, and $\mathbf{v} = c_1\mathbf{b}_1 + \cdots + c_n\mathbf{b}_n$ where $(c_1, \ldots, c_n) = [\mathbf{v}]_{\mathcal{B}}$. So once a basis is chosen, V and F^n correspond through a pair of linear maps; Section 4.5 develops this.

Example 2.1.9 (Maps of polynomials). Let $p = a_0 + a_1x + \cdots + a_nx^n \in F[x]$ (Definition 1.2.13).

- **Evaluation** at $t \in F$ is $\mathrm{ev}_t : F[x] \to F$, $\mathrm{ev}_t(p) = p(t) = a_0 + a_1t + \cdots + a_nt^n$.
- **Multiplication by** x is $M : F[x] \to F[x]$, $M(p) = xp = a_0x + a_1x^2 + \cdots + a_nx^{n+1}$.
- **Differentiation** is $D : F[x] \to F[x]$,

$$D(p) = a_1 + 2a_2x + 3a_3x^2 + \cdots + na_nx^{n-1},$$

  where ka_k means $a_k + \cdots + a_k$ (k terms). For $F = \mathbb{R}$ this is the derivative of calculus, and over any field we take the formula as the definition (the **formal derivative**). We also write p' for $D(p)$.

All three maps are linear, with the same proof. Let $q = b_0 + b_1x + \cdots + b_nx^n$ (padding with zero coefficients, we may use the same n for p and q) and $c \in F$. Polynomials are added and scaled coefficientwise, so $cp + q = \sum_k (ca_k + b_k)x^k$. Each of the three maps sends the coefficient of x^k to a fixed place and multiplies it by a factor that does not depend on the polynomial (t^k, 1, or k). For D,

$$D(cp+q)=\sum_{k=1}^{n}k(ca_k+b_k)x^{k-1}=c\sum_{k=1}^{n}ka_kx^{k-1}+\sum_{k=1}^{n}kb_kx^{k-1}=cD(p)+D(q),$$

where $k(ca_k+b_k)=c(ka_k)+kb_k$ because ky is a sum of k copies of y. The computations for ev_t and M are the same with t^k and x^{k+1} in place of kx^{k-1}.

Over a finite field the formal derivative behaves unlike the one from calculus. Over $\mathbb{F}_2$, for example, $D\big(x^2\big)=2x=0$, so a nonconstant polynomial can have derivative 0 (Exercise 2.1.34).

Example 2.1.10 (Integration). Let $C[0,1]$ be the real vector space of continuous functions $[0,1]\to\mathbb{R}$ (Section 1.2). The map

$$C[0,1]\to\mathbb{R},\quad f\mapsto\int_0^1 f(t)\,\mathrm{d}t,$$

is linear: $\int_0^1(cf+g)=c\int_0^1 f+\int_0^1 g$ is the linearity of the integral. Likewise $J:C[0,1]\to C[0,1]$, $(Jf)(x)=\int_0^x f(t)\,\mathrm{d}t$, is linear. Here Jf is continuous (even differentiable) by the fundamental theorem of calculus, and $J(cf+g)=cJf+Jg$ because the two functions agree at every $x\in[0,1]$.

Linear maps of the plane

Rotations, projections, and reflections of $\mathbb{R}^2$ that fix the origin are linear. In each case we derive a coordinate formula from the geometry. The formula has the shape of Example 2.1.7, so the map is linear.

Example 2.1.11 (Rotations, projections, and reflections). **Rotation.** Let $R_\theta:\mathbb{R}^2\to\mathbb{R}^2$ rotate the plane counterclockwise about $\mathbf{0}$ by the angle θ. Write a point in polar form, $(x,y)=(r\cos\varphi,r\sin\varphi)$. Rotation adds θ to the angle, so by the angle addition formulas,

$$\begin{aligned}R_\theta(x,y)&=(r\cos(\varphi+\theta),r\sin(\varphi+\theta))\\&=(r\cos\varphi\cos\theta-r\sin\varphi\sin\theta,r\sin\varphi\cos\theta+r\cos\varphi\sin\theta)\\&=(x\cos\theta-y\sin\theta,x\sin\theta+y\cos\theta).\end{aligned}$$

Projection. Let ℓ be the line through $\mathbf{0}$ in the direction of the unit vector $\mathbf{u}=(\cos\theta,\sin\theta)$. The projection $\mathrm{Pr}_\ell:\mathbb{R}^2\to\mathbb{R}^2$ sends $\mathbf{v}=(x,y)$ to the foot $t\mathbf{u}$ of the perpendicular from $\mathbf{v}$ to ℓ. Two vectors (a,b) and (c,d) are perpendicular when $ac+bd=0$, so t is determined by

$$(x-t\cos\theta)\cos\theta+(y-t\sin\theta)\sin\theta=0,\quad\text{that is,}\quad t=x\cos\theta+y\sin\theta,$$

using $\cos^2\theta+\sin^2\theta=1$. Hence

$$\begin{aligned}\mathrm{Pr}_\ell(x,y)&=(x\cos\theta+y\sin\theta)(\cos\theta,\sin\theta)\\&=\big(x\cos^2\theta+y\sin\theta\cos\theta,x\sin\theta\cos\theta+y\sin^2\theta\big).\end{aligned}$$

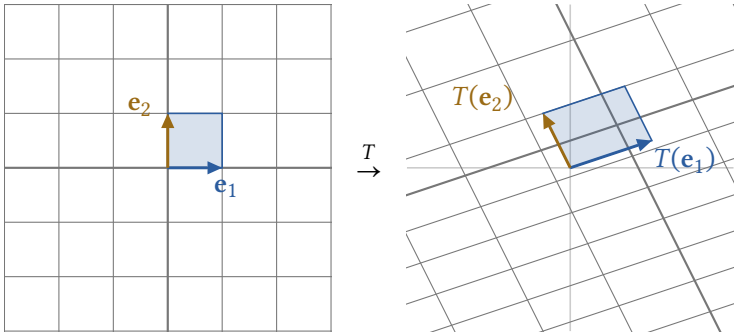
Reflection. The reflection S_ℓ across ℓ sends $\mathbf{v}$ to the point $S_\ell(\mathbf{v})$ for which $\mathrm{Pr}_\ell(\mathbf{v})$ is the midpoint of $\mathbf{v}$ and $S_\ell(\mathbf{v})$. So $S_\ell(\mathbf{v})=2\,\mathrm{Pr}_\ell(\mathbf{v})-\mathbf{v}$, and with the double angle formulas,

$$S_\ell(x,y)=(x\cos2\theta+y\sin2\theta,x\sin2\theta-y\cos2\theta).$$

All three formulas have the form of Example 2.1.7, so R_θ, Pr_ℓ, and S_ℓ are linear. For instance, if ℓ is the x-axis ($\theta=0$), then $\mathrm{Pr}_\ell(x,y)=(x,0)$ and $S_\ell(x,y)=(x,-y)$, and the rotation by a right angle is $R_{\pi/2}(x,y)=(-y,x)$. Orthogonal projections in any inner product space are the subject of Section 6.4.

Intuition (What a linear map does to the grid). Let $T:\mathbb{R}^2\to\mathbb{R}^2$ be linear. Since $(x,y)=x\mathbf{e}_1+y\mathbf{e}_2$, linearity gives

$$T(x,y)=xT(\mathbf{e}_1)+yT(\mathbf{e}_2).$$



So T is determined by the two vectors $T(\mathbf{e}_1)$ and $T(\mathbf{e}_2)$ (Section 2.2 proves the analogue for every basis), and the grid point (x, y) goes to x steps along $T(\mathbf{e}_1)$ followed by y steps along $T(\mathbf{e}_2)$. The square grid becomes a grid of parallelograms spanned by $T(\mathbf{e}_1)$ and $T(\mathbf{e}_2)$. To be precise about lines, apply T to the line through $\mathbf{p}$ in the direction $\mathbf{d}$:

$$T(\mathbf{p} + t\mathbf{d}) = T(\mathbf{p}) + tT(\mathbf{d}) \quad (t \in \mathbb{R}).$$

This is the line through $T(\mathbf{p})$ in the direction $T(\mathbf{d})$, or the single point $T(\mathbf{p})$ if $T(\mathbf{d}) = \mathbf{0}$. Reading off this formula:

- lines go to lines, or collapse to points;
- parallel lines, which share a direction $\mathbf{d}$, go to lines that share the direction $T(\mathbf{d})$ (they may coincide, or all collapse to points if $T(\mathbf{d}) = \mathbf{0}$);
- evenly spaced points $\mathbf{p}, \mathbf{p} + \mathbf{d}, \mathbf{p} + 2\mathbf{d}, \ldots$ go to evenly spaced points;
- the origin stays where it is.

Drag the tips of $T(\mathbf{e}_1)$ and $T(\mathbf{e}_2)$ below (or focus one and use the arrow keys) and watch the grid follow. The panel lists the four numbers in $T(x, y) = (ax + by, cx + dy)$ as an array A, the notation of Section 2.3; the handles labelled $A\mathbf{e}_1$ and $A\mathbf{e}_2$ are $T(\mathbf{e}_1) = (a, c)$ and $T(\mathbf{e}_2) = (b, d)$. The determinant readout belongs to Section 5.1 and can be ignored for now.

A linear map of the plane. Grid lines go to evenly spaced parallel lines, the unit square goes to the parallelogram spanned by $T(\mathbf{e}_1)$ and $T(\mathbf{e}_2)$, and the origin stays fixed. (Interactive in the web version.)

2.1.3 Non-examples

The quickest way to see that a map is not linear is to find that it moves the origin (Proposition 2.1.4). The simplest maps that do this are the affine maps.

Non-example 2.1.12 (Affine maps). Let $a, b \in F$. The map $f : F \to F$, $f(x) = ax + b$, is linear if and only if $b = 0$. Indeed, if $b \neq 0$, then $f(0) = b \neq 0$, so f is not linear by Proposition 2.1.4; if $b = 0$, then $f(x) = ax$ is linear by Exercise 2.1.5. So the "linear functions" of school algebra, whose graphs are lines, are linear maps only when the line passes through the origin.

More generally, for $L \in \mathrm{L}(V, W)$ and $\mathbf{b} \in W$, the map $T : V \to W$, $T(\mathbf{v}) = L(\mathbf{v}) + \mathbf{b}$, is called **affine**. Since $T(\mathbf{0}) = \mathbf{b}$, it is linear only if $\mathbf{b} = \mathbf{0}$.

Intuition. The failure of an affine map is more specific than "$T(\mathbf{0}) \neq \mathbf{0}$". Compute both sides of the defining equation of linearity for $T = L + \mathbf{b}$: the left side picks up one copy of $\mathbf{b}$, and the right side picks up $c_1 + \cdots + c_k$ copies. So, when $\mathbf{b} \neq \mathbf{0}$, T respects exactly those combinations whose coefficients add up to 1.

Proposition 2.1.13 (Which combinations an affine map respects). Let $L \in \mathrm{L}(V, W)$, $\mathbf{b} \in W$, and $T(\mathbf{v}) = L(\mathbf{v}) + \mathbf{b}$. For all $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$ and $c_1, \ldots, c_k \in F$,

$$T(c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k) - (c_1T(\mathbf{v}_1) + \cdots + c_kT(\mathbf{v}_k)) = (1 - c_1 - \cdots - c_k)\mathbf{b}.$$

In particular, if $\mathbf{b} \neq \mathbf{0}$, then $T\left(\sum_i c_i\mathbf{v}_i\right) = \sum_i c_iT(\mathbf{v}_i)$ holds if and only if $c_1 + \cdots + c_k = 1$. So T is linear if and only if $\mathbf{b} = \mathbf{0}$.

Proof. ROUTINE

Uses. Definition 2.1.1 (Linear map), Proposition 1.2.35 (Zero products)
Hint 1. Expand both $T\left(\sum_i c_i\mathbf{v}_i\right)$ and $\sum_i c_iT(\mathbf{v}_i)$ using the formula for T and the linearity of L.
Hint 2. The terms involving L cancel. What remains is $\mathbf{b} - (c_1 + \cdots + c_k)\mathbf{b}$. When is $s\mathbf{b} = \mathbf{0}$ for a nonzero $\mathbf{b}$?
Sketch. $T(\sum c_i\mathbf{v}_i) = \sum c_iL(\mathbf{v}_i) + \mathbf{b}$ and $\sum c_iT(\mathbf{v}_i) = \sum c_iL(\mathbf{v}_i) + (\sum c_i)\mathbf{b}$; subtract. If $\mathbf{b} \neq \mathbf{0}$, then $(1 - \sum c_i)\mathbf{b} = \mathbf{0}$ forces $\sum c_i = 1$. The combination $0 \cdot \mathbf{v}$ has coefficient sum 0, so T is not linear.

By the linearity of L,

$$T(c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k) = c_1L(\mathbf{v}_1) + \cdots + c_kL(\mathbf{v}_k) + \mathbf{b},$$

while, by distributivity in W,

$$c_1T(\mathbf{v}_1) + \cdots + c_kT(\mathbf{v}_k) = c_1L(\mathbf{v}_1) + \cdots + c_kL(\mathbf{v}_k) + (c_1 + \cdots + c_k)\mathbf{b}.$$

Subtracting gives the displayed identity. If $\mathbf{b} \neq \mathbf{0}$, then by Proposition 1.2.35, $(1 - c_1 - \cdots - c_k)\mathbf{b} = \mathbf{0}$ if and only if $c_1 + \cdots + c_k = 1$. In particular, the combination $0 \cdot \mathbf{v}$ (with $k = 1$ and $c_1 = 0$) is not respected, so T is not linear. If $\mathbf{b} = \mathbf{0}$, then $T = L$ is linear. □

Combinations whose coefficients add up to 1 are called **affine combinations**. Examples are the points $(1 - t)\mathbf{u} + t\mathbf{v}$ of the line through $\mathbf{u}$ and $\mathbf{v}$, and in particular the midpoint $\frac{1}{2}\mathbf{u} + \frac{1}{2}\mathbf{v}$ when $1 + 1 \neq 0$. An affine map respects these, which is why an affine map of $\mathbb{R}^2$, like a linear one, still sends lines to lines or points, parallel lines to lines with a common direction, and evenly spaced points to evenly spaced points. What it does not respect is anything that refers to the origin, such as the scalar multiple $2\mathbf{v}$, whose single coefficient is 2. Compare the first two panels of Figure 2.1.1: the affine map produces the same grid as the linear one, translated. Affine maps and affine combinations are the subject of Section 4.7.

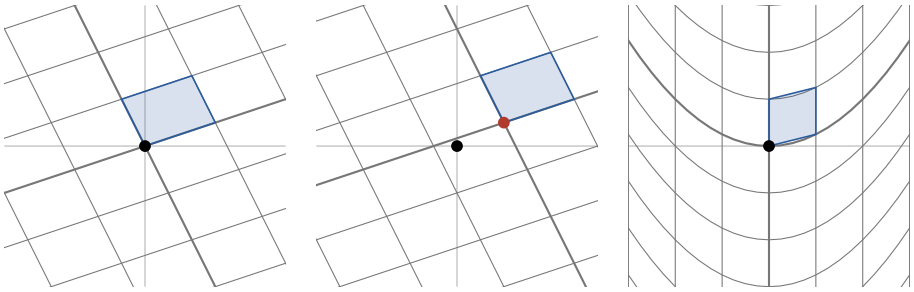


Figure 2.1.1. The square grid under three maps of $\mathbb{R}^2$; the faint lines are the original axes, and the shaded cell is the image of the unit square. Left: the linear map $T(x, y) = (1.5x - 0.5y, 0.5x + y)$. Middle: the affine map $\mathbf{v} \mapsto T(\mathbf{v}) + (1, 0.5)$, which moves the origin to the red point. Right: $(x, y) \mapsto \left(x, y + x^2/4\right)$, which fixes the origin but bends the horizontal grid lines, so it is not linear either.

Non-example 2.1.14 (Complex conjugation). Let $c : \mathbb{C} \to \mathbb{C}$ be complex conjugation, $c(a + bi) = \overline{a + bi} = a - bi$ for $a, b \in \mathbb{R}$. Regard $\mathbb{C}$ as a vector space over $\mathbb{R}$ (Section 1.2), with $a + bi$ corresponding to $(a, b) \in \mathbb{R}^2$. Then c is the map $(a, b) \mapsto (a, -b)$, the reflection in the real axis, which is $\mathbb{R}$-linear by Example 2.1.11.

Now regard $\mathbb{C}$ as a vector space over $\mathbb{C}$. Conjugation is still additive, since $\overline{z+w} = \overline{z} + \overline{w}$. But it is not homogeneous: $c(i \cdot 1) = \bar{i} = -i$, while $i \cdot c(1) = i$. So conjugation is $\mathbb{R}$-linear but not $\mathbb{C}$-linear. Whether a function is linear depends on the field of scalars, and not only on the sets and the function.

Formulas that are visibly nonlinear fail homogeneity at once. The map $\mathbb{R} \to \mathbb{R}$, $x \mapsto x^2$, sends $2 \cdot 1$ to $4 \neq 2 \cdot 1^2$, and $\mathbb{R} \to \mathbb{R}$, $x \mapsto \sin x$, sends $\pi = 2 \cdot \pi/2$ to $0 \neq 2\sin(\pi/2)$. As a rule of thumb, in a coordinate formula for a linear map, each output coordinate is a sum of constant multiples of the input coordinates: no constant terms, no products of coordinates, and no other functions applied to them. For maps $F^n \to F^m$, Proposition 2.3.17 makes this precise.

Exercise 2.1.15. ROUTINE Decide which of the following maps are linear.

(a) $T : \mathbb{R}^2 \to \mathbb{R}^2$, $T(x, y) = (y, x - 3y)$.

(b) $T : \mathbb{R}^2 \to \mathbb{R}^2$, $T(x, y) = (x + 1, y)$.

(c) $T : \mathbb{R} \to \mathbb{R}^2$, $T(x) = (x, |x|)$.

(d) $T : \mathbb{F}_2^2 \to \mathbb{F}_2$, $T(x, y) = xy$.

Solution on page 1104

2.1.4 What linear maps preserve

Intuition. A vector space is a set with an addition and a scalar multiplication, and nothing else. Every notion we have defined so far (linear combination, span, linear relation, linear dependence) is defined from these two operations. A linear map respects both, so it carries each notion in V to the corresponding notion in W, at least in one direction. The direction matters: a linear map may send different vectors to the same vector, so it can destroy independence, but it never creates independence where there was none.

For a subset $A \subseteq V$ we write $T(A) = \{T(\mathbf{a}) \mid \mathbf{a} \in A\}$, and for a list $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ in V we write $T(\mathcal{L})$ for the list $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)$ in W.

Proposition 2.1.16 (Linear maps preserve spans and linear relations). Let $T \in \mathrm{L}(V, W)$, and let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V.

(a) $\operatorname{im}\left(T|_{\operatorname{span}\mathcal{L}}\right) = \operatorname{span} T(\mathcal{L})$. In particular, if $\mathcal{L}$ spans V, then $T(\mathcal{L})$ spans $\operatorname{im} T$.

(b) If $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$, then $a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k) = \mathbf{0}$. Consequently, if $\mathcal{L}$ is linearly dependent, then so is $T(\mathcal{L})$. Equivalently, if $T(\mathcal{L})$ is linearly independent, then so is $\mathcal{L}$.

Proof. ROUTINE

Uses. Definition 1.3.10 (Span), Definition 2.1.1 (Linear map), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For (a), prove the two inclusions separately. An element of $\operatorname{span}\mathcal{L}$ is a combination $\sum a_i\mathbf{v}_i$; what is its image?
Hint 2. For (b), apply T to both sides of the relation. For the statement about dependence, use the description of dependence by a nontrivial representation of $\mathbf{0}$ (Theorem 1.5.5).
Sketch. $T(\sum a_i\mathbf{v}_i) = \sum a_iT(\mathbf{v}_i)$ shows both that images of elements of $\operatorname{span}\mathcal{L}$ lie in $\operatorname{span} T(\mathcal{L})$, and that every element of $\operatorname{span} T(\mathcal{L})$ is such an image. Applying T to a nontrivial relation $\sum a_i\mathbf{v}_i = \mathbf{0}$ gives a relation among the $T(\mathbf{v}_i)$ with the same, not all zero, coefficients.

(a) If $k = 0$, then $\operatorname{span}\mathcal{L} = \{\mathbf{0}\}$ and $\operatorname{span} T(\mathcal{L}) = \{\mathbf{0}\}$, and $T(\{\mathbf{0}\}) = \{\mathbf{0}\}$ by Proposition 2.1.4. Let $k \geq 1$. We prove the two inclusions.

($\subseteq$) An element of $\operatorname{im}\left(T|_{\operatorname{span}\mathcal{L}}\right)$ has the form $T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k)$ with $a_i \in F$. By linearity it equals $a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k)$, which lies in $\operatorname{span} T(\mathcal{L})$.

($\supseteq$) An element of $\operatorname{span} T(\mathcal{L})$ has the form $a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k)$, which by linearity equals $T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k)$. Since $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k \in \operatorname{span}\mathcal{L}$, this lies in $\operatorname{im}\left(T\restriction_{\operatorname{span}\mathcal{L}}\right)$.

If $\mathcal{L}$ spans V, then $\operatorname{im} T = \operatorname{im}\left(T\restriction_{\operatorname{span}\mathcal{L}}\right) = \operatorname{span} T(\mathcal{L})$, so $T(\mathcal{L})$ spans $\operatorname{im} T$.

(b) Applying T to both sides of $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ and using linearity and Proposition 2.1.4,

$$a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k) = T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k) = T(\mathbf{0}) = \mathbf{0}.$$

If $\mathcal{L}$ is linearly dependent, then by Theorem 1.5.5 there are scalars $a_1, \ldots, a_k$, not all 0, with $\sum_i a_i\mathbf{v}_i = \mathbf{0}$. By what we just showed, the same scalars give $\sum_i a_iT(\mathbf{v}_i) = \mathbf{0}$, a nontrivial representation of $\mathbf{0}$ by $T(\mathcal{L})$. So $T(\mathcal{L})$ is linearly dependent, again by Theorem 1.5.5. The last sentence of (b) is the contrapositive. □

The converse of the last statement fails. If ℓ is the x-axis, then Pr_ℓ sends the independent list $\mathbf{e}_1, \mathbf{e}_2$ to the dependent list $(1,0), (0,0)$, and the zero map sends every list to a list of zero vectors. The maps that preserve independence are identified in Section 2.6: they are the injective ones. Part (a) with $k = 1$ is the statement about lines from the grid picture: for $\mathbf{v} \neq \mathbf{0}$, the line $\operatorname{span}(\mathbf{v})$ through $\mathbf{0}$ goes to the line $\operatorname{span}(T(\mathbf{v}))$, or to $\{\mathbf{0}\}$ if $T(\mathbf{v}) = \mathbf{0}$.

2.1.5 Composition

Linear maps can be applied one after another. Recall that for functions $S : U \to V$ and $T : V \to W$, the **composition** $T \circ S : U \to W$ is $\mathbf{u} \mapsto T(S(\mathbf{u}))$ (Section A.1).

> **Proposition 2.1.17** (Compositions of linear maps are linear). Let U, V, and W be vector spaces over F. If $S \in \mathrm{L}(U, V)$ and $T \in \mathrm{L}(V, W)$, then $T \circ S \in \mathrm{L}(U, W)$.

Proof. ROUTINE

> *Uses.* Definition 2.1.1 (Linear map)
> *Hint 1.* Take a linear combination in U and follow it through S and then through T.
> *Hint 2.* Use the linearity of S to move the combination outside S, then the linearity of T to move it outside T.
> *Sketch.* $(T \circ S)(\sum a_i\mathbf{u}_i) = T(\sum a_iS(\mathbf{u}_i)) = \sum a_iT(S(\mathbf{u}_i))$.

Let $\mathbf{u}_1, \ldots, \mathbf{u}_k \in U$ and $a_1, \ldots, a_k \in F$. Then

$$\begin{aligned}
(T \circ S)(a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k) &= T(S(a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k)) && \text{(definition of } \circ\text{)} \\
&= T(a_1S(\mathbf{u}_1) + \cdots + a_kS(\mathbf{u}_k)) && \text{(linearity of } S\text{)} \\
&= a_1T(S(\mathbf{u}_1)) + \cdots + a_kT(S(\mathbf{u}_k)) && \text{(linearity of } T\text{)} \\
&= a_1(T \circ S)(\mathbf{u}_1) + \cdots + a_k(T \circ S)(\mathbf{u}_k) && \text{(definition of } \circ\text{),}
\end{aligned}$$

as desired. □

> **Notation 2.1.18.** For linear maps we usually write TS for $T \circ S$. For $T \in \mathrm{L}(V)$ and an integer $k \geq 1$, $T^k = TT\cdots T$ (k factors), and $T^0 = \mathrm{id}_V$. Composition is associative (Proposition 2.1.24), so T^k needs no parentheses, and $T^jT^k = T^{j+k}$.

Example 2.1.19 (Composites).

(a) $D^2 = DD$ on $F[x]$ is the second formal derivative,

$$D^2(a_0 + a_1x + \cdots + a_nx^n) = 2a_2 + 6a_3x + \cdots + n(n-1)a_nx^{n-2}.$$

Each application of D sends constants to 0 and lowers the degree of a nonconstant polynomial by at least one (by exactly one over $\mathbb{R}$ or $\mathbb{C}$; over $\mathbb{F}_2$, $D(x^2 + x) = 1$). So $D^{n+1}(p) = 0$ whenever $\deg p \le n$.

(b) Order matters. Let $P(x, y) = (x, 0)$ be the projection onto the x-axis and $R(x, y) = (-y, x)$ the rotation by a right angle (Example 2.1.11). Then

$$(PR)(x, y) = P(-y, x) = (-y, 0), \quad (RP)(x, y) = R(x, 0) = (0, x).$$

So $PR \neq RP$: for instance $(PR)(\mathbf{e}_1) = \mathbf{0}$, while $(RP)(\mathbf{e}_1) = \mathbf{e}_2$.

Composition of linear maps is not commutative: even when TS and ST are both defined, they need not be equal. For matrices this becomes the noncommutativity of matrix multiplication (Section 2.4).

Exercise 2.1.20. ROUTINE Let $S : \mathbb{R}^3 \to \mathbb{R}^2$ and $T : \mathbb{R}^2 \to \mathbb{R}^3$ be given by

$$S(x, y, z) = (x + y, y + z), \quad T(u, v) = (u - v, 2v, u).$$

Compute ST and TS.

Solution on page 1104

2.1.6 The vector space $\mathrm{L}(V, W)$

Functions with values in a vector space can be added and scaled value by value. For linear maps this makes $\mathrm{L}(V, W)$ a vector space, so everything we prove about vector spaces applies to spaces of linear maps.

Definition 2.1.21 (Pointwise operations). Let X be a set and W a vector space over F. For functions $f, g : X \to W$ and $c \in F$, define $f + g : X \to W$ and $cf : X \to W$ by

$$(f + g)(x) = f(x) + g(x), \quad (cf)(x) = cf(x) \quad (x \in X).$$

We write W^X for the set of all functions $X \to W$, with these operations.

Lemma 2.1.22 (Functions into a vector space). Let X be a set and W a vector space over F. Then W^X is a vector space over F. Its zero vector is the zero function $x \mapsto \mathbf{0}_W$, and the additive inverse of f is $x \mapsto -f(x)$.

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space), Definition 2.1.21 (Pointwise operations)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Each axiom is an equality between two functions $X \to W$. Two functions are equal when they agree at every point.
Hint 2. Evaluate both sides of an axiom at $x \in X$. You get the same axiom in W, applied to the vectors $f(x)$, $g(x)$, ...
Sketch. Each vector space axiom for W^X, evaluated at a point x, becomes the same axiom in W for the values at x. For example $(f + g)(x) = f(x) + g(x) = g(x) + f(x) = (g + f)(x)$.

The operations produce functions $X \to W$, so W^X is closed under them. Each vector space axiom asserts an equality between functions $X \to W$, and two such functions are equal when their values agree at every $x \in X$. At a point x, each axiom becomes the corresponding axiom of W. For example, for $f, g, h \in W^X$, $a, b \in F$, and $x \in X$:

$$\begin{aligned}
(f + g)(x) &= f(x) + g(x) = g(x) + f(x) = (g + f)(x), \\
((f + g) + h)(x) &= (f(x) + g(x)) + h(x) = f(x) + (g(x) + h(x)) = (f + (g + h))(x), \\
(a(f + g))(x) &= a(f(x) + g(x)) = af(x) + ag(x) = (af + ag)(x),
\end{aligned}$$

$$((a+b)f)(x) = (a+b)f(x) = af(x) + bf(x) = (af+bf)(x),$$

and similarly $((ab)f)(x) = (ab)f(x) = a(bf(x)) = (a(bf))(x)$ and $(1f)(x) = 1f(x) = f(x)$. Let z be the zero function and $-f$ the function $x \mapsto -f(x)$. Then $(f+z)(x) = f(x) + \mathbf{0}_W = f(x)$ and $(f + (-f))(x) = f(x) + (-f(x)) = \mathbf{0}_W = z(x)$, so z is an additive identity and $-f$ is an additive inverse of f. □

For $W = F$ this is the vector space F^X of Section 1.2. Now $\mathrm{L}(V,W)$ is a subset of W^V.

Intuition. We could check the vector space axioms for $\mathrm{L}(V,W)$ one at a time, by evaluating at each $\mathbf{v}$. That would repeat the proof of Lemma 2.1.22 word for word. Passing through W^V separates the two things that are true. The axioms hold for all functions $V \to W$, linear or not; what is special about linear maps is only that the operations of W^V do not destroy linearity. The subspace criterion asks for exactly that.

Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space). Let V and W be vector spaces over F. If $S, T \in \mathrm{L}(V,W)$ and $c \in F$, then $S+T$ and cT are linear. Hence $\mathrm{L}(V,W)$ is a subspace of W^V, and in particular it is a vector space over F. Its zero vector is the zero map, and $-T$ is the map $\mathbf{v} \mapsto -T(\mathbf{v})$.

Proof. ROUTINE

Uses. Lemma 2.1.22 (Functions into a vector space), Theorem 1.4.3 (Subspace criterion), Theorem 2.1.3 (Checking linearity), Example 2.1.6 (Zero, identity, and scaling maps)
Hint 1. By Lemma 2.1.22 and the subspace criterion, it suffices to show that the zero map is linear and that $S+T$ and cT are linear.
Hint 2. Check (iii) of Theorem 2.1.3 for $S+T$: expand $(S+T)(a\mathbf{u}+\mathbf{v})$ by the definition of $S+T$, use linearity of S and of T, and regroup.
Hint 3. For cT you need to move c past a. Which field axiom allows that?
Sketch. The zero map is linear. For $S+T$, $(S+T)(a\mathbf{u}+\mathbf{v}) = aS(\mathbf{u}) + S(\mathbf{v}) + aT(\mathbf{u}) + T(\mathbf{v}) = a(S+T)(\mathbf{u}) + (S+T)(\mathbf{v})$. For cT, $c(aT(\mathbf{u}) + T(\mathbf{v})) = a(cT(\mathbf{u})) + cT(\mathbf{v})$ since $ca = ac$. So $\mathrm{L}(V,W)$ is a nonempty subset of the vector space W^V, closed under both operations.

By Lemma 2.1.22, W^V is a vector space, and $\mathrm{L}(V,W) \subseteq W^V$. We check the conditions of Theorem 1.4.3. The zero map is linear (Example 2.1.6), so $\mathrm{L}(V,W)$ is nonempty and contains the zero vector of W^V.

Let $S, T \in \mathrm{L}(V,W)$, $c \in F$, $\mathbf{u}, \mathbf{v} \in V$, and $a \in F$. Using the definition of $S+T$, then the linearity of S and T, then the vector space axioms of W to regroup,

$$\begin{aligned}(S+T)(a\mathbf{u}+\mathbf{v}) &= S(a\mathbf{u}+\mathbf{v}) + T(a\mathbf{u}+\mathbf{v}) \\ &= (aS(\mathbf{u}) + S(\mathbf{v})) + (aT(\mathbf{u}) + T(\mathbf{v})) \\ &= a(S(\mathbf{u}) + T(\mathbf{u})) + (S(\mathbf{v}) + T(\mathbf{v})) = a(S+T)(\mathbf{u}) + (S+T)(\mathbf{v}).\end{aligned}$$

Similarly,

$$\begin{aligned}(cT)(a\mathbf{u}+\mathbf{v}) &= c(aT(\mathbf{u}) + T(\mathbf{v})) = (ca)T(\mathbf{u}) + cT(\mathbf{v}) \\ &= (ac)T(\mathbf{u}) + cT(\mathbf{v}) = a(cT)(\mathbf{u}) + (cT)(\mathbf{v}),\end{aligned}$$

where the step $ca = ac$ is the commutativity of multiplication in F. By Theorem 2.1.3, $S+T$ and cT are linear. So $\mathrm{L}(V,W)$ is a subspace of W^V, hence a vector space, with the same zero vector and the same additive inverses as W^V. □

Linear maps now have three operations: addition, scalar multiplication, and composition. The next proposition records how they interact.

Proposition 2.1.24 (Algebra of composition). Let U, V, W, and X be vector spaces over F, and let $a \in F$.
(a) $(RS)T = R(ST)$ for $T \in \mathrm{L}(U,V)$, $S \in \mathrm{L}(V,W)$, and $R \in \mathrm{L}(W,X)$.
(b) $\mathrm{id}_W T = T = T\mathrm{id}_V$ for $T \in \mathrm{L}(V,W)$.
(c) $(S_1+S_2)T = S_1T + S_2T$ and $S(T_1+T_2) = ST_1 + ST_2$ for $T, T_1, T_2 \in \mathrm{L}(U,V)$ and $S, S_1, S_2 \in \mathrm{L}(V,W)$.
(d) $(aS)T = a(ST) = S(aT)$ for $T \in \mathrm{L}(U,V)$ and $S \in \mathrm{L}(V,W)$.

Proof. ROUTINE

> *Uses.* Proposition 2.1.23 (L(V,W) is a vector space), Definition 2.1.21 (Pointwise operations), Theorem 2.1.3 (Checking linearity)
> *Hint 1.* Two maps are equal when they agree at every vector. Evaluate both sides of each identity at $\mathbf{u}$.
> *Hint 2.* Most identities follow from the definitions alone. In $S(T_1+T_2)=ST_1+ST_2$ and $S(aT)=a(ST)$ you need a property of S.
> *Sketch.* Evaluate at $\mathbf{u}$. Associativity and the identity laws hold for all functions. $((S_1+S_2)T)(\mathbf{u})=S_1(T(\mathbf{u}))+S_2(T(\mathbf{u}))$ by the definition of S_1+S_2. $(S(T_1+T_2))(\mathbf{u})=S(T_1(\mathbf{u})+T_2(\mathbf{u}))$ splits by additivity of S, and $S(aT(\mathbf{u}))=aS(T(\mathbf{u}))$ by homogeneity of S.

In each case both sides are maps with the same domain and codomain, so it suffices to show that they agree at every vector $\mathbf{u}$ of the domain.

(a) $((RS)T)(\mathbf{u})=(RS)(T(\mathbf{u}))=R(S(T(\mathbf{u})))=R((ST)(\mathbf{u}))=(R(ST))(\mathbf{u})$.

(b) $(\mathrm{id}_W T)(\mathbf{u})=\mathrm{id}_W(T(\mathbf{u}))=T(\mathbf{u})$ and $(T\mathrm{id}_V)(\mathbf{u})=T(\mathrm{id}_V(\mathbf{u}))=T(\mathbf{u})$.

(c) By the definition of the sum of two maps,

$$((S_1+S_2)T)(\mathbf{u})=(S_1+S_2)(T(\mathbf{u}))=S_1(T(\mathbf{u}))+S_2(T(\mathbf{u}))=(S_1T+S_2T)(\mathbf{u}).$$

By the definition of T_1+T_2 and then additivity of S,

$$(S(T_1+T_2))(\mathbf{u})=S(T_1(\mathbf{u})+T_2(\mathbf{u}))=S(T_1(\mathbf{u}))+S(T_2(\mathbf{u}))=(ST_1+ST_2)(\mathbf{u}).$$

(d) $((aS)T)(\mathbf{u})=aS(T(\mathbf{u}))=(a(ST))(\mathbf{u})$ by the definition of aS, and by the definition of aT and homogeneity of S,

$$(S(aT))(\mathbf{u})=S(aT(\mathbf{u}))=aS(T(\mathbf{u}))=(a(ST))(\mathbf{u}).$$

□

Only the second identity in (c) and the last one in (d) used linearity, in both cases of the left factor S. For functions that are not linear they can fail: for $s(x)=x^2$ on $\mathbb{R}$, $(s\circ(\mathrm{id}_{\mathbb{R}}+\mathrm{id}_{\mathbb{R}}))(1)=s(2)=4$, while $(s\circ\mathrm{id}_{\mathbb{R}}+s\circ\mathrm{id}_{\mathbb{R}})(1)=2$. Parts (c) and (d) also say that composition is linear in each factor: for fixed $T\in\mathrm{L}(U,V)$, the map $\mathrm{L}(V,W)\to\mathrm{L}(U,W)$, $S\mapsto ST$, is linear, and for fixed $S\in\mathrm{L}(V,W)$, so is $\mathrm{L}(U,V)\to\mathrm{L}(U,W)$, $T\mapsto ST$.

Exercise 2.1.25. ROUTINE Let $T:F^2\to F^2, T(x,y)=(y,x-y)$. Show that $T^2+T=\mathrm{id}_{F^2}$, and deduce that $T\big(T+\mathrm{id}_{F^2}\big)=\big(T+\mathrm{id}_{F^2}\big)T=\mathrm{id}_{F^2}$.

Solution on page 1105

Assembling linear maps

The results of this section and the last give a way to prove linearity without computing.

Technique 2.1.26 (Assemble linear maps from linear pieces). To show that a map is linear, write it as a sum, scalar multiple, or composite of maps already known to be linear. By Proposition 2.1.23 and Proposition 2.1.17 the result is linear, with no computation.

Reach for it when a map is given by a formula built out of evaluations, derivatives, integrals, coordinates, projections, or other maps from the examples above. It also handles whole families at once. For instance, for $T\in\mathrm{L}(V)$ and $a_0,\dots,a_n\in F$, every $a_0\mathrm{id}_V+a_1T+\cdots+a_nT^n$ is linear. Conversely, a formula that involves a product of two inputs, a constant term, or a nonlinear function of a coordinate is a candidate for a counterexample; test $T(\mathbf{0})$ and $T(2\mathbf{v})$ first. The canonical example is the reflection $S_\ell=2\,\mathrm{Pr}_\ell-\mathrm{id}_{\mathbb{R}^2}$ (Example 2.1.27).

Used in. Exercise 2.1.29, Exercise 2.1.42, Exercise 2.1.47, Theorem 2.2.1, Theorem 2.3.20, Exercise 2.8.5, Proposition 4.6.7.

Example 2.1.27 (Maps assembled from linear pieces).

(a) By Example 2.1.11, $S_\ell(\mathbf{v}) = 2\operatorname{Pr}_\ell(\mathbf{v}) - \mathbf{v}$ for every $\mathbf{v}$. That is, $S_\ell = 2\operatorname{Pr}_\ell - \mathrm{id}_{\mathbb{R}^2}$ in $\mathrm{L}(\mathbb{R}^2)$. Since Pr_ℓ is linear, so is S_ℓ, and the double angle formulas are not needed for this.

(b) The map $\varphi : F[x] \to F$, $\varphi(p) = p(1) - 3p'(0)$, is linear, because $\varphi = \operatorname{ev}_1 - 3\operatorname{ev}_0 D$ with ev_t and D from Example 2.1.9.

(c) On the real vector space of infinitely differentiable functions $\mathbb{R} \to \mathbb{R}$ (a subspace of $\mathbb{R}^{\mathbb{R}}$), differentiation $D : f \mapsto f'$ is linear, so $f \mapsto f'' - 3f' + 2f$ is linear, being $D^2 - 3D + 2\,\mathrm{id}$. This is why the differential equation $y'' - 3y' + 2y = 0$ is called linear: it asks for the vectors that a linear map sends to $\mathbf{0}$. By Section 2.6 such vectors always form a subspace.

Exercise 2.1.28. ROUTINE Fix $\mathbf{v}_0 \in V$. Show that the map $\mathrm{L}(V, W) \to W$, $T \mapsto T(\mathbf{v}_0)$, is linear.

Solution on page 1105

ASIDE: *Additive maps that are not linear* BEYOND 21-242

By Exercise 2.1.36 and Exercise 2.1.37, an additive map between vector spaces over $\mathbb{F}_p$ or over $\mathbb{Q}$ is automatically linear, because every scalar can be reached from 1 by addition, subtraction, and division by positive integers. Over $\mathbb{R}$ this is false, but no formula exhibits a counterexample. Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$. It has a basis (a **Hamel basis**), by Zorn's lemma (Section 15.1). Pick a basis vector $\mathbf{b}$, and let $T : \mathbb{R} \to \mathbb{R}$ send each real number to its coordinate along $\mathbf{b}$. Then T is $\mathbb{Q}$-linear, hence additive, and it takes only rational values. If T were $\mathbb{R}$-linear, then $T(x) = xT(1)$ for all x (Exercise 2.1.5); since T takes only rational values, this forces $T(1) = 0$, and then $T = 0$, contradicting $T(\mathbf{b}) = 1$. Such a map is wildly discontinuous: an additive map $\mathbb{R} \to \mathbb{R}$ that is continuous is linear (Exercise 2.1.51).

Exercises

Exercise 2.1.29. ROUTINE Decide which of the following maps are linear. Here F is any field, $A \in F^{2\times 2}$ has entries a_{ij}, and $F^{2\times 2}$ is added and scaled entrywise.

(a) $F^{2\times 2} \to F$, $A \mapsto a_{11} + a_{22}$.

(b) $F^{2\times 2} \to F$, $A \mapsto a_{11}a_{22} - a_{12}a_{21}$.

(c) $F^{2\times 2} \to F^{2\times 2}$, the map that swaps the entries a_{12} and a_{21}.

(d) $F[x] \to F[x]$, $p \mapsto p + p'$.

(e) $\mathbb{C} \to \mathbb{C}$, $z \mapsto i\overline{z}$, with $\mathbb{C}$ regarded first as a vector space over $\mathbb{C}$, then as one over $\mathbb{R}$.

Solution on page 1105

Exercise 2.1.30. STANDARD How many functions $\mathbb{F}_2^2 \to \mathbb{F}_2$ are there? How many of them send $\mathbf{0}$ to 0? How many are linear? List the linear ones.

Solution on page 1106

Exercise 2.1.31. ROUTINE Let $T \in \mathrm{L}(V, W)$ and let $\mathcal{L}$ be a list in V. Prove or disprove each statement.

(a) If $\mathcal{L}$ spans V, then $T(\mathcal{L})$ spans W.

(b) If $T(\mathcal{L})$ spans W, then $\mathcal{L}$ spans V.

(c) If $T(\mathcal{L})$ spans W, then $\operatorname{im} T = W$.

Solution on page 1106

Exercise 2.1.32. ROUTINE Fix $q \in F[x]$. For $p = a_0 + a_1 x + \cdots + a_n x^n$, let $p(q) = a_0 + a_1 q + \cdots + a_n q^n \in F[x]$ be the result of substituting q for x. Show that the map $C_q : F[x] \to F[x]$, $p \mapsto p(q)$, is linear. (For $q = x + 1$, this is the shift $p(x) \mapsto p(x + 1)$.)

Solution on page 1106

Exercise 2.1.33. STANDARD Now substitute in the other order. For $q \in \mathbb{R}[x]$, let $L_q : \mathbb{R}[x] \to \mathbb{R}[x]$ be $p \mapsto q(p)$, the result of substituting p for x in q (notation of Exercise 2.1.32). Find all q for which L_q is linear.

Solution on page 1106

Exercise 2.1.34. ROUTINE Find all $p \in \mathbb{F}_2[x]$ with $D(p) = 0$, where D is the formal derivative. Do the same over $\mathbb{F}_3$ and over $\mathbb{R}$.

Solution on page 1107

Exercise 2.1.35. ROUTINE Find the error in the following argument.

Claim. Every additive map $T : \mathbb{R} \to \mathbb{R}$ is linear.

Proof. Let $c, x \in \mathbb{R}$. Then

$$T(cx) = T(x + x + \cdots + x) = T(x) + T(x) + \cdots + T(x) = cT(x),$$

so T is homogeneous. Since it is also additive, it is linear.

Solution on page 1107

Exercise 2.1.36. STANDARD Let V and W be vector spaces over F, and let $T : V \to W$ be additive. Prove or disprove that T is linear when

(a) $F = \mathbb{F}_p$ for a prime p;

(b) $F = \mathbb{C}$.

Solution on page 1107

Exercise 2.1.37. STANDARD Let V and W be vector spaces over $\mathbb{Q}$, and let $T : V \to W$ be additive. Show that T is linear.

Solution on page 1108

Exercise 2.1.38. STANDARD Let F be any field. Find a function $T : F^2 \to F$ that is homogeneous but not additive.

Solution on page 1108

Exercise 2.1.39. STANDARD Let $T : V \to W$ satisfy $T(\mathbf{0}) = \mathbf{0}$ and

$$T(a\mathbf{u} + b\mathbf{v}) = aT(\mathbf{u}) + bT(\mathbf{v}) \quad \text{for all } \mathbf{u}, \mathbf{v} \in V \text{ and all } a, b \in F \text{ with } a + b = 1.$$

(a) Show that if $1 + 1 \neq 0$ in F, then T is linear.

(b) Show that the conclusion of (a) can fail over $\mathbb{F}_2$.

Solution on page 1108

Exercise 2.1.40. ROUTINE

(a) Find $S, T \in \mathrm{L}(\mathbb{R}^2)$ with $ST = 0$ but $TS \neq 0$.

(b) Find $T \in \mathrm{L}(\mathbb{R}^2)$ with $T \neq 0$ but $T^2 = 0$.

Solution on page 1109

Exercise 2.1.41. ROUTINE Find the error in the following argument.

Claim. If $P \in \mathrm{L}(V)$ satisfies $P^2 = P$, then $P = 0$ or $P = \mathrm{id}_V$.

Proof. Let $\mathbf{v} \in V$. Then $P(P(\mathbf{v}) - \mathbf{v}) = P^2(\mathbf{v}) - P(\mathbf{v}) = \mathbf{0}$. Since P is linear, either $P = 0$ or $P(\mathbf{v}) - \mathbf{v} = \mathbf{0}$. If $P \neq 0$, the second alternative holds for every $\mathbf{v}$, so $P = \mathrm{id}_V$.

Solution on page 1109

Exercise 2.1.42. STANDARD Let ℓ be the line through $\mathbf{0}$ at angle θ, and let $P = \mathrm{Pr}_\ell$ and $S = S_\ell$ be as in Example 2.1.11.

(a) Show from the formula for P that $P^2 = P$.

(b) Using only $S = 2P - \mathrm{id}$, (a), and Proposition 2.1.24, show that $S^2 = \mathrm{id}$ and $SP = PS = P$. Interpret these identities geometrically.

Solution on page 1109

Exercise 2.1.43. STANDARD For an angle α, let R_α be the rotation by α and S_α the reflection across the line through $\mathbf{0}$ at angle α (Example 2.1.11). Using the formulas, show that

$$R_\alpha R_\beta = R_{\alpha+\beta} \quad \text{and} \quad S_\alpha S_\beta = R_{2(\alpha-\beta)}.$$

Interpret the second identity geometrically.

Solution on page 1110

Exercise 2.1.44. ROUTINE Fix $\mathbf{v}_0 \in V$ and $\mathbf{w}_0 \in W$. Show that $\{T \in \mathrm{L}(V, W) \mid T(\mathbf{v}_0) = \mathbf{w}_0\}$ is a subspace of $\mathrm{L}(V, W)$ if and only if $\mathbf{w}_0 = \mathbf{0}$.

Solution on page 1110

Exercise 2.1.45. STANDARD Fix $A \in \mathrm{L}(V)$, and let $C(A) = \{T \in \mathrm{L}(V) \mid AT = TA\}$ be the set of operators that commute with A. Show that

(a) $C(A)$ is a subspace of $\mathrm{L}(V)$;

(b) if $S, T \in C(A)$, then $ST \in C(A)$;

(c) $a_0\mathrm{id}_V + a_1 A + \cdots + a_n A^n \in C(A)$ for all $a_0, \ldots, a_n \in F$.

Solution on page 1111

Exercise 2.1.46. STANDARD Let $M \in \mathrm{L}(F[x])$ be multiplication by x and D the formal derivative (Example 2.1.9).

(a) Show that $DM - MD = \mathrm{id}_{F[x]}$.

(b) Show that $DM^k - M^k D = kM^{k-1}$ for every $k \geq 1$, where kM^{k-1} means $(k \cdot 1)M^{k-1}$. What does this identity say when both sides are applied to a polynomial p?

Solution on page 1111

Exercise 2.1.47. STANDARD Regard $\mathbb{C}$ as a vector space over $\mathbb{R}$.

(a) Show that for every $\mathbb{R}$-linear $T : \mathbb{C} \to \mathbb{C}$ there are unique $\alpha, \beta \in \mathbb{C}$ with $T(z) = \alpha z + \beta \overline{z}$ for all $z \in \mathbb{C}$.

(b) Show that such a T is $\mathbb{C}$-linear if and only if $\beta = 0$, if and only if $T(i) = iT(1)$.

Solution on page 1111

Exercise 2.1.48. HARD Let $T \in \mathrm{L}(V)$ satisfy $T(\mathbf{v}) \in \operatorname{span}(\mathbf{v})$ for every $\mathbf{v} \in V$. Show that there is a $\lambda \in F$ with $T = \lambda \mathrm{id}_V$.

Solution on page 1112

Exercise 2.1.49. HARD A linear map $T : F[x] \to F[x]$ is a **derivation** if $T(pq) = T(p)q + pT(q)$ for all $p, q \in F[x]$.

(a) Show that the formal derivative D is a derivation (the product rule).

(b) Show that the derivations are exactly the maps $p \mapsto rD(p)$ for $r \in F[x]$, and that $r = T(x)$.

Solution on page 1112

Exercise 2.1.50. CHALLENGE Let $\mathbb{F}$ be $\mathbb{R}$ or $\mathbb{C}$, and let $T \in \mathrm{L}(\mathbb{F}[x])$ commute with D, that is, $TD = DT$. Show that there are scalars $c_0, c_1, c_2, \ldots \in \mathbb{F}$ such that

$$T(p) = c_0 p + c_1 D(p) + c_2 D^2(p) + \cdots + c_n D^n(p) \quad \text{for every } p \text{ with } \deg p \le n.$$

(The terms $c_k D^k(p)$ with $k > \deg p$ are 0, so the right side does not depend on the choice of $n \ge \deg p$.) Conversely, show that every map of this form is linear and commutes with D.

Solution on page 1113

Exercise 2.1.51. HARD BEYOND 21-242 Let $T : \mathbb{R} \to \mathbb{R}$ be additive and continuous. Show that $T(x) = xT(1)$ for every $x \in \mathbb{R}$, so that T is linear.

Solution on page 1114

2.2 Linear maps are determined by a basis

Suppose $T : \mathbb{R}^2 \to \mathbb{R}^2$ is linear, with $T(1,1) = (2,0)$ and $T(1,-1) = (0,4)$. Then T is already pinned down. For instance, $(3,1) = 2(1,1) + (1,-1)$, so linearity forces

$$T(3,1) = 2T(1,1) + T(1,-1) = (4,0) + (0,4) = (4,4),$$

and the same computation works at every vector, because every vector of $\mathbb{R}^2$ is a linear combination of $(1,1)$ and $(1,-1)$. Two questions remain. Is there a linear map with these two values at all? And if we wrote $(3,1)$ as a different combination, could the computation give a different answer? This section answers both questions for every basis of every vector space: a linear map may send the vectors of a basis anywhere, and once it has done so, it is determined. This is what will let us record a linear map by finitely many vectors, and in Section 2.3 by an array of scalars.

2.2.1 Existence and uniqueness

Intuition (Where the formula comes from). Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V, and suppose $T : V \to W$ is linear. Every $\mathbf{v} \in V$ is a linear combination $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$, and linearity gives

$$T(\mathbf{v}) = a_1 T(\mathbf{v}_1) + \cdots + a_n T(\mathbf{v}_n).$$

So the n vectors $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_n)$ determine T. Now turn this around. Given vectors $\mathbf{w}_1, \ldots, \mathbf{w}_n \in W$, a linear map with $T(\mathbf{v}_i) = \mathbf{w}_i$, if there is one, can only be

$$T(a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n) = a_1\mathbf{w}_1 + \cdots + a_n\mathbf{w}_n.$$

Read this as a recipe: to find $T(\mathbf{v})$, write $\mathbf{v}$ in terms of the basis, then replace each $\mathbf{v}_i$ by $\mathbf{w}_i$. For the recipe to define a function $V \to W$, two things must hold. Every $\mathbf{v}$ must have a representation, or the recipe says nothing about $\mathbf{v}$; spanning provides this. And no $\mathbf{v}$ may have two different representations, or the recipe could produce two different answers; linear independence provides this. A basis provides both, and then it remains to check that the function we get is linear.

Theorem 2.2.1 (Linear maps are determined by a basis). Let V and W be vector spaces over F, let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V, and let $\mathbf{w}_1, \ldots, \mathbf{w}_n$ be any list in W. Then there is exactly one linear map $T : V \to W$ such that $T(\mathbf{v}_i) = \mathbf{w}_i$ for $i = 1, \ldots, n$. It is given by

$$T(a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n) = a_1\mathbf{w}_1 + \cdots + a_n\mathbf{w}_n \quad \text{for all } a_1, \ldots, a_n \in F. \tag{2.2.1}$$

That is, $T(\mathbf{v}) = c_1\mathbf{w}_1 + \cdots + c_n\mathbf{w}_n$, where $(c_1, \ldots, c_n) = [\mathbf{v}]_{\mathcal{B}}$.

In other words, to specify a linear map out of V it suffices to say what it does to a basis of V, and every choice is allowed.

Proof, part 1 of 2: uniqueness. ROUTINE

Uses. Definition 1.3.10 (Span), Definition 2.1.1 (Linear map)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Suppose S and T both work. To compare them at an arbitrary $\mathbf{v} \in V$, write $\mathbf{v}$ in terms of the basis.
Hint 2. Apply the linearity of S and of T to $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. Both give $a_1\mathbf{w}_1 + \cdots + a_n\mathbf{w}_n$.
Sketch. Since $\mathcal{B}$ spans V, every $\mathbf{v}$ is some $\sum_i a_i\mathbf{v}_i$. Linearity gives $S(\mathbf{v}) = \sum_i a_i\mathbf{w}_i = T(\mathbf{v})$. The same computation shows that any such map satisfies (2.2.1).

Suppose $S, T \in \mathrm{L}(V, W)$ both satisfy $S(\mathbf{v}_i) = \mathbf{w}_i = T(\mathbf{v}_i)$ for every i. We will show that $S(\mathbf{v}) = T(\mathbf{v})$ for every $\mathbf{v} \in V$. Let $\mathbf{v} \in V$. Since $\mathcal{B}$ spans V, there are scalars $a_1, \ldots, a_n$ with $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. Then

$$\begin{aligned} S(\mathbf{v}) &= a_1S(\mathbf{v}_1) + \cdots + a_nS(\mathbf{v}_n) && \text{(linearity of } S\text{)} \\ &= a_1\mathbf{w}_1 + \cdots + a_n\mathbf{w}_n \\ &= a_1T(\mathbf{v}_1) + \cdots + a_nT(\mathbf{v}_n) = T(\mathbf{v}) && \text{(linearity of } T\text{)}. \end{aligned}$$

So $S = T$. The first two lines show more: every linear map that sends each $\mathbf{v}_i$ to $\mathbf{w}_i$ satisfies (2.2.1).

Intuition. The uniqueness proof did more than prove uniqueness: it found the only possible candidate, the map given by (2.2.1). This is a common way to organize an existence-and-uniqueness proof. First assume that a solution exists and work out what it must be, which proves uniqueness; then check that the forced candidate really is a solution, which proves existence. Here the check has three parts: (2.2.1) defines a function $V \to W$, this function sends $\mathbf{v}_i$ to $\mathbf{w}_i$, and it is linear. The uniqueness half used only that $\mathcal{B}$ spans V. Independence enters in the first part of the check.

Proof (directly), part 2 of 2: existence. ROUTINE

Uses. Definition 1.6.1 (Basis), Definition 1.5.1 (Linear independence), Definition 1.6.14 (Coordinates), Theorem 2.1.3 (Checking linearity)
Hint 1. Define $T(\mathbf{v})$ by (2.2.1), using the coordinates of $\mathbf{v}$. Why is this a single, well-defined vector of W?
Hint 2. What are the coordinates of $\mathbf{v}_i$ itself?
Hint 3. For linearity, if $\mathbf{u} = \sum_i b_i\mathbf{v}_i$ and $\mathbf{v} = \sum_i c_i\mathbf{v}_i$, then $a\mathbf{u} + \mathbf{v} = \sum_i (ab_i + c_i)\mathbf{v}_i$, and by uniqueness of representations this is *the* representation of $a\mathbf{u} + \mathbf{v}$.
Sketch. Each $\mathbf{v}$ has exactly one coordinate list $(c_1, \ldots, c_n)$ (at least one by spanning, at most one by independence), so $T(\mathbf{v}) = \sum_i c_i\mathbf{w}_i$ is a well-defined function. The coordinates of $\mathbf{v}_i$ are $\mathbf{e}_i$, so $T(\mathbf{v}_i) = \mathbf{w}_i$. The coordinates of $a\mathbf{u} + \mathbf{v}$ are $a[\mathbf{u}]_{\mathcal{B}} + [\mathbf{v}]_{\mathcal{B}}$, which gives linearity.

T is a function $V \to W$. Let $\mathbf{v} \in V$. Since $\mathcal{B}$ is a basis, $\mathbf{v}$ can be written as a linear combination of $\mathcal{B}$ in exactly one way (Definition 1.6.1): in at least one way because $\mathcal{B}$ spans V, and in at most one way because $\mathcal{B}$ is linearly independent (Definition 1.5.1). Let $(c_1, \dots, c_n) = [\mathbf{v}]_{\mathcal{B}}$ be the coefficients (Definition 1.6.14), and define

$$T(\mathbf{v}) = c_1\mathbf{w}_1 + \cdots + c_n\mathbf{w}_n.$$

This assigns to each $\mathbf{v} \in V$ exactly one vector of W. If $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$ is any representation, then $a_i = c_i$ for every i, so T satisfies (2.2.1).

$T(\mathbf{v}_i) = \mathbf{w}_i$. Since $\mathbf{v}_i = 0\mathbf{v}_1 + \cdots + 1\mathbf{v}_i + \cdots + 0\mathbf{v}_n$, (2.2.1) gives $T(\mathbf{v}_i) = 0\mathbf{w}_1 + \cdots + 1\mathbf{w}_i + \cdots + 0\mathbf{w}_n = \mathbf{w}_i$.

T is linear. Let $\mathbf{u}, \mathbf{v} \in V$ and $a \in F$, and write $\mathbf{u} = \sum_i b_i\mathbf{v}_i$ and $\mathbf{v} = \sum_i c_i\mathbf{v}_i$. By the vector space axioms,

$$a\mathbf{u} + \mathbf{v} = \sum_{i=1}^{n} (ab_i + c_i)\mathbf{v}_i,$$

and since (2.2.1) holds for every representation,

$$T(a\mathbf{u} + \mathbf{v}) = \sum_{i=1}^{n} (ab_i + c_i)\mathbf{w}_i = a\sum_{i=1}^{n} b_i\mathbf{w}_i + \sum_{i=1}^{n} c_i\mathbf{w}_i = aT(\mathbf{u}) + T(\mathbf{v}).$$

By Theorem 2.1.3, T is linear. □

The recipe "take coordinates, then form the combination with the $\mathbf{w}_i$" is a composite of two maps that we already know to be linear. Seeing it that way gives a second proof of existence with no computation at all.

Proof (via coordinates), part 2 of 2: existence. ROUTINE

> *Uses.* Definition 1.6.14 (Coordinates), Proposition 1.6.19 (Coordinates respect linear combinations), Example 2.1.8 (Coordinates), Proposition 2.1.17 (Compositions of linear maps are linear)
> *Techniques.* Assemble linear maps from linear pieces (Technique 2.1.26)
> *Hint 1.* The coordinate map $V \to F^n$ is linear, and so is $F^n \to W$, $(a_1, \dots, a_n) \mapsto \sum_i a_i\mathbf{w}_i$.
> *Hint 2.* Compose them, and compute the composite at $a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$.
> *Sketch.* Let $C(\mathbf{v}) = [\mathbf{v}]_{\mathcal{B}}$ and $L(a_1, \dots, a_n) = \sum_i a_i\mathbf{w}_i$. Both are linear, so $T = LC$ is linear, and $T\left(\sum_i a_i\mathbf{v}_i\right) = L(a_1, \dots, a_n) = \sum_i a_i\mathbf{w}_i$.

Let $C : V \to F^n$ be the coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$, which is linear by Proposition 1.6.19, and let $L : F^n \to W$ be the map $(a_1, \dots, a_n) \mapsto a_1\mathbf{w}_1 + \cdots + a_n\mathbf{w}_n$, which is linear by Example 2.1.8. By Proposition 2.1.17, $T = LC$ is linear. For scalars $a_1, \dots, a_n$, the definition of coordinates gives $[a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n]_{\mathcal{B}} = (a_1, \dots, a_n)$, so

$$T(a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n) = L(a_1, \dots, a_n) = a_1\mathbf{w}_1 + \cdots + a_n\mathbf{w}_n,$$

which is (2.2.1). In particular, taking $a_i = 1$ and the other coefficients 0, $T(\mathbf{v}_i) = \mathbf{w}_i$. □

In the second proof both halves of "basis" are hidden inside C: the coordinate vector $[\mathbf{v}]_{\mathcal{B}}$ is defined only because every vector has exactly one representation.

Nothing is assumed about $\mathbf{w}_1, \dots, \mathbf{w}_n$. They may be linearly dependent, or even all equal to $\mathbf{0}$, which gives the zero map. If $n = 0$, then $\mathcal{B}$ is the empty list, $V = \{\mathbf{0}\}$, and (2.2.1) with its empty sums says that the only linear map $\{\mathbf{0}\} \to W$ is the zero map.

Remark 2.2.2 (Where the two halves of "basis" were used). The proof of uniqueness used only that $\mathcal{B}$ spans V. The proof of existence used both halves: spanning so that the recipe applies to every $\mathbf{v}$, and independence so that it gives only one answer. Section 2.2.3 and Section 2.2.4 show what each half achieves on its own. A spanning list still gives uniqueness, but existence needs a condition on the $\mathbf{w}_i$. An independent list still gives existence, at least on its span, but if it does not span V, uniqueness fails (unless $W = \{\mathbf{0}\}$).

Geometrically, Theorem 2.2.1 says the following. A basis $\mathbf{b}_1, \mathbf{b}_2$ of $\mathbb{R}^2$ cuts the plane into a grid of parallelograms, and the grid point $a_1\mathbf{b}_1 + a_2\mathbf{b}_2$ is reached by a_1 steps along $\mathbf{b}_1$ and a_2 steps along $\mathbf{b}_2$. The linear

map with $T(\mathbf{b}_i) = \mathbf{w}_i$ sends it to the point reached by the same steps along $\mathbf{w}_1$ and $\mathbf{w}_2$ (Figure 2.2.1). This is the picture from Section 2.1, where $\mathbf{b}_1, \mathbf{b}_2$ was the standard basis.

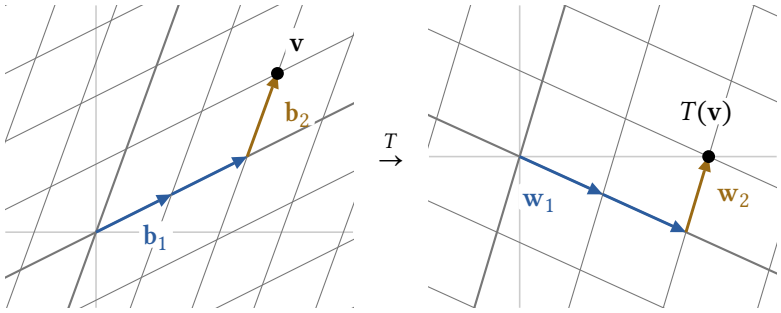

Figure 2.2.1. Left: the grid of $\mathcal{B}$-coordinates for the basis $\mathcal{B} = \mathbf{b}_1, \mathbf{b}_2$ of $\mathbb{R}^2$. The vector $\mathbf{v}$ with $[\mathbf{v}]_{\mathcal{B}} = (2, 1)$ is two steps along $\mathbf{b}_1$ and one along $\mathbf{b}_2$. Right: the linear map T with $T(\mathbf{b}_1) = \mathbf{w}_1$ and $T(\mathbf{b}_2) = \mathbf{w}_2$ carries the grid onto the grid built from $\mathbf{w}_1, \mathbf{w}_2$, and $T(\mathbf{v}) = 2\mathbf{w}_1 + \mathbf{w}_2$ is reached by the same steps.

In practice, Theorem 2.2.1 is used most often to build maps, by choosing a basis in which the desired map is easy to describe.

Example 2.2.3 (Building maps from a convenient basis). Let F be a field with $1 + 1 \neq 0$, and write $2 = 1 + 1$. In F^2 let $\mathbf{b}_1 = (1, 1)$ and $\mathbf{b}_2 = (1, -1)$. This is a basis of F^2. Indeed, $(x, y) = a\mathbf{b}_1 + b\mathbf{b}_2$ means $a + b = x$ and $a - b = y$. Adding and subtracting these equations gives $2a = x + y$ and $2b = x - y$, and since $2 \neq 0$,

$$a = \frac{x + y}{2}, \quad b = \frac{x - y}{2}.$$

Conversely these values satisfy both equations, so every (x, y) is a combination of $\mathbf{b}_1, \mathbf{b}_2$ in exactly one way.

By Theorem 2.2.1 there are unique linear maps $P, S : F^2 \to F^2$ with

$$P(\mathbf{b}_1) = \mathbf{b}_1, \quad P(\mathbf{b}_2) = \mathbf{0}, \quad S(\mathbf{b}_1) = \mathbf{b}_1, \quad S(\mathbf{b}_2) = -\mathbf{b}_2,$$

and (2.2.1) gives their formulas:

$$P(x, y) = \frac{x + y}{2}\mathbf{b}_1 = \left(\frac{x + y}{2}, \frac{x + y}{2}\right),$$
$$S(x, y) = \frac{x + y}{2}\mathbf{b}_1 - \frac{x - y}{2}\mathbf{b}_2 = (y, x).$$

Over $\mathbb{R}$, $\mathbf{b}_1$ spans the line ℓ given by $y = x$, and $\mathbf{b}_2$ is perpendicular to ℓ. So P fixes ℓ pointwise and kills the perpendicular direction: it is the projection Pr_ℓ. Similarly S fixes ℓ and flips the perpendicular direction: it is the reflection S_ℓ. The formulas agree with those of Example 2.1.11 for $\theta = \pi/4$, and this time no trigonometry was needed.

Over $\mathbb{F}_2$ the construction breaks down. There $\mathbf{b}_2 = (1, -1) = (1, 1) = \mathbf{b}_1$, so $\mathbf{b}_1, \mathbf{b}_2$ is not a basis, and indeed no linear map can send the same vector both to $\mathbf{b}_1$ and to $\mathbf{0}$.

> **Technique 2.2.4** (Construct a map by choosing it on a basis). To produce a linear map with some property, choose a basis of the domain that is adapted to the property, decide where each basis vector should go, and let Theorem 2.2.1 extend the choice to a linear map. Linearity then costs nothing, and the property itself can usually be checked on the basis (Technique 2.2.7). If a formula is wanted, write a general vector in the chosen basis and apply (2.2.1).
>
> Reach for it when the property is easy to state on special vectors (vectors to be fixed, sent to $\mathbf{0}$, swapped, or scaled), or when all you need is that some linear map with a given behaviour exists, as when building a

counterexample. The canonical example is the projection and reflection of Example 2.2.3. Another is that a subspace is the image of one linear map and the set of vectors sent to $\mathbf{0}$ by another (Exercise 2.2.35).
Used in. Proposition 2.2.11, Proposition 2.2.14, Exercise 2.2.28, Exercise 2.2.35, Exercise 2.2.40, Theorem 2.7.8, Theorem 2.7.4, Theorem 2.7.2, Exercise 2.7.29, Exercise 2.8.7, Problem 2.3, Problem 2.15, Proposition 3.5.9, Exercise 3.5.40, Proposition 4.1.19, Proposition 4.4.18, Exercise 4.4.42, Theorem 4.5.6, Theorem 4.5.8, Theorem 4.7.39, Problem 4.9, Problem 4.10, Corollary 8.4.7, Proposition 8.4.19, Exercise 7.2.58.

Exercise 2.2.5. ROUTINE Show that there is exactly one linear map $T : \mathbb{R}^2 \to \mathbb{R}$ with $T(1,1) = 1$ and $T(1,2) = 0$. Find $T(x,y)$ and $T(3,5)$.

Solution on page 1114

2.2.2 Checking on a basis

The proof of uniqueness in Theorem 2.2.1 used only that $\mathcal{B}$ spans V, so it proves more.

Corollary 2.2.6 (Agreeing on a spanning list). Let $S, T \in \mathrm{L}(V,W)$, and let $\mathbf{v}_1, \dots, \mathbf{v}_k$ be a list that spans V. If $S(\mathbf{v}_i) = T(\mathbf{v}_i)$ for every i, then $S = T$. In particular, two linear maps that agree on a basis are equal.

Proof (by computation). ROUTINE
Uses. Definition 1.3.10 (Span), Definition 2.1.1 (Linear map)
Hint 1. Take any $\mathbf{v} \in V$ and write it as a combination of the spanning list.
Hint 2. This is the uniqueness half of the proof of Theorem 2.2.1, with a spanning list in place of a basis.
Sketch. Write $\mathbf{v} = \sum_i a_i \mathbf{v}_i$. Then $S(\mathbf{v}) = \sum_i a_i S(\mathbf{v}_i) = \sum_i a_i T(\mathbf{v}_i) = T(\mathbf{v})$.

Let $\mathbf{v} \in V$. Since $\mathbf{v}_1, \dots, \mathbf{v}_k$ spans V, we can write $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. By linearity of S and T,

$$S(\mathbf{v}) = \sum_{i=1}^{k} a_i S(\mathbf{v}_i) = \sum_{i=1}^{k} a_i T(\mathbf{v}_i) = T(\mathbf{v}).$$

As $\mathbf{v}$ was arbitrary, $S = T$. □

The second proof does not compute with a general vector at all. It looks at the set of vectors on which S and T agree, and shows that this set is a subspace containing the spanning list.

Proof (via a subspace). ROUTINE
Uses. Theorem 1.4.3 (Subspace criterion), Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Hint 1. Consider $E = \{\mathbf{v} \in V \mid S(\mathbf{v}) = T(\mathbf{v})\}$. Which vectors do we know lie in E?
Hint 2. Show that E is a subspace. What is the smallest subspace containing $\mathbf{v}_1, \dots, \mathbf{v}_k$?
Sketch. $E = \{\mathbf{v} \mid S(\mathbf{v}) = T(\mathbf{v})\}$ contains $\mathbf{0}$ and is closed under addition and scalar multiplication, by linearity. It contains every $\mathbf{v}_i$, so it contains $\operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k) = V$.

Let $E = \{\mathbf{v} \in V \mid S(\mathbf{v}) = T(\mathbf{v})\}$. We check that E is a subspace of V with Theorem 1.4.3. It contains $\mathbf{0}$, since $S(\mathbf{0}) = \mathbf{0} = T(\mathbf{0})$ by Proposition 2.1.4. If $\mathbf{u}, \mathbf{v} \in E$ and $a \in F$, then

$$S(a\mathbf{u} + \mathbf{v}) = aS(\mathbf{u}) + S(\mathbf{v}) = aT(\mathbf{u}) + T(\mathbf{v}) = T(a\mathbf{u} + \mathbf{v}),$$

so $a\mathbf{u} + \mathbf{v} \in E$. By hypothesis, E contains $\mathbf{v}_1, \dots, \mathbf{v}_k$. Since the span of a list is the smallest subspace containing it (Proposition 1.4.14), $V = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k) \subseteq E$. So $E = V$, that is, $S = T$. □

The second proof applies to more than equality. Whenever the vectors with some property form a subspace, the property holds on all of V as soon as it holds on a spanning list. (In the language of Section 2.6, E is the kernel of $S - T$.)

Technique 2.2.7 (Check it on a basis). To prove that two linear maps $S, T : V \to W$ are equal, it is enough to check $S(\mathbf{v}_i) = T(\mathbf{v}_i)$ for the vectors of a basis of V, or of any spanning list (Corollary 2.2.6). Many statements can be put in this form. An identity such as $P^2 = P$, $ST = TS$, or $T = a\,\mathrm{id} + bR$ is an

equation between linear maps, because sums, scalar multiples, and composites of linear maps are linear (Proposition 2.1.23, Proposition 2.1.17). A containment $T(V) \subseteq U$, for a subspace U of W, holds as soon as $T(\mathbf{v}_i) \in U$ for every vector of a spanning list, because $T(V)$ is the span of the $T(\mathbf{v}_i)$ (Proposition 2.1.16).

Reach for it when the basis vectors are easy to compute with, typically for a basis on which the maps involved act simply, and when a computation at a general vector would be messy. Before using it, make sure that both sides really are linear in the vector. A condition such as "$T(\mathbf{v})$ is a multiple of $\mathbf{v}$" is not an equation between linear maps, and it can hold on a basis without holding everywhere (Exercise 2.2.25). The canonical example is Corollary 2.2.6 itself.

Used in. Exercise 2.1.49, Exercise 2.2.9, Proposition 2.2.14, Exercise 2.2.23, Exercise 2.2.25, Exercise 2.2.28, Exercise 2.2.29, Exercise 2.2.30, Exercise 2.2.33, Exercise 2.2.34, Exercise 2.2.36, Exercise 2.2.39, Exercise 2.2.40, Exercise 2.3.38, Proposition 2.4.28, Exercise 2.4.49, Exercise 2.4.50, Proposition 2.6.18, Proposition 2.6.22, Theorem 2.7.8, Theorem 2.7.4, Theorem 2.7.2, Exercise 2.8.6, Exercise 2.8.8, Problem 2.3, Problem 2.4, Problem 2.5, Problem 2.6, Problem 2.7, Lemma 3.2.6, Proposition 3.5.9, Exercise 4.1.55, Theorem 4.5.8, Proposition 4.5.35, Proposition 6.1.22, Theorem 6.6.3, Corollary 7.1.12, Proposition 7.2.4, Proposition 7.2.27, Proposition 7.4.7, Proposition 7.4.26, Proposition 7.5.2, Exercise 7.6.48, Problem 7.9, Exercise 2.6.26, Exercise 3.5.40, Exercise 4.5.47.

Example 2.2.8 (Identities checked on a basis). Let P and S be the projection and reflection of Example 2.2.3. We claim that

$$P^2 = P, \quad S^2 = \mathrm{id}, \quad S = 2P - \mathrm{id}, \quad SP = PS = P.$$

Each side of each identity is a linear map $F^2 \to F^2$ (Proposition 2.1.17, Proposition 2.1.23), so by Corollary 2.2.6 it suffices to compare the two sides at $\mathbf{b}_1$ and at $\mathbf{b}_2$. Every map involved sends $\mathbf{b}_1$ to $\mathbf{b}_1$ (for $2P - \mathrm{id}$, because $2\mathbf{b}_1 - \mathbf{b}_1 = \mathbf{b}_1$), so both sides of each identity send $\mathbf{b}_1$ to $\mathbf{b}_1$. At $\mathbf{b}_2$,

$$\begin{aligned} P^2(\mathbf{b}_2) &= P(\mathbf{0}) = \mathbf{0} = P(\mathbf{b}_2), \\ S^2(\mathbf{b}_2) &= S(-\mathbf{b}_2) = \mathbf{b}_2, \\ (2P - \mathrm{id})(\mathbf{b}_2) &= \mathbf{0} - \mathbf{b}_2 = S(\mathbf{b}_2), \\ SP(\mathbf{b}_2) &= S(\mathbf{0}) = \mathbf{0} = P(\mathbf{b}_2), \\ PS(\mathbf{b}_2) &= P(-\mathbf{b}_2) = \mathbf{0} = P(\mathbf{b}_2). \end{aligned}$$

Exercise 2.1.42 proves the same identities over $\mathbb{R}$ from the coordinate formulas. In the basis $\mathbf{b}_1, \mathbf{b}_2$ each map does something simple to each basis vector, and the identities become one-line checks.

Exercise 2.2.9. ROUTINE Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V, and let $T \in \mathrm{L}(V)$ be the linear map with $T(\mathbf{v}_i) = \mathbf{v}_i + \mathbf{v}_1$ for every i (so $T(\mathbf{v}_1) = 2\mathbf{v}_1$). Show that $T^2 = 3T - 2\mathrm{id}_V$.

Solution on page 1114

2.2.3 Spanning lists and linear relations

Theorem 2.2.1 needs both halves of "basis". Here is what happens with a list that spans but is not independent.

Non-example 2.2.10 (A spanning list that is not independent). The list $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$ spans $\mathbb{R}^2$. Try to prescribe $T(\mathbf{e}_1) = \mathbf{w}_1$, $T(\mathbf{e}_2) = \mathbf{w}_2$, and $T(\mathbf{e}_1 + \mathbf{e}_2) = \mathbf{w}_3$ for a linear map $T : \mathbb{R}^2 \to W$.

Uniqueness survives, since its proof used only spanning: any such T is $T(x, y) = x\mathbf{w}_1 + y\mathbf{w}_2$. Existence fails unless $\mathbf{w}_3 = \mathbf{w}_1 + \mathbf{w}_2$, because a linear map satisfies $T(\mathbf{e}_1 + \mathbf{e}_2) = T(\mathbf{e}_1) + T(\mathbf{e}_2)$. In terms of the recipe: the vector $(1, 1)$ has the two representations $1 \cdot (\mathbf{e}_1 + \mathbf{e}_2)$ and $1 \cdot \mathbf{e}_1 + 1 \cdot \mathbf{e}_2$, and the recipe turns them into $\mathbf{w}_3$ and $\mathbf{w}_1 + \mathbf{w}_2$.

The obstruction is a linear relation. If $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$, then every linear map satisfies $a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k) = \mathbf{0}$ (Proposition 2.1.16). So prescribed values must satisfy every linear relation that the vectors satisfy. For a spanning list, this is the only obstruction.

Proposition 2.2.11 (Prescribing values on a spanning list). Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list that spans V, and let $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$. There is a linear map $T : V \to W$ with $T(\mathbf{v}_i) = \mathbf{w}_i$ for every i if and only if, for all $a_1, \ldots, a_k \in F$,

$$a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0} \quad \Longrightarrow \quad a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k = \mathbf{0}. \tag{2.2.2}$$

In that case T is unique.

In words, the list $\mathbf{w}_1, \ldots, \mathbf{w}_k$ must satisfy every linear relation that $\mathcal{L}$ satisfies. If $\mathcal{L}$ is linearly independent, its only relation is the trivial one (Theorem 1.5.5), so the condition holds automatically, and we recover Theorem 2.2.1. There are two natural ways to prove the converse direction: repair the recipe directly, or throw away vectors until a basis remains.

Proof (directly). STANDARD

Uses. Proposition 2.1.16 (Linear maps preserve spans and linear relations), Corollary 2.2.6 (Agreeing on a spanning list), Theorem 2.1.3 (Checking linearity), Definition 1.3.10 (Span)
Hint 1. Necessity is Proposition 2.1.16. For sufficiency, define $T(\mathbf{v}) = \sum_i a_i\mathbf{w}_i$ for any representation $\mathbf{v} = \sum_i a_i\mathbf{v}_i$. Why does the choice of representation not matter?
Hint 2. If $\sum_i a_i\mathbf{v}_i = \sum_i b_i\mathbf{v}_i$, then $\sum_i(a_i - b_i)\mathbf{v}_i = \mathbf{0}$. Apply (2.2.2).
Hint 3. Once T is well defined, linearity and $T(\mathbf{v}_i) = \mathbf{w}_i$ follow because you may compute T from any representation you like.
Sketch. Necessity: apply T to a relation. Sufficiency: set $T\big(\sum_i a_i\mathbf{v}_i\big) = \sum_i a_i\mathbf{w}_i$. Two representations of the same vector differ by a relation of $\mathcal{L}$, which (2.2.2) turns into a relation of the $\mathbf{w}_i$, so the two values agree. Since any representation may be used, $T(\mathbf{v}_i) = \mathbf{w}_i$ and linearity follow as in Theorem 2.2.1. Uniqueness is Corollary 2.2.6.

Necessity. If T is linear with $T(\mathbf{v}_i) = \mathbf{w}_i$ and $\sum_i a_i\mathbf{v}_i = \mathbf{0}$, then $\sum_i a_i\mathbf{w}_i = \sum_i a_iT(\mathbf{v}_i) = \mathbf{0}$ by Proposition 2.1.16(b).

Sufficiency. Assume (2.2.2). Let $\mathbf{v} \in V$. Since $\mathcal{L}$ spans V, $\mathbf{v}$ has at least one representation $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. We claim that the vector $a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k$ is the same for all representations of $\mathbf{v}$. Indeed, if also $\mathbf{v} = b_1\mathbf{v}_1 + \cdots + b_k\mathbf{v}_k$, then subtracting,

$$(a_1 - b_1)\mathbf{v}_1 + \cdots + (a_k - b_k)\mathbf{v}_k = \mathbf{0},$$

so by (2.2.2), $\sum_i(a_i - b_i)\mathbf{w}_i = \mathbf{0}$, that is, $\sum_i a_i\mathbf{w}_i = \sum_i b_i\mathbf{w}_i$. So we may define $T : V \to W$ by

$$T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k) = a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k,$$

computed from any representation. Using the representation $\mathbf{v}_i = 0\mathbf{v}_1 + \cdots + 1\mathbf{v}_i + \cdots + 0\mathbf{v}_k$ gives $T(\mathbf{v}_i) = \mathbf{w}_i$. For linearity, let $\mathbf{u} = \sum_i a_i\mathbf{v}_i$, $\mathbf{v} = \sum_i b_i\mathbf{v}_i$, and $c \in F$. Then $c\mathbf{u} + \mathbf{v} = \sum_i(ca_i + b_i)\mathbf{v}_i$ is a representation of $c\mathbf{u} + \mathbf{v}$, so

$$T(c\mathbf{u} + \mathbf{v}) = \sum_{i=1}^{k}(ca_i + b_i)\mathbf{w}_i = cT(\mathbf{u}) + T(\mathbf{v}).$$

By Theorem 2.1.3, T is linear.

Uniqueness. Two such maps agree on the spanning list $\mathcal{L}$, so they are equal by Corollary 2.2.6. □

Proof (by reducing to a basis). STANDARD

Uses. Theorem 1.6.10 (Every spanning list contains a basis), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Corollary 2.2.6 (Agreeing on a spanning list)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. Some sublist of $\mathcal{L}$ is a basis of V (Theorem 1.6.10). Define T on that basis.

Hint 2. Each remaining $\mathbf{v}_j$ is a combination of the basis vectors. That expression is a linear relation among the vectors of $\mathcal{L}$; use (2.2.2) to compute $T(\mathbf{v}_j)$.
Sketch. Let $\mathbf{u}_1, \dots, \mathbf{u}_n$ be a sublist of $\mathcal{L}$ that is a basis of V, and let T send each $\mathbf{u}_r$ to its prescribed value. For any j, write $\mathbf{v}_j = \sum_r c_r \mathbf{u}_r$; this is a relation of $\mathcal{L}$, so the prescribed values satisfy it, and $T(\mathbf{v}_j) = \sum_r c_r T(\mathbf{u}_r)$ is the prescribed value $\mathbf{w}_j$.

Necessity and uniqueness are as in the first proof. For sufficiency, assume (2.2.2). By Theorem 1.6.10, some sublist $\mathbf{v}_{i_1}, \dots, \mathbf{v}_{i_n}$ of $\mathcal{L}$, with $i_1 < \cdots < i_n$, is a basis of V; write $\mathbf{u}_r = \mathbf{v}_{i_r}$. By Theorem 2.2.1 there is a linear map $T : V \to W$ with $T(\mathbf{u}_r) = \mathbf{w}_{i_r}$ for $r = 1, \dots, n$. We show that $T(\mathbf{v}_j) = \mathbf{w}_j$ for every j.

Fix j. Since $\mathbf{u}_1, \dots, \mathbf{u}_n$ spans V, there are scalars with $\mathbf{v}_j = c_1\mathbf{u}_1 + \cdots + c_n\mathbf{u}_n$. The equation

$$\mathbf{v}_j - c_1\mathbf{v}_{i_1} - \cdots - c_n\mathbf{v}_{i_n} = \mathbf{0}$$

is a linear relation among the vectors of $\mathcal{L}$ (collect the coefficient of each $\mathbf{v}_i$). By (2.2.2), the same combination of the $\mathbf{w}_i$ vanishes: $\mathbf{w}_j = c_1\mathbf{w}_{i_1} + \cdots + c_n\mathbf{w}_{i_n}$. Hence

$$T(\mathbf{v}_j) = c_1 T(\mathbf{u}_1) + \cdots + c_n T(\mathbf{u}_n) = c_1\mathbf{w}_{i_1} + \cdots + c_n\mathbf{w}_{i_n} = \mathbf{w}_j,$$

as desired. □

The first proof is the general method for defining a function by a formula that refers to a choice: show that the value does not depend on the choice. The second proof reduces to a case already handled, and it shows more than the statement does.

Remark 2.2.12 (Checking fewer relations). The second proof used (2.2.2) only for the $k - n$ relations $\mathbf{v}_j = c_1\mathbf{u}_1 + \cdots + c_n\mathbf{u}_n$ that express each vector of $\mathcal{L}$ outside the chosen basis in terms of the basis. So: if a sublist $\mathbf{u}_1, \dots, \mathbf{u}_n$ of $\mathcal{L}$ is a basis of V, and for each remaining $\mathbf{v}_j$ the prescribed values satisfy the relation expressing $\mathbf{v}_j$ in terms of $\mathbf{u}_1, \dots, \mathbf{u}_n$, then T exists. Every other relation of $\mathcal{L}$ is then satisfied automatically, by Proposition 2.1.16. In examples this is how existence is checked: one relation per redundant vector.

2.2.4 Prescribing values on any list

Now the other half: a list that is independent but does not span.

Non-example 2.2.13 (An independent list that does not span). The list $\mathbf{e}_1$ is linearly independent in $\mathbb{R}^2$ but does not span it. Prescribe $T(\mathbf{e}_1) = 1$ for a linear map $T : \mathbb{R}^2 \to \mathbb{R}$. Existence survives: $(x, y) \mapsto x$ works. Uniqueness fails: $(x, y) \mapsto x + cy$ works for every $c \in \mathbb{R}$. The recipe says nothing about $\mathbf{e}_2$, which has no representation in terms of $\mathbf{e}_1$, so $T(\mathbf{e}_2)$ can be anything.

In general, given vectors $\mathbf{v}_1, \dots, \mathbf{v}_k \in V$ and $\mathbf{w}_1, \dots, \mathbf{w}_k \in W$, we can first define a map on $\operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$ with Proposition 2.2.11, and then extend it to V by choosing values on vectors that complete a basis. The extension step needs such vectors to exist.

Proposition 2.2.14 (Prescribing values on any list). Let $\mathcal{L} = \mathbf{v}_1, \dots, \mathbf{v}_k$ be a list in V, and let $\mathbf{w}_1, \dots, \mathbf{w}_k \in W$. Suppose that V has a basis $\mathbf{u}_1, \dots, \mathbf{u}_m, \mathbf{x}_1, \dots, \mathbf{x}_r$ in which $\mathbf{u}_1, \dots, \mathbf{u}_m$ is a basis of $\operatorname{span}\mathcal{L}$.

(a) There is a linear map $T : V \to W$ with $T(\mathbf{v}_i) = \mathbf{w}_i$ for every i if and only if (2.2.2) holds.

(b) If such a T exists, it is unique if and only if $\mathcal{L}$ spans V or $W = \{\mathbf{0}\}$.

Proof. STANDARD

Uses. Proposition 2.2.11 (Prescribing values on a spanning list), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Theorem 2.2.1 (Linear maps are determined by a basis), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
Hint 1. $\operatorname{span}\mathcal{L}$ is a vector space spanned by $\mathcal{L}$, so Proposition 2.2.11 gives a linear map $S : \operatorname{span}\mathcal{L} \to W$. Extend it with Theorem 2.2.1.
Hint 2. Let T agree with S on $\mathbf{u}_1, \dots, \mathbf{u}_m$ and send the $\mathbf{x}_j$ anywhere. Why does T agree with S on all of $\operatorname{span}\mathcal{L}$?

Hint 3. For (b), if $\mathcal{L}$ does not span V, then $r \geq 1$. Change the value at $\mathbf{x}_1$.
Sketch. Necessity in (a) is Proposition 2.1.16. Conversely, Proposition 2.2.11 applied to span $\mathcal{L}$ gives S with $S(\mathbf{v}_i) = \mathbf{w}_i$; let T agree with S on the $\mathbf{u}$'s and vanish on the $\mathbf{x}$'s. Then $T = S$ on $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_m) = \operatorname{span} \mathcal{L}$. For (b), spanning gives uniqueness by Corollary 2.2.6; if $\mathcal{L}$ does not span, then $r \geq 1$, and changing $T(\mathbf{x}_1)$ to a nonzero vector gives a second map.

(a) If T exists, (2.2.2) holds by Proposition 2.1.16(b). Conversely, assume (2.2.2). The subspace span $\mathcal{L}$ is a vector space (Proposition 1.4.14), and $\mathcal{L}$ spans it. So Proposition 2.2.11, applied with span $\mathcal{L}$ in place of V, gives a linear map $S : \operatorname{span} \mathcal{L} \to W$ with $S(\mathbf{v}_i) = \mathbf{w}_i$ for every i. By Theorem 2.2.1 there is a linear map $T : V \to W$ with

$$T(\mathbf{u}_j) = S(\mathbf{u}_j) \quad (j = 1, \ldots, m), \quad T(\mathbf{x}_l) = \mathbf{0} \quad (l = 1, \ldots, r).$$

Every $\mathbf{v} \in \operatorname{span} \mathcal{L}$ is a combination $\mathbf{v} = c_1\mathbf{u}_1 + \cdots + c_m\mathbf{u}_m$, and then $T(\mathbf{v}) = \sum_j c_j S(\mathbf{u}_j) = S(\mathbf{v})$. In particular $T(\mathbf{v}_i) = S(\mathbf{v}_i) = \mathbf{w}_i$.

(b) If $\mathcal{L}$ spans V, two such maps agree on a spanning list and are equal by Corollary 2.2.6. If $W = \{\mathbf{0}\}$, there is only one function $V \to W$ at all. Conversely, suppose that $\mathcal{L}$ does not span V and that W contains some $\mathbf{w} \neq \mathbf{0}$. Then $r \geq 1$: if $r = 0$, then $\mathbf{u}_1, \ldots, \mathbf{u}_m$ would be a basis of V, and $V = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_m) = \operatorname{span} \mathcal{L}$. Let T be the map built in (a), and let T' be the linear map with $T'(\mathbf{u}_j) = S(\mathbf{u}_j)$ for all j, $T'(\mathbf{x}_1) = \mathbf{w}$, and $T'(\mathbf{x}_l) = \mathbf{0}$ for $l \geq 2$. The argument in (a) shows that $T'(\mathbf{v}_i) = \mathbf{w}_i$ for every i, but $T'(\mathbf{x}_1) = \mathbf{w} \neq \mathbf{0} = T(\mathbf{x}_1)$. So T is not unique. □

The hypothesis on V always holds when V is spanned by a finite list. By Theorem 1.6.10, span $\mathcal{L}$ has a basis taken from $\mathcal{L}$, and in Section 4.1 we will see that every linearly independent list in such a V extends to a basis (Theorem 4.1.16). In F^n one can also extend by hand, adding standard basis vectors one at a time. Without any finiteness assumption, the hypothesis still holds if one accepts the axiom of choice (Section 15.1).

Putting Proposition 2.2.11, Remark 2.2.12, and Proposition 2.2.14 together gives a procedure.

Algorithm 2.2.15 (Deciding whether a linear map with prescribed values exists)

Input Lists $\mathbf{v}_1, \ldots, \mathbf{v}_k$ in V and $\mathbf{w}_1, \ldots, \mathbf{w}_k$ in W.
Output Whether some $T \in \mathrm{L}(V, W)$ has $T(\mathbf{v}_i) = \mathbf{w}_i$ for every i, and whether it is unique.

1. Go through $\mathbf{v}_1, \ldots, \mathbf{v}_k$ in order, and discard each vector that is a linear combination of the vectors kept before it. The kept vectors form a basis $\mathcal{B}$ of $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$.
2. For each discarded $\mathbf{v}_j$, write $\mathbf{v}_j = \sum c_r \mathbf{u}_r$ with the $\mathbf{u}_r$ in $\mathcal{B}$, and check that the corresponding $\mathbf{w}$'s satisfy the same equation. If one check fails, no T exists. Otherwise a linear map with the prescribed values exists on $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$.
3. Suppose every check passed. If $\mathbf{v}_1, \ldots, \mathbf{v}_k$ spans V, then T exists and is unique. Otherwise extend $\mathcal{B}$ to a basis $\mathcal{B}, \mathbf{x}_1, \ldots, \mathbf{x}_r$ of V. Then T exists, its values at $\mathbf{x}_1, \ldots, \mathbf{x}_r$ can be chosen freely, and it is not unique unless $W = \{\mathbf{0}\}$.

In step 1, the kept vectors span the same subspace as the whole list, since each discarded vector is a combination of kept ones. They are linearly independent: otherwise, by the linear dependence lemma (Lemma 1.5.10), some kept vector would be a combination of the kept vectors before it, and it would have been discarded. Applied to $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$, Remark 2.2.12 justifies step 2, and Proposition 2.2.14 justifies step 3.

Example 2.2.16 (Deciding existence and uniqueness).

(a) Is there a linear $T : \mathbb{R}^2 \to \mathbb{R}^2$ with

$$T(1,2) = (1,1), \quad T(3,1) = (2,-1), \quad T(4,3) = (3,1)?$$

Keep $(1,2)$, and keep $(3,1)$, which is not a multiple of $(1,2)$. The two kept vectors form a basis of $\mathbb{R}^2$: the equations $a + 3b = x$ and $2a + b = y$ have the unique solution $b = (2x - y)/5$, $a = (3y - x)/5$. Then $(4,3) = (1,2) + (3,1)$ is discarded, and the check asks whether $(3,1) = (1,1) + (2,-1) = (3,0)$. It is not, so no such T exists.

(b) Change the last value to $T(4,3) = (3,0)$. Now the check passes, and the list spans $\mathbb{R}^2$, so exactly one T exists. With the coordinates from (a),

$$T(x,y) = \frac{3y - x}{5}(1,1) + \frac{2x - y}{5}(2,-1) = \left(\frac{3x + y}{5}, \frac{4y - 3x}{5}\right).$$

As a check, $T(1,2) = (1,1)$, $T(3,1) = (2,-1)$, and $T(4,3) = (3,0)$.

(c) Let F be any field. Is there a linear $T : F^3 \to F^2$ with

$$T(1,1,0) = (1,0), \quad T(0,1,1) = (0,1), \quad T(1,2,1) = (1,1)?$$

Keep $\mathbf{u}_1 = (1,1,0)$ and $\mathbf{u}_2 = (0,1,1)$, which is not a multiple of $\mathbf{u}_1$ (its first coordinate is 0 and its second is not). Discard $(1,2,1) = \mathbf{u}_1 + \mathbf{u}_2$; the check $(1,0) + (0,1) = (1,1)$ passes. The list does not span F^3: every vector $a\mathbf{u}_1 + b\mathbf{u}_2 = (a, a+b, b)$ of the span has middle coordinate equal to the sum of the other two, and $\mathbf{e}_1$ does not. Adding $\mathbf{e}_1$ gives a basis of F^3, because

$$(x,y,z) = a\mathbf{u}_1 + b\mathbf{u}_2 + c\mathbf{e}_1 = (a + c, a + b, b)$$

holds exactly when $b = z$, $a = y - z$, and $c = x - y + z$. So for each $\mathbf{c} \in F^2$ there is exactly one linear T with the prescribed values and $T(\mathbf{e}_1) = \mathbf{c}$, namely

$$T(x,y,z) = (y - z)(1,0) + z(0,1) + (x - y + z)\mathbf{c} = (y - z, z) + (x - y + z)\mathbf{c}.$$

Different choices of $\mathbf{c}$ give different maps, so T exists but is not unique.

2.2.5 Maps out of F^n

For $V = F^n$ with the standard basis, Theorem 2.2.1 takes a particularly concrete form.

Corollary 2.2.17 (Linear maps out of F^n). Let W be a vector space over F and $\mathbf{w}_1, \dots, \mathbf{w}_n \in W$. There is exactly one linear map $T : F^n \to W$ with $T(\mathbf{e}_j) = \mathbf{w}_j$ for $j = 1, \dots, n$, namely

$$T(x_1, \dots, x_n) = x_1\mathbf{w}_1 + \cdots + x_n\mathbf{w}_n.$$

In particular, every $T \in \mathrm{L}(F^n, W)$ satisfies $T(\mathbf{x}) = x_1T(\mathbf{e}_1) + \cdots + x_nT(\mathbf{e}_n)$ for all $\mathbf{x} = (x_1, \dots, x_n) \in F^n$.

Proof. ROUTINE

Uses. Definition 1.6.8 (Standard bases), Theorem 2.2.1 (Linear maps are determined by a basis)
Hint 1. Apply Theorem 2.2.1 to the standard basis.
Hint 2. What are the coordinates of $(x_1, \dots, x_n)$ in the standard basis?
Sketch. $\mathbf{e}_1, \dots, \mathbf{e}_n$ is a basis of F^n, and $(x_1, \dots, x_n) = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n$. Apply (2.2.1).

The standard basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ is a basis of F^n (Definition 1.6.8), and $(x_1, \dots, x_n) = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n$. So Theorem 2.2.1 gives exactly one linear T with $T(\mathbf{e}_j) = \mathbf{w}_j$, and (2.2.1) is the displayed formula. For an arbitrary $T \in \mathrm{L}(F^n, W)$, apply this with $\mathbf{w}_j = T(\mathbf{e}_j)$. □

Take $W = F^m$, and let a_{ij} be the i-th coordinate of $T(\mathbf{e}_j)$. Comparing i-th coordinates in $T(\mathbf{x}) = x_1T(\mathbf{e}_1) + \cdots + x_nT(\mathbf{e}_n)$ shows that the i-th coordinate of $T(\mathbf{x})$ is $a_{i1}x_1 + \cdots + a_{in}x_n$. So every linear map $F^n \to F^m$ is given by a linear formula as in Example 2.1.7, and the mn coefficients are the coordinates of $T(\mathbf{e}_1), \dots, T(\mathbf{e}_n)$. Writing these n vectors side by side, as the columns of an $m \times n$ array, is the starting point of Section 2.3.

The corollary also explains the rotation formula of Example 2.1.11. Rotating $\mathbf{e}_1$ by θ gives $(\cos\theta, \sin\theta)$, and rotating $\mathbf{e}_2$ gives $(-\sin\theta, \cos\theta)$. Once we know that R_θ is linear, Corollary 2.2.17 gives $R_\theta(x, y) = x(\cos\theta, \sin\theta) + y(-\sin\theta, \cos\theta)$ without the angle addition formulas. (In Example 2.1.11 linearity was deduced from the formula, so this is a consistency check rather than an independent proof.)

Taken together, existence and uniqueness say that linear maps out of V correspond exactly to lists of vectors in W.

Corollary 2.2.18 (Linear maps correspond to lists of vectors). Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V. The map

$$T \mapsto (T(\mathbf{v}_1), \ldots, T(\mathbf{v}_n))$$

is a bijection from $\mathrm{L}(V, W)$ onto the set of lists of length n in W. It respects the vector space operations: the list of $S + T$ is the entrywise sum of the lists of S and T, and the list of cT is c times the list of T.

Proof. ROUTINE

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Definition 2.1.21 (Pointwise operations)
Hint 1. Surjectivity is the existence half of Theorem 2.2.1. What is injectivity?
Hint 2. For the operations, use the definition of $S + T$ and cT (Definition 2.1.21).
Sketch. Existence in Theorem 2.2.1 says every list is the list of some T; uniqueness says different maps have different lists. $(S + T)(\mathbf{v}_i) = S(\mathbf{v}_i) + T(\mathbf{v}_i)$ and $(cT)(\mathbf{v}_i) = cT(\mathbf{v}_i)$ by definition.

Given a list $\mathbf{w}_1, \ldots, \mathbf{w}_n$ in W, the existence part of Theorem 2.2.1 gives $T \in \mathrm{L}(V, W)$ whose list is $\mathbf{w}_1, \ldots, \mathbf{w}_n$, so the map is surjective. If S and T have the same list, then $S = T$ by the uniqueness part, so the map is injective. Finally, by Definition 2.1.21, $(S + T)(\mathbf{v}_i) = S(\mathbf{v}_i) + T(\mathbf{v}_i)$ and $(cT)(\mathbf{v}_i) = cT(\mathbf{v}_i)$ for each i. □

Example 2.2.19 (Counting linear maps over $\mathbb{F}_p$). Let p be prime. The space $\mathbb{F}_p^m$ has p^m elements, so there are $(p^m)^n$ lists of length n in it. By Corollary 2.2.18, applied with the standard basis of $\mathbb{F}_p^n$,

$$\left|\mathrm{L}\left(\mathbb{F}_p^n, \mathbb{F}_p^m\right)\right| = p^{mn}.$$

For $n = 2$, $m = 1$, and $p = 2$ this gives the 4 linear maps $\mathbb{F}_2^2 \to \mathbb{F}_2$ found in Exercise 2.1.30. For comparison, there are $(p^m)^{p^n}$ functions $\mathbb{F}_p^n \to \mathbb{F}_p^m$ in all; for $\mathbb{F}_2^2 \to \mathbb{F}_2^2$ that is 256 functions, of which only 16 are linear.

2.2.6 Maps out of $F[x]$

No finite list spans $F[x]$ (Section 1.6), so Theorem 2.2.1 does not apply to it. But the monomials $1, x, x^2, \ldots$ behave like a basis: every polynomial is a combination of finitely many of them, and its coefficients are uniquely determined. The proof of Theorem 2.2.1 goes through unchanged.

Proposition 2.2.20 (Linear maps out of $F[x]$). Let W be a vector space over F, and let $\mathbf{w}_0, \mathbf{w}_1, \mathbf{w}_2, \ldots$ be any sequence of vectors in W. There is exactly one linear map $T : F[x] \to W$ with $T\left(x^k\right) = \mathbf{w}_k$ for every $k \geq 0$, namely

$$T\left(a_0 + a_1 x + \cdots + a_d x^d\right) = a_0\mathbf{w}_0 + a_1\mathbf{w}_1 + \cdots + a_d\mathbf{w}_d.$$

Proof. ROUTINE

Uses. Definition 1.2.13 (Polynomials), Notation 1.2.15, Theorem 2.1.3 (Checking linearity)
Hint 1. Imitate the proof of Theorem 2.2.1. What plays the role of the coordinates of a polynomial?
Hint 2. The coefficients of p are determined by p (Definition 1.2.13). Check that writing p with extra zero terms does not change the right side.
Sketch. Define $T(p) = \sum_k a_k\mathbf{w}_k$ over the coefficients a_k of p, a finite sum; extra zero terms contribute $0\mathbf{w}_k = \mathbf{0}$, so T is well defined. The operations on $F[x]$ are coefficientwise, which gives linearity, and x^k has a single coefficient 1, which gives $T\left(x^k\right) = \mathbf{w}_k$. A linear T' with $T'\left(x^k\right) = \mathbf{w}_k$ satisfies $T'(p) = \sum_k a_k T'\left(x^k\right) = T(p)$.

Let $p \in F[x]$ have coefficients $(a_0, a_1, \ldots)$, of which only finitely many are nonzero (Definition 1.2.13). Choose d with $a_k = 0$ for $k > d$, so that $p = a_0 + a_1 x + \cdots + a_d x^d$ (Notation 1.2.15), and define

$$T(p) = a_0\mathbf{w}_0 + a_1\mathbf{w}_1 + \cdots + a_d\mathbf{w}_d.$$

This does not depend on d, since increasing d only adds terms $0\mathbf{w}_k = \mathbf{0}$, and the coefficients are determined by p. So T is a function $F[x] \to W$.

Let $p, q \in F[x]$ have coefficients (a_k) and (b_k), let $c \in F$, and choose one d that works for both. The operations on $F[x]$ are coefficientwise, so $cp + q$ has coefficients $(ca_k + b_k)$, and

$$T(cp+q) = \sum_{k=0}^{d}(ca_k + b_k)\mathbf{w}_k = c\sum_{k=0}^{d} a_k\mathbf{w}_k + \sum_{k=0}^{d} b_k\mathbf{w}_k = cT(p) + T(q).$$

By Theorem 2.1.3, T is linear. The polynomial x^k has coefficient 1 in position k and 0 elsewhere, so $T\left(x^k\right) = \mathbf{w}_k$. Finally, if T' is linear and $T'\left(x^k\right) = \mathbf{w}_k$ for every k, then $T'(p) = \sum_{k=0}^{d} a_k T'\left(x^k\right) = \sum_{k=0}^{d} a_k\mathbf{w}_k = T(p)$, so $T' = T$. □

For example, the maps of Example 2.1.9 are the linear maps with $x^k \mapsto t^k$ (evaluation at t), $x^k \mapsto x^{k+1}$ (multiplication by x), and $x^k \mapsto kx^{k-1}$ (differentiation, with $1 \mapsto 0$), and the substitution map $p \mapsto p(q)$ of Exercise 2.1.32 is $x^k \mapsto q^k$. So Proposition 2.2.20 gives a second proof that these maps are linear. Its uniqueness half says that two linear maps out of $F[x]$ that agree on every monomial are equal, which is Technique 2.2.7 with the monomials in place of a basis; Exercise 2.1.49 used exactly this. The same argument works for any family of vectors such that every vector is a combination of them with uniquely determined coefficients, all but finitely many of which are 0. Such a family is a basis in the sense of Section 15.1.

Exercises

Exercise 2.2.21. ROUTINE

(a) Show that there is exactly one linear map $T : \mathbb{F}_5^2 \to \mathbb{F}_5^2$ with $T(1,2) = (1,0)$ and $T(2,1) = (0,1)$, and find $T(x,y)$.

(b) Show that there is no linear map $T : \mathbb{F}_3^2 \to \mathbb{F}_3^2$ with $T(1,2) = (1,0)$ and $T(2,1) = (0,1)$.

Solution on page 1115

Exercise 2.2.22. ROUTINE For each of the following, decide whether a linear map with the given values exists, and if so, whether it is unique.

(a) $T : \mathbb{R}^2 \to \mathbb{R}^2$ with $T(1,2) = (1,0)$ and $T(2,4) = (2,1)$.

(b) $T : \mathbb{R}^3 \to \mathbb{R}^2$ with $T(1,0,1) = (1,1)$, $T(0,1,1) = (2,0)$, and $T(1,1,2) = (3,1)$.

(c) $T : \mathbb{R}^2 \to \mathbb{R}$ with $T(1,1) = 2$, $T(1,-1) = 0$, and $T(3,1) = 4$.

(d) $T : \mathbb{F}_2^3 \to \mathbb{F}_2$ with $T(1,1,0) = T(0,1,1) = T(1,0,1) = 1$.

Solution on page 1115

Exercise 2.2.23. ROUTINE

(a) Show that the unique linear map $T : \mathbb{R}[x] \to \mathbb{R}$ with $T(x^n) = 1/(n+1)$ for every $n \geq 0$ is $p \mapsto \int_0^1 p(t)\,dt$.

(b) Let F be a field. Show that the unique linear map $U : F[x] \to F$ with $U(x^n) = n$ for every $n \geq 0$ (where n means $n \cdot 1 \in F$) is $p \mapsto p'(1)$. Compute $U\left(x^2 + x\right)$ over $\mathbb{R}$, over $\mathbb{F}_2$, and over $\mathbb{F}_3$.

Solution on page 1116

Exercise 2.2.24. ROUTINE Find the error in the following argument.

Claim. Let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ span V, and let $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$ be arbitrary. Then there is a linear map $T : V \to W$ with $T(\mathbf{v}_i) = \mathbf{w}_i$ for every i.

Proof. For each $\mathbf{v} \in V$, choose scalars with $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$, which is possible because the list spans V, and set $T(\mathbf{v}) = a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k$. Choosing $a_i = 1$ and $a_j = 0$ for $j \neq i$ shows $T(\mathbf{v}_i) = \mathbf{w}_i$. If $\mathbf{u} = \sum_i a_i\mathbf{v}_i$ and $\mathbf{v} = \sum_i b_i\mathbf{v}_i$, then $c\mathbf{u} + \mathbf{v} = \sum_i (ca_i + b_i)\mathbf{v}_i$, so $T(c\mathbf{u} + \mathbf{v}) = \sum_i (ca_i + b_i)\mathbf{w}_i = cT(\mathbf{u}) + T(\mathbf{v})$. So T is linear.

Solution on page 1116

Exercise 2.2.25. ROUTINE Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V, and let $T \in \mathrm{L}(V, W)$. Prove or disprove each statement.

(a) If $W = V$ and $T(\mathbf{v}_i) \in \operatorname{span}(\mathbf{v}_i)$ for every i, then $T(\mathbf{v}) \in \operatorname{span}(\mathbf{v})$ for every $\mathbf{v} \in V$.

(b) If U is a subspace of W and $T(\mathbf{v}_i) \in U$ for every i, then $T(V) \subseteq U$.

(c) If $T(\mathbf{v}_i) \neq \mathbf{0}$ for every i, then $T(\mathbf{v}) \neq \mathbf{0}$ for every nonzero $\mathbf{v} \in V$.

(d) If $T(\mathbf{v}_1) = T(\mathbf{v}_2) = \cdots = T(\mathbf{v}_n)$, then $T(V) \subseteq \operatorname{span}(T(\mathbf{v}_1))$.

Solution on page 1116

Exercise 2.2.26. STANDARD

(a) Find the error in the following argument.

Claim. There is a linear map $T : \mathbb{R}^2 \to \mathbb{R}$ with $T(1, 2) = 1$, $T(2, 1) = 1$, and $T(1, 1) = 1$.

Proof. Any two of the vectors $(1, 2)$, $(2, 1)$, $(1, 1)$ form a basis of $\mathbb{R}^2$. So by Theorem 2.2.1, for any two of the three prescribed values there is a linear map that takes them. Hence there is a linear map that takes all three.

(b) Find all $c \in \mathbb{R}$ for which some linear $T : \mathbb{R}^2 \to \mathbb{R}$ satisfies $T(1, 2) = T(2, 1) = 1$ and $T(1, 1) = c$.

Solution on page 1117

Exercise 2.2.27. STANDARD Regard $\mathbb{C}^2$ as a vector space over $\mathbb{C}$.

(a) Show that there is exactly one $\mathbb{C}$-linear map $T : \mathbb{C}^2 \to \mathbb{C}^2$ with $T(1, i) = (1, 0)$ and $T(1, -i) = (0, 1)$, and find $T(z_1, z_2)$.

(b) Show that there is no $\mathbb{C}$-linear map $T : \mathbb{C}^2 \to \mathbb{C}^2$ with $T(1, i) = (1, 0)$ and $T(i, -1) = (0, 1)$.

(c) Now regard $\mathbb{C}^2$ as a vector space over $\mathbb{R}$ (Proposition 1.2.19). Show that there is an $\mathbb{R}$-linear map $T : \mathbb{C}^2 \to \mathbb{C}^2$ with $T(1, i) = (1, 0)$ and $T(i, -1) = (0, 1)$.

Solution on page 1117

Exercise 2.2.28. STANDARD Let $U = \{(x, y, z) \in \mathbb{R}^3 \mid x + y + z = 0\}$. Show that there is exactly one linear map $T : \mathbb{R}^3 \to \mathbb{R}^3$ with $T(\mathbf{u}) = \mathbf{u}$ for every $\mathbf{u} \in U$ and $T(1, 1, 1) = \mathbf{0}$. Find a formula for T, and show that $T^2 = T$.

Solution on page 1118

Exercise 2.2.29. STANDARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V with $n \geq 1$, and let $T \in \mathrm{L}(V)$ be the linear map with $T(\mathbf{v}_i) = \mathbf{v}_{i+1}$ for $i < n$ and $T(\mathbf{v}_n) = \mathbf{v}_1$. Let $\mathbf{s} = \mathbf{v}_1 + \cdots + \mathbf{v}_n$ and $N = \mathrm{id}_V + T + T^2 + \cdots + T^{n-1}$.

(a) Show that $T^n = \mathrm{id}_V$.

(b) Show that $N(a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n) = (a_1 + \cdots + a_n)\mathbf{s}$ for all scalars a_i.

(c) Show that $TN = NT = N$.

Solution on page 1118

Exercise 2.2.30. STANDARD Let $R \in \mathrm{L}(\mathbb{R}^2)$ be the rotation $R(x, y) = (-y, x)$. Show that $T \in \mathrm{L}(\mathbb{R}^2)$ satisfies $TR = RT$ if and only if $T = a\,\mathrm{id} + bR$ for some $a, b \in \mathbb{R}$. Interpret the result using complex numbers.

Solution on page 1119

Exercise 2.2.31. STANDARD Let p be prime.

(a) How many $T \in \mathrm{L}(\mathbb{F}_p^2)$ satisfy $T(1, 1) \in \mathrm{span}((1, 1))$?

(b) How many $T \in \mathrm{L}(\mathbb{F}_p^2)$ satisfy both $T(1, 1) \in \mathrm{span}((1, 1))$ and $T(1, -1) \in \mathrm{span}((1, -1))$? (The answer depends on p.)

Solution on page 1119

Exercise 2.2.32. STANDARD Let $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a list in V.

(a) Suppose $W \neq \{\mathbf{0}\}$, and that for every list $\mathbf{w}_1, ..., \mathbf{w}_n$ in W there is a linear map $T : V \to W$ with $T(\mathbf{v}_i) = \mathbf{w}_i$ for every i. Show that $\mathcal{L}$ is linearly independent.

(b) Conversely, show that if $\mathcal{L}$ is linearly independent, then for every vector space W and every $\mathbf{w}_1, ..., \mathbf{w}_n \in W$ there is a linear map $\mathrm{span}\,\mathcal{L} \to W$ sending each $\mathbf{v}_i$ to $\mathbf{w}_i$.

Solution on page 1120

Exercise 2.2.33. STANDARD Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of V.

(a) Show that for each i there is exactly one linear map $\varphi_i : V \to F$ with $\varphi_i(\mathbf{v}_i) = 1$ and $\varphi_i(\mathbf{v}_j) = 0$ for $j \neq i$, and that $\varphi_i(\mathbf{v})$ is the i-th coordinate of $[\mathbf{v}]_{\mathcal{B}}$.

(b) Show that $\mathbf{v} = \varphi_1(\mathbf{v})\mathbf{v}_1 + \cdots + \varphi_n(\mathbf{v})\mathbf{v}_n$ for every $\mathbf{v} \in V$.

(c) Show that every $\varphi \in \mathrm{L}(V, F)$ equals $\varphi(\mathbf{v}_1)\varphi_1 + \cdots + \varphi(\mathbf{v}_n)\varphi_n$.

(The maps $\varphi_1, ..., \varphi_n$ form the *dual basis* of $\mathcal{B}$; see Section 13.1.)

Solution on page 1120

Exercise 2.2.34. STANDARD Let $\mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of V and $\mathbf{w}_1, ..., \mathbf{w}_m$ a basis of W. For $1 \leq i \leq m$ and $1 \leq j \leq n$, let $E_{ij} \in \mathrm{L}(V, W)$ be the linear map with $E_{ij}(\mathbf{v}_j) = \mathbf{w}_i$ and $E_{ij}(\mathbf{v}_k) = \mathbf{0}$ for $k \neq j$. Show that the list of the mn maps

$$E_{11}, E_{21}, ..., E_{m1}, E_{12}, ..., E_{m2}, ..., E_{1n}, ..., E_{mn}$$

is a basis of $\mathrm{L}(V, W)$. (Once dimension is defined in Section 4.1, this says $\dim \mathrm{L}(V, W) = mn$.)

Solution on page 1120

Exercise 2.2.35. STANDARD Let U be a subspace of V, and suppose that V has a basis $\mathbf{u}_1, ..., \mathbf{u}_m, \mathbf{x}_1, ..., \mathbf{x}_r$ in which $\mathbf{u}_1, ..., \mathbf{u}_m$ is a basis of U. (By the results of Section 4.1, this holds whenever V is finite-dimensional.)

(a) Construct $P \in \mathrm{L}(V)$ with $P(V) = U$ and $P(\mathbf{u}) = \mathbf{u}$ for every $\mathbf{u} \in U$.

(b) Construct $S \in \mathrm{L}(V)$ with $\{\mathbf{v} \in V \mid S(\mathbf{v}) = \mathbf{0}\} = U$.

(c) Carry out (a) and (b) for $U = \mathrm{span}((1, 2, 3)) \subseteq \mathbb{R}^3$, and give formulas for P and S.

(In the language of Section 2.6, every such U is the image of a linear map and the kernel of another.)

Solution on page 1121

Exercise 2.2.36. HARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V, and let $T \in \mathrm{L}(V)$ satisfy $T(\mathbf{v}_1) = \mathbf{0}$ and $T(\mathbf{v}_k) \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$ for $2 \le k \le n$. Show that $T^n = 0$.

Solution on page 1121

Exercise 2.2.37. HARD Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in V and $\mathcal{M} = \mathbf{w}_1, \ldots, \mathbf{w}_k$ a list in W. Show that there is a bijective linear map $S : \operatorname{span}\mathcal{L} \to \operatorname{span}\mathcal{M}$ with $S(\mathbf{v}_i) = \mathbf{w}_i$ for every i if and only if $\mathcal{L}$ and $\mathcal{M}$ satisfy the same linear relations: for all $a_1, \ldots, a_k \in F$,

$$a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0} \quad \Longleftrightarrow \quad a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k = \mathbf{0}.$$

Then decide whether such a map exists for $\mathcal{L} = (1,0), (0,1), (1,1)$ and $\mathcal{M} = (1,1), (1,-1), (2,0)$ in $\mathbb{R}^2$.

Solution on page 1122

Exercise 2.2.38. HARD Let $n \ge 2$, let $\mathbf{s} = \mathbf{e}_1 + \cdots + \mathbf{e}_n \in F^n$, and list the $n+1$ vectors $\mathbf{v}_1 = \mathbf{e}_1, \ldots, \mathbf{v}_n = \mathbf{e}_n, \mathbf{v}_{n+1} = \mathbf{s}$. For which permutations σ of $\{1, \ldots, n+1\}$ is there a linear map $T : F^n \to F^n$ with $T(\mathbf{v}_i) = \mathbf{v}_{\sigma(i)}$ for every i? The answer depends on whether $1 + 1 = 0$ in F.

Solution on page 1122

Exercise 2.2.39. HARD Find all linear maps $f : F[x] \to F[x]$ such that $f(pq) = f(p)f(q)$ for all $p, q \in F[x]$. (Products of polynomials are studied in Section 7.1. You may use that multiplication of polynomials is associative and commutative, distributes over addition, satisfies $c(pq) = (cp)q$ for $c \in F$, and has $x^j x^k = x^{j+k}$.)

Solution on page 1123

Exercise 2.2.40. CHALLENGE Let $n \ge 1$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_{n+1} \in V$ be such that any n of them, in their given order, form a basis of V.

(a) Show that $\mathbf{v}_{n+1} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$ with every $a_i \neq 0$.

(b) Show that if $T \in \mathrm{L}(V)$ satisfies $T(\mathbf{v}_i) \in \operatorname{span}(\mathbf{v}_i)$ for $i = 1, \ldots, n+1$, then $T = \lambda \mathrm{id}_V$ for some $\lambda \in F$.

(c) Let $\mathbf{w}_1, \ldots, \mathbf{w}_{n+1} \in W$ be such that any n of them form a basis of W. Show that there are a linear map $T : V \to W$ and nonzero scalars $c_1, \ldots, c_{n+1}$ with $T(\mathbf{v}_i) = c_i\mathbf{w}_i$ for every i, and that any two such maps are scalar multiples of each other.

Solution on page 1124

2.3 Matrices of linear maps

By Theorem 2.2.1, a linear map $T : V \to W$ is determined by its values $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_n)$ on a basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ of V, and these values can be any list in W (Corollary 2.2.18). If W has a basis $\mathbf{w}_1, \ldots, \mathbf{w}_m$ as well, each value $T(\mathbf{v}_j)$ is in turn determined by its coordinate vector in F^m. So T is recorded by mn scalars, and writing the n coordinate vectors side by side gives an $m \times n$ matrix, the matrix of T. Two things then have to be worked out: how to recover the values of T from its matrix, which will force the definition of the matrix–vector product, and how much the matrix depends on the chosen bases, which turns out to be a great deal.

Throughout this section, V and W are vector spaces over F with bases $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ of V and $\mathcal{C} = \mathbf{w}_1, \ldots, \mathbf{w}_m$ of W, where $n, m \ge 1$, unless other bases are named. (We leave out the zero space, because matrices with no rows or no columns are not defined in Definition 1.2.7.)

2.3.1 The matrix of a linear map

Definition 2.3.1 (Matrix of a linear map). Let $T \in \mathrm{L}(V, W)$. The **matrix of T with respect to $\mathcal{B}$ and $\mathcal{C}$** is the $m \times n$ matrix

$$[T]_{\mathcal{C}\mathcal{B}} = \begin{pmatrix} [T(\mathbf{v}_1)]_{\mathcal{C}} & [T(\mathbf{v}_2)]_{\mathcal{C}} & \cdots & [T(\mathbf{v}_n)]_{\mathcal{C}} \end{pmatrix}$$

whose j-th column is the coordinate vector of $T(\mathbf{v}_j)$ with respect to $\mathcal{C}$. Equivalently, its entries a_{ij} are the scalars with

$$T(\mathbf{v}_j) = a_{1j}\mathbf{w}_1 + a_{2j}\mathbf{w}_2 + \cdots + a_{mj}\mathbf{w}_m \quad (j = 1, \ldots, n).$$

For an operator $T \in \mathrm{L}(V)$, the **matrix of T with respect to $\mathcal{B}$** is $[T]_{\mathcal{B}\mathcal{B}}$.

The matrix is well defined, since each $T(\mathbf{v}_j)$ has exactly one coordinate vector with respect to the basis $\mathcal{C}$ (Definition 1.6.14).

The matrix has one column for each vector of $\mathcal{B}$ and one row for each vector of $\mathcal{C}$, so its size is (length of $\mathcal{C}$) $\times$ (length of $\mathcal{B}$). Column j records where T sends the j-th basis vector of the domain, written in the coordinates of the target, and the entry a_{ij} is the coefficient of $\mathbf{w}_i$ in $T(\mathbf{v}_j)$. To keep the indices straight, imagine $\mathbf{v}_1, \ldots, \mathbf{v}_n$ written above the columns and $\mathbf{w}_1, \ldots, \mathbf{w}_m$ written to the left of the rows. The target basis comes first in $[T]_{\mathcal{C}\mathcal{B}}$ so that the two copies of $\mathcal{B}$ sit next to each other in the formula $[T]_{\mathcal{C}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}}$ of Theorem 2.3.9 below. We always write both subscripts, even when they are equal.

Notation 2.3.2 (The standard basis $\mathcal{E}$). We write $\mathcal{E}$ for the standard basis $\mathbf{e}_1, \ldots, \mathbf{e}_k$ of F^k (Definition 1.6.8), with k determined by the context. Since $\mathbf{y} = y_1\mathbf{e}_1 + \cdots + y_k\mathbf{e}_k$ for $\mathbf{y} = (y_1, \ldots, y_k) \in F^k$, we have $[\mathbf{y}]_{\mathcal{E}} = \mathbf{y}$. That is, in the standard basis a vector of F^k is its own coordinate vector.

In particular, for a linear map $T : F^n \to F^m$, the matrix $[T]_{\mathcal{E}\mathcal{E}}$ with respect to the standard bases of F^n and F^m has the columns $T(\mathbf{e}_1), \ldots, T(\mathbf{e}_n)$.

Example 2.3.3 (Matrices with respect to standard bases).

(a) Let $T : \mathbb{R}^3 \to \mathbb{R}^2$, $T(x, y, z) = (2x - y + 3z, x + 5z)$, the map of Example 2.1.7. Then $T(\mathbf{e}_1) = (2, 1)$, $T(\mathbf{e}_2) = (-1, 0)$, and $T(\mathbf{e}_3) = (3, 5)$, so

$$[T]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} 2 & -1 & 3 \\ 1 & 0 & 5 \end{pmatrix}.$$

This is the matrix A of Example 2.1.7: the coefficient of the j-th variable in the i-th coordinate of $T(x, y, z)$ is the entry in row i and column j. Proposition 2.3.17 shows that this always happens.

(b) The rotation R_θ of $\mathbb{R}^2$ by the angle θ (Example 2.1.11) sends $\mathbf{e}_1$ to $(\cos\theta, \sin\theta)$ and $\mathbf{e}_2$ to $(-\sin\theta, \cos\theta)$, so

$$[R_\theta]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}, \quad \text{for example} \quad \left[R_{\pi/2}\right]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Example 2.3.4 (Differentiation). Let $V = F[x]_{\leq 2}$. Every element of V is $a + bx + cx^2$ for exactly one triple $(a, b, c) \in F^3$ (Definition 1.2.13, Definition 1.2.16), so $\mathcal{B} = 1, x, x^2$ is a basis of V and $\left[a + bx + cx^2\right]_{\mathcal{B}} = (a, b, c)$. Differentiation does not raise degrees, so D maps V into V, and we regard it as an operator $D \in \mathrm{L}(V)$ (Example 2.1.9). Since

$$D(1) = \mathbf{0}, \quad D(x) = 1, \quad D\left(x^2\right) = 2x,$$

whose coordinate vectors are $(0, 0, 0)$, $(1, 0, 0)$, and $(0, 2, 0)$,

$$[D]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix}.$$

Over $\mathbb{F}_2$ the entry 2 is 0. The domain and the target can also be different spaces. Regarded as a map $F[x]_{\leq 3} \to F[x]_{\leq 2}$, with the bases $\mathcal{B}' = 1, x, x^2, x^3$ and $\mathcal{B}$, differentiation has the 3×4 matrix

$$[D]_{\mathcal{B}\mathcal{B}'} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}.$$

Strictly speaking these are two different linear maps, since their domains differ.

Definition 2.3.5 (Identity matrix). The $n \times n$ **identity matrix** I_n is the matrix with columns $\mathbf{e}_1, \ldots, \mathbf{e}_n$. Its entry in row i and column j is 1 if $i = j$ and 0 if $i \neq j$. We write I when n is clear from the context.

Example 2.3.6 (The zero map and the identity map). The zero map $0 \in \mathrm{L}(V, W)$ sends each $\mathbf{v}_j$ to $\mathbf{0}$, whose coordinate vector is $\mathbf{0}$. So $[0]_{\mathcal{C}\mathcal{B}}$ is the zero matrix, for all bases. The identity map sends $\mathbf{v}_j$ to $\mathbf{v}_j = 0\mathbf{v}_1 + \cdots + 1\mathbf{v}_j + \cdots + 0\mathbf{v}_n$, whose $\mathcal{B}$-coordinate vector is $\mathbf{e}_j$. So

$$[\mathrm{id}_V]_{\mathcal{B}\mathcal{B}} = I_n \quad \text{for every basis } \mathcal{B} \text{ of } V.$$

Here the same basis is used on both sides. Section 2.3.5 shows that $[\mathrm{id}_V]_{\mathcal{C}\mathcal{B}}$ looks quite different when $\mathcal{C} \neq \mathcal{B}$.

Exercise 2.3.7. ROUTINE Let $T : F[x]_{\leq 1} \to F^2$, $T(p) = (p(0), p(1))$. Find $[T]_{\mathcal{E}\mathcal{B}}$ for the basis $\mathcal{B} = 1, x$, and $[T]_{\mathcal{E}\mathring{\mathcal{B}}}$ for the basis $\mathring{\mathcal{B}} = 1 - x, x$.

Solution on page 1125

2.3.2 The matrix–vector product

Suppose we know $A = [T]_{\mathcal{C}\mathcal{B}}$ and the coordinates $[\mathbf{v}]_{\mathcal{B}} = (x_1, \ldots, x_n)$ of a vector $\mathbf{v} \in V$, and we want the coordinates of $T(\mathbf{v})$.

Intuition (Computing $[T(\mathbf{v})]_{\mathcal{C}}$). Since $\mathbf{v} = x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n$, linearity of T gives $T(\mathbf{v}) = x_1T(\mathbf{v}_1) + \cdots + x_nT(\mathbf{v}_n)$. Taking $\mathcal{C}$-coordinates is linear as well (Proposition 1.6.19), so

$$[T(\mathbf{v})]_{\mathcal{C}} = x_1[T(\mathbf{v}_1)]_{\mathcal{C}} + \cdots + x_n[T(\mathbf{v}_n)]_{\mathcal{C}}.$$

The right side is the linear combination of the columns of A whose coefficients are the entries of $[\mathbf{v}]_{\mathcal{B}}$. Realize that it no longer mentions T, the spaces V and W, or the bases: it is computed from the matrix A and the column $(x_1, \ldots, x_n)$ alone. So it is an operation on a matrix and a column, and we give it a name.

Definition 2.3.8 (Matrix–vector product). Let $A \in F^{m \times n}$ have columns $\mathbf{a}_1, \ldots, \mathbf{a}_n \in F^m$, and let $\mathbf{x} = (x_1, \ldots, x_n) \in F^n$. The **product** of A and $\mathbf{x}$ is

$$A\mathbf{x} = x_1\mathbf{a}_1 + x_2\mathbf{a}_2 + \cdots + x_n\mathbf{a}_n \in F^m.$$

It is defined only when the number of columns of A equals the number of entries of $\mathbf{x}$, and then $A\mathbf{x}$ has as many entries as A has rows.

In words, $A\mathbf{x}$ is the linear combination of the columns of A with coefficients $x_1, \ldots, x_n$. With this definition, the computation above becomes a theorem.

Theorem 2.3.9 (The matrix of a map computes the map). For every $T \in \mathrm{L}(V, W)$ and every $\mathbf{v} \in V$,

$$[T]_{\mathcal{C}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}}.$$

Proof. ROUTINE

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 2.3.8 (Matrix–vector product), Definition 1.6.14 (Coordinates), Proposition 1.6.19 (Coordinates respect linear combinations), Definition 2.1.1 (Linear map)
Hint 1. Write $\mathbf{v}$ in terms of $\mathcal{B}$, using its coordinates $(x_1, \dots, x_n) = [\mathbf{v}]_{\mathcal{B}}$.
Hint 2. Apply T, then take $\mathcal{C}$-coordinates. Both steps respect linear combinations, and what comes out is a combination of the columns of $[T]_{\mathcal{C}\mathcal{B}}$.
Sketch. With $[\mathbf{v}]_{\mathcal{B}} = (x_1, \dots, x_n)$, linearity of T and of $[\cdot]_{\mathcal{C}}$ gives $[T(\mathbf{v})]_{\mathcal{C}} = \sum_j x_j \left[T(\mathbf{v}_j)\right]_{\mathcal{C}}$, a combination of the vectors $\left[T(\mathbf{v}_j)\right]_{\mathcal{C}}$. These are the columns of $[T]_{\mathcal{C}\mathcal{B}}$, so the combination is $[T]_{\mathcal{C}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}}$ by Definition 2.3.8.

Let $[\mathbf{v}]_{\mathcal{B}} = (x_1, \dots, x_n)$, so that $\mathbf{v} = x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n$ (Definition 1.6.14). Then

$$\begin{aligned} [T(\mathbf{v})]_{\mathcal{C}} &= [x_1 T(\mathbf{v}_1) + \cdots + x_n T(\mathbf{v}_n)]_{\mathcal{C}} && \text{(linearity of } T\text{)} \\ &= x_1[T(\mathbf{v}_1)]_{\mathcal{C}} + \cdots + x_n[T(\mathbf{v}_n)]_{\mathcal{C}} && \text{(linearity of } [\cdot]_{\mathcal{C}}\text{)} \\ &= [T]_{\mathcal{C}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}} && \text{(definition of the product),} \end{aligned}$$

since the j-th column of $[T]_{\mathcal{C}\mathcal{B}}$ is $\left[T(\mathbf{v}_j)\right]_{\mathcal{C}}$ (Definition 2.3.1). □

So to evaluate T in coordinates, take the $\mathcal{B}$-coordinates of $\mathbf{v}$, multiply by the matrix, and read the result as $\mathcal{C}$-coordinates. Another way to say this: there are two routes from a vector $\mathbf{v} \in V$ to a column in F^m. One applies T and then takes $\mathcal{C}$-coordinates; the other takes $\mathcal{B}$-coordinates and then multiplies by $A = [T]_{\mathcal{C}\mathcal{B}}$. Theorem 2.3.9 says that the two routes always arrive at the same column (Figure 2.3.1). In terms of maps, $[\cdot]_{\mathcal{C}} \circ T = T_A \circ [\cdot]_{\mathcal{B}}$, where T_A is multiplication by A (Definition 2.3.15 below). The map T_A does to coordinate vectors what T does to vectors.

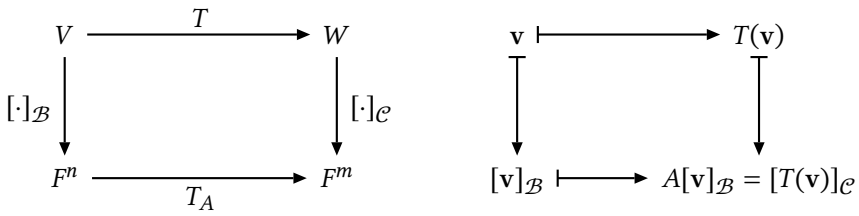

Figure 2.3.1. Two routes from V to F^m, where $A = [T]_{\mathcal{C}\mathcal{B}}$. Left: the spaces and maps. Right: what happens to a single vector $\mathbf{v}$. Going right and then down gives $[T(\mathbf{v})]_{\mathcal{C}}$, and going down and then right gives $A[\mathbf{v}]_{\mathcal{B}}$; Theorem 2.3.9 says that these agree.

You have probably met the product $A\mathbf{x}$ before, defined by a formula for its entries. The point here is that its definition is not a convention. Once we record vectors by their coordinates and linear maps by the columns $\left[T(\mathbf{v}_j)\right]_{\mathcal{C}}$, only one product makes Theorem 2.3.9 true. In fact, the special case of the standard bases already forces it.

Proposition 2.3.10 (The product is forced). Suppose that for all $m, n \geq 1$ we are given a rule that assigns to each $A \in F^{m\times n}$ and $\mathbf{x} \in F^n$ a vector $A \star \mathbf{x} \in F^m$, such that

$$[T]_{\mathcal{E}\mathcal{E}} \star \mathbf{x} = T(\mathbf{x}) \quad \text{for every } T \in \mathrm{L}(F^n, F^m) \text{ and every } \mathbf{x} \in F^n.$$

Then $A \star \mathbf{x} = A\mathbf{x}$ for all A and $\mathbf{x}$.

Since $[\mathbf{x}]_{\mathcal{E}} = \mathbf{x}$ and $[T(\mathbf{x})]_{\mathcal{E}} = T(\mathbf{x})$, the hypothesis is exactly Theorem 2.3.9 for $V = F^n$ and $W = F^m$ with their standard bases, with $\star$ in place of the product.

Proof. ROUTINE

Uses. Corollary 2.2.17 (Linear maps out of F^n), Definition 2.3.1 (Matrix of a linear map), Notation 2.3.2 (The standard basis $\mathcal{E}$), Definition 2.3.8 (Matrix–vector product)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Given A and $\mathbf{x}$, find a linear map $T : F^n \to F^m$ whose matrix with respect to the standard bases is A.
Hint 2. By Corollary 2.2.17 there is a linear T with $T(\mathbf{e}_j) = \mathbf{a}_j$, the j-th column of A. That corollary also tells you what $T(\mathbf{x})$ is.
Sketch. Let T be the linear map with $T(\mathbf{e}_j) = \mathbf{a}_j$. Then $[T]_{\mathcal{E}\mathcal{E}} = A$ and $T(\mathbf{x}) = \sum_j x_j \mathbf{a}_j$ (Corollary 2.2.17), so $A \star \mathbf{x} = T(\mathbf{x}) = A\mathbf{x}$.

Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$, and let $\mathbf{x} = (x_1, \dots, x_n) \in F^n$. By Corollary 2.2.17 there is a linear map $T : F^n \to F^m$ with $T(\mathbf{e}_j) = \mathbf{a}_j$ for each j, and $T(\mathbf{x}) = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$. The j-th column of $[T]_{\mathcal{E}\mathcal{E}}$ is $\big[T(\mathbf{e}_j)\big]_{\mathcal{E}} = \mathbf{a}_j$ (Notation 2.3.2), so $[T]_{\mathcal{E}\mathcal{E}} = A$. Hence

$$A \star \mathbf{x} = [T]_{\mathcal{E}\mathcal{E}} \star \mathbf{x} = T(\mathbf{x}) = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = A\mathbf{x}. \qquad \square$$

Matrix multiplication arises the same way in Section 2.4: it is the only product of matrices for which the matrix of a composite is the product of the matrices (Theorem 2.4.2).

The definition describes $A\mathbf{x}$ one column at a time. The familiar formula for its entries is a consequence.

Proposition 2.3.11 (Entries of $A\mathbf{x}$). Let $A = (a_{ij}) \in F^{m\times n}$ and $\mathbf{x} = (x_1, \dots, x_n) \in F^n$. For $i = 1, \dots, m$, the i-th entry of $A\mathbf{x}$ is

$$a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{in}x_n = \sum_{j=1}^{n} a_{ij}x_j.$$

Proof. ROUTINE

Uses. Definition 2.3.8 (Matrix–vector product), Definition 1.2.4 (The space F^n)
Hint 1. What is the i-th entry of the j-th column $\mathbf{a}_j$?
Hint 2. Vectors in F^m are added and scaled entry by entry.
Sketch. The i-th entry of $\mathbf{a}_j$ is a_{ij}, so the i-th entry of $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ is $x_1a_{i1} + \cdots + x_na_{in}$.

The j-th column $\mathbf{a}_j$ has i-th entry a_{ij}. Since the operations of F^m are entrywise (Definition 1.2.4), the i-th entry of $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ is $x_1a_{i1} + \cdots + x_na_{in} = a_{i1}x_1 + \cdots + a_{in}x_n$. $\square$

This is the row-times-column rule: the i-th entry of $A\mathbf{x}$ pairs row i of A with $\mathbf{x}$, multiplying entries in matching positions and adding. So there are two ways to read $A\mathbf{x}$. By columns, it is a linear combination of the columns of A, and this is the view to remember for proofs. By rows, it is a list of m numbers, each computed from one row of A. This is usually quicker by hand, and it is how Section 3.1 reads a system of equations.

Example 2.3.12 (A product computed two ways). Let $A = \begin{pmatrix} 1 & -2 & 0 \\ 3 & 1 & 4 \end{pmatrix} \in \mathbb{R}^{2\times 3}$ and $\mathbf{x} = (2, 1, -1)$. By columns,

$$A\mathbf{x} = 2\begin{pmatrix} 1 \\ 3 \end{pmatrix} + 1\begin{pmatrix} -2 \\ 1 \end{pmatrix} + (-1)\begin{pmatrix} 0 \\ 4 \end{pmatrix} = \begin{pmatrix} 2 - 2 + 0 \\ 6 + 1 - 4 \end{pmatrix} = \begin{pmatrix} 0 \\ 3 \end{pmatrix}.$$

By rows, the first entry is $1 \cdot 2 + (-2) \cdot 1 + 0 \cdot (-1) = 0$ and the second is $3 \cdot 2 + 1 \cdot 1 + 4 \cdot (-1) = 3$.

Proposition 2.3.13 (Linearity of the product). Let $A, A' \in F^{m\times n}$, $\mathbf{x}, \mathbf{y} \in F^n$, and $c \in F$, and let $\mathbf{a}_j$ be the j-th column of A.

(a) $A(c\mathbf{x} + \mathbf{y}) = cA\mathbf{x} + A\mathbf{y}$.
(b) $(cA + A')\mathbf{x} = cA\mathbf{x} + A'\mathbf{x}$.
(c) $A\mathbf{e}_j = \mathbf{a}_j$ for $j = 1, \dots, n$, and $I_n\mathbf{x} = \mathbf{x}$.

Proof. ROUTINE

Uses. Definition 2.3.8 (Matrix–vector product), Definition 1.2.7 (Matrices), Definition 2.3.5 (Identity matrix), Definition 1.2.4 (The space F^n)

Hint 1. Write each side as a combination of columns using Definition 2.3.8, and regroup with the vector space axioms of F^m.
Hint 2. For (b), what are the columns of $cA + A'$? For (c), what are the entries of $\mathbf{e}_j$?
Sketch. (a) Expand $\sum_j (cx_j + y_j)\mathbf{a}_j$ and regroup. (b) Matrices are added and scaled entrywise, so the j-th column of $cA + A'$ is $c\mathbf{a}_j + \mathbf{a}'_j$; expand $\sum_j x_j(c\mathbf{a}_j + \mathbf{a}'_j)$ and regroup. (c) $\mathbf{e}_j$ has a single nonzero entry, a 1 in position j, and I_n has columns $\mathbf{e}_1, \ldots, \mathbf{e}_n$.

(a) The vector $c\mathbf{x} + \mathbf{y}$ has entries $cx_j + y_j$ (Definition 1.2.4), so by Definition 2.3.8 and the vector space axioms of F^m,

$$A(c\mathbf{x} + \mathbf{y}) = \sum_{j=1}^{n} (cx_j + y_j)\mathbf{a}_j = c\sum_{j=1}^{n} x_j\mathbf{a}_j + \sum_{j=1}^{n} y_j\mathbf{a}_j = cA\mathbf{x} + A\mathbf{y}.$$

(b) Let $\mathbf{a}'_j$ be the j-th column of A'. Matrices are added and scaled entrywise (Definition 1.2.7), so the j-th column of $cA + A'$ is $c\mathbf{a}_j + \mathbf{a}'_j$. Hence

$$(cA + A')\mathbf{x} = \sum_{j=1}^{n} x_j(c\mathbf{a}_j + \mathbf{a}'_j) = c\sum_{j=1}^{n} x_j\mathbf{a}_j + \sum_{j=1}^{n} x_j\mathbf{a}'_j = cA\mathbf{x} + A'\mathbf{x}.$$

(c) The entries of $\mathbf{e}_j$ are 0 except for a 1 in position j, so $A\mathbf{e}_j = 0\mathbf{a}_1 + \cdots + 1\mathbf{a}_j + \cdots + 0\mathbf{a}_n = \mathbf{a}_j$. The columns of I_n are $\mathbf{e}_1, \ldots, \mathbf{e}_n$ (Definition 2.3.5), so $I_n\mathbf{x} = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n = \mathbf{x}$. □

Part (c) says that multiplying by $\mathbf{e}_j$ picks out the j-th column. It is the quickest way to get information about A out of the products $A\mathbf{x}$.

Exercise 2.3.14. ROUTINE Compute each product by columns and by rows.

(a) $\begin{pmatrix} 1 & 2 & 3 \\ 4 & 0 & 1 \end{pmatrix}\begin{pmatrix} 2 \\ 1 \\ 4 \end{pmatrix}$ over $\mathbb{F}_5$.

(b) $\begin{pmatrix} 1 & i \\ -i & 2 \end{pmatrix}\begin{pmatrix} i \\ 1 \end{pmatrix}$ over $\mathbb{C}$.

Solution on page 1125

2.3.3 Matrices as linear maps

Fixing the matrix and letting the vector vary turns the product into a function.

Definition 2.3.15 (The linear map of a matrix). For $A \in F^{m\times n}$, the map $T_A : F^n \to F^m$ is

$$T_A(\mathbf{x}) = A\mathbf{x}.$$

The map T_A is linear by Proposition 2.3.13(a). By Proposition 2.3.11, the i-th coordinate of $T_A(\mathbf{x})$ is $a_{i1}x_1 + \cdots + a_{in}x_n$, so T_A is the map given by a linear formula in Example 2.1.7, and the two definitions of T_A agree. So a matrix can be regarded either as a table of scalars or as a linear map. The next two results show that the two views carry the same information.

Proposition 2.3.16 (The matrix of T_A). For every $A \in F^{m\times n}$, $[T_A]_{\mathcal{E}\mathcal{E}} = A$.

Proof. ROUTINE

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 2.3.15 (The linear map of a matrix), Proposition 2.3.13 (Linearity of the product), Notation 2.3.2 (The standard basis $\mathcal{E}$)
Hint 1. What is the j-th column of $[T_A]_{\mathcal{E}\mathcal{E}}$?
Hint 2. Compute $T_A(\mathbf{e}_j) = A\mathbf{e}_j$ with Proposition 2.3.13(c).
Sketch. The j-th column of $[T_A]_{\mathcal{E}\mathcal{E}}$ is $[A\mathbf{e}_j]_{\mathcal{E}} = A\mathbf{e}_j = \mathbf{a}_j$.

By Definition 2.3.1 and Notation 2.3.2, the j-th column of $[T_A]_{\mathcal{E}\mathcal{E}}$ is $[T_A(\mathbf{e}_j)]_{\mathcal{E}} = T_A(\mathbf{e}_j) = A\mathbf{e}_j$, which is the j-th column of A by Proposition 2.3.13(c). So the two matrices have the same columns. □

Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A). For every $T \in \mathrm{L}(F^n, F^m)$ there is exactly one $A \in F^{m\times n}$ with $T = T_A$, namely $A = [T]_{\mathcal{E}\mathcal{E}}$, the matrix whose columns are $T(\mathbf{e}_1), \ldots, T(\mathbf{e}_n)$.

Proof. ROUTINE

Uses. Theorem 2.3.9 (The matrix of a map computes the map), Notation 2.3.2 (The standard basis $\mathcal{E}$), Proposition 2.3.13 (Linearity of the product)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For existence, apply Theorem 2.3.9 with the standard bases on both sides. What are $[\mathbf{x}]_{\mathcal{E}}$ and $[T(\mathbf{x})]_{\mathcal{E}}$?
Hint 2. For uniqueness, suppose that $T_A = T_{A'}$, and evaluate both maps at $\mathbf{e}_j$.
Sketch. With $A = [T]_{\mathcal{E}\mathcal{E}}$, Theorem 2.3.9 gives $T(\mathbf{x}) = A[\mathbf{x}]_{\mathcal{E}} = A\mathbf{x}$, since standard coordinates do nothing. If $T_A = T_{A'}$, then $A\mathbf{e}_j = A'\mathbf{e}_j$, so A and A' have the same j-th column for every j.

Existence. Let $A = [T]_{\mathcal{E}\mathcal{E}}$. Its columns are $\big[T(\mathbf{e}_j)\big]_{\mathcal{E}} = T(\mathbf{e}_j)$ (Notation 2.3.2). For $\mathbf{x} \in F^n$, Theorem 2.3.9 with the standard bases of F^n and F^m gives

$$T(\mathbf{x}) = [T(\mathbf{x})]_{\mathcal{E}} = [T]_{\mathcal{E}\mathcal{E}}[\mathbf{x}]_{\mathcal{E}} = A\mathbf{x} = T_A(\mathbf{x}).$$

So $T = T_A$.

Uniqueness. Suppose $T_A = T_{A'}$ for some $A, A' \in F^{m\times n}$. By Proposition 2.3.13(c), for each j the j-th columns of A and A' are

$$A\mathbf{e}_j = T_A(\mathbf{e}_j) = T_{A'}(\mathbf{e}_j) = A'\mathbf{e}_j.$$

So A and A' have the same columns, and $A = A'$. □

Together with Proposition 2.3.16, this says that $A \mapsto T_A$ and $T \mapsto [T]_{\mathcal{E}\mathcal{E}}$ are inverse bijections between $F^{m\times n}$ and $\mathrm{L}(F^n, F^m)$. Two consequences are worth spelling out. First, the linear maps $F^n \to F^m$ are exactly the maps given by linear formulas, which makes precise the rule of thumb at the end of Section 2.1.3. Second, finding the matrix of a linear map $F^n \to F^m$ requires no formula at all: compute $T(\mathbf{e}_1), \ldots, T(\mathbf{e}_n)$ and write them down as columns. From now on we often say "the matrix A" for the map T_A, and write $A\mathbf{x}$ rather than $T_A(\mathbf{x})$.

Exercise 2.3.18. ROUTINE For each linear map T, find the matrix A with $T = T_A$.

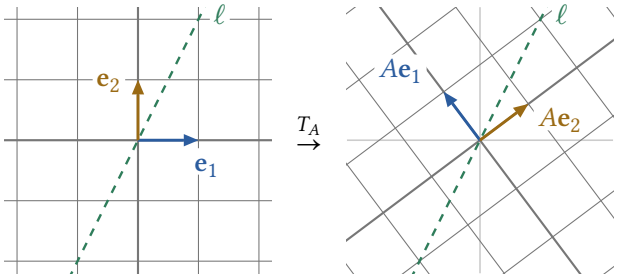
(a) $T : \mathbb{R}^3 \to \mathbb{R}^3$, $T(x, y, z) = (z, x, y)$.

(b) $T : \mathbb{R}^3 \to \mathbb{R}^3$, the projection $(x, y, z) \mapsto (x, y, 0)$ onto the xy-plane.

(c) $T : \mathbb{R}^3 \to \mathbb{R}$, $T(x, y, z) = x + y + z$.

(d) $T : \mathbb{F}_2^2 \to \mathbb{F}_2^2$, the linear map with $T(1, 0) = (1, 1)$ and $T(0, 1) = (0, 1)$. What is $T(1, 1)$?

Solution on page 1125



Example 2.3.19 (Projection and reflection). Let ℓ be the line $y = 2x$ in $\mathbb{R}^2$. It passes through $\mathbf{0}$ at the angle θ with $\cos\theta = 1/\sqrt{5}$ and $\sin\theta = 2/\sqrt{5}$, so $\cos^2\theta = 1/5$, $\sin\theta\cos\theta = 2/5$, $\sin^2\theta = 4/5$, $\cos 2\theta = -3/5$, and $\sin 2\theta = 4/5$. By the formulas of Example 2.1.11, the projection onto ℓ and the reflection across ℓ satisfy

$$\mathrm{Pr}_\ell(\mathbf{e}_1) = \left(\frac{1}{5}, \frac{2}{5}\right), \qquad \mathrm{Pr}_\ell(\mathbf{e}_2) = \left(\frac{2}{5}, \frac{4}{5}\right),$$
$$S_\ell(\mathbf{e}_1) = \left(-\frac{3}{5}, \frac{4}{5}\right), \qquad S_\ell(\mathbf{e}_2) = \left(\frac{4}{5}, \frac{3}{5}\right).$$

These are the columns of their matrices:

$$[\mathrm{Pr}_\ell]_{\mathcal{E}\mathcal{E}} = \frac{1}{5}\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}, \quad [S_\ell]_{\mathcal{E}\mathcal{E}} = \frac{1}{5}\begin{pmatrix} -3 & 4 \\ 4 & 3 \end{pmatrix}.$$

The plane transformer below shows the reflection. Its panel displays the matrix A, and its two handles are the columns $A\mathbf{e}_1$ and $A\mathbf{e}_2$, that is, the images of $\mathbf{e}_1$ and $\mathbf{e}_2$. Dragging a handle changes one column of A and leaves the other alone, and the whole grid follows, because $A(x, y) = xA\mathbf{e}_1 + yA\mathbf{e}_2$.

The reflection across the line $y = 2x$. Its matrix has columns $A\mathbf{e}_1 = (-0.6, 0.8)$ and $A\mathbf{e}_2 = (0.8, 0.6)$. Type the entries $0.2, 0.4, 0.4, 0.8$ for the projection onto the same line, which flattens the grid onto it, or $0, -1, 1, 0$ for the rotation by a right angle. In each case the columns of the matrix are where $\mathbf{e}_1$ and $\mathbf{e}_2$ go. (Interactive in the web version.)

For general V and W the same holds once the bases are fixed: a linear map is determined by its matrix, and every matrix of the right size is the matrix of some linear map.

Theorem 2.3.20 (Linear maps correspond to matrices). Let $\mathcal{B}$ be a basis of V of length n and $\mathcal{C}$ a basis of W of length m.

(a) If $S, T \in \mathrm{L}(V, W)$ and $[S]_{\mathcal{C}\mathcal{B}} = [T]_{\mathcal{C}\mathcal{B}}$, then $S = T$.

(b) For every $A \in F^{m\times n}$ there is a $T \in \mathrm{L}(V, W)$ with $[T]_{\mathcal{C}\mathcal{B}} = A$.

That is, $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is a bijection from $\mathrm{L}(V, W)$ onto $F^{m\times n}$.

Intuition. For $V = F^n$ and $W = F^m$ with their standard bases, this is Proposition 2.3.17 together with Proposition 2.3.16. In general there are two natural strategies. One is to notice that the matrix is another way of writing the list $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_n)$, which determines T by Section 2.2. The other is to move the problem into F^n and F^m with coordinates, where the special case applies, and move back. The first proof is shorter. The second exhibits every T as some T_A in disguise, which is the picture of Figure 2.3.1.

Proof (via lists). ROUTINE

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.14 (Coordinates), Definition 2.3.1 (Matrix of a linear map)

Hint 1. Two matrices are equal when their columns are equal. What does equality of the j-th columns of $[S]_{\mathcal{C}\mathcal{B}}$ and $[T]_{\mathcal{C}\mathcal{B}}$ say about $S(\mathbf{v}_j)$ and $T(\mathbf{v}_j)$?

Hint 2. For (b), the j-th column of A is the $\mathcal{C}$-coordinate vector of exactly one vector $\mathbf{y}_j \in W$. Send $\mathbf{v}_j$ there.

Sketch. (a) Equal columns mean $[S(\mathbf{v}_j)]_{\mathcal{C}} = [T(\mathbf{v}_j)]_{\mathcal{C}}$, so $S(\mathbf{v}_j) = T(\mathbf{v}_j)$ for all j, and $S = T$ by uniqueness in Theorem 2.2.1. (b) Let $\mathbf{y}_j = \sum_i a_{ij}\mathbf{w}_i$; the linear map with $T(\mathbf{v}_j) = \mathbf{y}_j$ has j-th column $[\mathbf{y}_j]_{\mathcal{C}} = \mathbf{a}_j$.

(a) Suppose $[S]_{\mathcal{C}\mathcal{B}} = [T]_{\mathcal{C}\mathcal{B}}$. Comparing j-th columns, $[S(\mathbf{v}_j)]_{\mathcal{C}} = [T(\mathbf{v}_j)]_{\mathcal{C}}$ for each j. A vector of W is determined by its coordinates: if $[\mathbf{w}]_{\mathcal{C}} = (c_1, \ldots, c_m)$, then $\mathbf{w} = c_1\mathbf{w}_1 + \cdots + c_m\mathbf{w}_m$ (Definition 1.6.14). So $S(\mathbf{v}_j) = T(\mathbf{v}_j)$ for every j, and $S = T$ by the uniqueness part of Theorem 2.2.1.

(b) Let $\mathbf{a}_1, \ldots, \mathbf{a}_n$ be the columns of A, and let $\mathbf{y}_j = a_{1j}\mathbf{w}_1 + \cdots + a_{mj}\mathbf{w}_m \in W$, so that $[\mathbf{y}_j]_{\mathcal{C}} = \mathbf{a}_j$. By Theorem 2.2.1 there is a linear map $T : V \to W$ with $T(\mathbf{v}_j) = \mathbf{y}_j$ for each j. The j-th column of $[T]_{\mathcal{C}\mathcal{B}}$ is $[\mathbf{y}_j]_{\mathcal{C}} = \mathbf{a}_j$, so $[T]_{\mathcal{C}\mathcal{B}} = A$. □

Proof (via coordinates). ROUTINE

Uses. Theorem 2.3.9 (The matrix of a map computes the map), Example 2.1.8 (Coordinates), Proposition 1.6.19 (Coordinates respect linear combinations), Definition 2.3.15 (The linear map of a matrix), Proposition 2.1.17 (Compositions of linear maps are linear)

Techniques. Assemble linear maps from linear pieces (Technique 2.1.26)
Hint 1. Let $\Phi : F^m \to W$ be the map $(y_1, \dots, y_m) \mapsto y_1\mathbf{w}_1 + \cdots + y_m\mathbf{w}_m$. How are Φ and $[\cdot]_{\mathcal{C}}$ related?
Hint 2. For (a), use Theorem 2.3.9 to compare $[S(\mathbf{v})]_{\mathcal{C}}$ and $[T(\mathbf{v})]_{\mathcal{C}}$. For (b), try $T = \Phi \circ T_A \circ [\cdot]_{\mathcal{B}}$.
Sketch. Φ and $[\cdot]_{\mathcal{C}}$ undo each other. (a) Both $[S(\mathbf{v})]_{\mathcal{C}}$ and $[T(\mathbf{v})]_{\mathcal{C}}$ equal $A[\mathbf{v}]_{\mathcal{B}}$; apply Φ. (b) $T = \Phi \circ T_A \circ [\cdot]_{\mathcal{B}}$ is a composite of linear maps, and $\left[T(\mathbf{v}_j)\right]_{\mathcal{C}} = A\mathbf{e}_j = \mathbf{a}_j$.

Let $\Phi : F^m \to W$ be the linear map $(y_1, \dots, y_m) \mapsto y_1\mathbf{w}_1 + \cdots + y_m\mathbf{w}_m$ of Example 2.1.8. It undoes $\mathcal{C}$-coordinates in both orders: $\Phi\big([\mathbf{w}]_{\mathcal{C}}\big) = \mathbf{w}$ for $\mathbf{w} \in W$, and $[\Phi(\mathbf{y})]_{\mathcal{C}} = \mathbf{y}$ for $\mathbf{y} \in F^m$.

(a) Let $A = [S]_{\mathcal{CB}} = [T]_{\mathcal{CB}}$. For $\mathbf{v} \in V$, Theorem 2.3.9 gives

$$[S(\mathbf{v})]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}},$$

and applying Φ gives $S(\mathbf{v}) = T(\mathbf{v})$.

(b) Define $T = \Phi \circ T_A \circ [\cdot]_{\mathcal{B}}$, that is, $T(\mathbf{v}) = \Phi(A[\mathbf{v}]_{\mathcal{B}})$. It is a composite of linear maps (Proposition 1.6.19, Definition 2.3.15, Example 2.1.8), so it is linear by Proposition 2.1.17. Since $\left[\mathbf{v}_j\right]_{\mathcal{B}} = \mathbf{e}_j$,

$$\left[T(\mathbf{v}_j)\right]_{\mathcal{C}} = \left[\Phi(A\mathbf{e}_j)\right]_{\mathcal{C}} = A\mathbf{e}_j = \mathbf{a}_j,$$

so the j-th column of $[T]_{\mathcal{CB}}$ is the j-th column of A. □

The second proof shows what an arbitrary linear map looks like through coordinates. By (a), every $T \in \mathrm{L}(V, W)$ is the map built in (b) from its own matrix: $T = \Phi \circ T_A \circ [\cdot]_{\mathcal{B}}$ with $A = [T]_{\mathcal{CB}}$. Read from right to left, this says: take coordinates, multiply by the matrix, and turn the resulting coordinates back into a vector. In Section 2.4 we will see that the bijection $T \mapsto [T]_{\mathcal{CB}}$ also respects addition and scalar multiplication and turns composition into matrix multiplication. So $\mathrm{L}(V, W)$ and $F^{m\times n}$ are isomorphic vector spaces (Section 4.5).

Exercise 2.3.21. ROUTINE Let $\mathcal{B} = 1, x$ and $\mathcal{C} = 1, 1 + x$, both bases of $F[x]_{\leq 1}$, and let $T \in \mathrm{L}\big(F[x]_{\leq 1}\big)$ be the operator with

$$[T]_{\mathcal{CB}} = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}.$$

Find $T(a + bx)$, and find $[T]_{\mathcal{BB}}$.

Solution on page 1126

2.3.4 Different bases, different matrices

The matrix $[T]_{\mathcal{CB}}$ depends on three things: the map T, the basis $\mathcal{B}$, and the basis $\mathcal{C}$. Changing either basis, even by reordering it, can change the matrix, and one map can have matrices that look nothing alike.

Example 2.3.22 (Differentiation in four bases). Let $V = F[x]_{\leq 2}$, and let $D \in \mathrm{L}(V)$ be differentiation, as in Example 2.3.4.

(a) For $\mathcal{B} = 1, x, x^2$, we found

$$[D]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix}.$$

(b) Reverse the order: $\mathcal{R} = x^2, x, 1$. Now $D(x^2) = 2x$, $D(x) = 1$, and $D(1) = \mathbf{0}$ have the $\mathcal{R}$-coordinates $(0, 2, 0)$, $(0, 0, 1)$, and $(0, 0, 0)$, so

$$[D]_{\mathcal{R}\mathcal{R}} = \begin{pmatrix} 0 & 0 & 0 \\ 2 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}.$$

The vectors are the same as in (a), but a basis is a list, and its order matters.

(c) Suppose that $2 \neq 0$ in F, and let $\mathring{\mathcal{B}} = 1, x, \frac{1}{2}x^2$. This is a basis, since $a + bx + cx^2 = a \cdot 1 + bx + 2c \cdot \frac{1}{2}x^2$, with only these coefficients possible. Now $D\left(\frac{1}{2}x^2\right) = x$, so

$$[D]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$

Each basis vector goes to the one before it, and the first goes to $\mathbf{0}$.

(d) Keep the assumption $2 \neq 0$, and use different bases on the two sides: $\mathcal{B}' = x, \frac{1}{2}x^2, 1$ in the domain and $\mathcal{B} = 1, x, x^2$ in the target. Then $D(x) = 1$, $D\left(\frac{1}{2}x^2\right) = x$, and $D(1) = \mathbf{0}$ have the $\mathcal{B}$-coordinates $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathbf{0}$, so

$$[D]_{\mathcal{B}\mathcal{B}'} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Intuition (One basis or two). The matrix in (d) is the matrix of the projection $(x_1, x_2, x_3) \mapsto (x_1, x_2, 0)$ of F^3, a map P with $P \circ P = P$. But D is nothing like that: $D(D(D(p))) = \mathbf{0}$ for every $p \in V$, since each application of D lowers the degree. Using different bases on the two sides gives so much freedom that the matrix forgets almost everything about D. What survives is how many independent values D takes, its rank (Section 4.2, and Theorem 3.5.27 for matrices).

For an operator $T \in \mathrm{L}(V)$, comparing $T(\mathbf{v})$ with $\mathbf{v}$ only makes sense in a single coordinate system, so we use the same basis on both sides, and then more survives. Let N be any of the three matrices in (a)–(c), with its basis $\mathcal{A}$. Applying Theorem 2.3.9 three times,

$$N\big(N\big(N[p]_{\mathcal{A}}\big)\big) = N\big(N[D(p)]_{\mathcal{A}}\big) = N[D(D(p))]_{\mathcal{A}} = [D(D(D(p)))]_{\mathcal{A}} = \mathbf{0}$$

for every p, and since every $\mathbf{x} \in F^3$ is $[p]_{\mathcal{A}}$ for some p, multiplying by N three times kills every vector. You can check this directly for each N. The matrix in (d) does not have this property: it fixes $\mathbf{e}_1$. Properties of an operator that are visible in its matrix in every basis are studied in Section 4.5, under the name of similarity.

Example 2.3.23 (Maps of the plane in adapted bases). Let ℓ be the line $y = 2x$, as in Example 2.3.19, and let $\mathcal{U} = \mathbf{u}_1, \mathbf{u}_2$ with $\mathbf{u}_1 = (1, 2)$ on ℓ and $\mathbf{u}_2 = (-2, 1)$ perpendicular to ℓ (since $1 \cdot (-2) + 2 \cdot 1 = 0$). This is a basis of $\mathbb{R}^2$: the equations $a - 2b = x$ and $2a + b = y$ have exactly one solution, $a = (x + 2y)/5$ and $b = (y - 2x)/5$.

The projection $P = \mathrm{Pr}_\ell$ fixes $\mathbf{u}_1$ and sends $\mathbf{u}_2$ to $\mathbf{0}$, and the reflection $S = S_\ell$ fixes $\mathbf{u}_1$ and sends $\mathbf{u}_2$ to $-\mathbf{u}_2$. (With the matrices of Example 2.3.19: $\frac{1}{5}(1 + 4, 2 + 8) = (1, 2)$ and $\frac{1}{5}(-2 + 2, -4 + 4) = (0, 0)$.) So

$$[P]_{\mathcal{UU}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad [S]_{\mathcal{UU}} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

compared with $\frac{1}{5}\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$ and $\frac{1}{5}\begin{pmatrix} -3 & 4 \\ 4 & 3 \end{pmatrix}$ in the standard basis. In the adapted basis, the matrices show what the maps do.

The rotation $R = R_{\pi/2}$ has $[R]_{\mathcal{EE}} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. In the reversed standard basis $\mathbf{e}_2, \mathbf{e}_1$, the vector $R(\mathbf{e}_2) = -\mathbf{e}_1$ has coordinates $(0, -1)$ and $R(\mathbf{e}_1) = \mathbf{e}_2$ has coordinates $(1, 0)$, so the matrix becomes $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. That is the standard matrix of the clockwise rotation $R_{-\pi/2}$: reordering the basis reverses the orientation of the coordinate system. In the basis $\mathcal{U}$, on the other hand, $R(\mathbf{u}_1) = (-2, 1) = \mathbf{u}_2$ and $R(\mathbf{u}_2) = (-1, -2) = -\mathbf{u}_1$, so $[R]_{\mathcal{UU}} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, the same as in the standard basis.

Two lessons. First, a matrix alone does not determine a map; only the matrix together with the bases does (Theorem 2.3.20). For instance $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ is $[S_\ell]_{\mathcal{UU}}$, and it is also the standard matrix of the reflection across the x-axis. Second, choosing a basis adapted to the map is how one understands it. If some basis consists of vectors that T sends to multiples of themselves, the matrix of T in that basis is diagonal. This is how Example 2.2.3 built P and S in the first place (Technique 2.2.4), and finding such bases is the subject of Section 7.4.

2.3.5 The identity map in two bases

By Example 2.3.6, $[\mathrm{id}_V]_{\mathcal{BB}} = I_n$ for every basis $\mathcal{B}$. With two different bases, the matrix of the identity map is a different matrix, and it can look like almost anything. What it does is given by Theorem 2.3.9: for any two bases $\mathcal{B}$ and $\mathcal{C}$ of V,

$$[\mathrm{id}_V]_{\mathcal{CB}}[\mathbf{v}]_{\mathcal{B}} = [\mathrm{id}_V(\mathbf{v})]_{\mathcal{C}} = [\mathbf{v}]_{\mathcal{C}} \quad \text{for every } \mathbf{v} \in V.$$

That is, the matrix of the identity converts $\mathcal{B}$-coordinates into $\mathcal{C}$-coordinates.

Example 2.3.24 (The identity in two bases). Let F be a field with $1 + 1 \neq 0$, and let $\mathcal{B} = (1, 1), (1, -1)$, a basis of F^2 (Example 2.2.3). The columns of $[\mathrm{id}]_{\mathcal{EB}}$ are the standard coordinates of $(1, 1)$ and $(1, -1)$, which are these vectors themselves. The columns of $[\mathrm{id}]_{\mathcal{BE}}$ are the $\mathcal{B}$-coordinates of $\mathbf{e}_1 = \frac{1}{2}(1, 1) + \frac{1}{2}(1, -1)$ and $\mathbf{e}_2 = \frac{1}{2}(1, 1) - \frac{1}{2}(1, -1)$. So

$$[\mathrm{id}]_{\mathcal{EB}} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}, \quad [\mathrm{id}]_{\mathcal{BE}} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

For $\mathbf{v} = (3, 1) = 2(1, 1) + (1, -1)$ we have $[\mathbf{v}]_{\mathcal{B}} = (2, 1)$, and indeed the two matrices convert between the two coordinate vectors of $\mathbf{v}$:

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 3 \\ 1 \end{pmatrix} = [\mathbf{v}]_{\mathcal{E}}, \quad \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} 3 \\ 1 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix} = [\mathbf{v}]_{\mathcal{B}}.$$

The example generalizes in one direction. For any basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of F^n, $[\mathrm{id}]_{\mathcal{EB}}$ is the matrix whose columns are $\mathbf{b}_1, \ldots, \mathbf{b}_n$, because $[\mathbf{b}_j]_{\mathcal{E}} = \mathbf{b}_j$. The other direction, $[\mathrm{id}]_{\mathcal{BE}}$, requires solving for coordinates.

Remark 2.3.25 (A warning about the identity). The phrase "the matrix of the identity map" means nothing until both bases are specified: $[\mathrm{id}_V]_{\mathcal{CB}} = I_n$ exactly when $\mathcal{B} = \mathcal{C}$ (Exercise 2.3.26). In general, $[\mathrm{id}_V]_{\mathcal{CB}}$ is the matrix that changes $\mathcal{B}$-coordinates into $\mathcal{C}$-coordinates. These matrices are the subject of Section 4.5 (Definition 4.5.10). There, once matrix multiplication is available (Section 2.4), they compute $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}$ from $[T]_{\mathcal{CB}}$ for any other bases $\mathring{\mathcal{B}}$ and $\mathring{\mathcal{C}}$, and explain the different matrices of D and of the plane maps found above.

Exercise 2.3.26. ROUTINE Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ and $\mathcal{C} = \mathbf{w}_1, \ldots, \mathbf{w}_n$ be bases of V of the same length. Show that $[\mathrm{id}_V]_{\mathcal{C}\mathcal{B}} = I_n$ if and only if $\mathcal{B} = \mathcal{C}$, that is, $\mathbf{v}_j = \mathbf{w}_j$ for every j.

Solution on page 1126

2.3.6 Translating between maps and matrices

The results of this section give a dictionary between linear maps of spaces with chosen bases and matrices.

- A vector $\mathbf{v} \in V$ corresponds to its coordinate vector $[\mathbf{v}]_{\mathcal{B}} \in F^n$, and a map $T \in \mathrm{L}(V, W)$ to its matrix $[T]_{\mathcal{C}\mathcal{B}} \in F^{m \times n}$.
- The value $T(\mathbf{v})$ corresponds to the product $[T]_{\mathcal{C}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}}$ (Theorem 2.3.9), and the value $T(\mathbf{v}_j)$ on a basis vector to the j-th column.
- Two maps are equal if and only if their matrices are (Theorem 2.3.20).
- For $V = F^n$ and $W = F^m$ with the standard bases, T corresponds to the unique A with $T = T_A$ (Proposition 2.3.17), and id corresponds to I_n.

Technique 2.3.27 (Translate between maps and matrices). A linear map between spaces with chosen bases and its matrix carry the same information, so a question about one can be translated into a question about the other, using the dictionary above.

In one direction, to compute with a linear map, replace vectors by their coordinate vectors and the map by its matrix. Evaluating T becomes a matrix–vector product, and an equation $T(\mathbf{v}) = \mathbf{w}$ becomes the linear system $[T]_{\mathcal{C}\mathcal{B}}\mathbf{x} = [\mathbf{w}]_{\mathcal{C}}$ in the unknown coordinates $\mathbf{x}$ of $\mathbf{v}$ (Section 3.1). In the other direction, to prove a statement about a matrix A, read it as a statement about the linear map T_A, prove it with the theory of linear maps, which needs no indices, and translate back with the uniqueness in Proposition 2.3.17.

Reach for the first direction when you need numbers, and for the second when a matrix identity would otherwise need a computation with indices. A rule of thumb: compute with matrices, prove with maps. Before translating, fix the bases and keep track of which basis each coordinate vector refers to; most errors come from mixing them up. The canonical example is Example 2.3.28. Later instances: matrix multiplication is defined by translating composition (Section 2.4), the rank of a matrix is the rank of its map (Section 4.2), and the determinant and the eigenvalues of an operator are read off from its matrix in any basis (Section 5.4, Section 7.3).

Used in. Exercise 2.3.32, Exercise 2.3.35, Exercise 2.3.42, Theorem 2.4.2, Proposition 2.4.14, Proposition 2.5.20, Proposition 2.6.20, Corollary 2.7.16, Exercise 2.8.8, Exercise 2.8.13, Problem 2.2, Problem 2.13, Problem 3.12, Theorem 4.1.1, Proposition 4.1.31, Theorem 4.2.11, Proposition 4.2.15, Proposition 4.5.12, Proposition 4.5.16, Theorem 4.5.17, Theorem 4.5.25, Proposition 4.5.27, Proposition 5.4.20, Theorem 6.6.15, Proposition 6.6.18, Corollary 7.3.13, Theorem 7.4.2, Proposition 7.5.25, Proposition 8.1.7, Corollary 8.1.11, Theorem 8.4.4, Proposition B.1.18, Exercise B.1.41, Exercise B.1.42, Exercise 2.5.22, Exercise 6.6.46.

Example 2.3.28 (Translating in both directions).

(a) *From maps to matrices.* We find all $p \in \mathbb{Q}[x]_{\le 2}$ with $p(x+1) - p(x) = x$. The map $\Delta : \mathbb{Q}[x]_{\le 2} \to \mathbb{Q}[x]_{\le 2}$, $\Delta(p) = p(x+1) - p(x)$, is linear, being the difference of the substitution map of Exercise 2.1.32 and the identity (Technique 2.1.26). With $\mathcal{B} = 1, x, x^2$,

$$\Delta(1) = \mathbf{0}, \quad \Delta(x) = (x+1) - x = 1, \quad \Delta\big(x^2\big) = (x+1)^2 - x^2 = 1 + 2x,$$

so

$$[\Delta]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix}.$$

By Theorem 2.3.9, $p = a + bx + cx^2$ satisfies $\Delta(p) = x$ if and only if $[\Delta]_{\mathcal{B}\mathcal{B}}(a, b, c) = [x]_{\mathcal{B}} = (0, 1, 0)$. By Proposition 2.3.11 this is the system $b + c = 0$, $2c = 1$, $0 = 0$, whose solutions are $c = 1/2$, $b = -1/2$, and a arbitrary. So the solutions are

$$p = a + \frac{x^2 - x}{2} \quad (a \in \mathbb{Q}).$$

This gives a formula for sums. For $q(t) = t(t-1)/2$ and every number t,

$$q(t+1) - q(t) = \frac{(t+1)t - t(t-1)}{2} = t,$$

so the sum $0 + 1 + \cdots + (n-1)$ telescopes:

$$\sum_{k=0}^{n-1} k = \sum_{k=0}^{n-1} (q(k+1) - q(k)) = q(n) - q(0) = \frac{n(n-1)}{2}.$$

(b) *From matrices to maps.* Let $A \in F^{n \times n}$, and suppose that for every $\mathbf{x} \in F^n$ the vector $A\mathbf{x}$ is a scalar multiple of $\mathbf{x}$. We show that $A = \lambda I_n$ for some $\lambda \in F$. The hypothesis says that $T_A(\mathbf{x}) \in \operatorname{span}(\mathbf{x})$ for every $\mathbf{x}$. By Exercise 2.1.48, $T_A = \lambda\,\mathrm{id}$ for some $\lambda \in F$. Now $(\lambda I_n)\mathbf{x} = \lambda(I_n\mathbf{x}) = \lambda\mathbf{x}$ by Proposition 2.3.13, so $\lambda\,\mathrm{id} = T_{\lambda I_n}$. Hence $T_A = T_{\lambda I_n}$, and $A = \lambda I_n$ by the uniqueness in Proposition 2.3.17. A direct proof with entries is possible, but it would repeat the argument of Exercise 2.1.48 in coordinates.

Exercises

Exercise 2.3.29. ROUTINE Let $T : \mathbb{R}^2 \to \mathbb{R}^3$, $T(x, y) = (x + y, x - y, 2x)$, and consider the bases $\mathcal{B} = (1, 1), (1, -1)$ of $\mathbb{R}^2$ and $\mathcal{C} = (1, 0, 0), (1, 1, 0), (1, 1, 1)$ of $\mathbb{R}^3$.

(a) Find $[T]_{\mathcal{C}\mathcal{B}}$.

(b) Check Theorem 2.3.9 for $\mathbf{v} = (3, 1)$ by computing both sides.

Solution on page 1126

Exercise 2.3.30. ROUTINE Find the error in the following computation, and correct it.

Let $\mathcal{B} = (1, 1), (1, -1)$, a basis of $\mathbb{R}^2$, and let $\mathbf{v} = (3, 1)$. The matrix $[\mathrm{id}]_{\mathcal{E}\mathcal{B}} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ relates the two bases, so the $\mathcal{B}$-coordinates of $\mathbf{v}$ are

$$[\mathbf{v}]_{\mathcal{B}} = [\mathrm{id}]_{\mathcal{E}\mathcal{B}}\mathbf{v} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} 3 \\ 1 \end{pmatrix} = \begin{pmatrix} 4 \\ 2 \end{pmatrix}.$$

Solution on page 1127

Exercise 2.3.31. ROUTINE Find the error in the following argument.

Claim. Let F be any field. If $A \in F^{2\times 2}$ satisfies $A(1,1) = (1,1)$ and $A(1,-1) = (1,-1)$, then $A = I_2$.

Proof. The maps T_A and $\mathrm{id} = T_{I_2}$ agree on the vectors $(1,1)$ and $(1,-1)$, which form a basis of F^2. Two linear maps that agree on a basis are equal, so $T_A = T_{I_2}$, and $A = I_2$ by Proposition 2.3.17.

Solution on page 1127

Exercise 2.3.32. STANDARD Let $T : F[x]_{\leq 3} \to F[x]_{\leq 3}$, $T(p) = p(x+1)$, which is linear by Exercise 2.1.32, and let $\mathcal{B} = 1, x, x^2, x^3$.

(a) Find $[T]_{\mathcal{B}\mathcal{B}}$ for $F = \mathbb{Q}$ and for $F = \mathbb{F}_2$.

(b) Over $\mathbb{F}_2$, use the matrix to find all $p \in \mathbb{F}_2[x]_{\leq 3}$ with $p(x+1) = p(x)$.

(c) Do the same over $\mathbb{Q}$.

Solution on page 1127

Exercise 2.3.33. STANDARD Let $T : F[x]_{\leq 2} \to F^3$, $T(p) = (p(0), p(1), p(2))$, where $2 = 1 + 1$.

(a) Find $[T]_{\mathcal{E}\mathcal{B}}$ for $\mathcal{B} = 1, x, x^2$.

(b) Suppose $2 \neq 0$ in F. Find a basis $\mathring{\mathcal{B}} = p_0, p_1, p_2$ of $F[x]_{\leq 2}$ with $[T]_{\mathcal{E}\mathring{\mathcal{B}}} = I_3$, and prove that it is a basis.

(c) With $\mathring{\mathcal{B}}$ as in (b), show that $[q]_{\mathring{\mathcal{B}}} = (q(0), q(1), q(2))$ for every $q \in F[x]_{\leq 2}$.

(d) Show that over $\mathbb{F}_2$ no basis $\mathring{\mathcal{B}}$ with $[T]_{\mathcal{E}\mathring{\mathcal{B}}} = I_3$ exists.

Solution on page 1128

Exercise 2.3.34. STANDARD Let $T : \mathbb{R}^2 \to \mathbb{R}^2$, $T(x,y) = (x+y, 2x+2y)$.

(a) Find bases $\mathcal{B}$ and $\mathcal{C}$ of $\mathbb{R}^2$ with $[T]_{\mathcal{C}\mathcal{B}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

(b) Show that there is no basis $\mathcal{B}$ of $\mathbb{R}^2$ with $[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

(c) Find a basis $\mathcal{B}$ of $\mathbb{R}^2$ for which $[T]_{\mathcal{B}\mathcal{B}}$ is diagonal.

Solution on page 1129

Exercise 2.3.35. STANDARD Regard $\mathbb{C}$ as a vector space over $\mathbb{R}$ with the basis $\mathcal{B} = 1, i$.

(a) For $z = a + bi$ with $a, b \in \mathbb{R}$, let $M_z : \mathbb{C} \to \mathbb{C}$, $M_z(w) = zw$. Find $[M_z]_{\mathcal{B}\mathcal{B}}$.

(b) Find the matrix of complex conjugation $w \mapsto \overline{w}$ with respect to $\mathcal{B}$.

(c) Show that a matrix $A \in \mathbb{R}^{2\times 2}$ is $[T]_{\mathcal{B}\mathcal{B}}$ for some $\mathbb{C}$-linear $T : \mathbb{C} \to \mathbb{C}$ if and only if $A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ for some $a, b \in \mathbb{R}$.

Solution on page 1129

Exercise 2.3.36. STANDARD Let V and W be vector spaces over $\mathbb{R}$ with bases. Prove or disprove each statement.

(a) If $S, T \in \mathrm{L}(V,W)$ and $[S]_{\mathcal{C}\mathcal{B}} = [T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}$ for some bases $\mathcal{B}, \mathring{\mathcal{B}}$ of V and $\mathcal{C}, \mathring{\mathcal{C}}$ of W, then $S = T$.

(b) If $T \in \mathrm{L}(V)$ and $[T]_{\mathcal{B}\mathcal{B}}$ is the zero matrix for some basis $\mathcal{B}$, then $T = 0$.

(c) If $T \in \mathrm{L}(V)$ and $[T]_{\mathcal{C}\mathcal{B}} = I_n$ for some bases $\mathcal{B}, \mathcal{C}$ of V, then $T = \mathrm{id}_V$.

(d) If $T \in \mathrm{L}(V)$ and $[T]_{\mathcal{B}\mathcal{B}}$ is diagonal for some basis $\mathcal{B}$, then $[T]_{\mathcal{C}\mathcal{C}}$ is diagonal for every basis $\mathcal{C}$ of V.

(e) There are bases $\mathcal{B}, \mathcal{C}$ of $\mathbb{R}^2$ with $[\mathrm{id}]_{\mathcal{C}\mathcal{B}} = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$.

Solution on page 1130

Exercise 2.3.37. STANDARD Let $T \in \mathrm{L}(V, W)$ and $A = [T]_{\mathcal{C}\mathcal{B}}$. Describe how A changes when the bases are modified as follows, and prove your answer. (Each modified list is again a basis; check this too.)

(a) Two vectors $\mathbf{v}_j$ and $\mathbf{v}_k$ of $\mathcal{B}$ are swapped.

(b) $\mathbf{v}_j$ is replaced by $c\mathbf{v}_j$, where $c \neq 0$.

(c) Two vectors $\mathbf{w}_i$ and $\mathbf{w}_k$ of $\mathcal{C}$ are swapped.

(d) $\mathbf{w}_i$ is replaced by $c\mathbf{w}_i$, where $c \neq 0$.

(e) $\mathbf{w}_k$ is replaced by $\mathbf{w}_k + c\mathbf{w}_i$, where $i \neq k$ and $c \in F$.

Solution on page 1130

Exercise 2.3.38. STANDARD A matrix $A \in F^{n\times n}$ is **upper triangular** if $a_{ij} = 0$ whenever $i > j$. Let $T \in \mathrm{L}(V)$, and for $k = 1, \ldots, n$ let $V_k = \mathrm{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$. Show that the following are equivalent.

(i) $[T]_{\mathcal{B}\mathcal{B}}$ is upper triangular.

(ii) $T(\mathbf{v}_k) \in V_k$ for $k = 1, \ldots, n$.

(iii) $T(V_k) \subseteq V_k$ for $k = 1, \ldots, n$.

Solution on page 1131

Exercise 2.3.39. HARD Let $N \in F^{4\times 4}$ be the matrix with 1 in positions $(1,2)$, $(2,3)$, $(3,4)$ and 0 elsewhere, and let D be differentiation on $F[x]_{\leq 3}$. For each of $F = \mathbb{Q}$, $\mathbb{F}_2$, $\mathbb{F}_3$, $\mathbb{F}_5$, decide whether there is a basis $\mathcal{B}$ of $F[x]_{\leq 3}$ with $[D]_{\mathcal{B}\mathcal{B}} = N$.

Solution on page 1131

Exercise 2.3.40. HARD Let $T \in \mathrm{L}(V)$, where V has a basis of length $n \geq 1$. Show that $[T]_{\mathcal{B}\mathcal{B}}$ is the same matrix for every basis $\mathcal{B}$ of V of length n if and only if $T = \lambda \mathrm{id}_V$ for some $\lambda \in F$. (In Section 4.1 we will see that every basis of V has length n.)

Solution on page 1132

Exercise 2.3.41. HARD *Lights out on a line.* A row of $n \geq 2$ lamps is controlled by n buttons. Pressing button i switches lamp i and its neighbours (lamps $i-1$ and $i+1$, when they exist) from on to off or from off to on. Record a configuration of the lamps as $\mathbf{s} \in \mathbb{F}_2^n$, with $s_i = 1$ when lamp i is on.

(a) Let $A \in \mathbb{F}_2^{n\times n}$ have $a_{ij} = 1$ when $|i - j| \leq 1$ and $a_{ij} = 0$ otherwise. Show that pressing buttons in any order changes the configuration $\mathbf{s}$ to $\mathbf{s} + A\mathbf{x}$, where $x_j \in \mathbb{F}_2$ is the number of times button j was pressed, modulo 2.

(b) Show that every configuration can be switched off completely if and only if n is not of the form $3k + 2$.

Solution on page 1133

Exercise 2.3.42. STANDARD Using the matrix of $\Delta(p) = p(x+1) - p(x)$ on $\mathbb{Q}[x]_{\leq 3}$ with respect to $1, x, x^2, x^3$, find all $p \in \mathbb{Q}[x]_{\leq 3}$ with $p(x+1) - p(x) = x^2$. Deduce a formula for $0^2 + 1^2 + \cdots + (n-1)^2$, as in Example 2.3.28.

Solution on page 1134

Exercise 2.3.43. STANDARD For $\mathbf{y} \in F^k$ let $s(\mathbf{y}) = y_1 + \cdots + y_k$ be the sum of its entries, and let $A \in F^{m\times n}$.

(a) Show that $s(A\mathbf{x}) = s(\mathbf{x})$ for every $\mathbf{x} \in F^n$ if and only if the entries of each column of A add up to 1.

(b) Show that $A(1, \ldots, 1) = c(1, \ldots, 1)$ if and only if the entries of each row of A add up to c.

(c) Let $F = \mathbb{R}$, and suppose that all entries of A are nonnegative and each column adds up to 1. Show that if the entries of $\mathbf{x}$ are nonnegative and add up to 1, then the entries of $A\mathbf{x}$ are also nonnegative and add up to 1.

Solution on page 1134

Exercise 2.3.44. STANDARD BEYOND 21-242 The matrix of an operator on $F[x]$, which has no finite basis, can still be defined. For $T \in \mathrm{L}(F[x])$, let $a_{ij} \in F$ $(i, j \geq 0)$ be the coefficients with $T(x^j) = \sum_i a_{ij} x^i$. Call the array $(a_{ij})_{i,j\geq 0}$ the matrix of T.

(a) Show that each column of the matrix has only finitely many nonzero entries, and that every array $(a_{ij})_{i,j\geq 0}$ with this property is the matrix of exactly one $T \in \mathrm{L}(F[x])$.

(b) Find the matrices of differentiation D and of multiplication by x.

(c) Show that if p has coefficients $(c_0, c_1, \ldots)$, then $T(p)$ has coefficients $\left(\sum_j a_{ij} c_j\right)_{i\geq 0}$, where each sum has only finitely many nonzero terms.

(d) Give an operator whose matrix has a row with infinitely many nonzero entries.

Solution on page 1135

Exercise 2.3.45. ROUTINE Let $T : \mathbb{C}^2 \to \mathbb{C}^2$, $T(z, w) = (z + iw, iz - w)$.

(a) Find $[T]_{\mathcal{E}\mathcal{E}}$.

(b) Show that $\mathcal{B} = (1, i), (1, -i)$ is a basis of $\mathbb{C}^2$, and find $[T]_{\mathcal{B}\mathcal{B}}$. What does it tell you about $T \circ T$?

Solution on page 1135

Exercise 2.3.46. STANDARD For $\varphi \in \mathbb{R}$, let $\mathbf{u}_1 = (\cos\varphi, \sin\varphi)$ and $\mathbf{u}_2 = (-\sin\varphi, \cos\varphi)$, and let $\mathcal{U} = \mathbf{u}_1, \mathbf{u}_2$. Let R_θ be the rotation by θ and S_α the reflection across the line through $\mathbf{0}$ at angle α (Example 2.1.11).

(a) Show that $a\mathbf{u}_1 + b\mathbf{u}_2 = R_\varphi(a, b)$, that $\mathcal{U}$ is a basis of $\mathbb{R}^2$, and that the vector $(r\cos\beta, r\sin\beta)$ has $\mathcal{U}$-coordinates $(r\cos(\beta - \varphi), r\sin(\beta - \varphi))$.

(b) Show that $[R_\theta]_{\mathcal{U}\mathcal{U}} = [R_\theta]_{\mathcal{E}\mathcal{E}}$.

(c) Show that $[S_\alpha]_{\mathcal{U}\mathcal{U}} = \left[S_{\alpha-\varphi}\right]_{\mathcal{E}\mathcal{E}}$, and interpret this.

Solution on page 1136

Exercise 2.3.47. HARD Let $A \in \mathbb{C}^{n\times n}$ satisfy

$$|a_{ii}| > \sum_{j\neq i} |a_{ij}| \quad \text{for every } i = 1, \ldots, n.$$

Show that if $A\mathbf{x} = \mathbf{0}$, then $\mathbf{x} = \mathbf{0}$.

Solution on page 1136

Exercise 2.3.48. CHALLENGE Let $n \geq 1$ and let $T : F[x]_{\leq n} \to F[x]_{\leq n}$, $T(f) = f(x + 1)$. Let $J \in F^{(n+1)\times(n+1)}$ have 1 in each diagonal position (k, k) and in each position $(k, k + 1)$ just above the diagonal, and 0 elsewhere. (Use the usual algebra of polynomials freely, including that substituting $x + 1$ respects products and that substituting twice in a row gives $f(x + 2)$; these facts are proved in Section 7.1.)

(a) Over $\mathbb{Q}$, let $b_0 = 1$ and $b_k = x(x-1)\cdots(x-k+1)/k!$ for $k \geq 1$. Show that $\mathcal{B} = b_0, b_1, \ldots, b_n$ is a basis of $\mathbb{Q}[x]_{\leq n}$ with $[T]_{\mathcal{B}\mathcal{B}} = J$.

(b) Let p be a prime. Show that over $\mathbb{F}_p$ there is a basis $\mathcal{B}$ of $\mathbb{F}_p[x]_{\leq n}$ with $[T]_{\mathcal{B}\mathcal{B}} = J$ if and only if $n < p$.

Solution on page 1137

2.4 Matrix multiplication

Once bases are fixed, a linear map and its matrix carry the same information (Theorem 2.3.20). Linear maps can be composed (Proposition 2.1.17), so matrices should be able to multiply, and the product of two matrices should be the matrix of the composite. This section takes that as the definition of the product. The formula for the entries, the algebraic laws, and the failures of commutativity and cancellation all follow from it, and each of them is the shadow of a fact about composition.

Throughout, U, V, and W are vector spaces over F with bases $\mathcal{A} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ of U, $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_m$ of V, and $\mathcal{C} = \mathbf{w}_1, \ldots, \mathbf{w}_\ell$ of W, where $n, m, \ell \geq 1$. As in Notation 2.1.18, we write TS for the composite $T \circ S$.

2.4.1 The product of two matrices

Intuition (Computing $[TS]$ from $[T]$ and $[S]$). Let $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$, so that $TS \in \mathrm{L}(U,W)$. The j-th column of $[TS]_{\mathcal{C}\mathcal{A}}$ is the coordinate vector of $(TS)(\mathbf{u}_j) = T\big(S(\mathbf{u}_j)\big)$. By Theorem 2.3.9, applied to T at the vector $S(\mathbf{u}_j)$,

$$\big[T(S(\mathbf{u}_j))\big]_{\mathcal{C}} = [T]_{\mathcal{C}\mathcal{B}}\big[S(\mathbf{u}_j)\big]_{\mathcal{B}},$$

and $\big[S(\mathbf{u}_j)\big]_{\mathcal{B}}$ is the j-th column of $[S]_{\mathcal{B}\mathcal{A}}$. So the j-th column of $[TS]_{\mathcal{C}\mathcal{A}}$ is $[T]_{\mathcal{C}\mathcal{B}}$ times the j-th column of $[S]_{\mathcal{B}\mathcal{A}}$. As with the matrix–vector product in Section 2.3.2, the answer no longer mentions S, T, the spaces, or the bases. It is computed from the two matrices alone, so it is an operation on matrices, and we give it a name.

Definition 2.4.1 (Matrix product). Let $A \in F^{\ell\times m}$ and $B \in F^{m\times n}$, and let $\mathbf{b}_1, \ldots, \mathbf{b}_n \in F^m$ be the columns of B. The **product** AB is the $\ell \times n$ matrix whose j-th column is $A\mathbf{b}_j$:

$$AB = \begin{pmatrix} A\mathbf{b}_1 & A\mathbf{b}_2 & \cdots & A\mathbf{b}_n \end{pmatrix}.$$

It is defined only when the number of columns of A equals the number of rows of B. By Proposition 2.3.11, applied to the j-th column, the entry of AB in row i and column j is

$$a_{i1}b_{1j} + a_{i2}b_{2j} + \cdots + a_{im}b_{mj} = \sum_{k=1}^{m} a_{ik}b_{kj}.$$

The sizes behave like dominoes: an $\ell \times m$ matrix times an $m \times n$ matrix is an $\ell \times n$ matrix, and the two inner sizes must match. A column $\mathbf{x} \in F^m$ is an $m \times 1$ matrix, and the product of A with it in the sense of Definition 2.4.1 has the single column $A\mathbf{x}$. So the matrix–vector product of Definition 2.3.8 is the special case $n = 1$, and the notation $A\mathbf{x}$ is unambiguous.

Theorem 2.4.2 (The matrix of a composite).

(a) For $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$,

$$[TS]_{\mathcal{C}\mathcal{A}} = [T]_{\mathcal{C}\mathcal{B}}[S]_{\mathcal{B}\mathcal{A}}.$$

(b) For $A \in F^{\ell\times m}$ and $B \in F^{m\times n}$, $T_{AB} = T_A T_B$. That is, $(AB)\mathbf{x} = A(B\mathbf{x})$ for every $\mathbf{x} \in F^n$.

Proof. ROUTINE

> *Uses.* Definition 2.3.1 (Matrix of a linear map), Theorem 2.3.9 (The matrix of a map computes the map), Definition 2.4.1 (Matrix product), Proposition 2.3.16 (The matrix of T_A), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Proposition 2.1.17 (Compositions of linear maps are linear)
> *Techniques.* Translate between maps and matrices (Technique 2.3.27)
> *Hint 1.* Two matrices of the same size are equal when their columns are. What is the j-th column of each side of (a)?
> *Hint 2.* The j-th column of $[TS]_{\mathcal{C}\mathcal{A}}$ is $\big[T\big(S(\mathbf{u}_j)\big)\big]_{\mathcal{C}}$. Apply Theorem 2.3.9 to T at the vector $S(\mathbf{u}_j)$.
> *Hint 3.* For (b), apply (a) with the standard bases, and then use that a linear map $F^n \to F^\ell$ is determined by its standard matrix.
> *Sketch.* (a) The j-th column of $[TS]_{\mathcal{C}\mathcal{A}}$ is $\big[T\big(S(\mathbf{u}_j)\big)\big]_{\mathcal{C}} = [T]_{\mathcal{C}\mathcal{B}}\big[S(\mathbf{u}_j)\big]_{\mathcal{B}}$, which is $[T]_{\mathcal{C}\mathcal{B}}$ times the j-th column of $[S]_{\mathcal{B}\mathcal{A}}$, the j-th column of the product. (b) By (a) with standard bases, $[T_A T_B]_{\mathcal{E}\mathcal{E}} = AB$, so $T_A T_B = T_{AB}$ by Proposition 2.3.17.

(a) Both sides are $\ell \times n$ matrices. By Definition 2.3.1, the j-th column of $[TS]_{\mathcal{C}\mathcal{A}}$ is $\big[(TS)(\mathbf{u}_j)\big]_{\mathcal{C}}$. By the definition of composition and Theorem 2.3.9,

$$\begin{aligned}\big[(TS)(\mathbf{u}_j)\big]_{\mathcal{C}} &= \big[T\big(S(\mathbf{u}_j)\big)\big]_{\mathcal{C}} \\ &= [T]_{\mathcal{C}\mathcal{B}}\big[S(\mathbf{u}_j)\big]_{\mathcal{B}}.\end{aligned}$$

The vector $\big[S(\mathbf{u}_j)\big]_{\mathcal{B}}$ is the j-th column of $[S]_{\mathcal{B}\mathcal{A}}$ (Definition 2.3.1), so by Definition 2.4.1 this is the j-th column of $[T]_{\mathcal{C}\mathcal{B}}[S]_{\mathcal{B}\mathcal{A}}$. The two matrices have the same columns, so they are equal.

(b) The map $T_A T_B : F^n \to F^\ell$ is linear (Proposition 2.1.17). By (a) with the standard bases of F^n, F^m, and F^ℓ, and by Proposition 2.3.16,

$$[T_A T_B]_{\mathcal{E}\mathcal{E}} = [T_A]_{\mathcal{E}\mathcal{E}}[T_B]_{\mathcal{E}\mathcal{E}} = AB.$$

By Proposition 2.3.17, every linear map $F^n \to F^\ell$ is multiplication by its standard matrix, so $T_A T_B = T_{AB}$. Evaluating at $\mathbf{x}$ gives $A(B\mathbf{x}) = (AB)\mathbf{x}$. □

The subscripts in (a) behave like the sizes: in $[T]_{\mathcal{C}\mathcal{B}}[S]_{\mathcal{B}\mathcal{A}}$ the two inner bases agree and drop out, leaving $[TS]_{\mathcal{C}\mathcal{A}}$. Also notice the order. TS means "first S, then T", and the matrix of the map applied first stands on the right, as S does in $T(S(\mathbf{u}))$. This is the price of writing functions to the left of their arguments, and it is why products of matrices are read from right to left.

As with the matrix–vector product (Proposition 2.3.10), the definition is not a convention. Even the special case of standard bases leaves no other choice.

> **Proposition 2.4.3** (The product is forced). Suppose that for all $\ell, m, n \geq 1$ we are given a rule that assigns to each $A \in F^{\ell\times m}$ and $B \in F^{m\times n}$ a matrix $A \star B \in F^{\ell\times n}$, such that for all $S \in \mathrm{L}(F^n, F^m)$ and $T \in \mathrm{L}\big(F^m, F^\ell\big)$,
>
> $$[TS]_{\mathcal{E}\mathcal{E}} = [T]_{\mathcal{E}\mathcal{E}} \star [S]_{\mathcal{E}\mathcal{E}}.$$
>
> Then $A \star B = AB$ for all A and B.

Proof. ROUTINE

> *Uses.* Proposition 2.3.16 (The matrix of T_A), Theorem 2.4.2 (The matrix of a composite)
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* Given A and B, find linear maps whose standard matrices are A and B.
> *Hint 2.* Take $T = T_A$ and $S = T_B$, and compute $[T_A T_B]_{\mathcal{E}\mathcal{E}}$ in two ways.
> *Sketch.* With $T = T_A$ and $S = T_B$, the hypothesis gives $A \star B = [T_A T_B]_{\mathcal{E}\mathcal{E}}$, and Theorem 2.4.2 gives $[T_A T_B]_{\mathcal{E}\mathcal{E}} = AB$.

Let $A \in F^{\ell\times m}$ and $B \in F^{m\times n}$. By Proposition 2.3.16, $[T_A]_{\mathcal{E}\mathcal{E}} = A$ and $[T_B]_{\mathcal{E}\mathcal{E}} = B$. Applying the hypothesis to $T = T_A$ and $S = T_B$, and then Theorem 2.4.2,

$$\begin{aligned}A \star B &= [T_A]_{\mathcal{E}\mathcal{E}} \star [T_B]_{\mathcal{E}\mathcal{E}} = [T_A T_B]_{\mathcal{E}\mathcal{E}} \\ &= [T_A]_{\mathcal{E}\mathcal{E}}[T_B]_{\mathcal{E}\mathcal{E}} = AB.\end{aligned}$$

□

Figure 2.4.1 shows Theorem 2.4.2(b) in the plane. The grid in the last panel of each row is the image of the square grid under the composite, and the two colored arrows are the columns of the product.

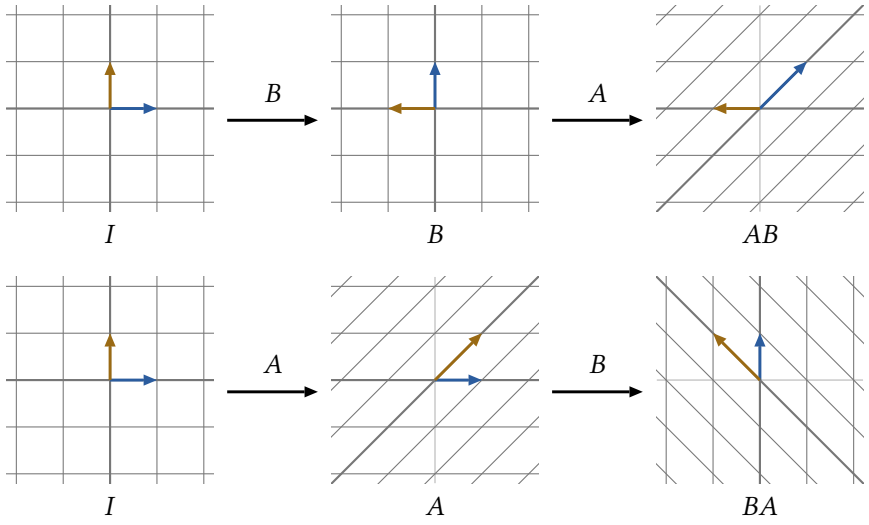


Figure 2.4.1. Composition in the plane, with $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ (a shear) and $B = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ (rotation by a right angle). Blue and ochre arrows are the images of $\mathbf{e}_1$ and $\mathbf{e}_2$. Top row: first B, then A. The result is $T_A T_B = T_{AB}$, and its arrows are the columns $(1, 1)$ and $(-1, 0)$ of $AB = \begin{pmatrix} 1 & -1 \\ 1 & 0 \end{pmatrix}$. Bottom row: the same two maps in the other order, giving $BA = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}$. The final grids differ, so $AB \neq BA$.

Example 2.4.4 (A product by columns). Let $A = \begin{pmatrix} 1 & -1 & 2 \\ 0 & 3 & 1 \end{pmatrix} \in \mathbb{R}^{2\times 3}$ and $B = \begin{pmatrix} 2 & 1 \\ 1 & 0 \\ -1 & 4 \end{pmatrix} \in \mathbb{R}^{3\times 2}$. The columns of AB are $A(2, 1, -1)$ and $A(1, 0, 4)$, which by Definition 2.3.8 are

$$2\begin{pmatrix} 1 \\ 0 \end{pmatrix} + \begin{pmatrix} -1 \\ 3 \end{pmatrix} - \begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} -1 \\ 2 \end{pmatrix},$$

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix} + 4\begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 9 \\ 4 \end{pmatrix},$$

so $AB = \begin{pmatrix} -1 & 9 \\ 2 & 4 \end{pmatrix}$. The product BA is also defined, but it is a 3×3 matrix:

$$BA = \begin{pmatrix} 2 & 1 & 5 \\ 1 & -1 & 2 \\ -1 & 13 & 2 \end{pmatrix},$$

whose columns are $B\begin{pmatrix} 1 \\ 0 \end{pmatrix}$, $B\begin{pmatrix} -1 \\ 3 \end{pmatrix}$, and $B\begin{pmatrix} 2 \\ 1 \end{pmatrix}$. Even the sizes of AB and BA differ.

Example 2.4.5 (Composites through their matrices).

(a) Let $D \in \mathrm{L}\big(F[x]_{\leq 2}\big)$ be differentiation and $\mathcal{B} = 1, x, x^2$, so that $N = [D]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix}$ (Example 2.3.4). By Theorem 2.4.2, $\big[D^2\big]_{\mathcal{B}\mathcal{B}} = NN$ and $\big[D^3\big]_{\mathcal{B}\mathcal{B}} = NNN$, and indeed

$$NN = \begin{pmatrix} 0 & 0 & 2 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad NNN = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

The first says $D^2\big(a + bx + cx^2\big) = 2c$. The second is the matrix form of $D^3 = 0$, which we could only observe one vector at a time in Intuition (One basis or two).

(b) Rotating by β and then by α is rotating by $\alpha + \beta$, so $R_\alpha R_\beta = R_{\alpha+\beta}$ (Exercise 2.1.43). By Theorem 2.4.2 and Example 2.3.3,

$$\begin{aligned} &\big[R_{\alpha+\beta}\big]_{\mathcal{E}\mathcal{E}} \\ &= \begin{pmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{pmatrix}\begin{pmatrix} \cos\beta & -\sin\beta \\ \sin\beta & \cos\beta \end{pmatrix}. \end{aligned}$$

The first column of the left side is $(\cos(\alpha+\beta), \sin(\alpha+\beta))$, and by the column view of the product, the first column of the right side is

$$\begin{aligned} &\cos\beta\begin{pmatrix} \cos\alpha \\ \sin\alpha \end{pmatrix} + \sin\beta\begin{pmatrix} -\sin\alpha \\ \cos\alpha \end{pmatrix} \\ &= \begin{pmatrix} \cos\alpha\cos\beta - \sin\alpha\sin\beta \\ \sin\alpha\cos\beta + \cos\alpha\sin\beta \end{pmatrix}. \end{aligned}$$

These are the angle addition formulas for $\cos(\alpha+\beta)$ and $\sin(\alpha+\beta)$. In Example 2.1.11 we used those formulas to show that rotations are linear, so here they are recovered rather than proved. But if one accepts from geometry that rotations are linear, then their matrices come from Corollary 2.2.17 without any trigonometric identity, as noted in Section 2.2.5, and this computation is a proof of the angle addition formulas.

(c) Let $\mathcal{B} = (1,1), (1,-1)$, a basis of F^2 when $1 + 1 \neq 0$. In Example 2.3.24 we found $[\mathrm{id}]_{\mathcal{E}\mathcal{B}} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ and $[\mathrm{id}]_{\mathcal{B}\mathcal{E}} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$. Since id id = id, Theorem 2.4.2 gives

$$[\mathrm{id}]_{\mathcal{E}\mathcal{B}}[\mathrm{id}]_{\mathcal{B}\mathcal{E}} = [\mathrm{id}]_{\mathcal{E}\mathcal{E}} = I_2,$$

and indeed $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$, which becomes I_2 after multiplying by $\frac{1}{2}$. Converting standard coordinates into $\mathcal{B}$-coordinates and back changes nothing. Matrices whose products are I in this way are the invertible matrices of Section 2.5, and those of the form $[\mathrm{id}]_{\mathcal{C}\mathcal{B}}$ are studied in Section 4.5.

Exercise 2.4.6. ROUTINE

(a) Over $\mathbb{F}_5$, let $A = \begin{pmatrix} 1 & 2 & 0 \\ 3 & 1 & 4 \end{pmatrix}$ and $B = \begin{pmatrix} 2 & 1 \\ 0 & 3 \\ 1 & 1 \end{pmatrix}$. Compute AB and BA. Which of $A^2 = AA$ and $B^2 = BB$ are defined?

(b) Over $\mathbb{C}$, compute $\begin{pmatrix} 1 & i \\ 0 & 2 \end{pmatrix}\begin{pmatrix} i & 1 \\ 1 & -i \end{pmatrix}$ and $\begin{pmatrix} i & 1 \\ 1 & -i \end{pmatrix}\begin{pmatrix} 1 & i \\ 0 & 2 \end{pmatrix}$.

Solution on page 1138

2.4.2 Four views of the product

The definition describes AB one column at a time, but a product can be read in several other ways, and choosing the right one often makes a problem easy. We first fix some notation.

Notation 2.4.7 (Entries, rows, and columns). For a matrix M given by an expression, such as AB, we write $(M)_{ij}$ or M_{ij} for its entry in row i and column j, and

$$M_{i,\cdot} = \text{row } i \text{ of } M, \quad M_{\cdot,j} = \text{column } j \text{ of } M.$$

A row of an $\ell \times m$ matrix is a $1 \times m$ matrix, and a column is an $\ell \times 1$ matrix, that is, an element of F^{ℓ}. We identify a 1×1 matrix (c) with the scalar c. The **Kronecker delta** is

$$\delta_{ij} = \begin{cases} 1 \text{ if } i = j \\ 0 \text{ if } i \neq j, \end{cases}$$

so that $I_n = (\delta_{ij})$ and $\mathbf{e}_j = (\delta_{1j}, \ldots, \delta_{nj})$.

Proposition 2.4.8 (Four views of the product). Let $A \in F^{\ell \times m}$ and $B \in F^{m \times n}$, and let $1 \leq i \leq \ell$ and $1 \leq j \leq n$.

(a) *Entries.* The (i, j) entry of AB is row i of A times column j of B:

$$(AB)_{ij} = A_{i,\cdot} B_{\cdot,j} = \sum_{k=1}^{m} a_{ik} b_{kj}.$$

(b) *Columns.* Column j of AB is a combination of the columns of A, with coefficients from column j of B:

$$\begin{aligned} (AB)_{\cdot,j} &= AB_{\cdot,j} \\ &= b_{1j} A_{\cdot,1} + \cdots + b_{mj} A_{\cdot,m}. \end{aligned}$$

(c) *Rows.* Row i of AB is a combination of the rows of B, with coefficients from row i of A:

$$\begin{aligned} (AB)_{i,\cdot} &= A_{i,\cdot} B \\ &= a_{i1} B_{1,\cdot} + \cdots + a_{im} B_{m,\cdot}. \end{aligned}$$

(d) *Columns times rows.* AB is a sum of m products of a column with a row:

$$AB = A_{\cdot,1} B_{1,\cdot} + \cdots + A_{\cdot,m} B_{m,\cdot}.$$

Proof. ROUTINE

Uses. Definition 2.4.1 (Matrix product), Definition 2.3.8 (Matrix–vector product), Definition 1.2.7 (Matrices)
Hint 1. (a) and (b) are restatements of Definition 2.4.1. For (c) and (d), compare entries using (a).
Hint 2. In (d), $A_{\cdot,k} B_{k,\cdot}$ is an $\ell \times 1$ matrix times a $1 \times n$ matrix. Its inner size is 1, so the sum in (a) has a single term. What is its (i, j) entry?
Sketch. (a) is the entry formula of Definition 2.4.1, read for a $1 \times m$ times $m \times 1$ product. (b) is the definition together with Definition 2.3.8. In (c) and (d), the (i, j) entry of each side is $\sum_k a_{ik} b_{kj}$: the matrix $A_{\cdot,k} B_{k,\cdot}$ has (i, j) entry $a_{ik} b_{kj}$, and the operations on matrices are entrywise.

(a) The formula $(AB)_{ij} = \sum_k a_{ik} b_{kj}$ is part of Definition 2.4.1. Applied to the $1 \times m$ matrix $A_{i,\cdot}$ and the $m \times 1$ matrix $B_{\cdot,j}$, the same formula says that $A_{i,\cdot} B_{\cdot,j}$ is the 1×1 matrix with entry $\sum_k a_{ik} b_{kj}$.

(b) By Definition 2.4.1, column j of AB is $A\mathbf{b}_j$ with $\mathbf{b}_j = B_{\cdot,j} = (b_{1j}, \ldots, b_{mj})$, and by Definition 2.3.8, $A\mathbf{b}_j = b_{1j} A_{\cdot,1} + \cdots + b_{mj} A_{\cdot,m}$.

(c) By (a), applied to $A_{i,\cdot} \in F^{1 \times m}$ and B, the $1 \times n$ matrix $A_{i,\cdot} B$ has j-th entry $\sum_k a_{ik} b_{kj}$. Matrices are added and scaled entrywise (Definition 1.2.7), so the j-th entry of $\sum_k a_{ik} B_{k,\cdot}$ is also $\sum_k a_{ik} b_{kj}$. By (a), both equal the j-th entry of $(AB)_{i,\cdot}$.

(d) By (a), applied with inner size 1, the $\ell \times n$ matrix $A_{\cdot,k}B_{k,\cdot}$ has (i,j) entry $a_{ik}b_{kj}$. Adding these matrices entrywise over $k = 1, \ldots, m$ gives the matrix with (i,j) entry $\sum_k a_{ik}b_{kj} = (AB)_{ij}$. □

Each view is the right one for some job.

- The **entry view** (a) is the quickest way to compute a product by hand, and the one to use in proofs about individual entries, such as the shape of a product of triangular matrices (Proposition 2.4.36).
- The **column view** (b) answers questions about columns. Since every column of AB is a linear combination of the columns of A, the span of the columns of AB is contained in the span of the columns of A (Proposition 1.4.14): multiplying A on the right cannot produce new directions. This is the first step towards $\operatorname{rank}(AB) \le \operatorname{rank} A$ (Section 4.3). It also says that multiplying on the right recombines columns, which is how column operations become matrix products (Section 3.2).
- The **row view** (c) is the mirror image: multiplying B on the left recombines its rows. This is why row operations, and Gauss–Jordan elimination as a whole, are left multiplications (Section 3.2, Section 3.3).
- The **column–row view** (d) writes AB as a sum of m simple pieces, each built from one column and one row. It is the view to use when A has few columns, for block multiplication (Theorem 2.4.34), and for decompositions of a matrix into simple pieces (Section 4.3, Section 9.1).

Example 2.4.9 (One product, four ways). Let $A = \begin{pmatrix} 1 & 2 \\ -1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 3 & 1 & 0 \\ 1 & -2 & 4 \end{pmatrix}$ over $\mathbb{R}$.

Entries. $(AB)_{11} = 1 \cdot 3 + 2 \cdot 1 = 5$, $(AB)_{12} = 1 - 4 = -3$, and so on, giving $AB = \begin{pmatrix} 5 & -3 & 8 \\ -3 & -1 & 0 \end{pmatrix}$.

Columns. $(AB)_{\cdot,1} = 3\begin{pmatrix} 1 \\ -1 \end{pmatrix} + 1\begin{pmatrix} 2 \\ 0 \end{pmatrix} = \begin{pmatrix} 5 \\ -3 \end{pmatrix}$, and similarly for the other two columns.

Rows. Row 1 of A is $(1 \;\; 2)$, so

$$\begin{aligned}(AB)_{1,\cdot} &= 1(3 \;\; 1 \;\; 0) + 2(1 \;\; -2 \;\; 4) \\ &= (5 \;\; -3 \;\; 8).\end{aligned}$$

Row 2 of A is $(-1 \;\; 0)$, so row 2 of AB is -1 times row 1 of B, that is, $(-3 \;\; -1 \;\; 0)$. The row view gave this row with no computation at all.

Columns times rows.

$$\begin{aligned}AB = &\begin{pmatrix} 1 \\ -1 \end{pmatrix}(3 \;\; 1 \;\; 0) \\ &+\begin{pmatrix} 2 \\ 0 \end{pmatrix}(1 \;\; -2 \;\; 4).\end{aligned}$$

The two terms are $\begin{pmatrix} 3 & 1 & 0 \\ -3 & -1 & 0 \end{pmatrix}$ and $\begin{pmatrix} 2 & -4 & 8 \\ 0 & 0 & 0 \end{pmatrix}$, and their sum is AB.

Example 2.4.10 (Diagonal matrices). A square matrix D is **diagonal** if $d_{ij} = 0$ whenever $i \ne j$. We write $D = \operatorname{diag}(d_1, \ldots, d_n)$ for the diagonal matrix with diagonal entries $d_1, \ldots, d_n$. Row i of D is $d_i \mathbf{e}_i$ written as a row, so by the row view, row i of DA is $d_i A_{i,\cdot}$: multiplying by D on the left scales row i by d_i. Column j of D is $d_j \mathbf{e}_j$, so by the column view, column j of AD is $d_j A_{\cdot,j}$: multiplying on the right scales columns. In particular

$$\begin{aligned}&\operatorname{diag}(c_1, \ldots, c_n)\operatorname{diag}(d_1, \ldots, d_n) \\ &\quad = \operatorname{diag}(c_1 d_1, \ldots, c_n d_n),\end{aligned}$$

so diagonal matrices multiply entry by entry and commute with each other.

Exercise 2.4.11. ROUTINE Let $A \in F^{\ell \times m}$ and $B \in F^{m \times n}$.

(a) Show that if column j of B is zero, then so is column j of AB, and that if row i of A is zero, then so is row i of AB.

(b) Show that if $B_{:,3} = B_{:,1} + 2B_{:,2}$, then $(AB)_{:,3} = (AB)_{:,1} + 2(AB)_{:,2}$.

(c) Give an example in which AB has a zero column but B has none.

Solution on page 1138

2.4.3 Sums and scalar multiples

Matrices of the same size can also be added and scaled entrywise (Definition 1.2.7), and linear maps can be added and scaled pointwise (Proposition 2.1.23). These operations correspond to each other as well.

Proposition 2.4.12 (Matrices of sums and scalar multiples). Let $S, T \in \mathrm{L}(V, W)$ and $a \in F$. Then

$$[S+T]_{\mathcal{C}\mathcal{B}} = [S]_{\mathcal{C}\mathcal{B}} + [T]_{\mathcal{C}\mathcal{B}},$$
$$[aT]_{\mathcal{C}\mathcal{B}} = a[T]_{\mathcal{C}\mathcal{B}}.$$

So $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is a linear bijection from $\mathrm{L}(V, W)$ onto $F^{\ell\times m}$.

Proof. ROUTINE

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 2.1.21 (Pointwise operations), Proposition 1.6.19 (Coordinates respect linear combinations), Definition 1.2.7 (Matrices), Theorem 2.3.20 (Linear maps correspond to matrices)
Hint 1. Compare the j-th columns of the two sides.
Hint 2. $(S+T)(\mathbf{v}_j) = S(\mathbf{v}_j) + T(\mathbf{v}_j)$ by the definition of $S+T$. Taking coordinates is linear.
Sketch. The j-th column of $[S+T]_{\mathcal{C}\mathcal{B}}$ is $\big[S(\mathbf{v}_j) + T(\mathbf{v}_j)\big]_{\mathcal{C}} = \big[S(\mathbf{v}_j)\big]_{\mathcal{C}} + \big[T(\mathbf{v}_j)\big]_{\mathcal{C}}$, the sum of the j-th columns of $[S]$ and $[T]$. Scalars are the same. Bijectivity is Theorem 2.3.20.

By Definition 2.3.1, Definition 2.1.21, and the linearity of $[\cdot]_{\mathcal{C}}$ (Proposition 1.6.19), the j-th column of $[S+T]_{\mathcal{C}\mathcal{B}}$ is

$$\begin{aligned}\big[(S+T)(\mathbf{v}_j)\big]_{\mathcal{C}} &= \big[S(\mathbf{v}_j) + T(\mathbf{v}_j)\big]_{\mathcal{C}} \\ &= \big[S(\mathbf{v}_j)\big]_{\mathcal{C}} + \big[T(\mathbf{v}_j)\big]_{\mathcal{C}}.\end{aligned}$$

Matrices are added entrywise (Definition 1.2.7), so the j-th column of $[S]_{\mathcal{C}\mathcal{B}} + [T]_{\mathcal{C}\mathcal{B}}$ is the sum of their j-th columns, which is the same vector. Likewise the j-th column of $[aT]_{\mathcal{C}\mathcal{B}}$ is $\big[aT(\mathbf{v}_j)\big]_{\mathcal{C}} = a\big[T(\mathbf{v}_j)\big]_{\mathcal{C}}$, the j-th column of $a[T]_{\mathcal{C}\mathcal{B}}$. So $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is linear, and it is a bijection by Theorem 2.3.20. □

So the dictionary of Section 2.3.6 has three more entries: sums, scalar multiples, and composites of maps correspond to sums, scalar multiples, and products of matrices. In the language of Section 4.5, the proposition says that $\mathrm{L}(V, W)$ and $F^{\ell\times m}$ are isomorphic vector spaces, and dimension counting there gives $\dim \mathrm{L}(V, W) = \ell m$.

Example 2.4.13 (The difference operator). Let $T \in \mathrm{L}\big(F[x]_{\leq 2}\big)$ be the substitution $T(p) = p(x+1)$, and $\mathcal{B} = 1, x, x^2$. From $T(1) = 1$, $T(x) = 1 + x$, and $T\big(x^2\big) = 1 + 2x + x^2$,

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}.$$

The difference operator of Example 2.3.28 is $\Delta = T - \mathrm{id}$, so by Proposition 2.4.12 and Example 2.3.6,

$$[\Delta]_{\mathcal{B}\mathcal{B}} = [T]_{\mathcal{B}\mathcal{B}} - I_3 = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix},$$

which is the matrix computed there column by column.

2.4.4 The algebraic laws

Proposition 2.4.14 (Algebra of matrices). Let $A, A' \in F^{\ell\times m}$, $B, B' \in F^{m\times n}$, $C \in F^{n\times p}$, and $a \in F$.
(a) *Associativity.* $(AB)C = A(BC)$.
(b) *Identities.* $I_\ell A = A = AI_m$.
(c) *Distributivity.* $A(B+B') = AB + AB'$ and $(A+A')B = AB + A'B$.
(d) *Scalars.* $(aA)B = a(AB) = A(aB)$.

Intuition (The laws come from composition). Read a product of matrices as a sequence of maps, applied from right to left:

$$F^p \xrightarrow{T_C} F^n \xrightarrow{T_B} F^m \xrightarrow{T_A} F^\ell.$$

Both $(AB)C$ and $A(BC)$ are the matrix of "first T_C, then T_B, then T_A". The parentheses only record which two of the three steps were combined first, and the composite of three functions does not depend on that: both are $\mathbf{x} \mapsto T_A(T_B(T_C(\mathbf{x})))$. So associativity of matrix multiplication should follow from associativity of composition (Proposition 2.1.24) with no computation, once we can translate in both directions. That translation is Technique 2.3.27, and the dictionary we need is now complete: $T_{AB} = T_A T_B$ (Theorem 2.4.2), $T_{aA+A'} = aT_A + T_{A'}$ and $T_{I_\ell} = \mathrm{id}$ (Proposition 2.3.13), and A is determined by T_A (Proposition 2.3.17).

Proof (via composition). ROUTINE

Uses. Theorem 2.4.2 (The matrix of a composite), Proposition 2.1.24 (Algebra of composition), Proposition 2.3.13 (Linearity of the product), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Two matrices of the same size are equal when the maps T_X they define are equal (Proposition 2.3.17). So compute $T_{(AB)C}$ and $T_{A(BC)}$.
Hint 2. $T_{(AB)C} = T_{AB}T_C = (T_AT_B)T_C$. Now use associativity of composition and go back.
Hint 3. For (b), (c), and (d) you also need $T_{I_\ell} = \mathrm{id}$, $T_{B+B'} = T_B + T_{B'}$, and $T_{aA} = aT_A$, all from Proposition 2.3.13.
Sketch. Translate each side into a composite of maps T_X with Theorem 2.4.2 and Proposition 2.3.13, apply the matching identity of Proposition 2.1.24, and translate back. For instance $T_{(AB)C} = (T_AT_B)T_C = T_A(T_BT_C) = T_{A(BC)}$, so $(AB)C = A(BC)$ by the uniqueness in Proposition 2.3.17.

By Proposition 2.3.17, two matrices $X, Y \in F^{r\times s}$ with $T_X = T_Y$ are equal. So in each case it suffices to show that the two sides define the same linear map. We use Theorem 2.4.2(b), $T_{XY} = T_XT_Y$, and Proposition 2.3.13, which says that $T_{cX+X'} = cT_X + T_{X'}$ and that $T_{I_r} = \mathrm{id}_{F^r}$.

(a) By Theorem 2.4.2 and part (a) of Proposition 2.1.24,

$$\begin{aligned} T_{(AB)C} &= T_{AB}T_C = (T_AT_B)T_C \\ &= T_A(T_BT_C) = T_AT_{BC} = T_{A(BC)}. \end{aligned}$$

(b) $T_{I_\ell A} = T_{I_\ell}T_A = \mathrm{id}\, T_A = T_A$, and $T_{AI_m} = T_A\, \mathrm{id} = T_A$, by part (b) of Proposition 2.1.24.

(c) By part (c) of Proposition 2.1.24,

$$\begin{aligned} T_{A(B+B')} &= T_A(T_B + T_{B'}) = T_AT_B + T_AT_{B'} \\ &= T_{AB} + T_{AB'} = T_{AB+AB'}, \end{aligned}$$

and in the same way $T_{(A+A')B} = (T_A + T_{A'})T_B$ equals $T_{AB+A'B}$.

(d) By part (d) of Proposition 2.1.24,

$$\begin{aligned} T_{(aA)B} &= (aT_A)T_B = a(T_AT_B) \\ &= T_A(aT_B) = T_{A(aB)}, \end{aligned}$$

and the middle expression is $aT_{AB} = T_{a(AB)}$. □

The first proof never looks at an entry. The second proof works with entries only, and it is the prototype of a move we will use constantly.

> **Technique 2.4.15** (Compute entry by entry). To prove an identity between matrices, show that the (i, j) entries of the two sides agree for all i and j. Write each entry of a product with Proposition 2.4.8(a), using a new summation index for every product, then rearrange: pull constant factors out of sums, exchange the order of two finite sums, $\sum_k \sum_l = \sum_l \sum_k$, and collapse sums containing a Kronecker delta, $\sum_k \delta_{ik} x_k = x_i$.
>
> Reach for it when the statement is about the entries themselves (transposes, traces, triangular or block shapes), or when there is no linear map in sight, for example for matrices whose entries are integers, polynomials, or other matrices. Two things go wrong in practice. Reusing a summation index in a nested sum silently identifies two different indices. And moving a factor past another needs commutativity of the entries, which holds for scalars but not for blocks (Section 2.4.8). The canonical example is the second proof of associativity below.
>
> *Used in.* Proposition 2.4.14, Proposition 2.4.23, Proposition 2.4.28, Theorem 2.4.34, Proposition 2.4.36, Proposition 2.4.39, Exercise 2.8.6, Exercise 2.8.11, Problem 2.4, Problem 2.12, Theorem 5.5.9, Proposition 6.3.27, Proposition 7.1.3, Theorem 7.6.28, Proposition 8.3.25, Exercise 2.6.46, Exercise 6.3.60, Exercise 8.2.45.

Proof (entry by entry). ROUTINE

> *Uses.* Proposition 2.4.8 (Four views of the product), Definition 1.1.1 (Field), Notation 2.4.7 (Entries, rows, and columns)
> *Techniques.* Compute entry by entry (Technique 2.4.15)
> *Hint 1.* Write $((AB)C)_{ij}$ as a double sum, using the entry formula twice with two different summation indices.
> *Hint 2.* $((AB)C)_{ij} = \sum_l \bigl(\sum_k a_{ik} b_{kl}\bigr) c_{lj}$. Distribute, exchange the two sums, and factor out a_{ik}.
> *Sketch.* Both $((AB)C)_{ij}$ and $(A(BC))_{ij}$ equal $\sum_k \sum_l a_{ik} b_{kl} c_{lj}$, after distributing and exchanging the finite sums. The other laws follow in the same way from the field axioms, with $(I_\ell)_{ik} = \delta_{ik}$ for (b).

(a) For $1 \le i \le \ell$ and $1 \le j \le p$, by Proposition 2.4.8(a) twice,

$$\begin{aligned}((AB)C)_{ij} &= \sum_{l=1}^{n} (AB)_{il} c_{lj} = \sum_{l=1}^{n} \left(\sum_{k=1}^{m} a_{ik} b_{kl} \right) c_{lj} \\ &= \sum_{l=1}^{n} \sum_{k=1}^{m} a_{ik} b_{kl} c_{lj} = \sum_{k=1}^{m} \sum_{l=1}^{n} a_{ik} b_{kl} c_{lj} \\ &= \sum_{k=1}^{m} a_{ik} \left(\sum_{l=1}^{n} b_{kl} c_{lj} \right) = \sum_{k=1}^{m} a_{ik} (BC)_{kj} \\ &= (A(BC))_{ij}.\end{aligned}$$

The steps used distributivity and associativity in F and the reordering of a finite sum.

(b) $(I_\ell A)_{ij} = \sum_k \delta_{ik} a_{kj} = a_{ij}$, since only the term $k = i$ survives, and similarly $(AI_m)_{ij} = \sum_k a_{ik} \delta_{kj} = a_{ij}$.

(c) By distributivity in F,

$$\begin{aligned}(A(B + B'))_{ij} &= \sum_k a_{ik} \bigl(b_{kj} + b'_{kj} \bigr) \\ &= \sum_k a_{ik} b_{kj} + \sum_k a_{ik} b'_{kj} \\ &= (AB + AB')_{ij},\end{aligned}$$

and the other law is the same with the factors on the other side.

(d) Using commutativity of F to move a to the front,

$$((aA)B)_{ij} = \sum_k (aa_{ik})b_{kj} = a\sum_k a_{ik}b_{kj}$$
$$= \sum_k a_{ik}\big(ab_{kj}\big) = (A(aB))_{ij},$$

and the middle expression is $(a(AB))_{ij}$. □

The two proofs teach different things. The first explains *why* the laws hold: matrices multiply like composites because they are composites in disguise, and composition of functions is associative for trivial reasons. All the work went into the dictionary between maps and matrices. The second is self-contained and mechanical. Look at what it used in (a): the laws of addition, associativity of multiplication, and distributivity, but nothing about inverses or commutativity of multiplication. So the same computation proves associativity for matrices with entries in $\mathbb{Z}$, in $F[x]$, or in any other number system with these laws, even one whose multiplication is not commutative, where there may be no vector spaces and linear maps to translate into. This is what makes block multiplication associative (Section 2.4.8), since blocks are matrices whose "entries" are matrices.

By associativity, products of three or more matrices need no parentheses.

Notation 2.4.16 (Powers of a matrix). For $A \in F^{n\times n}$ and an integer $k \geq 1$, $A^k = AA\cdots A$ (k factors), and $A^0 = I_n$. Then $A^jA^k = A^{j+k}$, and if $T \in \mathrm{L}(V)$ and $\mathcal{B}$ is a basis of V, then $\left[T^k\right]_{\mathcal{B}\mathcal{B}} = \left([T]_{\mathcal{B}\mathcal{B}}\right)^k$ by Theorem 2.4.2 and induction on k. Together with Proposition 2.4.12,

$$\left[a_0\,\mathrm{id} + a_1T + \cdots + a_kT^k\right]_{\mathcal{B}\mathcal{B}}$$
$$= a_0I_n + a_1A + \cdots + a_kA^k,$$

where $A = [T]_{\mathcal{B}\mathcal{B}}$.

Exercise 2.4.17. ROUTINE Let $A, B \in F^{n\times n}$. Show that $(A+B)^2 = A^2 + AB + BA + B^2$, and deduce that $(A+B)^2 = A^2 + 2AB + B^2$ if and only if $AB = BA$. (Here $2AB = AB + AB$.)

Solution on page 1139

2.4.5 What fails

Matrix multiplication shares associativity and distributivity with the multiplication of numbers, but three other familiar properties fail. In each case the failure is already visible for composition of maps.

Example 2.4.18 ($AB \neq BA$). Let

$$A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

Then

$$AB = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad BA = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

In terms of maps, T_A sends $\mathbf{e}_2 \mapsto \mathbf{e}_1 \mapsto \mathbf{0}$ and T_B sends $\mathbf{e}_1 \mapsto \mathbf{e}_2 \mapsto \mathbf{0}$. Following $\mathbf{e}_1$ through T_AT_B returns it to $\mathbf{e}_1$, but following it through T_BT_A kills it. For a geometric example, let P be the projection onto the x-axis and R the rotation by a right angle, so that $PR \neq RP$ by Example 2.1.19. In matrices,

$$\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix},$$

$$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

Figure 2.4.1 is a third example. When AB is defined, BA may not be, and if both are defined they may have different sizes (Example 2.4.4). So "$AB = BA$" is a strong condition, which we express by saying that A and B **commute**.

Example 2.4.19 (Zero divisors and the failure of cancellation). With A as above and $P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$,

$$A^2 = AP = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad PA = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

So a product of nonzero matrices can be zero, and even a nonzero square can be zero. In the language of Proposition 1.1.17, $F^{2\times 2}$ has **zero divisors**. Note also that $AP = 0$ while $PA \neq 0$.

Cancellation fails with them: $AP = A0$ with $A \neq 0$, but $P \neq 0$. In general, $AB = AC$ means $A(B - C) = 0$ (Proposition 2.4.14(c)), so cancelling A is legitimate exactly when $AX = 0$ forces $X = 0$. For A that are left-invertible (Section 2.5) this holds; for the A above it does not, since T_A kills $\mathbf{e}_1$, and any X whose columns lie in $\operatorname{span}(\mathbf{e}_1)$ satisfies $AX = 0$.

These examples are 2×2, which is the smallest size where anything can go wrong: $F^{1\times 1}$ is just F, where multiplication is commutative and there are no zero divisors. For $n \geq 2$, put the 2×2 examples in the top left corner of an $n \times n$ matrix that is zero elsewhere. By block multiplication (Theorem 2.4.34) the products are computed in that corner, so $F^{n\times n}$ has the same failures. Finding such examples is an instance of Technique 1.4.18: the first place to look is 2×2 matrices whose entries are 0 and 1.

Some matrices do commute. A scalar matrix cI_n commutes with every $A \in F^{n\times n}$, since $(cI_n)A = cA = A(cI_n)$ by Proposition 2.4.14. Any A commutes with its own powers, since $AA^k = A^{k+1} = A^kA$, and hence with every $a_0I_n + a_1A + \cdots + a_kA^k$. Diagonal matrices commute with each other (Example 2.4.10), and so do the rotation matrices $[R_\alpha]$ and $[R_\beta]$, since both products equal $[R_{\alpha+\beta}]$. Which matrices commute with a given one is a recurring question; see Exercise 2.4.42 and Exercise 2.4.43.

Exercise 2.4.20. STANDARD Find $A, B \in \mathbb{R}^{2\times 2}$, none of whose eight entries is 0, with $AB = 0$ but $BA \neq 0$.

Solution on page 1139

2.4.6 The transpose

The row view and the column view are mirror images of each other. The transpose makes the mirror precise.

Definition 2.4.21 (Transpose). The **transpose** of $A = (a_{ij}) \in F^{m\times n}$ is the matrix $A^{\mathsf{T}} \in F^{n\times m}$ with

$$\left(A^{\mathsf{T}}\right)_{ij} = a_{ji} \quad (1 \leq i \leq n, 1 \leq j \leq m).$$

That is, row i of A^{T} is column i of A written as a row, and column j of A^{T} is row j of A written as a column. A square matrix A is **symmetric** if $A^{\mathsf{T}} = A$ and **skew-symmetric** if $A^{\mathsf{T}} = -A$.

For example,

$$\begin{pmatrix} 1 & 0 & -2 \\ 3 & 5 & 4 \end{pmatrix}^{\mathsf{T}} = \begin{pmatrix} 1 & 3 \\ 0 & 5 \\ -2 & 4 \end{pmatrix},$$

$$\begin{pmatrix} 1 & 2 \\ 2 & 7 \end{pmatrix}^{\mathsf{T}} = \begin{pmatrix} 1 & 2 \\ 2 & 7 \end{pmatrix},$$

$$\begin{pmatrix} 0 & 3 \\ -3 & 0 \end{pmatrix}^{\mathsf{T}} = \begin{pmatrix} 0 & -3 \\ 3 & 0 \end{pmatrix}.$$

The second matrix is symmetric and the third skew-symmetric; symmetric matrices form the subspace of Example 1.4.11. A vector $\mathbf{x} \in F^n$ is a column, so $\mathbf{x}^{\mathsf{T}} = (x_1 \ \cdots \ x_n)$ is a row, and for $\mathbf{x}, \mathbf{y} \in F^n$ the 1×1 product

$$\mathbf{x}^{\mathsf{T}}\mathbf{y} = x_1y_1 + x_2y_2 + \cdots + x_ny_n$$

is a scalar. In the other order, for $\mathbf{u} \in F^m$ and $\mathbf{v} \in F^n$, the column–row product $\mathbf{u}\mathbf{v}^{\mathsf{T}} \in F^{m\times n}$ has (i,j) entry u_iv_j, as in Proposition 2.4.8(d).

Proposition 2.4.22 (Transpose is a linear involution). For $A, B \in F^{m\times n}$ and $a \in F$,

$$\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A, \quad I_n^{\mathsf{T}} = I_n,$$
$$(aA + B)^{\mathsf{T}} = aA^{\mathsf{T}} + B^{\mathsf{T}}.$$

So $A \mapsto A^{\mathsf{T}}$ is a linear bijection $F^{m\times n} \to F^{n\times m}$, whose inverse is transposition $F^{n\times m} \to F^{m\times n}$.

Proof. ROUTINE

Uses. Definition 2.4.21 (Transpose), Definition 1.2.7 (Matrices), Definition 2.3.5 (Identity matrix)
Hint 1. Compare entries. The (i,j) entry of $\left(A^{\mathsf{T}}\right)^{\mathsf{T}}$ is the (j,i) entry of A^{T}.
Hint 2. For the last claim, transposing twice gives back the matrix you started with, whichever of the two directions you apply first.
Sketch. $\left(\left(A^{\mathsf{T}}\right)^{\mathsf{T}}\right)_{ij} = \left(A^{\mathsf{T}}\right)_{ji} = a_{ij}$, $\left((aA+B)^{\mathsf{T}}\right)_{ij} = aa_{ji} + b_{ji}$, and $\delta_{ji} = \delta_{ij}$. The two transposition maps $F^{m\times n} \to F^{n\times m}$ and back are inverse to each other.

By Definition 2.4.21, $\left(\left(A^{\mathsf{T}}\right)^{\mathsf{T}}\right)_{ij} = \left(A^{\mathsf{T}}\right)_{ji} = a_{ij}$, and since matrices are added and scaled entrywise,

$$\begin{aligned}\left((aA+B)^{\mathsf{T}}\right)_{ij} &= (aA+B)_{ji} = aa_{ji} + b_{ji} \\ &= \left(aA^{\mathsf{T}} + B^{\mathsf{T}}\right)_{ij}.\end{aligned}$$

The (i,j) entry of I_n^{T} is $\delta_{ji} = \delta_{ij}$. So transposition is linear, and applying it twice gives the identity map. Hence it is a bijection from $F^{m\times n}$ to $F^{n\times m}$, with transposition $F^{n\times m} \to F^{m\times n}$ as its inverse. □

Intuition (Why the order reverses). Before guessing a formula for $(AB)^{\mathsf{T}}$, check sizes. If $A \in F^{\ell\times m}$ and $B \in F^{m\times n}$, then $(AB)^{\mathsf{T}}$ is $n \times \ell$, while $A^{\mathsf{T}} \in F^{m\times\ell}$ and $B^{\mathsf{T}} \in F^{n\times m}$. So $A^{\mathsf{T}}B^{\mathsf{T}}$ is not even defined unless $\ell = n$, and the only product of the two transposes with the right size is $B^{\mathsf{T}}A^{\mathsf{T}}$. The same reversal will appear for inverses of composites (Section 2.5) and for adjoints (Section 6.6).

Proposition 2.4.23 (Transpose of a product). For $A \in F^{\ell\times m}$ and $B \in F^{m\times n}$,

$$(AB)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}}.$$

Proof (entry by entry). ROUTINE

Uses. Definition 2.4.21 (Transpose), Proposition 2.4.8 (Four views of the product), Definition 1.1.1 (Field)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Compute the (i,j) entry of each side with Definition 2.4.21 and the entry formula.
Hint 2. $\left((AB)^{\mathsf{T}}\right)_{ij} = (AB)_{ji} = \sum_k a_{jk}b_{ki}$. Write each factor as an entry of a transpose, and reorder each product.
Sketch. The (i,j) entry of $(AB)^{\mathsf{T}}$ is $\sum_k a_{jk}b_{ki}$. Since $a_{jk}b_{ki} = b_{ki}a_{jk} = \left(B^{\mathsf{T}}\right)_{ik}\left(A^{\mathsf{T}}\right)_{kj}$, this sum is the (i,j) entry of $B^{\mathsf{T}}A^{\mathsf{T}}$.

Both sides are $n \times \ell$. Let $1 \le i \le n$ and $1 \le j \le \ell$. By Definition 2.4.21 and Proposition 2.4.8(a), then commutativity of multiplication in F, then Definition 2.4.21 and Proposition 2.4.8(a) again,

$$\left((AB)^{\mathsf{T}}\right)_{ij} = (AB)_{ji} = \sum_{k=1}^{m} a_{jk}b_{ki} = \sum_{k=1}^{m} b_{ki}a_{jk}$$
$$= \sum_{k=1}^{m} \left(B^{\mathsf{T}}\right)_{ik}\left(A^{\mathsf{T}}\right)_{kj} = \left(B^{\mathsf{T}}A^{\mathsf{T}}\right)_{ij}.$$

□

The first proof used commutativity of F at one step, and that step is where the order of the factors flips. The second proof explains the reversal through the views of the product: the row view of AB is the column view of $B^{\mathsf{T}}A^{\mathsf{T}}$ in a mirror.

Proof (rows become columns). ROUTINE

> *Uses.* Proposition 2.4.8 (Four views of the product), Proposition 2.4.22 (Transpose is a linear involution), Definition 2.4.21 (Transpose), Definition 2.3.8 (Matrix–vector product)
> *Hint 1.* Column i of $(AB)^{\mathsf{T}}$ is row i of AB, written as a column. What is row i of AB in the row view?
> *Hint 2.* Column i of $B^{\mathsf{T}}A^{\mathsf{T}}$ is B^{T} times column i of A^{T}. Expand this with the column view, and compare with the transpose of the row-view expansion.
> *Sketch.* By the row view, row i of AB is $\sum_k a_{ik}B_{k,\cdot}$; transposing (a linear operation) gives $\sum_k a_{ik}\left(B^{\mathsf{T}}\right)_{\cdot,k}$. By the column view, column i of $B^{\mathsf{T}}A^{\mathsf{T}}$ is $B^{\mathsf{T}}\left(A^{\mathsf{T}}\right)_{\cdot,i} = \sum_k a_{ik}\left(B^{\mathsf{T}}\right)_{\cdot,k}$, since $\left(A^{\mathsf{T}}\right)_{ki} = a_{ik}$. The two matrices have the same columns.

By Definition 2.4.21, column i of $(AB)^{\mathsf{T}}$ is the transpose of row i of AB. By the row view (Proposition 2.4.8(c)) and the linearity of transposition (Proposition 2.4.22),

$$\left((AB)_{i,\cdot}\right)^{\mathsf{T}} = \left(\sum_{k=1}^{m} a_{ik}B_{k,\cdot}\right)^{\mathsf{T}} = \sum_{k=1}^{m} a_{ik}\left(B_{k,\cdot}\right)^{\mathsf{T}}$$
$$= \sum_{k=1}^{m} a_{ik}\left(B^{\mathsf{T}}\right)_{\cdot,k},$$

since the transpose of row k of B is column k of B^{T}. On the other side, column i of A^{T} is the transpose of row i of A, with entries $a_{i1}, \ldots, a_{im}$. By the column view (Proposition 2.4.8(b)), column i of $B^{\mathsf{T}}A^{\mathsf{T}}$ is

$$B^{\mathsf{T}}\left(A^{\mathsf{T}}\right)_{\cdot,i} = a_{i1}\left(B^{\mathsf{T}}\right)_{\cdot,1} + \cdots + a_{im}\left(B^{\mathsf{T}}\right)_{\cdot,m}.$$

So $(AB)^{\mathsf{T}}$ and $B^{\mathsf{T}}A^{\mathsf{T}}$ have the same columns. □

By induction, $(A_1A_2\cdots A_k)^{\mathsf{T}} = A_k^{\mathsf{T}}\cdots A_2^{\mathsf{T}}A_1^{\mathsf{T}}$, and in particular $\left(A^k\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^k$. Proposition 2.4.23 is the engine of Technique 3.2.27, which turns facts about rows and left multiplication into facts about columns and right multiplication. The transpose also has a meaning in terms of linear maps, which needs more structure than a matrix: with an inner product it is the adjoint (Section 6.6), and in general it is the dual map (Section 13.1).

The column–row products $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ of standard basis vectors are the simplest matrices of all, and we will use them repeatedly.

Lemma 2.4.24 (Matrix units). For $1 \le i \le m$ and $1 \le j \le n$, the matrix $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}} \in F^{m\times n}$ has a 1 in position (i, j) and 0 everywhere else.

(a) Every $A \in F^{m\times n}$ is $A = \sum_{i=1}^{m}\sum_{j=1}^{n} a_{ij}\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$, and these are the only coefficients that work. So the mn matrices $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ form a basis of $F^{m\times n}$.
(b) For $A \in F^{m\times n}$: $A\mathbf{e}_j = A_{\cdot,j}$, $\mathbf{e}_i^{\mathsf{T}}A = A_{i,\cdot}$, and $\mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_j = a_{ij}$.
(c) $\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right)\left(\mathbf{e}_k\mathbf{e}_l^{\mathsf{T}}\right) = \delta_{jk}\mathbf{e}_i\mathbf{e}_l^{\mathsf{T}}$, for matrices of compatible sizes.

Proof. ROUTINE

> *Uses.* Proposition 2.4.8 (Four views of the product), Proposition 2.4.14 (Algebra of matrices), Proposition 2.3.13 (Linearity of the product), Definition 1.6.1 (Basis), Notation 2.4.7 (Entries, rows, and columns)
> *Hint 1.* The (k, l) entry of the column–row product $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is u_kv_l. For $\mathbf{u} = \mathbf{e}_i$ and $\mathbf{v} = \mathbf{e}_j$ that is $\delta_{ki}\delta_{lj}$.

Hint 2. For (c), regroup with associativity: $\mathbf{e}_i\big(\mathbf{e}_j^{\mathsf{T}}\mathbf{e}_k\big)\mathbf{e}_l^{\mathsf{T}}$, and the middle factor is a 1×1 matrix.
Sketch. The (k,l) entry of $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ is $\delta_{ki}\delta_{lj}$. (a) The (k,l) entry of $\sum c_{ij}\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ is c_{kl}, so it equals A exactly when $c_{kl}=a_{kl}$. (b) Column and row views. (c) Associativity and $\mathbf{e}_j^{\mathsf{T}}\mathbf{e}_k=\delta_{jk}$.

By Proposition 2.4.8(a) with inner size 1, the (k,l) entry of $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ is $\delta_{ki}\delta_{lj}$, which is 1 if $(k,l)=(i,j)$ and 0 otherwise.

(a) Since matrices are added and scaled entrywise, the (k,l) entry of $\sum_{i,j} c_{ij}\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ is $\sum_{i,j} c_{ij}\delta_{ki}\delta_{lj}=c_{kl}$. So this sum equals A if and only if $c_{kl}=a_{kl}$ for all k,l. Every matrix is therefore a linear combination of the $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ in exactly one way, which is what it means for them to form a basis (Definition 1.6.1), with the entries of A as its coordinates.

(b) $A\mathbf{e}_j=A_{\cdot,j}$ is Proposition 2.3.13(c). By the row view (Proposition 2.4.8(c)), $\mathbf{e}_i^{\mathsf{T}}A=\sum_k \delta_{ik}A_{k,\cdot}=A_{i,\cdot}$. Then $\mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_j=A_{i,\cdot}\mathbf{e}_j$ is the j-th entry of row i, which is a_{ij}.

(c) By associativity (Proposition 2.4.14) and (b), $\mathbf{e}_j^{\mathsf{T}}\mathbf{e}_k$ is the (j,k) entry of I, which is δ_{jk}. So

$$\big(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\big)\big(\mathbf{e}_k\mathbf{e}_l^{\mathsf{T}}\big)=\mathbf{e}_i\big(\mathbf{e}_j^{\mathsf{T}}\mathbf{e}_k\big)\mathbf{e}_l^{\mathsf{T}}=\delta_{jk}\mathbf{e}_i\mathbf{e}_l^{\mathsf{T}}.$$

□

Part (c) gives the noncommutativity of Example 2.4.18 in its purest form: for $i\neq j$, $\big(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\big)\big(\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\big)=\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$, while $\big(\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\big)\big(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\big)=\mathbf{e}_j\mathbf{e}_j^{\mathsf{T}}$. The matrices A and B of that example are $\mathbf{e}_1\mathbf{e}_2^{\mathsf{T}}$ and $\mathbf{e}_2\mathbf{e}_1^{\mathsf{T}}$.

Exercise 2.4.25. ROUTINE

(a) Show that $A^{\mathsf{T}}A$ and AA^{T} are symmetric for every $A\in F^{m\times n}$.

(b) Let $A,B\in F^{n\times n}$ be symmetric. Show that $AB+BA$ is symmetric, that $AB-BA$ is skew-symmetric, and that AB is symmetric if and only if $AB=BA$.

Solution on page 1139

2.4.7 The trace

Matrix multiplication is not commutative, but there is a number attached to a square matrix that cannot tell AB from BA.

Definition 2.4.26 (Trace). The **trace** of $A=\big(a_{ij}\big)\in F^{n\times n}$ is the sum of its diagonal entries,

$$\operatorname{tr}A=a_{11}+a_{22}+\cdots+a_{nn}=\sum_{i=1}^{n}a_{ii}.$$

For example, $\operatorname{tr}\left(\begin{smallmatrix}1&2\\3&4\end{smallmatrix}\right)=5$ and $\operatorname{tr}I_n=n*1$, which is n over $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$ and is 0 over $\mathbb{F}_p$ when $p\mid n$. In this notation, the trace-zero matrices of Example 1.4.11 are those with $\operatorname{tr}A=0$.

Proposition 2.4.27 (The trace is linear). For $A,B\in F^{n\times n}$ and $a\in F$, $\operatorname{tr}(aA+B)=a\operatorname{tr}A+\operatorname{tr}B$ and $\operatorname{tr}A^{\mathsf{T}}=\operatorname{tr}A$.

Proof. ROUTINE

Uses. Definition 2.4.26 (Trace), Definition 1.2.7 (Matrices), Definition 2.4.21 (Transpose)
Hint 1. The diagonal entries of $aA+B$ are $aa_{ii}+b_{ii}$.
Hint 2. Transposing does not move the diagonal entries: $\big(A^{\mathsf{T}}\big)_{ii}=a_{ii}$.
Sketch. The diagonal entries of $aA+B$ are $aa_{ii}+b_{ii}$; add them up. Transposing fixes the diagonal: $\big(A^{\mathsf{T}}\big)_{ii}=a_{ii}$.

Matrices are added and scaled entrywise, so

$$\operatorname{tr}(aA+B)=\sum_i(aa_{ii}+b_{ii})$$

$$= a \sum_i a_{ii} + \sum_i b_{ii} = a \operatorname{tr} A + \operatorname{tr} B.$$

By Definition 2.4.21, $\left(A^{\mathsf{T}}\right)_{ii} = a_{ii}$, so $\operatorname{tr} A^{\mathsf{T}} = \operatorname{tr} A$. □

The trace is not multiplicative: for $A = \operatorname{diag}(1,0)$ and $B = \operatorname{diag}(0,1)$ we have $AB = 0$, so $\operatorname{tr}(AB) = 0$, but $\operatorname{tr} A \operatorname{tr} B = 1$. What it does satisfy is the following.

Proposition 2.4.28 (Cyclicity of the trace). For $A \in F^{m\times n}$ and $B \in F^{n\times m}$,

$$\operatorname{tr}(AB) = \operatorname{tr}(BA).$$

Intuition. Here AB is $m \times m$ and BA is $n \times n$, so the two products may not even have the same size, let alone be equal. But the diagonal entries of AB are $(AB)_{ii} = \sum_k a_{ik}b_{ki}$, so $\operatorname{tr}(AB)$ is the sum of $a_{ik}b_{ki}$ over all pairs (i,k): every entry of A multiplied by the entry of B in the mirror position. That description is symmetric in A and B. There is also an approach that avoids indices. For fixed A, both sides are linear in B, so by Technique 2.2.7 it is enough to check the identity for the matrix units of Lemma 2.4.24.

Proof (entry by entry). ROUTINE

Uses. Definition 2.4.26 (Trace), Proposition 2.4.8 (Four views of the product), Definition 1.1.1 (Field)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Write $\operatorname{tr}(AB) = \sum_i (AB)_{ii}$ and expand each diagonal entry with the entry formula.
Hint 2. You get a double sum $\sum_i \sum_k a_{ik}b_{ki}$. Exchange the order of summation and recognize the diagonal entries of BA.
Sketch. Both $\operatorname{tr}(AB)$ and $\operatorname{tr}(BA)$ expand to the double sum of $a_{ik}b_{ki}$ over all $i \le m$ and $k \le n$; the two expansions differ only in the order of summation.

By Definition 2.4.26 and Proposition 2.4.8(a),

$$\begin{aligned}\operatorname{tr}(AB) &= \sum_{i=1}^{m} (AB)_{ii} = \sum_{i=1}^{m}\sum_{k=1}^{n} a_{ik}b_{ki} \\ &= \sum_{k=1}^{n}\sum_{i=1}^{m} b_{ki}a_{ik} \\ &= \sum_{k=1}^{n} (BA)_{kk} = \operatorname{tr}(BA),\end{aligned}$$

where we exchanged the two finite sums and used commutativity of multiplication in F. □

Proof (check on matrix units). STANDARD

Uses. Lemma 2.4.24 (Matrix units), Proposition 2.4.27 (The trace is linear), Proposition 2.4.14 (Algebra of matrices), Corollary 2.2.6 (Agreeing on a spanning list), Definition 2.4.26 (Trace)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. Fix A and define $\varphi, \psi : F^{n\times m} \to F$ by $\varphi(X) = \operatorname{tr}(AX)$ and $\psi(X) = \operatorname{tr}(XA)$. Why are these linear?
Hint 2. By Corollary 2.2.6, it is enough that φ and ψ agree on the matrix units $\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}$ $(1 \le k \le n,\ 1 \le i \le m)$.
Hint 3. $A\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}$ is zero except for column i, which is $A_{:,k}$. Which diagonal entry survives? Do the same for $\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}A$ with rows.
Sketch. $\varphi(X) = \operatorname{tr}(AX)$ and $\psi(X) = \operatorname{tr}(XA)$ are linear in X by distributivity and Proposition 2.4.27. $A\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right) = A_{:,k}\mathbf{e}_i^{\mathsf{T}}$ has only column i nonzero, so its trace is its (i,i) entry a_{ik}; $\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right)A = \mathbf{e}_k A_{i,:}$ has only row k nonzero, with (k,k) entry a_{ik}. They agree on a spanning list, so $\varphi = \psi$; take $X = B$.

Fix $A \in F^{m\times n}$, and define $\varphi, \psi : F^{n\times m} \to F$ by $\varphi(X) = \operatorname{tr}(AX)$ and $\psi(X) = \operatorname{tr}(XA)$. Both are linear: for instance $\varphi(cX + Y) = \operatorname{tr}(cAX + AY) = c\varphi(X) + \varphi(Y)$ by Proposition 2.4.14 and Proposition 2.4.27. By Lemma 2.4.24(a), the matrices $\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}$ with $1 \le k \le n$ and $1 \le i \le m$ span $F^{n\times m}$, so by Corollary 2.2.6 it suffices to show $\varphi\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right) = \psi\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right)$.

By associativity and Lemma 2.4.24(b), $A\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right) = (A\mathbf{e}_k)\mathbf{e}_i^{\mathsf{T}} = A_{:,k}\mathbf{e}_i^{\mathsf{T}}$. This $m \times m$ matrix has (r,s) entry $a_{rk}\delta_{si}$, so its only nonzero column is column i, and its only diagonal entry that can be nonzero is the (i,i) entry a_{ik}. Hence $\varphi\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right) = a_{ik}$. Similarly, $\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right)A = \mathbf{e}_k\left(\mathbf{e}_i^{\mathsf{T}}A\right) = \mathbf{e}_k A_{i,:}$ is the $n \times n$ matrix with (r,s) entry $\delta_{rk}a_{is}$,

whose only possibly nonzero diagonal entry is the (k,k) entry a_{ik}. So $\psi\left(\mathbf{e}_k\mathbf{e}_i^{\mathsf{T}}\right) = a_{ik}$ as well. Hence $\varphi = \psi$, and $\varphi(B) = \psi(B)$ is the claim. □

The first proof is shorter. The second shows what linearity in B buys: only mn very simple products need to be computed, and each is a picture (one nonzero column, one nonzero row) rather than a sum.

Cyclicity extends to longer products by grouping: $\operatorname{tr}(ABC) = \operatorname{tr}(A(BC)) = \operatorname{tr}((BC)A) = \operatorname{tr}(BCA)$, and likewise $\operatorname{tr}(BCA) = \operatorname{tr}(CAB)$. A product inside a trace can be rotated, but not rearranged arbitrarily (Exercise 2.4.32). This makes the trace a test for identities in which the order of factors matters.

Technique 2.4.29 (Cyclicity of trace). The trace is linear, and it does not see the order of two factors: $\operatorname{tr}(AB) = \operatorname{tr}(BA)$, so $\operatorname{tr}(A_1A_2\cdots A_k)$ is unchanged by rotating the factors cyclically. Take the trace of both sides of a claimed identity. If the traces differ, the identity is false; and quantities such as $AB - BA$, which are invisible to the trace, can be eliminated.

Reach for it when commutators $AB - BA$ appear (they always have trace 0), when a product is conjugated as in $S^{-1}AS$ (once inverses are available, $\operatorname{tr}\left(S^{-1}AS\right) = \operatorname{tr}\left(ASS^{-1}\right) = \operatorname{tr} A$, which makes the trace a similarity invariant, Section 4.5), and when an inner product of matrices is written as $\operatorname{tr}\left(B^{\mathsf{T}}A\right)$ (Section 6.1). Only cyclic rotations are allowed: $\operatorname{tr}(ABC)$ and $\operatorname{tr}(BAC)$ differ in general. And the trace detects nothing about a matrix of trace 0; it is a single number, so it can rule things out but rarely proves them. The canonical example is Proposition 2.4.30.

Used in. Proposition 2.4.30, Exercise 2.4.50, Exercise 2.4.52, Exercise 2.4.53, Exercise 2.4.54, Exercise 2.5.44, Exercise 2.8.12, Problem 2.9, Problem 2.16, Problem 2.17, Exercise 4.3.38, Exercise 4.3.43, Proposition 4.5.27, Exercise 4.5.47, Exercise 6.4.51, Exercise 6.5.38, Problem 6.11, Problem 6.18, Proposition 7.5.25, Corollary 7.5.26, Exercise 7.5.41, Exercise 7.5.44, Exercise 7.6.56, Exercise 8.1.33, Exercise 8.1.37, Exercise 8.1.38, Exercise 8.3.34, Exercise 6.3.48.

Proposition 2.4.30 ($AB - BA \neq I$). Let $n \geq 1$, and suppose that $n * 1 \neq 0$ in F; for instance, F has characteristic 0 (Definition 1.1.28). Then $AB - BA \neq I_n$ for all $A, B \in F^{n\times n}$.

Proof. ROUTINE

Uses. Proposition 2.4.27 (The trace is linear), Proposition 2.4.28 (Cyclicity of the trace), Definition 2.4.26 (Trace)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. Take the trace of both sides of $AB - BA = I_n$.
Hint 2. By linearity and cyclicity, $\operatorname{tr}(AB - BA) = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$. What is $\operatorname{tr} I_n$?
Sketch. $\operatorname{tr}(AB - BA) = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$, but $\operatorname{tr} I_n = n * 1 \neq 0$.

By Proposition 2.4.27 and Proposition 2.4.28, $\operatorname{tr}(AB - BA) = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$. But $\operatorname{tr} I_n = 1 + \cdots + 1 = n * 1$, which is nonzero by hypothesis. So $AB - BA$ and I_n have different traces and cannot be equal. □

In terms of maps: on the infinite-dimensional space $F[x]$, differentiation D and multiplication by x satisfy $DM - MD = \mathrm{id}$, by the product rule (Exercise 2.4.51). Proposition 2.4.30 says that this identity has no solution by $n \times n$ matrices, that is, by operators on F^n, when $n * 1 \neq 0$. In quantum mechanics the same relation holds between the position and momentum operators, and this is why they cannot act on a finite-dimensional space.

Remark 2.4.31 (The hypothesis $n * 1 \neq 0$ is needed). The matrices of Example 2.4.18 satisfy

$$AB - BA = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} - \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Over $\mathbb{F}_2$, where $-1 = 1$, this is I_2. There is no contradiction with Proposition 2.4.30, because $2 * 1 = 0$ in $\mathbb{F}_2$, and indeed $\operatorname{tr} I_2 = 0$ there. In general, over $\mathbb{F}_p$ there are $p \times p$ matrices with $AB - BA = I_p$ (Exercise 2.4.52).

Exercise 2.4.32. STANDARD Find the error in the following argument, and show that its conclusion is false.

Claim. For all $A, B, C \in F^{n\times n}$, $\operatorname{tr}(ABC) = \operatorname{tr}(BAC)$.

Proof. By associativity and Proposition 2.4.28,

$$\begin{aligned}\operatorname{tr}(ABC) &= \operatorname{tr}((AB)C)\\ &= \operatorname{tr}((BA)C) = \operatorname{tr}(BAC).\end{aligned}$$

Solution on page 1140

2.4.8 Block matrices

Large matrices often have structure that is visible only when we group their entries into rectangular pieces, such as a block of zeros or a copy of the identity. Multiplication respects this grouping.

Definition 2.4.33 (Block matrix). Let $A \in F^{\ell\times m}$. Split the row indices $1, \dots, \ell$ into r consecutive groups of sizes $\ell_1, \dots, \ell_r$, so $\ell_1 + \cdots + \ell_r = \ell$, and the column indices into s consecutive groups of sizes $m_1, \dots, m_s$. The **block** $A_{IK} \in F^{\ell_I \times m_K}$ is the submatrix of A formed by the entries in the I-th group of rows and the K-th group of columns. We then write A as an $r \times s$ array of blocks,

$$A = \begin{pmatrix} A_{11} & \cdots & A_{1s} \\ \vdots & & \vdots \\ A_{r1} & \cdots & A_{rs} \end{pmatrix},$$

and call this a **block matrix**, partitioned with row sizes $\ell_1, \dots, \ell_r$ and column sizes $m_1, \dots, m_s$. A block of zeros is written 0.

For example, with row sizes $1, 2$ and column sizes $2, 2$,

$$\left(\begin{array}{cc|cc} 1 & 2 & 0 & 3 \\ \hline 0 & 1 & 4 & 5 \\ 2 & 0 & 6 & 7 \end{array}\right) = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix},$$

where, for instance, $A_{11} = \begin{pmatrix} 1 & 2 \end{pmatrix}$ and $A_{22} = \begin{pmatrix} 4 & 5 \\ 6 & 7 \end{pmatrix}$. A square block matrix with square diagonal blocks $A_{11}, \dots, A_{rr}$ is **block diagonal** if all other blocks are zero, and **block upper triangular** if $A_{IK} = 0$ whenever $I > K$.

Theorem 2.4.34 (Block multiplication). Let $A \in F^{\ell\times m}$ be partitioned with row sizes $\ell_1, \dots, \ell_r$ and column sizes $m_1, \dots, m_s$, and let $B \in F^{m\times n}$ be partitioned with row sizes $m_1, \dots, m_s$ (the column sizes of A) and column sizes $n_1, \dots, n_t$. Partition AB with row sizes $\ell_1, \dots, \ell_r$ and column sizes $n_1, \dots, n_t$. Then

$$(AB)_{IJ} = \sum_{K=1}^{s} A_{IK} B_{KJ}$$

for $1 \le I \le r$ and $1 \le J \le t$. That is, block matrices are multiplied by the entry formula, treating blocks as entries and keeping each product in its order.

Proof (entry by entry). STANDARD

Uses. Definition 2.4.33 (Block matrix), Proposition 2.4.8 (Four views of the product)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Fix an entry of AB in block (I, J), and write it with the entry formula as a sum over $k = 1, \dots, m$.
Hint 2. Split that sum according to the group of columns of A (equivalently, rows of B) that k lies in. Each piece is an entry of some $A_{IK}B_{KJ}$.

Sketch. For row i in group I and column j in group J, $(AB)_{ij} = \sum_k a_{ik}b_{kj}$. Grouping the indices k by the K-th group of columns of A, the K-th partial sum is exactly the corresponding entry of $A_{IK}B_{KJ}$, by the entry formula for that product. Adding over K gives the entry of $\sum_K A_{IK}B_{KJ}$.

Let i be the p-th row index in the I-th group of rows, and j the q-th column index in the J-th group of columns. Write G_K for the K-th group of indices in $\{1, \dots, m\}$, which has m_K elements. For k the u-th element of G_K, the entries a_{ik} and b_{kj} are the entries $(A_{IK})_{pu}$ and $\big(B_{KJ}\big)_{uq}$ of the blocks. Splitting the sum over k into the groups $G_1, \dots, G_s$,

$$\begin{aligned}(AB)_{ij} &= \sum_{k=1}^{m} a_{ik}b_{kj} = \sum_{K=1}^{s} \sum_{k\in G_K} a_{ik}b_{kj} \\ &= \sum_{K=1}^{s} \sum_{u=1}^{m_K} (A_{IK})_{pu}\big(B_{KJ}\big)_{uq} \\ &= \sum_{K=1}^{s} \big(A_{IK}B_{KJ}\big)_{pq}.\end{aligned}$$

The left side is the (p, q) entry of $(AB)_{IJ}$ and the right side is the (p, q) entry of $\sum_K A_{IK}B_{KJ}$. □

The second proof reduces the theorem to three special cases, each of which is one of the views of Proposition 2.4.8.

Proof (from the views). STANDARD

Uses. Proposition 2.4.8 (Four views of the product), Definition 2.4.33 (Block matrix)
Hint 1. Handle three special cases first: only the columns of B are split; only the rows of A are split; only the inner index is split, $A = (A_1 \ \cdots \ A_s)$ and B is $B_1, \dots, B_s$ stacked.
Hint 2. The first two cases are the column and row views. For the third, group the terms of the column–row view.
Hint 3. For the general case, block (I, J) of AB is (rows of group I of A) times (columns of group J of B) by the first two cases; now apply the third.
Sketch. By the column view, the columns of AB in group J are A times the columns of B in group J; by the row view, the rows of AB in group I are the rows of A in group I times B. So $(AB)_{IJ} = A_I B^J$, with A_I the I-th block row of A and B^J the J-th block column of B. By the column–row view, $A_I B^J = \sum_k (A_I)_{\cdot,k}\big(B^J\big)_{k,\cdot}$, and grouping the k by blocks gives $\sum_K A_{IK}B_{KJ}$.

Let A_I be the I-th block row of A, that is, the $\ell_I \times m$ matrix formed by the rows of A in the I-th group, and let B^J be the J-th block column of B, the $m \times n_J$ matrix formed by its columns in the J-th group.

By the row view (Proposition 2.4.8(c)), each row of AB in the I-th group is the corresponding row of A times B, so these rows form the matrix $A_I B$. By the column view (Proposition 2.4.8(b)), applied to $A_I B$, its columns in the J-th group are A_I times the corresponding columns of B, which form $A_I B^J$. Hence $(AB)_{IJ} = A_I B^J$.

By the column–row view (Proposition 2.4.8(d)), $A_I B^J = \sum_{k=1}^{m} (A_I)_{\cdot,k}\big(B^J\big)_{k,\cdot}$. Group the terms by the groups $G_1, \dots, G_s$ of the index k. The columns of A_I with $k \in G_K$ are the columns of A_{IK}, and the rows of B^J with $k \in G_K$ are the rows of B_{KJ}, in the same order. So by the column–row view again, applied to $A_{IK}B_{KJ}$,

$$\sum_{k\in G_K} (A_I)_{\cdot,k}\big(B^J\big)_{k,\cdot} = A_{IK}B_{KJ},$$

and summing over K gives $(AB)_{IJ} = \sum_K A_{IK}B_{KJ}$. □

In the second proof the three special cases are what to remember: blocks of columns of B produce blocks of columns of AB, blocks of rows of A produce blocks of rows of AB, and splitting the inner index turns the product into a sum. The partitions must match: the column sizes of A must be the row sizes of B, or the products $A_{IK}B_{KJ}$ are not defined. And the factors cannot be swapped, since blocks are matrices: $A_{IK}B_{KJ}$ is not $B_{KJ}A_{IK}$.

For 2×2 block matrices the theorem says that the (I, J) block of AB is $A_{I1}B_{1J} + A_{I2}B_{2J}$, exactly as for the entries of a product of 2×2 matrices. For block diagonal matrices it gives

$$\begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix}\begin{pmatrix} B_1 & 0 \\ 0 & B_2 \end{pmatrix} = \begin{pmatrix} A_1B_1 & 0 \\ 0 & A_2B_2 \end{pmatrix},$$

and for block upper triangular matrices

$$\begin{pmatrix} A_1 & X \\ 0 & A_2 \end{pmatrix}\begin{pmatrix} B_1 & Y \\ 0 & B_2 \end{pmatrix} = \begin{pmatrix} A_1B_1 & A_1Y + XB_2 \\ 0 & A_2B_2 \end{pmatrix}.$$

So block diagonal matrices multiply block by block, and in particular $\operatorname{diag}(A_1, A_2)^k = \operatorname{diag}\left(A_1^k, A_2^k\right)$, where $\operatorname{diag}(A_1, A_2)$ denotes the block diagonal matrix.

Technique 2.4.35 (Block decomposition). Split matrices into blocks that match the structure of the problem, and compute with the blocks as if they were entries (Theorem 2.4.34). Typical splittings: off a single first row and column, to set up an induction on the size; along a basis that is split into two parts, for example a basis of a subspace extended to a basis of the whole space; or around a block of zeros or a copy of I.

Reach for it when a matrix has large zero or identity blocks, when an argument should reduce from size n to size $n-1$, or when a statement concerns a map that preserves a subspace. Two checks: the partitions must match, and products of blocks must keep their order. The canonical example is Proposition 2.4.36. Later it computes determinants of block triangular matrices (Section 5.4), compares AB with BA (Section 7.3), and organizes the generalized eigenspace decomposition and the Jordan form (Section 10.2, Section 10.3).

Used in. Proposition 2.4.36, Exercise 2.4.55, Exercise 2.5.40, Exercise 2.8.9, Problem 2.13, Problem 2.16, Theorem 3.5.27, Problem 3.4, Problem 3.14, Theorem 4.7.42, Lemma 4.8.2, Exercise 4.8.13, Problem 4.12, Theorem 5.4.26, Corollary 5.4.27, Exercise 5.4.43, Exercise 5.5.47, Exercise 5.6.14, Proposition 7.3.22, Problem 7.2, Problem 7.6, Theorem 8.3.23, Exercise 2.4.37, Exercise 2.4.52, Exercise 3.5.46, Exercise 4.5.53, Exercise 6.3.63.

Recall from Exercise 2.3.38 that $A \in F^{n\times n}$ is **upper triangular** if $a_{ij} = 0$ whenever $i > j$.

Proposition 2.4.36 (Products of upper triangular matrices). If $A, B \in F^{n\times n}$ are upper triangular, then so is AB, and its diagonal entries are $(AB)_{ii} = a_{ii}b_{ii}$.

Intuition. There are two natural strategies. The entry formula $(AB)_{ij} = \sum_k a_{ik}b_{kj}$ suggests looking at which terms can be nonzero. Alternatively, an upper triangular matrix of size n is a 1×1 corner, a row, a zero column, and an upper triangular matrix of size $n-1$. That suggests block multiplication and induction on n. The second strategy is longer here, but it is the template for every later induction on the size of a triangular matrix (Section 5.3, Section 7.5).

Proof (by blocks, induction on n). STANDARD

Uses. Theorem 2.4.34 (Block multiplication), Definition 2.4.33 (Block matrix)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Partition with row and column sizes $1, n-1$. What do the blocks of an upper triangular matrix look like?
Hint 2. Write $A = \begin{pmatrix} a_{11} & \mathbf{a}^{\mathsf{T}} \\ \mathbf{0} & A' \end{pmatrix}$ and similarly for B, with A' and B' upper triangular of size $n-1$. Multiply by blocks and apply the induction hypothesis to $A'B'$.

Sketch. Induct on n; $n = 1$ is clear. Split off the first row and column: $A = \begin{pmatrix} a_{11} & \mathbf{a}^{\mathsf{T}} \\ 0 & A' \end{pmatrix}$ and $B = \begin{pmatrix} b_{11} & \mathbf{b}^{\mathsf{T}} \\ 0 & B' \end{pmatrix}$ with A', B' upper triangular. By block multiplication, AB has corner $a_{11}b_{11}$, a zero column below it, and lower right block $A'B'$, which is upper triangular with diagonal entries $a_{ii}b_{ii}$ ($i \geq 2$) by induction.

We induct on n. For $n = 1$ every matrix is upper triangular and $(AB)_{11} = a_{11}b_{11}$.

Let $n \geq 2$ and assume the claim for size $n - 1$. Partition A and B with row sizes and column sizes $1, n-1$. Since A is upper triangular, its lower left block is the zero column $\mathbf{0} \in F^{n-1}$, and its lower right block A', which has entries a_{ij} with $i, j \geq 2$, is upper triangular. So

$$A = \begin{pmatrix} a_{11} & \mathbf{a}^{\mathsf{T}} \\ \mathbf{0} & A' \end{pmatrix}, \quad B = \begin{pmatrix} b_{11} & \mathbf{b}^{\mathsf{T}} \\ \mathbf{0} & B' \end{pmatrix},$$

for some $\mathbf{a}, \mathbf{b} \in F^{n-1}$ and upper triangular $A', B' \in F^{(n-1)\times(n-1)}$. By Theorem 2.4.34, the blocks of AB are

$$a_{11}b_{11} + \mathbf{a}^{\mathsf{T}}\mathbf{0} = a_{11}b_{11}, \qquad a_{11}\mathbf{b}^{\mathsf{T}} + \mathbf{a}^{\mathsf{T}}B',$$
$$\mathbf{0}b_{11} + A'\mathbf{0} = \mathbf{0}, \qquad \mathbf{0}\mathbf{b}^{\mathsf{T}} + A'B' = A'B',$$

that is,

$$AB = \begin{pmatrix} a_{11}b_{11} & a_{11}\mathbf{b}^{\mathsf{T}} + \mathbf{a}^{\mathsf{T}}B' \\ \mathbf{0} & A'B' \end{pmatrix}.$$

By the induction hypothesis, $A'B'$ is upper triangular with diagonal entries $a_{ii}b_{ii}$ for $i = 2, \ldots, n$. So every entry of AB below the diagonal is either in the zero column or below the diagonal of $A'B'$, hence zero, and the diagonal entries of AB are $a_{11}b_{11}$ and those of $A'B'$. □

Proof (entry by entry). ROUTINE

Uses. Proposition 2.4.8 (Four views of the product)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. In $(AB)_{ij} = \sum_k a_{ik}b_{kj}$, when can the term $a_{ik}b_{kj}$ be nonzero?
Hint 2. It needs $i \leq k$ and $k \leq j$.
Sketch. $a_{ik}b_{kj} \neq 0$ forces $i \leq k \leq j$. If $i > j$ there is no such k, and if $i = j$ only $k = i$ remains.

In $(AB)_{ij} = \sum_{k=1}^{n} a_{ik}b_{kj}$, the factor a_{ik} is zero unless $i \leq k$, and b_{kj} is zero unless $k \leq j$. So only terms with $i \leq k \leq j$ can be nonzero. If $i > j$ there are none, and $(AB)_{ij} = 0$. If $i = j$, the only such term is $k = i$, so $(AB)_{ii} = a_{ii}b_{ii}$. □

A third proof translates to maps: by Exercise 2.3.38, $[T]_{\mathcal{B}\mathcal{B}}$ is upper triangular exactly when T maps each $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$ into itself, and a composite of two maps with this property has it too. That proof is the one that generalizes to triangularization in Section 7.5.

Exercise 2.4.37. ROUTINE Let $X \in F^{p\times q}$, and let $M = \begin{pmatrix} I_p & X \\ 0 & I_q \end{pmatrix}$. Show that $M^k = \begin{pmatrix} I_p & kX \\ 0 & I_q \end{pmatrix}$ for every $k \geq 1$, where $kX = X + \cdots + X$ (k terms), and that $\begin{pmatrix} I_p & X \\ 0 & I_q \end{pmatrix}\begin{pmatrix} I_p & -X \\ 0 & I_q \end{pmatrix} = I_{p+q}$.

Solution on page 1140

2.4.9 Counting walks BEYOND 21-242

Applications to graphs are not part of 21-242.

Powers of a matrix count paths. This is the simplest instance of a theme that runs through Markov chains (Section 11.1) and spectral graph theory (Section 16.5). (Another application of the matrix product, homogeneous coordinates, which turn translations of F^n into matrix products, is in Section 4.7.)

Definition 2.4.38 (Adjacency matrix). A **directed graph** G on the vertices $1, \ldots, n$ is a set of ordered pairs (i, j) of vertices, called **edges**. A **walk of length** k from i to j is a sequence of vertices $i =$

$v_0, v_1, \dots, v_k = j$ such that (v_{t-1}, v_t) is an edge for each $t = 1, \dots, k$. The **adjacency matrix** of G is the $n \times n$ matrix A over $\mathbb{Q}$ with $a_{ij} = 1$ if (i, j) is an edge and $a_{ij} = 0$ otherwise. An undirected graph is a directed graph in which (j, i) is an edge whenever (i, j) is; its adjacency matrix is symmetric.

Proposition 2.4.39 (Powers count walks). Let A be the adjacency matrix of a directed graph G on $1, \dots, n$. For every $k \geq 0$, $\left(A^k\right)_{ij}$ is the number of walks of length k from i to j. In particular, $\operatorname{tr}\left(A^k\right)$ is the number of closed walks of length k, counted with their starting vertex.

Proof. STANDARD

Uses. Proposition 2.4.8 (Four views of the product), Definition 2.4.38 (Adjacency matrix), Notation 2.4.16 (Powers of a matrix)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Induct on k. For $k = 0$, $A^0 = I_n$, and a walk of length 0 from i to j exists only when $i = j$.
Hint 2. A walk of length $k + 1$ from i to j is a walk of length k from i to some vertex l, followed by the edge (l, j). Sort the walks by l, and compare with $\left(A^{k+1}\right)_{ij} = \sum_l \left(A^k\right)_{il} a_{lj}$.
Sketch. Induct on k. Grouping the walks of length $k + 1$ from i to j by their next-to-last vertex l, there are (walks of length k from i to l) $\times\, a_{lj}$ of them for each l, and the sum over l is $\sum_l \left(A^k\right)_{il} a_{lj} = \left(A^{k+1}\right)_{ij}$.

We induct on k. For $k = 0$, $\left(A^0\right)_{ij} = \delta_{ij}$, and there is exactly one walk of length 0 from i to i (the sequence $v_0 = i$) and none from i to $j \neq i$.

Suppose the claim holds for k. A walk $v_0, \dots, v_{k+1}$ of length $k + 1$ from i to j consists of the walk $v_0, \dots, v_k$ of length k from i to $l = v_k$, followed by the edge (l, j); conversely, any walk of length k from i to l can be extended in this way exactly when (l, j) is an edge. So the number of walks of length $k + 1$ from i to j whose next-to-last vertex is l equals the number of walks of length k from i to l times a_{lj}, which is $\left(A^k\right)_{il} a_{lj}$ by the induction hypothesis. Summing over l, the number of walks of length $k + 1$ from i to j is

$$\sum_{l=1}^{n} \left(A^k\right)_{il} a_{lj} = \left(A^{k+1}\right)_{ij}.$$

The last claim follows by adding the diagonal entries. □

Example 2.4.40 (Walks in a small graph).

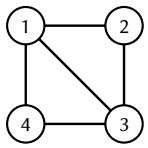

Figure 2.4.2. The undirected graph with edges $\{1, 2\}$, $\{2, 3\}$, $\{3, 4\}$, $\{4, 1\}$, and $\{1, 3\}$.

The graph of Figure 2.4.2 has

$$A = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix},$$

$$A^2 = \begin{pmatrix} 3 & 1 & 2 & 1 \\ 1 & 2 & 1 & 2 \\ 2 & 1 & 3 & 1 \\ 1 & 2 & 1 & 2 \end{pmatrix}.$$

For instance $(A^2)_{13} = 2$ counts the walks $1,2,3$ and $1,4,3$. In an undirected graph, $(A^2)_{ii}$ is the number of neighbours of i, and $(A^2)_{ij}$ is the number of common neighbours of i and j. The diagonal entries of A^3 are $4,2,4,2$, so $\operatorname{tr}(A^3) = 12$. A closed walk of length 3 in a graph without loops goes around a triangle, and each triangle gives 6 closed walks (3 starting vertices, 2 directions). So the graph has $12/6 = 2$ triangles, namely $\{1,2,3\}$ and $\{1,3,4\}$.

Exercises

Exercise 2.4.41. ROUTINE Let $D : F[x]_{\le 3} \to F[x]_{\le 2}$ be differentiation and $M : F[x]_{\le 2} \to F[x]_{\le 3}$ multiplication by x, with the bases $\mathcal{B}_2 = 1, x, x^2$ and $\mathcal{B}_3 = 1, x, x^2, x^3$.

(a) Find $[D]_{\mathcal{B}_2\mathcal{B}_3}$ and $[M]_{\mathcal{B}_3\mathcal{B}_2}$.

(b) Compute $[DM]_{\mathcal{B}_2\mathcal{B}_2}$ and $[MD]_{\mathcal{B}_3\mathcal{B}_3}$ as products of matrices, and check the answers against the formulas $DM(p) = (xp)'$ and $MD(p) = xp'$.

(c) Compare $\operatorname{tr}(DM)$ and $\operatorname{tr}(MD)$, meaning the traces of these two matrices.

Solution on page 1140

Exercise 2.4.42. STANDARD Let $D = \operatorname{diag}(d_1, \ldots, d_n) \in F^{n\times n}$.

(a) Show that $(DX)_{ij} = d_i x_{ij}$ and $(XD)_{ij} = x_{ij} d_j$ for $X \in F^{n\times n}$.

(b) Suppose $d_1, \ldots, d_n$ are distinct. Show that X commutes with D if and only if X is diagonal.

(c) Find all $X \in F^{3\times 3}$ that commute with $\operatorname{diag}(1,1,0)$.

Solution on page 1141

Exercise 2.4.43. STANDARD Let $n \ge 2$. Show that $A \in F^{n\times n}$ commutes with every upper triangular matrix in $F^{n\times n}$ if and only if $A = cI_n$ for some $c \in F$.

Solution on page 1142

Exercise 2.4.44. STANDARD Prove or disprove each statement about matrices in $F^{n\times n}$, $n \ge 2$.

(a) If $A^2 = I_n$, then $A = I_n$ or $A = -I_n$.

(b) If A and B are symmetric, then AB is symmetric.

(c) $(AB)^2 = A^2B^2$.

(d) If $F = \mathbb{R}$ and $A^{\mathsf{T}}A = 0$, then $A = 0$. What if $F = \mathbb{C}$ or $F = \mathbb{F}_2$?

(e) If A is upper triangular and $A^2 = 0$, then every diagonal entry of A is 0.

Solution on page 1142

Exercise 2.4.45. STANDARD

(a) Show that $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$ satisfies $A^2 = 0$ if and only if $a + d = 0$ and $a^2 + bc = 0$.

(b) Let p be prime. How many $A \in \mathbb{F}_p^{2\times 2}$ satisfy $A^2 = 0$?

Solution on page 1143

Exercise 2.4.46. STANDARD

(a) For $\lambda \in F$, let $J = \begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix}$. Show that $J^k = \begin{pmatrix} \lambda^k & k\lambda^{k-1} \\ 0 & \lambda^k \end{pmatrix}$ for every $k \geq 1$, where $k\lambda^{k-1}$ means $(k * 1)\lambda^{k-1}$.

(b) Deduce that $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^p = I_2$ over $\mathbb{F}_p$.

(c) Find $A \in \mathbb{F}_2^{2\times 2}$ and $A' \in \mathbb{R}^{2\times 2}$ with $A^3 = I_2$ and $A'^3 = I_2$, neither equal to I_2.

Solution on page 1143

Exercise 2.4.47. STANDARD Let $f_0 = 0$, $f_1 = 1$, and $f_{k+1} = f_k + f_{k-1}$ for $k \geq 1$ (the Fibonacci numbers), and let $Q = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \in \mathbb{Q}^{2\times 2}$.

(a) Show that $Q^k = \begin{pmatrix} f_{k+1} & f_k \\ f_k & f_{k-1} \end{pmatrix}$ for every $k \geq 1$.

(b) Deduce that $f_{m+n} = f_{m+1}f_n + f_m f_{n-1}$ for all $m, n \geq 1$, and in particular $f_{2n} = f_n(f_{n+1} + f_{n-1})$.

Solution on page 1144

Exercise 2.4.48. ROUTINE Find the error in the following computation, which claims that $(AB)^\mathsf{T} = A^\mathsf{T}B^\mathsf{T}$ for $A, B \in F^{n\times n}$:

$$\begin{aligned}\left((AB)^\mathsf{T}\right)_{ij} = (AB)_{ji} &= \sum_k a_{jk}b_{ki} \\ &= \sum_k \left(A^\mathsf{T}\right)_{kj}\left(B^\mathsf{T}\right)_{ik} = \left(A^\mathsf{T}B^\mathsf{T}\right)_{ij}.\end{aligned}$$

Solution on page 1144

Exercise 2.4.49. STANDARD Let $A \in F^{m\times n}$.

(a) Show that $\operatorname{tr}\left(A\mathbf{e}_j\mathbf{e}_i^\mathsf{T}\right) = a_{ij}$ for $1 \leq i \leq m$ and $1 \leq j \leq n$.

(b) Show that if $\operatorname{tr}(AX) = 0$ for every $X \in F^{n\times m}$, then $A = 0$.

(c) Show that every linear map $\varphi : F^{n\times m} \to F$ has the form $\varphi(X) = \operatorname{tr}(BX)$ for exactly one $B \in F^{m\times n}$.

Solution on page 1145

Exercise 2.4.50. HARD Let $\varphi : F^{n\times n} \to F$ be linear with $\varphi(AB) = \varphi(BA)$ for all $A, B \in F^{n\times n}$. Show that $\varphi = c\operatorname{tr}$ for some $c \in F$. (So the trace is, up to a scalar, the only linear functional with the property of Proposition 2.4.28.)

Solution on page 1145

Exercise 2.4.51. STANDARD Let $D, M \in \mathrm{L}(F[x])$ be differentiation and multiplication by x (Example 2.1.9).

(a) Show that $DM - MD = \mathrm{id}_{F[x]}$.

(b) Explain why (a) does not contradict Proposition 2.4.30, even over $\mathbb{Q}$.

(c) Show that if U is a subspace of $F[x]$ spanned by finitely many polynomials and $M(U) \subseteq U$, then $U = \{\mathbf{0}\}$.

Solution on page 1145

Exercise 2.4.52. HARD Let p be prime.

(a) Let $A, B \in \mathbb{F}_p^{p\times p}$ be the matrices with $A\mathbf{e}_1 = \mathbf{0}$, $A\mathbf{e}_{k+1} = k\mathbf{e}_k$ for $1 \leq k \leq p-1$, and $B\mathbf{e}_k = \mathbf{e}_{k+1}$ for $k \leq p-1$, $B\mathbf{e}_p = \mathbf{0}$. Show that $AB - BA = I_p$.

(b) Show that there are $X, Y \in \mathbb{F}_p^{n\times n}$ with $XY - YX = I_n$ if and only if p divides n.

Solution on page 1146

Exercise 2.4.53. HARD Let $A, B \in F^{n\times n}$, and suppose that $C = AB - BA$ commutes with A. Show that $\operatorname{tr}\left(C^k\right) = 0$ for every $k \geq 1$.

Solution on page 1146

Exercise 2.4.54. CHALLENGE Let $A, B \in \mathbb{R}^{n\times n}$ be symmetric. Show that $\operatorname{tr}(ABAB) \leq \operatorname{tr}\left(A^2B^2\right)$, with equality if and only if $AB = BA$.

Solution on page 1147

Exercise 2.4.55. STANDARD Let $A \in F^{p\times p}$, $X \in F^{p\times q}$, and $D \in F^{q\times q}$, and let $N = \begin{pmatrix} A & X \\ 0 & D \end{pmatrix}$.

(a) Show that $N^k = \begin{pmatrix} A^k & X_k \\ 0 & D^k \end{pmatrix}$ for every $k \geq 1$, where $X_k = \sum_{i=0}^{k-1} A^i X D^{k-1-i}$.

(b) Deduce that if $A^k = 0$ and $D^k = 0$, then $N^{2k} = 0$.

Solution on page 1147

Exercise 2.4.56. ROUTINE BEYOND 21-242 Let G be the directed graph on $1, 2, 3$ with edges $(1, 2)$, $(2, 3)$, $(3, 1)$, and $(1, 1)$.

(a) Write down its adjacency matrix A and compute A^2 and A^3.

(b) How many walks of length 3 go from 1 to 1? List them. How many closed walks of length 3 are there in all?

Solution on page 1148

Exercise 2.4.57. HARD BEYOND 21-242 Let $n \geq 2$, let $J \in \mathbb{Q}^{n\times n}$ be the matrix all of whose entries are 1, and let $A = J - I_n$, the adjacency matrix of the complete graph on n vertices (every two distinct vertices are joined).

(a) Show that $J^2 = nJ$.

(b) Show that $A^k = a_k J + (-1)^k I_n$ for $k \geq 1$, where $a_k = \left((n-1)^k - (-1)^k\right)/n$.

(c) How many walks of length k are there between two distinct vertices, and how many closed walks of length k are there in all?

Solution on page 1148

2.5 Invertibility

To solve $T(\mathbf{v}) = \mathbf{w}$ is to undo T. In F, multiplication by $a \neq 0$ is undone by multiplication by a^{-1}, and $a^{-1}a = aa^{-1} = 1$, so it does not matter on which side a^{-1} stands. For linear maps the two sides come apart, and they do different jobs. Let $T \in \mathrm{L}(V, W)$ and $S \in \mathrm{L}(W, V)$. If $ST = \mathrm{id}_V$, then every solution of $T(\mathbf{v}) = \mathbf{w}$ satisfies

$$\mathbf{v} = S(T(\mathbf{v})) = S(\mathbf{w}),$$

so there is at most one solution. If $TS = \mathrm{id}_W$, then $T(S(\mathbf{w})) = \mathbf{w}$, so $S(\mathbf{w})$ is a solution. A map that undoes T on one side therefore answers one of the two questions about $T(\mathbf{v}) = \mathbf{w}$, uniqueness or existence, and the inverses of this section are the maps that answer both.

Throughout, U, V, and W are vector spaces over F, and as in Notation 2.1.18 we write TS for $T \circ S$.

2.5.1 Left and right inverses

Definition 2.5.1 (Left inverse). Let $T \in \mathrm{L}(V, W)$. A linear map $S \in \mathrm{L}(W, V)$ is a **left inverse** of T if $ST = \mathrm{id}_V$, that is, $S(T(\mathbf{v})) = \mathbf{v}$ for every $\mathbf{v} \in V$. If T has a left inverse, T is **left-invertible**.

Likewise, for $A \in F^{m\times n}$, a matrix $B \in F^{n\times m}$ is a **left inverse** of A if $BA = I_n$, and A is **left-invertible** if it has a left inverse.

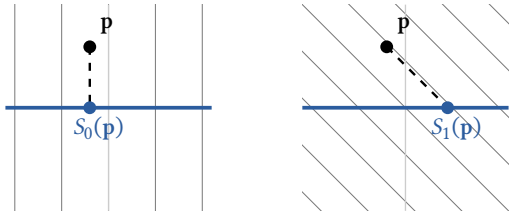
Definition 2.5.2 (Right inverse). Let $T \in \mathrm{L}(V, W)$. A linear map $S \in \mathrm{L}(W, V)$ is a **right inverse** of T if $TS = \mathrm{id}_W$, that is, $T(S(\mathbf{w})) = \mathbf{w}$ for every $\mathbf{w} \in W$. If T has a right inverse, T is **right-invertible**.

Likewise, for $A \in F^{m\times n}$, a matrix $C \in F^{n\times m}$ is a **right inverse** of A if $AC = I_m$, and A is **right-invertible** if it has a right inverse.

"Left" and "right" refer to the side on which S stands in the product that equals the identity. The two notions are mirror images: S is a left inverse of T exactly when T is a right inverse of S. Note the sizes. A one-sided inverse of an $m \times n$ matrix is $n \times m$, so that BA and AC are both defined and square, but they are identity matrices of different sizes, I_n and I_m. Also, we insist that one-sided inverses be linear; Remark 2.5.8 explains what changes without this.

The definitions for matrices are the definitions for maps, applied to T_A. Indeed $T_B T_A = T_{BA}$ by Theorem 2.4.2, and $T_{I_n} = \mathrm{id}_{F^n}$ by Proposition 2.3.13. A matrix is determined by its map (Proposition 2.3.17), so $BA = I_n$ if and only if $T_B T_A = \mathrm{id}_{F^n}$. Thus B is a left inverse of A exactly when T_B is a left inverse of T_A. Since every linear map $F^m \to F^n$ is T_B for some B, it follows that A is left-invertible exactly when T_A is. The same holds on the right, and Proposition 2.5.20 extends all of this to matrices of maps in arbitrary bases.

Example 2.5.3 (The x-axis in the plane). Let $T : F \to F^2$, $T(x) = (x, 0)$, whose standard matrix is the column $\begin{pmatrix}1\\0\end{pmatrix}$. For $c \in F$, let



$$S_c : F^2 \to F, \quad S_c(x, y) = x + cy.$$

Each S_c is linear, and $S_c(T(x)) = S_c(x, 0) = x$, so every S_c is a left inverse of T. There are no others. By Corollary 2.2.17, a linear map $S : F^2 \to F$ is $S(x, y) = ax + by$ with $a = S(\mathbf{e}_1)$ and $b = S(\mathbf{e}_2)$, and $S(T(1)) = S(\mathbf{e}_1) = a$, so $ST = \mathrm{id}_F$ forces $a = 1$. In matrix terms, the left inverses of $\begin{pmatrix}1\\0\end{pmatrix}$ are the rows $\begin{pmatrix}1 & c\end{pmatrix}$ with $c \in F$.

On the other hand, T has no right inverse. If $TS = \mathrm{id}_{F^2}$ for some $S \in \mathrm{L}\big(F^2, F\big)$, then

$$(0, 1) = T(S(0, 1)) = (S(0, 1), 0),$$

and comparing second coordinates gives $1 = 0$, which is false. The obstruction is that $(0, 1)$ is not a value of T at all.

$S_0(x, y) = x$ $\qquad$ $S_1(x, y) = x + y$

Figure 2.5.1. Two left inverses of $T(x) = (x, 0)$ over $\mathbb{R}$. The values of T form the x-axis (blue). S_c is constant along each line $x + cy = t$ (grey) and sends the whole line to its intersection $(t, 0)$ with the axis, identified with t. Both maps fix the axis pointwise, as a left inverse must, but they treat the point $\mathbf{p}$ differently.

Intuition (Choices off the image). A left inverse S of T must send $T(\mathbf{v})$ back to $\mathbf{v}$, so its values on the set $T(V)$ of values of T are forced. Off that set, S is constrained only by linearity, and in Example 2.5.3 this leaves a free choice: S_c collapses the plane onto the x-axis along the direction $(-c, 1)$, and every direction other than that of the axis itself works (Figure 2.5.1). A right inverse has the opposite problem. It must produce, for every $\mathbf{w} \in W$, a vector $S(\mathbf{w})$ with $T(S(\mathbf{w})) = \mathbf{w}$, and this is impossible as soon as some $\mathbf{w}$ is not a value of T. So left inverses are about T losing no information, and right inverses about T reaching everything.

To make this precise, recall that a function $f : X \to Y$ is *injective* if $f(x) = f(x')$ implies $x = x'$, and *surjective* if every $y \in Y$ equals $f(x)$ for some $x \in X$ (Section A.1). These properties of linear maps are the subject of Section 2.6.

Proposition 2.5.4 (Left inverses give uniqueness). Suppose $T \in \mathrm{L}(V, W)$ has a left inverse S. If $T(\mathbf{v}) = \mathbf{w}$, then $\mathbf{v} = S(\mathbf{w})$. In particular, T is injective.

Likewise, if $A \in F^{m\times n}$ has a left inverse B and $A\mathbf{x} = \mathbf{y}$, then $\mathbf{x} = B\mathbf{y}$, and T_A is injective.

Proof. ROUTINE

Uses. Definition 2.5.1 (Left inverse)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Apply S to both sides of $T(\mathbf{v}) = \mathbf{w}$.
Hint 2. For injectivity, suppose $T(\mathbf{v}) = T(\mathbf{v}')$. Both $\mathbf{v}$ and $\mathbf{v}'$ solve $T(\mathbf{x}) = \mathbf{w}$ for one and the same $\mathbf{w}$.
Sketch. Applying S to $T(\mathbf{v}) = \mathbf{w}$ gives $\mathbf{v} = S(T(\mathbf{v})) = S(\mathbf{w})$. If $T(\mathbf{v}) = T(\mathbf{v}') = \mathbf{w}$, then $\mathbf{v}$ and $\mathbf{v}'$ both equal $S(\mathbf{w})$. The matrix statement is the same argument with $BA = I_n$.

Suppose $T(\mathbf{v}) = \mathbf{w}$. Applying S to both sides and using $ST = \mathrm{id}_V$,

$$\mathbf{v} = \mathrm{id}_V(\mathbf{v}) = S(T(\mathbf{v})) = S(\mathbf{w}).$$

Now let $\mathbf{v}, \mathbf{v}' \in V$ with $T(\mathbf{v}) = T(\mathbf{v}')$, and call this vector $\mathbf{w}$. By what we just showed, $\mathbf{v} = S(\mathbf{w}) = \mathbf{v}'$. So T is injective.

For the matrix statement, if $A\mathbf{x} = \mathbf{y}$, then $\mathbf{x} = I_n\mathbf{x} = (BA)\mathbf{x} = B(A\mathbf{x}) = B\mathbf{y}$ by Theorem 2.4.2, and injectivity of T_A follows as before. □

Proposition 2.5.5 (Right inverses give existence). Suppose $T \in \mathrm{L}(V, W)$ has a right inverse S. Then for every $\mathbf{w} \in W$, the vector $\mathbf{v} = S(\mathbf{w})$ satisfies $T(\mathbf{v}) = \mathbf{w}$. In particular, T is surjective.

Likewise, if $A \in F^{m\times n}$ has a right inverse C, then $\mathbf{x} = C\mathbf{y}$ satisfies $A\mathbf{x} = \mathbf{y}$ for every $\mathbf{y} \in F^m$, and T_A is surjective.

Proof. ROUTINE

Uses. Definition 2.5.2 (Right inverse)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Fix $\mathbf{w} \in W$. Which vector could possibly map to $\mathbf{w}$, if all you know about T is $TS = \mathrm{id}_W$?
Hint 2. Compute $T(S(\mathbf{w}))$.
Sketch. $T(S(\mathbf{w})) = (TS)(\mathbf{w}) = \mathrm{id}_W(\mathbf{w}) = \mathbf{w}$, so every $\mathbf{w}$ is a value of T. For matrices, $A(C\mathbf{y}) = (AC)\mathbf{y} = I_m\mathbf{y} = \mathbf{y}$.

Let $\mathbf{w} \in W$ and $\mathbf{v} = S(\mathbf{w})$. Then

$$T(\mathbf{v}) = T(S(\mathbf{w})) = (TS)(\mathbf{w}) = \mathrm{id}_W(\mathbf{w}) = \mathbf{w}.$$

As $\mathbf{w}$ was arbitrary, every vector of W is a value of T, so T is surjective. For matrices, $A(C\mathbf{y}) = (AC)\mathbf{y} = I_m\mathbf{y} = \mathbf{y}$ by Theorem 2.4.2 and Proposition 2.3.13. □

Neither proposition says more than it claims. A left inverse produces the only possible solution, but that candidate need not be a solution. With $A = \begin{pmatrix}1\\0\end{pmatrix}$, its left inverse $B = \begin{pmatrix}1 & 0\end{pmatrix}$ from Example 2.5.3, and $\mathbf{y} = (0, 1)$, the candidate is $B\mathbf{y} = 0$, but $Ax = (x, 0) \neq \mathbf{y}$ for every x: the system has no solution at all. A right inverse

produces a solution, but not necessarily the only one. The row $A = (1 \;\; 0)$ has the right inverses $\begin{pmatrix}1\\0\end{pmatrix}$ and $\begin{pmatrix}1\\1\end{pmatrix}$, and applied to $y = 1$ they give the two different solutions $(1,0)$ and $(1,1)$ of $A\mathbf{x} = 1$. So "at most one solution" and "at least one solution" really are separate properties, detected by inverses on separate sides.

The uniqueness half has a useful reformulation for products.

Corollary 2.5.6 (One-sided cancellation). Let $T \in \mathrm{L}(V,W)$.
(a) If T is left-invertible, then $TR_1 = TR_2$ implies $R_1 = R_2$, for all $R_1, R_2 \in \mathrm{L}(U,V)$.
(b) If T is right-invertible, then $R_1T = R_2T$ implies $R_1 = R_2$, for all $R_1, R_2 \in \mathrm{L}(W,U)$.

Likewise, if $A \in F^{m\times n}$ is left-invertible, then $AX = AY$ implies $X = Y$ for $X, Y \in F^{n\times p}$, and if A is right-invertible, then $XA = YA$ implies $X = Y$ for $X, Y \in F^{p\times m}$.

Proof. ROUTINE

Uses. Definition 2.5.1 (Left inverse), Definition 2.5.2 (Right inverse), Proposition 2.1.24 (Algebra of composition), Proposition 2.4.14 (Algebra of matrices)
Hint 1. Multiply both sides of $TR_1 = TR_2$ by a left inverse S of T, on the left.
Hint 2. Regroup with associativity: $S(TR_i) = (ST)R_i = R_i$.
Sketch. With $ST = \mathrm{id}_V$: $R_1 = (ST)R_1 = S(TR_1) = S(TR_2) = (ST)R_2 = R_2$. With $TS = \mathrm{id}_W$: $R_1 = R_1(TS) = (R_1T)S = (R_2T)S = R_2$. Matrices are the same with Proposition 2.4.14.

(a) Let S be a left inverse of T. By Proposition 2.1.24,

$$\begin{aligned} R_1 &= \mathrm{id}_V R_1 = (ST)R_1 = S(TR_1) \\ &= S(TR_2) = (ST)R_2 = \mathrm{id}_V R_2 = R_2. \end{aligned}$$

(b) Let S be a right inverse of T. Then

$$\begin{aligned} R_1 &= R_1\mathrm{id}_W = R_1(TS) = (R_1T)S \\ &= (R_2T)S = R_2(TS) = R_2. \end{aligned}$$

The matrix statements are the same computations, with $BA = I_n$ or $AC = I_m$ and associativity and identities from Proposition 2.4.14. □

This answers the question left open in Example 2.4.19: a left-invertible matrix can be cancelled on the left, and in particular $AX = 0$ forces $X = 0$. The side matters. $A = \begin{pmatrix}1\\0\end{pmatrix}$ is left-invertible, yet $(0 \;\; 1)A = 0 = (0 \;\; 0)A$; cancelling A on the right would need a right inverse.

Remark 2.5.7 (The converses). Every injective linear map between finite-dimensional spaces has a left inverse, and every surjective one has a right inverse. For T_A these statements are among the Fundamental Theorems (Theorem 2.7.2, Theorem 2.7.4), which are stated in Section 2.7, where one-sided inverses are also built directly from a basis, and completed in Section 3.5, where they are constructed by row reduction. The converses are harder than the two propositions because a left inverse must be defined, linearly, on all of W, while injectivity of T only says what it has to do on $T(V)$.

Remark 2.5.8 (Why one-sided inverses must be linear). Every injective function $f : X \to Y$ with X nonempty has a left inverse function, and every surjective function has a right inverse function (Section A.1). For a linear map we ask for more, a *linear* one-sided inverse. Without linearity there are many more left inverses: for $T(x) = (x, 0)$ from $\mathbb{R}$ to $\mathbb{R}^2$, the function $g(x,y) = x + y^2$ satisfies $g(T(x)) = x$ for all x, but g is not linear, since $g(0,2) = 4 \neq 2g(0,1)$. For two-sided inverses the distinction disappears: the inverse function of a bijective linear map is automatically linear (Proposition 2.7.7).

Exercise 2.5.9. ROUTINE Let $A \in F^{m\times n}$.

(a) Show that if some column of A is zero, then A has no left inverse.

(b) Show that if some row of A is zero, then A has no right inverse.

Solution on page 1149

2.5.2 Invertible maps and matrices

In Example 2.5.3 the map T had many left inverses and no right inverse. That is no accident. A left inverse S_l and a right inverse S_r of T are both maps $W \to V$, and to compare them we want a single expression that involves both. The composite $S_l T S_r$ is one: grouping it as $S_l(TS_r)$ uses that S_r is a right inverse, and grouping it as $(S_lT)S_r$ uses that S_l is a left inverse.

Theorem 2.5.10 (Left and right inverses agree). Let $T \in \mathrm{L}(V,W)$. If $S_l \in \mathrm{L}(W,V)$ is a left inverse of T and $S_r \in \mathrm{L}(W,V)$ is a right inverse of T, then $S_l = S_r$.

Consequently, if T has both a left inverse and a right inverse, then it has exactly one left inverse and exactly one right inverse, these are equal, and this map is both a left and a right inverse of T.

The same holds for matrices: if $A \in F^{m\times n}$ and $B, C \in F^{n\times m}$ satisfy $BA = I_n$ and $AC = I_m$, then $B = C$.

Proof. ROUTINE

Uses. Definition 2.5.1 (Left inverse), Definition 2.5.2 (Right inverse), Proposition 2.1.24 (Algebra of composition), Proposition 2.4.14 (Algebra of matrices)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Find one composite that involves S_l, T, and S_r, and evaluate it in two ways.
Hint 2. Group S_lTS_r as $S_l(TS_r)$, and then as $(S_lT)S_r$.
Hint 3. For the second paragraph: if R is another left inverse, apply the first paragraph to R and S_r.
Sketch. By associativity, $S_l = S_l\mathrm{id}_W = S_l(TS_r) = (S_lT)S_r = \mathrm{id}_V S_r = S_r$. Every left inverse therefore equals the fixed right inverse S_r, so there is only one left inverse; symmetrically there is only one right inverse, and the two coincide. Matrices: $B = B(AC) = (BA)C = C$.

By Proposition 2.1.24,

$$\begin{aligned} S_l &= S_l\mathrm{id}_W && \text{(identity)} \\ &= S_l(TS_r) && \text{(as } S_r \text{ is a right inverse)} \\ &= (S_lT)S_r && \text{(associativity)} \\ &= \mathrm{id}_V S_r && \text{(as } S_l \text{ is a left inverse)} \\ &= S_r && \text{(identity).} \end{aligned}$$

Now suppose T has a left inverse S_l and a right inverse S_r. If R is any left inverse, the first part applied to R and S_r gives $R = S_r$. So every left inverse equals S_r, and T has exactly one left inverse, namely S_r. In the same way every right inverse equals S_l, so S_l is the only right inverse. Finally, the common map $S_l = S_r$ is a left inverse (as S_l) and a right inverse (as S_r).

For matrices, by Proposition 2.4.14,

$$B = BI_m = B(AC) = (BA)C = I_nC = C,$$

and the rest follows as for maps. □

This is Technique 1.1.8 once more. The expression S_lTS_r plays the role that $0 + 0'$ played for the zero of a field (Theorem 1.1.9): it is evaluated twice, once using the property of each candidate. Read contrapositively, the theorem explains Example 2.5.3.

Corollary 2.5.11 (Many one-sided inverses). If $T \in \mathrm{L}(V, W)$ has two different left inverses, then T has no right inverse. If T has two different right inverses, then T has no left inverse. The same holds for matrices.

Proof. ROUTINE

Uses. Theorem 2.5.10 (Left and right inverses agree)
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. Prove the contrapositive.
Hint 2. If T has a right inverse and a left inverse, how many left inverses can it have?
Sketch. If T had a right inverse S_r, then by Theorem 2.5.10 every left inverse would equal S_r, so any two left inverses would be equal. The second statement is symmetric.

Suppose S and S' are left inverses of T and T has a right inverse S_r. By Theorem 2.5.10, $S = S_r$ and $S' = S_r$, so $S = S'$. Hence if T has two different left inverses, it has no right inverse. The statement about right inverses is proved the same way, and the matrix statements follow from the matrix part of Theorem 2.5.10. □

In Example 2.5.3, $S_0(x, y) = x$ and $S_1(x, y) = x + y$ are different left inverses of T, since $S_0(0, 1) = 0 \neq 1 = S_1(0, 1)$. So Corollary 2.5.11 gives a second proof that T has no right inverse, one that never needed to find a vector outside $T(F)$.

Definition 2.5.12 (Invertible). A linear map $T \in \mathrm{L}(V, W)$ is **invertible** if there is a linear map $S \in \mathrm{L}(W, V)$ that is both a left and a right inverse of T:

$$ST = \mathrm{id}_V \quad \text{and} \quad TS = \mathrm{id}_W.$$

Such an S is a **two-sided inverse** of T. By Theorem 2.5.10, T is invertible if and only if it is both left-invertible and right-invertible, and in that case it has exactly one two-sided inverse, called **the inverse** of T and written T^{-1}.

Likewise, $A \in F^{m\times n}$ is **invertible** if there is $B \in F^{n\times m}$ with $BA = I_n$ and $AB = I_m$. Again B is unique; it is **the inverse** of A, written A^{-1}, and A is invertible if and only if it is both left-invertible and right-invertible.

So an invertible map satisfies $T^{-1}T = \mathrm{id}_V$ and $TT^{-1} = \mathrm{id}_W$. By Proposition 2.5.4 and Proposition 2.5.5 it is injective and surjective, so for every $\mathbf{w} \in W$ the equation $T(\mathbf{v}) = \mathbf{w}$ has exactly one solution, $\mathbf{v} = T^{-1}(\mathbf{w})$. In particular T^{-1} is the inverse function of the bijection T. Conversely, every bijective linear map is invertible, because its inverse function turns out to be linear (Proposition 2.7.7). By the discussion after Definition 2.5.2, a matrix A is invertible exactly when T_A is, and then $(T_A)^{-1} = T_{A^{-1}}$; this is also part (c) of Proposition 2.5.20 below.

Remark 2.5.13 (Invertible matrices are square). The definition does not ask A to be square, and nothing so far rules out an invertible $m \times n$ matrix with $m \neq n$: Theorem 2.5.10 shows that a left inverse and a right inverse coincide, not that $m = n$. In fact every invertible matrix is square (Corollary 3.5.15). The proof uses rank (Section 3.5), although over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$ the trace gives a short argument (Exercise 2.5.44). Nothing below depends on it.

Example 2.5.14 (Invertible maps and matrices).

(a) id_V is its own inverse, and $I_n^{-1} = I_n$. For $c \in F$ with $c \neq 0$, $c\mathrm{id}_V$ is invertible with inverse $c^{-1}\mathrm{id}_V$, since $\big(c^{-1}\mathrm{id}_V\big)(c\mathrm{id}_V) = \big(c^{-1}c\big)\mathrm{id}_V = \mathrm{id}_V$ in both orders (Proposition 2.1.24(d)).

(b) Rotating by θ and then by $-\theta$ in either order is rotating by 0, so $R_\theta R_{-\theta} = R_{-\theta}R_\theta = \mathrm{id}_{\mathbb{R}^2}$ (Exercise 2.1.43), and $R_\theta^{-1} = R_{-\theta}$. In matrices,

$$\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}^{-1} = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix}.$$

A reflection satisfies $S_\ell^2 = \mathrm{id}_{\mathbb{R}^2}$ (Exercise 2.1.42), so it is its own inverse: reflecting twice returns every point.

(c) For a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of V, the coordinate map $V \to F^n$, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$, is invertible, and its inverse is $(a_1, \ldots, a_n) \mapsto a_1\mathbf{b}_1 + \cdots + a_n\mathbf{b}_n$ (Example 2.1.8).

(d) If $d_1, \ldots, d_n \in F$ are all nonzero, then $\mathrm{diag}(d_1, \ldots, d_n)$ is invertible with inverse $\mathrm{diag}\big(d_1^{-1}, \ldots, d_n^{-1}\big)$, because diagonal matrices multiply entry by entry (Example 2.4.10). If some $d_i = 0$, then column i is zero, and Exercise 2.5.9 shows that the matrix has no left inverse.

(e) Suppose $1 + 1 \neq 0$ in F, and write $2 = 1 + 1$. Let $T : F[x] \to F[x]$ be $\sum_k a_k x^k \mapsto \sum_k 2^k a_k x^k$, the substitution $p(x) \mapsto p(2x)$. The map $S : \sum_k a_k x^k \mapsto \sum_k 2^{-k} a_k x^k$ is linear for the same reason as T, and both ST and TS multiply the coefficient of each x^k by $2^k 2^{-k} = 1$. So $T^{-1} = S$, that is, $T^{-1}(p) = p(x/2)$.

(f) The map $T(x, y) = (y, x - y)$ of Exercise 2.1.25 satisfies $T(T + \mathrm{id}) = (T + \mathrm{id})T = \mathrm{id}$, so $T^{-1} = T + \mathrm{id}$, that is, $T^{-1}(x, y) = (x + y, x)$.

Non-example 2.5.15 (Maps that are not invertible). The projection Pr_ℓ onto a line ℓ through $\mathbf{0}$ in $\mathbb{R}^2$ (Example 2.1.11) is neither left- nor right-invertible: it sends every vector perpendicular to ℓ to $\mathbf{0}$, so it is not injective, and its values all lie on ℓ, so it is not surjective. The zero map $V \to W$ is not left-invertible unless $V = \{\mathbf{0}\}$, and not right-invertible unless $W = \{\mathbf{0}\}$. Differentiation D on $F[x]$ is not left-invertible, since $D(1) = 0 = D(0)$; whether it is right-invertible is taken up in Example 2.5.24.

2.5.3 The algebra of inverses

To show that a map is invertible, we never have to solve for its inverse. It is enough to name a candidate and check it.

> **Technique 2.5.16** (Guess the inverse, then check both products). To show that T is invertible and to identify T^{-1}, produce a candidate S and verify $ST = \mathrm{id}$ and $TS = \mathrm{id}$. Then T is invertible and $S = T^{-1}$, by the uniqueness in Theorem 2.5.10. How the candidate was found plays no role in the proof.
>
> Candidates come from undoing: to undo a rotation by θ, rotate by $-\theta$, and to undo a composite, undo its steps in reverse order. A polynomial identity also produces one: if $T^2 + T = \mathrm{id}$, then $T(T + \mathrm{id}) = \mathrm{id} = (T + \mathrm{id})T$, and if $N^k = 0$, then $(\mathrm{id} - N)\big(\mathrm{id} + N + \cdots + N^{k-1}\big) = \mathrm{id} - N^k = \mathrm{id}$, which is the geometric series $1/(1 - x) = 1 + x + x^2 + \cdots$ cut off (Exercise 2.5.39). Heuristics of this kind may be as informal as you like, because the verification is what proves the result.
>
> Check both products, unless you already know that T has an inverse on the other side. One product shows only that S is a one-sided inverse, and one-sided inverses need not be two-sided (Example 2.5.24). The canonical example is Proposition 2.5.17.
>
> *Used in.* Proposition 2.5.17, Proposition 2.5.26, Proposition 2.5.28, Exercise 2.5.38, Exercise 2.5.39, Exercise 2.5.40, Exercise 2.5.47, Exercise 2.7.31, Exercise 2.8.9, Exercise 2.8.10, Exercise 2.8.14, Problem 2.5, Problem 2.10, Exercise 4.3.37, Proposition 6.6.18, Exercise 2.5.19, Exercise 2.5.22, Exercise 2.5.35, Exercise 8.1.35.

Intuition (Socks and shoes). To undo "first put on socks, then shoes", take off the shoes first, then the socks. Likewise, to undo TS, which is "first S, then T", first undo T and then undo S. So the candidate for $(TS)^{-1}$ is $S^{-1}T^{-1}$, with the order reversed, as it was for transposes in Proposition 2.4.23.

Proposition 2.5.17 (Algebra of inverses).

(a) If $T \in \mathrm{L}(V,W)$ is invertible, then so is T^{-1}, and $\left(T^{-1}\right)^{-1} = T$.

(b) If $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$ are invertible, then so is $TS \in \mathrm{L}(U,W)$, and

$$(TS)^{-1} = S^{-1}T^{-1}.$$

(c) If $T \in \mathrm{L}(V,W)$ is invertible and $a \in F$ is nonzero, then aT is invertible, and $(aT)^{-1} = a^{-1}T^{-1}$.

(d) Statements (a)–(c) hold for matrices of compatible sizes. Moreover, if $A \in F^{m\times n}$ is invertible, then so is A^{T}, and $\left(A^{\mathsf{T}}\right)^{-1} = \left(A^{-1}\right)^{\mathsf{T}}$.

Proof. ROUTINE

Uses. Definition 2.5.12 (Invertible), Theorem 2.5.10 (Left and right inverses agree), Proposition 2.1.24 (Algebra of composition), Proposition 2.4.14 (Algebra of matrices), Proposition 2.4.23 (Transpose of a product), Proposition 2.4.22 (Transpose is a linear involution)

Techniques. Guess the inverse, then check both products (Technique 2.5.16)

Hint 1. In each part the formula names the candidate. Multiply it by the given map on both sides and simplify.

Hint 2. For (b), regroup $(TS)\left(S^{-1}T^{-1}\right)$ as $T\left(SS^{-1}\right)T^{-1}$.

Hint 3. For (d), transpose the equations $A^{-1}A = I_n$ and $AA^{-1} = I_m$ with Proposition 2.4.23.

Sketch. (a) The equations $T^{-1}T = \mathrm{id}_V$ and $TT^{-1} = \mathrm{id}_W$ say that T is a two-sided inverse of T^{-1}. (b) $(TS)\left(S^{-1}T^{-1}\right) = T\left(SS^{-1}\right)T^{-1} = TT^{-1} = \mathrm{id}_W$, and similarly in the other order. (c) $\left(a^{-1}T^{-1}\right)(aT) = \left(a^{-1}a\right)T^{-1}T = \mathrm{id}_V$, and similarly. (d) $A^{\mathsf{T}}\left(A^{-1}\right)^{\mathsf{T}} = \left(A^{-1}A\right)^{\mathsf{T}} = I_n$ and $\left(A^{-1}\right)^{\mathsf{T}}A^{\mathsf{T}} = \left(AA^{-1}\right)^{\mathsf{T}} = I_m$.

In each part we exhibit a two-sided inverse; by Definition 2.5.12 the map or matrix is then invertible, and by Theorem 2.5.10 the exhibited inverse is *the* inverse.

(a) The equations $T^{-1}T = \mathrm{id}_V$ and $TT^{-1} = \mathrm{id}_W$, read with T^{-1} as the map being inverted, say that T is a left and a right inverse of T^{-1}. So T^{-1} is invertible with inverse T.

(b) By associativity and the identity laws (Proposition 2.1.24),

$$\begin{aligned}(TS)\left(S^{-1}T^{-1}\right) &= T\left(SS^{-1}\right)T^{-1} = T\mathrm{id}_V T^{-1}\\ &= TT^{-1} = \mathrm{id}_W,\\ \left(S^{-1}T^{-1}\right)(TS) &= S^{-1}\left(T^{-1}T\right)S = S^{-1}\mathrm{id}_V S\\ &= S^{-1}S = \mathrm{id}_U.\end{aligned}$$

(c) By Proposition 2.1.24(d), $\left(a^{-1}T^{-1}\right)(aT) = \left(a^{-1}a\right)\left(T^{-1}T\right) = \mathrm{id}_V$, and likewise $(aT)\left(a^{-1}T^{-1}\right) = \mathrm{id}_W$.

(d) For matrices, the computations in (a)–(c) work verbatim, with Proposition 2.4.14 in place of Proposition 2.1.24 and identity matrices in place of identity maps. For the transpose, $A^{-1} \in F^{n\times m}$, with $A^{-1}A = I_n$ and $AA^{-1} = I_m$. By Proposition 2.4.23 and Proposition 2.4.22,

$$\begin{aligned}A^{\mathsf{T}}\left(A^{-1}\right)^{\mathsf{T}} &= \left(A^{-1}A\right)^{\mathsf{T}} = I_n^{\mathsf{T}} = I_n,\\ \left(A^{-1}\right)^{\mathsf{T}}A^{\mathsf{T}} &= \left(AA^{-1}\right)^{\mathsf{T}} = I_m^{\mathsf{T}} = I_m,\end{aligned}$$

so $\left(A^{-1}\right)^{\mathsf{T}}$ is a two-sided inverse of A^{T}. □

By induction on k, part (b) gives $(T_1T_2\cdots T_k)^{-1} = T_k^{-1}\cdots T_2^{-1}T_1^{-1}$ for invertible $T_1,\ldots,T_k$ that can be composed, and in particular $\left(T^k\right)^{-1} = \left(T^{-1}\right)^k$ for invertible $T \in \mathrm{L}(V)$. We write T^{-k} for this map, and A^{-k} for $\left(A^{-1}\right)^k$.

Part (b) also runs backwards: if two of S, T, and TS are invertible, the third can be written as a product of invertible maps.

Corollary 2.5.18 (Two out of three). Let $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$. If two of S, T, and TS are invertible, then so is the third. The same holds for matrices.

Proof. ROUTINE

Uses. Proposition 2.5.17 (Algebra of inverses), Proposition 2.1.24 (Algebra of composition)
Hint 1. If S and T are invertible, this is Proposition 2.5.17(b). In the other two cases, express the unknown factor as a product of two invertible maps.
Hint 2. $S = T^{-1}(TS)$ and $T = (TS)S^{-1}$.
Sketch. The case where S and T are invertible is Proposition 2.5.17(b). If T and TS are invertible, then $S = T^{-1}(TS)$ is a product of invertible maps; if S and TS are, then $T = (TS)S^{-1}$ is. Apply Proposition 2.5.17(a) and (b).

If S and T are invertible, then TS is invertible by Proposition 2.5.17(b).

If T and TS are invertible, then by associativity $T^{-1}(TS) = \big(T^{-1}T\big)S = S$. The map T^{-1} is invertible by Proposition 2.5.17(a), so S is a composite of two invertible maps, which is invertible by Proposition 2.5.17(b). Explicitly, $S^{-1} = (TS)^{-1}T$.

If S and TS are invertible, then $(TS)S^{-1} = T\big(SS^{-1}\big) = T$ is invertible in the same way, with $T^{-1} = S(TS)^{-1}$. The matrix case is identical. □

If only TS is known to be invertible, neither factor need be (Example 2.5.27).

Exercise 2.5.19. ROUTINE Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$ in $\mathbb{Q}^{2\times 2}$.

(a) Check that $A^{-1} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$ and $B^{-1} = \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}$.

(b) Compute $(AB)^{-1}$, $A^{-1}B^{-1}$, and $B^{-1}A^{-1}$. Which two agree?

Solution on page 1149

Inverses also translate between maps and matrices, in every pair of bases. The proof is a direct application of Technique 2.3.27.

Proposition 2.5.20 (Inverses and matrices). Let $\mathcal{B}$ be a basis of V of length n and $\mathcal{C}$ a basis of W of length m, and let $T \in \mathrm{L}(V,W)$ and $S \in \mathrm{L}(W,V)$.

(a) S is a left inverse of T if and only if $[S]_{\mathcal{B}\mathcal{C}}$ is a left inverse of $[T]_{\mathcal{C}\mathcal{B}}$, and S is a right inverse of T if and only if $[S]_{\mathcal{B}\mathcal{C}}$ is a right inverse of $[T]_{\mathcal{C}\mathcal{B}}$.

(b) T is left-invertible, right-invertible, or invertible if and only if $[T]_{\mathcal{C}\mathcal{B}}$ is. If T is invertible, then

$$\big[T^{-1}\big]_{\mathcal{B}\mathcal{C}} = \big([T]_{\mathcal{C}\mathcal{B}}\big)^{-1}.$$

(c) In particular, $A \in F^{m\times n}$ is left-invertible, right-invertible, or invertible if and only if T_A is, and if A is invertible, then $(T_A)^{-1} = T_{A^{-1}}$.

Proof. STANDARD

Uses. Theorem 2.4.2 (The matrix of a composite), Example 2.3.6 (The zero map and the identity map), Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 2.3.16 (The matrix of T_A), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Definition 2.5.12 (Invertible)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. By Theorem 2.4.2, $[S]_{\mathcal{B}\mathcal{C}}[T]_{\mathcal{C}\mathcal{B}} = [ST]_{\mathcal{B}\mathcal{B}}$. What is the matrix of id_V in the bases $\mathcal{B}, \mathcal{B}$?
Hint 2. Two maps $V \to V$ are equal exactly when their matrices in $\mathcal{B}, \mathcal{B}$ are equal (Theorem 2.3.20(a)).
Hint 3. For the "if" in (b), you are given a matrix. Use Theorem 2.3.20(b) to find a map with that matrix, then apply (a).
Sketch. (a) $[S]_{\mathcal{B}\mathcal{C}}[T]_{\mathcal{C}\mathcal{B}} = [ST]_{\mathcal{B}\mathcal{B}}$ and $I_n = [\mathrm{id}_V]_{\mathcal{B}\mathcal{B}}$, and maps $V \to V$ are determined by their matrices, so $ST = \mathrm{id}_V$ iff the matrix product is I_n; the right side is the same with TS and I_m. (b) "Only if" is (a). For "if", realize a one-sided inverse X of $[T]$ as $[S]$ by Theorem 2.3.20(b) and apply (a). The inverse formula is (a) plus uniqueness. (c) is (b) for the standard bases, where $[T_A]_{\mathcal{E}\mathcal{E}} = A$.

(a) By Theorem 2.4.2, $[S]_{\mathcal{BC}}[T]_{\mathcal{CB}} = [ST]_{\mathcal{BB}}$, and by Example 2.3.6, $[\mathrm{id}_V]_{\mathcal{BB}} = I_n$. Both ST and id_V lie in $\mathrm{L}(V)$, and by Theorem 2.3.20(a) (with the basis $\mathcal{B}$ on both sides) they are equal if and only if their matrices are. So

$$\begin{aligned} ST = \mathrm{id}_V &\iff [ST]_{\mathcal{BB}} = [\mathrm{id}_V]_{\mathcal{BB}} \\ &\iff [S]_{\mathcal{BC}}[T]_{\mathcal{CB}} = I_n. \end{aligned}$$

In the same way, $TS = \mathrm{id}_W$ if and only if $[T]_{\mathcal{CB}}[S]_{\mathcal{BC}} = [TS]_{\mathcal{CC}} = [\mathrm{id}_W]_{\mathcal{CC}} = I_m$.

(b) If T has a left inverse S, then $[S]_{\mathcal{BC}}$ is a left inverse of $[T]_{\mathcal{CB}}$ by (a). Conversely, suppose $X \in F^{n\times m}$ is a left inverse of $[T]_{\mathcal{CB}}$. By Theorem 2.3.20(b) there is $S \in \mathrm{L}(W, V)$ with $[S]_{\mathcal{BC}} = X$, and by (a) this S is a left inverse of T. The same argument works for right inverses, and invertibility means having both (Definition 2.5.12).

If T is invertible, then by (a) the matrix $\left[T^{-1}\right]_{\mathcal{BC}}$ is both a left and a right inverse of $[T]_{\mathcal{CB}}$. By the uniqueness in Definition 2.5.12, it is $\left([T]_{\mathcal{CB}}\right)^{-1}$.

(c) Apply (b) to $T_A \in \mathrm{L}(F^n, F^m)$ with the standard bases, where $[T_A]_{\mathcal{EE}} = A$ (Proposition 2.3.16). If A is invertible, (b) gives $\left[(T_A)^{-1}\right]_{\mathcal{EE}} = A^{-1}$, so $(T_A)^{-1} = T_{A^{-1}}$ by Proposition 2.3.17. □

Example 2.5.21 (Change of coordinates is invertible). Let $\mathcal{B}$ and $\mathcal{C}$ be bases of V. The identity map id_V is its own inverse, so by Proposition 2.5.20(b), applied with the basis $\mathcal{B}$ on the domain and $\mathcal{C}$ on the target,

$$\left([\mathrm{id}_V]_{\mathcal{CB}}\right)^{-1} = [\mathrm{id}_V]_{\mathcal{BC}}.$$

The matrix converting $\mathcal{B}$-coordinates into $\mathcal{C}$-coordinates is invertible, and its inverse converts back. Example 2.4.5(c) checked one instance by multiplying out. These matrices are the subject of Section 4.5. Once we know that invertible matrices are square (Corollary 3.5.15), this also shows that any two bases of the same space have the same length, which Section 4.1 proves by other means.

Exercise 2.5.22. ROUTINE Let $T \in \mathrm{L}\left(F[x]_{\le 2}\right)$ be the shift $T(p) = p(x+1)$, whose matrix in $\mathcal{B} = 1, x, x^2$ is $[T]_{\mathcal{BB}} = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}$ (Example 2.4.13). Let $S \in \mathrm{L}\left(F[x]_{\le 2}\right)$ be the shift $S(p) = p(x-1)$. Compute $[S]_{\mathcal{BB}}$, and use Proposition 2.5.20 to show that T is invertible with $T^{-1} = S$.

Solution on page 1150

2.5.4 One-sided inverses that are not two-sided

Here are the main sources of maps and matrices that have an inverse on one side but not on the other. In each example below there are many inverses on the one side, and by Corollary 2.5.11 having two of them already rules out an inverse on the other side.

Matrices that are not square

Example 2.5.23 (One-sided inverses of a tall matrix). Let $p, q \ge 1$ and $X \in F^{q\times p}$, and consider the $(p+q)\times p$ matrix

$$A = \begin{pmatrix} I_p \\ X \end{pmatrix}.$$

It sends $\mathbf{x} \in F^p$ to $(\mathbf{x}, X\mathbf{x})$, the vector $\mathbf{x}$ followed by q more entries. For every $Y \in F^{p\times q}$, block multiplication (Theorem 2.4.34) gives

$$\begin{pmatrix} I_p - YX & Y \end{pmatrix}\begin{pmatrix} I_p \\ X \end{pmatrix}$$

$$= \big(I_p - YX\big) + YX = I_p,$$

so $B_Y = \begin{pmatrix} I_p - YX & Y \end{pmatrix}$ is a left inverse of A. These are all of them: if $B = \begin{pmatrix} B_1 & B_2 \end{pmatrix}$ with $B_1 \in F^{p\times p}$ and $B_2 \in F^{p\times q}$ satisfies $BA = B_1 + B_2X = I_p$, then $B_1 = I_p - B_2X$, so $B = B_{B_2}$. Different Y give different B_Y, since Y is the right block of B_Y, so A has more than one left inverse, and therefore no right inverse (Corollary 2.5.11).

For instance, take $p = 2$, $q = 1$, and $X = \begin{pmatrix} 2 & -1 \end{pmatrix}$. With $Y = \begin{pmatrix} s \\ t \end{pmatrix}$, the left inverses of

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 2 & -1 \end{pmatrix}$$

are the matrices

$$B_{s,t} = \begin{pmatrix} 1-2s & s & s \\ -2t & 1+t & t \end{pmatrix} \quad (s,t \in F).$$

The simplest, $B_{0,0} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$, reads off the first two entries. The others also use the third entry $2x_1 - x_2$, which is redundant information, so it can be mixed in with any weight.

Transposing turns this into right inverses of wide matrices: $(BA)^{\mathsf{T}} = A^{\mathsf{T}}B^{\mathsf{T}}$, so B is a left inverse of A exactly when B^{T} is a right inverse of A^{T} (Exercise 2.5.45). The pattern is general. A left-invertible $m \times n$ matrix has $n \le m$, and a right-invertible one has $n \ge m$ (Theorem 3.5.12, Theorem 3.5.13). So a matrix that is not square can have an inverse on at most one side.

Differentiation and integration

Example 2.5.24 (Differentiation has a right inverse but no left inverse). Let F be a field of characteristic 0 (Definition 1.1.28), such as $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, so that $k * 1 = 1 + \cdots + 1$ (k terms) is nonzero for every $k \ge 1$; we write $1/k$ for its inverse. Let $D : F[x] \to F[x]$ be differentiation (Example 2.1.9), and let $J : F[x] \to F[x]$ be the antiderivative with constant term 0,

$$J\left(\sum_{k=0}^{n} a_k x^k\right) = \sum_{k=0}^{n} \frac{a_k}{k+1} x^{k+1}.$$

Like D, the map J moves each coefficient to a fixed place and multiplies it by a fixed scalar, so it is linear.

- $DJ = \mathrm{id}_{F[x]}$. Both sides are linear, and $D\Big(J\big(x^k\big)\Big) = D\big(x^{k+1}/(k+1)\big) = x^k$ for every $k \ge 0$. The monomials span $F[x]$, so $DJ = \mathrm{id}$ by Corollary 2.2.6. So J is a right inverse of D, and D is a left inverse of J. This is the fundamental theorem of calculus, in its polynomial form.
- $JD \ne \mathrm{id}_{F[x]}$, since $J(D(1)) = J(0) = 0$. In general $J(D(p)) = p - a_0$: differentiating loses the constant term, and J cannot recover it.
- D has no left inverse, since $D(1) = 0 = D(0)$ shows that D is not injective (Proposition 2.5.4). J has no right inverse, since every value of J has constant term 0, so 1 is not a value of J (Proposition 2.5.5).
- D has many right inverses. If $E \in \mathrm{L}(F[x])$ takes only constant values, then $DE = 0$ and $D(J + E) = \mathrm{id}$. For instance, for $t \in F$ the map $J_t(p) = J(p) - (J(p))(t)$, where the scalar $(J(p))(t)$ is subtracted as a constant polynomial, is a right inverse of D. It sends p to its antiderivative that vanishes at t, and $J_0 = J$.

The same happens between finite-dimensional spaces of different dimensions. For $n \ge 1$, differentiation $D : F[x]_{\le n} \to F[x]_{\le n-1}$ and the antiderivative $J : F[x]_{\le n-1} \to F[x]_{\le n}$ still satisfy $DJ = \mathrm{id}$ and $JD \ne \mathrm{id}$. For $n = 2$, in the bases $1, x, x^2$ and $1, x$,

$$[D][J] = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1/2 \end{pmatrix} = I_2,$$

$$[J][D] = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \neq I_3.$$

The finite-dimensional version is an instance of the previous subsection: a 2×3 matrix with a right inverse. The version on $F[x]$ is new. There D and J map a space to *itself*, and still $DJ = \mathrm{id}$ while $JD \neq \mathrm{id}$. For a linear map from a finite-dimensional space to itself this cannot happen: a one-sided inverse of a square matrix is automatically two-sided (Theorem 3.5.23), and correspondingly an operator on a finite-dimensional space is injective if and only if it is surjective (Corollary 4.2.18). $F[x]$ escapes because no finite list spans it, so D can be onto without being one-to-one: it shifts the monomials down by one step, and the bottom one, 1, falls off. Over $\mathbb{F}_p$ even the right inverse is lost (Exercise 2.5.42).

Remark 2.5.25 (One-sided inverses in infinite dimensions). BEYOND 21-242 The converses of Remark 2.5.7 hold in every vector space: an injective linear map has a left inverse and a surjective one has a right inverse. Both proofs need a basis of W (in the injective case, one that extends a basis of $T(V)$), and in infinite dimensions bases are known to exist only by Zorn's lemma (Section 15.1).

Products

If S and T are invertible, so is TS (Proposition 2.5.17). The converse fails, but a one-sided version survives.

Proposition 2.5.26 (One-sided inverses of composites). Let $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$.

(a) If S and T are left-invertible, so is TS. If S and T are right-invertible, so is TS.
(b) If TS is left-invertible, then so is S. If TS is right-invertible, then so is T.
(c) In particular, if TS is invertible, then $(TS)^{-1}T$ is a left inverse of S, and $S(TS)^{-1}$ is a right inverse of T.

The same holds for matrices: for instance, if $A \in F^{m\times n}$ and $B \in F^{n\times m}$ and AB is invertible, then $B(AB)^{-1}$ is a right inverse of A and $(AB)^{-1}A$ is a left inverse of B.

Proof. ROUTINE

Uses. Definition 2.5.1 (Left inverse), Definition 2.5.2 (Right inverse), Proposition 2.1.24 (Algebra of composition), Proposition 2.4.14 (Algebra of matrices)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. For (a), the candidate is the composite of the one-sided inverses in reverse order, as in Proposition 2.5.17(b).
Hint 2. For (b), if $R(TS) = \mathrm{id}_U$, regroup: $(RT)S = \mathrm{id}_U$.
Sketch. (a) If $S'S = \mathrm{id}_U$ and $T'T = \mathrm{id}_V$, then $(S'T')(TS) = S'(T'T)S = S'S = \mathrm{id}_U$; right inverses are symmetric. (b) $R(TS) = \mathrm{id}_U$ gives $(RT)S = \mathrm{id}_U$, and $(TS)R = \mathrm{id}_W$ gives $T(SR) = \mathrm{id}_W$. (c) is (b) with $R = (TS)^{-1}$.

(a) Let $S'S = \mathrm{id}_U$ and $T'T = \mathrm{id}_V$. By Proposition 2.1.24,

$$(S'T')(TS) = S'(T'T)S = S'\mathrm{id}_V S = S'S = \mathrm{id}_U,$$

so $S'T'$ is a left inverse of TS. If $SS'' = \mathrm{id}_V$ and $TT'' = \mathrm{id}_W$, then $(TS)(S''T'') = T(SS'')T'' = TT'' = \mathrm{id}_W$, so $S''T''$ is a right inverse of TS.

(b) If $R(TS) = \mathrm{id}_U$, then $(RT)S = \mathrm{id}_U$, so RT is a left inverse of S. If $(TS)R = \mathrm{id}_W$, then $T(SR) = \mathrm{id}_W$, so SR is a right inverse of T.

(c) Apply (b) with $R = (TS)^{-1}$, which is both a left and a right inverse of TS. The matrix statements are the same computations with Proposition 2.4.14. □

Example 2.5.27 (An invertible product of non-invertible factors). Let $A = \begin{pmatrix} 1 & 0 \end{pmatrix} \in F^{1\times 2}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \in F^{2\times 1}$. Then $AB = (1) = I_1$ is invertible. But A is not: it has the two right inverses $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$, so by

Corollary 2.5.11 it has no left inverse. Similarly B has the two left inverses $(1\ \ 0)$ and $(1\ \ 1)$, so it has no right inverse. In the other order, $BA = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ has a zero row and is not even right-invertible (Exercise 2.5.9).

For a 2×2 example of the same kind, take $A = (I_2\ \ 0) \in F^{2\times 3}$ and $B = \begin{pmatrix} I_2 \\ 0 \end{pmatrix} \in F^{3\times 2}$, so that $AB = I_2$ by block multiplication. For an example with maps from a space to itself, take $DJ = \mathrm{id}_{F[x]}$ from Example 2.5.24, where neither D nor J is invertible.

These examples use matrices that are not square, or a space that is not finite-dimensional, and they have to. For square matrices, AB invertible implies that A and B are both invertible (Theorem 3.5.23).

2.5.5 Inverting 2×2 matrices

For 2×2 matrices there is a formula for the inverse, and a single number decides whether it exists. The candidate comes from the following computation. With $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, swap the diagonal entries and negate the other two:

$$\begin{aligned} &\begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \\ &= \begin{pmatrix} ad - bc & 0 \\ 0 & ad - bc \end{pmatrix} \\ &= \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \end{aligned}$$

So the second matrix is an inverse of A up to the scalar $ad - bc$.

Proposition 2.5.28 (Inverse of a 2×2 matrix). Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, and let $\Delta = ad - bc$.

(a) If $\Delta \neq 0$, then A is invertible, and

$$A^{-1} = \frac{1}{\Delta}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.$$

(b) If $\Delta = 0$, then A has neither a left inverse nor a right inverse.

Proof. ROUTINE

Uses. Definition 2.5.12 (Invertible), Proposition 2.4.14 (Algebra of matrices), Proposition 2.4.8 (Four views of the product)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Let $A' = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$. Compute AA' and $A'A$.
Hint 2. Both products are ΔI_2. For (a), divide by Δ.
Hint 3. For (b), suppose $BA = I_2$. Then $A' = (BA)A' = B(AA')$. What is AA' when $\Delta = 0$, and what does that say about A', and then about A?
Sketch. With $A' = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$, the entry formula gives $AA' = A'A = \Delta I_2$. (a) $\Delta^{-1}A'$ is a two-sided inverse. (b) If $\Delta = 0$, then $AA' = A'A = 0$. A left inverse B would give $A' = BAA' = 0$, so $a = b = c = d = 0$ and $A = 0$, which has no left inverse. A right inverse C gives $A' = A'AC = 0$ in the same way.

Let $A' = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$. By the entry formula,

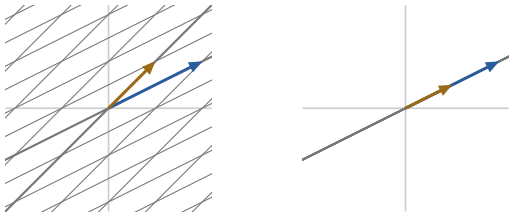
$$AA' = \begin{pmatrix} ad - bc & -ab + ba \\ cd - dc & -cb + da \end{pmatrix} = \Delta I_2,$$

$$A'A = \begin{pmatrix} da - bc & db - bd \\ -ca + ac & -cb + ad \end{pmatrix} = \Delta I_2.$$

(a) If $\Delta \neq 0$, then by Proposition 2.4.14(d),

$$A\left(\Delta^{-1}A'\right) = \Delta^{-1}(AA') = \Delta^{-1}\Delta I_2 = I_2,$$

and likewise $(\Delta^{-1}A')A = I_2$. So $\Delta^{-1}A'$ is a two-sided inverse of A.



(b) Suppose $\Delta = 0$, so that $AA' = A'A = 0$. If B is a left inverse of A, then

$$A' = I_2A' = (BA)A' = B(AA') = B0 = 0.$$

So $a = b = c = d = 0$ and $A = 0$. But the zero matrix has no left inverse, since $B0 = 0 \neq I_2$, a contradiction. If C is a right inverse of A, then $A' = A'(AC) = (A'A)C = 0$, and we reach the same contradiction. □

The number $\Delta = ad - bc$ is the **determinant** of A, studied in Chapter 5, and A' is the 2×2 case of the adjugate matrix, which inverts matrices of every size (Theorem 5.5.9). For a rotation, $\Delta = \cos^2\theta + \sin^2\theta = 1$ and the formula returns $[R_{-\theta}]$, as in Example 2.5.14(b).

Geometrically, $|\Delta|$ is the area of the parallelogram spanned by the columns of A, which is the image of the unit square under T_A (Section 5.1). When $\Delta = 0$ the columns are parallel, and T_A flattens the plane onto a line through $\mathbf{0}$, or onto $\{\mathbf{0}\}$. A flattened plane cannot be unflattened: two points that land on the same point cannot both be recovered. Drag the columns below until they line up, and watch the area reach 0.

The map of $A = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$, with $\Delta = 1$. Move $A\mathbf{e}_2$ onto the line through $A\mathbf{e}_1$ (for example to $(1, 1/2)$) and the grid collapses onto that line; the signed area $ad - bc$ is then 0, and by Proposition 2.5.28 the matrix has no inverse on either side. (Interactive in the web version.)

Example 2.5.29 (One matrix over several fields). Let $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$, with $\Delta = 4 - 6 = -2$. Whether A is invertible depends on the field in which we read its entries.

- Over $\mathbb{Q}$, $\Delta = -2 \neq 0$ and $A^{-1} = -\frac{1}{2}\begin{pmatrix} 4 & -2 \\ -3 & 1 \end{pmatrix} = \begin{pmatrix} -2 & 1 \\ 3/2 & -1/2 \end{pmatrix}$.
- Over $\mathbb{F}_5$, $\Delta = -2 = 3$ and $3^{-1} = 2$, so $A^{-1} = 2\begin{pmatrix} 4 & -2 \\ -3 & 1 \end{pmatrix} = \begin{pmatrix} 8 & -4 \\ -6 & 2 \end{pmatrix} = \begin{pmatrix} 3 & 1 \\ 4 & 2 \end{pmatrix}$. As a check, $\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}\begin{pmatrix} 3 & 1 \\ 4 & 2 \end{pmatrix} = \begin{pmatrix} 11 & 5 \\ 25 & 11 \end{pmatrix}$, which is I_2 modulo 5.
- Over $\mathbb{F}_3$, $\Delta = -2 = 1$ and $A = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$, so $A^{-1} = \begin{pmatrix} 1 & -2 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.
- Over $\mathbb{F}_2$, $\Delta = 0$, so A is not invertible. Indeed $A = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ there, with a zero column.

So a matrix with integer entries can be invertible over $\mathbb{Q}$ and over some $\mathbb{F}_p$ but not others; here it fails exactly for $p = 2$, the only prime dividing $\Delta = -2$.

Exercises

Exercise 2.5.30. ROUTINE Let $\mathbf{a} = \begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix} \in \mathbb{Q}^{3\times 1}$.

(a) Find all left inverses of $\mathbf{a}$.

(b) Show that $\mathbf{a}$ has no right inverse, in two ways: directly from Definition 2.5.2, and from (a).

Solution on page 1151

Exercise 2.5.31. ROUTINE

(a) Over $\mathbb{C}$, find the inverse of $\begin{pmatrix} 1 & i \\ i & 2 \end{pmatrix}$.

(b) Over $\mathbb{F}_7$, find the inverse of $\begin{pmatrix} 3 & 5 \\ 2 & 6 \end{pmatrix}$, and check your answer.

(c) For which $t \in \mathbb{R}$ is $\begin{pmatrix} t & 1 \\ 4 & t \end{pmatrix}$ invertible? For which $t \in \mathbb{F}_5$?

Solution on page 1151

Exercise 2.5.32. ROUTINE Let $A \in F^{n\times n}$ with $n \geq 1$.

(a) Show that if A is invertible and $AB = 0$ for some $B \in F^{n\times p}$, then $B = 0$.

(b) Show that if $A^k = 0$ for some $k \geq 1$, then A is not invertible.

(c) Show that if A is invertible and $A^2 = A$, then $A = I_n$.

(d) Show that if $A^k = I_n$ for some $k \geq 1$, then A is invertible with $A^{-1} = A^{k-1}$.

Solution on page 1151

Exercise 2.5.33. ROUTINE Let $T \in \mathrm{L}(V, W)$ and $S \in \mathrm{L}(W, V)$.

(a) Suppose $ST = \mathrm{id}_V$ and T is surjective. Show that $TS = \mathrm{id}_W$.

(b) Suppose $TS = \mathrm{id}_W$ and T is injective. Show that $ST = \mathrm{id}_V$.

(c) Deduce that a left-invertible linear map is invertible if and only if it is surjective, and a right-invertible one is invertible if and only if it is injective.

Solution on page 1152

Exercise 2.5.34. STANDARD Find the error in the following argument, and show that its conclusion is false. Then add a hypothesis on A under which the conclusion holds.

Claim. Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$. If $AB = I_m$, then $BA = I_n$.

Proof. Since $AB = I_m$, the matrix B is the inverse of A, that is, $B = A^{-1}$. Hence $BA = A^{-1}A = I_n$.

Solution on page 1152

Exercise 2.5.35. STANDARD Prove or disprove each statement, where $m, n \geq 1$.

(a) If $A, B \in F^{n\times n}$ are invertible, then $A + B$ is invertible.

(b) If $A \in F^{n\times n}$ and A^2 is invertible, then A is invertible.

(c) If $A \in F^{n\times n}$ is invertible and symmetric, then A^{-1} is symmetric.

(d) If $A \in F^{m\times n}$ and $A^{\mathsf{T}}A$ is invertible, then A is left-invertible.

(e) If $A \in F^{m\times n}$ is left-invertible, then $A^{\mathsf{T}}A$ is invertible.

Solution on page 1152

Exercise 2.5.36. STANDARD Let p be a prime and $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 0 \end{pmatrix} \in \mathbb{F}_p^{3\times 2}$.

(a) How many left inverses does A have?

(b) Does A have a right inverse?

(c) How many right inverses does A^{T} have?

Solution on page 1153

Exercise 2.5.37. STANDARD Let $T \in \mathrm{L}(V,W)$, and let S be a left inverse of T. Show that T is invertible if and only if S is left-invertible, and that in this case $T^{-1} = S$.

Solution on page 1153

Exercise 2.5.38. STANDARD Let $T \in \mathrm{L}(V)$, and suppose that $a_k T^k + \cdots + a_1 T + a_0 \mathrm{id}_V = 0$ for some $a_0, \ldots, a_k \in F$ with $a_0 \neq 0$.

(a) Show that T is invertible, and that $T^{-1} = -a_0^{-1}\left(a_k T^{k-1} + \cdots + a_2 T + a_1 \mathrm{id}_V\right)$.

(b) Let $A = \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix} \in \mathbb{R}^{2\times 2}$. Verify that $A^2 - A + I_2 = 0$, find A^{-1} from (a), and show that $A^3 = -I_2$.

Solution on page 1154

Exercise 2.5.39. STANDARD

(a) Let $N \in \mathrm{L}(V)$ with $N^k = 0$ for some $k \geq 1$. Show that $\mathrm{id}_V - N$ and $\mathrm{id}_V + N$ are invertible, with

$$(\mathrm{id}_V - N)^{-1} = \mathrm{id}_V + N + N^2 + \cdots + N^{k-1}.$$

(b) Use (a) to invert $\begin{pmatrix} 1 & a & b \\ 0 & 1 & c \\ 0 & 0 & 1 \end{pmatrix}$ for $a, b, c \in F$.

(c) Show that $\mathrm{id} + D$ is invertible on $F[x]_{\leq 3}$, where D is differentiation, and compute $(\mathrm{id} + D)^{-1}\left(x^3\right)$.

Solution on page 1154

Exercise 2.5.40. STANDARD Let $A \in F^{p\times p}$ and $D \in F^{q\times q}$ be invertible, and let $X \in F^{p\times q}$.

(a) Show that $M = \begin{pmatrix} A & X \\ 0 & D \end{pmatrix}$ is invertible, with

$$M^{-1} = \begin{pmatrix} A^{-1} & -A^{-1}XD^{-1} \\ 0 & D^{-1} \end{pmatrix}.$$

(b) Use (a) to invert $\begin{pmatrix} 1 & 2 & 1 \\ 1 & 3 & 0 \\ 0 & 0 & 2 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$.

Solution on page 1155

Exercise 2.5.41. STANDARD Let $M : F[x] \to F[x]$ be multiplication by x, $M(p) = xp$, and let $L : F[x] \to F[x]$ be

$$\begin{aligned} &L(a_0 + a_1 x + \cdots + a_n x^n) \\ &= a_1 + a_2 x + \cdots + a_n x^{n-1}. \end{aligned}$$

(a) Show that $LM = \mathrm{id}_{F[x]}$, compute ML, and show that M has no right inverse and L no left inverse.

(b) Find all left inverses of M.

Solution on page 1156

Exercise 2.5.42. STANDARD

(a) On $\mathbb{Q}[x]$, construct a right inverse R of differentiation D such that $(R(p))(1) = 0$ for every $p \in \mathbb{Q}[x]$.

(b) Let p be a prime. Show that x^{p-1} is not a value of $D : \mathbb{F}_p[x] \to \mathbb{F}_p[x]$, and conclude that over $\mathbb{F}_p$, D has no right inverse.

Solution on page 1156

Exercise 2.5.43. STANDARD Let p be a prime. Use Proposition 2.5.28 to show that exactly $\left(p^2-1\right)\left(p^2-p\right)$ matrices in $\mathbb{F}_p^{2\times 2}$ are invertible. List them for $p=2$.

Solution on page 1157

Exercise 2.5.44. STANDARD

(a) Let $A \in F^{m\times n}$ be invertible. Show that $m * 1 = n * 1$ in F. Deduce that over a field of characteristic 0, such as $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, every invertible matrix is square.

(b) More generally, let $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $AB = I_m$, and suppose $m * 1 \neq n * 1$ in F. Show that $BA \neq I_n$.

(c) Explain why this argument does not show that invertible matrices over $\mathbb{F}_2$ are square.

Solution on page 1158

Exercise 2.5.45. ROUTINE Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$. Show that B is a left inverse of A if and only if B^{T} is a right inverse of A^{T}. Deduce that A is left-invertible if and only if A^{T} is right-invertible, and that A is invertible if and only if A^{T} is.

Solution on page 1158

Exercise 2.5.46. HARD

(a) Show that every $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$ satisfies

$$A^2 - (a+d)A + (ad-bc)I_2 = 0.$$

(b) Use (a) and Exercise 2.5.38 to give a second proof of Proposition 2.5.28(a).

(c) Let p be an odd prime. How many $A \in \mathbb{F}_p^{2\times 2}$ satisfy $A^{-1} = A$?

Solution on page 1158

Exercise 2.5.47. HARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$.

(a) Suppose that $I_m - AB$ is invertible. Show that $I_n - BA$ is invertible, with

$$(I_n - BA)^{-1} = I_n + B(I_m - AB)^{-1}A.$$

(b) Deduce: if $\mathbf{u}, \mathbf{v} \in F^n$ and $1 + \mathbf{v}^{\mathsf{T}}\mathbf{u} \neq 0$, then $I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ is invertible, with inverse $I_n - \left(1+\mathbf{v}^{\mathsf{T}}\mathbf{u}\right)^{-1}\mathbf{u}\mathbf{v}^{\mathsf{T}}$.

Solution on page 1159

Exercise 2.5.48. HARD Let $S, T \in \mathrm{L}(V)$ satisfy $ST = S + T$.

(a) Show that $(\mathrm{id} - S)(\mathrm{id} - T) = \mathrm{id}$.

(b) Suppose that $\mathrm{id} - S$ is invertible. Show that $ST = TS$. (When $V = F^n$, this hypothesis follows from (a) by Theorem 3.5.23.)

(c) Find $S, T \in \mathrm{L}(\mathbb{Q}[x])$ with $ST = S + T$ but $ST \neq TS$.

Solution on page 1160

Exercise 2.5.49. CHALLENGE Let $A, B \in F^{n\times n}$ with $n \geq 1$ and $AB = I_n$. You may use that any n^2+1 matrices in $F^{n\times n}$ are linearly dependent, because $F^{n\times n}$ has dimension n^2 (Section 4.1).

(a) Show that $A^r B^k = B^{k-r}$ whenever $k \geq r \geq 0$.

(b) Show that B has a right inverse that is a linear combination of $I_n, B, B^2, \ldots$.

(c) Conclude that $BA = I_n$.

Solution on page 1161

2.6 Kernel and image

In Section 2.5, a left inverse of T showed that the equation $T(\mathbf{v}) = \mathbf{w}$ has at most one solution, and a right inverse showed that it has at least one. This section studies the two properties themselves. As properties of functions they are injectivity and surjectivity, and each is a statement about every $\mathbf{w} \in W$ at once. For a linear map, linearity packs each of them into a single subspace: the kernel, which consists of the vectors sent to $\mathbf{0}$, and the image, which consists of the vectors that are reached. In particular, whether $T(\mathbf{v}) = \mathbf{w}$ has at most one solution for every $\mathbf{w}$ is decided by the one equation $T(\mathbf{v}) = \mathbf{0}$.

Throughout, U, V, and W are vector spaces over F, and $T \in \mathrm{L}(V, W)$ unless said otherwise.

2.6.1 Injective, surjective, and bijective maps

The three notions below make sense for any function $f : X \to Y$ between sets, and Section A.1 treats them in that generality. For $y \in Y$, an element $x \in X$ with $f(x) = y$ is a **preimage** of y. The definitions count preimages.

Definition 2.6.1 (Injective). A function $f : X \to Y$ is **injective** if every $y \in Y$ has at most one preimage. Equivalently, for all $x, x' \in X$, if $f(x) = f(x')$, then $x = x'$.

Definition 2.6.2 (Surjective). A function $f : X \to Y$ is **surjective** if every $y \in Y$ has at least one preimage, that is, if for every $y \in Y$ there is some $x \in X$ with $f(x) = y$.

Definition 2.6.3 (Bijective). A function $f : X \to Y$ is **bijective** if every $y \in Y$ has exactly one preimage, that is, if f is both injective and surjective.

The two forms of injectivity say the same thing: if $f(x) = f(x') = y$, then x and x' are both preimages of y, and "at most one" says that they are equal. The second form is the one we use in proofs. Its contrapositive reads: different inputs have different values. Other common names are *one-to-one* for injective, *onto* for surjective, and *one-to-one correspondence* for a bijection.

For a linear map T, the preimages of $\mathbf{w}$ are the solutions of the equation $T(\mathbf{v}) = \mathbf{w}$. So T is injective if and only if this equation has at most one solution for every $\mathbf{w} \in W$, surjective if and only if it has at least one, and bijective if and only if it has exactly one. In this language, Proposition 2.5.4 and Proposition 2.5.5 say that a left-invertible linear map is injective and a right-invertible one is surjective, so an invertible linear map is bijective. Conversely, a bijective linear map is invertible, because its inverse function turns out to be linear (Proposition 2.7.7). The converses for one-sided inverses are harder (Remark 2.5.7).

Example 2.6.4 (Injective, surjective, both, neither).

(a) $T : F \to F^2$, $T(x) = (x, 0)$, is injective: if $(x, 0) = (x', 0)$, then $x = x'$. It is not surjective, since $(0, 1)$ has no preimage (Example 2.5.3).

(b) $P : F^2 \to F$, $P(x, y) = x$, is surjective, since $x = P(x, 0)$ for every $x \in F$. It is not injective, since $P(0, 1) = 0 = P(0, 0)$.

(c) The rotation R_θ of $\mathbb{R}^2$ is bijective, since it is invertible with inverse $R_{-\theta}$ (Example 2.5.14).

(d) The projection Pr_ℓ onto a line ℓ through $\mathbf{0}$ in $\mathbb{R}^2$ is neither injective nor surjective (Non-example 2.5.15).

(e) On $F[x]$, multiplication by x, $M(p) = xp$ (Example 2.1.9), is injective but not surjective. If $p = \sum_k a_k x^k$, then $xp = \sum_k a_k x^{k+1}$ has the coefficients of p, moved up by one place, so $xp = xq$ forces $p = q$. Every value of M has constant term 0, so 1 has no preimage. In the other direction, if F has characteristic 0, then differentiation D is surjective but not injective (Example 2.5.24).

In (e), an operator on $F[x]$ is injective without being surjective, and another is surjective without being injective. For an operator on a finite-dimensional space this cannot happen (Corollary 4.2.18).

2.6.2 Kernel and image

Checking injectivity straight from Definition 2.6.1 means comparing $T(\mathbf{v})$ with $T(\mathbf{v}')$ for every pair of vectors. For a linear map there is a shortcut, since $T(\mathbf{v}) = T(\mathbf{v}')$ if and only if $T(\mathbf{v} - \mathbf{v}') = \mathbf{0}$. Every coincidence of values is therefore recorded by a vector that T sends to $\mathbf{0}$. Surjectivity, on the other hand, asks which vectors T reaches.

Definition 2.6.5 (Kernel). The **kernel** of $T \in \mathrm{L}(V, W)$ is the set of vectors that T sends to $\mathbf{0}$,

$$\ker T = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{0}_W\} \subseteq V.$$

Definition 2.6.6 (Image). The **image** of $T \in \mathrm{L}(V, W)$ is the set of values of T,

$$\mathrm{im}\, T = \{\mathbf{w} \in W \mid \mathbf{w} = T(\mathbf{v}) \text{ for some } \mathbf{v} \in V\} = T(V) \subseteq W.$$

The kernel is also called the **null space** of T, and the image its **range**. Note where each one lives: $\ker T$ is a subset of the domain V, and $\mathrm{im}\, T$ is a subset of the target W. Directly from Definition 2.6.2, T is surjective if and only if $\mathrm{im}\, T = W$. The kernel always contains $\mathbf{0}_V$, since $T(\mathbf{0}_V) = \mathbf{0}_W$ (Proposition 2.1.4).

Example 2.6.7 (First kernels and images).

(a) The zero map $V \to W$ has kernel V and image $\{\mathbf{0}\}$. The identity id_V has kernel $\{\mathbf{0}\}$ and image V.

(b) For $T(x) = (x, 0)$ from Example 2.6.4(a), $\ker T = \{0\}$ and $\mathrm{im}\, T = \{(x, 0) \mid x \in F\} = \mathrm{span}(\mathbf{e}_1)$. For $P(x, y) = x$ from part (b) of that example, $\ker P = \mathrm{span}(\mathbf{e}_2)$ and $\mathrm{im}\, P = F$.

(c) Let $Q : F^3 \to F^3$, $Q(x, y, z) = (x, y, 0)$. Then $Q(x, y, z) = \mathbf{0}$ if and only if $x = y = 0$, so $\ker Q = \mathrm{span}(\mathbf{e}_3)$, the z-axis. Every value of Q has third entry 0, and every such vector is a value, since $Q(x, y, 0) = (x, y, 0)$. So $\mathrm{im}\, Q = \mathrm{span}(\mathbf{e}_1, \mathbf{e}_2)$, the xy-plane.

(d) Let $\ell = \mathrm{span}(\mathbf{u})$ with $\mathbf{u} = (c, s) = (\cos\theta, \sin\theta)$. By Example 2.1.11, $\mathrm{Pr}_\ell(x, y) = (xc + ys)\mathbf{u}$. Since $\mathbf{u} \neq \mathbf{0}$, $\mathrm{Pr}_\ell(x, y) = \mathbf{0}$ if and only if $xc + ys = 0$ (Proposition 1.2.35). Using $c^2 + s^2 = 1$, every $(x, y) \in \mathbb{R}^2$ satisfies

$$(x, y) = (xc + ys)(c, s) + (yc - xs)(-s, c),$$

so the solutions of $xc + ys = 0$ are exactly the multiples of $(-s, c)$. Hence $\ker \mathrm{Pr}_\ell = \mathrm{span}((-s, c))$, the line through $\mathbf{0}$ perpendicular to ℓ. Every value of Pr_ℓ lies on ℓ, and every $t\mathbf{u} \in \ell$ is a value, since $\mathrm{Pr}_\ell(t\mathbf{u}) = t(c^2 + s^2)\mathbf{u} = t\mathbf{u}$. So $\mathrm{im}\, \mathrm{Pr}_\ell = \ell$.

Intuition (What the kernel and the image measure). The kernel measures how far T is from being injective, and the image measures how close it comes to being surjective. Two vectors with the same value differ

by an element of the kernel, so a large kernel means that T glues many vectors together and loses information. Theorem 2.6.11 below shows that T loses nothing exactly when the kernel is as small as it can be, namely $\{\mathbf{0}\}$. The image is what T reaches, and T is surjective exactly when the image is as large as it can be, namely W. In Example 2.6.7(d), Pr_ℓ forgets the component perpendicular to ℓ and reaches only ℓ.

Both sets are subspaces (Proposition 2.6.8), so in finite dimensions their sizes can be measured by dimension. Rank–nullity (Section 4.2) shows that the two measurements are tied together: the more T loses, the less it reaches.

Proposition 2.6.8 (Kernels and images are subspaces). For every $T \in \mathrm{L}(V, W)$, $\ker T$ is a subspace of V and $\operatorname{im} T$ is a subspace of W.

Proof. ROUTINE

Uses. Theorem 1.4.3 (Subspace criterion), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Definition 2.1.1 (Linear map), Proposition 1.2.33 (The zero vector)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Use part (III) of the subspace criterion (Theorem 1.4.3): check that each set contains the zero vector and is closed under addition and scalar multiplication.
Hint 2. For the kernel, apply T to $\mathbf{u}+\mathbf{v}$ and to $a\mathbf{u}$, where $T(\mathbf{u}) = T(\mathbf{v}) = \mathbf{0}$. For the image, write $T(\mathbf{u}) + T(\mathbf{v})$ and $aT(\mathbf{u})$ as single values of T.
Sketch. Both sets contain $\mathbf{0}$ because $T(\mathbf{0}) = \mathbf{0}$. For $\mathbf{u}, \mathbf{v} \in \ker T$, linearity gives $T(\mathbf{u}+\mathbf{v}) = \mathbf{0}+\mathbf{0} = \mathbf{0}$ and $T(a\mathbf{u}) = a\mathbf{0} = \mathbf{0}$. For values, $T(\mathbf{u}) + T(\mathbf{v}) = T(\mathbf{u}+\mathbf{v})$ and $aT(\mathbf{u}) = T(a\mathbf{u})$.

The kernel. By Proposition 2.1.4, $T(\mathbf{0}_V) = \mathbf{0}_W$, so $\mathbf{0}_V \in \ker T$. Let $\mathbf{u}, \mathbf{v} \in \ker T$ and $a \in F$. Since T is linear,

$$T(\mathbf{u}+\mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v}) = \mathbf{0}+\mathbf{0} = \mathbf{0}, \quad T(a\mathbf{u}) = aT(\mathbf{u}) = a\mathbf{0} = \mathbf{0},$$

where the last step is Proposition 1.2.33. So $\mathbf{u}+\mathbf{v}$ and $a\mathbf{u}$ lie in $\ker T$, and $\ker T$ is a subspace of V by Theorem 1.4.3.

The image. Again $\mathbf{0}_W = T(\mathbf{0}_V) \in \operatorname{im} T$. Let $\mathbf{w}, \mathbf{w}' \in \operatorname{im} T$ and $a \in F$, say $\mathbf{w} = T(\mathbf{u})$ and $\mathbf{w}' = T(\mathbf{v})$ with $\mathbf{u}, \mathbf{v} \in V$. Since T is linear,

$$\mathbf{w}+\mathbf{w}' = T(\mathbf{u}+\mathbf{v}), \quad a\mathbf{w} = T(a\mathbf{u}),$$

so both vectors lie in $\operatorname{im} T$, and $\operatorname{im} T$ is a subspace of W by Theorem 1.4.3. □

The proof used only that $\{\mathbf{0}\}$ is a subspace of W and that V is a subspace of itself. The same argument shows that the image $\operatorname{im}(T|_X)$ of a subspace X of V is a subspace of W, and that the set of $\mathbf{v}$ with $T(\mathbf{v}) \in U$ is a subspace of V for every subspace U of W (Exercise 2.6.51). Linearity cannot be dropped.

Non-example 2.6.9 (Without linearity).

(a) The function $f : \mathbb{R}^2 \to \mathbb{R}$, $f(x, y) = xy$, sends exactly the points of the two coordinate axes to 0. This set contains $(1, 0)$ and $(0, 1)$ but not their sum.

(b) The values of $g : \mathbb{R} \to \mathbb{R}^2$, $g(t) = (t, t^2)$, form the parabola $y = x^2$. It contains $(1, 1)$ but not $2(1, 1) = (2, 2)$, since $2 \neq 2^2$.

(c) An affine map $\mathbf{v} \mapsto T(\mathbf{v}) + \mathbf{b}$ with $\mathbf{b} \neq \mathbf{0}$ (Non-example 2.1.12) sends $\mathbf{0}$ to $\mathbf{b}$, so the set of vectors it sends to $\mathbf{0}$ does not contain $\mathbf{0}$.

Exercise 2.6.10. ROUTINE Find the kernel and the image of each map, and decide whether it is injective and whether it is surjective.

(a) $T : \mathbb{R}^2 \to \mathbb{R}^2$, $T(x, y) = (x - y, 2y - 2x)$.

(b) $S : F^2 \to F^3$, $S(x, y) = (x, x + y, y)$.

(c) $\mathrm{ev}_1 : F[x]_{\leq 1} \to F$, $\mathrm{ev}_1(p) = p(1)$.

Solution on page 1161

2.6.3 Injectivity and the kernel

Intuition. Suppose $T(\mathbf{v}) = T(\mathbf{v}')$. Then $T(\mathbf{v} - \mathbf{v}') = \mathbf{0}$, so the difference $\mathbf{v} - \mathbf{v}'$ lies in $\ker T$. Conversely, adding a vector $\mathbf{z} \in \ker T$ does not change values: $T(\mathbf{v} + \mathbf{z}) = T(\mathbf{v}) + \mathbf{0} = T(\mathbf{v})$. So T gives two vectors the same value exactly when they differ by an element of the kernel. A coincidence anywhere in V is a coincidence with $\mathbf{0}$, moved over, and the coincidences with $\mathbf{0}$ are recorded by the nonzero vectors of $\ker T$.

Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$). A linear map $T \in \mathrm{L}(V, W)$ is injective if and only if $\ker T = \{\mathbf{0}\}$.

Proof. ROUTINE

Uses. Definition 2.6.1 (Injective), Definition 2.6.5 (Kernel), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For "only if", recall that $\mathbf{0} \in \ker T$ always. If $\mathbf{v} \in \ker T$, compare $T(\mathbf{v})$ with $T(\mathbf{0})$.
Hint 2. For "if", suppose $T(\mathbf{v}) = T(\mathbf{v}')$ and apply T to $\mathbf{v} - \mathbf{v}'$.
Sketch. If T is injective and $T(\mathbf{v}) = \mathbf{0} = T(\mathbf{0})$, then $\mathbf{v} = \mathbf{0}$. If $\ker T = \{\mathbf{0}\}$ and $T(\mathbf{v}) = T(\mathbf{v}')$, then $T(\mathbf{v} - \mathbf{v}') = \mathbf{0}$ by linearity, so $\mathbf{v} - \mathbf{v}' = \mathbf{0}$.

Only if. Suppose T is injective. We always have $\mathbf{0} \in \ker T$ (Proposition 2.1.4). If $\mathbf{v} \in \ker T$, then $T(\mathbf{v}) = \mathbf{0} = T(\mathbf{0})$, and injectivity gives $\mathbf{v} = \mathbf{0}$. So $\ker T = \{\mathbf{0}\}$.

If. Suppose $\ker T = \{\mathbf{0}\}$, and let $\mathbf{v}, \mathbf{v}' \in V$ with $T(\mathbf{v}) = T(\mathbf{v}')$. By Proposition 2.1.4,

$$T(\mathbf{v} - \mathbf{v}') = T(\mathbf{v}) - T(\mathbf{v}') = \mathbf{0},$$

so $\mathbf{v} - \mathbf{v}' \in \ker T = \{\mathbf{0}\}$. Hence $\mathbf{v} = \mathbf{v}'$, and T is injective. □

Linearity is essential here. The function $f : \mathbb{R} \to \mathbb{R}$, $f(x) = x^2$, sends only 0 to 0, but $f(1) = f(-1)$.

Technique 2.6.12 (Test injectivity at $\mathbf{0}$). To prove that a linear map T is injective, take a vector $\mathbf{v}$ with $T(\mathbf{v}) = \mathbf{0}$ and show that $\mathbf{v} = \mathbf{0}$ (Theorem 2.6.11). This replaces a statement about all pairs of vectors by a statement about one equation, and $T(\mathbf{v}) = \mathbf{0}$ is usually the easiest equation to analyze. To prove that T is *not* injective, exhibit a single nonzero vector of $\ker T$.

The same move is how injectivity gets used. A relation $a_1 T(\mathbf{v}_1) + \cdots + a_k T(\mathbf{v}_k) = \mathbf{0}$ can be pulled back through T: by linearity it says $T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k) = \mathbf{0}$, and if T is injective, then $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$.

Reach for it whenever injectivity of a linear map is to be proved or used. Check linearity first: for other functions the test proves nothing, as $x \mapsto x^2$ shows. The canonical example is Example 2.6.13.
Used in. Proposition 2.6.14, Exercise 2.6.16, Proposition 2.6.22, Exercise 2.8.7, Exercise 2.8.10, Problem 2.1, Problem 2.15, Problem 2.18, Problem 2.19, Exercise 4.4.35, Proposition 6.5.13, Proposition 6.5.21, Corollary 8.4.6, Exercise 2.6.37.

Example 2.6.13 (Testing at $\mathbf{0}$).

(a) Let $T : F[x] \to F[x]$, $T(p) = p + D(p)$, where D is differentiation. We claim that T is injective over every field. Differentiation lowers the degree of every nonzero polynomial: if $\deg p = d \geq 1$, then $D(p)$ has degree at most $d - 1$ by the formula in Example 2.1.9, and if p is a nonzero constant, then $D(p) = \mathbf{0}$, whose degree is $-\infty$. So for $p \neq \mathbf{0}$ the degrees of p and $D(p)$ differ, and Proposition 1.2.18(a) gives $\deg(p + D(p)) = \deg p \geq 0$. In particular $T(p) \neq \mathbf{0}$. Hence $\ker T = \{\mathbf{0}\}$, and T is injective by Theorem 2.6.11. Differentiation alone is not injective; adding the identity repairs this.

(b) Let $S : F^2 \to F^2$, $S(x, y) = (x + y, x - y)$. If $S(x, y) = \mathbf{0}$, then $x + y = 0$ and $x - y = 0$. Adding and subtracting the two equations gives $2x = 0$ and $2y = 0$, where $2 = 1 + 1$. If $2 \neq 0$ in F, then $x = y = 0$, so S is injective. Over $\mathbb{F}_2$, $S(1, 1) = (1 + 1, 1 - 1) = \mathbf{0}$, so $(1, 1)$ is a nonzero vector of $\ker S$, and S is not injective.

Proposition 2.1.16(b) says that every linear map sends linearly dependent lists to linearly dependent lists. It may also send independent lists to dependent ones, as Pr_ℓ does with $\mathbf{e}_1, \mathbf{e}_2$. The injective maps are exactly the ones that never do.

Proposition 2.6.14 (Injective maps preserve independence). For $T \in \mathrm{L}(V, W)$, the following are equivalent.

(I) T is injective.

(II) For every linearly independent list $\mathcal{L} = \mathbf{v}_1, ..., \mathbf{v}_k$ in V, the list $T(\mathcal{L}) = T(\mathbf{v}_1), ..., T(\mathbf{v}_k)$ is linearly independent.

Proof. ROUTINE

Uses. Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.5.15 (Short lists, zeros, and repeats), Definition 2.1.1 (Linear map)
Techniques. Test injectivity at $\mathbf{0}$ (Technique 2.6.12), Contrapositive (Technique 1.5.4)
Hint 1. For (I) $\Rightarrow$ (II), start from a relation $\sum_i a_i T(\mathbf{v}_i) = \mathbf{0}$ and pull it back through T.
Hint 2. For (II) $\Rightarrow$ (I), work with the kernel. Which list could you feed to (II) to learn something about a vector $\mathbf{v} \in \ker T$?
Hint 3. A single nonzero vector forms a linearly independent list, and the list $\mathbf{0}$ is linearly dependent.
Sketch. (I) $\Rightarrow$ (II): $\sum_i a_i T(\mathbf{v}_i) = \mathbf{0}$ gives $T\left(\sum_i a_i \mathbf{v}_i\right) = \mathbf{0}$, so $\sum_i a_i \mathbf{v}_i = \mathbf{0}$, and all $a_i = 0$. (II) $\Rightarrow$ (I): if $\ker T$ contained some $\mathbf{v} \neq \mathbf{0}$, the list $\mathbf{v}$ would be independent while its image, the list $\mathbf{0}$, is not.

(I) $\Rightarrow$ (II). Suppose T is injective, let $\mathcal{L}$ be linearly independent, and suppose that $a_1 T(\mathbf{v}_1) + \cdots + a_k T(\mathbf{v}_k) = \mathbf{0}$. By linearity, $T(a_1 \mathbf{v}_1 + \cdots + a_k \mathbf{v}_k) = \mathbf{0}$, so $a_1 \mathbf{v}_1 + \cdots + a_k \mathbf{v}_k \in \ker T = \{\mathbf{0}\}$ by Theorem 2.6.11. As $\mathcal{L}$ is linearly independent, $a_1 = \cdots = a_k = 0$ (Theorem 1.5.5). So $\mathbf{0}$ has only the trivial representation by $T(\mathcal{L})$, and $T(\mathcal{L})$ is linearly independent by Theorem 1.5.5.

(II) $\Rightarrow$ (I). We prove the contrapositive. Suppose T is not injective. By Theorem 2.6.11 there is a vector $\mathbf{v} \neq \mathbf{0}$ in $\ker T$. The list $\mathbf{v}$ is linearly independent, but its image is the list $T(\mathbf{v}) = \mathbf{0}$, which is linearly dependent (Proposition 1.5.15). So (II) fails. □

Composites

Under composition, kernels can only grow and images can only shrink.

Proposition 2.6.15 (Kernels and images of composites). Let $S \in \mathrm{L}(U, V)$ and $T \in \mathrm{L}(V, W)$.

(a) $\ker S \subseteq \ker(TS)$, with equality if T is injective.

(b) $\mathrm{im}(TS) = \mathrm{im}(T|_{\mathrm{im}\, S}) \subseteq \mathrm{im}\, T$, with equality if S is surjective.

(c) If TS is injective, then S is injective. If TS is surjective, then T is surjective.

Proof. ROUTINE

Uses. Definition 2.6.5 (Kernel), Definition 2.6.6 (Image), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For (a): if $S(\mathbf{u}) = \mathbf{0}$, what is $T(S(\mathbf{u}))$? For the equality, if $T(S(\mathbf{u})) = \mathbf{0}$, which vector lies in $\ker T$?
Hint 2. For (b), unwind the definitions: a value of TS is T applied to a value of S.

Hint 3. (c) follows from (a) and (b): $\ker S \subseteq \ker(TS)$ and $\operatorname{im}(TS) \subseteq \operatorname{im} T$.
Sketch. (a) $T(S(\mathbf{u})) = T(\mathbf{0}) = \mathbf{0}$ for $\mathbf{u} \in \ker S$; if T is injective and $T(S(\mathbf{u})) = \mathbf{0}$, then $S(\mathbf{u}) \in \ker T = \{\mathbf{0}\}$. (b) Both $\operatorname{im}(TS)$ and $\operatorname{im}(T\restriction_{\operatorname{im} S})$ are the set of all $T(S(\mathbf{u}))$, which lie in $\operatorname{im} T$; if $\operatorname{im} S = V$, then $T\restriction_{\operatorname{im} S} = T$. (c) $\ker S \subseteq \ker(TS) = \{\mathbf{0}\}$, and $W = \operatorname{im}(TS) \subseteq \operatorname{im} T$.

(a) If $\mathbf{u} \in \ker S$, then $(TS)(\mathbf{u}) = T(\mathbf{0}) = \mathbf{0}$ by Proposition 2.1.4, so $\mathbf{u} \in \ker(TS)$. If T is injective and $\mathbf{u} \in \ker(TS)$, then $S(\mathbf{u}) \in \ker T = \{\mathbf{0}\}$ by Theorem 2.6.11, so $\mathbf{u} \in \ker S$.

(b) By definition, $\operatorname{im}(TS) = \{T(S(\mathbf{u})) \mid \mathbf{u} \in U\}$, and

$$\operatorname{im}(T\restriction_{\operatorname{im} S}) = \{T(\mathbf{v}) \mid \mathbf{v} \in \operatorname{im} S\} = \{T(S(\mathbf{u})) \mid \mathbf{u} \in U\}$$

as well. Each $T(S(\mathbf{u}))$ is a value of T, so this set is contained in $\operatorname{im} T$. If S is surjective, then $\operatorname{im} S = V$, so $T\restriction_{\operatorname{im} S} = T$ and the two images agree.

(c) If TS is injective, then by (a) and Theorem 2.6.11, $\ker S \subseteq \ker(TS) = \{\mathbf{0}\}$. So $\ker S = \{\mathbf{0}\}$, and S is injective. If TS is surjective, then by (b), $W = \operatorname{im}(TS) \subseteq \operatorname{im} T \subseteq W$, so $\operatorname{im} T = W$. □

Part (c) is the counterpart of Proposition 2.5.26(b) for injectivity and surjectivity, and it cannot be improved. With $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, the composite $T_A T_B = T_{AB} = \mathrm{id}_F$ is bijective, but $T_A(x, y) = x$ is not injective and $T_B(x) = (x, 0)$ is not surjective (Example 2.5.27).

Exercise 2.6.16. ROUTINE

(a) Show that $T : F^2 \to F^3$, $T(x, y) = (x, x + y, x + 2y)$, is injective over every field.

(b) Show that $T : F[x] \to F[x]$, $T(p) = xp + p$, is injective. (Look at the coefficient of the highest power of x in $T(p)$.)

(c) Let $T \in \mathrm{L}(V)$ with $T^2 = 0$. Show that T is not injective unless $V = \{\mathbf{0}\}$.

Solution on page 1162

2.6.4 Null space and column space

A matrix $A \in F^{m \times n}$ gives the linear map $T_A : F^n \to F^m$, $\mathbf{x} \mapsto A\mathbf{x}$ (Definition 2.3.15), and the kernel and image of T_A have names of their own.

Definition 2.6.17 (Null space and column space). Let $A \in F^{m \times n}$. The **null space** of A is

$$\ker T_A = \{\mathbf{x} \in F^n \mid A\mathbf{x} = \mathbf{0}\},$$

a subspace of F^n, and the **column space** of A is

$$\operatorname{im} T_A = \{A\mathbf{x} \mid \mathbf{x} \in F^n\},$$

a subspace of F^m. We sometimes abbreviate them to $\ker A$ and $\operatorname{im} A$.

By Proposition 3.1.8, the null space of A is the solution set of the homogeneous system $A\mathbf{x} = \mathbf{0}$, and the system $A\mathbf{x} = \mathbf{y}$ has a solution exactly when $\mathbf{y}$ lies in the column space. The name "column space" comes from the following description.

Proposition 2.6.18 (The column space is spanned by the columns). Let $A \in F^{m \times n}$ have columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$. Then

$$\operatorname{im} T_A = \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n).$$

Proof (from the definition of $A\mathbf{x}$). ROUTINE

Uses. Definition 2.3.8 (Matrix–vector product), Definition 1.3.10 (Span), Definition 2.6.6 (Image)
Hint 1. What is $A\mathbf{x}$, by definition, in terms of the columns of A?

Hint 2. As $\mathbf{x}$ runs over F^n, its entries $x_1, \dots, x_n$ run over all lists of n scalars.
Sketch. $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$, and as $\mathbf{x}$ runs over F^n these are all the linear combinations of the columns.

By Definition 2.3.8, $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ for $\mathbf{x} = (x_1, \dots, x_n)$. Every list of scalars $x_1, \dots, x_n$ is the list of entries of some $\mathbf{x} \in F^n$, so the values of T_A are exactly the linear combinations of $\mathbf{a}_1, \dots, \mathbf{a}_n$. By Definition 1.3.10, the set of these is $\operatorname{span}(\mathbf{a}_1, \dots, \mathbf{a}_n)$. □

Proof (from a spanning list). ROUTINE

Uses. Proposition 2.1.16 (Linear maps preserve spans and linear relations), Proposition 2.3.13 (Linearity of the product), Proposition 1.6.7 (Standard bases)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. The standard basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ spans F^n. What does Proposition 2.1.16(a) say about the image of T_A?
Hint 2. $A\mathbf{e}_j = \mathbf{a}_j$ by Proposition 2.3.13(c).
Sketch. Since $\mathbf{e}_1, \dots, \mathbf{e}_n$ spans F^n, $\operatorname{im} T_A = \operatorname{span}(A\mathbf{e}_1, \dots, A\mathbf{e}_n) = \operatorname{span}(\mathbf{a}_1, \dots, \mathbf{a}_n)$.

The standard basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ spans F^n (Proposition 1.6.7). By Proposition 2.1.16(a) and Proposition 2.3.13(c),

$$\operatorname{im} T_A = \operatorname{span}(A\mathbf{e}_1, \dots, A\mathbf{e}_n) = \operatorname{span}(\mathbf{a}_1, \dots, \mathbf{a}_n).$$ □

The first proof is a reading of the definition of the product. The second uses nothing about matrices except $A\mathbf{e}_j = \mathbf{a}_j$, so it proves more: for every $T \in \mathrm{L}(V, W)$ and every list $\mathcal{L}$ that spans V,

$$\operatorname{im} T = \operatorname{span} T(\mathcal{L}). \tag{2.6.1}$$

That is, the image of a linear map is spanned by the values on any spanning list. Section 2.6.5 builds on this.

Example 2.6.19 (Computing a null space and a column space).

(a) Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 7 \end{pmatrix}$, over any field F.

Null space. A vector $\mathbf{x}$ lies in $\ker T_A$ if and only if $x_1 + 2x_2 + 3x_3 = 0$ and $2x_1 + 4x_2 + 7x_3 = 0$. If $\mathbf{x}$ satisfies both, then subtracting twice the first equation from the second gives $x_3 = 0$, and then the first gives $x_1 = -2x_2$. Conversely, $(-2t, t, 0)$ satisfies both equations for every $t \in F$. So $\ker T_A = \operatorname{span}((-2, 1, 0))$.

Column space. By Proposition 2.6.18, $\operatorname{im} T_A = \operatorname{span}((1, 2), (2, 4), (3, 7))$. The second column is twice the first, so it can be dropped without changing the span (Corollary 1.3.20(c)). The remaining two columns span all of F^2, since

$$7(1, 2) - 2(3, 7) = (1, 0), \quad -3(1, 2) + (3, 7) = (0, 1),$$

and a subspace containing $\mathbf{e}_1$ and $\mathbf{e}_2$ contains $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) = F^2$ (Proposition 1.4.14). So T_A is surjective but not injective: every system $A\mathbf{x} = \mathbf{y}$ has solutions, and Section 2.6.7 shows that the solutions of each one form a translate of the line $\ker T_A$.

(b) Let $A = \begin{pmatrix} 1 & 2i \\ i & -2 \end{pmatrix} \in \mathbb{C}^{2\times 2}$. Its columns are $\mathbf{a}_1 = (1, i)$ and $\mathbf{a}_2 = (2i, -2) = 2i\mathbf{a}_1$, so $\operatorname{im} T_A = \operatorname{span}(\mathbf{a}_1, 2i\mathbf{a}_1) = \operatorname{span}((1, i))$, a line in $\mathbb{C}^2$. Also, $A\mathbf{x} = x_1\mathbf{a}_1 + x_2\mathbf{a}_2 = (x_1 + 2ix_2)\mathbf{a}_1$, which is $\mathbf{0}$ if and only if $x_1 + 2ix_2 = 0$, since $\mathbf{a}_1 \neq \mathbf{0}$ (Proposition 1.2.35). So $\ker T_A = \{(-2it, t) \mid t \in \mathbb{C}\} = \operatorname{span}((-2i, 1))$, and T_A is neither injective nor surjective.

For larger matrices both computations are done by Gauss–Jordan elimination. Theorem 3.4.9 writes every vector of the null space as a linear combination of the *basic solutions* of A, one for each free variable, and Section 4.2 reads off from the reduced matrix which columns of A suffice to span the column space.

In the span explorer below, the vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ are the columns of

$$A = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 2 \end{pmatrix},$$

so their span is the column space of A, the plane $\{(a,b,c) \mid c = a+b\}$ in $\mathbb{R}^3$. The explorer finds the linear relation $\mathbf{v}_1 + \mathbf{v}_2 - \mathbf{v}_3 = \mathbf{0}$, which says that $(1,1,-1) \in \ker T_A$. For a target $\mathbf{w}$ in the plane it shows coefficients x_1, x_2, x_3 with $x_1\mathbf{v}_1 + x_2\mathbf{v}_2 + x_3\mathbf{v}_3 = \mathbf{w}$, and (x_1, x_2, x_3) is a solution of $A\mathbf{x} = \mathbf{w}$. Move the target off the plane and the system becomes inconsistent. Drag $\mathbf{v}_3$ off the plane and the columns span $\mathbb{R}^3$: then T_A is surjective, and the explorer finds no relation, so T_A is also injective (Corollary 2.6.24).

$$\mathbf{v}_1 + \mathbf{v}_2 - \mathbf{v}_3 = \mathbf{0}, \quad (1,-1,0) = \mathbf{v}_1 - \mathbf{v}_2,$$
$$\operatorname{im} T_A = \{(a,b,c) \in \mathbb{R}^3 \mid c = a+b\}.$$

The columns $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ of A span the plane $c = a + b$, the column space of A. The relation $\mathbf{v}_1 + \mathbf{v}_2 - \mathbf{v}_3 = \mathbf{0}$ gives the vector $(1,1,-1)$ of $\ker T_A$, and the target $\mathbf{w} = (1,-1,0) = \mathbf{v}_1 - \mathbf{v}_2$ lies in the column space, so $A\mathbf{x} = \mathbf{w}$ is consistent. (Interactive in the web version.)

Kernels and images through a matrix

By Proposition 2.3.16, $[T_A]_{\mathcal{E}\mathcal{E}} = A$, so the null space and the column space of A are the kernel and the image of the linear map whose matrix in the standard bases is A. In the other direction, the kernel and the image of any linear map between spaces with bases can be computed from any matrix of the map.

Proposition 2.6.20 (Kernel and image in coordinates). Let $\mathcal{B}$ be a basis of V of length n and $\mathcal{C}$ a basis of W of length m, let $T \in \mathrm{L}(V,W)$, and let $A = [T]_{\mathcal{C}\mathcal{B}}$.

(a) For $\mathbf{v} \in V$: $\mathbf{v} \in \ker T$ if and only if $[\mathbf{v}]_{\mathcal{B}} \in \ker T_A$.
(b) For $\mathbf{w} \in W$: $\mathbf{w} \in \operatorname{im} T$ if and only if $[\mathbf{w}]_{\mathcal{C}} \in \operatorname{im} T_A$.
(c) T is injective if and only if T_A is, and T is surjective if and only if T_A is.

In particular, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ maps $\ker T$ bijectively onto $\ker T_A$, and $\mathbf{w} \mapsto [\mathbf{w}]_{\mathcal{C}}$ maps $\operatorname{im} T$ bijectively onto $\operatorname{im} T_A$.

Proof (by chasing coordinates). STANDARD

Uses. Theorem 2.3.9 (The matrix of a map computes the map), Proposition 1.6.16 (The coordinate map is a bijection), Proposition 1.6.19 (Coordinates respect linear combinations), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. The bridge between T and T_A is $A[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}}$ (Theorem 2.3.9).
Hint 2. The coordinate maps are bijections that send $\mathbf{0}$ to $\mathbf{0}$. So $[\mathbf{w}]_{\mathcal{C}} = \mathbf{0}$ if and only if $\mathbf{w} = \mathbf{0}$, and every $\mathbf{x} \in F^n$ is $[\mathbf{v}]_{\mathcal{B}}$ for some $\mathbf{v}$.
Sketch. (a) $A[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}}$, which is $\mathbf{0}$ iff $T(\mathbf{v}) = \mathbf{0}$. (b) If $\mathbf{w} = T(\mathbf{v})$, then $[\mathbf{w}]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}}$. If $[\mathbf{w}]_{\mathcal{C}} = A\mathbf{x}$, write $\mathbf{x} = [\mathbf{v}]_{\mathcal{B}}$; then $[\mathbf{w}]_{\mathcal{C}} = [T(\mathbf{v})]_{\mathcal{C}}$, so $\mathbf{w} = T(\mathbf{v})$. The bijections follow because the coordinate maps are bijections, and (c) follows from the bijections, which match $\{\mathbf{0}\}$ with $\{\mathbf{0}\}$ and W with F^m.

By Theorem 2.3.9, $A[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}}$ for every $\mathbf{v} \in V$. The coordinate maps $V \to F^n$ and $W \to F^m$ are bijections (Proposition 1.6.16) that send $\mathbf{0}$ to $\mathbf{0}$ (Proposition 1.6.19).

(a) $[\mathbf{v}]_{\mathcal{B}} \in \ker T_A$ means $[T(\mathbf{v})]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}} = \mathbf{0}$. Since the coordinate map of W is injective and $[\mathbf{0}]_{\mathcal{C}} = \mathbf{0}$, this holds if and only if $T(\mathbf{v}) = \mathbf{0}$.

(b) If $\mathbf{w} = T(\mathbf{v})$, then $[\mathbf{w}]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}} \in \operatorname{im} T_A$. Conversely, suppose that $[\mathbf{w}]_{\mathcal{C}} = A\mathbf{x}$ for some $\mathbf{x} \in F^n$. Since the coordinate map of V is surjective, $\mathbf{x} = [\mathbf{v}]_{\mathcal{B}}$ for some $\mathbf{v} \in V$, and then $[\mathbf{w}]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}} = [T(\mathbf{v})]_{\mathcal{C}}$. Since the coordinate map of W is injective, $\mathbf{w} = T(\mathbf{v}) \in \operatorname{im} T$.

The bijections. By (a), the coordinate map of V, which is injective, sends $\ker T$ into $\ker T_A$. Every $\mathbf{x} \in \ker T_A$ is $[\mathbf{v}]_{\mathcal{B}}$ for some $\mathbf{v} \in V$, and this $\mathbf{v}$ lies in $\ker T$ by (a). So $\ker T \to \ker T_A$, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$, is a bijection. The same argument with (b) and the coordinate map of W shows that $\operatorname{im} T \to \operatorname{im} T_A$, $\mathbf{w} \mapsto [\mathbf{w}]_{\mathcal{C}}$, is a bijection.

(c) The bijection $\ker T \to \ker T_A$ sends $\mathbf{0}$ to $\mathbf{0}$, so $\ker T = \{\mathbf{0}\}$ if and only if $\ker T_A = \{\mathbf{0}\}$. By Theorem 2.6.11, T is injective if and only if T_A is. If $\operatorname{im} T = W$, then $\operatorname{im} T_A$ is the image of all of W under the coordinate map

of W, which is F^m. Conversely, if $\operatorname{im} T_A = F^m$, then $[\mathbf{w}]_{\mathcal{C}} \in \operatorname{im} T_A$ for every $\mathbf{w} \in W$, so every $\mathbf{w}$ lies in $\operatorname{im} T$ by (b). □

Proof (through the square of maps). STANDARD

> *Uses.* Theorem 2.3.9 (The matrix of a map computes the map), Example 2.5.14 (Invertible maps and matrices), Proposition 2.6.15 (Kernels and images of composites), Proposition 2.1.17 (Compositions of linear maps are linear)
> *Techniques.* Translate between maps and matrices (Technique 2.3.27)
> *Hint 1.* Write $C_{\mathcal{B}} : V \to F^n$ and $C_{\mathcal{C}} : W \to F^m$ for the coordinate maps. Rewrite Theorem 2.3.9 as an equation between composites.
> *Hint 2.* $C_{\mathcal{C}} T = T_A C_{\mathcal{B}}$, and both coordinate maps are invertible. Apply Proposition 2.6.15 to each side, using that $C_{\mathcal{C}}$ is injective and $C_{\mathcal{B}}$ is surjective.
> *Sketch.* With $C_{\mathcal{C}} T = T_A C_{\mathcal{B}}$: since $C_{\mathcal{C}}$ is injective, $\ker T = \ker(C_{\mathcal{C}} T) = \ker(T_A C_{\mathcal{B}})$, which is (a). Since $C_{\mathcal{B}}$ is surjective, $\operatorname{im}(C_{\mathcal{C}}|_{\operatorname{im} T}) = \operatorname{im}(C_{\mathcal{C}} T) = \operatorname{im}(T_A C_{\mathcal{B}}) = \operatorname{im} T_A$, which with injectivity of $C_{\mathcal{C}}$ is (b). For (c), $T_A = C_{\mathcal{C}} T C_{\mathcal{B}}^{-1}$ and $T = C_{\mathcal{C}}^{-1} T_A C_{\mathcal{B}}$, and composites of injective (surjective) maps are injective (surjective).

Let $C_{\mathcal{B}} : V \to F^n$ and $C_{\mathcal{C}} : W \to F^m$ be the coordinate maps. They are linear and invertible (Example 2.5.14(c)), hence bijective, and Theorem 2.3.9 says that

$$C_{\mathcal{C}} \circ T = T_A \circ C_{\mathcal{B}},$$

that is, the two routes around the square of Figure 2.3.1 agree.

(a) Since $C_{\mathcal{C}}$ is injective, Proposition 2.6.15(a) gives $\ker T = \ker(C_{\mathcal{C}} T) = \ker(T_A C_{\mathcal{B}})$. A vector $\mathbf{v}$ lies in $\ker(T_A C_{\mathcal{B}})$ exactly when $C_{\mathcal{B}}(\mathbf{v}) = [\mathbf{v}]_{\mathcal{B}}$ lies in $\ker T_A$.

(b) Since $C_{\mathcal{B}}$ is surjective, Proposition 2.6.15(b) gives

$$\operatorname{im}(C_{\mathcal{C}}|_{\operatorname{im} T}) = \operatorname{im}(C_{\mathcal{C}} T) = \operatorname{im}(T_A C_{\mathcal{B}}) = \operatorname{im} T_A.$$

So $C_{\mathcal{C}}$ maps $\operatorname{im} T$ onto $\operatorname{im} T_A$, and it is injective. In particular, if $[\mathbf{w}]_{\mathcal{C}} \in \operatorname{im} T_A$, then $[\mathbf{w}]_{\mathcal{C}} = [\mathbf{w}']_{\mathcal{C}}$ for some $\mathbf{w}' \in \operatorname{im} T$, and $\mathbf{w} = \mathbf{w}' \in \operatorname{im} T$. The converse is immediate.

(c) By Proposition 2.6.15(a) and (b), a composite of injective linear maps is injective (its kernel is the kernel of the first map) and a composite of surjective linear maps is surjective (its image is the image of the last map). Now $T_A = C_{\mathcal{C}} T C_{\mathcal{B}}^{-1}$ and $T = C_{\mathcal{C}}^{-1} T_A C_{\mathcal{B}}$, and the coordinate maps and their inverses are bijective. So if T is injective or surjective, so is T_A, and conversely. □

The first proof keeps track of individual vectors. The second works with whole maps: it records $[T(\mathbf{v})]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}}$ as the equation $C_{\mathcal{C}} T = T_A C_{\mathcal{B}}$ between linear maps and lets Proposition 2.6.15 do the rest. Any property that is preserved by composing with invertible maps on both sides transfers between T and T_A in this way, and Section 4.5 uses the same idea for change of basis.

Example 2.6.21 (Differentiation in coordinates). Let $D : F[x]_{\le 3} \to F[x]_{\le 2}$ be differentiation. By Example 2.3.4, its matrix in the bases $1, x, x^2, x^3$ and $1, x, x^2$ is

$$A = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}, \quad \text{so} \quad A\mathbf{x} = (x_2, 2x_3, 3x_4).$$

If $2 \neq 0$ and $3 \neq 0$ in F (for instance if F has characteristic 0), then $A\mathbf{x} = \mathbf{0}$ if and only if $x_2 = x_3 = x_4 = 0$, so $\ker T_A = \operatorname{span}(\mathbf{e}_1)$. The columns $\mathbf{0}, \mathbf{e}_1, 2\mathbf{e}_2, 3\mathbf{e}_3$ span F^3. By Proposition 2.6.20, $\ker D$ consists of the polynomials with coordinates in $\operatorname{span}(\mathbf{e}_1)$, the constants, and D is surjective.

Over $\mathbb{F}_3$, the entry 3 is 0, so $A\mathbf{x} = (x_2, 2x_3, 0)$. Now $\ker T_A = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_4)$ and $\operatorname{im} T_A = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$. Translating back, $\ker D = \operatorname{span}(1, x^3)$ and $\operatorname{im} D = \operatorname{span}(1, x) = \mathbb{F}_3[x]_{\le 1}$. Indeed $D(x^3) = 3x^2 = 0$, and no polynomial of degree at most 3 over $\mathbb{F}_3$ has derivative x^2.

2.6.5 Testing on a basis

Intuition. By Theorem 2.2.1, a linear map is determined by its values on a basis $\mathcal{B}$ of V, and those values can be chosen freely. So every property of T must be visible in the list $T(\mathcal{B})$. Injectivity and surjectivity are visible in the simplest possible way. They become linear independence and spanning, the two halves of "basis" (Proposition 1.6.2), carried over to W.

Proposition 2.6.22 (Testing injectivity and surjectivity on a basis). Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of V, let $T \in \mathrm{L}(V, W)$, and write $T(\mathcal{B}) = T(\mathbf{v}_1), ..., T(\mathbf{v}_n)$.

(a) T is injective if and only if $T(\mathcal{B})$ is linearly independent.
(b) T is surjective if and only if $T(\mathcal{B})$ spans W.
(c) T is bijective if and only if $T(\mathcal{B})$ is a basis of W.
(d) In every case $T(\mathcal{B})$ spans $\operatorname{im} T$, and it is a basis of $\operatorname{im} T$ if and only if T is injective.

Proof. ROUTINE

Uses. Proposition 2.6.14 (Injective maps preserve independence), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Theorem 1.5.5 (Independence is decided at zero), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Proposition 1.6.2 (Bases are independent spanning lists), Definition 2.6.3 (Bijective)
Techniques. Test injectivity at $\mathbf{0}$ (Technique 2.6.12), Check it on a basis (Technique 2.2.7)
Hint 1. For (a), one direction is Proposition 2.6.14. For the other, take $\mathbf{v} \in \ker T$, expand it in the basis $\mathcal{B}$, and apply T.
Hint 2. For (b) and (d), express $\operatorname{im} T$ in terms of $T(\mathcal{B})$ with Proposition 2.1.16(a).
Hint 3. (c) is (a) and (b) together.
Sketch. (a) An injective map preserves independence. Conversely, if $\mathbf{v} = \sum_i a_i \mathbf{v}_i \in \ker T$, then $\sum_i a_i T(\mathbf{v}_i) = \mathbf{0}$, so all $a_i = 0$ and $\mathbf{v} = \mathbf{0}$. (b) $\operatorname{im} T = \operatorname{span} T(\mathcal{B})$ since $\mathcal{B}$ spans V, and this equals W iff $T(\mathcal{B})$ spans W. (c) Combine (a) and (b). (d) A list spanning $\operatorname{im} T$ is a basis of it iff it is independent, iff T is injective by (a).

(a) If T is injective, then $T(\mathcal{B})$ is linearly independent by Proposition 2.6.14, since $\mathcal{B}$ is. Conversely, suppose that $T(\mathcal{B})$ is linearly independent, and let $\mathbf{v} \in \ker T$. Since $\mathcal{B}$ spans V, $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$ for some scalars a_i, and by linearity

$$\mathbf{0} = T(\mathbf{v}) = a_1 T(\mathbf{v}_1) + \cdots + a_n T(\mathbf{v}_n).$$

As $T(\mathcal{B})$ is linearly independent, $a_1 = \cdots = a_n = 0$ (Theorem 1.5.5), so $\mathbf{v} = \mathbf{0}$. Hence $\ker T = \{\mathbf{0}\}$, and T is injective by Theorem 2.6.11.

(b) Since $\mathcal{B}$ spans V, Proposition 2.1.16(a) gives

$$\operatorname{im} T = \operatorname{span} T(\mathcal{B}).$$

So $\operatorname{im} T = W$, which is surjectivity, holds if and only if $\operatorname{span} T(\mathcal{B}) = W$.

(c) By Definition 2.6.3 and Proposition 1.6.2, (c) is (a) and (b) together.

(d) The first claim was shown in (b). The list $T(\mathcal{B})$ lies in $\operatorname{im} T$ and spans it, so it is a basis of $\operatorname{im} T$ if and only if it is linearly independent (Proposition 1.6.2), which by (a) happens if and only if T is injective. □

So whether T is injective, and whether it is surjective, can be decided on one basis of V: a list of n vectors instead of all of V. This is Technique 2.2.7 in a new form. There, the property to be checked was an equation between linear maps; here it is a property of the list of values.

Remark 2.6.23 (Which half of "basis" is used where). The proof of (a) used both halves of "basis": independence of $\mathcal{B}$ in the "only if" direction (through Proposition 2.6.14), and spanning in the "if" direction, to expand $\mathbf{v}$. Part (b) used only that $\mathcal{B}$ spans V, so it holds for every spanning list: if $\mathcal{L}$ spans V, then T is surjective if and only if $T(\mathcal{L})$ spans W. The "if" direction of (a) fails for lists that do not span. The map $P(x, y) = x$ sends the independent list $\mathbf{e}_1$ to the independent list 1, yet P is not injective. Compare Remark 2.2.2, where the two halves played similar roles in constructing maps.

For a matrix, the values on the standard basis are the columns.

Corollary 2.6.24 (The columns decide). Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$.
(a) T_A is injective if and only if $\mathbf{a}_1, \dots, \mathbf{a}_n$ is linearly independent.
(b) T_A is surjective if and only if $\mathbf{a}_1, \dots, \mathbf{a}_n$ spans F^m.
(c) T_A is bijective if and only if $\mathbf{a}_1, \dots, \mathbf{a}_n$ is a basis of F^m.

Proof. ROUTINE

Uses. Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Proposition 1.6.7 (Standard bases), Proposition 2.3.13 (Linearity of the product)
Hint 1. Apply Proposition 2.6.22 to T_A and a basis of F^n whose values you know.
Hint 2. The standard basis: $T_A(\mathbf{e}_j) = A\mathbf{e}_j = \mathbf{a}_j$.
Sketch. $\mathbf{e}_1, \dots, \mathbf{e}_n$ is a basis of F^n and $T_A(\mathbf{e}_j) = \mathbf{a}_j$, so $T_A(\mathcal{E})$ is the list of columns. Apply Proposition 2.6.22(a)–(c).

The standard basis $\mathcal{E} = \mathbf{e}_1, \dots, \mathbf{e}_n$ is a basis of F^n (Proposition 1.6.7), and $T_A(\mathbf{e}_j) = A\mathbf{e}_j = \mathbf{a}_j$ by Proposition 2.3.13(c). So $T_A(\mathcal{E})$ is the list of columns of A, and (a)–(c) are parts (a)–(c) of Proposition 2.6.22. □

Part (a) can also be read off from the definition of the product. Since $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$, a nonzero vector of $\ker T_A$ is the same thing as a nontrivial linear relation among the columns, so $\ker T_A = \{\mathbf{0}\}$ says exactly that the columns are linearly independent (Theorem 1.5.5). The three parts of the corollary are the equivalences (I) ⇔ (III) in the Fundamental Theorems of Section 2.7. Combined with Proposition 2.6.20, they decide injectivity and surjectivity of any map between spaces with bases from the columns of one of its matrices.

Example 2.6.25 (Evaluating at three points). Let $E : F[x]_{\le 2} \to F^3$, $E(p) = (p(0), p(1), p(2))$, where $2 = 1 + 1$. Each entry of E is an evaluation map, so E is linear (Example 2.1.9). On the basis $1, x, x^2$,

$$E(1) = (1, 1, 1), \quad E(x) = (0, 1, 2), \quad E\big(x^2\big) = (0, 1, 4).$$

Suppose $a(1,1,1) + b(0,1,2) + c(0,1,4) = \mathbf{0}$. The first entry gives $a = 0$, then $b + c = 0$ and $2b + 4c = 0$, so $2c = (2b + 4c) - 2(b + c) = 0$.

If $2 \neq 0$ in F, then $c = 0$ and $b = 0$, so the three values are linearly independent and E is injective by Proposition 2.6.22(a). They also span F^3, because

$$\mathbf{e}_3 = 2^{-1}\big(E\big(x^2\big) - E(x)\big), \quad \mathbf{e}_2 = E(x) - 2\mathbf{e}_3, \quad \mathbf{e}_1 = E(1) - \mathbf{e}_2 - \mathbf{e}_3,$$

so E is bijective by Proposition 2.6.22(c): for every $(y_0, y_1, y_2) \in F^3$ there is exactly one $p \in F[x]_{\le 2}$ with $p(0) = y_0$, $p(1) = y_1$, and $p(2) = y_2$. This is a case of polynomial interpolation (Theorem 3.4.24).

Over $\mathbb{F}_2$, $2 = 4 = 0$, so $E(x) = E\big(x^2\big) = (0, 1, 0)$, and the values are linearly dependent. So E is not injective; indeed $E\big(x^2 + x\big) = (0, 1 + 1, 0) = \mathbf{0}$. Nor is it surjective: every value of E has equal first and third entries, because over $\mathbb{F}_2$ the points 0 and 2 coincide, so $(1, 0, 0) \notin \operatorname{im} E$.

Exercise 2.6.26. ROUTINE For $c \in F$, let $T_c : F[x]_{\le 2} \to F[x]_{\le 2}$, $T_c(p) = D(xp) - cp$, where D is differentiation.

(a) Compute $T_c(1)$, $T_c(x)$, and $T_c\big(x^2\big)$.

(b) Over $\mathbb{Q}$, find all c for which T_c is injective, and all c for which it is surjective.

(c) Answer the same questions over $\mathbb{F}_2$, over $\mathbb{F}_3$, and over $\mathbb{F}_5$.

Solution on page 1162

2.6.6 Computing kernels and images

Here are the kernels and images of the main examples of Section 2.1.

Example 2.6.27 (Differentiation on $F[x]$). Let $D : F[x] \to F[x]$ be differentiation. For $f = \sum_{k=0}^{n} a_k x^k$, Example 2.1.9 gives $D(f) = \sum_{k=1}^{n} (ka_k) x^{k-1}$, where $ka_k = (k * 1)a_k$, so the coefficient of x^{k-1} in $D(f)$ is $(k * 1)a_k$.

Kernel. $D(f) = \mathbf{0}$ if and only if $(k * 1)a_k = 0$ for every $k \geq 1$. If F has characteristic 0 (Definition 1.1.28), then $k * 1 \neq 0$ for $k \geq 1$, so this forces $a_k = 0$ for all $k \geq 1$ (Proposition 1.1.17). Hence $\ker D = \operatorname{span}(1)$, the constant polynomials. Over $\mathbb{F}_p$, $k * 1 = 0$ exactly when p divides k, so $D(f) = \mathbf{0}$ if and only if $a_k = 0$ for every k not divisible by p. Hence $\ker D$ consists of the polynomials $b_0 + b_1 x^p + b_2 x^{2p} + \cdots$, those in which only powers of x^p occur.

Image. In characteristic 0, $DJ = \mathrm{id}$ for the antiderivative J of Example 2.5.24, so D is surjective by Proposition 2.5.5. Over $\mathbb{F}_p$ it is not. The coefficient of x^{k-1} in $D(f)$ is $(k * 1)a_k$, which is 0 whenever p divides k, so every value of D has coefficient 0 at $x^{p-1}, x^{2p-1}, x^{3p-1}, \ldots$. Conversely, if $q = \sum_j c_j x^j$ has $c_j = 0$ whenever p divides $j + 1$, then

$$q = D\left(\sum_{p \nmid j+1} ((j+1) * 1)^{-1} c_j x^{j+1} \right).$$

So $\operatorname{im} D$ consists of the polynomials whose coefficients at $x^{p-1}, x^{2p-1}, \ldots$ vanish. In particular $x^p \in \ker D$ and $x^{p-1} \notin \operatorname{im} D$, as in Exercise 2.5.42.

Example 2.6.28 (The trace). For $n \geq 1$, the trace $\operatorname{tr} : F^{n \times n} \to F$ is linear (Proposition 2.4.27). Write $U_{ij} = \mathbf{e}_i \mathbf{e}_j^{\mathsf{T}}$ for the matrix units, which form a basis of $F^{n \times n}$ (Lemma 2.4.24). Then $\operatorname{tr} U_{ij}$ is 1 if $i = j$ and 0 otherwise.

Image. The values $\operatorname{tr} U_{ij}$ include 1, which spans F, so tr is surjective by Proposition 2.6.22(b). Explicitly, $c = \operatorname{tr}(cU_{11})$.

Kernel. $\ker \operatorname{tr}$ is the subspace of **trace-zero** matrices, $\{A \in F^{n \times n} \mid a_{11} + \cdots + a_{nn} = 0\}$. For $n \geq 2$ it contains $U_{12} \neq 0$, so tr is not injective. To find a spanning list, let $\operatorname{tr} A = 0$. Then $a_{nn} = -\big(a_{11} + \cdots + a_{n-1,n-1}\big)$, and expanding A in matrix units gives

$$A = \sum_{i \neq j} a_{ij} U_{ij} + \sum_{i=1}^{n-1} a_{ii} (U_{ii} - U_{nn}).$$

So $\ker \operatorname{tr}$ is spanned by the $n^2 - n$ matrices U_{ij} with $i \neq j$ and the $n - 1$ matrices $U_{ii} - U_{nn}$, all of which have trace 0. By Proposition 2.4.28, every commutator $AB - BA$ lies in $\ker \operatorname{tr}$, which is why $AB - BA = I_n$ is impossible when $n * 1 \neq 0$ (Proposition 2.4.30).

Example 2.6.29 (Evaluation at 0, and multiplication by x). Let $\mathrm{ev}_0 : F[x] \to F$, $\mathrm{ev}_0(p) = p(0)$, and let $M : F[x] \to F[x]$, $M(p) = xp$. For $p = a_0 + a_1 x + \cdots + a_n x^n$, $\mathrm{ev}_0(p) = a_0$. So ev_0 is surjective, since $c = \mathrm{ev}_0(c)$ for each constant c, and its kernel is the set of polynomials with constant term 0.

That kernel is exactly $\operatorname{im} M$. Every xq has constant term 0, and conversely $a_1 x + a_2 x^2 + \cdots + a_n x^n = M\big(a_1 + a_2 x + \cdots + a_n x^{n-1}\big)$. So in

$$F[x] \xrightarrow{M} F[x] \xrightarrow{\mathrm{ev}_0} F,$$

M is injective (Example 2.6.4(e)), ev_0 is surjective, and the vectors that the second map sends to 0 are precisely the values of the first.

For $t \in F$, the kernel of $\mathrm{ev}_t(p) = p(t)$ consists of the polynomials with root t. It contains every value of $M - t\,\mathrm{id}$: if $q = \sum_k b_k x^k$, then $(xq)(t) = \sum_k b_k t^{k+1} = tq(t)$, so $(xq - tq)(t) = tq(t) - tq(t) = 0$ by Proposition 1.2.18(c). In fact $\ker \mathrm{ev}_t = \operatorname{im}(M - t\,\mathrm{id})$: this is the factor theorem, a consequence of division with remainder (Theorem 7.1.14).

2.6.7 Preimages and the equation $T(\mathbf{v}) = \mathbf{w}$

The kernel describes the solutions of $T(\mathbf{v}) = \mathbf{0}$, and the image records which equations $T(\mathbf{v}) = \mathbf{w}$ have solutions at all. Together they describe the solutions of every such equation.

Notation 2.6.30 (Preimages). For $Y \subseteq W$, the **preimage** of Y under T is

$$T^{-1}(Y) = \{\mathbf{v} \in V \mid T(\mathbf{v}) \in Y\}.$$

For $\mathbf{w} \in W$, we write $T^{-1}(\mathbf{w})$ for $T^{-1}(\{\mathbf{w}\})$, the set of solutions of $T(\mathbf{v}) = \mathbf{w}$, also called the **fiber** of T over $\mathbf{w}$.

The notation does not presuppose that T is invertible: $T^{-1}(\mathbf{w})$ is a set, possibly empty. If T happens to be invertible, it is the one-element set $\{T^{-1}(\mathbf{w})\}$, and we will never need to tell the two apart. In this notation $\ker T = T^{-1}(\mathbf{0})$, and T is injective if and only if every fiber has at most one element, surjective if and only if every fiber is nonempty.

Corollary 2.6.31 (Fibers are translates of the kernel). Let $\mathbf{w} \in W$.

(a) If $\mathbf{w} \notin \operatorname{im} T$, then $T^{-1}(\mathbf{w}) = \emptyset$.

(b) If $\mathbf{w} \in \operatorname{im} T$ and $\mathbf{v}_0 \in T^{-1}(\mathbf{w})$, then $T^{-1}(\mathbf{w}) = \mathbf{v}_0 + \ker T$, and $\mathbf{z} \mapsto \mathbf{v}_0 + \mathbf{z}$ is a bijection from $\ker T$ onto $T^{-1}(\mathbf{w})$.

(c) Every $\mathbf{v} \in V$ lies in exactly one fiber, namely $T^{-1}(T(\mathbf{v}))$. So V is the disjoint union of the fibers $T^{-1}(\mathbf{w})$ with $\mathbf{w} \in \operatorname{im} T$, each of which is a translate of $\ker T$.

Proof. ROUTINE

Uses. Definition 2.6.6 (Image), Definition 2.6.5 (Kernel), Notation 3.1.17 (Translates), Proposition 3.1.19 (Solution sets are translates of the kernel)
Techniques. Particular plus homogeneous (Technique 3.1.18), Double containment (Technique 1.3.14)
Hint 1. (a) is the definition of the image. For (b), prove the two containments: apply T to $\mathbf{v}_0 + \mathbf{z}$ with $\mathbf{z} \in \ker T$, and for a solution $\mathbf{v}$, look at $\mathbf{v} - \mathbf{v}_0$.
Hint 2. For (c), $\mathbf{v} \in T^{-1}(\mathbf{w})$ means $T(\mathbf{v}) = \mathbf{w}$. How many $\mathbf{w}$ satisfy this for a fixed $\mathbf{v}$?
Sketch. (a) No $\mathbf{v}$ has $T(\mathbf{v}) = \mathbf{w}$. (b) $T(\mathbf{v}_0 + \mathbf{z}) = \mathbf{w} + \mathbf{0}$ for $\mathbf{z} \in \ker T$, and if $T(\mathbf{v}) = \mathbf{w}$, then $\mathbf{v} - \mathbf{v}_0 \in \ker T$; this is Proposition 3.1.19. The map $\mathbf{z} \mapsto \mathbf{v}_0 + \mathbf{z}$ is injective by cancellation. (c) $\mathbf{v}$ lies in $T^{-1}(\mathbf{w})$ exactly when $\mathbf{w} = T(\mathbf{v})$.

(a) If $\mathbf{w} \notin \operatorname{im} T$, then no $\mathbf{v} \in V$ satisfies $T(\mathbf{v}) = \mathbf{w}$ (Definition 2.6.6).

(b) This is Proposition 3.1.19; we repeat the argument. If $\mathbf{z} \in \ker T$, then $T(\mathbf{v}_0 + \mathbf{z}) = \mathbf{w} + \mathbf{0} = \mathbf{w}$, so $\mathbf{v}_0 + \ker T \subseteq T^{-1}(\mathbf{w})$. If $T(\mathbf{v}) = \mathbf{w}$, then $T(\mathbf{v} - \mathbf{v}_0) = \mathbf{w} - \mathbf{w} = \mathbf{0}$, so $\mathbf{v} = \mathbf{v}_0 + (\mathbf{v} - \mathbf{v}_0) \in \mathbf{v}_0 + \ker T$. Hence $T^{-1}(\mathbf{w}) = \mathbf{v}_0 + \ker T$, which says that $\mathbf{z} \mapsto \mathbf{v}_0 + \mathbf{z}$ maps $\ker T$ onto the fiber. It is injective, because $\mathbf{v}_0 + \mathbf{z} = \mathbf{v}_0 + \mathbf{z}'$ implies $\mathbf{z} = \mathbf{z}'$.

(c) $\mathbf{v} \in T^{-1}(\mathbf{w})$ means $T(\mathbf{v}) = \mathbf{w}$, which holds for exactly one $\mathbf{w}$, namely $\mathbf{w} = T(\mathbf{v}) \in \operatorname{im} T$. So the fibers over the vectors of $\operatorname{im} T$ are disjoint and cover V. By (b), each of them is a translate of $\ker T$. □

So the domain is sliced into parallel copies of $\ker T$, one for each vector of $\operatorname{im} T$. The map T collapses each slice to a single vector, and different slices go to different vectors. In this picture, Theorem 2.6.11 says that T is injective exactly when the slices are single points. Figure 2.6.1 shows the slices for

$$A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix}, \quad T_A(\mathbf{x}) = (x_1 + 2x_2)\begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

Here $\ker T_A$ is the line $x_1 + 2x_2 = 0$, the column space is $\operatorname{im} T_A = \operatorname{span}((1,1))$, and the fiber over $t(1,1)$ is the line $x_1 + 2x_2 = t$, parallel to the kernel.

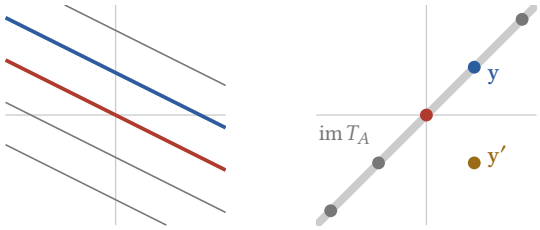


Figure 2.6.1. The fibers of T_A for $A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix}$ over $\mathbb{R}$. Left: $\ker T_A$ (red) and the fibers $x_1 + 2x_2 = t$ for $t = -4, -2, 2, 4$, parallel translates of the kernel. The blue one is the fiber over $\mathbf{y} = (2, 2)$, the solution set of $A\mathbf{x} = \mathbf{y}$. Right: the column space $\operatorname{im} T_A = \operatorname{span}((1, 1))$ (grey), with the vectors $t(1, 1)$ onto which the fibers collapse. The vector $\mathbf{y}' = (2, -2)$ is not in $\operatorname{im} T_A$, so its fiber is empty.

The row and column pictures in Section 3.4.4 show the same phenomenon interactively for a single fiber: there $\mathbf{y}$ can be dragged along the column space, where the solutions form a line parallel to the kernel, and off it, where there are none.

Remark 2.6.32 (What the slicing leads to). The slicing suggests a count: V consists of as many copies of $\ker T$ as there are vectors in $\operatorname{im} T$. Over a finite field this is literally true, $|V| = |\ker T| \cdot |\operatorname{im} T|$ (Exercise 2.6.44). For finite-dimensional spaces over any field, the count becomes the dimension formula $\dim V = \dim \ker T + \dim \operatorname{im} T$, which is rank–nullity (Theorem 4.2.11). Treating each slice as a single object leads to the quotient space $V/\ker T$, and the bijection between the slices and $\operatorname{im} T$ becomes the first isomorphism theorem (Theorem 4.6.34).

Exercise 2.6.33. ROUTINE Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 7 \end{pmatrix}$ as in Example 2.6.19(a). Find one solution of $A\mathbf{x} = (1, 3)$ by inspection, and then describe all of them.

Solution on page 1162

Exercises

Exercise 2.6.34. ROUTINE Let $T : \mathbb{R}^3 \to \mathbb{R}^3$, $T(x, y, z) = (x + y, y + z, x - z)$.

(a) Find $\ker T$, and describe $\operatorname{im} T$ by a single linear equation.

(b) Decide whether $(1, 2, 3)$ and $(2, 1, 1)$ lie in $\operatorname{im} T$. For the one that does, find all of its preimages.

Solution on page 1163

Exercise 2.6.35. ROUTINE Let $A = \begin{pmatrix} 1 & i & 1+i \\ i & -1 & i-1 \end{pmatrix} \in \mathbb{C}^{2\times 3}$.

(a) Show that every column of A is a multiple of $(1, i)$, and find $\operatorname{im} T_A$.

(b) Find $\ker T_A$ as the span of two vectors.

(c) Is T_A injective? Is it surjective? Find all solutions of $A\mathbf{x} = (1 + i, i - 1)$.

Solution on page 1163

Exercise 2.6.36. ROUTINE Let $S, T \in \mathrm{L}(V, W)$.

(a) Show that $\ker S \cap \ker T \subseteq \ker(S + T)$.

(b) Show that $\operatorname{im}(S + T) \subseteq \operatorname{im} S + \operatorname{im} T$, the sum of subspaces from Proposition 1.4.24.

(c) Show that both inclusions can be strict.

Solution on page 1163

Exercise 2.6.37. STANDARD Prove or disprove each statement.

(a) If $S, T \in \mathrm{L}(V, W)$ satisfy $\ker S = \ker T$ and $\operatorname{im} S = \operatorname{im} T$, then $S = T$.

(b) For every $T \in \mathrm{L}(V)$, $\ker T \cap \operatorname{im} T = \{\mathbf{0}\}$.

(c) If $P \in \mathrm{L}(V)$ satisfies $P^2 = P$, then $\ker P \cap \operatorname{im} P = \{\mathbf{0}\}$.

(d) If $T \in \mathrm{L}(V, W)$ is injective and U is a subspace of V, then the restriction $T|_U : U \to W$ is injective.

(e) If $T \in \mathrm{L}(V, W)$ is not injective, then T is not surjective.

Solution on page 1164

Exercise 2.6.38. STANDARD

(a) Find $T \in \mathrm{L}(F^2)$ with $\ker T = \operatorname{im} T$.

(b) Find $T \in \mathrm{L}(F^4)$ with $\ker T = \operatorname{im} T$.

(c) Show that every $T \in \mathrm{L}(V)$ with $\ker T = \operatorname{im} T$ satisfies $T^2 = 0$, and that $T^2 = 0$ does not imply $\ker T = \operatorname{im} T$.

Solution on page 1164

Exercise 2.6.39. STANDARD Let $S \in \mathrm{L}(U, V)$ and $T \in \mathrm{L}(V, W)$.

(a) Show that $\ker(TS) = \ker S$ if and only if $\ker T \cap \operatorname{im} S = \{\mathbf{0}\}$.

(b) Show that $\operatorname{im}(TS) = \operatorname{im} T$ if and only if $\operatorname{im} S + \ker T = V$.

(c) Deduce that for $T \in \mathrm{L}(V)$, $\ker T^2 = \ker T$ if and only if $\ker T \cap \operatorname{im} T = \{\mathbf{0}\}$, and $\operatorname{im} T^2 = \operatorname{im} T$ if and only if $\ker T + \operatorname{im} T = V$.

Solution on page 1164

Exercise 2.6.40. ROUTINE Find the error in the following argument, show that its claim is false, and state a correct version.

Claim. Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of V and $T \in \mathrm{L}(V, W)$. If $T(\mathbf{v}_i) \neq \mathbf{0}$ for every i, then T is injective.

Proof. Let $\mathbf{v} \in \ker T$ and write $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. Then $\mathbf{0} = T(\mathbf{v}) = a_1T(\mathbf{v}_1) + \cdots + a_nT(\mathbf{v}_n)$. None of the vectors $T(\mathbf{v}_i)$ is $\mathbf{0}$, so every coefficient a_i must be 0. Hence $\mathbf{v} = \mathbf{0}$, and T is injective by Theorem 2.6.11.

Solution on page 1165

Exercise 2.6.41. STANDARD

(a) Let $D \in \mathrm{L}(\mathbb{F}_2[x]_{\leq 3})$ be differentiation. Find $\ker D$ and $\operatorname{im} D$, and show that they are equal.

(b) Find $\ker D$ and $\operatorname{im} D$ for differentiation $D \in \mathrm{L}(\mathbb{F}_3[x]_{\leq 3})$. Are they equal?

(c) Show that $D^2 = 0$ on all of $\mathbb{F}_2[x]$.

Solution on page 1165

Exercise 2.6.42. STANDARD Let $T \in \mathrm{L}(V, W)$ be injective, and let $S \in \mathrm{L}(U, W)$.

(a) Suppose $\operatorname{im} S \subseteq \operatorname{im} T$. Show that there is exactly one linear map $R : U \to V$ with $TR = S$.

(b) Show that the hypothesis $\operatorname{im} S \subseteq \operatorname{im} T$ in (a) is necessary.

Solution on page 1166

Exercise 2.6.43. HARD Let $T \in \mathrm{L}(V,W)$ be surjective, and let $S \in \mathrm{L}(V,U)$.

(a) Suppose $\ker T \subseteq \ker S$. Show that there is exactly one linear map $R : W \to U$ with $RT = S$.

(b) Show that the hypothesis $\ker T \subseteq \ker S$ in (a) is necessary.

Solution on page 1166

Exercise 2.6.44. STANDARD Let p be a prime, let V and W be vector spaces over $\mathbb{F}_p$ with V finite, and let $T \in \mathrm{L}(V,W)$.

(a) Show that $|V| = |\ker T| \cdot |\operatorname{im} T|$.

(b) Deduce that if $T : \mathbb{F}_p^n \to \mathbb{F}_p^m$ is linear and injective, then $n \leq m$, and if it is linear and surjective, then $n \geq m$.

Solution on page 1167

Exercise 2.6.45. HARD Let p be a prime. Show that exactly $\left(p^3-1\right)\left(p^3-p\right)$ linear maps $\mathbb{F}_p^3 \to \mathbb{F}_p^2$ are surjective. (Every such map is T_A for exactly one $A \in \mathbb{F}_p^{2\times 3}$, by Theorem 2.3.20 and Proposition 2.3.16. Use Corollary 2.6.24 and Theorem 1.4.25.)

Solution on page 1167

Exercise 2.6.46. STANDARD Let $\Phi : F^{n\times n} \to F^{n\times n}$, $\Phi(A) = A - A^{\mathsf{T}}$.

(a) Show that Φ is linear and that $\ker \Phi$ is the subspace of symmetric matrices.

(b) Suppose $1+1 \neq 0$ in F. Show that $\operatorname{im} \Phi$ is the subspace of skew-symmetric matrices.

(c) Over $\mathbb{F}_2$, show that $\operatorname{im} \Phi$ consists of the symmetric matrices with all diagonal entries 0. Deduce that $\operatorname{im} \Phi$ is strictly smaller than the set of skew-symmetric matrices when $n \geq 1$.

Solution on page 1168

Exercise 2.6.47. HARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$.

(a) Show that if $\mathbf{x} \in \ker T_{I_n - BA}$, then $A\mathbf{x} \in \ker T_{I_m - AB}$, and that if $\mathbf{y} \in \ker T_{I_m - AB}$, then $B\mathbf{y} \in \ker T_{I_n - BA}$.

(b) Show that $\mathbf{x} \mapsto A\mathbf{x}$ is a bijection from $\ker T_{I_n - BA}$ onto $\ker T_{I_m - AB}$, with inverse $\mathbf{y} \mapsto B\mathbf{y}$.

(c) Deduce that $T_{I_n - BA}$ is injective if and only if $T_{I_m - AB}$ is.

Solution on page 1168

Exercise 2.6.48. ROUTINE Let $\ell = \operatorname{span}(\mathbf{u})$ be a line in $\mathbb{R}^2$, with $\mathbf{u} = (\cos\theta, \sin\theta)$, and let $\ell^\perp = \operatorname{span}((-\sin\theta, \cos\theta))$. Let Pr_ℓ be the projection onto ℓ and $S_\ell = 2\operatorname{Pr}_\ell - \mathrm{id}$ the reflection across ℓ (Example 2.1.11). Find the kernel and the image of each map.

(a) $\operatorname{Pr}_\ell - \mathrm{id}$.

(b) $S_\ell - \mathrm{id}$.

(c) $S_\ell + \mathrm{id}$.

(d) $R_\varphi - \mathrm{id}$, for a rotation angle φ that is not a multiple of 2π.

Solution on page 1169

Exercise 2.6.49. HARD Let $T \in \mathrm{L}(V)$ satisfy $T^3 = T$, and suppose $1+1 \neq 0$ in F.

(a) Show that every $\mathbf{v} \in V$ can be written as $\mathbf{v} = \mathbf{v}_0 + \mathbf{v}_+ + \mathbf{v}_-$ with $\mathbf{v}_0 \in \ker T$, $\mathbf{v}_+ \in \ker(T - \mathrm{id})$, and $\mathbf{v}_- \in \ker(T + \mathrm{id})$.

(b) Show that the decomposition in (a) is unique.

(c) Show that (a) fails over $\mathbb{F}_2$ for $T = T_A$, $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.

Solution on page 1169

Exercise 2.6.50. CHALLENGE

(a) Let $S, T \in \mathrm{L}(V, W)$ both be nonzero. Show that some $\mathbf{v} \in V$ has $S(\mathbf{v}) \neq \mathbf{0}$ and $T(\mathbf{v}) \neq \mathbf{0}$.

(b) Find three nonzero linear maps $T_1, T_2, T_3 : \mathbb{F}_2^2 \to \mathbb{F}_2$ such that every $\mathbf{v} \in \mathbb{F}_2^2$ lies in some $\ker T_i$.

(c) Let F be infinite, and let $T_1, \ldots, T_k \in \mathrm{L}(V, W)$ all be nonzero. Show that some $\mathbf{v} \in V$ has $T_i(\mathbf{v}) \neq \mathbf{0}$ for every i.

Solution on page 1170

Exercise 2.6.51. STANDARD Let $T \in \mathrm{L}(V, W)$.

(a) Show that $\mathrm{im}(T\restriction_X)$ is a subspace of W for every subspace X of V, and that $T^{-1}(U)$ is a subspace of V containing $\ker T$ for every subspace U of W.

(b) Show that $\mathrm{im}\left(T\restriction_{T^{-1}(U)}\right) = U \cap \mathrm{im}\, T$ for every subspace U of W.

(c) Show that $T^{-1}(\mathrm{im}(T\restriction_X)) = X + \ker T$ for every subspace X of V.

Solution on page 1171

Exercise 2.6.52. STANDARD Let $S, T \in \mathrm{L}(V)$ with $ST = TS$.

(a) Show that S maps $\ker T$ into $\ker T$ and $\mathrm{im}\, T$ into $\mathrm{im}\, T$.

(b) Deduce that for every $\lambda \in F$, T maps $\ker(T - \lambda\,\mathrm{id})$ into itself and $\mathrm{im}(T - \lambda\,\mathrm{id})$ into itself.

(c) Show by an example that (a) can fail if $ST \neq TS$.

Solution on page 1171

2.7 The Fundamental Theorems

For a matrix $A \in F^{m \times n}$, the last two sections produced a long list of properties. The map T_A can be injective or surjective, its kernel can be $\{\mathbf{0}\}$ and its image F^m, the columns of A can be linearly independent or span F^m, A can have a left or a right inverse, and the equation $A\mathbf{x} = \mathbf{y}$ can have at most one or at least one solution for each $\mathbf{y}$. Many of these turned out to be the same property in different words. The three Fundamental Theorems sort them into three groups: the conditions that say "at most one", those that say "at least one", and those that say "exactly one". Almost every equivalence among them is a result we already have, read the right way. The exception is that an injective T_A has a linear left inverse, and a surjective one a linear right inverse. These need a construction, which the lecture postpones until row reduction is available (Section 3.5). We give a direct construction here as well.

Each theorem is a list of equivalent statements, so we start with how such lists are proved. Throughout, $A \in F^{m \times n}$ has columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, and $T_A : F^n \to F^m$ is the linear map $\mathbf{x} \mapsto A\mathbf{x}$ (Definition 2.3.15).

2.7.1 Proving that statements are equivalent

A theorem of the form "the following are equivalent" (TFAE) about statements $P_1, \ldots, P_k$ asserts that they are all true or all false. Proving every implication $P_i \Rightarrow P_j$ separately would take $k(k-1)$ arguments, which is 20 for the five conditions of a Fundamental Theorem. Implications can be chained, so far fewer are needed.

Technique 2.7.1 (Proving TFAE). To prove that $P_1, \ldots, P_k$ are equivalent, prove some implications $P_i \Rightarrow P_j$ such that every statement can be reached from every other by following implications. Then any P_i implies any P_j, by chaining. Two shapes cover most cases.

- A **cycle** $P_1 \Rightarrow P_2 \Rightarrow \cdots \Rightarrow P_k \Rightarrow P_1$ uses k implications, the fewest possible. The order is ours to choose, and a good order makes every step short. Usually one goes from the most informative statement (one that hands us an object, such as an inverse) toward the least informative, and closes the loop with the one step that needs an idea.
- A **hub with spokes** fixes one statement, say P_1, and proves $P_i \Leftrightarrow P_1$ for every other i. It uses more implications than a cycle, but it is the natural shape when earlier results already relate each P_i to P_1. Each spoke is then a citation, and the citations are a complete proof, because equivalence is transitive.

Mixed shapes are fine. Draw the statements as points and the proved implications as arrows, and check that you can travel from any point to any other along arrows. Two mistakes are common. Equivalences inside two separate groups of statements say nothing about one group versus the other (Exercise 2.7.21). And each arrow must be proved without the theorem it belongs to, and without any result that depends on that theorem. Going around a cycle is not circular reasoning, since every arrow is proved on its own; quoting the theorem to prove one of its own arrows would be.

The payoff comes after the proof. To show that one of the statements holds, check whichever is easiest; to use one, use whichever is strongest. We have already seen cycles in Theorem 1.4.3 and Theorem 2.1.3. The canonical example is the First Fundamental Theorem (Theorem 2.7.2), whose proof is a hub with three spokes plus two implications about inverses.

Used in. Theorem 1.4.3, Theorem 2.7.2, Theorem 2.7.4, Exercise 2.7.6, Theorem 2.7.8, Exercise 2.7.15, Corollary 2.7.16, Exercise 2.7.21, Exercise 2.7.23, Exercise 2.8.11, Corollary 3.4.20, Theorem 3.5.12, Theorem 3.5.13, Theorem 3.5.14, Corollary 3.5.25, Theorem 4.4.7, Corollary 4.5.21, Theorem 4.5.25, Lemma 4.6.14, Theorem 4.7.22, Theorem 4.7.37, Proposition 6.3.34, Theorem 7.4.16, Proposition 7.5.2, Theorem 7.6.15, Theorem 8.2.5, Theorem 8.2.12, Theorem 8.3.5, Proposition 8.3.15, Theorem 8.4.4, Theorem 8.4.11, Theorem 8.4.15, Theorem A.2.1, Lemma A.3.5, Exercise 2.7.19, Exercise 4.2.50, Exercise 6.4.57, Exercise 6.6.40.

2.7.2 The First and Second Fundamental Theorems

Intuition (Five ways to say that nothing is lost). Each condition of the First Fundamental Theorem says, in its own language, that T_A loses no information. In (I), different inputs give different outputs. In (II), each equation $A\mathbf{x} = \mathbf{y}$ pins down $\mathbf{x}$ whenever it has a solution at all. In (III), no nontrivial combination of the columns vanishes, so the coefficients of a combination can be recovered from its value. In (IV), no nonzero vector is sent to $\mathbf{0}$. In (V), a linear map recovers the input from the output. The first four are visibly one statement in four languages, and Section 2.6 proved as much. The fifth is of a different kind, since it asserts that a certain map exists.

Theorem 2.7.2 (First Fundamental Theorem). Let $A \in F^{m\times n}$. The following are equivalent.

(I) T_A is injective.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has at most one solution $\mathbf{x} \in F^n$.
(III) The columns of A are linearly independent.
(IV) $\ker T_A = \{\mathbf{0}\}$.
(V) T_A has a left inverse: a linear map $S : F^m \to F^n$ with $S \circ T_A = \mathrm{id}_{F^n}$.

We use (I) as the hub. Parts 1 and 2 of the proof only reread earlier results. Part 3 needs a construction, and it is given in Section 2.7.4.

Proof, part 1 of 3: (I)–(IV) are equivalent. ROUTINE

> *Uses.* Definition 2.6.1 (Injective), Definition 2.3.15 (The linear map of a matrix), Corollary 2.6.24 (The columns decide), Proposition 2.3.13 (Linearity of the product), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
> *Techniques.* Proving TFAE (Technique 2.7.1)
> *Hint 1.* Each of (II), (III), and (IV) is equivalent to (I) by a definition or by a result of Section 2.6. Find the right one for each.
> *Hint 2.* In the language of the map T_A, what is a solution of $A\mathbf{x} = \mathbf{y}$? What are the values of T_A on the standard basis?
> *Hint 3.* (I) ⇔ (III) is Corollary 2.6.24(a), and (I) ⇔ (IV) is Theorem 2.6.11.
> *Sketch.* Hub at (I). A solution of $A\mathbf{x} = \mathbf{y}$ is a preimage of $\mathbf{y}$ under T_A, so (II) is the definition of injectivity. The columns are the values $T_A(\mathbf{e}_j)$, so (I) ⇔ (III) is the basis test of Corollary 2.6.24(a). Since T_A is linear, (I) ⇔ (IV) is Theorem 2.6.11.

We prove (I) ⇔ (II), (I) ⇔ (III), and (I) ⇔ (IV).

(I) ⇔ (II). By Definition 2.3.15, $\mathbf{x}$ is a solution of $A\mathbf{x} = \mathbf{y}$ exactly when $T_A(\mathbf{x}) = \mathbf{y}$, that is, when $\mathbf{x}$ is a preimage of $\mathbf{y}$ under T_A. So (II) says that every $\mathbf{y} \in F^m$ has at most one preimage under T_A, which is the definition of injectivity (Definition 2.6.1).

(I) ⇔ (III). This is Corollary 2.6.24(a).

(I) ⇔ (IV). T_A is linear (Proposition 2.3.13), so this is Theorem 2.6.11 applied to $T = T_A$.

Proof, part 2 of 3: (V) ⇒ (I). ROUTINE

> *Uses.* Proposition 2.5.4 (Left inverses give uniqueness)
> *Hint 1.* Suppose $S \circ T_A = \mathrm{id}_{F^n}$ and $A\mathbf{x} = A\mathbf{x}'$. Apply S to both sides.
> *Hint 2.* This is Proposition 2.5.4.
> *Sketch.* Applying S to $A\mathbf{x} = A\mathbf{x}'$ gives $\mathbf{x} = \mathbf{x}'$. This is Proposition 2.5.4.

Let S be a left inverse of T_A. By Proposition 2.5.4, T_A is injective. Explicitly, if $T_A(\mathbf{x}) = T_A(\mathbf{x}')$, then

$$\mathbf{x} = S(T_A(\mathbf{x})) = S(T_A(\mathbf{x}')) = \mathbf{x}'.$$

What remains is to show that an injective T_A has a left inverse. Since (I)–(IV) are already known to be equivalent, we may start from whichever of them is most convenient, and in Section 2.7.4 we start from (III). Figure 2.7.1 shows the whole web of implications.

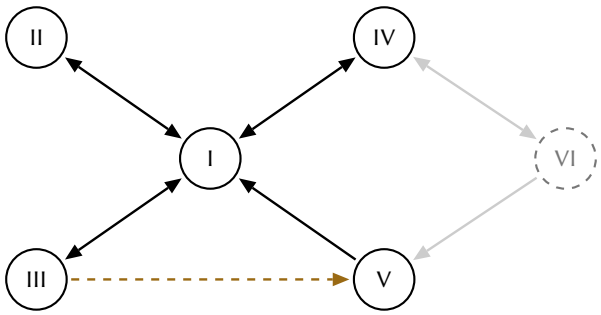

Figure 2.7.1. The implications proved for Theorem 2.7.2. The solid arrows are parts 1 and 2 of the proof, which reread earlier results. The dashed arrow (III) ⇒ (V) is the construction of part 3 (Section 2.7.4). Every node can be reached from every other, so (I)–(V) are equivalent. The faint node is a sixth condition, rank $A = n$, which Section 3.5.2 attaches by the faint arrows. For Theorem 2.7.4 the picture is the same, except that the construction starts from (II), and (VI) attaches at (II) rather than (IV).

Remark 2.7.3 (Reinterpreting earlier results). Part 1 of the proof cites one definition and two earlier results, and nothing else, yet it is a complete proof. Each spoke is a definition or a theorem proved earlier, the hypotheses of the theorems hold here, and equivalence is transitive. What part 1 adds is the translation that lets each earlier result be read as a statement about A. A solution of $A\mathbf{x} = \mathbf{y}$ is a preimage of $\mathbf{y}$ under T_A. The columns of A are the values of T_A on the standard basis. And T_A is linear, so every theorem about linear maps applies to it.

When you cite a result in this way, check two things: that its hypotheses really hold, and that its conclusion, after translation, is literally the implication you need. For instance, Proposition 2.6.22(a) decides injectivity from the values on a *basis* of the domain; Corollary 2.6.24 is its special case for the standard basis of F^n, whose values are the columns. The real work was done in Section 2.6. Collecting the conditions into one theorem is still worthwhile, because in a problem we rarely know in advance which of them is easiest to check, and the theorem lets us check that one and use any other.

> *Intuition (Five ways to say that everything is reached).* The Second Fundamental Theorem is the mirror image of the first. Each of its conditions says that T_A reaches every vector of F^m: as a map (I); as a statement about equations (II); as a statement about combinations of the columns (III); as a statement about the image (IV); and, in (V), by a linear map that produces, for each $\mathbf{y}$, an input that reaches it.

Theorem 2.7.4 (Second Fundamental Theorem). Let $A \in F^{m\times n}$. The following are equivalent.

(I) T_A is surjective.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has at least one solution $\mathbf{x} \in F^n$.
(III) The columns of A span F^m.
(IV) $\operatorname{im} T_A = F^m$.
(V) T_A has a right inverse: a linear map $S : F^m \to F^n$ with $T_A \circ S = \mathrm{id}_{F^m}$.

Proof, part 1 of 3: (I)–(IV) are equivalent. ROUTINE

> *Uses.* Definition 2.6.2 (Surjective), Definition 2.6.6 (Image), Definition 2.3.15 (The linear map of a matrix), Corollary 2.6.24 (The columns decide)
> *Techniques.* Proving TFAE (Technique 2.7.1)
> *Hint 1.* Use (I) as the hub again. Two of the spokes are the definition of surjectivity, read in two ways.
> *Hint 2.* (I) ⇔ (III) is the other half of Corollary 2.6.24.
> *Sketch.* A solution of $A\mathbf{x} = \mathbf{y}$ is a preimage of $\mathbf{y}$, so (I) ⇔ (II) is the definition of surjectivity, and so is (I) ⇔ (IV), since $\operatorname{im} T_A$ is the set of values of T_A. (I) ⇔ (III) is Corollary 2.6.24(b).

(I) ⇔ (II). As in the proof of Theorem 2.7.2, the solutions of $A\mathbf{x} = \mathbf{y}$ are the preimages of $\mathbf{y}$ under T_A. So (II) says that every $\mathbf{y} \in F^m$ has at least one preimage, which is Definition 2.6.2.

(I) ⇔ (IV). By Definition 2.6.6, $\operatorname{im} T_A$ is the set of values of T_A, so $\operatorname{im} T_A = F^m$ says that every vector of F^m is a value, which is again Definition 2.6.2.

(I) ⇔ (III). This is Corollary 2.6.24(b).

Instead of the last spoke we could have linked (III) and (IV) directly, since $\operatorname{im} T_A$ is the span of the columns (Proposition 2.6.18). The resulting chain (II) ⇔ (I) ⇔ (IV) ⇔ (III) is just as good.

Proof, part 2 of 3: (V) ⇒ (I). ROUTINE

> *Uses.* Proposition 2.5.5 (Right inverses give existence)
> *Hint 1.* Suppose $T_A \circ S = \mathrm{id}_{F^m}$, and let $\mathbf{y} \in F^m$. Which vector could T_A send to $\mathbf{y}$?
> *Hint 2.* This is Proposition 2.5.5.
> *Sketch.* $T_A(S(\mathbf{y})) = \mathbf{y}$ for every $\mathbf{y}$. This is Proposition 2.5.5.

Let S be a right inverse of T_A. For every $\mathbf{y} \in F^m$, $T_A(S(\mathbf{y})) = \mathbf{y}$, so $\mathbf{y}$ is a value of T_A. This is Proposition 2.5.5.

Again the implication from (I)–(IV) to (V) needs a construction, and it is part 3 of the proof, in Section 2.7.4.

Example 2.7.5 (A tall matrix). Let

$$A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{pmatrix} \in F^{3\times 2}, \quad T_A(x, y) = (x, x + y, y),$$

over any field F. Its columns $\mathbf{a}_1 = (1, 1, 0)$ and $\mathbf{a}_2 = (0, 1, 1)$ are linearly independent: if $x\mathbf{a}_1 + y\mathbf{a}_2 = (x, x + y, y) = \mathbf{0}$, then $x = y = 0$. So condition (III) of Theorem 2.7.2 holds, and with it all of (I)–(V). For instance, by (II) each system $A\mathbf{x} = \mathbf{y}$ has at most one solution, and by (V) there is a left inverse. Here one is easy to find, since x and y can be read off the first and third entries of $(x, x + y, y)$:

$$C = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad CA = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = I_2.$$

They can also be read off differently, using $x = (x + y) - y$:

$$C' = \begin{pmatrix} 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}, \quad C'A = I_2.$$

Indeed, the first row of C' sends $\mathbf{a}_1$ to $0 + 1 - 0 = 1$ and $\mathbf{a}_2$ to $0 + 1 - 1 = 0$.

On the other hand, T_A is not surjective. The vector $(0, 1, 0)$ would need $x = 0$, $y = 0$, and $x + y = 1$, which is impossible. So no condition of Theorem 2.7.4 holds: the columns do not span F^3, and there is no right inverse. (Corollary 2.5.11 also rules out a right inverse, since $C \neq C'$.) Uniqueness of solutions and existence of solutions really are independent properties.

Over $\mathbb{R}$, the span explorer below shows the columns of this A and a target $\mathbf{w}$. While $\mathbf{w}$ lies in the plane spanned by the columns, the explorer finds coefficients x, y with $x\mathbf{a}_1 + y\mathbf{a}_2 = \mathbf{w}$, and they are unique: this is (II) of Theorem 2.7.2. Drag $\mathbf{w}$ off the plane and there are none, as Theorem 2.7.4 fails. Adding a third vector off the plane makes the list independent (Proposition 1.5.14), and the explorer reports that it also spans $\mathbb{R}^3$; for three vectors in $\mathbb{R}^3$ that is no accident (Corollary 3.5.16). The 3×3 matrix with these columns then satisfies all three theorems.

$$(1, 2, 1) = \mathbf{a}_1 + \mathbf{a}_2,$$
$$\operatorname{span}(\mathbf{a}_1, \mathbf{a}_2) = \{(a, b, c) \in \mathbb{R}^3 \mid b = a + c\}.$$

The columns $\mathbf{a}_1 = (1, 1, 0)$ and $\mathbf{a}_2 = (0, 1, 1)$ of the matrix A of Example 2.7.5. They are independent, so a target in their span has exactly one pair of coefficients; the target $\mathbf{w} = (1, 2, 1) = \mathbf{a}_1 + \mathbf{a}_2$ gives $(x, y) = (1, 1)$. A target off the plane has none. (Interactive in the web version.)

Exercise 2.7.6. ROUTINE Let $\mathbf{a} \in F^m$, regarded as a matrix in $F^{m\times 1}$, so that $T_{\mathbf{a}} : F \to F^m$ is $x \mapsto x\mathbf{a}$. Show directly, without quoting Theorem 2.7.2, that the following are equivalent: (i) $T_{\mathbf{a}}$ is injective; (ii) $\mathbf{a} \neq \mathbf{0}$; (iii) $\mathbf{a}$ has a left inverse $\mathbf{c} \in F^{1\times m}$, that is, $\mathbf{ca} = 1$. Which step corresponds to the construction in part 3 of the proof of Theorem 2.7.2?

Solution on page 1171

2.7.3 The Third Fundamental Theorem

For the Third Fundamental Theorem, the implication from bijectivity to invertibility is much easier than the corresponding implications for one-sided inverses. As the lecture puts it, there is only one plausible choice for the inverse.

Intuition (Only one candidate). Let $T \in \mathrm{L}(V, W)$ be bijective. If S is a two-sided inverse of T, then $T(S(\mathbf{w})) = \mathbf{w}$ for every $\mathbf{w} \in W$, so $S(\mathbf{w})$ is a preimage of $\mathbf{w}$. Since T is bijective, $\mathbf{w}$ has exactly one preimage. So S has to be the inverse function of T, which sends each $\mathbf{w}$ to its unique preimage, and the only question

is whether that function is linear. For a left inverse of an injective map there is no such uniqueness: its values off the image are free, and many choices are not linear (Remark 2.5.8).

Proposition 2.7.7 (Bijective linear maps are invertible). Let $T \in \mathrm{L}(V, W)$ be bijective, and let $S : W \to V$ be its inverse function: $S(\mathbf{w})$ is the unique $\mathbf{v} \in V$ with $T(\mathbf{v}) = \mathbf{w}$. Then S is linear. Consequently T is invertible, and $T^{-1} = S$.

Proof. ROUTINE

Uses. Definition 2.6.3 (Bijective), Definition 2.1.1 (Linear map), Definition 2.5.12 (Invertible), Section A.1
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. To compute S at a vector, find the vector that T sends there. Fix $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$ and scalars $a_1, \ldots, a_k$, and look for the vector that T sends to $a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k$.
Hint 2. Put $\mathbf{v}_i = S(\mathbf{w}_i)$, so that $T(\mathbf{v}_i) = \mathbf{w}_i$. What is $T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k)$?
Sketch. With $\mathbf{v}_i = S(\mathbf{w}_i)$, linearity of T gives $T(\sum a_i\mathbf{v}_i) = \sum a_i\mathbf{w}_i$, so by the definition of S, $S(\sum a_i\mathbf{w}_i) = \sum a_i\mathbf{v}_i = \sum a_iS(\mathbf{w}_i)$. Since S is the inverse function, $ST = \mathrm{id}_V$ and $TS = \mathrm{id}_W$.

Since T is bijective, every $\mathbf{w} \in W$ has exactly one preimage (Definition 2.6.3), so S is a well-defined function $W \to V$, and $T(S(\mathbf{w})) = \mathbf{w}$ for every $\mathbf{w}$.

Fix $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$ and $a_1, \ldots, a_k \in F$. We will show that $S(a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k) = a_1S(\mathbf{w}_1) + \cdots + a_kS(\mathbf{w}_k)$. Put $\mathbf{v}_i = S(\mathbf{w}_i)$, so that $T(\mathbf{v}_i) = \mathbf{w}_i$. Since T is linear,

$$\begin{aligned} T(a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k) &= a_1T(\mathbf{v}_1) + \cdots + a_kT(\mathbf{v}_k) \\ &= a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k. \end{aligned}$$

So $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$ is the preimage of $a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k$, and by the definition of S,

$$\begin{aligned} S(a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k) &= a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k \\ &= a_1S(\mathbf{w}_1) + \cdots + a_kS(\mathbf{w}_k), \end{aligned}$$

as desired. Thus S is linear (Definition 2.1.1).

Finally, S is the inverse function of T (Section A.1): $S(T(\mathbf{v})) = \mathbf{v}$, because $\mathbf{v}$ is the preimage of $T(\mathbf{v})$, and $T(S(\mathbf{w})) = \mathbf{w}$. So S is a linear map that is both a left and a right inverse of T, and T is invertible with $T^{-1} = S$ (Definition 2.5.12). □

No basis appeared in the proof, so the proposition holds for every bijective linear map, between any two vector spaces. Together with Proposition 2.5.4 and Proposition 2.5.5 it says that a linear map is invertible if and only if it is bijective.

Intuition (The third theorem from the first two). "Exactly one" means "at most one and at least one". Each condition (I)–(IV) of the Third Fundamental Theorem below is, in the same way, the combination of condition (I)–(IV) of Theorem 2.7.2 with the same condition of Theorem 2.7.4: bijective means injective and surjective, a basis is an independent spanning list, and (IV) is written as a combination. So the equivalence of (I)–(IV) is inherited from the first two theorems, and only (V) needs an argument.

Theorem 2.7.8 (Third Fundamental Theorem). Let $A \in F^{m\times n}$. The following are equivalent.

(I) T_A is bijective.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has exactly one solution $\mathbf{x} \in F^n$.
(III) The columns of A form a basis of F^m.
(IV) $\ker T_A = \{\mathbf{0}\}$ and $\operatorname{im} T_A = F^m$.
(V) T_A is invertible.

Proof, part 1 of 3: (I)–(IV) are equivalent. ROUTINE

Uses. Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Definition 2.6.3 (Bijective), Proposition 1.6.2 (Bases are independent spanning lists)

Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Write each of (I)–(IV) as "P and Q", where P is the corresponding condition of Theorem 2.7.2 and Q that of Theorem 2.7.4.
Hint 2. If $P_i \Leftrightarrow P_j$ and $Q_i \Leftrightarrow Q_j$, then (P_i and Q_i) $\Leftrightarrow$ (P_j and Q_j). Use only parts 1 of the proofs of the first two theorems.
Sketch. Bijective = injective and surjective; exactly one = at most one and at least one; basis = independent and spanning (Proposition 1.6.2); (IV) is the combination of the two (IV)s. By parts 1 of the proofs of Theorem 2.7.2 and Theorem 2.7.4, the first halves are equivalent to each other, and so are the second halves; hence so are the conjunctions.

Each of the conditions (I)–(IV) of the present theorem combines the condition with the same numeral in Theorem 2.7.2 with the one in Theorem 2.7.4:

- (I) says that T_A is injective and surjective (Definition 2.6.3);
- (II) says that $A\mathbf{x} = \mathbf{y}$ has at most one and at least one solution, for every $\mathbf{y}$;
- (III) says that the columns of A are linearly independent and span F^m (Proposition 1.6.2);
- (IV) says that $\ker T_A = \{\mathbf{0}\}$ and $\operatorname{im} T_A = F^m$.

By part 1 of the proof of Theorem 2.7.2, the first halves of these four conditions are equivalent to one another, and by part 1 of the proof of Theorem 2.7.4, so are the second halves. If $P \Leftrightarrow P'$ and $Q \Leftrightarrow Q'$, then (P and Q) $\Leftrightarrow$ (P' and Q'). So (I)–(IV) are equivalent.

Proof, part 2 of 3: (V) $\Rightarrow$ (I). ROUTINE

Uses. Definition 2.5.12 (Invertible), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence)
Hint 1. An inverse is both a left and a right inverse.
Hint 2. Apply Proposition 2.5.4 and Proposition 2.5.5.
Sketch. T_A^{-1} is a left inverse, so T_A is injective, and a right inverse, so T_A is surjective.

If T_A is invertible, then T_A^{-1} is a left inverse and a right inverse of T_A (Definition 2.5.12). By Proposition 2.5.4 and Proposition 2.5.5, T_A is injective and surjective, that is, bijective.

For the last step we give two proofs. The first is the lecture's; the second builds the inverse on a basis, and it is the model for the constructions in Section 2.7.4.

Proof (via the inverse function), part 3 of 3: (I) $\Rightarrow$ (V). ROUTINE

Uses. Proposition 2.7.7 (Bijective linear maps are invertible), Proposition 2.3.13 (Linearity of the product)
Hint. T_A is a bijective linear map. What do we know about the inverse function of such a map?
Sketch. The inverse function of the bijective linear map T_A is linear (Proposition 2.7.7), so it is a linear two-sided inverse.

T_A is linear (Proposition 2.3.13) and, by (I), bijective. By Proposition 2.7.7 it is invertible. □

Proof (by building the inverse on a basis), part 3 of 3: (III) $\Rightarrow$ (V). ROUTINE

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 1.6.7 (Standard bases), Proposition 2.3.13 (Linearity of the product)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
Hint 1. An inverse S must send $\mathbf{a}_j = T_A(\mathbf{e}_j)$ back to $\mathbf{e}_j$. Since $\mathbf{a}_1, \ldots, \mathbf{a}_n$ is a basis of F^m, these values can be prescribed.
Hint 2. Let S be the linear map with $S(\mathbf{a}_j) = \mathbf{e}_j$. Check $S \circ T_A = \mathrm{id}$ on $\mathbf{e}_1, \ldots, \mathbf{e}_n$, and $T_A \circ S = \mathrm{id}$ on $\mathbf{a}_1, \ldots, \mathbf{a}_n$.
Sketch. By Theorem 2.2.1 there is a linear $S : F^m \to F^n$ with $S(\mathbf{a}_j) = \mathbf{e}_j$. Then $S(T_A(\mathbf{e}_j)) = \mathbf{e}_j$ and $T_A(S(\mathbf{a}_j)) = \mathbf{a}_j$, so $S \circ T_A$ and $T_A \circ S$ agree with the identity on a basis, and are the identity.

Suppose the columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$ form a basis of F^m. By Theorem 2.2.1 there is a linear map $S : F^m \to F^n$ with $S(\mathbf{a}_j) = \mathbf{e}_j$ for $j = 1, \ldots, n$. Recall that $T_A(\mathbf{e}_j) = A\mathbf{e}_j = \mathbf{a}_j$ (Proposition 2.3.13(c)). Then

$$(S \circ T_A)(\mathbf{e}_j) = S(\mathbf{a}_j) = \mathbf{e}_j,$$
$$(T_A \circ S)(\mathbf{a}_j) = T_A(\mathbf{e}_j) = \mathbf{a}_j$$

for every j. So the linear maps $S \circ T_A$ and id_{F^n} agree on the basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$ of F^n (Proposition 1.6.7), and $T_A \circ S$ and id_{F^m} agree on the basis $\mathbf{a}_1, \ldots, \mathbf{a}_n$ of F^m. By the uniqueness in Theorem 2.2.1, $S \circ T_A = \mathrm{id}_{F^n}$ and $T_A \circ S = \mathrm{id}_{F^m}$. So S is a linear two-sided inverse of T_A. □

The first proof works for any bijective linear map, with no bases at all. The second uses that the columns are a basis of the target, and it explains where the inverse comes from: it undoes T_A on the columns, and the columns are a basis, so nothing else needs to be decided. In Section 2.7.4 the columns will only be independent, or only spanning, and then something does have to be decided.

Example 2.7.9 (One matrix over three fields). Let $A = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$. The system $A\mathbf{x} = \mathbf{y}$ reads

$$x_1 + x_2 = y_1, \quad x_1 - x_2 = y_2.$$

Adding and subtracting the equations shows that every solution satisfies $2x_1 = y_1 + y_2$ and $2x_2 = y_1 - y_2$, where $2 = 1 + 1$.

Over $\mathbb{Q}$, or any field with $2 \neq 0$, this gives $x_1 = 2^{-1}(y_1 + y_2)$ and $x_2 = 2^{-1}(y_1 - y_2)$, and conversely these values solve the system. So the system has exactly one solution for every $\mathbf{y}$, which is (II) of Theorem 2.7.8, and A is invertible. The solution formula is the inverse:

$$A^{-1} = 2^{-1}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

Over $\mathbb{F}_3$, where $2^{-1} = 2$ and $-1 = 2$, this reads $A = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$ and $A^{-1} = \begin{pmatrix} 2 & 2 \\ 2 & 1 \end{pmatrix}$, and indeed $AA^{-1} = \begin{pmatrix} 4 & 3 \\ 6 & 4 \end{pmatrix} = I_2$ in $\mathbb{F}_3$.

Over $\mathbb{F}_2$, $-1 = 1$, so both columns are $(1, 1)$, and $A(1, 1) = \mathbf{0}$. So (IV) of Theorem 2.7.2 fails, and with it every condition of Theorem 2.7.2 and Theorem 2.7.8. Every value $A\mathbf{x} = (x_1 + x_2)(1, 1)$ is a multiple of $(1, 1)$, so $(1, 0)$ is not a value, and every condition of Theorem 2.7.4 fails as well.

2.7.4 Constructing one-sided inverses

It remains to prove (I) $\Rightarrow$ (V) in the first two theorems: an injective T_A has a left inverse, and a surjective T_A has a right inverse.

> *Intuition (What has to be chosen).* A left inverse S of an injective T_A is forced on the image: it must send $A\mathbf{x}$ to $\mathbf{x}$. Off the image nothing forces it, but whatever we choose there has to fit together into a linear map on all of F^m. A right inverse of a surjective T_A must pick, for each $\mathbf{y} \in F^m$, one solution $S(\mathbf{y})$ of $A\mathbf{x} = \mathbf{y}$, and when T_A is not injective there are many solutions to pick from. Again the picks must fit together linearly. Choices made one vector at a time usually do not, as the next example shows. Choices made on a basis always do, by Theorem 2.2.1, and that is all the proofs below use (Technique 2.2.4).

The lecture does not prove these implications at this point. It returns to them in Section 3.5, after row reduction, where left and right inverses are computed from $\operatorname{rref}(A)$ as explicit matrices (Proposition 3.5.9, Proposition 3.5.8), and the completed theorems (Theorem 3.5.12, Theorem 3.5.13) close the loops through a sixth condition. That is the route to use for computing. Here is a second route, which needs only Theorem 2.2.1 (and, for left inverses, Proposition 1.5.14) and no row reduction.

Non-example 2.7.10 (Choices that are not linear).

(a) Let $T : F \to F^2$, $T(x) = (x, 0)$, the map of Example 2.5.3. Undo T on its image and send everything else to 0:

$$g(x, 0) = x, \quad g(x, y) = 0 \text{ if } y \neq 0.$$

Then $g(T(x)) = x$ for every x, but g is not linear, since $g(1, 1) = 0$ while $g(1, 0) + g(0, 1) = 1 + 0 = 1$.

(b) Let $A = (1 \;\; 1) \in \mathbb{R}^{1\times 2}$, so $T_A(x_1, x_2) = x_1 + x_2$. For each $y \in \mathbb{R}$, choose the solution

$$h(y) = (y, 0) \text{ if } y \geq 0, \quad h(y) = (0, y) \text{ if } y < 0.$$

Then $T_A(h(y)) = y$ for every y, but h is not linear, since $h(1) + h(-1) = (1, -1)$ while $h(0) = (0, 0)$.

For a right inverse, the basis to choose on is the standard basis of the target.

Proof of Theorem 2.7.4, part 3 of 3: (II) ⇒ (V). ROUTINE

> *Uses.* Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 1.6.7 (Standard bases), Definition 2.5.2 (Right inverse)
> *Techniques.* Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
> *Hint 1.* A right inverse has to choose a solution of $A\mathbf{x} = \mathbf{y}$ for every $\mathbf{y}$. Make the choice only for $\mathbf{y} = \mathbf{e}_1, \dots, \mathbf{e}_m$.
> *Hint 2.* Choose solutions $\mathbf{x}_i$ of $A\mathbf{x} = \mathbf{e}_i$, let S be the linear map with $S(\mathbf{e}_i) = \mathbf{x}_i$, and check $T_A \circ S = \mathrm{id}$ on the standard basis.
> *Sketch.* By (II), choose $\mathbf{x}_i$ with $A\mathbf{x}_i = \mathbf{e}_i$ for $i = 1, \dots, m$. Let S be the linear map with $S(\mathbf{e}_i) = \mathbf{x}_i$ (Theorem 2.2.1). Then $T_A(S(\mathbf{e}_i)) = \mathbf{e}_i$, so $T_A \circ S$ agrees with id_{F^m} on a basis and equals it. In matrices, $AB = I_m$ for the matrix B with columns $\mathbf{x}_1, \dots, \mathbf{x}_m$.

Suppose (II). For each $i = 1, \dots, m$, the equation $A\mathbf{x} = \mathbf{e}_i$ has a solution; choose one and call it $\mathbf{x}_i$. Since $\mathbf{e}_1, \dots, \mathbf{e}_m$ is a basis of F^m (Proposition 1.6.7), Theorem 2.2.1 gives a linear map $S : F^m \to F^n$ with $S(\mathbf{e}_i) = \mathbf{x}_i$ for every i. Then

$$(T_A \circ S)(\mathbf{e}_i) = A\mathbf{x}_i = \mathbf{e}_i = \mathrm{id}_{F^m}(\mathbf{e}_i) \quad (i = 1, \dots, m),$$

so the linear maps $T_A \circ S$ and id_{F^m} agree on a basis, and they are equal by the uniqueness in Theorem 2.2.1. So S is a right inverse of T_A (Definition 2.5.2). In matrix terms, $S = T_B$ for the matrix $B \in F^{n \times m}$ with columns $\mathbf{x}_1, \dots, \mathbf{x}_m$, and $AB = I_m$. □

For a left inverse the values on the columns are forced, $S(\mathbf{a}_j) = \mathbf{e}_j$. The columns are independent but need not span F^m, so before we can use Theorem 2.2.1 we must complete them to a basis.

Proof of Theorem 2.7.2, part 3 of 3: (III) ⇒ (V). STANDARD

> *Uses.* Proposition 1.5.14 (Appending a vector), Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 1.6.7 (Standard bases), Proposition 1.6.2 (Bases are independent spanning lists), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.3.13 (Linearity of the product), Definition 2.5.1 (Left inverse)
> *Techniques.* Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
> *Hint 1.* A left inverse must send $\mathbf{a}_j = T_A(\mathbf{e}_j)$ to $\mathbf{e}_j$. To prescribe these values with Theorem 2.2.1, the $\mathbf{a}_j$ have to be part of a basis of F^m.
> *Hint 2.* Go through $\mathbf{e}_1, \dots, \mathbf{e}_m$ in turn, and append each one that is not in the span of the list built so far. Why does the final list span F^m, and why is it still independent?
> *Hint 3.* Define S on the resulting basis by $S(\mathbf{a}_j) = \mathbf{e}_j$ and $S = \mathbf{0}$ on the appended vectors. Check $S \circ T_A = \mathrm{id}$ on the standard basis of F^n.
> *Sketch.* Append to $\mathbf{a}_1, \dots, \mathbf{a}_n$ each $\mathbf{e}_i$ that is not in the span of the list so far. By Proposition 1.5.14 the list stays independent, and every $\mathbf{e}_i$ ends up in its span, so it becomes a basis $\mathbf{a}_1, \dots, \mathbf{a}_n, \mathbf{e}_{i_1}, \dots, \mathbf{e}_{i_t}$ of F^m. Let $S(\mathbf{a}_j) = \mathbf{e}_j$ and $S(\mathbf{e}_{i_s}) = \mathbf{0}$. Then $S(T_A(\mathbf{e}_j)) = \mathbf{e}_j$, so $S \circ T_A = \mathrm{id}_{F^n}$.

Suppose the columns $\mathbf{a}_1, \dots, \mathbf{a}_n$ are linearly independent.

Completing the columns to a basis. Let $\mathcal{L}_0$ be the list $\mathbf{a}_1, \dots, \mathbf{a}_n$. For $i = 1, \dots, m$ in turn, let $\mathcal{L}_i = \mathcal{L}_{i-1}$ if $\mathbf{e}_i \in \mathrm{span}(\mathcal{L}_{i-1})$, and let $\mathcal{L}_i$ be $\mathcal{L}_{i-1}$ with $\mathbf{e}_i$ appended otherwise. By Proposition 1.5.14 and induction on i, every $\mathcal{L}_i$ is linearly independent. For each i, the vector $\mathbf{e}_i$ lies in $\mathrm{span}(\mathcal{L}_i)$, either because it was already in $\mathrm{span}(\mathcal{L}_{i-1})$ or because it was appended, and $\mathrm{span}(\mathcal{L}_i) \subseteq \mathrm{span}(\mathcal{L}_m)$, since $\mathcal{L}_i$ is an initial part of $\mathcal{L}_m$. So the subspace $\mathrm{span}(\mathcal{L}_m)$ contains $\mathbf{e}_1, \dots, \mathbf{e}_m$, hence all of their linear combinations (Proposition 1.4.14), which is all of F^m (Proposition 1.6.7). Thus

$$\mathcal{L}_m = \mathbf{a}_1, \dots, \mathbf{a}_n, \mathbf{e}_{i_1}, \dots, \mathbf{e}_{i_t}$$

is linearly independent and spans F^m, so it is a basis of F^m (Proposition 1.6.2).

Defining S. By Theorem 2.2.1 there is a linear map $S : F^m \to F^n$ with

$$S(\mathbf{a}_j) = \mathbf{e}_j \quad (j = 1, \dots, n),$$
$$S(\mathbf{e}_{i_s}) = \mathbf{0} \quad (s = 1, \dots, t).$$

Since $T_A(\mathbf{e}_j) = \mathbf{a}_j$ (Proposition 2.3.13(c)), we get $(S \circ T_A)(\mathbf{e}_j) = S(\mathbf{a}_j) = \mathbf{e}_j$ for every j. So $S \circ T_A$ and id_{F^n} agree on the standard basis of F^n, and they are equal by the uniqueness in Theorem 2.2.1. That is, S is a left inverse of T_A (Definition 2.5.1). □

This completes the proofs of all three theorems.

Remark 2.7.11 (What was chosen, and what was not). In both constructions, the choices are exactly the freedom that one-sided inverses have. A right inverse is determined by its values $S(\mathbf{e}_i)$, which may be any solutions of $A\mathbf{x} = \mathbf{e}_i$; when T_A is not injective, each of these equations has many solutions. A left inverse is forced on the columns, and its values on the appended vectors $\mathbf{e}_{i_s}$ were set to $\mathbf{0}$ only for definiteness; any values work. So when T_A is injective but not surjective, it has many left inverses, in line with Corollary 2.5.11.

The completion step is the special case of Theorem 4.1.16 in which the spanning list is $\mathbf{e}_1, \dots, \mathbf{e}_m$. In F^m it needs no theory of dimension, because each of the m standard basis vectors is tested once. The same proof works for $T \in \mathrm{L}(V, W)$ whenever V and W have finite bases: if T is injective and $\mathcal{B}$ is a basis of V, complete the independent list $T(\mathcal{B})$ to a basis of W, testing the vectors of a basis of W in place of $\mathbf{e}_1, \dots, \mathbf{e}_m$ (compare Corollary 2.7.16 below). For arbitrary vector spaces one needs Zorn's lemma (Remark 2.5.25).

Example 2.7.12 (All left inverses of the tall matrix). Return to $A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{pmatrix}$ from Example 2.7.5, with columns $\mathbf{a}_1 = (1, 1, 0)$ and $\mathbf{a}_2 = (0, 1, 1)$. Their span consists of the vectors $(x, x + y, y)$, whose middle entry is the sum of the other two. The vector $\mathbf{e}_1 = (1, 0, 0)$ fails this test, so it is appended. Now every vector is a combination of $\mathbf{a}_1, \mathbf{a}_2, \mathbf{e}_1$, since

$$(p, q, r) = \alpha\mathbf{a}_1 + \beta\mathbf{a}_2 + \gamma\mathbf{e}_1 = (\alpha + \gamma, \alpha + \beta, \beta)$$

holds for $\beta = r$, $\alpha = q - r$, and $\gamma = p - q + r$. So $\mathbf{e}_2$ and $\mathbf{e}_3$ are not appended, and $\mathbf{a}_1, \mathbf{a}_2, \mathbf{e}_1$ is a basis of F^3.

A linear map $S : F^3 \to F^2$ is a left inverse of T_A exactly when $S(\mathbf{a}_1) = \mathbf{e}_1$ and $S(\mathbf{a}_2) = \mathbf{e}_2$ (check $S \circ T_A = \mathrm{id}$ on $\mathbf{e}_1, \mathbf{e}_2$). Its value $S(\mathbf{e}_1) = (c, d)$ is free. With the coordinates above,

$$S(p, q, r) = (q - r)\mathbf{e}_1 + r\mathbf{e}_2 + (p - q + r)(c, d).$$

Collecting the coefficients of p, q, and r in each entry, the left inverses of A are exactly the matrices

$$S_{c,d} = \begin{pmatrix} c & 1 - c & c - 1 \\ d & -d & 1 + d \end{pmatrix} \quad (c, d \in F).$$

The construction in the proof, with $S(\mathbf{e}_1) = \mathbf{0}$, gives $S_{0,0} = C'$, and $S_{1,0} = C$; these are the two left inverses found by inspection in Example 2.7.5. Over $\mathbb{F}_2$ there are exactly four left inverses, and over $\mathbb{Q}$ infinitely many.

With the constructions in hand, the theorems can be used in the direction that the propositions of Section 2.5 could not reach: a matrix without a one-sided inverse fails the other conditions too.

> **Exercise 2.7.13.** ROUTINE Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$. Show that the following are equivalent: T_A is injective; T_A is surjective; $ad - bc \neq 0$. (Use Proposition 2.5.28.)

Solution on page 1172

2.7.5 Using the theorems

Once a list of conditions is known to be equivalent, a question posed in one language can be answered in another. The following is a typical instance.

Example 2.7.14 (Products of matrices with independent columns). Let $A \in F^{m\times n}$ and $B \in F^{n\times p}$ both have linearly independent columns. We claim that AB does too.

Stated with columns, the claim takes some unwinding, since the columns of AB are the vectors $A\mathbf{b}_k$, each a combination of the columns of A with coefficients from a column of B (Proposition 2.4.8). In the language of kernels it takes one line. By Theorem 2.7.2, (III) ⇒ (IV), $\ker T_A = \{\mathbf{0}\}$ and $\ker T_B = \{\mathbf{0}\}$. If $(AB)\mathbf{x} = \mathbf{0}$, then $A(B\mathbf{x}) = \mathbf{0}$, so $B\mathbf{x} \in \ker T_A$, so $B\mathbf{x} = \mathbf{0}$, so $\mathbf{x} = \mathbf{0}$. Thus $\ker T_{AB} = \{\mathbf{0}\}$, and by (IV) ⇒ (III) for AB, the columns of AB are independent.

Condition (V) gives another one-line proof. By Proposition 2.5.20(c), (V) says that the matrix has a left inverse. If $CA = I_n$ and $DB = I_p$, then $(DC)(AB) = D(CA)B = DB = I_p$, so AB has a left inverse (Proposition 2.5.26(a)).

> **Exercise 2.7.15.** ROUTINE Let $A \in F^{m\times n}$ and $B \in F^{n\times p}$. Show that if the columns of A span F^m and the columns of B span F^n, then the columns of AB span F^m.

Solution on page 1172

2.7.6 Linear maps between spaces with bases

The theorems are stated for maps $F^n \to F^m$, but every linear map between spaces with finite bases is represented by a matrix (Technique 2.3.27), and injectivity, surjectivity, and one-sided inverses all survive the translation.

> **Corollary 2.7.16** (The Fundamental Theorems for linear maps). Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V and $\mathcal{C}$ a basis of W of length m, let $T \in \mathrm{L}(V, W)$, and let $A = [T]_{\mathcal{C}\mathcal{B}}$, whose columns are the coordinate vectors $[T(\mathbf{v}_j)]_{\mathcal{C}}$.
>
> (a) The following are equivalent: T is injective; $\ker T = \{\mathbf{0}\}$; the list $T(\mathcal{B})$ is linearly independent; the columns of A are linearly independent; T has a left inverse.
>
> (b) The following are equivalent: T is surjective; $\operatorname{im} T = W$; the list $T(\mathcal{B})$ spans W; the columns of A span F^m; T has a right inverse.
>
> (c) The following are equivalent: T is bijective; the list $T(\mathcal{B})$ is a basis of W; the columns of A form a basis of F^m; T is invertible.

Proof. STANDARD

Uses. Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Proposition 2.6.20 (Kernel and image in coordinates), Proposition 2.5.20 (Inverses and matrices), Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.7.8 (Third Fundamental Theorem), Proposition 2.7.7 (Bijective linear maps are invertible), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence)
Techniques. Proving TFAE (Technique 2.7.1), Translate between maps and matrices (Technique 2.3.27)
Hint 1. Use "T is injective" (in (b): surjective; in (c): bijective) as a hub. Two spokes are results of Section 2.6 about T itself.
Hint 2. The other spokes cross over to T_A. Which results transfer injectivity, surjectivity, and one-sided inverses between T and its matrix?
Hint 3. Proposition 2.6.20(c) and Proposition 2.5.20(b), (c). Then apply the Fundamental Theorems to A.
Sketch. Hub at "T is injective". $\ker T = \{\mathbf{0}\}$ by Theorem 2.6.11; $T(\mathcal{B})$ independent by Proposition 2.6.22(a). T is injective iff T_A is (Proposition 2.6.20(c)), iff the columns of A are independent, iff T_A has a left inverse (Theorem 2.7.2), iff A does, iff T does (Proposition 2.5.20). Part (b) is the same with Theorem 2.7.4, and (c) uses Theorem 2.7.8 and Proposition 2.7.7.

(a) We use "T is injective" as the hub. By Theorem 2.6.11 it is equivalent to $\ker T = \{\mathbf{0}\}$, and by Proposition 2.6.22(a) to the linear independence of $T(\mathcal{B})$. By Proposition 2.6.20(c), T is injective if and only if T_A is, and by Theorem 2.7.2, (I) ⇔ (III), this holds if and only if the columns of A are linearly independent. Finally, by Proposition 2.5.20(b) and (c), T has a left inverse if and only if A does, if and only if T_A does, and by Theorem 2.7.2, (I) ⇔ (V), this holds if and only if T_A is injective, that is, if and only if T is.

(b) The same argument with "surjective" in place of "injective". T is surjective if and only if $\operatorname{im} T = W$ (Definition 2.6.2), if and only if $T(\mathcal{B})$ spans W (Proposition 2.6.22(b)), if and only if T_A is surjective

(Proposition 2.6.20(c)), and Theorem 2.7.4 and Proposition 2.5.20(b), (c) handle the columns of A and right inverses.

(c) T is bijective if and only if $T(\mathcal{B})$ is a basis of W (Proposition 2.6.22(c)). By Proposition 2.6.20(c), T is bijective if and only if T_A is, and by Theorem 2.7.8, (I) $\Leftrightarrow$ (III), if and only if the columns of A form a basis of F^m. Finally, a bijective linear map is invertible (Proposition 2.7.7), and an invertible one is injective and surjective (Proposition 2.5.4, Proposition 2.5.5). □

So injectivity, surjectivity, and invertibility of T can be read off any one matrix of T, whatever bases were used to compute it.

Example 2.7.17 (Differentiation plus the identity). Let $T : F[x]_{\le 2} \to F[x]_{\le 2}$, $T(p) = p + D(p)$, where D is differentiation (Example 2.1.9). On the basis $\mathcal{B} = 1, x, x^2$,

$$T(1) = 1, \quad T(x) = 1 + x, \quad T\big(x^2\big) = 2x + x^2,$$

so

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}.$$

The system $[T]_{\mathcal{B}\mathcal{B}}\mathbf{c} = \mathbf{y}$ reads $c_1 + c_2 = y_1$, $c_2 + 2c_3 = y_2$, $c_3 = y_3$, and working from the bottom up it has exactly one solution,

$$c_3 = y_3, \quad c_2 = y_2 - 2y_3, \quad c_1 = y_1 - y_2 + 2y_3.$$

By Theorem 2.7.8, (II) $\Rightarrow$ (III), the columns of the matrix form a basis of F^3, so by Corollary 2.7.16(c), T is invertible and $1, 1 + x, 2x + x^2$ is a basis of $F[x]_{\le 2}$, over every field. The solution formula gives the inverse: for $q = y_1 + y_2 x + y_3 x^2$,

$$\begin{aligned} T^{-1}(q) &= (y_1 - y_2 + 2y_3) + (y_2 - 2y_3)x + y_3 x^2 \\ &= q - D(q) + D^2(q). \end{aligned}$$

So $T^{-1} = D^2 - D + \mathrm{id}$. This is the geometric series of Technique 2.5.16, cut off because $D^3 = 0$ on $F[x]_{\le 2}$: indeed $T = D + \mathrm{id}$, and $(D + \mathrm{id})\big(D^2 - D + \mathrm{id}\big) = D^3 + \mathrm{id} = \mathrm{id}$.

2.7.7 The theorems side by side

Table 2.7.1 lines up the three theorems condition by condition. In each row, the entry for the third theorem is the combination of the other two.

	First	Second	Third
(I)	injective	surjective	bijective
(II)	at most one	at least one	exactly one
(III)	independent	span F^m	basis of F^m
(IV)	$\ker T_A = \{\mathbf{0}\}$	$\operatorname{im} T_A = F^m$	both
(V)	left inverse	right inverse	inverse
(VI)	$\operatorname{rank} A = n$	$\operatorname{rank} A = m$	$\operatorname{rank} A = m = n$
size	$n \leq m$	$n \geq m$	$n = m$

Table 2.7.1. The three Fundamental Theorems (Theorem 2.7.2, Theorem 2.7.4, Theorem 2.7.8) for $A \in F^{m\times n}$. Rows (I), (IV), and (V) are about the map T_A; row (II) gives the number of solutions of $A\mathbf{x} = \mathbf{y}$, for every $\mathbf{y} \in F^m$; row (III) is about the columns of A. The last two rows are added in Section 3.5.2.

The lecture's statements of the theorems contain two more pieces. Each theorem has a sixth condition, about a single number computed from A by row reduction, and each ends with a constraint on the shape of A: "moreover, $n \leq m$" for the first theorem, $n \geq m$ for the second, and $n = m$ for the third. The sixth condition needs row reduction. The constraints on the shape can already be proved with the tools of this chapter (Exercise 2.7.32), but the text proves both pieces together in Section 3.5.2. There the rank of A is defined as the number of pivots of $\operatorname{rref}(A)$ (Definition 3.5.1); the sixth conditions are $\operatorname{rank} A = n$, $\operatorname{rank} A = m$, and $\operatorname{rank} A = m = n$ (Theorem 3.5.12, Theorem 3.5.13, Theorem 3.5.14); and the constraints on the shape follow from $\operatorname{rank} A \leq \min(m, n)$. In particular, invertible matrices are square (Corollary 3.5.15).

Intuition (Why the shape is constrained). An injective T_A sends the n independent vectors $\mathbf{e}_1, \ldots, \mathbf{e}_n$ to the n independent columns of A in F^m, and F^m should not have room for more than m independent vectors. A surjective T_A produces all of F^m from combinations of n columns, and m "directions" should need at least m vectors. Making "room" and "directions" precise is what dimension does (Section 4.1). With what we already have, the constraints are within reach by an induction on m (Exercise 2.7.32), and over $\mathbb{F}_p$ by counting (Exercise 2.6.44).

The dictionary in Table 3.1.1 arranges the same facts by the three ways of reading a linear system: as equations, as the map T_A, and as a question about the columns.

Remark 2.7.18 (On the name). The name follows the lecture, and the course notes abbreviate the three theorems FTLA1, FTLA2, and FTLA3. Elsewhere, "fundamental theorem" refers to other results. In LADR, the *fundamental theorem of linear maps* is rank–nullity, $\dim V = \dim \ker T + \dim \operatorname{im} T$ (Theorem 4.2.11). Strang's *fundamental theorem of linear algebra* describes the four subspaces attached to a matrix and their dimensions (Definition 4.3.12). The statements of this section are closest to what many books call the *invertible matrix theorem*, a list of conditions equivalent to invertibility of a square matrix (Corollary 3.5.25). The Fundamental Theorems split it into an injective half and a surjective half, and do not assume that A is square.

Exercises

Exercise 2.7.19. ROUTINE For each matrix, decide which of the three Fundamental Theorems have their conditions satisfied, and justify your answer by checking one convenient condition of each theorem.

(a) $\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$ over $\mathbb{Q}$.

(b) $\begin{pmatrix} 1 & i \\ i & -1 \\ 0 & 1 \end{pmatrix}$ over $\mathbb{C}$.

(c) $\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$ over $\mathbb{F}_2$.

(d) $\begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 2 \end{pmatrix}$ over $\mathbb{F}_3$.

Solution on page 1172

Exercise 2.7.20. ROUTINE

(a) Let $T : F[x]_{\leq 2} \to F^3$, $T(p) = (p(0), (Dp)(0), p(1))$, where D is differentiation. Use Corollary 2.7.16 to show that T is invertible over every field, and find T^{-1}.

(b) Let $U : F[x]_{\leq 2} \to F^3$, $U(p) = (p(0), (Dp)(0), (Dp)(1))$. For which fields F is U invertible?

Solution on page 1173

Exercise 2.7.21. ROUTINE Find the error in the following argument, and show that its claim is false.

Claim. For $A \in F^{m\times n}$, the following are equivalent: (i) T_A is injective; (ii) the columns of A are linearly independent; (iii) T_A is surjective; (iv) the columns of A span F^m.

Proof. (i) $\Leftrightarrow$ (ii) is Corollary 2.6.24(a), and (iii) $\Leftrightarrow$ (iv) is Corollary 2.6.24(b). Hence the four statements are equivalent.

Solution on page 1173

Exercise 2.7.22. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{n\times p}$. Prove or disprove each statement.

(a) If $A\mathbf{x} = \mathbf{0}$ has only the solution $\mathbf{x} = \mathbf{0}$, then $A\mathbf{x} = \mathbf{y}$ has a solution for every $\mathbf{y} \in F^m$.

(b) If A has two different left inverses, then T_A is not surjective.

(c) If T_{AB} is bijective, then T_A and T_B are bijective.

(d) If T_{AB} is bijective, then the columns of A span F^m and the columns of B are linearly independent.

Solution on page 1174

Exercise 2.7.23. STANDARD Let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$. Show that the following are equivalent: (i) P is injective; (ii) P is surjective; (iii) P is invertible; (iv) $P = \mathrm{id}_V$. Here V need not have a finite basis.

Solution on page 1174

Exercise 2.7.24. STANDARD Find the error in the following argument, and repair it.

Claim. If $T_A : F^n \to F^m$ is injective, then T_A has a left inverse.

Proof. Regard T_A as a map $F^n \to \operatorname{im} T_A$. As such it is linear, injective, and surjective, so by Proposition 2.7.7 it has a linear inverse $R : \operatorname{im} T_A \to F^n$, with $R(T_A(\mathbf{x})) = \mathbf{x}$ for every $\mathbf{x} \in F^n$. So R is a left inverse of T_A.

Solution on page 1174

Exercise 2.7.25. STANDARD Let $A \in F^{m\times n}$. The columns of A^{T} are the rows of A, read as vectors in F^n. Show that:

(a) the columns of A are linearly independent if and only if the rows of A span F^n;

(b) the columns of A span F^m if and only if the rows of A are linearly independent.

Solution on page 1175

Exercise 2.7.26. STANDARD Let p be a prime.

(a) Show that exactly $(p^3-1)(p^3-p)$ linear maps $\mathbb{F}_p^2 \to \mathbb{F}_p^3$ are injective.

(b) By Exercise 2.6.45, the same number of linear maps $\mathbb{F}_p^3 \to \mathbb{F}_p^2$ are surjective. Explain the coincidence with Exercise 2.7.25.

Solution on page 1175

Exercise 2.7.27. STANDARD Let $A \in F^{m\times n}$. Prove or disprove: if the columns of A are linearly independent, then so are the columns of $A^{\mathsf{T}}A \in F^{n\times n}$.

(a) For $F = \mathbb{R}$. (b) For $F = \mathbb{C}$. (c) For $F = \mathbb{F}_2$.

Solution on page 1176

Exercise 2.7.28. STANDARD For $c \in F$, let

$$A_c = \begin{pmatrix} 1 & c & 0 \\ 0 & 1 & c \\ c & 0 & 1 \end{pmatrix}.$$

(a) Show that A_c is invertible if and only if $1 + c^3 \neq 0$, and that otherwise T_{A_c} is neither injective nor surjective.

(b) List the c for which A_c is not invertible over $\mathbb{R}$, over $\mathbb{C}$, and over $\mathbb{F}_7$.

Solution on page 1176

Exercise 2.7.29. HARD Let $A \in F^{m\times n}$.

(a) Show that A has exactly one left inverse if and only if A is invertible.

(b) Show that A has exactly one right inverse if and only if A is invertible.

Solution on page 1177

Exercise 2.7.30. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $AB = I_m$.

(a) Show that if T_B is surjective, then $BA = I_n$.

(b) Show that if T_A is injective, then $BA = I_n$.

Solution on page 1177

Exercise 2.7.31. STANDARD Let $n \geq 2$, let $J \in F^{n\times n}$ be the matrix with every entry 1, and let $A = J - I_n$, the matrix with 0 on the diagonal and 1 elsewhere. Write n also for $n * 1 \in F$.

(a) Show that $J^2 = nJ$.

(b) Show that if $n - 1 \neq 0$ in F, then A is invertible with $A^{-1} = (n-1)^{-1}J - I_n$.

(c) Show that if $n - 1 = 0$ in F, then T_A is neither injective nor surjective.

(d) For which primes p is the 5×5 matrix A invertible over $\mathbb{F}_p$?

Solution on page 1178

Exercise 2.7.32. HARD This exercise proves the constraints on the shape of A without rank.

(a) Show by induction on $m \geq 1$ that every list of $m+1$ vectors in F^m is linearly dependent.

(b) Deduce that if $T_A : F^n \to F^m$ is injective, then $n \leq m$; that if T_A is surjective, then $n \geq m$; and that if A is invertible, then $m = n$.

Solution on page 1178

Exercise 2.7.33. ROUTINE Let $A \in F^{m\times n}$, and let $G \in F^{m\times m}$ and $H \in F^{n\times n}$ be invertible. Show that T_{GAH} is injective if and only if T_A is, and surjective if and only if T_A is. Deduce that GAH is invertible if and only if A is.

Solution on page 1179

Exercise 2.7.34. STANDARD Let $A \in F^{m\times n}$ and $p \geq 1$, and let $L_A : F^{n\times p} \to F^{m\times p}$, $L_A(X) = AX$.

(a) Show that L_A is linear.

(b) Show that L_A is injective if and only if T_A is injective.

(c) Show that L_A is surjective if and only if T_A is surjective.

(d) Deduce that L_A is invertible if and only if A is invertible.

Solution on page 1179

Exercise 2.7.35. CHALLENGE For a matrix A with integer entries and a prime p, let $\overline{A} \in \mathbb{F}_p^{m\times n}$ be the matrix of remainders of the entries of A modulo p.

(a) Let $A \in \mathbb{Z}^{m\times n}$. Show that if the columns of $\overline{A}$ are linearly independent over $\mathbb{F}_p$, then the columns of A are linearly independent over $\mathbb{Q}$.

(b) Show that every $n \times n$ matrix with odd integers on the diagonal and even integers off the diagonal has linearly independent columns over $\mathbb{Q}$.

(c) Show that the converse of (a) is false.

Solution on page 1180

2.8 Proof patterns

A linear map can be handled at four levels: as a map, through its values on a basis, through a matrix, or through the entries of that matrix. Once bases are fixed, all four carry the same information (Section 2.3.6), so most proofs in this chapter begin by choosing a level, and the choice decides how long the proof is. This section sorts the chapter's proofs by the question they answer, compares the levels on examples from the chapter, and says when a tool is the wrong one. The exercises at the end practice one move at a time, and the problem set (Problems for Chapter 2) mixes them.

2.8.1 Showing that a map is linear, or building one

There are three moves, and they answer different questions.

- *Check the definition.* Expand $T(a\mathbf{u} + \mathbf{v})$ and regroup, as in (iii) of Theorem 2.1.3. This verifies a map that is given by a formula, and it is the default for formulas in coordinates or coefficients (Example 2.1.7, Example 2.1.9).
- *Assemble the map* from sums, scalar multiples, and composites of maps already known to be linear (Technique 2.1.26). This transfers linearity without computing, but it only covers the operations of $\mathrm{L}(V, W)$. A pointwise product of two linear maps, such as $x \mapsto x \cdot x$, is not covered, and neither is an inverse function, whose linearity needed its own argument (Proposition 2.7.7).

- *Define the map on a basis* and extend it (Technique 2.2.4). This creates a map with prescribed behaviour, and linearity is free. It does not show that a given formula is linear: to identify a given map with the one built on the basis, we have to evaluate the given map at a general vector, which is the first move again. The exception is a formula that already has the form (2.2.1), as for the maps of $F[x]$ that move each coefficient to a fixed place (Proposition 2.2.20).

Constructions go wrong at the choices. A map defined by choosing a value for each vector separately is usually not linear (Non-example 2.7.10), and values prescribed on a spanning list must respect its linear relations (Proposition 2.2.11, Exercise 2.2.24, Exercise 2.2.26). Choices made on a basis are always safe. To show that a map is *not* linear, the tests $T(\mathbf{0})$ and $T(2\mathbf{v})$ catch most formulas, but not over $\mathbb{F}_2$, where $2 = 0$ and every function that fixes $\mathbf{0}$ is homogeneous. There, test additivity (Exercise 2.1.15(d), Exercise 2.8.5).

Example 2.8.1 (One map, three routes). The reflection S_ℓ across a line ℓ through $\mathbf{0}$ appeared three times in the chapter. In Example 2.1.11 it came with a coordinate formula, obtained from the double angle formulas, and the formula has the shape of Example 2.1.7, so S_ℓ is linear by the first move. In Example 2.1.27(a) we noticed that $S_\ell = 2\,\mathrm{Pr}_\ell - \mathrm{id}_{\mathbb{R}^2}$, which proves linearity with no trigonometry, once Pr_ℓ is known to be linear. In Example 2.2.3, for the line $y = x$, we chose $\mathbf{b}_1 = (1, 1)$ on the line and $\mathbf{b}_2 = (1, -1)$ across it, and *defined* S by $S(\mathbf{b}_1) = \mathbf{b}_1$ and $S(\mathbf{b}_2) = -\mathbf{b}_2$. Linearity came for free, the formula $S(x, y) = (y, x)$ came out of (2.2.1), and identities such as $S^2 = \mathrm{id}$ became one-line checks on the basis (Example 2.2.8).

The formula verifies a map that is already given, assembly transfers linearity from maps we trust, and the basis creates a map from a description of what it should do. The last route has a cost: the basis must exist and must be found. Over $\mathbb{F}_2$ the vectors $(1, 1)$ and $(1, -1)$ coincide, and the construction of Example 2.2.3 breaks down, although $(x, y) \mapsto (y, x)$ is still linear there.

Practice: Exercise 2.8.5 and Exercise 2.8.7.

2.8.2 Showing that two maps or two matrices are equal

For linear maps, the default is to compare them on a basis, or on any spanning list (Technique 2.2.7, Corollary 2.2.6); on $F[x]$ the monomials play the role of the basis (Proposition 2.2.20). Matrices can be compared entry by entry, column by column ($A = B$ as soon as $A\mathbf{e}_j = B\mathbf{e}_j$ for every j, by Lemma 2.4.24(b)), or through their maps ($A = B$ as soon as $T_A = T_B$, by Proposition 2.3.17). Two maps are also equal when their matrices in one pair of bases are (Theorem 2.3.20(a)). Often the shortest route compares no values at all and derives the identity from identities already known, with the algebra of Proposition 2.1.24 and Proposition 2.4.14.

Before checking on a basis, check two things. Both sides must be linear in the vector being tested. An identity between sums and composites of linear maps is, but a condition such as "$T(\mathbf{v}) \in \mathrm{span}(\mathbf{v})$" is not, and it can hold on a basis without holding everywhere (Exercise 2.2.25). And the list must be a basis over the field at hand: $(1, 1), (1, -1)$ is a basis of F^2 only when $1 + 1 \neq 0$ (Exercise 2.3.31).

Example 2.8.2 ($S^2 = \mathrm{id}$, three ways). Let ℓ be the line $y = 2x$ in $\mathbb{R}^2$ and $S = S_\ell$, whose standard matrix is $\frac{1}{5}\begin{pmatrix} -3 & 4 \\ 4 & 3 \end{pmatrix}$ (Example 2.3.19).

Entries. $\frac{1}{25}\begin{pmatrix} -3 & 4 \\ 4 & 3 \end{pmatrix}^2 = \frac{1}{25}\begin{pmatrix} 9+16 & -12+12 \\ -12+12 & 16+9 \end{pmatrix} = I_2$. This settles one line; for a general line the same computation needs $\cos^2\theta + \sin^2\theta = 1$ again.

On an adapted basis. With $\mathbf{u}_1 = (1, 2)$ on ℓ and $\mathbf{u}_2 = (-2, 1)$ across it, $S(\mathbf{u}_1) = \mathbf{u}_1$ and $S(\mathbf{u}_2) = -\mathbf{u}_2$ (Example 2.3.23). So S^2 fixes both basis vectors, and $S^2 = \mathrm{id}$ by Corollary 2.2.6. This explains the identity: reflecting twice flips the perpendicular direction twice.

By algebra. $S = 2P - \mathrm{id}$ with $P = \mathrm{Pr}_\ell$ and $P^2 = P$ (Exercise 2.1.42), so by Proposition 2.1.24,

$$S^2 = 4P^2 - 4P + \mathrm{id} = \mathrm{id}.$$

This uses no basis and no coordinates, and it proves more: $(2P - \mathrm{id})^2 = \mathrm{id}$ for every operator P with $P^2 = P$, on every vector space over every field.

Each route is the wrong one somewhere. The entries do not show why the identity holds, the adapted basis must be found first, and the algebra needs the right identity to start from. When no convenient identity is at hand, as for $DM - MD = \mathrm{id}$ on $F[x]$, the computation has to be done, and the monomials are the natural place to do it (Exercise 2.4.51); the product rule gives another proof, but it is a fact about products of polynomials, which is more than the identity needs.

Practice: Exercise 2.8.6 and Exercise 2.8.8.

2.8.3 Proving a matrix identity

The chapter proved its matrix identities in four ways, and many identities admit more than one.

- *Translate to maps* (Technique 2.3.27). If both sides are built from products, sums, and scalar multiples, read them as composites and use a fact about maps. Associativity and distributivity came this way (first proof of Proposition 2.4.14), and all the work went into the dictionary, Theorem 2.4.2. The translation does not see entries, which depend on the bases while maps do not. So it does not reach the transpose, which needs more structure to mean anything for a map (Section 13.1).
- *Compute entry by entry* (Technique 2.4.15). This is the tool for statements about entries: transposes (Proposition 2.4.23), traces (Proposition 2.4.28), triangular shapes (Proposition 2.4.36). It is mechanical, and it uses only the ring laws of the entries, which is why it also proves associativity for block matrices, whose entries do not commute (second proof of Proposition 2.4.14).
- *Use a view of the product* (Proposition 2.4.8). Statements about the columns or rows of a product take one line in the right view: right multiplication recombines columns (Exercise 2.4.11), and left multiplication by a diagonal matrix scales rows (Example 2.4.10).
- *Split into blocks* (Technique 2.4.35). This exploits zero blocks and identity blocks, and it sets up induction on the size.

When the identity is linear in one of the matrices, Technique 2.2.7 on the matrix units is a fifth option, as in the second proof of Proposition 2.4.28.

Example 2.8.3 (Strictly upper triangular matrices are nilpotent, three ways). Let $N \in F^{n\times n}$ be strictly upper triangular, $N_{ij} = 0$ whenever $i \geq j$. We show $N^n = 0$.

Maps. Let $V_k = \mathrm{span}(\mathbf{e}_1, \ldots, \mathbf{e}_k)$, with $V_0 = \{\mathbf{0}\}$. Column j of N is zero from row j down, so $N\mathbf{e}_j \in V_{j-1}$. Hence N maps V_k into V_{k-1} (Proposition 2.1.16), N^k maps V_k into V_0, and N^n kills $F^n = V_n$. This is Exercise 2.2.36 for T_N.

Entries. We claim $\left(N^k\right)_{ij} = 0$ whenever $j - i < k$. For $k = 1$ this is the hypothesis. If it holds for k, then a term of

$$\left(N^{k+1}\right)_{ij} = \sum_{l=1}^{n} \left(N^k\right)_{il} N_{lj}$$

can be nonzero only if $l - i \geq k$ and $j - l \geq 1$, so only if $j - i \geq k + 1$. For $k = n$, every pair has $j - i \leq n - 1 < n$.

Blocks. We induct on n; for $n = 1$, $N = 0$. For $n \geq 2$, write $N = \begin{pmatrix} 0 & \mathbf{r}^{\mathsf{T}} \\ \mathbf{0} & N' \end{pmatrix}$ with $\mathbf{r} \in F^{n-1}$ and N' strictly upper triangular of size $n - 1$. Block multiplication and induction on k give $N^k = \begin{pmatrix} 0 & \mathbf{r}^{\mathsf{T}} N'^{k-1} \\ \mathbf{0} & N'^k \end{pmatrix}$, and by the induction hypothesis $N'^{n-1} = 0$, so $N^n = 0$.

The map proof explains the result: each application of N pushes vectors one step down the chain $V_n \supseteq \cdots \supseteq V_0$, so N^k maps V_j into V_{j-k}, which is exactly the band of zeros $\left(N^k\right)_{ij} = 0$ for $j - i < k$ that the entrywise proof computes. In the form of Exercise 2.2.36 it needs no particular basis: any basis in which each vector is sent into the span of the earlier ones will do, while the entrywise proof needs the matrix already in triangular shape. The entrywise proof, in turn, is the most mechanical, and needs no subspaces at all. For $n \geq 2$ the shift $N = \sum_{i<n} \mathbf{e}_i \mathbf{e}_{i+1}^{\mathsf{T}}$ has $\left(N^{n-1}\right)_{1n} = 1$, so the bound n cannot be lowered. The block proof is the longest here, but it is the template for every later induction on the size of a triangular matrix (Proposition 2.4.36).

Practice: Exercise 2.8.9 and Exercise 2.8.12.

2.8.4 Proving injectivity, surjectivity, or invertibility

The chapter collected certificates for each property.

- *Injective:* a nonzero vector has a nonzero value (the kernel test, Technique 2.6.12); the values on a basis are independent (Proposition 2.6.22(a)); a left inverse (Proposition 2.5.4); an injective composite TS, which makes S injective (Proposition 2.6.15(c)).
- *Surjective:* a solution of $T(\mathbf{v}) = \mathbf{w}$ for a general $\mathbf{w}$; the values on a spanning list span (Proposition 2.6.22(b), Remark 2.6.23); a right inverse (Proposition 2.5.5); a surjective composite TS, which makes T surjective.
- *Invertible:* a candidate inverse, checked on both sides (Technique 2.5.16); injective and surjective, after which the inverse is linear for free (Proposition 2.7.7); the values on a basis form a basis (Proposition 2.6.22(c)); an invertible matrix in some pair of bases (Proposition 2.5.20, Corollary 2.7.16); for a 2×2 matrix, $ad - bc \neq 0$ (Proposition 2.5.28).

The kernel test is usually the shortest, but it proves injectivity and nothing else. Nothing in this chapter turns injectivity into surjectivity. For square matrices that is a theorem of the next chapter (Theorem 3.5.23), for operators on finite-dimensional spaces it is Corollary 4.2.18, and on $F[x]$ it is false (Example 2.6.4(e)).

Example 2.8.4 (One operator, four certificates). Let $T = \mathrm{id} + D$ on $F[x]$, over any field, where D is differentiation.

The kernel test. For $p \neq \mathbf{0}$ the degrees of p and $D(p)$ differ, so $T(p)$ has the degree of p and is nonzero (Example 2.6.13(a)). So T is injective, and that is all this argument gives.

Values on a basis. On $F[x]_{\leq 2}$, T sends $1, x, x^2$ to $1, 1+x, 2x+x^2$. Their span contains 1, then $x = (1+x) - 1$, then $x^2 = \left(2x + x^2\right) - 2x$, so it is $F[x]_{\leq 2}$. Together with the kernel test, Proposition 2.6.22 shows that T is bijective on $F[x]_{\leq 2}$, and the same works on each $F[x]_{\leq n}$. Since every polynomial lies in some $F[x]_{\leq n}$, which T maps onto itself, T is surjective on $F[x]$ as well. This reaches $F[x]$ only through its finite pieces, and it gives no formula for the inverse.

A guessed inverse. The series $1/(1+t) = 1 - t + t^2 - \cdots$ suggests $S = \mathrm{id} - D + D^2 - \cdots$. On a polynomial of degree at most d the series stops, since $D^{d+1}(p) = \mathbf{0}$ (Example 2.1.19(a)). So set $S(p) = \sum_{k=0}^{d} (-1)^k D^k(p)$ for any $d \geq \deg p$. The extra terms are $\mathbf{0}$, so the choice of d does not matter, and S agrees on each $F[x]_{\leq d}$ with the linear map $\sum_{k \leq d} (-1)^k D^k$, so S is linear. For $\deg p \leq d$ the sum telescopes:

$$\begin{aligned} T(S(p)) &= \sum_{k=0}^{d} (-1)^k D^k(p) + \sum_{k=0}^{d} (-1)^k D^{k+1}(p) \\ &= p + (-1)^d D^{d+1}(p) = p, \end{aligned}$$

and $S(T(p)) = p$ in the same way, since $T(p)$ also has degree at most d. By Technique 2.5.16, T is invertible on all of $F[x]$, with $T^{-1} = \mathrm{id} - D + D^2 - \cdots$.

A matrix. In the basis $1, x, x^2$ of $F[x]_{\leq 2}$, the matrix of T is upper triangular with every diagonal entry equal to 1, and back substitution solves every system (Example 2.7.17).

The kernel test cannot finish on $F[x]$, and the basis argument needs pieces $F[x]_{\leq n}$ that T maps into themselves. The guessed inverse works on all of $F[x]$ at once and gives a formula. The heuristic behind it is not a proof. The same guess for $\mathrm{id} + M$, with M multiplication by x, gives $\mathrm{id} - M + M^2 - \cdots$, which never stops; $\mathrm{id} + M$ does not map any $F[x]_{\leq n}$ into itself either, and indeed it is injective but not surjective: every value $(1 + x)q$ vanishes at -1, and the constant 1 does not (Example 2.6.29). The series becomes a proof when it terminates.

Practice: Exercise 2.8.10 and Exercise 2.8.15.

2.8.5 Proving that conditions are equivalent

The chapter's equivalence theorems use each shape of Technique 2.7.1. Theorem 2.1.3 is a cycle: (i) ⇒ (iii) ⇒ (ii) are choices of special values, and (ii) ⇒ (i) is an induction on the length of a combination. Theorem 2.7.2 and Theorem 2.7.4 are hubs: the three spokes and the arrow (V) ⇒ (I) are earlier results read in the right language (Remark 2.7.3), and one arrow, the construction of a one-sided inverse, needs an idea. Theorem 2.7.8 inherits the equivalence of (I)–(IV) from the first two, since each of these conditions is the conjunction of the corresponding conditions there, and only (V) needs an argument of its own. Corollary 2.7.16 carries all three from F^n to spaces with bases by composing with coordinate maps.

Two decisions shape such a proof. The first is where to spend the construction. Arrows out of a condition that hands us an object, such as a left inverse, are short (Proposition 2.5.4). Arrows into it are the hard ones, so they should start from whichever equivalent condition makes the construction easiest. For a left inverse that is (III) of Theorem 2.7.2, since independent columns can be completed to a basis. For a right inverse it is (II) of Theorem 2.7.4, since the solutions of $A\mathbf{x} = \mathbf{e}_i$ are exactly the values the construction needs. The second decision is to check connectivity. Two separately proved groups of equivalent statements say nothing about each other (Exercise 2.7.21), and no arrow may use the theorem it belongs to. Practice: Exercise 2.8.11.

2.8.6 Reading the chapter's proofs

Definitions that are theorems in disguise. The products $A\mathbf{x}$ and AB were not chosen. Each was derived from a statement we wanted to be true, Theorem 2.3.9 and Theorem 2.4.2, and shown to be the only choice that makes it true (Proposition 2.3.10, Proposition 2.4.3). So the entry formula $\sum_k a_{ik}b_{kj}$ is a consequence, not a convention to memorize, and every algebraic law of the product is a law of composition seen through coordinates. Associativity is the clearest case. The composite of three functions does not depend on how they are grouped, for trivial reasons, so $(AB)C = A(BC)$ as soon as the dictionary is in place (first proof of Proposition 2.4.14). The failures come from composition too: $AB \neq BA$ and zero divisors are already visible for maps of the plane (Example 2.1.19, Exercise 2.1.40). The entrywise proof of associativity looks more elementary, but its reach is different: it uses only the ring laws of the entries, so it covers block matrices, where no single linear map is in sight (Section 2.4.8).

Uniqueness first, then existence. The proof of Theorem 2.2.1 assumed that a linear map with the given values exists and computed what it had to be. That proved uniqueness and produced the only candidate, which was then checked. The same move found the inverse of a bijective linear map, which can only be the inverse function (Proposition 2.7.7), and it compared a left and a right inverse through the single expression $S_l T S_r$ (Theorem 2.5.10).

Well-definedness. A definition that refers to a choice must not depend on it. When values are prescribed on a spanning list, a vector may have several representations, and the first proof of Proposition 2.2.11 checks

that any two give the same value: two representations differ by a linear relation, and the hypothesis says that the prescribed values respect it. Skipping this check is the error in Exercise 2.2.24.

Which hypothesis was used where. Remark 2.2.2 and Remark 2.6.23 record which half of "basis" each argument used, and the record tells us how far a result extends: spanning alone gives uniqueness of a map and the surjectivity test, and independence alone gives existence on the span. In the same way, Proposition 2.4.30 uses $n * 1 \neq 0$ at exactly one step, and over $\mathbb{F}_p$ with p dividing n that step fails (Remark 2.4.31).

Forced and free. A left inverse of T is forced on the image of T and free off it. That is why an injective map that is not surjective has many left inverses, and why two different left inverses rule out a right inverse (Corollary 2.5.11, Remark 2.7.11). Counting the free choices counts the one-sided inverses (Problem 2.3).

2.8.7 Common errors

Most of these appear in the chapter as find-the-error exercises.

- *Commuting factors.* In general $AB \neq BA$ (Example 2.4.18), so $(A+B)^2 \neq A^2 + 2AB + B^2$ (Exercise 2.4.17) and $(AB)^2 \neq A^2B^2$ (Exercise 2.4.44(c)). Inside a trace, a product may be rotated but not rearranged (Exercise 2.4.32).
- *Cancelling.* $AB = AC$ gives $B = C$ when A is left-invertible (Corollary 2.5.6), but not in general (Example 2.4.19), and $AB = 0$ does not force $A = 0$ or $B = 0$ (Exercise 2.4.20). The idempotent version, $P(P - \mathrm{id}) = 0$ hence $P \in \{0, \mathrm{id}\}$, is Exercise 2.1.41, and cancelling on the side where no inverse exists is Exercise 2.8.15.
- *Inverting or transposing a product.* $(AB)^{-1} = B^{-1}A^{-1}$ and $(AB)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}}$, in reversed order (Exercise 2.8.14, Exercise 2.4.48).
- *One side for two.* A one-sided inverse need not be an inverse: $AB = I_m$ does not give $BA = I_n$ (Exercise 2.5.34), and on $\mathbb{Q}[x]$, $DJ = \mathrm{id}$ while $JD \neq \mathrm{id}$ (Example 2.5.24).
- *Injective for surjective.* For operators on $F[x]$ neither implies the other: multiplication by x is injective but not surjective, and its left inverse L of Exercise 2.5.41 is surjective but not injective (Example 2.6.4(e), Exercise 2.6.37(e)). For square matrices the implication is a theorem that this chapter does not have (Theorem 3.5.23).
- *Swapped bases.* $[T]_{\mathcal{C}\mathcal{B}}$ takes $\mathcal{B}$-coordinates to $\mathcal{C}$-coordinates, so $[\mathrm{id}]_{\mathcal{E}\mathcal{B}}$ converts $\mathcal{B}$-coordinates into standard ones and not the other way (Exercise 2.3.30). In a product of matrices of maps, the inner subscripts must match (Exercise 2.8.13, Problem 2.2).
- *Tests that are not tests.* A list that is a basis over one field need not be one over another (Exercise 2.3.31); a condition that is not linear in the vector cannot be checked on a basis (Exercise 2.2.25); and nonzero values on a basis do not make a map injective (Exercise 2.6.40).
- *Values on a dependent list.* They must respect every relation of the list (Exercise 2.2.24, Exercise 2.2.26).
- *Integer multiples for all scalars.* Additivity gives $T(n\mathbf{v}) = nT(\mathbf{v})$ for integers n, not for all scalars (Exercise 2.1.35).
- *Partial equivalences and partial inverses.* Equivalences proved inside two groups of conditions do not connect the groups (Exercise 2.7.21), and an inverse defined on the image of T only is not a left inverse of T (Exercise 2.7.24).
- *The kernel test without linearity.* On $\mathbb{R}$, $x \mapsto x^2$ sends only 0 to 0 and is not injective; for maps that are homogeneous but not additive the test fails as well (Problem 2.1).

Exercises

Exercise 2.8.5. ROUTINE Decide which of the following maps are linear, and give the shortest argument you can.

(a) $F^{n\times n} \to F^{n\times n}$, $X \mapsto AXB - X^{\mathsf{T}}$, where $A, B \in F^{n\times n}$ are fixed.

(b) $F[x] \to F[x]$, $p \mapsto p(x+1) - 2p + p(x-1)$.

(c) $F^{n\times n} \to F$, $X \mapsto \operatorname{tr}(X^2)$, where $n \geq 1$. (The answer depends on F.)

Solution on page 1180

Exercise 2.8.6. STANDARD Let $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}} \in F^{n\times n}$ be the matrix units.

(a) Show that $\sum_{i=1}^n \sum_{j=1}^n U_{ij} A U_{ji} = (\operatorname{tr} A) I_n$ for every $A \in F^{n\times n}$, twice: by checking on the matrix units, and entry by entry.

(b) Suppose A commutes with every matrix in $F^{n\times n}$. Show that $(n * 1)A = (\operatorname{tr} A) I_n$. Deduce that if $n * 1 \neq 0$ in F, the matrices that commute with every matrix are exactly the scalar multiples of I_n.

Solution on page 1181

Exercise 2.8.7. STANDARD In $\mathbb{Q}^4$, let $K = \operatorname{span}((1,1,0,0),(0,0,1,1))$ and $L = \operatorname{span}((1,0,1,0),(0,1,0,1))$.

(a) Construct $T \in \mathrm{L}(\mathbb{Q}^4)$ with $\ker T = K$ and $\operatorname{im} T = L$, and give its standard matrix.

(b) Show that no $T \in \mathrm{L}(\mathbb{Q}^4)$ with $\ker T = K$ and $\operatorname{im} T = L$ satisfies $T^2 = T$.

Solution on page 1182

Exercise 2.8.8. STANDARD Let p be a prime and D differentiation on $\mathbb{F}_p[x]$.

(a) Show that $D^p = 0$.

(b) Let $n \geq 1$, and let N be the matrix of D on $\mathbb{F}_p[x]_{\leq n}$ with respect to $1, x, \ldots, x^n$. Show that $N^p = 0$ without multiplying matrices. Show also that over $\mathbb{Q}$ the corresponding matrix satisfies $N^n \neq 0$.

(c) Show that $\mathrm{id} + D$ is invertible on $\mathbb{F}_p[x]$, with inverse $(\mathrm{id} + D)^{p-1}$. You may use the binomial theorem for commuting operators, which has the same proof as for numbers, and that p divides $\binom{p}{k}$ for $0 < k < p$.

Solution on page 1182

Exercise 2.8.9. STANDARD Let $p, q, r \geq 1$, let $A \in F^{p\times q}$, $B \in F^{p\times r}$, and $C \in F^{q\times r}$, and let

$$M = \begin{pmatrix} I_p & A & B \\ 0 & I_q & C \\ 0 & 0 & I_r \end{pmatrix}.$$

(a) Write $M = I + N$, compute N^2 and N^3 by block multiplication, and deduce M^{-1}.

(b) For numbers,

$$\begin{pmatrix} 1 & a & b \\ 0 & 1 & c \\ 0 & 0 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} 1 & -a & ac-b \\ 0 & 1 & -c \\ 0 & 0 & 1 \end{pmatrix},$$

and the corner entry $ac - b$ could also be written $ca - b$. Which block version is correct, and why does the other one fail?

Solution on page 1183

Exercise 2.8.10. STANDARD Let $c \in F$, and let M and D be multiplication by x and differentiation on $F[x]$.

(a) Show that $M - c\,\mathrm{id}$ is injective but not surjective.

(b) Suppose $c \neq 0$. Show that $D - c\,\mathrm{id}$ is invertible, and find its inverse.

(c) Explain why the kernel test alone could not have decided (b).

Solution on page 1184

Exercise 2.8.11. STANDARD Let $n \geq 1$, $A \in F^{n\times n}$, and $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$. Show that the following are equivalent, and arrange the proof so that as many arrows as possible are citations of earlier results.

(i) $A = \lambda I_n$ for some $\lambda \in F$.
(ii) $AX = XA$ for every $X \in F^{n\times n}$.
(iii) $AU_{ij} = U_{ij}A$ for all i, j.
(iv) $A\mathbf{x} \in \operatorname{span}(\mathbf{x})$ for every $\mathbf{x} \in F^n$.
(v) $[T_A]_{\mathcal{B}\mathcal{B}} = A$ for every basis $\mathcal{B}$ of F^n of length n.

Solution on page 1185

Exercise 2.8.12. STANDARD Let $n \geq 1$.

(a) Show that there are no $A, B \in \mathbb{R}^{n\times n}$ with $AB - BA = AA^{\mathsf{T}} + I_n$.

(b) Show that the statement of (a) is false over $\mathbb{C}$ and over $\mathbb{F}_2$.

(c) Show that $\operatorname{tr}\left(AA^{\mathsf{T}}\right) = 0$ forces $A = 0$ for $A \in \mathbb{R}^{n\times n}$, but find nonzero $A \in \mathbb{C}^{2\times 2}$ and $A \in \mathbb{F}_2^{2\times 2}$ with $\operatorname{tr}\left(AA^{\mathsf{T}}\right) = 0$.

Solution on page 1185

Exercise 2.8.13. ROUTINE Let $T \in \mathrm{L}\left(\mathbb{Q}^2\right)$, $T(x, y) = (y, x)$, and let $\mathcal{B}$ be the basis $\mathbf{b}_1 = (1, 0)$, $\mathbf{b}_2 = (1, 1)$. Find the error in the following computation, and compute $[T]_{\mathcal{B}\mathcal{B}}$ correctly.

Computation. Let $P = [\mathrm{id}]_{\mathcal{E}\mathcal{B}} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, whose columns are $\mathbf{b}_1$ and $\mathbf{b}_2$. Changing from the standard basis to $\mathcal{B}$ means applying P, so

$$[T]_{\mathcal{B}\mathcal{B}} = P[T]_{\mathcal{E}\mathcal{E}}P^{-1} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & -1 \end{pmatrix}.$$

Solution on page 1186

Exercise 2.8.14. ROUTINE Find the error in the following argument, show that its claim is false, and determine exactly when its conclusion holds.

Claim. If $A, B \in F^{n\times n}$ are invertible, then $(AB)^{-1} = A^{-1}B^{-1}$.

Proof. By associativity, $(AB)\left(A^{-1}B^{-1}\right) = AA^{-1}BB^{-1} = I_n$, and similarly $\left(A^{-1}B^{-1}\right)(AB) = I_n$. So $(AB)^{-1} = A^{-1}B^{-1}$ by Technique 2.5.16.

Solution on page 1186

Exercise 2.8.15. STANDARD Find the error in the following argument, show that its claim is false, and add a hypothesis under which the argument becomes correct.

Claim. If $T \in \mathrm{L}(V)$ has a left inverse, then T is invertible.

Proof. Let $ST = \mathrm{id}_V$. Then $TST = T = \mathrm{id}_V T$, so $(TS - \mathrm{id}_V)T = 0 = 0T$. Cancelling T on the right gives $TS - \mathrm{id}_V = 0$. So $TS = \mathrm{id}_V$, and S is a two-sided inverse of T.

Solution on page 1187

Problems for Chapter 2

These problems combine the sections of Chapter 2 with each other, and several combine them with Chapters 1 and 3. The first three are review prompts: state a main result, prove it without looking, and then answer a question that the text did not ask. The rest are ordered roughly by difficulty. Problems of kind "competition" are harder than anything the course expects. Some problems multiply polynomials, which Section 7.1 develops; each of them says what may be used. Section 2.8 compares the techniques these problems call for.

Review: state and prove

Problem 2.1. STANDARD

(a) State Theorem 2.6.11 and Proposition 2.6.14.

(b) Prove both.

(c) The proof of the theorem uses only part of linearity. Show that its statement holds for every additive map $T : V \to W$, with $\ker T = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{0}\}$ as before. Then show that it fails for homogeneous maps: find a function $T : \mathbb{F}_2^2 \to \mathbb{F}_2$ with $T(a\mathbf{v}) = aT(\mathbf{v})$ for all $a \in \mathbb{F}_2$ and $\mathbf{v} \in \mathbb{F}_2^2$, such that $T(\mathbf{v}) = 0$ only for $\mathbf{v} = \mathbf{0}$, but T is not injective.

Solution on page 1187

Problem 2.2. STANDARD

(a) State Theorem 2.4.2(a).

(b) Prove it from the definitions, and deduce from it, without computing any entry, that $(AB)C = A(BC)$ for all matrices of compatible sizes.

(c) Let $\mathcal{B}$ and $\mathcal{C}$ be bases of V of the same length n. Show that $[T]_{\mathcal{C}\mathcal{B}}[T]_{\mathcal{C}\mathcal{B}} = \left[T^2\right]_{\mathcal{C}\mathcal{B}}$ holds for every $T \in \mathrm{L}(V)$ if and only if $\mathcal{B} = \mathcal{C}$.

Solution on page 1188

Problem 2.3. STANDARD

(a) State Theorem 2.7.4.

(b) Prove (II) $\Rightarrow$ (V). Explain why the construction chooses solutions of $A\mathbf{x} = \mathbf{y}$ only for $\mathbf{y} = \mathbf{e}_1, \ldots, \mathbf{e}_m$, and not for every $\mathbf{y}$ separately.

(c) Let p be a prime, and let $A \in \mathbb{F}_p^{m \times n}$ with T_A surjective. Show that A has exactly $p^{m(n-m)}$ right inverses. Check the count against Exercise 2.5.36(c).

Solution on page 1189

Synthesis problems

Problem 2.4. STANDARD For $A, B \in F^{n \times n}$ let $L_{A,B} : F^{n \times n} \to F^{n \times n}$ be $L_{A,B}(X) = AXB$, and let $\tau(X) = X^{\mathsf{T}}$. Let $\mathcal{U}$ be the basis of $F^{n \times n}$ formed by the matrix units $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ (Lemma 2.4.24), in any fixed order. For an operator Φ on $F^{n \times n}$, write $\operatorname{tr}\Phi$ for the trace of $[\Phi]_{\mathcal{U}\mathcal{U}}$.

(a) Show that $L_{A,B}$ is linear, that $L_{A,B}L_{C,D} = L_{AC,DB}$, and that $\tau L_{A,B}\tau = L_{B^\intercal,A^\intercal}$.

(b) Show that $\operatorname{tr} L_{A,B} = (\operatorname{tr} A)(\operatorname{tr} B)$. Compute $\operatorname{tr}\tau$, and $\operatorname{tr} C_A$ for $C_A(X) = AX - XA$.

(c) Show that every linear map $\Phi : F^{n\times n} \to F^{n\times n}$ is a sum of maps of the form $L_{A,B}$, and write τ in this form.

Solution on page 1189

Problem 2.5. STANDARD For $c \in F$, let $S_c \in \mathrm{L}(F[x])$ be the substitution $S_c(f) = f(x+c)$ (Exercise 2.1.32), and let D be differentiation. You may use the binomial theorem $(x+c)^m = \sum_{k=0}^m \binom{m}{k} c^k x^{m-k}$ in $F[x]$, that $S_c S_d = S_{c+d}$, and that p divides $\binom{p}{k}$ for a prime p and $0 < k < p$.

(a) Let $F = \mathbb{Q}$ and $n \geq 0$. Show that on $\mathbb{Q}[x]_{\leq n}$,

$$S_c = \sum_{k=0}^{n} \frac{c^k}{k!} D^k.$$

In particular $f(x+1) = \sum_k D^k(f)/k!$, Taylor's formula.

(b) Deduce that S_1 is invertible on $\mathbb{Q}[x]_{\leq n}$, and find its inverse as a combination of powers of D.

(c) Let p be a prime and $F = \mathbb{F}_p$. Show that $S_1 = \sum_{k=0}^n (k!)^{-1} D^k$ on $\mathbb{F}_p[x]_{\leq n}$ when $n < p$, but that for $n \geq p$ there are no scalars $a_0, \ldots, a_r$ with $S_1 = \sum_{k=0}^r a_k D^k$ on $\mathbb{F}_p[x]_{\leq n}$.

Solution on page 1190

Problem 2.6. STANDARD Let M and D be multiplication by x and differentiation on $F[x]$. You may use that multiplication of polynomials is associative and commutative and distributes over addition, that $\deg(fg) = \deg f + \deg g$ for nonzero f, g, and the product rule $D(fg) = D(f)g + fD(g)$ (Exercise 2.1.49(a)).

(a) Show that $T \in \mathrm{L}(F[x])$ satisfies $TM = MT$ if and only if there is $q \in F[x]$ with $T(f) = qf$ for every f, and that then $q = T(1)$.

(b) For such T, show that T is injective if and only if $q \neq \mathbf{0}$, and surjective if and only if q is a nonzero constant.

(c) Find all $T \in \mathrm{L}(F[x])$ that commute with both M and D, when F has characteristic 0 and when $F = \mathbb{F}_p$.

Solution on page 1191

Problem 2.7. STANDARD Let $n \geq 0$, let $c_0, \ldots, c_n \in F$ be distinct, and let $L_0, \ldots, L_n \in F[x]_{\leq n}$ be the Lagrange polynomials (Definition 3.4.26), so that $L_i(c_k)$ is 1 for $k = i$ and 0 otherwise. Write $V = F[x]_{\leq n}$ and $\mathrm{ev}_c : V \to F$, $f \mapsto f(c)$.

(a) Show that $L_0, \ldots, L_n$ is a basis of V, and that every $\varphi \in \mathrm{L}(V, F)$ satisfies $\varphi = \sum_{i=0}^n \varphi(L_i)\,\mathrm{ev}_{c_i}$. Deduce that $\mathrm{ev}_{c_0}, \ldots, \mathrm{ev}_{c_n}$ is a basis of $\mathrm{L}(V, F)$.

(b) Let $n = 2$ and $(c_0, c_1, c_2) = (0, 1, 2)$, and suppose $2 \neq 0$ in F. Find the scalars w_0, w_1, w_2 with $f'(0) = w_0 f(0) + w_1 f(1) + w_2 f(2)$ for every $f \in F[x]_{\leq 2}$, where $f' = D(f)$. Write the formula over $\mathbb{F}_3$.

(c) Show that over $\mathbb{Q}$ no w_0, w_1, w_2 make the formula of (b) hold for every $f \in \mathbb{Q}[x]_{\leq 3}$.

Solution on page 1191

Problem 2.8. STANDARD A matrix P is **idempotent** if $P^2 = P$. By Exercise 2.5.46(a), every $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$ satisfies $A^2 - (a+d)A + (ad - bc)I_2 = 0$.

(a) Show that $A \in F^{2\times 2}$ is idempotent if and only if $A = 0$, $A = I_2$, or ($a + d = 1$ and $ad - bc = 0$).

(b) Let p be a prime. Show that exactly $p^2 + p + 2$ matrices in $\mathbb{F}_p^{2\times 2}$ are idempotent.

(c) Suppose $1 + 1 \neq 0$ in F. Show that $P \mapsto 2P - I_n$ is a bijection from the idempotent matrices in $F^{n\times n}$ onto the matrices S with $S^2 = I_n$. Compare (b) with Exercise 2.5.46(c).

(d) Over $\mathbb{F}_2$, count the $S \in \mathbb{F}_2^{2\times 2}$ with $S^2 = I_2$, and show that every $A \in \mathbb{F}_2^{2\times 2}$ is invertible, idempotent, or satisfies $A^2 = 0$. Show that this fails over $\mathbb{F}_3$.

Solution on page 1192

Problem 2.9. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$. A square matrix N is **nilpotent** if $N^k = 0$ for some $k \geq 1$.

(a) Show that $(BA)^{k+1} = B(AB)^k A$ for every $k \geq 0$.

(b) Deduce that AB is nilpotent if and only if BA is, and that $(AB)^k = 0$ implies $(BA)^{k+1} = 0$.

(c) Find $A, B \in F^{2\times 2}$ with $AB = 0$ and $BA \neq 0$. So the exponents in (b) can differ.

(d) Show that $\operatorname{tr}\left((AB)^k\right) = \operatorname{tr}\left((BA)^k\right)$ for every $k \geq 1$.

Solution on page 1193

Problem 2.10. STANDARD Call $N \in \mathrm{L}(V)$ **nilpotent** if $N^k = 0$ for some $k \geq 1$. You may use the binomial theorem for commuting operators, which has the same proof as for numbers.

(a) Show that the sum of two commuting nilpotent operators is nilpotent.

(b) Show that the sum of two nilpotent matrices in $F^{2\times 2}$ can be invertible. Deduce that the nilpotent matrices in $F^{2\times 2}$ do not form a subspace.

(c) Let $G \in \mathrm{L}(V)$ be invertible and $N \in \mathrm{L}(V)$ nilpotent, with $GN = NG$. Show that $G + N$ is invertible, and find its inverse.

(d) Show that (c) can fail if $GN \neq NG$.

Solution on page 1194

Problem 2.11. STANDARD Let $n \geq 2$, and let $X \in F^{n\times n}$ be invertible with columns $\mathbf{x}_1, \ldots, \mathbf{x}_n$. Let $Y \in F^{n\times n}$ have columns $\mathbf{x}_2, \ldots, \mathbf{x}_n, \mathbf{0}$, the columns of X moved one place to the left with a zero column at the end.

(a) Find a matrix N, not depending on X, with $Y = XN$.

(b) Show that $X^{-1}Y$ and YX^{-1} are nilpotent, and that $\left(X^{-1}Y\right)^{n-1} \neq 0$ and $\left(YX^{-1}\right)^{n-1} \neq 0$.

Solution on page 1194

Problem 2.12. STANDARD Let $n \geq 1$, let W be a subspace of $F^{n\times n}$, and let $U_{ij} = \mathbf{e}_i \mathbf{e}_j^{\mathsf{T}}$.

(a) Suppose that $AX \in W$ and $XA \in W$ for all $A \in F^{n\times n}$ and $X \in W$. Show that $W = \{0\}$ or $W = F^{n\times n}$.

(b) Let $n \geq 2$, and let W_1 be the set of matrices whose columns $2, \ldots, n$ are zero. Show that $AX \in W_1$ for all $A \in F^{n\times n}$ and $X \in W_1$, but that $XA \notin W_1$ for some $X \in W_1$ and A.

(c) Let $\psi : F^{n\times n} \to F^{m\times m}$ be linear and nonzero, with $\psi(XY) = \psi(X)\psi(Y)$ for all X, Y. Show that ψ is injective, and give an example with $m = 2n$.

Solution on page 1195

Problem 2.13. STANDARD For $Z \in \mathbb{C}^{m\times n}$ write $Z = X + iY$ with $X, Y \in \mathbb{R}^{m\times n}$ (the entrywise real and imaginary parts), and let

$$\rho(Z) = \begin{pmatrix} X & -Y \\ Y & X \end{pmatrix} \in \mathbb{R}^{2m\times 2n}.$$

(a) Show that $\rho(ZW) = \rho(Z)\rho(W)$ for $Z \in \mathbb{C}^{m\times n}$ and $W \in \mathbb{C}^{n\times p}$, that ρ is $\mathbb{R}$-linear, and that $\rho(I_n) = I_{2n}$.

(b) Regard $\mathbb{C}^n$ as a vector space over $\mathbb{R}$ (Proposition 1.2.19), with the list $\mathcal{B}_n = \mathbf{e}_1, \ldots, \mathbf{e}_n, i\mathbf{e}_1, \ldots, i\mathbf{e}_n$. Show that $\mathcal{B}_n$ is a basis, that $T_Z : \mathbb{C}^n \to \mathbb{C}^m$ is $\mathbb{R}$-linear, and that $[T_Z]_{\mathcal{B}_m\mathcal{B}_n} = \rho(Z)$.

(c) Show that $Z \in \mathbb{C}^{n\times n}$ is invertible if and only if $\rho(Z)$ is, and that then $\rho\big(Z^{-1}\big) = \rho(Z)^{-1}$.

(d) Show that $\operatorname{tr}\rho(Z) = 2\operatorname{Re}(\operatorname{tr} Z)$ for $Z \in \mathbb{C}^{n\times n}$.

Solution on page 1195

Problem 2.14. STANDARD Prove or disprove each statement.

(a) If $P, Q \in F^{n\times n}$ satisfy $P^2 = P$, $Q^2 = Q$, and $PQ = QP$, then $P + Q - PQ$ is idempotent.

(b) If $T \in \mathrm{L}(V)$ and $\ker T = \ker T^2$, then $\operatorname{im} T = \operatorname{im} T^2$.

(c) If $A \in F^{n\times n}$ and $\operatorname{tr}\big(A^k\big) = 0$ for every $k \geq 1$, then $A^k = 0$ for some k.

(d) If $P, Q \in F^{n\times n}$ are idempotent, with $n \geq 2$, then $P + Q$ is idempotent.

(e) If $T \in \mathrm{L}(V, W)$ and $S \in \mathrm{L}(W, V)$ satisfy $ST = \mathrm{id}_V$ and TS is injective, then T is invertible.

Solution on page 1196

Problem 2.15. HARD Let p be a prime, $\mathbf{u} = (1, 1, 1) \in \mathbb{F}_p^3$, and $\ell = \operatorname{span}(\mathbf{u})$.

(a) Show that exactly p^4 linear maps $T : \mathbb{F}_p^3 \to \mathbb{F}_p^2$ satisfy $T(\mathbf{u}) = \mathbf{0}$.

(b) Show that exactly $\big(p^2 - 1\big)\big(p^2 - p\big)$ of them have $\ker T = \ell$, and that each of these is surjective.

(c) Show that every surjective linear map $\mathbb{F}_p^3 \to \mathbb{F}_p^2$ has a line $\operatorname{span}(\mathbf{v})$, $\mathbf{v} \neq \mathbf{0}$, as its kernel. Use (b) and the number of lines in $\mathbb{F}_p^3$ (Problem 1.13) to count the surjective linear maps $\mathbb{F}_p^3 \to \mathbb{F}_p^2$, and compare with Exercise 2.6.45.

Solution on page 1197

Problem 2.16. HARD

(a) Let $P \in F^{n\times n}$ satisfy $P^2 = P$, and let $k = \operatorname{rank} P$. Show that $\operatorname{tr} P = k * 1$.

(b) Let $A \in F^{n\times n}$ satisfy $A^2 = 0$. Show that $\operatorname{tr} A = 0$.

(c) Let $P_1, \ldots, P_r \in \mathbb{Q}^{n\times n}$ be idempotent with $P_1 + \cdots + P_r = I_n$. Show that $\operatorname{rank} P_1 + \cdots + \operatorname{rank} P_r = n$. Show that this fails over $\mathbb{F}_2$.

Solution on page 1198

Problem 2.17. HARD Let $A, B \in F^{n\times n}$ satisfy $AB = 0$.

(a) Show that $\operatorname{tr}\big((A + B)^k\big) = \operatorname{tr}\big(A^k\big) + \operatorname{tr}\big(B^k\big)$ for every $k \geq 1$.

(b) Show that $(A + B)^k = A^k + B^k$ can fail: find $A, B \in F^{2\times 2}$ with $AB = 0$ and $(A + B)^2 \neq A^2 + B^2$.

Solution on page 1198

Problem 2.18. HARD A town has n residents and k clubs. Every club has an odd number of members, and every two different clubs have an even number of members in common.

(a) Show that $k \leq n$.

(b) Show that $k = n$ is possible for every $n \geq 1$.

(c) Suppose instead that every club has an *even* number of members, and every two different clubs still share an even number. Show that there can be more than n clubs: find 7 nonempty clubs in a town of 6 residents.

Solution on page 1199

Problem 2.19. HARD Let $A, B \in \mathbb{R}^{n \times n}$ be different matrices with $A^3 = B^3$ and $A^2B = B^2A$.

(a) Can $A^2 + B^2$ be invertible?

(b) Show that $A^2 + B^2$ need not be 0.

Solution on page 1200

Problem 2.20. CHALLENGE Let $A, B \in F^{n \times n}$ satisfy $ABAB = 0$.

(a) Show that if $n = 2$, then $BABA = 0$.

(b) Show that for every $n \geq 3$ there are $A, B \in F^{n \times n}$ with $ABAB = 0$ but $BABA \neq 0$.

Solution on page 1200

Chapter 3

Linear systems and row reduction

Gauss–Jordan elimination as the engine of the theory, rank, and the Fundamental Theorems completed.

3.1 Linear systems

The Fundamental Theorems (Section 2.7) are statements about the equation $A\mathbf{x} = \mathbf{y}$: whether it has a solution for every $\mathbf{y}$, and whether solutions are unique. They do not tell us how to settle either question for a particular matrix, let alone how to find the solutions. This chapter develops the tool that does, Gauss–Jordan elimination, and then uses it to finish the proofs of the theorems. This section sets up the problem. A linear system can be read as a list of equations, as one matrix equation, or as a question about linear combinations of columns, and its solution set always has the same shape: it is empty, or it is one solution plus the kernel of T_A.

3.1.1 Linear systems

Definition 3.1.1 (Linear system). Let F be a field. A **linear equation** in the unknowns $x_1, \dots, x_n$ over F is an equation

$$a_1x_1 + a_2x_2 + \cdots + a_nx_n = b,$$

where the **coefficients** $a_1, \dots, a_n$ and the **right-hand side** b are fixed elements of F. A **linear system** (or **system of linear equations**) of m equations in n unknowns is a list of m linear equations in the same unknowns,

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= y_1, \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= y_2, \\ &\vdots \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= y_m, \end{aligned}$$

with all a_{ij} and y_i in F. A **solution** of the system is a vector $\mathbf{x} = (x_1, \dots, x_n) \in F^n$ that satisfies all m equations, and the **solution set** is the set of all solutions. The system is **consistent** if it has at least one solution and **inconsistent** otherwise. Two systems in the same unknowns are **equivalent** if they have the same solution set.

The word "linear" refers to the unknowns: each term is a scalar times a single unknown, and nothing else involves the unknowns. The coefficients can be any scalars. An equation such as $2x_1 + 3 = x_2 - x_1$ also counts, since adding $-3 - x_2 + x_1$ to both sides turns it into $3x_1 - x_2 = -3$ without changing its solutions.

Example 3.1.2 (A system with a line of solutions). Over $\mathbb{R}$, consider the system of three equations in three unknowns

$$\begin{aligned} x_1 + 2x_2 - x_3 &= 1, \\ 2x_1 + 5x_2 + x_3 &= 5, \\ 3x_1 + 7x_2 &= 6. \end{aligned}$$

The vector $(2, 0, 1)$ is a solution, since $2 + 0 - 1 = 1$, $4 + 0 + 1 = 5$, and $6 + 0 = 6$. So is $(-5, 3, 0)$. The vector $(1, 0, 0)$ satisfies the first equation but not the second, so it is not a solution. We will find the whole solution set in Example 3.1.13: it is a line in $\mathbb{R}^3$. We call it the *running system* and return to it several times.

Non-example 3.1.3 (Equations that are not linear). Over $\mathbb{R}$, the equations $x_1 x_2 = 1$, $x_1^2 + x_2^2 = 1$, and $x_1 + \sin x_2 = 0$ are not linear: the unknowns are multiplied together, squared, or fed into a function. Their solution sets in $\mathbb{R}^2$ are a hyperbola, a circle, and a sine curve, and none of them contains a straight line. By Corollary 3.1.23, the solution set of a linear system contains the whole line through any two of its points, so none of these curves is the solution set of a linear system. On the other hand, $\sqrt{2}x_1 + \pi x_2 = e$ is a linear equation; its coefficients are just unusual real numbers.

3.1.2 Three faces of one problem

A linear system is determined by its coefficients a_{ij} and its right-hand sides y_i; what we call the unknowns plays no role. Collecting the coefficients into a matrix and the right-hand sides into a vector turns the m equations into a single equation, and that equation can be read in two further ways.

Definition 3.1.4 (Coefficient matrix; matrix and vector forms). The **coefficient matrix** of the system in Definition 3.1.1 is the matrix $A \in F^{m \times n}$ whose (i, j) entry is a_{ij}, the coefficient of x_j in the ith equation. Write $\mathbf{y} = (y_1, \ldots, y_m) \in F^m$ for the vector of right-hand sides, and $\mathbf{a}_1, \ldots, \mathbf{a}_n \in F^m$ for the columns of A. The **matrix form** of the system is the equation

$$A\mathbf{x} = \mathbf{y}$$

in the unknown $\mathbf{x} \in F^n$, and its **vector form** is the equation

$$x_1\mathbf{a}_1 + x_2\mathbf{a}_2 + \cdots + x_n\mathbf{a}_n = \mathbf{y}$$

in the unknown scalars $x_1, \ldots, x_n$. We refer to the system itself as "the system $A\mathbf{x} = \mathbf{y}$".

For the running system (Example 3.1.2),

$$A = \begin{pmatrix} 1 & 2 & -1 \\ 2 & 5 & 1 \\ 3 & 7 & 0 \end{pmatrix}, \quad \mathbf{y} = \begin{pmatrix} 1 \\ 5 \\ 6 \end{pmatrix}, \quad x_1\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} + x_2\begin{pmatrix} 2 \\ 5 \\ 7 \end{pmatrix} + x_3\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 5 \\ 6 \end{pmatrix}.$$

The missing x_3 in the third equation is a coefficient 0.

Proposition 3.1.5 (Three faces of a linear system). Let $A \in F^{m \times n}$ have columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, let $\mathbf{y} \in F^m$, and let $\mathbf{x} = (x_1, \ldots, x_n) \in F^n$. The following are equivalent.

(i) $\mathbf{x}$ is a solution of the linear system with coefficient matrix A and right-hand sides $\mathbf{y}$.
(ii) $A\mathbf{x} = \mathbf{y}$.
(iii) $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = \mathbf{y}$.

Proof. ROUTINE

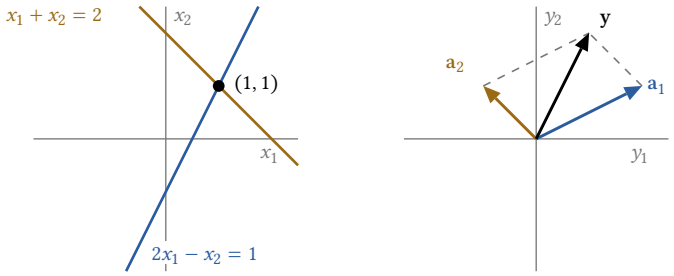
Uses. Definition 2.3.8 (Matrix–vector product), Definition 1.2.4 (The space F^n)
Hint 1. Two of the three statements are the same equation by a definition. Which two?
Hint 2. For the remaining equivalence, compare the ith entries of the two sides of (iii).

Sketch. By the definition of $A\mathbf{x}$ as a combination of the columns of A, (ii) and (iii) are the same equation. The ith entry of $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ is $a_{i1}x_1 + \cdots + a_{in}x_n$, the left side of the ith equation, so (iii) holds exactly when all m equations do.

By Definition 2.3.8, $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$, so (ii) and (iii) are the same equation.

For (i) $\Leftrightarrow$ (iii), recall that vectors in F^m are added and scaled entry by entry, and that two vectors in F^m are equal exactly when their entries are (Definition 1.2.4). The ith entry of $\mathbf{a}_j$ is a_{ij}, so the ith entry of $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ is

$$x_1a_{i1} + x_2a_{i2} + \cdots + x_na_{in} = a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{in}x_n.$$



Hence (iii) holds if and only if, for each $i = 1, \ldots, m$, the left side of the ith equation equals y_i. That is, (iii) holds if and only if $\mathbf{x}$ is a solution. □

Example 3.1.6 (Two pictures of one system). The system $2x_1 - x_2 = 1$, $x_1 + x_2 = 2$ over $\mathbb{R}$ has matrix form and vector form

$$\begin{pmatrix} 2 & -1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}, \quad x_1\begin{pmatrix} 2 \\ 1 \end{pmatrix} + x_2\begin{pmatrix} -1 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}.$$

Read as equations, it asks for the points of $\mathbb{R}^2$ that lie on two lines; the lines cross at $(1, 1)$ (Figure 3.1.1, left). Read as a vector equation, it asks how to reach $(1, 2)$ by scaling $\mathbf{a}_1 = (2, 1)$ and $\mathbf{a}_2 = (-1, 1)$ and adding; the answer is one of each, since $(2, 1) + (-1, 1) = (1, 2)$ (Figure 3.1.1, right).

Realize that the two pictures live in different spaces. The **row picture** is drawn in F^n, the space where the unknown $\mathbf{x}$ lives, and has one line (in $\mathbb{R}^3$, one plane) per equation. The **column picture** is drawn in F^m, the space where the right-hand side $\mathbf{y}$ lives, and has one vector per unknown.

Row picture Column picture

Figure 3.1.1. The system $2x_1 - x_2 = 1$, $x_1 + x_2 = 2$. Left: the solution is the point where the two lines meet. Right: the same solution, $(x_1, x_2) = (1, 1)$, gives the coefficients that combine the columns into $\mathbf{y}$.

Exercise 3.1.7. ROUTINE Write the system

$$x_1 - x_3 = 2, \quad x_2 + 2x_3 = -1, \quad x_1 + x_2 = 1$$

over $\mathbb{R}$ in matrix form and in vector form. Is $(2, -1, 0)$ a solution? Is $(3, -3, 1)$?

Solution on page 1201

What each face is good for

Intuition (Three ways to read $A\mathbf{x} = \mathbf{y}$). The *equations* are what we manipulate. Adding a multiple of one equation to another, swapping two equations, or scaling one by a nonzero scalar does not change the solution set, and elimination is built from exactly these moves (Section 3.1.3). Geometrically, the solution set of a system is the intersection of the solution sets of its equations, which is the row picture.

The *matrix equation* brings in the linear map $T_A : F^n \to F^m, \mathbf{x} \mapsto A\mathbf{x}$ (Definition 2.3.15). Solving the system means finding every $\mathbf{x}$ with $T_A(\mathbf{x}) = \mathbf{y}$, that is, the preimage of $\mathbf{y}$ under T_A. Consistency asks whether $\mathbf{y} \in \operatorname{im} T_A$, and the solution set of $A\mathbf{x} = \mathbf{0}$ is $\ker T_A$. Everything we know about kernels and images applies, and so does linearity: $A(\mathbf{x} + \mathbf{x}') = A\mathbf{x} + A\mathbf{x}'$ tells us how solutions of systems with the same coefficient matrix combine. This is the view in which the structure of the solution set (Proposition 3.1.19) is proved.

The *vector equation* asks whether $\mathbf{y}$ is a linear combination of the columns of A, and if so in how many ways. Read backwards, it says that every question about a span or about linear independence of a list in F^m is a question about a linear system. So a procedure that solves linear systems also answers, by computation, the questions of Chapter 1.

The first two readings are related by the following proposition, which is little more than a translation of definitions.

Proposition 3.1.8 (Systems and the map T_A). Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, and let $\mathbf{y} \in F^m$.

(a) The system $A\mathbf{x} = \mathbf{y}$ is consistent if and only if $\mathbf{y} \in \operatorname{im} T_A$, if and only if $\mathbf{y} \in \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n)$.

(b) The solution set of the homogeneous system $A\mathbf{x} = \mathbf{0}$ is $\ker T_A$.

Proof. ROUTINE

Uses. Proposition 3.1.5 (Three faces of a linear system), Definition 2.3.15 (The linear map of a matrix), Definition 2.6.6 (Image), Definition 2.6.5 (Kernel), Definition 1.3.10 (Span)
Hint 1. Unwind the definitions: what does $\mathbf{y} \in \operatorname{im} T_A$ say? What does $\mathbf{y} \in \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ say?
Hint 2. Each of them says that some $\mathbf{x} \in F^n$ satisfies one of the forms in Proposition 3.1.5.
Sketch. $\mathbf{y} \in \operatorname{im} T_A$ means $A\mathbf{x} = \mathbf{y}$ for some $\mathbf{x}$, and $\mathbf{y} \in \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ means $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = \mathbf{y}$ for some scalars x_j. By Proposition 3.1.5, each says that the system has a solution. For (b), $\mathbf{x}$ solves $A\mathbf{x} = \mathbf{0}$ exactly when $T_A(\mathbf{x}) = \mathbf{0}$.

(a) By Definition 2.6.6 and Definition 2.3.15, $\mathbf{y} \in \operatorname{im} T_A$ means that $A\mathbf{x} = \mathbf{y}$ for some $\mathbf{x} \in F^n$. By Definition 1.3.10, $\mathbf{y} \in \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ means that $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = \mathbf{y}$ for some $x_1, \ldots, x_n \in F$. By Proposition 3.1.5, each of these says that the system has a solution $\mathbf{x} = (x_1, \ldots, x_n)$.

(b) By Proposition 3.1.5, $\mathbf{x} \in F^n$ solves $A\mathbf{x} = \mathbf{0}$ if and only if $T_A(\mathbf{x}) = A\mathbf{x} = \mathbf{0}$, that is, if and only if $\mathbf{x} \in \ker T_A$ (Definition 2.6.5). □

Combining Proposition 3.1.8 with the Fundamental Theorems gives a dictionary between the three faces (Table 3.1.1). Each row says the same thing about A in three ways. Most of the questions we ask about a matrix in the next two chapters are entries of this table, and Gauss–Jordan elimination will answer each of them by inspecting a single matrix.

The system $A\mathbf{x} = \mathbf{y}$	The map T_A	The columns of A
is consistent	$\mathbf{y} \in \operatorname{im} T_A$	$\mathbf{y}$ is in their span
with $\mathbf{y} = \mathbf{0}$ has a solution $\mathbf{x} \neq \mathbf{0}$	$\ker T_A \neq \{\mathbf{0}\}$	they are linearly dependent
is consistent for every $\mathbf{y} \in F^m$	T_A is surjective	they span F^m
has at most one solution for every $\mathbf{y}$	T_A is injective	they are linearly independent
has exactly one solution for every $\mathbf{y}$	T_A is bijective	they form a basis of F^m

Table 3.1.1. Three readings of the same property. The first two rows come from Proposition 3.1.8 and the definition of linear independence (Definition 1.5.1). The last three are parts of Theorem 2.7.4, Theorem 2.7.2, and Theorem 2.7.8.

The third reading turns questions about vectors into linear systems. This move is used so often that it deserves a name.

Technique 3.1.9 (Undetermined coefficients). To decide whether an object with prescribed properties exists, and to find all such objects, write the unknown object in terms of unknown scalars, the **undetermined coefficients**, and translate each requirement into an equation in those scalars. When the requirements are linear in the scalars, the result is a linear system, and the question becomes whether that system is consistent and what its solution set is.

Reach for it whenever you are asked whether a vector is a linear combination of given vectors, whether a list is linearly independent, or whether a polynomial or a linear map with given properties exists. Membership of $\mathbf{w}$ in $\operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$ is the system $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k = \mathbf{w}$ in the unknowns c_i. Linear independence of $\mathbf{v}_1, \dots, \mathbf{v}_k$ asks whether the homogeneous system $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k = \mathbf{0}$ has only the trivial solution. The canonical example is Example 3.1.10.

Used in. Exercise 3.1.11, Exercise 3.1.29, Exercise 3.1.37, Exercise 3.1.38, Exercise 3.1.39, Exercise 3.1.40, Exercise 3.1.41, Theorem 3.4.24, Exercise 3.6.12, Problem 3.9, Problem 3.11, Problem 3.13, Exercise 3.4.43, Exercise 6.3.49, Exercise 6.6.48.

Example 3.1.10 (Membership and independence over $\mathbb{R}$ and over $\mathbb{F}_2$). Let $\mathbf{v}_1 = (1, 0, 1)$, $\mathbf{v}_2 = (1, 1, 0)$, and $\mathbf{v}_3 = (0, 1, 1)$. Is $\mathbf{w} = (1, 1, 1)$ a linear combination of $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$? Writing $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + c_3\mathbf{v}_3 = \mathbf{w}$ and comparing entries gives the system

$$c_1 + c_2 = 1, \quad c_2 + c_3 = 1, \quad c_1 + c_3 = 1.$$

Adding the three equations shows that every solution satisfies $2(c_1 + c_2 + c_3) = 3$.

Over $\mathbb{R}$ we may divide by 2, so every solution has $c_1 + c_2 + c_3 = 3/2$. Subtracting each of the three equations from this one gives $c_3 = 1/2$, $c_1 = 1/2$, and $c_2 = 1/2$. Conversely, $(1/2, 1/2, 1/2)$ satisfies all three equations. So $\mathbf{w} = \frac{1}{2}(\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3)$, and this is the only way to write $\mathbf{w}$ as a combination of the $\mathbf{v}_i$. The same computation with right-hand side $\mathbf{0}$ shows that $c_1 + c_2 = c_2 + c_3 = c_1 + c_3 = 0$ has only the trivial solution, so $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ is linearly independent over $\mathbb{R}$.

Over $\mathbb{F}_2$ we have $2 = 0$ and $3 = 1$, so every solution would satisfy $0 = 1$. The system is inconsistent, and $\mathbf{w} \notin \operatorname{span}(\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3)$. The homogeneous system now has the nontrivial solution $(1, 1, 1)$, because $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 = (2, 2, 2) = \mathbf{0}$, so the list is linearly dependent over $\mathbb{F}_2$.

The only step that distinguished the two fields was a division by 2. Elimination divides by nonzero scalars all the time, and which scalars are nonzero depends on the field.

Exercise 3.1.11. ROUTINE Set up a linear system whose solutions are exactly the triples $(c_1, c_2, c_3) \in \mathbb{R}^3$ with

$$x^2 = c_1(x + 1)^2 + c_2(x - 1)^2 + c_3$$

in $\mathbb{R}[x]$, and solve it.

Solution on page 1201

3.1.3 Augmented matrices and elimination

Definition 3.1.12 (Augmented matrix). The **augmented matrix** of the system $A\mathbf{x} = \mathbf{y}$, where $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$, is the $m \times (n + 1)$ matrix $(A \mid \mathbf{y})$ obtained by adjoining $\mathbf{y}$ to A as a last column. A vertical bar separates the coefficients from the right-hand sides.

The augmented matrix of the running system (Example 3.1.2) is

$$\left(\begin{array}{ccc|c} 1 & 2 & -1 & 1 \\ 2 & 5 & 1 & 5 \\ 3 & 7 & 0 & 6 \end{array}\right).$$

Row i of the augmented matrix records equation i, so operations on equations become operations on rows, and we can skip writing the unknowns.

Example 3.1.13 (Elimination on the running system). We solve the running system by eliminating unknowns. Subtract 2 times the first equation from the second, and 3 times the first from the third:

$$\left(\begin{array}{ccc|c} 1 & 2 & -1 & 1 \\ 0 & 1 & 3 & 3 \\ 0 & 1 & 3 & 3 \end{array}\right).$$

Now subtract the second equation from the third, and 2 times the second from the first:

$$\left(\begin{array}{ccc|c} 1 & 0 & -7 & -5 \\ 0 & 1 & 3 & 3 \\ 0 & 0 & 0 & 0 \end{array}\right).$$

The last row is the equation $0 = 0$, which every vector satisfies. The other two rows say $x_1 - 7x_3 = -5$ and $x_2 + 3x_3 = 3$. Whatever value t we give x_3, these determine $x_1 = -5 + 7t$ and $x_2 = 3 - 3t$. So the solution set is

$$\{(-5 + 7t, 3 - 3t, t) \mid t \in \mathbb{R}\} = \{(-5, 3, 0) + t(7, -3, 1) \mid t \in \mathbb{R}\},$$

the line through $(-5, 3, 0)$ in the direction of $(7, -3, 1)$. The solutions $(-5, 3, 0)$ and $(2, 0, 1)$ from Example 3.1.2 are the points with $t = 0$ and $t = 1$.

If the third right-hand side were 7 instead of 6, the same operations would end with the row $(0, 0, 0 \mid 1)$, which is the equation $0 = 1$. No vector satisfies it, so that system is inconsistent.

These moves never change the solution set. Each new equation is a combination of the old ones, so every solution of the old system also solves the new one. And each move can be undone by a move of the same kind: subtracting 2 times the first equation from the second is undone by adding 2 times the first equation back, which is possible because the first equation is still there. (In each step of the example, the equations we subtracted were themselves left unchanged in that step.) So the old equations are combinations of the new ones as well, and every solution of the new system solves the old one. The two systems are equivalent. Section 3.2 makes this precise by writing each move as left multiplication by an invertible matrix, and Exercise 3.1.35 shows what goes wrong when a move cannot be undone.

> *Intuition (Why we need an algorithm).* Elimination by hand worked here, but each step was a choice, and we stopped when the answer looked readable. To prove theorems with elimination we need a precise procedure: one that always terminates, whose steps provably never change the solution set, and whose output has a standard shape from which the solution set, and every row of Table 3.1.1, can be read off directly. Gauss–Jordan elimination (Section 3.3) is that procedure. Section 3.2 sets up its bookkeeping, Section 3.4 reads solutions off its output, and Section 3.5 uses it to finish the Fundamental Theorems. It stays the computational engine through Chapter 4, where it computes bases, dimensions, and ranks.

3.1.4 Homogeneous systems and the shape of the solution set

Definition 3.1.14 (Homogeneous system). A linear system $A\mathbf{x} = \mathbf{y}$ is **homogeneous** if $\mathbf{y} = \mathbf{0}$. The **associated homogeneous system** of $A\mathbf{x} = \mathbf{y}$ is $A\mathbf{x} = \mathbf{0}$. Every homogeneous system has the **trivial solution** $\mathbf{x} = \mathbf{0}$; any other solution is **nontrivial**.

Example 3.1.15 (The running system, made homogeneous). The associated homogeneous system of the running system is $x_1 + 2x_2 - x_3 = 0, 2x_1 + 5x_2 + x_3 = 0, 3x_1 + 7x_2 = 0$. The row operations of Example 3.1.13

never mix the last column into the others, and a last column of zeros stays zero, so they end with $x_1 - 7x_3 = 0$ and $x_2 + 3x_3 = 0$. The solution set is

$$\{t(7, -3, 1) \mid t \in \mathbb{R}\} = \operatorname{span}((7, -3, 1)),$$

a line through the origin, parallel to the solution line of the running system.

Corollary 3.1.16 (Homogeneous solution sets are subspaces). The solution set of a homogeneous system $A\mathbf{x} = \mathbf{0}$, where $A \in F^{m\times n}$, is the subspace $\ker T_A$ of F^n.

Proof. ROUTINE

Uses. Proposition 3.1.8 (Systems and the map T_A), Proposition 2.6.8 (Kernels and images are subspaces)
Hint 1. Which subset of F^n is the solution set, by Proposition 3.1.8?
Hint 2. Kernels of linear maps are subspaces.
Sketch. By Proposition 3.1.8 the solution set is $\ker T_A$, and the kernel of a linear map is a subspace of its domain.

By part (b) of Proposition 3.1.8, the solution set is $\ker T_A$. Since $T_A : F^n \to F^m$ is linear, $\ker T_A$ is a subspace of F^n by Proposition 2.6.8. □

Concretely: sums and scalar multiples of solutions of a homogeneous system are again solutions. A system with $\mathbf{y} \neq \mathbf{0}$ has no such luck. Its solution set never contains $\mathbf{0}$, since $A\mathbf{0} = \mathbf{0} \neq \mathbf{y}$, so it is never a subspace. The running system shows what it is instead: the line of solutions in Example 3.1.13 is the line of Example 3.1.15, moved over so that it passes through one solution. To say this in general we need a name for a moved-over subset.

Notation 3.1.17 (Translates). Let V be a vector space, $\mathbf{v} \in V$, and $U \subseteq V$. The **translate** of U by $\mathbf{v}$ is

$$\mathbf{v} + U = \{\mathbf{v} + \mathbf{u} \mid \mathbf{u} \in U\}.$$

Intuition. Suppose $\mathbf{x}$ and $\mathbf{x}'$ both solve $A\mathbf{x} = \mathbf{y}$. Then $A(\mathbf{x}' - \mathbf{x}) = \mathbf{y} - \mathbf{y} = \mathbf{0}$, so any two solutions differ by a solution of the homogeneous system. Conversely, adding a homogeneous solution $\mathbf{z}$ to a solution $\mathbf{x}$ gives another solution, since $A(\mathbf{x} + \mathbf{z}) = \mathbf{y} + \mathbf{0}$. So once we know one solution, the others are exactly the ones we reach from it by adding elements of $\ker T_A$. Only linearity is involved, so the same holds for any linear map in place of T_A.

Technique 3.1.18 (Particular plus homogeneous). To find every solution of a linear equation $T(\mathbf{x}) = \mathbf{y}$, find *one* solution $\mathbf{x}_0$, called a **particular solution**, and *all* solutions of the homogeneous equation $T(\mathbf{z}) = \mathbf{0}$. Every solution is $\mathbf{x}_0 + \mathbf{z}$ for exactly one such $\mathbf{z}$. This splits the problem in two: existence of a solution depends on $\mathbf{y}$, while the shape of the solution set, and in particular uniqueness, depends on $\ker T$ alone.

Reach for it whenever you need all solutions of a linear problem, such as a linear system, a linear recurrence, or a linear differential equation, and whenever you need to show that a solution is unique: a solution, if one exists, is unique exactly when the homogeneous equation has only the trivial solution. The canonical example is Proposition 3.1.19.
Used in. Corollary 2.6.31, Exercise 2.6.33, Proposition 3.1.19, Exercise 3.1.21, Corollary 3.1.22, Corollary 3.1.23, Exercise 3.1.31, Exercise 3.1.37, Exercise 3.1.38, Exercise 3.1.46, Exercise 3.1.47, Theorem 3.4.9, Exercise 3.6.12, Problem 3.1, Problem 3.5, Problem 3.9, Problem 3.16, Theorem 4.7.8, Corollary 7.1.30, Exercise 2.6.34, Exercise 3.1.29, Exercise 3.1.30.

Proposition 3.1.19 (Solution sets are translates of the kernel). Let $T : V \to W$ be a linear map, let $\mathbf{y} \in W$, and let $S = \{\mathbf{x} \in V \mid T(\mathbf{x}) = \mathbf{y}\}$. If $\mathbf{x}_0 \in S$, then

$$S = \mathbf{x}_0 + \ker T,$$

and the map $\ker T \to S$, $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$, is a bijection. In particular, the solution set of a linear system $A\mathbf{x} = \mathbf{y}$ is either empty or equal to $\mathbf{x}_0 + \ker T_A$, where $\mathbf{x}_0$ is any one solution.

Proof. ROUTINE

> *Uses.* Definition 2.1.1 (Linear map), Definition 2.6.5 (Kernel), Notation 3.1.17 (Translates), Proposition 1.2.34 (Negatives and the scalar -1), Proposition 3.1.5 (Three faces of a linear system)
> *Techniques.* Double containment (Technique 1.3.14), Particular plus homogeneous (Technique 3.1.18)
> *Hint 1.* Prove $\mathbf{x}_0 + \ker T \subseteq S$ and $S \subseteq \mathbf{x}_0 + \ker T$ separately.
> *Hint 2.* For the first containment, apply T to $\mathbf{x}_0 + \mathbf{z}$, where $\mathbf{z} \in \ker T$.
> *Hint 3.* For the second, given $\mathbf{x} \in S$, the only possible choice of $\mathbf{z}$ is $\mathbf{x} - \mathbf{x}_0$. Show that it lies in $\ker T$.
> *Sketch.* If $T(\mathbf{z}) = \mathbf{0}$, then $T(\mathbf{x}_0 + \mathbf{z}) = \mathbf{y} + \mathbf{0} = \mathbf{y}$. If $T(\mathbf{x}) = \mathbf{y}$, then $T(\mathbf{x} - \mathbf{x}_0) = \mathbf{y} - \mathbf{y} = \mathbf{0}$, and $\mathbf{x} = \mathbf{x}_0 + (\mathbf{x} - \mathbf{x}_0)$. So $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$ maps $\ker T$ onto S, and it is injective by cancellation. For a system, take $T = T_A$ and use Proposition 3.1.5.

Suppose $\mathbf{x}_0 \in S$, so that $T(\mathbf{x}_0) = \mathbf{y}$. We prove the two containments.

$\mathbf{x}_0 + \ker T \subseteq S$. Let $\mathbf{z} \in \ker T$. Since T is linear,

$$T(\mathbf{x}_0 + \mathbf{z}) = T(\mathbf{x}_0) + T(\mathbf{z}) = \mathbf{y} + \mathbf{0} = \mathbf{y},$$

so $\mathbf{x}_0 + \mathbf{z} \in S$.

$S \subseteq \mathbf{x}_0 + \ker T$. Let $\mathbf{x} \in S$, and put $\mathbf{z} = \mathbf{x} - \mathbf{x}_0 = \mathbf{x} + (-1)\mathbf{x}_0$ (Proposition 1.2.34). Since T is linear,

$$T(\mathbf{z}) = T(\mathbf{x}) + (-1)T(\mathbf{x}_0) = \mathbf{y} - \mathbf{y} = \mathbf{0},$$

so $\mathbf{z} \in \ker T$, and $\mathbf{x} = \mathbf{x}_0 + \mathbf{z} \in \mathbf{x}_0 + \ker T$.

Hence $S = \mathbf{x}_0 + \ker T$, which says exactly that $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$ maps $\ker T$ onto S. This map is also injective: if $\mathbf{x}_0 + \mathbf{z} = \mathbf{x}_0 + \mathbf{z}'$, adding $-\mathbf{x}_0$ to both sides gives $\mathbf{z} = \mathbf{z}'$. So it is a bijection.

For the last statement, let $A \in F^{m \times n}$ and $\mathbf{y} \in F^m$. By Proposition 3.1.5, the solution set of the system $A\mathbf{x} = \mathbf{y}$ is $\{\mathbf{x} \in F^n \mid T_A(\mathbf{x}) = \mathbf{y}\}$. If it is nonempty, we apply what we proved to $T = T_A$ and any solution $\mathbf{x}_0$. □

So the solution set of a consistent system is $\ker T_A$ slid over to pass through any one solution, and which solution we slide it to does not matter. For the running system, Example 3.1.13 and Example 3.1.15 give

$$\left\{\mathbf{x} \in \mathbb{R}^3 \;\middle|\; A\mathbf{x} = \mathbf{y}\right\} = (-5, 3, 0) + \operatorname{span}((7, -3, 1)) = (2, 0, 1) + \operatorname{span}((7, -3, 1)).$$

The proof used nothing about V and W beyond the linearity of T, so the proposition applies to linear equations far from F^n.

Example 3.1.20 (A linear equation in $\mathbb{R}[x]$). Let $D : \mathbb{R}[x] \to \mathbb{R}[x]$ be differentiation, $D(f) = f'$, which is linear (Section 2.1). Which polynomials f satisfy $f' = 2x + 1$? One solution is $x^2 + x$. The kernel of D consists of the constant polynomials: if $f = c_0 + c_1 x + \cdots + c_d x^d$ and $f' = c_1 + 2c_2 x + \cdots + dc_d x^{d-1} = 0$, then $kc_k = 0$, hence $c_k = 0$, for every $k \geq 1$. By Proposition 3.1.19, the solutions are exactly the polynomials $x^2 + x + c$ with $c \in \mathbb{R}$: the "$+C$" of an antiderivative is the kernel of D.

Over $\mathbb{F}_p$ the step from $kc_k = 0$ to $c_k = 0$ fails when p divides k. For instance $D(x^p) = px^{p-1} = 0$, so the kernel of D on $\mathbb{F}_p[x]$ is larger, and so is every nonempty solution set.

ASIDE: *Linear differential equations*

Proposition 3.1.19 is the reason behind the recipe "general solution = particular solution + complementary solution" for linear differential equations. For instance, $f \mapsto f'' + f$ is a linear map on the space of twice-differentiable functions $\mathbb{R} \to \mathbb{R}$, its kernel consists of the functions $a\cos x + b\sin x$, and $f(x) = x$ is one solution of $f'' + f = x$. So every solution is $x + a\cos x + b\sin x$. Identifying that kernel takes some analysis; the shape of the answer is linear algebra.

Exercise 3.1.21. ROUTINE Let $A \in \mathbb{R}^{2\times 3}$, and suppose that $(1, 2, 0)$ and $(0, 1, 1)$ both solve $A\mathbf{x} = (3, 1)$. Find a nonzero vector in $\ker T_A$, a solution of $A\mathbf{x} = (6, 2)$, and infinitely many solutions of $A\mathbf{x} = (3, 1)$.

Solution on page 1201

Consequences

Proposition 3.1.19 separates the two questions every system raises. Whether $A\mathbf{x} = \mathbf{y}$ has a solution depends on $\mathbf{y}$. How many solutions it has, once it has one, depends only on $\ker T_A$.

Corollary 3.1.22 (Uniqueness depends only on A). Let $A \in F^{m\times n}$.

(a) A consistent system $A\mathbf{x} = \mathbf{y}$ has exactly one solution if and only if $\ker T_A = \{\mathbf{0}\}$.

(b) If $A\mathbf{x} = \mathbf{y}$ has exactly one solution for some $\mathbf{y} \in F^m$, then $A\mathbf{x} = \mathbf{y}'$ has at most one solution for every $\mathbf{y}' \in F^m$.

Proof. ROUTINE

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. Proposition 3.1.19 gives a bijection between the solution set and $\ker T_A$. When does a set in bijection with $\ker T_A$ have exactly one element?
Hint 2. $\ker T_A$ always contains $\mathbf{0}$. For (b), apply (a) twice, and remember that $A\mathbf{x} = \mathbf{y}'$ might be inconsistent.
Sketch. The solution set of a consistent system is in bijection with $\ker T_A$, which contains $\mathbf{0}$, so it is a single vector exactly when $\ker T_A = \{\mathbf{0}\}$. For (b), (a) gives $\ker T_A = \{\mathbf{0}\}$, and then (a) again says that each consistent $A\mathbf{x} = \mathbf{y}'$ has one solution, while an inconsistent one has none.

(a) Let S be the solution set and $\mathbf{x}_0 \in S$. By Proposition 3.1.19, $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$ is a bijection from $\ker T_A$ onto S, so S has exactly one element if and only if $\ker T_A$ does. Since $\mathbf{0} \in \ker T_A$ (Proposition 2.1.4), $\ker T_A$ has exactly one element if and only if $\ker T_A = \{\mathbf{0}\}$.

(b) By (a), applied to the system with exactly one solution, $\ker T_A = \{\mathbf{0}\}$. Let $\mathbf{y}' \in F^m$. If $A\mathbf{x} = \mathbf{y}'$ is inconsistent, it has no solutions. Otherwise it has exactly one solution, by (a) again. □

Part (a) recovers the implication "if $\ker T_A = \{\mathbf{0}\}$, then $A\mathbf{x} = \mathbf{y}$ has at most one solution for every $\mathbf{y}$" of Theorem 2.7.2, now seen from the shape of the solution set. Part (b) cannot be improved to "exactly one solution for every $\mathbf{y}'$": see Exercise 3.1.34.

Over $\mathbb{R}$, two solutions of a system determine a line, and the whole line consists of solutions. In general:

Corollary 3.1.23 (Lines through solutions). If $\mathbf{u}$ and $\mathbf{v}$ are solutions of the system $A\mathbf{x} = \mathbf{y}$ over F, then so is $\mathbf{u} + t(\mathbf{v} - \mathbf{u})$ for every $t \in F$.

Proof. ROUTINE

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 3.1.16 (Homogeneous solution sets are subspaces)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. Use Proposition 3.1.19 with $\mathbf{x}_0 = \mathbf{u}$. Where does $\mathbf{v} - \mathbf{u}$ lie?
Hint 2. $\ker T_A$ is a subspace, so it is closed under scalar multiplication.
Sketch. $\mathbf{v} - \mathbf{u} \in \ker T_A$ since both are solutions; hence $t(\mathbf{v} - \mathbf{u}) \in \ker T_A$, and $\mathbf{u} + t(\mathbf{v} - \mathbf{u}) \in \mathbf{u} + \ker T_A$, which is the solution set.

Let S be the solution set. By Proposition 3.1.19 with $\mathbf{x}_0 = \mathbf{u}$, we have $S = \mathbf{u} + \ker T_A$. Since $\mathbf{v} \in S$, $\mathbf{v} = \mathbf{u} + \mathbf{z}$ for some $\mathbf{z} \in \ker T_A$, namely $\mathbf{z} = \mathbf{v} - \mathbf{u}$. As $\ker T_A$ is a subspace (Corollary 3.1.16), $t\mathbf{z} \in \ker T_A$ for each $t \in F$, so $\mathbf{u} + t(\mathbf{v} - \mathbf{u}) = \mathbf{u} + t\mathbf{z} \in S$. □

Corollary 3.1.24 (No, one, or infinitely many solutions). Let F be an infinite field, such as $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$. Every linear system over F has no solutions, exactly one solution, or infinitely many solutions.

Proof. ROUTINE

Uses. Corollary 3.1.23 (Lines through solutions), Proposition 1.2.35 (Zero products)
Hint 1. Suppose the system has two different solutions $\mathbf{u}$ and $\mathbf{v}$. Produce infinitely many more.

Hint 2. Use Corollary 3.1.23, and check that different values of t give different points: if $\mathbf{u}+t(\mathbf{v}-\mathbf{u})=\mathbf{u}+t'(\mathbf{v}-\mathbf{u})$, what can you say about $t-t'$?
Sketch. If $\mathbf{u}\neq\mathbf{v}$ are solutions, the points $\mathbf{u}+t(\mathbf{v}-\mathbf{u})$ are solutions, and they are distinct for distinct t because $(t-t')(\mathbf{v}-\mathbf{u})=\mathbf{0}$ with $\mathbf{v}-\mathbf{u}\neq\mathbf{0}$ forces $t=t'$. An infinite field gives infinitely many values of t.

Suppose a system has at least two solutions; we show that it has infinitely many. Let $\mathbf{u}\neq\mathbf{v}$ be solutions. By Corollary 3.1.23, $\mathbf{u}+t(\mathbf{v}-\mathbf{u})$ is a solution for every $t\in F$. These solutions are pairwise distinct: if $\mathbf{u}+t(\mathbf{v}-\mathbf{u})=\mathbf{u}+t'(\mathbf{v}-\mathbf{u})$, then $(t-t')(\mathbf{v}-\mathbf{u})=\mathbf{0}$, and since $\mathbf{v}-\mathbf{u}\neq\mathbf{0}$, Proposition 1.2.35 gives $t-t'=0$. As F is infinite, the system has infinitely many solutions. □

For a finite field the third option is impossible, and the right replacement is a count.

Corollary 3.1.25 (Counting solutions over a finite field). Let F be a finite field and $A\in F^{m\times n}$. Every consistent system $A\mathbf{x}=\mathbf{y}$ has exactly as many solutions as the homogeneous system $A\mathbf{x}=\mathbf{0}$.

Proof. ROUTINE

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Proposition 3.1.8 (Systems and the map T_A)
Hint 1. What is the solution set of the homogeneous system, as a subset of F^n?
Hint 2. Proposition 3.1.19 gives a bijection from it onto the solution set of $A\mathbf{x}=\mathbf{y}$.
Sketch. The homogeneous solution set is $\ker T_A$, and $\mathbf{z}\mapsto\mathbf{x}_0+\mathbf{z}$ is a bijection from $\ker T_A$ onto the solution set of $A\mathbf{x}=\mathbf{y}$. Finite sets in bijection have the same size.

By Proposition 3.1.8, the solution set of $A\mathbf{x}=\mathbf{0}$ is $\ker T_A$. If $A\mathbf{x}=\mathbf{y}$ is consistent with a solution $\mathbf{x}_0$, then by Proposition 3.1.19 the map $\mathbf{z}\mapsto\mathbf{x}_0+\mathbf{z}$ is a bijection from $\ker T_A$ onto its solution set. Both sets are finite, as subsets of the finite set F^n, so they have the same number of elements. □

Example 3.1.26 (Exactly two solutions). Over $\mathbb{F}_2$, the equation $x_1+x_2=1$ has exactly two solutions, $(1,0)$ and $(0,1)$, and its homogeneous version $x_1+x_2=0$ has exactly two, $(0,0)$ and $(1,1)$. So Corollary 3.1.24 really needs F to be infinite. The "line" through the two solutions, $\mathbf{u}+t(\mathbf{v}-\mathbf{u})$ with $t\in\mathbb{F}_2$, consists of $\mathbf{u}$ and $\mathbf{v}$ alone, because $\mathbb{F}_2$ has only two values of t. Once we have dimension, Corollary 3.1.25 becomes a formula: over a field with q elements, a consistent system has exactly q^k solutions, where $k=\dim\ker T_A$ (Section 4.1).

3.1.5 Pictures in $\mathbb{R}^2$ and $\mathbb{R}^3$

Over $\mathbb{R}$ we can draw what the results of this section say.

The row picture

An equation $a_1x_1+a_2x_2=b$ with $(a_1,a_2)\neq(0,0)$ describes a line in $\mathbb{R}^2$. An equation with $a_1=a_2=0$ reads $0=b$; its solution set is all of $\mathbb{R}^2$ if $b=0$ and empty otherwise. The solution set of a system is the intersection of the solution sets of its equations, so two equations in two unknowns, each with a nonzero coefficient, describe the intersection of two lines. There are three possibilities (Figure 3.1.2): the lines cross in one point, they are parallel and distinct, or they coincide.

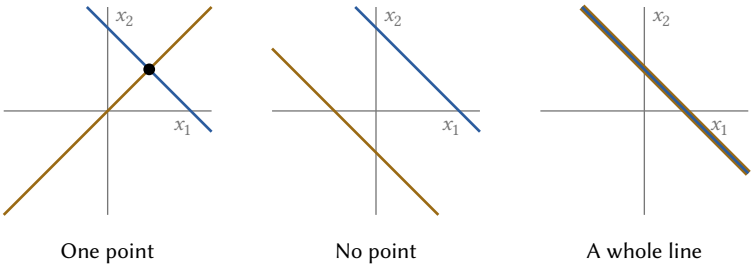


Figure 3.1.2. Two equations in two unknowns over $\mathbb{R}$. Left: $x_1 + x_2 = 2$, $x_1 - x_2 = 0$, with the single solution $(1, 1)$. Middle: $x_1 + x_2 = 2$, $x_1 + x_2 = -1$, which is inconsistent. Right: $x_1 + x_2 = 1$, $2x_1 + 2x_2 = 2$, two equations with the same solution set.

An equation in x_1, x_2, x_3 with some nonzero coefficient describes a plane in $\mathbb{R}^3$, and a system describes an intersection of planes. Two planes meet in a line, are parallel and distinct, or coincide. Three planes have more options. They can meet in a single point; pass through a common line, as the planes of the running system do (Example 3.1.13); coincide; or have no point in common. The last case occurs when two of the planes are parallel and distinct, but also in a less obvious way. Changing the right-hand side of the running system from $(1, 5, 6)$ to $(1, 5, 7)$ moves the third plane off the common line of the first two, but keeps it parallel to that line. The result is three planes, no two of them parallel, that meet in pairs along three parallel lines and have no point in common (Figure 3.1.3). Elimination detected this as the equation $0 = 1$.

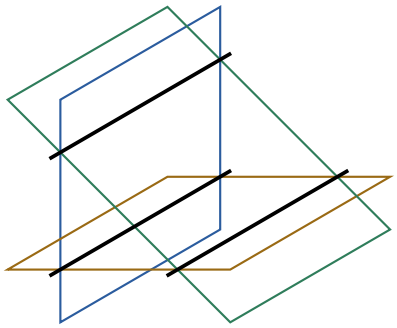

Figure 3.1.3. Three planes, no two of them parallel, with no common point. Each pair meets in a line (black), and the three lines are parallel. The planes of the running system with right-hand side $(1, 5, 7)$ are arranged like this, with the three lines parallel to $(7, -3, 1)$.

The column picture

The columns $(1, 2, 3)$, $(2, 5, 7)$, $(-1, 1, 0)$ of the running system all satisfy $y_3 = y_1 + y_2$, and this condition is preserved by sums and scalar multiples, so every combination of the columns satisfies it too. Hence $A\mathbf{x} = \mathbf{y}$ can only be consistent if $y_3 = y_1 + y_2$. The right-hand side $(1, 5, 6)$ passes this test and $(1, 5, 7)$ fails it, which explains the inconsistency without any elimination. Conversely, every $\mathbf{y}$ with $y_3 = y_1 + y_2$ is reached, since

$$(5y_1 - 2y_2)\begin{pmatrix}1\\2\\3\end{pmatrix} + (y_2 - 2y_1)\begin{pmatrix}2\\5\\7\end{pmatrix} = \begin{pmatrix}y_1\\y_2\\y_1 + y_2\end{pmatrix}.$$

So $\operatorname{im} T_A$ is the plane $y_3 = y_1 + y_2$ in $\mathbb{R}^3$. The row picture lives in the space of unknowns and the column picture in the space of right-hand sides, and the two describe the same system from opposite ends.

Many right-hand sides

Proposition 3.1.19 adds the last piece. For a fixed A, the nonempty solution sets of $A\mathbf{x} = \mathbf{y}$, as $\mathbf{y}$ varies, are all translates of the single subspace $\ker T_A$, so they are parallel to each other (Figure 3.1.4).

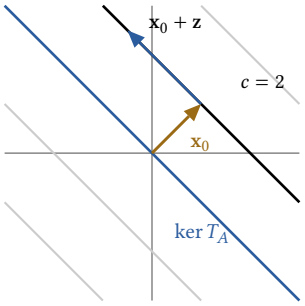

Figure 3.1.4. The solution sets of $x_1 + x_2 = c$ in $\mathbb{R}^2$ for several values of c. Each is a translate of $\ker T_A$, the solution set for $c = 0$ (blue). For $c = 2$, the particular solution $\mathbf{x}_0 = (1, 1)$ plus any $\mathbf{z} \in \ker T_A$ is again a solution.

Remark 3.1.27 (What a solution set can look like). The subspaces of $\mathbb{R}^2$ are $\{\mathbf{0}\}$, the lines through $\mathbf{0}$, and $\mathbb{R}^2$; the subspaces of $\mathbb{R}^3$ are $\{\mathbf{0}\}$, the lines and planes through $\mathbf{0}$, and $\mathbb{R}^3$. (This follows from the theory of dimension in Section 4.1.) So by Proposition 3.1.19, the solution set of a real linear system in two or three unknowns is empty, a point, a line, a plane, or the whole space. It is never a circle or a pair of points.

In any vector space, a translate $\mathbf{v} + U$ of a subspace U is called an *affine subspace* (Definition 4.7.1). In this language, Proposition 3.1.19 says that the solution set of a consistent system is an affine subspace, and that it is a translate of $\ker T_A$. Section 4.7 studies affine subspaces in their own right.

Exercises

Exercise 3.1.28. ROUTINE Which of the following are linear systems in the unknowns x_1, x_2, x_3 over $\mathbb{R}$? For each one that is, write its coefficient matrix and its augmented matrix.

(a) $x_1 = 2x_2 - x_3 + 1$ and $x_3 = 4x_1$.

(b) $x_1 x_2 = 0$ and $x_3 = 1$.

(c) $(\sin 1)x_1 + ex_2 = \pi x_3$.

(d) $2x_1 + 3 = x_2 - x_1$ and $x_2 + x_3 = \sqrt{2}$.

Solution on page 1202

Exercise 3.1.29. ROUTINE Let $\mathbf{a}_1 = (1, 2, 3)$, $\mathbf{a}_2 = (2, 1, 0)$, and $\mathbf{a}_3 = (3, 3, 3)$ in $\mathbb{R}^3$.

(a) Write $(1, 5, 9)$ as a linear combination of $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$ in every possible way.

(b) Show that $(1, 0, 0)$ is not a linear combination of $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$.

Solution on page 1202

Exercise 3.1.30. ROUTINE List all solutions of the system

$$x_1 + x_2 + x_3 = 1, \quad x_1 + 2x_2 = 0$$

over $\mathbb{F}_3$, and check that their number agrees with Corollary 3.1.25. How many solutions does the same system have over $\mathbb{R}$?

Solution on page 1203

Exercise 3.1.31. STANDARD Let p be a prime, $n \geq 1$, and $c \in \mathbb{F}_p$.

(a) Show that the equation $x_1 + x_2 + \cdots + x_n = c$ has exactly p^{n-1} solutions in $\mathbb{F}_p^n$.

(b) Deduce that a set with $n \geq 1$ elements has exactly 2^{n-1} subsets with an even number of elements.

Solution on page 1203

Solution on page 1203

Exercise 3.1.32. STANDARD Consider the system $x_1 + kx_2 = 1$, $kx_1 + x_2 = 1$.

(a) Over $\mathbb{R}$, for which k does it have no solution, exactly one solution, or infinitely many? Find the solution when it is unique.

(b) Over $\mathbb{F}_3$, find the number of solutions for each $k \in \mathbb{F}_3$.

Solution on page 1204

Exercise 3.1.33. ROUTINE Let $A \in F^{m \times n}$. Prove or disprove each statement.

(a) If $A\mathbf{x} = \mathbf{y}_1$ and $A\mathbf{x} = \mathbf{y}_2$ are consistent, then so are $A\mathbf{x} = \mathbf{y}_1 + \mathbf{y}_2$ and $A\mathbf{x} = c\mathbf{y}_1$ for every $c \in F$.

(b) If $A\mathbf{x} = \mathbf{y}_1$ and $A\mathbf{x} = \mathbf{y}_2$ are inconsistent, then so is $A\mathbf{x} = \mathbf{y}_1 + \mathbf{y}_2$.

Solution on page 1204

Exercise 3.1.34. ROUTINE Find the error in the following argument, and show by an example that its conclusion is false.

Claim. If $A\mathbf{x} = \mathbf{0}$ has only the trivial solution, then $A\mathbf{x} = \mathbf{y}$ has exactly one solution for every $\mathbf{y} \in F^m$.

Proof. Let $\mathbf{y} \in F^m$. By Proposition 3.1.19, the solution set of $A\mathbf{x} = \mathbf{y}$ is $\mathbf{x}_0 + \ker T_A = \mathbf{x}_0 + \{\mathbf{0}\} = \{\mathbf{x}_0\}$, a single vector.

Solution on page 1204

Exercise 3.1.35. STANDARD A student solves $x_1 + x_2 = 2$, $x_1 - x_2 = 0$ over $\mathbb{R}$ as follows. "Replace the first equation by the first minus the second, and the second by the second minus the first. This gives $2x_2 = 2$ and $-2x_2 = -2$. So $x_2 = 1$ and x_1 is arbitrary, and the solution set is $\{(t, 1) \mid t \in \mathbb{R}\}$." Find the error, and say exactly which solutions were gained or lost.

Solution on page 1204

Exercise 3.1.36. STANDARD Call the planes $a_1x_1 + a_2x_2 + a_3x_3 = b$ and $a_1'x_1 + a_2'x_2 + a_3'x_3 = b'$ in $\mathbb{R}^3$ (with nonzero coefficient vectors) **parallel** if $(a_1', a_2', a_3') = c(a_1, a_2, a_3)$ for some $c \in \mathbb{R}$. Find the error in the following argument, and give a counterexample to its conclusion.

Claim. Three planes in $\mathbb{R}^3$, no two of them parallel, always have a common point.

Proof. The first two planes are not parallel, so they meet in a line L. The third plane is parallel to neither of the first two, so it is not parallel to L. Hence it meets L in a single point, which lies on all three planes.

Solution on page 1205

Exercise 3.1.37. STANDARD

(a) Find all polynomials $p \in \mathbb{R}[x]_{\leq 2}$ with $p(-1) = 2$, $p(0) = 1$, and $p(1) = 4$.

(b) Find all $q \in \mathbb{R}[x]_{\leq 3}$ with the same three values, and explain the form of the answer using Proposition 3.1.19.

Solution on page 1205

Exercise 3.1.38. STANDARD Four one-way roads form a loop through the intersections A, B, C, D, carrying x_1, x_2, x_3, x_4 cars per hour as shown. In addition, 300 cars per hour enter at A, 200 leave at B, 100 enter at C, and 200 leave at D. At each intersection, the number of cars arriving per hour equals the number leaving.

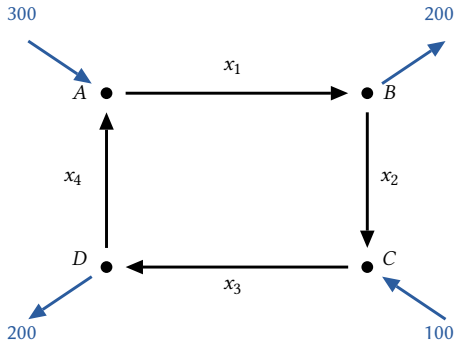

Figure 3.1.5. The road network. Black arrows are the four one-way roads; blue arrows are cars entering or leaving the network.

(a) Write down the linear system for x_1, x_2, x_3, x_4 and find all its solutions.

(b) Explain why any one of the four equations follows from the other three.

(c) Since the roads are one-way, $x_i \geq 0$ for all i. What is the smallest possible flow on each road? Can all four minima occur at once?

Solution on page 1206

Exercise 3.1.39. STANDARD A chemical equation is **balanced** when each element occurs equally often on both sides. Unknown coefficients make balancing a homogeneous linear system.

(a) Find all balancings $a\,\mathrm{Cu} + b\mathrm{HNO_3} \to c\mathrm{Cu(NO_3)_2} + d\,\mathrm{NO} + e\mathrm{H_2O}$, and the one with the smallest positive integer coefficients.

(b) Show that every balancing $a\mathrm{H_2} + b\mathrm{O_2} \to c\mathrm{H_2O} + d\mathrm{H_2O_2}$ is a linear combination of $(2, 1, 2, 0)$ and $(1, 1, 0, 1)$. What does this say chemically?

Solution on page 1206

Exercise 3.1.40. STANDARD A 2×2 grid of lights is controlled by pressing lights: pressing a light toggles it and the lights directly next to it horizontally and vertically (not diagonally). Number the lights 1 (top left), 2 (top right), 3 (bottom left), 4 (bottom right).

(a) Explain why a set of presses can be recorded as $\mathbf{x} \in \mathbb{F}_2^4$ and a pattern of lit lights as $\mathbf{y} \in \mathbb{F}_2^4$, and why pressing according to $\mathbf{x}$ switches off the pattern $\mathbf{y}$ exactly when $A\mathbf{x} = \mathbf{y}$ for a matrix $A \in \mathbb{F}_2^{4\times 4}$. Find A.

(b) Show that $A^2 = I_4$ over $\mathbb{F}_2$. Deduce that every pattern can be switched off, by exactly one set of presses.

(c) Which lights should be pressed to switch off a single lit corner?

Solution on page 1207

Exercise 3.1.41. STANDARD

(a) Find a homogeneous linear system in x_1, x_2, x_3 over $\mathbb{R}$ whose solution set is $\operatorname{span}((1,2,0),(0,1,1))$.

(b) Find a linear system in x_1, x_2, x_3 over $\mathbb{R}$ whose solution set is the line through $(1,0,2)$ and $(2,1,1)$.

Solution on page 1208

Exercise 3.1.42. STANDARD For a field F, let $S_F = \left\{(x_1, x_2) \in F^2 \;\middle|\; x_1^2 + x_2^2 = x_1 + x_2\right\}$. Prove or disprove: S_F is the solution set of some linear system in x_1, x_2 over F, when

(a) $F = \mathbb{R}$, (b) $F = \mathbb{F}_2$, (c) $F = \mathbb{F}_3$.

Solution on page 1208

Exercise 3.1.43. STANDARD Let $A \in F^{m\times n}$, and suppose that for each $i = 1, \ldots, m$ the system $A\mathbf{x} = \mathbf{e}_i$ has a solution $\mathbf{b}_i \in F^n$.

(a) Show that $A\mathbf{x} = \mathbf{y}$ is consistent for every $\mathbf{y} \in F^m$, and give an explicit solution in terms of the $\mathbf{b}_i$.

(b) Let $B \in F^{n\times m}$ be the matrix with columns $\mathbf{b}_1, \ldots, \mathbf{b}_m$. Show that $AB = I_m$, and conclude that T_A has a right inverse.

Solution on page 1209

Exercise 3.1.44. STANDARD

(a) Suppose that some linear system over a field F has exactly two solutions. Show that F has exactly two elements.

(b) More generally, suppose F is finite and a linear system over F has more than one solution. Show that it has at least $|F|$ solutions.

Solution on page 1209

Exercise 3.1.45. STANDARD Let V be a vector space.

(a) Let U, U' be subspaces of V and $\mathbf{v}, \mathbf{v}' \in V$. Show that if $\mathbf{v} + U = \mathbf{v}' + U'$, then $U = U'$ and $\mathbf{v}' - \mathbf{v} \in U$.

(b) Deduce that if two systems $A\mathbf{x} = \mathbf{y}$ and $B\mathbf{x} = \mathbf{z}$ in the same n unknowns have the same nonempty solution set, then $\ker T_A = \ker T_B$.

(c) Give an example of (b) with $A \neq B$, both in $\mathbb{R}^{2\times 2}$.

Solution on page 1209

Exercise 3.1.46. STANDARD Let $n \geq 3$. Find all real solutions of the cyclic system

$$x_1 + x_2 = 2, \quad x_2 + x_3 = 2, \quad \ldots, \quad x_{n-1} + x_n = 2, \quad x_n + x_1 = 2.$$

The answer depends on n. What are the solutions over $\mathbb{F}_2$?

Solution on page 1210

Exercise 3.1.47. HARD A metal plate is modelled by a finite set $G \subseteq \mathbb{Z}^2$ of interior grid points. The **boundary** ∂G is the set of points of $\mathbb{Z}^2 \setminus G$ that are adjacent (at distance 1, horizontally or vertically) to some point of G. The temperatures b_q at the boundary points $q \in \partial G$ are fixed real numbers, and in equilibrium the temperature u_p at each interior point is the average of the temperatures at its four neighbors. This is a linear system with one unknown u_p for each $p \in G$:

$$4u_p - \sum_{q\sim p, q\in G} u_q = \sum_{q\sim p, q\in \partial G} b_q \quad (p \in G),$$

where $q \sim p$ means that q and p are adjacent. Show that this system has at most one solution.

Solution on page 1210

Exercise 3.1.48. HARD BEYOND 21-242 Call a subset $S \subseteq F^n$ **line-closed** if $\mathbf{u} + t(\mathbf{v} - \mathbf{u}) \in S$ for all $\mathbf{u}, \mathbf{v} \in S$ and $t \in F$. By Corollary 3.1.23, solution sets of linear systems are line-closed.

(a) Suppose $1 + 1 \neq 0$ in F. Show that every nonempty line-closed set S is a translate $\mathbf{v} + U$ of a subspace U of F^n.

(b) Show that $\{(0,0),(1,0),(0,1)\} \subseteq \mathbb{F}_2^2$ is line-closed but is not a translate of any subspace.

Solution on page 1211

Exercise 3.1.49. CHALLENGE Thirteen weights with integer masses have the following property: whichever one of them is removed, the remaining twelve can be split into two groups of six with equal total mass. Prove that all thirteen masses are equal.

Solution on page 1211

3.2 Elementary matrices

In Example 3.1.13 we solved the running system by adding multiples of one row of its augmented matrix to another, and the paragraph after it argued that such steps never change the solution set, because each can be undone. This section turns that argument into algebra. Every row operation is left multiplication by an invertible matrix, an *elementary matrix*, so a sequence of row operations is left multiplication by a single invertible matrix G. Then "row operations do not change the solutions" becomes the statement $A\mathbf{x} = \mathbf{y} \Leftrightarrow GA\mathbf{x} = G\mathbf{y}$, and a run of Gauss–Jordan elimination (Section 3.3) is recorded in one equation, $GA = \operatorname{rref}(A)$, which we can reason about with matrix algebra.

3.2.1 Row operations as matrix multiplication

Definition 3.2.1 (Elementary row operations). Let A be a matrix with m rows, and let $1 \leq i, j \leq m$. An **elementary row operation** on A is one of the following.

1. **Swap** rows i and j, where $i \neq j$.
2. **Scale** row i by a scalar $c \neq 0$, that is, multiply every entry of row i by c.
3. **Add** c **times row** i **to row** j, where $i \neq j$ and $c \in F$. That is, replace row j by row j plus c times row i, and leave every other row, row i included, unchanged.

These are the operations of **type 1**, **type 2**, and **type 3**. An operation of type 3 is also called a **row replacement**.

These are the moves on equations from Section 3.1.3, performed on rows, with two restrictions. Both restrictions are there to make each operation reversible. Scaling a row by 0 turns it into a zero row, and nothing done afterwards can recover the old row. Adding c times row i to row i itself is scaling row i by $1 + c$, which erases the row when $c = -1$. When $i \neq j$, a replacement leaves row i in place, so subtracting c times row i from row j undoes it. (The error in Exercise 3.1.35 was to use a row that had already been replaced.)

Intuition (Why row operations should be matrix products). A row operation treats all columns of A alike: the new lth column depends only on the old lth column, and it is computed from it by the same rule for every l. Applied to a single column $\mathbf{x} = (x_1, \ldots, x_m) \in F^m$, the three operations are the maps that

- exchange the entries x_i and x_j;
- replace x_i by cx_i;
- replace x_j by $x_j + cx_i$, that is, $\mathbf{x} \mapsto \mathbf{x} + cx_i\mathbf{e}_j$.

Each is linear, since every entry of the output is a fixed linear combination of the entries of $\mathbf{x}$. Every linear map $F^m \to F^m$ is multiplication by the $m \times m$ matrix whose columns are the images of $\mathbf{e}_1, \ldots, \mathbf{e}_m$ (Proposition 2.3.17). Since $\mathbf{e}_1, \ldots, \mathbf{e}_m$ are the columns of the identity matrix I_m, those images are the columns of the matrix we get by performing the operation on I_m. So each row operation should be left multiplication by "the operation performed on I_m".

Definition 3.2.2 (Elementary matrices). Let $m \geq 1$, let $1 \leq i \leq m$, and let $c \in F$. We define three kinds of $m \times m$ matrices.

- For $1 \leq j \leq m$ with $j \neq i$, E_{ij} is the result of swapping rows i and j of I_m.
- For $c \neq 0$, E_{ic} is the result of scaling row i of I_m by c.
- For $1 \leq j \leq m$ with $j \neq i$, E_{icj} is the result of adding c times row i of I_m to row j.

A matrix of one of these forms is an **elementary matrix**, of type 1, 2, or 3 respectively. Equivalently, an $m \times m$ matrix is elementary if it is obtained from I_m by a single elementary row operation.

Each elementary matrix differs from I_m in very few entries. E_{ic} is diagonal, with c in position (i, i) and 1 elsewhere on the diagonal. E_{icj} is I_m with one more nonzero entry, c in position (j, i). That entry sits in row j, the row that changes, and in column i, the number of the row that is added. E_{ij} agrees with I_m outside rows i and j; its row i has its 1 in column j, and its row j has its 1 in column i.

Example 3.2.3 (Elementary matrices of size 3). With $m = 3$,

$$E_{13} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad E_{2,5} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad E_{3,2,1} = \begin{pmatrix} 1 & 0 & 2 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad E_{1,-2,3} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -2 & 0 & 1 \end{pmatrix}.$$

The first swaps rows 1 and 3, the second scales row 2 by 5, the third adds 2 times row 3 to row 1, and the fourth adds -2 times row 1 to row 3.

Remark 3.2.4 (Reading the subscripts). The size m is not part of the notation. It is always clear from context, since E multiplies a matrix with m rows on the left (or, in Section 3.2.5, a matrix with m columns on the right). The number of subscripts tells the types apart: two for types 1 and 2, three for type 3. When the scalar is a specific number, we separate the subscripts by commas: $E_{2,5}$ scales row 2 by 5, and $E_{1,-2,3}$ adds -2 times row 1 to row 3. A swap carries no scalar, so its subscripts are never separated: E_{25} swaps rows 2 and 5. (We also use commas when an index is a longer expression, as in $E_{k,s,k+1}$.) A matrix can have several names. For instance $E_{ij} = E_{ji}$, and $I_m = E_{1,1}$ is itself elementary (when $m \geq 2$, it is also $E_{1,0,2}$). Some books write E_{ij} for the matrix with a single 1 in position (i, j) and zeros elsewhere; we never do.

Non-example 3.2.5 (Two operations at once). The matrix $\begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$ is not elementary. It differs from I_2 in all four entries, and the only elementary matrices that differ from I_2 in more than one entry are swaps, whose entries are all 0 or 1. It is the result of two operations on I_2: swapping the rows gives E_{12}, and then scaling row 1 by 2 gives $\begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$. By Proposition 3.2.7 below, this makes it the product $E_{1,2}E_{12}$, in which the swap acts first.

The intuition above says that we only need to know what an operation does to a single column. The following lemma makes this precise. We write $\rho[A]$ for the result of applying a map ρ to each column of A, to distinguish it from ρ applied to a vector.

Lemma 3.2.6 (Operations that act column by column). Let $\rho : F^m \to F^m$ be linear. For $A \in F^{m\times n}$ with columns $\mathbf{a}_1, \dots, \mathbf{a}_n$, let $\rho[A]$ be the $m \times n$ matrix with columns $\rho(\mathbf{a}_1), \dots, \rho(\mathbf{a}_n)$. Then

$$\rho[A] = \rho[I_m]A.$$

Proof. ROUTINE

> *Uses.* Definition 2.3.8 (Matrix–vector product), Definition 2.4.1 (Matrix product), Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.8 (Standard bases), Definition 2.3.15 (The linear map of a matrix)
> *Techniques.* Check it on a basis (Technique 2.2.7)
> *Hint 1.* Let $R = \rho[I_m]$. What is the kth column of R, and what is $R\mathbf{e}_k$?
> *Hint 2.* The linear maps $\mathbf{x} \mapsto R\mathbf{x}$ and ρ agree on the standard basis. Then compare RA and $\rho[A]$ column by column.
> *Sketch.* $R = \rho[I_m]$ has columns $\rho(\mathbf{e}_1), \dots, \rho(\mathbf{e}_m)$, so $R\mathbf{e}_k = \rho(\mathbf{e}_k)$. Two linear maps that agree on a basis are equal, so $R\mathbf{x} = \rho(\mathbf{x})$ for all $\mathbf{x}$. The lth column of RA is $R\mathbf{a}_l = \rho(\mathbf{a}_l)$.

Let $R = \rho[I_m]$. The columns of I_m are $\mathbf{e}_1, \dots, \mathbf{e}_m$, so the kth column of R is $\rho(\mathbf{e}_k)$. By Definition 2.3.8, $R\mathbf{e}_k$ is the kth column of R. So the linear maps $T_R : \mathbf{x} \mapsto R\mathbf{x}$ and ρ agree on the standard basis $\mathbf{e}_1, \dots, \mathbf{e}_m$, and by the uniqueness part of Theorem 2.2.1 they are equal: $R\mathbf{x} = \rho(\mathbf{x})$ for every $\mathbf{x} \in F^m$. By Definition 2.4.1, the lth column of RA is $R\mathbf{a}_l = \rho(\mathbf{a}_l)$, which is the lth column of $\rho[A]$. Hence $RA = \rho[A]$. □

Proposition 3.2.7 (Row operations are left multiplications). Let $A \in F^{m\times n}$, let $1 \le i, j \le m$ with $i \ne j$, and let the elementary matrices below be $m \times m$.

(a) $E_{ij}A$ is A with rows i and j swapped.

(b) If $c \ne 0$, then $E_{ic}A$ is A with row i scaled by c.

(c) $E_{icj}A$ is A with c times row i added to row j.

That is, performing an elementary row operation on A gives EA, where E is the result of performing the same operation on I_m.

The two proofs below differ in kind. The first explains why the matrix is "the operation performed on I_m", and it works for any operation that acts on each column by the same linear map. The second computes entries, and on the way it shows what left multiplication by an arbitrary matrix does to rows.

Proof (do it to the identity). ROUTINE

> *Uses.* Lemma 3.2.6 (Operations that act column by column), Definition 3.2.2 (Elementary matrices), Definition 1.2.4 (The space F^n)
> *Hint 1.* Show that performing the operation on A gives $\rho[A]$ for a linear map $\rho : F^m \to F^m$.
> *Hint 2.* Write $\rho(\mathbf{x})$ as $\mathbf{x}$ plus a multiple of $\mathbf{e}_i$ or $\mathbf{e}_j$, and apply Lemma 3.2.6.
> *Sketch.* Each operation changes every column by one map $\rho : F^m \to F^m$, for example $\rho(\mathbf{x}) = \mathbf{x} + cx_i\mathbf{e}_j$ for a replacement. Each ρ is linear because $\mathbf{x} \mapsto x_k$ is. By Lemma 3.2.6 the result is $\rho[I_m]A$, and $\rho[I_m]$ is the elementary matrix by definition.

Fix one of the three operations, and let $\rho : F^m \to F^m$ be the result of performing it on a single column $\mathbf{x} = (x_1, \dots, x_m)$. Explicitly,

$$\begin{aligned} \text{swap:} \quad & \rho(\mathbf{x}) = \mathbf{x} + (x_j - x_i)\mathbf{e}_i + (x_i - x_j)\mathbf{e}_j, \\ \text{scaling:} \quad & \rho(\mathbf{x}) = \mathbf{x} + (c-1)x_i\mathbf{e}_i, \\ \text{replacement:} \quad & \rho(\mathbf{x}) = \mathbf{x} + cx_i\mathbf{e}_j. \end{aligned}$$

(In the first line, the ith entry of $\rho(\mathbf{x})$ is $x_i + (x_j - x_i) = x_j$ and the jth entry is x_i.) Since vectors in F^m are added and scaled entry by entry (Definition 1.2.4), each map $\mathbf{x} \mapsto x_k$ is linear, and so each ρ is linear. A row operation changes every column of A by the same rule, so performing it on A gives $\rho[A]$, and performing

it on I_m gives $\rho[I_m]$, which is the elementary matrix E of Definition 3.2.2. By Lemma 3.2.6, the result of the operation on A is $\rho[A] = \rho[I_m]A = EA$. □

Proof (entry by entry). ROUTINE

> *Uses.* Definition 2.4.1 (Matrix product), Definition 2.3.8 (Matrix–vector product)
> *Hint 1.* Show that the (k,l) entry of GA is $g_{k1}a_{1l} + \cdots + g_{km}a_{ml}$ for any $G \in F^{m\times m}$.
> *Hint 2.* If row k of E equals row k of I_m, then row k of EA is row k of A. Check the remaining rows of E one type at a time.
> *Sketch.* Row k of GA is g_{k1} times row 1 of A, plus $\cdots$, plus g_{km} times row m. Rows of E that agree with I_m copy the corresponding rows of A. Row j of E_{icj} has 1 in column j and c in column i, so row j of $E_{icj}A$ is row j plus c times row i. Swaps and scalings are similar.

Let $G \in F^{m\times m}$ have entries g_{kp} and columns $\mathbf{g}_1, \ldots, \mathbf{g}_m$. By Definition 2.4.1 and Definition 2.3.8, the lth column of GA is $G\mathbf{a}_l = a_{1l}\mathbf{g}_1 + \cdots + a_{ml}\mathbf{g}_m$, whose kth entry is

$$(GA)_{kl} = g_{k1}a_{1l} + g_{k2}a_{2l} + \cdots + g_{km}a_{ml}.$$

In words: row k of GA is g_{k1} times row 1 of A, plus g_{k2} times row 2, and so on. In particular, if row k of G equals row k of I_m, with a single 1 in column k, then row k of GA is row k of A. So for $G = E$ elementary, we only have to look at the rows where E differs from I_m.

(a) Row i of E_{ij} has its 1 in column j, so row i of $E_{ij}A$ is row j of A. Likewise, row j of $E_{ij}A$ is row i of A.

(b) Row i of E_{ic} has c in column i and zeros elsewhere, so row i of $E_{ic}A$ is c times row i of A.

(c) Row j of E_{icj} has 1 in column j, c in column i, and zeros elsewhere (here $i \neq j$ matters). By the formula above, $\big(E_{icj}A\big)_{jl} = a_{jl} + ca_{il}$, so row j of $E_{icj}A$ is row j of A plus c times row i of A. □

The second proof shows more than we needed. For any $G \in F^{m\times m}$, writing $\mathbf{r}_1, \ldots, \mathbf{r}_m$ for the rows of A,

$$\text{row } k \text{ of } GA = g_{k1}\mathbf{r}_1 + g_{k2}\mathbf{r}_2 + \cdots + g_{km}\mathbf{r}_m,$$

the linear combination of the rows of A whose coefficients are the entries of row k of G. Left multiplication recombines rows. The elementary matrices are the simplest recombinations: each changes one row, using at most one other row.

Example 3.2.8 (The running system, recorded). The elimination of Example 3.1.13 performed four row operations on the augmented matrix $(A \mid \mathbf{y})$ of the running system: add -2 times row 1 to row 2; add -3 times row 1 to row 3; add -1 times row 2 to row 3; add -2 times row 2 to row 1. By Proposition 3.2.7 these are left multiplications by $E_{1,-2,2}$, $E_{1,-3,3}$, $E_{2,-1,3}$, $E_{2,-2,1}$, in that order. By associativity of matrix multiplication, the final matrix is

$$E_{2,-2,1}\big(E_{2,-1,3}\big(E_{1,-3,3}\big(E_{1,-2,2}(A \mid \mathbf{y})\big)\big)\big) = G(A \mid \mathbf{y}),$$

where

$$G = E_{2,-2,1}E_{2,-1,3}E_{1,-3,3}E_{1,-2,2}.$$

Realize that the first operation is the rightmost factor of G. To compute G, perform the same four operations on I_3 (each step is left multiplication by the next factor, by Proposition 3.2.7 again):

$$I_3 \to \begin{pmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \to \begin{pmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ -3 & 0 & 1 \end{pmatrix} \to \begin{pmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ -1 & -1 & 1 \end{pmatrix} \to \begin{pmatrix} 5 & -2 & 0 \\ -2 & 1 & 0 \\ -1 & -1 & 1 \end{pmatrix} = G.$$

Multiplying out confirms that G does the whole elimination at once:

$$\left(\begin{array}{ccc} 5 & -2 & 0 \\ -2 & 1 & 0 \\ -1 & -1 & 1 \end{array}\right)\left(\begin{array}{ccc|c} 1 & 2 & -1 & 1 \\ 2 & 5 & 1 & 5 \\ 3 & 7 & 0 & 6 \end{array}\right) = \left(\begin{array}{ccc|c} 1 & 0 & -7 & -5 \\ 0 & 1 & 3 & 3 \\ 0 & 0 & 0 & 0 \end{array}\right).$$

In Section 3.3 the same bookkeeping, applied to a complete run of Gauss–Jordan elimination, produces the equation $GA = \operatorname{rref}(A)$ (Theorem 3.3.10).

Exercise 3.2.9. ROUTINE Let $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \end{pmatrix}$. Find elementary matrices E and E' with

$$EA = \begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 3 & 2 \end{pmatrix}, \quad E'A = \begin{pmatrix} 5 & 6 \\ 3 & 4 \\ 1 & 2 \end{pmatrix},$$

and write each of them out as a 3×3 array.

Solution on page 1212

3.2.2 Inverses

Each elementary row operation is undone by an operation of the same type: swap the same two rows again, scale row i by c^{-1}, or add $-c$ times row i to row j. In the language of matrices:

Proposition 3.2.10 (Inverses of elementary matrices). Every elementary matrix is invertible, and its inverse is an elementary matrix of the same type:

$$E_{ij}^{-1} = E_{ij}, \quad E_{ic}^{-1} = E_{ic^{-1}}, \quad E_{icj}^{-1} = E_{i(-c)j}.$$

Proof. ROUTINE

Uses. Proposition 3.2.7 (Row operations are left multiplications), Definition 3.2.2 (Elementary matrices), Definition 2.5.12 (Invertible)
Hint 1. Guess the inverse E' from the operation that undoes E. To verify $EE' = I_m$, apply Proposition 3.2.7 with $A = E'$: the product EE' is E' with the operation of E performed on it.
Hint 2. For type 3, you need row i of $E_{i(-c)j}$. Why is it row i of I_m?
Sketch. By Proposition 3.2.7, EE' is E' with the operation of E performed on it. Swapping rows i, j of E_{ij} gives I_m; scaling row i of $E_{ic^{-1}}$ by c gives I_m; adding c times row i of $E_{i(-c)j}$, which is row i of I_m because $i \neq j$, to its row j gives I_m. The same holds with the factors exchanged.

We check that each proposed inverse E' satisfies $EE' = I_m$ and $E'E = I_m$ (Definition 2.5.12). By Proposition 3.2.7, EE' is E' with the operation of E performed on it.

Type 1. $E_{ij}E_{ij}$ is E_{ij} with rows i and j swapped. Since E_{ij} is I_m with those rows swapped, swapping them back gives I_m.

Type 2. Let $c \neq 0$. Row i of $E_{ic^{-1}}$ has c^{-1} in column i and zeros elsewhere, and all other rows are rows of I_m. Scaling row i by c gives $cc^{-1} = 1$ in column i, so $E_{ic}E_{ic^{-1}} = I_m$. Exchanging the roles of c and c^{-1} gives $E_{ic^{-1}}E_{ic} = I_m$.

Type 3. The matrix $E_{i(-c)j}$ differs from I_m only in row j, so, as $i \neq j$, its row i is row i of I_m: a 1 in column i and zeros elsewhere. Its row j has 1 in column j and $-c$ in column i. Adding c times row i to row j turns the entry $-c$ into $-c + c = 0$ and changes nothing else, so $E_{icj}E_{i(-c)j} = I_m$. Exchanging the roles of c and $-c$ gives $E_{i(-c)j}E_{icj} = I_m$. □

The hypothesis $i \neq j$ was used exactly once, to know that the operation leaves row i alone. Without it, "adding -1 times row i to row i" would produce I_m with row i replaced by zeros, a matrix that sends $\mathbf{e}_i$ to $\mathbf{0}$ and so is not invertible.

Corollary 3.2.11 (Products of elementary matrices). Let $E_1, \dots, E_k \in F^{m\times m}$ be elementary. Then $G = E_k \cdots E_2 E_1$ is invertible, and

$$G^{-1} = E_1^{-1} E_2^{-1} \cdots E_k^{-1}$$

is again a product of elementary matrices. (For $k = 0$, the empty product is I_m.)

Proof. ROUTINE

Uses. Proposition 3.2.10 (Inverses of elementary matrices), Definition 2.5.12 (Invertible), induction on k
Hint 1. Induct on k. Write $G = E_k G'$, where G' is a product of $k-1$ elementary matrices.
Hint 2. Check that $H' E_k^{-1}$ is a two-sided inverse of $E_k G'$ when H' is a two-sided inverse of G'.
Sketch. If $G'H' = H'G' = I_m$, then $(E_k G')\left(H' E_k^{-1}\right) = E_k E_k^{-1} = I_m$ and $\left(H' E_k^{-1}\right)(E_k G') = H'G' = I_m$. Induction on k gives $G^{-1} = E_1^{-1} \cdots E_k^{-1}$, and each E_l^{-1} is elementary by Proposition 3.2.10.

We induct on k. For $k = 0$, $G = I_m$ is its own inverse. Let $k \geq 1$, and suppose $G' = E_{k-1} \cdots E_1$ is invertible with inverse $H' = E_1^{-1} \cdots E_{k-1}^{-1}$. Then $G = E_k G'$, and with $H = H' E_k^{-1}$, associativity gives

$$GH = E_k (G'H') E_k^{-1} = E_k E_k^{-1} = I_m, \quad HG = H'\left(E_k^{-1} E_k\right) G' = H'G' = I_m.$$

So G is invertible with $G^{-1} = H = E_1^{-1} \cdots E_k^{-1}$, as desired. By Proposition 3.2.10 each E_l^{-1} is elementary. □

Example 3.2.12 (Undoing the running elimination). For the matrix $G = E_{2,-2,1} E_{2,-1,3} E_{1,-3,3} E_{1,-2,2}$ of Example 3.2.8, Corollary 3.2.11 and Proposition 3.2.10 give

$$G^{-1} = E_{1,2,2} E_{1,3,3} E_{2,1,3} E_{2,2,1}.$$

To compute it, perform on I_3 first the operation of the rightmost factor (add 2 times row 2 to row 1), then the others from right to left. The result is

$$G^{-1} = \begin{pmatrix} 1 & 2 & 0 \\ 2 & 5 & 0 \\ 3 & 7 & 1 \end{pmatrix}.$$

Its first two columns are the first two columns $\mathbf{a}_1, \mathbf{a}_2$ of A. This is no accident: GA has first two columns $\mathbf{e}_1$ and $\mathbf{e}_2$, so $G\mathbf{a}_1 = \mathbf{e}_1$ and $G\mathbf{a}_2 = \mathbf{e}_2$, that is, $\mathbf{a}_1 = G^{-1}\mathbf{e}_1$ and $\mathbf{a}_2 = G^{-1}\mathbf{e}_2$.

Exercise 3.2.13. ROUTINE Over $\mathbb{F}_5$, write $\left(E_{12} E_{1,3} E_{2,4,1}\right)^{-1}$ as a product of 2×2 elementary matrices, and compute it as a matrix.

Solution on page 1212

3.2.3 Row operations preserve solution sets

We can now prove what Section 3.1.3 argued informally. Replacing the equations of a system by combinations of them never loses a solution, and when the replacement can be undone, it gains none either.

Proposition 3.2.14 (Invertible matrices preserve solution sets). Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$, and let $G \in F^{m\times m}$ be invertible. Then for every $\mathbf{x} \in F^n$,

$$A\mathbf{x} = \mathbf{y} \Leftrightarrow (GA)\mathbf{x} = G\mathbf{y}.$$

So the systems $A\mathbf{x} = \mathbf{y}$ and $(GA)\mathbf{x} = G\mathbf{y}$ are equivalent. Their augmented matrices are related by $G(A \mid \mathbf{y}) = (GA \mid G\mathbf{y})$.

Proof. ROUTINE

Uses. Theorem 2.4.2 (The matrix of a composite), Definition 2.5.12 (Invertible), Definition 2.4.1 (Matrix product), Definition 3.1.12 (Augmented matrix), Definition 3.1.1 (Linear system)
Hint 1. The direction $\Rightarrow$ holds for every G. Which property of G does $\Leftarrow$ need?

Hint 2. Multiply $G(A\mathbf{x}) = G\mathbf{y}$ on the left by G^{-1}, using $(GA)\mathbf{x} = G(A\mathbf{x})$.
Sketch. Since $(GA)\mathbf{x} = G(A\mathbf{x})$, applying G to $A\mathbf{x} = \mathbf{y}$ gives $(GA)\mathbf{x} = G\mathbf{y}$; applying G^{-1} to $G(A\mathbf{x}) = G\mathbf{y}$ gives back $A\mathbf{x} = \mathbf{y}$. The columns of $G(A \mid \mathbf{y})$ are $G\mathbf{a}_1, \ldots, G\mathbf{a}_n, G\mathbf{y}$.

By Theorem 2.4.2, $T_{GA} = T_G \circ T_A$, that is, $(GA)\mathbf{x} = G(A\mathbf{x})$ for every $\mathbf{x} \in F^n$; likewise $(HG)\mathbf{z} = H(G\mathbf{z})$ for all $H \in F^{m\times m}$ and $\mathbf{z} \in F^m$.

($\Rightarrow$) If $A\mathbf{x} = \mathbf{y}$, then $(GA)\mathbf{x} = G(A\mathbf{x}) = G\mathbf{y}$.

($\Leftarrow$) Suppose $(GA)\mathbf{x} = G\mathbf{y}$, that is, $G(A\mathbf{x}) = G\mathbf{y}$. Applying G^{-1} to both sides,

$$A\mathbf{x} = \big(G^{-1}G\big)(A\mathbf{x}) = G^{-1}(G(A\mathbf{x})) = G^{-1}(G\mathbf{y}) = \big(G^{-1}G\big)\mathbf{y} = \mathbf{y}.$$

So the two systems have the same solutions, which is what it means for them to be equivalent (Definition 3.1.1). Finally, by Definition 2.4.1, the columns of $G(A \mid \mathbf{y})$ are $G\mathbf{a}_1, \ldots, G\mathbf{a}_n, G\mathbf{y}$, where $\mathbf{a}_1, \ldots, \mathbf{a}_n$ are the columns of A. The first n of these are the columns of GA, so $G(A \mid \mathbf{y}) = (GA \mid G\mathbf{y})$. □

Corollary 3.2.15 (Row operations preserve solution sets). If $(A' \mid \mathbf{y}')$ is obtained from $(A \mid \mathbf{y})$ by a finite sequence of elementary row operations, then the systems $A\mathbf{x} = \mathbf{y}$ and $A'\mathbf{x} = \mathbf{y}'$ are equivalent.

Proof. ROUTINE
Uses. Proposition 3.2.7 (Row operations are left multiplications), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.2.14 (Invertible matrices preserve solution sets)
Hint 1. Write the sequence of operations as left multiplication by one matrix G.
Hint 2. G is a product of elementary matrices. Now apply Proposition 3.2.14.
Sketch. If $E_1, \ldots, E_k$ perform the operations, then $(A' \mid \mathbf{y}') = G(A \mid \mathbf{y}) = (GA \mid G\mathbf{y})$ with $G = E_k \cdots E_1$ invertible, so $A' = GA$ and $\mathbf{y}' = G\mathbf{y}$, and Proposition 3.2.14 applies.

Let $E_1, \ldots, E_k$ be the elementary matrices of the operations, in the order performed. By Proposition 3.2.7, applied k times, and associativity,

$$(A' \mid \mathbf{y}') = E_k(\cdots(E_1(A \mid \mathbf{y}))\cdots) = G(A \mid \mathbf{y}), \quad G = E_k \cdots E_1.$$

By Proposition 3.2.14, $G(A \mid \mathbf{y}) = (GA \mid G\mathbf{y})$, so $A' = GA$ and $\mathbf{y}' = G\mathbf{y}$. Since G is invertible (Corollary 3.2.11), Proposition 3.2.14 says that $A\mathbf{x} = \mathbf{y}$ and $A'\mathbf{x} = \mathbf{y}'$ are equivalent. □

Remark 3.2.16 (Where invertibility is used). The direction $\Rightarrow$ of Proposition 3.2.14 holds for every matrix G, even a non-square one: replacing the equations of a system by combinations of them never loses a solution. Only $\Leftarrow$ needs G^{-1}, and without it solutions can be gained. The failed elimination in Exercise 3.1.35 replaced the equations of $x_1 + x_2 = 2$, $x_1 - x_2 = 0$ by "first minus second" and "second minus first" at the same time, which is left multiplication by

$$G = \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}.$$

This G is not invertible: $G(1, 1) = \mathbf{0}$, whereas an invertible matrix sends only $\mathbf{0}$ to $\mathbf{0}$ (if $G\mathbf{z} = \mathbf{0}$, then $\mathbf{z} = G^{-1}G\mathbf{z} = \mathbf{0}$). Accordingly, the new system had solutions that the old one did not. Performed one after the other, the two replacements are $E_{2,-1,1}$ followed by $E_{1,-1,2}$, and their product $E_{1,-1,2}E_{2,-1,1} = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$ is invertible. In fact a left inverse of G is all that $\Leftarrow$ needs; see Exercise 3.2.45.

Row operations change the columns of A, but they do not change the linear relations among them. This is the fact that will let us read off relations among the columns of A from a much simpler matrix.

Corollary 3.2.17 (Row operations preserve relations among columns). Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, and let $G \in F^{m\times m}$ be invertible, so that GA has columns $G\mathbf{a}_1, \ldots, G\mathbf{a}_n$. For all $x_1, \ldots, x_n \in F$,

$$x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = \mathbf{0} \Leftrightarrow x_1(G\mathbf{a}_1) + \cdots + x_n(G\mathbf{a}_n) = \mathbf{0}.$$

In particular:

(a) for distinct indices $l_1, \dots, l_r$, the list $\mathbf{a}_{l_1}, \dots, \mathbf{a}_{l_r}$ is linearly independent if and only if the list $G\mathbf{a}_{l_1}, \dots, G\mathbf{a}_{l_r}$ is;

(b) for scalars c_l, $\mathbf{a}_k = \sum_{l \neq k} c_l \mathbf{a}_l$ if and only if $G\mathbf{a}_k = \sum_{l \neq k} c_l G\mathbf{a}_l$.

Proof. ROUTINE

Uses. Proposition 3.2.14 (Invertible matrices preserve solution sets), Definition 2.3.8 (Matrix–vector product), Definition 2.4.1 (Matrix product), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. Write both sides as matrix–vector products: $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = A\mathbf{x}$.
Hint 2. Apply Proposition 3.2.14 with $\mathbf{y} = \mathbf{0}$. For (a) and (b), view a relation among some of the columns as a relation among all of them.
Sketch. By Definition 2.3.8 the two sides are $A\mathbf{x} = \mathbf{0}$ and $(GA)\mathbf{x} = \mathbf{0} = G\mathbf{0}$, which are equivalent by Proposition 3.2.14. A relation among $\mathbf{a}_{l_1}, \dots, \mathbf{a}_{l_r}$ is a relation among all columns with the other coefficients 0, so the two lists have the same relations, in particular the same nontrivial ones. For (b), use the relation with coefficient -1 on $\mathbf{a}_k$.

The columns of GA are $G\mathbf{a}_1, \dots, G\mathbf{a}_n$ by Definition 2.4.1. Let $\mathbf{x} = (x_1, \dots, x_n)$. By Definition 2.3.8, the left side of the displayed equivalence says $A\mathbf{x} = \mathbf{0}$, and the right side says $(GA)\mathbf{x} = \mathbf{0}$. Since $G\mathbf{0} = \mathbf{0}$, these are equivalent by Proposition 3.2.14 with $\mathbf{y} = \mathbf{0}$.

(a) Taking $x_l = 0$ for every l outside $\{l_1, \dots, l_r\}$, the equivalence says that $\sum_q x_{l_q}\mathbf{a}_{l_q} = \mathbf{0}$ if and only if $\sum_q x_{l_q} G\mathbf{a}_{l_q} = \mathbf{0}$. So the two lists satisfy the same linear relations. By Theorem 1.5.5, one of them is linearly independent exactly when it satisfies only the trivial relation, and then so does the other.

(b) $\mathbf{a}_k = \sum_{l \neq k} c_l \mathbf{a}_l$ says that $x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n = \mathbf{0}$ with $x_k = -1$ and $x_l = c_l$ for $l \neq k$. By the equivalence, this holds if and only if the same relation holds among the $G\mathbf{a}_l$, which says $G\mathbf{a}_k = \sum_{l \neq k} c_l G\mathbf{a}_l$. □

Example 3.2.18 (Reading a relation off the reduced matrix). In Example 3.2.8, GA has columns $\mathbf{e}_1$, $\mathbf{e}_2$, and $(-7, 3, 0) = -7\mathbf{e}_1 + 3\mathbf{e}_2$. So the third column of GA is -7 times the first plus 3 times the second, and by part (b) of Corollary 3.2.17 the same holds in A:

$$\mathbf{a}_3 = -7\mathbf{a}_1 + 3\mathbf{a}_2, \quad \text{that is,} \quad \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix} = -7\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} + 3\begin{pmatrix} 2 \\ 5 \\ 7 \end{pmatrix}.$$

This is the relation $7\mathbf{a}_1 - 3\mathbf{a}_2 + \mathbf{a}_3 = \mathbf{0}$ behind the homogeneous solution $(7, -3, 1)$ of Example 3.1.15. By part (a), $\mathbf{a}_1, \mathbf{a}_2$ is linearly independent, because $\mathbf{e}_1, \mathbf{e}_2$ is.

Non-example 3.2.19 (Row operations move the column space). The relations among the columns survive, but the columns themselves move, and so does their span. The columns of the running matrix A all lie in the plane $y_3 = y_1 + y_2$, which is $\operatorname{im} T_A$ (Section 3.1.5). The columns of GA all have third entry 0, so $\operatorname{im} T_{GA}$ is the plane $y_3 = 0$. A smaller example: for $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$, the row operation $E_{1,-1,2}$ gives $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$, and $\operatorname{span}((1,1)) \neq \operatorname{span}((1,0))$. So Proposition 3.2.14 does not say that $A\mathbf{x} = \mathbf{y}$ and $(GA)\mathbf{x} = \mathbf{y}$ are equivalent: the right-hand side must be replaced by $G\mathbf{y}$.

Exercise 3.2.20. ROUTINE Let

$$A = \begin{pmatrix} 1 & 1 & 3 \\ 2 & 0 & 2 \\ 1 & 3 & 7 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 0 \end{pmatrix}.$$

Find row operations that turn A into B. Then, using Corollary 3.2.17 and without further computation, write the third column of A as a combination of the first two, and decide whether the first two columns of A are linearly independent. Check your answers directly.

Solution on page 1213

3.2.4 Row equivalence

Because row operations can be undone, the relation "B can be reached from A by row operations" is symmetric, and it partitions matrices of a given size into classes.

Definition 3.2.21 (Row equivalence). Matrices $A, B \in F^{m\times n}$ are **row equivalent**, written $A \sim B$, if B can be obtained from A by a finite sequence of elementary row operations. By Proposition 3.2.7, this means that $B = E_k \cdots E_1 A$ for some elementary matrices $E_1, \ldots, E_k \in F^{m\times m}$, where $k \geq 0$ (for $k = 0$, $B = A$).

Proposition 3.2.22 (Row equivalence is an equivalence relation). For all $A, B, C \in F^{m\times n}$:

- (reflexivity) $A \sim A$;
- (symmetry) if $A \sim B$, then $B \sim A$;
- (transitivity) if $A \sim B$ and $B \sim C$, then $A \sim C$.

Proof. ROUTINE

Uses. Definition 3.2.21 (Row equivalence), Proposition 3.2.10 (Inverses of elementary matrices)
Hint 1. For symmetry, undo the operations in the reverse order.
Hint 2. Write $B = E_k \cdots E_1 A$ and multiply on the left by E_k^{-1}, then by E_{k-1}^{-1}, and so on. Why is each E_l^{-1} allowed?
Sketch. The empty sequence gives $A \sim A$. If $B = E_k \cdots E_1 A$, then $A = E_1^{-1} \cdots E_k^{-1} B$, and each E_l^{-1} is elementary by Proposition 3.2.10. If $B = E_k \cdots E_1 A$ and $C = E'_r \cdots E'_1 B$, then $C = E'_r \cdots E'_1 E_k \cdots E_1 A$.

Reflexivity. Take $k = 0$.

Symmetry. Let $B = E_k \cdots E_1 A$. Multiplying on the left by E_k^{-1}, then by E_{k-1}^{-1}, and so on, gives $A = E_1^{-1} E_2^{-1} \cdots E_k^{-1} B$. By Proposition 3.2.10 each E_l^{-1} is elementary, so $B \sim A$: the operations of $E_k^{-1}, \ldots, E_1^{-1}$, performed in that order, turn B into A.

Transitivity. If $B = E_k \cdots E_1 A$ and $C = E'_r \cdots E'_1 B$, then $C = E'_r \cdots E'_1 E_k \cdots E_1 A$, so $A \sim C$. □

In this language, Corollary 3.2.15 says that row equivalent augmented matrices describe equivalent systems. Taking $\mathbf{y} = \mathbf{0}$ gives an invariant that is easy to compute.

Corollary 3.2.23 (Row equivalent matrices have the same kernel). If $A \in F^{m\times n}$ and $G \in F^{m\times m}$ is invertible, then $\ker T_{GA} = \ker T_A$. In particular, if $A \sim B$, then $\ker T_A = \ker T_B$.

Proof. ROUTINE

Uses. Proposition 3.2.14 (Invertible matrices preserve solution sets), Proposition 3.1.8 (Systems and the map T_A), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. The kernel is the solution set of a homogeneous system.
Hint 2. Apply Proposition 3.2.14 with $\mathbf{y} = \mathbf{0}$.
Sketch. $\mathbf{x} \in \ker T_{GA}$ means $(GA)\mathbf{x} = \mathbf{0} = G\mathbf{0}$, which by Proposition 3.2.14 is equivalent to $A\mathbf{x} = \mathbf{0}$. If $A \sim B$, then $B = GA$ with G a product of elementary matrices, which is invertible.

By Proposition 3.1.8, $\ker T_A$ and $\ker T_{GA}$ are the solution sets of $A\mathbf{x} = \mathbf{0}$ and $(GA)\mathbf{x} = \mathbf{0}$. Since $G\mathbf{0} = \mathbf{0}$, these systems are equivalent by Proposition 3.2.14, so the kernels are equal. If $A \sim B$, then $B = GA$ with $G = E_k \cdots E_1$, which is invertible by Corollary 3.2.11. □

Example 3.2.24 (Telling matrices apart by their kernels). The matrices $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ are not row equivalent: the first sends (x_1, x_2) to $(x_1, 0)$ and the second to $(x_2, 0)$, so their kernels are $\operatorname{span}(\mathbf{e}_2)$ and $\operatorname{span}(\mathbf{e}_1)$. On the other hand, $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \sim \begin{pmatrix} 0 & 0 \\ 3 & 0 \end{pmatrix}$: swap the rows, then scale row 2 by 3.

Similarly, a matrix $A \in F^{m\times m}$ with $A \sim I_m$ is invertible: by symmetry (Proposition 3.2.22) $I_m \sim A$, so $A = GI_m = G$ for a product G of elementary matrices. The converse, that every invertible matrix is row equivalent to I_m, is proved in Section 3.3 (Theorem 3.3.23); it gives Theorem 3.5.19 in Section 3.5.

Remark 3.2.25. The converse of Corollary 3.2.23 is also true: two $m \times n$ matrices with the same kernel are row equivalent. The proof needs the reduced row echelon form of Section 3.3. Each matrix is row equivalent

to its reduced row echelon form, and a matrix in reduced row echelon form turns out to be determined by its kernel together with its size. So the kernel is a *complete* invariant of row equivalence.

Exercise 3.2.26. ROUTINE Which of the following matrices are row equivalent to $A = \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$?

$$\text{(i)} \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}, \quad \text{(ii)} \begin{pmatrix} 2 & 1 \\ 4 & 2 \end{pmatrix}, \quad \text{(iii)} \begin{pmatrix} 0 & 0 \\ 3 & 6 \end{pmatrix}.$$

Solution on page 1213

3.2.5 Column operations

The **elementary column operations** on a matrix with n columns are defined like the row operations: swap columns i and j ($i \neq j$), scale column i by $c \neq 0$, and add c times column j to column i ($i \neq j$). Right multiplication recombines columns: by Definition 2.4.1 and Definition 2.3.8, column l of AH is

$$A\mathbf{h}_l = h_{1l}\mathbf{a}_1 + h_{2l}\mathbf{a}_2 + \cdots + h_{nl}\mathbf{a}_n,$$

the combination of the columns of A with coefficients from column l of H. So we expect column operations to be right multiplications. They are, by the same elementary matrices, with the roles of the indices exchanged.

Rows and columns are exchanged by the transpose, so we can obtain this from Proposition 3.2.7 instead of proving it from scratch. The move is worth naming.

Technique 3.2.27 (Transpose to trade rows for columns). The transpose turns the rows of a matrix into the columns of A^{T}, and it reverses products: $(AB)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}}$ (Proposition 2.4.23). So a statement about the rows of A, or about left multiplication, becomes a statement about the columns of A^{T}, or about right multiplication, once everything is transposed. Prove whichever version is easier, and transpose to get the other.

Reach for it whenever you have a result about rows and need its mirror image about columns, or the other way around. The canonical example is Proposition 3.2.28, where column operations come from row operations. Later instances are the equality of row rank and column rank (Section 4.3) and $\det A^{\mathsf{T}} = \det A$, which makes every column property of the determinant a row property too (Section 5.4).
Used in. Exercise 2.5.45, Proposition 3.2.28, Exercise 3.2.46, Theorem 3.5.27, Exercise 3.6.8, Problem 3.2, Theorem 4.3.8, Corollary 4.3.10, Proposition 4.3.23, Exercise 4.3.29, Problem 4.2, Theorem 5.4.14, Corollary 5.4.15, Theorem 5.5.3, Problem 7.7.

Proposition 3.2.28 (Column operations are right multiplications). Let $A \in F^{m\times n}$, let $1 \leq i, j \leq n$ with $i \neq j$, and let the elementary matrices below be $n \times n$.

(a) AE_{ij} is A with columns i and j swapped.

(b) If $c \neq 0$, then AE_{ic} is A with column i scaled by c.

(c) AE_{icj} is A with c times column j added to column i.

Proof (transpose). ROUTINE

Uses. Proposition 3.2.7 (Row operations are left multiplications), Proposition 2.4.23 (Transpose of a product), Definition 2.4.21 (Transpose)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. Compute $(AE)^{\mathsf{T}}$ with Proposition 2.4.23. What is E^{T} for each type?
Hint 2. E_{icj} has its extra entry c in position (j, i). Which elementary matrix has c in position (i, j)?
Sketch. $(AE)^{\mathsf{T}} = E^{\mathsf{T}}A^{\mathsf{T}}$. Swaps and scalings are symmetric, and $E_{icj}^{\mathsf{T}} = E_{jci}$. So $E^{\mathsf{T}}A^{\mathsf{T}}$ is A^{T} with a row operation performed, by Proposition 3.2.7; the rows of A^{T} are the columns of A, and E_{jci} adds c times row j to row i. Transposing back gives the column statement.

By Proposition 2.4.23, $(AE)^{\mathsf{T}} = E^{\mathsf{T}}A^{\mathsf{T}}$, so $AE = \left(E^{\mathsf{T}}A^{\mathsf{T}}\right)^{\mathsf{T}}$. Row k of A^{T} is column k of A, written as a row (Definition 2.4.21).

(c) E_{icj} is I_n with an extra entry c in position (j,i), so E_{icj}^{T} is I_n with c in position (i,j), which is E_{jci}. By Proposition 3.2.7, $E_{jci}A^{\mathsf{T}}$ is A^{T} with c times row j added to row i. Transposing turns rows into columns, so $AE_{icj} = \left(E_{jci}A^{\mathsf{T}}\right)^{\mathsf{T}}$ is A with c times column j added to column i.

(a), (b) E_{ij} and E_{ic} are symmetric: $E_{ij}^{\mathsf{T}} = E_{ij}$ and $E_{ic}^{\mathsf{T}} = E_{ic}$. By Proposition 3.2.7, $E_{ij}A^{\mathsf{T}}$ and $E_{ic}A^{\mathsf{T}}$ are A^{T} with rows i and j swapped, respectively with row i scaled by c, and transposing gives the claims. □

Proof (directly). ROUTINE

> *Uses.* Definition 2.4.1 (Matrix product), Definition 2.3.8 (Matrix–vector product)
> *Hint 1.* By Definition 2.4.1, column l of AE is A times column l of E.
> *Hint 2.* Find the columns of E_{icj}. Which of them differs from a standard basis vector?
> *Sketch.* Column l of AE is A times column l of E. Column i of E_{icj} is $\mathbf{e}_i + c\mathbf{e}_j$ and the others are $\mathbf{e}_l$, so column i of AE_{icj} is $\mathbf{a}_i + c\mathbf{a}_j$ and the others are unchanged. Columns i and j of E_{ij} are $\mathbf{e}_j$ and $\mathbf{e}_i$, and column i of E_{ic} is $c\mathbf{e}_i$.

By Definition 2.4.1, column l of AE is $A\mathbf{u}_l$, where $\mathbf{u}_l$ is column l of E, and $A\mathbf{e}_l = \mathbf{a}_l$ by Definition 2.3.8.

(c) Column l of E_{icj} is $\mathbf{e}_l$ for $l \neq i$, and column i is $\mathbf{e}_i + c\mathbf{e}_j$, since the extra entry c is in row j of column i. So column l of AE_{icj} is $\mathbf{a}_l$ for $l \neq i$, and column i is $A\left(\mathbf{e}_i + c\mathbf{e}_j\right) = \mathbf{a}_i + c\mathbf{a}_j$.

(a), (b) Columns i and j of E_{ij} are $\mathbf{e}_j$ and $\mathbf{e}_i$, and column i of E_{ic} is $c\mathbf{e}_i$; all other columns are those of I_n. So AE_{ij} has columns i and j equal to $\mathbf{a}_j$ and $\mathbf{a}_i$, and AE_{ic} has column i equal to $c\mathbf{a}_i$, with the other columns unchanged. □

The direct proof is shorter here. The transposed proof shows that the column statement carries no new information: it is the row statement seen in a mirror.

Remark 3.2.29 (One matrix, two operations). The matrix E_{icj}, which has c in position (j,i), is at once the result of adding c times row i to row j of the identity and the result of adding c times column j to column i of the identity. So the subscript icj reads left to right for rows ("from row i into row j") and right to left for columns ("from column j into column i"). For example, with $A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}$,

$$AE_{1,-2,2} = \begin{pmatrix} 1-4 & 2 & 3 \\ 4-10 & 5 & 6 \end{pmatrix} = \begin{pmatrix} -3 & 2 & 3 \\ -6 & 5 & 6 \end{pmatrix},$$

where $E_{1,-2,2}$ is 3×3 and adds -2 times column 2 to column 1. The 2×2 matrix with the same name acts on the left and adds -2 times row 1 to row 2: $E_{1,-2,2}A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 0 \end{pmatrix}$. Also note the order of factors: if column operations with matrices $E_1, \ldots, E_k$ are performed on A in that order, the result is $AE_1E_2\cdots E_k$, so the first operation is now the *leftmost* factor.

Row operations do not change the kernel (Corollary 3.2.23) but can change the image (Non-example 3.2.19). Column operations behave the other way around.

> **Proposition 3.2.30** (Column operations preserve the image). Let $A \in F^{m\times n}$, and let $H \in F^{n\times n}$ be invertible. Then $\operatorname{im} T_{AH} = \operatorname{im} T_A$. In particular, column operations do not change the span of the columns of a matrix.

Proof. ROUTINE

> *Uses.* Definition 2.6.6 (Image), Theorem 2.4.2 (The matrix of a composite), Definition 2.5.12 (Invertible), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.1.8 (Systems and the map T_A)
> *Techniques.* Double containment (Technique 1.3.14)
> *Hint 1.* Prove the two containments separately.
> *Hint 2.* $AH\mathbf{x} = A(H\mathbf{x})$, and $A\mathbf{x} = (AH)\left(H^{-1}\mathbf{x}\right)$.
> *Sketch.* Every $(AH)\mathbf{x} = A(H\mathbf{x})$ lies in $\operatorname{im} T_A$. Conversely $A\mathbf{x} = (AH)\left(H^{-1}\mathbf{x}\right) \in \operatorname{im} T_{AH}$. Column operations multiply on the right by a product of elementary matrices, which is invertible.

We prove both containments, using $(AH)\mathbf{x} = A(H\mathbf{x})$ (Theorem 2.4.2) throughout.

$\operatorname{im} T_{AH} \subseteq \operatorname{im} T_A$. For $\mathbf{x} \in F^n$, $(AH)\mathbf{x} = A(H\mathbf{x}) \in \operatorname{im} T_A$.

$\operatorname{im} T_A \subseteq \operatorname{im} T_{AH}$. For $\mathbf{x} \in F^n$, $A\mathbf{x} = A\big(\big(HH^{-1}\big)\mathbf{x}\big) = (AH)\big(H^{-1}\mathbf{x}\big) \in \operatorname{im} T_{AH}$.

A sequence of column operations multiplies A on the right by a product of elementary matrices (Proposition 3.2.28), which is invertible by Corollary 3.2.11, and $\operatorname{im} T_A$ is the span of the columns of A (Proposition 3.1.8). □

Non-example 3.2.31 (Column operations change the kernel). For $A = \begin{pmatrix} 1 & 1 \end{pmatrix}$, $\ker T_A = \operatorname{span}((1,-1))$. Adding -1 times column 2 to column 1 gives $AE_{1,-1,2} = \begin{pmatrix} 0 & 1 \end{pmatrix}$, whose kernel is $\operatorname{span}((1,0))$. In general $\ker T_{AH} = \left\{H^{-1}\mathbf{x} \;\middle|\; \mathbf{x} \in \ker T_A\right\}$: the kernel is moved by H^{-1}.

This is why we solve systems with row operations. The solution set of a consistent system $A\mathbf{x} = \mathbf{y}$ is a translate of $\ker T_A$ (Proposition 3.1.19), and row operations keep the kernel and the solution set. Column operations keep the image, so they suit questions about the span of the columns, and both kinds together reduce every matrix to a very simple form, the rank normal form of Theorem 3.5.27.

> **Exercise 3.2.32.** ROUTINE Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}$. Find a 3×3 elementary matrix E with $AE = \begin{pmatrix} 1 & 0 & 3 \\ 4 & -3 & 6 \end{pmatrix}$. What does the same matrix E do to a 3×3 matrix B when it multiplies on the left?

Solution on page 1213

3.2.6 Elementary matrices in the plane

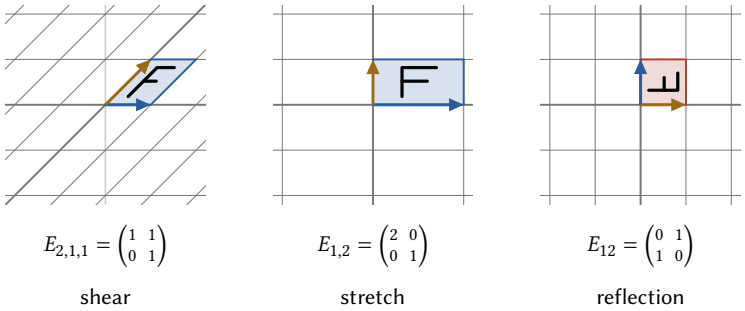
Over $\mathbb{R}$, a 2×2 matrix E is a linear map T_E of the plane, and we can watch what it does. Realize that a vector $\mathbf{x} \in \mathbb{R}^2$ is itself a 2×1 matrix, so by Proposition 3.2.7, $E\mathbf{x}$ is $\mathbf{x}$ with the row operation of E performed on its two entries. The elementary 2×2 matrices are

$$E_{12} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad E_{1c} = \begin{pmatrix} c & 0 \\ 0 & 1 \end{pmatrix}, \quad E_{2c} = \begin{pmatrix} 1 & 0 \\ 0 & c \end{pmatrix}, \quad E_{1c2} = \begin{pmatrix} 1 & 0 \\ c & 1 \end{pmatrix}, \quad E_{2c1} = \begin{pmatrix} 1 & c \\ 0 & 1 \end{pmatrix},$$

with $c \neq 0$ for the two scalings, and they act as follows.

Example 3.2.33 (The elementary maps of the plane).

- *Swap.* $T_{E_{12}}(x_1, x_2) = (x_2, x_1)$ is the reflection across the line $x_1 = x_2$. It fixes that line pointwise and reverses orientation: in Figure 3.2.1 the letter F is mirrored.
- *Scaling.* $T_{E_{1c}}(x_1, x_2) = (cx_1, x_2)$. For $c > 0$ it stretches the plane horizontally by the factor c (a compression if $c < 1$) and fixes the x_2-axis pointwise. For $c < 0$ it stretches by $|c|$ and also reflects across the x_2-axis. E_{2c} does the same vertically.
- *Replacement.* $T_{E_{2c1}}(x_1, x_2) = (x_1 + cx_2, x_2)$ is a horizontal **shear**. It slides each horizontal line $x_2 = t$ along itself by ct, so the x_1-axis is fixed pointwise, and the higher a point is, the farther it moves. The unit square becomes a parallelogram with the same base and the same height. E_{1c2} is a vertical shear.



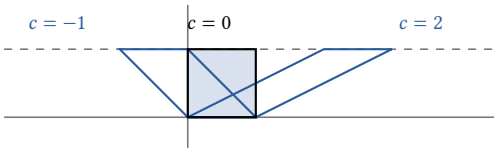


Figure 3.2.1. The three types of 2×2 elementary matrices acting on the plane. Each panel shows the images of the grid, of the unit square, and of $\mathbf{e}_1$ (blue) and $\mathbf{e}_2$ (ochre). The reflection reverses orientation, so its image of the letter F is mirrored and its square is drawn in red.

The inverses of Proposition 3.2.10 are visible here: the shear by c is undone by the shear by $-c$, the stretch by c by the stretch by c^{-1}, and the reflection by itself.

The plane transformer, starting at the shear $E_{2,1,1}$. Move $A\mathbf{e}_2$ along the horizontal grid line $x_2 = 1$ (focus it and use the left and right arrow keys): every position gives a shear $E_{2c1} = \begin{pmatrix} 1 & c \\ 0 & 1 \end{pmatrix}$. Move $A\mathbf{e}_1$ along the x_1-axis back and forth through 0 to see the scalings E_{1c}, and how the square flattens at $c = 0$, which is why $c = 0$ is excluded. For the swap, type the entries $0, 1, 1, 0$. (Interactive in the web version.)

Example 3.2.34 (A rotation built from shears). The rotation of the plane by 90° counterclockwise sends $\mathbf{e}_1 \mapsto \mathbf{e}_2$ and $\mathbf{e}_2 \mapsto -\mathbf{e}_1$, so its matrix is $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. It is not elementary, but it is a product of three shears. With $S = E_{2,-1,1} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$ and $L = E_{1,1,2} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$,

$$SLS = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = R.$$

Figure 3.2.2 shows the three steps: a horizontal shear, a vertical shear, and the first shear again. The same R is also a product of two reflections, $R = E_{1,-1}E_{12}$: first reflect across the line $x_1 = x_2$, then across the x_2-axis. So a matrix can be written as a product of elementary matrices in several ways, and the number and types of the factors are not determined by the matrix.

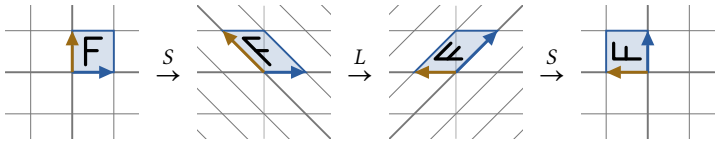

Figure 3.2.2. The rotation by 90° as three shears, $R = SLS$. From left to right: the unit square and the letter F, then their images under S, under LS, and under $SLS = R$.

Intuition (Elementary maps as building blocks). Section 3.5 proves that every invertible matrix is a product of elementary matrices (Theorem 3.5.19). For the plane this says that every invertible linear map of $\mathbb{R}^2$ is a composition of shears, stretches along the axes (possibly with a reflection), and the reflection across

$x_1 = x_2$. The figures also show how each building block changes area. A shear keeps the area of the unit square. The stretch E_{1c} multiplies it by $|c|$. The swap keeps it but reverses orientation. Recorded with signs, these are the numbers 1, c, and -1, which will be the determinants of the three types, and the determinant of any invertible matrix is then pinned down by its factorization into elementary matrices.

Remark 3.2.35 (Where elementary matrices reappear). Elementary matrices are bookkeeping for elimination, and they come back several times.

- In Section 3.3, a run of Gauss–Jordan elimination on A is recorded by a product $G = E_k \cdots E_1$ with $GA = \operatorname{rref}(A)$ (Theorem 3.3.10). By Proposition 3.2.14, the system $A\mathbf{x} = \mathbf{y}$ can then be solved in the form $\operatorname{rref}(A)\mathbf{x} = G\mathbf{y}$ (Section 3.4).
- In Section 3.5, every invertible matrix turns out to be a product of elementary matrices (Theorem 3.5.19). This yields a proof technique, reducing to elementary matrices (Technique 5.4.6): to prove a statement about all invertible matrices that is preserved under products, prove it for each of the three types.
- In Section 5.4, that technique computes $\det(AE) = \det A \cdot \det E$ type by type, and from it $\det(AB) = \det A \cdot \det B$ (Theorem 5.4.10) and $\det A^{\mathsf{T}} = \det A$ (Theorem 5.4.14).

Exercises

Exercise 3.2.36. ROUTINE Which of the following matrices are elementary? For each one that is, name the row operation it performs and write down its inverse. All matrices are over $\mathbb{R}$, except (h), which is over $\mathbb{F}_3$.

$$\text{(a)}\ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},\quad \text{(b)}\ \begin{pmatrix} 1 & 0 \\ -3 & 1 \end{pmatrix},\quad \text{(c)}\ \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},\quad \text{(d)}\ \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix},\quad \text{(e)}\ \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

$$\text{(f)}\ \begin{pmatrix} 1 & 0 & 4 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},\quad \text{(g)}\ \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix},\quad \text{(h)}\ \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix},\quad \text{(i)}\ \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}.$$

Solution on page 1214

Exercise 3.2.37. ROUTINE For each matrix A below, find elementary matrices $E_1, \ldots, E_k$ with $E_k \cdots E_1 A = I_2$, compute $G = E_k \cdots E_1$, and check that $AG = I_2$ as well.

(a) $A = \begin{pmatrix} 2 & 4 \\ 1 & 1 \end{pmatrix}$ over $\mathbb{F}_5$.

(b) $A = \begin{pmatrix} 1 & i \\ i & 2 \end{pmatrix}$ over $\mathbb{C}$.

Solution on page 1214

Exercise 3.2.38. ROUTINE Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$. Compute $E_{1,2,3}A$ and $AE_{1,2,3}$ and describe each in words. Then find the elementary matrix E for which AE is A with 2 times column 1 added to column 3.

Solution on page 1215

Exercise 3.2.39. ROUTINE Let $i \neq j$ and $c, d \in F$.

(a) Show that $E_{icj}E_{idj} = E_{i(c+d)j}$ and, for $c, d \neq 0$, that $E_{ic}E_{id} = E_{i(cd)}$.

(b) Deduce that $E_{icj}^k = E_{i(kc)j}$ for every positive integer k, and that $E_{icj}^p = I_m$ when $F = \mathbb{F}_p$.

Solution on page 1215

Exercise 3.2.40. STANDARD Let $m = 3$ and $c, d \in F$.

(a) Compute $E_{2d3}E_{1c2}$ and $E_{1c2}E_{2d3}$, and explain the difference in terms of row operations.

(b) Show that $E_{2d3}E_{1c2} = E_{1(cd)3}E_{1c2}E_{2d3}$.

(c) Show that E_{1c2} commutes with E_{1d3} and with E_{3d2}.

Solution on page 1216

Exercise 3.2.41. STANDARD Let $i \neq j$.

(a) Show that $E_{ij} = E_{i,-1}E_{i,1,j}E_{j,-1,i}E_{i,1,j}$. So a swap can be performed with three replacements and one scaling.

(b) Show that over $\mathbb{F}_2$, E_{ij} is a product of three elementary matrices of type 3.

(c) Deduce that every product of elementary matrices is a product of elementary matrices of types 2 and 3 only.

Solution on page 1216

Exercise 3.2.42. STANDARD For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, let $D(A) = ad - bc$.

(a) Show that $D(EA) = D(A)$ for every 2×2 elementary matrix E of type 3, that $D(E_{12}A) = -D(A)$, and that $D(E_{is}A) = sD(A)$ for $i = 1, 2$ and $s \neq 0$.

(b) Suppose $1 + 1 \neq 0$ in F. Show that E_{12} is not a product of elementary matrices of type 3. Why does this not contradict Exercise 3.2.41(b)?

(c) Is $E_{1,2} \in \mathbb{R}^{2\times 2}$ a product of elementary matrices of type 3?

Solution on page 1217

Exercise 3.2.43. ROUTINE Find the error in the following argument, and give a counterexample to its conclusion.

Claim. If $A \in F^{m\times n}$ and $G \in F^{m\times m}$ is invertible, then $\operatorname{im} T_{GA} = \operatorname{im} T_A$.

Proof. Let $\mathbf{y} \in F^m$. By Proposition 3.2.14, the system $(GA)\mathbf{x} = \mathbf{y}$ has a solution if and only if $A\mathbf{x} = \mathbf{y}$ has one. So $\mathbf{y} \in \operatorname{im} T_{GA}$ if and only if $\mathbf{y} \in \operatorname{im} T_A$.

Solution on page 1217

Exercise 3.2.44. STANDARD Let $A, B \in F^{m\times n}$ with $A \sim B$. Prove or disprove each statement.

(a) $A^{\mathsf{T}} \sim B^{\mathsf{T}}$.

(b) $AC \sim BC$ for every $C \in F^{n\times p}$.

(c) $CA \sim CB$ for every $C \in F^{q\times m}$.

(d) If also $C \sim D$ in $F^{m\times n}$, then $A + C \sim B + D$.

(e) If $m = n$ and A is invertible, then B is invertible.

Solution on page 1217

Exercise 3.2.45. STANDARD Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$, and let $G \in F^{p\times m}$, where p need not equal m.

(a) Suppose G has a left inverse, that is, $HG = I_m$ for some $H \in F^{m\times p}$. Show that $A\mathbf{x} = \mathbf{y}$ and $(GA)\mathbf{x} = G\mathbf{y}$ have the same solutions.

(b) Give an example with $m = 2$ and $p = 3$, and interpret it as an operation on the equations of a system.

(c) Conversely, suppose that for every $A \in F^{m\times 1}$ and every $\mathbf{y} \in F^m$ the systems $A\mathbf{x} = \mathbf{y}$ and $(GA)\mathbf{x} = G\mathbf{y}$ have the same solutions. Show that T_G is injective.

Solution on page 1218

Exercise 3.2.46. STANDARD The **row space** of $A \in F^{m\times n}$ is the span of its rows, viewed as vectors in F^n; equivalently, it is $\operatorname{im} T_{A^{\mathsf{T}}}$. Show that row equivalent matrices have the same row space.

Solution on page 1218

Solution on page 1219

Exercise 3.2.47. STANDARD

(a) Show that two $1 \times n$ matrices are row equivalent if and only if one is a nonzero scalar multiple of the other.

(b) Find all $B \in \mathbb{R}^{2\times 2}$ with $B \sim \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$.

Solution on page 1219

Exercise 3.2.48. STANDARD Let p be a prime and $m \geq 1$. How many different matrices in $\mathbb{F}_p^{m\times m}$ are elementary? List them for $p = 2$ and $m = 2$.

Solution on page 1219

Exercise 3.2.49. STANDARD Let $R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$ be the rotation of $\mathbb{R}^2$ by θ, and for $t \in \mathbb{R}$ let $S(t) = E_{2t1} = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}$ and $L(t) = E_{1t2} = \begin{pmatrix} 1 & 0 \\ t & 1 \end{pmatrix}$.

(a) Show that if θ is not an odd multiple of π, then $R_\theta = S(-\tan(\theta/2))\, L(\sin\theta)\, S(-\tan(\theta/2))$.

(b) Write $R_\pi = -I_2$ as a product of five shears.

Solution on page 1220

Exercise 3.2.50. STANDARD

(a) Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$ with $ad - bc \neq 0$. Find elementary matrices $E_1, \ldots, E_k$ with $E_k \cdots E_1 A = I_2$, and conclude that A is a product of elementary matrices.

(b) Carry this out for $A = \begin{pmatrix} 0 & 1 \\ -2 & 3 \end{pmatrix} \in \mathbb{R}^{2\times 2}$, and describe T_A as a composition of shears, stretches, and reflections.

Solution on page 1220

Exercise 3.2.51. STANDARD Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 7 \end{pmatrix} \in \mathbb{R}^{2\times 3}$.

(a) Find elementary column operations that turn A into $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$, and compute the product H of the corresponding elementary matrices, so that $AH = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$.

(b) Let $\mathbf{h}_3$ be the third column of H. Show that $\ker T_A = \operatorname{span}(\mathbf{h}_3)$.

Solution on page 1221

Exercise 3.2.52. STANDARD Let $m \geq 2$ and $M \in F^{m\times m}$. Show that M commutes with every elementary matrix of type 3 if and only if $M = \lambda I_m$ for some $\lambda \in F$.

Solution on page 1221

Exercise 3.2.53. HARD Let F be any field and $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$ with $ad - bc = 1$. Show that A is a product of at most four elementary matrices of type 3, that is, of shears.

Solution on page 1222

Exercise 3.2.54. HARD Let a, b be integers, not both 0, and let $g = \gcd(a, b)$. Call a 2×2 matrix an **integer elementary matrix** if it is E_{12}, $E_{1,-1}$, $E_{2,-1}$, or E_{icj} with $c \in \mathbb{Z}$.

(a) Show that integer elementary matrices have integer entries, and that their inverses are integer elementary matrices.

(b) Show that there are integer elementary matrices $E_1, \ldots, E_k$ with $E_k \cdots E_1 \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} g \\ 0 \end{pmatrix}$.

(c) Deduce Bézout's identity: there are integers u, v with $ua + vb = g$.

(d) Carry out (b) and (c) for $(a, b) = (42, 30)$.

Solution on page 1222

Exercise 3.2.55. HARD Start with the integer matrix $M = \begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix}$. A **move** adds an integer multiple of one row to the other row, or an integer multiple of one column to the other column.

(a) Show that a move changes neither $ad - bc$ nor the greatest common divisor of the four entries of a matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$.

(b) Which of $\begin{pmatrix} 1 & 0 \\ 0 & -8 \end{pmatrix}$, $\begin{pmatrix} 2 & 0 \\ 0 & 4 \end{pmatrix}$, and $\begin{pmatrix} 2 & 0 \\ 0 & -4 \end{pmatrix}$ can be reached from M by a sequence of moves?

Solution on page 1223

Exercise 3.2.56. CHALLENGE BEYOND 21-242 Let $n \geq 2$ and let $A \in F^{n\times n}$ be invertible. Using Theorem 3.5.19, show that

$$A = PE_{nd}$$

for some product P of elementary matrices of type 3 and some $d \neq 0$. (In Chapter 5, d turns out to be $\det A$.)

Solution on page 1224

3.3 Gauss–Jordan elimination

In Example 3.1.13 we solved the running system by eliminating unknowns, choosing each move by eye and stopping when the answer looked readable. To prove theorems with elimination we need a procedure with no judgment calls in it. This section states one, Gauss–Jordan elimination, proves that it terminates, and studies its output, the reduced row echelon form $\operatorname{rref}(A)$. With the bookkeeping of Section 3.2, a whole run of the algorithm is recorded by one invertible matrix G with $GA = \operatorname{rref}(A)$. The main theorem of the section says that $\operatorname{rref}(A)$ depends only on A: every way of row reducing A to a matrix of this shape ends at the same matrix. As a first application, we decide whether a square matrix is invertible, and compute its inverse, by row reduction.

3.3.1 The algorithm

Intuition (How elimination is organized). Read the rows of A as equations and the columns as unknowns. Elimination uses one equation to remove one unknown from all the other equations, and the natural order is left to right. Find the first unknown x_j that occurs in some equation, move such an equation to the top, divide it by its coefficient of x_j, and subtract multiples of it from every other equation, so that x_j occurs in no other equation. The top equation is now used up; we call its row *pivoted*. Then do the same with the equations that are left: find the leftmost unknown that still occurs in one of them, and so on.

Gauss–Jordan elimination clears the column of each new pivot above it as well as below it, so at the end each pivot is alone in its column. (Clearing only below gives Gaussian elimination, Section 3.3.6.) A column whose nonzero entries all lie in pivoted rows is skipped: it is already a combination of earlier pivot columns, and in Section 3.4 its unknown becomes a free variable.

In the algorithm below, M is the current matrix and k is the number of pivoted rows. The pivoted rows are always rows $1, \ldots, k$ of M, and the other rows are **unpivoted**.

Algorithm 3.3.1 (Gauss–Jordan elimination)

Input A matrix $A \in F^{m \times n}$.
Output The matrix $\operatorname{rref}(A) \in F^{m \times n}$, and its pivot columns $p_1 < p_2 < \cdots < p_r$.

Start with $M = A$ and $k = 0$.

1. **Scan.** Find the leftmost column j of M that has a nonzero entry in an unpivoted row, that is, in one of the rows $k+1, \ldots, m$. If there is no such column, halt and output M.
2. **Swap.** If the entry of M in position $(k+1, j)$ is 0, swap row $k+1$ with the topmost row below it whose entry in column j is nonzero.
3. **Scale.** Scale row $k+1$ by the inverse of its entry in column j, so that this entry becomes 1. (If it is 1 already, there is nothing to do.) Declare this entry a **pivot**, set $p_{k+1} = j$, and increase k by 1. Row k is now pivoted.
4. **Clear.** For each row $i \neq k$ whose entry c in column j is nonzero, add $-c$ times row k to row i.
5. **Repeat.** Go back to step 1.

One execution of step 1 through step 4 that does not halt in step 1 is a **pass**. Each pass creates exactly one pivot, so after r passes the pivots sit in positions $(1, p_1), (2, p_2), \ldots, (r, p_r)$. (Later passes never move a pivoted row: swaps only involve unpivoted rows.) We call $p_1, \ldots, p_r$ the **pivot columns** and rows $1, \ldots, r$ the **pivot rows**. The **leading entry** of a nonzero row is its first nonzero entry, reading from the left.

Each step can be carried out. In step 2, column j has a nonzero entry in some unpivoted row, so if row $k+1$ has a 0 there, a row below it does not. In step 3 the entry is nonzero, so it has an inverse in F. In step 4 every operation adds a multiple of row k, which the step never changes, so the operations can be performed one at a time in any order with the same result. (Compare Exercise 3.1.35, where a row was used after it had been replaced.)

Remark 3.3.2 (The one free choice). Every step is determined by the current matrix except, in principle, step 2. The lecture's version of that step says only "swap rows to make the topmost unpivoted entry of this column nonzero", leaving open which row to bring up. We have fixed the choice (the topmost suitable row, and no swap when none is needed) so that the output is a function of A. Other choices have their uses. By hand one might bring up a row whose entry is 1, to avoid fractions; in floating-point arithmetic one brings up the entry of largest absolute value to limit rounding errors (*partial pivoting*). Whether a different choice can change the output is a real question. Corollary 3.3.18 answers it: it cannot.

Example 3.3.3 (A complete run). We run the algorithm on

$$A = \begin{pmatrix} 0 & 0 & 2 & 4 \\ 2 & 4 & 2 & 0 \\ 1 & 2 & 3 & 4 \end{pmatrix} \in \mathbb{Q}^{3\times 4}.$$

Pass 1. No row is pivoted, and column 1 has nonzero entries, so $j = 1$. The entry in position $(1, 1)$ is 0, and the topmost row below it with a nonzero entry in column 1 is row 2, so we swap rows 1 and 2. Then we scale row 1 by $1/2$ and declare the pivot $(1, 1)$, so $p_1 = 1$. In column 1, row 2 already has a 0 and row 3 has a 1, so we add -1 times row 1 to row 3:

$$A \xrightarrow{E_{12}} \begin{pmatrix} 2 & 4 & 2 & 0 \\ 0 & 0 & 2 & 4 \\ 1 & 2 & 3 & 4 \end{pmatrix} \xrightarrow{E_{1,1/2}} \begin{pmatrix} 1 & 2 & 1 & 0 \\ 0 & 0 & 2 & 4 \\ 1 & 2 & 3 & 4 \end{pmatrix}$$

$$\xrightarrow{E_{1,-1,3}} \begin{pmatrix} 1 & 2 & 1 & 0 \\ 0 & 0 & 2 & 4 \\ 0 & 0 & 2 & 4 \end{pmatrix}.$$

Pass 2. Rows 2 and 3 are unpivoted. Column 2 has entries $0, 0$ in these rows (the 2 in row 1 does not count, since row 1 is pivoted), so the scan moves on and finds $j = 3$. The entry in position $(2, 3)$ is $2 \neq 0$, so there is no swap. We scale row 2 by $1/2$ and declare the pivot $(2, 3)$, so $p_2 = 3$. Then we clear column 3 above and below the pivot:

$$\xrightarrow{E_{2,1/2}} \begin{pmatrix} 1 & 2 & 1 & 0 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 2 & 4 \end{pmatrix} \xrightarrow{E_{2,-1,1}} \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 2 & 4 \end{pmatrix}$$

$$\xrightarrow{E_{2,-2,3}} \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

End. Only row 3 is unpivoted, and it is zero, so the next scan finds no column and the algorithm halts after two passes. The output is

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

with pivot columns $p_1 = 1$ and $p_2 = 3$. The run used six row operations, with elementary matrices (in the notation of Definition 3.2.2) E_{12}, $E_{1,1/2}$, $E_{1,-1,3}$, $E_{2,1/2}$, $E_{2,-1,1}$, $E_{2,-2,3}$.

The row reducer below performs the same run, one row operation at a time. Next to the current matrix M it shows the product G of the elementary matrices used so far, and $GA = M$ at every step (Theorem 3.3.10).

$$\begin{pmatrix} 0 & 0 & 2 & 4 \\ 2 & 4 & 2 & 0 \\ 1 & 2 & 3 & 4 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Gauss–Jordan elimination on the matrix of Example 3.3.3. Step forward and back to see each elementary matrix; pivots are boxed. Use "Edit" to row reduce your own matrix, over $\mathbb{Q}$ or over $\mathbb{F}_p$. (Interactive in the web version.)

The running system is also a good test. In Example 3.1.13 the four operations on its coefficient matrix were exactly the two passes of the algorithm (in pass 2 we cleared row 3 before row 1, which does not matter). So Example 3.2.8 already computed

$$\operatorname{rref}\begin{pmatrix} 1 & 2 & -1 \\ 2 & 5 & 1 \\ 3 & 7 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 & -7 \\ 0 & 1 & 3 \\ 0 & 0 & 0 \end{pmatrix},$$

together with the product G of the four elementary matrices.

Exercise 3.3.4. ROUTINE Run Gauss–Jordan elimination on

$$B = \begin{pmatrix} 0 & 2 & 4 \\ 1 & 1 & 1 \\ 2 & 3 & 4 \end{pmatrix} \in \mathbb{Q}^{3\times 3},$$

listing the elementary matrix of every row operation. What are the pivot columns?

Solution on page 1224

3.3.2 Termination and the shape of the output

An algorithm is a construction, and a construction can be a proof: running Gauss–Jordan elimination on A will prove that A is row equivalent to a matrix of a very special shape. For that we have to show two things about every run, not just the one in Example 3.3.3. It stops, and what it stops with has the shape we want. The method is worth naming.

Technique 3.3.5 (Algorithms as proofs: invariants and termination). To prove that something exists, it is often enough to give a procedure that builds it. Two things then have to be proved about the procedure.

Termination. Find a quantity that moves in one direction at every step and cannot do so forever, such as a nonnegative integer that decreases, or an integer that increases and is bounded above. (Such a quantity is sometimes called a *monovariant*.)

Correctness. Find an **invariant**: a statement about the current state that is true at the start and that each step keeps true. When the procedure halts, the invariant together with the reason for halting gives the property of the output. Formally this is induction on the number of steps.

The art is in choosing the invariant. The property we want at the end is rarely preserved step by step on its own, and usually has to be strengthened, by adding facts about the intermediate states, until it is. Reach for this technique whenever a result says that some reduction is always possible ("every matrix can be brought to the form ...", "the process ends with ..."). The canonical example is Gauss–Jordan elimination: termination is Proposition 3.3.6, and the invariant is Lemma 3.3.7. Later examples are Gram–Schmidt orthogonalization (Section 6.4) and the Euclidean algorithm for polynomials (Section 7.1); Exercise 3.2.54 is a small one.

Used in. Proposition 3.3.6, Lemma 3.3.7, Proposition 3.3.8, Theorem 3.3.10, Theorem 3.3.12, Exercise 3.3.53, Exercise 3.3.56, Exercise 3.6.11, Exercise 5.2.43, Algorithm 5.4.22, Theorem 6.4.15, Theorem 7.1.45, Proposition 8.3.25, Exercise 3.3.47, Exercise 5.4.48.

Proposition 3.3.6 (Termination). Let $A \in F^{m\times n}$. Gauss–Jordan elimination on A halts after completing at most m passes, and so performs at most $m(m+1)$ elementary row operations.

Proof. ROUTINE

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Find a quantity that changes in the same direction in every pass.

Hint 2. Track k, the number of pivoted rows. What does each pass do to it, and how large can it get?
Sketch. Each pass increases k by 1 in step 3, no step decreases it, and $k \leq m$, since once $k = m$ there is no unpivoted row and step 1 halts. A pass performs at most one swap, one scaling, and $m - 1$ replacements.

Every pass increases the number k of pivoted rows by 1, in step 3, and no step decreases k. A pass can only begin if some row is unpivoted, that is, if $k < m$; when $k = m$, step 1 finds no column and halts. So at most m passes are completed before the algorithm halts. Each pass performs at most one swap, at most one scaling, and at most $m - 1$ replacements (one for each row other than row k), so at most $m + 1$ row operations. In total there are at most $m(m + 1)$. □

Now for the shape of the output. In Example 3.3.3 the pivots formed a staircase descending to the right, each pivot was alone in its column, and the leftover row was zero. The first two facts are what each pass sets up for its own pivot; the real issue is that later passes must not undo the work of earlier ones.

Intuition (Choosing the invariant). The obvious invariant is that the current matrix is GA for a product G of elementary matrices, but it says nothing about the shape. For the shape we want three facts about the pivots found so far: each pivot column is a standard basis vector, the pivots descend to the right, and each pivot row vanishes to the left of its pivot. The first one maintains itself. A later pass swaps and scales unpivoted rows and adds multiples of an unpivoted row to other rows, and every unpivoted row has a 0 in column p_s, because that column is $\mathbf{e}_s$. The other two depend on where the next pivot is found. They are safe if the unpivoted rows vanish in every column up to the last pivot, so we add this to the invariant. It is exactly what choosing the *leftmost* column in step 1, followed by clearing, keeps true.

Lemma 3.3.7 (The loop invariant). Let $A \in F^{m \times n}$, and suppose Gauss–Jordan elimination on A has completed k passes, with pivot columns $p_1, \ldots, p_k$ and current matrix M. Put $p_0 = 0$. Then:

(a) $M = GA$ for some product G of elementary matrices;

(b) $p_1 < p_2 < \cdots < p_k$;

(c) for $1 \leq s \leq k$, column p_s of M is $\mathbf{e}_s$;

(d) for $1 \leq s \leq k$, row s of M has zeros in columns $1, \ldots, p_s - 1$;

(e) rows $k + 1, \ldots, m$ of M have zeros in columns $1, \ldots, p_k$.

Proof. STANDARD

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Proposition 3.2.7 (Row operations are left multiplications), induction on k
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Induct on k. In pass $k + 1$, let j be the column chosen by step 1. What does the choice of j say about rows $k + 1, \ldots, m$ in columns $1, \ldots, j - 1$?
Hint 2. Let $\mathbf{u}$ be row $k + 1$ after step 3. Every operation of the pass either moves or scales unpivoted rows, or adds a multiple of $\mathbf{u}$ to another row. Where is $\mathbf{u}$ zero?
Hint 3. For (b), use (e) for the old k: the unpivoted rows vanish in columns $1, \ldots, p_k$, so the scan cannot stop before column $p_k + 1$.
Sketch. By the choice of j, rows $k + 1, \ldots, m$ vanish in columns $1, \ldots, j - 1$, and so does the new pivot row $\mathbf{u}$; by (e), $j > p_k$. The pass only swaps and scales unpivoted rows and adds multiples of $\mathbf{u}$, so columns p_s with $s \leq k$ and the zeros in (d) are untouched, while step 4 turns column j into $\mathbf{e}_{k+1}$. Rows $k + 2, \ldots, m$ are old unpivoted rows plus multiples of $\mathbf{u}$, so they vanish in columns $1, \ldots, j$.

We induct on k. Before the first pass, $k = 0$ and $M = A = I_m A$, and (b)–(e) say nothing.

Suppose that (a)–(e) hold after k passes, with current matrix M, and that pass $k + 1$ takes place, with column j chosen in step 1. Let M' be the matrix after the pass. By the choice of j as the *leftmost* suitable column,

$$\text{rows } k + 1, \ldots, m \text{ of } M \text{ have zeros in columns } 1, \ldots, j - 1. \tag{3.3.1}$$

The pass does three things. step 2 may exchange two rows among rows $k+1, \dots, m$. step 3 scales row $k+1$; call the resulting row $\mathbf{u}$. step 4 adds multiples of $\mathbf{u}$ to other rows and leaves row $k+1$ equal to $\mathbf{u}$. By (3.3.1), $\mathbf{u}$ has zeros in columns $1, \dots, j-1$, and by step 3 it has entry 1 in column j.

(a) Each operation of the pass is left multiplication by an elementary matrix (Proposition 3.2.7). So $M' = EM = (EG)A$, where E is the product of the elementary matrices of the pass, and EG is again a product of elementary matrices.

(b) If $k \geq 1$, then by (e), rows $k+1, \dots, m$ of M vanish in columns $1, \dots, p_k$, so the column j found by the scan satisfies $j > p_k$. Hence $p_1 < \cdots < p_k < p_{k+1} = j$.

(c) Let $s \leq k$. Column p_s of M is $\mathbf{e}_s$, so its entries in rows $k+1, \dots, m$ are 0. Steps step 2 and step 3 only exchange or scale entries in these rows, and step 4 adds multiples of $\mathbf{u}$, which is a multiple of one of these rows and so also has entry 0 in column p_s. So column p_s of M' is still $\mathbf{e}_s$. For the new pivot: after step 3 the entry of row $k+1$ in column j is 1, and each operation of step 4 changes a single row $i \neq k+1$, replacing its entry c in column j by $c - c \cdot 1 = 0$. So column j of M' is $\mathbf{e}_{k+1}$.

(d) Let $s \leq k$. Row s is not touched by steps step 2 and step 3, and in step 4 it changes by a multiple of $\mathbf{u}$, which vanishes in columns $1, \dots, j-1$, a range containing $1, \dots, p_s - 1$. So row s of M' still vanishes in columns $1, \dots, p_s - 1$. Row $k+1$ of M' is $\mathbf{u}$, which vanishes in columns $1, \dots, j-1 = p_{k+1} - 1$.

(e) Let $i \geq k+2$. Row i of M' is one of the rows $k+1, \dots, m$ of M (possibly moved by the swap) plus a multiple of $\mathbf{u}$. By (3.3.1) both vanish in columns $1, \dots, j-1$, so row i of M' does too, and its entry in column j is 0 by (c). So rows $k+2, \dots, m$ of M' vanish in columns $1, \dots, p_{k+1}$.

This completes the induction. □

Proposition 3.3.8 (Properties of the output). Let R be the output of Gauss–Jordan elimination on $A \in F^{m \times n}$, with pivot columns $p_1 < \cdots < p_r$. Then $r \leq \min(m, n)$, and:

(a) rows $r+1, \dots, m$ of R are zero;

(b) for $1 \leq s \leq r$, the leading entry of row s is the pivot, a 1 in column p_s;

(c) for $1 \leq s \leq r$, column p_s of R is $\mathbf{e}_s$.

In particular, R satisfies the following conditions.

(R1) Every zero row lies below every nonzero row.

(R2) The leading entry of every nonzero row is 1.

(R3) The leading entry of each nonzero row lies strictly to the right of the leading entry of every row above it.

(R4) In a column that contains the leading entry of some row, every other entry is 0.

Proof. ROUTINE

Uses. Lemma 3.3.7 (The loop invariant), Proposition 3.3.6 (Termination)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Apply Lemma 3.3.7 after the last pass, and ask why the algorithm halted.
Hint 2. The scan found no column with a nonzero entry in rows $r+1, \dots, m$. What does that say about those rows?
Sketch. There are at most m passes and the p_s are distinct columns, so $r \leq \min(m, n)$. The algorithm halted because rows $r+1, \dots, m$ have no nonzero entry, which is (a). Parts (b) and (c) are (c) and (d) of Lemma 3.3.7. Then (R1)–(R4) follow, using $p_1 < \cdots < p_r$ for (R3).

The algorithm completes r passes and then halts. By Proposition 3.3.6, $r \leq m$, and by Lemma 3.3.7(b), $p_1 < \cdots < p_r$ are r distinct columns, so $r \leq n$.

(a) The algorithm halted because step 1 found no column with a nonzero entry in one of the rows $r+1, \dots, m$. So these rows are zero.

(b), (c) By Lemma 3.3.7(d), row s of R vanishes in columns $1, \dots, p_s - 1$, and by Lemma 3.3.7(c), column p_s of R is $\mathbf{e}_s$, so the entry of row s in column p_s is 1.

By (a) and (b), the nonzero rows of R are exactly rows $1, \dots, r$, which gives (R1). Their leading entries are the pivots, which are 1 and lie in the columns $p_1 < \cdots < p_r$; this gives (R2) and (R3). The columns containing leading entries are $p_1, \dots, p_r$, so (R4) is (c). □

3.3.3 Reduced row echelon form

Definition 3.3.9 (Reduced row echelon form). Let $A \in F^{m\times n}$. The **reduced row echelon form** of A, written $\operatorname{rref}(A)$ or A_r, is the output of Gauss–Jordan elimination (Algorithm 3.3.1) on A. The **pivots** and **pivot columns** of A are those found by this run; by Proposition 3.3.8(b), the pivots are the leading entries of the nonzero rows of $\operatorname{rref}(A)$. A matrix R is **in reduced row echelon form** (or **in RREF**) if $\operatorname{rref}(R) = R$.

This is the lecture's definition: $\operatorname{rref}(A)$ is *whatever the algorithm outputs*. It has the advantage of being concrete, and the drawback that it is not yet clear which matrices are in RREF, or whether a different way of row reducing A could end somewhere else. We settle both questions in this section and the next. First, the bookkeeping of Section 3.2 turns the run into one matrix.

Theorem 3.3.10 ($GA = \operatorname{rref}(A)$). For every $A \in F^{m\times n}$ there is a matrix $G \in F^{m\times m}$ that is a product of elementary matrices, and hence invertible, with

$$GA = \operatorname{rref}(A).$$

Explicitly, $G = E_t \cdots E_2 E_1$, where $E_1, \dots, E_t$ are the elementary matrices of the row operations of the run, in the order performed.

Proof. ROUTINE

Uses. Lemma 3.3.7 (The loop invariant), Proposition 3.2.7 (Row operations are left multiplications), Corollary 3.2.11 (Products of elementary matrices)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Which part of Lemma 3.3.7 is about GA?
Hint 2. Apply it after the last pass, and recall that products of elementary matrices are invertible.
Sketch. By Lemma 3.3.7(a) after the last pass, $\operatorname{rref}(A) = GA$ with $G = E_t \cdots E_1$ the product of the elementary matrices of the run (Proposition 3.2.7). Such a product is invertible by Corollary 3.2.11.

By Proposition 3.2.7, performing the operations of the run one after another gives $E_1 A$, then $E_2 E_1 A$, and so on; this is the content of Lemma 3.3.7(a). After the last operation the matrix is $\operatorname{rref}(A) = E_t \cdots E_1 A = GA$. By Corollary 3.2.11, G is invertible. □

In other words, running the algorithm on A is the same as multiplying A on the left by one well-chosen invertible matrix. Two consequences are immediate. First, $A \sim \operatorname{rref}(A)$ (Definition 3.2.21). Second, by Corollary 3.2.23, $\ker T_A = \ker T_{\operatorname{rref}(A)}$, and by Proposition 3.2.14, $A\mathbf{x} = \mathbf{y}$ if and only if $\operatorname{rref}(A)\mathbf{x} = G\mathbf{y}$. Section 3.4 reads the solutions off this second system.

The matrix G is found by performing the operations of the run on I_m. It is convenient to do this alongside the run itself, by adjoining I_m to A.

Proposition 3.3.11 (Carrying extra columns along). Let $A \in F^{m\times n}$ and $B \in F^{m\times p}$, and let G be as in Theorem 3.3.10.

(a) $G(A \mid B) = (\operatorname{rref}(A) \mid GB)$.

(b) Performing on the $m \times (n + p)$ matrix $(A \mid B)$ the run of Gauss–Jordan elimination with step 1 restricted to the first n columns ends at $(\operatorname{rref}(A) \mid GB)$.

In particular, the restricted run on $(A \mid I_m)$ ends at $(\operatorname{rref}(A) \mid G)$.

Proof. ROUTINE

Uses. Definition 2.4.1 (Matrix product), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.2.7 (Row operations are left multiplications)
Hint 1. Compute $G(A \mid B)$ one column at a time.
Hint 2. For (b): the decisions in steps step 1 through step 4 depend only on entries in the scanned columns. How do row operations act on the individual columns of a matrix?
Sketch. Column l of GM is G times column l of M, which gives (a). A row operation changes each column by itself, so during the restricted run the first n columns evolve exactly as in the run on A; since every decision depends only on them, the restricted run performs the same operations $E_1, \dots, E_t$ and ends at $G(A \mid B)$.

(a) By Definition 2.4.1, column l of GM is G times column l of M, for any matrix M with m rows. The first n columns of $(A \mid B)$ are those of A and the last p are those of B, so the first n columns of $G(A \mid B)$ form $GA = \operatorname{rref}(A)$ and the last p form GB.

(b) For the same reason, if E is elementary, the first n columns of $E(A \mid B)$ form EA. So as long as the restricted run on $(A \mid B)$ and the run on A perform the same operations, the first n columns of the current matrix of the former are the current matrix of the latter. Every decision in steps step 1 through step 4 (which column, which rows, which scalars, whether to halt) depends only on the entries in the scanned columns. So, by induction on the number of operations, the two runs perform the same operations $E_1, \dots, E_t$, and the restricted run ends at $E_t \cdots E_1(A \mid B) = G(A \mid B)$, which is $(\operatorname{rref}(A) \mid GB)$ by (a). □

The row reducer does exactly this when it shows G: it carries I_m along. For Example 3.3.3,

$$(A \mid I_3) = \left(\begin{array}{cccc|ccc} 0 & 0 & 2 & 4 & 1 & 0 & 0 \\ 2 & 4 & 2 & 0 & 0 & 1 & 0 \\ 1 & 2 & 3 & 4 & 0 & 0 & 1 \end{array}\right)$$

$$\rightsquigarrow \left(\begin{array}{cccc|ccc} 1 & 2 & 0 & -2 & -1/2 & 1/2 & 0 \\ 0 & 0 & 1 & 2 & 1/2 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & -1/2 & 1 \end{array}\right),$$

so

$$G = \begin{pmatrix} -1/2 & 1/2 & 0 \\ 1/2 & 0 & 0 \\ -1 & -1/2 & 1 \end{pmatrix}, \quad GA = \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix} = \operatorname{rref}(A).$$

The last row of G is worth a look. Since the last row of GA is zero, -1 times row 1 of A, minus $1/2$ times row 2, plus row 3, is the zero row. So a zero row of $\operatorname{rref}(A)$ records a linear relation among the rows of A (see Exercise 3.3.57).

Which matrices are in RREF

We now characterize the matrices in RREF by their shape, without reference to the algorithm. One direction is Proposition 3.3.8. For the other, we run the algorithm on a matrix of the right shape and watch it do nothing.

Theorem 3.3.12 (Matrices in RREF). A matrix $R \in F^{m \times n}$ is in reduced row echelon form if and only if it satisfies conditions (R1)–(R4) of Proposition 3.3.8. In that case the pivots of R are its leading entries.

Proof. STANDARD

Uses. Proposition 3.3.8 (Properties of the output), Algorithm 3.3.1 (Gauss–Jordan elimination), Definition 3.3.9 (Reduced row echelon form), induction on the number of passes
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. One direction is Proposition 3.3.8, applied to $R = \operatorname{rref}(R)$.
Hint 2. For the other, let rows $1, \dots, r$ be the nonzero rows of R, with leading entries in columns $c_1 < \cdots < c_r$. Run the algorithm on R and show by induction that pass k changes nothing.

Hint 3. In pass k, which is the leftmost column with a nonzero entry in rows $k, \dots, m$? What is the entry in row k there, and what does (R4) say about the rest of that column?
Sketch. If $\operatorname{rref}(R) = R$, then R is an output, so (R1)–(R4) hold by Proposition 3.3.8. Conversely, if (R1)–(R4) hold, then in pass k the rows $k, \dots, m$ vanish to the left of c_k, the leading entry of row k, which is 1. So the scan picks c_k, there is no swap and no scaling, and by (R4) nothing needs clearing. After r passes only zero rows are unpivoted, and the algorithm halts with output R.

Suppose R is in RREF. Then $R = \operatorname{rref}(R)$ is an output of the algorithm, so it satisfies (R1)–(R4) by Proposition 3.3.8, and by Proposition 3.3.8(b) its pivots are its leading entries.

Conversely, suppose R satisfies (R1)–(R4). By (R1), its nonzero rows are rows $1, \dots, r$ for some r, and by (R3), their leading entries lie in columns $c_1 < c_2 < \cdots < c_r$. We show by induction on $k = 0, 1, \dots, r$ that after k passes of Gauss–Jordan elimination on R, the current matrix is still R and the pivots are the leading entries of rows $1, \dots, k$. For $k = 0$ there is nothing to show.

Suppose this holds for some $k < r$, and consider pass $k + 1$. Rows $k + 2, \dots, r$ have their leading entries in columns $c_{k+2}, \dots, c_r$, all to the right of c_{k+1}, and rows $r + 1, \dots, m$ are zero. Together with the leading entry of row $k + 1$, this shows that rows $k + 1, \dots, m$ vanish in columns $1, \dots, c_{k+1} - 1$, and that row $k + 1$ has a nonzero entry in column c_{k+1}. So step 1 picks $j = c_{k+1}$, and step 2 does nothing. By (R2) the entry in position $(k + 1, c_{k+1})$ is already 1, so step 3 changes nothing and declares this leading entry a pivot. By (R4) all other entries of column c_{k+1} are 0, so step 4 changes nothing. This completes the induction.

After r passes the unpivoted rows are rows $r + 1, \dots, m$, which are zero by (R1), so the algorithm halts and outputs R. Hence $\operatorname{rref}(R) = R$, and the pivots are the leading entries. □

Since $\operatorname{rref}(A)$ satisfies (R1)–(R4) by Proposition 3.3.8, Theorem 3.3.12 gives $\operatorname{rref}(\operatorname{rref}(A)) = \operatorname{rref}(A)$: running the algorithm a second time changes nothing. The shape described by (R1)–(R4) is a staircase. For instance, every 4×6 matrix in RREF with pivot columns $1, 3, 6$ looks like

$$\begin{pmatrix} 1 & * & 0 & * & * & 0 \\ 0 & 0 & 1 & * & * & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

where each $*$ is an arbitrary scalar. The pivot columns are $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$, everything below the staircase is 0, and the non-pivot columns are free above it.

Example 3.3.13 (Matrices in RREF). The identity I_n and the zero matrix $0 \in F^{m \times n}$ are in RREF. (For I_n the leading entries are the diagonal entries; the zero matrix has no nonzero rows, so (R2)–(R4) say nothing.) So are

$$\begin{pmatrix} 1 & 0 & 3 \\ 0 & 1 & -2 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 & 5 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 & 4 \end{pmatrix}, \quad \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

In the second matrix, the entry 5 sits in a non-pivot column, where (R4) imposes nothing.

Non-example 3.3.14 (Four ways to fail). Over $\mathbb{Q}$, each matrix below violates exactly one condition:

$$\text{(R1)}: \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \text{(R2)}: \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}, \quad \text{(R3)}: \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \text{(R4)}: \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$

In the first, a zero row lies above a nonzero row. In the second, a leading entry is 2. In the third, the leading entry of row 2 lies to the left of that of row 1. In the fourth, the leading entry of row 2 has a nonzero entry above it. The last three have reduced row echelon form I_2, and the first has $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

Exercise 3.3.15. ROUTINE

(a) Which of the following matrices are in RREF? For each one that is not, name a condition among (R1)–(R4) that fails.

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 4 & 0 & 2 \\ 0 & 0 & 1 & 3 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

(b) Find all 2×2 matrices over a field F that are in RREF. How many are there over $\mathbb{F}_p$?

Solution on page 1225

3.3.4 Uniqueness

Two people row reducing the same matrix by hand will rarely perform the same operations. One may bring up a different row in step 2, or clear everything below the pivots first and the entries above them afterwards. If both end with a matrix satisfying (R1)–(R4), do they end with the same matrix? Equivalently, can one row equivalence class contain two different matrices in RREF? This matters beyond hand computation. Properties we read off $\operatorname{rref}(A)$, such as the number of pivots (the rank, Section 3.5) or which columns are pivot columns, should belong to A, and we will constantly want to replace A by a row equivalent matrix GA without changing them.

The answer is that the reduced row echelon form is unique. We first record how to read the columns of a matrix in RREF.

Lemma 3.3.16 (Reading the columns of a matrix in RREF). Let $R \in F^{m \times n}$ be in RREF, with columns $\mathbf{r}_1, \ldots, \mathbf{r}_n$, entries r_{ij}, and pivot columns $p_1 < \cdots < p_r$. Put $p_t = n + 1$ for $t > r$.

(a) For $0 \le s \le m$, every column $\mathbf{r}_j$ with $j < p_{s+1}$ has zeros in rows $s+1, \ldots, m$. That is, $\mathbf{r}_j = r_{1j}\mathbf{e}_1 + \cdots + r_{sj}\mathbf{e}_s$.

(b) $\mathbf{r}_{p_s} = \mathbf{e}_s$ for $1 \le s \le r$.

(c) Column j is a pivot column if and only if $\mathbf{r}_j$ is not a linear combination of $\mathbf{r}_1, \ldots, \mathbf{r}_{j-1}$.

(d) If column j is not a pivot column, and $p_1, \ldots, p_t$ are the pivot columns to the left of it, then

$$\mathbf{r}_j = r_{1j}\mathbf{r}_{p_1} + r_{2j}\mathbf{r}_{p_2} + \cdots + r_{tj}\mathbf{r}_{p_t}.$$

Proof. STANDARD

Uses. Theorem 3.3.12 (Matrices in RREF), Proposition 3.3.8 (Properties of the output), Definition 1.3.4 (Linear combination)
Hint 1. For (a), take a row $i \ge s+1$. Where is its leading entry, if it has one?
Hint 2. For (c), a pivot column $\mathbf{r}_{p_s} = \mathbf{e}_s$ has a 1 in row s. What is the entry in row s of every earlier column, and of every combination of them?
Hint 3. For (d), apply (a) with $s = t$ and substitute $\mathbf{e}_s = \mathbf{r}_{p_s}$.
Sketch. (a) A row $i > s$ is zero or has its leading entry in column $p_i \ge p_{s+1} > j$. (b) is (R2) with (R4). For (c), columns before p_s vanish in row s by (a), and so do their combinations, while $\mathbf{r}_{p_s} = \mathbf{e}_s$ does not. For a non-pivot column j with t pivot columns before it, $j < p_{t+1}$, so (a) and (b) give (d), which exhibits $\mathbf{r}_j$ as a combination of earlier columns.

By Theorem 3.3.12, R satisfies (R1)–(R4) and its pivots are its leading entries: the leading entry of row s is a 1 in column p_s for $s \le r$, and rows $r+1, \ldots, m$ are zero.

(a) Let $j < p_{s+1}$ and $i \ge s+1$. If $i \le r$, the leading entry of row i is in column $p_i \ge p_{s+1} > j$, so $r_{ij} = 0$. If $i > r$, row i is zero. So $r_{ij} = 0$ for all $i \ge s+1$.

(b) Column p_s contains the leading entry of row s, which is 1 by (R2), and its other entries are 0 by (R4).

(c), (d) Suppose first that $j = p_s$ is a pivot column. By (a), applied with $s-1$, every column $\mathbf{r}_l$ with $l < j$ has entry 0 in row s, and therefore so does every linear combination of $\mathbf{r}_1, \dots, \mathbf{r}_{j-1}$. But $\mathbf{r}_j = \mathbf{e}_s$ has entry 1 in row s. So $\mathbf{r}_j$ is not such a combination.

Now suppose j is not a pivot column, and let $p_1, \dots, p_t$ be the pivot columns to its left ($t = 0$ if there are none). Then $p_{t+1} > j$, so by (a) and (b),

$$\mathbf{r}_j = r_{1j}\mathbf{e}_1 + \cdots + r_{tj}\mathbf{e}_t = r_{1j}\mathbf{r}_{p_1} + \cdots + r_{tj}\mathbf{r}_{p_t}.$$

This is (d), and since $p_1, \dots, p_t < j$, it shows that $\mathbf{r}_j$ is a combination of earlier columns. (For $t = 0$, it says $\mathbf{r}_j = \mathbf{0}$, the empty combination.) Together with the first case, this proves (c). □

So a matrix in RREF records two kinds of information: *which* columns are new, in the sense of not being combinations of earlier columns (the pivot columns, which are $\mathbf{e}_1, \mathbf{e}_2, \dots$ in order), and *how* each other column is built from the pivot columns before it (its entries).

> *Intuition (Two strategies for uniqueness).* We want to show: if R and $R' = GR$ are both in RREF and G is invertible, then $R = R'$. There are two natural ways to think about this.
>
> *Track G.* Left multiplication by G sends column p_s of R, which is $\mathbf{e}_s$, to column p_s of R'. If we knew that R' had its pivots in the same columns, that column would be $\mathbf{e}_s$ too, so $G\mathbf{e}_s = \mathbf{e}_s$: the first r columns of G are $\mathbf{e}_1, \dots, \mathbf{e}_r$. Then G fixes every vector in $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_r)$, which contains every column of R, so $GR = R$. So everything comes down to showing that the pivot columns agree, and it is natural to do this one pivot at a time, from left to right, using invertibility of G to rule out a pivot that appears earlier in one matrix than in the other. This is an induction on the pivots.
>
> *Forget G.* Row operations preserve the linear relations among the columns (Corollary 3.2.17). By Lemma 3.3.16, these relations determine which columns are pivot columns, and how the other columns are expressed through them. So two RREF matrices with the same relations among their columns are equal.
>
> The first approach gives information about G that the second does not; the second is shorter and proves a stronger statement (Corollary 3.3.20).

Theorem 3.3.17 (Uniqueness of the reduced row echelon form). Let $R, R' \in F^{m\times n}$ be in RREF, and suppose $R' = GR$ for some invertible $G \in F^{m\times m}$. Then $R' = R$.

Proof (pivot by pivot). HARD

> *Uses.* Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.3.8 (Matrix–vector product), Definition 2.5.12 (Invertible), induction on s
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* Let $\mathbf{g}_1, \dots, \mathbf{g}_m$ be the columns of G. Column j of R' is $G\mathbf{r}_j = r_{1j}\mathbf{g}_1 + \cdots + r_{mj}\mathbf{g}_m$. Why are the $\mathbf{g}_i$ linearly independent?
> *Hint 2.* Let p_s and q_s be the pivot columns of R and R' (with value $n+1$ when there are fewer than s pivots). Prove by induction on s that $p_s = q_s$, and that $\mathbf{g}_s = \mathbf{e}_s$ when $p_s \le n$.
> *Hint 3.* If $p_s < q_s$, compute column p_s of R' in two ways: as $G\mathbf{e}_s = \mathbf{g}_s$, and with Lemma 3.3.16(a) for R'. If $q_s < p_s$, compute column q_s of R' in two ways and look at its sth entry.
> *Sketch.* The columns $\mathbf{g}_i$ of G are independent since $G\mathbf{c} = \mathbf{0}$ forces $\mathbf{c} = \mathbf{0}$. By induction on s: if $p_s < q_s$, then $\mathbf{g}_s = G\mathbf{e}_s$ is column p_s of R', which lies in the span of $\mathbf{e}_1, \dots, \mathbf{e}_{s-1}$, that is, of $\mathbf{g}_1, \dots, \mathbf{g}_{s-1}$: a contradiction. If $q_s < p_s$, column q_s of R lies in $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_{s-1})$, and G fixes that span, so column q_s of R' has sth entry 0, not $\mathbf{e}_s$. So $p_s = q_s$, and then $\mathbf{g}_s = G\mathbf{e}_s = \mathbf{e}_s$. Finally every column of R lies in $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_r)$, which G fixes.

Write $\mathbf{r}_j$, $\mathbf{r}'_j$, and $\mathbf{g}_i$ for the columns of R, R', and G, and $p_1 < \cdots < p_r$ and $q_1 < \cdots < q_{r'}$ for the pivot columns of R and R'. Put $p_s = n+1$ for $s > r$ and $q_s = n+1$ for $s > r'$. We use two facts.

- By Definition 2.3.8, column j of R' is

$$\mathbf{r}'_j = G\mathbf{r}_j = r_{1j}\mathbf{g}_1 + \cdots + r_{mj}\mathbf{g}_m.$$

In particular $G\mathbf{e}_i = \mathbf{g}_i$.

- The columns of G are linearly independent: if $c_1\mathbf{g}_1 + \cdots + c_m\mathbf{g}_m = \mathbf{0}$, then $G\mathbf{c} = \mathbf{0}$ for $\mathbf{c} = (c_1, \ldots, c_m)$, so $\mathbf{c} = G^{-1}G\mathbf{c} = \mathbf{0}$.

We prove by induction on $s = 1, 2, \ldots, m$ that

$$p_s = q_s, \quad \text{and} \quad \mathbf{g}_s = \mathbf{e}_s \text{ if } p_s \le n.$$

Fix s, and assume this holds for every $t < s$.

Suppose $p_s < q_s$. Then $p_s \le n$, so $s \le r$, and for $t < s$ we have $p_t < p_s \le n$, hence $q_t = p_t \le n$ and $\mathbf{g}_t = \mathbf{e}_t$ by the induction hypothesis. By Lemma 3.3.16(b), $\mathbf{r}'_{p_s} = G\mathbf{r}_{p_s} = G\mathbf{e}_s = \mathbf{g}_s$. On the other hand $p_s < q_s$, so by Lemma 3.3.16(a) for R', the column $\mathbf{r}'_{p_s}$ lies in $\operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{s-1})$, which is $\operatorname{span}(\mathbf{g}_1, \ldots, \mathbf{g}_{s-1})$. So $\mathbf{g}_s$ is a linear combination of $\mathbf{g}_1, \ldots, \mathbf{g}_{s-1}$, contradicting the independence of the columns of G.

Suppose $q_s < p_s$. Then $q_s \le n$, so $s \le r'$, and for $t < s$, $q_t < q_s \le n$; by the induction hypothesis $p_t = q_t \le n$ and $\mathbf{g}_t = \mathbf{e}_t$. By Lemma 3.3.16(a) for R, $\mathbf{r}_{q_s} = \sum_{t<s} r_{tq_s}\mathbf{e}_t$, so

$$\mathbf{r}'_{q_s} = G\mathbf{r}_{q_s} = \sum_{t<s} r_{tq_s}\mathbf{g}_t = \sum_{t<s} r_{tq_s}\mathbf{e}_t,$$

whose sth entry is 0. But $\mathbf{r}'_{q_s} = \mathbf{e}_s$ by Lemma 3.3.16(b) for R', a contradiction.

Hence $p_s = q_s$. If this number is at most n, then by Lemma 3.3.16(b) for both matrices, $\mathbf{e}_s = \mathbf{r}'_{p_s} = G\mathbf{r}_{p_s} = G\mathbf{e}_s = \mathbf{g}_s$. This completes the induction.

In particular $r = r'$, since r is the number of s with $p_s \le n$, and $\mathbf{g}_s = \mathbf{e}_s$ for $s \le r$. Finally, let j be any column. By Lemma 3.3.16(a) with $s = r$, $\mathbf{r}_j = \sum_{t\le r} r_{tj}\mathbf{e}_t$, so

$$\mathbf{r}'_j = G\mathbf{r}_j = \sum_{t\le r} r_{tj}\mathbf{g}_t = \sum_{t\le r} r_{tj}\mathbf{e}_t = \mathbf{r}_j.$$

So $R' = R$, as desired. □

Proof (via relations among columns). HARD

> *Uses.* Corollary 3.2.17 (Row operations preserve relations among columns), Lemma 3.3.16 (Reading the columns of a matrix in RREF)
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* By Corollary 3.2.17, R and $R' = GR$ satisfy the same linear relations among their columns. Use only this.
> *Hint 2.* By Lemma 3.3.16(c), being a pivot column is a statement about relations among the columns. Conclude that R and R' have the same pivot columns.
> *Hint 3.* A non-pivot column of R satisfies the relation of Lemma 3.3.16(d). Transfer that relation to R'.
> *Sketch.* The columns satisfy $\sum_l x_l\mathbf{r}_l = \mathbf{0} \Leftrightarrow \sum_l x_l\mathbf{r}'_l = \mathbf{0}$. "Column j is a combination of earlier columns" is such a relation, so by Lemma 3.3.16(c) the pivot columns agree, and pivot columns are $\mathbf{e}_s$ in both. A non-pivot column satisfies $\mathbf{r}_j = \sum_s r_{sj}\mathbf{r}_{p_s}$; the same relation in R' gives $\mathbf{r}'_j = \sum_s r_{sj}\mathbf{e}_s = \mathbf{r}_j$.

Let $\mathbf{r}_j$ and $\mathbf{r}'_j = G\mathbf{r}_j$ be the columns of R and R'. By Corollary 3.2.17, for all $x_1, \ldots, x_n \in F$,

$$x_1\mathbf{r}_1 + \cdots + x_n\mathbf{r}_n = \mathbf{0} \quad \Leftrightarrow \quad x_1\mathbf{r}'_1 + \cdots + x_n\mathbf{r}'_n = \mathbf{0}. \tag{3.3.2}$$

We show that (3.3.2) alone forces $R = R'$.

The pivot columns agree. For scalars $c_1, \ldots, c_{j-1}$, the equation

$$\mathbf{r}_j = c_1\mathbf{r}_1 + \cdots + c_{j-1}\mathbf{r}_{j-1}$$

is the relation in (3.3.2) with $x_l = c_l$ for $l < j$, $x_j = -1$, and $x_l = 0$ for $l > j$. So it holds if and only if the same equation holds with $\mathbf{r}'$ in place of $\mathbf{r}$. Hence $\mathbf{r}_j$ is a linear combination of the earlier columns of R if and only if $\mathbf{r}'_j$ is a linear combination of the earlier columns of R'. By Lemma 3.3.16(c), applied to R and to R', column j is a pivot column of R if and only if it is a pivot column of R'. Let $p_1 < \cdots < p_r$ be the common pivot columns.

The columns agree. By Lemma 3.3.16(b), $\mathbf{r}_{p_s} = \mathbf{e}_s = \mathbf{r}'_{p_s}$ for each s. Let j be a non-pivot column, with pivot columns $p_1, \dots, p_t$ to its left. By Lemma 3.3.16(d) for R,

$$\mathbf{r}_j = r_{1j}\mathbf{r}_{p_1} + \cdots + r_{tj}\mathbf{r}_{p_t}.$$

This is a relation among the columns of R, so by (3.3.2) the same relation holds in R':

$$\mathbf{r}'_j = r_{1j}\mathbf{r}'_{p_1} + \cdots + r_{tj}\mathbf{r}'_{p_t} = r_{1j}\mathbf{e}_1 + \cdots + r_{tj}\mathbf{e}_t = \mathbf{r}_j,$$

where the last equality is Lemma 3.3.16(d) and (b) for R again. So every column of R' equals the corresponding column of R. □

The two proofs teach different things. The first shows how rigid G is: whenever GR is again in RREF, the first r columns of G are $\mathbf{e}_1, \dots, \mathbf{e}_r$, although its other columns can be anything that keeps G invertible (Exercise 3.3.46). The second never looks at G. It used only that R and R' satisfy the same linear relations among their columns, that is, that $\ker T_R = \ker T_{R'}$, and we will exploit this in Corollary 3.3.20.

Corollary 3.3.18 (RREF and row equivalence). Let $A, B \in F^{m\times n}$.

(a) $\operatorname{rref}(GA) = \operatorname{rref}(A)$ for every invertible $G \in F^{m\times m}$.

(b) $A \sim B$ if and only if $\operatorname{rref}(A) = \operatorname{rref}(B)$.

(c) If R is in RREF and $A \sim R$, then $R = \operatorname{rref}(A)$. In particular, any sequence of elementary row operations that turns A into a matrix satisfying (R1)–(R4), performed in any order and with any choices, ends at $\operatorname{rref}(A)$.

Proof. STANDARD

Uses. Theorem 3.3.17 (Uniqueness of the reduced row echelon form), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Theorem 3.3.12 (Matrices in RREF), Proposition 3.3.8 (Properties of the output), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.2.22 (Row equivalence is an equivalence relation), Definition 3.2.21 (Row equivalence)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), write $\operatorname{rref}(A) = NA$ and $\operatorname{rref}(GA) = MGA$ with M, N invertible, and express $\operatorname{rref}(GA)$ as an invertible matrix times $\operatorname{rref}(A)$.
Hint 2. For (b), use (a) in one direction, and $A \sim \operatorname{rref}(A)$ with symmetry and transitivity of $\sim$ in the other.
Sketch. (a) $\operatorname{rref}(GA) = \left(MGN^{-1}\right)\operatorname{rref}(A)$, both sides are in RREF, and MGN^{-1} is invertible, so Theorem 3.3.17 applies. (b) If $B = E_k \cdots E_1 A$, apply (a). If $\operatorname{rref}(A) = \operatorname{rref}(B)$, then $A \sim \operatorname{rref}(A) = \operatorname{rref}(B) \sim B$. (c) is (b) with $B = R$, since $\operatorname{rref}(R) = R$; matrices satisfying (R1)–(R4) are in RREF by Theorem 3.3.12.

(a) By Theorem 3.3.10 there are invertible $N, M \in F^{m\times m}$ with $\operatorname{rref}(A) = NA$ and $\operatorname{rref}(GA) = M(GA)$. Then

$$\operatorname{rref}(GA) = MGA = \left(MGN^{-1}\right)(NA) = \left(MGN^{-1}\right)\operatorname{rref}(A),$$

and MGN^{-1} is invertible, with inverse $NG^{-1}M^{-1}$. Both $\operatorname{rref}(GA)$ and $\operatorname{rref}(A)$ are in RREF (by Proposition 3.3.8 and Theorem 3.3.12), so Theorem 3.3.17 gives $\operatorname{rref}(GA) = \operatorname{rref}(A)$.

(b) If $A \sim B$, then $B = GA$ with $G = E_k \cdots E_1$ a product of elementary matrices, which is invertible, so $\operatorname{rref}(B) = \operatorname{rref}(A)$ by (a). Conversely, suppose $\operatorname{rref}(A) = \operatorname{rref}(B)$. By Theorem 3.3.10, $A \sim \operatorname{rref}(A)$ and $B \sim \operatorname{rref}(B)$, so by symmetry and transitivity (Proposition 3.2.22), $A \sim \operatorname{rref}(A) = \operatorname{rref}(B) \sim B$.

(c) If R is in RREF, then $\operatorname{rref}(R) = R$, and $A \sim R$ gives $\operatorname{rref}(A) = \operatorname{rref}(R) = R$ by (b). A sequence of row operations that turns A into a matrix R satisfying (R1)–(R4) shows $A \sim R$, and R is in RREF by Theorem 3.3.12. □

Part (c) settles the question from Remark 3.3.2. A run of the algorithm that makes other choices in step 2 still ends at a matrix satisfying (R1)–(R4), since the proofs of Lemma 3.3.7 and Proposition 3.3.8 never used which row was brought up; so it ends at $\operatorname{rref}(A)$. The same goes for Gaussian elimination followed by clearing upward (Section 3.3.6), and for any improvised hand computation. It also shows that the pivot columns, and their number, are determined by A. Here is a description of them that does not mention the algorithm at all.

Corollary 3.3.19 (Pivot columns, intrinsically). Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$, and let r_{ij} be the entries of $\operatorname{rref}(A)$.

(a) Column j is a pivot column of A if and only if $\mathbf{a}_j$ is not a linear combination of $\mathbf{a}_1, \dots, \mathbf{a}_{j-1}$.

(b) If column j is not a pivot column and $p_1, \dots, p_t$ are the pivot columns to its left, then

$$\mathbf{a}_j = r_{1j}\mathbf{a}_{p_1} + \cdots + r_{tj}\mathbf{a}_{p_t}.$$

Proof. ROUTINE

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Corollary 3.2.17 (Row operations preserve relations among columns), Lemma 3.3.16 (Reading the columns of a matrix in RREF)
Hint 1. Write $\operatorname{rref}(A) = GA$. How are the columns of $\operatorname{rref}(A)$ related to those of A, and which relations do they share?
Hint 2. Combine Corollary 3.2.17(b) with Lemma 3.3.16(c) and (d).
Sketch. With $\operatorname{rref}(A) = GA$ and G invertible, the columns $\mathbf{r}_l = G\mathbf{a}_l$ satisfy the same relations as the $\mathbf{a}_l$. So $\mathbf{a}_j$ is a combination of earlier columns, with given coefficients, exactly when $\mathbf{r}_j$ is; now apply Lemma 3.3.16(c) and (d).

By Theorem 3.3.10, $\operatorname{rref}(A) = GA$ with G invertible, so the columns of $\operatorname{rref}(A)$ are $\mathbf{r}_l = G\mathbf{a}_l$. By Corollary 3.2.17(b), applied with $c_l = 0$ for $l > j$, we have $\mathbf{a}_j = \sum_{l<j} c_l\mathbf{a}_l$ if and only if $\mathbf{r}_j = \sum_{l<j} c_l\mathbf{r}_l$. So $\mathbf{a}_j$ is a combination of $\mathbf{a}_1, \dots, \mathbf{a}_{j-1}$ if and only if $\mathbf{r}_j$ is a combination of $\mathbf{r}_1, \dots, \mathbf{r}_{j-1}$, and (a) follows from Lemma 3.3.16(c). Similarly, (b) follows from the relation of Lemma 3.3.16(d). □

For the matrix of Example 3.3.3, the pivot columns are 1 and 3, and Corollary 3.3.19(b) reads off $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_4 = -2\mathbf{a}_1 + 2\mathbf{a}_3$ from the entries of $\operatorname{rref}(A)$. Indeed $-2(0,2,1) + 2(2,2,3) = (4,0,4)$. Chapter 4 uses this description to extract bases from spanning lists.

Finally, we can prove the converse promised in Remark 3.2.25.

Corollary 3.3.20 (The kernel is a complete invariant). For $A, B \in F^{m\times n}$, the following are equivalent:

(i) $A \sim B$;
(ii) $\operatorname{rref}(A) = \operatorname{rref}(B)$;
(iii) $\ker T_A = \ker T_B$.

Proof. STANDARD

Uses. Corollary 3.3.18 (RREF and row equivalence), Corollary 3.2.23 (Row equivalent matrices have the same kernel), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Definition 2.3.8 (Matrix–vector product), Theorem 3.3.17 (Uniqueness of the reduced row echelon form)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. (i) ⇔ (ii) is Corollary 3.3.18(b), and (i) ⇒ (iii) is Corollary 3.2.23. Only (iii) ⇒ (ii) is new.
Hint 2. Reduce to RREF: $\ker T_{\operatorname{rref}(A)} = \ker T_A$. What does $\mathbf{x} \in \ker T_R$ say about the columns of R?
Hint 3. Reread the second proof of Theorem 3.3.17. Which hypothesis did it really use?
Sketch. If $\ker T_A = \ker T_B$, then $R = \operatorname{rref}(A)$ and $R' = \operatorname{rref}(B)$ have the same kernel by Corollary 3.2.23. By Definition 2.3.8, $\mathbf{x} \in \ker T_R$ says $x_1\mathbf{r}_1 + \cdots + x_n\mathbf{r}_n = \mathbf{0}$, so R and R' satisfy the same linear relations among their columns. The second proof of Theorem 3.3.17 used nothing else, so $R = R'$.

(i) ⇔ (ii) is Corollary 3.3.18(b), and (i) ⇒ (iii) is Corollary 3.2.23. We prove (iii) ⇒ (ii).

Suppose $\ker T_A = \ker T_B$, and let $R = \operatorname{rref}(A)$ and $R' = \operatorname{rref}(B)$. By Theorem 3.3.10 and Corollary 3.2.23, $\ker T_R = \ker T_A = \ker T_B = \ker T_{R'}$. By Definition 2.3.8, $R\mathbf{x} = x_1\mathbf{r}_1 + \cdots + x_n\mathbf{r}_n$, so $\ker T_R = \ker T_{R'}$ says exactly that for all $x_1, \dots, x_n \in F$,

$$x_1\mathbf{r}_1 + \cdots + x_n\mathbf{r}_n = \mathbf{0} \quad \Leftrightarrow \quad x_1\mathbf{r}'_1 + \cdots + x_n\mathbf{r}'_n = \mathbf{0},$$

where $\mathbf{r}_l$ and $\mathbf{r}'_l$ are the columns of R and R'. This is (3.3.2). The second proof of Theorem 3.3.17 deduced $R = R'$ from (3.3.2) and Lemma 3.3.16 alone, so $R = R'$. □

So the kernel of T_A, a subspace of F^n, determines the row equivalence class of A among $m \times n$ matrices, and $\operatorname{rref}(A)$ is a canonical representative of that class. For example, a 2×3 matrix A has $\ker T_A = \operatorname{span}((1,1,1))$ if and only if $\operatorname{rref}(A) = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix}$ (Exercise 3.3.49).

Exercise 3.3.21. ROUTINE Decide which two of the following real matrices are row equivalent:

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 7 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 2 & 2 \end{pmatrix}, \quad C = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 6 & 9 \end{pmatrix}.$$

Solution on page 1225

3.3.5 Inverses by row reduction

For a square matrix A, row reduction decides whether A is invertible and, if it is, computes A^{-1}. The idea is one we will use again and again: invertibility does not change when A is multiplied on the left by an invertible matrix, and for a matrix in RREF it is visible at a glance.

Technique 3.3.22 (Reduce to RREF). Many properties of a matrix A do not change when A is replaced by GA with G invertible: for example, the kernel $\ker T_A$ (Corollary 3.2.23), the linear relations among the columns (Corollary 3.2.17), and, for square A, invertibility. To decide such a property, replace A by $\operatorname{rref}(A) = GA$ (Theorem 3.3.10), where the answer can be read off the pivots and the zero rows. Two things have to be checked: that the property really is unchanged by left multiplication by invertible matrices, and what the property says about a matrix in RREF.

Reach for it whenever a question about A is really about $\ker T_A$, about relations among the columns of A, or about solutions of $A\mathbf{x} = \mathbf{y}$ (where $\mathbf{y}$ must be replaced by $G\mathbf{y}$, Proposition 3.2.14). The canonical example is Theorem 3.3.23. It is the method of Section 3.4 and Section 3.5, and later of rank–nullity (Section 4.2) and of the equality of row rank and column rank (Section 4.3).

Used in. Corollary 3.3.20, Theorem 3.3.23, Proposition 3.4.1, Corollary 3.4.4, Theorem 3.4.9, Proposition 3.4.15, Proposition 3.4.16, Corollary 3.4.20, Exercise 3.4.45, Theorem 3.5.19, Theorem 3.5.27, Exercise 3.6.6, Exercise 3.6.7, Exercise 3.6.9, Exercise 3.6.10, Problem 3.3, Problem 3.4, Problem 3.5, Problem 3.6, Problem 3.8, Problem 3.10, Problem 3.11, Problem 3.12, Problem 3.14, Problem 3.17, Theorem 4.2.7, Theorem 4.2.11, Theorem 4.3.8, Problem 4.6, Exercise 3.3.49, Exercise 3.3.50, Exercise 3.5.42, Exercise 3.5.45.

Theorem 3.3.23 (Invertibility and RREF). Let $A \in F^{n \times n}$, and let G be a product of elementary matrices with $GA = \operatorname{rref}(A)$ (Theorem 3.3.10). Then A is invertible if and only if $\operatorname{rref}(A) = I_n$, and in that case $A^{-1} = G$.

Proof. STANDARD

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.3.8 (Properties of the output), Definition 2.5.12 (Invertible)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. If $\operatorname{rref}(A) = I_n$, then $GA = I_n$ with G invertible. Why does this make G a two-sided inverse of A?
Hint 2. Conversely, a square matrix in RREF with n pivots is I_n. If there are fewer pivots, what does the last row look like?
Hint 3. A matrix whose last row is zero has no right inverse. If A were invertible, would GA be?
Sketch. If $GA = I_n$, then $A = G^{-1}$, so $AG = I_n$ too and $A^{-1} = G$. If $R = \operatorname{rref}(A)$ has n pivots, its pivot columns are $1, \dots, n$ and $R = I_n$. Otherwise its last row is zero, so the last row of RX is zero for every X and R is not invertible; but if A were invertible, $R = GA$ would be.

Suppose $\operatorname{rref}(A) = I_n$, so $GA = I_n$. Since G is invertible (Corollary 3.2.11), multiplying on the left by G^{-1} gives $A = G^{-1}$. Hence $AG = G^{-1}G = I_n$ as well, so A is invertible with $A^{-1} = G$.

Conversely, suppose $R = \operatorname{rref}(A) \neq I_n$, and let $p_1 < \cdots < p_r$ be its pivot columns. If $r = n$, then $p_1, \dots, p_n$ are n increasing numbers among $1, \dots, n$, so $p_s = s$ for every s, and by Proposition 3.3.8(c) column s of R is $\mathbf{e}_s$; that is, $R = I_n$, which we have excluded. So $r < n$, and row n of R is zero by Proposition 3.3.8(a). Then for every

$X \in F^{n\times n}$, the (n,l) entry of RX is $\sum_k r_{nk}x_{kl} = 0$, so $RX \neq I_n$; thus R is not invertible. If A were invertible, then $R = GA$ would be invertible, with inverse $A^{-1}G^{-1}$. So A is not invertible. □

This gives an algorithm. To find the operations of the run and their product G at the same time, we carry I_n along as in Proposition 3.3.11.

Algorithm 3.3.24 (Inverting a matrix by row reduction)

Input A square matrix $A \in F^{n\times n}$.
Output A^{-1}, or the conclusion that A is not invertible.

1. Form the $n \times 2n$ matrix $(A \mid I_n)$.
2. Row reduce it with Gauss–Jordan elimination, scanning only the first n columns in step 1 of Algorithm 3.3.1. The result is $(\mathrm{rref}(A) \mid G)$.
3. If the left block is I_n, output $A^{-1} = G$. Otherwise A is not invertible.

The algorithm is correct by Proposition 3.3.11 and Theorem 3.3.23. Two practical remarks. If A is invertible, all n pivots lie in the left block, so restricting the scan makes no difference; it only matters when A is not invertible. And one may stop as soon as the left block acquires a zero row: at that moment the left block is $G'A$ with G' invertible, and a matrix with a zero row is not invertible (as in the proof above), so neither is A.

Intuition (Why carrying I_n along works). Column j of A^{-1} is the solution of $A\mathbf{x} = \mathbf{e}_j$, since $A\big(A^{-1}\mathbf{e}_j\big) = \mathbf{e}_j$. So inverting A means solving the n systems $A\mathbf{x} = \mathbf{e}_1, \ldots, A\mathbf{x} = \mathbf{e}_n$, which share the coefficient matrix A. Row reducing $(A \mid I_n)$ solves all of them at once: when the left block becomes I_n, the system $A\mathbf{x} = \mathbf{e}_j$ has become $I_n\mathbf{x} = G\mathbf{e}_j$ (Proposition 3.2.14), whose solution, column j of G, can be read off.

Example 3.3.25 (Inverting a 3×3 matrix). Let

$$A = \begin{pmatrix} 0 & 2 & 1 \\ 1 & 1 & 0 \\ 2 & 1 & 0 \end{pmatrix} \in \mathbb{Q}^{3\times 3}.$$

Swapping rows 1 and 2 of $(A \mid I_3)$ and then adding -2 times row 1 to row 3 finishes pass 1:

$$\left(\begin{array}{ccc|ccc} 0 & 2 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 2 & 1 & 0 & 0 & 0 & 1 \end{array}\right) \xrightarrow{E_{12}} \left(\begin{array}{ccc|ccc} 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 2 & 1 & 1 & 0 & 0 \\ 2 & 1 & 0 & 0 & 0 & 1 \end{array}\right)$$

$$\xrightarrow{E_{1,-2,3}} \left(\begin{array}{ccc|ccc} 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 2 & 1 & 1 & 0 & 0 \\ 0 & -1 & 0 & 0 & -2 & 1 \end{array}\right).$$

Pass 2 scales row 2 by $1/2$ and clears column 2 with $E_{2,-1,1}$ and $E_{2,1,3}$; pass 3 scales row 3 by 2 and clears column 3 with $E_{3,1/2,1}$ and $E_{3,-1/2,2}$:

$$\longrightarrow \left(\begin{array}{ccc|ccc} 1 & 0 & -1/2 & -1/2 & 1 & 0 \\ 0 & 1 & 1/2 & 1/2 & 0 & 0 \\ 0 & 0 & 1/2 & 1/2 & -2 & 1 \end{array}\right)$$

$$\longrightarrow \left(\begin{array}{ccc|ccc} 1 & 0 & 0 & 0 & -1 & 1 \\ 0 & 1 & 0 & 0 & 2 & -1 \\ 0 & 0 & 1 & 1 & -4 & 2 \end{array}\right).$$

The left block is I_3, so A is invertible and

$$A^{-1} = \begin{pmatrix} 0 & -1 & 1 \\ 0 & 2 & -1 \\ 1 & -4 & 2 \end{pmatrix}.$$

As a check, the first row of A times the columns of A^{-1} gives $(0+0+1, 0+4-4, 0-2+2) = (1,0,0)$, and similarly for the other rows. Fractions appeared along the way even though A and A^{-1} have integer entries; Exercise 3.3.61 explains when integer arithmetic suffices.

$$(A \mid I_3) \rightsquigarrow \left(\begin{array}{ccc|ccc} 1 & 0 & 0 & 0 & -1 & 1 \\ 0 & 1 & 0 & 0 & 2 & -1 \\ 0 & 0 & 1 & 1 & -4 & 2 \end{array}\right)$$

Inverting the matrix of Example 3.3.25: $(A \mid I_3)$ is row reduced, with pivots sought only in the left block. Edit the left block to try other matrices; when it does not reduce to I_3, the summary says that A is not invertible. (Interactive in the web version.)

Example 3.3.26 (A matrix that is not invertible). Let $A \in \mathbb{Q}^{3\times 3}$ have rows $(1,2,3)$, $(4,5,6)$, $(7,8,9)$. The algorithm gives

$$(A \mid I_3) \rightsquigarrow \left(\begin{array}{ccc|ccc} 1 & 0 & -1 & -5/3 & 2/3 & 0 \\ 0 & 1 & 2 & 4/3 & -1/3 & 0 \\ 0 & 0 & 0 & 1 & -2 & 1 \end{array}\right).$$

The left block is not I_3, so A is not invertible. The last row of G says more: since the last row of GA is zero, row 1 of A minus twice row 2 plus row 3 is zero, which is easy to confirm.

For square matrices, Theorem 3.3.23 says in particular that an invertible matrix is row equivalent to I_n. Section 3.5 turns this into the statement that every invertible matrix is a product of elementary matrices (Theorem 3.5.19), and fits it into the Fundamental Theorems. Also note that in the proof, $GA = I_n$ was enough to conclude $AG = I_n$, because G was known to be invertible. That a one-sided inverse of a square matrix is always two-sided is Theorem 3.5.23.

Exercise 3.3.27. ROUTINE Let

$$A = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

Use Algorithm 3.3.24 to decide whether A is invertible over $\mathbb{Q}$, and over $\mathbb{F}_3$, and find A^{-1} when it exists.

Solution on page 1226

3.3.6 Row echelon form BEYOND 21-242

Echelon forms and triangular factorizations are standard in LADW and in numerical linear algebra, but not part of the course.

Clearing above the pivots is not needed to solve a system: once each pivot has zeros below it, the equations can be solved from the bottom up. This gives a cheaper algorithm and a weaker normal form.

Definition 3.3.28 (Row echelon form). A matrix $U \in F^{m\times n}$ is in **row echelon form** if it satisfies (R1) and (R3): every zero row lies below every nonzero row, and the leading entry of each nonzero row lies strictly to the right of the leading entry of every row above it. The leading entries of the nonzero rows are the **pivots** of U. A **row echelon form of** A is a matrix in row echelon form that is row equivalent to A.

Gaussian elimination is Algorithm 3.3.1 with two changes: step 3 of Algorithm 3.3.1 only declares the pivot, without scaling, and step 4 of Algorithm 3.3.1 clears only the rows *below* row k. If the pivot is a and row $i > k$ has entry c in the pivot column, the pass adds $-\ell_{ik}$ times row k to row i, where $\ell_{ik} = c/a$ is the **multiplier**. The proof of Lemma 3.3.7 goes through with (c) weakened to "column p_s of M has a nonzero entry in row s and zeros below it" (a pivot row is never changed after its own pass), and as in Proposition 3.3.8 the output is a row echelon form of A.

Example 3.3.29 (Row echelon forms are not unique). Let $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$ over $\mathbb{Q}$. Gaussian elimination gives $\begin{pmatrix} 1 & 2 \\ 0 & -2 \end{pmatrix}$. Swapping the rows first and then clearing gives $\begin{pmatrix} 3 & 4 \\ 0 & 2/3 \end{pmatrix}$, and $\operatorname{rref}(A) = I_2$ is also a row echelon form of A. All three have their pivots in columns 1 and 2.

The pivot positions, unlike the entries, are always the same.

Proposition 3.3.30 (Pivots of row echelon forms). If U is a row echelon form of A, then the columns containing the pivots of U are the pivot columns of A.

Proof. STANDARD

Uses. Corollary 3.3.18 (RREF and row equivalence), Theorem 3.3.12 (Matrices in RREF)
Hint 1. Turn U into a matrix in RREF by row operations that do not move any leading entry.
Hint 2. Scale each nonzero row by the inverse of its leading entry. Then clear above the pivots, one pivot at a time. Check that clearing column c_s never disturbs a leading entry or a column cleared earlier.
Sketch. Scaling makes the leading entries 1. Clearing above the pivots (say from the last one up) only adds multiples of a pivot row to rows above it, which changes those rows only to the right of their own leading entries, and never refills a column already cleared, since a pivot row is zero in the columns of later pivots once those are cleared. The result satisfies (R1)–(R4), has the same leading positions as U, and is row equivalent to A, so it is $\operatorname{rref}(A)$.

Let rows $1, \dots, r$ be the nonzero rows of U, with leading entries in columns $c_1 < \cdots < c_r$. First scale each row $s \le r$ by the inverse of its leading entry. Then, for $s = r, r-1, \dots, 1$ in this order, add suitable multiples of row s to rows $1, \dots, s-1$ so that column c_s has zeros above row s. Row s vanishes in the columns before c_s, so adding a multiple of it to a row $i < s$ changes row i only in columns $c_s, \dots, n$, all to the right of c_i. Moreover, when we process s, row s has already been cleared in the columns $c_{s+1}, \dots, c_r$ (it lies above those pivots), so the columns cleared earlier are not disturbed. The final matrix R therefore satisfies (R1)–(R4) with leading entries in columns $c_1, \dots, c_r$, and it is row equivalent to U, hence to A. By Corollary 3.3.18(c), $R = \operatorname{rref}(A)$, so $c_1, \dots, c_r$ are the pivot columns of A (Theorem 3.3.12). □

The second phase of this proof, scaling and clearing upward from the last pivot, is called **back substitution**. Gaussian elimination followed by back substitution is the usual way of computing $\operatorname{rref}(A)$ by hand, and by Corollary 3.3.18 it gives the same answer as Gauss–Jordan elimination.

3.3.7 LU and PLU factorizations BEYOND 21-242

Suppose we must solve $A\mathbf{x} = \mathbf{y}$ for one A and many right-hand sides $\mathbf{y}$, as happens constantly in applications. The work of elimination is almost all spent on A and does not depend on $\mathbf{y}$, so it is worth recording once and for all. Gaussian elimination without swaps only adds multiples of a row to rows *below* it, and the elementary matrices of such operations are lower triangular. This suggests factoring A into triangular pieces.

Definition 3.3.31 (Triangular matrices). A matrix $L \in F^{n \times n}$ is **lower triangular** if $l_{ij} = 0$ whenever $i < j$, and **unit lower triangular** if moreover $l_{ii} = 1$ for every i. **Upper triangular** and **unit upper triangular** matrices are defined in the same way with $i > j$. A **diagonal** matrix is one that is both.

Lemma 3.3.32 (Products and inverses of triangular matrices).

(a) If $L, L' \in F^{n\times n}$ are lower triangular, then so is LL', and $(LL')_{ii} = l_{ii}l'_{ii}$.

(b) A unit lower triangular matrix is invertible, and its inverse is unit lower triangular.

(c) The same statements hold for upper triangular matrices.

Proof. STANDARD

Uses. Definition 2.4.1 (Matrix product), Proposition 3.2.7 (Row operations are left multiplications), Corollary 3.2.11 (Products of elementary matrices), Proposition 2.4.23 (Transpose of a product)
Hint 1. For (a), in $(LL')_{ij} = \sum_k l_{ik}l'_{kj}$, which k can give a nonzero term?
Hint 2. For (b), reduce L to I_n by clearing below the diagonal one column at a time, from left to right, and check that every elementary matrix used is unit lower triangular.
Sketch. (a) A term $l_{ik}l'_{kj}$ can be nonzero only if $j \le k \le i$. (b) When column s is processed, row s is $\mathbf{e}_s^{\mathsf{T}}$, so adding multiples of it to the rows below only kills the entries below the diagonal in column s. This gives $GL = I_n$ with G a product of matrices E_{sci}, $s < i$, which are unit lower triangular; so $L^{-1} = G$ is unit lower triangular by (a). (c) Transpose.

(a) We have $(LL')_{ij} = \sum_k l_{ik}l'_{kj}$, and $l_{ik}l'_{kj}$ can be nonzero only if $k \le i$ and $k \ge j$. If $i < j$ there is no such k, so $(LL')_{ij} = 0$. If $i = j$, only $k = i$ contributes, giving $l_{ii}l'_{ii}$.

(b) Let L be unit lower triangular. For $s = 1, \dots, n-1$ in turn, and for each $i > s$, add $-c$ times row s to row i, where c is the current (i, s) entry. We claim that just before column s is processed, the current matrix is unit lower triangular with columns $1, \dots, s-1$ equal to $\mathbf{e}_1, \dots, \mathbf{e}_{s-1}$. This holds for $s = 1$. If it holds for s, then row s has zeros in columns $1, \dots, s-1$ (as those columns are $\mathbf{e}_1, \dots, \mathbf{e}_{s-1}$), a 1 in column s, and zeros after it; so row s is $\mathbf{e}_s^{\mathsf{T}}$. Adding a multiple of it to row $i > s$ changes only the (i, s) entry, which becomes 0. So afterwards column s is $\mathbf{e}_s$ and the claim holds for $s + 1$. At the end the matrix is I_n, so $GL = I_n$, where G is the product of the elementary matrices E_{sci} with $s < i$ that were used. Each of these is unit lower triangular (its only off-diagonal entry is in position (i, s)), so G is unit lower triangular by (a). Since G is invertible (Corollary 3.2.11), $L = G^{-1}$, and $L^{-1} = G$.

(c) A matrix is (unit) upper triangular if and only if its transpose is (unit) lower triangular. If U, U' are upper triangular, then $UU' = \left(U'^{\mathsf{T}}U^{\mathsf{T}}\right)^{\mathsf{T}}$ by Proposition 2.4.23, which is upper triangular by (a), with the same diagonal entries. If U is unit upper triangular, then U^{T} has a unit lower triangular inverse V by (b), and transposing $U^{\mathsf{T}}V = VU^{\mathsf{T}} = I_n$ shows that V^{T}, which is unit upper triangular, is the inverse of U. □

A **permutation matrix** is a product of swap matrices E_{ij} (equivalently, a matrix with exactly one 1 in each row and each column and zeros elsewhere; see Definition 5.2.29).

Theorem 3.3.33 (PLU and LU factorizations). Let $A \in F^{m\times n}$.

(a) There are a permutation matrix $P \in F^{m\times m}$, a unit lower triangular $L \in F^{m\times m}$, and a matrix $U \in F^{m\times n}$ in row echelon form such that $PA = LU$.

(b) If Gaussian elimination on A never needs a swap, then $A = LU$, where U is the output of Gaussian elimination and the entry of L in position (i, s), for $i > s$, is the multiplier ℓ_{is} of pass s (and 0 if there is no pass s).

Proof. HARD

Uses. Definition 2.4.33 (Block matrix), Definition 3.3.31 (Triangular matrices), Definition 3.3.28 (Row echelon form), Definition 5.2.29 (Permutation matrix), induction on m
Hint 1. Induct on the number of rows. Perform the first pass of Gaussian elimination and write the result in block form.
Hint 2. After moving a row with a nonzero entry a in the first nonzero column j to the top, write the first pass of Gaussian elimination as a factorization $P_1A = \begin{pmatrix} 1 & 0 \\ \ell & I \end{pmatrix}\begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & A' \end{pmatrix}$.
Hint 3. Apply the induction hypothesis $P'A' = L'U'$ and assemble P, L, U in block form. Where does P' have to act on ℓ?
Sketch. Bring a nonzero entry a of the first nonzero column j to the top with a swap P_1. With $\mathbf{b}$ the rest of column j and $\ell = a^{-1}\mathbf{b}$, $P_1A = \begin{pmatrix} 1 & 0 \\ \ell & I \end{pmatrix}\begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & A' \end{pmatrix}$, the first pass of elimination. If $P'A' = L'U'$, then $P = \begin{pmatrix} 1 & 0 \\ 0 & P' \end{pmatrix}P_1$, $L = \begin{pmatrix} 1 & 0 \\ P'\ell & L' \end{pmatrix}$,

$U = \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & U' \end{pmatrix}$ work, by block multiplication. Without swaps $P = I_m$, and the columns of L are the multipliers, pass by pass.

(a) We induct on m. If $m = 1$, take $P = L = (1)$ and $U = A$; a single row is in row echelon form. Let $m \geq 2$. If $A = 0$, take $P = L = I_m$ and $U = 0$. Otherwise, let j be the first nonzero column of A, choose a row i with $a_{ij} \neq 0$, and let $P_1 = E_{1i}$ (or $P_1 = I_m$ if $i = 1$). Then $B = P_1 A$ has first $j-1$ columns zero and a nonzero entry $a = b_{1j}$. Write

$$B = \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & \mathbf{b} & B' \end{pmatrix},$$

where the zero blocks have $j-1$ columns, $\mathbf{b} \in F^{m-1}$ is the rest of column j, $\mathbf{w} \in F^{1\times(n-j)}$, and $B' \in F^{(m-1)\times(n-j)}$. Let $\ell = a^{-1}\mathbf{b}$ and $A' = B' - \ell\mathbf{w}$. Multiplying blockwise (Definition 2.4.33),

$$B = \begin{pmatrix} 1 & 0 \\ \ell & I_{m-1} \end{pmatrix} \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & A' \end{pmatrix}, \tag{3.3.3}$$

since the lower blocks of the product are $\ell a = \mathbf{b}$ and $\ell\mathbf{w} + A' = B'$. (The right factor is the result of the first pass of Gaussian elimination on B.) If $j = n$, the blocks $\mathbf{w}$, B', A' are empty, and (3.3.3) is the required factorization with $P = P_1$. If $j < n$, the induction hypothesis gives a permutation matrix P', a unit lower triangular L', and a row echelon form U' with $P'A' = L'U'$. Put

$$P = \begin{pmatrix} 1 & 0 \\ 0 & P' \end{pmatrix} P_1, \quad L = \begin{pmatrix} 1 & 0 \\ P'\ell & L' \end{pmatrix}, \quad U = \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & U' \end{pmatrix}.$$

By (3.3.3) and blockwise multiplication,

$$PA = \begin{pmatrix} 1 & 0 \\ 0 & P' \end{pmatrix} B = \begin{pmatrix} 1 & 0 \\ P'\ell & P' \end{pmatrix} \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & A' \end{pmatrix} = \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & P'\ell a & P'\ell\mathbf{w} + P'A' \end{pmatrix},$$

$$LU = \begin{pmatrix} 1 & 0 \\ P'\ell & L' \end{pmatrix} \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & 0 & U' \end{pmatrix} = \begin{pmatrix} 0 & a & \mathbf{w} \\ 0 & P'\ell a & P'\ell\mathbf{w} + L'U' \end{pmatrix},$$

and these agree because $P'A' = L'U'$. Here L is unit lower triangular because L' is. P is a permutation matrix, because if P' is a product of swaps E_{kl} of size $m-1$, then $\begin{pmatrix} 1 & 0 \\ 0 & P' \end{pmatrix}$ is the product of the swaps $E_{(k+1)(l+1)}$ of size m. Finally, U is in row echelon form: its first row has leading entry a in column j, its other rows vanish in columns $1, \ldots, j$, and below the first row it has the shape of U', which is in row echelon form.

(b) If Gaussian elimination needs no swaps, then at every stage of the induction the $(1, j)$ entry is already nonzero and we may take $P_1 = I$; then $P = I_m$. In (3.3.3) the entries of $\ell = a^{-1}\mathbf{b}$ are the multipliers of the first pass, and A' is the lower right part of the matrix after the first pass, on which the later passes operate. So by induction column s of L holds the multipliers of pass s below the diagonal, and U is the output of Gaussian elimination. □

Example 3.3.34 (An LU factorization). Let

$$A = \begin{pmatrix} 2 & 1 & 1 \\ 4 & 3 & 3 \\ 8 & 7 & 9 \end{pmatrix}.$$

Pass 1 uses the multipliers $\ell_{21} = 2$ and $\ell_{31} = 4$ and leaves rows $(0, 1, 1)$ and $(0, 3, 5)$; pass 2 uses $\ell_{32} = 3$ and leaves $(0, 0, 2)$. So

$$A = LU = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 4 & 3 & 1 \end{pmatrix}\begin{pmatrix} 2 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix}.$$

The multipliers drop into L with no further computation. By contrast, $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has no LU factorization: if $\left(\begin{smallmatrix} 1 & 0 \\ \ell & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} u & v \\ 0 & w \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, then $u = 0$ from the $(1,1)$ entry, and then the $(2,1)$ entry is $\ell u = 0 \neq 1$. A swap is unavoidable here, and $P = E_{12}$ gives $PA = I_2 = I_2 I_2$.

Once $PA = LU$ is known, $A\mathbf{x} = \mathbf{y}$ is equivalent to $L(U\mathbf{x}) = P\mathbf{y}$. One solves $L\mathbf{z} = P\mathbf{y}$ from the top down (z_1 first, then z_2, and so on: **forward substitution**) and then $U\mathbf{x} = \mathbf{z}$ from the bottom up (back substitution). For $A \in F^{n\times n}$ each of these costs about n^2 arithmetic operations, while the factorization itself costs a multiple of n^3:

Remark 3.3.35 (How much work elimination takes). Let $A \in F^{n\times n}$ be invertible, and suppose no swaps are needed. In pass k of Gauss–Jordan elimination the pivot is in position (k,k), and the pivot row vanishes in columns $1, \dots, k-1$ (Lemma 3.3.7(d)). So the scaling touches $n-k+1$ entries, and each of the $n-1$ replacements touches $n-k+1$ entries, with one multiplication and one addition each. The total number of multiplications is at most

$$\sum_{k=1}^{n} n(n-k+1) = n \cdot \frac{n(n+1)}{2} \approx \frac{n^3}{2},$$

and there are about as many additions: roughly n^3 arithmetic operations in all. Gaussian elimination only clears the $n-k$ rows below the pivot, which costs

$$\sum_{k=1}^{n} (n-k)(n-k+1) = \frac{n^3 - n}{3}$$

multiplications and divisions, and about as many additions: about $2n^3/3$ operations in all; back substitution adds only about n^2 per right-hand side. Either way, doubling the size of the matrix multiplies the work by about 8. A system with a few thousand unknowns is routine for a computer, whereas the formula for the solution that comes out of determinants in Section 5.5 involves sums with $n!$ terms.

Example 3.3.36 (A PLU factorization). For the matrix A of Example 3.3.25, the $(1,1)$ entry is 0, so the proof of Theorem 3.3.33 starts with $P_1 = E_{12}$. Then $\ell = (0, 2)$, and the remaining 2×2 block $A' = \left(\begin{smallmatrix} 2 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ needs no swap: its multiplier is $-1/2$, leaving $1/2$. So

$$E_{12}A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 2 & 1 \\ 2 & 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 2 & -1/2 & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 & 0 \\ 0 & 2 & 1 \\ 0 & 0 & 1/2 \end{pmatrix}.$$

3.3.8 Symmetric matrices: LDL^{T} BEYOND 21-242

A matrix A is **symmetric** if $A^{\mathsf{T}} = A$. Elimination does not see symmetry: the U of an LU factorization of a symmetric matrix is usually not symmetric. But the symmetry is hiding in the factorization, and it can be recovered.

Theorem 3.3.37 (LDL^{T} factorization). Let $A \in F^{n\times n}$ be symmetric, and suppose $A = LU$ with L unit lower triangular and U upper triangular with nonzero diagonal entries. Let D be the diagonal matrix with the same diagonal entries as U. Then $U = DL^{\mathsf{T}}$, so

$$A = LDL^{\mathsf{T}}.$$

Proof. HARD

Uses. Lemma 3.3.32 (Products and inverses of triangular matrices), Proposition 2.4.23 (Transpose of a product), Definition 3.3.31 (Triangular matrices)
Hint 1. Factor $U = DU_1$ with U_1 unit upper triangular, so $A = LDU_1$. Transpose this equation.
Hint 2. You get $LDU_1 = U_1^{\mathsf{T}} DL^{\mathsf{T}}$. Rearrange it so that one side is lower triangular and the other upper triangular.
Hint 3. A matrix that is both lower and upper triangular is diagonal. Compare diagonal entries.
Sketch. Write $U = DU_1$ with $U_1 = D^{-1}U$ unit upper triangular. Transposing $A = LDU_1$ gives $A = U_1^{\mathsf{T}} DL^{\mathsf{T}}$, and moving the outer factors across shows that $\left(U_1^{\mathsf{T}}\right)^{-1} LD$, which is lower triangular with diagonal D, equals $DL^{\mathsf{T}} U_1^{-1}$, which is upper triangular. So both equal D. Hence $\left(U_1^{\mathsf{T}}\right)^{-1} L = I_n$, so $U_1 = L^{\mathsf{T}}$ and $U = DL^{\mathsf{T}}$.

Since the diagonal entries $d_i = u_{ii}$ are nonzero, D is invertible, with D^{-1} diagonal with entries d_i^{-1}. Let $U_1 = D^{-1}U$; this scales row i of U by d_i^{-1}, so U_1 is unit upper triangular, and $U = DU_1$. Then $A = LDU_1$, and transposing (Proposition 2.4.23, with $D^{\mathsf{T}} = D$) gives

$$LDU_1 = A = A^{\mathsf{T}} = U_1^{\mathsf{T}} DL^{\mathsf{T}}.$$

Here U_1^{T} is unit lower triangular and L^{T} is unit upper triangular. Multiplying on the left by $\left(U_1^{\mathsf{T}}\right)^{-1}$ and on the right by U_1^{-1}, which exist by Lemma 3.3.32, gives

$$\left(U_1^{\mathsf{T}}\right)^{-1} LD = DL^{\mathsf{T}} U_1^{-1}.$$

By Lemma 3.3.32, $\left(U_1^{\mathsf{T}}\right)^{-1} L$ is unit lower triangular, so the left side is lower triangular with diagonal entries $d_1, \dots, d_n$; the right side is upper triangular. So both sides are diagonal, and comparing diagonals they equal D. Thus $\left(U_1^{\mathsf{T}}\right)^{-1} LD = D$, and multiplying on the right by D^{-1} gives $\left(U_1^{\mathsf{T}}\right)^{-1} L = I_n$, that is, $L = U_1^{\mathsf{T}}$. Hence $U_1 = L^{\mathsf{T}}$ and $U = DL^{\mathsf{T}}$. □

The hypothesis holds whenever A is invertible and Gaussian elimination on A needs no swaps. Then $A = LU$ by Theorem 3.3.33(b), and by Proposition 3.3.30 the pivots of U lie in the pivot columns of A, which are $1, \dots, n$ since $\operatorname{rref}(A) = I_n$ (Theorem 3.3.23); so the diagonal entries of U are its pivots, which are nonzero.

Example 3.3.38 (An LDL^{T} factorization). For the symmetric matrix

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 3 & 4 & 6 \end{pmatrix},$$

Gaussian elimination uses the multipliers $\ell_{21} = 2$, $\ell_{31} = 3$, $\ell_{32} = 2$, and its output U has rows $(1, 2, 3)$, $(0, -1, -2)$, $(0, 0, 1)$. So $D = \operatorname{diag}(1, -1, 1)$ and

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 3 & 2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}.$$

Over $\mathbb{R}$, when every diagonal entry of D is positive, $D = D_0^2$ with D_0 diagonal with entries $\sqrt{d_i}$, and $A = (LD_0)(LD_0)^{\mathsf{T}}$ is a product of a lower triangular matrix and its transpose. This is the **Cholesky factorization** of a positive definite matrix (Section 8.3). The signs of the d_i are not an accident of the computation either: by Sylvester's law of inertia (Section 12.2), the numbers of positive and of negative d_i are determined by A.

Exercises

Exercise 3.3.39. ROUTINE Let

$$A = \begin{pmatrix} 1 & 2 & 1 & 0 & 1 \\ 2 & 4 & 3 & 1 & 0 \\ 1 & 2 & 2 & 2 & 1 \end{pmatrix} \in \mathbb{Q}^{3\times 5}.$$

(a) Find $\operatorname{rref}(A)$, its pivot columns, and a matrix G with $GA = \operatorname{rref}(A)$.

(b) Without further row reduction, write each non-pivot column of A as a linear combination of the pivot columns.

Solution on page 1226

Exercise 3.3.40. ROUTINE Find the reduced row echelon form of

$$A = \begin{pmatrix} 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix}$$

over $\mathbb{Q}$ and over $\mathbb{F}_2$. Where do the two computations part ways, and why?

Solution on page 1227

Exercise 3.3.41. ROUTINE Over $\mathbb{C}$, let

$$A = \begin{pmatrix} 1 & i & 0 \\ 0 & 1 & i \\ i & 0 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 & i \\ 0 & 1 & 1 \\ i & 1 & 0 \end{pmatrix}.$$

Use Algorithm 3.3.24 to find A^{-1}, and to show that B is not invertible. For B, find the linear relation among its rows that the algorithm produces.

Solution on page 1227

Exercise 3.3.42. STANDARD For a scalar c, let

$$A_c = \begin{pmatrix} 1 & 2 & 1 \\ 2 & c & 2 \\ 1 & 2 & c \end{pmatrix}.$$

(a) Find $\operatorname{rref}(A_c)$ for every $c \in \mathbb{R}$. For which c is A_c invertible?

(b) Answer the same questions over $\mathbb{F}_3$, for $c \in \mathbb{F}_3$.

Solution on page 1228

Exercise 3.3.43. ROUTINE Let $A \in F^{m\times n}$ and $R = \operatorname{rref}(A)$.

(a) Show that $\operatorname{rref}(cA) = R$ for every nonzero $c \in F$.

(b) Show that $\operatorname{rref}((A \mid A)) = (R \mid R)$.

(c) Let $\begin{pmatrix} A \\ A \end{pmatrix} \in F^{2m\times n}$ be the matrix with A stacked on top of itself. Show that $\operatorname{rref}\begin{pmatrix} A \\ A \end{pmatrix} = \begin{pmatrix} R \\ 0 \end{pmatrix}$.

Solution on page 1229

Exercise 3.3.44. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{m\times p}$.

(a) Show that the first n columns of $\operatorname{rref}((A \mid B))$ form $\operatorname{rref}(A)$.

(b) Give an example in which the last p columns of $\operatorname{rref}((A \mid B))$ differ from the matrix GB of Proposition 3.3.11.

Solution on page 1229

Exercise 3.3.45. STANDARD Prove or disprove each statement. Throughout, A and B are matrices over F of sizes for which the expressions make sense.

(a) $\operatorname{rref}\left(A^{\mathsf{T}}\right) = \operatorname{rref}(A)^{\mathsf{T}}$ for every square A.

(b) $\operatorname{rref}(AB) = \operatorname{rref}(A)\operatorname{rref}(B)$.

(c) If $\operatorname{rref}(A) = \operatorname{rref}(B)$, then $\operatorname{im} T_A = \operatorname{im} T_B$.

(d) If A and B have the same size and $\operatorname{im} T_A = \operatorname{im} T_B$, then $\operatorname{rref}(A) = \operatorname{rref}(B)$.

(e) $\operatorname{rref}(\operatorname{rref}(A)B) = \operatorname{rref}(AB)$.

Solution on page 1230

Exercise 3.3.46. STANDARD

(a) Find the error in the following argument, and give a counterexample to its conclusion.

Claim. If $R \in F^{m\times n}$ is in RREF and $G \in F^{m\times m}$ is invertible with $GR = R$, then $G = I_m$.

Proof. Apply the first proof of Theorem 3.3.17 with $R' = R$. Its induction shows that $\mathbf{g}_s = \mathbf{e}_s$ for every s, so every column of G is the corresponding column of I_m.

(b) Suppose R has r pivots. Describe all invertible G with $GR = R$.

Solution on page 1230

Exercise 3.3.47. STANDARD Find the error in the following argument, and give a counterexample to its conclusion.

Claim. Change step 1 of Algorithm 3.3.1 of Algorithm 3.3.1 so that it picks *any* column with a nonzero entry in an unpivoted row, not necessarily the leftmost one. The output of the modified algorithm is still in RREF.

Proof. The proofs of Lemma 3.3.7 and Proposition 3.3.8 go through word for word.

Solution on page 1231

Exercise 3.3.48. STANDARD Let p be a prime.

(a) Show that exactly $2p^2 + 2p + 3$ matrices in $\mathbb{F}_p^{2\times 3}$ are in RREF.

(b) Deduce that $\mathbb{F}_p^{2\times 3}$ splits into exactly $2p^2 + 2p + 3$ row equivalence classes. How many is that for $p = 2$?

Solution on page 1231

Exercise 3.3.49. STANDARD Find all matrices $A \in \mathbb{R}^{2\times 3}$ with $\ker T_A = \operatorname{span}((1,1,1))$.

Solution on page 1232

Exercise 3.3.50. STANDARD For $\mathbf{u}, \mathbf{x} \in F^n$ write $\mathbf{u}\cdot\mathbf{x} = u_1x_1 + \cdots + u_nx_n$. The **row space** of $A \in F^{m\times n}$ is the span of its rows, viewed as vectors in F^n.

(a) Show that $\mathbf{x} \in \ker T_A$ if and only if $\mathbf{v}\cdot\mathbf{x} = 0$ for every $\mathbf{v}$ in the row space of A.

(b) Deduce that $A, B \in F^{m\times n}$ are row equivalent if and only if they have the same row space.

Solution on page 1232

Exercise 3.3.51. STANDARD Let $a \in F$, and let $B \in F^{n\times n}$ have 1 in every diagonal position, a in every position $(i, i+1)$ directly above the diagonal, and 0 elsewhere.

(a) Row reduce $(B \mid I_n)$ to show that B is invertible, and that B^{-1} has entry $(-a)^{j-i}$ in position (i, j) for $j \geq i$, and 0 for $j < i$.

(b) Find the inverse of the $n \times n$ matrix U with $u_{ij} = 1$ for $j \geq i$ and $u_{ij} = 0$ for $j < i$.

Solution on page 1232

Exercise 3.3.52. STANDARD Let $n \geq 1$, and let $A \in F^{n\times n}$ have every diagonal entry 0 and every other entry 1. Write $c = (n-1) * 1 = 1 + \cdots + 1$ ($n-1$ terms) in F. Show that A is invertible if and only if $c \neq 0$, and find A^{-1} in that case. For which n is A invertible over $\mathbb{F}_p$?

Solution on page 1233

Exercise 3.3.53. STANDARD A matrix $U \in F^{n\times n}$ is **upper triangular** if $u_{ij} = 0$ whenever $i > j$.

(a) Let U be upper triangular with every diagonal entry nonzero. Show that Gauss–Jordan elimination on U performs no swaps, and that every elementary matrix it uses is upper triangular. Deduce that U is invertible, and that U^{-1} is upper triangular with diagonal entries $u_{11}^{-1}, \ldots, u_{nn}^{-1}$.

(b) Let U be upper triangular with some diagonal entry 0. Find a nonzero $\mathbf{x}$ with $U\mathbf{x} = \mathbf{0}$, and conclude that U is not invertible.

Solution on page 1234

Exercise 3.3.54. STANDARD Let F be a subfield of a field K (for example $\mathbb{Q} \subseteq \mathbb{R}$ or $\mathbb{R} \subseteq \mathbb{C}$), and let $A \in F^{m\times n}$, so that A is also a matrix over K.

(a) Show that $\operatorname{rref}(A)$ is the same whether it is computed over F or over K.

(b) Deduce that if $A \in F^{n\times n}$ is invertible as a matrix over K, then A^{-1} has all its entries in F.

(c) Show that $A, B \in F^{m\times n}$ are row equivalent over K (using elementary matrices with entries in K) if and only if they are row equivalent over F.

Solution on page 1235

Exercise 3.3.55. STANDARD

(a) Describe a procedure that, given $A, B \in F^{m\times n}$, decides whether $A \sim B$ and, if so, finds an invertible G with $GA = B$.

(b) Carry it out for $A = \begin{pmatrix} 1 & 2 & 1 \\ 2 & 4 & 3 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 2 & 2 \end{pmatrix}$ over $\mathbb{Q}$.

Solution on page 1235

Exercise 3.3.56. HARD Let $\mathbb{F}$ be $\mathbb{R}$ or $\mathbb{C}$. A matrix $A \in \mathbb{F}^{n\times n}$ is **strictly diagonally dominant** if in every row the diagonal entry outweighs the rest:

$$|a_{ii}| > \sum_{j \neq i} |a_{ij}| \quad \text{for } i = 1, \ldots, n.$$

Show that Gauss–Jordan elimination on such an A never needs a swap, and conclude that A is invertible.

Solution on page 1236

Exercise 3.3.57. HARD Let $A \in F^{m\times n}$, and let $G \in F^{m\times m}$ be invertible with $GA = \operatorname{rref}(A)$, which has r pivots. For a row vector $\mathbf{z} = (z_1, \ldots, z_m)$, the product $\mathbf{z}A$ is z_1 times row 1 of A, plus $\cdots$, plus z_m times row

m. Call $\mathbf{z}$ a **relation among the rows** of A if $\mathbf{z}A = \mathbf{0}$. Show that the relations among the rows of A are exactly the linear combinations of the last $m - r$ rows of G.

Solution on page 1236

Exercise 3.3.58. HARD Let p be a prime. For $0 \le r \le n$, let $N(r,n)$ be the number of $r \times n$ matrices over $\mathbb{F}_p$ that are in RREF and have no zero row; put $N(0,n) = 1$, and $N(r,n) = 0$ for $r > n$.

(a) Show that for $1 \le r \le n$ and $n \ge 2$,

$$N(r,n) = p^r N(r,n-1) + N(r-1,n-1).$$

(b) For $p = 2$, compute $N(2,4)$, and the number of row equivalence classes in $\mathbb{F}_2^{2\times 4}$.

Solution on page 1237

Exercise 3.3.59. ROUTINE BEYOND 21-242 Let

$$A = \begin{pmatrix} 1 & 2 & 0 \\ 3 & 7 & 2 \\ -2 & -1 & 5 \end{pmatrix}, \quad S = \begin{pmatrix} 4 & 2 & -2 \\ 2 & 5 & 1 \\ -2 & 1 & 6 \end{pmatrix}.$$

(a) Find the LU factorization of A.

(b) Find the LDL^{T} factorization of the symmetric matrix S, and write $S = MM^{\mathsf{T}}$ with M lower triangular.

Solution on page 1238

Exercise 3.3.60. STANDARD BEYOND 21-242 Show that an invertible matrix $A \in F^{n\times n}$ has at most one factorization $A = LU$ with L unit lower triangular and U upper triangular.

Solution on page 1238

Exercise 3.3.61. CHALLENGE BEYOND 21-242 Call an $n \times n$ matrix an **integer elementary matrix** if it is a swap E_{ij}, a sign change $E_{i,-1}$, or a replacement E_{icj} with $c \in \mathbb{Z}$. Show that for $A \in \mathbb{Z}^{n\times n}$ the following are equivalent:

(i) A is invertible (over $\mathbb{Q}$), and A^{-1} has integer entries;

(ii) A is a product of integer elementary matrices.

In other words, the matrices that can be inverted without leaving $\mathbb{Z}$ are exactly those that can be row reduced to I_n without leaving $\mathbb{Z}$.

Solution on page 1239

3.4 Solving linear systems

By Theorem 3.3.10, Gauss–Jordan elimination turns A into $\operatorname{rref}(A) = GA$ with G invertible, and by Proposition 3.2.14 the system $A\mathbf{x} = \mathbf{y}$ has the same solutions as the system $\operatorname{rref}(A)\mathbf{x} = G\mathbf{y}$. In Example 3.1.13 we read the solutions of one reduced system off by eye. This section does it in general. A reduced system says two things. Its zero rows decide whether there is a solution at all, and its other rows split the unknowns into free ones, which can take any values, and pivot ones, which the free ones then determine. From this we get a criterion for uniqueness and a criterion for existence, both in terms of pivots, and a first substantial application: through $n+1$ points with distinct first coordinates there passes exactly one polynomial of degree at most n.

3.4.1 Reducing to RREF

As in Definition 3.3.9, we write $A_r = \operatorname{rref}(A)$.

Proposition 3.4.1 (Solving with the reduced matrix). Let $A \in F^{m\times n}$, and let $G \in F^{m\times m}$ be invertible with $GA = A_r$ (Theorem 3.3.10). Then for all $\mathbf{x} \in F^n$ and $\mathbf{y} \in F^m$,

$$A\mathbf{x} = \mathbf{y} \quad \Leftrightarrow \quad A_r\mathbf{x} = G\mathbf{y}.$$

Moreover, if G is the product of the elementary matrices of the run of Gauss–Jordan elimination on A (Theorem 3.3.10), then the run on the augmented matrix $(A \mid \mathbf{y})$, with step 1 of Algorithm 3.3.1 restricted to the first n columns, ends at $(A_r \mid G\mathbf{y})$.

Proof. ROUTINE

Uses. Proposition 3.2.14 (Invertible matrices preserve solution sets), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.3.11 (Carrying extra columns along)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. Which result of Section 3.2 says that multiplying a system on the left by an invertible matrix does not change its solutions?
Hint 2. For $\Leftarrow$, multiply $A_r\mathbf{x} = G\mathbf{y}$ on the left by G^{-1} and use $G^{-1}A_r = A$. For the augmented matrix, apply Proposition 3.3.11 with $B = \mathbf{y}$.
Sketch. If $A\mathbf{x} = \mathbf{y}$, then $A_r\mathbf{x} = GA\mathbf{x} = G\mathbf{y}$. If $A_r\mathbf{x} = G\mathbf{y}$, then $A\mathbf{x} = G^{-1}A_r\mathbf{x} = G^{-1}G\mathbf{y} = \mathbf{y}$. The statement about $(A \mid \mathbf{y})$ is Proposition 3.3.11(b) with $B = \mathbf{y}$.

($\Rightarrow$) If $A\mathbf{x} = \mathbf{y}$, then $A_r\mathbf{x} = (GA)\mathbf{x} = G(A\mathbf{x}) = G\mathbf{y}$.

($\Leftarrow$) Since $GA = A_r$, we have $A = G^{-1}A_r$. So if $A_r\mathbf{x} = G\mathbf{y}$, then

$$A\mathbf{x} = G^{-1}(A_r\mathbf{x}) = G^{-1}(G\mathbf{y}) = \mathbf{y}.$$

(This is Proposition 3.2.14 for our particular G.) The last statement is Proposition 3.3.11(b), applied with $B = \mathbf{y} \in F^{m\times 1}$; it concerns the particular G produced by the run. (When A has fewer than m pivots, other invertible matrices G' also satisfy $G'A = A_r$, and the equivalence holds for each of them.) □

So the analysis of an arbitrary system reduces to that of a system whose coefficient matrix is in RREF. We never need G separately: we row reduce $(A \mid \mathbf{y})$, and $\mathbf{y}$ rides along in the last column. To treat every right-hand side at once, we can let the last column hold the symbols $y_1, \ldots, y_m$, which amounts to carrying I_m along and producing G (Proposition 3.3.11).

Definition 3.4.2 (Pivot and free variables). Let $A \in F^{m\times n}$, and let $p_1 < p_2 < \cdots < p_k$ be its pivot columns (Definition 3.3.9). The other columns, $f_1 < f_2 < \cdots < f_\ell$, are the **free columns** of A; thus $k + \ell = n$. In the system $A\mathbf{x} = \mathbf{y}$, the unknowns $x_{p_1}, \ldots, x_{p_k}$ are the **pivot variables** and $x_{f_1}, \ldots, x_{f_\ell}$ are the **free variables**.

These notions belong to A alone. They do not involve $\mathbf{y}$, and they do not depend on how A was reduced (Corollary 3.3.18). In fact Corollary 3.3.19 describes them without any reduction: column j is free exactly when $\mathbf{a}_j$ is a linear combination of $\mathbf{a}_1, \ldots, \mathbf{a}_{j-1}$. The k pivots lie in rows $1, \ldots, k$ and in distinct columns (Proposition 3.3.8), so $k \le \min(m, n)$. The number k is the *rank* of A, the subject of Section 3.5. For the matrix of Example 3.3.3,

$$A = \begin{pmatrix} 0 & 0 & 2 & 4 \\ 2 & 4 & 2 & 0 \\ 1 & 2 & 3 & 4 \end{pmatrix}, \quad A_r = \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

the pivot columns are $p_1 = 1$ and $p_2 = 3$, and the free columns are $f_1 = 2$ and $f_2 = 4$. In $A\mathbf{x} = \mathbf{y}$ the pivot variables are x_1, x_3, and the free variables are x_2, x_4.

3.4.2 Reading off the solutions

Intuition (What a reduced system says). Let $R = A_r$, with entries r_{ij}, and $\mathbf{z} = G\mathbf{y}$. Row $i \le k$ of R has its pivot, a 1, in column p_i, and zeros in the other pivot columns, because the pivot columns of R are $\mathbf{e}_1, \dots, \mathbf{e}_k$ (Lemma 3.3.16(b)). So the ith equation of $R\mathbf{x} = \mathbf{z}$ contains exactly one pivot variable, with coefficient 1, plus some free variables:

$$x_{p_i} + \sum_{j=1}^{\ell} r_{if_j} x_{f_j} = z_i.$$

The rows below row k are zero, so their equations read $0 = z_i$. These contain no unknowns at all: each one is either automatically true or impossible. For instance, a 4×6 matrix in RREF with pivot columns $1, 3, 6$ gives a system of the shape

$$\begin{aligned} x_1 + r_{12}x_2 + r_{14}x_4 + r_{15}x_5 &= z_1, \\ x_3 + r_{24}x_4 + r_{25}x_5 &= z_2, \\ x_6 &= z_3, \\ 0 &= z_4. \end{aligned}$$

If $z_4 \neq 0$, there is nothing to be done. If $z_4 = 0$, we may give the free variables x_2, x_4, x_5 any values we like, and then each of the first three equations determines its own pivot variable.

Theorem 3.4.3 (Solving a system in reduced form). Let $R \in F^{m \times n}$ be in RREF, with entries r_{ij}, pivot columns $p_1 < \cdots < p_k$, and free columns $f_1 < \cdots < f_\ell$. Let $\mathbf{z} \in F^m$.

(a) If $z_i \neq 0$ for some $i > k$, then $R\mathbf{x} = \mathbf{z}$ has no solution.

(b) If $z_i = 0$ for every $i > k$, then $\mathbf{x} \in F^n$ solves $R\mathbf{x} = \mathbf{z}$ if and only if

$$x_{p_i} = z_i - \sum_{j=1}^{\ell} r_{if_j} x_{f_j} \quad \text{for } i = 1, \dots, k. \tag{3.4.1}$$

In particular, for every choice of $t_1, \dots, t_\ell \in F$ there is exactly one solution with $x_{f_1} = t_1, \dots, x_{f_\ell} = t_\ell$.

Proof. ROUTINE

Uses. Definition 2.3.8 (Matrix–vector product), Proposition 3.3.8 (Properties of the output), Theorem 3.3.12 (Matrices in RREF), Lemma 3.3.16 (Reading the columns of a matrix in RREF)
Hint 1. Write out the ith entry of $R\mathbf{x}$, and split the sum over the columns into a sum over pivot columns and a sum over free columns.
Hint 2. Rows $k+1, \dots, m$ of R are zero. For $i \le k$, use that column p_s of R is $\mathbf{e}_s$.
Hint 3. For the last claim: every index $1, \dots, n$ is exactly one of $p_1, \dots, p_k, f_1, \dots, f_\ell$. So the values t_j together with (3.4.1) specify each coordinate of $\mathbf{x}$ exactly once.
Sketch. Split the ith entry of $R\mathbf{x}$ into a sum over the pivot columns and a sum over the free columns. For $i > k$ row i of R is zero, so equation i reads $0 = z_i$, which is (a). For $i \le k$, r_{ip_s} is 1 if $s = i$ and 0 otherwise, so equation i involves the pivot variable x_{p_i} with coefficient 1 and otherwise only free variables, which is (3.4.1). Free values plus (3.4.1) define one vector, and every solution with those free values is that vector.

Since R is in RREF, $R = \operatorname{rref}(R)$ is an output of Gauss–Jordan elimination, and its pivots are its leading entries (Theorem 3.3.12). By Proposition 3.3.8, rows $k+1, \dots, m$ of R are zero, and by Lemma 3.3.16(b), column p_s of R is $\mathbf{e}_s$ for $s = 1, \dots, k$.

By Definition 2.3.8, the ith entry of $R\mathbf{x}$ is $\sum_{l=1}^{n} r_{il}x_l$. Each index $l \in \{1, \dots, n\}$ is exactly one of $p_1, \dots, p_k, f_1, \dots, f_\ell$, so

$$(R\mathbf{x})_i = \sum_{s=1}^{k} r_{ip_s} x_{p_s} + \sum_{j=1}^{\ell} r_{if_j} x_{f_j}. \tag{3.4.2}$$

(a) If $i > k$, row i of R is zero, so $(R\mathbf{x})_i = 0$ for every $\mathbf{x}$. If moreover $z_i \neq 0$, the ith equation fails for every $\mathbf{x} \in F^n$.

(b) For $i > k$, both sides of the ith equation are 0, so it holds for every $\mathbf{x}$. For $i \leq k$, the entry r_{ip_s} is the ith entry of $\mathbf{e}_s$, which is 1 if $s = i$ and 0 otherwise. So by (3.4.2),

$$(R\mathbf{x})_i = x_{p_i} + \sum_{j=1}^{\ell} r_{if_j} x_{f_j},$$

and the ith equation $(R\mathbf{x})_i = z_i$ holds if and only if (3.4.1) holds for this i. Hence $R\mathbf{x} = \mathbf{z}$ if and only if (3.4.1) holds for $i = 1, \ldots, k$.

For the last claim, let $t_1, \ldots, t_\ell \in F$. Define $\mathbf{x} \in F^n$ by $x_{f_j} = t_j$ for each j and

$$x_{p_i} = z_i - \sum_{j=1}^{\ell} r_{if_j} t_j$$

for each i. Since each index is exactly one pivot or free column, this specifies every coordinate exactly once, and $\mathbf{x}$ is a solution by what we just proved. Conversely, a solution with $x_{f_j} = t_j$ for all j has its pivot coordinates given by (3.4.1), so it is this $\mathbf{x}$. □

The theorem is the lecture's recipe, made precise: the free variables can be anything, and then the pivot variables are determined from the free variables and the corresponding z_i. Applied to $R = A_r$ and $\mathbf{z} = G\mathbf{y}$, it settles consistency at once.

Corollary 3.4.4 (Consistency). Let $A \in F^{m\times n}$ have k pivots, let G be invertible with $GA = A_r$, and let $\mathbf{y} \in F^m$. Then $A\mathbf{x} = \mathbf{y}$ is consistent if and only if

$$(G\mathbf{y})_i = 0 \quad \text{for every } i \text{ with } k < i \leq m.$$

Equivalently, $A\mathbf{x} = \mathbf{y}$ is inconsistent exactly when the reduced augmented matrix $(A_r \mid G\mathbf{y})$ has a row $(0\cdots0 \mid c)$ with $c \neq 0$. In particular,

$$\operatorname{im} T_A = \{\mathbf{y} \in F^m \mid (G\mathbf{y})_i = 0 \text{ for } k < i \leq m\}.$$

Proof. ROUTINE

Uses. Proposition 3.4.1 (Solving with the reduced matrix), Theorem 3.4.3 (Solving a system in reduced form), Proposition 3.3.8 (Properties of the output), Proposition 3.1.8 (Systems and the map T_A)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. By Proposition 3.4.1, $A\mathbf{x} = \mathbf{y}$ has the same solutions as $A_r\mathbf{x} = G\mathbf{y}$. Apply Theorem 3.4.3 to the latter.
Hint 2. Which rows of A_r are zero? The image of T_A is the set of $\mathbf{y}$ for which the system is consistent.
Sketch. The system has the same solutions as $A_r\mathbf{x} = \mathbf{z}$ with $\mathbf{z} = G\mathbf{y}$. If some $z_i \neq 0$ with $i > k$, there is no solution by Theorem 3.4.3(a); otherwise there is one, for instance with all free variables 0, by Theorem 3.4.3(b). Rows $1, \ldots, k$ of A_r are nonzero and the others are zero, which gives the reformulation. The image of T_A consists of the $\mathbf{y}$ for which the system is consistent.

Let $\mathbf{z} = G\mathbf{y}$. By Proposition 3.4.1, $A\mathbf{x} = \mathbf{y}$ and $A_r\mathbf{x} = \mathbf{z}$ have the same solutions. If $z_i \neq 0$ for some $i > k$, the latter has no solution by Theorem 3.4.3(a). If $z_i = 0$ for all $i > k$, it has a solution by Theorem 3.4.3(b), for instance the one whose free variables are all 0.

By Proposition 3.3.8, rows $1, \ldots, k$ of A_r are nonzero (they contain the pivots) and rows $k+1, \ldots, m$ are zero. So a row of $(A_r \mid \mathbf{z})$ of the form $(0\cdots0 \mid c)$ with $c \neq 0$ is exactly a row $i > k$ with $z_i = c \neq 0$.

Finally, by Proposition 3.1.8(a), $\mathbf{y} \in \operatorname{im} T_A$ if and only if $A\mathbf{x} = \mathbf{y}$ is consistent, which we have just characterized. □

The description of $\operatorname{im} T_A$ is worth a second look. The conditions $(G\mathbf{y})_i = 0$ for $i > k$ are $m-k$ homogeneous linear equations in $y_1, \dots, y_m$, whose coefficients are the last $m-k$ rows of G. So the image of T_A, which is defined as a set of outputs, is also the solution set of a homogeneous system, that is, a kernel. For the running system, the last row of G in Example 3.2.8 is $(-1,-1,1)$, and the single condition $-y_1 - y_2 + y_3 = 0$ is the plane $y_3 = y_1 + y_2$ that Section 3.1.5 found by inspecting the columns.

If we row reduce $(A \mid \mathbf{y})$ all the way, without restricting the scan, the test reads slightly differently, and it has a proof that never mentions G.

Corollary 3.4.5 (Consistency from the augmented matrix). Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$. Then $A\mathbf{x} = \mathbf{y}$ is consistent if and only if the last column of the augmented matrix $(A \mid \mathbf{y})$ is not one of its pivot columns, that is, if and only if $\operatorname{rref}((A \mid \mathbf{y}))$ has no row $(0\cdots0 \mid 1)$.

Proof. ROUTINE

Uses. Corollary 3.3.19 (Pivot columns, intrinsically), Proposition 3.1.8 (Systems and the map T_A), Definition 3.3.9 (Reduced row echelon form), Proposition 3.3.8 (Properties of the output)
Hint 1. Apply Corollary 3.3.19(a) to the $m \times (n+1)$ matrix $(A \mid \mathbf{y})$ and its last column.
Hint 2. When is $\mathbf{y}$ a linear combination of the columns of A?
Sketch. By Corollary 3.3.19(a), the last column $\mathbf{y}$ is a pivot column exactly when it is not a combination of $\mathbf{a}_1, \dots, \mathbf{a}_n$, that is, by Proposition 3.1.8(a), exactly when the system is inconsistent. A pivot in the last column of a matrix in RREF is the leading 1 of a row that vanishes elsewhere, a row $(0\cdots0 \mid 1)$.

The columns of $(A \mid \mathbf{y})$ are $\mathbf{a}_1, \dots, \mathbf{a}_n, \mathbf{y}$. By Corollary 3.3.19(a), applied to this matrix and its column $n+1$, the last column is a pivot column if and only if $\mathbf{y}$ is not a linear combination of $\mathbf{a}_1, \dots, \mathbf{a}_n$. By Proposition 3.1.8(a), this happens if and only if $A\mathbf{x} = \mathbf{y}$ is inconsistent.

By Definition 3.3.9 and Proposition 3.3.8(b), the pivots of $(A \mid \mathbf{y})$ are the leading entries of the nonzero rows of $\operatorname{rref}((A \mid \mathbf{y}))$, and they are 1. So the last column is a pivot column if and only if some row has its leading entry, a 1, in the last column, that is, if and only if some row is $(0\cdots0 \mid 1)$. □

The two tests agree, as they must: by Exercise 3.3.44 the first n columns of $\operatorname{rref}((A \mid \mathbf{y}))$ form A_r, and the unrestricted run simply goes on to clear the last column once a row $(0\cdots0 \mid c)$ with $c \neq 0$ appears.

Example 3.4.6 (A complete solution). We solve $A\mathbf{x} = \mathbf{y}$ for the matrix A of Example 3.3.3 and every $\mathbf{y} \in \mathbb{Q}^3$. Carrying I_3 along in Section 3.3.3 produced

$$G = \begin{pmatrix} -1/2 & 1/2 & 0 \\ 1/2 & 0 & 0 \\ -1 & -1/2 & 1 \end{pmatrix},$$

so by Proposition 3.4.1 the system is equivalent to

$$\left(\begin{array}{cccc|c} 1 & 2 & 0 & -2 & (-y_1+y_2)/2 \\ 0 & 0 & 1 & 2 & y_1/2 \\ 0 & 0 & 0 & 0 & -y_1 - y_2/2 + y_3 \end{array}\right).$$

Here $k = 2$, so there is one consistency condition. By Corollary 3.4.4, the system is consistent if and only if $y_3 = y_1 + y_2/2$, and $\operatorname{im} T_A$ is the plane $2y_3 = 2y_1 + y_2$ in $\mathbb{Q}^3$. (Each column of A satisfies this, for example $2\cdot 4 = 2\cdot 4 + 0$ for $\mathbf{a}_4 = (4,0,4)$.)

Take $\mathbf{y} = (4,2,5)$. Then $G\mathbf{y} = (-1,2,0)$, the condition holds, and by (3.4.1) the solutions are exactly the vectors with

$$x_1 = -1 - 2x_2 + 2x_4, \quad x_3 = 2 - 2x_4, \quad x_2, x_4 \in \mathbb{Q} \text{ arbitrary}.$$

For $\mathbf{y} = (4,2,6)$, instead, $G\mathbf{y} = (-1,2,1)$, and the last equation of the reduced system reads $0 = 1$: there is no solution.

The row reducer below carries out the reduction of $(A \mid \mathbf{y})$ for $\mathbf{y} = (4, 2, 5)$, scanning only the columns of A. At the end it reports the pivot and free columns and whether the system is consistent. Edit the last column to $(4, 2, 6)$ to see the row $(0, 0, 0, 0 \mid 1)$ appear.

$$\left(\begin{array}{cccc|c} 0 & 0 & 2 & 4 & 4 \\ 2 & 4 & 2 & 0 & 2 \\ 1 & 2 & 3 & 4 & 5 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|c} 1 & 2 & 0 & -2 & -1 \\ 0 & 0 & 1 & 2 & 2 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right)$$

Solving the system of Example 3.4.6. Pivots are boxed; the bar separates A from $\mathbf{y}$. (Interactive in the web version.)

Exercise 3.4.7. ROUTINE Let

$$A = \begin{pmatrix} 0 & 1 & 2 & 1 \\ 0 & 2 & 4 & 3 \\ 0 & 1 & 2 & 0 \end{pmatrix} \in \mathbb{R}^{3\times 4}.$$

Find A_r and the pivot and free variables. For which $\mathbf{y} \in \mathbb{R}^3$ is $A\mathbf{x} = \mathbf{y}$ consistent? Find all solutions for $\mathbf{y} = (1, 2, 1)$.

Solution on page 1239

3.4.3 The shape of the solution set

Formula (3.4.1) expresses the pivot variables through the free ones. Collecting, for each free variable, the terms that involve it writes every solution as one fixed vector plus a combination of vectors that do not depend on $\mathbf{y}$, which is the form Proposition 3.1.19 predicts.

Definition 3.4.8 (Basic solutions). Let $A \in F^{m\times n}$, with $A_r = GA$ as above, entries r_{ij} of A_r, pivot columns $p_1 < \cdots < p_k$, and free columns $f_1 < \cdots < f_\ell$.

(a) For $j = 1, \ldots, \ell$, the jth **basic solution** of A is the vector $\mathbf{s}_j \in F^n$ with

$$(\mathbf{s}_j)_{f_j} = 1, \quad (\mathbf{s}_j)_{f_{j'}} = 0 \text{ for } j' \neq j, \quad (\mathbf{s}_j)_{p_i} = -r_{if_j} \text{ for } i = 1, \ldots, k.$$

(b) If $A\mathbf{x} = \mathbf{y}$ is consistent, its **particular solution** $\mathbf{x}_0 \in F^n$ has $(\mathbf{x}_0)_{p_i} = (G\mathbf{y})_i$ for $i = 1, \ldots, k$, and $(\mathbf{x}_0)_{f_j} = 0$ for $j = 1, \ldots, \ell$.

In words: $\mathbf{s}_j$ is the solution of $A\mathbf{x} = \mathbf{0}$ obtained by setting the free variable x_{f_j} to 1 and the other free variables to 0, and $\mathbf{x}_0$ is the solution of $A\mathbf{x} = \mathbf{y}$ obtained by setting every free variable to 0. (Both are solutions by Theorem 3.4.3(b) and Proposition 3.4.1.) The $\mathbf{s}_j$ depend only on A_r, which depends only on A. The vector $\mathbf{x}_0$ is the *only* solution whose free variables all vanish, by Theorem 3.4.3(b), so it does not depend on which G we used either. Realize also that $\mathbf{s}_j$ can be copied from column f_j of A_r: negate its first k entries and put them in the pivot positions $p_1, \ldots, p_k$, put a 1 in position f_j, and zeros elsewhere.

Theorem 3.4.9 (All solutions). Let $A \in F^{m\times n}$, and suppose $A\mathbf{x} = \mathbf{y}$ is consistent. Let $\mathbf{x}_0$ be its particular solution and $\mathbf{s}_1, \ldots, \mathbf{s}_\ell$ the basic solutions of A (Definition 3.4.8).

(a) The solutions of $A\mathbf{x} = \mathbf{y}$ are exactly the vectors

$$\mathbf{x} = \mathbf{x}_0 + t_1\mathbf{s}_1 + t_2\mathbf{s}_2 + \cdots + t_\ell\mathbf{s}_\ell \quad (t_1, \ldots, t_\ell \in F),$$

and each solution arises from exactly one choice of $t_1, \ldots, t_\ell$, namely $t_j = x_{f_j}$.

(b) $\ker T_A = \operatorname{span}(\mathbf{s}_1, \ldots, \mathbf{s}_\ell)$, and each vector of $\ker T_A$ is a linear combination of $\mathbf{s}_1, \ldots, \mathbf{s}_\ell$ in exactly one way.

So the solution set of $A\mathbf{x} = \mathbf{y}$ is $\mathbf{x}_0 + \operatorname{span}(\mathbf{s}_1, \ldots, \mathbf{s}_\ell) = \mathbf{x}_0 + \ker T_A$.

Proof. STANDARD

Uses. Theorem 3.4.3 (Solving a system in reduced form), Proposition 3.4.1 (Solving with the reduced matrix), Corollary 3.4.4 (Consistency), Proposition 3.1.8 (Systems and the map T_A), Definition 1.3.10 (Span)
Techniques. Particular plus homogeneous (Technique 3.1.18), Reduce to RREF (Technique 3.3.22)
Hint 1. Fix $t_1, \ldots, t_\ell$ and compute the coordinates of $\mathbf{w} = \mathbf{x}_0 + \sum_j t_j \mathbf{s}_j$: first those in the free positions, then those in the pivot positions.
Hint 2. The f_j-coordinate of $\mathbf{w}$ is t_j, and its p_i-coordinate is $z_i - \sum_j r_{if_j} t_j$, where $\mathbf{z} = G\mathbf{y}$. Compare with (3.4.1).
Hint 3. For (b), apply (a) with $\mathbf{y} = \mathbf{0}$. What is the particular solution then?
Sketch. With $\mathbf{z} = G\mathbf{y}$, the vector $\mathbf{w} = \mathbf{x}_0 + \sum_j t_j \mathbf{s}_j$ has f_j-coordinate t_j and p_i-coordinate $z_i - \sum_j r_{if_j} t_j$. By Theorem 3.4.3(b), $\mathbf{w}$ is a solution, and every solution $\mathbf{x}$ equals the $\mathbf{w}$ with $t_j = x_{f_j}$, because both have the same free coordinates and the pivot coordinates are determined by them. Reading off free coordinates gives uniqueness of the t_j. For $\mathbf{y} = \mathbf{0}$ the particular solution is $\mathbf{0}$, which gives (b).

Let $\mathbf{z} = G\mathbf{y}$. Since the system is consistent, $z_i = 0$ for $i > k$ (Corollary 3.4.4), and by Proposition 3.4.1 its solutions are those of $A_r\mathbf{x} = \mathbf{z}$.

(a) For $t_1, \ldots, t_\ell \in F$, let $\mathbf{w} = \mathbf{x}_0 + t_1\mathbf{s}_1 + \cdots + t_\ell\mathbf{s}_\ell$. In position f_j, the vector $\mathbf{x}_0$ has a 0, $\mathbf{s}_j$ has a 1, and $\mathbf{s}_{j'}$ has a 0 for $j' \neq j$, so

$$w_{f_j} = t_j.$$

In position p_i, $\mathbf{x}_0$ has z_i and $\mathbf{s}_j$ has $-r_{if_j}$, so

$$w_{p_i} = z_i - \sum_{j=1}^{\ell} r_{if_j} t_j = z_i - \sum_{j=1}^{\ell} r_{if_j} w_{f_j}.$$

This is (3.4.1) for $\mathbf{w}$, so $\mathbf{w}$ solves $A_r\mathbf{x} = \mathbf{z}$ by Theorem 3.4.3(b), and hence $A\mathbf{x} = \mathbf{y}$.

Conversely, let $\mathbf{x}$ be a solution, and let $\mathbf{w}$ be the vector above with $t_j = x_{f_j}$ for each j. Then $\mathbf{x}$ and $\mathbf{w}$ are solutions with the same free coordinates, so by the uniqueness in Theorem 3.4.3(b) they are equal. Finally, if $\mathbf{x} = \mathbf{x}_0 + \sum_j t_j\mathbf{s}_j$, then $x_{f_j} = t_j$ by the computation above, so $t_1, \ldots, t_\ell$ are determined by $\mathbf{x}$.

(b) By Proposition 3.1.8(b), $\ker T_A$ is the solution set of $A\mathbf{x} = \mathbf{0}$, which is consistent. Its particular solution is $\mathbf{0}$, since $G\mathbf{0} = \mathbf{0}$. By (a), its solutions are exactly the vectors $t_1\mathbf{s}_1 + \cdots + t_\ell\mathbf{s}_\ell$, each for exactly one choice of the t_j. By Definition 1.3.10, the set of these vectors is $\operatorname{span}(\mathbf{s}_1, \ldots, \mathbf{s}_\ell)$.

The last sentence of the theorem combines (a) and (b). □

This is Proposition 3.1.19 made explicit. That proposition said that once we know one solution, the others are obtained by adding elements of $\ker T_A$; the theorem produces the one solution, $\mathbf{x}_0$, and describes $\ker T_A$ by ℓ vectors, one for each free variable. It is the canonical instance of Technique 3.1.18. There is also a quick way to see that $A\mathbf{s}_j = \mathbf{0}$ without the theorem. By Corollary 3.3.19(b), column f_j of A is $\sum_i r_{if_j}\mathbf{a}_{p_i}$ (the terms with $p_i > f_j$ are zero by Lemma 3.3.16(a)). Moving everything to one side gives a relation among the columns of A whose coefficient vector is exactly $\mathbf{s}_j$.

Example 3.4.10 (The complete solution, in vector form). In Example 3.4.6, with $\mathbf{y} = (4, 2, 5)$, we have $G\mathbf{y} = (-1, 2, 0)$ and

$$A_r = \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

The particular solution has -1 and 2 in the pivot positions $1, 3$, and 0 in the free positions $2, 4$. The basic solutions come from columns 2 and 4 of A_r:

$$\mathbf{x}_0 = \begin{pmatrix} -1 \\ 0 \\ 2 \\ 0 \end{pmatrix}, \quad \mathbf{s}_1 = \begin{pmatrix} -2 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \quad \mathbf{s}_2 = \begin{pmatrix} 2 \\ 0 \\ -2 \\ 1 \end{pmatrix}.$$

By Theorem 3.4.9, the solution set is

$$\{(-1,0,2,0) + t_1(-2,1,0,0) + t_2(2,0,-2,1) \mid t_1, t_2 \in \mathbb{Q}\},$$

a plane in $\mathbb{Q}^4$, and $\ker T_A = \operatorname{span}((-2,1,0,0),(2,0,-2,1))$. The relations among the columns behind $\mathbf{s}_1$ and $\mathbf{s}_2$ are $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_4 = -2\mathbf{a}_1 + 2\mathbf{a}_3$, which we already read off in Section 3.3.4.

Remark 3.4.11 (A basis of the kernel). Part (b) of Theorem 3.4.9 says that every vector of $\ker T_A$ is a linear combination of $\mathbf{s}_1, \ldots, \mathbf{s}_\ell$ in exactly one way. In the language of Section 1.5 and Section 1.6, the list $\mathbf{s}_1, \ldots, \mathbf{s}_\ell$ is linearly independent (Definition 1.5.1) and spans $\ker T_A$, so it is a basis of $\ker T_A$ (Definition 1.6.1). It has one vector for each free variable, so $\ell = n - k$ vectors. Once dimension is defined, this says that $\dim \ker T_A$ is the number of free columns of A, which is the starting point of rank–nullity (Section 4.2).

Remark 3.4.12 (Checking a description of the solutions). Solutions are often written down by some other method, or the parameters are chosen differently. A description $\mathbf{x}_{0'} + \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$ is easy to test in one direction: if $A\mathbf{x}_{0'} = \mathbf{y}$ and $A\mathbf{u}_i = \mathbf{0}$ for every i, then every vector in it is a solution. But this test cannot detect missing solutions: dropping one of the $\mathbf{u}_i$ still passes it. The description is complete exactly when $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r) = \ker T_A$, and by Theorem 3.4.9 this holds if and only if each basic solution $\mathbf{s}_j$ is a combination of the $\mathbf{u}_i$. (Section 4.2 gives a quicker test: $r = \ell$ linearly independent vectors of $\ker T_A$ always span it.) Exercise 3.4.34 is an example.

The whole procedure fits in a few lines.

Algorithm 3.4.13 (Solving a linear system)

Input A matrix $A \in F^{m \times n}$ and a vector $\mathbf{y} \in F^m$.
Output The solution set of $A\mathbf{x} = \mathbf{y}$, in the form $\mathbf{x}_0 + \operatorname{span}(\mathbf{s}_1, \ldots, \mathbf{s}_\ell)$, or the conclusion that the system is inconsistent.

1. Row reduce $(A \mid \mathbf{y})$ by Gauss–Jordan elimination, scanning only the first n columns in step 1 of Algorithm 3.3.1. The result is $(A_r \mid \mathbf{z})$ with $\mathbf{z} = G\mathbf{y}$. Record the pivot columns $p_1, \ldots, p_k$ and the free columns $f_1, \ldots, f_\ell$.
2. If $z_i \neq 0$ for some $i > k$, stop: the system is inconsistent.
3. Otherwise, let $\mathbf{x}_0$ have z_i in position p_i for $i = 1, \ldots, k$, and 0 in every free position.
4. For each $j = 1, \ldots, \ell$, let $\mathbf{s}_j$ have 1 in position f_j, 0 in the other free positions, and $-r_{if_j}$ in position p_i, where r_{if_j} is the ith entry of column f_j of A_r.
5. Output $\mathbf{x}_0 + \operatorname{span}(\mathbf{s}_1, \ldots, \mathbf{s}_\ell)$.

It is correct by Proposition 3.4.1, Corollary 3.4.4, and Theorem 3.4.9. The bijection $(t_1, \ldots, t_\ell) \mapsto \mathbf{x}_0 + \sum_j t_j \mathbf{s}_j$ of Theorem 3.4.9(a) also counts the solutions.

Corollary 3.4.14 (Counting solutions). Suppose $A\mathbf{x} = \mathbf{y}$ is consistent, where $A \in F^{m \times n}$ has ℓ free columns.

(a) The system has exactly one solution if and only if $\ell = 0$, that is, if and only if every column of A is a pivot column.

(b) If F is finite with q elements, the system has exactly q^ℓ solutions.

(c) If F is infinite and $\ell \geq 1$, the system has infinitely many solutions.

Proof. ROUTINE

> *Uses.* Theorem 3.4.9 (All solutions)
> *Hint 1.* Theorem 3.4.9(a) sets up a bijection between the solution set and the set of lists $(t_1, \dots, t_\ell)$ of scalars.
> *Hint 2.* For (a) with $\ell \geq 1$, compare $\mathbf{x}_0$ and $\mathbf{x}_0 + \mathbf{s}_1$.
> *Sketch.* By Theorem 3.4.9(a), $(t_1, \dots, t_\ell) \mapsto \mathbf{x}_0 + \sum_j t_j \mathbf{s}_j$ is a bijection from F^ℓ onto the solution set (for $\ell = 0$, the solution set is $\{\mathbf{x}_0\}$). Count: F^ℓ has q^ℓ elements when $|F| = q$, and infinitely many when F is infinite and $\ell \geq 1$. If $\ell \geq 1$, the solutions $\mathbf{x}_0$ and $\mathbf{x}_0 + \mathbf{s}_1$ differ in position f_1.

By Theorem 3.4.9(a), each solution is $\mathbf{x}_0 + \sum_j t_j \mathbf{s}_j$ for exactly one list $(t_1, \dots, t_\ell) \in F^\ell$, and every such vector is a solution. So the solution set is in bijection with F^ℓ. If $\ell = 0$, there are no parameters and the only solution is $\mathbf{x}_0$.

(a) If $\ell = 0$, the only solution is $\mathbf{x}_0$. If $\ell \geq 1$, then $\mathbf{x}_0$ and $\mathbf{x}_0 + \mathbf{s}_1$ are solutions, and they differ, since their f_1 -coordinates are 0 and 1.

(b) F^ℓ has q^ℓ elements (and $q^0 = 1$ covers $\ell = 0$).

(c) If $\ell \geq 1$ and F is infinite, the vectors $\mathbf{x}_0 + t\mathbf{s}_1$, $t \in F$, are infinitely many distinct solutions. □

Part (b) is the formula promised after Example 3.1.26, where the equation $x_1 + x_2 = 1$ over $\mathbb{F}_2$ has one free variable and 2^1 solutions. We did not need dimension: the number of free variables does the counting. Part (c) recovers Corollary 3.1.24, and adds that the number of solutions of a consistent system is decided by A alone.

3.4.4 Pivots in every column, pivots in every row

> *Intuition (Free variables and zero rows).* Every system $A\mathbf{x} = \mathbf{y}$ raises two questions: is there a solution, and is it unique? We have now located the source of each answer in A_r. Non-uniqueness comes from free variables, since each one can be varied independently. Inconsistency comes from zero rows, since each one produces an equation $0 = (G\mathbf{y})_i$, which fails for a suitable $\mathbf{y}$. A free variable is a column without a pivot, and a zero row is a row without a pivot. So we expect: a pivot in every column means uniqueness, and a pivot in every row means existence for every right-hand side. Uniqueness is a property of $\ker T_A$ (Corollary 3.1.22), so the first statement is about the homogeneous system.

Proposition 3.4.15 (A pivot in every column). Let $A \in F^{m \times n}$. The following are equivalent.
(I) A_r has a pivot in every column.
(II) The equation $A\mathbf{x} = \mathbf{0}$ has only the trivial solution $\mathbf{x} = \mathbf{0}$.

The homogeneous system is consistent, so this is the case $\mathbf{y} = \mathbf{0}$ of Corollary 3.4.14(a). The lecture proves it directly, and the direct argument is worth having: it constructs a nonzero solution whenever one exists.

Proof (set one free variable to 1). ROUTINE

> *Uses.* Proposition 3.4.1 (Solving with the reduced matrix), Theorem 3.4.3 (Solving a system in reduced form), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.3.8 (Matrix–vector product)
> *Techniques.* Reduce to RREF (Technique 3.3.22), Contrapositive (Technique 1.5.4)
> *Hint 1.* Reduce: $A\mathbf{x} = \mathbf{0}$ if and only if $A_r\mathbf{x} = \mathbf{0}$. If every column of A_r is a pivot column, what are its columns?
> *Hint 2.* For (II) $\Rightarrow$ (I), prove the contrapositive. If some column f has no pivot, x_f is a free variable. Choose values of the free variables and solve for the pivot variables with Theorem 3.4.3.
> *Hint 3.* Set $x_f = 1$ and every other free variable to 0.
> *Sketch.* $A\mathbf{x} = \mathbf{0}$ iff $A_r\mathbf{x} = \mathbf{0}$, since $G\mathbf{0} = \mathbf{0}$. If every column is a pivot column, then $k = n$, $p_s = s$, and A_r has columns $\mathbf{e}_1, \dots, \mathbf{e}_n$, so $A_r\mathbf{x}$ lists $x_1, \dots, x_n$ followed by zeros, and vanishes only for $\mathbf{x} = \mathbf{0}$. If column f is free, Theorem 3.4.3(b) gives a solution with $x_f = 1$ and the other free variables 0; it is nonzero.

By Proposition 3.4.1 with $\mathbf{y} = \mathbf{0}$, and since $G\mathbf{0} = \mathbf{0}$, the equations $A\mathbf{x} = \mathbf{0}$ and $A_r\mathbf{x} = \mathbf{0}$ have the same solutions.

(I) ⇒ (II). Suppose every column of A_r is a pivot column. Then $k = n$, and $p_1 < \cdots < p_n$ are n increasing numbers in $\{1, \ldots, n\}$, so $p_s = s$ for every s. By Lemma 3.3.16(b), column s of A_r is $\mathbf{e}_s$, so by Definition 2.3.8

$$A_r\mathbf{x} = x_1\mathbf{e}_1 + \cdots + x_n\mathbf{e}_n,$$

the vector of F^m whose first n entries are $x_1, \ldots, x_n$ and whose remaining $m - n$ entries are 0. It is $\mathbf{0}$ only if $\mathbf{x} = \mathbf{0}$.

(II) ⇒ (I). We prove the contrapositive. Suppose some column of A_r has no pivot, so it is a free column f_j. The right-hand side $\mathbf{0}$ certainly has $z_i = 0$ for $i > k$, so by Theorem 3.4.3(b) the system $A_r\mathbf{x} = \mathbf{0}$ has a solution $\mathbf{x}$ with $x_{f_j} = 1$ and every other free variable 0. This $\mathbf{x}$ is nonzero, as its f_j-coordinate is 1, and $A\mathbf{x} = \mathbf{0}$. So (II) fails. □

Proof (via relations among the columns). STANDARD

> *Uses.* Definition 2.3.8 (Matrix–vector product), Theorem 1.5.5 (Independence is decided at zero), Corollary 3.3.19 (Pivot columns, intrinsically), Lemma 1.5.10 (Linear dependence lemma)
> *Techniques.* Contrapositive (Technique 1.5.4)
> *Hint 1.* By Definition 2.3.8, a solution of $A\mathbf{x} = \mathbf{0}$ is a linear relation among the columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$. Restate (II) in terms of linear independence.
> *Hint 2.* Corollary 3.3.19(a) restates (I): no column is a linear combination of the columns before it.
> *Hint 3.* Connect the two restatements with the linear dependence lemma (Lemma 1.5.10).
> *Sketch.* (II) says that $\mathbf{a}_1, \ldots, \mathbf{a}_n$ has only the trivial relation, that is, is linearly independent (Theorem 1.5.5). (I) says that no $\mathbf{a}_j$ lies in $\operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_{j-1})$ (Corollary 3.3.19(a)). If some $\mathbf{a}_j = \sum_{l<j} c_l\mathbf{a}_l$, then $\sum_{l<j} c_l\mathbf{a}_l - \mathbf{a}_j = \mathbf{0}$ is a nontrivial relation; if the columns are dependent, Lemma 1.5.10 provides such a j.

By Definition 2.3.8, $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$. So (II) says that the only linear relation among $\mathbf{a}_1, \ldots, \mathbf{a}_n$ is the trivial one, which by Theorem 1.5.5 means that the list $\mathbf{a}_1, \ldots, \mathbf{a}_n$ is linearly independent. By Corollary 3.3.19(a), (I) says that for no j is $\mathbf{a}_j$ a linear combination of $\mathbf{a}_1, \ldots, \mathbf{a}_{j-1}$.

If (I) fails, then $\mathbf{a}_j = c_1\mathbf{a}_1 + \cdots + c_{j-1}\mathbf{a}_{j-1}$ for some j and some scalars c_l, and then

$$c_1\mathbf{a}_1 + \cdots + c_{j-1}\mathbf{a}_{j-1} + (-1)\mathbf{a}_j = \mathbf{0}$$

is a linear relation with a nonzero coefficient, so (II) fails. If (II) fails, the columns are linearly dependent, and the linear dependence lemma (Lemma 1.5.10) gives an index j with $\mathbf{a}_j \in \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_{j-1})$, so (I) fails. □

The first proof is constructive: when (I) fails, it hands us a nonzero solution, namely a basic solution. The second explains what a missing pivot means: a column that depends on the columns before it. It also shows that a pivot in every column is the same as linear independence of the columns. By Theorem 2.6.11, (II) says that T_A is injective, so a pivot in every column is a mechanical test for the equivalent conditions of Theorem 2.7.2. Section 3.5 adds it to that theorem.

Proposition 3.4.16 (A pivot in every row). Let $A \in F^{m\times n}$. The following are equivalent.

(I) A_r has a pivot in every row.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has a solution $\mathbf{x} \in F^n$.

Proof. ROUTINE

> *Uses.* Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.3.8 (Properties of the output), Corollary 3.4.4 (Consistency), Theorem 3.4.3 (Solving a system in reduced form), Definition 2.5.12 (Invertible)
> *Techniques.* Reduce to RREF (Technique 3.3.22), Contrapositive (Technique 1.5.4)
> *Hint 1.* By Corollary 3.4.4, consistency is decided by the entries $(G\mathbf{y})_i$ with $i > k$. How many such i are there when every row has a pivot?
> *Hint 2.* For (II) ⇒ (I), prove the contrapositive. It suffices to find $\mathbf{z}$ such that $A_r\mathbf{x} = \mathbf{z}$ has no solution, and then take $\mathbf{y} = G^{-1}\mathbf{z}$.
> *Hint 3.* If some row has no pivot, the last row of A_r is zero. Try $\mathbf{z} = \mathbf{e}_m$.

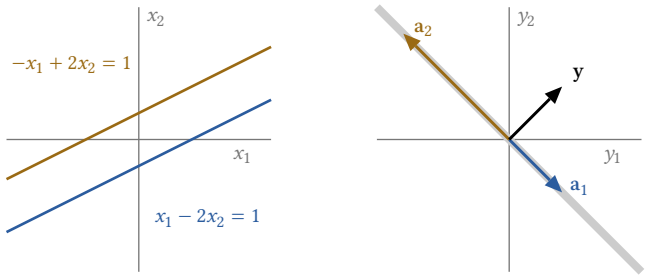
Sketch. The pivots lie in rows $1, \dots, k$, so (I) says $k = m$. If $k = m$, the consistency conditions of Corollary 3.4.4 are vacuous; explicitly, $x_{p_i} = (G\mathbf{y})_i$ with all free variables 0 is a solution. If $k < m$, the last row of A_r is zero. With $\mathbf{y} = G^{-1}\mathbf{e}_m$, the system $A\mathbf{x} = \mathbf{y}$ is equivalent to $A_r\mathbf{x} = \mathbf{e}_m$, whose last equation reads $0 = 1$.

Let G be invertible with $GA = A_r$ (Theorem 3.3.10), and let k be the number of pivots. By Proposition 3.3.8 the pivots lie in rows $1, \dots, k$, one in each, so (I) says exactly that $k = m$.

(I) ⇒ (II). Suppose $k = m$, and let $\mathbf{y} \in F^m$. There is no index i with $k < i \le m$, so the condition in Corollary 3.4.4 holds trivially, and $A\mathbf{x} = \mathbf{y}$ is consistent. Explicitly, by Theorem 3.4.3(b) and Proposition 3.4.1, the vector with $x_{p_i} = (G\mathbf{y})_i$ for $i = 1, \dots, m$ and all free variables 0 is a solution.

(II) ⇒ (I). We prove the contrapositive. Suppose $k < m$, so that row m of A_r is zero (Proposition 3.3.8(a)). Let $\mathbf{y} = G^{-1}\mathbf{e}_m$. Then $G\mathbf{y} = \mathbf{e}_m$ has mth entry $1 \neq 0$, and $m > k$, so $A\mathbf{x} = \mathbf{y}$ is inconsistent by Corollary 3.4.4. (Directly: $A\mathbf{x} = \mathbf{y}$ if and only if $A_r\mathbf{x} = \mathbf{e}_m$, and the mth entry of $A_r\mathbf{x}$ is 0 for every $\mathbf{x}$.) So (II) fails. □

Remark 3.4.17 (Why G^{-1}). It is tempting to take $\mathbf{y} = \mathbf{e}_m$ itself in the last proof, but row operations move the image of T_A (Non-example 3.2.19), and $A\mathbf{x} = \mathbf{e}_m$ may well be consistent. For instance,



$$A = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad A_r = \begin{pmatrix} 1 \\ 0 \end{pmatrix} = E_{12}A,$$

and $A\mathbf{x} = \mathbf{e}_2$ has the solution $x = 1$. With $G = E_{12}$, the bad right-hand side is $G^{-1}\mathbf{e}_2 = \mathbf{e}_1$: the equation $A\mathbf{x} = \mathbf{e}_1$ says $0 = 1$.

By Proposition 3.1.8(a), (II) says that T_A is surjective, equivalently that the columns of A span F^m, so a pivot in every row is a mechanical test for the conditions of Theorem 2.7.4. For a 2×2 matrix both failures can be watched at once. The component below starts with

$$A = \begin{pmatrix} 1 & -2 \\ -1 & 2 \end{pmatrix}, \quad A_r = \begin{pmatrix} 1 & -2 \\ 0 & 0 \end{pmatrix}.$$

The columns $\mathbf{a}_1 = (1, -1)$ and $\mathbf{a}_2 = (-2, 2) = -2\mathbf{a}_1$ lie on one line, and A_r has one pivot: its second column is free and its second row is zero. For $\mathbf{y} = (1, 1)$, off the line $\operatorname{span}(\mathbf{a}_1)$, the two lines of the row picture are parallel and there is no solution. Drag $\mathbf{y}$ onto the line spanned by the columns and the two lines of the row picture coincide: now there are infinitely many solutions, one for each value of the free variable x_2. Drag $\mathbf{a}_2$ off that line and both defects disappear at once, as they must for a square matrix (Corollary 3.4.20).

Row picture Column picture

The system $x_1 - 2x_2 = 1$, $-x_1 + 2x_2 = 1$. Left: the row picture, with one line per equation. Right: the column picture, where $\mathbf{y}$ must be reached as $x_1\mathbf{a}_1 + x_2\mathbf{a}_2$. Drag $\mathbf{a}_1$, $\mathbf{a}_2$, $\mathbf{y}$, or type new entries. (Interactive in the web version.)

Exercise 3.4.18. ROUTINE Each matrix below is A_r for some A. For each one, decide whether $A\mathbf{x} = \mathbf{0}$ has only the trivial solution, and whether $A\mathbf{x} = \mathbf{y}$ is consistent for every $\mathbf{y}$.

$$R_1 = \begin{pmatrix} 1 & 0 & 3 \\ 0 & 1 & -1 \end{pmatrix}, \quad R_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad R_3 = \begin{pmatrix} 1 & 4 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad R_4 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Solution on page 1240

Since there are at most $\min(m, n)$ pivots, the shape of A alone can rule out one of the two properties.

Corollary 3.4.19 (More unknowns than equations). Let $A \in F^{m \times n}$.

(a) If $n > m$, then $A\mathbf{x} = \mathbf{0}$ has a nontrivial solution.

(b) If $m > n$, then $A\mathbf{x} = \mathbf{y}$ is inconsistent for some $\mathbf{y} \in F^m$.

Proof. ROUTINE

Uses. Proposition 3.3.8 (Properties of the output), Proposition 3.4.15 (A pivot in every column), Proposition 3.4.16 (A pivot in every row)
Hint 1. How many pivots can A_r have?
Hint 2. If $n > m$, there are more columns than pivots.
Sketch. There are $k \leq \min(m, n)$ pivots. If $n > m$, then $k \leq m < n$, so some column has no pivot, and Proposition 3.4.15 applies. If $m > n$, then $k \leq n < m$, so some row has no pivot, and Proposition 3.4.16 applies.

By Proposition 3.3.8, A_r has $k \leq \min(m, n)$ pivots, in distinct rows and distinct columns. If $n > m$, then $k \leq m < n$, so at least one of the n columns has no pivot, and $A\mathbf{x} = \mathbf{0}$ has a nontrivial solution by Proposition 3.4.15. If $m > n$, then $k \leq n < m$, so at least one of the m rows has no pivot, and some $A\mathbf{x} = \mathbf{y}$ is inconsistent by Proposition 3.4.16. □

Part (a) has a geometric reading over $\mathbb{R}$: two planes through the origin in $\mathbb{R}^3$ always share a line, since two homogeneous equations in three unknowns have a nontrivial solution. In terms of the Fundamental Theorems, (a) and (b) say that T_A can be injective only if $n \leq m$, and surjective only if $m \leq n$. Section 3.5 draws the consequences, among them that every invertible matrix is square.

For square matrices the two properties cannot be separated.

Corollary 3.4.20 (Square systems). Let $A \in F^{n \times n}$. The following are equivalent.

(i) A_r has a pivot in every column.
(ii) A_r has a pivot in every row.
(iii) $A_r = I_n$.
(iv) $A\mathbf{x} = \mathbf{0}$ has only the trivial solution.
(v) $A\mathbf{x} = \mathbf{y}$ has a solution for every $\mathbf{y} \in F^n$.
(vi) $A\mathbf{x} = \mathbf{y}$ has exactly one solution for every $\mathbf{y} \in F^n$.
(vii) A is invertible.

Proof. STANDARD

Uses. Proposition 3.3.8 (Properties of the output), Proposition 3.4.15 (A pivot in every column), Proposition 3.4.16 (A pivot in every row), Corollary 3.1.22 (Uniqueness depends only on A), Proposition 3.1.8 (Systems and the map T_A), Theorem 3.3.23 (Invertibility and RREF)
Techniques. Proving TFAE (Technique 2.7.1), Reduce to RREF (Technique 3.3.22)
Hint 1. Each pivot occupies its own row and its own column. What do (i) and (ii) say about the number k of pivots of a square matrix?
Hint 2. (i) ⇔ (iv) and (ii) ⇔ (v) are the two propositions. For (vi), combine existence with Corollary 3.1.22.
Hint 3. (iii) ⇔ (vii) is Theorem 3.3.23.
Sketch. With k pivots in distinct rows and columns, (i) and (ii) both say $k = n$; and $k = n$ forces $p_s = s$ and $A_r = I_n$, while I_n has n pivots. The propositions give (i) ⇔ (iv) and (ii) ⇔ (v). (vi) implies (iv) (take $\mathbf{y} = \mathbf{0}$) and (v); conversely (iv) and (v) together give (vi) by Corollary 3.1.22. Finally (iii) ⇔ (vii) is Theorem 3.3.23.

Let k be the number of pivots of A. By Proposition 3.3.8 they lie in rows $1, \dots, k$ and in k distinct columns $p_1 < \cdots < p_k$. So (i) says $k = n$, and since A has n rows, (ii) also says $k = n$. Hence (i) $\Leftrightarrow$ (ii).

(i) $\Leftrightarrow$ (iii). If $k = n$, then $p_s = s$ for every s (as in the first proof of Proposition 3.4.15), and column s of A_r is $\mathbf{e}_s$ by Proposition 3.3.8(c), so $A_r = I_n$. Conversely, the pivots of I_n are its diagonal entries (Example 3.3.13), one in each column.

(i) $\Leftrightarrow$ (iv) and (ii) $\Leftrightarrow$ (v) are Proposition 3.4.15 and Proposition 3.4.16.

(iv), (v) $\Leftrightarrow$ (vi). If (vi) holds, then (v) holds, and the unique solution of $A\mathbf{x} = \mathbf{0}$ is the trivial one, which is (iv). Conversely, suppose (iv) and (v) hold. By (iv) and Proposition 3.1.8(b), $\ker T_A = \{\mathbf{0}\}$. Let $\mathbf{y} \in F^n$. By (v), $A\mathbf{x} = \mathbf{y}$ is consistent, and by Corollary 3.1.22(a) it has exactly one solution. Since (iv) $\Leftrightarrow$ (i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (v), each of (iv) and (v) implies the other, so each is equivalent to (vi).

(iii) $\Leftrightarrow$ (vii) is Theorem 3.3.23. □

The equivalence of (iv) and (v) is the remarkable one. For a square system, knowing that the homogeneous system has only the trivial solution, a statement about uniqueness, gives a solution of $A\mathbf{x} = \mathbf{y}$ for every $\mathbf{y}$, a statement about existence, and conversely. For non-square matrices both implications fail: $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ has a pivot in every row but not in every column, and the 2×1 matrix with column $(1, 0)$ the reverse. The corollary also completes Exercise 3.1.47. That exercise showed that the equilibrium temperatures of a plate are unique, and its system has as many equations as unknowns, so they also exist, for every choice of boundary temperatures.

This is a proof strategy in its own right.

> **Technique 3.4.21** (Uniqueness gives existence). To show that a linear problem has a solution for *every* choice of data, it can be much easier to show that it has *at most one*. This works whenever the problem is a square linear system, with as many conditions as unknowns: by Corollary 3.4.20, if the homogeneous problem has only the zero solution, then every instance of the problem has exactly one solution. Uniqueness is usually the easier half because it is a statement about the homogeneous problem, where all data vanish, and it amounts to showing that some object is zero, often by a structural argument (a polynomial with too many roots, a maximum principle) rather than by computation. Existence then comes for free, without ever constructing a solution.
>
> The setup has two requirements: the conditions are linear in the unknowns, and the number of conditions equals the number of unknowns. With those in place, the one thing left to prove is uniqueness itself, namely that the homogeneous problem has only the zero solution. Counting conditions and unknowns alone proves nothing (Exercise 3.6.14). Reach for it when existence looks hard and uniqueness looks easy, typically for interpolation-type problems (find an object of a given size with prescribed values) and for discrete boundary value problems such as Exercise 3.1.47. The canonical example is polynomial interpolation (Theorem 3.4.24). Section 4.2 extends it from square matrices to linear maps $V \to W$ with $\dim V = \dim W$.
>
> *Used in.* Theorem 3.4.24, Exercise 3.4.42, Exercise 3.6.13, Exercise 3.6.14, Problem 3.13, Problem 3.15, Problem 3.16, Problem 3.19, Exercise 4.2.47, Theorem 7.1.14, Exercise 7.1.57, Exercise 3.5.39.

3.4.5 Polynomial interpolation

Two points in the plane with different first coordinates lie on exactly one line, the graph of a polynomial of degree at most 1. Three points with distinct first coordinates lie on exactly one graph of a polynomial of degree at most 2, as Exercise 3.1.37 found in one example. In general, through $n + 1$ points with distinct first coordinates there passes exactly one graph of a polynomial of degree at most n, and this holds over every field. The proof is an application of everything in this section.

Throughout, $c_0, c_1, \ldots, c_n \in F$ are distinct (the **nodes**) and $d_0, d_1, \ldots, d_n \in F$ are arbitrary (the **values**). We look for $p \in F[x]_{\leq n}$ with

$$p(c_0) = d_0, \quad p(c_1) = d_1, \quad \ldots, \quad p(c_n) = d_n. \tag{3.4.3}$$

By Technique 3.1.9, write $p = a_0 + a_1 x + \cdots + a_n x^n$ with unknown coefficients. By Definition 1.2.17, the condition $p(c_i) = d_i$ reads

$$a_0 + a_1 c_i + a_2 c_i^2 + \cdots + a_n c_i^n = d_i,$$

a linear equation in $a_0, \ldots, a_n$. So (3.4.3) is a linear system of $n+1$ equations in $n+1$ unknowns, with the following coefficient matrix.

Definition 3.4.22 (Vandermonde matrix). For $c_0, \ldots, c_n \in F$, the **Vandermonde matrix** $V(c_0, \ldots, c_n) \in F^{(n+1)\times(n+1)}$ is the matrix whose row $i+1$ is $\left(1, c_i, c_i^2, \ldots, c_i^n\right)$, for $i = 0, \ldots, n$:

$$V(c_0, \ldots, c_n) = \begin{pmatrix} 1 & c_0 & c_0^2 & \cdots & c_0^n \\ 1 & c_1 & c_1^2 & \cdots & c_1^n \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & c_n & c_n^2 & \cdots & c_n^n \end{pmatrix}.$$

With $\mathbf{a} = (a_0, \ldots, a_n)$ and $\mathbf{d} = (d_0, \ldots, d_n)$ in F^{n+1}, the conditions (3.4.3) say exactly that $V\mathbf{a} = \mathbf{d}$, where $V = V(c_0, \ldots, c_n)$. The system is square, so by Technique 3.4.21 it is enough to show that $V\mathbf{a} = \mathbf{0}$ forces $\mathbf{a} = \mathbf{0}$, that is, that a polynomial of degree at most n that vanishes at $n+1$ distinct points is the zero polynomial.

Intuition (Splitting off a root). The familiar reason is that each root c of p contributes a factor $x - c$, and a polynomial of degree at most n has room for at most n such factors. We cannot multiply polynomials until Section 7.1, but we can split off the factor by hand, because of an identity in the field:

$$t^j - c^j = (t - c)\left(t^{j-1} + t^{j-2}c + \cdots + c^{j-1}\right).$$

Summing these over the terms of p shows that $p(t) - p(c)$ equals $t - c$ times the value at t of an explicit polynomial q of degree at most $n-1$. If p vanishes at $c_0, \ldots, c_n$, then q vanishes at $c_1, \ldots, c_n$, and induction on n takes over.

Lemma 3.4.23 (Too many roots). Let $n \geq 0$ and $p \in F[x]_{\leq n}$. If $p(c_0) = p(c_1) = \cdots = p(c_n) = 0$ for distinct $c_0, \ldots, c_n \in F$, then $p = \mathbf{0}$.

Proof. STANDARD

Uses. Definition 1.2.16 (Degree), Definition 1.2.17 (Evaluation), Proposition 1.1.17 (No zero divisors), induction on n

Hint 1. Induct on n. For the inductive step, look for a polynomial q of degree at most $n-1$ with $p(t) - p(c_0) = (t - c_0)q(t)$ for every $t \in F$.

Hint 2. Use the telescoping identity for $t^j - c^j$ from the intuition above, and collect the coefficient of t^i. It is $b_i = \sum_{j>i} a_j c^{j-1-i}$.

Hint 3. q vanishes at $c_1, \ldots, c_n$, so $q = \mathbf{0}$ by induction. Recover $a_n, a_{n-1}, \ldots, a_1$ from $b_{n-1} = a_n$ and $b_i = a_{i+1} + c_0 b_{i+1}$.

Sketch. Write $p = \sum_j a_j x^j$ and $c = c_0$. Telescoping gives $p(t) - p(c) = (t - c)q(t)$ for all t, where $q = \sum_{i<n} b_i x^i$ and $b_i = \sum_{j>i} a_j c^{j-1-i}$. For $i \geq 1$, $0 = (c_i - c)q(c_i)$ with $c_i - c \neq 0$, so q vanishes at the n distinct points $c_1, \ldots, c_n$, and $q = \mathbf{0}$ by induction. Since $b_{n-1} = a_n$ and $b_i = a_{i+1} + c b_{i+1}$, all of $a_1, \ldots, a_n$ vanish, and then $a_0 = p(c_0) = 0$.

We induct on n. If $n = 0$, then $p = a_0$ is constant, and $a_0 = p(c_0) = 0$.

Let $n \geq 1$, and assume the lemma for $n-1$. Write $p = a_0 + a_1 x + \cdots + a_n x^n$, and put $c = c_0$. For $j \geq 1$ and $t \in F$, the following sum telescopes:

$$(t - c)\sum_{i=0}^{j-1} t^i c^{j-1-i} = \sum_{i=0}^{j-1} t^{i+1} c^{j-1-i} - \sum_{i=0}^{j-1} t^i c^{j-i} = t^j - c^j.$$

Multiplying by a_j, summing over $j = 1, \dots, n$, and collecting the terms with the same power t^i (for a fixed i, the index j runs over $i+1, \dots, n$), we get

$$p(t) - p(c) = \sum_{j=1}^{n} a_j\left(t^j - c^j\right) = (t-c)\sum_{i=0}^{n-1} b_i t^i, \quad \text{where } b_i = \sum_{j=i+1}^{n} a_j c^{j-1-i}.$$

Let

$$q = b_0 + b_1 x + \cdots + b_{n-1}x^{n-1} \in F[x]_{\le n-1}.$$

We have shown that

$$p(t) - p(c_0) = (t - c_0)q(t) \quad \text{for every } t \in F. \tag{3.4.4}$$

For $i = 1, \dots, n$, since $p(c_i) = p(c_0) = 0$, (3.4.4) gives $(c_i - c_0)q(c_i) = 0$. Here $c_i - c_0 \neq 0$ because the nodes are distinct, so $q(c_i) = 0$ by Proposition 1.1.17. Thus q has degree at most $n-1$ and vanishes at the n distinct points $c_1, \dots, c_n$, and by the induction hypothesis $q = \mathbf{0}$, that is, $b_0 = b_1 = \cdots = b_{n-1} = 0$.

Now $b_{n-1} = a_n$, and for $0 \le i \le n-2$, splitting off the term $j = i+1$,

$$b_i = a_{i+1} + c\sum_{j=i+2}^{n} a_j c^{j-2-i} = a_{i+1} + c b_{i+1}.$$

Hence $a_n = b_{n-1} = 0$, and $a_{i+1} = b_i - c b_{i+1} = 0$ for $i = n-2, \dots, 0$. So $a_1 = \cdots = a_n = 0$, and finally $a_0 = p(c_0) = 0$. Thus $p = \mathbf{0}$. □

The recursion $b_i = a_{i+1} + c b_{i+1}$, started from $b_{n-1} = a_n$, is Horner's scheme (or synthetic division) for dividing p by $x - c$. Once polynomials can be multiplied, (3.4.4) becomes the factorization $p - p(c) = (x-c)q$, and the same induction shows that a nonzero polynomial has at most $\deg p$ roots (Proposition 7.1.22).

Theorem 3.4.24 (Polynomial interpolation). Let $c_0, \dots, c_n \in F$ be distinct, and let $d_0, \dots, d_n \in F$. There is exactly one polynomial $p \in F[x]_{\le n}$ with $p(c_i) = d_i$ for $i = 0, 1, \dots, n$. In particular, the Vandermonde matrix $V(c_0, \dots, c_n)$ is invertible.

Proof. STANDARD

Uses. Definition 3.4.22 (Vandermonde matrix), Definition 1.2.17 (Evaluation), Definition 1.2.16 (Degree), Definition 2.3.8 (Matrix–vector product), Lemma 3.4.23 (Too many roots), Corollary 3.4.20 (Square systems)
Techniques. Undetermined coefficients (Technique 3.1.9), Uniqueness gives existence (Technique 3.4.21)
Hint 1. Write $p = a_0 + a_1 x + \cdots + a_n x^n$, and translate the conditions $p(c_i) = d_i$ into a linear system for the a_j. What is its coefficient matrix?
Hint 2. The system is square. By Corollary 3.4.20 it is enough to show that the homogeneous system has only the trivial solution.
Hint 3. A solution of the homogeneous system gives a polynomial of degree at most n that vanishes at $n+1$ distinct points.
Sketch. For $\mathbf{a} \in F^{n+1}$ let $p_{\mathbf{a}} = \sum_j a_j x^j$. The entry of $V\mathbf{a}$ in the row of c_i is $p_{\mathbf{a}}(c_i)$, so the interpolating polynomials correspond to the solutions of $V\mathbf{a} = \mathbf{d}$. If $V\mathbf{a} = \mathbf{0}$, then $p_{\mathbf{a}}$ vanishes at $c_0, \dots, c_n$, so $p_{\mathbf{a}} = \mathbf{0}$ by Lemma 3.4.23 and $\mathbf{a} = \mathbf{0}$. Since V is square, Corollary 3.4.20 gives exactly one solution of $V\mathbf{a} = \mathbf{d}$ for each $\mathbf{d}$, and invertibility of V.

Let $V = V(c_0, \dots, c_n)$ and $\mathbf{d} = (d_0, \dots, d_n)$. For $\mathbf{a} = (a_0, \dots, a_n) \in F^{n+1}$, write $p_{\mathbf{a}} = a_0 + a_1 x + \cdots + a_n x^n$. By Definition 1.2.16, every $p \in F[x]_{\le n}$ equals $p_{\mathbf{a}}$ for exactly one $\mathbf{a}$, namely its list of coefficients $a_0, \dots, a_n$. By Definition 2.3.8 and Definition 1.2.17, the entry of $V\mathbf{a}$ in the row of c_i is

$$a_0 + a_1 c_i + \cdots + a_n c_i^n = p_{\mathbf{a}}(c_i).$$

So $p_{\mathbf{a}}$ satisfies $p_{\mathbf{a}}(c_i) = d_i$ for all i if and only if $V\mathbf{a} = \mathbf{d}$. Through $\mathbf{a} \mapsto p_{\mathbf{a}}$, the polynomials we want correspond exactly to the solutions of $V\mathbf{a} = \mathbf{d}$.

Suppose $V\mathbf{a} = \mathbf{0}$. Then $p_{\mathbf{a}}$ has degree at most n and vanishes at the $n+1$ distinct points $c_0, \ldots, c_n$, so $p_{\mathbf{a}} = \mathbf{0}$ by Lemma 3.4.23, that is, $\mathbf{a} = \mathbf{0}$. So the homogeneous system $V\mathbf{a} = \mathbf{0}$ has only the trivial solution. Since V is square, Corollary 3.4.20 ((iv) $\Rightarrow$ (vi) and (vii)) shows that $V\mathbf{a} = \mathbf{d}$ has exactly one solution, and that V is invertible. Hence there is exactly one polynomial $p \in F[x]_{\leq n}$ with $p(c_i) = d_i$ for all i. □

The proof never solved anything. Existence came from uniqueness: $n+1$ conditions on $n+1$ unknown coefficients form a square system, and the homogeneous version asks for a polynomial with too many roots. Both hypotheses are needed. If two nodes coincide, say $c_0 = c_1$, then V has two equal rows, and for $d_0 \neq d_1$ there is no solution at all. And the degree bound n is exactly right. With degree at most $n-1$ there are only n unknowns for $n+1$ conditions, so by Corollary 3.4.19(b) some values cannot be interpolated. With degree at most $n+1$ there are $n+2$ unknowns, so by Corollary 3.4.19(a) the homogeneous system has a nontrivial solution and uniqueness fails (Figure 3.4.1; see also Exercise 3.4.39).

Example 3.4.25 (A cubic through four points). Find the polynomial $p \in \mathbb{Q}[x]_{\leq 3}$ with

$$p(-1) = 2, \quad p(0) = 1, \quad p(1) = 0, \quad p(2) = 5.$$

With $p = a_0 + a_1 x + a_2 x^2 + a_3 x^3$, the system $V\mathbf{a} = \mathbf{d}$ is

$$\left(\begin{array}{cccc|c} 1 & -1 & 1 & -1 & 2 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 0 \\ 1 & 2 & 4 & 8 & 5 \end{array}\right).$$

The second equation gives $a_0 = 1$, and the others become $-a_1 + a_2 - a_3 = 1$, $a_1 + a_2 + a_3 = -1$, and $2a_1 + 4a_2 + 8a_3 = 4$. Adding the first two gives $a_2 = 0$. Then $a_1 + a_3 = -1$ and $a_1 + 4a_3 = 2$, so $a_3 = 1$ and $a_1 = -2$. Hence

$$p = 1 - 2x + x^3.$$

Check: $p(-1) = 1 + 2 - 1 = 2$, $p(0) = 1$, $p(1) = 1 - 2 + 1 = 0$, and $p(2) = 1 - 4 + 8 = 5$.

$$\left(\begin{array}{cccc|c} 1 & -1 & 1 & -1 & 2 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 0 \\ 1 & 2 & 4 & 8 & 5 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|c} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & -2 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 \end{array}\right)$$

The system $V\mathbf{a} = \mathbf{d}$ of Example 3.4.25. The left block reduces to I_4, and the last column becomes the coefficient vector $(1, -2, 0, 1)$. Edit the last column to interpolate other values at the same nodes. (Interactive in the web version.)

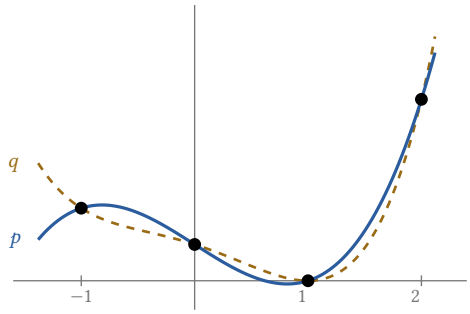


Figure 3.4.1. The cubic $p = 1 - 2x + x^3$ of Example 3.4.25 (solid) is the only polynomial of degree at most 3 through the four points. The quartic $q = 1 - x - x^2/2 + x^4/2$ (dashed) passes through them too: $q - p = (x^4 - 2x^3 - x^2 + 2x)/2$ vanishes at $-1, 0, 1, 2$. With degree at most 4 there are five unknown coefficients and only four conditions.

Lagrange's formula

The theorem gives the interpolating polynomial for each list of values separately. Linearity lets us do all of them at once: it is enough to interpolate the simplest values, a single 1 and zeros elsewhere.

Definition 3.4.26 (Lagrange polynomials). Let $c_0, \dots, c_n \in F$ be distinct. For $i = 0, \dots, n$, the ith **Lagrange polynomial** $L_i \in F[x]_{\le n}$ is the unique polynomial of degree at most n with

$$L_i(c_i) = 1 \quad \text{and} \quad L_i(c_k) = 0 \text{ for } k \neq i.$$

It exists and is unique by Theorem 3.4.24.

Proposition 3.4.27 (Lagrange's formula). Let $c_0, \dots, c_n \in F$ be distinct, and let $d_0, \dots, d_n \in F$. The unique $p \in F[x]_{\le n}$ with $p(c_i) = d_i$ for all i is

$$p = d_0 L_0 + d_1 L_1 + \cdots + d_n L_n.$$

Proof. ROUTINE

Uses. Definition 3.4.26 (Lagrange polynomials), Proposition 1.2.18 (Degree and evaluation versus the operations), Theorem 3.4.24 (Polynomial interpolation)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Evaluate the right side at c_k, using that evaluation is linear (Proposition 1.2.18(c)).
Hint 2. Conclude with the uniqueness in Theorem 3.4.24.
Sketch. The right side q has degree at most n, and $q(c_k) = \sum_i d_i L_i(c_k) = d_k$ by linearity of evaluation. By uniqueness in Theorem 3.4.24, $q = p$.

Let $q = d_0 L_0 + \cdots + d_n L_n$. By Proposition 1.2.18(a) and (b), sums and nonzero scalar multiples of polynomials of degree at most n have degree at most n (and $0 L_i = \mathbf{0}$ trivially does), so $q \in F[x]_{\le n}$. By Proposition 1.2.18(c), for each k,

$$q(c_k) = \sum_{i=0}^{n} d_i L_i(c_k) = d_k \cdot 1 + \sum_{i \neq k} d_i \cdot 0 = d_k.$$

So q satisfies the same conditions as p, and $q = p$ by the uniqueness in Theorem 3.4.24. □

Example 3.4.28 (Lagrange polynomials for the nodes $-1, 0, 1, 2$). For the nodes of Example 3.4.25, the Lagrange polynomials are

$$L_0 = -\frac{1}{3}x + \frac{1}{2}x^2 - \frac{1}{6}x^3, \quad L_1 = 1 - \frac{1}{2}x - x^2 + \frac{1}{2}x^3,$$

$$L_2 = x + \frac{1}{2}x^2 - \frac{1}{2}x^3, \qquad L_3 = -\frac{1}{6}x + \frac{1}{6}x^3.$$

Each claim is checked by evaluating at the four nodes; for instance $L_3(2) = -\frac{1}{3} + \frac{8}{6} = 1$ and $L_3(-1) = \frac{1}{6} - \frac{1}{6} = 0$. By Proposition 3.4.27, the cubic of Example 3.4.25 is

$$2L_0 + L_1 + 0L_2 + 5L_3 = 1 + \left(-\frac{2}{3} - \frac{1}{2} - \frac{5}{6}\right)x + (1-1)x^2 + \left(-\frac{1}{3} + \frac{1}{2} + \frac{5}{6}\right)x^3 = 1 - 2x + x^3,$$

as before. Once polynomials can be multiplied (Section 7.1), each L_i has the closed form

$$L_i = \prod_{j \neq i} \frac{x - c_j}{c_i - c_j},$$

because the product has degree n and takes the right values, so it is L_i by uniqueness. For instance

$$L_3 = \frac{(x+1)x(x-1)}{3 \cdot 2 \cdot 1} = \frac{x^3 - x}{6}.$$

Section 7.1 revisits interpolation from this side.

The Lagrange polynomials also describe V^{-1}. The coefficient vector $\mathbf{l}_i$ of L_i solves $V\mathbf{a} = \mathbf{e}_{i+1}$, since L_i takes the value 1 at c_i and 0 at the other nodes. So the columns of V^{-1} are the coefficient vectors of $L_0, \ldots, L_n$, and Lagrange's formula is the equation $V^{-1}\mathbf{d} = d_0\mathbf{l}_0 + \cdots + d_n\mathbf{l}_n$. For the nodes $-1, 0, 1, 2$, the first column of V^{-1} is $(0, -1/3, 1/2, -1/6)$, the coefficients of L_0.

Finally, V is a square matrix, so its invertibility can also be decided by a determinant. Section 5.5 computes

$$\det V(c_0, \ldots, c_n) = \prod_{i<j} (c_j - c_i)$$

(Theorem 5.5.21), which is nonzero exactly when the nodes are distinct; by Theorem 5.4.7 this gives a second proof that V is invertible.

Exercise 3.4.29. ROUTINE

(a) Over $\mathbb{Q}$, find the Lagrange polynomials for the nodes $0, 1, 3$, and use them to find the $p \in \mathbb{Q}[x]_{\leq 2}$ with $p(0) = 2$, $p(1) = -1$, and $p(3) = 5$.

(b) Find the $p \in \mathbb{F}_5[x]_{\leq 2}$ with the same three values, read in $\mathbb{F}_5$.

Solution on page 1240

Exercises

Exercise 3.4.30. ROUTINE Let

$$A = \begin{pmatrix} 1 & 2 & 0 & 1 & 3 \\ 2 & 4 & 1 & 4 & 7 \\ -1 & -2 & 1 & 1 & -2 \end{pmatrix} \in \mathbb{Q}^{3\times 5}.$$

(a) Find all $\mathbf{y} \in \mathbb{Q}^3$ for which $A\mathbf{x} = \mathbf{y}$ is consistent.

(b) For $\mathbf{y} = (1, 3, 0)$, write the solution set in the form $\mathbf{x}_0 + \operatorname{span}(\mathbf{s}_1, \ldots, \mathbf{s}_\ell)$ of Theorem 3.4.9.

Solution on page 1241

Exercise 3.4.31. ROUTINE Let A be the matrix of Exercise 3.3.40,

$$A = \begin{pmatrix} 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix}.$$

Solve $A\mathbf{x} = (1, 0, 1)$ over $\mathbb{Q}$ and over $\mathbb{F}_2$. Over $\mathbb{F}_2$, list all solutions, and compare their number with Corollary 3.4.14.

Solution on page 1241

Exercise 3.4.32. ROUTINE Over $\mathbb{C}$, consider

$$x_1 + ix_2 = 1, \quad ix_1 - x_2 + x_3 = 2 + i, \quad x_3 = 2.$$

(a) Find all solutions in $\mathbb{C}^3$.

(b) For which $\mathbf{y} \in \mathbb{C}^3$ is the system with these left sides and right side $\mathbf{y}$ consistent?

(c) Which of the solutions in (a) lie in $\mathbb{R}^3$?

Solution on page 1242

Exercise 3.4.33. STANDARD For a, b in a field F, consider the system

$$x_1 + x_2 + ax_3 = 1, \quad x_1 + ax_2 + x_3 = 1, \quad ax_1 + x_2 + x_3 = b.$$

(a) For $F = \mathbb{R}$, find all (a, b) for which the system has no solution, exactly one solution, and infinitely many solutions.

(b) Answer the same question for $F = \mathbb{F}_3$, and count the solutions in each case.

Solution on page 1242

Exercise 3.4.34. STANDARD Let A be the matrix of Example 3.4.6, and $\mathbf{y} = (4, 2, 5)$. Two students describe the solution set of $A\mathbf{x} = \mathbf{y}$.

Student 1. "The solution set is $(-1, 0, 2, 0) + \operatorname{span}((0, 1, -2, 1))$. Proof: $A(-1, 0, 2, 0) = (4, 2, 5)$ and $A(0, 1, -2, 1) = \mathbf{0}$, so every vector of this form is a solution, by Proposition 3.1.19."

Student 2. The solution set is

$$(1, -1, 2, 0) + \operatorname{span}((0, 1, -2, 1), (4, -1, -2, 1)).$$

(a) Find the error in Student 1's argument, and a solution that Student 1 has missed.

(b) Decide whether Student 2 is right.

Solution on page 1243

Exercise 3.4.35. STANDARD Let $A \in F^{m \times n}$. Prove or disprove each statement.

(a) If $A\mathbf{x} = \mathbf{y}$ has exactly one solution for some $\mathbf{y} \in F^m$, then A_r has a pivot in every column.

(b) If $A\mathbf{x} = \mathbf{0}$ has only the trivial solution, then $A\mathbf{x} = \mathbf{y}$ is consistent for every $\mathbf{y}$.

(c) If A_r has a pivot in every column, and B is obtained from A by deleting some of its columns, then B_r has a pivot in every column.

(d) If A_r has a pivot in every row, and B is obtained from A by deleting some of its columns, then B_r has a pivot in every row.

Solution on page 1244

Exercise 3.4.36. STANDARD Let F be a finite field with q elements, and let $A \in F^{m\times n}$ have k pivots.

(a) Show that $A\mathbf{x} = \mathbf{y}$ is consistent for exactly q^k vectors $\mathbf{y} \in F^m$.

(b) Each consistent system $A\mathbf{x} = \mathbf{y}$ has q^{n-k} solutions. Explain why $q^k \cdot q^{n-k} = q^n$ is no coincidence.

Solution on page 1244

Exercise 3.4.37. STANDARD Let $A \in F^{m\times n}$ and $1 \le j \le n$. Show that x_j is a free variable of A if and only if there is a solution $\mathbf{x}$ of $A\mathbf{x} = \mathbf{0}$ with $x_j = 1$ and $x_l = 0$ for every $l > j$.

Solution on page 1244

Exercise 3.4.38. STANDARD Let F be a subfield of a field K (for example $\mathbb{Q} \subseteq \mathbb{R}$ or $\mathbb{R} \subseteq \mathbb{C}$). Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$.

(a) Show that if $A\mathbf{x} = \mathbf{y}$ has a solution $\mathbf{x} \in K^n$, then it has a solution in F^n.

(b) Show that if $A\mathbf{x} = \mathbf{y}$ has exactly one solution in K^n, then that solution lies in F^n.

(c) Show that if $A\mathbf{x} = \mathbf{0}$ has a nontrivial solution in K^n, then it has one in F^n.

Solution on page 1245

Exercise 3.4.39. STANDARD Let $m \ge 1$, let $c_1, \ldots, c_m \in F$ be distinct, let $d \ge 0$, and let $W \in F^{m\times(d+1)}$ be the matrix with rows $\left(1, c_i, c_i^2, \ldots, c_i^d\right)$, $i = 1, \ldots, m$. Show that:

(a) W_r has a pivot in every column if and only if $m \ge d + 1$;

(b) W_r has a pivot in every row if and only if $m \le d + 1$.

Interpret both statements as statements about polynomials of degree at most d with prescribed values at $c_1, \ldots, c_m$.

Solution on page 1245

Exercise 3.4.40. STANDARD Let p be a prime.

(a) Show that every function $g : \mathbb{F}_p \to \mathbb{F}_p$ is the polynomial function of exactly one polynomial $f \in \mathbb{F}_p[x]_{\le p-1}$. Check this by counting both sides.

(b) Find that polynomial for the function g with $g(0) = 1$ and $g(c) = 0$ for $c \ne 0$.

Solution on page 1246

Exercise 3.4.41. STANDARD For each prime p, find the number of $(a_0, a_1, a_2) \in \mathbb{F}_p^3$ with

$$a_0 + a_1 + a_2 = 1, \quad a_0 + 2a_1 + 4a_2 = 2, \quad a_0 + 3a_1 + 9a_2 = 4.$$

Solution on page 1246

Exercise 3.4.42. STANDARD For $p = a_0 + a_1x + a_2x^2 + a_3x^3 \in \mathbb{R}[x]$, write $p' = a_1 + 2a_2x + 3a_3x^2$.

(a) Show that for all $u_0, v_0, u_1, v_1 \in \mathbb{R}$ there is exactly one $p \in \mathbb{R}[x]_{\le 3}$ with

$$p(0) = u_0, \quad p'(0) = v_0, \quad p(1) = u_1, \quad p'(1) = v_1.$$

(b) Find the four polynomials h_1, h_2, h_3, h_4 obtained when one of u_0, v_0, u_1, v_1 is 1 and the others are 0, and write the general p in terms of them.

Solution on page 1246

Exercise 3.4.43. STANDARD

(a) Find all $w_0, w_1, w_2 \in \mathbb{R}$ such that

$$\int_{-1}^{1} p(t)\,\mathrm{d}t = w_0 p(-1) + w_1 p(0) + w_2 p(1)$$

for every $p \in \mathbb{R}[x]_{\leq 2}$.

(b) Show that the resulting rule is exact for every $p \in \mathbb{R}[x]_{\leq 3}$ as well, but not for x^4.

Solution on page 1247

Exercise 3.4.44. HARD Let $A, B \in F^{m\times n}$ and $\mathbf{y}, \mathbf{w} \in F^m$.

(a) Show that if the systems $A\mathbf{x} = \mathbf{y}$ and $B\mathbf{x} = \mathbf{w}$ have the same solution set, and it is nonempty, then the augmented matrices $(A \mid \mathbf{y})$ and $(B \mid \mathbf{w})$ are row equivalent.

(b) Show by an example that (a) fails without the word "nonempty".

Solution on page 1247

Exercise 3.4.45. HARD Let $\mathbf{x}_0, \mathbf{u}_1, \ldots, \mathbf{u}_r \in F^n$.

(a) Describe a procedure that produces a linear system whose solution set is exactly $\mathbf{x}_0 + \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$, and prove that it works.

(b) Carry it out over $\mathbb{R}$ for $\mathbf{x}_0 = (1, 0, 2, 0)$, $\mathbf{u}_1 = (1, 1, 0, 0)$, and $\mathbf{u}_2 = (0, 0, 1, 1)$.

Solution on page 1248

Exercise 3.4.46. HARD **Secret sharing.** A secret $s \in \mathbb{F}_p$ is to be shared among N people, where $N < p$, so that any $t + 1$ of them together can recover it, but any t of them together learn nothing about it ($0 \leq t < N$). The dealer chooses $a_1, \ldots, a_t \in \mathbb{F}_p$ at random, forms $f = s + a_1 x + \cdots + a_t x^t$, and gives person i the **share** $f(i)$, for $i = 1, \ldots, N$.

(a) Show that any $t + 1$ people can compute s from their shares.

(b) Let $i_1, \ldots, i_t$ be t of the people, with shares $v_1, \ldots, v_t$. Show that for every $s' \in \mathbb{F}_p$ there is exactly one choice of $(a_1, \ldots, a_t) \in \mathbb{F}_p^t$ for which a dealer with secret s' would have produced exactly these shares. Explain why this means that the t people learn nothing about s.

Solution on page 1249

Exercise 3.4.47. CHALLENGE For $n \geq 0$, let $p_n \in \mathbb{Q}[x]_{\leq n}$ be the polynomial with $p_n(k) = 2^k$ for $k = 0, 1, \ldots, n$. Show that $p_n(n + 1) = 2^{n+1} - 1$.

Solution on page 1249

3.5 Rank and the Fundamental Theorems

The two propositions of Section 3.4.4 located the answers to the two basic questions about $A\mathbf{x} = \mathbf{y}$ in the pivots of $A_r = \operatorname{rref}(A)$. A pivot in every column means that solutions are unique (Proposition 3.4.15), and a pivot in every row means that there is a solution for every $\mathbf{y}$ (Proposition 3.4.16). Each row and each column holds at most one pivot, so both conditions are statements about a single number, the number of pivots. This number is the rank of A. With it we complete the Fundamental Theorems of Section 2.7: the rank supplies the sixth condition in each of them, and the inequality $\operatorname{rank} A \leq \min(m, n)$ supplies their constraints on the shape of A. In particular, invertible matrices are square. Along the way we construct

one-sided inverses directly from the pivots, show that every invertible matrix is a product of elementary matrices, and show that a one-sided inverse of a square matrix is automatically two-sided. Finally, allowing column operations as well as row operations, we bring every matrix to a normal form that depends only on its rank.

3.5.1 Rank

Definition 3.5.1 (Rank). Let $A \in F^{m\times n}$. The **rank** of A, written $\operatorname{rank} A$ or $\operatorname{rank}(A)$, is the number of pivots of A, that is, the number of pivots of $\operatorname{rref}(A)$ (Definition 3.3.9).

This is the number k of Section 3.4. Since $\operatorname{rref}(A)$ is determined by A, however the reduction is carried out (Corollary 3.3.18), so is the rank. Everything we know about pivots translates into statements about it.

Proposition 3.5.2 (First properties of rank). Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$.

(a) $\operatorname{rank} A \le \min(m, n)$. Moreover, $\operatorname{rank} A = m$ if and only if A_r has a pivot in every row, and $\operatorname{rank} A = n$ if and only if A_r has a pivot in every column.

(b) A has exactly $n - \operatorname{rank} A$ free columns, and A_r has exactly $m - \operatorname{rank} A$ zero rows.

(c) $\operatorname{rank}(GA) = \operatorname{rank} A$ for every invertible $G \in F^{m\times m}$. In particular, row equivalent matrices have the same rank.

(d) $\operatorname{rank} A$ is the number of indices $j \in \{1, \dots, n\}$ with $\mathbf{a}_j \notin \operatorname{span}(\mathbf{a}_1, \dots, \mathbf{a}_{j-1})$.

Proof. ROUTINE

Uses. Proposition 3.3.8 (Properties of the output), Definition 3.4.2 (Pivot and free variables), Corollary 3.3.18 (RREF and row equivalence), Definition 3.2.21 (Row equivalence), Corollary 3.2.11 (Products of elementary matrices), Corollary 3.3.19 (Pivot columns, intrinsically), Definition 1.3.10 (Span)
Hint 1. Where does Proposition 3.3.8 put the pivots? Count the rows and the columns they occupy.
Hint 2. For (c), compare $\operatorname{rref}(GA)$ with $\operatorname{rref}(A)$. For (d), which result describes the pivot columns without running the algorithm?
Sketch. The r pivots sit in positions $(1, p_1), \dots, (r, p_r)$ with $p_1 < \cdots < p_r$: one in each of the first r rows and one in each of r distinct columns. This gives (a) and (b). Part (c) is $\operatorname{rref}(GA) = \operatorname{rref}(A)$, and (d) is Corollary 3.3.19(a), which says that the pivot columns are exactly the columns that are not combinations of earlier ones.

Let $r = \operatorname{rank} A$ and let $p_1 < \cdots < p_r$ be the pivot columns. By Proposition 3.3.8, the pivots are the entries in positions $(1, p_1), \dots, (r, p_r)$ of A_r, rows $1, \dots, r$ of A_r are nonzero, and rows $r+1, \dots, m$ are zero.

(a) The pivots lie in r distinct rows and r distinct columns, so $r \le m$ and $r \le n$. Each row contains at most one pivot, so every one of the m rows contains a pivot if and only if $r = m$. The same argument applies to the n columns.

(b) By Definition 3.4.2, the columns other than $p_1, \dots, p_r$ are the free columns, and there are $n - r$ of them. The zero rows of A_r are rows $r+1, \dots, m$.

(c) By Corollary 3.3.18(a), $\operatorname{rref}(GA) = \operatorname{rref}(A)$, so GA and A have the same pivots. If $A \sim B$, then $B = E_k \cdots E_1 A$ for elementary matrices E_i (Definition 3.2.21), and the product $E_k \cdots E_1$ is invertible (Corollary 3.2.11).

(d) By Corollary 3.3.19(a), column j is a pivot column if and only if $\mathbf{a}_j$ is not a linear combination of $\mathbf{a}_1, \dots, \mathbf{a}_{j-1}$, that is, if and only if $\mathbf{a}_j \notin \operatorname{span}(\mathbf{a}_1, \dots, \mathbf{a}_{j-1})$ (Definition 1.3.10; for $j = 1$ the span of the empty list is $\{\mathbf{0}\}$). So the indices in (d) are exactly the pivot columns, and there are r of them. □

Part (d) describes the rank without reference to the algorithm. Scan the columns of A from left to right and count those that are not combinations of the columns before them; the count is $\operatorname{rank} A$. For instance, $\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$ has rank 1: its first column is nonzero, and the other two are multiples of it.

Part (c) is about row operations. Column operations also preserve the rank, $\operatorname{rank}(AH) = \operatorname{rank} A$ for invertible H, but row reduction gives no direct handle on this, because $\operatorname{rref}(AH)$ and $\operatorname{rref}(A)$ are in general different matrices. We prove it in Exercise 3.5.41, and Section 4.3 gives two more proofs.

Example 3.5.3 (A rank that depends on the field). Let

$$A = \begin{pmatrix} 1 & 2 & 0 & 0 & 1 \\ 2 & 4 & 1 & 3 & 7 \\ 2 & 4 & 2 & 0 & 6 \\ 0 & 0 & 3 & 0 & 6 \end{pmatrix}.$$

Over $\mathbb{Q}$, pass 1 adds -2 times row 1 to rows 2 and 3. Pass 2 finds the pivot $(2,3)$ and adds -2 and -3 times row 2 to rows 3 and 4. Pass 3 scales row 3 by $-1/6$ and clears column 4:

$$A \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & 0 & 1 \\ 0 & 0 & 1 & 3 & 5 \\ 0 & 0 & 2 & 0 & 4 \\ 0 & 0 & 3 & 0 & 6 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & 0 & 1 \\ 0 & 0 & 1 & 3 & 5 \\ 0 & 0 & 0 & -6 & -6 \\ 0 & 0 & 0 & -9 & -9 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix} = A_r.$$

So over $\mathbb{Q}$, $\operatorname{rank} A = 3 < \min(4,5)$, the pivot columns are $1, 3, 4$, and the free columns are $2, 5$. In terms of Proposition 3.5.2(d), $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_5 = \mathbf{a}_1 + 2\mathbf{a}_3 + \mathbf{a}_4$ are the columns that bring nothing new (Corollary 3.3.19(b)).

Now read the same entries in $\mathbb{F}_3$. The first two passes are the same computation with every entry reduced modulo 3, and the entries -6 and -9 of the second matrix are 0 in $\mathbb{F}_3$. So after pass 2 the last two rows are zero, the algorithm halts, and $\operatorname{rank} A = 2$ over $\mathbb{F}_3$. Over $\mathbb{F}_p$ with $p \geq 5$ the computation over $\mathbb{Q}$ goes through unchanged, since the only scalar we divided by is -6, which is nonzero in $\mathbb{F}_p$; so the rank is 3 there.

So the rank of a matrix with integer entries can depend on the field in which we read them. Enlarging the field never changes it: if F is a subfield of K and $A \in F^{m\times n}$, then $\operatorname{rref}(A)$ is the same over F and over K (Exercise 3.3.54), so a rational matrix has the same rank over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$.

$$\begin{pmatrix} 1 & 2 & 0 & 0 & 1 \\ 2 & 4 & 1 & 3 & 7 \\ 2 & 4 & 2 & 0 & 6 \\ 0 & 0 & 3 & 0 & 6 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

The matrix of Example 3.5.3 over $\mathbb{Q}$. At the end the summary reports the rank, the pivot columns, and the free columns. Use "Edit" to switch the field to $\mathbb{F}_3$ and watch the third pivot disappear, or to $\mathbb{F}_2$, where the rank is 3 again for different reasons. (Interactive in the web version.)

Exercise 3.5.4. ROUTINE Find the rank of each matrix.

(a) $\begin{pmatrix} 1 & -1 & 2 \\ -2 & 2 & -4 \\ 3 & -3 & 6 \end{pmatrix}$ over $\mathbb{Q}$.

(b) The Vandermonde matrix $V(1,2,3) = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 4 \\ 1 & 3 & 9 \end{pmatrix}$ (Definition 3.4.22), over $\mathbb{Q}$ and over $\mathbb{F}_2$.

(c) The $n \times n$ matrix all of whose entries are 1, over any field.

Solution on page 1250

Exercise 3.5.5. STANDARD Let $n \geq 2$, and let $A \in F^{n\times n}$ be the matrix with entry $i + j$ in position (i, j) (that is, the element $(i + j) * 1$ of F). Show that $\operatorname{rank} A = 2$, whatever the field F.

Solution on page 1250

The rank also answers the consistency question for a single right-hand side. Adjoining $\mathbf{y}$ to A as an extra column can create at most one new pivot, and it does so exactly when the system has no solution.

Proposition 3.5.6 (Consistency and rank). Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$. Then

$$\operatorname{rank} A \leq \operatorname{rank}(A \mid \mathbf{y}) \leq \operatorname{rank} A + 1,$$

and $A\mathbf{x} = \mathbf{y}$ is consistent if and only if $\operatorname{rank}(A \mid \mathbf{y}) = \operatorname{rank} A$.

Proof. ROUTINE

Uses. Corollary 3.3.19 (Pivot columns, intrinsically), Corollary 3.4.5 (Consistency from the augmented matrix), Proposition 3.5.2 (First properties of rank)
Hint 1. Describe the pivot columns of $(A \mid \mathbf{y})$ with Corollary 3.3.19(a). Does whether column $j \leq n$ is a pivot column depend on the last column?
Hint 2. So the two matrices have the same pivot columns among $1, \ldots, n$. When is column $n + 1$ a pivot column?
Sketch. By Corollary 3.3.19(a), column j of a matrix is a pivot column exactly when it is not a combination of the earlier columns, a condition involving only columns $1, \ldots, j$. So for $j \leq n$, column j is a pivot column of $(A \mid \mathbf{y})$ if and only if it is one of A. Hence $\operatorname{rank}(A \mid \mathbf{y})$ is $\operatorname{rank} A + 1$ if the last column is a pivot column and $\operatorname{rank} A$ otherwise, and by Corollary 3.4.5 the last column is a pivot column exactly when the system is inconsistent.

The first n columns of $(A \mid \mathbf{y})$ are $\mathbf{a}_1, \ldots, \mathbf{a}_n$. By Corollary 3.3.19(a), for $j \leq n$, column j is a pivot column of $(A \mid \mathbf{y})$ if and only if $\mathbf{a}_j$ is not a linear combination of $\mathbf{a}_1, \ldots, \mathbf{a}_{j-1}$, which is also the condition for column j to be a pivot column of A. So the two matrices have the same pivot columns among $1, \ldots, n$. Hence $\operatorname{rank}(A \mid \mathbf{y}) = \operatorname{rank} A$ if column $n + 1$ is not a pivot column of $(A \mid \mathbf{y})$, and $\operatorname{rank}(A \mid \mathbf{y}) = \operatorname{rank} A + 1$ if it is. By Corollary 3.4.5, column $n + 1$ is a pivot column if and only if $A\mathbf{x} = \mathbf{y}$ is inconsistent. □

In other words, $A\mathbf{x} = \mathbf{y}$ is consistent exactly when $\mathbf{y}$ brings nothing new beyond the columns of A. This criterion is often called the Rouché–Capelli theorem. It is convenient when ranks are already known, but in practice one row reduces $(A \mid \mathbf{y})$ and looks at the last column, which is what the proof does.

3.5.2 The Fundamental Theorems, completed

In Section 2.7 we stated three Fundamental Theorems for $T_A : F^n \to F^m$, each a list of equivalent conditions (I)–(V), and left open a sixth condition (the lecture marked it "secret") and the constraint each theorem puts on the shape of A. We can now fill in both.

Intuition (What the rank counts). Think of $A_r\mathbf{x} = G\mathbf{y}$ as the system $A\mathbf{x} = \mathbf{y}$ after elimination. Each of the $\operatorname{rank} A$ nonzero rows of A_r determines one pivot variable. The other $n - \operatorname{rank} A$ unknowns are free, and each free variable is an independent direction in which a solution can be moved without changing $A\mathbf{x}$; this is the failure of uniqueness. The remaining $m - \operatorname{rank} A$ rows of A_r are zero, and each produces a consistency condition $(G\mathbf{y})_i = 0$ on the right-hand side; this is the failure of existence. So $n - \operatorname{rank} A$ measures how far T_A is from injective, and $m - \operatorname{rank} A$ how far it is from surjective. Since $\operatorname{rank} A \leq$

$\min(m, n)$, a matrix with more columns than rows always has free variables, and a matrix with more rows than columns always has zero rows.

One-sided inverses from the pivots

Condition (V) of the first two theorems asks for a linear map: a left inverse of T_A, or a right inverse. That (V) implies the other conditions is quick (Proposition 2.5.4, Proposition 2.5.5). The converse requires producing the inverse, and row reduction produces it explicitly. First, a remark that lets us work with matrices instead of maps.

Remark 3.5.7 (Inverses of T_A and inverses of A). For $C \in F^{n\times m}$ we have $T_C \circ T_A = T_{CA}$ (Theorem 2.4.2(b)), and $T_{I_n} = \mathrm{id}_{F^n}$ (Proposition 2.3.13). Every linear map $S : F^m \to F^n$ is T_C for exactly one $C \in F^{n\times m}$ (Proposition 2.3.17). So $S = T_C$ is a left inverse of T_A if and only if $T_{CA} = T_{I_n}$, that is, if and only if $CA = I_n$, by the uniqueness in Proposition 2.3.17. Likewise T_C is a right inverse of T_A if and only if $AC = I_m$. Such a C is a left inverse, respectively a right inverse, of the matrix A (Definition 2.5.1, Definition 2.5.2), and we pass freely between the two readings.

Intuition (Choosing solutions linearly). A right inverse X of A is a rule that picks, for each $\mathbf{y}$, one solution $\mathbf{x} = X\mathbf{y}$ of $A\mathbf{x} = \mathbf{y}$, and does so linearly. When there are free variables, $A\mathbf{x} = \mathbf{y}$ has many solutions, and an arbitrary choice for each $\mathbf{y}$ need not be linear. But one choice is visibly linear: the particular solution, which sets every free variable to 0 and reads the pivot variables off $G\mathbf{y}$ (Definition 3.4.8). Writing this rule as a matrix gives the lecture's construction.

Proposition 3.5.8 (Right inverses from the pivots). Let $A \in F^{m\times n}$ with $\operatorname{rank} A = m$. Then A has a right inverse. Explicitly, let $p_1 < \cdots < p_m$ be the pivot columns of A, let $G \in F^{m\times m}$ be invertible with $GA = A_r$, and let $B \in F^{n\times m}$ be the matrix with entry 1 in position (p_i, i) for $i = 1, \ldots, m$ and 0 elsewhere. Then $A_rB = I_m$ and

$$A(BG) = I_m.$$

Moreover, for each $\mathbf{y} \in F^m$, the vector $BG\mathbf{y}$ is the particular solution of $A\mathbf{x} = \mathbf{y}$.

Proof. ROUTINE

Uses. Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.3.8 (Matrix–vector product), Definition 2.4.1 (Matrix product), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Definition 3.4.8 (Basic solutions)
Hint 1. Compute A_rB one column at a time. Column i of B is a standard basis vector of F^n. Which one?
Hint 2. Column i of A_rB is $A_r\mathbf{e}_{p_i}$, which is column p_i of A_r. What is that column?
Hint 3. Write $A = G^{-1}A_r$ and compute ABG.
Sketch. Column i of B is $\mathbf{e}_{p_i}$, so column i of A_rB is column p_i of A_r, which is $\mathbf{e}_i$; hence $A_rB = I_m$. Then $ABG = G^{-1}A_rBG = G^{-1}G = I_m$. Finally, $B\mathbf{z}$ has z_i in position p_i and 0 in every free position, so $BG\mathbf{y}$ is the particular solution.

By construction, column i of B is $\mathbf{e}_{p_i} \in F^n$. By Definition 2.4.1 and Definition 2.3.8, column i of A_rB is $A_r\mathbf{e}_{p_i}$, which is column p_i of A_r. Since A_r is in RREF with pivot columns $p_1, \ldots, p_m$, this column is $\mathbf{e}_i \in F^m$ (Lemma 3.3.16(b)). So $A_rB = I_m$.

Since $GA = A_r$ and G is invertible, $A = G^{-1}A_r$. Hence

$$A(BG) = G^{-1}A_rBG = G^{-1}I_mG = I_m,$$

as desired.

For the last claim, let $\mathbf{z} = G\mathbf{y}$. The vector $B\mathbf{z} = z_1\mathbf{e}_{p_1} + \cdots + z_m\mathbf{e}_{p_m}$ has z_i in position p_i for each i, and 0 in every other position, that is, in every free position. Since $\operatorname{rank} A = m$, there are no consistency conditions, and by Definition 3.4.8(b) this is the particular solution of $A\mathbf{x} = \mathbf{y}$. □

So the ith column of BG is the particular solution of $A\mathbf{x} = \mathbf{e}_i$. In other words, the right inverse is found by solving the m systems $A\mathbf{x} = \mathbf{e}_1, \ldots, A\mathbf{x} = \mathbf{e}_m$, just as the inverse of a square matrix is (compare the intuition

after Algorithm 3.3.24). Any other choice of solutions would also give a right inverse; the particular solutions are simply the ones the reduced matrix hands us.

For left inverses the roles of rows and columns are exchanged. If rank $A = n$ there are no free variables, and the reduced system $A_r\mathbf{x} = G\mathbf{y}$ lists the unknowns $x_1, \dots, x_n$ themselves, so $\mathbf{x}$ can be read off from $G\mathbf{y}$. We give this argument, and a second one that never row reduces and instead extends the columns of A to a basis.

Proposition 3.5.9 (Left inverses). Let $A \in F^{m\times n}$ with rank $A = n$. Then A has a left inverse.

Proof (from the pivots). ROUTINE

Uses. Proposition 3.5.2 (First properties of rank), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Definition 2.4.1 (Matrix product)
Hint 1. If every column of A_r is a pivot column, what are $p_1, \dots, p_n$, and what does A_r look like?
Hint 2. $A_r = \begin{pmatrix} I_n \\ 0 \end{pmatrix}$. Find an $n \times m$ matrix C with $CA_r = I_n$, and then use $GA = A_r$.
Sketch. Every column is a pivot column, so $p_s = s$ and column s of A_r is $\mathbf{e}_s$: $A_r = \begin{pmatrix} I_n \\ 0 \end{pmatrix}$. With $C = \begin{pmatrix} I_n & 0 \end{pmatrix} \in F^{n\times m}$, $CA_r = I_n$, so $(CG)A = CA_r = I_n$. The matrix CG consists of the first n rows of G.

Let $G \in F^{m\times m}$ be invertible with $GA = A_r$ (Theorem 3.3.10). By Proposition 3.5.2(a), every column of A_r is a pivot column. So $p_1 < \cdots < p_n$ are n increasing numbers in $\{1, \dots, n\}$, which forces $p_s = s$, and by Lemma 3.3.16(b) column s of A_r is $\mathbf{e}_s \in F^m$. In block form,

$$A_r = \begin{pmatrix} I_n \\ 0 \end{pmatrix},$$

where the zero block has $m - n$ rows (and is absent if $m = n$). Let $C = \begin{pmatrix} I_n & 0 \end{pmatrix} \in F^{n\times m}$. For $s \le n$, column s of CA_r is $C\mathbf{e}_s$, which is column s of C, namely $\mathbf{e}_s \in F^n$. So $CA_r = I_n$, and

$$(CG)A = C(GA) = CA_r = I_n.$$

Thus CG is a left inverse of A. By Definition 2.4.1, row i of CG is row i of C times G, which is row i of G; so CG consists of the first n rows of G. □

Proof (by extending the columns to a basis). STANDARD

Uses. Proposition 3.4.15 (A pivot in every column), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.5.14 (Appending a vector), Proposition 1.4.14 (The span is the smallest subspace containing a list), Definition 1.6.1 (Basis), Theorem 2.2.1 (Linear maps are determined by a basis), Remark 3.5.7 (Inverses of T_A and inverses of A)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
Hint 1. The columns $\mathbf{a}_1, \dots, \mathbf{a}_n$ of A are linearly independent. A left inverse S must send $\mathbf{a}_j = A\mathbf{e}_j$ to $\mathbf{e}_j$. On what kind of list can we prescribe the values of a linear map freely?
Hint 2. Extend $\mathbf{a}_1, \dots, \mathbf{a}_n$ to a basis of F^m by going through $\mathbf{e}_1, \dots, \mathbf{e}_m$ and appending each one that is not yet in the span (Proposition 1.5.14).
Hint 3. Define S on that basis by $S(\mathbf{a}_j) = \mathbf{e}_j$ and $S = \mathbf{0}$ on the appended vectors, and check $S \circ T_A = \mathrm{id}$ on the standard basis of F^n.
Sketch. The columns are independent (a pivot in every column). Appending each $\mathbf{e}_i$ that is not in the span so far keeps the list independent and eventually puts every $\mathbf{e}_i$ in its span, so it becomes a basis $\mathbf{a}_1, \dots, \mathbf{a}_n, \mathbf{e}_{i_1}, \dots, \mathbf{e}_{i_t}$ of F^m. Let S be the linear map with $S(\mathbf{a}_j) = \mathbf{e}_j$ and $S(\mathbf{e}_{i_s}) = \mathbf{0}$. Then $S(T_A\mathbf{e}_j) = S(\mathbf{a}_j) = \mathbf{e}_j$, so $S \circ T_A$ and id agree on a basis and are equal.

Since rank $A = n$, A_r has a pivot in every column (Proposition 3.5.2(a)), so $A\mathbf{x} = \mathbf{0}$ only for $\mathbf{x} = \mathbf{0}$ (Proposition 3.4.15). As $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$, this says that the columns $\mathbf{a}_1, \dots, \mathbf{a}_n$ are linearly independent (Theorem 1.5.5).

Extending to a basis. Let $\mathcal{L}_0$ be the list $\mathbf{a}_1, \dots, \mathbf{a}_n$. For $i = 1, \dots, m$, let $\mathcal{L}_i = \mathcal{L}_{i-1}$ if $\mathbf{e}_i \in \operatorname{span}(\mathcal{L}_{i-1})$, and let $\mathcal{L}_i$ be $\mathcal{L}_{i-1}$ with $\mathbf{e}_i$ appended otherwise. By Proposition 1.5.14 and induction on i, each $\mathcal{L}_i$ is linearly independent. Each $\mathbf{e}_i$ lies in $\operatorname{span}(\mathcal{L}_i)$, either because it was already in $\operatorname{span}(\mathcal{L}_{i-1}) \subseteq \operatorname{span}(\mathcal{L}_i)$ or because it was appended, and $\operatorname{span}(\mathcal{L}_i) \subseteq \operatorname{span}(\mathcal{L}_m)$ since $\mathcal{L}_i$ is a sublist of $\mathcal{L}_m$. So $\operatorname{span}(\mathcal{L}_m)$ is a subspace of F^m containing $\mathbf{e}_1, \dots, \mathbf{e}_m$, hence containing every linear combination of them (Proposition 1.4.14), that is, all of F^m. Thus

$$\mathcal{L}_m = \mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_t}$$

is linearly independent and spans F^m: it is a basis of F^m (Definition 1.6.1).

Defining S. By Theorem 2.2.1 there is a linear map $S : F^m \to F^n$ with $S(\mathbf{a}_j) = \mathbf{e}_j$ for $j = 1, \ldots, n$ and $S(\mathbf{e}_{i_s}) = \mathbf{0}$ for $s = 1, \ldots, t$. For each j, $(S \circ T_A)(\mathbf{e}_j) = S(A\mathbf{e}_j) = S(\mathbf{a}_j) = \mathbf{e}_j$. So the linear maps $S \circ T_A$ and id_{F^n} agree on the basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$, and by the uniqueness in Theorem 2.2.1 they are equal. By Remark 3.5.7, $S = T_C$ for a left inverse C of A. □

The first approach gives a formula: the first n rows of any invertible G with $GA = A_r$ form a left inverse of A. The second shows where the freedom lies. A left inverse is forced on the columns of A, which it must send to $\mathbf{e}_1, \ldots, \mathbf{e}_n$, but on the appended vectors $\mathbf{e}_{i_s}$ we could have prescribed any values at all. It also uses nothing about F^m beyond a finite spanning list, which is why it survives in abstract vector spaces (Exercise 3.5.40).

Example 3.5.10 (One-sided inverses, computed). *A right inverse.* Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 7 \end{pmatrix} \in \mathbb{Q}^{2\times 3}$. Gauss–Jordan elimination performs $E_{1,-2,2}$ and then $E_{2,-3,1}$, and carrying I_2 along (Proposition 3.3.11) gives

$$\left(\begin{array}{ccc|cc} 1 & 2 & 3 & 1 & 0 \\ 2 & 4 & 7 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccc|cc} 1 & 2 & 3 & 1 & 0 \\ 0 & 0 & 1 & -2 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccc|cc} 1 & 2 & 0 & 7 & -3 \\ 0 & 0 & 1 & -2 & 1 \end{array}\right).$$

So $\operatorname{rank} A = 2$, the pivot columns are $p_1 = 1$ and $p_2 = 3$, and $G = \begin{pmatrix} 7 & -3 \\ -2 & 1 \end{pmatrix}$. The matrix B has 1s in positions $(1,1)$ and $(3,2)$, so

$$B = \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad BG = \begin{pmatrix} 7 & -3 \\ 0 & 0 \\ -2 & 1 \end{pmatrix}.$$

Check: the rows of A times the columns of BG give $7 - 6 = 1$, $-3 + 3 = 0$, $14 - 14 = 0$, and $-6 + 7 = 1$, so $A(BG) = I_2$. The middle row of BG is zero because x_2 is a free variable, set to 0 in every particular solution. Another right inverse is $BG + \begin{pmatrix} -2 \\ 1 \\ 0 \end{pmatrix}(1 \;\; 1)$, since $(-2, 1, 0)$ lies in $\ker T_A$; right inverses are far from unique.

A left inverse. Let $A' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} \in \mathbb{Q}^{3\times 2}$. Elimination performs $E_{1,-1,2}$, $E_{1,-2,3}$, and $E_{2,-1,3}$, ending at $A'_r = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$, and the same operations turn I_3 into

$$G = \begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ -1 & -1 & 1 \end{pmatrix}.$$

So $\operatorname{rank} A' = 2$, and by the first approach the first two rows of G form a left inverse $C = \begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \end{pmatrix}$; indeed $CA' = I_2$. The second approach extends the columns $(1,1,2)$ and $(0,1,1)$ to a basis. The vector $\mathbf{e}_1$ is not in their span (a combination $x(1,1,2) + y(0,1,1) = (x, x+y, 2x+y)$ equal to $\mathbf{e}_1$ needs $x = 1$, $y = -1$, and then $2x + y = 1 \neq 0$), so the basis is $(1,1,2), (0,1,1), \mathbf{e}_1$. Solving for the coordinates of $\mathbf{e}_2$ and $\mathbf{e}_3$ in this basis,

$$\mathbf{e}_2 = -(1,1,2) + 2(0,1,1) + \mathbf{e}_1,$$
$$\mathbf{e}_3 = (1,1,2) - (0,1,1) - \mathbf{e}_1,$$

so $S(\mathbf{e}_1) = \mathbf{0}$, $S(\mathbf{e}_2) = (-1, 2)$, and $S(\mathbf{e}_3) = (1, -1)$:

$$S = \begin{pmatrix} 0 & -1 & 1 \\ 0 & 2 & -1 \end{pmatrix}.$$

Check: S sends the columns $(1,1,2)$ and $(0,1,1)$ of A' to $(0-1+2, 0+2-2) = (1,0)$ and $(0-1+1, 0+2-1) = (0,1)$, so $SA' = I_2$. The two left inverses differ: $S - C = \begin{pmatrix} -1 & -1 & 1 \\ 1 & 1 & -1 \end{pmatrix}$. Each row of the difference is a multiple of $(-1,-1,1)$, the last row of G, which kills the columns of A'; Exercise 3.5.33 shows that this is the general pattern.

The row reducer below carries out the first computation. With I_2 carried along, the right block at the end is G.

$$\left(\begin{array}{ccc|cc} 1 & 2 & 3 & 1 & 0 \\ 2 & 4 & 7 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccc|cc} 1 & 2 & 0 & 7 & -3 \\ 0 & 0 & 1 & -2 & 1 \end{array}\right)$$

Reducing $(A \mid I_2)$ for the matrix A of Example 3.5.10. The left block becomes A_r, with pivots in columns 1 and 3, and the right block becomes G. Placing the rows of G in rows $p_1 = 1$ and $p_2 = 3$ of a 3×2 matrix, with zeros in row 2, gives the right inverse BG. (Interactive in the web version.)

Exercise 3.5.11. ROUTINE Let $A = \begin{pmatrix} 1 & 1 & 0 & 2 \\ 0 & 1 & 1 & 1 \end{pmatrix} \in \mathbb{Q}^{2\times 4}$. Find its rank and pivot columns, and use Proposition 3.5.8 to find a right inverse. Check your answer.

Solution on page 1251

The completed theorems

We restate each Fundamental Theorem in full. Conditions (I)–(V) are those of Section 2.7, and (VI) is new.

Theorem 3.5.12 (First Fundamental Theorem, completed). Let $A \in F^{m\times n}$. The following are equivalent.

(I) T_A is injective.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has at most one solution $\mathbf{x} \in F^n$.
(III) The columns of A are linearly independent.
(IV) $\ker T_A = \{\mathbf{0}\}$.
(V) T_A has a left inverse: a linear map $S : F^m \to F^n$ with $S \circ T_A = \mathrm{id}_{F^n}$.
(VI) $\operatorname{rank} A = n$.

Moreover, if these hold, then $n \le m$.

Proof. ROUTINE

Uses. Theorem 2.7.2 (First Fundamental Theorem), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 3.5.2 (First properties of rank), Proposition 3.4.15 (A pivot in every column), Definition 2.6.5 (Kernel), Proposition 3.5.9 (Left inverses), Remark 3.5.7 (Inverses of T_A and inverses of A)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Theorem 2.7.2 already ties (I)–(IV) together and shows (V) ⇒ (I). Which of (I)–(IV) is closest to a statement about pivots?
Hint 2. (IV) says that $A\mathbf{x} = \mathbf{0}$ has only the trivial solution. Combine Proposition 3.4.15 with Proposition 3.5.2(a).
Hint 3. For (VI) ⇒ (V), use Proposition 3.5.9. For the last claim, recall $\operatorname{rank} A \le m$.
Sketch. (I)–(IV) are equivalent and (V) implies (I) by Theorem 2.7.2. (IV) says $A\mathbf{x} = \mathbf{0}$ only for $\mathbf{x} = \mathbf{0}$, which by Proposition 3.4.15 means a pivot in every column, that is, $\operatorname{rank} A = n$. (VI) gives a left inverse matrix by Proposition 3.5.9, hence a left inverse map. So (V) ⇒ (I) ⇒ (IV) ⇒ (VI) ⇒ (V). Finally $n = \operatorname{rank} A \le m$.

By Theorem 2.7.2, conditions (I)–(IV) are equivalent, and (V) implies (I) (this is Proposition 2.5.4). We show (IV) ⇒ (VI) ⇒ (V), which closes the cycle (V) ⇒ (I) ⇒ (IV) ⇒ (VI) ⇒ (V). In fact we show (IV) ⇔ (VI).

(IV) ⇔ (VI). By Definition 2.6.5, $\ker T_A = \{\mathbf{0}\}$ says that $A\mathbf{x} = \mathbf{0}$ has only the trivial solution. By Proposition 3.4.15 this holds if and only if A_r has a pivot in every column, which by Proposition 3.5.2(a) means $\operatorname{rank} A = n$.

(VI) ⇒ (V). By Proposition 3.5.9 there is $C \in F^{n\times m}$ with $CA = I_n$, and by Remark 3.5.7 the linear map $S = T_C$ satisfies $S \circ T_A = \mathrm{id}_{F^n}$.

Finally, if the conditions hold, then $n = \operatorname{rank} A \le m$ by Proposition 3.5.2(a). □

Theorem 3.5.13 (Second Fundamental Theorem, completed). Let $A \in F^{m\times n}$. The following are equivalent.

(I) T_A is surjective.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has at least one solution $\mathbf{x} \in F^n$.
(III) The columns of A span F^m.
(IV) $\operatorname{im} T_A = F^m$.
(V) T_A has a right inverse: a linear map $S : F^m \to F^n$ with $T_A \circ S = \mathrm{id}_{F^m}$.
(VI) $\operatorname{rank} A = m$.

Moreover, if these hold, then $n \ge m$.

Proof. ROUTINE

Uses. Theorem 2.7.4 (Second Fundamental Theorem), Proposition 2.5.5 (Right inverses give existence), Proposition 3.5.2 (First properties of rank), Proposition 3.4.16 (A pivot in every row), Proposition 3.5.8 (Right inverses from the pivots), Remark 3.5.7 (Inverses of T_A and inverses of A)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Mirror the proof of Theorem 3.5.12. Which of (I)–(IV) is a statement about pivots in rows?
Hint 2. (II) is the second condition of Proposition 3.4.16. For (VI) ⇒ (V), use Proposition 3.5.8.
Sketch. (I)–(IV) are equivalent and (V) implies (I) by Theorem 2.7.4. (II) holds iff A_r has a pivot in every row (Proposition 3.4.16), iff $\operatorname{rank} A = m$. (VI) gives the right inverse BG of Proposition 3.5.8. So (V) ⇒ (I) ⇒ (II) ⇒ (VI) ⇒ (V), and $m = \operatorname{rank} A \le n$.

By Theorem 2.7.4, conditions (I)–(IV) are equivalent, and (V) implies (I) (this is Proposition 2.5.5). We show (II) ⇔ (VI) and (VI) ⇒ (V), which closes the cycle (V) ⇒ (I) ⇒ (II) ⇒ (VI) ⇒ (V).

(II) ⇔ (VI). By Proposition 3.4.16, (II) holds if and only if A_r has a pivot in every row, which by Proposition 3.5.2(a) means $\operatorname{rank} A = m$.

(VI) ⇒ (V). By Proposition 3.5.8 there is $X = BG \in F^{n\times m}$ with $AX = I_m$, and by Remark 3.5.7 the linear map $S = T_X$ satisfies $T_A \circ S = \mathrm{id}_{F^m}$.

Finally, if the conditions hold, then $m = \operatorname{rank} A \le n$ by Proposition 3.5.2(a). □

Theorem 3.5.14 (Third Fundamental Theorem, completed). Let $A \in F^{m\times n}$. The following are equivalent.

(I) T_A is bijective.
(II) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has exactly one solution $\mathbf{x} \in F^n$.
(III) The columns of A form a basis of F^m.
(IV) $\ker T_A = \{\mathbf{0}\}$ and $\operatorname{im} T_A = F^m$.
(V) T_A is invertible.
(VI) $\operatorname{rank} A = m = n$.

Moreover, if these hold, then $m = n$.

Proof. ROUTINE

Uses. Theorem 2.7.8 (Third Fundamental Theorem), Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed), Proposition 2.7.7 (Bijective linear maps are invertible)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. A bijection is a map that is both injective and surjective.
Hint 2. Apply the two previous theorems.
Sketch. (I)–(V) are equivalent by Theorem 2.7.8. T_A is bijective iff it is injective and surjective, iff $\operatorname{rank} A = n$ and $\operatorname{rank} A = m$ by Theorem 3.5.12 and Theorem 3.5.13.

By Theorem 2.7.8, conditions (I)–(V) are equivalent; the step from (I) to (V) is that the inverse of a bijective linear map is linear (Proposition 2.7.7). For (I) ⇔ (VI): T_A is bijective if and only if it is injective and surjective, which by Theorem 3.5.12 and Theorem 3.5.13 holds if and only if rank $A = n$ and rank $A = m$. In that case $m = \operatorname{rank} A = n$. □

So the sixth conditions are rank $A = n$, rank $A = m$, and rank $A = m = n$, and the "moreover" parts follow from rank $A \leq \min(m, n)$. By Remark 3.5.7, condition (V) can be read for matrices: A has a left inverse, a right inverse, or an inverse, respectively. With this reading, the "moreover" parts give the fact that the lecture singles out: invertible matrices are square.

Corollary 3.5.15 (Invertible matrices are square). Let $A \in F^{m\times n}$.

(a) If A has a left inverse, then $n \leq m$.

(b) If A has a right inverse, then $n \geq m$.

(c) If A is invertible, that is, $AB = I_m$ and $BA = I_n$ for some $B \in F^{n\times m}$, then $m = n$.

Proof. ROUTINE

Uses. Remark 3.5.7 (Inverses of T_A and inverses of A), Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed)
Hint 1. Translate "A has a left inverse" into condition (V) of one of the theorems.
Hint 2. Apply the "moreover" parts.
Sketch. A left inverse C of A gives the left inverse T_C of T_A, so (V) of Theorem 3.5.12 holds and $n \leq m$. Right inverses give $n \geq m$ by Theorem 3.5.13, and an inverse is both.

(a) If $CA = I_n$, then T_C is a left inverse of T_A (Remark 3.5.7), so condition (V) of Theorem 3.5.12 holds, and $n \leq m$.

(b) If $AC = I_m$, then T_C is a right inverse of T_A, so condition (V) of Theorem 3.5.13 holds, and $n \geq m$.

(c) An inverse B is both a left and a right inverse, so $n \leq m$ and $n \geq m$ by (a) and (b). □

Here is what the theorems say about a list of vectors in F^m, read through the matrix that has them as columns.

Corollary 3.5.16 (Lists of vectors in F^m). Let $\mathbf{v}_1, \ldots, \mathbf{v}_n \in F^m$, and let $A \in F^{m\times n}$ be the matrix with columns $\mathbf{v}_1, \ldots, \mathbf{v}_n$.

(a) The list is linearly independent if and only if rank $A = n$. In that case $n \leq m$.

(b) The list spans F^m if and only if rank $A = m$. In that case $n \geq m$.

(c) If $n = m$, the list is linearly independent if and only if it spans F^m, if and only if it is a basis of F^m.

Proof. ROUTINE

Uses. Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed), Definition 1.6.1 (Basis)
Hint 1. Which conditions of the completed theorems are about the columns of A?
Hint 2. For (c), when $n = m$, the conditions rank $A = n$ and rank $A = m$ coincide.
Sketch. (a) is (III) ⇔ (VI) of Theorem 3.5.12 with its "moreover", and (b) is the same for Theorem 3.5.13. If $n = m$, both say rank $A = m$; a basis is a list that is both independent and spanning.

(a) By (III) ⇔ (VI) of Theorem 3.5.12, the columns of A are linearly independent if and only if rank $A = n$, and then $n \leq m$.

(b) By (III) ⇔ (VI) of Theorem 3.5.13, the columns of A span F^m if and only if rank $A = m$, and then $n \geq m$.

(c) If $n = m$, the conditions in (a) and (b) are the same condition rank $A = m$. So the list is independent if and only if it spans F^m, and in that case it is both, which is the definition of a basis (Definition 1.6.1). □

In particular a basis of F^m, being independent and spanning, has $n \le m$ and $n \ge m$ vectors: every basis of F^m has exactly m vectors. This is how Section 4.1 begins (Theorem 4.1.1), on the way to defining the dimension of a vector space. Part (c) is a first instance of a principle that Section 4.2 makes general: for a list whose length is right, independence and spanning are the same condition. Part (a) also explains Corollary 3.4.19(a) from the side of the columns: more than m vectors in F^m are always dependent.

Remark 3.5.17 (Rank of a linear map). For a linear map $T : V \to W$ and bases $\mathcal{B}$ of V and $\mathcal{C}$ of W, it is tempting to define $\operatorname{rank} T$ as $\operatorname{rank} [T]_{\mathcal{C}\mathcal{B}}$. This is a good definition, but only because the rank of $[T]_{\mathcal{C}\mathcal{B}}$ does not depend on the choice of bases, and that needs ideas we do not have yet. Section 4.2 defines the rank of T intrinsically, as the dimension of $\operatorname{im} T$ (Definition 4.2.14), and shows that it equals $\operatorname{rank} [T]_{\mathcal{C}\mathcal{B}}$ for every choice of bases.

Exercise 3.5.18. ROUTINE For each item, either give an example or explain why none exists.

(a) $A \in \mathbb{R}^{3\times 5}$ with T_A injective.

(b) $A \in \mathbb{R}^{3\times 5}$ with T_A surjective.

(c) $A \in \mathbb{R}^{5\times 3}$ with $\operatorname{rank} A = 3$ and a right inverse.

(d) $A \in \mathbb{R}^{4\times 4}$ with $\operatorname{rank} A = 4$ that is not invertible.

Solution on page 1251

3.5.3 Invertible matrices are products of elementary matrices

Elementary matrices are invertible, and so are their products (Corollary 3.2.11). The converse says that the elementary matrices generate all invertible matrices: there are no others.

Theorem 3.5.19 (Invertible matrices are products of elementary matrices). Every invertible matrix $A \in F^{n\times n}$ is a product of elementary matrices. Explicitly, if Gauss–Jordan elimination on A performs the row operations with elementary matrices $E_1, \dots, E_t$, in this order, then

$$A = E_1^{-1} E_2^{-1} \cdots E_t^{-1},$$

and each E_i^{-1} is elementary. Consequently, a square matrix is invertible if and only if it is a product of elementary matrices.

Proof. ROUTINE

Uses. Theorem 3.3.23 (Invertibility and RREF), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.2.10 (Inverses of elementary matrices)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. What is $\operatorname{rref}(A)$ for an invertible A?
Hint 2. $GA = I_n$ with $G = E_t \cdots E_1$. Solve for A.
Sketch. By Theorem 3.3.23, $\operatorname{rref}(A) = I_n$, so $E_t \cdots E_1 A = I_n$ and $A = (E_t \cdots E_1)^{-1} = E_1^{-1} \cdots E_t^{-1}$, a product of elementary matrices by Proposition 3.2.10. The converse is Corollary 3.2.11.

Let $G = E_t \cdots E_1$, so that $GA = \operatorname{rref}(A)$ (Theorem 3.3.10). Since A is invertible, $\operatorname{rref}(A) = I_n$ by Theorem 3.3.23, so $GA = I_n$. By Corollary 3.2.11, G is invertible with $G^{-1} = E_1^{-1} \cdots E_t^{-1}$, and multiplying $GA = I_n$ on the left by G^{-1} gives

$$A = G^{-1} = E_1^{-1} E_2^{-1} \cdots E_t^{-1}.$$

Each E_i^{-1} is elementary by Proposition 3.2.10. (If $t = 0$, then $A = I_n$, the empty product.) Conversely, every product of elementary matrices is invertible by Corollary 3.2.11. □

Example 3.5.20 (Factoring an invertible matrix). Let $A = \begin{pmatrix} 3 & 6 \\ 1 & 3 \end{pmatrix} \in \mathbb{Q}^{2\times 2}$. Elimination scales row 1 by $1/3$, adds -1 times row 1 to row 2, and adds -2 times row 2 to row 1:

$$A \xrightarrow{E_{1,1/3}} \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix} \xrightarrow{E_{1,-1,2}} \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} \xrightarrow{E_{2,-2,1}} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Inverting each operation and reversing the order (Proposition 3.2.10),

$$A = E_{1,3}E_{1,1,2}E_{2,2,1} = \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}.$$

Read from the right, this builds A out of I_2: $E_{2,2,1}$ turns I_2 into $\begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$, then adding row 1 to row 2 gives $\begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix}$, and scaling row 1 by 3 gives A. In the plane, T_A is a horizontal shear, followed by a vertical shear, followed by a stretch along the x_1-axis (Example 3.2.33).

Combined with Section 3.3, the theorem gives several descriptions of the same class of matrices.

Corollary 3.5.21 (Invertibility and row equivalence).

(a) For $A \in F^{n\times n}$, the following are equivalent: A is invertible; A is a product of elementary matrices; $A \sim I_n$; $\operatorname{rref}(A) = I_n$.

(b) For $A, B \in F^{m\times n}$, we have $A \sim B$ if and only if $B = GA$ for some invertible $G \in F^{m\times m}$.

Proof. ROUTINE

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Definition 3.2.21 (Row equivalence), Proposition 3.2.22 (Row equivalence is an equivalence relation), Theorem 3.3.23 (Invertibility and RREF), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. By Definition 3.2.21, $A \sim B$ means $B = E_k \cdots E_1 A$. Compare this with "$B = GA$ for a product G of elementary matrices".
Hint 2. For (a), $A \sim I_n$ means $I_n = GA$ for a product G of elementary matrices; equivalently (by symmetry) $A = G'I_n$.
Sketch. By Definition 3.2.21, $A \sim B$ iff $B = GA$ with G a product of elementary matrices, and by Theorem 3.5.19 these G are exactly the invertible matrices; this is (b). For (a), $A \sim I_n$ iff $I_n \sim A$ iff $A = GI_n = G$ for an invertible G, and $\operatorname{rref}(A) = I_n$ is Theorem 3.3.23.

(b) By Definition 3.2.21, $A \sim B$ if and only if $B = GA$ for some product G of elementary matrices. By Theorem 3.5.19 and Corollary 3.2.11, the products of elementary matrices in $F^{m\times m}$ are exactly the invertible matrices.

(a) By Theorem 3.5.19, A is invertible if and only if it is a product of elementary matrices. By (b) and the symmetry of $\sim$ (Proposition 3.2.22), $A \sim I_n$ if and only if $A = GI_n = G$ for some invertible G, that is, if and only if A is invertible. Finally, A is invertible if and only if $\operatorname{rref}(A) = I_n$ by Theorem 3.3.23. □

The theorem is what makes the method of Technique 5.4.6 work: a statement about all invertible matrices that is easy to check for swaps, scalings, and replacements, and that survives products, holds for every invertible matrix. Its main use is in Section 5.4, where it proves $\det(AB) = \det A \det B$. Here is a first, simple instance, which turns statements about GAH into statements about row and column operations.

Corollary 3.5.22 (Row and column operations). Let $A, B \in F^{m\times n}$. Then $B = GAH$ for some invertible $G \in F^{m\times m}$ and $H \in F^{n\times n}$ if and only if B can be obtained from A by a finite sequence of elementary row operations and elementary column operations.

Proof. ROUTINE

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.28 (Column operations are right multiplications)
Techniques. Reduce to elementary matrices (Technique 5.4.6)
Hint 1. A row operation is left multiplication by an elementary matrix, and a column operation is right multiplication by one.
Hint 2. For $\Rightarrow$, factor G and H into elementary matrices.

Hint 3. Row operations and column operations commute: $(EX)E' = E(XE')$. So the operations may be performed in any interleaving.
Sketch. A row operation is $X \mapsto EX$ and a column operation is $X \mapsto XE'$ (Proposition 3.2.7, Proposition 3.2.28); since $(EX)E' = E(XE')$, any sequence of them turns A into $(E_s \cdots E_1)A(E'_1 \cdots E'_t)$, and both products are invertible. Conversely, factor $G = E_s \cdots E_1$ and $H = E'_1 \cdots E'_t$ by Theorem 3.5.19 and perform the corresponding operations.

By Proposition 3.2.7, performing a row operation on a matrix X replaces it by EX for an elementary $E \in F^{m\times m}$, and by Proposition 3.2.28, performing a column operation replaces it by XE' for an elementary $E' \in F^{n\times n}$. By associativity, $(EX)E' = E(XE')$, so in any sequence of such operations the row operations and column operations can be collected separately. A sequence with row operations $E_1, \ldots, E_s$ and column operations $E'_1, \ldots, E'_t$ (each list in the order performed) therefore turns A into

$$(E_s \cdots E_1)A(E'_1 \cdots E'_t),$$

and both products are invertible by Corollary 3.2.11.

Conversely, suppose $B = GAH$ with G, H invertible. By Theorem 3.5.19, $G = E_s \cdots E_1$ and $H = E'_1 \cdots E'_t$ for elementary matrices E_i and E'_j. Performing on A the row operations of $E_1, \ldots, E_s$ and then the column operations of $E'_1, \ldots, E'_t$ produces $(E_s \cdots E_1)A(E'_1 \cdots E'_t) = GAH = B$. □

So the theorem lets us pass between "multiply by an invertible matrix" and "perform elementary operations" in both directions. The first is convenient in algebra, the second in computation and in proofs by induction on the number of operations.

3.5.4 Square matrices

For a square matrix, $m = n$, so the sixth conditions of the three Fundamental Theorems all read $\operatorname{rank} A = n$. Injectivity, surjectivity, and bijectivity of T_A are then the same condition. The most useful consequence is that a square matrix needs only a one-sided inverse to be invertible.

Theorem 3.5.23 (One-sided inverses of square matrices). Let $A, B \in F^{n\times n}$. If $BA = I_n$, then $AB = I_n$. Consequently, if a square matrix A has a left inverse or a right inverse B, then A is invertible and $B = A^{-1}$.

Proof. STANDARD

Uses. Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.14 (Third Fundamental Theorem, completed), Remark 3.5.7 (Inverses of T_A and inverses of A), Definition 2.5.12 (Invertible)
Hint 1. $BA = I_n$ says that A has a left inverse. What does Theorem 3.5.12 then say about $\operatorname{rank} A$, and what does that mean when $m = n$?
Hint 2. A is invertible by Theorem 3.5.14. Compute $B = B\big(AA^{-1}\big)$.
Hint 3. For a right inverse, swap the roles: $AB = I_n$ says that A is a left inverse of B.
Sketch. If $BA = I_n$, then T_A has a left inverse, so $\operatorname{rank} A = n$ by Theorem 3.5.12. As A is square, $\operatorname{rank} A = n = m$, so A is invertible by Theorem 3.5.14. Then $B = B\big(AA^{-1}\big) = (BA)A^{-1} = A^{-1}$, so $AB = AA^{-1} = I_n$. If instead $AB = I_n$, apply this to the pair (B, A) to get $BA = I_n$.

Suppose $BA = I_n$. By Remark 3.5.7, T_B is a left inverse of T_A, so condition (V) of Theorem 3.5.12 holds and $\operatorname{rank} A = n$. Since A is $n \times n$, this says $\operatorname{rank} A = n = m$, so by Theorem 3.5.14 and Remark 3.5.7, A has an inverse A^{-1}, with $AA^{-1} = A^{-1}A = I_n$. Then

$$B = BI_n = B\big(AA^{-1}\big) = (BA)A^{-1} = I_nA^{-1} = A^{-1},$$

and therefore $AB = AA^{-1} = I_n$.

For the second sentence: if $BA = I_n$, we have just shown that A is invertible with $A^{-1} = B$. If $AB = I_n$, then the first sentence, applied with the roles of A and B exchanged, gives $BA = I_n$, so again $B = A^{-1}$. □

Intuition (Why squareness matters). The proof turned a statement about uniqueness into a statement about existence. $BA = I_n$ gives $A\mathbf{x} = \mathbf{0} \Rightarrow \mathbf{x} = BA\mathbf{x} = \mathbf{0}$, so there are no free variables; a square matrix

without free variables has as many pivots as rows, so there are no zero rows either, and every equation $A\mathbf{x} = \mathbf{y}$ is solvable. This is Technique 3.4.21 again. Both hypotheses are needed. For $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ we have $AB = (1) = I_1$, but $BA = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \neq I_2$. And the analogue for linear maps of an infinite-dimensional space fails: on $F[x]$, let S and L be the linear maps with $S\left(x^k\right) = x^{k+1}$ for all $k \geq 0$, and $L\left(x^k\right) = x^{k-1}$ for $k \geq 1$ and $L(1) = \mathbf{0}$ (Proposition 2.2.20). Then $L \circ S = \mathrm{id}$, but $(S \circ L)(1) = \mathbf{0}$, so $S \circ L \neq \mathrm{id}$.

The theorem halves the work of checking that a matrix is an inverse. It also gives the converse of the familiar fact that products of invertible matrices are invertible.

Corollary 3.5.24 (Products of square matrices). Let $A, B \in F^{n\times n}$. Then AB is invertible if and only if both A and B are invertible.

Proof. ROUTINE

Uses. Theorem 3.5.23 (One-sided inverses of square matrices), Definition 2.5.12 (Invertible)
Hint 1. If AB has inverse C, then $A(BC) = I_n$. What does that say about A?
Hint 2. For B, regroup $C(AB) = I_n$.
Sketch. If $C = (AB)^{-1}$, then $A(BC) = I_n$ and $(CA)B = I_n$, so A has a right inverse and B a left inverse; both are invertible by Theorem 3.5.23. Conversely, $(AB)\left(B^{-1}A^{-1}\right) = I_n$.

Suppose AB is invertible, with inverse C. Then $A(BC) = (AB)C = I_n$, so A has a right inverse, and $(CA)B = C(AB) = I_n$, so B has a left inverse. By Theorem 3.5.23, A and B are invertible.

Conversely, if A and B are invertible, then $(AB)\left(B^{-1}A^{-1}\right) = A\left(BB^{-1}\right)A^{-1} = AA^{-1} = I_n$, so AB has a right inverse and is invertible by Theorem 3.5.23. □

Again squareness is essential: with $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, the product $AB = I_1$ is invertible, but neither factor is, since neither is square. What survives without squareness is that A has a right inverse and B a left inverse, as the first two lines of the proof show (compare Section 2.5).

We collect what we know about square matrices. Every item below has appeared already; the point is that they are all one condition.

Corollary 3.5.25 (The invertible matrix theorem). Let $A \in F^{n\times n}$. The following are equivalent.

(a) A is invertible.
(b) A has a left inverse.
(c) A has a right inverse.
(d) $\operatorname{rank} A = n$.
(e) $\operatorname{rref}(A) = I_n$.
(f) A is a product of elementary matrices.
(g) Any one of the conditions (I)–(VI) of Theorem 3.5.12, Theorem 3.5.13, or Theorem 3.5.14 holds.

In particular, $T_A : F^n \to F^n$ is injective if and only if it is surjective.

Proof. ROUTINE

Uses. Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed), Theorem 3.5.14 (Third Fundamental Theorem, completed), Theorem 3.5.23 (One-sided inverses of square matrices), Theorem 3.3.23 (Invertibility and RREF), Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Remark 3.5.7 (Inverses of T_A and inverses of A)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Show that each condition is equivalent to (d).
Hint 2. When $m = n$, what do the sixth conditions of the three theorems say?
Sketch. With $m = n$, condition (VI) of each of the three theorems reads $\operatorname{rank} A = n$, so every condition (I)–(VI) of each theorem is equivalent to (d). (a), (b), (c) are (V) of the three theorems, read for matrices; (e) and (f) are equivalent to (a) by Theorem 3.3.23 and Theorem 3.5.19.

Since $m = n$, condition (VI) of each of Theorem 3.5.12, Theorem 3.5.13, and Theorem 3.5.14 says rank $A = n$. So, by those theorems, every one of their conditions is equivalent to (d), which gives (d) ⇔ (g). By Remark 3.5.7, (b), (c), and (a) are condition (V) of the three theorems, read for matrices, so they are equivalent to (d) as well. (Alternatively, (b) ⇔ (a) ⇔ (c) is Theorem 3.5.23.) Finally, (a) ⇔ (e) is Theorem 3.3.23, and (a) ⇔ (f) is Theorem 3.5.19. The last sentence is the equivalence of (I) in Theorem 3.5.12 with (I) in Theorem 3.5.13. □

This contains Corollary 3.4.20, which was proved by counting pivots directly. The equivalence of injectivity and surjectivity for $T_A : F^n \to F^n$ extends to every linear map $T : V \to V$ of a finite-dimensional space, once dimension is available (Section 4.2).

Exercise 3.5.26. ROUTINE Find the error in the following argument, and show that its conclusion is false.

Claim. If $A \in F^{m\times n}$ and $B \in F^{n\times m}$ satisfy $AB = I_m$, then $BA = I_n$.

Proof. Since $AB = I_m$, we have $ABA = I_m A = A = AI_n$. Cancelling A on the left gives $BA = I_n$.

Solution on page 1252

3.5.5 Rank normal form

Row operations bring A to A_r, and no further: A_r is the simplest matrix row equivalent to A. If column operations are allowed too, more can be cleared. Each free column of A_r is a combination of the pivot columns to its left (Lemma 3.3.16(d)), and the pivot columns are $\mathbf{e}_1, \dots, \mathbf{e}_k$, so column operations can subtract those combinations and leave zero. After moving the pivot columns to the front, what remains is determined by the rank alone.

Theorem 3.5.27 (Rank normal form). Let $A \in F^{m\times n}$ and $k = \operatorname{rank} A$, and let $N_k \in F^{m\times n}$ be the matrix

$$N_k = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix},$$

with 1 in positions $(1,1), \dots, (k,k)$ and 0 elsewhere. There are invertible matrices $G \in F^{m\times m}$ and $H \in F^{n\times n}$ such that

$$GAH = N_k.$$

Here G can be any invertible matrix with $GA = A_r$.

Proof (column operations on the reduced form). STANDARD

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Proposition 3.3.8 (Properties of the output), Definition 2.4.1 (Matrix product), Theorem 2.4.34 (Block multiplication), Theorem 3.5.14 (Third Fundamental Theorem, completed), Remark 3.5.7 (Inverses of T_A and inverses of A), Definition 2.5.12 (Invertible)
Techniques. Reduce to RREF (Technique 3.3.22), Block decomposition (Technique 2.4.35)
Hint 1. Start from $GA = A_r$. It remains to find an invertible H with $A_r H = N_k$, that is, to clear A_r by column operations.
Hint 2. First reorder the columns so that the pivot columns come first. In block form, the result is $\begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix}$ for some $k \times (n-k)$ matrix X.
Hint 3. Multiply on the right by $\begin{pmatrix} I_k & -X \\ 0 & I_{n-k} \end{pmatrix}$. Why is that matrix invertible?
Sketch. Let P have columns $\mathbf{e}_{p_1}, \dots, \mathbf{e}_{p_k}, \mathbf{e}_{f_1}, \dots, \mathbf{e}_{f_\ell}$, a reordering of the standard basis, so P is invertible. Then $A_r P$ lists the pivot columns $\mathbf{e}_1, \dots, \mathbf{e}_k$ first, and all columns vanish below row k, so $A_r P = \begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix}$. With $U = \begin{pmatrix} I_k & -X \\ 0 & I_\ell \end{pmatrix}$, invertible with inverse $\begin{pmatrix} I_k & X \\ 0 & I_\ell \end{pmatrix}$, block multiplication gives $A_r PU = N_k$. Take $H = PU$.

Let G be invertible with $GA = A_r$ (Theorem 3.3.10), with pivot columns $p_1 < \cdots < p_k$ and free columns $f_1 < \cdots < f_\ell$, where $\ell = n - k$. It suffices to find an invertible H with $A_r H = N_k$, since then $GAH = A_r H = N_k$.

Moving the pivot columns to the front. Let $P \in F^{n\times n}$ be the matrix with columns $\mathbf{e}_{p_1}, \dots, \mathbf{e}_{p_k}, \mathbf{e}_{f_1}, \dots, \mathbf{e}_{f_\ell}$. These are $\mathbf{e}_1, \dots, \mathbf{e}_n$ in another order, so they form a basis of F^n, and P is invertible by Theorem 3.5.14 ((III) ⇒

(V)) and Remark 3.5.7. Column j of A_rP is A_r times column j of P (Definition 2.4.1). For $j \le k$ this is $A_r\mathbf{e}_{p_j}$, column p_j of A_r, which is $\mathbf{e}_j$ (Lemma 3.3.16(b)). For $j = k+i$ it is column f_i of A_r. Rows $k+1, \dots, m$ of A_r are zero (Proposition 3.3.8(a)), so every column of A_rP vanishes below row k. In block form, with row sizes $k, m-k$ and column sizes k, ℓ,

$$A_rP = \begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix},$$

where column i of $X \in F^{k\times\ell}$ consists of the first k entries of column f_i of A_r.

Clearing X. Let

$$U = \begin{pmatrix} I_k & -X \\ 0 & I_\ell \end{pmatrix}, \quad U' = \begin{pmatrix} I_k & X \\ 0 & I_\ell \end{pmatrix} \in F^{n\times n}.$$

By block multiplication (Theorem 2.4.34),

$$UU' = \begin{pmatrix} I_k & X - X \\ 0 & I_\ell \end{pmatrix} = I_n,$$

$$U'U = \begin{pmatrix} I_k & -X + X \\ 0 & I_\ell \end{pmatrix} = I_n,$$

so U is invertible (Definition 2.5.12), and

$$\begin{aligned} A_rPU &= \begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix}\begin{pmatrix} I_k & -X \\ 0 & I_\ell \end{pmatrix} \\ &= \begin{pmatrix} I_k & -X + X \\ 0 & 0 \end{pmatrix} = N_k. \end{aligned}$$

So $H = PU$ is invertible, as a product of invertible matrices, and $GAH = N_k$. (If $k = 0$, then $A_r = 0 = N_0$ and $H = I_n$ works; if $\ell = 0$, then $P = I_n$ and X and U are not needed. Blocks of size zero are simply absent.) □

Proof (by row reducing the transpose). STANDARD

> *Uses.* Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Proposition 3.3.8 (Properties of the output), Definition 2.4.21 (Transpose), Proposition 2.4.23 (Transpose of a product), Proposition 3.5.9 (Left inverses), Proposition 3.5.2 (First properties of rank), Corollary 3.5.16 (Lists of vectors in F^m)
> *Techniques.* Transpose to trade rows for columns (Technique 3.2.27), Reduce to RREF (Technique 3.3.22)
> *Hint 1.* Column operations on A_r are row operations on A_r^{T}. So row reduce $A_r^{\mathsf{T}} \in F^{n\times m}$.
> *Hint 2.* The first k columns of A_r^{T} are the nonzero rows of A_r, transposed, and the others are zero. Why are those k columns linearly independent?
> *Hint 3.* Row s of A_r has a 1 in column p_s, while every other row has a 0 there.
> *Sketch.* The first k columns of A_r^{T} form an $n \times k$ matrix M whose column s is row s of A_r; its p_t-th entry is 1 if $s = t$ and 0 otherwise, so the columns are independent and $\operatorname{rank} M = k$. As in the proof of Proposition 3.5.9, some invertible K has $KM = \begin{pmatrix} I_k \\ 0 \end{pmatrix}$, so $KA_r^{\mathsf{T}} = N_k^{\mathsf{T}}$ (the remaining columns are zero). Transposing, $A_rK^{\mathsf{T}} = N_k$, and K^{T} is invertible.

Let G be invertible with $GA = A_r$, and let $p_1 < \cdots < p_k$ be the pivot columns. By Proposition 3.3.8, rows $k+1, \dots, m$ of A_r are zero, so the transpose $A_r^{\mathsf{T}} \in F^{n\times m}$ (Definition 2.4.21) has the block form

$$A_r^{\mathsf{T}} = (M \;\; 0),$$

where $M \in F^{n\times k}$ has as its column s the transpose of row s of A_r, and the zero block has $m-k$ columns.

The columns of M are independent. Column p_t of A_r is $\mathbf{e}_t$ (Lemma 3.3.16(b)), so row s of A_r has entry 1 in column p_t if $s = t$, and 0 if $s \neq t$. Hence if $c_1, \dots, c_k \in F$ and $c_1\mathbf{m}_1 + \cdots + c_k\mathbf{m}_k = \mathbf{0}$, where $\mathbf{m}_s$ is column s of M, then the entry in position p_t gives $c_t = 0$, for each t. So the columns of M are linearly independent, and $\operatorname{rank} M = k$ by Corollary 3.5.16(a).

Reducing M. By Theorem 3.3.10 there is an invertible $K \in F^{n\times n}$ with $KM = \operatorname{rref}(M)$, and since $\operatorname{rank} M = k$ is the number of columns of M, the proof of Proposition 3.5.9 (first approach) shows that $\operatorname{rref}(M) = \begin{pmatrix} I_k \\ 0 \end{pmatrix}$. Therefore

$$KA_r^{\mathsf{T}} = (KM \;\; K0) = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix} = N_k^{\mathsf{T}} \in F^{n\times m}.$$

Transposing with Proposition 2.4.23, $A_r K^{\mathsf{T}} = \left(KA_r^{\mathsf{T}}\right)^{\mathsf{T}} = N_k$. The matrix $H = K^{\mathsf{T}}$ is invertible, with inverse $\left(K^{-1}\right)^{\mathsf{T}}$, since $K^{\mathsf{T}}\left(K^{-1}\right)^{\mathsf{T}} = \left(K^{-1}K\right)^{\mathsf{T}} = I_n$ and similarly in the other order. So $GAH = A_r H = N_k$. □

The first proof writes H down: a reordering of the columns followed by subtracting multiples of the first k columns from the others. The second explains why the transpose of A_r is no harder to reduce than A_r itself: its nonzero columns are independent, because the pivot structure of A_r makes the nonzero *rows* of A_r independent. By Corollary 3.5.22, the theorem says that every matrix of rank k can be brought to N_k by elementary row and column operations.

Example 3.5.28 (A rank normal form). For the matrix A of Example 3.3.3 we found

$$A_r = \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad G = \begin{pmatrix} -1/2 & 1/2 & 0 \\ 1/2 & 0 & 0 \\ -1 & -1/2 & 1 \end{pmatrix},$$

with pivot columns $1, 3$ and free columns $2, 4$, so $k = 2$. Following the first proof, P has columns $\mathbf{e}_1, \mathbf{e}_3, \mathbf{e}_2, \mathbf{e}_4$, and

$$A_r P = \begin{pmatrix} 1 & 0 & 2 & -2 \\ 0 & 1 & 0 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad X = \begin{pmatrix} 2 & -2 \\ 0 & 2 \end{pmatrix},$$

$$U = \begin{pmatrix} 1 & 0 & -2 & 2 \\ 0 & 1 & 0 & -2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

and $H = PU$ is U with rows 2 and 3 exchanged,

$$H = \begin{pmatrix} 1 & 0 & -2 & 2 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & -2 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

Then

$$GAH = A_r H = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} = N_2.$$

The last two columns of H, $(-2, 1, 0, 0)$ and $(2, 0, -2, 1)$, are the basic solutions $\mathbf{s}_1, \mathbf{s}_2$ of Example 3.4.10. This is no accident: in general, column $k + i$ of $H = PU$ is $\mathbf{e}_{f_i} - \sum_s x_{si}\mathbf{e}_{p_s}$, which is the basic solution $\mathbf{s}_i$ (Definition 3.4.8).

What does the normal form say about the map T_A? Read $GAH = N_k$ as $AH = G^{-1}N_k$. The columns of H and of G^{-1} form bases of F^n and of F^m, and in these bases T_A is as simple as a linear map can be.

Corollary 3.5.29 (Bases adapted to T_A). Let $A \in F^{m\times n}$ have rank k. There are a basis $\mathbf{b}_1, \ldots, \mathbf{b}_n$ of F^n and a basis $\mathbf{c}_1, \ldots, \mathbf{c}_m$ of F^m such that

$$A\mathbf{b}_j = \mathbf{c}_j \quad (1 \le j \le k), \quad A\mathbf{b}_j = \mathbf{0} \quad (k < j \le n).$$

That is, with $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ and $\mathcal{C} = \mathbf{c}_1, \ldots, \mathbf{c}_m$, we have $[T_A]_{\mathcal{C}\mathcal{B}} = N_k$. Moreover

$$\ker T_A = \operatorname{span}(\mathbf{b}_{k+1}, \ldots, \mathbf{b}_n),$$
$$\operatorname{im} T_A = \operatorname{span}(\mathbf{c}_1, \ldots, \mathbf{c}_k).$$

Proof. STANDARD

Uses. Theorem 3.5.27 (Rank normal form), Theorem 3.5.14 (Third Fundamental Theorem, completed), Remark 3.5.7 (Inverses of T_A and inverses of A), Definition 2.4.1 (Matrix product), Definition 2.3.1 (Matrix of a linear map), Corollary 1.5.17 (Sublists), Definition 1.3.10 (Span)
Hint 1. Take $\mathbf{b}_j$ to be the columns of H and $\mathbf{c}_i$ the columns of G^{-1}. Why are these bases?
Hint 2. Compare column j of AH with column j of $G^{-1}N_k$.
Hint 3. For the kernel, write $\mathbf{x} = \sum_j x_j\mathbf{b}_j$ and use that $\mathbf{c}_1, \ldots, \mathbf{c}_k$ are independent.
Sketch. With $GAH = N_k$, let $\mathbf{b}_j$ be the columns of H and $\mathbf{c}_i$ those of G^{-1}; both lists are bases by Theorem 3.5.14, since H and G^{-1} are invertible. Column j of $AH = G^{-1}N_k$ is $A\mathbf{b}_j$ on the left and $G^{-1}\mathbf{e}_j = \mathbf{c}_j$ (for $j \le k$) or $\mathbf{0}$ (for $j > k$) on the right. Then $A\sum_j x_j\mathbf{b}_j = \sum_{j\le k} x_j\mathbf{c}_j$, which is $\mathbf{0}$ iff $x_1 = \cdots = x_k = 0$ and ranges over $\operatorname{span}(\mathbf{c}_1, \ldots, \mathbf{c}_k)$.

By Theorem 3.5.27 there are invertible G and H with $GAH = N_k$, so $AH = G^{-1}N_k$. Let $\mathbf{b}_1, \ldots, \mathbf{b}_n$ be the columns of H and $\mathbf{c}_1, \ldots, \mathbf{c}_m$ the columns of G^{-1}. Since T_H and $T_{G^{-1}}$ are invertible (Remark 3.5.7), the columns of H form a basis of F^n and those of G^{-1} a basis of F^m, by Theorem 3.5.14 ((V) $\Rightarrow$ (III)).

By Definition 2.4.1, column j of AH is $A\mathbf{b}_j$, and column j of $G^{-1}N_k$ is G^{-1} times column j of N_k. That column is $\mathbf{e}_j \in F^m$ if $j \le k$ and $\mathbf{0}$ if $j > k$, so column j of $G^{-1}N_k$ is $\mathbf{c}_j$ if $j \le k$ and $\mathbf{0}$ if $j > k$. This proves the displayed equations. By Definition 2.3.1, column j of $[T_A]_{\mathcal{C}\mathcal{B}}$ is the coordinate vector of $A\mathbf{b}_j$ in the basis $\mathcal{C}$, which is $\mathbf{e}_j$ for $j \le k$ and $\mathbf{0}$ for $j > k$; so $[T_A]_{\mathcal{C}\mathcal{B}} = N_k$.

Every $\mathbf{x} \in F^n$ is $\mathbf{x} = x_1\mathbf{b}_1 + \cdots + x_n\mathbf{b}_n$ for unique scalars x_j, and by linearity

$$A\mathbf{x} = x_1\mathbf{c}_1 + \cdots + x_k\mathbf{c}_k.$$

Since $\mathbf{c}_1, \ldots, \mathbf{c}_k$ is linearly independent (a sublist of a basis, Corollary 1.5.17), $A\mathbf{x} = \mathbf{0}$ if and only if $x_1 = \cdots = x_k = 0$, that is, if and only if $\mathbf{x} \in \operatorname{span}(\mathbf{b}_{k+1}, \ldots, \mathbf{b}_n)$. And as $\mathbf{x}$ ranges over F^n, the scalars $x_1, \ldots, x_k$ range over all of F, so $A\mathbf{x}$ ranges over $\operatorname{span}(\mathbf{c}_1, \ldots, \mathbf{c}_k)$. □

So every linear map $F^n \to F^m$ of rank k is, in suitable coordinates, the map $(x_1, \ldots, x_n) \mapsto (x_1, \ldots, x_k, 0, \ldots, 0)$: it keeps k coordinates and kills the rest. Choosing bases to make a map simple is a theme of the rest of the book (Section 4.5, and diagonalization in Section 7.4). The corollary also previews Section 4.2. In the first proof of Theorem 3.5.27, the last $n-k$ columns of H are the basic solutions, and the first k columns of G^{-1} are $A\mathbf{e}_{p_1}, \ldots, A\mathbf{e}_{p_k}$, the pivot columns of A. So the kernel is spanned by $n-k$ vectors, one for each free variable, and the image by the k pivot columns of A. Once dimension is defined, this says $\dim\ker T_A + \dim\operatorname{im} T_A = n$.

Is k the only number for which A has a normal form N_k? It is: if $GAH = N_j$ for some invertible G and H, then $j = \operatorname{rank} A$. This amounts to $\operatorname{rank}(AH) = \operatorname{rank} A$ for invertible H, and is proved in Exercise 3.5.41. It follows that two matrices $A, B \in F^{m\times n}$ satisfy $B = GAH$ for some invertible G, H if and only if they have the same rank: rank is the only invariant of a matrix under row and column operations together.

Exercise 3.5.30. ROUTINE Let $A = \begin{pmatrix} 1 & i & 1+i \\ i & -1 & -1+i \end{pmatrix} \in \mathbb{C}^{2\times 3}$. Find invertible G and H with $GAH = N_k$, where $k = \operatorname{rank} A$.

Solution on page 1252

Exercises

Exercise 3.5.31. STANDARD For a scalar t, let

$$A_t = \begin{pmatrix} t & 1 & 1 \\ 1 & t & 1 \\ 1 & 1 & t \end{pmatrix}.$$

(a) Find $\operatorname{rank} A_t$ for every $t \in \mathbb{R}$.

(b) Find $\operatorname{rank} A_t$ for every $t \in \mathbb{F}_3$. Which rank that occurs over $\mathbb{R}$ never occurs over $\mathbb{F}_3$, and why?

Solution on page 1252

Exercise 3.5.32. ROUTINE Over $\mathbb{F}_5$, let $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 0 & 1 \end{pmatrix}$. Show that $\operatorname{rank} A = 2$, find a left inverse of A with the first approach to Proposition 3.5.9, and find a second left inverse. How many left inverses does A have? (Use Exercise 3.5.33 for the count.)

Solution on page 1253

Exercise 3.5.33. STANDARD Let $A \in F^{m\times n}$, and let $G \in F^{m\times m}$ be invertible with $GA = A_r$.

(a) Suppose $\operatorname{rank} A = m$, and let X_0 be a right inverse of A. Show that the right inverses of A are exactly the matrices $X_0 + K$ with $AK = 0$, that is, with every column of K in $\ker T_A$.

(b) Suppose $\operatorname{rank} A = n$, and let C_0 consist of the first n rows of G. Show that $C \in F^{n\times m}$ is a left inverse of A if and only if every row of $C - C_0$ is a linear combination of the last $m - n$ rows of G.

(c) Let F be finite with q elements. Show that a matrix of rank m has exactly $q^{m(n-m)}$ right inverses, and a matrix of rank n has exactly $q^{n(m-n)}$ left inverses.

(d) Over an arbitrary field, show that a matrix with a one-sided inverse has exactly one such inverse if and only if it is square.

Solution on page 1254

Exercise 3.5.34. STANDARD Prove or disprove each statement. Matrices are over a field F and have the indicated sizes.

(a) If $A \in F^{m\times n}$ has rank n and $B \in F^{n\times p}$ has rank p, then AB has rank p.

(b) If $A \in F^{m\times n}$ has rank m and $B \in F^{n\times p}$ has rank n, then AB has rank m.

(c) For every $A \in F^{n\times n}$, $\operatorname{rank}(A^2) = \operatorname{rank} A$.

(d) If $A \in F^{m\times n}$ has rank n, then A^{T} has rank n.

(e) The matrices G and H in Theorem 3.5.27 are determined by A.

(f) If $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $m > n$, then AB is not invertible.

Solution on page 1255

Exercise 3.5.35. STANDARD *Claim.* Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $BA = I_n$. Then $AB = I_m$.

Proof. Let $P = AB$. Then $P^2 = A(BA)B = AI_nB = AB = P$. Multiplying $P^2 = P$ on the left by P^{-1} gives $P = I_m$.

(a) Find the error.

(b) Give a counterexample to the claim.

(c) Show that whenever $BA = I_n$, the matrix $P = AB$ satisfies $P^2 = P$, and that $P = I_m$ if and only if $m = n$.

Solution on page 1255

Exercise 3.5.36. STANDARD Let $A \in F^{m\times n}$, $B \in F^{p\times q}$, and $C \in F^{m\times q}$.

(a) Show that $\operatorname{rank}\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} = \operatorname{rank} A + \operatorname{rank} B$.

(b) Show that $\operatorname{rank}\begin{pmatrix} A & C \\ 0 & B \end{pmatrix} \geq \operatorname{rank} A + \operatorname{rank} B$, and give an example where the inequality is strict.

Solution on page 1255

Exercise 3.5.37. STANDARD Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$. Show that exactly one of the following holds:

(i) $A\mathbf{x} = \mathbf{y}$ has a solution $\mathbf{x} \in F^n$;

(ii) there is $\mathbf{z} \in F^m$ with $\mathbf{z}^{\mathsf{T}}A = \mathbf{0}$ and $\mathbf{z}^{\mathsf{T}}\mathbf{y} \neq 0$.

Then find such a $\mathbf{z}$ for the inconsistent system of Example 3.4.6, with $\mathbf{y} = (4, 2, 6)$.

Solution on page 1256

Exercise 3.5.38. STANDARD Let $A, B, C \in F^{n\times n}$ with $ABC = I_n$. Prove or disprove:

(a) $BCA = I_n$;

(b) $CAB = I_n$;

(c) $BAC = I_n$.

Solution on page 1256

Exercise 3.5.39. HARD Let $A, B \in F^{n\times n}$ satisfy $AB = A + B$. Show that $AB = BA$.

Solution on page 1257

Exercise 3.5.40. STANDARD Let V and W be vector spaces over F, and let $T : V \to W$ be linear.

(a) Suppose V has a basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ and W is spanned by a finite list $\mathbf{w}_1, \ldots, \mathbf{w}_p$. Show that if T is injective, then T has a left inverse.

(b) Suppose W has a basis $\mathbf{c}_1, \ldots, \mathbf{c}_m$. Show that if T is surjective, then T has a right inverse. (No assumption on V is needed.)

Solution on page 1257

Exercise 3.5.41. HARD This exercise shows that the number k in Theorem 3.5.27 is determined by A, and draws the consequences. Throughout, $N_j \in F^{m\times n}$ is as in Theorem 3.5.27.

(a) Let $Q \in F^{n\times n}$ be invertible and $k \leq \min(m, n)$. Show that $\operatorname{rank}(N_k Q) = k$.

(b) Let $A \in F^{m\times n}$. Show that if $GAH = N_j$ for some invertible G and H, then $j = \operatorname{rank} A$.

(c) Show that $\operatorname{rank}(AH) = \operatorname{rank} A$ for every invertible $H \in F^{n\times n}$.

(d) Show that $A, B \in F^{m\times n}$ satisfy $B = GAH$ for some invertible G, H if and only if $\operatorname{rank} A = \operatorname{rank} B$.

Solution on page 1258

Exercise 3.5.42. STANDARD A matrix $P \in F^{n\times n}$ is **idempotent** if $P^2 = P$. Show that every $A \in F^{n\times n}$ can be written as $A = SP$ with S invertible and P idempotent, and also as $A = P'S'$ with P' idempotent and S' invertible.

Solution on page 1259

Exercise 3.5.43. HARD Let $A \in F^{m\times n}$. A matrix $X \in F^{n\times m}$ is a **generalized inverse** of A if $AXA = A$ and $XAX = X$.

(a) Show that every A has a generalized inverse.

(b) Show that if A has a left inverse or a right inverse, then every left inverse or right inverse of A is a generalized inverse.

(c) Let X satisfy $AXA = A$. Show that whenever $A\mathbf{x} = \mathbf{y}$ is consistent, $\mathbf{x} = X\mathbf{y}$ is a solution.

Solution on page 1259

Exercise 3.5.44. HARD Let $A \in F^{n\times n}$. Show that A is not invertible if and only if there is a nonzero $B \in F^{n\times n}$ with $AB = BA = 0$.

Solution on page 1260

Exercise 3.5.45. HARD

(a) Let F be a field with at least three elements. Show that every $A \in F^{n\times n}$ is the sum of two invertible matrices.

(b) Show that (a) fails for $F = \mathbb{F}_2$ and $n = 1$.

Solution on page 1260

Exercise 3.5.46. CHALLENGE Show that for $n \geq 2$, every $A \in \mathbb{F}_2^{n\times n}$ is the sum of two invertible matrices. (Compare Exercise 3.5.45.)

Solution on page 1260

3.6 Proof patterns

Nearly every proof in this chapter ran through Gauss–Jordan elimination, but it used the algorithm in only a handful of ways: as a reduction to a simpler matrix, as an object whose correctness had to be proved, as a way to settle existence questions, and as a table from which structure can be read. This section sorts the chapter's proofs by the question they answer, compares the tools on examples from the chapter, and says when each tool is the wrong one. The exercises at the end practice one move at a time, and the chapter's problems (Problems for Chapter 3) mix them.

3.6.1 Proving a statement about every matrix

The chapter has two reductions. Technique 3.3.22 replaces A by $\operatorname{rref}(A) = GA$ with G invertible (Theorem 3.3.10). Technique 5.4.6, which is named in Section 5.4 but first used here, writes an invertible matrix as a product of elementary matrices (Theorem 3.5.19) and checks the three types one at a time. The rank normal form $GAH = N_k$ (Theorem 3.5.27) is a two-sided version of the first. To choose between them, ask what the property you want has to survive.

Reducing to RREF needs a property P with $P(A) \Leftrightarrow P(GA)$ for every invertible G. The chapter found many: the kernel (Corollary 3.2.23), the linear relations among the columns (Corollary 3.2.17), and

everything defined from these, such as which columns are pivot columns (Corollary 3.3.19), the rank (Proposition 3.5.2(c)), and, for square A, invertibility. Solution sets survive only if the right-hand side moves too: $A\mathbf{x} = \mathbf{y}$ becomes $\operatorname{rref}(A)\mathbf{x} = G\mathbf{y}$ (Proposition 3.2.14). Once invariance is checked, the question is about a matrix whose pivot columns are $\mathbf{e}_1, \ldots, \mathbf{e}_r$ and whose zero rows are visible, and it usually answers itself. This is how Theorem 3.3.23, Proposition 3.4.15, and Corollary 3.3.20 were proved.

Reducing to elementary matrices needs something else: a statement about invertible matrices that survives products. Then two checks suffice, one computation for each type and one step showing that the statement passes from A to EA (or AE). Invariance under $A \mapsto GA$ plays no role. This is how Corollary 3.5.22 turned "multiply by invertible matrices" into "perform row and column operations", and how Section 5.4 proves $\det(AB) = \det A \det B$. The method only reaches invertible matrices, because products of elementary matrices are invertible. A statement about all square matrices needs a second argument for the others. Often both sides of the claim simply vanish there; otherwise one reduces to RREF, writes $A = G^{-1}\operatorname{rref}(A)$, and uses the zero row of $\operatorname{rref}(A)$ (Exercise 3.6.10). Forgetting this case is the error in Exercise 5.4.35.

Example 3.6.1 (Which reduction fits). *Commuting with every invertible matrix.* Which $M \in F^{n\times n}$ satisfy $MX = XM$ for every invertible X? Reducing to RREF is useless here, since M commuting with X says nothing about M commuting with GX. But the property survives products: if $MX = XM$ and $MY = YM$, then $MXY = XMY = XYM$. So by Theorem 3.5.19, M commutes with every invertible matrix if and only if it commutes with every elementary one, and for $n \geq 2$ the type 3 matrices alone already force $M = \lambda I_n$ (Exercise 3.2.52; for $n = 1$ every M works).

Rank under row and column operations. That $\operatorname{rank}(GA) = \operatorname{rank} A$ for invertible G is one line by reducing to RREF: $\operatorname{rref}(GA) = \operatorname{rref}(A)$ (Corollary 3.3.18(a)). The same attempt for AH fails. With $A = \begin{pmatrix} 0 & 1 \end{pmatrix}$ and $H = E_{12}$ we get $AH = \begin{pmatrix} 1 & 0 \end{pmatrix}$, and A and AH are both in RREF, so $\operatorname{rref}(AH) \neq \operatorname{rref}(A)$, although both have rank 1. Right multiplication does not preserve the reduced form, so the reduction cannot see that $\operatorname{rank}(AH) = \operatorname{rank} A$. A different argument is needed: the uniqueness of the rank normal form (Exercise 3.5.41), or transposition, which turns the column operations into row operations of A^{T} and so reduces the question to the equality $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$ of Section 4.3.

3.6.2 Proving that an algorithm is correct

An algorithm proves that something exists once two things are shown about every run (Technique 3.3.5). For *termination*, find a quantity that moves in one direction and cannot do so forever: in Gauss–Jordan elimination, the number k of pivoted rows grows by 1 in each pass and never exceeds m (Proposition 3.3.6). For *correctness*, find an invariant that the starting state satisfies and every step preserves, and that, combined with the reason for halting, gives the property of the output.

The invariant is where the work is, and its typical feature is visible in Lemma 3.3.7. The property we want at the end, conditions (R1)–(R4), is not preserved pass by pass: halfway through, the unpivoted rows are an arbitrary mess. The invariant has to say something about that mess, and part (e) does: the unpivoted rows vanish in every column up to the last pivot. Part (e) is what forces each new pivot to lie to the right of the old ones, which is (b), and it, together with the vanishing of the new pivot row to the left of its pivot, is exactly what choosing the *leftmost* column in step 1 of Algorithm 3.3.1 keeps true. Drop that choice and both the proof and the algorithm break (Exercise 3.3.47). The same pattern recurs in the exercises: Euclid's algorithm by row operations has the monovariant $|b|$ and the invariant "the common divisors of the two entries" (Exercise 3.2.54), and elimination on a strictly diagonally dominant matrix needs no swap because the block still to be processed stays diagonally dominant (Exercise 3.3.56). Even Theorem 3.3.12 was proved by running the algorithm, on a matrix of the right shape, with the invariant "nothing has changed yet". Exercise 3.6.11 practices the technique on an algorithm that has nothing to do with elimination.

An algorithm proves that *some* output with the guaranteed properties exists. It does not prove that this output is the only object with those properties, and a run that made different choices could, as far as the invariant knows, stop somewhere else. That is why the uniqueness of the reduced row echelon form needed its own theorem (Theorem 3.3.17), and why, before it, we could not say that another way of reducing A finds the same pivots, or that $\operatorname{rank}(GA) = \operatorname{rank} A$ (Remark 3.3.2). For echelon forms that are not reduced, uniqueness really fails (Example 3.3.29).

3.6.3 Turning an existence question into a linear system

"Is there a polynomial, a combination, a map, a set of weights, such that ...?" The move of Technique 3.1.9 is to write the unknown object with unknown scalars, translate each requirement into an equation in them, and check that the equations are linear. The question has become the consistency of a linear system, and the set of all answers has the shape of Technique 3.1.18: one answer plus everything that solves the homogeneous version. The chapter used this for membership in a span (Example 3.1.10), interpolation (Theorem 3.4.24), chemical balancing (Exercise 3.1.39), quadrature weights (Exercise 3.4.43), and antiderivatives, where the homogeneous solutions are the constants (Example 3.1.20).

Example 3.6.2 (One question, three answers). Which polynomials take the values $2, 1, 4$ at $-1, 0, 1$? The answer depends on how many coefficients we allow, that is, on the number of unknowns against the three equations (Exercise 3.1.37).

- In $\mathbb{R}[x]_{\leq 1}$, write $p = a + bx$. The conditions $a - b = 2$, $a = 1$, $a + b = 4$ give $b = -1$ and $b = 3$, so there is no solution: three equations, two unknowns, and an inconsistent system.
- In $\mathbb{R}[x]_{\leq 2}$ there are three unknowns and exactly one solution, $1 + x + 2x^2$.
- In $\mathbb{R}[x]_{\leq 3}$ there are four unknowns, and the solutions are $1 + x + 2x^2 + t\big(x^3 - x\big)$ for $t \in \mathbb{R}$: the particular solution from the previous case plus the cubics that vanish at $-1, 0, 1$.

The count of unknowns against equations predicts what can happen (Corollary 3.4.19), but only the system decides. The square case has exactly one solution here because of a structural fact, which is the subject of the next subsection.

The technique is the wrong tool when the requirements are not linear in the unknowns. Asking for a matrix X with $X^2 = A$ gives quadratic equations in the entries of X, and elimination does not apply. Side conditions such as positivity or integrality are not linear either: the linear system only finds the subspace of all balancings in Exercise 3.1.39, and a separate divisibility argument picks the smallest positive integer one; the nonnegative flows of Exercise 3.1.38 come from an inequality on the parameter. Also remember that the system lives over a field, and solving it divides by scalars: in Example 3.1.10 the same equations are solvable over $\mathbb{R}$ and inconsistent over $\mathbb{F}_2$, because one step divided by 2.

3.6.4 When uniqueness gives existence

Uniqueness and existence behave differently. Uniqueness is a property of the homogeneous problem alone, for a matrix of any size: a consistent system has exactly one solution if and only if $\ker T_A = \{\mathbf{0}\}$ (Corollary 3.1.22). Existence for every right-hand side is a property of the zero rows of $\operatorname{rref}(A)$ (Proposition 3.4.16). For a square matrix the two conditions coincide, since both say $\operatorname{rank} A = n$ (Corollary 3.4.20). So for square problems the homogeneous statement buys existence for free (Technique 3.4.21). The homogeneous statement says that a single object is zero, and it is usually proved by structure rather than computation: a polynomial with too many roots (Lemma 3.4.23), a maximum principle (Exercise 3.1.47), or the observation that $BA = I_n$ leaves no room for free variables (Theorem 3.5.23).

Example 3.6.3 (Existence, with and without a formula). Interpolation (Theorem 3.4.24) was proved without solving anything: $n + 1$ conditions on $n + 1$ coefficients, and a polynomial of degree at most n with $n + 1$ roots is zero. The Lagrange polynomials (Definition 3.4.26) were then *defined* through the theorem,

so Lagrange's formula did not give a second existence proof. That needs the closed form $L_i = \prod_{j \neq i}(x - c_j)/(c_i - c_j)$, which is a construction, and which waits for polynomial multiplication in Section 7.1. The construction gives more, a formula, but only when a formula is available. For the plate of Exercise 3.1.47 there is none, and uniqueness is the natural route to existence.

There are three ways to misuse the technique. First, on a non-square system it proves nothing: $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ has trivial kernel and $Ax = (1, 0)$ has no solution (Exercise 3.1.34). Second, counting conditions is not the proof; the homogeneous problem must actually have only the zero solution, and when it does not, existence fails too for some data. In the cyclic system of Exercise 3.1.46 with n even, the homogeneous solution $(1, -1, \ldots, 1, -1)$ comes with the condition that the alternating sum of the right-hand sides vanish, since the alternating sum of the left sides is 0. Exercise 3.6.14 is a smaller instance. Third, the technique depends on finite size. On $F[x]$, the shift S with $S\left(x^k\right) = x^{k+1}$ has a left inverse but is not surjective (the intuition after Theorem 3.5.23), and Section 4.2 replaces "square" by $\dim V = \dim W$.

3.6.5 Reading structure off the reduced form

Once $GA = R = \operatorname{rref}(A)$ is computed, a great deal can be read off without further work:

- a pivot in every column means at most one solution for each $\mathbf{y}$, independent columns, and injectivity of T_A (Proposition 3.4.15, Theorem 3.5.12); a pivot in every row means solutions for every $\mathbf{y}$, spanning columns, and surjectivity (Proposition 3.4.16, Theorem 3.5.13);
- the pivot columns are the columns of A that are not combinations of earlier ones, and the entries of R in a free column are the coefficients that build that column of A from the pivot columns (Corollary 3.3.19);
- the basic solutions, one for each free column, describe $\ker T_A$ (Theorem 3.4.9);
- the last $m - \operatorname{rank} A$ rows of G give the consistency conditions, so they describe $\operatorname{im} T_A$ (Corollary 3.4.4), and they are also the relations among the rows of A (Exercise 3.3.57).

Everything in the first three items is about relations among the columns, and R carries it alone. The image is different: it needs G, or the original columns of A.

Example 3.6.4 (Everything about one matrix). For the matrix A of Example 3.3.3, with columns $\mathbf{a}_1, \ldots, \mathbf{a}_4$,

$$A = \begin{pmatrix} 0 & 0 & 2 & 4 \\ 2 & 4 & 2 & 0 \\ 1 & 2 & 3 & 4 \end{pmatrix},$$

$$R = \begin{pmatrix} 1 & 2 & 0 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$G = \begin{pmatrix} -1/2 & 1/2 & 0 \\ 1/2 & 0 & 0 \\ -1 & -1/2 & 1 \end{pmatrix}.$$

The rank is 2, with pivot columns 1, 3 and free columns 2, 4. From the entries of R, $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_4 = -2\mathbf{a}_1 + 2\mathbf{a}_3$. The basic solutions $(-2, 1, 0, 0)$ and $(2, 0, -2, 1)$ describe $\ker T_A$ (Example 3.4.10). The last row of G gives the single consistency condition $-y_1 - y_2/2 + y_3 = 0$, so $\operatorname{im} T_A$ is the plane $2y_3 = 2y_1 + y_2$ (Example 3.4.6), spanned by the pivot columns $\mathbf{a}_1 = (0, 2, 1)$ and $\mathbf{a}_3 = (2, 2, 3)$ of A.

The classic error is to take the pivot columns of R instead. They are $\mathbf{e}_1$ and $\mathbf{e}_2$, and $\mathbf{e}_1 = (1, 0, 0)$ is not in $\operatorname{im} T_A$, since $2 \cdot 0 \neq 2 \cdot 1 + 0$. The columns of R span $\operatorname{im} T_R$, which is $\operatorname{im} T_A$ moved by G (Non-example 3.2.19). The fix is to read *which* columns are pivot columns from R and to take those columns *from* A. Exercise 3.6.6 and Exercise 3.6.7 practice the distinction.

3.6.6 Row operations and column operations

Row operations multiply on the left by an invertible G, and column operations multiply on the right by an invertible H. They preserve different things (Table 3.6.1).

Property of A	Row operations, $A \mapsto GA$	Column operations, $A \mapsto AH$
$\ker T_A$	kept (Corollary 3.2.23)	moved by H^{-1}
relations among the columns	kept (Corollary 3.2.17)	changed
$\operatorname{im} T_A$, the span of the columns	moved by G	kept (Proposition 3.2.30)
relations among the rows	changed	kept (Exercise 3.6.8)
$\operatorname{rref}(A)$ and the pivot columns	kept (Corollary 3.3.18)	changed
$\operatorname{rank} A$	kept (Proposition 3.5.2)	kept (Exercise 3.5.41)

Table 3.6.1. What the two kinds of operations preserve. "Moved by G" means that the new image is $\{G\mathbf{y} \mid \mathbf{y} \in \operatorname{im} T_A\}$, and similarly for the kernel, which becomes $\{H^{-1}\mathbf{x} \mid \mathbf{x} \in \ker T_A\}$. Transposing turns column operations on A into row operations on A^{T} (Technique 3.2.27); for instance, the relations among the rows of A form the kernel of $T_{A^{\mathsf{T}}}$, which is why column operations keep them.

Example 3.6.5 (One matrix, both operations). Let $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$, so $\ker T_A = \operatorname{span}((1,-1))$ and $\operatorname{im} T_A = \operatorname{span}((1,1))$. The row operation $E_{1,-1,2}$ gives $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, with the same kernel and the image $\operatorname{span}((1,0))$. The column operation "add -1 times column 1 to column 2", which is right multiplication by $H = E_{2,-1,1} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$, gives $\begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$, with the same image and the kernel $\operatorname{span}((0,1))$. Indeed $H^{-1}(1,-1) = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 \\ -1 \end{pmatrix} = (0,-1)$, as the table predicts.

So row operations are the tool for solving systems and for finding relations among the columns, and column operations are the tool for questions about the span of the columns. Using column operations to solve $A\mathbf{x} = \mathbf{y}$ changes the unknowns: $AH\mathbf{x}' = \mathbf{y}$ is solved by $\mathbf{x}'$ exactly when $A\mathbf{x} = \mathbf{y}$ is solved by $\mathbf{x} = H\mathbf{x}'$, so the answer must be translated back. Using row operations on a question about the span of the columns moves the span. This is why the bad right-hand side in the proof of Proposition 3.4.16 is $G^{-1}\mathbf{e}_m$ and not $\mathbf{e}_m$ (Remark 3.4.17). With both kinds of operations allowed, only the rank survives, and every matrix of rank k becomes N_k (Theorem 3.5.27).

3.6.7 Reading the chapter's proofs

Uniqueness of the reduced form, two ways. Writing $R' = GR$ column by column suggests the first proof of Theorem 3.3.17: track G, and show pivot by pivot, from the left, that the pivot columns agree and that G fixes $\mathbf{e}_1, \ldots, \mathbf{e}_r$. It needs invertibility of G in a concrete form, the independence of its columns, to rule out a pivot that appears too early in one matrix. The second proof forgets G. It notices that everything about a matrix in RREF, which columns are pivot columns and what the other columns are, is determined by the linear relations among its columns (Lemma 3.3.16), and that row operations preserve those relations. The comparison teaches a habit: after a proof, list the hypotheses it actually used. The second proof used one consequence of $R' = GR$, namely that R and R' have the same kernel, so it proves the stronger statement Corollary 3.3.20 at no extra cost. The first proof, in turn, says something the second does not: G is rigid on $\mathbf{e}_1, \ldots, \mathbf{e}_r$ and free elsewhere (Exercise 3.3.46).

Constructive and structural proofs. Several results got one proof of each kind. Proposition 3.4.15 was proved by setting one free variable to 1, which produces a nonzero solution, and by the linear dependence lemma, which explains what a missing pivot means. Proposition 3.5.9 was proved from the pivots, which gives a formula, and by extending the columns to a basis, which works for linear maps between abstract vector

spaces as long as the domain has a finite basis and the target a finite spanning list (Exercise 3.5.40). Theorem 3.5.27 was proved by clearing columns and by row reducing the transpose. The computational proof usually produces a formula or a witness, and the structural one usually survives the passage to abstract vector spaces.

Do it to the identity. To find the matrix of an operation that acts on each column by the same linear map, perform the operation on I_m (Lemma 3.2.6, the first proof of Proposition 3.2.7). The same idea, run along with the algorithm, records the whole elimination: carrying I_m next to A produces G (Proposition 3.3.11), and carrying I_n next to a square A produces A^{-1} (Algorithm 3.3.24).

3.6.8 Common errors

Each of these appears in the chapter, most of them as find-the-error exercises.

- *Simultaneous row operations.* Replacing two equations at once, where the second replacement uses an equation the first one changed, can gain solutions (Exercise 3.1.35). So can scaling a row by 0, which is why it is not an elementary operation.
- *The order of the factors.* The first row operation is the rightmost factor of $G = E_t \cdots E_1$ (Example 3.2.8); for column operations it is the leftmost (Remark 3.2.29).
- *Row operations do not preserve the image.* $A\mathbf{x} = \mathbf{y}$ is equivalent to $GA\mathbf{x} = G\mathbf{y}$, not to $GA\mathbf{x} = \mathbf{y}$ (Exercise 3.2.43, Remark 3.4.17), and the columns of $\operatorname{rref}(A)$ do not span $\operatorname{im} T_A$ (Exercise 3.6.6).
- *Uniqueness is not existence.* A trivial kernel gives at most one solution, not one (Exercise 3.1.34). Checking that some vectors are solutions does not show that they are all of them (Exercise 3.4.34, Remark 3.4.12). Counting equations and unknowns does not replace proving uniqueness (Exercise 3.6.14).
- *The shape bounds the rank only from above.* $\operatorname{rank} A \leq \min(m, n)$, and equality is a condition to check, not a consequence of the shape (Problem 3.7).
- *One-sided inverses of non-square matrices.* Cancelling a matrix that has only a right inverse, or inverting AB when A is not square, is invalid (Exercise 3.5.26, Exercise 3.5.35).
- *Rigidity overstated.* $GR = R$ with R in RREF does not force $G = I_m$ (Exercise 3.3.46).
- *Reducing to elementary matrices beyond its reach.* Only invertible matrices are products of elementary matrices; the other case needs its own argument (Exercise 5.4.35, Problem 3.7).
- *Hidden division.* Pivots, ranks, and inverses depend on the field, because elimination divides (Example 3.5.3, Exercise 3.3.27).
- *Pictures from the plane.* Three planes in $\mathbb{R}^3$, no two of them parallel, can still have no common point (Exercise 3.1.36).

Exercises

Exercise 3.6.6. ROUTINE Let

$$A = \begin{pmatrix} 1 & 2 & 0 \\ 2 & 4 & 1 \\ 3 & 6 & 1 \end{pmatrix} \in \mathbb{R}^{3\times 3}, \quad \operatorname{rref}(A) = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$

A student argues: "Row operations do not change the linear relations among the columns, and the pivot columns of $\operatorname{rref}(A)$ are independent. So $\operatorname{im} T_A$ has the independent spanning list $(1, 0, 0), (0, 1, 0)$, the pivot columns of $\operatorname{rref}(A)$."

(a) Show that $(1, 0, 0) \notin \operatorname{im} T_A$, and find the error.

(b) Find two vectors that span $\operatorname{im} T_A$, and an equation for $\operatorname{im} T_A$.

Solution on page 1261

Exercise 3.6.7. ROUTINE A matrix $A \in \mathbb{R}^{3\times 4}$ has

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & 2 & 0 & -1 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

and its first and third columns are $\mathbf{a}_1 = (1, 1, 2)$ and $\mathbf{a}_3 = (0, 1, -1)$.

(a) Find A.

(b) Find vectors spanning $\ker T_A$, and an equation describing $\operatorname{im} T_A$.

Solution on page 1262

Exercise 3.6.8. STANDARD Let $A \in F^{m\times n}$ and let $H \in F^{n\times n}$ be invertible. Decide which of the following are always the same for A and for AH, with a proof or a counterexample.

(a) The image $\operatorname{im} T_A$.
(b) The kernel $\ker T_A$.
(c) The set of row vectors $\mathbf{z} \in F^{1\times m}$ with $\mathbf{z}A = \mathbf{0}$ (the relations among the rows).
(d) The reduced row echelon form.
(e) The rank.
(f) Whether there is a left inverse.

Solution on page 1262

Exercise 3.6.9. HARD Let $A \in F^{m\times n}$ and $B \in F^{p\times n}$.

(a) Show that $\ker T_A \subseteq \ker T_B$ if and only if $B = XA$ for some $X \in F^{p\times m}$.

(b) Deduce that $\ker T_A \subseteq \ker T_B$ if and only if every row of B is a linear combination of the rows of A.

Solution on page 1263

Exercise 3.6.10. STANDARD For $X = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, let $D(X) = ad - bc$. Prove that $D(XY) = D(X)D(Y)$ for all $X, Y \in F^{2\times 2}$, by reducing to elementary matrices: first for invertible X, then separately for X that are not invertible. You may use Exercise 3.2.42.

Solution on page 1264

Exercise 3.6.11. STANDARD Start with a real $m \times n$ matrix. A **move** chooses a row or a column whose entries have a negative sum and multiplies every entry of it by -1.

(a) Show that every sequence of moves is finite, whatever choices are made.

(b) Deduce that some finite sequence of moves produces a matrix all of whose row sums and column sums are nonnegative.

(c) Express the final matrix as $D_1 A D_2$, where A is the starting matrix and D_1, D_2 are products of elementary matrices of one type.

Solution on page 1264

Exercise 3.6.12. STANDARD

(a) Find all $p \in \mathbb{Q}[x]_{\leq 4}$ such that $p(t+1) - p(t) = t^3$ for every $t \in \mathbb{Q}$.

(b) Deduce that $0^3 + 1^3 + \cdots + (N-1)^3 = (N(N-1)/2)^2$ for every integer $N \geq 1$.

Solution on page 1265

Exercise 3.6.13. STANDARD Let $n \geq 3$. Read indices modulo n, so that $x_0 = x_n$ and $x_{n+1} = x_1$.

(a) Show that for every $\mathbf{y} \in \mathbb{R}^n$ there is exactly one $\mathbf{x} \in \mathbb{R}^n$ with

$$4x_i - x_{i-1} - x_{i+1} = y_i \quad (i = 1, \ldots, n).$$

(b) Now replace 4 by 2. Show that the system $2x_i - x_{i-1} - x_{i+1} = y_i$ $(i = 1, \ldots, n)$ has a solution if and only if $y_1 + \cdots + y_n = 0$. You may use Exercise 3.5.37.

Solution on page 1266

Exercise 3.6.14. ROUTINE For $p = a + bx + cx^2 \in \mathbb{R}[x]_{\leq 2}$, write $p' = b + 2cx$. Find the error in the following argument, and decide for which $(u, v, w) \in \mathbb{R}^3$ the conclusion holds.

Claim. For all $u, v, w \in \mathbb{R}$ there is exactly one $p \in \mathbb{R}[x]_{\leq 2}$ with $p(0) = u$, $p(1) = v$, and $p'(1/2) = w$.

Proof. The three conditions are linear equations in the three unknown coefficients of p. The system is square, so by Technique 3.4.21 it has exactly one solution.

Solution on page 1267

Problems for Chapter 3

These problems combine the sections of Chapter 3, and some of them combine it with Chapters 1 and 2. The first four are review prompts: state a main result, prove it without looking, and then answer a question that the text did not ask. The rest are ordered roughly by difficulty. Problems of kind "competition" are harder than anything the course expects. Section 3.6 surveys the techniques they use.

Review: state and prove

Problem 3.1. STANDARD

(a) State the theorem that describes the solution set of a consistent linear equation $T(\mathbf{x}) = \mathbf{y}$, where $T : V \to W$ is linear, and prove it.

(b) Let $A \in F^{m \times n}$. Show that the set of $\mathbf{y} \in F^m$ for which $A\mathbf{x} = \mathbf{y}$ has *exactly one* solution is either empty or all of $\operatorname{im} T_A$, and decide which in terms of $\ker T_A$.

Solution on page 1267

Problem 3.2. STANDARD

(a) State the theorem on the uniqueness of the reduced row echelon form, and prove it by comparing the linear relations among the columns.

(b) Show that the analogous statement for column operations is false: find matrices $R \neq R'$, both in RREF, and an invertible H with $R' = RH$.

(c) Show that nevertheless, if R is in RREF, H is invertible, and RH is also in RREF, then R and RH have the same number of pivots.

Solution on page 1268

Problem 3.3. STANDARD

(a) State the criterion for invertibility of a square matrix in terms of its reduced row echelon form, prove it, and explain why Algorithm 3.3.24 is correct.

(b) Suppose that while row reducing $(A \mid I_n)$, at some intermediate stage, row i of the left block is zero. Show that row i of the right block is then a nonzero row vector $\mathbf{z}$ with $\mathbf{z}A = \mathbf{0}$, and deduce directly from this, without using (a), that A is not invertible.

(c) Carry out (b) for the integer matrix $A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 0 & 1 \\ 3 & 2 & 9 \end{pmatrix}$, read over $\mathbb{F}_5$. Is A invertible over $\mathbb{Q}$?

Solution on page 1269

Problem 3.4. STANDARD

(a) State the rank normal form theorem and prove it.

(b) Deduce that every $A \in F^{m\times n}$ of rank $k \geq 1$ is a sum of k matrices of rank 1.

(c) Deduce that every $A \in F^{m\times n}$ of rank $k \geq 1$ can be written as $A = CS$ with $C \in F^{m\times k}$ and $S \in F^{k\times n}$.

Solution on page 1270

Synthesis problems

Problem 3.5. ROUTINE Let

$$A = \begin{pmatrix} 1 & 2 & 0 & 1 & 3 \\ 2 & 4 & 1 & 4 & 1 \\ 1 & 2 & 1 & 3 & 3 \end{pmatrix}.$$

(a) Find $\operatorname{rref}(A)$ and $\operatorname{rank} A$ over $\mathbb{Q}$ and over $\mathbb{F}_5$. Find a relation among the rows of A over $\mathbb{F}_5$ that explains the difference.

(b) Over $\mathbb{F}_5$, write each free column of A as a combination of the pivot columns, and find vectors spanning $\ker T_A$.

(c) Over $\mathbb{F}_5$, for which $\mathbf{y}$ is $A\mathbf{x} = \mathbf{y}$ consistent, and how many such $\mathbf{y}$ are there? Find all solutions of $A\mathbf{x} = (1, 1, 0)$, and count them.

(d) Over $\mathbb{Q}$, find a right inverse of A. Does A have a right inverse over $\mathbb{F}_5$?

Solution on page 1271

Problem 3.6. ROUTINE Let $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. For each of the fields $\mathbb{R}$, $\mathbb{C}$, $\mathbb{F}_2$, $\mathbb{F}_3$, and $\mathbb{F}_5$, find every scalar λ for which $A - \lambda I_2$ is not invertible, and for each such λ find all $\mathbf{x}$ with $A\mathbf{x} = \lambda\mathbf{x}$.

Solution on page 1272

Problem 3.7. ROUTINE Find the error in each argument, and give a counterexample to its conclusion.

(a) *Claim.* Every $A \in F^{m\times n}$ with $m \leq n$ has a right inverse.

Proof. Run Gauss–Jordan elimination on A. Each pivot uses up one row and one column, and there are at least as many columns as rows, so every row receives a pivot. Hence $\operatorname{rank} A = m$, and Proposition 3.5.8 gives a right inverse.

(b) *Claim.* $\operatorname{rank}(AB) = \operatorname{rank} B$ for all $A \in F^{m\times m}$ and $B \in F^{m\times n}$.

Proof. By Theorem 3.5.19, $A = E_1E_2\cdots E_t$ with each E_i elementary. Multiplying B on the left by E_t, then by E_{t-1}, and so on, performs row operations on B, and row operations do not change the rank (Proposition 3.5.2(c)).

Solution on page 1273

Problem 3.8. STANDARD Prove or disprove each statement.

(a) If $A \in F^{m\times n}$ and $A\mathbf{x} = \mathbf{y}$ has exactly one solution for some $\mathbf{y}$, then $n \le m$.

(b) If $A, B \in F^{m\times n}$ and, for every $\mathbf{y} \in F^m$, the systems $A\mathbf{x} = \mathbf{y}$ and $B\mathbf{x} = \mathbf{y}$ have the same solution set, then $A = B$.

(c) If $A \in F^{m\times n}$ and $B \in F^{p\times n}$ satisfy $\ker T_A = \ker T_B$, then $\operatorname{rank} A = \operatorname{rank} B$, even when $m \neq p$.

(d) If $A \in F^{m\times n}$ and $H \in F^{n\times n}$ is invertible, then A and AH have the same pivot columns.

(e) If column j of $\operatorname{rref}(A)$ is zero, then column j of A is zero.

(f) The matrices of rank at most 1 form a subspace of $F^{2\times 2}$.

Solution on page 1273

Problem 3.9. STANDARD Let F be a finite field with q elements, let $n \ge 0$ and $k \ge 1$, let $c_1, \dots, c_k \in F$ be distinct, and let $d_1, \dots, d_k \in F$.

(a) Suppose $k \le n+1$. Show that exactly q^{n+1-k} polynomials $p \in F[x]_{\le n}$ satisfy $p(c_i) = d_i$ for $i = 1, \dots, k$.

(b) Suppose $k > n+1$. Show that at most one $p \in F[x]_{\le n}$ satisfies these conditions, and that for some choice of the d_i there is none.

(c) How many $p \in \mathbb{F}_7[x]_{\le 4}$ satisfy $p(1) = 2$, $p(2) = 3$, and $p(4) = 0$? How many of these also satisfy $p(0) = 0$?

Solution on page 1274

Problem 3.10. STANDARD Let $\mathbf{a}_1, \dots, \mathbf{a}_n \in F^m$ be linearly independent, and let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$.

(a) Show that the pivot columns of the $m \times (n+m)$ matrix $(A \mid I_m)$ are $1, \dots, n$ together with some columns $n + i_1 < \cdots < n + i_t$, and that $\mathbf{a}_1, \dots, \mathbf{a}_n, \mathbf{e}_{i_1}, \dots, \mathbf{e}_{i_t}$ is a basis of F^m. Show also that $n + t = m$.

(b) Carry this out for $\mathbf{a}_1 = (2, 1, 0, 0)$ and $\mathbf{a}_2 = (1, 1, 1, 0)$ in $\mathbb{Q}^4$, and express the standard basis vectors left out as combinations of the basis you found.

(c) In the second proof of Proposition 3.5.9, the columns of A were extended to a basis by appending, for $i = 1, \dots, m$ in turn, each $\mathbf{e}_i$ not in the span of the list built so far. Show that this appends exactly $\mathbf{e}_{i_1}, \dots, \mathbf{e}_{i_t}$.

Solution on page 1274

Problem 3.11. STANDARD Let $m, n \ge 1$, and let $\mathbf{u}_1, \dots, \mathbf{u}_k \in F^n$ and $\mathbf{w}_1, \dots, \mathbf{w}_k \in F^m$.

(a) Show that there is a linear map $T : F^n \to F^m$ with $T(\mathbf{u}_j) = \mathbf{w}_j$ for $j = 1, \dots, k$ if and only if every linear relation among the $\mathbf{u}_j$ also holds among the $\mathbf{w}_j$: whenever $c_1\mathbf{u}_1 + \cdots + c_k\mathbf{u}_k = \mathbf{0}$, also $c_1\mathbf{w}_1 + \cdots + c_k\mathbf{w}_k = \mathbf{0}$.

(b) Suppose such a T exists. Show that it is unique if and only if $\mathbf{u}_1, \dots, \mathbf{u}_k$ span F^n.

(c) Find all such T for $\mathbf{u}_1 = (1, 0, 1)$, $\mathbf{u}_2 = (1, 1, 0)$, $\mathbf{u}_3 = (3, 1, 2)$ and $\mathbf{w}_1 = (1, 1)$, $\mathbf{w}_2 = (0, 2)$, $\mathbf{w}_3 = (2, 4)$ over $\mathbb{Q}$. What changes if $\mathbf{w}_3 = (2, 5)$?

Solution on page 1275

Problem 3.12. STANDARD For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, define $C_A : F^{2\times 2} \to F^{2\times 2}$ by $C_A(X) = AX - XA$.

(a) Show that C_A is linear, and find its matrix M with respect to the basis $\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}, \mathbf{e}_1\mathbf{e}_2^{\mathsf{T}}, \mathbf{e}_2\mathbf{e}_1^{\mathsf{T}}, \mathbf{e}_2\mathbf{e}_2^{\mathsf{T}}$ of matrix units.

(b) Show that $\operatorname{rank} M = 0$ if A is a scalar multiple of I_2, and $\operatorname{rank} M = 2$ otherwise.

(c) For $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, find all X with $AX = XA$, and all matrices of the form $AX - XA$.

Solution on page 1276

Problem 3.13. STANDARD For $p = a_0 + a_1x + a_2x^2 + a_3x^3 \in \mathbb{R}[x]_{\le 3}$, write $p' = a_1 + 2a_2x + 3a_3x^2$ and $p'' = 2a_2 + 6a_3x$. Given values $d_0, d_1, d_2 \in \mathbb{R}$, a **natural cubic spline** through $(-1, d_0)$, $(0, d_1)$, $(1, d_2)$ is a pair (p, q) of polynomials in $\mathbb{R}[x]_{\le 3}$ (the pieces on $[-1, 0]$ and on $[0, 1]$) such that

$$p(-1) = d_0, \quad p(0) = q(0) = d_1, \quad q(1) = d_2, \quad p'(0) = q'(0), \quad p''(0) = q''(0), \quad p''(-1) = q''(1) = 0.$$

(a) Show that these conditions form a square linear system in the coefficients of p and q.

(b) Show that for all d_0, d_1, d_2 there is exactly one natural cubic spline.

(c) Find the spline for $(d_0, d_1, d_2) = (0, 1, 0)$. Use (b) to shorten the computation.

Solution on page 1277

Problem 3.14. STANDARD Let $A \in F^{k\times k}$ be invertible, $B \in F^{k\times \ell}$, $C \in F^{\ell\times k}$, $D \in F^{\ell\times \ell}$, and

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}, \quad S = D - CA^{-1}B \in F^{\ell\times \ell}.$$

The matrix S is the **Schur complement** of A in M.

(a) Find invertible block matrices P and Q with $PMQ = \begin{pmatrix} A & 0 \\ 0 & S \end{pmatrix}$.

(b) Deduce that $\operatorname{rank} M = k + \operatorname{rank} S$. In particular, M is invertible if and only if S is.

(c) For which $t \in \mathbb{Q}$ does the following matrix have rank 4?

$$M_t = \begin{pmatrix} 1 & 2 & 1 & 0 \\ 3 & 4 & 0 & 1 \\ 1 & 0 & t & 1 \\ 0 & 1 & 1 & t \end{pmatrix}$$

Solution on page 1278

Problem 3.15. HARD An electrical network has nodes $0, 1, \ldots, n$. Some pairs of nodes are joined by a resistor; let $c_{ij} = c_{ji} > 0$ be the conductance (the reciprocal of the resistance) if i and j are joined, and $c_{ij} = 0$ otherwise, with $c_{ii} = 0$. The network is **connected**: any node can be reached from any other along resistors. Node 0 is grounded, so its potential is $v_0 = 0$. An external source injects a current s_i into node i for $i = 1, \ldots, n$. By Ohm's law, the current from i to j through their resistor is $c_{ij}(v_i - v_j)$, and Kirchhoff's current law at node i says

$$\sum_{j=0}^{n} c_{ij}(v_i - v_j) = s_i \quad (i = 1, \ldots, n).$$

(a) Show that for every $\mathbf{s} \in \mathbb{R}^n$ there is exactly one vector of potentials $\mathbf{v} = (v_1, \ldots, v_n)$ satisfying these equations.

(b) Show that the current flowing into the ground node through the resistors is automatically $s_1 + \cdots + s_n$.

(c) In the network of Figure 3.1, one ampere is injected at node 2. Find the potentials, the current through the diagonal resistor, and the **effective resistance** between nodes 2 and 0, which is v_2 divided by the injected current.

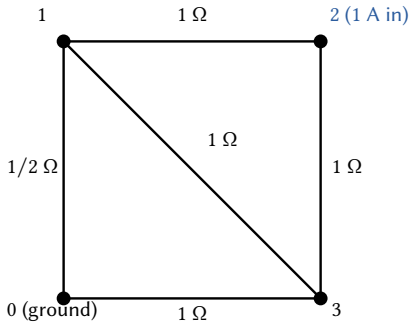

Figure 3.1. Four nodes on a square with one diagonal. The resistor between nodes 0 and 1 has resistance $1/2$ Ω (conductance 2); the other four have resistance 1 Ω.

Solution on page 1279

Problem 3.16. HARD For $n \geq 1$, let $P_n \in F^{n \times n}$ have entry 1 in every position (i, j) with $|i - j| \leq 1$, and 0 elsewhere.

(a) Show that, over every field F, P_n is invertible if and only if n is not congruent to 2 modulo 3.

(b) Over $\mathbb{F}_2$, P_n is the matrix of "lights out" on a row of n lamps, where pressing a lamp toggles it and its immediate neighbors (compare Exercise 3.1.40). Suppose $n \equiv 2 \bmod 3$. Show that a pattern $\mathbf{y} \in \mathbb{F}_2^n$ of lit lamps can be switched off if and only if the number of lit lamps in positions not divisible by 3 is even. You may use Exercise 3.5.37.

Solution on page 1280

Problem 3.17. HARD Let F be a field and $1 \leq r \leq \min(m, n)$.

(a) Let $A \in F^{m \times n}$ have rank r, and let $S \in F^{r \times n}$ consist of the r nonzero rows of $\operatorname{rref}(A)$. Show that $A = CS$ for exactly one $C \in F^{m \times r}$, and that this C has rank r. Conversely, show that if $S \in F^{r \times n}$ is in RREF with no zero row and $C \in F^{m \times r}$ has rank r, then CS has rank r and $\operatorname{rref}(CS) = \begin{pmatrix} S \\ 0 \end{pmatrix}$.

(b) Let F have q elements, and let $N(r, n)$ be the number of $r \times n$ matrices in RREF with no zero row (compare Exercise 3.3.58). Show that the number of matrices in $F^{m \times n}$ of rank r is

$$N(r, n)(q^m - 1)(q^m - q)\cdots\left(q^m - q^{r-1}\right).$$

(c) Deduce that

$$N(r, n) = \frac{(q^n - 1)(q^n - q)\cdots\left(q^n - q^{r-1}\right)}{(q^r - 1)(q^r - q)\cdots\left(q^r - q^{r-1}\right)},$$

and check this against Exercise 3.3.48 for $r = 2$, $n = 3$.

Solution on page 1281

Problem 3.18. HARD For $A \in \mathbb{Z}^{n\times n}$, let $\overline{A} \in \mathbb{F}_2^{n\times n}$ be the matrix of remainders of its entries modulo 2.

(a) Show that if $\overline{A}$ is invertible over $\mathbb{F}_2$, then A is invertible as a real matrix.

(b) Deduce that an integer matrix whose diagonal entries are odd and whose other entries are even is invertible over $\mathbb{R}$.

(c) Show that an integer matrix whose diagonal entries are even and whose other entries are odd is invertible over $\mathbb{R}$ when n is even, and give a non-invertible example with $n = 3$.

(d) Show that the converse of (a) is false.

Solution on page 1282

Problem 3.19. CHALLENGE Let F be a field, let $a_1, \ldots, a_n \in F$ be distinct, let $b_1, \ldots, b_n \in F$ be distinct, and suppose $a_i + b_j \neq 0$ for all i, j.

(a) Show that the **Cauchy matrix** $C \in F^{n\times n}$ with entries $c_{ij} = 1/\big(a_i + b_j\big)$ is invertible.

(b) Deduce that the **Hilbert matrix** $H_n \in \mathbb{Q}^{n\times n}$ with entries $1/(i + j - 1)$ is invertible.

Solution on page 1283

CHAPTER 4

Dimension

Dimension, rank–nullity, rank inequalities, sums and direct sums, change of basis, quotients, and affine geometry.

4.1 Dimension

The standard bases of F^n, $F^{m\times n}$, and $F[x]_{\le n}$ have n, mn, and $n+1$ entries. Each of these spaces has many other bases (Section 1.6), and this section begins by showing that all of them have the same length. That length is the dimension of the space. We prove it twice: with the matrix machinery of Section 3.5, as the lecture does, and with the exchange lemma, which works inside V and says more, namely that an independent list is never longer than a spanning list.

Dimension then turns many questions into counting. A list of the right length is a basis as soon as it is independent or spanning, every independent list extends to a basis, and a subspace is no bigger than the space around it. The counting has consequences well beyond bases. When a chain $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \dots$ ends in $\mathbf{0}$, its nonzero vectors are independent, so an operator on an n-dimensional space that is eventually 0 is already 0 after n steps. Any n^2+1 matrices of size $n\times n$ satisfy a linear relation, so every square matrix satisfies a polynomial equation. And over a field with q elements, a space of dimension n has exactly q^n vectors.

Throughout, V is a vector space over a field F.

4.1.1 Bases of F^m

Intuition (Why the number of vectors should be fixed). A basis $\mathcal{B} = \mathbf{v}_1, \dots, \mathbf{v}_n$ of V names every vector by its coordinates $[\mathbf{v}]_{\mathcal{B}} \in F^n$, and the coordinate map $V \to F^n$ is a bijection that respects linear combinations (Proposition 1.6.16, Proposition 1.6.19). So a basis of length n makes V a copy of F^n with the vectors renamed. If V also had a basis of length m, it would be a copy of F^m as well, and translating from one set of names to the other would give a bijection $F^m \to F^n$ that respects linear combinations, that is, an invertible linear map. Every linear map $F^m \to F^n$ is T_A for a matrix $A \in F^{n\times m}$ (Proposition 2.3.17), and invertible matrices are square (Corollary 3.5.15). So $m = n$. The lecture runs this argument in the simplest case, $V = F^m$, where no translation is needed.

Theorem 4.1.1 (Bases of F^m). Every basis of F^m has exactly m vectors.

Proof (via the Third Fundamental Theorem). ROUTINE

Uses. Theorem 3.5.14 (Third Fundamental Theorem, completed), Definition 1.6.1 (Basis)
Techniques. Translate between maps and matrices (Technique 2.3.27)

Hint 1. Put the vectors of a basis $\mathcal{B}$ of F^m into a matrix as its columns. What is its size?
Hint 2. Condition (III) of Theorem 3.5.14 is a statement about the columns of a matrix. What does the "moreover" part of that theorem conclude?
Sketch. If $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ is a basis of F^m, the $m \times n$ matrix with columns $\mathbf{v}_1, ..., \mathbf{v}_n$ satisfies condition (III) of Theorem 3.5.14, so $m = n$ by the "moreover" part.

Let $\mathcal{B} = \mathbf{v}_1, ..., \mathbf{v}_n$ be a basis of F^m, and let

$$A = \begin{pmatrix} \mathbf{v}_1 & \cdots & \mathbf{v}_n \end{pmatrix} \in F^{m \times n}$$

be the matrix whose columns are $\mathbf{v}_1, ..., \mathbf{v}_n$. Its columns form a basis of F^m, which is condition (III) of Theorem 3.5.14. By the "moreover" part of that theorem, $m = n$. □

The proof is two lines because the work was done in Section 3.5. The "moreover" part of Theorem 3.5.14 comes from the inequality $\operatorname{rank} A \leq \min(m, n)$, which holds because the pivots of $\operatorname{rref}(A)$ occupy distinct rows and distinct columns (Proposition 3.5.2). So the theorem is really a count of pivots. To prove the corresponding statement in an arbitrary vector space without first choosing coordinates, we need a count that happens inside V. That count is the exchange lemma.

4.1.2 The exchange lemma

Intuition (Trading spanning vectors for independent ones). Let $\mathbf{u}_1, ..., \mathbf{u}_m$ be independent and let $\mathbf{w}_1, ..., \mathbf{w}_n$ span V. Since the $\mathbf{w}_i$ span, $\mathbf{u}_1$ is a linear combination of them, and since $\mathbf{u}_1 \neq \mathbf{0}$, some $\mathbf{w}_i$ appears with a nonzero coefficient. Solving for that $\mathbf{w}_i$ shows that it lies in the span of $\mathbf{u}_1$ and the other $\mathbf{w}$'s, so we can trade it for $\mathbf{u}_1$ and still have a spanning list of length n. This is the exchange of Exercise 1.3.34 and Exercise 1.5.33. Now trade a second $\mathbf{w}$ for $\mathbf{u}_2$, and so on. The independence of the $\mathbf{u}$'s guarantees that each trade removes a $\mathbf{w}$, and never one of the $\mathbf{u}$'s brought in earlier. If there were more $\mathbf{u}$'s than $\mathbf{w}$'s, we would run out of $\mathbf{w}$'s to trade.

Lemma 4.1.2 (Exchange lemma). Let $\mathbf{u}_1, ..., \mathbf{u}_m$ be a linearly independent list in V, and let $\mathbf{w}_1, ..., \mathbf{w}_n$ be a list that spans V. Then $m \leq n$. More precisely, the $\mathbf{w}_i$ can be renumbered so that

$$\mathbf{u}_1, ..., \mathbf{u}_m, \mathbf{w}_{m+1}, ..., \mathbf{w}_n$$

spans V.

In words: an independent list is never longer than a spanning list, and the independent list can replace an equal number of entries of the spanning list without losing the span. The result is often called the Steinitz exchange lemma. The first proof makes the trades of the intuition one at a time, and an induction keeps track of them.

Proof (by exchange). STANDARD

Uses. Lemma 1.5.10 (Linear dependence lemma), Corollary 1.5.13 (Independence, one entry at a time), Corollary 1.5.17 (Sublists), Proposition 1.5.18 (Operations that preserve independence), Corollary 1.3.20 (Operations that preserve the span)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Prove by induction on $k = 0, 1, ..., m$: $k \leq n$, and after renumbering the $\mathbf{w}_i$, the list $\mathbf{u}_1, ..., \mathbf{u}_k, \mathbf{w}_{k+1}, ..., \mathbf{w}_n$ spans V.
Hint 2. In the inductive step, insert $\mathbf{u}_{k+1}$ right after $\mathbf{u}_k$. Why is the longer list dependent, and what does Lemma 1.5.10 then let you delete?
Hint 3. The deleted entry is in the span of the entries before it. It cannot be one of $\mathbf{u}_1, ..., \mathbf{u}_{k+1}$, which come first and form an independent list (Corollary 1.5.13). So it is a $\mathbf{w}$, and in particular some $\mathbf{w}$ was still there.
Sketch. Induct on k. Suppose $\mathcal{B}_k = \mathbf{u}_1, ..., \mathbf{u}_k, \mathbf{w}_{k+1}, ..., \mathbf{w}_n$ spans V. Inserting $\mathbf{u}_{k+1} \in \operatorname{span}(\mathcal{B}_k)$ after $\mathbf{u}_k$ gives a dependent list that still spans. By Lemma 1.5.10, some entry lies in the span of the entries before it, and deleting it keeps the span. It is not among the independent $\mathbf{u}_1, ..., \mathbf{u}_{k+1}$ at the front, so it is some $\mathbf{w}_i$ with $i > k$. Hence $k + 1 \leq n$, and after renumbering, deleting it gives $\mathcal{B}_{k+1}$. At $k = m$ we get $m \leq n$.

We prove by induction on $k \in \{0, 1, ..., m\}$ the statement

$P(k)$: $k \le n$, and the $\mathbf{w}_i$ can be renumbered so that $\mathcal{B}_k = \mathbf{u}_1, ..., \mathbf{u}_k, \mathbf{w}_{k+1}, ..., \mathbf{w}_n$ spans V.

For $k = m$ this is the lemma.

Base case. $P(0)$ says that $0 \le n$ and that $\mathbf{w}_1, ..., \mathbf{w}_n$ spans V, which is the hypothesis.

Inductive step. Let $0 \le k < m$ and assume $P(k)$, with the $\mathbf{w}_i$ numbered so that $\mathcal{B}_k$ spans V. Let

$$\mathcal{L} = \mathbf{u}_1, ..., \mathbf{u}_k, \mathbf{u}_{k+1}, \mathbf{w}_{k+1}, ..., \mathbf{w}_n$$

be $\mathcal{B}_k$ with $\mathbf{u}_{k+1}$ inserted after $\mathbf{u}_k$. The list $\mathcal{L}$ spans V, since it contains every entry of $\mathcal{B}_k$ (Corollary 1.3.20). It is linearly dependent: $\mathbf{u}_{k+1} \in V = \operatorname{span}(\mathcal{B}_k)$, so the reordering $\mathcal{B}_k, \mathbf{u}_{k+1}$ of $\mathcal{L}$ is dependent by Corollary 1.5.13, and reordering does not affect independence (Proposition 1.5.18(a)).

By Lemma 1.5.10, some entry of $\mathcal{L}$ lies in the span of the entries before it, and deleting that entry does not change the span. The first $k+1$ entries of $\mathcal{L}$ form the list $\mathbf{u}_1, ..., \mathbf{u}_{k+1}$, which is independent as a sublist of an independent list (Corollary 1.5.17). By Corollary 1.5.13, none of them lies in the span of the entries before it. So the entry in question is $\mathbf{w}_i$ for some i with $k+1 \le i \le n$. In particular $k+1 \le n$. Renumber $\mathbf{w}_{k+1}, ..., \mathbf{w}_n$ so that this entry becomes $\mathbf{w}_{k+1}$. Deleting it from $\mathcal{L}$ leaves

$$\mathcal{B}_{k+1} = \mathbf{u}_1, ..., \mathbf{u}_{k+1}, \mathbf{w}_{k+2}, ..., \mathbf{w}_n,$$

whose span is $\operatorname{span}(\mathcal{L}) = V$. This is $P(k+1)$. □

Each step of the induction removes a $\mathbf{w}$ that is still present, so the steps assign to each $\mathbf{u}$ a different $\mathbf{w}$, and $m \le n$ is the pigeonhole principle. The second proof replaces the trades by a single linear system. It shows that $m \le n$, but not the renumbering statement.

Proof (via a homogeneous system). STANDARD

> *Uses.* Definition 1.3.12 (Spanning list), Corollary 3.4.19 (More unknowns than equations), Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 2.3.11 (Entries of $A\mathbf{x}$)
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9)
> *Hint 1.* Write each $\mathbf{u}_j$ as a linear combination of $\mathbf{w}_1, ..., \mathbf{w}_n$, and collect the coefficients into a matrix A. What is its size?
> *Hint 2.* Suppose $m > n$. Then the system $A\mathbf{x} = \mathbf{0}$ has more unknowns than equations. Turn a nonzero solution into a linear relation among the $\mathbf{u}_j$.
> *Sketch.* Write $\mathbf{u}_j = \sum_i a_{ij}\mathbf{w}_i$ and let $A = (a_{ij}) \in F^{n \times m}$. If $m > n$, some $\mathbf{x} \ne \mathbf{0}$ has $A\mathbf{x} = \mathbf{0}$ (Corollary 3.4.19). Regrouping, $\sum_j x_j \mathbf{u}_j = \sum_i (A\mathbf{x})_i \mathbf{w}_i = \mathbf{0}$, a nontrivial relation among the independent $\mathbf{u}_j$.

Suppose, to the contrary, that $m > n$. Since $\mathbf{w}_1, ..., \mathbf{w}_n$ spans V, for each j there are scalars $a_{1j}, ..., a_{nj}$ with

$$\mathbf{u}_j = a_{1j}\mathbf{w}_1 + \cdots + a_{nj}\mathbf{w}_n.$$

Let $A = (a_{ij}) \in F^{n \times m}$. It has more columns than rows, so by Corollary 3.4.19(a) there is $\mathbf{x} = (x_1, ..., x_m) \ne \mathbf{0}$ with $A\mathbf{x} = \mathbf{0}$. Regrouping the double sum by repeated use of Lemma 1.3.9,

$$\sum_{j=1}^{m} x_j \mathbf{u}_j = \sum_{j=1}^{m} x_j \sum_{i=1}^{n} a_{ij}\mathbf{w}_i = \sum_{i=1}^{n} \left(\sum_{j=1}^{m} a_{ij} x_j \right) \mathbf{w}_i = \sum_{i=1}^{n} (A\mathbf{x})_i \mathbf{w}_i = \mathbf{0},$$

where $(A\mathbf{x})_i = \sum_j a_{ij} x_j$ is the i-th entry of $A\mathbf{x}$ (Proposition 2.3.11). Since some $x_j \ne 0$, this is a nontrivial linear relation of $\mathbf{u}_1, ..., \mathbf{u}_m$, contradicting their independence (Theorem 1.5.5). So $m \le n$. □

Example 4.1.3 (The exchange, step by step). In $\mathbb{R}^3$, let $\mathbf{u}_1 = (1, 1, 0)$ and $\mathbf{u}_2 = (0, 1, 1)$, which are independent since neither is a multiple of the other, and let $\mathbf{w}_1, \mathbf{w}_2, \mathbf{w}_3 = \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$.

Step 1. Insert $\mathbf{u}_1$ at the front: $\mathbf{u}_1, \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$. The relation $\mathbf{u}_1 - \mathbf{e}_1 - \mathbf{e}_2 = \mathbf{0}$ shows that $\mathbf{e}_2 \in \operatorname{span}(\mathbf{u}_1, \mathbf{e}_1)$, and $\mathbf{e}_2$ is the first entry with this property, since $\mathbf{e}_1 \notin \operatorname{span}(\mathbf{u}_1)$. Delete it: $\mathbf{u}_1, \mathbf{e}_1, \mathbf{e}_3$ spans $\mathbb{R}^3$.

Step 2. Insert $\mathbf{u}_2$: $\mathbf{u}_1, \mathbf{u}_2, \mathbf{e}_1, \mathbf{e}_3$. Now $\mathbf{u}_2 = \mathbf{u}_1 - \mathbf{e}_1 + \mathbf{e}_3$, so $\mathbf{e}_3 \in \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2, \mathbf{e}_1)$. Here $\mathbf{e}_3$ is the only entry in the span of the earlier ones: $\mathbf{u}_1$ and $\mathbf{u}_2$ cannot be, and $\mathbf{e}_1 = (1, 0, 0) \notin \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$, whose vectors $a(1, 1, 0) +$

$b(0,1,1) = (a, a+b, b)$ have middle coordinate equal to the sum of the others. Delete $\mathbf{e}_3$: the list $\mathbf{u}_1, \mathbf{u}_2, \mathbf{e}_1$ spans $\mathbb{R}^3$.

Two independent vectors pushed out two of the three standard basis vectors, and the one that survived, $\mathbf{e}_1$, was enough to complete $\mathbf{u}_1, \mathbf{u}_2$ to a spanning list of $\mathbb{R}^3$. (So would $\mathbf{e}_2$ or $\mathbf{e}_3$ have been; the exchange simply found one.)

With the lemma, the theorem on F^m has a proof that uses nothing but the standard basis.

Proof of Theorem 4.1.1 (via the exchange lemma). ROUTINE

> *Uses.* Lemma 4.1.2 (Exchange lemma), Proposition 1.6.7 (Standard bases), Proposition 1.6.2 (Bases are independent spanning lists)
> *Hint 1.* Compare a basis $\mathcal{B}$ of F^m of length n with the standard basis $\mathbf{e}_1, \ldots, \mathbf{e}_m$. Both lists are independent and both span.
> *Hint 2.* Apply Lemma 4.1.2 twice, with the roles of the two lists swapped.
> *Sketch.* $\mathcal{B}$ is independent and $\mathbf{e}_1, \ldots, \mathbf{e}_m$ spans F^m, so $n \le m$. The standard basis is independent and $\mathcal{B}$ spans, so $m \le n$.

Let $\mathcal{B}$ be a basis of F^m of length n. The standard basis $\mathbf{e}_1, \ldots, \mathbf{e}_m$ is a basis of F^m (Proposition 1.6.7). By Proposition 1.6.2 both lists are independent and both span F^m. Applying Lemma 4.1.2 to the independent list $\mathcal{B}$ and the spanning list $\mathbf{e}_1, \ldots, \mathbf{e}_m$ gives $n \le m$. Applying it to the independent list $\mathbf{e}_1, \ldots, \mathbf{e}_m$ and the spanning list $\mathcal{B}$ gives $m \le n$. Hence $n = m$. □

> *Intuition (Matrix machinery versus pure exchange).* Both proofs of Theorem 4.1.1 are counting arguments, and they count different things. The first counts pivots: $\operatorname{rank} A \le \min(m, n)$ because each pivot of $\operatorname{rref}(A)$ has a row and a column to itself. Behind it stands all of Gauss–Jordan elimination, and in return the proof is a computation: row reduce, and the pivots show which columns are independent and whether they span. The second counts trades: each $\mathbf{u}$ pushes out a $\mathbf{w}$ that has not been pushed out before. It never mentions matrices or coordinates, and the only tool it uses is the linear dependence lemma. That is why it works verbatim in $F[x]_{\le n}$, in spaces of functions, and in subspaces cut out by equations, where there is no matrix to reduce until a basis has been chosen. The price is that it is not a computation. It asserts that some $\mathbf{w}$ can be removed, and finding one means testing membership in spans, which in practice is again a row reduction.
>
> The second proof of the exchange lemma sits between the two. It uses coordinates, but only with respect to a spanning list, which need not be a basis, and the single fact about linear systems that it needs is that a homogeneous system with more unknowns than equations has a nonzero solution.

4.1.3 Dimension

The theorem on F^m extends to every finite-dimensional space, again in two ways. The lecture transports the question to F^m by coordinates. The exchange lemma answers it in V directly.

> **Theorem 4.1.4** (All bases have the same length). Let V be finite-dimensional. Any two bases of V have the same length.

Proof (via coordinates). ROUTINE

> *Uses.* Proposition 1.6.20 (Coordinates translate questions about V into F^n), Theorem 4.1.1 (Bases of F^m)
> *Hint 1.* Take bases $\mathcal{B}$ of length m and $\mathcal{C}$ of length n. Use $\mathcal{B}$-coordinates to move the list $\mathcal{C}$ into F^m.
> *Hint 2.* By Proposition 1.6.20(c), the coordinate vectors of a basis of V form a basis of F^m. How long is every basis of F^m?
> *Sketch.* If $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_m$ and $\mathcal{C} = \mathbf{w}_1, \ldots, \mathbf{w}_n$ are bases, then $[\mathbf{w}_1]_{\mathcal{B}}, \ldots, [\mathbf{w}_n]_{\mathcal{B}}$ is a basis of F^m by Proposition 1.6.20(c), so $n = m$ by Theorem 4.1.1.

Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_m$ and $\mathcal{C} = \mathbf{w}_1, \ldots, \mathbf{w}_n$ be bases of V. Since $\mathcal{C}$ is a basis of V, Proposition 1.6.20(c), applied with the basis $\mathcal{B}$, shows that $[\mathbf{w}_1]_{\mathcal{B}}, \ldots, [\mathbf{w}_n]_{\mathcal{B}}$ is a basis of F^m. It has n vectors, so $n = m$ by Theorem 4.1.1.□

Proof (via the exchange lemma). ROUTINE

> *Uses.* Lemma 4.1.2 (Exchange lemma), Proposition 1.6.2 (Bases are independent spanning lists)

Hint 1. A basis is both independent and spanning.
Hint 2. Apply Lemma 4.1.2 with $\mathcal{B}$ as the independent list and $\mathcal{C}$ as the spanning list, and then the other way around.
Sketch. $\mathcal{B}$ is independent and $\mathcal{C}$ spans, so $m \le n$; symmetrically $n \le m$.

Let $\mathcal{B}$ and $\mathcal{C}$ be bases of V of lengths m and n. By Proposition 1.6.2, $\mathcal{B}$ is independent and $\mathcal{C}$ spans V, so $m \le n$ by Lemma 4.1.2. Exchanging the roles of $\mathcal{B}$ and $\mathcal{C}$ gives $n \le m$. □

The first proof reduces the question about V to the same question about F^m, and the dictionary of Proposition 1.6.20 guarantees that nothing is lost in translation. The second proof needs no dictionary. Both are worth knowing: transporting a problem to F^n by coordinates is how most computations in abstract spaces are done, and arguing inside V is how most proofs about them are written.

By Corollary 1.6.24 a finite-dimensional space has a basis, and by Theorem 4.1.4 all of its bases have the same length. So the following definition makes sense.

Definition 4.1.5 (Dimension). Let V be a finite-dimensional vector space. The **dimension** of V, written $\dim V$, is the length of any basis of V. If $\dim V = n$, we say that V is **n-dimensional**. If V is infinite-dimensional, we write $\dim V = \infty$.

The symbol ∞ is shorthand and not a number we compute with. It lets us write statements such as "$\dim V < \infty$" for "V is finite-dimensional". Since $\{\mathbf{0}\}$ has the basis $()$ and every other space has a nonzero vector, which no basis of length 0 can represent, $\dim V = 0$ exactly when $V = \{\mathbf{0}\}$.

Remark 4.1.6 (The field is part of the data). Whether a list is a basis depends on which scalars are allowed (Example 1.6.5), so the dimension depends on the field. When the field matters we write $\dim_F V$. For example, $\dim_{\mathbb{C}} \mathbb{C} = 1$, with basis 1, while $\dim_{\mathbb{R}} \mathbb{C} = 2$, with basis $1, i$. The set and the addition are the same; only the scalars differ.

Example 4.1.7 (Dimensions of the standard spaces).

(a) By Proposition 1.6.7, $\dim F^n = n$, $\dim F^{m\times n} = mn$, and $\dim F[x]_{\le n} = n + 1$.

(b) The plane $P = \{(x, y, z) \in \mathbb{R}^3 \mid x + y + z = 0\}$ has the basis $(1, 0, -1), (0, 1, -1)$ (Example 1.6.3(b)), so $\dim P = 2$.

(c) If V is a vector space over $\mathbb{C}$ with $\dim_{\mathbb{C}} V = n$ and basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$, then $\mathbf{v}_1, i\mathbf{v}_1, \ldots, \mathbf{v}_n, i\mathbf{v}_n$ is a basis of V over $\mathbb{R}$. It is independent over $\mathbb{R}$ by Exercise 1.5.37, and it spans V over $\mathbb{R}$, since every $\mathbf{v} \in V$ is $\sum_j (a_j + b_j i)\mathbf{v}_j = \sum_j (a_j \mathbf{v}_j + b_j (i\mathbf{v}_j))$ with $a_j, b_j \in \mathbb{R}$. So $\dim_{\mathbb{R}} V = 2n$; for instance $\dim_{\mathbb{R}} \mathbb{C}^n = 2n$.

(d) $F[x]$ is infinite-dimensional (Proposition 1.6.25), and so is $\mathbb{R}$ over $\mathbb{Q}$ (Exercise 1.3.45). In both cases $\dim = \infty$. For $F[x]$ the set $\{1, x, x^2, \ldots\}$ is a basis in the infinite sense of Aside (Bases of infinite-dimensional spaces). For $\mathbb{R}$ over $\mathbb{Q}$ every such basis is uncountable, and none can be described explicitly; their existence rests on the axiom of choice (Section 15.1).

(e) Linear maps $F^n \to F^m$ correspond to matrices in $F^{m\times n}$ (Theorem 2.3.20), and the correspondence respects sums and scalar multiples (Proposition 2.4.12). We will see in Section 4.5 that this makes $\dim \mathrm{L}(V, W) = (\dim V)(\dim W)$ for all finite-dimensional V and W.

Non-example 4.1.8 (What the dimension does not count).

(a) Every vector of the plane P in (b) above has three coordinates, but $\dim P = 2$. The dimension counts the vectors in a basis of P, not the coordinates used to write down its elements.

(b) The list $(1, 0), (0, 1), (1, 1)$ spans $\mathbb{R}^2$ but $\dim \mathbb{R}^2 = 2$. A spanning list can be longer than the dimension, and Corollary 4.1.11 below shows that it can never be shorter.

(c) $\mathbb{C}$ and $\mathbb{R}^2$ can be identified as sets with the same addition (Example 1.6.5), yet $\dim_{\mathbb{C}} \mathbb{C} = 1$ and $\dim_{\mathbb{R}} \mathbb{R}^2 = 2$. Without the field, "the dimension of $\mathbb{C}$" is ambiguous.

Exercise 4.1.9. ROUTINE Find a basis and the dimension of $U = \{(a, b, a+b, a-b) \mid a, b \in F\} \subseteq F^4$.

Solution on page 1284

4.1.4 Lists of the right length

Once $\dim V$ is known, the length of a list already says a good deal about it. The lecture proves the next theorem with coordinates and the First and Third Fundamental Theorems. The exchange lemma gives a second proof.

Theorem 4.1.10 (Independent lists are short). Let V be finite-dimensional with $\dim V = n$, and let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a linearly independent list in V.

(a) $k \leq n$.

(b) If $k = n$, then $\mathcal{L}$ is a basis of V.

Proof (via coordinates and the Fundamental Theorems). ROUTINE

Uses. Proposition 1.6.20 (Coordinates translate questions about V into F^n), Corollary 3.5.16 (Lists of vectors in F^m), Definition 4.1.5 (Dimension)
Hint 1. Fix a basis $\mathcal{B}$ of V, of length n, and pass to the coordinate vectors $[\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_k]_{\mathcal{B}} \in F^n$. Are they independent?
Hint 2. Corollary 3.5.16 describes independent and spanning lists in F^n. Apply (a) of it, and for $k = n$ apply (c), then translate back with Proposition 1.6.20.
Sketch. With a basis $\mathcal{B}$ of length n, the coordinate vectors $[\mathbf{v}_i]_{\mathcal{B}}$ form an independent list of length k in F^n (Proposition 1.6.20(a)), so $k \leq n$ by Corollary 3.5.16(a). If $k = n$, they form a basis of F^n by Corollary 3.5.16(c), so $\mathcal{L}$ is a basis of V by Proposition 1.6.20(c).

Fix a basis $\mathcal{B}$ of V; it has length n (Definition 4.1.5). By Proposition 1.6.20(a), the list $[\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_k]_{\mathcal{B}}$ is linearly independent in F^n.

(a) By Corollary 3.5.16(a), applied to the $n \times k$ matrix with these columns, $k \leq n$.

(b) If $k = n$, then by Corollary 3.5.16(c) the independent list $[\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_n]_{\mathcal{B}}$ is a basis of F^n. By Proposition 1.6.20(c), $\mathcal{L}$ is a basis of V. □

Proof (via the exchange lemma). ROUTINE

Uses. Lemma 4.1.2 (Exchange lemma), Proposition 1.5.14 (Appending a vector), Proposition 1.6.2 (Bases are independent spanning lists), Definition 4.1.5 (Dimension)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. For (a), a basis of V is a spanning list of length n.
Hint 2. For (b), suppose $\mathcal{L}$ does not span V. Append a vector outside its span and count.
Sketch. (a) A basis of V spans and has length n, so $k \leq n$ by Lemma 4.1.2. (b) If an independent $\mathcal{L}$ of length n did not span, appending $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$ would give an independent list of length $n+1$ (Proposition 1.5.14), contradicting (a).

(a) A basis of V spans V and has length n, so $k \leq n$ by Lemma 4.1.2.

(b) Suppose $k = n$. If $\mathcal{L}$ did not span V, there would be some $\mathbf{w} \in V$ with $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, and $\mathcal{L}, \mathbf{w}$ would be an independent list of length $n+1$ by Proposition 1.5.14, contradicting (a). So $\mathcal{L}$ spans V, and being independent, it is a basis (Proposition 1.6.2). □

The contrapositive of (a) is used constantly: in an n-dimensional space, every list of more than n vectors is linearly dependent. For instance, any four vectors in $\mathbb{R}^3$ are dependent, which is what the span explorer of Section 1.5.3 showed for three vectors in $\mathbb{R}^2$. Spanning lists satisfy the mirror-image statements.

Corollary 4.1.11 (Spanning lists are long). Let V be finite-dimensional with $\dim V = n$, and let $\mathcal{S}$ be a list of length l that spans V.

(a) $l \geq n$.

(b) If $l = n$, then $\mathcal{S}$ is a basis of V.

Proof. ROUTINE

> *Uses.* Theorem 1.6.10 (Every spanning list contains a basis), Theorem 4.1.4 (All bases have the same length), Definition 4.1.5 (Dimension)
> *Hint 1.* Every spanning list contains a basis as a sublist (Theorem 1.6.10). How long is that basis?
> *Hint 2.* For (b), a sublist with as many entries as the whole list is the whole list.
> *Sketch.* $\mathcal{S}$ has a sublist that is a basis, of length n (Theorem 4.1.4), so $n \le l$. If $l = n$, that sublist has all l entries, so it is $\mathcal{S}$.

By Theorem 1.6.10, some sublist $\mathcal{S}'$ of $\mathcal{S}$ is a basis of V, and by Theorem 4.1.4 it has length n.

(a) A sublist is obtained by deleting entries, so $n = |\mathcal{S}'| \le l$.

(b) If $l = n$, then $\mathcal{S}'$ is obtained from $\mathcal{S}$ by deleting $l - n = 0$ entries, so $\mathcal{S}' = \mathcal{S}$, and $\mathcal{S}$ is a basis. □

Part (a) also follows from Lemma 4.1.2, applied to a basis of V and $\mathcal{S}$. Together, the two results say that for a list of length exactly $\dim V$, being independent, spanning, and being a basis are the same condition. So to check that a list of the right length is a basis, check whichever of the two properties is easier, and the other comes for free. In F^m this is Corollary 3.5.16(c), now available in every finite-dimensional space.

Example 4.1.12 (Two bases for the price of one property).

(a) Let $c \in F$ and $n \ge 0$. The polynomials $1, x-c, (x-c)^2, \ldots, (x-c)^n$ are nonzero with distinct degrees $0, 1, \ldots, n$, so they are independent (Proposition 1.5.24). There are $n+1 = \dim F[x]_{\le n}$ of them, so they form a basis of $F[x]_{\le n}$ by Theorem 4.1.10(b). We never had to show that every polynomial of degree at most n is a combination of powers of $x - c$. The coordinates of p in this basis are the coefficients of its expansion in powers of $x - c$, which over $\mathbb{R}$ are the Taylor coefficients at c; Exercise 1.6.18 computed them for $n = 2$ and $c = 1$.

(b) In $\mathbb{C}^{2\times 2}$, consider

$$I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad X = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad Z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

If $aI_2 + bX + cY + dZ = 0$, then

$$\begin{pmatrix} a+d & b-ic \\ b+ic & a-d \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Adding and subtracting the diagonal entries gives $2a = 2d = 0$, and the off-diagonal entries give $2b = 0$ and $2ic = 0$. So $a = b = c = d = 0$, the list is independent, and since $\dim \mathbb{C}^{2\times 2} = 4$ it is a basis. (These are the Pauli matrices of quantum mechanics.)

> *Intuition (Halving the work, and where the halving comes from).* For a list of length $\dim V$, independence and spanning are equivalent. In F^n this was the square case of the Fundamental Theorems: for a square matrix, "pivot in every column" and "pivot in every row" both say that there are n pivots. In general it is the exchange lemma: an independent list that did not span could be lengthened, and a spanning list that was dependent could be shortened, and either would produce a list whose length is on the wrong side of $\dim V$. The count only works when the length is *exactly* right. A list of length less than $\dim V$ is never spanning, one of length more is never independent, and these are the shape constraints of Corollary 3.5.16(a) and (b) in disguise.

Dimension also gives a convenient test for infinite dimension. It is the test promised after Proposition 1.6.25.

Corollary 4.1.13 (Detecting infinite dimension). A vector space V is infinite-dimensional if and only if for every $k \ge 0$ it contains a linearly independent list of length k.

Proof. ROUTINE

Uses. Theorem 4.1.10 (Independent lists are short), Proposition 1.5.14 (Appending a vector), Definition 1.6.23 (Finite-dimensional), Proposition 1.5.15 (Short lists, zeros, and repeats)
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. For (⇐), if V were finite-dimensional with $\dim V = n$, which length of independent list would be impossible?
Hint 2. For (⇒), build the lists by induction on k. If V is infinite-dimensional, can an independent list span it?
Sketch. (⇐) If $\dim V = n$, an independent list of length $n+1$ contradicts Theorem 4.1.10(a). (⇒) Induct on k, starting from $()$. An independent list $\mathcal{L}$ of length k does not span V, since no list does, so appending some $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$ gives an independent list of length $k+1$ (Proposition 1.5.14).

(⇐) We prove the contrapositive. If V is finite-dimensional, say $\dim V = n$, then by Theorem 4.1.10(a) there is no independent list of length $n+1$ in V.

(⇒) Suppose V is infinite-dimensional. We show by induction on k that V contains an independent list of length k. For $k = 0$ take $()$ (Proposition 1.5.15(a)). If $\mathcal{L}$ is independent of length k, then $\mathcal{L}$ does not span V, because no list spans V (Definition 1.6.23). So there is $\mathbf{w} \in V$ with $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, and $\mathcal{L}, \mathbf{w}$ is independent of length $k+1$ by Proposition 1.5.14. □

Example 4.1.14 (Function spaces are infinite-dimensional). Let $I \subseteq \mathbb{R}$ be an infinite set, for instance $\mathbb{R}$ or $[0,1]$. For each k, the functions $1, t, t^2, \ldots, t^k$ on I are linearly independent in $\mathbb{R}^I$: if $a_0 + a_1 t + \cdots + a_k t^k = 0$ for every $t \in I$, then the polynomial $a_0 + a_1 x + \cdots + a_k x^k$ has infinitely many roots, so it is the zero polynomial (Proposition 7.1.22), and all $a_i = 0$. By Corollary 4.1.13, $\mathbb{R}^I$ is infinite-dimensional. These functions are continuous, so the subspace $C[0,1]$ of $\mathbb{R}^{[0,1]}$ is infinite-dimensional as well.

Exercise 4.1.15. ROUTINE Show that $1 + x, (1+x)^2, x^2 + x^3, x^3$ is a basis of $F[x]_{\leq 3}$ for every field F.

Solution on page 1284

4.1.5 Extending to a basis

A spanning list can be thinned to a basis (Theorem 1.6.10). Remark 1.6.26 described the opposite process: grow an independent list by appending vectors outside its span. It warned that growing need not stop, as in $F[x]$. In a finite-dimensional space it does stop, because Theorem 4.1.10 caps the length of an independent list. This is the lecture's corollary, and the homework step of appending one vector (Proposition 1.5.14) is what drives it. We also record which vectors can be appended.

Theorem 4.1.16 (Extending to a basis). Let V be finite-dimensional with $\dim V = n$, and let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ be a linearly independent list in V. Then $\mathcal{L}$ extends to a basis of V: there are vectors $\mathbf{w}_1, \ldots, \mathbf{w}_{n-k} \in V$ such that

$$\mathbf{v}_1, \ldots, \mathbf{v}_k, \mathbf{w}_1, \ldots, \mathbf{w}_{n-k}$$

is a basis of V. Moreover, if $\mathcal{S}$ is any list that spans V, the $\mathbf{w}_j$ can be chosen among the entries of $\mathcal{S}$.

Proof. STANDARD

Uses. Theorem 4.1.10 (Independent lists are short), Proposition 1.5.14 (Appending a vector), Proposition 1.4.14 (The span is the smallest subspace containing a list), Theorem 4.1.4 (All bases have the same length), Definition 4.1.5 (Dimension)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. By Theorem 4.1.10, $k \leq n$, and if $k = n$ there is nothing to do. Induct on $n - k$.
Hint 2. If $k < n$, then $\mathcal{L}$ does not span V. Why must some entry of $\mathcal{S}$ lie outside $\operatorname{span}(\mathcal{L})$?
Hint 3. Append that entry. The new list is independent (Proposition 1.5.14) and one entry longer, so the inductive hypothesis applies to it.
Sketch. By Theorem 4.1.10, $k \leq n$; induct on $d = n - k$. If $d = 0$, $\mathcal{L}$ is already a basis. If $d > 0$, $\mathcal{L}$ is not a basis (wrong length), so it does not span. If every entry of $\mathcal{S}$ were in $\operatorname{span}(\mathcal{L})$, then $V = \operatorname{span}(\mathcal{S}) \subseteq \operatorname{span}(\mathcal{L})$; so some entry $\mathbf{s}$ of $\mathcal{S}$ is not. Then $\mathcal{L}, \mathbf{s}$ is independent of length $k+1$, and the inductive hypothesis extends it by entries of $\mathcal{S}$.

Fix a spanning list $\mathcal{S}$ of V; one exists because V is finite-dimensional. By Theorem 4.1.10(a), every independent list in V has length at most n. We prove by induction on $d \geq 0$ that every independent list of length $n -$

d extends to a basis of V by appending d entries of $\mathcal{S}$. Taking $\mathcal{S}$ to be any spanning list proves the theorem, including the "moreover".

Base case. If $d = 0$, then $\mathcal{L}$ is independent of length n, so it is a basis by Theorem 4.1.10(b), and we append nothing.

Inductive step. Let $d \geq 1$, assume the claim for $d-1$, and let $\mathcal{L}$ be independent of length $k = n - d < n$. Then $\mathcal{L}$ is not a basis of V, since every basis has length n (Theorem 4.1.4), so $\mathcal{L}$ does not span V. If every entry of $\mathcal{S}$ were in $\operatorname{span}(\mathcal{L})$, then, since $\operatorname{span}(\mathcal{L})$ is a subspace, $V = \operatorname{span}(\mathcal{S}) \subseteq \operatorname{span}(\mathcal{L})$ by Proposition 1.4.14(b), which is false. So some entry $\mathbf{s}$ of $\mathcal{S}$ lies outside $\operatorname{span}(\mathcal{L})$. By Proposition 1.5.14, $\mathcal{L}, \mathbf{s}$ is independent, of length $k+1 = n-(d-1)$. By the inductive hypothesis, it extends to a basis of V by appending $d-1$ entries of $\mathcal{S}$. Together with $\mathbf{s}$, these are d entries of $\mathcal{S}$ appended to $\mathcal{L}$, as desired. □

The lecture remarks that its argument "may be formalized as an induction on $d-k$", where its d is the dimension; our $d = n - k$ is that quantity. Unwound, the proof says: test the entries of $\mathcal{S}$ one at a time and append each one that is not in the span of the list built so far. The list stays independent, and the process stops because its length cannot exceed n. Finite dimension enters exactly there, in the cap on the length. In $F[x]$ there is no spanning list to draw from, and appending vectors outside the span can go on forever (Remark 1.6.26). In infinite dimensions, an extension to a basis in the sense of Aside (Bases of infinite-dimensional spaces) needs Zorn's lemma (Section 15.1).

Unwound in this way, the procedure is the sifting of Section 1.6.3 applied to the list $\mathcal{L}, \mathcal{S}$. Since $\mathcal{L}$ is independent, no entry of $\mathcal{L}$ lies in the span of the entries before it (Corollary 1.5.13), so sifting keeps all of $\mathcal{L}$, and it keeps exactly the entries of $\mathcal{S}$ not already accounted for. In F^n, with $\mathcal{S} = \mathbf{e}_1, \ldots, \mathbf{e}_n$, sifting is row reduction: by Corollary 3.3.19, the pivot columns of a matrix are exactly the columns that are not combinations of the columns before them.

Example 4.1.17 (Extending by row reduction). Extend $\mathbf{v}_1 = (1,1,0,0)$ and $\mathbf{v}_2 = (1,1,1,1)$ to a basis of $\mathbb{Q}^4$. Row reduce the matrix with columns $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4$:

$$\begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & -1 \\ 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & -1 \end{pmatrix}.$$

The pivot columns are $1, 2, 3, 5$. So $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_1, \mathbf{e}_3$ is a basis of $\mathbb{Q}^4$. The free columns explain the rejections: column 4 of the reduced matrix says $\mathbf{e}_2 = \mathbf{v}_1 - \mathbf{e}_1$, and column 6 says $\mathbf{e}_4 = -\mathbf{v}_1 + \mathbf{v}_2 - \mathbf{e}_3$ (Corollary 3.3.19(b)).

$$\begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & -1 \\ 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & -1 \end{pmatrix}$$

The reduction of Example 4.1.17. The first two columns are $\mathbf{v}_1, \mathbf{v}_2$ and the last four are $\mathbf{e}_1, \ldots, \mathbf{e}_4$. The pivot columns are the columns that survive sifting. Use "Edit" to put your own independent vectors in the first columns, or switch to $\mathbb{F}_p$; as long as those vectors are independent over the chosen field, they always end up as pivot columns. (Interactive in the web version.)

Extension is most useful when the independent list is a basis of a subspace. Then the extended basis is adapted to the subspace: its first vectors describe the subspace, and the remaining ones describe "the rest" of V, on which we are free to do as we like.

Technique 4.1.18 (Extend a basis of a subspace). To study a subspace U of a finite-dimensional space V, choose a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of U and extend it to a basis $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{w}_1, \dots, \mathbf{w}_r$ of V (Theorem 4.1.16). The new vectors are independent of U in a strong sense: a combination of them lies in U only if it is $\mathbf{0}$. Since a linear map may be prescribed freely on a basis (Theorem 2.2.1), the extension lets us define maps that do one thing on U and anything we like on the $\mathbf{w}_j$. Since the extended list is a basis, it also lets us count: $\dim V - \dim U$ is the number r of new vectors.

Reach for it when you need a linear map with prescribed behavior on a subspace, when you need to compare a subspace with the whole space, or when you want coordinates in which a subspace looks like the span of the first few standard basis vectors. The canonical example is Proposition 4.1.19. Later the same move proves rank–nullity (Section 4.2), produces complements and the dimension formula for sums (Section 4.4), and starts the proof of triangularization (Section 7.5).

Used in. Proposition 4.1.19, Theorem 4.2.11, Proposition 4.2.26, Proposition 4.4.16, Proposition 4.4.18, Theorem 4.4.19, Exercise 4.4.38, Exercise 4.4.42, Exercise 4.4.50, Corollary 4.5.22, Theorem 4.6.27, Problem 4.1, Problem 4.13, Problem 7.11, Proposition 8.4.19.

Proposition 4.1.19 (Extending linear maps and separating vectors). Let V be finite-dimensional, and let U be a subspace of V.

(a) For every vector space W and every linear map $S : U \to W$, there is a linear map $T : V \to W$ with $T(\mathbf{u}) = S(\mathbf{u})$ for all $\mathbf{u} \in U$.

(b) For every $\mathbf{v} \in V$ with $\mathbf{v} \notin U$, there is a linear map $f : V \to F$ with $f(\mathbf{u}) = 0$ for all $\mathbf{u} \in U$ and $f(\mathbf{v}) = 1$.

The proof uses that U has a basis. That every subspace of a finite-dimensional space is finite-dimensional is Proposition 4.1.21(a) below, whose proof does not use this proposition.

Proof. STANDARD

Uses. Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 1.5.14 (Appending a vector)
Techniques. Extend a basis of a subspace (Technique 4.1.18), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. Take a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of U and extend it to a basis of V. A linear map on V can be prescribed freely on this basis.
Hint 2. For (a), send $\mathbf{u}_i$ to $S(\mathbf{u}_i)$ and the new basis vectors to $\mathbf{0}$. Why do T and S then agree on all of U?
Hint 3. For (b), first extend $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}$, which is independent because $\mathbf{v} \notin U$.
Sketch. Take a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of U. (a) Extend it to a basis $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{w}_1, \dots, \mathbf{w}_r$ of V and let T send $\mathbf{u}_i \mapsto S(\mathbf{u}_i)$, $\mathbf{w}_j \mapsto \mathbf{0}$ (Theorem 2.2.1). Then $T(\sum c_i \mathbf{u}_i) = \sum c_i S(\mathbf{u}_i) = S(\sum c_i \mathbf{u}_i)$. (b) $\mathbf{v} \notin \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$, so $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}$ is independent; extend it to a basis and let f be 1 on $\mathbf{v}$ and 0 on every other basis vector.

By Proposition 4.1.21(a), U is finite-dimensional; let $\mathbf{u}_1, \dots, \mathbf{u}_k$ be a basis of U. It is an independent list in V.

(a) By Theorem 4.1.16 there are $\mathbf{w}_1, \dots, \mathbf{w}_r$ such that $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{w}_1, \dots, \mathbf{w}_r$ is a basis of V. By Theorem 2.2.1 there is a linear map $T : V \to W$ with $T(\mathbf{u}_i) = S(\mathbf{u}_i)$ for all i and $T(\mathbf{w}_j) = \mathbf{0}$ for all j. Let $\mathbf{u} \in U$, and write $\mathbf{u} = c_1\mathbf{u}_1 + \cdots + c_k\mathbf{u}_k$. Since T and S are both linear,

$$T(\mathbf{u}) = \sum_{i=1}^{k} c_i T(\mathbf{u}_i) = \sum_{i=1}^{k} c_i S(\mathbf{u}_i) = S(\mathbf{u}),$$

as desired.

(b) Since $U = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$ and $\mathbf{v} \notin U$, the list $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}$ is independent by Proposition 1.5.14. By Theorem 4.1.16 it extends to a basis $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}, \mathbf{w}_1, \dots, \mathbf{w}_r$ of V. By Theorem 2.2.1 there is a linear map f :

$V \to F$ with $f(\mathbf{v}) = 1$ and with value 0 on every other vector of this basis. For $\mathbf{u} = \sum_i c_i \mathbf{u}_i \in U$, linearity gives $f(\mathbf{u}) = \sum_i c_i f(\mathbf{u}_i) = 0$. □

Part (b) says that a vector outside a subspace can always be told apart from the subspace by a linear function. It is the starting point of duality (Section 13.1). Neither part is automatic in infinite dimensions without Zorn's lemma, which is needed even to extend a basis of U (Section 15.1).

Exercise 4.1.20. ROUTINE Extend $(1, 2, 1)$ to a basis of F^3 by appending standard basis vectors, (a) for $F = \mathbb{Q}$, and (b) for $F = \mathbb{F}_3$. Which standard basis vectors are appended?

Solution on page 1285

4.1.6 Dimensions of subspaces

Every subspace of F^3 ought to have dimension 0, 1, 2, or 3. Proving that a subspace U of a finite-dimensional space has dimension at most $\dim V$ looks like a direct application of Theorem 4.1.10, but there is a gap: the theorem applies to a basis of U, and we do not yet know that U has one. A basis of V is no help, since none of its vectors need lie in U. (In $\mathbb{R}^2$, the line $\operatorname{span}((1, 1))$ contains neither $\mathbf{e}_1$ nor $\mathbf{e}_2$.) The lecture closes the gap by growing an independent list inside U. The bound on independent lists in V forces the growth to stop, and it can only stop at a basis of U.

Proposition 4.1.21 (Dimensions of subspaces). Let V be finite-dimensional with $\dim V = n$, and let U be a subspace of V.

(a) U is finite-dimensional, and $\dim U \leq n$.

(b) $\dim U = n$ if and only if $U = V$.

Proof. STANDARD

Uses. Theorem 4.1.10 (Independent lists are short), Proposition 1.5.14 (Appending a vector), Proposition 1.6.2 (Bases are independent spanning lists), Proposition 1.4.14 (The span is the smallest subspace containing a list), Definition 1.4.1 (Subspace)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. An independent list in U is also an independent list in V, so it has length at most n. Choose an independent list in U that is as long as possible.
Hint 2. If that list did not span U, what could you append to it?
Hint 3. For (b), a basis of U of length n is an independent list of length n in V. Apply Theorem 4.1.10(b).
Sketch. Independent lists in U are independent in V, so they have length at most n. Take one, $\mathcal{L}$, of maximal length. If some $\mathbf{u} \in U$ were outside $\operatorname{span}(\mathcal{L})$, then $\mathcal{L}, \mathbf{u}$ would be a longer independent list in U. So $\mathcal{L}$ spans U and is a basis of U of length at most n. For (b), if $\dim U = n$, a basis of U is independent of length n in V, hence a basis of V, so $V = \operatorname{span}(\mathcal{L}) \subseteq U$.

A linear relation among vectors of U is computed with the operations of V (Definition 1.4.1), so a list in U is independent in U if and only if it is independent in V.

(a) By Theorem 4.1.10(a), every independent list in U has length at most n. The empty list is independent, so the lengths of the independent lists in U form a nonempty set of integers between 0 and n. Choose an independent list $\mathcal{L}$ in U whose length k is as large as possible. Suppose, to the contrary, that some $\mathbf{u} \in U$ is not in $\operatorname{span}(\mathcal{L})$. Then $\mathcal{L}, \mathbf{u}$ is an independent list in U (Proposition 1.5.14) of length $k + 1$, contradicting the choice of $\mathcal{L}$. So $\mathcal{L}$ spans U, and it is a basis of U (Proposition 1.6.2). Hence U is finite-dimensional, and $\dim U = k \leq n$.

(b) If $U = V$, then $\dim U = n$. Conversely, suppose $\dim U = n$, and let $\mathcal{L}$ be a basis of U. It is an independent list in V of length n, so it is a basis of V by Theorem 4.1.10(b). Since U is a subspace containing the entries of $\mathcal{L}$, Proposition 1.4.14 gives $V = \operatorname{span}(\mathcal{L}) \subseteq U$. Hence $U = V$. □

The lecture's proof is the same argument told as a process: grow an independent list in U, one vector at a time, and observe that the process cannot reach length $n+1$. Choosing a longest list in advance replaces the process by an extremal choice (Technique 1.5.9), and then there is no need to say "and so on".

Since every subspace is a vector space in its own right, (b) can be applied with W in place of V: if $U \subseteq W$ are subspaces of a finite-dimensional space and $\dim U = \dim W$, then $U = W$. This is how equality of subspaces is usually proved in practice. Show one containment, and compare dimensions. Equivalently, a proper subspace has strictly smaller dimension, so a subspace can be pinned down by squeezing its dimension between two bounds.

Example 4.1.22 (Squeezing a dimension). Let $U = \{A \in F^{2\times 2} \mid \operatorname{tr} A = 0\}$, the trace-zero matrices of Example 1.4.11. The matrices

$$U_{12}, \quad U_{21}, \quad U_{11} - U_{22}$$

lie in U and are independent, since $aU_{12} + bU_{21} + c(U_{11} - U_{22}) = \begin{pmatrix} c & a \\ b & -c \end{pmatrix}$ is 0 only if $a = b = c = 0$. So $\dim U \geq 3$, by Theorem 4.1.10(a) applied in U. On the other hand $U_{11} \notin U$, so $U \neq F^{2\times 2}$ and $\dim U < 4$ by Proposition 4.1.21(b). Hence $\dim U = 3$, and by Theorem 4.1.10(b) the three matrices form a basis of U. We never checked that they span. The same squeeze shows that the trace-zero matrices in $F^{n\times n}$ have dimension $n^2 - 1$ (Exercise 4.1.43).

Example 4.1.23 (The subspaces of F^3). Let U be a subspace of F^3. By Proposition 4.1.21, $\dim U \in \{0, 1, 2, 3\}$, and U has a basis of that length:

- $\dim U = 0$: $U = \{\mathbf{0}\}$;
- $\dim U = 1$: $U = \operatorname{span}(\mathbf{v})$ for some $\mathbf{v} \neq \mathbf{0}$, a line through $\mathbf{0}$;
- $\dim U = 2$: $U = \operatorname{span}(\mathbf{v}, \mathbf{w})$ for some independent $\mathbf{v}, \mathbf{w}$, a plane through $\mathbf{0}$;
- $\dim U = 3$: $U = F^3$, by Proposition 4.1.21(b).

Over $\mathbb{R}$ these are the subspaces of $\mathbb{R}^3$ that Section 1.4 anticipated: the origin, the lines and the planes through it, and $\mathbb{R}^3$. The proof of Theorem 1.4.25 for F^2 worked by cases on how many independent directions U contains. Dimension is that count, and it settles F^n for every n at once.

Exercise 4.1.24. ROUTINE Let $U = \{p \in \mathbb{R}[x]_{\leq 3} \mid p(2) = 0\}$. Find $\dim U$ and a basis of U, by a squeeze.

Solution on page 1285

4.1.7 Nilpotent chains

Some operators become 0 after finitely many applications. On F^4, the shift

$$N(x_1, x_2, x_3, x_4) = (x_2, x_3, x_4, 0)$$

moves every entry one place up and pushes a 0 in at the bottom, so $N^4 = 0$. Following one vector,

$$\mathbf{e}_4 \xrightarrow{N} \mathbf{e}_3 \xrightarrow{N} \mathbf{e}_2 \xrightarrow{N} \mathbf{e}_1 \xrightarrow{N} \mathbf{0},$$

so $N^3 \neq 0$ but $N^4 = 0$. Over $\mathbb{R}$, differentiation on $\mathbb{R}[x]_{\leq 3}$ behaves the same way:

$$x^3 \xrightarrow{D} 3x^2 \xrightarrow{D} 6x \xrightarrow{D} 6 \xrightarrow{D} \mathbf{0}.$$

An operator $T \in \mathrm{L}(V)$ with $T^m = 0$ for some $m \geq 1$ is called **nilpotent**; Chapter 10 studies these operators in depth (Section 10.1). In both examples the chain of images ends at $\mathbf{0}$ after exactly $\dim V$ steps, and the vectors in the chain form a basis. That is no accident. The vectors in such a chain are always independent, and the reason is a move worth naming.

Technique 4.1.25 (Apply an operator to a relation to kill terms). To show that $\mathbf{v}_1, \dots, \mathbf{v}_k$ is independent, take a relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ and apply a linear map L that sends all but a few of the $\mathbf{v}_i$ to $\mathbf{0}$. Since $L(\mathbf{0}) = \mathbf{0}$, the result is a shorter relation, ideally a single term $a_j L(\mathbf{v}_j) = \mathbf{0}$ with $L(\mathbf{v}_j) \neq \mathbf{0}$, which forces $a_j = 0$. Then repeat with another map, or on the shorter relation that remains.

Reach for it when the vectors come with an operator that acts on them in simple and distinguishable ways: a power of T along a chain $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \dots$; differentiation or a shift on exponentials and geometric sequences (Example 1.5.27, Exercise 1.5.44); evaluation at a point for functions that vanish at all but one point; a dot product with one of the vectors when they are mutually orthogonal (Exercise 1.5.46). The canonical example is Proposition 4.1.26. The same move shows that eigenvectors for distinct eigenvalues are independent (Section 7.2), and it organizes the Jordan chains of Section 10.3.

Used in. Example 1.5.27, Exercise 1.5.47, Proposition 4.1.26, Corollary 4.1.27, Exercise 4.1.45, Exercise 4.1.51, Exercise 4.1.60, Proposition 4.4.29, Proposition 4.6.28, Exercise 4.8.5, Exercise 4.8.8, Exercise 4.8.14, Problem 4.3, Problem 4.5, Problem 4.8, Theorem 7.2.21, Proposition 7.2.37, Exercise 7.2.51, Exercise 7.7.9, Problem 7.1, Problem 7.3, Problem 7.4, Problem 7.12, Problem 7.15, Exercise 4.5.50.

Proposition 4.1.26 (Nilpotent chains are independent). Let $T \in \mathrm{L}(V)$, let $\mathbf{v} \in V$, and let $k \geq 0$ be such that

$$T^k\mathbf{v} \neq \mathbf{0} \quad \text{and} \quad T^{k+1}\mathbf{v} = \mathbf{0}.$$

Then $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \dots, T^k\mathbf{v}$ is linearly independent.

Intuition. The chain $\mathbf{v} \mapsto T\mathbf{v} \mapsto \cdots \mapsto T^k\mathbf{v} \mapsto \mathbf{0}$ has a last nonzero vector. Applying T^k to the chain kills every vector except the first, which it sends to that last nonzero vector $T^k\mathbf{v}$. So applying T^k to a relation isolates the coefficient of $\mathbf{v}$. Once that coefficient is known to be 0, applying T^{k-1} isolates the next one, and so on down the chain.

Proof. STANDARD

Uses. Theorem 1.5.5 (Independence is decided at zero), Notation 2.1.18, Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Proposition 1.2.35 (Zero products)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Take a relation $a_0\mathbf{v} + a_1T\mathbf{v} + \cdots + a_kT^k\mathbf{v} = \mathbf{0}$ and apply T^k. Which terms survive?
Hint 2. $T^k(T^j\mathbf{v}) = T^{k+j}\mathbf{v}$, and this is $\mathbf{0}$ for $j \geq 1$, since $T^{k+j}\mathbf{v} = T^{j-1}(T^{k+1}\mathbf{v})$. So only $a_0T^k\mathbf{v}$ is left.
Hint 3. Prove $a_i = 0$ by induction on i: if $a_0 = \cdots = a_{i-1} = 0$, apply T^{k-i} to the relation.
Sketch. Let $\sum_{j=0}^{k} a_jT^j\mathbf{v} = \mathbf{0}$. Since $T^l\mathbf{v} = \mathbf{0}$ for all $l \geq k+1$, applying T^k leaves $a_0T^k\mathbf{v} = \mathbf{0}$, so $a_0 = 0$. If $a_0 = \cdots = a_{i-1} = 0$, applying T^{k-i} to $\sum_{j\geq i} a_jT^j\mathbf{v} = \mathbf{0}$ leaves $a_iT^k\mathbf{v} = \mathbf{0}$, so $a_i = 0$.

First, $T^l\mathbf{v} = \mathbf{0}$ for every $l \geq k+1$, because $T^l\mathbf{v} = T^{l-k-1}(T^{k+1}\mathbf{v}) = T^{l-k-1}(\mathbf{0}) = \mathbf{0}$ (Notation 2.1.18, Proposition 2.1.4). Suppose that

$$a_0\mathbf{v} + a_1T\mathbf{v} + \cdots + a_kT^k\mathbf{v} = \mathbf{0}. \tag{4.1.1}$$

We show by induction on $i \in \{0, 1, \dots, k\}$ that $a_i = 0$. Let i be given and assume that $a_j = 0$ for all $j < i$, which is no assumption when $i = 0$. Then (4.1.1) reads $\sum_{j=i}^{k} a_jT^j\mathbf{v} = \mathbf{0}$. Apply the linear map T^{k-i} to both sides:

$$\mathbf{0} = \sum_{j=i}^{k} a_jT^{k-i+j}\mathbf{v} = a_iT^k\mathbf{v} + \sum_{j=i+1}^{k} a_jT^{k+(j-i)}\mathbf{v} = a_iT^k\mathbf{v},$$

since every exponent $k + (j - i)$ in the last sum is at least $k + 1$. As $T^k\mathbf{v} \neq \mathbf{0}$, Proposition 1.2.35 gives $a_i = 0$. By induction all $a_i = 0$, so the list is independent by Theorem 1.5.5. □

apply	$a_0\mathbf{v}$	$a_1T\mathbf{v}$	$a_2T^2\mathbf{v}$	$a_3T^3\mathbf{v}$	gives
T^3	$a_0T^3\mathbf{v}$	$\mathbf{0}$	$\mathbf{0}$	$\mathbf{0}$	$a_0 = 0$
T^2	·	$a_1T^3\mathbf{v}$	$\mathbf{0}$	$\mathbf{0}$	$a_1 = 0$
T	·	·	$a_2T^3\mathbf{v}$	$\mathbf{0}$	$a_2 = 0$
id	·	·	·	$a_3T^3\mathbf{v}$	$a_3 = 0$

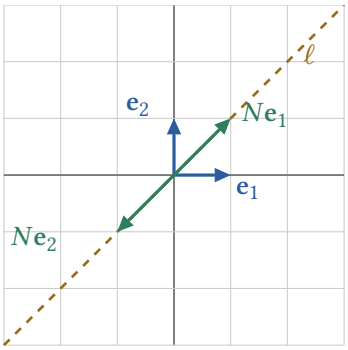
Table 4.1.1. The proof of Proposition 4.1.26 for $k = 3$. Each row applies a power of T to the relation $a_0\mathbf{v} + a_1T\mathbf{v} + a_2T^2\mathbf{v} + a_3T^3\mathbf{v} = \mathbf{0}$. Terms pushed past $T^3\mathbf{v}$ become $\mathbf{0}$; a dot marks a term whose coefficient is already known to be 0. Exactly one term survives in each row, and it is a multiple of $T^3\mathbf{v} \neq \mathbf{0}$.

The proposition did not assume that V is finite-dimensional. Combined with the bound on independent lists, it bounds how long an operator on a finite-dimensional space can take to reach 0. The striking part is that the bound depends only on $\dim V$: nothing about the particular operator enters.

Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps). Let V be finite-dimensional with $\dim V = n$, and let $T \in \mathrm{L}(V)$ with $T^m = 0$ for some $m \geq 1$. Then $T^n = 0$. Similarly, if $A \in F^{n\times n}$ and $A^m = 0$ for some $m \geq 1$, then $A^n = 0$.

Proof. STANDARD

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Theorem 2.4.2 (The matrix of a composite), Definition 2.3.15 (The linear map of a matrix)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Fix $\mathbf{v} \neq \mathbf{0}$. Since $T^m\mathbf{v} = \mathbf{0}$, there is a largest k with $T^k\mathbf{v} \neq \mathbf{0}$. What does Proposition 4.1.26 say about $\mathbf{v}, T\mathbf{v}, \ldots, T^k\mathbf{v}$?
Hint 2. That list has $k+1$ entries in an n-dimensional space, so $k+1 \leq n$. Now compute $T^n\mathbf{v}$.
Sketch. For $\mathbf{v} \neq \mathbf{0}$, let k be the largest integer with $T^k\mathbf{v} \neq \mathbf{0}$; it exists, and $k < m$, because $T^0\mathbf{v} = \mathbf{v} \neq \mathbf{0}$ and $T^m\mathbf{v} = \mathbf{0}$. By Proposition 4.1.26 the chain $\mathbf{v}, \ldots, T^k\mathbf{v}$ is independent, so $k+1 \leq n$. Hence $T^n\mathbf{v} = T^{n-k-1}\big(T^{k+1}\mathbf{v}\big) = \mathbf{0}$. For matrices, apply this to T_A.



Let $\mathbf{v} \in V$. If $\mathbf{v} = \mathbf{0}$, then $T^n\mathbf{v} = \mathbf{0}$. Suppose $\mathbf{v} \neq \mathbf{0}$. The set of integers $j \geq 0$ with $T^j\mathbf{v} \neq \mathbf{0}$ contains 0, as $T^0\mathbf{v} = \mathbf{v}$, and contains no $j \geq m$, as $T^j\mathbf{v} = T^{j-m}(T^m\mathbf{v}) = \mathbf{0}$ for those. Let k be its largest element. Then $T^k\mathbf{v} \neq \mathbf{0}$ and $T^{k+1}\mathbf{v} = \mathbf{0}$, so by Proposition 4.1.26 the list $\mathbf{v}, T\mathbf{v}, \ldots, T^k\mathbf{v}$ is independent. It has $k+1$ entries, so $k+1 \leq n$ by Theorem 4.1.10(a). Therefore

$$T^n\mathbf{v} = T^{n-k-1}\big(T^{k+1}\mathbf{v}\big) = T^{n-k-1}(\mathbf{0}) = \mathbf{0}.$$

This holds for every $\mathbf{v}$, so $T^n = 0$.

For $A \in F^{n\times n}$, the linear map $T_A : F^n \to F^n$ satisfies $(T_A)^j = T_{A^j}$ for all $j \geq 1$, by Theorem 2.4.2 and induction on j. So $(T_A)^m = T_{A^m} = 0$, and by the first part $T_{A^n} = (T_A)^n = 0$. The columns of A^n are the vectors $A^n\mathbf{e}_j = T_{A^n}(\mathbf{e}_j) = \mathbf{0}$, so $A^n = 0$. □

The exponent n cannot be lowered in general: the shift N on F^4 above has $N^3 \neq 0$. And the corollary rules out operators that take longer. For instance, there is no $A \in \mathbb{R}^{3\times3}$ with $A^3 \neq 0$ but $A^4 = 0$, however cleverly its entries are chosen. In the plane, the corollary says that a nilpotent 2×2 matrix satisfies $A^2 = 0$.

The map of $N = \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix}$ (called A in the interactive version) flattens the plane onto the line ℓ through $(1,1)$, and it sends ℓ itself to $\mathbf{0}$, since $N(1,1) = \mathbf{0}$. So $N^2 = 0$. For any $\mathbf{v}$ off ℓ, such as $\mathbf{e}_1$, the chain $\mathbf{v}, N\mathbf{v}$ ends at $\mathbf{0}$; by Proposition 4.1.26 it is independent, and having length $2 = \dim \mathbb{R}^2$, it is a basis (Theorem 4.1.10(b)). In the interactive version, move the columns: a nonzero 2×2 matrix is nilpotent exactly when it flattens the plane onto a line and sends that line to $\mathbf{0}$. (Interactive in the web version.)

Over a field in which some integer is 0, the derivative dies much sooner than in characteristic 0, sooner than $\dim V$ steps.

Example 4.1.28 (Differentiation over $\mathbb{F}_p$). Let p be a prime and let D be the formal derivative on $\mathbb{F}_p[x]$ (Example 2.1.9). Then $D^p\big(x^j\big) = j(j-1)\cdots(j-p+1)x^{j-p}$ for $j \geq p$, and the product of the p consecutive integers $j, j-1, \ldots, j-p+1$ is divisible by p, so it is 0 in $\mathbb{F}_p$. For $j < p$, $D^p\big(x^j\big) = 0$ already. So $D^p = 0$ on all of $\mathbb{F}_p[x]$, an infinite-dimensional space.

For $p = 2$, on $\mathbb{F}_2[x]_{\leq 3}$ the chains are

$$x^3 \xrightarrow{D} x^2 \xrightarrow{D} \mathbf{0}, \quad x \xrightarrow{D} 1 \xrightarrow{D} \mathbf{0},$$

since $D\big(x^3\big) = 3x^2 = x^2$ and $D\big(x^2\big) = 2x = 0$. Here $D^2 = 0$ although $\dim \mathbb{F}_2[x]_{\leq 3} = 4$. The basis $x^3, x^2, x, 1$ splits into two chains of length 2 instead of one chain of length 4. How a nilpotent operator splits a space into chains is the subject of Section 10.3.

Exercise 4.1.29. ROUTINE For which n is there a matrix $A \in F^{n\times n}$ with $A^4 \neq 0$ and $A^5 = 0$? For each such n, give one.

Solution on page 1285

4.1.8 Too many vectors

Theorem 4.1.10 also works in the other direction. To prove that some linear relation exists, without being able to write one down, it is enough to produce more vectors than the dimension of a space that contains them.

Technique 4.1.30 (Too many vectors force a dependence). If a list of more than n vectors lies in a space of dimension at most n, it is linearly dependent (Theorem 4.1.10(a)), so it has a nontrivial linear relation. The relation is the output: it is a statement about the vectors that we did not have to guess. Natural sources of many vectors in a space of known dimension are powers $I, A, A^2, \ldots$ of a matrix, iterates $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ of a vector, and powers $1, \alpha, \alpha^2, \ldots$ of a number inside a space spanned by a few known quantities. Often the relation is then refined, for instance by choosing one with the smallest index of a nonzero coefficient (Technique 1.5.9).

Reach for it when you need an identity or an equation of a given shape and have no formula for it, but can count. The canonical example is Proposition 4.1.31. The iterates $\mathbf{v}, T\mathbf{v}, \ldots, T^n\mathbf{v}$ give eigenvalues

without determinants in Section 7.3; the powers of T lead to the minimal polynomial (Section 7.6); and the powers of a number lead to algebraic numbers (Section 14.2).
Used in. Exercise 2.5.49, Proposition 4.1.31, Exercise 4.1.33, Exercise 4.1.56, Exercise 4.1.57, Exercise 4.1.60, Exercise 4.8.4, Exercise 4.8.9, Problem 4.15, Proposition 7.2.35, Theorem 7.3.27, Proposition 7.6.4.

Proposition 4.1.31 (Every square matrix satisfies a polynomial).

(a) Let $A \in F^{n\times n}$ with $n \geq 1$. There are $c_0, c_1, \ldots, c_{n^2} \in F$, not all 0, with

$$c_0 I_n + c_1 A + c_2 A^2 + \cdots + c_{n^2} A^{n^2} = 0.$$

(b) Let V be finite-dimensional with $\dim V = n \geq 1$, and let $T \in \mathrm{L}(V)$. There are $c_0, \ldots, c_{n^2} \in F$, not all 0, with $c_0 \mathrm{id}_V + c_1 T + \cdots + c_{n^2} T^{n^2} = 0$.

Proof. ROUTINE

Uses. Example 4.1.7 (Dimensions of the standard spaces), Theorem 4.1.10 (Independent lists are short), Theorem 1.5.5 (Independence is decided at zero), Notation 2.4.16 (Powers of a matrix), Theorem 2.3.20 (Linear maps correspond to matrices)
Techniques. Too many vectors force a dependence (Technique 4.1.30), Translate between maps and matrices (Technique 2.3.27)
Hint 1. Count the matrices $I_n, A, A^2, \ldots, A^{n^2}$, and recall $\dim F^{n\times n}$.
Hint 2. For (b), apply (a) to $A = [T]_{\mathcal{B}\mathcal{B}}$ for a basis $\mathcal{B}$ of V, and use $\left[T^j\right]_{\mathcal{B}\mathcal{B}} = A^j$ (Notation 2.4.16).
Sketch. The list $I_n, A, \ldots, A^{n^2}$ has n^2+1 entries in $F^{n\times n}$, which has dimension n^2, so it is dependent, and a nontrivial relation is the claim. For (b), take the relation for $A = [T]_{\mathcal{B}\mathcal{B}}$; by Notation 2.4.16 it says $\left[\sum c_j T^j\right]_{\mathcal{B}\mathcal{B}} = 0 = [0]_{\mathcal{B}\mathcal{B}}$, and a map is determined by its matrix.

(a) The list $I_n, A, A^2, \ldots, A^{n^2}$ has n^2+1 entries, and it lies in $F^{n\times n}$, which has dimension n^2 (Example 4.1.7). By Theorem 4.1.10(a) it is linearly dependent, so by Theorem 1.5.5 it has a nontrivial linear relation. That relation is the claim.

(b) Fix a basis $\mathcal{B}$ of V and let $A = [T]_{\mathcal{B}\mathcal{B}} \in F^{n\times n}$. Take $c_0, \ldots, c_{n^2}$, not all 0, as in (a). By Notation 2.4.16,

$$\left[c_0 \mathrm{id}_V + c_1 T + \cdots + c_{n^2} T^{n^2}\right]_{\mathcal{B}\mathcal{B}} = c_0 I_n + c_1 A + \cdots + c_{n^2} A^{n^2} = 0 = [0]_{\mathcal{B}\mathcal{B}}.$$

By Theorem 2.3.20, a linear map $V \to V$ is determined by its matrix with respect to $\mathcal{B}$, so $c_0 \mathrm{id}_V + c_1 T + \cdots + c_{n^2} T^{n^2} = 0$. □

In the language of polynomials, A is a root of the nonzero polynomial $c_0 + c_1 x + \cdots + c_{n^2} x^{n^2}$. Evaluating polynomials at matrices and operators is made formal in Section 7.1 and Section 7.2, and Section 7.6 studies the polynomial of smallest degree that A satisfies. The bound n^2 is far from the truth: the Cayley–Hamilton theorem (Theorem 7.6.20) gives a nonzero polynomial of degree n. For now, the point is that the existence of *some* polynomial costs nothing beyond counting.

Example 4.1.32 ($\sqrt{2}+\sqrt{3}$ is a root of a rational polynomial). Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$ (Example 1.2.20), and let $\alpha = \sqrt{2}+\sqrt{3}$. Expanding,

$$\alpha^2 = 5 + 2\sqrt{6}, \quad \alpha^3 = 11\sqrt{2} + 9\sqrt{3}, \quad \alpha^4 = 49 + 20\sqrt{6}.$$

So $1, \alpha, \alpha^2, \alpha^3, \alpha^4$ all lie in $W = \mathrm{span}_{\mathbb{Q}}\left(1, \sqrt{2}, \sqrt{3}, \sqrt{6}\right)$, which has dimension at most 4 by Corollary 4.1.11(a). Five vectors in a space of dimension at most 4 are dependent: there are rationals $c_0, \ldots, c_4$, not all 0, with $c_0 + c_1\alpha + \cdots + c_4\alpha^4 = 0$. Before computing anything, we know that α is a root of a nonzero polynomial with rational coefficients and degree at most 4.

To find one, note that the even powers lie in $\mathrm{span}_{\mathbb{Q}}\left(1, \sqrt{6}\right)$, and look for $\alpha^4 + a\alpha^2 + b = 0$:

$$49 + 20\sqrt{6} + a\left(5 + 2\sqrt{6}\right) + b = (49 + 5a + b) + (20 + 2a)\sqrt{6}.$$

Taking $a = -10$ and $b = 1$ makes both brackets 0, so $\alpha^4 - 10\alpha^2 + 1 = 0$. Making the brackets 0 is sufficient whether or not $1, \sqrt{6}$ is independent over $\mathbb{Q}$. (It is: $a' + b'\sqrt{6} = 0$ with $b' \neq 0$ would make $\sqrt{6}$ rational.)

Exercise 4.1.33. ROUTINE Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. By Proposition 4.1.31, $I_2, A, \ldots, A^4$ satisfy a nontrivial relation. Find a nontrivial relation among I_2, A, A^2 alone, and use it to compute A^{10}.

Solution on page 1286

4.1.9 Dimension over a finite field

Over a finite field, dimension counts elements. In Exercise 1.5.43 and Exercise 1.6.38 we counted spans and bases in F^n by hand; with dimension available, the counts hold in every finite-dimensional space and come with a short proof.

Proposition 4.1.34 (Size of a vector space over a finite field). Let F be a finite field with q elements, and let V be a vector space over F. Then V is finite-dimensional if and only if V is a finite set, and in that case

$$|V| = q^{\dim V}.$$

Proof. ROUTINE

Uses. Proposition 1.6.16 (The coordinate map is a bijection), Definition 1.6.23 (Finite-dimensional), Definition 1.2.4 (The space F^n), Definition 4.1.5 (Dimension)
Hint 1. If V is a finite set, find a spanning list directly.
Hint 2. If $\dim V = n$, the coordinate map of a basis is a bijection $V \to F^n$. How many elements does F^n have?
Sketch. A finite V is spanned by the list of all its elements. Conversely, a basis of length $n = \dim V$ gives a bijection $V \to F^n$ (Proposition 1.6.16), and F^n has q^n elements, one for each choice of n entries.

If V is finite, the list of all elements of V spans V, so V is finite-dimensional. Conversely, suppose $\dim V = n$, and let $\mathcal{B}$ be a basis of V. By Proposition 1.6.16, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ is a bijection $V \to F^n$. An element of F^n is a list of n entries, each chosen from q elements, so $|F^n| = q^n$. Hence V is finite and $|V| = q^n$. □

So every subspace of $\mathbb{F}_p^n$ has a power of p as its number of elements, and a subspace with p^k elements has dimension k. For instance, no subspace of $\mathbb{F}_3^5$ has 30 elements, and a subspace of $\mathbb{F}_2^7$ with 16 elements is 4-dimensional.

Corollary 4.1.35 (Counting independent lists and bases). Let F be a finite field with q elements, and let V be a vector space over F with $\dim V = n$. For $0 \leq k \leq n$, the number of linearly independent lists of length k in V is

$$N_q(n,k) = (q^n - 1)(q^n - q)\left(q^n - q^2\right)\cdots\left(q^n - q^{k-1}\right).$$

In particular V has exactly $N_q(n,n)$ bases.

Proof. STANDARD

Uses. Proposition 4.1.34 (Size of a vector space over a finite field), Proposition 1.5.14 (Appending a vector), Corollary 1.5.17 (Sublists), Proposition 1.6.2 (Bases are independent spanning lists), Theorem 4.1.10 (Independent lists are short), Theorem 4.1.4 (All bases have the same length)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. An independent list of length $k+1$ is an independent list $\mathcal{L}$ of length k followed by a vector outside $\operatorname{span}(\mathcal{L})$. How many vectors does $\operatorname{span}(\mathcal{L})$ have?
Hint 2. $\mathcal{L}$ is a basis of $\operatorname{span}(\mathcal{L})$, so $|\operatorname{span}(\mathcal{L})| = q^k$ by Proposition 4.1.34. Induct on k. For bases, use Theorem 4.1.10(b).
Sketch. By Corollary 1.5.17 and Proposition 1.5.14, the independent lists of length $k+1$ are the lists $\mathcal{L}, \mathbf{w}$ with $\mathcal{L}$ independent of length k and $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$. Since $\mathcal{L}$ is a basis of $\operatorname{span}(\mathcal{L})$, that span has q^k elements, leaving $q^n - q^k$ choices of $\mathbf{w}$. Induction on k gives the product. The bases are exactly the independent lists of length n.

Let I_k be the number of independent lists of length k in V. We show $I_k = N_q(n,k)$ by induction on k. For $k = 0$, the only list of length 0 is (), which is independent, and $N_q(n,0) = 1$ is the empty product.

Let $0 \le k < n$. A list $\mathcal{L}, \mathbf{w}$ of length $k+1$ is independent if and only if $\mathcal{L}$ is independent and $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$: if it is independent, so is its sublist $\mathcal{L}$ (Corollary 1.5.17), and then $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$ by Proposition 1.5.14; the converse is Proposition 1.5.14. For an independent $\mathcal{L}$ of length k, the subspace $\operatorname{span}(\mathcal{L})$ has $\mathcal{L}$ as a basis (Proposition 1.6.2), so it has dimension k and q^k elements by Proposition 4.1.34. That leaves $q^n - q^k$ choices of $\mathbf{w}$ for each of the I_k choices of $\mathcal{L}$. So

$$I_{k+1} = I_k\left(q^n - q^k\right) = N_q(n,k)\left(q^n - q^k\right) = N_q(n,k+1).$$

Every basis of V has length n (Theorem 4.1.4) and is independent, and every independent list of length n is a basis (Theorem 4.1.10(b)). So the bases of V are the independent lists of length n, and there are $N_q(n,n)$ of them. □

By Theorem 3.5.14, a matrix in $F^{n\times n}$ is invertible if and only if its columns form a basis of F^n, and the columns determine the matrix. So there are exactly $N_q(n,n)$ invertible $n \times n$ matrices over a field with q elements. Over $\mathbb{F}_2$ this gives $3 \cdot 2 = 6$ invertible 2×2 matrices and $7 \cdot 6 \cdot 4 = 168$ invertible 3×3 matrices.

Counting subspaces BEYOND 21-242

Counting subspaces over finite fields is standard combinatorics, but it is not part of 21-242.

How many k-dimensional subspaces does $\mathbb{F}_2^3$ have? Each such subspace has many bases, and each independent list spans exactly one subspace. Counting the pairs (subspace, basis) in two ways answers the question, and the move is worth a name.

Technique 4.1.36 (Double counting). To count a set X that is hard to list, find a second set P of pairs (x,y) with $x \in X$ that is easy to count in another way. If every $x \in X$ occurs in the same number d of pairs, then $|P| = |X| \cdot d$, and $|X| = |P|/d$. Its cousin, the pigeonhole principle, compares two sets through a one-to-one assignment: the proof by exchange of Lemma 4.1.2 assigns to each $\mathbf{u}$ a different $\mathbf{w}$, which is why $m \le n$.

Reach for it when the objects to be counted are hard to enumerate but each one is described by many easy-to-count objects, such as subspaces by their bases. The canonical example is Proposition 4.1.37. Counting over finite fields returns in Section 14.3.

Used in. Proposition 4.1.37, Exercise 4.1.54, Exercise 4.4.52, Exercise 4.7.63, Problem 4.10, Problem 4.14, Exercise 7.3.52.

Proposition 4.1.37 (Counting subspaces). Let F be a finite field with q elements, let $\dim V = n$, and let $0 \le k \le n$. With N_q as in Corollary 4.1.35, the number of k-dimensional subspaces of V is

$$N_q \frac{n,k}{N_q}(k,k) = \frac{(q^n-1)(q^n-q)\cdots\left(q^n-q^{k-1}\right)}{\left(q^k-1\right)\left(q^k-q\right)\cdots\left(q^k-q^{k-1}\right)}.$$

Proof. STANDARD

Uses. Corollary 4.1.35 (Counting independent lists and bases), Theorem 1.6.10 (Every spanning list contains a basis), Definition 4.1.5 (Dimension)
Techniques. Double counting (Technique 4.1.36)
Hint 1. Count the pairs $(U, \mathcal{L})$, where U is a k-dimensional subspace of V and $\mathcal{L}$ is a basis of U.
Hint 2. Counted by U first: each U has $N_q(k,k)$ bases. Counted by $\mathcal{L}$ first: which lists $\mathcal{L}$ occur, and in how many pairs?
Sketch. Let P be the set of pairs $(U, \mathcal{L})$ with $\dim U = k$ and $\mathcal{L}$ a basis of U. Each k-dimensional U has $N_q(k,k)$ bases (Corollary 4.1.35 applied to U), so $|P| = s \cdot N_q(k,k)$, where s is the number of subspaces. Each independent list $\mathcal{L}$ of length k in V occurs in exactly one pair, with $U = \operatorname{span}(\mathcal{L})$, so $|P| = N_q(n,k)$.

Let s be the number of k-dimensional subspaces of V, and let P be the set of pairs $(U, \mathcal{L})$ in which U is a k-dimensional subspace of V and $\mathcal{L}$ is a basis of U. We count P in two ways.

By subspaces. A k-dimensional subspace U is a vector space over F of dimension k, so by Corollary 4.1.35 it has $N_q(k,k)$ bases. Hence $|P| = s \cdot N_q(k,k)$.

By lists. If $(U, \mathcal{L}) \in P$, then $\mathcal{L}$ is an independent list of length k in V, and $U = \operatorname{span}(\mathcal{L})$ is determined by $\mathcal{L}$. Conversely, every independent list $\mathcal{L}$ of length k in V is a basis of the subspace $\operatorname{span}(\mathcal{L})$ (Theorem 1.6.10), which then has dimension k, so $(\operatorname{span}(\mathcal{L}), \mathcal{L}) \in P$. So the pairs in P correspond to the independent lists of length k in V, and $|P| = N_q(n,k)$ by Corollary 4.1.35.

Comparing, $s \cdot N_q(k,k) = N_q(n,k)$. Since $N_q(k,k) \geq 1$ (a k-dimensional space has a basis), we may divide.□

Example 4.1.38 (The subspaces of $\mathbb{F}_2^3$). For $q = 2$ and $n = 3$: the number of 1-dimensional subspaces is $N_2(3,1)/N_2(1,1) = 7/1 = 7$, one for each nonzero vector, since a line over $\mathbb{F}_2$ is $\{\mathbf{0}, \mathbf{v}\}$. The number of 2-dimensional subspaces is

$$N_2 \frac{3,2}{N_2}(2,2) = \frac{7 \cdot 6}{3 \cdot 2} = 7.$$

Each plane has $2^2 = 4$ elements and contains 3 of the 7 lines. Taking the 7 lines as points and the 7 planes as lines, with "lies in" as incidence, gives the Fano plane of combinatorics.

Exercise 4.1.39. ROUTINE (a) Can a vector space over $\mathbb{F}_5$ have exactly 100 elements? (b) How many elements does a 3-dimensional subspace of $\mathbb{F}_5^7$ have? (c) How many bases does $\mathbb{F}_3^2$ have?

Solution on page 1286

Exercises

Exercise 4.1.40. ROUTINE Find a basis and the dimension of each subspace.

(a) $U_1 = \{\mathbf{x} \in F^4 \mid x_1 + x_2 + x_3 + x_4 = 0\}$.

(b) $U_2 = \{p \in F[x]_{\leq 3} \mid p(0) = p(1) = 0\}$.

(c) U_3, the upper triangular matrices in $F^{3\times 3}$, those with $a_{ij} = 0$ whenever $i > j$.

Solution on page 1286

Exercise 4.1.41. ROUTINE Let V be a vector space with $\dim V = 4$. Prove or disprove each statement.

(a) Every list of 5 vectors in V spans V.

(b) Every list of 3 vectors in V is linearly independent.

(c) If $\mathbf{v}_1, \ldots, \mathbf{v}_4$ spans V, then it is linearly independent.

(d) If U and W are subspaces of V with $\dim U = \dim W$, then $U = W$.

(e) If $U \subseteq W$ are subspaces of V with $\dim U = \dim W$, then $U = W$.

(f) $\mathbb{R}^2$ is a 2-dimensional subspace of $\mathbb{R}^3$.

Solution on page 1286

Exercise 4.1.42. ROUTINE Let $\mathbf{v}_1 = (0,0,1,2)$ and $\mathbf{v}_2 = (1,0,2,1)$. Extend $\mathbf{v}_1, \mathbf{v}_2$ to a basis of F^4 by sifting the list $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4$, first for $F = \mathbb{Q}$ and then for $F = \mathbb{F}_3$. Explain why the answers differ.

Solution on page 1287

Exercise 4.1.43. ROUTINE Let $n \geq 1$. Show that the trace-zero matrices $U = \{A \in F^{n\times n} \mid \operatorname{tr} A = 0\}$ form a subspace of dimension $n^2 - 1$, and find a basis of U.

Solution on page 1287

Exercise 4.1.44. ROUTINE Let $A \in F^{n\times n}$ with $A^m = 0$ for some $m \geq 1$. Show that $I_n - A$ is invertible with inverse $I_n + A + A^2 + \cdots + A^{n-1}$, however large m is.

Solution on page 1288

Exercise 4.1.45. ROUTINE Let X be a set, and for $x \in X$ let $\delta_x \in F^X$ be the function with $\delta_x(x) = 1$ and $\delta_x(y) = 0$ for $y \neq x$.

(a) If $X = \{x_1, \ldots, x_n\}$ has n elements, show that $\delta_{x_1}, \ldots, \delta_{x_n}$ is a basis of F^X, so $\dim F^X = n$.

(b) If X is infinite, show that F^X is infinite-dimensional.

Solution on page 1288

Exercise 4.1.46. STANDARD Let $n \geq 1$. In $F^{n\times n}$, let S be the symmetric matrices ($a_{ij} = a_{ji}$ for all i, j) and K the skew-symmetric matrices ($a_{ij} = -a_{ji}$ for all i, j), as in Exercise 1.4.36.

(a) Show that $\dim S = n(n+1)/2$.

(b) Show that $\dim K = n(n-1)/2$ if $1 + 1 \neq 0$ in F, and $\dim K = n(n+1)/2$ if $1 + 1 = 0$.

Solution on page 1288

Exercise 4.1.47. STANDARD A matrix $A \in \mathbb{C}^{n\times n}$ is **Hermitian** if $a_{ji} = \overline{a_{ij}}$ for all i, j, where $\overline{z}$ is the complex conjugate of z (Definition B.1.1). Let H be the set of Hermitian matrices.

(a) Show that H is a subspace of $\mathbb{C}^{n\times n}$ regarded as a vector space over $\mathbb{R}$, but not a subspace of $\mathbb{C}^{n\times n}$ over $\mathbb{C}$.

(b) Show that $\dim_{\mathbb{R}} H = n^2$, while $\dim_{\mathbb{R}} \mathbb{C}^{n\times n} = 2n^2$.

Solution on page 1289

Exercise 4.1.48. STANDARD Find the error in the following argument, and decide whether the claim is true.

Claim. Let $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V, and let U be a subspace of V. Then the entries of $\mathcal{B}$ that lie in U form a basis of U.

Proof. Let $\mathcal{B}'$ be the sublist of entries of $\mathcal{B}$ that lie in U. It is independent, as a sublist of an independent list. Let $\mathbf{u} \in U$, and write $\mathbf{u} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. Since $\mathbf{u} \in U$ and U is a subspace, each term $a_i\mathbf{v}_i$ lies in U. So $a_i = 0$ whenever $\mathbf{v}_i \notin U$, and $\mathbf{u} \in \operatorname{span}(\mathcal{B}')$. Hence $\mathcal{B}'$ spans U.

Solution on page 1290

Exercise 4.1.49. STANDARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be linearly independent in V, with $m \geq 1$, and let $\mathbf{w} \in V$.

(a) Show that $\mathbf{v}_1 - \mathbf{w}, \ldots, \mathbf{v}_m - \mathbf{w}$ is linearly dependent if and only if $\mathbf{w} = t_1\mathbf{v}_1 + \cdots + t_m\mathbf{v}_m$ for some scalars with $t_1 + \cdots + t_m = 1$.

(b) Show that $\dim \operatorname{span}(\mathbf{v}_1 - \mathbf{w}, \ldots, \mathbf{v}_m - \mathbf{w}) \geq m - 1$ in all cases.

Solution on page 1290

Exercise 4.1.50. STANDARD Let $\dim V = n$.

(a) Show that if $U_0 \subsetneq U_1 \subsetneq \cdots \subsetneq U_k$ are subspaces of V, then $k \leq n$.

(b) Show that such a chain with $k = n$ exists, and that in every such chain $\dim U_i = i$ for all i. In particular $U_0 = \{\mathbf{0}\}$ and $U_n = V$.

Solution on page 1290

Exercise 4.1.51. STANDARD Let $n \geq 0$ and let F be a field in which $n! = 1 \cdot 2 \cdots n$ is nonzero, such as $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, or $\mathbb{F}_p$ with $p > n$. Let D be the formal derivative on $F[x]$ (Example 2.1.9).

(a) Let $p \in F[x]$ have degree n. Show that $p, Dp, D^2p, \ldots, D^np$ is a basis of $F[x]_{\leq n}$.

(b) Show that (a) fails for $F = \mathbb{F}_2$, $n = 2$, and $p = x^2$.

Solution on page 1291

Exercise 4.1.52. STANDARD Let $\dim V = n \geq 1$, and let $T \in \mathrm{L}(V)$ satisfy $T^{n-1} \neq 0$ and $T^n = 0$.

(a) Show that there is $\mathbf{v} \in V$ such that $\mathbf{v}, T\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is a basis of V.

(b) Find the matrix of T with respect to the basis $\mathcal{B} = T^{n-1}\mathbf{v}, \ldots, T\mathbf{v}, \mathbf{v}$.

Solution on page 1291

Exercise 4.1.53. STANDARD

(a) What fraction of the matrices in $\mathbb{F}_2^{3\times 3}$ are invertible?

(b) Show that for every $n \geq 1$, more than a quarter of the matrices in $\mathbb{F}_2^{n\times n}$ are invertible.

Solution on page 1292

Exercise 4.1.54. STANDARD BEYOND 21-242

(a) For $0 \leq k \leq 4$, find the number of k-dimensional subspaces of $\mathbb{F}_2^4$.

(b) Let F have q elements and $\dim V = n$. Show that V has as many k-dimensional subspaces as $(n-k)$-dimensional ones.

Solution on page 1292

Exercise 4.1.55. HARD Let $\dim V = n \geq 1$, and let $N \in \mathrm{L}(V)$ satisfy $N^{n-1} \neq 0$ and $N^n = 0$. Show that $S \in \mathrm{L}(V)$ commutes with N, that is, $SN = NS$, if and only if

$$S = c_0\mathrm{id}_V + c_1N + \cdots + c_{n-1}N^{n-1}$$

for some $c_0, \ldots, c_{n-1} \in F$.

Solution on page 1293

Exercise 4.1.56. HARD Let V be finite-dimensional, and let $T \in \mathrm{L}(V)$ be injective.

(a) Show that T is invertible, and that $T^{-1} = b_0\mathrm{id}_V + b_1T + \cdots + b_dT^d$ for some $d \geq 0$ and scalars $b_0, \ldots, b_d$.

(b) Let $M \in \mathrm{L}(F[x])$ be multiplication by x (Example 2.1.9). Show that M is injective but not surjective. Which step of (a) fails for M?

Solution on page 1293

Exercise 4.1.57. HARD Let $A_1, \ldots, A_{n+1}$ be nonempty subsets of $\{1, \ldots, n\}$. Show that there are disjoint nonempty sets $I, J \subseteq \{1, \ldots, n+1\}$ with

$$\bigcup_{i\in I} A_i = \bigcup_{j\in J} A_j.$$

Solution on page 1294

Exercise 4.1.58. HARD Show that for every field F and every $n \geq 1$, the space $F^{n\times n}$ has a basis consisting of invertible matrices. Write one down for $\mathbb{F}_2^{2\times 2}$.

Solution on page 1294

Exercise 4.1.59. HARD Let $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ and $\mathcal{C} = \mathbf{c}_1, \ldots, \mathbf{c}_n$ be bases of V, and fix i. Show that there is an index j such that both of the following are bases of V:

(a) $\mathcal{B}$ with $\mathbf{b}_i$ replaced by $\mathbf{c}_j$;

(b) $\mathcal{C}$ with $\mathbf{c}_j$ replaced by $\mathbf{b}_i$.

Solution on page 1295

Exercise 4.1.60. CHALLENGE Let F be a field of characteristic 0 (Definition 1.1.28), such as $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, and let $A, B \in F^{n\times n}$ satisfy $AB - BA = A$. Show that $A^n = 0$.

Solution on page 1295

4.2 Rank–nullity

A linear map $T : V \to W$ collapses $\ker T$ to $\mathbf{0}$ and reaches $\operatorname{im} T$. In Section 2.6 we measured the two separately; with dimension available we can compare them. The answer is the rank–nullity theorem: if V is finite-dimensional, then

$$\dim \ker T + \dim \operatorname{im} T = \dim V.$$

Informally, each of the $\dim V$ independent directions in V is either collapsed by T or carried over to W. For a matrix, the statement is that every column is either a pivot column or a free column.

We follow the lecture's route. Restricting a map to a subspace (Section 4.2.1) lets us compute $\dim \operatorname{im} T_A = \operatorname{rank} A$ (Section 4.2.3), and counting free columns then proves rank–nullity for matrices. A second proof, which extends a basis of $\ker T$, works directly for every linear map (Section 4.2.4). The rest of the section draws consequences. Among them are the fact that the rank of a matrix of a linear map does not depend on the bases, which closes a question left open in Section 3.5, and dimension counting, a way to prove that vectors with some property exist without finding them. We end with an application outside the course, error-correcting codes over $\mathbb{F}_2$.

Throughout, V and W are vector spaces over a field F.

4.2.1 Restriction

Restricting a function keeps its rule and shrinks its set of inputs. We have already written $\operatorname{im}(T\restriction_X)$ for the set of values of T on a subset X (Proposition 2.1.16, Proposition 2.6.15). Here is the definition behind the notation.

Definition 4.2.1 (Restriction). Let $g : X \to Y$ be a function and let $A \subseteq X$. The **restriction** of g to A is the function

$$g\restriction_A : A \to Y, \quad a \mapsto g(a).$$

Only the domain changes. The target is still Y, even when every value of $g{\restriction}_A$ happens to lie in some smaller set. The image of the restriction,

$$\operatorname{im}(g{\restriction}_A) = \{g(a) \mid a \in A\},$$

is the set of values of g on A, which Section 2.1.4 wrote as $T(A)$; from now on we always write $\operatorname{im}(g{\restriction}_A)$. (For any function $g : X \to Y$, $\operatorname{im} g = \{g(x) \mid x \in X\}$, as for linear maps.)

Example 4.2.2 (What restriction can change).

(a) Let $P : \mathbb{R}^2 \to \mathbb{R}^2$, $P(x, y) = (x, 0)$, be the projection onto the x-axis, and let $\ell = \operatorname{span}((1, 1))$. Then $P{\restriction}_\ell : \ell \to \mathbb{R}^2$ sends $(t, t) \mapsto (t, 0)$. It is injective, although P is not, and its image is the x-axis, all of $\operatorname{im} P$. Restricted to the y-axis instead, P becomes the zero map.

(b) Let $Q : \mathbb{R}^2 \to \mathbb{R}$, $Q(x, y) = x + y$. It is surjective. Its restriction to the x-axis is still surjective (and now injective as well), but its restriction to the line $y = -x$ is the zero map, which is not surjective.

The lecture records the general behavior.

Proposition 4.2.3 (Properties of restriction).

(a) If $g : X \to Y$ is injective, then $g{\restriction}_A$ is injective for every $A \subseteq X$.

(b) If $f : X \to Y$ and $g : Y \to Z$ are functions, then $\operatorname{im}(g \circ f) = \operatorname{im}\left(g{\restriction}_{\operatorname{im} f}\right)$.

(c) If $T \in \mathrm{L}(V, W)$ and U is a subspace of V, then $T{\restriction}_U \in \mathrm{L}(U, W)$ and $\ker(T{\restriction}_U) = U \cap \ker T$. In particular, $T{\restriction}_U$ is injective if and only if $U \cap \ker T = \{\mathbf{0}\}$.

Proof. ROUTINE

Uses. Definition 4.2.1 (Restriction), Definition 1.4.1 (Subspace), Definition 2.1.1 (Linear map), Definition 2.6.5 (Kernel), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Each part is an unwinding of definitions. For (b), write out both sides as sets of values.
Hint 2. For (c), the operations of U are those of V, so the linearity identities for $T{\restriction}_U$ are instances of those for T. Which $\mathbf{u} \in U$ does $T{\restriction}_U$ send to $\mathbf{0}$?
Sketch. (a) $g(a) = g(a')$ forces $a = a'$ already in X. (b) Both sides are $\{g(f(x)) \mid x \in X\}$. (c) Linearity is inherited, since U is closed under the operations; the kernel is the set of $\mathbf{u} \in U$ with $T(\mathbf{u}) = \mathbf{0}$, which is $U \cap \ker T$; apply Theorem 2.6.11.

(a) If $a, a' \in A$ and $g{\restriction}_A(a) = g{\restriction}_A(a')$, then $g(a) = g(a')$, so $a = a'$ because g is injective.

(b) By definition,

$$\operatorname{im}(g \circ f) = \{g(f(x)) \mid x \in X\} = \{g(y) \mid y \in \operatorname{im} f\} = \operatorname{im}\left(g{\restriction}_{\operatorname{im} f}\right).$$

For linear maps this is Proposition 2.6.15(b), whose proof did not use linearity.

(c) By Definition 1.4.1, U is a vector space with the operations of V. For $\mathbf{u}, \mathbf{u}' \in U$ and $a \in F$, the vectors $\mathbf{u} + \mathbf{u}'$ and $a\mathbf{u}$ lie in U, and

$$T{\restriction}_U(\mathbf{u} + \mathbf{u}') = T(\mathbf{u}) + T(\mathbf{u}'), \quad T{\restriction}_U(a\mathbf{u}) = aT(\mathbf{u})$$

because T is linear. So $T{\restriction}_U$ is linear (Definition 2.1.1). Its kernel is $\{\mathbf{u} \in U \mid T(\mathbf{u}) = \mathbf{0}\} = U \cap \ker T$. The last statement is Theorem 2.6.11 applied to $T{\restriction}_U$. □

Part (a) and Example 4.2.2(b) are the lecture's remarks that restriction preserves injectivity but not surjectivity. Shrinking the domain removes inputs, which can remove coincidences of values but can also remove values. Part (b) says that the composite $g \circ f$ uses g only on the part of Y that f reaches.

Exercise 4.2.4. ROUTINE Let $D : \mathbb{R}[x]_{\leq 3} \to \mathbb{R}[x]_{\leq 3}$ be differentiation.

(a) Let $U = \operatorname{span}(x^2, x^3)$. Find $\ker(D|_U)$ and $\operatorname{im}(D|_U)$.

(b) Let $U' = \operatorname{span}(1, x)$. Find $\ker(D|_{U'})$ and $\operatorname{im}(D|_{U'})$.

(c) Find a subspace U'' such that $D|_{U''}$ is injective and $\operatorname{im}(D|_{U''}) = \operatorname{im} D$.

Solution on page 1296

Restriction is a small idea that we will use constantly, so we name it.

Technique 4.2.5 (Restrict to a subspace). To study a linear map on part of its domain, restrict it. For a subspace U of V, the map $T|_U : U \to W$ is linear, its kernel is $U \cap \ker T$, and its image is the set of values of T on U (Proposition 4.2.3). Everything known about linear maps then applies to $T|_U$, which is often better behaved than T: it can be injective when T is not, and its domain is smaller. The most common entry point is the identity $\operatorname{im}(TS) = \operatorname{im}(T|_{\operatorname{im} S})$, which says that the composite TS sees T only on the subspace $\operatorname{im} S$.

Reach for it when a composite is involved, when a hypothesis concerns only part of V (an image, a kernel, a subspace that T maps into itself), or when T is injective on a subspace you care about. The canonical example is the proof of Theorem 4.2.7, which restricts $T_{G^{-1}}$ to $\operatorname{im} T_{A_r}$. Later the same move bounds the rank of a product (Section 4.3) and turns an operator into a smaller operator on an invariant subspace (Section 7.2).

Used in. Proposition 4.2.6, Theorem 4.2.7, Proposition 4.2.15, Proposition 4.2.26, Exercise 4.2.44, Exercise 4.2.52, Exercise 4.2.53, Proposition 4.3.1, Theorem 4.3.3, Proposition 4.3.5, Proposition 4.6.29, Exercise 4.8.7, Exercise 4.8.10, Exercise 4.8.11, Problem 4.2, Problem 4.18, Corollary 6.6.22, Proposition 7.6.10, Proposition 7.6.12, Theorem 7.6.31, Notation 8.3.10, Exercise 4.6.52.

4.2.2 Injective maps preserve dimension

An injective linear map loses nothing, so it should not lower dimension. The lecture proves this by pushing a basis forward, which we already did in Proposition 2.6.22.

Proposition 4.2.6 (Injective maps preserve dimension). Let $T \in \mathrm{L}(V, W)$.

(a) If V is finite-dimensional and T is injective, then $\operatorname{im} T$ is finite-dimensional and $\dim \operatorname{im} T = \dim V$. More precisely, for every basis $\mathcal{B}$ of V, the list $T(\mathcal{B})$ is a basis of $\operatorname{im} T$.

(b) If U is a finite-dimensional subspace of V with $U \cap \ker T = \{\mathbf{0}\}$, then $\dim \operatorname{im}(T|_U) = \dim U$.

Proof. ROUTINE

Uses. Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Proposition 4.2.3 (Properties of restriction), Definition 4.1.5 (Dimension)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. Take a basis $\mathcal{B}$ of V. What does Proposition 2.6.22(d) say about $T(\mathcal{B})$?
Hint 2. For (b), find an injective map to which (a) applies.
Sketch. (a) For injective T, the list $T(\mathcal{B})$ spans $\operatorname{im} T$ and is independent (Proposition 2.6.22(d)), so it is a basis of $\operatorname{im} T$ with $\dim V$ entries. (b) $T|_U$ is injective by Proposition 4.2.3(c); apply (a) to it.

(a) Let $\mathcal{B}$ be a basis of V, of length $\dim V$. By Proposition 2.6.22(d), $T(\mathcal{B})$ spans $\operatorname{im} T$, and it is a basis of $\operatorname{im} T$ because T is injective. So $\operatorname{im} T$ is finite-dimensional, and $\dim \operatorname{im} T$ is the length of $T(\mathcal{B})$, which is $\dim V$.

(b) By Proposition 4.2.3(c), $T|_U \in \mathrm{L}(U, W)$ is injective. Applying (a) to it gives $\dim \operatorname{im}(T|_U) = \dim U$. □

Without injectivity, $T(\mathcal{B})$ still spans $\operatorname{im} T$, so $\operatorname{im} T$ is finite-dimensional with $\dim \operatorname{im} T \leq \dim V$ (Corollary 4.1.11(a)), and equality holds only if the spanning list $T(\mathcal{B})$ is a basis, that is, only if T is injective.

4.2.3 The image of a matrix

We now compute $\dim \operatorname{im} T_A$. The lecture's strategy has three steps:

- write $A = G^{-1}A_r$, where $A_r = \operatorname{rref}(A)$ and G is invertible;
- show that the pivot columns of A_r form a basis of $\operatorname{im} T_{A_r}$, which is easy because they are standard basis vectors;
- slide this basis along G^{-1}, which is injective, to get a basis of $\operatorname{im} T_A$.

The last step lands on the pivot columns of A itself, because G^{-1} times a column of A_r is the corresponding column of A.

Theorem 4.2.7 (The image of T_A). Let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$, let $k = \operatorname{rank} A$, and let $p_1 < \cdots < p_k$ be the pivot columns of A. Then $\mathbf{a}_{p_1}, \dots, \mathbf{a}_{p_k}$ is a basis of $\operatorname{im} T_A$. In particular,

$$\dim \operatorname{im} T_A = \operatorname{rank} A.$$

Proof (through the reduced form, by restriction). STANDARD

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Proposition 3.3.8 (Properties of the output), Proposition 2.6.18 (The column space is spanned by the columns), Corollary 1.3.19 (Equal spans), Theorem 2.4.2 (The matrix of a composite), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 4.2.3 (Properties of restriction), Proposition 4.2.6 (Injective maps preserve dimension), Definition 2.4.1 (Matrix product)
Techniques. Restrict to a subspace (Technique 4.2.5), Reduce to RREF (Technique 3.3.22)
Hint 1. First solve the problem for A_r. Which columns of A_r are pivot columns, and in which rows can the other columns have nonzero entries?
Hint 2. Write $A = G^{-1}A_r$, so $T_A = T_{G^{-1}} \circ T_{A_r}$. By Proposition 4.2.3(b), $\operatorname{im} T_A$ is the image of $T_{G^{-1}}$ restricted to $\operatorname{im} T_{A_r}$.
Hint 3. $T_{G^{-1}}$ is injective, so it carries a basis of $\operatorname{im} T_{A_r}$ to a basis of $\operatorname{im} T_A$. Compute $G^{-1}\mathbf{e}_s$ column by column from $A = G^{-1}A_r$.
Sketch. The pivot columns of A_r are $\mathbf{e}_1, \dots, \mathbf{e}_k$, and every column of A_r vanishes below row k, so $\mathbf{e}_1, \dots, \mathbf{e}_k$ is a basis of $\operatorname{im} T_{A_r}$. With $GA = A_r$, $T_A = T_{G^{-1}}T_{A_r}$, so $\operatorname{im} T_A = \operatorname{im}\left(T_{G^{-1}}|_{\operatorname{im} T_{A_r}}\right)$. The injective map $T_{G^{-1}}$ sends the basis $\mathbf{e}_1, \dots, \mathbf{e}_k$ to a basis of $\operatorname{im} T_A$, and $G^{-1}\mathbf{e}_s = G^{-1}$ (column p_s of A_r) $= \mathbf{a}_{p_s}$.

Let $G \in F^{m\times m}$ be invertible with $GA = A_r$ (Theorem 3.3.10), so that $A = G^{-1}A_r$.

The reduced matrix. By Lemma 3.3.16(b), the pivot columns of A_r are $\mathbf{e}_1, \dots, \mathbf{e}_k \in F^m$, which are linearly independent. By Proposition 3.3.8, rows $k+1, \dots, m$ of A_r are zero, so every column of A_r lies in $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_k)$. Since $\mathbf{e}_1, \dots, \mathbf{e}_k$ are themselves columns of A_r, Corollary 1.3.19 and Proposition 2.6.18 give

$$\operatorname{im} T_{A_r} = \operatorname{span}(\text{columns of } A_r) = \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_k),$$

and $\mathbf{e}_1, \dots, \mathbf{e}_k$ is a basis of $\operatorname{im} T_{A_r}$.

Sliding by G^{-1}. By Theorem 2.4.2, $T_A = T_{G^{-1}A_r} = T_{G^{-1}} \circ T_{A_r}$, so Proposition 4.2.3(b) gives

$$\operatorname{im} T_A = \operatorname{im}\left(T_{G^{-1}}|_{\operatorname{im} T_{A_r}}\right).$$

The map $T_{G^{-1}}$ is injective, because T_G is a left inverse of it: $T_G \circ T_{G^{-1}} = T_{GG^{-1}} = T_{I_m} = \mathrm{id}$ (Proposition 2.5.4). Its restriction to $\operatorname{im} T_{A_r}$ is injective as well (Proposition 4.2.3(a)), so by Proposition 4.2.6(a) it sends the basis $\mathbf{e}_1, \dots, \mathbf{e}_k$ of $\operatorname{im} T_{A_r}$ to a basis $G^{-1}\mathbf{e}_1, \dots, G^{-1}\mathbf{e}_k$ of $\operatorname{im} T_A$. Finally, column p_s of $A = G^{-1}A_r$ is G^{-1} times column p_s of A_r (Definition 2.4.1), that is,

$$\mathbf{a}_{p_s} = G^{-1}\mathbf{e}_s \quad (s = 1, \dots, k).$$

So $\mathbf{a}_{p_1}, \dots, \mathbf{a}_{p_k}$ is a basis of $\operatorname{im} T_A$, and $\dim \operatorname{im} T_A = k = \operatorname{rank} A$. □

The second proof skips G and uses the description of pivot columns from Section 3.3.4, which never mentions the algorithm.

Proof (by sifting the columns). ROUTINE

Uses. Corollary 3.3.19 (Pivot columns, intrinsically), Corollary 1.5.13 (Independence, one entry at a time), Corollary 1.3.19 (Equal spans), Proposition 2.6.18 (The column space is spanned by the columns), Proposition 1.6.2 (Bases are independent spanning lists)

Hint 1. Corollary 3.3.19 describes the pivot columns of A directly. Which of its two parts gives independence, and which gives spanning?
Hint 2. Independence: $\mathbf{a}_{p_s}$ is not a combination of $\mathbf{a}_1, \dots, \mathbf{a}_{p_s-1}$, so in particular not of the earlier pivot columns. Use Corollary 1.5.13.
Hint 3. Spanning: every free column is a combination of pivot columns (Corollary 3.3.19(b)).
Sketch. By Corollary 3.3.19(a), $\mathbf{a}_{p_s} \notin \operatorname{span}\left(\mathbf{a}_1, \dots, \mathbf{a}_{p_s-1}\right) \supseteq \operatorname{span}\left(\mathbf{a}_{p_1}, \dots, \mathbf{a}_{p_{s-1}}\right)$, so the pivot columns are independent by Corollary 1.5.13. By (b), every free column lies in their span, so their span contains all the columns and equals $\operatorname{im} T_A$.

Let $\mathcal{P} = \mathbf{a}_{p_1}, \dots, \mathbf{a}_{p_k}$.

Independent. Let $1 \leq s \leq k$. By Corollary 3.3.19(a), $\mathbf{a}_{p_s}$ is not a linear combination of $\mathbf{a}_1, \dots, \mathbf{a}_{p_s-1}$. Since $p_1, \dots, p_{s-1} < p_s$, it is in particular not a combination of $\mathbf{a}_{p_1}, \dots, \mathbf{a}_{p_{s-1}}$. By Corollary 1.5.13, $\mathcal{P}$ is linearly independent.

Spanning. Each pivot column is an entry of $\mathcal{P}$, and by Corollary 3.3.19(b) each free column is a linear combination of pivot columns. So every column of A lies in $\operatorname{span}(\mathcal{P})$, and every entry of $\mathcal{P}$ is a column of A. By Corollary 1.3.19 and Proposition 2.6.18, $\operatorname{span}(\mathcal{P}) = \operatorname{span}(\mathbf{a}_1, \dots, \mathbf{a}_n) = \operatorname{im} T_A$.

So $\mathcal{P}$ is a basis of $\operatorname{im} T_A$ (Proposition 1.6.2), of length $k = \operatorname{rank} A$. □

The first proof does the easy case A_r and transports the answer along an injective map. The second is the sifting procedure of Section 1.6.3 applied to the columns of A: scanning left to right and keeping each column that is not a combination of the earlier ones keeps exactly the pivot columns. Both rest on one fact, that row operations do not change the linear relations among the columns (Corollary 3.2.17). The first proof uses it through G; the second uses it through Corollary 3.3.19, which was proved from it.

The theorem names columns of A, not of A_r, and the distinction matters.

Non-example 4.2.8 (The columns of A_r are the wrong vectors). Let $A = \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$, so $A_r = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$. Then $\operatorname{im} T_{A_r} = \operatorname{span}(\mathbf{e}_1)$, while $\operatorname{im} T_A = \operatorname{span}((1,2))$, a different line. The pivot column $\mathbf{e}_1$ of A_r does not even lie in $\operatorname{im} T_A$. Row operations change the column space. What they preserve is the linear relations among the columns, so A_r tells us *which* columns to take, and we must then take them from A.

For the kernel, the free columns do the same job. Theorem 3.4.9 writes every vector of $\ker T_A$ as a combination of the basic solutions, one for each free column, and Remark 3.4.11 observed that they form a basis. So the reduced form gives bases of both subspaces at once.

Example 4.2.9 (Bases for the kernel and the image). Let

$$A = \begin{pmatrix} 1 & 2 & 0 & 3 & 1 \\ 2 & 4 & 1 & 8 & 1 \\ -1 & -2 & 2 & 1 & -3 \end{pmatrix} \in \mathbb{Q}^{3\times 5}, \quad A_r = \begin{pmatrix} 1 & 2 & 0 & 3 & 1 \\ 0 & 0 & 1 & 2 & -1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

The pivot columns are $1, 3$ and the free columns are $2, 4, 5$, so $\operatorname{rank} A = 2$.

Image. By Theorem 4.2.7, columns 1 and 3 of A form a basis of $\operatorname{im} T_A$:

$$\operatorname{im} T_A = \operatorname{span}((1,2,-1),(0,1,2)),$$

a plane in $\mathbb{Q}^3$. (It does not contain the pivot column $\mathbf{e}_1$ of A_r: $a(1,2,-1) + b(0,1,2) = (1,0,0)$ forces $a = 1$, then $b = -2$, and then the third entry is -5.)

Kernel. Copying the free columns of A_r into Definition 3.4.8, the basic solutions are

$$\mathbf{s}_1 = \begin{pmatrix} -2 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad \mathbf{s}_2 = \begin{pmatrix} -3 \\ 0 \\ -2 \\ 1 \\ 0 \end{pmatrix}, \quad \mathbf{s}_3 = \begin{pmatrix} -1 \\ 0 \\ 1 \\ 0 \\ 1 \end{pmatrix},$$

and they form a basis of $\ker T_A$. Each one records how a free column is built from pivot columns: $A\mathbf{s}_2 = \mathbf{0}$ says $\mathbf{a}_4 = 3\mathbf{a}_1 + 2\mathbf{a}_3$, and $A\mathbf{s}_3 = \mathbf{0}$ says $\mathbf{a}_5 = \mathbf{a}_1 - \mathbf{a}_3$.

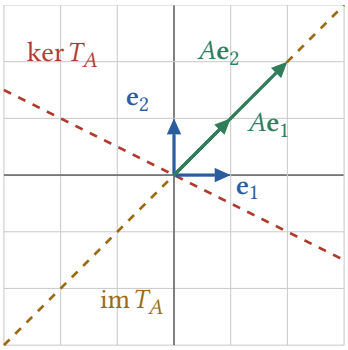
So $\dim \operatorname{im} T_A = 2$ and $\dim \ker T_A = 3$, one for each pivot column and one for each free column, and $2 + 3 = 5$ is the number of columns.

$$\begin{pmatrix} 1 & 2 & 0 & 3 & 1 \\ 2 & 4 & 1 & 8 & 1 \\ -1 & -2 & 2 & 1 & -3 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & 3 & 1 \\ 0 & 0 & 1 & 2 & -1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

The reduction of Example 4.2.9. At the end the summary lists the pivot columns, whose columns *in* A form a basis of $\operatorname{im} T_A$, and the free columns, which index the basic solutions, a basis of $\ker T_A$. Use "Edit" to try your own matrix: the number of pivot columns plus the number of free columns is always the number of columns. (Interactive in the web version.)

Exercise 4.2.10. ROUTINE Let $A = \begin{pmatrix} 1 & -1 & 2 & 0 \\ 2 & -2 & 5 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix} \in \mathbb{Q}^{3\times 4}$.

(a) Find a basis of $\operatorname{im} T_A$ consisting of columns of A, and a basis of $\ker T_A$.



(b) Is $(1, 0, 0)$ in $\operatorname{im} T_A$?

Solution on page 1297

4.2.4 Rank–nullity

Intuition (Lost plus reached). Take $A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix}$. Both columns lie on the line $y = x$, so T_A flattens the plane onto that line: $\operatorname{im} T_A = \operatorname{span}((1, 1))$, of dimension 1. The vectors it sends to $\mathbf{0}$ are those with $x + 2y = 0$, so $\ker T_A = \operatorname{span}((2, -1))$, also of dimension 1. One dimension of $\mathbb{R}^2$ is lost and the other survives, and $1 + 1 = 2$.

There is more to see. Any line ℓ through $\mathbf{0}$ other than $\ker T_A$ meets the kernel only in $\mathbf{0}$, so $T_A|_\ell$ is injective, and it maps ℓ onto the image line. So the plane consists of the directions T_A kills, together with a line that T_A carries faithfully onto $\operatorname{im} T_A$. In general, V is made of $\ker T$ together with further directions on which T is injective; those are carried to independent directions that fill out $\operatorname{im} T$, and counting gives $\dim V = \dim \ker T + \dim \operatorname{im} T$. For a matrix the two kinds of direction have names: free variables and pivot variables.

The map of $A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix}$ squashes the whole plane onto its image, the line $y = x$, and sends its kernel, the line $x + 2y = 0$, to $\mathbf{0}$. In the interactive version, drag the columns Ae_1 and Ae_2. While they are independent the image is the whole plane and the kernel is $\{\mathbf{0}\}$; when they line up, the image drops to a line and a line of kernel appears (and if both are $\mathbf{0}$, the image is $\{\mathbf{0}\}$ and the kernel is the plane), so the two dimensions always add up to 2. (Interactive in the web version.)

Theorem 4.2.11 (Rank–nullity).
(a) Let $A \in F^{m\times n}$. Then

$$\dim \ker T_A + \operatorname{rank} A = n.$$

(b) Let V be finite-dimensional and let $T \in \mathrm{L}(V, W)$. Then $\operatorname{im} T$ is finite-dimensional, and

$$\dim \ker T + \dim \operatorname{im} T = \dim V.$$

In (a), n is the number of columns, the dimension of the domain F^n; the number of rows plays no role. In (b), only V is assumed finite-dimensional, and W may be any vector space. The first proof is the lecture's: it counts pivots for matrices and transfers the count to arbitrary maps with coordinates.

Proof (by counting pivots). STANDARD

Uses. Proposition 3.5.2 (First properties of rank), Remark 3.4.11 (A basis of the kernel), Theorem 4.2.7 (The image of T_A), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Definition 1.6.23 (Finite-dimensional), Proposition 2.6.20 (Kernel and image in coordinates), Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 1.6.16 (The coordinate map is a bijection), Proposition 4.2.3 (Properties of restriction), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Reduce to RREF (Technique 3.3.22), Translate between maps and matrices (Technique 2.3.27)
Hint 1. For (a): the free columns index a basis of $\ker T_A$, and the pivot columns of A form a basis of $\operatorname{im} T_A$. How many of each are there?
Hint 2. For (b), choose bases and pass to a matrix of T. A matrix needs a finite-dimensional target. Why may you replace W by $\operatorname{im} T$, and why is $\operatorname{im} T$ finite-dimensional?
Hint 3. The coordinate maps are injective and linear, and by Proposition 2.6.20 they carry $\ker T$ onto $\ker T_A$ and $\operatorname{im} T$ onto $\operatorname{im} T_A$. What do injective linear maps do to dimension?
Sketch. (a) The $n - \operatorname{rank} A$ basic solutions form a basis of $\ker T_A$ (Remark 3.4.11), and $\dim \operatorname{im} T_A = \operatorname{rank} A$ (Theorem 4.2.7). (b) $\operatorname{im} T$ is spanned by $T(\mathcal{B})$ for a basis $\mathcal{B}$ of V, so it is finite-dimensional, say of dimension r. The cases $\dim V = 0$ and $r = 0$ are immediate. Otherwise regard T as a surjective map $T' : V \to \operatorname{im} T$ and let $A = [T']_{\mathcal{C}\mathcal{B}} \in F^{r\times n}$. Then T_A is surjective, so $\operatorname{rank} A = r$, and the coordinate map restricted to $\ker T$ is an injective linear map onto $\ker T_A$, so $\dim \ker T = \dim \ker T_A = n - r$ by (a).

(a) Let $k = \operatorname{rank} A$. By Proposition 3.5.2(b), A has exactly $n - k$ free columns, and by Remark 3.4.11 the basic solutions, one for each free column, form a basis of $\ker T_A$. So $\dim \ker T_A = n - k$, and $\dim \ker T_A + \operatorname{rank} A = (n - k) + k = n$. (By Theorem 4.2.7, the k here is also $\dim \operatorname{im} T_A$: the pivot columns count the image, and the free columns count the kernel.)

(b) Let $n = \dim V$ and let $\mathcal{B}$ be a basis of V. By Proposition 2.1.16(a), $T(\mathcal{B})$ spans $\operatorname{im} T$, so $\operatorname{im} T$ is finite-dimensional (Definition 1.6.23). Let $r = \dim \operatorname{im} T$. If $n = 0$, then $V = \{\mathbf{0}\}$ and both sides are 0; if $r = 0$, then $T = 0$ and $\ker T = V$. So assume $n, r \geq 1$, and let $\mathcal{C}$ be a basis of $\operatorname{im} T$. The function

$$T' : V \to \operatorname{im} T, \quad T'(\mathbf{v}) = T(\mathbf{v}),$$

is T with its target shrunk to $\operatorname{im} T$. It is linear, it is surjective, and $\ker T' = \ker T$. Let $A = [T']_{\mathcal{C}\mathcal{B}} \in F^{r \times n}$.

Since T' is surjective, so is T_A, by Proposition 2.6.20(c). So $\operatorname{im} T_A = F^r$ and $\operatorname{rank} A = r$ by Theorem 4.2.7. By the same proposition, the coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ sends $\ker T'$ onto $\ker T_A$. That map is linear and injective (Proposition 1.6.19, Proposition 1.6.16), so its restriction to the subspace $\ker T$ is an injective linear map with image $\ker T_A$ (Proposition 4.2.3). Since $\ker T$ is finite-dimensional (Proposition 4.1.21(a)), Proposition 4.2.6(a) gives $\dim \ker T = \dim \ker T_A$. By (a), $\dim \ker T_A = n - r$. Hence

$$\dim \ker T + \dim \operatorname{im} T = (n - r) + r = n = \dim V. \qquad \square$$

The second proof is the one in LADR. It never chooses coordinates, and it explains the formula rather than verifying it: it finds the directions of the intuition above inside V.

Proof (by extending a basis of the kernel). STANDARD

> *Uses.* Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.6.2 (Bases are independent spanning lists), Definition 2.6.5 (Kernel), Theorem 4.2.7 (The image of T_A)
> *Techniques.* Extend a basis of a subspace (Technique 4.1.18)
> *Hint 1.* Start from a basis $\mathbf{u}_1, \ldots, \mathbf{u}_k$ of $\ker T$ and extend it to a basis $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{v}_1, \ldots, \mathbf{v}_r$ of V. Which vectors should form a basis of $\operatorname{im} T$?
> *Hint 2.* $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_r)$ span $\operatorname{im} T$: apply T to an arbitrary vector, written in the basis, and watch the $\mathbf{u}_i$ disappear.
> *Hint 3.* For independence: if $\sum_j b_j T(\mathbf{v}_j) = \mathbf{0}$, then $\sum_j b_j \mathbf{v}_j \in \ker T$, so it is a combination of the $\mathbf{u}_i$. Now use the independence of the whole basis of V.
> *Sketch.* $\ker T$ has a basis $\mathbf{u}_1, \ldots, \mathbf{u}_k$ (Proposition 4.1.21(a)), which extends to a basis $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{v}_1, \ldots, \mathbf{v}_r$ of V. Since T kills the $\mathbf{u}_i$, the vectors $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_r)$ span $\operatorname{im} T$. If $\sum_j b_j T(\mathbf{v}_j) = \mathbf{0}$, then $\sum_j b_j \mathbf{v}_j \in \ker T = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$, which gives a linear relation among basis vectors of V, so all $b_j = 0$. Hence $\dim \operatorname{im} T = r = \dim V - \dim \ker T$. Part (a) is (b) for T_A, with Theorem 4.2.7.

We prove (b). Then (a) follows by applying (b) to $T_A : F^n \to F^m$, since $\dim \operatorname{im} T_A = \operatorname{rank} A$ (Theorem 4.2.7).

By Proposition 4.1.21(a), the subspace $\ker T$ of V is finite-dimensional; let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be a basis of it. By Theorem 4.1.16, it extends to a basis

$$\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{v}_1, \ldots, \mathbf{v}_r$$

of V, where $k + r = \dim V$. We claim that $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_r)$ is a basis of $\operatorname{im} T$. Then $\operatorname{im} T$ is finite-dimensional and $\dim \operatorname{im} T = r = \dim V - \dim \ker T$, as desired.

Spanning. Let $\mathbf{w} \in \operatorname{im} T$, say $\mathbf{w} = T(\mathbf{v})$, and write $\mathbf{v} = \sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{v}_j$. Since $T(\mathbf{u}_i) = \mathbf{0}$ for every i,

$$\mathbf{w} = \sum_{i=1}^{k} a_i T(\mathbf{u}_i) + \sum_{j=1}^{r} b_j T(\mathbf{v}_j) = \sum_{j=1}^{r} b_j T(\mathbf{v}_j).$$

So the vectors $T(\mathbf{v}_j)$, which lie in $\operatorname{im} T$, span it.

Independent. Suppose $\sum_j b_j T(\mathbf{v}_j) = \mathbf{0}$. Then $T\left(\sum_j b_j \mathbf{v}_j\right) = \mathbf{0}$, so $\sum_j b_j \mathbf{v}_j \in \ker T$, and there are scalars $a_1, \ldots, a_k$ with $\sum_j b_j \mathbf{v}_j = \sum_i a_i \mathbf{u}_i$. Then

$$\sum_{i=1}^{k} (-a_i) \mathbf{u}_i + \sum_{j=1}^{r} b_j \mathbf{v}_j = \mathbf{0}$$

is a linear relation among the vectors of a basis of V, so all its coefficients are 0 (Theorem 1.5.5). In particular $b_1 = \cdots = b_r = 0$. $\square$

In the language of Section 4.2.1, the second proof sets $U = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_r)$. Independence says that $U \cap \ker T = \{\mathbf{0}\}$, so $T|_U$ is injective, and spanning says that $\operatorname{im}(T|_U) = \operatorname{im} T$. So $\operatorname{im} T$ is a faithful copy of U, and Proposition 4.2.6(b) gives $\dim \operatorname{im} T = \dim U = r$.

Remark 4.2.12 (A third proof). The second proof chose the vectors $\mathbf{v}_j$, and different choices give different subspaces U; only $\dim U$ is determined by T. In the plane example of Intuition (Lost plus reached), every line other than $\ker T_A$ is a possible U. Section 4.6 removes the choice: it replaces U by the quotient space $V/\ker T$, built from V and $\ker T$ alone, whose elements are the translates $\mathbf{v} + \ker T$. The map T induces an isomorphism $V/\ker T \to \operatorname{im} T$ (Theorem 4.6.34), and $\dim V/\ker T = \dim V - \dim \ker T$, which is rank–nullity once more. Quotients are not part of the course.

> *Intuition (Comparing the proofs).* The pivot-counting proof is a computation. Row reduction sorts the columns of A into pivot columns and free columns; the free ones index a basis of the kernel, and the pivot ones are a basis of the image. For matrices, the theorem is then the observation that every column is one or the other. The proof produces explicit bases, which is what we want in examples. Its weakness is that it only sees matrices: for an abstract T we had to choose bases, and the real content of (b) moved into the transfer step, which says that coordinates do not change the dimensions of kernels and images.
>
> The basis-extension proof never mentions matrices and works for every T whose domain is finite-dimensional. It shows *why* the formula holds: V is built from $\ker T$ and a subspace U on which T is injective, and T carries U onto $\operatorname{im} T$ without loss. Its price is a choice of U, which the quotient proof removes. When computing, count pivots. When proving something about an abstract map, extend a basis of the kernel.

The bases in the second proof are adapted to T. If W is finite-dimensional, extend the independent list $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_r)$ to a basis of W. In the bases $\mathbf{v}_1, \ldots, \mathbf{v}_r, \mathbf{u}_1, \ldots, \mathbf{u}_k$ of V and this basis of W, the matrix of T is the rank normal form N_r of Theorem 3.5.27. This is Corollary 3.5.29 for abstract maps, and Section 4.5 returns to it.

> **Exercise 4.2.13.** ROUTINE Let $T : F^3 \to F^3$, $T(x_1, x_2, x_3) = (x_1 - x_2, x_2 - x_3, x_3 - x_1)$.
>
> (a) Find $\ker T$.
>
> (b) Show that $\operatorname{im} T = \{\mathbf{y} \in F^3 \mid y_1 + y_2 + y_3 = 0\}$, without solving $T(\mathbf{x}) = \mathbf{y}$.

Solution on page 1297

4.2.5 The rank of a linear map

Rank–nullity suggests measuring a linear map by the dimensions of its kernel and image. Remark 3.5.17 promised an intrinsic definition of rank; here it is.

> **Definition 4.2.14** (Rank and nullity of a linear map). Let $T \in \mathrm{L}(V, W)$. If $\operatorname{im} T$ is finite-dimensional, the **rank** of T is
>
> $$\operatorname{rank} T = \dim \operatorname{im} T.$$
>
> If $\ker T$ is finite-dimensional, the **nullity** of T is $\operatorname{nullity} T = \dim \ker T$.

When V is finite-dimensional both are defined (Theorem 4.2.11, Proposition 4.1.21), and rank–nullity reads

$$\operatorname{rank} T + \operatorname{nullity} T = \dim V,$$

which is where the theorem's name comes from. For a matrix, $\operatorname{rank} T_A = \dim \operatorname{im} T_A = \operatorname{rank} A$ by Theorem 4.2.7, so the two meanings of "rank" agree, and we use $\operatorname{rank} A$ and $\operatorname{rank} T_A$ interchangeably. Likewise the **nullity** of A is $\operatorname{nullity} A = \dim \ker T_A = n - \operatorname{rank} A$.

For a map between finite-dimensional spaces, we can also compute the rank of any of its matrices. The lecture's observation is that the answer does not depend on which matrix we pick.

Proposition 4.2.15 (Rank through any matrix). Let V and W be nonzero finite-dimensional spaces, with bases $\mathcal{B}$ and $\mathcal{C}$, let $T \in \mathrm{L}(V, W)$, and let $A = [T]_{\mathcal{C}\mathcal{B}}$. Then

$$\operatorname{rank} A = \operatorname{rank} T \quad \text{and} \quad \operatorname{nullity} A = \operatorname{nullity} T.$$

In particular, $\operatorname{rank} [T]_{\mathcal{C}\mathcal{B}}$ does not depend on the choice of $\mathcal{B}$ and $\mathcal{C}$.

Proof. ROUTINE

Uses. Proposition 2.6.20 (Kernel and image in coordinates), Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 1.6.16 (The coordinate map is a bijection), Proposition 4.2.3 (Properties of restriction), Proposition 4.2.6 (Injective maps preserve dimension), Theorem 4.2.7 (The image of T_A)
Techniques. Translate between maps and matrices (Technique 2.3.27), Restrict to a subspace (Technique 4.2.5)
Hint 1. Under $\mathcal{C}$-coordinates, which subspace of F^m corresponds to $\operatorname{im} T$? See Proposition 2.6.20.
Hint 2. The coordinate map of W, restricted to $\operatorname{im} T$, is linear and injective. What does that do to dimension?
Sketch. By Proposition 2.6.20, $\mathbf{w} \mapsto [\mathbf{w}]_{\mathcal{C}}$ maps $\operatorname{im} T$ onto $\operatorname{im} T_A$, and it is the restriction of an injective linear map, so $\dim \operatorname{im} T = \dim \operatorname{im} T_A = \operatorname{rank} A$ (Proposition 4.2.6, Theorem 4.2.7). The same argument with $\mathcal{B}$-coordinates matches $\ker T$ with $\ker T_A$.

By Proposition 2.6.20, the coordinate map $\mathbf{w} \mapsto [\mathbf{w}]_{\mathcal{C}}$ sends $\operatorname{im} T$ onto $\operatorname{im} T_A$. It is linear and injective on all of W (Proposition 1.6.19, Proposition 1.6.16), so its restriction to $\operatorname{im} T$ is an injective linear map with image $\operatorname{im} T_A$ (Proposition 4.2.3). The space $\operatorname{im} T$ is finite-dimensional (Theorem 4.2.11), so Proposition 4.2.6(a) and Theorem 4.2.7 give

$$\operatorname{rank} T = \dim \operatorname{im} T = \dim \operatorname{im} T_A = \operatorname{rank} A.$$

In the same way, $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ restricts to an injective linear map from $\ker T$ onto $\ker T_A$, so $\operatorname{nullity} T = \dim \ker T_A = \operatorname{nullity} A$. □

This settles Remark 3.5.17. Once the change-of-basis formula of Section 4.5 expresses two matrices of T through each other by invertible factors, the proposition also shows that such factors do not change the rank; Section 4.3 proves that directly.

Example 4.2.16 (One map, two matrices). Let $\ell = \operatorname{span}(\mathbf{u})$ with $\mathbf{u} = (c, s) = (\cos\theta, \sin\theta)$, and let Pr_ℓ be the orthogonal projection onto ℓ, so $\mathrm{Pr}_\ell(x, y) = (xc + ys)\mathbf{u}$ (Example 2.6.7(d)). In the standard basis,

$$[\mathrm{Pr}_\ell]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} c^2 & cs \\ cs & s^2 \end{pmatrix},$$

whose columns $c\mathbf{u}$ and $s\mathbf{u}$ are multiples of the nonzero vector $\mathbf{u}$, not both $\mathbf{0}$; so its rank is 1. Let $\mathbf{u}^\perp = (-s, c)$. By Example 2.6.7(d), every vector of $\mathbb{R}^2$ is a combination of $\mathbf{u}$ and $\mathbf{u}^\perp$, so $\mathcal{B} = \mathbf{u}, \mathbf{u}^\perp$ is a basis (Corollary 4.1.11(b)). In this basis $\mathrm{Pr}_\ell(\mathbf{u}) = \mathbf{u}$ and $\mathrm{Pr}_\ell(\mathbf{u}^\perp) = \mathbf{0}$, so

$$[\mathrm{Pr}_\ell]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

The two matrices look different, but both have rank $1 = \dim \ell = \operatorname{rank} \mathrm{Pr}_\ell$.

Exercise 4.2.17. ROUTINE Let $T : F[x]_{\leq 2} \to F^3$, $T(p) = (p(0), p(1), p(2))$. Using the matrix of T in the bases $1, x, x^2$ and $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$, find $\operatorname{rank} T$ and $\operatorname{nullity} T$ for $F = \mathbb{Q}$ and for $F = \mathbb{F}_2$. For $F = \mathbb{F}_2$, find a nonzero $p \in \ker T$.

Solution on page 1297

4.2.6 Consequences

Rank–nullity turns statements about vectors into statements about numbers. This subsection collects the consequences that the course uses.

Injective, surjective, bijective

For a map between finite sets of the same size, injective and surjective are equivalent. Dimension plays the role of size.

Corollary 4.2.18 (Injective if and only if surjective). Let V and W be finite-dimensional with $\dim V = \dim W$, and let $T \in \mathrm{L}(V, W)$. The following are equivalent.

(i) T is injective.
(ii) T is surjective.
(iii) T is bijective.

In particular, for V finite-dimensional, an operator $T \in \mathrm{L}(V)$ is injective if and only if it is surjective.

Proof. ROUTINE

Uses. Theorem 4.2.11 (Rank–nullity), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 4.1.21 (Dimensions of subspaces), Definition 2.6.3 (Bijective)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Translate injectivity and surjectivity into statements about $\dim\ker T$ and $\dim\operatorname{im} T$.
Hint 2. $\operatorname{im} T$ is a subspace of W. When is a subspace of W equal to W?
Sketch. Let $n = \dim V = \dim W$. T is injective iff $\dim\ker T = 0$, iff $\dim\operatorname{im} T = n$ by rank–nullity, iff $\operatorname{im} T = W$ by Proposition 4.1.21(b). Bijective means both.

Let $n = \dim V = \dim W$. By Theorem 2.6.11, T is injective if and only if $\ker T = \{\mathbf{0}\}$, that is, $\dim\ker T = 0$. By Theorem 4.2.11 this holds if and only if $\dim\operatorname{im} T = n$. Since $\operatorname{im} T$ is a subspace of W and $\dim W = n$, Proposition 4.1.21(b) says that $\dim\operatorname{im} T = n$ if and only if $\operatorname{im} T = W$, that is, T is surjective. So (i) $\Leftrightarrow$ (ii), and (iii) is (i) and (ii) together (Definition 2.6.3). □

So for maps between spaces of the same finite dimension, uniqueness gives existence, which extends Technique 3.4.21 from square matrices to linear maps: to show that $T(\mathbf{v}) = \mathbf{w}$ is solvable for every $\mathbf{w}$, it suffices to show that $T(\mathbf{v}) = \mathbf{0}$ only for $\mathbf{v} = \mathbf{0}$.

Example 4.2.19 (Uniqueness gives existence, for polynomials). Let $T : \mathbb{R}[x]_{\le n} \to \mathbb{R}[x]_{\le n}$, $T(p) = p + p'$. If $p \neq \mathbf{0}$ has degree d with leading coefficient a_d, then p' has degree less than d, so the coefficient of x^d in $p + p'$ is $a_d \neq 0$. Hence $\ker T = \{\mathbf{0}\}$, and T is surjective by Corollary 4.2.18: for every $q \in \mathbb{R}[x]_{\le n}$, the equation $p + p' = q$ has a solution $p \in \mathbb{R}[x]_{\le n}$, and only one. For instance, for $q = x^2$, trying $p = x^2 + bx + c$ gives $p + p' = x^2 + (b+2)x + (b+c)$, so $b = -2$, $c = 2$, and $p = x^2 - 2x + 2$. We knew a solution existed before we looked for it.

The finite dimension is essential. On $F[x]$, multiplication by x is injective but not surjective, and in characteristic 0 differentiation is surjective but not injective (Example 2.6.4(e)).

Remark 4.2.20 (One-sided inverses of operators). Let V be finite-dimensional and $S, T \in \mathrm{L}(V)$ with $ST = \mathrm{id}_V$. Then T is injective (Proposition 2.5.4), hence bijective by Corollary 4.2.18, and its inverse is linear (Proposition 2.7.7). So $S = S\big(TT^{-1}\big) = (ST)T^{-1} = T^{-1}$, and $TS = \mathrm{id}_V$ as well. A one-sided inverse of an operator on a finite-dimensional space is two-sided. This is Theorem 3.5.23 for operators, and the same argument works for $T \in \mathrm{L}(V, W)$ and $S \in \mathrm{L}(W, V)$ when $\dim V = \dim W < \infty$.

Dimension obstructions

Corollary 4.2.21 (Dimension obstructions). Let V and W be finite-dimensional, and let $T \in \mathrm{L}(V, W)$.

(a) $\operatorname{rank} T \le \min(\dim V, \dim W)$, and $\dim \ker T \ge \dim V - \dim W$.
(b) If T is injective, then $\dim V \le \dim W$. So if $\dim V > \dim W$, no linear map $V \to W$ is injective.
(c) If T is surjective, then $\dim V \ge \dim W$. So if $\dim V < \dim W$, no linear map $V \to W$ is surjective.

Proof. ROUTINE

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. $\operatorname{im} T$ is a subspace of W, and rank–nullity gives $\operatorname{rank} T = \dim V - \dim \ker T$.
Hint 2. For (b) and (c), put $\dim \ker T = 0$, respectively $\operatorname{rank} T = \dim W$, into (a).
Sketch. (a) $\operatorname{rank} T \le \dim W$ since $\operatorname{im} T \subseteq W$, and $\operatorname{rank} T = \dim V - \dim \ker T \le \dim V$; rearranging $\operatorname{rank} T \le \dim W$ gives the bound on $\dim \ker T$. (b) Injective means $\dim \ker T = 0$, so $\dim V = \operatorname{rank} T \le \dim W$. (c) Surjective means $\operatorname{rank} T = \dim W$, so $\dim W \le \dim V$.

(a) Since $\operatorname{im} T$ is a subspace of W, $\operatorname{rank} T \le \dim W$ (Proposition 4.1.21(a)). By Theorem 4.2.11, $\operatorname{rank} T = \dim V - \dim \ker T \le \dim V$. Rearranging $\dim V - \dim \ker T = \operatorname{rank} T \le \dim W$ gives $\dim \ker T \ge \dim V - \dim W$.

(b) If T is injective, then $\dim \ker T = 0$ (Theorem 2.6.11), so $\dim V = \operatorname{rank} T \le \dim W$ by rank–nullity and (a).

(c) If T is surjective, then $\operatorname{rank} T = \dim W$, and $\operatorname{rank} T \le \dim V$ by (a). □

For T_A with $A \in F^{m\times n}$, (b) and (c) are the "moreover" parts of Theorem 3.5.12 and Theorem 3.5.13: an injective T_A has $n \le m$, and a surjective one has $n \ge m$. Now they hold for all linear maps. Part (b) is the precise sense in which a bigger space cannot be fitted into a smaller one. As sets, $\mathbb{R}^2$ and $\mathbb{R}$ are in bijection, but no injective map $\mathbb{R}^2 \to \mathbb{R}$ is linear.

Exercise 4.2.22. ROUTINE For each item, give an example or show that none exists.

(a) An injective linear map $F^{2\times 3} \to F[x]_{\le 4}$.
(b) A surjective linear map $F[x]_{\le 3} \to F^{2\times 2}$.
(c) A linear map $T : \mathbb{R}^5 \to \mathbb{R}^2$ with $\ker T = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$.
(d) A linear map $T : \mathbb{R}^4 \to \mathbb{R}^3$ with $\ker T = \operatorname{span}(\mathbf{e}_1)$.

Solution on page 1298

Linear systems, revisited

Rank–nullity gives a second view of Corollary 3.4.19, and it says how many parameters a description of a solution set needs.

Corollary 4.2.23 (Dimension of solution sets). Let $A \in F^{m\times n}$.
(a) $\dim \ker T_A = n - \operatorname{rank} A \ge n - m$. In particular, if $n > m$, then $A\mathbf{x} = \mathbf{0}$ has a nontrivial solution.
(b) Suppose $A\mathbf{x} = \mathbf{y}$ has a solution $\mathbf{x}_0$, and that its solution set is $\mathbf{x}_0 + \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_r)$ for some $\mathbf{u}_1, \dots, \mathbf{u}_r \in F^n$. Then $r \ge n - \operatorname{rank} A$, with equality if and only if $\mathbf{u}_1, \dots, \mathbf{u}_r$ is linearly independent.
(c) Conversely, if $\mathbf{u}_1, \dots, \mathbf{u}_r \in \ker T_A$ are linearly independent and $r = n - \operatorname{rank} A$, then the solution set of $A\mathbf{x} = \mathbf{y}$ is $\mathbf{x}_0 + \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_r)$ for every solution $\mathbf{x}_0$.

Proof. ROUTINE

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 3.5.2 (First properties of rank), Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 4.1.11 (Spanning lists are long), Theorem 4.1.10 (Independent lists are short), Proposition 1.6.2 (Bases are independent spanning lists)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. (a) is rank–nullity for T_A, with $\operatorname{rank} A \le m$.

Hint 2. For (b), the solution set is also $\mathbf{x}_0 + \ker T_A$ (Proposition 3.1.19). Deduce $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r) = \ker T_A$, and compare the length of a spanning list with the dimension.
Sketch. (a) $\dim \ker T_A = n - \operatorname{rank} A$ and $\operatorname{rank} A \leq m$. (b) The solution set is $\mathbf{x}_0 + \ker T_A$, so $\operatorname{span}(\mathbf{u}_i) = \ker T_A$. A spanning list of a space of dimension $n - \operatorname{rank} A$ has at least that many entries, with equality iff it is a basis, iff it is independent. (c) An independent list of length $\dim \ker T_A$ in $\ker T_A$ is a basis of it.

(a) By Theorem 4.2.11(a), $\dim \ker T_A = n - \operatorname{rank} A$, and $\operatorname{rank} A \leq m$ (Proposition 3.5.2(a)). If $n > m$, then $\dim \ker T_A \geq n - m \geq 1$, so $\ker T_A$ contains a nonzero vector.

(b) By Proposition 3.1.19, the solution set is $\mathbf{x}_0 + \ker T_A$. For $\mathbf{v} \in F^n$, the vector $\mathbf{x}_0 + \mathbf{v}$ is a solution if and only if $\mathbf{v} \in \ker T_A$, and also if and only if $\mathbf{v} \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$. So $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r) = \ker T_A$, a space of dimension $d = n - \operatorname{rank} A$. A list spanning it has length $r \geq d$ (Corollary 4.1.11(a)). If $r = d$, the list is a basis (Corollary 4.1.11(b)), hence independent. If the list is independent, it is a basis of $\ker T_A$ (Proposition 1.6.2), so $r = d$.

(c) An independent list in $\ker T_A$ of length $\dim \ker T_A$ is a basis of $\ker T_A$ (Theorem 4.1.10(b)), so its span is $\ker T_A$, and the solution set is $\mathbf{x}_0 + \ker T_A$ by Proposition 3.1.19. □

Part (a) is Corollary 3.4.19(a) from the other side. There, more columns than pivots forced a free variable. Here, the image has room for at most m of the n dimensions of F^n, so the kernel must absorb at least $n - m$ of them. Part (b) says that the number of parameters in a description of the solutions is at least $n - \operatorname{rank} A$, however the description was found, and part (c) is the quick completeness test promised in Remark 3.4.12: $n - \operatorname{rank} A$ independent solutions of the homogeneous system always span its solution space. Over a field with q elements, a consistent system has $q^{n - \operatorname{rank} A}$ solutions (Corollary 3.4.14(b)).

Dimension counting

Rank–nullity and the bounds of Section 4.1 prove that certain vectors exist without exhibiting them. That is worth a name.

Technique 4.2.24 (Dimension counting). To show that a subspace is nonzero, that two subspaces are equal, or that a linear map is injective or surjective, compute dimensions instead of vectors. The tools are rank–nullity, which ties $\dim \ker T$ to $\dim \operatorname{im} T$; Proposition 4.1.21(b), which turns one containment and equal dimensions into equality; and Theorem 4.1.10, which makes long lists dependent. A typical argument computes whichever of $\dim \ker T$ and $\dim \operatorname{im} T$ is easier and reads off the other. Often the image is easy because it obviously contains a basis of the target, or the kernel is easy because a structural reason (degrees, a top coefficient) forces it to be small.

Reach for it when a direct computation would mean solving equations you would rather not solve, or when you need a nonzero vector with some properties (in an intersection, in a kernel) and only its existence matters. The canonical example is that two 3-dimensional subspaces of $\mathbb{R}^5$ meet in a nonzero vector (Proposition 4.2.26, Example 4.2.27). Later the same counting gives the rank inequalities (Section 4.3), the dimension formula for sums (Section 4.4), the bounds on eigenspaces (Section 7.4), and the min–max principles (Section 12.3).

Used in. Exercise 4.2.13, Corollary 4.2.18, Corollary 4.2.21, Corollary 4.2.23, Proposition 4.2.26, Exercise 4.2.39, Exercise 4.2.42, Exercise 4.2.46, Exercise 4.2.47, Exercise 4.2.49, Exercise 4.2.51, Exercise 4.2.52, Proposition 4.3.1, Theorem 4.3.3, Proposition 4.3.5, Proposition 4.3.20, Proposition 4.3.23, Exercise 4.3.42, Theorem 4.4.13, Theorem 4.4.19, Proposition 4.4.21, Exercise 4.4.23, Theorem 4.4.27, Exercise 4.4.34, Exercise 4.4.40, Exercise 4.4.45, Exercise 4.4.46, Exercise 4.4.48, Exercise 4.4.49, Exercise 4.4.50, Theorem 4.5.6, Exercise 4.5.41, Theorem 4.6.5, Corollary 4.6.10, Proposition 4.6.11, Theorem 4.6.27, Exercise 4.6.47, Exercise 4.6.48, Theorem 4.7.8, Exercise 4.7.52, Exercise 4.8.4, Exercise 4.8.6, Exercise 4.8.7, Exercise 4.8.8, Exercise 4.8.9, Problem 4.1, Problem 4.5, Problem 4.6, Problem 4.8, Problem 4.9, Problem 4.11, Problem 4.16, Problem 4.17, Corollary 6.4.25, Theorem 6.4.26, Corollary 6.6.22, Problem 6.10, Theorem 7.1.14, Exercise 7.1.57, Theorem 7.4.16, Theorem 7.4.30, Proposition 7.5.8, Proposition 7.6.12, Exercise 7.7.9, Problem 7.2, Problem 7.3, Problem 7.12, Exercise 4.2.40, Exercise 4.2.50, Exercise 4.3.30, Exercise 4.3.31, Exercise 4.6.38, Exercise 4.6.54, Exercise 6.5.45, Exercise 6.6.43, Exercise 7.2.45, Exercise 7.2.46, Exercise 7.2.50.

The simplest instance: one nonzero linear condition cuts the dimension by exactly one.

Example 4.2.25 (Kernels of linear functionals). Let V be finite-dimensional, and let $f : V \to F$ be linear and not the zero map. Then $\operatorname{im} f$ is a nonzero subspace of F, so $\operatorname{im} f = F$ (Proposition 4.1.21(b), as $\dim F = 1$), and by rank–nullity

$$\dim \ker f = \dim V - 1.$$

For instance:

(a) For $\mathbf{a} \in F^n$ with $\mathbf{a} \neq \mathbf{0}$, the solutions of $a_1x_1 + \cdots + a_nx_n = 0$ form a subspace of F^n of dimension $n - 1$.

(b) The trace-zero matrices form a subspace of $F^{n\times n}$ of dimension $n^2 - 1$, since $\operatorname{tr} : F^{n\times n} \to F$ is linear (Proposition 2.4.27) and $\operatorname{tr} U_{11} = 1$.

(c) For $c \in F$, the polynomials $p \in F[x]_{\leq n}$ with $p(c) = 0$ form a subspace of dimension n, since evaluation at c is linear (Example 2.1.9) and sends 1 to 1.

In Section 4.1, (b) and (c) needed an explicit basis or a squeeze (Exercise 4.1.43, Exercise 4.1.24). Here we only had to check that the functional is not zero.

The next proposition is the canonical example of the technique. In $\mathbb{R}^3$, two planes through $\mathbf{0}$ always share a line, since $2 + 2 > 3$. In $\mathbb{R}^4$ they need not: $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) \cap \operatorname{span}(\mathbf{e}_3, \mathbf{e}_4) = \{\mathbf{0}\}$. The count behind this: U and W together supply $\dim U + \dim W$ independent directions, and V has room for only $\dim V$ of them, so the excess must be shared.

Proposition 4.2.26 (Subspaces that must meet). Let V be finite-dimensional, and let U and W be subspaces of V. Then

$$\dim(U \cap W) \geq \dim U + \dim W - \dim V.$$

In particular, if $\dim U + \dim W > \dim V$, then $U \cap W \neq \{\mathbf{0}\}$.

To make the count precise, we build a linear map whose kernel records $U \cap W$. The first proof uses both subspaces symmetrically.

Proof (with a difference map). STANDARD

Uses. Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.2.11 (Rank–nullity), Corollary 4.2.21 (Dimension obstructions), Theorem 1.5.5 (Independence is decided at zero), Proposition 4.2.6 (Injective maps preserve dimension), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Take bases $\mathbf{u}_1, \ldots, \mathbf{u}_k$ of U and $\mathbf{w}_1, \ldots, \mathbf{w}_l$ of W, and consider $L : F^{k+l} \to V$, $L(\mathbf{a}, \mathbf{b}) = \sum_i a_i\mathbf{u}_i - \sum_j b_j\mathbf{w}_j$. How large is $\ker L$?
Hint 2. An element of $\ker L$ says that $\sum_i a_i\mathbf{u}_i = \sum_j b_j\mathbf{w}_j$, a vector of $U \cap W$. Show that $(\mathbf{a}, \mathbf{b}) \mapsto \sum_i a_i\mathbf{u}_i$ is injective on $\ker L$.
Sketch. With L as in the hint, rank–nullity gives $\dim \ker L = k + l - \operatorname{rank} L \geq k + l - n$. The linear map $\varphi : \ker L \to V$, $(\mathbf{a}, \mathbf{b}) \mapsto \sum_i a_i\mathbf{u}_i$, takes values in $U \cap W$ and is injective: if $\sum_i a_i\mathbf{u}_i = \mathbf{0}$, then $\mathbf{a} = \mathbf{0}$, and then $\sum_j b_j\mathbf{w}_j = \mathbf{0}$ gives $\mathbf{b} = \mathbf{0}$. So $\dim(U \cap W) \geq \dim \ker L \geq k + l - n$.

Let $n = \dim V$. By Proposition 4.1.21(a), U and W are finite-dimensional; let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ and $\mathbf{w}_1, \ldots, \mathbf{w}_l$ be bases. Write elements of F^{k+l} as $(\mathbf{a}, \mathbf{b})$ with $\mathbf{a} \in F^k$ and $\mathbf{b} \in F^l$, and define

$$L : F^{k+l} \to V, \quad L(\mathbf{a}, \mathbf{b}) = a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k - b_1\mathbf{w}_1 - \cdots - b_l\mathbf{w}_l.$$

It is linear, since each coordinate enters linearly. By Theorem 4.2.11 and Corollary 4.2.21(a),

$$\dim \ker L = (k + l) - \operatorname{rank} L \geq k + l - n.$$

Define $\varphi : \ker L \to V$ by $\varphi(\mathbf{a}, \mathbf{b}) = \sum_i a_i\mathbf{u}_i$; it is linear. If $(\mathbf{a}, \mathbf{b}) \in \ker L$, then $\varphi(\mathbf{a}, \mathbf{b}) = \sum_i a_i\mathbf{u}_i = \sum_j b_j\mathbf{w}_j$ lies in U and in W, so $\operatorname{im}\varphi \subseteq U \cap W$. And φ is injective: if $\sum_i a_i\mathbf{u}_i = \mathbf{0}$, then $\mathbf{a} = \mathbf{0}$ by independence of the $\mathbf{u}_i$ (Theorem 1.5.5), so $\sum_j b_j\mathbf{w}_j = \sum_i a_i\mathbf{u}_i = \mathbf{0}$ and $\mathbf{b} = \mathbf{0}$ likewise. By Proposition 4.2.6(a) and Proposition 4.1.21(a),

$$\dim(U \cap W) \geq \dim \operatorname{im} \varphi = \dim \ker L \geq k + l - n,$$

as desired. □

The second proof describes W by linear equations and restricts them to U.

Proof (by restricting a map that kills W). STANDARD

> *Uses.* Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 4.2.3 (Properties of restriction), Theorem 4.2.11 (Rank–nullity), Corollary 4.2.21 (Dimension obstructions)
> *Techniques.* Restrict to a subspace (Technique 4.2.5), Extend a basis of a subspace (Technique 4.1.18), Dimension counting (Technique 4.2.24)
> *Hint 1.* Find a linear map $L : V \to F^{n-l}$, where $l = \dim W$ and $n = \dim V$, with $\ker L = W$. Extending a basis of W helps.
> *Hint 2.* Restrict L to U. What is $\ker(L|_U)$, and how large can $\operatorname{im}(L|_U)$ be?
> *Sketch.* Extend a basis $\mathbf{w}_1, \ldots, \mathbf{w}_l$ of W to a basis $\mathbf{w}_1, \ldots, \mathbf{w}_l, \mathbf{v}_1, \ldots, \mathbf{v}_{n-l}$ of V, and let L send $\mathbf{w}_j \mapsto \mathbf{0}$ and $\mathbf{v}_i \mapsto \mathbf{e}_i \in F^{n-l}$. Then $\ker L = W$, so $\ker(L|_U) = U \cap W$, and rank–nullity for $L|_U$ gives $\dim U = \dim(U \cap W) + \operatorname{rank}(L|_U) \leq \dim(U \cap W) + n - l$.

Let $n = \dim V$ and $l = \dim W$. Let $\mathbf{w}_1, \ldots, \mathbf{w}_l$ be a basis of W (Proposition 4.1.21(a)), and extend it to a basis $\mathbf{w}_1, \ldots, \mathbf{w}_l, \mathbf{v}_1, \ldots, \mathbf{v}_{n-l}$ of V (Theorem 4.1.16). By Theorem 2.2.1 there is a linear map $L : V \to F^{n-l}$ with $L(\mathbf{w}_j) = \mathbf{0}$ for all j and $L(\mathbf{v}_i) = \mathbf{e}_i$ for all i. If $\mathbf{v} = \sum_j b_j \mathbf{w}_j + \sum_i c_i \mathbf{v}_i$, then $L(\mathbf{v}) = (c_1, \ldots, c_{n-l})$, which is $\mathbf{0}$ exactly when all $c_i = 0$, that is, when $\mathbf{v} \in W$. So $\ker L = W$.

By Proposition 4.2.3(c), $L|_U : U \to F^{n-l}$ is linear with kernel $U \cap W$. By Theorem 4.2.11 and Corollary 4.2.21(a),

$$\dim U = \dim(U \cap W) + \operatorname{rank}(L|_U) \leq \dim(U \cap W) + (n - l).$$

Rearranging gives $\dim(U \cap W) \geq \dim U + \dim W - \dim V$. □

The first proof gives more if we look closer. The image of L is $U + W$, and φ maps $\ker L$ onto $U \cap W$, so rank–nullity for L is an equation, $\dim(U + W) + \dim(U \cap W) = \dim U + \dim W$; that is the dimension formula of Section 4.4 (Theorem 4.4.19). The second proof is the one to remember in practice. The map L has $n - l$ coordinates, each a linear condition, and W is the set where all of them vanish. Restricted to U, each condition lowers the dimension by at most one. So a subspace of U cut out by s linear conditions has dimension at least $\dim U - s$.

Example 4.2.27 (Two subspaces of $\mathbb{R}^5$).

(a) Two 3-dimensional subspaces of $\mathbb{R}^5$ meet in at least a line, since $3 + 3 - 5 = 1$. The bound is attained by $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$ and $\operatorname{span}(\mathbf{e}_3, \mathbf{e}_4, \mathbf{e}_5)$, which meet in $\operatorname{span}(\mathbf{e}_3)$, and the intersection can be larger (take $U = W$). In $\mathbb{R}^6$, two 3-dimensional subspaces need not share a nonzero vector: $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3) \cap \operatorname{span}(\mathbf{e}_4, \mathbf{e}_5, \mathbf{e}_6) = \{\mathbf{0}\}$.

(b) The polynomials $p \in \mathbb{R}[x]_{\leq 4}$ with $p(0) = p'(0) = 0$ form a 3-dimensional subspace W, with basis x^2, x^3, x^4. So by Proposition 4.2.26, every 3-dimensional subspace U of the 5-dimensional space $\mathbb{R}[x]_{\leq 4}$ contains a nonzero p with $p(0) = p'(0) = 0$. For $U = \operatorname{span}\big(1, 1 + x + x^2, x + x^3\big)$, writing $p = a + b\big(1 + x + x^2\big) + c\big(x + x^3\big)$, the conditions are $a + b = 0$ and $b + c = 0$, solved by $(a, b, c) = (1, -1, 1)$:

$$p = 1 - \big(1 + x + x^2\big) + \big(x + x^3\big) = x^3 - x^2.$$

Dimension counting also proves existence statements about polynomials, sometimes with a formula as a by-product.

Example 4.2.28 (Sums of powers). Let $n \geq 1$, and let $\Delta : \mathbb{Q}[x]_{\leq n} \to \mathbb{Q}[x]_{\leq n-1}$ be the linear map with

$$\Delta\big(x^j\big) = (x + 1)^j - x^j = \sum_{i=0}^{j-1} \binom{j}{i} x^i \quad (0 \leq j \leq n)$$

(Theorem 2.2.1). By the binomial theorem in $\mathbb{Q}$, $(\Delta p)(t) = p(t+1) - p(t)$ for every p and every $t \in \mathbb{Q}$.

Kernel. Constants are in $\ker \Delta$. Conversely, if $\Delta p = \mathbf{0}$, then $p(t+1) = p(t)$ for all t, so $p(0) = p(1) = \cdots = p(n)$. Then p and the constant polynomial $p(0)$ have the same values at the $n+1$ distinct points $0, 1, \ldots, n$, so they are equal by the uniqueness in Theorem 3.4.24. Hence $\ker \Delta$ is the constants, and $\dim \ker \Delta = 1$.

Image. By rank–nullity, $\operatorname{rank} \Delta = (n+1) - 1 = n = \dim \mathbb{Q}[x]_{\leq n-1}$, so Δ is surjective (Proposition 4.1.21(b)). So for every $q \in \mathbb{Q}[x]_{\leq n-1}$ there is $p \in \mathbb{Q}[x]_{\leq n}$ with $p(t+1) - p(t) = q(t)$ for all t, and the sum telescopes:

$$q(0) + q(1) + \cdots + q(N-1) = \sum_{t=0}^{N-1} (p(t+1) - p(t)) = p(N) - p(0).$$

So for every nonzero polynomial q, the sum $\sum_{t=0}^{N-1} q(t)$ is a polynomial in N of degree at most $\deg q + 1$.

For $q = x^2$, some $p \in \mathbb{Q}[x]_{\leq 3}$ has $\Delta p = q$, and subtracting its constant term (which lies in $\ker \Delta$) we may take $p = ax^3 + bx^2 + cx$. Since $\Delta\left(x^3\right) = 3x^2 + 3x + 1$, $\Delta\left(x^2\right) = 2x + 1$, and $\Delta(x) = 1$,

$$\Delta p = 3ax^2 + (3a + 2b)x + (a + b + c),$$

and $\Delta p = x^2$ gives $a = 1/3$, $b = -1/2$, $c = 1/6$, that is, $p = x(x-1)(2x-1)/6$. Hence

$$0^2 + 1^2 + \cdots + (N-1)^2 = \frac{N(N-1)(2N-1)}{6}.$$

The dimension count guaranteed in advance that this linear system for a, b, c had a solution.

Linear maps on spaces of matrices

Spaces of matrices are vector spaces of known dimension, so maps between them are natural targets for dimension counting.

> **Technique 4.2.29** (Study a linear map on a space of matrices). Many questions about matrices ask which X satisfy a linear condition, such as $AX = XA$, $AX = XB$, or $X^{\mathsf{T}} = -X$, or which matrices can be written in a given linear form, such as $AX - XA$. Treat $X \mapsto (AX - XA)$, or whatever the expression is, as a linear map on $F^{n\times n}$ (or $F^{m\times n}$), a space of dimension n^2 (or mn) by Example 4.1.7. The first kind of question asks for its kernel and the second for its image, and rank–nullity relates the two. So an easy description of the kernel gives the dimension of an image that is hard to describe, and with one easy containment the dimension often identifies the image completely.
>
> Reach for it when a matrix equation is linear in the unknown matrix. The canonical example is Example 4.2.30. The trace argument that $AB - BA \neq I_n$ when $n \cdot 1 \neq 0$ in F (Technique 2.4.29) is an instance: the image of $X \mapsto AX - XA$ lies in the trace-zero matrices. Later instances are Sylvester equations $AX - XB = C$ (Section 10.3) and transposition as an operator with eigenvalues ± 1 (Section 7.4).
> *Used in.* Exercise 4.2.41, Exercise 4.2.43, Problem 4.4, Exercise 7.3.55, Exercise 7.4.41, Exercise 7.5.45, Exercise 7.7.11, Problem 7.13, Exercise 4.5.48, Exercise 7.5.44.

Example 4.2.30 (Commutators with a diagonal matrix). Let $D = \operatorname{diag}(d_1, \ldots, d_n) \in F^{n\times n}$ with distinct diagonal entries $d_1, \ldots, d_n$, and let $\operatorname{ad}_D : F^{n\times n} \to F^{n\times n}$, $\operatorname{ad}_D(X) = DX - XD$. It is linear (Proposition 2.4.14). Multiplying by D on the left scales row i by d_i, and on the right scales column j by d_j (Example 2.4.10), so

$$(DX - XD)_{ij} = \left(d_i - d_j\right)x_{ij}.$$

Kernel. $\operatorname{ad}_D(X) = 0$ means $\left(d_i - d_j\right)x_{ij} = 0$ for all i, j. For $i \neq j$, $d_i - d_j \neq 0$, so $x_{ij} = 0$. So $\ker \operatorname{ad}_D$ is the space of diagonal matrices, of dimension n, and $\operatorname{rank} \operatorname{ad}_D = n^2 - n$.

Image. Every $DX - XD$ has zero diagonal, since its (i,i) entry is $(d_i - d_i)x_{ii} = 0$. The matrices with zero diagonal form a subspace Z with basis U_{ij}, $i \neq j$, so $\dim Z = n^2 - n$. Since $\operatorname{im} \operatorname{ad}_D \subseteq Z$ and the dimensions agree, $\operatorname{im} \operatorname{ad}_D = Z$ (Proposition 4.1.21(b)): every matrix with zero diagonal is $DX - XD$ for some X.

Here we could also have solved for X directly, $x_{ij} = c_{ij}/(d_i - d_j)$ for $i \neq j$. The count did not need the formula, which is what makes it useful when no formula is in sight.

4.2.7 Application: error-correcting codes BEYOND 21-242

Coding theory is not part of 21-242. This subsection uses only rank–nullity and arithmetic in $\mathbb{F}_2$.

Suppose we send blocks of 4 bits over a channel that occasionally flips a bit. Sending each bit three times and taking a majority vote corrects any single flipped bit, at the cost of 12 bits per block. Hamming found a way to correct any single flipped bit in a block using 7 bits. The construction is a kernel, and rank–nullity is what makes the numbers work.

We work in $\mathbb{F}_2^n$, where $-\mathbf{x} = \mathbf{x}$, so subtraction and addition agree.

Definition 4.2.31 (Linear codes). A **linear code** of length n is a subspace C of $\mathbb{F}_2^n$, and its elements are **codewords**. If $\dim C = k$, we call C an $[n,k]$ code. The **weight** $\operatorname{wt}(\mathbf{x})$ of $\mathbf{x} \in \mathbb{F}_2^n$ is the number of nonzero entries of $\mathbf{x}$, and the **distance** between $\mathbf{x}$ and $\mathbf{y}$ is $d(\mathbf{x},\mathbf{y}) = \operatorname{wt}(\mathbf{x} - \mathbf{y})$, the number of positions in which they differ. The **minimum distance** of $C \neq \{\mathbf{0}\}$ is the smallest weight of a nonzero codeword.

Since $\mathbf{c} - \mathbf{c}' \in C$ for codewords $\mathbf{c}, \mathbf{c}'$, and $\operatorname{wt}(\mathbf{c}) = d(\mathbf{c},\mathbf{0})$, the minimum distance is also the smallest distance between two different codewords. The distance satisfies the triangle inequality $d(\mathbf{x},\mathbf{z}) \leq d(\mathbf{x},\mathbf{y}) + d(\mathbf{y},\mathbf{z})$: a position in which $\mathbf{x}$ and $\mathbf{z}$ differ is a position in which $\mathbf{x}$ differs from $\mathbf{y}$ or $\mathbf{y}$ differs from $\mathbf{z}$.

A convenient way to specify a code is as a kernel. If $H \in \mathbb{F}_2^{r \times n}$, then $C = \ker T_H$ is a linear code of length n, the codewords are the vectors that pass the r **parity checks** given by the rows of H, and H is a **parity-check matrix** of C. By rank–nullity,

$$\dim C = n - \operatorname{rank} H, \quad |C| = 2^{n - \operatorname{rank} H}$$

(Proposition 4.1.34).

Example 4.2.32 (The Hamming code). Let $H \in \mathbb{F}_2^{3\times 7}$ be the matrix whose jth column $\mathbf{h}_j$ is the binary expansion of j, highest digit on top:

$$H = \begin{pmatrix} 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{pmatrix}.$$

Columns $4, 2, 1$ are $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$, so the columns span $\mathbb{F}_2^3$, and $\operatorname{rank} H = \dim \operatorname{im} T_H = 3$ (Proposition 2.6.18, Theorem 4.2.7). So the **Hamming code** $C = \ker T_H$ is a $[7,4]$ code with $2^4 = 16$ codewords.

Listing the rows of H from the bottom up already gives the reduced form,

$$H_r = \begin{pmatrix} 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{pmatrix},$$

with pivot columns $1, 2, 4$ and free columns $3, 5, 6, 7$. By Theorem 3.4.9, a codeword is determined by its free coordinates, which are arbitrary, and the others are

$$\begin{aligned} x_1 &= x_3 + x_5 + x_7, \\ x_2 &= x_3 + x_6 + x_7, \\ x_4 &= x_5 + x_6 + x_7. \end{aligned}$$

So to encode a message (m_1, m_2, m_3, m_4), put it in positions $3, 5, 6, 7$ and fill in the **parity bits** in positions $1, 2, 4$. The message 1011 becomes the codeword 0110011.

$$\begin{pmatrix} 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{pmatrix} \quad \text{over } \mathbb{F}_2$$

The parity-check matrix of the Hamming code over $\mathbb{F}_2$. The only row operation is the swap of rows 1 and 3. The summary reports rank 3, pivot columns $1, 2, 4$ (the parity bits), and free columns $3, 5, 6, 7$ (the message bits). (Interactive in the web version.)

The columns of H are nonzero and pairwise distinct, and that is what makes the code correct errors.

Proposition 4.2.33 (Distinct columns give distance three). Let $H \in \mathbb{F}_2^{r \times n}$ have nonzero, pairwise distinct columns $\mathbf{h}_1, \ldots, \mathbf{h}_n$, and let $C = \ker T_H$. Then every nonzero codeword has weight at least 3.

Proof. ROUTINE

Uses. Definition 2.3.8 (Matrix–vector product), Definition 4.2.31 (Linear codes)
Hint 1. Over $\mathbb{F}_2$, $H\mathbf{x}$ is the sum of the columns $\mathbf{h}_j$ at the positions where $\mathbf{x}$ has a 1.
Hint 2. Rule out codewords of weight 1 and 2.
Sketch. $H\mathbf{x} = \sum_{x_j=1} \mathbf{h}_j$. A vector of weight 1 has $H\mathbf{x} = \mathbf{h}_j \neq \mathbf{0}$, and one of weight 2 has $H\mathbf{x} = \mathbf{h}_j + \mathbf{h}_k$, which is $\mathbf{0}$ only if $\mathbf{h}_j = \mathbf{h}_k$.

By Definition 2.3.8, $H\mathbf{x} = \sum_j x_j \mathbf{h}_j$, which over $\mathbb{F}_2$ is the sum of the $\mathbf{h}_j$ with $x_j = 1$. If $\mathrm{wt}(\mathbf{x}) = 1$, with its 1 in position j, then $H\mathbf{x} = \mathbf{h}_j \neq \mathbf{0}$. If $\mathrm{wt}(\mathbf{x}) = 2$, with 1s in positions $j \neq k$, then $H\mathbf{x} = \mathbf{h}_j + \mathbf{h}_k$, which is $\mathbf{0}$ only if $\mathbf{h}_j = -\mathbf{h}_k = \mathbf{h}_k$, and the columns are distinct. So no vector of weight 1 or 2 lies in C. □

For the Hamming code the bound is attained: $\mathbf{h}_1 + \mathbf{h}_2 + \mathbf{h}_3 = (0,0,1) + (0,1,0) + (0,1,1) = \mathbf{0}$, so 1110000 is a codeword of weight 3, and the minimum distance is 3.

Theorem 4.2.34 (Syndrome decoding). Let H and C be as in Proposition 4.2.33, let $\mathbf{c} \in C$, and let $\mathbf{r} = \mathbf{c} + \mathbf{e}_j$ be $\mathbf{c}$ with its jth bit flipped.

(a) The **syndrome** $H\mathbf{r}$ equals $\mathbf{h}_j$. So $H\mathbf{r}$ determines j, and $\mathbf{c} = \mathbf{r} + \mathbf{e}_j$.
(b) $\mathbf{c}$ is the only codeword at distance at most 1 from $\mathbf{r}$.

For the Hamming code, the syndrome of a word with one flipped bit is the binary expansion of the position of the flip, and the syndrome of a codeword is $\mathbf{0}$.

Proof. ROUTINE

Uses. Proposition 4.2.33 (Distinct columns give distance three), Definition 4.2.31 (Linear codes), Definition 2.6.5 (Kernel)
Hint 1. $H\mathbf{c} = \mathbf{0}$ and $H\mathbf{e}_j = \mathbf{h}_j$.
Hint 2. For (b), use the triangle inequality and Proposition 4.2.33.
Sketch. (a) $H\mathbf{r} = H\mathbf{c} + H\mathbf{e}_j = \mathbf{h}_j$; distinct columns determine j; $\mathbf{r} + \mathbf{e}_j = \mathbf{c} + 2\mathbf{e}_j = \mathbf{c}$. (b) If $\mathbf{c}' \in C$ and $d(\mathbf{r}, \mathbf{c}') \leq 1$, then $d(\mathbf{c}, \mathbf{c}') \leq 2$, so $\mathbf{c} - \mathbf{c}'$ is a codeword of weight at most 2, hence $\mathbf{0}$.

(a) Since $\mathbf{c} \in \ker T_H$, $H\mathbf{r} = H\mathbf{c} + H\mathbf{e}_j = \mathbf{0} + \mathbf{h}_j = \mathbf{h}_j$. The columns are distinct, so $\mathbf{h}_j$ determines j. Over $\mathbb{F}_2$, $\mathbf{e}_j + \mathbf{e}_j = \mathbf{0}$, so $\mathbf{r} + \mathbf{e}_j = \mathbf{c}$.

(b) $d(\mathbf{r}, \mathbf{c}) = \mathrm{wt}(\mathbf{e}_j) = 1$. If $\mathbf{c}' \in C$ and $d(\mathbf{r}, \mathbf{c}') \leq 1$, the triangle inequality gives $d(\mathbf{c}, \mathbf{c}') \leq 2$, so $\mathbf{c} - \mathbf{c}'$ is a codeword of weight at most 2, and it is $\mathbf{0}$ by Proposition 4.2.33.

For the Hamming code, $\mathbf{h}_j$ is the binary expansion of j by construction. □

For example, suppose 0110011 is sent and $\mathbf{r} = 0110111$ is received. Its syndrome is the sum of the columns at the 1s of $\mathbf{r}$, which is $\mathbf{h}_2 + \mathbf{h}_3 + \mathbf{h}_5 + \mathbf{h}_6 + \mathbf{h}_7 = (0,1,0) + (0,1,1) + (1,0,1) + (1,1,0) + (1,1,1) = (1,0,1)$, binary for 5. Flipping bit 5 recovers 0110011, and reading positions $3, 5, 6, 7$ recovers the message 1011.

The numbers fit exactly. The sets $B(\mathbf{c}) = \{\mathbf{x} \mid d(\mathbf{x}, \mathbf{c}) \le 1\}$ for the 16 codewords $\mathbf{c}$ are pairwise disjoint: if $\mathbf{x} \in B(\mathbf{c}) \cap B(\mathbf{c}')$, then $d(\mathbf{c}, \mathbf{c}') \le 2$ by the triangle inequality, so $\mathbf{c} = \mathbf{c}'$ by Proposition 4.2.33. Each $B(\mathbf{c})$ has $1 + 7 = 8$ elements. Together they contain $16 \cdot 8 = 128 = 2^7$ vectors, all of $\mathbb{F}_2^7$: every word of length 7 is within distance 1 of exactly one codeword. Codes with this property are called **perfect**. In terms of the syndrome map $T_H : \mathbb{F}_2^7 \to \mathbb{F}_2^3$, which is surjective, the 8 possible syndromes correspond to "no error" and to the 7 possible error positions, and the count $7 = 4 + 3$ is rank–nullity. The Hamming code transmits 4 bits in 7, against 4 in 12 for the triple repetition code. Dual codes, which reverse the roles of the rows of H and the codewords, return in Section 12.4.

Exercises

Exercise 4.2.35. ROUTINE Let $A = \begin{pmatrix} 1 & i & 0 & 1 \\ i & -1 & 1 & 2i \\ 0 & 0 & 1+i & -1+i \end{pmatrix} \in \mathbb{C}^{3\times 4}$. Find bases of $\ker T_A$ and of $\operatorname{im} T_A$, and check rank–nullity.

Solution on page 1298

Exercise 4.2.36. ROUTINE Let $M = \begin{pmatrix} 0 & 0 & 1 & 1 \\ -1 & -2 & 2 & 0 \\ -2 & 2 & 3 & -1 \end{pmatrix}$, a matrix with integer entries. Find $\operatorname{rank} M$ and a basis of $\ker T_M$ over $\mathbb{Q}$ and over $\mathbb{F}_3$. Explain why the rational kernel vector, read modulo 3, lies in the kernel over $\mathbb{F}_3$, and why the converse fails.

Solution on page 1298

Exercise 4.2.37. ROUTINE Let $A \in \mathbb{C}^{m\times n}$. Since real scalars are complex scalars, $T_A : \mathbb{C}^n \to \mathbb{C}^m$ is also a linear map of vector spaces over $\mathbb{R}$. Show that its rank over $\mathbb{R}$ is $2 \operatorname{rank} A$ and that $\dim_{\mathbb{R}} \ker T_A = 2 \dim_{\mathbb{C}} \ker T_A$.

Solution on page 1299

Exercise 4.2.38. ROUTINE Prove or disprove. All spaces are finite-dimensional.

(a) Every $T \in \mathrm{L}(\mathbb{R}^7, \mathbb{R}^4)$ has $\dim \ker T \ge 3$.

(b) If $T \in \mathrm{L}(V, W)$ is surjective and $\dim V = 5$, then $\dim W \le 5$.

(c) There is an injective linear map $F^{2\times 3} \to F[x]_{\le 4}$.

(d) If $S, T \in \mathrm{L}(V, W)$ have the same kernel, then they have the same image.

(e) If $T \in \mathrm{L}(V)$ satisfies $\ker T = \operatorname{im} T$, then $\dim V$ is even.

Solution on page 1299

Exercise 4.2.39. ROUTINE Let $T : F[x]_{\le 3} \to F^2$, $T(p) = (p(1), p'(1))$, where p' is the formal derivative. Show that T is surjective, find $\dim \ker T$, and show that $(x-1)^2, (x-1)^3$ is a basis of $\ker T$, without solving $T(p) = \mathbf{0}$.

Solution on page 1300

Exercise 4.2.40. STANDARD Let p be a prime and $n \ge 1$, and let D be the formal derivative on $\mathbb{F}_p[x]_{\le n}$. Find nullity D and rank D, and describe $\operatorname{im} D$. Work out the case $p = 3$, $n = 7$.

Solution on page 1300

Exercise 4.2.41. STANDARD Let $n \ge 1$ and $T : F^{n\times n} \to F^{n\times n}$, $T(X) = X - X^{\mathsf{T}}$.

(a) Show that $\ker T$ is the space of symmetric matrices and that $\operatorname{rank} T = n(n-1)/2$.

(b) If $1+1 \neq 0$ in F, show that $\operatorname{im} T$ is the space of skew-symmetric matrices.

(c) If $1+1=0$ in F, show that $\operatorname{im} T$ is the space of symmetric matrices with zero diagonal. In particular, over $\mathbb{F}_2$ the image is a proper subspace of the symmetric matrices, although every value of T is symmetric.

Solution on page 1300

Exercise 4.2.42. STANDARD Let $n \geq 1$, and let $Z_n \subseteq F^{n\times n}$ be the set of matrices all of whose row sums and column sums are 0.

(a) Show that $\dim Z_n = (n-1)^2$. (Consider the map $\Phi : F^{n\times n} \to F^{2n}$ sending X to its n row sums followed by its n column sums.)

(b) Show that the matrices $U_{ij} - U_{in} - U_{nj} + U_{nn}$, for $1 \leq i, j \leq n-1$, form a basis of Z_n.

Solution on page 1301

Exercise 4.2.43. STANDARD Let $A \in F^{m\times n}$ and $p \geq 1$, and let $L_A : F^{n\times p} \to F^{m\times p}$, $L_A(X) = AX$. Show that $\operatorname{rank} L_A = p \cdot \operatorname{rank} A$.

Solution on page 1302

Exercise 4.2.44. STANDARD Let $T \in \mathrm{L}(V, W)$.

(a) Let U be a finite-dimensional subspace of V. Show that $\dim \operatorname{im}(T\restriction_U) = \dim U - \dim(U \cap \ker T)$.

(b) Let V be finite-dimensional. Show that there is a subspace U of V with $U \cap \ker T = \{\mathbf{0}\}$ and $\operatorname{im}(T\restriction_U) = \operatorname{im} T$, and that every such U has $\dim U = \operatorname{rank} T$.

(c) For $T : \mathbb{R}^3 \to \mathbb{R}^2$, $T(x, y, z) = (x + y, y + z)$, give two different subspaces U as in (b).

Solution on page 1302

Exercise 4.2.45. STANDARD Find the error in the following argument, show that its claim is false, and repair it.

Claim. Let V be finite-dimensional, $T \in \mathrm{L}(V, W)$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be a basis of V such that $T(\mathbf{v}_{k+1}), \ldots, T(\mathbf{v}_n)$ is a basis of $\operatorname{im} T$. Then $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is a basis of $\ker T$.

Proof. By rank–nullity, $\dim \ker T = n - (n-k) = k$. The list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is linearly independent, as a sublist of a basis, and it has length $k = \dim \ker T$. By Theorem 4.1.10(b), it is a basis of $\ker T$.

Solution on page 1302

Exercise 4.2.46. STANDARD Let $n \geq 1$ and $0 \leq k \leq n$. Show that there is $T \in \mathrm{L}(F^n)$ with $T^2 = 0$ and $\operatorname{rank} T = k$ if and only if $2k \leq n$.

Solution on page 1303

Exercise 4.2.47. STANDARD Let F be any field, and let $T : F[x]_{\leq 3} \to F^4$, $T(p) = (p(0), p'(0), p(1), p'(1))$.

(a) Show that T is bijective. So for any prescribed values and slopes at 0 and 1 there is exactly one polynomial of degree at most 3 with them.

(b) Find the p with $p(0) = p'(0) = p'(1) = 0$ and $p(1) = 1$.

Solution on page 1303

Exercise 4.2.48. STANDARD With Δ as in Example 4.2.28, find $p \in \mathbb{Q}[x]_{\leq 4}$ with $\Delta p = x^3$, and deduce that $1^3 + 2^3 + \cdots + N^3 = (N(N+1)/2)^2$.

Solution on page 1303

Exercise 4.2.49. STANDARD Let V be finite-dimensional with $\dim V = n$.

(a) Let $U_1, \ldots, U_k$ be subspaces of V. Show that

$$\dim(U_1 \cap \cdots \cap U_k) \geq \dim U_1 + \cdots + \dim U_k - (k-1)n.$$

(b) Let $n \geq 2$. Deduce that any $n-1$ subspaces of V of dimension $n-1$ have a nonzero vector in common.

(c) Show that n subspaces of dimension $n-1$ need not have one.

Solution on page 1304

Exercise 4.2.50. STANDARD Let V be finite-dimensional and $T \in \mathrm{L}(V)$. Show that the following are equivalent:

(i) $\ker T \cap \operatorname{im} T = \{\mathbf{0}\}$;
(ii) $\ker T^2 = \ker T$;
(iii) $\operatorname{rank} T^2 = \operatorname{rank} T$;
(iv) $\operatorname{im} T^2 = \operatorname{im} T$;
(v) $\ker T + \operatorname{im} T = V$.

Show by an example on an infinite-dimensional space that (i) and (iv) are not equivalent in general.

Solution on page 1304

Exercise 4.2.51. HARD Let V be finite-dimensional with $\dim V = n$, and let $T \in \mathrm{L}(V)$.

(a) Show that $\ker T^k = \ker T^{k+1}$ for some k with $0 \leq k \leq n$.

(b) Show that if $\ker T^k = \ker T^{k+1}$, then $\ker T^m = \ker T^k$ for every $m \geq k$. Deduce that $\ker T^{2n} = \ker T^n$.

(c) Deduce that $\ker T^n \cap \operatorname{im} T^n = \{\mathbf{0}\}$ and $\dim \ker T^n + \dim \operatorname{im} T^n = n$. In particular, for every $A \in F^{n\times n}$, $\ker T_{A^n} \cap \operatorname{im} T_{A^n} = \{\mathbf{0}\}$.

Solution on page 1305

Exercise 4.2.52. HARD Let V be finite-dimensional with $\dim V = n$, let $T \in \mathrm{L}(V)$, and for $k \geq 1$ let $d_k = \dim \ker T^k - \dim \ker T^{k-1}$.

(a) Show that $d_k = \dim\big(\operatorname{im} T^{k-1} \cap \ker T\big)$. (Restrict T^{k-1} to $\ker T^k$.)

(b) Deduce that $d_1 \geq d_2 \geq d_3 \geq \cdots$.

(c) Suppose $T^m = 0$ for some $m \geq 1$. Show that $\dim \ker T \geq n/m$, so that $\operatorname{rank} T \leq (m-1)n/m$.

Solution on page 1305

Exercise 4.2.53. HARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$.

(a) Show that $\mathbf{x} \mapsto B\mathbf{x}$ maps $\ker T_{I_m - AB}$ injectively into $\ker T_{I_n - BA}$.

(b) Deduce that $\dim \ker(I_m - AB) = \dim \ker(I_n - BA)$.

(c) Deduce that $I_m - AB$ is invertible if and only if $I_n - BA$ is.

Solution on page 1306

Exercise 4.2.54. HARD Let S be a subspace of $F^{n\times n}$ in which every nonzero matrix is invertible.

(a) Show that $\dim S \le n$.

(b) Show that $S = \left\{ \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \;\middle|\; a, b \in \mathbb{R} \right\}$ is such a subspace of $\mathbb{R}^{2\times 2}$ with $\dim S = 2$.

(c) Find such a subspace of $\mathbb{F}_2^{2\times 2}$ of dimension 2.

Solution on page 1306

Exercise 4.2.55. CHALLENGE For $\mathbf{x}, \mathbf{y} \in \mathbb{F}_2^n$, let $\mathbf{x}\cdot\mathbf{y} = x_1y_1 + \cdots + x_ny_n \in \mathbb{F}_2$.

(a) Let C be a subspace of $\mathbb{F}_2^n$ with $\dim C = k$, and let $C^\perp = \{\mathbf{y} \in \mathbb{F}_2^n \mid \mathbf{c}\cdot\mathbf{y} = 0 \text{ for all } \mathbf{c} \in C\}$. Show that $C^\perp$ is a subspace of dimension $n-k$.

(b) (*Eventown.*) A town has n residents, who form clubs. Every club has an even number of members, every two clubs have an even number of members in common, and no two clubs have exactly the same members. Show that there are at most $2^{\lfloor n/2 \rfloor}$ clubs, and that this many is possible.

Solution on page 1306

Exercise 4.2.56. STANDARD BEYOND 21-242 Let $r \ge 2$, $n = 2^r - 1$, and let $H_r \in \mathbb{F}_2^{r\times n}$ be a matrix whose columns are the n nonzero vectors of $\mathbb{F}_2^r$, in some order. Let $C_r = \ker T_{H_r}$, the Hamming code of length n.

(a) Show that C_r is an $[n, n-r]$ code.

(b) Show that its minimum distance is 3.

(c) Show that every $\mathbf{x} \in \mathbb{F}_2^n$ is within distance 1 of exactly one codeword.

Solution on page 1307

Exercise 4.2.57. ROUTINE BEYOND 21-242 Use the Hamming code of Example 4.2.32.

(a) Encode the message 0110.

(b) Decode the received words 1000110 and 1101011, assuming each has at most one flipped bit.

(c) The codeword 0000000 is sent, and bits 1 and 2 are flipped. What does syndrome decoding return?

Solution on page 1308

4.3 Rank inequalities and the transpose

Rank–nullity measures one matrix at a time. This section compares the ranks of matrices built from one another. Multiplying by an invertible matrix does not change the rank, and multiplying by an arbitrary matrix can only lower it:

$$\operatorname{rank}(AB) \le \min(\operatorname{rank} A, \operatorname{rank} B).$$

We prove this in three ways, by comparing images, by comparing kernels, and by restricting A to the image of B, and the last proof says exactly how much rank is lost. The transpose A^{T} has the same rank as A, although its columns are the rows of A and live in a different space. This equality, row rank equals column rank, is the main theorem of the section. It completes the count of dimensions of the four subspaces attached to a matrix. Finally, matrices of rank one are exactly the products $\mathbf{u}\mathbf{v}^{\mathsf{T}}$, rank is subadditive, and the column–row factorization $A = CR$ writes a matrix of rank r as a sum of r matrices of rank one, which is the fewest possible.

Throughout, F is a field. For $A \in F^{m\times n}$ we write $\operatorname{im} A = \operatorname{im} T_A \subseteq F^m$ and $\ker A = \ker T_A \subseteq F^n$ for the column space and the null space (Definition 2.6.17). So $\operatorname{rank} A = \dim \operatorname{im} A$ (Theorem 4.2.7) and $\dim \ker A = n - \operatorname{rank} A$ (Theorem 4.2.11).

4.3.1 Invertible factors

We already know that $\operatorname{rank}(GA) = \operatorname{rank} A$ for invertible G, because $\operatorname{rref}(GA) = \operatorname{rref}(A)$ (Proposition 3.5.2(c)), and that $\operatorname{rank}(AH) = \operatorname{rank} A$ for invertible H, from the uniqueness of the rank normal form (Exercise 3.5.41(c)). The second proof was roundabout, because row reduction cannot see column operations. Now that rank is a dimension, both statements have short proofs. They are also the reason the rank of a linear map can be read off any of its matrices: changing bases multiplies $[T]_{\mathcal{C}\mathcal{B}}$ on the left and on the right by invertible matrices (Section 4.5), and that cannot change the rank.

Intuition (Outputs and inputs). In GA the matrix G acts after A, on the outputs $A\mathbf{x}$. An invertible G is injective, so it never sends a nonzero output to $\mathbf{0}$: $GA\mathbf{x} = \mathbf{0}$ only when $A\mathbf{x} = \mathbf{0}$, and $\ker(GA) = \ker A$. But G moves the outputs, so $\operatorname{im}(GA)$, the set of vectors $G\mathbf{y}$ with $\mathbf{y} \in \operatorname{im} A$, is in general a different subspace of F^m. It has the same dimension, since an injective map preserves dimension.

In AH the matrix H acts before A, on the inputs. An invertible H is surjective, so AH still sees every input, and $\operatorname{im}(AH) = \operatorname{im} A$. But the kernel moves: $AH\mathbf{x} = \mathbf{0}$ exactly when $H\mathbf{x} \in \ker A$. So each of GA and AH keeps one of the two subspaces and moves the other by an invertible map.

Proposition 4.3.1 (Invertible factors preserve rank). Let $A \in F^{m\times n}$, and let $G \in F^{m\times m}$ and $H \in F^{n\times n}$ be invertible.

(a) $\ker(GA) = \ker A$, and $\operatorname{rank}(GA) = \operatorname{rank} A$.
(b) $\operatorname{im}(AH) = \operatorname{im} A$, and $\operatorname{rank}(AH) = \operatorname{rank} A$.

In particular, $\operatorname{rank}(GAH) = \operatorname{rank} A$.

The first proof is the lecture's. It compares images, using the restriction identity $\operatorname{im}(TS) = \operatorname{im}(T|_{\operatorname{im} S})$.

Proof (by restriction, comparing images). ROUTINE

Uses. Theorem 2.4.2 (The matrix of a composite), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence), Proposition 4.2.3 (Properties of restriction), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 2.6.15 (Kernels and images of composites), Theorem 4.2.7 (The image of T_A)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. Write $T_{GA} = T_G \circ T_A$. By Proposition 4.2.3(b), $\operatorname{im}(GA)$ is the image of T_G restricted to $\operatorname{im} A$. What do you know about T_G?
Hint 2. T_G is injective, so its restriction to $\operatorname{im} A$ is an injective linear map onto $\operatorname{im}(GA)$. For AH, what is $\operatorname{im} T_H$?
Sketch. $\operatorname{im}(GA) = \operatorname{im}(T_G|_{\operatorname{im} A})$, and T_G is injective because $T_{G^{-1}}$ is a left inverse, so the restriction carries $\operatorname{im} A$ injectively onto $\operatorname{im}(GA)$ and the dimensions agree. On the other side, $\operatorname{im}(AH) = \operatorname{im}(T_A|_{\operatorname{im} H}) = \operatorname{im}(T_A|_{F^n}) = \operatorname{im} A$, because T_H is surjective. The kernel statement in (a) is Proposition 2.6.15(a).

By Theorem 2.4.2, $T_{GA} = T_G \circ T_A$ and $T_{AH} = T_A \circ T_H$. Since $G^{-1}G = I_m$ and $HH^{-1} = I_n$, the map T_G is injective (Proposition 2.5.4) and T_H is surjective (Proposition 2.5.5).

(a) By Proposition 4.2.3(b), $\operatorname{im}(GA) = \operatorname{im}(T_G|_{\operatorname{im} A})$. The restriction $T_G|_{\operatorname{im} A}$ is linear and injective (Proposition 4.2.3(a), (c)), so Proposition 4.2.6(a), applied to it, gives $\dim \operatorname{im}(GA) = \dim \operatorname{im} A$. That is, $\operatorname{rank}(GA) = \operatorname{rank} A$ (Theorem 4.2.7). Since T_G is injective, $\ker(GA) = \ker A$ by Proposition 2.6.15(a).

(b) By Proposition 4.2.3(b), $\operatorname{im}(AH) = \operatorname{im}(T_A|_{\operatorname{im} H})$. Since $\operatorname{im} H = F^n$, this restriction is T_A itself, so $\operatorname{im}(AH) = \operatorname{im} A$, and in particular $\operatorname{rank}(AH) = \operatorname{rank} A$.

Finally, $\operatorname{rank}(GAH) = \operatorname{rank}(G(AH)) = \operatorname{rank}(AH) = \operatorname{rank} A$ by (a) and (b). □

The lecture remarks that the same statements follow from kernels and rank–nullity. Here is that proof.

Proof (by kernels and rank–nullity). ROUTINE

> *Uses.* Proposition 2.6.15 (Kernels and images of composites), Theorem 4.2.11 (Rank–nullity), Proposition 4.2.3 (Properties of restriction), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 4.1.21 (Dimensions of subspaces)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* GA and AH have n columns, as A does. By rank–nullity it suffices to compare $\dim\ker(GA)$ and $\dim\ker(AH)$ with $\dim\ker A$.
> *Hint 2.* G can be cancelled from $GA\mathbf{x}=\mathbf{0}$. For AH, show that $\mathbf{x}\in\ker(AH)$ if and only if $H\mathbf{x}\in\ker A$, and use T_H to move one kernel onto the other.
> *Sketch.* If $GA\mathbf{x}=\mathbf{0}$, then $A\mathbf{x}=G^{-1}GA\mathbf{x}=\mathbf{0}$, so $\ker(GA)=\ker A$, and rank–nullity gives $\operatorname{rank}(GA)=n-\dim\ker A=\operatorname{rank}A$. Next, $\mathbf{x}\in\ker(AH)$ if and only if $H\mathbf{x}\in\ker A$, so T_H restricts to an injective linear map from $\ker(AH)$ onto $\ker A$. The kernels have the same dimension, so $\operatorname{rank}(AH)=\operatorname{rank}A$ by rank–nullity, and then $\operatorname{im}(AH)\subseteq\operatorname{im}A$ with equal dimensions forces $\operatorname{im}(AH)=\operatorname{im}A$.

(a) By Proposition 2.6.15(a), $\ker A\subseteq\ker(GA)$. Conversely, if $GA\mathbf{x}=\mathbf{0}$, then $A\mathbf{x}=G^{-1}(GA\mathbf{x})=\mathbf{0}$. So $\ker(GA)=\ker A$. The matrices GA and A both have n columns, so by Theorem 4.2.11(a),

$$\operatorname{rank}(GA)=n-\dim\ker(GA)=n-\dim\ker A=\operatorname{rank}A.$$

(b) For $\mathbf{x}\in F^n$, we have $AH\mathbf{x}=\mathbf{0}$ if and only if $H\mathbf{x}\in\ker A$. So T_H maps $\ker(AH)$ into $\ker A$. Since $H^{-1}H=I_n$, T_H is injective, so its restriction to $\ker(AH)$ is linear and injective (Proposition 4.2.3). It maps onto $\ker A$: if $\mathbf{y}\in\ker A$, then $\mathbf{x}=H^{-1}\mathbf{y}$ satisfies $AH\mathbf{x}=A\mathbf{y}=\mathbf{0}$ and $H\mathbf{x}=\mathbf{y}$. By Proposition 4.2.6(a), $\dim\ker(AH)=\dim\ker A$, and since AH has n columns, Theorem 4.2.11(a) gives

$$\operatorname{rank}(AH)=n-\dim\ker(AH)=n-\dim\ker A=\operatorname{rank}A.$$

Finally, $\operatorname{im}(AH)\subseteq\operatorname{im}A$ by Proposition 2.6.15(b), and these subspaces of F^m have the same dimension, so they are equal (Proposition 4.1.21(b)).

As in the first proof, $\operatorname{rank}(GAH)=\operatorname{rank}A$ follows from (a) and (b). □

The two proofs split the work in opposite ways. In the first, the left factor needs an argument (an injective map preserves dimension) and the right factor is free (a surjective map on the inputs changes nothing). In the second, the left factor is free (the kernel does not change) and the right factor needs the argument. The same split reappears in Section 4.3.2, where an arbitrary product is compared with its factors.

By Exercise 3.5.41(d), two matrices $A,B\in F^{m\times n}$ satisfy $B=GAH$ for some invertible G and H if and only if they have the same rank. So the rank is the only information about A that row and column operations together preserve. In particular, similar matrices $B=PAP^{-1}$ have the same rank, a fact we return to in Section 4.5.

Exercise 4.3.2. ROUTINE Let $A=\begin{pmatrix}1&2\\2&4\end{pmatrix}$, $G=\begin{pmatrix}1&0\\-2&1\end{pmatrix}$, and $H=\begin{pmatrix}1&-2\\0&1\end{pmatrix}$, over $\mathbb{Q}$. Compute GA and AH, and find the kernel and the image of each of A, GA, and AH. Which subspaces agree, and which do not?

Solution on page 1308

4.3.2 The rank of a product

Intuition (A pipeline is no wider than its narrowest stage). For $\mathbf{x}\in F^p$, $AB\mathbf{x}=A(B\mathbf{x})$: first B, then A. Every output of AB is an output of A, so $\operatorname{im}(AB)\subseteq\operatorname{im}A$; the product cannot reach a direction that A cannot reach. On the other hand, A only ever receives the vectors $B\mathbf{x}$, which fill a space of dimension $\operatorname{rank}B$, and a linear map does not raise dimension. So

$$\operatorname{rank}(AB)\le\operatorname{rank}A\quad\text{and}\quad\operatorname{rank}(AB)\le\operatorname{rank}B.$$

The first bound is about where the outputs land and is immediate. The second is about how many independent directions enter A, and it needs a dimension argument.

Theorem 4.3.3 (Rank of a product).
(a) Let $A \in F^{m\times n}$ and $B \in F^{n\times p}$. Then $\operatorname{im}(AB) \subseteq \operatorname{im} A$ and $\ker B \subseteq \ker(AB)$, and

$$\operatorname{rank}(AB) \leq \min(\operatorname{rank} A, \operatorname{rank} B).$$

(b) More generally, let U and V be finite-dimensional, and let $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$. Then

$$\operatorname{rank}(TS) \leq \min(\operatorname{rank} T, \operatorname{rank} S).$$

Part (a) is part (b) for $S = T_B$ and $T = T_A$, since $T_{AB} = T_A \circ T_B$ (Theorem 2.4.2) and $\operatorname{rank} A = \operatorname{rank} T_A$ (Definition 4.2.14); the two containments in (a) are Proposition 2.6.15. So we prove (b). In both proofs below, the bound by $\operatorname{rank} T$ comes from $\operatorname{im}(TS) \subseteq \operatorname{im} T$. They differ in how they prove the bound by $\operatorname{rank} S$.

Proof (comparing images). ROUTINE

> *Uses.* Proposition 2.6.15 (Kernels and images of composites), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Proposition 4.2.3 (Properties of restriction), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Corollary 4.1.11 (Spanning lists are long)
> *Techniques.* Restrict to a subspace (Technique 4.2.5)
> *Hint 1.* $\operatorname{im}(TS) \subseteq \operatorname{im} T$, which gives one inequality at once.
> *Hint 2.* For the other, $\operatorname{im}(TS) = \operatorname{im}(T{\restriction}_{\operatorname{im} S})$ consists of the values of T on $\operatorname{im} S$. Take a basis of $\operatorname{im} S$ and push it forward with T.
> *Hint 3.* A space spanned by r vectors has dimension at most r.
> *Sketch.* $\operatorname{im}(TS) \subseteq \operatorname{im} T$ gives $\operatorname{rank}(TS) \leq \operatorname{rank} T$. If $\mathbf{s}_1, \dots, \mathbf{s}_r$ is a basis of $\operatorname{im} S$, then $\operatorname{im}(TS) = \operatorname{im}(T{\restriction}_{\operatorname{im} S})$ is spanned by $T(\mathbf{s}_1), \dots, T(\mathbf{s}_r)$, so its dimension is at most $r = \operatorname{rank} S$.

Since U and V are finite-dimensional, $\operatorname{im} S$, $\operatorname{im} T$, and $\operatorname{im}(TS)$ are finite-dimensional (Theorem 4.2.11(b)), so all three ranks are defined.

The bound by $\operatorname{rank} T$. By Proposition 2.6.15(b), $\operatorname{im}(TS) \subseteq \operatorname{im} T$, so $\operatorname{rank}(TS) \leq \operatorname{rank} T$ by Proposition 4.1.21(a).

The bound by $\operatorname{rank} S$. Let $r = \operatorname{rank} S$ and let $\mathbf{s}_1, \dots, \mathbf{s}_r$ be a basis of $\operatorname{im} S$ (the empty list if $r = 0$). By Proposition 4.2.3(b) and Proposition 2.1.16(a),

$$\operatorname{im}(TS) = \operatorname{im}(T{\restriction}_{\operatorname{im} S}) = \operatorname{span}(T(\mathbf{s}_1), \dots, T(\mathbf{s}_r)).$$

So $\operatorname{im}(TS)$ is spanned by a list of length r, and $\dim \operatorname{im}(TS) \leq r$ by Corollary 4.1.11(a). That is, $\operatorname{rank}(TS) \leq \operatorname{rank} S$. □

The second proof moves the comparison to the domain U, where S and TS have a common domain and rank–nullity applies to both.

Proof (comparing kernels, with rank–nullity). ROUTINE

> *Uses.* Proposition 2.6.15 (Kernels and images of composites), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.2.11 (Rank–nullity)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* The bound by $\operatorname{rank} T$ is the image comparison $\operatorname{im}(TS) \subseteq \operatorname{im} T$. For the bound by $\operatorname{rank} S$, compare kernels instead: which of $\ker S$ and $\ker(TS)$ contains the other?
> *Hint 2.* $\ker S \subseteq \ker(TS)$, both subspaces of U. Apply rank–nullity to S and to TS.
> *Sketch.* $\operatorname{rank}(TS) \leq \operatorname{rank} T$ because $\operatorname{im}(TS) \subseteq \operatorname{im} T$. Since $\ker S \subseteq \ker(TS)$, rank–nullity on U gives $\operatorname{rank}(TS) = \dim U - \dim \ker(TS) \leq \dim U - \dim \ker S = \operatorname{rank} S$.

As in the first proof, $\operatorname{im}(TS) \subseteq \operatorname{im} T$ (Proposition 2.6.15(b)), so $\operatorname{rank}(TS) \leq \operatorname{rank} T$ (Proposition 4.1.21(a)).

By Proposition 2.6.15(a), $\ker S \subseteq \ker(TS)$. Both are subspaces of the finite-dimensional space U, so $\dim \ker S \leq \dim \ker(TS)$ (Proposition 4.1.21(a)). By Theorem 4.2.11(b), applied to S and to TS, which are both defined on U,

$$\begin{aligned} \operatorname{rank}(TS) &= \dim U - \dim \ker(TS) \\ &\leq \dim U - \dim \ker S = \operatorname{rank} S, \end{aligned}$$

as desired. □

Both inequalities can be strict, even at the same time.

Example 4.3.4 (A product of rank zero). Let $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, so $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_2 = \mathbf{e}_1$. Then $\operatorname{rank} N = 1$, but $N^2 = 0$ has rank $0 < \min(\operatorname{rank} N, \operatorname{rank} N)$. In NN, the left factor kills exactly what the right factor produces: $\operatorname{im} N = \operatorname{span}(\mathbf{e}_1) = \ker N$. The order of the factors matters too: with $M = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $MN = N$ has rank 1 but $NM = 0$, so $\operatorname{rank}(AB)$ and $\operatorname{rank}(BA)$ can differ even for square matrices.

What a product loses

The example shows where the rank goes. AB applies A to the vectors of $\operatorname{im} B$, and A kills those that lie in $\ker A$. Restricting A to $\operatorname{im} B$ makes this exact. This is the lecture's restriction view of a composite, and it gives the third proof of the bound by $\operatorname{rank} B$.

Proposition 4.3.5 (Rank of a product, exactly). Let $S \in \mathrm{L}(U, V)$ and $T \in \mathrm{L}(V, W)$, with U finite-dimensional.

(a) $\operatorname{rank}(TS) = \operatorname{rank} S - \dim(\operatorname{im} S \cap \ker T)$.

(b) $\operatorname{rank}(TS) = \operatorname{rank} S$ if and only if $\operatorname{im} S \cap \ker T = \{\mathbf{0}\}$. If V is also finite-dimensional, then $\operatorname{rank}(TS) = \operatorname{rank} T$ if and only if $\operatorname{im} S + \ker T = V$.

For matrices $A \in F^{m\times n}$ and $B \in F^{n\times p}$, (a) reads

$$\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A). \tag{4.3.1}$$

Proof (by restriction). STANDARD

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.2.3 (Properties of restriction), Exercise 4.2.44, Proposition 2.6.15 (Kernels and images of composites), Proposition 4.1.21 (Dimensions of subspaces), Exercise 2.6.39, Theorem 2.4.2 (The matrix of a composite)
Techniques. Restrict to a subspace (Technique 4.2.5), Dimension counting (Technique 4.2.24)
Hint 1. $\operatorname{im}(TS) = \operatorname{im}(T|_{\operatorname{im} S})$. What is the kernel of $T|_{\operatorname{im} S}$?
Hint 2. Apply rank–nullity to $T|_{\operatorname{im} S}$, whose domain is the finite-dimensional space $\operatorname{im} S$.
Hint 3. For the last statement, $\operatorname{im}(TS) \subseteq \operatorname{im} T$; when do two finite-dimensional nested subspaces have the same dimension? Then use Exercise 2.6.39(b).
Sketch. The restriction $R = T|_{\operatorname{im} S}$ has domain $\operatorname{im} S$, of dimension $\operatorname{rank} S$, kernel $\operatorname{im} S \cap \ker T$, and image $\operatorname{im}(TS)$. Rank–nullity for R is (a), and (a) gives the first half of (b). For the second half, $\operatorname{im}(TS) \subseteq \operatorname{im} T$, so the ranks agree exactly when the images agree, which by Exercise 2.6.39(b) means $\operatorname{im} S + \ker T = V$.

(a) Since U is finite-dimensional, so is $\operatorname{im} S$, and $\dim \operatorname{im} S = \operatorname{rank} S$ (Theorem 4.2.11(b)). Let $R = T|_{\operatorname{im} S} : \operatorname{im} S \to W$. By Proposition 4.2.3, R is linear, $\ker R = \operatorname{im} S \cap \ker T$, and $\operatorname{im} R = \operatorname{im}(TS)$. Rank–nullity for R (Theorem 4.2.11(b)) gives

$$\operatorname{rank} S = \dim \operatorname{im} S = \dim(\operatorname{im} S \cap \ker T) + \dim \operatorname{im}(TS),$$

which is (a). (This is Exercise 4.2.44(a) for the subspace $\operatorname{im} S$.)

(b) By (a), $\operatorname{rank}(TS) = \operatorname{rank} S$ if and only if $\dim(\operatorname{im} S \cap \ker T) = 0$, that is, $\operatorname{im} S \cap \ker T = \{\mathbf{0}\}$. Now let V be finite-dimensional, so that $\operatorname{im} T$ is finite-dimensional. Since $\operatorname{im}(TS) \subseteq \operatorname{im} T$ (Proposition 2.6.15(b)), Proposition 4.1.21(b) shows that $\operatorname{rank}(TS) = \operatorname{rank} T$ if and only if $\operatorname{im}(TS) = \operatorname{im} T$, and by Exercise 2.6.39(b) this holds if and only if $\operatorname{im} S + \ker T = V$.

The matrix statement is (a) for $S = T_B$ and $T = T_A$ (Theorem 2.4.2). □

Intuition (Three proofs of $\operatorname{rank}(TS) \le \operatorname{rank} S$*).* The image proof works in the middle space V: it pushes a basis of $\operatorname{im} S$ forward with T and observes that at most $\operatorname{rank} S$ vectors come out. The kernel proof works in the domain U: whatever S kills, TS kills too, and rank–nullity converts a larger kernel into a smaller image. The restriction proof is the sharpest, because it computes the loss instead of bounding it: TS loses exactly the directions that S produces and T destroys, $\operatorname{im} S \cap \ker T$. It answers the question of when the inequality is an equality, and it also gives lower bounds for $\operatorname{rank}(TS)$, which are the subject

of Exercise 4.3.30 and Exercise 4.3.31. When all you need is the inequality, the image proof is the one to remember.

Example 4.3.6 (Powers of a square matrix). Let $A \in F^{n\times n}$. By (4.3.1) with $B = A$,

$$\operatorname{rank}(A^2) = \operatorname{rank} A - \dim(\operatorname{im} A \cap \ker A).$$

So $\operatorname{rank}(A^2) = \operatorname{rank} A$ if and only if $\operatorname{im} A \cap \ker A = \{\mathbf{0}\}$. For the projection $P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $\operatorname{im} P = \operatorname{span}(\mathbf{e}_1)$ and $\ker P = \operatorname{span}(\mathbf{e}_2)$ meet only in $\mathbf{0}$, and indeed $P^2 = P$. For N of Example 4.3.4, $\operatorname{im} N = \ker N$, and $\operatorname{rank}(N^2) = 1 - 1 = 0$.

With $B = A^k$ instead, the formula gives $\operatorname{rank}(A^{k+1}) = \operatorname{rank}(A^k) - \dim(\operatorname{im} A^k \cap \ker A)$. The subspaces $\operatorname{im} A^k$ shrink as k grows, so the drops $\operatorname{rank}(A^k) - \operatorname{rank}(A^{k+1})$ can only decrease. This is Exercise 4.2.52 in the language of images, and by Exercise 4.2.51 the ranks stop decreasing by $k = n$.

Exercise 4.3.7. ROUTINE Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $m < n$.

(a) Show that $BA \in F^{n\times n}$ is not invertible.

(b) Give an example with $AB = I_m$.

(c) Show that if $AB = I_m$, then $\operatorname{rank}(BA) = m$.

Solution on page 1308

4.3.3 Row rank equals column rank

Intuition (Why this is surprising). Consider

$$A = \begin{pmatrix} 1 & 2 & 1 & 4 \\ 2 & 4 & 0 & 6 \\ 1 & 2 & -1 & 2 \end{pmatrix} \in \mathbb{Q}^{3\times 4}.$$

Its four columns are vectors in $\mathbb{Q}^3$. They satisfy $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_4 = 3\mathbf{a}_1 + \mathbf{a}_3$, and $\mathbf{a}_1, \mathbf{a}_3$ are independent, so exactly two of the columns are independent. Its three rows are vectors in $\mathbb{Q}^4$. They satisfy one relation, $\text{row}_1 - \text{row}_2 + \text{row}_3 = \mathbf{0}$, and any two of them are independent, so again exactly two of the rows are independent.

Nothing in the definitions suggests that these two numbers should agree. The columns satisfy two independent relations and the rows only one; the columns live in F^3 and the rows in F^4. For a 3×100 matrix, one count is about 100 vectors in F^3 and the other is about 3 vectors in F^{100}. Yet the two counts always agree. Equivalently, the numbers of independent relations always differ by exactly the difference between the numbers of columns and rows: here $2 - 1 = 4 - 3$.

The columns of A^{T} are the rows of A, written as columns (Definition 2.4.21). So $\operatorname{im} A^{\mathsf{T}} \subseteq F^n$ is the span of the rows of A (Proposition 2.6.18), and $\operatorname{rank} A^{\mathsf{T}}$ is its dimension.

Theorem 4.3.8 (Row rank equals column rank). For every $A \in F^{m\times n}$,

$$\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A.$$

That is, the span of the rows of A, viewed as vectors in F^n, has the same dimension as the span of its columns in F^m.

The first proof reduces A to its rank normal form, where the statement is obvious.

Proof (via the rank normal form). ROUTINE

Uses. Theorem 3.5.27 (Rank normal form), Proposition 2.4.23 (Transpose of a product), Proposition 2.5.17 (Algebra of inverses), Proposition 4.3.1 (Invertible factors preserve rank), Proposition 2.6.18 (The column space is spanned by the columns), Theorem 4.2.7 (The image of T_A)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. The statement is obvious for $N_k = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix}$. Reduce to it.
Hint 2. Transpose $GAH = N_k$. Which factors of the result are invertible, and what is the rank of N_k^{T}?
Sketch. With $GAH = N_k$ and $k = \operatorname{rank} A$, transposing gives $H^{\mathsf{T}}A^{\mathsf{T}}G^{\mathsf{T}} = N_k^{\mathsf{T}}$, with H^{T} and G^{T} invertible. By Proposition 4.3.1, $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} N_k^{\mathsf{T}}$, and N_k^{T} has columns $\mathbf{e}_1, \dots, \mathbf{e}_k$ followed by zero columns, so its rank is k.

Let $k = \operatorname{rank} A$. By Theorem 3.5.27 there are invertible $G \in F^{m\times m}$ and $H \in F^{n\times n}$ with $GAH = N_k$. Transposing with Proposition 2.4.23,

$$H^{\mathsf{T}}A^{\mathsf{T}}G^{\mathsf{T}} = (GAH)^{\mathsf{T}} = N_k^{\mathsf{T}}.$$

The matrices H^{T} and G^{T} are invertible (Proposition 2.5.17(d)), so $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank}\left(H^{\mathsf{T}}A^{\mathsf{T}}G^{\mathsf{T}}\right) = \operatorname{rank} N_k^{\mathsf{T}}$ by Proposition 4.3.1. The matrix $N_k^{\mathsf{T}} \in F^{n\times m}$ has 1 in positions $(1,1), \dots, (k,k)$ and 0 elsewhere, so its columns are $\mathbf{e}_1, \dots, \mathbf{e}_k \in F^n$ followed by $m-k$ zero columns. Hence $\operatorname{im} N_k^{\mathsf{T}} = \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_k)$ (Proposition 2.6.18), which has the basis $\mathbf{e}_1, \dots, \mathbf{e}_k$. So $\operatorname{rank} N_k^{\mathsf{T}} = k$ (Theorem 4.2.7), and $\operatorname{rank} A^{\mathsf{T}} = k = \operatorname{rank} A$. □

The second proof uses only row operations. They change the column space of A but keep its row space, and the reduced form exposes a basis of the row space.

Proof (row operations keep the row space, and RREF exposes it). STANDARD

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 2.4.23 (Transpose of a product), Proposition 2.5.17 (Algebra of inverses), Proposition 4.3.1 (Invertible factors preserve rank), Proposition 3.3.8 (Properties of the output), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Proposition 2.6.18 (The column space is spanned by the columns), Theorem 1.5.5 (Independence is decided at zero), Theorem 4.2.7 (The image of T_A)
Techniques. Reduce to RREF (Technique 3.3.22), Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. Transpose $GA = A_r$, and recall from Proposition 4.3.1(b) that an invertible factor on the right does not change the image.
Hint 2. So A and A_r have the same row space. Which rows of A_r are nonzero, and why are they linearly independent?
Hint 3. Row s of A_r has a 1 in the pivot column p_s, and every other row has a 0 there.
Sketch. From $GA = A_r$ we get $A_r^{\mathsf{T}} = A^{\mathsf{T}}G^{\mathsf{T}}$ with G^{T} invertible, so $\operatorname{im} A_r^{\mathsf{T}} = \operatorname{im} A^{\mathsf{T}}$ by Proposition 4.3.1(b): A and A_r have the same row space. The nonzero rows of A_r are its first $k = \operatorname{rank} A$ rows. They span its row space, and they are independent because row s is the only one with a nonzero entry in column p_s. So the row space has dimension k.

Let $k = \operatorname{rank} A$, and let $G \in F^{m\times m}$ be invertible with $GA = A_r$ (Theorem 3.3.10). Transposing, $A_r^{\mathsf{T}} = A^{\mathsf{T}}G^{\mathsf{T}}$ (Proposition 2.4.23), and G^{T} is invertible (Proposition 2.5.17(d)). By Proposition 4.3.1(b),

$$\operatorname{im} A_r^{\mathsf{T}} = \operatorname{im} A^{\mathsf{T}}.$$

That is, A and A_r have the same row space.

By Proposition 3.3.8(a), rows $k+1, \dots, m$ of A_r are zero. Let $\boldsymbol{\rho}_1, \dots, \boldsymbol{\rho}_k \in F^n$ be the transposes of rows $1, \dots, k$ of A_r. These are the first k columns of A_r^{T}, and its other columns are zero, so $\operatorname{im} A_r^{\mathsf{T}} = \operatorname{span}(\boldsymbol{\rho}_1, \dots, \boldsymbol{\rho}_k)$ (Proposition 2.6.18). We show that $\boldsymbol{\rho}_1, \dots, \boldsymbol{\rho}_k$ is linearly independent. Let $p_1 < \cdots < p_k$ be the pivot columns of A_r. Column p_t of A_r is $\mathbf{e}_t$ (Lemma 3.3.16(b)), so entry p_t of $\boldsymbol{\rho}_s$ is 1 if $s = t$ and 0 if $s \neq t$. Hence if $c_1\boldsymbol{\rho}_1 + \cdots + c_k\boldsymbol{\rho}_k = \mathbf{0}$, then entry p_t of the left side is c_t, so $c_t = 0$ for every t (Theorem 1.5.5).

So $\boldsymbol{\rho}_1, \dots, \boldsymbol{\rho}_k$ is a basis of $\operatorname{im} A_r^{\mathsf{T}} = \operatorname{im} A^{\mathsf{T}}$, and $\operatorname{rank} A^{\mathsf{T}} = \dim \operatorname{im} A^{\mathsf{T}} = k = \operatorname{rank} A$ (Theorem 4.2.7). □

Both proofs reduce A to a form in which the theorem can be seen, but they teach different things. The first uses row and column operations together and lands on N_k, whose transpose is again of the same shape. The second uses only row operations, and it rests on a contrast. Row operations change the column space but keep the relations among the columns (Corollary 3.2.17), hence the number of independent columns. They keep the row space itself. So reduction preserves both numbers, and in A_r both are visibly the number of pivots. The second proof also computes something: the nonzero rows of $\operatorname{rref}(A)$ form a basis of the row

space of A. A third proof, from the column–row factorization, is in Section 4.3.6, and for real matrices Exercise 4.3.33 gives a fourth. The transpose of a matrix is the matrix of the *dual map*, and the coordinate-free form of the theorem is that a linear map and its dual have the same rank (Section 13.1). That point of view is beyond the course.

Remark 4.3.9 (The two halves of the product inequality). With the transpose available, the two bounds in Theorem 4.3.3 are mirror images of each other (Technique 3.2.27). If we only knew the easy bound $\operatorname{rank}(XY) \le \operatorname{rank} X$, which comes from $\operatorname{im}(XY) \subseteq \operatorname{im} X$, then

$$\begin{aligned}\operatorname{rank}(AB) &= \operatorname{rank}\big((AB)^{\mathsf{T}}\big) = \operatorname{rank}\big(B^{\mathsf{T}}A^{\mathsf{T}}\big)\\ &\le \operatorname{rank} B^{\mathsf{T}} = \operatorname{rank} B.\end{aligned}$$

So the bound that needed a dimension argument follows from the bound about images, once rows and columns are known to have the same rank.

The theorem adds a condition about rows to the Second Fundamental Theorem.

Corollary 4.3.10 (Independent rows). Let $A \in F^{m\times n}$. The following are equivalent.

(i) The rows of A are linearly independent.
(ii) $\operatorname{rank} A = m$.
(iii) For every $\mathbf{y} \in F^m$, the equation $A\mathbf{x} = \mathbf{y}$ has a solution.

In particular, a square matrix is invertible if and only if its rows are linearly independent.

Proof. ROUTINE

Uses. Theorem 4.3.8 (Row rank equals column rank), Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed), Corollary 3.5.25 (The invertible matrix theorem)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint. The rows of A are the columns of $A^{\mathsf{T}} \in F^{n\times m}$. Apply the First Fundamental Theorem to A^{T}.
Sketch. The rows of A are independent iff the m columns of A^{T} are, iff $\operatorname{rank} A^{\mathsf{T}} = m$ (Theorem 3.5.12 for A^{T}), iff $\operatorname{rank} A = m$, iff T_A is surjective (Theorem 3.5.13).

The rows of A, written as columns, are the m columns of $A^{\mathsf{T}} \in F^{n\times m}$. By (III) ⇔ (VI) of Theorem 3.5.12 for A^{T}, they are linearly independent if and only if $\operatorname{rank} A^{\mathsf{T}} = m$, that is, $\operatorname{rank} A = m$ by Theorem 4.3.8. This proves (i) ⇔ (ii), and (ii) ⇔ (iii) is (VI) ⇔ (II) of Theorem 3.5.13. For $m = n$, condition (ii) says that A is invertible (Corollary 3.5.25). □

Read as a statement about equations, (i) ⇔ (iii) is natural in one direction. If some combination of the rows vanishes, say $z_1(\text{row } 1) + \cdots + z_m(\text{row } m) = \mathbf{0}$ with not all $z_i = 0$, then every solvable right side satisfies $z_1y_1 + \cdots + z_my_m = 0$, so not every $\mathbf{y}$ is reachable. The corollary says that this is the only obstruction.

Exercise 4.3.11. ROUTINE Over $\mathbb{F}_5$, let $A = \begin{pmatrix} 1 & 2 & 0 & 3 \\ 2 & 1 & 1 & 0 \\ 0 & 4 & 2 & 3 \end{pmatrix}$.

(a) Find $\operatorname{rank} A$, and a basis of the row space of A from $\operatorname{rref}(A)$.

(b) Find a basis of the row space consisting of rows of A, and express the remaining row in terms of it.

Solution on page 1309

4.3.4 The four fundamental subspaces

A matrix $A \in F^{m\times n}$ has a kernel and an image, and so does its transpose. Together they are the four subspaces attached to A.

Definition 4.3.12 (The four fundamental subspaces). Let $A \in F^{m\times n}$. The **four fundamental subspaces** of A are

- the **column space** $\operatorname{im} A \subseteq F^m$, the span of the columns of A;
- the **null space** $\ker A \subseteq F^n$;
- the **row space** $\operatorname{im} A^{\mathsf{T}} \subseteq F^n$, the span of the rows of A written as columns;
- the **left null space** $\ker A^{\mathsf{T}} \subseteq F^m$.

The **column rank** of A is $\dim \operatorname{im} A$, and the **row rank** is $\dim \operatorname{im} A^{\mathsf{T}}$.

So Theorem 4.3.8 says that the row rank equals the column rank, and both equal $\operatorname{rank} A$. Table 4.3.1 summarizes the dimensions and bases found below. The name "left null space" comes from writing the condition on the left: since $\left(A^{\mathsf{T}}\mathbf{y}\right)^{\mathsf{T}} = \mathbf{y}^{\mathsf{T}}A$ (Proposition 2.4.23), a vector $\mathbf{y} \in F^m$ lies in $\ker A^{\mathsf{T}}$ exactly when $\mathbf{y}^{\mathsf{T}}A = \mathbf{0}^{\mathsf{T}}$, that is,

$$y_1(\text{row 1 of } A) + \cdots + y_m(\text{row } m \text{ of } A) = \mathbf{0}.$$

So the null space records the linear relations among the columns of A, and the left null space records the linear relations among the rows, or equivalently among the equations of the system $A\mathbf{x} = \mathbf{y}$.

Proposition 4.3.13 (Dimensions of the four subspaces). Let $A \in F^{m\times n}$ have rank r, and let $G \in F^{m\times m}$ be invertible with $GA = A_r$.

(a) $\dim \operatorname{im} A = r$, $\dim \ker A = n - r$, $\dim \operatorname{im} A^{\mathsf{T}} = r$, and $\dim \ker A^{\mathsf{T}} = m - r$.

(b) The pivot columns of A form a basis of $\operatorname{im} A$; the basic solutions form a basis of $\ker A$; the nonzero rows of A_r, written as columns, form a basis of $\operatorname{im} A^{\mathsf{T}}$; and the last $m - r$ rows of G, written as columns, form a basis of $\ker A^{\mathsf{T}}$.

Proof. ROUTINE

Uses. Theorem 4.2.7 (The image of T_A), Theorem 4.2.11 (Rank–nullity), Theorem 4.3.8 (Row rank equals column rank), Remark 3.4.11 (A basis of the kernel), Exercise 3.3.57, Corollary 4.1.11 (Spanning lists are long)

Hint 1. Rank–nullity for A gives two of the dimensions. Rank–nullity for $A^{\mathsf{T}} \in F^{n\times m}$, together with Theorem 4.3.8, gives the other two.

Hint 2. For the basis of $\ker A^{\mathsf{T}}$, Exercise 3.3.57 shows that the last $m - r$ rows of G span the relations among the rows of A. How many of them are there?

Sketch. (a) $\dim \operatorname{im} A = r$ and $\dim \ker A = n - r$ are Theorem 4.2.7 and rank–nullity. For $A^{\mathsf{T}} \in F^{n\times m}$, $\operatorname{rank} A^{\mathsf{T}} = r$ and rank–nullity gives $\dim \ker A^{\mathsf{T}} = m - r$. (b) The first two bases are Theorem 4.2.7 and Remark 3.4.11, and the third is the second proof of Theorem 4.3.8. The last $m - r$ rows of G, transposed, span $\ker A^{\mathsf{T}}$ by Exercise 3.3.57, and $m - r$ vectors spanning a space of dimension $m - r$ form a basis.

(a) By Theorem 4.2.7 and Theorem 4.2.11(a), $\dim \operatorname{im} A = r$ and $\dim \ker A = n - r$. The transpose $A^{\mathsf{T}} \in F^{n\times m}$ has m columns and rank r (Theorem 4.3.8), so $\dim \operatorname{im} A^{\mathsf{T}} = r$ and $\dim \ker A^{\mathsf{T}} = m - r$, by the same two results applied to A^{T}.

(b) The pivot columns of A form a basis of $\operatorname{im} A$ by Theorem 4.2.7, and the basic solutions form a basis of $\ker A$ by Remark 3.4.11. The nonzero rows of A_r, transposed, form a basis of $\operatorname{im} A^{\mathsf{T}}$, as shown in the second proof of Theorem 4.3.8. Finally, $\mathbf{y} \in \ker A^{\mathsf{T}}$ if and only if $\mathbf{y}^{\mathsf{T}}A = \mathbf{0}^{\mathsf{T}}$, that is, $\mathbf{y}^{\mathsf{T}}$ is a relation among the rows of A. By Exercise 3.3.57, these relations are exactly the linear combinations of the last $m - r$ rows of G. So the transposes of these $m - r$ rows span $\ker A^{\mathsf{T}}$, a space of dimension $m - r$ by (a), and they form a basis by Corollary 4.1.11(b). □

Subspace	Dimension	Basis, from $GA = A_r$
$\operatorname{im} A \subseteq F^m$	r	the pivot columns of A
$\ker A \subseteq F^n$	$n - r$	the basic solutions
$\operatorname{im} A^{\mathsf{T}} \subseteq F^n$	r	the nonzero rows of A_r
$\ker A^{\mathsf{T}} \subseteq F^m$	$m - r$	the last $m - r$ rows of G

Table 4.3.1. The four fundamental subspaces of $A \in F^{m\times n}$ of rank r (Proposition 4.3.13). Rows are written as columns. The two subspaces of F^n have dimensions adding to n, and the two subspaces of F^m have dimensions adding to m.

Example 4.3.14 (The four subspaces of a 3×4 matrix). Take the matrix of Intuition (Why this is surprising),

$$A = \begin{pmatrix} 1 & 2 & 1 & 4 \\ 2 & 4 & 0 & 6 \\ 1 & 2 & -1 & 2 \end{pmatrix}, \quad A_r = \begin{pmatrix} 1 & 2 & 0 & 3 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Here $m = 3$, $n = 4$, $r = 2$, and the pivot columns are 1 and 3.

- *Column space.* Columns 1 and 3 of A: $\operatorname{im} A = \operatorname{span}((1,2,1),(1,0,-1))$, of dimension 2.
- *Null space.* The free columns are 2 and 4, with basic solutions $(-2,1,0,0)$ and $(-3,0,-1,1)$, so $\dim\ker A = 2$.
- *Row space.* The nonzero rows of A_r: $\operatorname{im} A^{\mathsf{T}} = \operatorname{span}((1,2,0,3),(0,0,1,1))$, of dimension 2.
- *Left null space.* The relation $\text{row}_1 - \text{row}_2 + \text{row}_3 = \mathbf{0}$ gives $(1,-1,1) \in \ker A^{\mathsf{T}}$, and $\dim\ker A^{\mathsf{T}} = 3 - 2 = 1$, so $\ker A^{\mathsf{T}} = \operatorname{span}((1,-1,1))$.

The dimensions are $2 + 2 = 4 = n$ in F^n and $2 + 1 = 3 = m$ in F^m.

In this example something more is true. Every vector of the row space has dot product 0 with every vector of the null space: for instance $(1,2,0,3)\cdot(-3,0,-1,1) = -3 + 3 = 0$. Likewise $(1,2,1)\cdot(1,-1,1) = 0 = (1,0,-1)\cdot(1,-1,1)$. This always happens. Writing $\mathbf{u}\cdot\mathbf{x} = u_1x_1 + \cdots + u_nx_n$, entry i of $A\mathbf{x}$ is (row i) $\cdot\,\mathbf{x}$, so $\mathbf{x} \in \ker A$ exactly when every vector of the row space has dot product 0 with $\mathbf{x}$ (Exercise 3.3.50(a)); applied to A^{T}, the same holds for the column space and the left null space. Over $\mathbb{R}$, the row space and the null space are then *orthogonal complements* in $\mathbb{R}^n$: they meet only in $\mathbf{0}$, and together they span $\mathbb{R}^n$. So $\mathbb{R}^n$ splits into two perpendicular pieces, of dimensions r and $n - r$, and $\mathbb{R}^m$ into two perpendicular pieces of dimensions r and $m - r$. This picture is behind least squares (Section 6.5), and it is proved in Section 6.6 (Theorem 6.6.21). Over some other fields, such as $\mathbb{F}_2$ and $\mathbb{C}$, the dimensions still add up, but the two pieces can overlap.

Non-example 4.3.15 (Row space and null space can overlap). Over $\mathbb{F}_2$, let $A = \begin{pmatrix} 1 & 1 \end{pmatrix}$. Its row space is $\operatorname{span}((1,1))$, and $(1,1)$ lies in $\ker A$, since $1 + 1 = 0$. So $\operatorname{im} A^{\mathsf{T}} = \ker A$: the two subspaces of $\mathbb{F}_2^2$ coincide, although their dimensions $1 + 1 = 2$ add up correctly.

Over $\mathbb{C}$, let $A = \begin{pmatrix} 1 & i \end{pmatrix}$. Then $(1,i) \in \operatorname{im} A^{\mathsf{T}}$, and $A(1,i) = 1 + i^2 = 0$, so $(1,i) \in \ker A$ as well. Over $\mathbb{C}$ the cure is to replace A^{T} by the conjugate transpose A^* of Definition 6.3.26: the column space of A^* meets $\ker A$ only in $\mathbf{0}$ (Section 6.6). Over $\mathbb{F}_2$ no such repair exists: for every symmetric bilinear pairing on $\mathbb{F}_2^n$ with $n \geq 2$, some nonzero vector pairs to 0 with itself (Section 12.4).

4.3.5 Rank-one matrices and sums

The simplest nonzero matrices have rank one. In

$$\begin{pmatrix} 2 & -1 \\ 4 & -2 \end{pmatrix} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}\begin{pmatrix} 2 & -1 \end{pmatrix},$$

every column is a multiple of $(1,2)$ and every row is a multiple of $(2,-1)$, and the matrix is the product of these two vectors.

Proposition 4.3.16 (Rank-one matrices). Let $A \in F^{m\times n}$. Then $\operatorname{rank} A = 1$ if and only if $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ for some nonzero $\mathbf{u} \in F^m$ and $\mathbf{v} \in F^n$. In that case $\operatorname{im} A = \operatorname{span}(\mathbf{u})$ and $\operatorname{im} A^{\mathsf{T}} = \operatorname{span}(\mathbf{v})$, and if also $A = \mathbf{u}'\mathbf{v}'^{\mathsf{T}}$, then $\mathbf{u}' = c\mathbf{u}$ and $\mathbf{v}' = c^{-1}\mathbf{v}$ for some nonzero $c \in F$.

Proof. ROUTINE

Uses. Proposition 2.4.8 (Four views of the product), Proposition 2.6.18 (The column space is spanned by the columns), Proposition 1.2.35 (Zero products), Theorem 4.2.7 (The image of T_A), Proposition 2.4.23 (Transpose of a product)
Hint 1. Column j of $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $v_j\mathbf{u}$. What does this say about $\operatorname{im}\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right)$?
Hint 2. Conversely, if $\operatorname{rank} A = 1$, then $\operatorname{im} A = \operatorname{span}(\mathbf{u})$ for some $\mathbf{u} \neq \mathbf{0}$. Write each column of A as a multiple of $\mathbf{u}$.
Hint 3. For uniqueness, $\mathbf{u}'$ lies in $\operatorname{im} A = \operatorname{span}(\mathbf{u})$. Then compare $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u}'\mathbf{v}'^{\mathsf{T}}$ in a row where $\mathbf{u}$ is nonzero.
Sketch. Column j of $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $v_j\mathbf{u}$, so $\operatorname{im}\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \operatorname{span}(\mathbf{u})$ when $\mathbf{v} \neq \mathbf{0}$, a line. If $\operatorname{rank} A = 1$, then $\operatorname{im} A = \operatorname{span}(\mathbf{u})$, so column j is $v_j\mathbf{u}$ for some v_j, and $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$. Transposing gives the row space. If $\mathbf{u}\mathbf{v}^{\mathsf{T}} = \mathbf{u}'\mathbf{v}'^{\mathsf{T}}$, then $\operatorname{span}(\mathbf{u}') = \operatorname{span}(\mathbf{u})$, so $\mathbf{u}' = c\mathbf{u}$, and row i with $u_i \neq 0$ gives $\mathbf{v} = c\mathbf{v}'$.

If. Let $\mathbf{u} \neq \mathbf{0}$ and $\mathbf{v} \neq \mathbf{0}$. By the column view (Proposition 2.4.8(b)), column j of $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $v_j\mathbf{u}$. So every column lies in $\operatorname{span}(\mathbf{u})$, and $\operatorname{im}\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right) \subseteq \operatorname{span}(\mathbf{u})$ by Proposition 2.6.18. Some v_j is nonzero, and then $v_j\mathbf{u} \neq \mathbf{0}$ (Proposition 1.2.35), so $\operatorname{im}\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right)$ is a nonzero subspace of the line $\operatorname{span}(\mathbf{u})$, hence equal to it. So $\operatorname{rank}\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = 1$ (Theorem 4.2.7) and $\operatorname{im} A = \operatorname{span}(\mathbf{u})$.

Only if. Let $\operatorname{rank} A = 1$. Then $\operatorname{im} A$ is one-dimensional, so $\operatorname{im} A = \operatorname{span}(\mathbf{u})$ for any nonzero $\mathbf{u} \in \operatorname{im} A$. Each column $\mathbf{a}_j$ lies in $\operatorname{im} A$, so $\mathbf{a}_j = v_j\mathbf{u}$ for some $v_j \in F$. With $\mathbf{v} = (v_1, \ldots, v_n)$, column j of $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $v_j\mathbf{u} = \mathbf{a}_j$, so $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$. And $\mathbf{v} \neq \mathbf{0}$, since $A \neq 0$.

The row space and uniqueness. By Proposition 2.4.23, $A^{\mathsf{T}} = \mathbf{v}\mathbf{u}^{\mathsf{T}}$, so $\operatorname{im} A^{\mathsf{T}} = \operatorname{span}(\mathbf{v})$ by the first paragraph. If also $A = \mathbf{u}'\mathbf{v}'^{\mathsf{T}}$ with $\mathbf{u}', \mathbf{v}'$ nonzero, then $\operatorname{span}(\mathbf{u}') = \operatorname{im} A = \operatorname{span}(\mathbf{u})$, so $\mathbf{u}' = c\mathbf{u}$ with $c \neq 0$. Then $\mathbf{u}(\mathbf{v} - c\mathbf{v}')^{\mathsf{T}} = \mathbf{u}\mathbf{v}^{\mathsf{T}} - \mathbf{u}'\mathbf{v}'^{\mathsf{T}} = 0$. Choose i with $u_i \neq 0$. By the row view (Proposition 2.4.8(c)), row i of the left side is $u_i(\mathbf{v} - c\mathbf{v}')^{\mathsf{T}}$, which is therefore zero, so $\mathbf{v} = c\mathbf{v}'$, that is, $\mathbf{v}' = c^{-1}\mathbf{v}$. □

The rank normal form gives the same factorization in one line: if $GAH = N_1 = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$, then $A = \left(G^{-1}\mathbf{e}_1\right)\left(\mathbf{e}_1^{\mathsf{T}}H^{-1}\right)$, a column of G^{-1} times a row of H^{-1}. The form $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is worth reaching for whenever rank one appears.

Technique 4.3.17 (Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$). A matrix of rank one is $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u}, \mathbf{v} \neq \mathbf{0}$ (Proposition 4.3.16). In this form products collapse to scalars, because $\mathbf{v}^{\mathsf{T}}\mathbf{w}$ is a 1×1 matrix and can be moved out of the way:

$$\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right)\mathbf{x} = \left(\mathbf{v}^{\mathsf{T}}\mathbf{x}\right)\mathbf{u},$$
$$\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right)\left(\mathbf{w}\mathbf{z}^{\mathsf{T}}\right) = \left(\mathbf{v}^{\mathsf{T}}\mathbf{w}\right)\mathbf{u}\mathbf{z}^{\mathsf{T}},$$
$$\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right)^2 = \left(\mathbf{v}^{\mathsf{T}}\mathbf{u}\right)\mathbf{u}\mathbf{v}^{\mathsf{T}}.$$

Reach for it when a hypothesis says that a matrix has rank one, when a matrix differs from a known one by a rank-one matrix (as $I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ or $A + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ do), and when a matrix is to be split into simple pieces. The canonical example is Proposition 4.3.16, and Example 4.3.18 shows the collapse at work. Later instances are the matrix determinant lemma for $\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right)$ (Theorem 5.5.27) and the singular value decomposition, which writes every matrix as a sum of rank-one pieces in the best possible way (Section 9.1).
Used in. Exercise 4.3.19, Corollary 4.3.24, Exercise 4.3.37, Exercise 4.3.38, Exercise 4.3.40, Exercise 4.3.41, Exercise 4.5.51, Exercise 7.4.40, Problem 7.7, Problem 7.13, Exercise 4.3.39, Exercise 8.1.26.

Example 4.3.18 (Powers of a rank-one matrix). Let $A = \mathbf{u}\mathbf{v}^{\mathsf{T}} \in F^{n\times n}$ have rank one. Its diagonal entries are $u_i v_i$, so $\mathbf{v}^{\mathsf{T}}\mathbf{u} = u_1v_1 + \cdots + u_nv_n = \operatorname{tr} A$. By Technique 4.3.17,

$$A^2 = \mathbf{u}\big(\mathbf{v}^{\mathsf{T}}\mathbf{u}\big)\mathbf{v}^{\mathsf{T}} = (\operatorname{tr} A)A,$$

and by induction $A^k = (\operatorname{tr} A)^{k-1}A$ for $k \geq 1$. So a rank-one matrix is nilpotent if and only if $\operatorname{tr} A = 0$, in which case already $A^2 = 0$; and $A^2 = A$ if and only if $\operatorname{tr} A = 1$, since $A \neq 0$. For instance $\begin{pmatrix} 2 & -1 \\ 4 & -2 \end{pmatrix} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}\begin{pmatrix} 2 & -1 \end{pmatrix}$ has trace 0, and its square is 0; while $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} = \mathbf{e}_1\begin{pmatrix} 1 & 1 \end{pmatrix}$ has trace 1 and equals its square.

Exercise 4.3.19. ROUTINE Let $A = \begin{pmatrix} 3 & 1 & 1 \\ 6 & 2 & 2 \\ -3 & -1 & -1 \end{pmatrix}$.

(a) Over $\mathbb{Q}$, show that $\operatorname{rank} A = 1$ by writing $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$, and compute A^{10}.

(b) Over $\mathbb{F}_2$, compute A^2.

Solution on page 1309

For sums, the image of $A + B$ lies inside $\operatorname{im} A + \operatorname{im} B$, which gives an upper bound but no exact formula.

Proposition 4.3.20 (Rank is subadditive). For $A, B \in F^{m\times n}$,

$$\operatorname{rank}(A + B) \leq \operatorname{rank} A + \operatorname{rank} B.$$

Proof (comparing images). ROUTINE

Uses. Proposition 1.4.24 (The sum of two subspaces), Proposition 4.1.21 (Dimensions of subspaces), Corollary 4.1.11 (Spanning lists are long)
Hint 1. $(A + B)\mathbf{x} = A\mathbf{x} + B\mathbf{x}$. Which subspace contains $\operatorname{im}(A + B)$?
Hint 2. Concatenate a basis of $\operatorname{im} A$ and a basis of $\operatorname{im} B$.
Sketch. Every $(A + B)\mathbf{x} = A\mathbf{x} + B\mathbf{x}$ lies in $\operatorname{im} A + \operatorname{im} B$, which is spanned by a basis of $\operatorname{im} A$ followed by a basis of $\operatorname{im} B$, a list of length $\operatorname{rank} A + \operatorname{rank} B$.

For every $\mathbf{x} \in F^n$, $(A + B)\mathbf{x} = A\mathbf{x} + B\mathbf{x} \in \operatorname{im} A + \operatorname{im} B$, so $\operatorname{im}(A + B) \subseteq \operatorname{im} A + \operatorname{im} B$, a subspace of F^m (Proposition 1.4.24). Let $\mathbf{a}_1, \ldots, \mathbf{a}_k$ and $\mathbf{b}_1, \ldots, \mathbf{b}_l$ be bases of $\operatorname{im} A$ and $\operatorname{im} B$. Every vector of $\operatorname{im} A + \operatorname{im} B$ is a sum of a combination of the $\mathbf{a}_i$ and a combination of the $\mathbf{b}_j$, so the list $\mathbf{a}_1, \ldots, \mathbf{a}_k, \mathbf{b}_1, \ldots, \mathbf{b}_l$ spans $\operatorname{im} A + \operatorname{im} B$, and $\dim(\operatorname{im} A + \operatorname{im} B) \leq k + l$ (Corollary 4.1.11(a)). Hence

$$\begin{aligned} \operatorname{rank}(A + B) &\leq \dim(\operatorname{im} A + \operatorname{im} B) \\ &\leq k + l = \operatorname{rank} A + \operatorname{rank} B \end{aligned}$$

by Proposition 4.1.21(a). □

Proof (comparing kernels). ROUTINE

Uses. Proposition 4.2.26 (Subspaces that must meet), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. $\ker A \cap \ker B \subseteq \ker(A + B)$.
Hint 2. How large must $\ker A \cap \ker B$ be? Use Proposition 4.2.26 in F^n.
Sketch. $\ker A \cap \ker B \subseteq \ker(A + B)$, and by Proposition 4.2.26, $\dim(\ker A \cap \ker B) \geq (n - \operatorname{rank} A) + (n - \operatorname{rank} B) - n$. So $\dim \ker(A + B) \geq n - \operatorname{rank} A - \operatorname{rank} B$, and rank–nullity gives the claim.

If $A\mathbf{x} = B\mathbf{x} = \mathbf{0}$, then $(A + B)\mathbf{x} = \mathbf{0}$, so $\ker A \cap \ker B \subseteq \ker(A + B)$. By Proposition 4.1.21(a), Proposition 4.2.26 in F^n, and Theorem 4.2.11(a),

$$\begin{aligned} \dim \ker(A + B) &\geq \dim(\ker A \cap \ker B) \\ &\geq (n - \operatorname{rank} A) + (n - \operatorname{rank} B) - n \\ &= n - \operatorname{rank} A - \operatorname{rank} B. \end{aligned}$$

By Theorem 4.2.11(a) again, $\operatorname{rank}(A+B) = n - \dim\ker(A+B) \le \operatorname{rank} A + \operatorname{rank} B$. □

As for products, the image proof works in the target and the kernel proof in the domain. On the kernel side, the inequality is the statement that two large subspaces of F^n must overlap (Proposition 4.2.26).

By induction on k, a sum of k matrices of rank one has rank at most k. The next subsection shows that this bound is attained: every matrix of rank r is a sum of r matrices of rank one.

4.3.6 The column–row factorization

The pivot columns of A form a basis of $\operatorname{im} A$ (Theorem 4.2.7), so every column of A is a combination of them, and the coefficients can be read off $\operatorname{rref}(A)$ (Lemma 3.3.16(d), Corollary 3.2.17). Recording all these combinations at once is a matrix product.

Theorem 4.3.21 (Column–row factorization). Let $A \in F^{m\times n}$ have rank $r \ge 1$ and pivot columns $p_1 < \cdots < p_r$. Let $C \in F^{m\times r}$ be the matrix whose columns are the pivot columns $\mathbf{a}_{p_1}, \ldots, \mathbf{a}_{p_r}$ of A, and let $R \in F^{r\times n}$ consist of the first r rows of $\operatorname{rref}(A)$, which are its nonzero rows. Then

$$A = CR.$$

Moreover, the columns of C form a basis of $\operatorname{im} A$, and the rows of R, written as columns, form a basis of $\operatorname{im} A^{\mathsf{T}}$. In particular $\operatorname{rank} C = \operatorname{rank} R = r$.

Proof. ROUTINE

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.3.8 (Properties of the output), Theorem 2.4.34 (Block multiplication), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.4.1 (Matrix product), Theorem 4.2.7 (The image of T_A), Theorem 4.3.8 (Row rank equals column rank), Theorem 3.3.12 (Matrices in RREF)
Hint 1. Write $A = G^{-1}A_r$, where $A_r = \begin{pmatrix} R \\ 0 \end{pmatrix}$ in block form.
Hint 2. Split G^{-1} into its first r columns and the rest, and multiply in blocks. Then identify column s of G^{-1} by looking at column p_s of $A = G^{-1}A_r$.
Sketch. $GA = A_r = \begin{pmatrix} R \\ 0 \end{pmatrix}$. With $G^{-1} = (C' \;\; C'')$ split after r columns, block multiplication gives $A = C'R$. Column s of C' is $G^{-1}\mathbf{e}_s$, and since column p_s of A_r is $\mathbf{e}_s$, column p_s of A is also $G^{-1}\mathbf{e}_s$; so $C' = C$. The basis statements are Theorem 4.2.7 and the second proof of Theorem 4.3.8.

Let $G \in F^{m\times m}$ be invertible with $GA = A_r$ (Theorem 3.3.10). By Proposition 3.3.8(a), rows $r+1, \ldots, m$ of A_r are zero, so in block form $A_r = \begin{pmatrix} R \\ 0 \end{pmatrix}$, with a zero block of $m-r$ rows. Split $G^{-1} = (C' \;\; C'')$, where $C' \in F^{m\times r}$ consists of the first r columns of G^{-1}. By Theorem 2.4.34,

$$A = G^{-1}A_r = (C' \;\; C'')\begin{pmatrix} R \\ 0 \end{pmatrix} = C'R + C''0 = C'R.$$

Column s of C' is $G^{-1}\mathbf{e}_s$. Column p_s of A_r is $\mathbf{e}_s$ (Lemma 3.3.16(b)), so column p_s of $A = G^{-1}A_r$ is $G^{-1}\mathbf{e}_s$ (Definition 2.4.1). Hence column s of C' is $\mathbf{a}_{p_s}$, that is, $C' = C$, and $A = CR$.

The columns of C form a basis of $\operatorname{im} A$ by Theorem 4.2.7, so $\operatorname{rank} C = r$. The rows of R are the nonzero rows of A_r, and the second proof of Theorem 4.3.8 showed that, written as columns, they form a basis of $\operatorname{im} A^{\mathsf{T}}$. Finally, R satisfies (R1)–(R4) with r pivots, so it is in RREF and $\operatorname{rank} R = r$ (Theorem 3.3.12). □

Read column by column (Proposition 2.4.8(b)), $A = CR$ says that column j of A is the combination of the pivot columns of A whose coefficients are column j of $\operatorname{rref}(A)$:

$$\mathbf{a}_j = R_{1j}\mathbf{a}_{p_1} + \cdots + R_{rj}\mathbf{a}_{p_r}.$$

This is Corollary 3.2.17 once more: the free columns of $\operatorname{rref}(A)$ record how the free columns of A are built from its pivot columns.

Example 4.3.22 (A column–row factorization). For the matrix A of Example 4.3.14, the pivot columns are 1 and 3, so $A = CR$ with

$$C = \begin{pmatrix} 1 & 1 \\ 2 & 0 \\ 1 & -1 \end{pmatrix}, \quad R = \begin{pmatrix} 1 & 2 & 0 & 3 \\ 0 & 0 & 1 & 1 \end{pmatrix}.$$

Column 4 of R is $(3, 1)$, and indeed $\mathbf{a}_4 = 3\mathbf{a}_1 + \mathbf{a}_3$; column 2 of R is $(2, 0)$, and $\mathbf{a}_2 = 2\mathbf{a}_1$. By the column–row view of the product (Proposition 2.4.8(d)), A is a sum of two matrices of rank one:

$$\begin{aligned} A &= \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}\begin{pmatrix} 1 & 2 & 0 & 3 \end{pmatrix} + \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}\begin{pmatrix} 0 & 0 & 1 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & 2 & 0 & 3 \\ 2 & 4 & 0 & 6 \\ 1 & 2 & 0 & 3 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & -1 \end{pmatrix}. \end{aligned}$$

$$\begin{pmatrix} 1 & 2 & 1 & 4 \\ 2 & 4 & 0 & 6 \\ 1 & 2 & -1 & 2 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 2 & 0 & 3 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

The reduction of Example 4.3.22. At the end, the pivot columns listed in the summary pick out the columns of A that form C, and the nonzero rows of the final matrix form R. Use "Edit" to try your own matrix: the number of pivots is both the number of columns of C and the number of rows of R. (Interactive in the web version.)

The column–row factorization is one of many factorizations of A through F^r, and the next proposition says that all of them carry the same information.

Proposition 4.3.23 (Factorizations through F^k). Let $A = XY$ with $X \in F^{m\times k}$ and $Y \in F^{k\times n}$.

(a) $\operatorname{rank} A \le k$.

(b) If $k = \operatorname{rank} A$, then the columns of X form a basis of $\operatorname{im} A$, and the rows of Y, written as columns, form a basis of $\operatorname{im} A^{\mathsf{T}}$.

Proof. ROUTINE

Uses. Theorem 4.3.3 (Rank of a product), Proposition 3.5.2 (First properties of rank), Proposition 2.6.18 (The column space is spanned by the columns), Proposition 4.1.21 (Dimensions of subspaces), Corollary 4.1.11 (Spanning lists are long), Proposition 2.4.23 (Transpose of a product), Theorem 4.3.8 (Row rank equals column rank)
Techniques. Dimension counting (Technique 4.2.24), Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. X has only k columns.
Hint 2. For (b), $\operatorname{im} A \subseteq \operatorname{im} X$, and $\operatorname{im} X$ is spanned by k vectors. Compare dimensions. For Y, transpose.
Sketch. (a) $\operatorname{rank} A \le \operatorname{rank} X \le k$. (b) $\operatorname{im} A \subseteq \operatorname{im} X$, and $\operatorname{im} X$ is spanned by the k columns of X, so $\dim \operatorname{im} X \le k = \dim \operatorname{im} A$. Hence $\operatorname{im} A = \operatorname{im} X$, and k vectors spanning a k-dimensional space form a basis. Apply the same argument to $A^{\mathsf{T}} = Y^{\mathsf{T}}X^{\mathsf{T}}$, of rank k by Theorem 4.3.8.

(a) By Theorem 4.3.3 and Proposition 3.5.2(a), $\operatorname{rank} A = \operatorname{rank}(XY) \le \operatorname{rank} X \le k$.

(b) Let $k = \operatorname{rank} A$. By Theorem 4.3.3, $\operatorname{im} A \subseteq \operatorname{im} X$, and $\operatorname{im} X$ is spanned by the k columns of X (Proposition 2.6.18), so $\dim \operatorname{im} X \le k = \dim \operatorname{im} A$ (Corollary 4.1.11(a)). Also $\dim \operatorname{im} A \le \dim \operatorname{im} X$ (Proposition 4.1.21(a)), so the dimensions agree and $\operatorname{im} A = \operatorname{im} X$ by Proposition 4.1.21(b). This is a space of dimension k spanned by the k columns of X; so these columns form a basis of $\operatorname{im} A$ (Corollary 4.1.11(b)). Next, $A^{\mathsf{T}} = Y^{\mathsf{T}}X^{\mathsf{T}}$ (Proposition 2.4.23), with $Y^{\mathsf{T}} \in F^{n\times k}$, and $\operatorname{rank} A^{\mathsf{T}} = k$ (Theorem 4.3.8). The argument just given, applied to A^{T}, shows that the columns of Y^{T}, which are the rows of Y written as columns, form a basis of $\operatorname{im} A^{\mathsf{T}}$. □

So in any factorization $A = XY$ with inner size $\operatorname{rank} A$, the left factor is a basis of the column space and the right factor a basis of the row space. Two such factorizations differ by an invertible $r \times r$ matrix (Exercise 4.3.44), and the column–row factorization is the one in which the right factor is in RREF. Every matrix of rank r is therefore a sum of r rank-one matrices, and Proposition 4.3.20 says that fewer will not do.

Corollary 4.3.24 (Rank as a number of rank-one pieces). Let $A \in F^{m\times n}$. Then $\operatorname{rank} A$ is the smallest $k \geq 0$ such that A is a sum of k matrices of rank one (the empty sum being 0).

Proof. ROUTINE

Uses. Theorem 4.3.21 (Column–row factorization), Proposition 2.4.8 (Four views of the product), Proposition 4.3.16 (Rank-one matrices), Proposition 4.3.20 (Rank is subadditive)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. For a decomposition with rank A terms, write $A = CR$ and use the column–row view of the product.
Hint 2. For the lower bound, use Proposition 4.3.20 and induction on the number of terms.
Sketch. If $r = \operatorname{rank} A \geq 1$, then $A = CR = \sum_{s=1}^{r} \mathbf{c}_s R_{s,\cdot}$, where $\mathbf{c}_s$ is column s of C and $R_{s,\cdot}$ is row s of R; both are nonzero, so each term has rank one. Conversely, a sum of k rank-one matrices has rank at most k by subadditivity.

Let $r = \operatorname{rank} A$. If $r = 0$, then $A = 0$ is the empty sum. If $r \geq 1$, write $A = CR$ as in Theorem 4.3.21. By the column–row view (Proposition 2.4.8(d)),

$$A = \mathbf{c}_1 R_{1,\cdot} + \cdots + \mathbf{c}_r R_{r,\cdot},$$

where $\mathbf{c}_s$ is column s of C and $R_{s,\cdot}$ is row s of R. Each $\mathbf{c}_s$ is nonzero, as a vector of a basis, and each row of R is nonzero, as it contains a pivot. So each term has rank one by Proposition 4.3.16, and A is a sum of r matrices of rank one.

Conversely, if $A = A_1 + \cdots + A_k$ with $\operatorname{rank} A_i = 1$ for each i, then by Proposition 4.3.20 and induction on k, $\operatorname{rank} A \leq \operatorname{rank} A_1 + \cdots + \operatorname{rank} A_k = k$. So no sum of fewer than r rank-one matrices equals A. □

The lower bound can also be seen from Proposition 4.3.23(a): a sum $\sum_{i=1}^{k} \mathbf{u}_i \mathbf{v}_i^{\mathsf{T}}$ is the product of the $m \times k$ matrix with columns $\mathbf{u}_i$ and the $k \times n$ matrix with rows $\mathbf{v}_i^{\mathsf{T}}$, so its rank is at most k. Storing C and R takes $r(m+n)$ numbers instead of the mn entries of A, which is far fewer when r is small. Low-rank approximation (Section 16.3) exploits this to compress data.

The factorization also gives a third proof of Theorem 4.3.8, the one in LADR. It never row reduces, and its idea is to prove an inequality for every matrix and then apply it to the transpose.

Proof of Theorem 4.3.8 (via a column–row factorization). ROUTINE

Uses. Theorem 4.2.7 (The image of T_A), Proposition 2.4.8 (Four views of the product), Proposition 2.4.23 (Transpose of a product), Theorem 4.3.3 (Rank of a product), Proposition 3.5.2 (First properties of rank), Proposition 2.4.22 (Transpose is a linear involution)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. It suffices to prove $\operatorname{rank} A^{\mathsf{T}} \leq \operatorname{rank} A$ for every matrix A. Why?
Hint 2. Write $A = CR$ with C consisting of a basis of $\operatorname{im} A$, so that R has only $r = \operatorname{rank} A$ rows. What does $A^{\mathsf{T}} = R^{\mathsf{T}} C^{\mathsf{T}}$ say about $\operatorname{rank} A^{\mathsf{T}}$?
Sketch. Let $r = \operatorname{rank} A$ and let C have as columns a basis of $\operatorname{im} A$. Every column of A is a combination of these, so $A = CR$ with $R \in F^{r\times n}$. Then $A^{\mathsf{T}} = R^{\mathsf{T}} C^{\mathsf{T}}$, and $\operatorname{rank} A^{\mathsf{T}} \leq \operatorname{rank} R^{\mathsf{T}} \leq r$, since R^{T} has r columns. So $\operatorname{rank} A^{\mathsf{T}} \leq \operatorname{rank} A$ for every A; applied to A^{T}, it gives the reverse inequality.

We first show that $\operatorname{rank} A^{\mathsf{T}} \leq \operatorname{rank} A$ for every $A \in F^{m\times n}$. Let $r = \operatorname{rank} A$. If $r = 0$, then $A = 0$, so $A^{\mathsf{T}} = 0$ and both ranks are 0. Otherwise let $\mathbf{c}_1, \ldots, \mathbf{c}_r$ be a basis of $\operatorname{im} A$ (for instance the pivot columns, Theorem 4.2.7), and let $C \in F^{m\times r}$ have these columns. Each column $\mathbf{a}_j$ of A lies in $\operatorname{im} A$, so $\mathbf{a}_j = x_{1j}\mathbf{c}_1 + \cdots + x_{rj}\mathbf{c}_r$ for some scalars x_{sj}. Let $R = (x_{sj}) \in F^{r\times n}$. By the column view (Proposition 2.4.8(b)), column j of CR is $\sum_s x_{sj}\mathbf{c}_s = \mathbf{a}_j$, so $A = CR$. Transposing, $A^{\mathsf{T}} = R^{\mathsf{T}} C^{\mathsf{T}}$ (Proposition 2.4.23), and by Theorem 4.3.3 and Proposition 3.5.2(a),

$$\operatorname{rank} A^{\mathsf{T}} \leq \operatorname{rank} R^{\mathsf{T}} \leq r = \operatorname{rank} A,$$

since $R^{\mathsf{T}} \in F^{n\times r}$ has only r columns.

Applying this to A^{T}, whose transpose is A (Proposition 2.4.22), gives $\operatorname{rank} A \leq \operatorname{rank} A^{\mathsf{T}}$. Hence $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$. □

Intuition (Comparing the proofs that row rank equals column rank). The normal-form proof reduces A to the simplest matrix of its rank and observes that transposing does not disturb it; the work was done in proving Theorem 3.5.27 and Proposition 4.3.1. The row-operation proof is the computational one: it finds a basis of the row space, and it explains the theorem through what row operations preserve. The factorization proof is the shortest, given Theorem 4.3.3, and it shows the mechanism most directly: every row of $A = CR$ is a combination of the r rows of R, so the rows cannot span more than r dimensions. Its last step, proving an inequality for all matrices and then applying it to the transpose to get the reverse inequality, is a pattern worth remembering.

Exercise 4.3.25. ROUTINE Find the column–row factorization of

$$A = \begin{pmatrix} 1 & i & 0 & 2 \\ i & -1 & 1 & 2i \\ 1+i & -1+i & 1 & 2+2i \end{pmatrix} \in \mathbb{C}^{3\times 4},$$

and write A as a sum of rank A matrices of rank one.

Solution on page 1310

Exercises

Exercise 4.3.26. ROUTINE Over $\mathbb{Q}$, let

$$A = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 2 \end{pmatrix},$$

$$B_1 = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ -1 & 0 \end{pmatrix}, \quad B_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

(a) Find $\ker A$, and for $i = 1, 2$ find $\operatorname{im} B_i \cap \ker A$. Use (4.3.1) to find $\operatorname{rank}(AB_i)$, and check by computing AB_i.

(b) Is there a matrix $B \in \mathbb{Q}^{3\times 2}$ of rank 2 with $AB = 0$?

Solution on page 1310

Exercise 4.3.27. ROUTINE Let $A = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix}$.

(a) Over $\mathbb{F}_2$, find bases of the four fundamental subspaces of A, and check the dimensions against Proposition 4.3.13. Show that $\operatorname{im} A^{\mathsf{T}} = \ker A$.

(b) Over $\mathbb{Q}$, do the same, and show that $\operatorname{im} A^{\mathsf{T}} \cap \ker A = \{\mathbf{0}\}$.

Solution on page 1311

Exercise 4.3.28. ROUTINE For each item, find a matrix with the given properties, or show that none exists.

(a) $A \in \mathbb{R}^{3\times 3}$ with $\operatorname{im} A = \operatorname{span}((1,0,1))$ and $\ker A = \operatorname{span}((1,1,0),(0,1,1))$.

(b) $A \in F^{2\times 4}$ with $\ker A = \operatorname{span}(\mathbf{e}_1)$.

(c) $A \in F^{3\times 3}$ whose row space contains $(1,1,0)$ and whose null space contains $(1,0,0)$.

(d) $A \in F^{2\times 2}$ with $\operatorname{im} A = \ker A$.

(e) $A \in F^{3\times 3}$ with $\operatorname{im} A = \ker A$.

Solution on page 1311

Exercise 4.3.29. ROUTINE Let $A, B \in F^{m\times n}$. Prove or disprove.

(a) If A and B have the same four fundamental subspaces, then $A = B$.

(b) If A and B have the same row space, then $\ker A = \ker B$.

(c) If A and B have the same column space, then $\ker A^{\mathsf{T}} = \ker B^{\mathsf{T}}$.

(d) If $\ker A = \ker B$, then $\operatorname{im} A = \operatorname{im} B$.

Solution on page 1312

Exercise 4.3.30. STANDARD (*Sylvester's rank inequality.*) Let $A \in F^{m\times n}$ and $B \in F^{n\times p}$.

(a) Show that $\operatorname{rank}(AB) \geq \operatorname{rank} A + \operatorname{rank} B - n$.

(b) Deduce that if $AB = 0$, then $\operatorname{rank} A + \operatorname{rank} B \leq n$.

(c) Show that for $A_1, \ldots, A_k \in F^{n\times n}$,

$$\operatorname{rank}(A_1 A_2 \cdots A_k) \geq \operatorname{rank} A_1 + \cdots + \operatorname{rank} A_k - (k-1)n.$$

(d) Deduce that if $A \in F^{n\times n}$ has rank $n-1$, then $\operatorname{rank}\left(A^k\right) \geq n-k$ for every $k \geq 1$, and show by an example that equality can hold for every $k \leq n$.

Solution on page 1312

Exercise 4.3.31. HARD (*Frobenius's rank inequality.*) Let $A \in F^{m\times n}$, $B \in F^{n\times p}$, and $C \in F^{p\times q}$.

(a) Show that

$$\operatorname{rank}(AB) + \operatorname{rank}(BC) \leq \operatorname{rank} B + \operatorname{rank}(ABC).$$

(b) Deduce Sylvester's inequality (Exercise 4.3.30(a)).

(c) Let $A \in F^{n\times n}$ and $d_k = \operatorname{rank}\left(A^k\right) - \operatorname{rank}\left(A^{k+1}\right)$ for $k \geq 0$. Deduce from (a) that $d_0 \geq d_1 \geq d_2 \geq \cdots$ (compare Example 4.3.6).

Solution on page 1313

Exercise 4.3.32. HARD Let $0 \leq a \leq \min(m,n)$ and $0 \leq b \leq \min(n,p)$ be integers. Show that there are $A \in F^{m\times n}$ of rank a and $B \in F^{n\times p}$ of rank b with $\operatorname{rank}(AB) = r$ if and only if

$$\max(0, a+b-n) \leq r \leq \min(a,b).$$

For $m = n = p = 5$, $a = 3$, and $b = 4$, list the possible values of $\operatorname{rank}(AB)$ and give a pair A, B for each.

Solution on page 1313

Exercise 4.3.33. STANDARD Let $A \in F^{m\times n}$.

(a) Show that, over any field, $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A - \dim\left(\operatorname{im} A \cap \ker A^{\mathsf{T}}\right)$.

(b) Let $F = \mathbb{R}$. Show that $\operatorname{im} A \cap \ker A^{\mathsf{T}} = \{\mathbf{0}\}$, and deduce that $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$.

(c) Let $F = \mathbb{R}$. Without using Theorem 4.3.8, deduce from (b) that $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$ and $\operatorname{rank}\left(AA^{\mathsf{T}}\right) = \operatorname{rank} A$.

Solution on page 1314

Exercise 4.3.34. STANDARD Prove or disprove.

(a) Over $\mathbb{F}_2$, $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$ for every matrix A.

(b) Over $\mathbb{C}$, $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$ for every matrix A.

(c) Over $\mathbb{Q}$, $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$ for every matrix A.

(d) Over $\mathbb{F}_2$, if the columns of A are linearly independent, then $A^{\mathsf{T}}A$ is invertible.

Which step of Exercise 4.3.33(b) fails in the false cases?

Solution on page 1314

Exercise 4.3.35. STANDARD Find the error in the following argument. Is its conclusion true? Give a matrix for which the false step fails, and repair the argument.

Claim. For every $A \in F^{m\times n}$, $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$.

Proof. Let $A_r = \operatorname{rref}(A)$, with r pivots. Row operations do not change the column space, so $\operatorname{im} A = \operatorname{im} A_r$. The columns of A_r lie in $\operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_r)$ and include $\mathbf{e}_1, \ldots, \mathbf{e}_r$, so $\operatorname{im} A = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_r)$, and $\operatorname{rank} A = r$. Row operations do not change the row space either, and the r nonzero rows of A_r are linearly independent, so $\operatorname{rank} A^{\mathsf{T}} = r$ as well.

Solution on page 1315

Exercise 4.3.36. STANDARD Prove or disprove. All matrices are over a field F.

(a) $\operatorname{rank}(AB) = \operatorname{rank}(BA)$ for all $A, B \in F^{n\times n}$.

(b) If $A \in F^{m\times n}$ and $B \in F^{n\times p}$ both have rank n, then $\operatorname{rank}(AB) = n$.

(c) If $A, B \in F^{m\times n}$ and $\operatorname{im} A \cap \operatorname{im} B = \{\mathbf{0}\}$, then $\operatorname{rank}(A + B) = \operatorname{rank} A + \operatorname{rank} B$.

(d) If $A \in F^{n\times n}$ and $\operatorname{rank}\left(A^2\right) = \operatorname{rank} A$, then $\operatorname{rank}\left(A^k\right) = \operatorname{rank} A$ for every $k \geq 1$.

Solution on page 1315

Exercise 4.3.37. STANDARD Let $\mathbf{u}, \mathbf{v} \in F^n$, and let $s = \mathbf{v}^{\mathsf{T}}\mathbf{u}$.

(a) Show that if $1 + s \neq 0$, then $I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ is invertible, with

$$\left(I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right)^{-1} = I_n - \frac{1}{1+s}\mathbf{u}\mathbf{v}^{\mathsf{T}}.$$

(b) Show that if $1 + s = 0$, then $I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ is not invertible, and that its rank is $n - 1$.

(c) Let $J \in F^{n\times n}$ have every entry equal to 1. For which $c \in F$ is $I_n + cJ$ invertible, and what is its inverse? Is $I_4 + J$ invertible over $\mathbb{Q}$? Over $\mathbb{F}_5$?

Solution on page 1316

Exercise 4.3.38. STANDARD Let $A, B \in F^{n\times n}$ and suppose that $\operatorname{rank}(AB - BA) = 1$. Show that $(AB - BA)^2 = 0$. Give an example in which $\operatorname{rank}(AB - BA) = 1$.

Solution on page 1317

Exercise 4.3.39. ROUTINE

(a) Show that $\operatorname{rank}(A+B) \geq |\operatorname{rank} A - \operatorname{rank} B|$ for $A, B \in F^{m\times n}$.

(b) Show that changing one entry of a matrix changes its rank by at most 1.

(c) Let $M_t \in \mathbb{R}^{5\times 5}$ have every diagonal entry equal to 1 and every other entry equal to t. Show that $\operatorname{rank} M_t \geq 4$ for every $t \neq 1$.

Solution on page 1317

Exercise 4.3.40. HARD Let $n \geq 3$, and let $A \in F^{n\times n}$ have entries $a_{ij} = (i-j)^2$, read as elements of F.

(a) Show that $\operatorname{rank} A \leq 3$ over every field, by writing A as a sum of three matrices of rank at most one.

(b) Show that $\operatorname{rank} A = 3$ if $1+1 \neq 0$ in F.

(c) Find $\operatorname{rank} A$ over $\mathbb{F}_2$.

Solution on page 1317

Exercise 4.3.41. STANDARD

(a) Let $A \in F^{m\times n}$. Show that $\operatorname{rank} A \leq 1$ if and only if $a_{ij}a_{kl} = a_{il}a_{kj}$ for all $i,k \in \{1,\ldots,m\}$ and $j,l \in \{1,\ldots,n\}$.

(b) Find all $t \in \mathbb{R}$ for which $\begin{pmatrix} 1 & t & 2 \\ t & 4 & 2t \end{pmatrix}$ has rank 1.

Solution on page 1318

Exercise 4.3.42. HARD Let $A \in F^{n\times n}$. Show that

$$\operatorname{rank} A + \operatorname{rank}(I_n - A) = n$$

if and only if $A^2 = A$.

Solution on page 1319

Exercise 4.3.43. HARD Let $A \in F^{n\times n}$ satisfy $A^2 = A$, and let $r = \operatorname{rank} A \geq 1$.

(a) Let $A = CR$ be a factorization with $C \in F^{n\times r}$ and $R \in F^{r\times n}$, as in Theorem 4.3.21. Show that $RC = I_r$.

(b) Deduce that $\operatorname{tr} A = r \cdot 1$, the sum of r copies of 1 in F.

(c) Deduce that over $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, the rank of an idempotent matrix equals its trace. Show by an example that over $\mathbb{F}_2$ the rank of an idempotent is not determined by its trace.

Solution on page 1319

Exercise 4.3.44. HARD Let $A \in F^{m\times n}$ have rank $r \geq 1$, and suppose $A = CR = C'R'$ with $C, C' \in F^{m\times r}$ and $R, R' \in F^{r\times n}$.

(a) Show that there is exactly one invertible $P \in F^{r\times r}$ with $C' = CP$, and that then $R' = P^{-1}R$.

(b) Deduce that the factorization of Theorem 4.3.21 is the only factorization $A = C'R'$ with inner size r in which R' is in RREF.

Solution on page 1319

Exercise 4.3.45. CHALLENGE Let $A \in F^{n\times n}$.

(a) Suppose $\operatorname{rank}(A^2) = \operatorname{rank} A = r \geq 1$, and let $A = CR$ be a factorization with inner size r. Show that $RC \in F^{r\times r}$ is invertible.

(b) Under the hypothesis of (a), show that $X = C(RC)^{-2}R$ satisfies

$$AXA = A, \quad XAX = X, \quad AX = XA.$$

(c) Conversely, show that if some $X \in F^{n\times n}$ satisfies the three equations in (b), then $\operatorname{rank}(A^2) = \operatorname{rank} A$.

Solution on page 1320

4.4 Sums and direct sums

In Section 1.4.5 we met the sum $U + W$ of two subspaces, the smallest subspace that contains both. This section answers two questions about it: how large it is, and when a vector of $U + W$ can be written as $\mathbf{u} + \mathbf{w}$ in only one way. Two pictures in $\mathbb{R}^3$ already suggest the answers. Every vector of $\mathbb{R}^3$ is, in exactly one way, a vector of the xy-plane plus a vector of the z-axis, and $2 + 1 = 3$. The xy-plane and the xz-plane also add up to $\mathbb{R}^3$, but now $(1, 0, 0) = (1, 0, 0) + \mathbf{0} = \mathbf{0} + (1, 0, 0)$ has two decompositions, and $2 + 2$ overshoots 3 by exactly 1, the dimension of the x-axis, where the two planes overlap. Both questions are answered by looking at the intersection.

Sums in which decompositions are unique, the direct sums, are to subspaces what bases are to vectors. A basis cuts V into lines, and the coordinates of a vector name its pieces; a direct sum cuts V into subspaces of any dimension. Later chapters understand an operator by cutting V into pieces that it maps into themselves. A diagonalizable operator is one for which V is the direct sum of its eigenspaces (Section 7.4), and the Jordan form starts from a direct sum of generalized eigenspaces (Section 10.2). Both need direct sums of more than two subspaces, and that is where the subtleties are.

Throughout, V is a vector space over a field F, and U, W, X, U_1, U_2, ... denote subspaces of V.

4.4.1 Sums of several subspaces

The sum of two subspaces extends to any finite number of them.

Definition 4.4.1 (Sum of subspaces). Let $U_1, \ldots, U_k$ be subspaces of V, where $k \geq 1$. Their **sum** is

$$U_1 + \cdots + U_k = \{\mathbf{u}_1 + \cdots + \mathbf{u}_k \mid \mathbf{u}_i \in U_i \text{ for } i = 1, \ldots, k\},$$

also written $\sum_{i=1}^{k} U_i$. An expression $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_k$ with $\mathbf{u}_i \in U_i$ for each i is a **decomposition** of $\mathbf{v}$ along $U_1, \ldots, U_k$, with **components** $\mathbf{u}_1, \ldots, \mathbf{u}_k$.

For $k = 2$ this is the sum $U_1 + U_2$ of Proposition 1.4.24, and for $k = 1$ it is U_1. By convention, a sum of no subspaces is $\{\mathbf{0}\}$, just as an empty sum of vectors is $\mathbf{0}$. The sum of k subspaces is the sum of two, applied repeatedly, so the two-subspace facts carry over.

Proposition 4.4.2 (Sums are the smallest containing subspaces). Let $U_1, \ldots, U_k$ be subspaces of V.

(a) If $k \geq 2$, then $U_1 + \cdots + U_k = (U_1 + \cdots + U_{k-1}) + U_k$.

(b) $U_1 + \cdots + U_k$ is a subspace of V that contains every U_i, and it is contained in every subspace of V that contains every U_i.

(c) If $U_i = \operatorname{span}(\mathcal{L}_i)$ for lists $\mathcal{L}_1, \ldots, \mathcal{L}_k$, then $U_1 + \cdots + U_k = \operatorname{span}(\mathcal{L}_1, \ldots, \mathcal{L}_k)$.

Proof. ROUTINE

Uses. Definition 4.4.1 (Sum of subspaces), Proposition 1.4.24 (The sum of two subspaces), Exercise 1.3.36
Techniques. Double containment (Technique 1.3.14), Induction on the number of summands (Technique 4.4.10)

Hint 1. For (a), an element of the left side is $(\mathbf{u}_1 + \cdots + \mathbf{u}_{k-1}) + \mathbf{u}_k$. Check both containments.
Hint 2. For (b) and (c), induct on k. By (a), the case of k subspaces is a sum of two, $S + U_k$ with $S = U_1 + \cdots + U_{k-1}$, where Proposition 1.4.24 and Exercise 1.3.36 apply.
Sketch. (a) is regrouping. By (a), the sum is $S + U_k$ with $S = U_1 + \cdots + U_{k-1}$, so (b) and (c) follow by induction on k from the two-subspace facts: $S + U_k$ is the smallest subspace containing S and U_k, and $\operatorname{span}(\mathcal{L}) + \operatorname{span}(\mathcal{M}) = \operatorname{span}(\mathcal{L}, \mathcal{M})$.

(a) Let $S = U_1 + \cdots + U_{k-1}$. An element of $U_1 + \cdots + U_k$ has the form $\mathbf{u}_1 + \cdots + \mathbf{u}_k = (\mathbf{u}_1 + \cdots + \mathbf{u}_{k-1}) + \mathbf{u}_k$ with $\mathbf{u}_i \in U_i$, and this lies in $S + U_k$. Conversely, an element of $S + U_k$ is $\mathbf{s} + \mathbf{u}_k$ with $\mathbf{s} = \mathbf{u}_1 + \cdots + \mathbf{u}_{k-1} \in S$ and $\mathbf{u}_k \in U_k$, which is an element of $U_1 + \cdots + U_k$.

(b) We induct on k. For $k = 1$ the sum is U_1, and there is nothing to prove. Let $k \geq 2$, and assume that $S = U_1 + \cdots + U_{k-1}$ is a subspace containing $U_1, \ldots, U_{k-1}$ and contained in every subspace that contains them. By (a) and Proposition 1.4.24(a), $U_1 + \cdots + U_k = S + U_k$ is a subspace containing S and U_k, hence every U_i. If X is a subspace containing every U_i, then $S \subseteq X$ by the inductive hypothesis and $U_k \subseteq X$, so $S + U_k \subseteq X$ by Proposition 1.4.24(b).

(c) Again we induct on k, and $k = 1$ is trivial. For $k \geq 2$, the inductive hypothesis gives $U_1 + \cdots + U_{k-1} = \operatorname{span}(\mathcal{L}_1, \ldots, \mathcal{L}_{k-1})$. So by (a) and Exercise 1.3.36, applied to the lists $\mathcal{L}_1, \ldots, \mathcal{L}_{k-1}$ and $\mathcal{L}_k$,

$$U_1 + \cdots + U_k = \operatorname{span}(\mathcal{L}_1, \ldots, \mathcal{L}_{k-1}) + \operatorname{span}(\mathcal{L}_k) = \operatorname{span}(\mathcal{L}_1, \ldots, \mathcal{L}_k). \qquad \square$$

By (b), the sum depends only on the subspaces involved, not on their order or grouping. For instance $U + W = W + U$ and $(U + W) + X = U + (W + X)$, since each side is the smallest subspace containing U, W (and X).

Example 4.4.3 (Sums).

(a) In F^3, $\operatorname{span}(\mathbf{e}_1) + \operatorname{span}(\mathbf{e}_2) + \operatorname{span}(\mathbf{e}_3) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3) = F^3$ by Proposition 4.4.2(c). In $\mathbb{R}^2$, the three lines $\operatorname{span}(\mathbf{e}_1)$, $\operatorname{span}(\mathbf{e}_2)$, and $\operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$ also add up to $\mathbb{R}^2$, although the third is not needed.

(b) In $F^{n\times n}$, let Y be the subspace of upper triangular matrices and Z the subspace of lower triangular matrices. Every matrix is the sum of its part on and above the diagonal, which lies in Y, and its part below the diagonal, which lies in Z. So $Y + Z = F^{n\times n}$. The two subspaces overlap in the diagonal matrices, so many matrices have more than one decomposition: $I_n = I_n + 0 = 0 + I_n$.

(c) For $S, T \in \mathrm{L}(V, W)$ we have $(S + T)(\mathbf{v}) = S(\mathbf{v}) + T(\mathbf{v})$, so $\operatorname{im}(S + T) \subseteq \operatorname{im} S + \operatorname{im} T$. Together with the bound $\dim(\operatorname{im} S + \operatorname{im} T) \leq \dim \operatorname{im} S + \dim \operatorname{im} T$ of Theorem 4.4.13 below, this is the reason that rank is subadditive (Proposition 4.3.20). The containment can be strict: for $T \neq 0$, $\operatorname{im}(T + (-T)) = \{\mathbf{0}\}$ is smaller than $\operatorname{im} T + \operatorname{im}(-T) = \operatorname{im} T$.

4.4.2 Direct sums

A basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ of V writes every vector in exactly one way as $a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$. Each term $a_i\mathbf{v}_i$ lies in the line $\operatorname{span}(\mathbf{v}_i)$, so the basis exhibits V as a sum of lines in which every vector has exactly one decomposition. Direct sums keep the uniqueness and allow pieces of any dimension.

Definition 4.4.4 (Direct sum). Let $U_1, \ldots, U_k$ be subspaces of V. The sum $U_1 + \cdots + U_k$ is **direct** if every vector of $U_1 + \cdots + U_k$ has exactly one decomposition along $U_1, \ldots, U_k$. In that case we also say that $U_1, \ldots, U_k$ are **independent**, and we write the sum as

$$U_1 \oplus \cdots \oplus U_k \quad \text{or} \quad \bigoplus_{i=1}^{k} U_i.$$

If moreover $U_1 + \cdots + U_k = V$, we write $V = U_1 \oplus \cdots \oplus U_k$ and say that V is the **direct sum** of $U_1, \ldots, U_k$.

So writing $U \oplus W$ is an assertion, not a new operation: it denotes the subspace $U + W$, together with the claim that the sum is direct. (The *external* direct sum, which builds a new space out of two unrelated ones, is the product of Section 4.6.) Some texts define independent subspaces by condition (II) of Theorem 4.4.7 below instead; the theorem shows that the two definitions agree.

Example 4.4.5 (Direct sums).

(a) *Bases.* If $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis of V, then $V = \operatorname{span}(\mathbf{v}_1) \oplus \cdots \oplus \operatorname{span}(\mathbf{v}_n)$. A decomposition of $\mathbf{v}$ has components $a_i\mathbf{v}_i$ with $a_i \in F$, and the component determines the scalar: if $a\mathbf{v}_i = b\mathbf{v}_i$, then $(a-b)\mathbf{v}_i = \mathbf{0}$, so $a = b$ by Proposition 1.2.35, since $\mathbf{v}_i \neq \mathbf{0}$. So decompositions of $\mathbf{v}$ correspond to representations $\mathbf{v} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$, and there is exactly one. The components of $\mathbf{v}$ are its coordinates times the basis vectors.

(b) *Triangular parts.* Let Y be the upper triangular matrices in $F^{n\times n}$ and Z° the *strictly* lower triangular ones, whose diagonal entries are 0. Then $F^{n\times n} = Y \oplus Z^\circ$: in a decomposition $A = B + C$ with $B \in Y$ and $C \in Z^\circ$, the entries of A on and above the diagonal must be those of B and the entries below must be those of C.

(c) *Even and odd functions.* In $\mathbb{R}^{\mathbb{R}}$, the even functions E and the odd functions O satisfy $E \cap O = \{\mathbf{0}\}$ and $E + O = \mathbb{R}^{\mathbb{R}}$ (Exercise 1.4.35). By Theorem 4.4.7 below, this says $\mathbb{R}^{\mathbb{R}} = E \oplus O$.

(d) *Even and odd polynomials.* In $F[x]$, let E be the polynomials whose coefficients of $x, x^3, x^5, \ldots$ vanish and O those whose coefficients of $1, x^2, x^4, \ldots$ vanish. Every polynomial is the sum of its even-degree terms and its odd-degree terms, and in a decomposition $p = q + r$ with $q \in E$ and $r \in O$, each coefficient of p belongs to exactly one of q and r. So $F[x] = E \oplus O$ over every field, including $\mathbb{F}_2$. Compare Exercise 1.4.35(b), where even and odd *functions* on $\mathbb{F}_2$ coincide.

Non-example 4.4.6 (Sums that are not direct).

(a) The xy-plane and the xz-plane add up to $\mathbb{R}^3$, but $\mathbf{0} = (1,0,0) + (-1,0,0)$ is a second decomposition of $\mathbf{0}$, besides $\mathbf{0} + \mathbf{0}$.

(b) In $\mathbb{R}^2$, the three lines $\ell_1 = \operatorname{span}(\mathbf{e}_1)$, $\ell_2 = \operatorname{span}(\mathbf{e}_2)$, $\ell_3 = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$ meet pairwise only in $\mathbf{0}$. Their sum is still not direct:

$$\mathbf{0} = \mathbf{e}_1 + \mathbf{e}_2 + (-(\mathbf{e}_1 + \mathbf{e}_2))$$

is a decomposition of $\mathbf{0}$ with nonzero components.

Part (b) is the trap of this section. For three or more subspaces, "no two of them overlap" is not the right notion of independence. The analogy with lists explains why: three vectors of $\mathbb{R}^2$, no two of them parallel, are still dependent. Independence of a list compares each vector with the span of the *others* (Corollary 1.5.13), and the right condition for subspaces compares each subspace with the sum of the others.

> *Intuition (What the criteria say).* The theorem below gives three tests for directness. Condition (II) is uniqueness at $\mathbf{0}$; as for lists, uniqueness everywhere follows by subtracting two decompositions. Conditions (III) and (IV) are the subspace versions of "no vector is a combination of the others" and "no vector is a combination of the earlier ones". Condition (IV) is the economical one to check: it asks for $k-1$ intersections to be $\{\mathbf{0}\}$, each with a sum that is built up one subspace at a time.

Theorem 4.4.7 (Criteria for direct sums). Let $U_1, \ldots, U_k$ be subspaces of V. The following are equivalent.

(I) The sum $U_1 + \cdots + U_k$ is direct.

(II) $\mathbf{0}$ has only the trivial decomposition: if $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ with $\mathbf{u}_i \in U_i$ for each i, then $\mathbf{u}_1 = \cdots = \mathbf{u}_k = \mathbf{0}$.

(III) Each U_j meets the sum of the others only in $\mathbf{0}$: $U_j \cap \sum_{i \neq j} U_i = \{\mathbf{0}\}$ for $j = 1, \ldots, k$.

(IV) Each U_j meets the sum of the earlier ones only in $\mathbf{0}$: $U_j \cap \left(U_1 + \cdots + U_{j-1}\right) = \{\mathbf{0}\}$ for $j = 2, \ldots, k$.

In particular, for two subspaces, $U + W$ is direct if and only if $U \cap W = \{\mathbf{0}\}$.

Here $\sum_{i \neq j} U_i$ is the sum of all U_i except U_j. (For $k = 1$ it is the empty sum $\{\mathbf{0}\}$, and all four conditions hold.) The first proof is a cycle of implications.

Technique 4.4.8 (Compare components). In a direct sum, an equation between decompositions splits into one equation per summand. If $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{u}_1' + \cdots + \mathbf{u}_k'$ with $\mathbf{u}_i, \mathbf{u}_i' \in U_i$ and the sum is direct, then $\mathbf{u}_i = \mathbf{u}_i'$ for every i. This is the analogue of comparing coefficients with respect to a basis. To use it, sort every term of an equation into the summand it belongs to, then read off the components one at a time.

Proving that a sum is direct runs the same move backwards. Take two decompositions of one vector, subtract them, and move terms across so that the two sides of the resulting equation lie in different subspaces. Then both sides lie in the intersection, and if the intersection is $\{\mathbf{0}\}$, both sides vanish. For two subspaces this is the whole argument: $\mathbf{u} + \mathbf{w} = \mathbf{u}' + \mathbf{w}'$ gives $\mathbf{u} - \mathbf{u}' = \mathbf{w}' - \mathbf{w} \in U \cap W$.

Reach for it whenever a vector is given as a sum of pieces from known subspaces. The canonical example is Theorem 4.4.7. Later uses include orthogonal decompositions (Section 6.4), the independence of eigenvectors with distinct eigenvalues (Section 7.2), and the generalized eigenspace decomposition (Section 10.2).

Used in. Theorem 4.4.7, Proposition 4.4.9, Exercise 4.4.11, Proposition 4.4.12, Proposition 4.4.26, Theorem 4.4.27, Proposition 4.4.29, Proposition 4.4.31, Exercise 4.4.36, Exercise 4.4.44, Exercise 4.4.51, Problem 4.7.

Proof (by a cycle of implications). STANDARD

Uses. Definition 4.4.4 (Direct sum), Definition 4.4.1 (Sum of subspaces)
Techniques. Proving TFAE (Technique 2.7.1), Compare components (Technique 4.4.8), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Prove (I) ⇔ (II) first, by subtracting two decompositions. Then prove (II) ⇒ (III) ⇒ (IV) ⇒ (II).
Hint 2. For (II) ⇒ (III), a vector $\mathbf{v} \in U_j$ that also equals $\sum_{i \neq j} \mathbf{u}_i$ gives a decomposition of $\mathbf{0}$ whose jth component is $-\mathbf{v}$.
Hint 3. For (IV) ⇒ (II), take a decomposition $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$. If some $\mathbf{u}_i \neq \mathbf{0}$, look at the largest such index j and solve for $\mathbf{u}_j$.
Sketch. (I) ⇔ (II): $\mathbf{0} + \cdots + \mathbf{0}$ is one decomposition of $\mathbf{0}$, and the difference of two decompositions of $\mathbf{v}$ is a decomposition of $\mathbf{0}$. (II) ⇒ (III): if $\mathbf{v} \in U_j$ equals $\sum_{i \neq j} \mathbf{u}_i$, then $\sum_{i \neq j} \mathbf{u}_i + (-\mathbf{v}) = \mathbf{0}$, so $\mathbf{v} = \mathbf{0}$. (III) ⇒ (IV): the sum of the earlier subspaces is contained in the sum of the others. (IV) ⇒ (II): if j is the largest index with $\mathbf{u}_j \neq \mathbf{0}$, then $\mathbf{u}_j = -\left(\mathbf{u}_1 + \cdots + \mathbf{u}_{j-1}\right) \in U_j \cap \left(U_1 + \cdots + U_{j-1}\right)$, a contradiction.

We prove (I) ⇔ (II), and then (II) ⇒ (III) ⇒ (IV) ⇒ (II).

(I) ⇒ (II). Since $\mathbf{0} \in U_i$ for each i, $\mathbf{0} = \mathbf{0} + \cdots + \mathbf{0}$ is a decomposition of $\mathbf{0}$. By (I) it is the only one.

(II) ⇒ (I). Suppose $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{u}_1' + \cdots + \mathbf{u}_k'$ with $\mathbf{u}_i, \mathbf{u}_i' \in U_i$. Then

$$\left(\mathbf{u}_1 - \mathbf{u}_1'\right) + \cdots + \left(\mathbf{u}_k - \mathbf{u}_k'\right) = \mathbf{v} - \mathbf{v} = \mathbf{0},$$

and $\mathbf{u}_i - \mathbf{u}_i' \in U_i$, since U_i is a subspace. By (II), $\mathbf{u}_i - \mathbf{u}_i' = \mathbf{0}$ for each i, so the two decompositions agree.

(II) ⇒ (III). Fix j, and let $\mathbf{v} \in U_j \cap \sum_{i \neq j} U_i$, say $\mathbf{v} = \sum_{i \neq j} \mathbf{u}_i$ with $\mathbf{u}_i \in U_i$. Then

$$\mathbf{u}_1 + \cdots + \mathbf{u}_{j-1} + (-\mathbf{v}) + \mathbf{u}_{j+1} + \cdots + \mathbf{u}_k = \mathbf{0}$$

is a decomposition of $\mathbf{0}$, as $-\mathbf{v} \in U_j$. By (II) all its components vanish. In particular $-\mathbf{v} = \mathbf{0}$, so $\mathbf{v} = \mathbf{0}$.

(III) ⇒ (IV). Let $2 \le j \le k$. Every element $\mathbf{u}_1 + \cdots + \mathbf{u}_{j-1}$ of $U_1 + \cdots + U_{j-1}$ is also an element of $\sum_{i \ne j} U_i$: take the components $\mathbf{0}$ in U_i for $i > j$. So

$$U_j \cap \big(U_1 + \cdots + U_{j-1}\big) \subseteq U_j \cap \sum_{i \ne j} U_i = \{\mathbf{0}\}.$$

(IV) ⇒ (II). Let $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ with $\mathbf{u}_i \in U_i$. Suppose, for a contradiction, that some $\mathbf{u}_i \ne \mathbf{0}$, and let j be the largest index with $\mathbf{u}_j \ne \mathbf{0}$. Then $\mathbf{u}_i = \mathbf{0}$ for $i > j$, so

$$\mathbf{u}_j = -\big(\mathbf{u}_1 + \cdots + \mathbf{u}_{j-1}\big) = (-\mathbf{u}_1) + \cdots + \big(-\mathbf{u}_{j-1}\big).$$

If $j = 1$, the right side is the empty sum $\mathbf{0}$, which contradicts $\mathbf{u}_1 \ne \mathbf{0}$. If $j \ge 2$, the left side lies in U_j and the right side in $U_1 + \cdots + U_{j-1}$, so $\mathbf{u}_j \in U_j \cap \big(U_1 + \cdots + U_{j-1}\big) = \{\mathbf{0}\}$, again a contradiction. Hence every $\mathbf{u}_i = \mathbf{0}$.

For $k = 2$, condition (III) says $U_1 \cap U_2 = \{\mathbf{0}\}$, which proves the last sentence. □

The step (IV) ⇒ (II) chose an extremal index, the largest j with $\mathbf{u}_j \ne \mathbf{0}$, exactly as the linear dependence lemma does for lists. The other natural route is induction on the number of summands. It rests on a fact that is useful in its own right: independent subspaces can be grouped.

Proposition 4.4.9 (Grouping summands). Let $U_1, \ldots, U_k$ be subspaces of V, let $1 \le m < k$, and write $S = U_1 + \cdots + U_m$ and $S' = U_{m+1} + \cdots + U_k$. Then $U_1 + \cdots + U_k$ is direct if and only if both of the following hold.

(i) The sums $U_1 + \cdots + U_m$ and $U_{m+1} + \cdots + U_k$ are direct.

(ii) $S \cap S' = \{\mathbf{0}\}$.

Moreover, independence of subspaces does not depend on their order, and if $U_1, \ldots, U_k$ are independent, then so is any selection of them.

Proof. ROUTINE

Uses. Theorem 4.4.7 (Criteria for direct sums), Definition 4.4.1 (Sum of subspaces)
Techniques. Compare components (Technique 4.4.8)
Hint 1. Use condition (II) of Theorem 4.4.7 throughout. Only its equivalence with (I) is needed.
Hint 2. For the backward direction, given $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$, set $\mathbf{s} = \mathbf{u}_1 + \cdots + \mathbf{u}_m$ and $\mathbf{s}' = \mathbf{u}_{m+1} + \cdots + \mathbf{u}_k$. Then $\mathbf{s} = -\mathbf{s}'$.
Sketch. (⇒) A decomposition of $\mathbf{0}$ along $U_1, \ldots, U_m$, padded with zero components, is one along all k subspaces, so (i) follows from (II). If $\mathbf{v} \in S \cap S'$, write $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{u}_{m+1} + \cdots + \mathbf{u}_k$; moving everything to one side gives a decomposition of $\mathbf{0}$, so all $\mathbf{u}_i = \mathbf{0}$ and $\mathbf{v} = \mathbf{0}$. (≤) If $\sum_i \mathbf{u}_i = \mathbf{0}$, then $\mathbf{s} = -\mathbf{s}' \in S \cap S' = \{\mathbf{0}\}$, and (i) kills each block. The last sentence holds because (II) does not refer to the order, and padding with zeros works for any selection.

We use the equivalence of (I) and (II) in Theorem 4.4.7.

(⇒) Suppose the sum of all k subspaces is direct. If $\mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{0}$ with $\mathbf{u}_i \in U_i$, then $\mathbf{u}_1 + \cdots + \mathbf{u}_m + \mathbf{0} + \cdots + \mathbf{0} = \mathbf{0}$ is a decomposition of $\mathbf{0}$ along $U_1, \ldots, U_k$, so every $\mathbf{u}_i = \mathbf{0}$. Hence $U_1 + \cdots + U_m$ is direct, and likewise $U_{m+1} + \cdots + U_k$. For (ii), let $\mathbf{v} \in S \cap S'$, say $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{u}_{m+1} + \cdots + \mathbf{u}_k$ with $\mathbf{u}_i \in U_i$. Then

$$\mathbf{u}_1 + \cdots + \mathbf{u}_m + (-\mathbf{u}_{m+1}) + \cdots + (-\mathbf{u}_k) = \mathbf{0}$$

is a decomposition of $\mathbf{0}$, so all components vanish and $\mathbf{v} = \mathbf{0}$.

(≤) Suppose (i) and (ii), and let $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ with $\mathbf{u}_i \in U_i$. Put $\mathbf{s} = \mathbf{u}_1 + \cdots + \mathbf{u}_m \in S$ and $\mathbf{s}' = \mathbf{u}_{m+1} + \cdots + \mathbf{u}_k \in S'$. Then $\mathbf{s} = -\mathbf{s}'$ lies in S and in S', so $\mathbf{s} = \mathbf{0} = \mathbf{s}'$ by (ii). Now $\mathbf{s} = \mathbf{0}$ is a decomposition of $\mathbf{0}$ along $U_1, \ldots, U_m$, so $\mathbf{u}_1 = \cdots = \mathbf{u}_m = \mathbf{0}$ by (i), and likewise $\mathbf{u}_{m+1} = \cdots = \mathbf{u}_k = \mathbf{0}$. So the sum is direct.

Finally, condition (II) does not refer to the order of $U_1, \ldots, U_k$, since a sum of vectors does not depend on the order of its terms. If $U_{i_1}, \ldots, U_{i_r}$ are some of the U_i (with distinct indices), a decomposition of $\mathbf{0}$ along them becomes a decomposition of $\mathbf{0}$ along $U_1, \ldots, U_k$ once we insert the component $\mathbf{0}$ for every other U_i. If $U_1, \ldots, U_k$ are independent, all its components vanish. □

With $m = k-1$, the proposition says: $U_1 + \cdots + U_k$ is direct exactly when $U_1 + \cdots + U_{k-1}$ is direct and $(U_1 + \cdots + U_{k-1}) \cap U_k = \{\mathbf{0}\}$. That is an inductive description of directness, one new subspace at a time.

Technique 4.4.10 (Induction on the number of summands). To prove a statement about k subspaces $U_1, \ldots, U_k$, group the first $k-1$ of them into $S = U_1 + \cdots + U_{k-1}$ and treat $S + U_k$ as a sum of two subspaces. Proposition 4.4.2(a) says that $S + U_k$ is the whole sum, and Proposition 4.4.9 says that it is direct exactly when S is direct and $S \cap U_k = \{\mathbf{0}\}$. So the two-subspace case and the inductive hypothesis for S combine into the case of k subspaces.

Reach for it when the statement for two subspaces is easy, typically because it reduces to $U \cap W = \{\mathbf{0}\}$, and the general case looks messy. Watch the hypothesis in the inductive step: it needs $S \cap U_k = \{\mathbf{0}\}$, an intersection with a sum, and not just $U_i \cap U_k = \{\mathbf{0}\}$ for each $i < k$ (Non-example 4.4.6(b)). The canonical example is the second proof of Theorem 4.4.7. The same induction shows that eigenspaces for distinct eigenvalues are independent (Section 7.2).

Used in. Proposition 4.4.2, Theorem 4.4.7, Exercise 4.4.37, Exercise 4.4.40.

Proof of Theorem 4.4.7 (of (IV) ⇒ (II), by induction on k). STANDARD

Uses. Proposition 4.4.9 (Grouping summands)
Techniques. Induction on the number of summands (Technique 4.4.10)
Hint 1. Induct on k. Condition (IV) for $U_1, \ldots, U_k$ contains condition (IV) for $U_1, \ldots, U_{k-1}$.
Hint 2. With $S = U_1 + \cdots + U_{k-1}$, condition (IV) for $j = k$ says $S \cap U_k = \{\mathbf{0}\}$. Apply Proposition 4.4.9 with $m = k-1$.
Sketch. For $k = 1$, (II) is trivial. If $U_1, \ldots, U_k$ satisfy (IV), so do $U_1, \ldots, U_{k-1}$, which are therefore independent by induction. Condition (IV) for $j = k$ is $(U_1 + \cdots + U_{k-1}) \cap U_k = \{\mathbf{0}\}$, and Proposition 4.4.9 with $m = k-1$ turns these two facts into directness of the whole sum.

This proof uses only (I) ⇔ (II), which was proved directly above, through Proposition 4.4.9, whose proof uses nothing else. We induct on k. For $k = 1$, condition (II) says that $\mathbf{u}_1 = \mathbf{0}$ implies $\mathbf{u}_1 = \mathbf{0}$.

Let $k \geq 2$, assume the implication for $k-1$ subspaces, and suppose $U_1, \ldots, U_k$ satisfy (IV). The conditions of (IV) for $j = 2, \ldots, k-1$ are condition (IV) for $U_1, \ldots, U_{k-1}$, so by the inductive hypothesis these subspaces satisfy (II), and their sum $S = U_1 + \cdots + U_{k-1}$ is direct. The sum U_k of one subspace is trivially direct. Condition (IV) for $j = k$ says $S \cap U_k = \{\mathbf{0}\}$. By Proposition 4.4.9 with $m = k-1$, the sum $U_1 + \cdots + U_k$ is direct, which is (II). □

The second proof explains where (IV) comes from: it is exactly what the induction consumes, and each step asks only that the new subspace avoid everything built so far.

Exercise 4.4.11. ROUTINE Let $U_1 = \operatorname{span}((1,1,0))$, $U_2 = \operatorname{span}((1,0,1))$, and $U_3 = \operatorname{span}((0,1,1))$ in F^3.

(a) Show that $U_i \cap U_j = \{\mathbf{0}\}$ whenever $i \neq j$, over every field F.

(b) Show that $U_1 + U_2 + U_3$ is direct if $1 + 1 \neq 0$ in F, and not direct if $F = \mathbb{F}_2$.

Solution on page 1320

4.4.3 Bases and dimension

For lists, independence is what makes a spanning list a basis. For subspaces it plays the same role one level up: bases of the summands concatenate to a basis of the sum exactly when the summands are independent. The lists version is a recitation exercise.

Proposition 4.4.12 (Concatenating independent lists). Let $\mathcal{L}_1, \ldots, \mathcal{L}_k$ be linearly independent lists in V. The concatenation $\mathcal{L}_1, \ldots, \mathcal{L}_k$ is linearly independent if and only if $\operatorname{span}(\mathcal{L}_1), \ldots, \operatorname{span}(\mathcal{L}_k)$ are independent subspaces. In particular, for linearly independent lists $\mathcal{L}$ and $\mathcal{M}$, the concatenation $\mathcal{L}, \mathcal{M}$ is linearly independent if and only if $\operatorname{span}(\mathcal{L}) \cap \operatorname{span}(\mathcal{M}) = \{\mathbf{0}\}$.

Proof. ROUTINE

Uses. Theorem 4.4.7 (Criteria for direct sums), Theorem 1.5.5 (Independence is decided at zero), Definition 1.3.10 (Span)
Techniques. Compare components (Technique 4.4.8)
Hint 1. A linear combination of the concatenation is a sum of k pieces, the ith of which is a combination of $\mathcal{L}_i$ and so lies in $\operatorname{span}(\mathcal{L}_i)$.
Hint 2. So a linear relation among the concatenation is the same thing as a decomposition of $\mathbf{0}$ along the spans, together with a representation of each component. Compare (II) of Theorem 1.5.5 with (II) of Theorem 4.4.7.
Sketch. Write $\mathcal{L}_i = \mathbf{v}_{i1}, \dots, \mathbf{v}_{in_i}$. A relation $\sum_i \sum_j a_{ij}\mathbf{v}_{ij} = \mathbf{0}$ is a decomposition $\mathbf{0} = \mathbf{u}_1 + \cdots + \mathbf{u}_k$ with $\mathbf{u}_i = \sum_j a_{ij}\mathbf{v}_{ij} \in \operatorname{span}(\mathcal{L}_i)$, and since $\mathcal{L}_i$ is independent, $\mathbf{u}_i = \mathbf{0}$ exactly when all $a_{ij} = 0$. So "only the trivial relation" and "only the trivial decomposition of $\mathbf{0}$" say the same thing.

Write $\mathcal{L}_i = \mathbf{v}_{i1}, \dots, \mathbf{v}_{in_i}$ and $W_i = \operatorname{span}(\mathcal{L}_i)$.

($\leq$) Suppose $W_1, \dots, W_k$ are independent, and let $\sum_{i=1}^{k} \sum_{j=1}^{n_i} a_{ij}\mathbf{v}_{ij} = \mathbf{0}$. Put $\mathbf{u}_i = \sum_j a_{ij}\mathbf{v}_{ij} \in W_i$. Then $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$, so every $\mathbf{u}_i = \mathbf{0}$ by (II) of Theorem 4.4.7. Since $\mathcal{L}_i$ is independent, $a_{i1} = \cdots = a_{in_i} = 0$ (Theorem 1.5.5). So the concatenation has only the trivial relation and is independent.

($\Rightarrow$) Suppose the concatenation is independent, and let $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ with $\mathbf{u}_i \in W_i$, say $\mathbf{u}_i = \sum_j a_{ij}\mathbf{v}_{ij}$. Then $\sum_i \sum_j a_{ij}\mathbf{v}_{ij} = \mathbf{0}$, so all $a_{ij} = 0$ and every $\mathbf{u}_i = \mathbf{0}$. By (II) of Theorem 4.4.7, $W_1, \dots, W_k$ are independent.

The case $k = 2$ follows from the last sentence of Theorem 4.4.7. □

Theorem 4.4.13 (Bases and dimension of a sum). Let $U_1, \dots, U_k$ be finite-dimensional subspaces of V, and for each i let $\mathcal{B}_i$ be a basis of U_i.

(a) The concatenation $\mathcal{B}_1, \dots, \mathcal{B}_k$ spans $U_1 + \cdots + U_k$. Hence $U_1 + \cdots + U_k$ is finite-dimensional, and
$$\dim(U_1 + \cdots + U_k) \leq \dim U_1 + \cdots + \dim U_k.$$
(b) The sum $U_1 + \cdots + U_k$ is direct if and only if $\mathcal{B}_1, \dots, \mathcal{B}_k$ is a basis of $U_1 + \cdots + U_k$.
(c) The sum $U_1 + \cdots + U_k$ is direct if and only if $\dim(U_1 + \cdots + U_k) = \dim U_1 + \cdots + \dim U_k$.

Proof. ROUTINE

Uses. Proposition 4.4.2 (Sums are the smallest containing subspaces), Proposition 4.4.12 (Concatenating independent lists), Definition 1.6.23 (Finite-dimensional), Corollary 4.1.11 (Spanning lists are long), Theorem 4.1.4 (All bases have the same length)
Techniques. Glue bases of the summands (Technique 4.4.14), Dimension counting (Technique 4.2.24)
Hint 1. (a) is Proposition 4.4.2(c), together with the fact that a spanning list is at least as long as the dimension.
Hint 2. For (b), the concatenation already spans, so it is a basis exactly when it is independent. For (c), when is a spanning list whose length equals the dimension a basis?
Sketch. (a) By Proposition 4.4.2(c), the concatenation, of length $n_1 + \cdots + n_k$ with $n_i = \dim U_i$, spans the sum, so the sum is finite-dimensional with dimension at most $n_1 + \cdots + n_k$. (b) A spanning list is a basis iff it is independent, iff the sum is direct by Proposition 4.4.12. (c) A spanning list is a basis iff its length is the dimension, so (c) reduces to (b).

Let $n_i = \dim U_i$, so that $\mathcal{B}_i$ has length n_i, and let $N = n_1 + \cdots + n_k$ be the length of the concatenation $\mathcal{B} = \mathcal{B}_1, \dots, \mathcal{B}_k$.

(a) By Proposition 4.4.2(c), $\operatorname{span}(\mathcal{B}) = \operatorname{span}(\mathcal{B}_1) + \cdots + \operatorname{span}(\mathcal{B}_k) = U_1 + \cdots + U_k$. So the sum is spanned by a finite list and is finite-dimensional (Definition 1.6.23), and its dimension is at most N by Corollary 4.1.11(a).

(b) By (a), $\mathcal{B}$ spans the sum, so $\mathcal{B}$ is a basis of the sum if and only if it is linearly independent. Each $\mathcal{B}_i$ is independent with span U_i, so by Proposition 4.4.12, $\mathcal{B}$ is independent if and only if $U_1, \dots, U_k$ are independent.

(c) Let $d = \dim(U_1 + \cdots + U_k)$. If $\mathcal{B}$ is a basis of the sum, then $N = d$ by Theorem 4.1.4. Conversely, if $N = d$, then $\mathcal{B}$ is a spanning list of length d, hence a basis by Corollary 4.1.11(b). So $d = N$ if and only if $\mathcal{B}$ is a basis, and (b) finishes the proof. □

In particular, if $V = U_1 \oplus \cdots \oplus U_k$ is finite-dimensional, then $\dim V = \dim U_1 + \cdots + \dim U_k$. Taking $U_i = \operatorname{span}(\mathbf{v}_i)$ with $\mathbf{v}_i \neq \mathbf{0}$, whose basis is the list $\mathbf{v}_i$, part (b) also gives the converse of Example 4.4.5(a): $V = \operatorname{span}(\mathbf{v}_1) \oplus \cdots \oplus \operatorname{span}(\mathbf{v}_n)$ if and only if $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis. And part (c) gives a second look at Non-example 4.4.6(b): three lines in $\mathbb{R}^2$ have dimensions adding up to $3 > 2$, so their sum cannot be direct.

Technique 4.4.14 (Glue bases of the summands). When $V = U_1 \oplus \cdots \oplus U_k$, choose a basis of each U_i and concatenate. The result is a basis of V (Theorem 4.4.13) adapted to the decomposition: each basis vector lies in one summand, so the coordinates of a vector split into blocks, one block for each component. In the other direction, to show that subspaces are independent, it suffices to check that bases of them concatenate to an independent list, or just to compare dimensions.

Reach for it to compute the dimension of a direct sum, or to turn a statement about subspaces into one about lists. The canonical example is Theorem 4.4.13. Later, a basis glued from bases of eigenspaces is an eigenbasis (Section 7.4), and Jordan bases are glued from chains (Section 10.3).
Used in. Theorem 4.4.13, Proposition 4.4.16, Theorem 7.4.16, Theorem 7.6.34, Exercise 8.2.36, Exercise 7.6.49, Exercise 8.1.36.

The span explorer shows the case of a plane and a line in $\mathbb{R}^3$.

$$\text{With } U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) \text{ and } W = \operatorname{span}((1,1,1)):$$
$$(2,1,3) = (-1,-2,0) + (3,3,3) \quad \text{with } (-1,-2,0) \in U, (3,3,3) \in W.$$

The first two vectors span a plane U and the third spans a line W. By Proposition 4.4.12, the list is independent exactly when $U \cap W = \{\mathbf{0}\}$, and then the coefficients of the target $\mathbf{w}$ split it as $(a_1\mathbf{v}_1 + a_2\mathbf{v}_2) + a_3\mathbf{v}_3 \in U \oplus W$. Drag $\mathbf{v}_3$ into the plane: the list becomes dependent, and the dependence relation, rearranged, exhibits a nonzero vector of $U \cap W$. (Interactive in the web version.)

4.4.4 Complements

Given a subspace U of V, can V be split as $U \oplus W$? In finite dimensions it always can, by extending a basis.

Definition 4.4.15 (Complement). Let U be a subspace of V. A **complement** of U in V is a subspace W of V with $V = U \oplus W$.

By Theorem 4.4.7, W is a complement of U if and only if $U + W = V$ and $U \cap W = \{\mathbf{0}\}$. The relation is symmetric: W is a complement of U if and only if U is a complement of W.

Proposition 4.4.16 (Complements exist). Let V be finite-dimensional, and let U be a subspace of V.

(a) If $\mathbf{u}_1, \ldots, \mathbf{u}_k$ is a basis of U and $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{w}_1, \ldots, \mathbf{w}_r$ is a basis of V, then $\operatorname{span}(\mathbf{w}_1, \ldots, \mathbf{w}_r)$ is a complement of U. In particular, U has a complement.

(b) Every complement of U arises as in (a), and every complement W of U has $\dim W = \dim V - \dim U$.

Proof. ROUTINE

Uses. Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis), Proposition 4.4.2 (Sums are the smallest containing subspaces), Proposition 4.4.12 (Concatenating independent lists), Theorem 4.4.13 (Bases and dimension of a sum)
Techniques. Extend a basis of a subspace (Technique 4.1.18), Glue bases of the summands (Technique 4.4.14)
Hint 1. For (a), the extended list spans V and is independent. Translate these two facts into statements about $U + W$ and $U \cap W$.
Hint 2. For (b), concatenate a basis of U with a basis of a complement W and apply Theorem 4.4.13.
Sketch. (a) Let $W = \operatorname{span}(\mathbf{w}_1, \ldots, \mathbf{w}_r)$. The concatenation spans V, so $U + W = V$ (Proposition 4.4.2(c)), and it is independent, so $U \cap W = \{\mathbf{0}\}$ (Proposition 4.4.12). A basis of U exists and extends (Proposition 4.1.21, Theorem 4.1.16). (b) If $V =$

$U \oplus W$, then W is finite-dimensional, and a basis of U followed by a basis of W is a basis of V (Theorem 4.4.13(b)), so W arises as in (a), with $r = \dim V - k$.

(a) Let $W = \operatorname{span}(\mathbf{w}_1, \ldots, \mathbf{w}_r)$. By Proposition 4.4.2(c), $U + W = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{w}_1, \ldots, \mathbf{w}_r) = V$. The lists $\mathbf{u}_1, \ldots, \mathbf{u}_k$ and $\mathbf{w}_1, \ldots, \mathbf{w}_r$ are independent (the second as part of a basis), and their concatenation is independent, so $U \cap W = \{\mathbf{0}\}$ by Proposition 4.4.12. Hence $V = U \oplus W$ by Theorem 4.4.7.

For the existence of a complement: U is finite-dimensional (Proposition 4.1.21(a)), so it has a basis $\mathbf{u}_1, \ldots, \mathbf{u}_k$, which is independent in V and extends to a basis of V (Theorem 4.1.16). Apply the first part.

(b) Let W be a complement of U. It is finite-dimensional (Proposition 4.1.21(a)); let $\mathbf{w}_1, \ldots, \mathbf{w}_r$ be a basis of W, and $\mathbf{u}_1, \ldots, \mathbf{u}_k$ a basis of U. Since $V = U \oplus W$, Theorem 4.4.13(b) says that $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{w}_1, \ldots, \mathbf{w}_r$ is a basis of V, and W is the span of the added vectors, as in (a). Counting, $\dim V = k + r$, so $\dim W = r = \dim V - \dim U$. □

Example 4.4.17 (Complements are not unique). In $\mathbb{R}^2$, every line through $\mathbf{0}$ other than the x-axis is a complement of the x-axis: two distinct lines meet only in $\mathbf{0}$, and their sum has dimension $1 + 1 = 2$ by Theorem 4.4.13(c), so it is $\mathbb{R}^2$.

In $\mathbb{Q}^4$, Example 4.1.17 extended $\mathbf{v}_1 = (1, 1, 0, 0)$, $\mathbf{v}_2 = (1, 1, 1, 1)$ by $\mathbf{e}_1, \mathbf{e}_3$ to a basis of $\mathbb{Q}^4$. So $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ is a complement of $U = \operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$. So is $\operatorname{span}(\mathbf{e}_2, \mathbf{e}_4)$. A vector $a\mathbf{v}_1 + b\mathbf{v}_2 = (a + b, a + b, b, b)$ of U lies in $\operatorname{span}(\mathbf{e}_2, \mathbf{e}_4)$ only if its first and third coordinates vanish, that is, $a + b = 0$ and $b = 0$, so $U \cap \operatorname{span}(\mathbf{e}_2, \mathbf{e}_4) = \{\mathbf{0}\}$. By Proposition 4.4.12, $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_2, \mathbf{e}_4$ is independent; having length 4, it is a basis (Theorem 4.1.10(b)), and (a) applies.

What a subspace does determine is the dimension of its complements, by (b). Exercise 4.4.46 shows that a subspace has only one complement exactly when it is $\{\mathbf{0}\}$ or V, and Exercise 4.4.49 counts the complements over a finite field.

Complements also show that nothing distinguishes kernels or images among subspaces.

Proposition 4.4.18 (Every subspace is a kernel and an image). Let V be finite-dimensional, and let U be a subspace of V with a complement W. There are $S, T \in \mathrm{L}(V)$ with

$$\operatorname{im} S = U, \quad \ker S = W, \quad \ker T = U, \quad \operatorname{im} T = W.$$

In particular, every subspace of V is the image of some operator on V and the kernel of another.

Proof. ROUTINE

Uses. Proposition 4.4.16 (Complements exist), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Extend a basis of a subspace (Technique 4.1.18), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. Concatenate bases of U and W to get a basis of V, and define S and T on it.
Hint 2. Let S fix the basis vectors of U and kill those of W; let T do the opposite.
Sketch. With bases $\mathbf{u}_1, \ldots, \mathbf{u}_k$ of U and $\mathbf{w}_1, \ldots, \mathbf{w}_r$ of W, which together form a basis of V, let $S(\mathbf{u}_i) = \mathbf{u}_i$, $S(\mathbf{w}_j) = \mathbf{0}$, $T(\mathbf{u}_i) = \mathbf{0}$, and $T(\mathbf{w}_j) = \mathbf{w}_j$. Then $S(\sum a_i\mathbf{u}_i + \sum b_j\mathbf{w}_j) = \sum a_i\mathbf{u}_i$, which is $\mathbf{0}$ iff all $a_i = 0$; read off kernels and images. Complements exist by Proposition 4.4.16.

Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ and $\mathbf{w}_1, \ldots, \mathbf{w}_r$ be bases of U and W. Since $V = U \oplus W$, their concatenation is a basis of V (Theorem 4.4.13(b)). By Theorem 2.2.1 there are $S, T \in \mathrm{L}(V)$ with

$$S(\mathbf{u}_i) = \mathbf{u}_i, \quad S(\mathbf{w}_j) = \mathbf{0}, \quad T(\mathbf{u}_i) = \mathbf{0}, \quad T(\mathbf{w}_j) = \mathbf{w}_j$$

for all i and j. For $\mathbf{v} = \sum_i a_i\mathbf{u}_i + \sum_j b_j\mathbf{w}_j$, we get $S(\mathbf{v}) = \sum_i a_i\mathbf{u}_i$ and $T(\mathbf{v}) = \sum_j b_j\mathbf{w}_j$.

The image of S is the span of $S(\mathbf{u}_1), \ldots, S(\mathbf{w}_r)$, which is $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{0}, \ldots, \mathbf{0}) = U$ (Proposition 2.1.16). Since $\mathbf{u}_1, \ldots, \mathbf{u}_k$ is independent, $S(\mathbf{v}) = \mathbf{0}$ if and only if all $a_i = 0$ (Theorem 1.5.5), that is, if and only if $\mathbf{v} \in$

W. So $\ker S = W$. Exchanging the roles of U and W gives $\ker T = U$ and $\operatorname{im} T = W$. Every subspace has a complement by Proposition 4.4.16, which proves the last sentence. □

For $V = F^n$ this says that every subspace of F^n is a column space (which is clear: put a spanning list in the columns) and a null space. The second statement is the useful one: every subspace of F^n is the solution set of a homogeneous linear system. The operators S and T will reappear in Section 4.4.6 as the projections attached to $V = U \oplus W$.

ASIDE: *Complements in infinite dimensions* BEYOND 21-242

The proof of Proposition 4.4.16 extends a basis, which needs V to be finite-dimensional. Some subspaces of infinite-dimensional spaces have evident complements; in $F[x]$, the polynomials with $p(0) = 0$ have the constants as a complement. In fact every subspace of every vector space has a complement, but in general the proof needs Zorn's lemma (Section 15.1), and it produces no explicit complement.

4.4.5 The dimension formula

Intuition (Inclusion–exclusion for subspaces). For finite sets, $|A \cup B| = |A| + |B| - |A \cap B|$, because the elements of $A \cap B$ are counted twice. For subspaces, $U + W$ takes the place of the union (it is the smallest subspace containing it), and dimension takes the place of size. A basis of U together with a basis of W spans $U + W$, and we expect it to overcount by $\dim(U \cap W)$ directions. For arbitrary bases this is not visible: no entry of either basis need lie in $U \cap W$ (Exercise 4.4.38). So the first proof chooses bases that are adapted to $U \cap W$, which is the extension technique again.

Theorem 4.4.19 (Dimension of a sum). Let U and W be finite-dimensional subspaces of V. Then $U + W$ and $U \cap W$ are finite-dimensional, and

$$\dim(U + W) = \dim U + \dim W - \dim(U \cap W).$$

Proof (by extending a basis of $U \cap W$). STANDARD

Uses. Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis), Proposition 1.4.14 (The span is the smallest subspace containing a list), Theorem 1.5.5 (Independence is decided at zero), Theorem 4.1.4 (All bases have the same length)
Techniques. Extend a basis of a subspace (Technique 4.1.18)
Hint 1. Start with a basis $\mathbf{x}_1, \ldots, \mathbf{x}_m$ of $U \cap W$ and extend it twice: to a basis of U and to a basis of W.
Hint 2. Show that the $\mathbf{x}$'s, the new vectors of U, and the new vectors of W together form a basis of $U + W$. Spanning is easy.
Hint 3. For independence, take a relation and put the terms coming from W on one side. That side lies in W, and the other side lies in U.
Sketch. Extend a basis $\mathbf{x}_1, \ldots, \mathbf{x}_m$ of $U \cap W$ to bases $\mathbf{x}, \mathbf{u}_1, \ldots, \mathbf{u}_j$ of U and $\mathbf{x}, \mathbf{w}_1, \ldots, \mathbf{w}_l$ of W. The combined list spans $U + W$. In a relation $\sum a_i\mathbf{x}_i + \sum b_i\mathbf{u}_i + \sum c_i\mathbf{w}_i = \mathbf{0}$, the vector $\sum c_i\mathbf{w}_i$ equals $-(\sum a_i\mathbf{x}_i + \sum b_i\mathbf{u}_i) \in U$, so it lies in $U \cap W$ and is a combination of the $\mathbf{x}$'s; independence of $\mathbf{x}, \mathbf{w}$ forces $c = \mathbf{0}$, and then independence of $\mathbf{x}, \mathbf{u}$ forces $a = b = \mathbf{0}$. Count: $m + j + l = (m + j) + (m + l) - m$.

Since $U \cap W$ is a subspace of the finite-dimensional space U, it is finite-dimensional (Proposition 4.1.21(a)). Let $\mathbf{x}_1, \ldots, \mathbf{x}_m$ be a basis of $U \cap W$. It is an independent list in U, so it extends to a basis $\mathbf{x}_1, \ldots, \mathbf{x}_m, \mathbf{u}_1, \ldots, \mathbf{u}_j$ of U (Theorem 4.1.16, applied in U), and likewise to a basis $\mathbf{x}_1, \ldots, \mathbf{x}_m, \mathbf{w}_1, \ldots, \mathbf{w}_l$ of W. Then $\dim U = m + j$ and $\dim W = m + l$. We claim that

$$\mathcal{L} = \mathbf{x}_1, \ldots, \mathbf{x}_m, \mathbf{u}_1, \ldots, \mathbf{u}_j, \mathbf{w}_1, \ldots, \mathbf{w}_l$$

is a basis of $U + W$. Then $U + W$ is finite-dimensional, and

$$\dim(U + W) = m + j + l = (m + j) + (m + l) - m = \dim U + \dim W - \dim(U \cap W).$$

$\mathcal{L}$ *spans* $U+W$. Every entry of $\mathcal{L}$ lies in U or in W, hence in the subspace $U+W$, so $\operatorname{span}(\mathcal{L}) \subseteq U+W$ (Proposition 1.4.14(b)). Conversely, let $\mathbf{u}+\mathbf{w} \in U+W$ with $\mathbf{u} \in U$ and $\mathbf{w} \in W$. Then $\mathbf{u}$ is a combination of the $\mathbf{x}$'s and $\mathbf{u}$'s, and $\mathbf{w}$ is a combination of the $\mathbf{x}$'s and $\mathbf{w}$'s, so $\mathbf{u}+\mathbf{w} \in \operatorname{span}(\mathcal{L})$.

$\mathcal{L}$ *is independent.* Suppose

$$\sum_{i=1}^{m} a_i \mathbf{x}_i + \sum_{i=1}^{j} b_i \mathbf{u}_i + \sum_{i=1}^{l} c_i \mathbf{w}_i = \mathbf{0}.$$

Then $\mathbf{y} = \sum_i c_i \mathbf{w}_i = -\left(\sum_i a_i \mathbf{x}_i + \sum_i b_i \mathbf{u}_i\right)$ lies in W (by the first expression) and in U (by the second), so $\mathbf{y} \in U \cap W$, and $\mathbf{y} = \sum_i d_i \mathbf{x}_i$ for some scalars d_i. Hence

$$\sum_{i=1}^{l} c_i \mathbf{w}_i - \sum_{i=1}^{m} d_i \mathbf{x}_i = \mathbf{0},$$

and since $\mathbf{x}_1, \ldots, \mathbf{x}_m, \mathbf{w}_1, \ldots, \mathbf{w}_l$ is independent, all c_i (and d_i) are 0 (Theorem 1.5.5). The original relation becomes $\sum_i a_i \mathbf{x}_i + \sum_i b_i \mathbf{u}_i = \mathbf{0}$, and since $\mathbf{x}_1, \ldots, \mathbf{x}_m, \mathbf{u}_1, \ldots, \mathbf{u}_j$ is independent, all a_i and b_i are 0 as well. □

The second proof reduces the formula to the direct case. Inside U, split off the part of U that overlaps W; what remains of U meets W trivially.

Proof (via a complement inside U). STANDARD

> *Uses.* Proposition 4.4.16 (Complements exist), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.4.7 (Criteria for direct sums), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 4.4.2 (Sums are the smallest containing subspaces)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* Choose a complement X of $U \cap W$ inside the finite-dimensional space U, so that $U = (U \cap W) \oplus X$. Show that $U + W = X \oplus W$.
> *Hint 2.* Since $X \subseteq U$, a vector of $X \cap W$ lies in $U \cap W$. For the sum, $U = (U \cap W) + X \subseteq W + X$.
> *Sketch.* Let X be a complement of $U \cap W$ in U, so $\dim X = \dim U - \dim(U \cap W)$. Since $X \subseteq U$, $X \cap W = X \cap (U \cap W) = \{\mathbf{0}\}$. Since $U = (U \cap W) + X \subseteq X + W$, $U + W = X + W$. So $U + W = X \oplus W$, and Theorem 4.4.13(c) gives $\dim(U+W) = \dim X + \dim W$.

As in the first proof, $U \cap W$ is finite-dimensional. Apply Proposition 4.4.16 in the finite-dimensional space U to its subspace $U \cap W$: there is a subspace $X \subseteq U$ with $U = (U \cap W) \oplus X$, and $\dim X = \dim U - \dim(U \cap W)$.

First, $X \cap W = \{\mathbf{0}\}$: a vector of $X \cap W$ lies in U (as $X \subseteq U$) and in W, so it lies in $X \cap (U \cap W) = \{\mathbf{0}\}$. Second, $X + W = U + W$: since $X \subseteq U$, we have $X + W \subseteq U + W$; and since $U \cap W \subseteq W$, we have $U = (U \cap W) + X \subseteq X + W$, so the subspace $X + W$ contains U and W and hence $U + W$ (Proposition 4.4.2(b)). By Theorem 4.4.7, $U + W = X \oplus W$, and by Theorem 4.4.13, $U + W$ is finite-dimensional with

$$\dim(U+W) = \dim X + \dim W = \dim U - \dim(U \cap W) + \dim W.$$ □

The third proof counts a kernel and an image. It completes the remark after Proposition 4.2.26, whose first proof used the same map to bound $\dim(U \cap W)$.

Proof (by rank–nullity). STANDARD

> *Uses.* Theorem 4.2.11 (Rank–nullity), Proposition 4.2.6 (Injective maps preserve dimension), Theorem 1.5.5 (Independence is decided at zero), Proposition 4.2.26 (Subspaces that must meet), Proposition 4.1.21 (Dimensions of subspaces)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* With bases $\mathbf{u}_1, \ldots, \mathbf{u}_k$ of U and $\mathbf{w}_1, \ldots, \mathbf{w}_l$ of W, consider $L : F^{k+l} \to V$, $L(\mathbf{a}, \mathbf{b}) = \sum_i a_i \mathbf{u}_i - \sum_j b_j \mathbf{w}_j$. What is $\operatorname{im} L$?
> *Hint 2.* An element of $\ker L$ is a pair of coordinate vectors describing one vector of $U \cap W$. Show that $(\mathbf{a}, \mathbf{b}) \mapsto \sum_i a_i \mathbf{u}_i$ is a bijection from $\ker L$ onto $U \cap W$.
> *Sketch.* $\operatorname{im} L = U + W$, since $\mathbf{b}$ and $-\mathbf{b}$ range over the same set. The linear map $\varphi(\mathbf{a}, \mathbf{b}) = \sum_i a_i \mathbf{u}_i$ sends $\ker L$ into $U \cap W$ and is injective, as in Proposition 4.2.26. It is onto $U \cap W$: if $\mathbf{v} = \sum_i a_i \mathbf{u}_i = \sum_j b_j \mathbf{w}_j$, then $(\mathbf{a}, \mathbf{b}) \in \ker L$ and $\varphi(\mathbf{a}, \mathbf{b}) = \mathbf{v}$. So $\dim \ker L = \dim(U \cap W)$, and rank–nullity for L reads $k + l = \dim(U \cap W) + \dim(U + W)$.

Let $\mathbf{u}_1, \dots, \mathbf{u}_k$ and $\mathbf{w}_1, \dots, \mathbf{w}_l$ be bases of U and W. Write elements of F^{k+l} as $(\mathbf{a}, \mathbf{b})$ with $\mathbf{a} \in F^k$ and $\mathbf{b} \in F^l$, and define the linear map

$$L : F^{k+l} \to V, \quad L(\mathbf{a}, \mathbf{b}) = a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k - b_1\mathbf{w}_1 - \cdots - b_l\mathbf{w}_l.$$

Every value of L is a vector of U plus a vector of W, and every $\mathbf{u} + \mathbf{w}$ with $\mathbf{u} = \sum_i a_i\mathbf{u}_i$ and $\mathbf{w} = \sum_j b_j\mathbf{w}_j$ equals $L(\mathbf{a}, -\mathbf{b})$. So $\operatorname{im} L = U + W$. By rank–nullity (Theorem 4.2.11(b)), $U + W$ is finite-dimensional and

$$k + l = \dim \ker L + \dim(U + W).$$

Define $\varphi : \ker L \to V$ by $\varphi(\mathbf{a}, \mathbf{b}) = \sum_i a_i\mathbf{u}_i$; it is linear. For $(\mathbf{a}, \mathbf{b}) \in \ker L$ we have $\sum_i a_i\mathbf{u}_i = \sum_j b_j\mathbf{w}_j$, so $\varphi(\mathbf{a}, \mathbf{b})$ lies in U and in W. Conversely, every $\mathbf{v} \in U \cap W$ can be written as $\mathbf{v} = \sum_i a_i\mathbf{u}_i = \sum_j b_j\mathbf{w}_j$, and then $(\mathbf{a}, \mathbf{b}) \in \ker L$ with $\varphi(\mathbf{a}, \mathbf{b}) = \mathbf{v}$. So $\operatorname{im} \varphi = U \cap W$. Finally, φ is injective: if $\sum_i a_i\mathbf{u}_i = \mathbf{0}$, then $\mathbf{a} = \mathbf{0}$, so $\sum_j b_j\mathbf{w}_j = \mathbf{0}$ and $\mathbf{b} = \mathbf{0}$ (Theorem 1.5.5). By Proposition 4.2.6(a), applied to φ on the finite-dimensional space $\ker L$, $\dim(U \cap W) = \dim \ker L$. Substituting gives $k + l = \dim(U \cap W) + \dim(U + W)$, as desired. □

The three proofs teach different things. The first builds an explicit basis of $U + W$ and is the one to adapt when a basis is wanted. The second shows that the formula is the direct case, $\dim(X \oplus W) = \dim X + \dim W$, in disguise. The third is how one computes: for $U, W \subseteq F^n$, $\ker L$ is the null space of the matrix whose columns are the $\mathbf{u}_i$ and the $-\mathbf{w}_j$, so one row reduction finds $\dim(U + W)$ and a basis of $U \cap W$ at once. With the quotient spaces of Section 4.6, the formula can also be read as $(U + W)/W \cong U/(U \cap W)$.

Example 4.4.20 (Computing a sum and an intersection). In $\mathbb{Q}^4$, let $U = \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$ and $W = \operatorname{span}(\mathbf{w}_1, \mathbf{w}_2)$, where

$$\mathbf{u}_1 = (1, 0, 1, 0), \quad \mathbf{u}_2 = (0, 1, 1, 1), \quad \mathbf{w}_1 = (2, 0, -1, 1), \quad \mathbf{w}_2 = (1, 1, -1, 2).$$

Row reduce the matrix whose columns are $\mathbf{u}_1, \mathbf{u}_2, \mathbf{w}_1, \mathbf{w}_2$:

$$\begin{pmatrix} 1 & 0 & 2 & 1 \\ 0 & 1 & 0 & 1 \\ 1 & 1 & -1 & -1 \\ 0 & 1 & 1 & 2 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & 0 & -1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

The first two columns are pivot columns, so $\mathbf{u}_1, \mathbf{u}_2$ is independent and $\dim U = 2$. The vectors $\mathbf{w}_1, \mathbf{w}_2$ are not parallel (look at the second coordinates), so $\dim W = 2$. By Proposition 4.4.2(c), $U + W$ is the column space, so $\dim(U + W) = 3$, the number of pivots (Theorem 4.2.7). The formula gives

$$\dim(U \cap W) = 2 + 2 - 3 = 1.$$

To find the line $U \cap W$, read the free column: it says $\mathbf{w}_2 = -\mathbf{u}_1 + \mathbf{u}_2 + \mathbf{w}_1$ (Corollary 3.3.19(b)). Sorting the terms by subspace,

$$-\mathbf{u}_1 + \mathbf{u}_2 = -\mathbf{w}_1 + \mathbf{w}_2 = (-1, 1, 0, 1).$$

The left side lies in U and the right side in W, so this nonzero vector spans $U \cap W$. In the language of the third proof, $(\mathbf{a}, \mathbf{b}) = ((-1, 1), (-1, 1))$ spans $\ker L$.

Since $U + W \subseteq V$, the formula recovers Proposition 4.2.26: $\dim(U \cap W) = \dim U + \dim W - \dim(U + W) \geq \dim U + \dim W - \dim V$. It also says by how much that bound can miss, namely by $\dim V - \dim(U + W)$. The most frequent use is a test for complements.

Proposition 4.4.21 (Two out of three). Let V be finite-dimensional, and let U and W be subspaces of V. Consider the conditions

(i) $U \cap W = \{\mathbf{0}\}$;

(ii) $U + W = V$;

(iii) $\dim U + \dim W = \dim V$.

Any two of them imply the third, and then $V = U \oplus W$.

Proof. ROUTINE

Uses. Theorem 4.4.19 (Dimension of a sum), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.4.7 (Criteria for direct sums)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Write the dimension formula as $\dim(U+W) + \dim(U \cap W) = \dim U + \dim W$ and substitute each pair of conditions.
Hint 2. To get (ii) from a dimension count, use that a subspace of V of dimension $\dim V$ is V.
Sketch. By Theorem 4.4.19, $\dim(U+W) + \dim(U \cap W) = \dim U + \dim W$. (i) and (ii) make the left side $\dim V$. (i) and (iii) give $\dim(U+W) = \dim V$, so $U + W = V$. (ii) and (iii) give $\dim(U \cap W) = 0$. Then $V = U \oplus W$ by Theorem 4.4.7.

By Theorem 4.4.19,

$$\dim(U+W) + \dim(U \cap W) = \dim U + \dim W.$$

If (i) and (ii) hold, the left side is $\dim V + 0$, which gives (iii). If (i) and (iii) hold, then $\dim(U+W) = \dim V$, so $U + W = V$ by Proposition 4.1.21(b), which is (ii). If (ii) and (iii) hold, then $\dim V + \dim(U \cap W) = \dim V$, so $\dim(U \cap W) = 0$ and $U \cap W = \{\mathbf{0}\}$, which is (i). In each case (i) and (ii) hold, so $V = U \oplus W$ by Theorem 4.4.7. □

This is the subspace version of the fact that a list of length $\dim V$ is a basis as soon as it is independent or spanning (Theorem 4.1.10, Corollary 4.1.11): with the right dimensions, checking one of "meet trivially" and "add up to V" gives the other for free.

Remark 4.4.22 (No formula for three subspaces). There is no formula of this kind for three subspaces in terms of the dimensions of their intersections. For the three lines ℓ_1, ℓ_2, ℓ_3 of Non-example 4.4.6(b), all pairwise intersections and the triple intersection are $\{\mathbf{0}\}$, so the inclusion–exclusion expression $1 + 1 + 1 - 0 - 0 - 0 + 0$ gives 3, while $\dim(\ell_1 + \ell_2 + \ell_3) = 2$. The two-subspace proofs break down because $(U+W) \cap X$ can be larger than $(U \cap X) + (W \cap X)$; Exercise 4.4.39 shows that this is the only obstruction.

Exercise 4.4.23. ROUTINE Let $U = \{\mathbf{x} \in F^4 \mid x_1 + x_2 + x_3 + x_4 = 0\}$.

(a) Show that the complements of U in F^4 are exactly the lines $\operatorname{span}(\mathbf{v})$ with $\mathbf{v} \notin U$.

(b) Is $\operatorname{span}((1,1,1,1))$ a complement of U when $F = \mathbb{Q}$? When $F = \mathbb{F}_2$? When $F = \mathbb{F}_3$?

Solution on page 1321

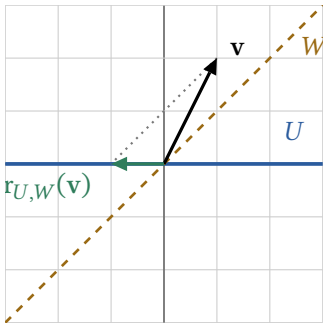
4.4.6 Projections

A decomposition $V = U \oplus W$ gives every vector a well-defined U-component. Taking that component is a linear map, and the maps that arise in this way are exactly the operators P with $P^2 = P$.

Definition 4.4.24 (Projection along a complement). Suppose $V = U \oplus W$. The **projection onto** U **along** W is the map

$$\operatorname{Pr}_{U,W} : V \to V, \quad \mathbf{u} + \mathbf{w} \mapsto \mathbf{u} \quad (\mathbf{u} \in U, \mathbf{w} \in W).$$

It is well defined because every vector of V has exactly one decomposition $\mathbf{u} + \mathbf{w}$. The order of the subscripts matters: $\operatorname{Pr}_{U,W}$ keeps the U-component and $\operatorname{Pr}_{W,U}$ keeps the W-component. Changing W changes the map, even though its image is still U. The orthogonal projection Pr_W of Section 6.4 is the special case $\operatorname{Pr}_{W,W^\perp}$.



Example 4.4.25 (Projecting along a slanted line). In F^2, let $U = \operatorname{span}(\mathbf{e}_1)$ and $W = \operatorname{span}((1,1))$. Every vector decomposes as

$$(x, y) = (x - y, 0) + (y, y),$$

with $(x - y, 0) \in U$ and $(y, y) \in W$. So $\operatorname{Pr}_{U,W}(x, y) = (x - y, 0)$ and $\operatorname{Pr}_{W,U}(x, y) = (y, y)$, and their matrices with respect to the standard basis are

$$\begin{pmatrix} 1 & -1 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 \\ 0 & 1 \end{pmatrix}.$$

Each matrix squares to itself, the two add up to I_2, and their products in either order are 0. Over $\mathbb{R}$, $\operatorname{Pr}_{U,W}$ slides every point parallel to $(1,1)$ until it reaches the x-axis. It is not the perpendicular projection onto the x-axis, which is $(x, y) \mapsto (x, 0)$, the projection onto U along the y-axis.

The projection $\operatorname{Pr}_{U,W}$ of Example 4.4.25, with U the x-axis and $W = \operatorname{span}((1,1))$. The plane collapses onto U, every point moves parallel to W, and the points of W go to $\mathbf{0}$. In the static picture, $\mathbf{v} = (1,2)$ goes to $\operatorname{Pr}_{U,W}(\mathbf{v}) = (-1,0)$, and the dotted segment from $\mathbf{v}$ to its image is parallel to W. In the interactive version you can change the matrix; the result is a projection exactly when $A^2 = A$. (Interactive in the web version.)

Proposition 4.4.26 (Properties of projections). Suppose $V = U \oplus W$, and let $P = \operatorname{Pr}_{U,W}$ and $Q = \operatorname{Pr}_{W,U}$.

(a) P is linear.

(b) $\operatorname{im} P = U$ and $\ker P = W$, and $P(\mathbf{u}) = \mathbf{u}$ for every $\mathbf{u} \in U$.

(c) $P^2 = P$.

(d) $P + Q = \mathrm{id}_V$ and $PQ = QP = 0$.

Proof. ROUTINE

Uses. Definition 4.4.24 (Projection along a complement), Definition 4.4.4 (Direct sum), Definition 2.1.1 (Linear map)
Techniques. Compare components (Technique 4.4.8)
Hint 1. For (a), if $\mathbf{v} = \mathbf{u} + \mathbf{w}$ and $\mathbf{v}' = \mathbf{u}' + \mathbf{w}'$, write down a decomposition of $\mathbf{v} + \mathbf{v}'$ and of $a\mathbf{v}$. Uniqueness does the rest.
Hint 2. For (b), the decomposition of a vector $\mathbf{u} \in U$ is $\mathbf{u} + \mathbf{0}$. For (d), $\mathbf{v} = P(\mathbf{v}) + Q(\mathbf{v})$ by definition.
Sketch. (a) $(\mathbf{u} + \mathbf{u}') + (\mathbf{w} + \mathbf{w}')$ and $a\mathbf{u} + a\mathbf{w}$ are decompositions of $\mathbf{v} + \mathbf{v}'$ and $a\mathbf{v}$, hence the decompositions, so $P(\mathbf{v} + \mathbf{v}') = \mathbf{u} + \mathbf{u}'$ and $P(a\mathbf{v}) = a\mathbf{u}$. (b) $\mathbf{u} = \mathbf{u} + \mathbf{0}$ gives $P(\mathbf{u}) = \mathbf{u}$, so $\operatorname{im} P = U$; and $P(\mathbf{u} + \mathbf{w}) = \mathbf{0}$ iff $\mathbf{u} = \mathbf{0}$. (c) $P(\mathbf{v}) \in U$ is fixed. (d) $\mathbf{v} = \mathbf{u} + \mathbf{w} = P(\mathbf{v}) + Q(\mathbf{v})$, and $P(Q(\mathbf{v})) = P(\mathbf{w}) = \mathbf{0}$ since $\mathbf{w} \in W = \ker P$; symmetrically $QP = 0$.

Throughout, $\mathbf{v} = \mathbf{u} + \mathbf{w}$ and $\mathbf{v}' = \mathbf{u}' + \mathbf{w}'$ with $\mathbf{u}, \mathbf{u}' \in U$ and $\mathbf{w}, \mathbf{w}' \in W$.

(a) Since U and W are subspaces, $\mathbf{v} + \mathbf{v}' = (\mathbf{u} + \mathbf{u}') + (\mathbf{w} + \mathbf{w}')$ and $a\mathbf{v} = a\mathbf{u} + a\mathbf{w}$ are decompositions of $\mathbf{v} + \mathbf{v}'$ and $a\mathbf{v}$ along $U \oplus W$, so they are *the* decompositions. Hence $P(\mathbf{v} + \mathbf{v}') = \mathbf{u} + \mathbf{u}' = P(\mathbf{v}) + P(\mathbf{v}')$ and $P(a\mathbf{v}) = a\mathbf{u} = aP(\mathbf{v})$.

(b) Every value of P lies in U. For $\mathbf{u} \in U$, the decomposition of $\mathbf{u}$ is $\mathbf{u} + \mathbf{0}$, so $P(\mathbf{u}) = \mathbf{u}$; hence $U \subseteq \operatorname{im} P$, and $\operatorname{im} P = U$. Next, $P(\mathbf{v}) = \mathbf{u}$ is $\mathbf{0}$ if and only if $\mathbf{v} = \mathbf{w} \in W$, so $\ker P = W$.

(c) For every $\mathbf{v}$, $P(\mathbf{v}) \in U$, so $P(P(\mathbf{v})) = P(\mathbf{v})$ by (b).

(d) By definition $P(\mathbf{v}) + Q(\mathbf{v}) = \mathbf{u} + \mathbf{w} = \mathbf{v}$, so $P + Q = \mathrm{id}_V$. Since $Q(\mathbf{v}) = \mathbf{w} \in W = \ker P$, we get $PQ(\mathbf{v}) = \mathbf{0}$. Exchanging the roles of U and W (so that $Q = \mathrm{Pr}_{W,U}$ has kernel U) gives $QP = 0$. □

An operator P with $P^2 = P$ is called **idempotent**. The converse of (c) is the main result of this subsection: every idempotent operator is a projection.

> **Theorem 4.4.27** (Idempotents are projections). Let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$. Then
>
> $$V = \operatorname{im} P \oplus \ker P,$$
>
> and $P = \mathrm{Pr}_{\operatorname{im} P, \ker P}$. Moreover, $\operatorname{im} P = \{\mathbf{v} \in V \mid P(\mathbf{v}) = \mathbf{v}\}$.

Together with Proposition 4.4.26, the theorem gives a bijection between the ways of writing $V = U \oplus W$ (with U and W in this order) and the idempotent operators on V: a decomposition gives $\mathrm{Pr}_{U,W}$, and an idempotent P gives the decomposition $V = \operatorname{im} P \oplus \ker P$.

Proof (by writing down the decomposition). ROUTINE

> *Uses.* Theorem 4.4.7 (Criteria for direct sums), Definition 4.4.24 (Projection along a complement), Proposition 2.6.8 (Kernels and images are subspaces)
> *Techniques.* Compare components (Technique 4.4.8)
> *Hint 1.* Every $\mathbf{v}$ can be written as $P(\mathbf{v}) + (\mathbf{v} - P(\mathbf{v}))$. Where do the two pieces lie?
> *Hint 2.* If $\mathbf{v} \in \operatorname{im} P \cap \ker P$, write $\mathbf{v} = P(\mathbf{x})$ and apply P.
> *Sketch.* $P(\mathbf{v} - P(\mathbf{v})) = P(\mathbf{v}) - P^2(\mathbf{v}) = \mathbf{0}$, so $\mathbf{v} = P(\mathbf{v}) + (\mathbf{v} - P(\mathbf{v})) \in \operatorname{im} P + \ker P$. If $\mathbf{v} = P(\mathbf{x})$ and $P(\mathbf{v}) = \mathbf{0}$, then $\mathbf{v} = P^2(\mathbf{x}) = P(\mathbf{v}) = \mathbf{0}$. So $V = \operatorname{im} P \oplus \ker P$, and the $\operatorname{im} P$-component of $\mathbf{v}$ is $P(\mathbf{v})$. Vectors $P(\mathbf{x})$ of $\operatorname{im} P$ are fixed, as $P(P(\mathbf{x})) = P(\mathbf{x})$.

Let $\mathbf{v} \in V$. Then $P(\mathbf{v}) \in \operatorname{im} P$, and

$$P(\mathbf{v} - P(\mathbf{v})) = P(\mathbf{v}) - P^2(\mathbf{v}) = P(\mathbf{v}) - P(\mathbf{v}) = \mathbf{0},$$

so $\mathbf{v} - P(\mathbf{v}) \in \ker P$. Hence

$$\mathbf{v} = P(\mathbf{v}) + (\mathbf{v} - P(\mathbf{v}))$$

is a decomposition of $\mathbf{v}$ along $\operatorname{im} P$ and $\ker P$, and $V = \operatorname{im} P + \ker P$. Next, let $\mathbf{v} \in \operatorname{im} P \cap \ker P$, say $\mathbf{v} = P(\mathbf{x})$. Then $\mathbf{v} = P(\mathbf{x}) = P^2(\mathbf{x}) = P(\mathbf{v}) = \mathbf{0}$. By Theorem 4.4.7, $V = \operatorname{im} P \oplus \ker P$, and by the displayed decomposition, the $\operatorname{im} P$-component of $\mathbf{v}$ is $P(\mathbf{v})$, that is, $P = \mathrm{Pr}_{\operatorname{im} P, \ker P}$.

Finally, if $P(\mathbf{v}) = \mathbf{v}$, then $\mathbf{v} \in \operatorname{im} P$; conversely, if $\mathbf{v} = P(\mathbf{x})$, then $P(\mathbf{v}) = P^2(\mathbf{x}) = P(\mathbf{x}) = \mathbf{v}$. □

In finite dimensions there is a second proof, which never writes down the decomposition $\mathbf{v} = P(\mathbf{v}) + (\mathbf{v} - P(\mathbf{v}))$ and lets a dimension count produce the sum instead.

Proof (in finite dimensions, by counting). ROUTINE

> *Uses.* Theorem 4.2.11 (Rank–nullity), Proposition 4.4.21 (Two out of three), Definition 4.4.24 (Projection along a complement)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* Show $\operatorname{im} P \cap \ker P = \{\mathbf{0}\}$ as in the first proof.
> *Hint 2.* Rank–nullity gives $\dim \operatorname{im} P + \dim \ker P = \dim V$. Which result turns this and a trivial intersection into a direct sum?
> *Sketch.* If $\mathbf{v} = P(\mathbf{x})$ and $P(\mathbf{v}) = \mathbf{0}$, then $\mathbf{v} = P^2(\mathbf{x}) = \mathbf{0}$. Rank–nullity gives $\dim \operatorname{im} P + \dim \ker P = \dim V$, so $V = \operatorname{im} P \oplus \ker P$ by Proposition 4.4.21. For $\mathbf{v} = P(\mathbf{x}) + \mathbf{w}$ with $\mathbf{w} \in \ker P$, $P(\mathbf{v}) = P^2(\mathbf{x}) = P(\mathbf{x})$, the $\operatorname{im} P$-component.

Assume that V is finite-dimensional. As in the first proof, if $\mathbf{v} = P(\mathbf{x})$ lies in $\ker P$, then $\mathbf{v} = P^2(\mathbf{x}) = P(\mathbf{v}) = \mathbf{0}$, so $\operatorname{im} P \cap \ker P = \{\mathbf{0}\}$. By Theorem 4.2.11, $\dim \operatorname{im} P + \dim \ker P = \dim V$. Conditions (i) and (iii) of Proposition 4.4.21 hold, so $V = \operatorname{im} P \oplus \ker P$. To identify P, let $\mathbf{v} = P(\mathbf{x}) + \mathbf{w}$ with $\mathbf{w} \in \ker P$. Then $P(\mathbf{v}) = P^2(\mathbf{x}) + P(\mathbf{w}) = P(\mathbf{x})$, which is the $\operatorname{im} P$-component of $\mathbf{v}$. So $P = \mathrm{Pr}_{\operatorname{im} P, \ker P}$. □

The counting proof does not reach infinite-dimensional spaces, and even in finite dimensions the first proof is more informative: it says what the components of $\mathbf{v}$ are.

> **Technique 4.4.28** (Split the space with an idempotent). To decompose V as a direct sum, look for an operator P with $P^2 = P$. Then $V = \operatorname{im} P \oplus \ker P$, every vector splits as $\mathbf{v} = P(\mathbf{v}) + (\mathbf{v} - P(\mathbf{v}))$, and $\operatorname{im} P$ is the set of vectors that P fixes (Theorem 4.4.27). In the other direction, every decomposition $V = U \oplus W$ comes with its projections, and statements about decompositions become algebra of operators: $P^2 = P$, $P + Q = \mathrm{id}_V$, $PQ = QP = 0$.
>
> Reach for it when a formula suggests "the part of $\mathbf{v}$ that ...", such as the symmetric part $\left(A + A^{\mathsf{T}}\right)/2$ of a matrix, or more generally the average of $\mathbf{v}$ and $T(\mathbf{v})$ for an operator with $T^2 = \mathrm{id}_V$ (Exercise 4.4.43). Each is $P(\mathbf{v})$ for an idempotent P. The canonical example is Theorem 4.4.27. Later, idempotent matrices over $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$ have trace equal to rank (Exercise 4.3.43), and orthogonal projections are the idempotents that are self-adjoint (Section 6.6).
>
> *Used in.* Exercise 4.4.30, Exercise 4.4.43, Exercise 4.4.51, Problem 4.4.

A direct sum of k subspaces comes with k projections, one for each summand. They are the algebraic form of the decomposition, and they are how Chapters 7 and 8 talk about splitting V into eigenspaces.

> **Proposition 4.4.29** (Projections of a direct sum).
>
> (a) Suppose $V = U_1 \oplus \cdots \oplus U_k$, and let $P_i : V \to V$ send each vector to its component in U_i. Then each P_i is linear with $\operatorname{im} P_i = U_i$, and
>
> $$P_1 + \cdots + P_k = \mathrm{id}_V, \quad P_i^2 = P_i, \quad P_i P_j = 0 \quad (i \neq j).$$
>
> (b) Conversely, let $P_1, \ldots, P_k \in \mathrm{L}(V)$ satisfy $P_1 + \cdots + P_k = \mathrm{id}_V$ and $P_i P_j = 0$ for $i \neq j$. Then each P_i is idempotent, $V = \operatorname{im} P_1 \oplus \cdots \oplus \operatorname{im} P_k$, and P_i sends each vector to its component in $\operatorname{im} P_i$.

Proof. STANDARD

> *Uses.* Theorem 4.4.7 (Criteria for direct sums), Proposition 4.4.26 (Properties of projections), Definition 4.4.24 (Projection along a complement), Proposition 4.4.2 (Sums are the smallest containing subspaces)
> *Techniques.* Apply an operator to a relation to kill terms (Technique 4.1.25), Compare components (Technique 4.4.8)
> *Hint 1.* For (a), let W_i be the sum of the summands other than U_i. Show $V = U_i \oplus W_i$ and $P_i = \mathrm{Pr}_{U_i, W_i}$.
> *Hint 2.* For (b), multiply $\mathrm{id}_V = \sum_j P_j$ on the left by P_i to get idempotence.
> *Hint 3.* For directness in (b), take $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ with $\mathbf{u}_i = P_i(\mathbf{x}_i)$ and apply P_j: every term but one is killed.
> *Sketch.* (a) With $W_i = \sum_{j \neq i} U_j$, criterion (III) gives $V = U_i \oplus W_i$, and $P_i = \mathrm{Pr}_{U_i, W_i}$, which is linear and idempotent with image U_i and kernel W_i. For $j \neq i$, $P_j(\mathbf{v}) \in U_j \subseteq W_i$, so $P_i P_j = 0$; and $\mathbf{v} = \sum_i P_i(\mathbf{v})$. (b) $P_i = P_i \sum_j P_j = P_i^2$. Since $\mathbf{v} = \sum_i P_i(\mathbf{v})$, the images add up to V. If $\sum_i P_i(\mathbf{x}_i) = \mathbf{0}$, applying P_j leaves $P_j^2(\mathbf{x}_j) = P_j(\mathbf{x}_j) = \mathbf{0}$, so the sum is direct, and $\mathbf{v} = \sum_i P_i(\mathbf{v})$ is the decomposition of $\mathbf{v}$.

(a) Fix i and let $W_i = \sum_{j \neq i} U_j$. Every $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_k$ (with $\mathbf{u}_j \in U_j$) is $\mathbf{u}_i + \sum_{j \neq i} \mathbf{u}_j \in U_i + W_i$, and $U_i \cap W_i = \{\mathbf{0}\}$ by (III) of Theorem 4.4.7. So $V = U_i \oplus W_i$, and the U_i-component of $\mathbf{v}$ in this decomposition is again $\mathbf{u}_i$. That is, $P_i = \mathrm{Pr}_{U_i, W_i}$, which is linear and idempotent with image U_i and kernel W_i by Proposition 4.4.26. For $j \neq i$ and $\mathbf{v} \in V$, $P_j(\mathbf{v}) \in U_j \subseteq W_i = \ker P_i$, so $P_i P_j = 0$. Finally, $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_k = P_1(\mathbf{v}) + \cdots + P_k(\mathbf{v})$, so $P_1 + \cdots + P_k = \mathrm{id}_V$.

(b) For each i,

$$P_i = P_i \mathrm{id}_V = P_i(P_1 + \cdots + P_k) = P_i P_1 + \cdots + P_i P_k = P_i^2,$$

since every term $P_i P_j$ with $j \neq i$ is 0. For $\mathbf{v} \in V$, $\mathbf{v} = P_1(\mathbf{v}) + \cdots + P_k(\mathbf{v})$, so $V = \operatorname{im} P_1 + \cdots + \operatorname{im} P_k$. For directness we check (II) of Theorem 4.4.7. Let $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ with $\mathbf{u}_i = P_i(\mathbf{x}_i) \in \operatorname{im} P_i$, and fix j. Applying P_j kills every term with $i \neq j$, because $P_j(\mathbf{u}_i) = P_j P_i(\mathbf{x}_i) = \mathbf{0}$, and leaves $P_j(\mathbf{u}_j) = P_j^2(\mathbf{x}_j) = P_j(\mathbf{x}_j) = \mathbf{u}_j$. So $\mathbf{u}_j = P_j(\mathbf{0}) = \mathbf{0}$. Hence $V = \operatorname{im} P_1 \oplus \cdots \oplus \operatorname{im} P_k$, and since $\mathbf{v} = \sum_i P_i(\mathbf{v})$ with $P_i(\mathbf{v}) \in \operatorname{im} P_i$, the component of $\mathbf{v}$ in $\operatorname{im} P_i$ is $P_i(\mathbf{v})$. □

Exercise 4.4.30. ROUTINE In $\mathbb{Q}^3$, let $U = \{\mathbf{x} \mid x_1 + x_2 + x_3 = 0\}$ and $W = \operatorname{span}((1,1,1))$.

(a) Show that $\mathbb{Q}^3 = U \oplus W$, and find the matrices of $\operatorname{Pr}_{U,W}$ and $\operatorname{Pr}_{W,U}$ with respect to the standard basis.

(b) Show that over $\mathbb{F}_3$, $U + W \neq \mathbb{F}_3^3$. Which step of (a) fails?

Solution on page 1321

4.4.7 Linear maps on direct sums

A linear map is determined by its values on a basis, and those values can be prescribed freely (Theorem 2.2.1). A direct sum decomposition gives the same freedom, one summand at a time.

Proposition 4.4.31 (Defining maps summand by summand). Suppose $V = U_1 \oplus \cdots \oplus U_k$, and let $S_i \in \mathrm{L}(U_i, W)$ for each i. There is exactly one $T \in \mathrm{L}(V, W)$ with $T(\mathbf{u}) = S_i(\mathbf{u})$ for every i and every $\mathbf{u} \in U_i$, namely

$$T(\mathbf{u}_1 + \cdots + \mathbf{u}_k) = S_1(\mathbf{u}_1) + \cdots + S_k(\mathbf{u}_k) \quad (\mathbf{u}_i \in U_i).$$

Proof. ROUTINE

Uses. Definition 4.4.4 (Direct sum), Proposition 4.4.29 (Projections of a direct sum), Proposition 2.1.17 (Compositions of linear maps are linear), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Compare components (Technique 4.4.8)
Hint 1. Uniqueness: a linear T that agrees with each S_i on U_i must satisfy the displayed formula.
Hint 2. Existence: the formula is well defined because decompositions are unique. For linearity, write T in terms of the projections of Proposition 4.4.29.
Sketch. If T is linear and agrees with S_i on U_i, then $T\big(\sum_i \mathbf{u}_i\big) = \sum_i T(\mathbf{u}_i) = \sum_i S_i(\mathbf{u}_i)$, so T is unique. The formula defines a function because each vector has one decomposition, and it equals $\sum_i S_i \circ P_i'$, where $P_i' : V \to U_i$ takes the U_i-component; this is linear. On $\mathbf{u} \in U_i$ the decomposition is $\mathbf{u}$ in slot i and $\mathbf{0}$ elsewhere, so $T(\mathbf{u}) = S_i(\mathbf{u})$.

Uniqueness. If $T \in \mathrm{L}(V,W)$ agrees with S_i on U_i for each i, then for $\mathbf{u}_i \in U_i$,

$$T(\mathbf{u}_1 + \cdots + \mathbf{u}_k) = T(\mathbf{u}_1) + \cdots + T(\mathbf{u}_k) = S_1(\mathbf{u}_1) + \cdots + S_k(\mathbf{u}_k).$$

Every vector of V is of this form, so T is determined.

Existence. Since every $\mathbf{v} \in V$ has exactly one decomposition, the displayed formula defines a function $T : V \to W$. Let $P_i' : V \to U_i$ send $\mathbf{v}$ to its component in U_i; it is the projection P_i of Proposition 4.4.29(a) with its target shrunk to U_i, so it is linear. Then $T = S_1 \circ P_1' + \cdots + S_k \circ P_k'$, which is linear by Proposition 2.1.17 and Proposition 2.1.23. Finally, for $\mathbf{u} \in U_i$, the decomposition of $\mathbf{u}$ has component $\mathbf{u}$ in U_i and $\mathbf{0}$ in every other summand, so $T(\mathbf{u}) = S_i(\mathbf{u}) + \sum_{j \neq i} S_j(\mathbf{0}) = S_i(\mathbf{u})$. □

When $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis and $U_i = \operatorname{span}(\mathbf{v}_i)$, a linear map $S_i : U_i \to W$ is determined by $S_i(\mathbf{v}_i)$, which can be any vector of W, and the proposition becomes Theorem 2.2.1.

Remark 4.4.32 (Block diagonal matrices). Suppose $V = U \oplus W$ is finite-dimensional, and $T \in \mathrm{L}(V)$ maps U into U and W into W. Let $T_U \in \mathrm{L}(U)$ and $T_W \in \mathrm{L}(W)$ be the operators $\mathbf{u} \mapsto T(\mathbf{u})$ and $\mathbf{w} \mapsto T(\mathbf{w})$. Glue a basis $\mathcal{B}_U$ of U and a basis $\mathcal{B}_W$ of W into a basis $\mathcal{B}$ of V (Technique 4.4.14). The image of a vector of $\mathcal{B}_U$ is a combination of $\mathcal{B}_U$ alone, and similarly for $\mathcal{B}_W$, so the matrix of T is block diagonal (Definition 2.4.33):

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} [T_U]_{\mathcal{B}_U\mathcal{B}_U} & 0 \\ 0 & [T_W]_{\mathcal{B}_W\mathcal{B}_W} \end{pmatrix}.$$

By Proposition 4.4.31, T is determined by T_U and T_W, so T can be studied through the two smaller operators. This is the strategy of the eigenvalue chapters. An operator is diagonalizable when V is a direct sum of subspaces on each of which T acts as multiplication by a scalar (Section 7.4), and the Jordan form refines such a splitting (Section 10.3). Exercise 4.4.44 computes the kernel and image of such a T.

Exercises

Exercise 4.4.33. ROUTINE In F^4, let $U = \operatorname{span}((1,1,0,0),(0,1,1,0),(0,0,1,1))$ and

$$W = \{\mathbf{x} \in F^4 \mid x_1 + x_2 + x_3 + x_4 = 0 \text{ and } x_1 = x_3\}.$$

(a) For $F = \mathbb{Q}$, find $\dim U$, $\dim W$, a basis of $U \cap W$, and $\dim(U + W)$.

(b) Repeat (a) for $F = \mathbb{F}_2$.

Solution on page 1322

Exercise 4.4.34. ROUTINE Let U, W, X be subspaces of a finite-dimensional space V. Prove or disprove:

(a) If $U \cap W = U \cap X = W \cap X = \{\mathbf{0}\}$, then $U + W + X$ is direct.

(b) If $U + W + X$ is direct, then $U + W$ is direct.

(c) If $V = U \oplus W$ and $V = U \oplus X$, then $W = X$.

(d) If $V = U \oplus W$ and $V = U \oplus X$, then $\dim W = \dim X$.

(e) If $V = U \oplus W$, then $X = (X \cap U) \oplus (X \cap W)$.

(f) If $U + W = V$ and $\dim U + \dim W = \dim V$, then $V = U \oplus W$.

Solution on page 1322

Exercise 4.4.35. ROUTINE Let $T \in \mathrm{L}(V, W)$, and let $U_1, \ldots, U_k$ be subspaces of V.

(a) Show that $\operatorname{im}\left(T\restriction_{U_1+\cdots+U_k}\right) = \operatorname{im}\left(T\restriction_{U_1}\right) + \cdots + \operatorname{im}\left(T\restriction_{U_k}\right)$.

(b) Show that if T is injective and $U_1, \ldots, U_k$ are independent, then $\operatorname{im}\left(T\restriction_{U_1}\right), \ldots, \operatorname{im}\left(T\restriction_{U_k}\right)$ are independent.

(c) Show by an example that (b) can fail if T is not injective.

Solution on page 1323

Exercise 4.4.36. ROUTINE In $\mathbb{C}^2$, let $U = \operatorname{span}((1, i))$ and $W = \operatorname{span}((1, -i))$.

(a) Show that $\mathbb{C}^2 = U \oplus W$. Find the matrix P of $\mathrm{Pr}_{U,W}$ with respect to the standard basis, and check that $P^2 = P$.

(b) Let $R(x, y) = (-y, x)$, the rotation by a quarter turn. Find scalars λ and μ with $R(\mathbf{u}) = \lambda\mathbf{u}$ for all $\mathbf{u} \in U$ and $R(\mathbf{w}) = \mu\mathbf{w}$ for all $\mathbf{w} \in W$.

Solution on page 1323

Exercise 4.4.37. STANDARD Find the error in the following argument.

Claim. Let U_1, U_2, U_3 be finite-dimensional subspaces of V with $U_i \cap U_j = \{\mathbf{0}\}$ whenever $i \neq j$. Then $\dim(U_1 + U_2 + U_3) = \dim U_1 + \dim U_2 + \dim U_3$.

Proof. Let $\mathcal{B}_i$ be a basis of U_i, and let $\mathcal{B}$ be the concatenation $\mathcal{B}_1, \mathcal{B}_2, \mathcal{B}_3$, which spans $U_1 + U_2 + U_3$. Suppose $\mathcal{B}$ is dependent. By the linear dependence lemma, some entry $\mathbf{b}$ of $\mathcal{B}$ is a combination of the entries before it. Say $\mathbf{b}$ is in $\mathcal{B}_3$; the other cases are similar. Move the terms that come from $\mathcal{B}_3$ to the left side. The left side is now $\mathbf{b}$ minus a combination of earlier entries of $\mathcal{B}_3$, so it lies in U_3. The right side is a combination of entries of $\mathcal{B}_1$ and $\mathcal{B}_2$, so it lies in U_1 or in U_2. Hence both sides lie in $U_3 \cap U_1$ or in $U_3 \cap U_2$, which are $\{\mathbf{0}\}$. So $\mathbf{b}$ is a combination of earlier entries of $\mathcal{B}_3$, contradicting the independence of $\mathcal{B}_3$. Therefore $\mathcal{B}$ is a basis, and the claim follows.

Solution on page 1324

Exercise 4.4.38. STANDARD Find the error in the following proof of Theorem 4.4.19.

Proof. Let $\mathcal{B}$ be a basis of U and $\mathcal{C}$ a basis of W. The concatenation $\mathcal{B}, \mathcal{C}$ spans $U + W$. The vectors that occur in both $\mathcal{B}$ and $\mathcal{C}$ lie in $U \cap W$, and they form a basis of $U \cap W$. Deleting one copy of each of them from $\mathcal{B}, \mathcal{C}$ leaves a basis of $U + W$ with $\dim U + \dim W - \dim(U \cap W)$ entries.

Solution on page 1324

Exercise 4.4.39. STANDARD For finite-dimensional subspaces U, W, X of V, let

$$e(U, W, X) = \dim U + \dim W + \dim X - \dim(U \cap W) - \dim(U \cap X) - \dim(W \cap X) + \dim(U \cap W \cap X).$$

(a) Find subspaces of $\mathbb{R}^2$ with $\dim(U + W + X) \neq e(U, W, X)$.

(b) Show that $(U \cap X) + (W \cap X) \subseteq (U + W) \cap X$ always.

(c) Show that $\dim(U + W + X) = e(U, W, X)$ whenever $(U + W) \cap X = (U \cap X) + (W \cap X)$.

Solution on page 1324

Exercise 4.4.40. STANDARD Let V have dimension n, and let $U_1, \ldots, U_k$ be subspaces of V.

(a) Show that $\dim(U_1 \cap \cdots \cap U_k) \geq \dim U_1 + \cdots + \dim U_k - (k-1)n$.

(b) Let $k \leq n$. Show that the bound in (a) is attained by the subspaces $U_i = \{\mathbf{x} \in F^n \mid x_i = 0\}$, $i = 1, \ldots, k$.

(c) Deduce that if $n \geq 2$, any $n - 1$ subspaces of V of dimension $n - 1$ have a nonzero vector in common.

Solution on page 1325

Exercise 4.4.41. STANDARD Let $A, B \in F^{m \times n}$, and let $\begin{pmatrix} A & B \end{pmatrix} \in F^{m \times 2n}$ be the matrix whose columns are those of A followed by those of B.

(a) Show that $\operatorname{rank}\begin{pmatrix} A & B \end{pmatrix} = \operatorname{rank} A + \operatorname{rank} B - \dim(\operatorname{im} A \cap \operatorname{im} B)$.

(b) Deduce that $\operatorname{rank}(A + B) \leq \operatorname{rank} A + \operatorname{rank} B - \dim(\operatorname{im} A \cap \operatorname{im} B)$. This sharpens Proposition 4.3.20.

(c) Find $A, B \in F^{2 \times 2}$ with $\operatorname{im} A \cap \operatorname{im} B = \{\mathbf{0}\}$ but $\operatorname{rank}(A + B) < \operatorname{rank} A + \operatorname{rank} B$.

Solution on page 1325

Exercise 4.4.42. STANDARD Let V be finite-dimensional, and let U and W be subspaces of V.

(a) Show that there is $T \in \mathrm{L}(V)$ with $\ker T = U$ and $\operatorname{im} T = W$ if and only if $\dim U + \dim W = \dim V$.

(b) Show that T in (a) can be chosen with $T^2 = T$ if and only if $V = U \oplus W$.

(c) In $\mathbb{R}^2$, let $U = W = \operatorname{span}(\mathbf{e}_1)$. Find T as in (a), and explain directly why no such T satisfies $T^2 = T$.

Solution on page 1326

Exercise 4.4.43. STANDARD Suppose $1 + 1 \neq 0$ in F, and let $T \in \mathrm{L}(V)$ satisfy $T^2 = \mathrm{id}_V$. Let

$$V_+ = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{v}\}, \quad V_- = \{\mathbf{v} \in V \mid T(\mathbf{v}) = -\mathbf{v}\}.$$

(a) Show that $V = V_+ \oplus V_-$.

(b) Deduce that $F^{n \times n}$ is the direct sum of the subspace of symmetric matrices ($A^{\mathsf{T}} = A$) and the subspace of skew-symmetric matrices ($A^{\mathsf{T}} = -A$), and find the dimensions of both.

(c) Over $\mathbb{F}_2$, find $T \in \mathrm{L}\left(\mathbb{F}_2^2\right)$ with $T^2 = \mathrm{id}$ but $V_+ + V_- \neq \mathbb{F}_2^2$.

Solution on page 1326

Exercise 4.4.44. STANDARD Suppose $V = U \oplus W$, and let $T \in \mathrm{L}(V)$ satisfy $T(\mathbf{u}) \in U$ for all $\mathbf{u} \in U$ and $T(\mathbf{w}) \in W$ for all $\mathbf{w} \in W$.

(a) Show that $\ker T = (U \cap \ker T) \oplus (W \cap \ker T)$ and $\operatorname{im} T = \operatorname{im}(T{\restriction_U}) \oplus \operatorname{im}(T{\restriction_W})$.

(b) Deduce that if V is finite-dimensional, then $\operatorname{rank} T = \operatorname{rank}(T{\restriction_U}) + \operatorname{rank}(T{\restriction_W})$.

(c) Show that (a) can fail without the hypothesis on T: find $T \in \mathrm{L}\big(\mathbb{R}^2\big)$ with $\ker T \neq (U \cap \ker T) + (W \cap \ker T)$, where $U = \operatorname{span}(\mathbf{e}_1)$ and $W = \operatorname{span}(\mathbf{e}_2)$.

Solution on page 1327

Exercise 4.4.45. STANDARD Let $A \in F^{m\times n}$. Prove that $F^n = \ker A \oplus \operatorname{im} A^{\mathsf{T}}$ when $F = \mathbb{R}$, and show by examples that this can fail when $F = \mathbb{C}$ and when $F = \mathbb{F}_2$.

Solution on page 1327

Exercise 4.4.46. STANDARD Let V be finite-dimensional, and let U be a subspace of V. Show that U has exactly one complement if and only if $U = \{\mathbf{0}\}$ or $U = V$.

Solution on page 1328

Exercise 4.4.47. STANDARD Let $0 \leq k \leq n$, let $c_0, \ldots, c_k \in F$ be distinct, and let

$$Z = \big\{p \in F[x]_{\leq n} \;\big|\; p(c_0) = p(c_1) = \cdots = p(c_k) = 0\big\}.$$

Show that $F[x]_{\leq n} = Z \oplus F[x]_{\leq k}$, and compute $\dim Z$ in two ways.

Solution on page 1328

Exercise 4.4.48. STANDARD Let $A, B \in F^{n\times n}$ satisfy $AB = 0$, and suppose that $A + B$ is invertible.

(a) Show that $\operatorname{rank} A + \operatorname{rank} B = n$ and $F^n = \operatorname{im} A \oplus \operatorname{im} B$.

(b) Show that $\operatorname{im} B = \ker A$.

(c) Show that if also $BA = 0$, then $\operatorname{im} A = \ker B$. Show by an example that $\operatorname{im} A = \ker B$ can fail without the hypothesis $BA = 0$.

Solution on page 1329

Exercise 4.4.49. HARD Let V be finite-dimensional with $V = U \oplus W_0$.

(a) For $S \in \mathrm{L}(W_0, U)$, let $\Gamma_S = \{\mathbf{w} + S(\mathbf{w}) \mid \mathbf{w} \in W_0\}$. Show that Γ_S is a complement of U.

(b) Show that every complement of U equals Γ_S for exactly one $S \in \mathrm{L}(W_0, U)$.

(c) Deduce that if F has q elements, $\dim V = n$, and $\dim U = k$, then U has exactly $q^{k(n-k)}$ complements in V.

(d) List the complements of $U = \operatorname{span}((1,1,0))$ in $\mathbb{F}_2^3$.

Solution on page 1329

Exercise 4.4.50. HARD Let V be finite-dimensional.

(a) Let U and W be subspaces of V with $\dim U = \dim W$. Show that U and W have a common complement, that is, a subspace X with $V = U \oplus X = W \oplus X$.

(b) Show that the three lines through $\mathbf{0}$ in $\mathbb{F}_2^2$ have no common complement.

Solution on page 1330

Exercise 4.4.51. HARD Let F be $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, and let $P_1, \ldots, P_k \in F^{n\times n}$ satisfy $P_i^2 = P_i$ for each i and $P_1 + \cdots + P_k = I_n$.

(a) Show that $F^n = \operatorname{im} P_1 \oplus \cdots \oplus \operatorname{im} P_k$.

(b) Deduce that $P_i P_j = 0$ whenever $i \neq j$.

(c) Show that the conclusion of (b) can fail over $\mathbb{F}_2$.

Solution on page 1331

Exercise 4.4.52. CHALLENGE Let F be a field with q elements. Call subspaces $U_1, \ldots, U_m$ of F^4 a **spread** if each has dimension 2 and any two of them are complements of each other.

(a) Show that a spread has at most $q^2 + 1$ members.

(b) For $F = \mathbb{F}_2$, construct a spread with 5 members. (For $M \in \mathbb{F}_2^{2\times 2}$, consider the subspace of vectors (x_1, x_2, y_1, y_2) with $(y_1, y_2) = M(x_1, x_2)$.)

Solution on page 1331

4.5 Isomorphisms and change of basis

A basis of length n turns V into F^n: every vector gets a column of coordinates, and every linear map gets a matrix. But a vector space has many bases, and nothing in V prefers one of them. This section studies that freedom. First we make precise when two vector spaces differ only in the names of their vectors; for finite-dimensional spaces this happens exactly when their dimensions agree. Then we work out how coordinates and matrices change with the basis. This takes one formula, and it leads to similarity: two square matrices are similar exactly when they are matrices of one operator in two bases. Whatever all matrices of an operator have in common, such as their rank and their trace, is then a property of the operator itself, and the freedom to pick the basis becomes a proof technique.

Throughout, F is a field.

4.5.1 Isomorphisms

The coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ of a basis $\mathcal{B}$ of length n is a linear bijection $V \to F^n$ (Proposition 1.6.19, Proposition 1.6.16). Through it, V and F^n have the same arithmetic: adding two vectors adds their coordinate columns, and scaling a vector scales its column. So V is F^n with different names for the vectors. Linear bijections are exactly the maps that rename vectors in this way.

Definition 4.5.1 (Isomorphism). An **isomorphism** is an invertible linear map $T \in \mathrm{L}(V, W)$. If there is an isomorphism from V to W, then V and W are **isomorphic**, and we write $V \cong W$.

By Proposition 2.7.7, a linear map is an isomorphism if and only if it is bijective, since the inverse function of a bijective linear map is automatically linear. So to show that T is an isomorphism, we may either show that it is injective and surjective, or exhibit a linear two-sided inverse.

Example 4.5.2 (Isomorphisms).

(a) For every basis $\mathcal{B}$ of V of length $n \geq 1$, the coordinate map $V \to F^n$ is an isomorphism, with inverse $(a_1, \ldots, a_n) \mapsto a_1\mathbf{b}_1 + \cdots + a_n\mathbf{b}_n$ (Example 2.5.14(c)). For $V = F[x]_{\leq n}$ and the basis $1, x, \ldots, x^n$, it is the map $a_0 + a_1x + \cdots + a_nx^n \mapsto (a_0, \ldots, a_n)$, so $F[x]_{\leq n} \cong F^{n+1}$.

(b) Stacking the columns of a matrix, $A \mapsto (a_{11}, \ldots, a_{m1}, a_{12}, \ldots, a_{m2}, \ldots, a_{mn})$, is a linear bijection $F^{m\times n} \to F^{mn}$: both spaces use entrywise operations, and unstacking is an inverse. So $F^{2\times 3} \cong F^6$.

(c) The map $(x, y) \mapsto (x, y, 0)$ is an isomorphism from F^2 onto the plane $P = \{(x, y, 0) \mid x, y \in F\}$ of F^3, with inverse $(x, y, 0) \mapsto (x, y)$. This is the sense in which P is "a copy of F^2" (Exercise 4.1.41(f)), even though F^2 is not a subset of F^3.

(d) The map $\mathrm{L}(F, V) \to V$, $T \mapsto T(1)$, is an isomorphism. It is linear because the operations on $\mathrm{L}(F, V)$ are pointwise. Its inverse sends $\mathbf{v}$ to the map $a \mapsto a\mathbf{v}$, since every $T \in \mathrm{L}(F, V)$ satisfies $T(a) = aT(1)$.

Non-example 4.5.3 (Bijections that are not isomorphisms).

(a) Complex conjugation $z \mapsto \overline{z}$ is a bijection $\mathbb{C} \to \mathbb{C}$ that respects addition and multiplication by real numbers, so it is an isomorphism of vector spaces over $\mathbb{R}$. It is not linear over $\mathbb{C}$: $\overline{i \cdot 1} = -i$, while $i \cdot \overline{1} = i$. Whether a map is an isomorphism depends on the field, as dimension does (Remark 4.1.6).

(b) The bijection $\mathbb{R} \to \mathbb{R}$, $x \mapsto x^3$, is not additive, since $(1 + 1)^3 = 8 \neq 2 = 1^3 + 1^3$. A bijection between vector spaces renames the vectors, but unless it respects the operations, the arithmetic does not survive the renaming.

Proposition 4.5.4 (Isomorphism is an equivalence relation). For all vector spaces U, V, and W over F:

(a) $V \cong V$;
(b) if $V \cong W$, then $W \cong V$;
(c) if $U \cong V$ and $V \cong W$, then $U \cong W$.

Proof. ROUTINE

Uses. Definition 4.5.1 (Isomorphism), Proposition 2.5.17 (Algebra of inverses), Example 2.5.14 (Invertible maps and matrices)
Hint 1. Each part asks for one isomorphism. Which maps are available?
Hint 2. Use id_V, the inverse of a given isomorphism, and the composite of two given isomorphisms, and quote Proposition 2.5.17.
Sketch. id_V is invertible. If $T : V \to W$ is invertible, so is $T^{-1} : W \to V$. If $S : U \to V$ and $T : V \to W$ are invertible, so is $TS : U \to W$.

(a) id_V is its own inverse (Example 2.5.14(a)). **(b)** If $T \in \mathrm{L}(V, W)$ is an isomorphism, then $T^{-1} \in \mathrm{L}(W, V)$ is invertible by Proposition 2.5.17(a). **(c)** If $S \in \mathrm{L}(U, V)$ and $T \in \mathrm{L}(V, W)$ are isomorphisms, then $TS \in \mathrm{L}(U, W)$ is invertible by Proposition 2.5.17(b), with inverse $S^{-1}T^{-1}$. □

So the vector spaces over F fall into isomorphism classes (Section A.3). Within a class, every statement that is phrased in terms of the vector space operations transfers from one space to another. Here are the statements we use most.

Proposition 4.5.5 (Isomorphisms preserve linear structure). Let $T \in \mathrm{L}(V, W)$ be an isomorphism.

(a) A list $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ in V is linearly independent if and only if $T(\mathcal{L}) = T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)$ is. It spans V if and only if $T(\mathcal{L})$ spans W, and it is a basis of V if and only if $T(\mathcal{L})$ is a basis of W.

(b) For every subspace U of V, $\mathrm{im}(T{\restriction}_U)$ is a subspace of W, and $T{\restriction}_U$ is an isomorphism from U onto $\mathrm{im}(T{\restriction}_U)$.

(c) V is finite-dimensional if and only if W is, and in that case $\dim V = \dim W$. More generally, $\dim \mathrm{im}(T{\restriction}_U) = \dim U$ for every finite-dimensional subspace U of V.

Proof. ROUTINE

Uses. Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 2.5.17 (Algebra of inverses), Proposition 4.2.3 (Properties of restriction), Proposition 2.6.8 (Kernels and images are subspaces), Proposition 2.7.7 (Bijective linear maps are invertible), Definition 4.1.5 (Dimension)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Linearity gives $c_1T(\mathbf{v}_1) + \cdots + c_kT(\mathbf{v}_k) = T(c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k)$. For the "only if" directions use that T is injective or surjective; for the "if" directions apply the same argument to T^{-1}.
Hint 2. For (b), a restriction of an injective map is injective, and every map is onto its own image. For (c), apply (a) to a basis.
Sketch. (a) A relation $\sum c_iT(\mathbf{v}_i) = \mathbf{0}$ says $T(\sum c_i\mathbf{v}_i) = \mathbf{0}$, so $\sum c_i\mathbf{v}_i = \mathbf{0}$ by injectivity. If $\mathcal{L}$ spans, every $\mathbf{w} = T\big(T^{-1}\mathbf{w}\big)$ is T of a combination of $\mathcal{L}$. The converses are the same statements for T^{-1}. (b) $T{\restriction_U}$ is linear and injective, and bijective onto its image. (c) A finite spanning list or basis of V is carried to one of W of the same length, and back by T^{-1}; for U, apply this to the isomorphism of (b).

Since T is linear, for all scalars $c_1, \ldots, c_k$,

$$c_1T(\mathbf{v}_1) + \cdots + c_kT(\mathbf{v}_k) = T(c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k). \tag{4.5.1}$$

(a) Suppose $\mathcal{L}$ is independent, and $\sum_i c_iT(\mathbf{v}_i) = \mathbf{0}$. By (4.5.1), $\sum_i c_i\mathbf{v}_i \in \ker T$, and $\ker T = \{\mathbf{0}\}$ because T is injective (Theorem 2.6.11). So $\sum_i c_i\mathbf{v}_i = \mathbf{0}$, and all $c_i = 0$. Suppose $\mathcal{L}$ spans V, and let $\mathbf{w} \in W$. Then $T^{-1}(\mathbf{w}) = \sum_i c_i\mathbf{v}_i$ for some scalars, and by (4.5.1), $\mathbf{w} = T\big(T^{-1}(\mathbf{w})\big) = \sum_i c_iT(\mathbf{v}_i)$. So $T(\mathcal{L})$ spans W.

For the converses, recall that $T^{-1} \in \mathrm{L}(W, V)$ is an isomorphism (Proposition 2.5.17(a)) and that $T^{-1}(T(\mathcal{L})) = \mathcal{L}$. Applying what we just proved to T^{-1} and the list $T(\mathcal{L})$ shows that if $T(\mathcal{L})$ is independent or spanning, then so is $\mathcal{L}$. The statement about bases combines the two.

(b) By Proposition 4.2.3(c), $T{\restriction_U} \in \mathrm{L}(U, W)$, so its image is a subspace of W (Proposition 2.6.8). It is injective by Proposition 4.2.3(a), and it maps U onto its own image. So it is a linear bijection $U \to \operatorname{im}(T{\restriction_U})$, hence an isomorphism (Proposition 2.7.7).

(c) If $\mathcal{L}$ is a finite list spanning V, then $T(\mathcal{L})$ is a finite list spanning W by (a); applying this to T^{-1} gives the converse. If V is finite-dimensional with basis $\mathcal{B}$, then $T(\mathcal{B})$ is a basis of W of the same length by (a), so $\dim W = \dim V$. Finally, if U is a finite-dimensional subspace of V, apply this to the isomorphism $T{\restriction_U} : U \to \operatorname{im}(T{\restriction_U})$ of (b). □

Now the main theorem. By (c), isomorphic spaces have equal dimensions. The converse is the surprise: for finite-dimensional spaces, dimension is the only thing that can tell two vector spaces apart.

Theorem 4.5.6 (Classification by dimension). Let V and W be finite-dimensional vector spaces over F. Then $V \cong W$ if and only if $\dim V = \dim W$. In particular, for $n \geq 1$, a vector space is isomorphic to F^n if and only if it is finite-dimensional of dimension n.

We give two proofs. The first works with bases directly; the second assembles the isomorphism from coordinate maps and gets the dimension count from rank–nullity.

Proof (with bases). ROUTINE

Uses. Proposition 4.5.5 (Isomorphisms preserve linear structure), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Proposition 2.7.7 (Bijective linear maps are invertible), Definition 4.1.5 (Dimension)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. For "only if", what does an isomorphism do to a basis?
Hint 2. For "if", choose bases $\mathbf{v}_1, \ldots, \mathbf{v}_n$ of V and $\mathbf{w}_1, \ldots, \mathbf{w}_n$ of W. Which linear map is the obvious candidate?
Hint 3. The map with $T(\mathbf{v}_i) = \mathbf{w}_i$ sends a basis to a basis. Use Proposition 2.6.22(c).
Sketch. An isomorphism carries a basis to a basis of the same length (Proposition 4.5.5). Conversely, if both spaces have bases of length n, the linear map sending the i-th vector of one to the i-th vector of the other carries a basis to a basis, so it is bijective. The last claim follows since $\dim F^n = n$.

If $V \cong W$, then $\dim V = \dim W$ by Proposition 4.5.5(c).

Conversely, suppose $\dim V = \dim W = n$. If $n = 0$, then $V = \{\mathbf{0}\}$ and $W = \{\mathbf{0}\}$, and the zero map is a bijection between them. If $n \geq 1$, choose bases $\mathbf{v}_1, \ldots, \mathbf{v}_n$ of V and $\mathbf{w}_1, \ldots, \mathbf{w}_n$ of W. By Theorem 2.2.1 there is a linear map $T : V \to W$ with $T(\mathbf{v}_i) = \mathbf{w}_i$ for each i. It carries a basis of V to a basis of W, so it is bijective by Proposition 2.6.22(c), and an isomorphism by Proposition 2.7.7.

For the last statement: $\dim F^n = n$, so a finite-dimensional space of dimension n is isomorphic to F^n by what we just proved. Conversely, if $V \cong F^n$, then V is finite-dimensional with $\dim V = n$ by Proposition 4.5.5(c).□

Proof (with coordinate maps and rank–nullity). ROUTINE

> *Uses.* Example 2.5.14 (Invertible maps and matrices), Proposition 4.5.4 (Isomorphism is an equivalence relation), Theorem 4.2.11 (Rank–nullity), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 4.5.5 (Isomorphisms preserve linear structure)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* For "if", both V and W are isomorphic to the same space. Which one?
> *Hint 2.* The coordinate maps give $V \cong F^n$ and $W \cong F^n$; use Proposition 4.5.4. For "only if", what are $\dim \ker T$ and $\dim \operatorname{im} T$ for an isomorphism T?
> *Sketch.* If $\dim V = \dim W = n \geq 1$, the coordinate maps give $V \cong F^n \cong W$, and the composite $C_{\mathcal{C}}^{-1} C_{\mathcal{B}}$ is an isomorphism. If $T : V \to W$ is an isomorphism, rank–nullity gives $\dim V = \dim \ker T + \dim \operatorname{im} T = 0 + \dim W$.

Suppose $\dim V = \dim W = n$. For $n = 0$ both spaces are $\{\mathbf{0}\}$, as in the first proof. For $n \geq 1$, choose bases $\mathcal{B}$ of V and $\mathcal{C}$ of W. The coordinate maps $C_{\mathcal{B}} : V \to F^n$ and $C_{\mathcal{C}} : W \to F^n$ are isomorphisms (Example 2.5.14(c)), so by Proposition 4.5.4, $C_{\mathcal{C}}^{-1} C_{\mathcal{B}} : V \to W$ is an isomorphism. Explicitly, it sends $\sum_i a_i \mathbf{v}_i$ to $\sum_i a_i \mathbf{w}_i$: it is the map of the first proof.

Conversely, let $T : V \to W$ be an isomorphism. Then $\ker T = \{\mathbf{0}\}$ (Theorem 2.6.11) and $\operatorname{im} T = W$, so by Theorem 4.2.11(b),

$$\dim V = \dim \ker T + \dim \operatorname{im} T = 0 + \dim W.$$

The last statement follows as in the first proof. □

> *Intuition (Choosing an isomorphism is choosing a basis).* The theorem says that up to renaming, the only n-dimensional vector space is F^n. It does not say that there is a preferred renaming. In fact the isomorphisms $V \to F^n$ are exactly the coordinate maps of the bases of V (Exercise 1.6.37): an isomorphism φ is the coordinate map of the basis $\varphi^{-1}(\mathbf{e}_1), \ldots, \varphi^{-1}(\mathbf{e}_n)$. So there are as many ways to identify V with F^n as there are bases, and in a space like $F[x]_{\leq 2}$, or a plane in $\mathbb{R}^3$, none of them is singled out. The rest of this section is about how the identifications compare.

Technique 4.5.7 (Transport along an isomorphism). An isomorphism $T : V \to W$ carries every statement about V that is phrased in terms of the vector space operations (independence, span, bases, subspaces and their dimensions, kernels and images of linear maps) to the corresponding statement about W, and back. So to answer such a question about an unfamiliar space, transport it along an isomorphism to a space where it is easier, answer it there, and transport the answer back.

Reach for it when the space is made of polynomials, matrices, functions, or linear maps, and the question only involves linear structure. The usual target is F^n, through coordinates: Proposition 1.6.20 was an early instance, and Theorem 4.5.6 says that every n-dimensional space can be transported to F^n. The canonical example is the computation of $\dim \mathrm{L}(V, W)$ below, which transports the question to matrices. Be careful to transport only statements made of the linear operations: a property such as "every entry is positive" or "the polynomial has a root" is not preserved by isomorphisms.
Used in. Theorem 4.5.8, Exercise 4.8.12, Exercise 4.5.41, Exercise 4.5.42.

The dimension of $\mathrm{L}(V, W)$

In Section 2.4 we saw that $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is a linear bijection $\mathrm{L}(V, W) \to F^{m \times n}$ (Proposition 2.4.12). In the language of this section, it is an isomorphism, and Technique 4.5.7 gives the dimension of $\mathrm{L}(V, W)$.

Theorem 4.5.8 (Dimension of $\mathrm{L}(V,W)$). Let V and W be finite-dimensional with $\dim V = n$ and $\dim W = m$. Then $\mathrm{L}(V,W)$ is finite-dimensional, and

$$\dim \mathrm{L}(V,W) = mn.$$

If $n, m \geq 1$ and $\mathcal{B}$, $\mathcal{C}$ are bases of V, W, then $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is an isomorphism $\mathrm{L}(V,W) \to F^{m\times n}$.

Proof (by transport to matrices). ROUTINE

> *Uses.* Proposition 2.4.12 (Matrices of sums and scalar multiples), Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 4.5.5 (Isomorphisms preserve linear structure), Example 4.1.7 (Dimensions of the standard spaces), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
> *Techniques.* Transport along an isomorphism (Technique 4.5.7)
> *Hint 1.* Dispose of $n = 0$ or $m = 0$ first: what are the linear maps out of $\{\mathbf{0}\}$, or into $\{\mathbf{0}\}$?
> *Hint 2.* For $n, m \geq 1$, Proposition 2.4.12 gives a linear bijection to a space whose dimension you know.
> *Sketch.* If V or W is zero, the only linear map $V \to W$ is 0, so $\dim \mathrm{L}(V,W) = 0 = mn$. Otherwise $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is a linear bijection onto $F^{m\times n}$, which has dimension mn, and isomorphisms preserve dimension.

If $n = 0$, then $V = \{\mathbf{0}\}$, and every linear map $T : V \to W$ is zero since $T(\mathbf{0}) = \mathbf{0}$ (Proposition 2.1.4). If $m = 0$, then every map into $W = \{\mathbf{0}\}$ is zero. In both cases $\mathrm{L}(V,W) = \{0\}$ has dimension $0 = mn$.

Now let $n, m \geq 1$. By Proposition 2.4.12 and Theorem 2.3.20, $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ is a linear bijection from $\mathrm{L}(V,W)$ onto $F^{m\times n}$, that is, an isomorphism. Since $\dim F^{m\times n} = mn$ (Example 4.1.7(a)), Proposition 4.5.5(c) shows that $\mathrm{L}(V,W)$ is finite-dimensional of dimension mn. □

The second proof writes down a basis of $\mathrm{L}(V,W)$. It is longer, but it shows what the isomorphism does: it matches a natural basis of $\mathrm{L}(V,W)$ with the standard basis of $F^{m\times n}$.

Proof (with an explicit basis). STANDARD

> *Uses.* Theorem 2.2.1 (Linear maps are determined by a basis), Definition 2.3.1 (Matrix of a linear map), Definition 1.6.1 (Basis), Definition 1.5.1 (Linear independence), Definition 2.1.21 (Pointwise operations)
> *Techniques.* Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
> *Hint 1.* For bases $\mathbf{v}_1, \dots, \mathbf{v}_n$ of V and $\mathbf{w}_1, \dots, \mathbf{w}_m$ of W, define mn maps by saying what each does on the basis of V. Which maps correspond to the matrices U_{ij}?
> *Hint 2.* Let φ_{ij} send $\mathbf{v}_j$ to $\mathbf{w}_i$ and every other $\mathbf{v}_k$ to $\mathbf{0}$. To prove that they span, compare T with $\sum a_{ij}\varphi_{ij}$ on the basis. To prove independence, evaluate a relation at $\mathbf{v}_k$.
> *Sketch.* Let φ_{ij} be the linear map with $\varphi_{ij}(\mathbf{v}_k) = \mathbf{w}_i$ if $k = j$ and $\mathbf{0}$ otherwise. If $T(\mathbf{v}_k) = \sum_i a_{ik}\mathbf{w}_i$, then $\sum_{i,j} a_{ij}\varphi_{ij}$ agrees with T on each $\mathbf{v}_k$, so they are equal. If $\sum c_{ij}\varphi_{ij} = 0$, evaluating at $\mathbf{v}_k$ gives $\sum_i c_{ik}\mathbf{w}_i = \mathbf{0}$, so all $c_{ik} = 0$. So the mn maps form a basis.

The zero cases are as in the first proof, so let $n, m \geq 1$, and let $\mathbf{v}_1, \dots, \mathbf{v}_n$ and $\mathbf{w}_1, \dots, \mathbf{w}_m$ be bases of V and W. For $1 \leq i \leq m$ and $1 \leq j \leq n$, let $\varphi_{ij} \in \mathrm{L}(V,W)$ be the linear map with

$$\varphi_{ij}(\mathbf{v}_k) = \begin{cases} \mathbf{w}_i & \text{if } k = j \\ \mathbf{0} & \text{if } k \neq j \end{cases}$$

(Theorem 2.2.1). We show that the mn maps φ_{ij}, listed in any order, form a basis of $\mathrm{L}(V,W)$.

They span. Let $T \in \mathrm{L}(V,W)$, and write $T(\mathbf{v}_k) = \sum_{i=1}^{m} a_{ik}\mathbf{w}_i$ for each k. Let $S = \sum_{i,j} a_{ij}\varphi_{ij}$. Since the operations on $\mathrm{L}(V,W)$ are pointwise,

$$S(\mathbf{v}_k) = \sum_{i=1}^{m}\sum_{j=1}^{n} a_{ij}\varphi_{ij}(\mathbf{v}_k) = \sum_{i=1}^{m} a_{ik}\mathbf{w}_i = T(\mathbf{v}_k)$$

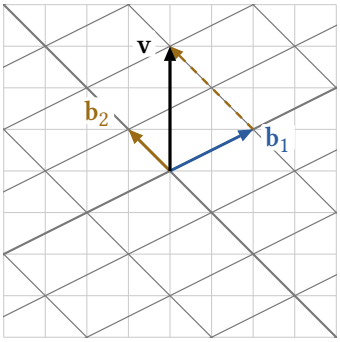
for each k, because only the terms with $j = k$ survive. Two linear maps that agree on a basis are equal (Theorem 2.2.1), so $T = S$.

They are independent. Suppose $\sum_{i,j} c_{ij}\varphi_{ij} = 0$. Evaluating at $\mathbf{v}_k$ as above gives $\sum_{i=1}^{m} c_{ik}\mathbf{w}_i = \mathbf{0}$, so $c_{1k} = \cdots = c_{mk} = 0$ because $\mathbf{w}_1, \dots, \mathbf{w}_m$ is independent. This holds for every k.

So $\mathrm{L}(V,W)$ has a basis of mn maps, and $\dim \mathrm{L}(V,W) = mn$. □

The coefficients a_{ij} in the second proof are the entries of $[T]_{\mathcal{CB}}$, and $\left[\varphi_{ij}\right]_{\mathcal{CB}} = U_{ij}$, since φ_{ij} sends the j-th basis vector to $\mathbf{w}_i$ and the others to $\mathbf{0}$. So the isomorphism of the first proof carries the basis φ_{ij} to the standard basis U_{ij} of $F^{m\times n}$.

Two special cases come up constantly. For an operator space, $\dim \mathrm{L}(V) = n^2$; so for every $T \in \mathrm{L}(V)$, the $n^2 + 1$ operators $\mathrm{id}_V, T, \ldots, T^{n^2}$ are dependent, which is Proposition 4.1.31(b) again. For $W = F$, $\dim \mathrm{L}(V,F) = n$. The linear maps $V \to F$ are the linear functionals, and $\mathrm{L}(V,F)$ is the dual space of V, the subject of Section 13.1.



Exercise 4.5.9. ROUTINE Sort the following vector spaces over F into isomorphism classes.

(a) $F^{2\times 3}$.
(b) $F[x]_{\leq 5}$.
(c) $\mathrm{L}\left(F^2, F^3\right)$.
(d) The upper triangular matrices in $F^{3\times 3}$.
(e) $\left\{p \in F[x]_{\leq 6} \;\middle|\; p(0) = 0\right\}$.
(f) $\mathrm{L}\left(F^3, F\right)$.
(g) $\left\{A \in F^{2\times 2} \;\middle|\; \operatorname{tr} A = 0\right\}$.

Solution on page 1332

4.5.2 Change of coordinates

Intuition (One vector, two grids). In $\mathbb{R}^2$, let $\mathbf{b}_1 = (2,1)$ and $\mathbf{b}_2 = (-1,1)$. The vector $\mathbf{v} = (0,3)$ has standard coordinates $(0,3)$. It is also $\mathbf{b}_1 + 2\mathbf{b}_2$, so in the basis $\mathcal{B} = \mathbf{b}_1, \mathbf{b}_2$ its coordinates are $(1,2)$. Draw the grid of integer combinations of $\mathbf{b}_1$ and $\mathbf{b}_2$ on top of the standard grid: the arrow $\mathbf{v}$ is the same arrow, and each grid reads off its own pair of numbers. Changing the basis does not move any vector. It changes the grid on which we read the vectors, and the question is how the two readings are related.

The vector $\mathbf{v} = (0,3)$ on the standard grid and on the grid of $\mathcal{B} = (2,1), (-1,1)$. Read on the first grid, $[\mathbf{v}]_{\mathcal{E}} = (0,3)$; read on the second, $\mathbf{v} = \mathbf{b}_1 + 2\mathbf{b}_2$, so $[\mathbf{v}]_{\mathcal{B}} = (1,2)$. In the interactive version, drag $\mathbf{b}_1$, $\mathbf{b}_2$, or $\mathbf{v}$ (or focus one and use the arrow keys); the panel shows $[\mathrm{id}]_{\mathcal{EB}}$ and the conversion $[\mathbf{v}]_{\mathcal{B}} = [\mathrm{id}]_{\mathcal{BE}}[\mathbf{v}]_{\mathcal{E}}$. When $\mathbf{b}_1$ and $\mathbf{b}_2$ become parallel, the second grid collapses and the coordinates are no longer defined. (Interactive in the web version.)

The conversion between the two readings is the matrix of the identity map with different bases on the two sides, which we met in Section 2.3.5. We give it a name.

Definition 4.5.10 (Change-of-coordinates matrix). Let V be a vector space with $\dim V = n \geq 1$, and let $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ and $\mathring{\mathcal{B}} = \mathring{\mathbf{b}}_1, \ldots, \mathring{\mathbf{b}}_n$ be bases of V. The **change-of-coordinates matrix** from $\mathcal{B}$ to $\mathring{\mathcal{B}}$ is

$$[\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathcal{B}} = \left([\mathbf{b}_1]_{\mathring{\mathcal{B}}}\ [\mathbf{b}_2]_{\mathring{\mathcal{B}}}\ \cdots\ [\mathbf{b}_n]_{\mathring{\mathcal{B}}}\right) \in F^{n\times n},$$

whose j-th column holds the $\mathring{\mathcal{B}}$-coordinates of the j-th vector of $\mathcal{B}$. By Theorem 2.3.9,

$$[\mathbf{v}]_{\mathring{\mathcal{B}}} = [\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}} \quad \text{for every } \mathbf{v} \in V.$$

As with every matrix of a map, the subscripts are target first: $[\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathcal{B}}$ eats $\mathcal{B}$-coordinates and returns $\mathring{\mathcal{B}}$-coordinates. Books disagree on which of the two matrices to call "the change-of-basis matrix from $\mathcal{B}$ to $\mathring{\mathcal{B}}$", so it is safest to trust the subscripts and not the words. We drop the subscript V from id_V when the space is clear.

Example 4.5.11 (Two grids in the plane). Let F be a field in which $3 \neq 0$, let $\mathcal{E}$ be the standard basis of F^2, and let $\mathcal{B} = (2,1), (-1,1)$. The columns of $[\mathrm{id}]_{\mathcal{E}\mathcal{B}}$ are the standard coordinates of the vectors of $\mathcal{B}$, which are those vectors themselves. The columns of $[\mathrm{id}]_{\mathcal{B}\mathcal{E}}$ are the $\mathcal{B}$-coordinates of $\mathbf{e}_1$ and $\mathbf{e}_2$, which we find by solving: $\mathbf{e}_1 = \frac{1}{3}(2,1) - \frac{1}{3}(-1,1)$ and $\mathbf{e}_2 = \frac{1}{3}(2,1) + \frac{2}{3}(-1,1)$. So

$$[\mathrm{id}]_{\mathcal{E}\mathcal{B}} = \begin{pmatrix} 2 & -1 \\ 1 & 1 \end{pmatrix}, \quad [\mathrm{id}]_{\mathcal{B}\mathcal{E}} = \frac{1}{3}\begin{pmatrix} 1 & 1 \\ -1 & 2 \end{pmatrix}.$$

For $\mathbf{v} = (0,3)$, we get $[\mathbf{v}]_{\mathcal{B}} = \frac{1}{3}(0+3, 0+6) = (1,2)$, as in the picture. (If $3 = 0$ in F, then $(-1,1) = (2,1)$ and $\mathcal{B}$ is not a basis.)

The general rules are consequences of the composition theorem.

Proposition 4.5.12 (Calculus of change of coordinates). Let $\mathcal{B}$, $\mathcal{B}'$, and $\mathcal{B}''$ be bases of V, where $\dim V = n \geq 1$.

(a) $[\mathrm{id}]_{\mathcal{B}''\mathcal{B}'}[\mathrm{id}]_{\mathcal{B}'\mathcal{B}} = [\mathrm{id}]_{\mathcal{B}''\mathcal{B}}$, and $[\mathrm{id}]_{\mathcal{B}\mathcal{B}} = I_n$.
(b) $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$ is invertible, with inverse $[\mathrm{id}]_{\mathcal{B}\mathcal{B}'}$.
(c) $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$ is the only matrix $P \in F^{n\times n}$ with $P[\mathbf{v}]_{\mathcal{B}} = [\mathbf{v}]_{\mathcal{B}'}$ for every $\mathbf{v} \in V$.

Proof. ROUTINE

Uses. Theorem 2.4.2 (The matrix of a composite), Example 2.3.6 (The zero map and the identity map), Definition 2.5.12 (Invertible), Theorem 2.3.9 (The matrix of a map computes the map), Definition 2.3.1 (Matrix of a linear map)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. For (a), $\mathrm{id} \circ \mathrm{id} = \mathrm{id}$. Which theorem turns a composite into a product of matrices?
Hint 2. (b) follows from (a) with $\mathcal{B}'' = \mathcal{B}$. For (c), apply P to the coordinates of a basis vector $\mathbf{b}_j$.
Sketch. (a) is Theorem 2.4.2 for $\mathrm{id} \circ \mathrm{id} = \mathrm{id}$, with the middle basis $\mathcal{B}'$. (b) Taking $\mathcal{B}'' = \mathcal{B}$ in (a), and then exchanging the roles of $\mathcal{B}$ and $\mathcal{B}'$, both products are I_n. (c) Existence is Theorem 2.3.9; if P converts coordinates, then $P\mathbf{e}_j = P[\mathbf{b}_j]_{\mathcal{B}} = [\mathbf{b}_j]_{\mathcal{B}'}$ is the j-th column of $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$.

(a) By Theorem 2.4.2 applied to $\mathrm{id}_V \circ \mathrm{id}_V = \mathrm{id}_V$, with $\mathcal{B}$ on the domain, $\mathcal{B}'$ in the middle, and $\mathcal{B}''$ on the target, $[\mathrm{id}]_{\mathcal{B}''\mathcal{B}'}[\mathrm{id}]_{\mathcal{B}'\mathcal{B}} = [\mathrm{id}]_{\mathcal{B}''\mathcal{B}}$. And $[\mathrm{id}]_{\mathcal{B}\mathcal{B}} = I_n$ by Example 2.3.6.

(b) By (a) with $\mathcal{B}'' = \mathcal{B}$, $[\mathrm{id}]_{\mathcal{B}\mathcal{B}'}[\mathrm{id}]_{\mathcal{B}'\mathcal{B}} = [\mathrm{id}]_{\mathcal{B}\mathcal{B}} = I_n$. Exchanging the roles of $\mathcal{B}$ and $\mathcal{B}'$ gives $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}[\mathrm{id}]_{\mathcal{B}\mathcal{B}'} = I_n$. So $[\mathrm{id}]_{\mathcal{B}\mathcal{B}'}$ is a two-sided inverse of $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$ (Definition 2.5.12). (This is also Example 2.5.21.)

(c) $P = [\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$ converts coordinates by Theorem 2.3.9. Conversely, suppose $P[\mathbf{v}]_{\mathcal{B}} = [\mathbf{v}]_{\mathcal{B}'}$ for every $\mathbf{v}$. Taking $\mathbf{v} = \mathbf{b}_j$, the j-th vector of $\mathcal{B}$, whose $\mathcal{B}$-coordinates are $\mathbf{e}_j$, gives $P\mathbf{e}_j = [\mathbf{b}_j]_{\mathcal{B}'}$. The left side is the j-th column of P, and the right side is the j-th column of $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$ (Definition 2.3.1). □

In F^n there is a standard way to compute. For a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of F^n, $[\mathrm{id}]_{\mathcal{E}\mathcal{B}}$ is the matrix with columns $\mathbf{b}_1, \ldots, \mathbf{b}_n$, since $[\mathbf{b}_j]_{\mathcal{E}} = \mathbf{b}_j$. For two bases $\mathcal{B}$ and $\mathring{\mathcal{B}}$ of F^n, route through the standard basis: by Proposition 4.5.12,

$$[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = [\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{E}}[\mathrm{id}]_{\mathcal{E}\mathcal{B}} = \left([\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}}\right)^{-1}[\mathrm{id}]_{\mathcal{E}\mathcal{B}}.$$

To compute $M^{-1}N$ without computing M^{-1} first, row reduce $(M \mid N)$: if $GM = I_n$, then $G = M^{-1}$, and the reduction ends at $\left(I_n \mid M^{-1}N\right)$ (Theorem 3.3.10).

Exercise 4.5.13. ROUTINE Over $\mathbb{F}_5$, let $\mathcal{B} = (1,2),(3,4)$ and $\mathring{\mathcal{B}} = (1,1),(1,4)$.

(a) Show that both lists are bases of $\mathbb{F}_5^2$, and compute $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}}$.
(b) The vector $\mathbf{v}$ has $[\mathbf{v}]_{\mathcal{B}} = (1,1)$. Find $\mathbf{v}$ and $[\mathbf{v}]_{\mathring{\mathcal{B}}}$, and check your answer.

Solution on page 1332

The next example changes coordinates in a polynomial space, where the new coordinates have a meaning of their own.

Example 4.5.14 (Expanding around a point). Let $V = F[x]_{\leq 2}$, with $\mathcal{B} = 1, x, x^2$ and $\mathring{\mathcal{B}} = 1, x-1, (x-1)^2$. Since

$$x = 1 + (x-1), \quad x^2 = 1 + 2(x-1) + (x-1)^2,$$

the three vectors of $\mathring{\mathcal{B}}$ span V (their span contains 1, x, and x^2), so they form a basis (Corollary 4.1.11(b)). The displayed identities give the columns of the change-of-coordinates matrix, and expanding $(x-1)$ and $(x-1)^2$ in powers of x gives the columns of its inverse:

$$[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}, \quad [\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = \begin{pmatrix} 1 & -1 & 1 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{pmatrix}.$$

(Multiply them to check that the product is I_3.) So for $p = a + bx + cx^2$,

$$[p]_{\mathring{\mathcal{B}}} = (a+b+c, b+2c, c), \quad \text{that is,} \quad p = (a+b+c) + (b+2c)(x-1) + c(x-1)^2.$$

Over $\mathbb{R}$, the new coordinates are $p(1)$, $p'(1)$, and $p''(1)/2$: changing to the basis $\mathring{\mathcal{B}}$ is Taylor expansion at 1.

The matrix $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}}$ also appeared in Example 2.4.13, as the matrix in the basis $\mathcal{B}$ of the shift $p(x) \mapsto p(x+1)$. The next remark explains why.

Remark 4.5.15 (Moving the grid or moving the vectors). A change-of-coordinates matrix is also the matrix of an operator in a single basis. Given bases $\mathcal{B}$ and $\mathring{\mathcal{B}}$ of V, let $R \in \mathrm{L}(V)$ be the operator with $R(\mathbf{b}_j) = \mathring{\mathbf{b}}_j$ for each j (Theorem 2.2.1). The j-th column of $[R]_{\mathcal{B}\mathcal{B}}$ is $\left[\mathring{\mathbf{b}}_j\right]_{\mathcal{B}}$, which is also the j-th column of $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$. So

$$[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = [R]_{\mathcal{B}\mathcal{B}}, \quad \text{and hence} \quad [\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = ([R]_{\mathcal{B}\mathcal{B}})^{-1} = \left[R^{-1}\right]_{\mathcal{B}\mathcal{B}}$$

by Proposition 4.5.12(b) and Proposition 2.5.20(b) (R is invertible because it carries a basis to a basis). In Example 4.5.14, $R(x^j) = (x-1)^j$, so R is the substitution $p(x) \mapsto p(x-1)$ and R^{-1} is $p(x) \mapsto p(x+1)$.

So there are two ways to read the same matrix. In the passive reading, the vectors stay put and the grid changes from $\mathcal{B}$ to $\mathring{\mathcal{B}}$. In the active reading, the grid stays put and the vectors move by R^{-1}. Moving the grid forward by R looks, in coordinates, exactly like moving the vectors back by R^{-1}.

So every change-of-coordinates matrix is invertible. Conversely, every invertible matrix changes coordinates, from any given basis to a suitable new one. This is what makes the change-of-basis formula below reversible.

Proposition 4.5.16 (Every invertible matrix changes coordinates). Let $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V, and let $S = (s_{ij}) \in F^{n\times n}$ be invertible.

(a) There is exactly one basis $\mathring{\mathcal{B}}$ of V with $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = S$, namely

$$\mathring{\mathbf{b}}_j = s_{1j}\mathbf{b}_1 + s_{2j}\mathbf{b}_2 + \cdots + s_{nj}\mathbf{b}_n \quad (1 \le j \le n).$$

(b) There is exactly one basis $\mathcal{B}'$ of V with $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}} = S$.

Proof (through coordinates). ROUTINE

Uses. Definition 4.5.10 (Change-of-coordinates matrix), Definition 1.6.14 (Coordinates), Corollary 3.5.25 (The invertible matrix theorem), Theorem 4.1.10 (Independent lists are short), Proposition 1.6.20 (Coordinates translate questions about V into F^n), Proposition 4.5.12 (Calculus of change of coordinates), Proposition 2.5.17 (Algebra of inverses)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. The j-th column of $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$ is $\left[\mathring{\mathbf{b}}_j\right]_{\mathcal{B}}$. So if $\mathring{\mathcal{B}}$ exists, its vectors are forced. Which vectors?
Hint 2. With $\mathring{\mathbf{b}}_j$ defined as in the statement, $\left[\mathring{\mathbf{b}}_j\right]_{\mathcal{B}}$ is the j-th column of S. Why do the columns of an invertible matrix form a basis of F^n, and how does that transfer to V?
Hint 3. For (b), apply (a) to S^{-1} and use Proposition 4.5.12(b).
Sketch. (a) The equation $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = S$ says $\left[\mathring{\mathbf{b}}_j\right]_{\mathcal{B}} = \mathbf{s}_j$ (the j-th column of S) for each j, which determines $\mathring{\mathbf{b}}_j$. These vectors form a basis because their coordinate vectors, the columns of the invertible S, form a basis of F^n (Proposition 1.6.20(c)). (b) $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}} = S$ if and only if $[\mathrm{id}]_{\mathcal{B}\mathcal{B}'} = S^{-1}$; apply (a) to S^{-1}.

(a) Let $\mathbf{s}_j$ be the j-th column of S. For any basis $\mathring{\mathcal{B}}$, the j-th column of $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$ is $\left[\mathring{\mathbf{b}}_j\right]_{\mathcal{B}}$ (Definition 4.5.10). So $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = S$ holds exactly when $\left[\mathring{\mathbf{b}}_j\right]_{\mathcal{B}} = \mathbf{s}_j$ for every j, that is, when $\mathring{\mathbf{b}}_j = s_{1j}\mathbf{b}_1 + \cdots + s_{nj}\mathbf{b}_n$ (Definition 1.6.14). This proves uniqueness, and it remains to show that these vectors form a basis. Since S is invertible, its columns are independent (Corollary 3.5.25), and n independent vectors in F^n form a basis (Theorem 4.1.10(b)). The coordinate vectors of $\mathring{\mathbf{b}}_1, \ldots, \mathring{\mathbf{b}}_n$ are $\mathbf{s}_1, \ldots, \mathbf{s}_n$, so $\mathring{\mathcal{B}}$ is a basis of V by Proposition 1.6.20(c).

(b) By Proposition 4.5.12(b), for a basis $\mathcal{B}'$ we have $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}} = S$ if and only if $[\mathrm{id}]_{\mathcal{B}\mathcal{B}'} = S^{-1}$. The matrix S^{-1} is invertible (Proposition 2.5.17(a)), so by (a) there is exactly one such basis. □

Proof (by moving the basis). ROUTINE

Uses. Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 2.5.20 (Inverses and matrices), Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Remark 4.5.15 (Moving the grid or moving the vectors)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Use the active reading of Remark 4.5.15: look for an operator R with $R(\mathbf{b}_j) = \mathring{\mathbf{b}}_j$.
Hint 2. Let $R \in \mathrm{L}(V)$ have $[R]_{\mathcal{B}\mathcal{B}} = S$. Why is R invertible, and what is $R(\mathcal{B})$?
Sketch. Let $R \in \mathrm{L}(V)$ be the operator with $[R]_{\mathcal{B}\mathcal{B}} = S$. It is invertible because S is, so $\mathring{\mathcal{B}} = R(\mathcal{B})$ is a basis, and $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = [R]_{\mathcal{B}\mathcal{B}} = S$ by Remark 4.5.15. Uniqueness and (b) are as in the first proof.

(a) By Theorem 2.3.20(b) there is $R \in \mathrm{L}(V)$ with $[R]_{\mathcal{B}\mathcal{B}} = S$, and R is invertible because S is (Proposition 2.5.20(b)). So $\mathring{\mathcal{B}} = R(\mathbf{b}_1), \ldots, R(\mathbf{b}_n)$ is a basis of V (Proposition 2.6.22(c)), and by Remark 4.5.15, $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = [R]_{\mathcal{B}\mathcal{B}} = S$. The j-th vector of $\mathring{\mathcal{B}}$ is $R(\mathbf{b}_j) = \sum_i s_{ij}\mathbf{b}_i$, because the j-th column of $[R]_{\mathcal{B}\mathcal{B}}$ is $\mathbf{s}_j$. Uniqueness is proved as in the first proof: the columns of $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$ determine the vectors of $\mathring{\mathcal{B}}$.

(b) As in the first proof, apply (a) to S^{-1}. □

In particular, for a fixed basis $\mathcal{B}$, the map $\mathring{\mathcal{B}} \mapsto [\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$ is a bijection from the set of bases of V onto the set of invertible $n \times n$ matrices. Over a field with q elements, the number of invertible $n \times n$ matrices is therefore the number of bases of F^n, which Corollary 4.1.35 computed: $(q^n - 1)(q^n - q)\cdots(q^n - q^{n-1})$.

4.5.3 The change-of-basis formula

Now let $T \in \mathrm{L}(V, W)$, where $\dim V = n \ge 1$ and $\dim W = m \ge 1$. If we replace the basis $\mathcal{B}$ of V by $\mathring{\mathcal{B}}$ and the basis $\mathcal{C}$ of W by $\mathring{\mathcal{C}}$, how is the new matrix $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}$ related to the old one?

Theorem 4.5.17 (Change of basis). Let $\mathcal{B}$ and $\mathring{\mathcal{B}}$ be bases of V, let $\mathcal{C}$ and $\mathring{\mathcal{C}}$ be bases of W, and let $T \in \mathrm{L}(V, W)$. Then

$$[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}} = [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}[T]_{\mathcal{C}\mathcal{B}}[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}.$$

In particular, if $T \in \mathrm{L}(V)$ and $P = [\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}$, then

$$[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = P^{-1}[T]_{\mathcal{B}\mathcal{B}}P.$$

Intuition (Reading the formula). Read the right side from right to left, as the composite it is. Start with the $\mathring{\mathcal{B}}$-coordinates of a vector $\mathbf{v}$. The factor $[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}$ converts them into $\mathcal{B}$-coordinates, in which we know how to apply T; the factor $[T]_{\mathcal{C}\mathcal{B}}$ does so and produces the $\mathcal{C}$-coordinates of $T(\mathbf{v})$; and $[\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}$ converts those into $\mathring{\mathcal{C}}$-coordinates. The result is what $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}$ does in one step.

There is also a bookkeeping rule. In a product of matrices of maps, adjacent subscripts must match, like dominoes: $\mathring{\mathcal{C}}\mathcal{C} \cdot \mathcal{C}\mathcal{B} \cdot \mathcal{B}\mathring{\mathcal{B}}$. The two outer subscripts, $\mathring{\mathcal{C}}$ and $\mathring{\mathcal{B}}$, are the bases of the result. A formula whose subscripts do not chain this way is wrong, whatever its other merits.

The first proof is the lecture's: the formula is the composition theorem applied to $T = \mathrm{id}_W \circ T \circ \mathrm{id}_V$, with each copy of a space carrying a different basis.

Proof (by composition). ROUTINE

Uses. Theorem 2.4.2 (The matrix of a composite), Proposition 2.1.24 (Algebra of composition), Proposition 4.5.12 (Calculus of change of coordinates)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Write T as a composite of three maps in which identity maps change the basis.
Hint 2. $T = \mathrm{id}_W \circ T \circ \mathrm{id}_V$. Apply Theorem 2.4.2 twice, choosing the bases $\mathring{\mathcal{B}}$, $\mathcal{B}$, $\mathcal{C}$, $\mathring{\mathcal{C}}$ on the four copies of V and W.
Sketch. $T = \mathrm{id}_W \circ T \circ \mathrm{id}_V$ (Proposition 2.1.24(b)). By Theorem 2.4.2, with $\mathring{\mathcal{B}}$ on the first copy of V, $\mathcal{B}$ on the second, $\mathcal{C}$ on the first copy of W, and $\mathring{\mathcal{C}}$ on the second, the matrix of the composite is the product of the three matrices. For operators, $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = P^{-1}$ by Proposition 4.5.12(b).

By Proposition 2.1.24(b), $T = \mathrm{id}_W \circ (T \circ \mathrm{id}_V)$. Apply Theorem 2.4.2 to $T \circ \mathrm{id}_V$, with $\mathring{\mathcal{B}}$ on the domain, $\mathcal{B}$ on the middle copy of V, and $\mathcal{C}$ on W:

$$[T]_{\mathcal{C}\mathring{\mathcal{B}}} = [T \circ \mathrm{id}_V]_{\mathcal{C}\mathring{\mathcal{B}}} = [T]_{\mathcal{C}\mathcal{B}}[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}.$$

Apply it again to $\mathrm{id}_W \circ T$, with $\mathring{\mathcal{B}}$ on V, $\mathcal{C}$ on the middle copy of W, and $\mathring{\mathcal{C}}$ on the target:

$$[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}} = [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}[T]_{\mathcal{C}\mathring{\mathcal{B}}} = [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}[T]_{\mathcal{C}\mathcal{B}}[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}.$$

For $T \in \mathrm{L}(V)$, take $\mathcal{C} = \mathcal{B}$ and $\mathring{\mathcal{C}} = \mathring{\mathcal{B}}$. Then $[\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathcal{B}} = P^{-1}$ by Proposition 4.5.12(b). □

The second proof chases a single vector through the diagram of Figure 4.5.1. It is the lecture's proof of $[\mathbf{v}]_{\mathring{\mathcal{B}}} = [\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}}$, extended by two squares.

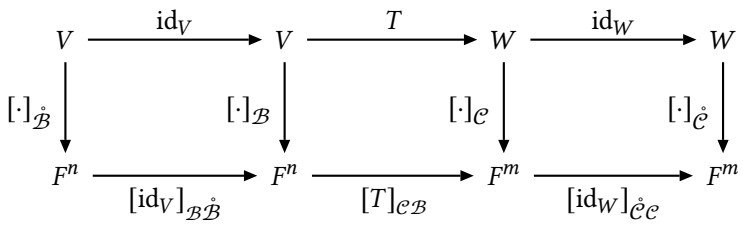


Figure 4.5.1. Three commuting squares. The top row composes to T, and the bottom row multiplies three matrices. Each square says that two routes from its top left corner to its bottom right corner agree (Theorem 2.3.9), so a vector can be pushed along the bottom row instead of the top. The outer rectangle is the change-of-basis formula.

Proof (by chasing a vector). ROUTINE

Uses. Theorem 2.3.9 (The matrix of a map computes the map), Proposition 1.6.16 (The coordinate map is a bijection), Definition 2.3.8 (Matrix–vector product)
Techniques. Translate between maps and matrices (Technique 2.3.27), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Two $m \times n$ matrices are equal if they give the same result on every $\mathbf{x} \in F^n$: compare them on $\mathbf{e}_j$.
Hint 2. Every $\mathbf{x} \in F^n$ is $[\mathbf{v}]_{\mathring{\mathcal{B}}}$ for some $\mathbf{v} \in V$. Multiply $[\mathbf{v}]_{\mathring{\mathcal{B}}}$ by the right side one factor at a time, using Theorem 2.3.9 at each step.
Sketch. For $\mathbf{v} \in V$, multiplying $[\mathbf{v}]_{\mathring{\mathcal{B}}}$ by the three factors in turn gives $[\mathbf{v}]_{\mathcal{B}}$, then $[T(\mathbf{v})]_{\mathcal{C}}$, then $[T(\mathbf{v})]_{\mathring{\mathcal{C}}}$, which is also $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}[\mathbf{v}]_{\mathring{\mathcal{B}}}$. Every column in F^n is a $\mathring{\mathcal{B}}$-coordinate vector, in particular each $\mathbf{e}_j$, so the two matrices have the same columns.

Let M be the right side of the formula, and let $\mathbf{v} \in V$. Applying Theorem 2.3.9 three times (to id_V, to T, and to id_W),

$$\begin{aligned} M[\mathbf{v}]_{\mathring{\mathcal{B}}} &= [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}[T]_{\mathcal{C}\mathcal{B}}\big([\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}[\mathbf{v}]_{\mathring{\mathcal{B}}}\big) \\ &= [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}\big([T]_{\mathcal{C}\mathcal{B}}[\mathbf{v}]_{\mathcal{B}}\big) \\ &= [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}[T(\mathbf{v})]_{\mathcal{C}} = [T(\mathbf{v})]_{\mathring{\mathcal{C}}}, \end{aligned}$$

and $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}[\mathbf{v}]_{\mathring{\mathcal{B}}} = [T(\mathbf{v})]_{\mathring{\mathcal{C}}}$ as well. The coordinate map of $\mathring{\mathcal{B}}$ is onto F^n (Proposition 1.6.16), so for each j we may choose $\mathbf{v}$ with $[\mathbf{v}]_{\mathring{\mathcal{B}}} = \mathbf{e}_j$. Then the j-th columns $M\mathbf{e}_j$ and $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}\mathbf{e}_j$ agree (Definition 2.3.8), and the two matrices are equal. The statement for operators follows as in the first proof. □

The first proof is shorter, because Theorem 2.4.2 already did the vector chase once and for all. The second is the one to remember when the subscripts get confusing: follow one vector around the diagram, and the order of the factors takes care of itself.

Example 4.5.18 (An oblique projection). Let $\ell_1 = \mathrm{span}((1,1))$ and $\ell_2 = \mathrm{span}((1,2))$ in F^2. The vectors $\mathbf{u}_1 = (1,1)$ and $\mathbf{u}_2 = (1,2)$ form a basis $\mathcal{U}$ of F^2 over every field, since $\begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$ has $1 \cdot 2 - 1 \cdot 1 = 1 \neq 0$. Let $P \in \mathrm{L}(F^2)$ be the projection onto ℓ_1 along ℓ_2: $P(\mathbf{u}_1) = \mathbf{u}_1$ and $P(\mathbf{u}_2) = \mathbf{0}$. Its matrix in $\mathcal{U}$ is obvious, and the theorem converts it into the standard matrix. With $Q = [\mathrm{id}]_{\mathcal{E}\mathcal{U}} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$, whose inverse is $\begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix}$,

$$[P]_{\mathcal{E}\mathcal{E}} = Q[P]_{\mathcal{U}\mathcal{U}}Q^{-1} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix} = \begin{pmatrix} 2 & -1 \\ 2 & -1 \end{pmatrix}.$$

Check: $\begin{pmatrix} 2 & -1 \\ 2 & -1 \end{pmatrix}\begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and $\begin{pmatrix} 2 & -1 \\ 2 & -1 \end{pmatrix}\begin{pmatrix} 1 \\ 2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$. Here we used the theorem with $\mathcal{E}$ as the new basis: $[P]_{\mathcal{E}\mathcal{E}} = [\mathrm{id}]_{\mathcal{E}\mathcal{U}}[P]_{\mathcal{U}\mathcal{U}}[\mathrm{id}]_{\mathcal{U}\mathcal{E}}$.

Example 4.5.19 (Differentiation, revisited). In Example 2.3.22(c), with $2 \neq 0$ in F, we found the matrix of differentiation D on $F[x]_{\leq 2}$ in the basis $\mathring{\mathcal{B}} = 1, x, \frac{1}{2}x^2$ by applying D to each basis vector. The theorem gives it from $[D]_{\mathcal{B}\mathcal{B}}$, where $\mathcal{B} = 1, x, x^2$. Here $P = [\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = \mathrm{diag}\big(1, 1, \frac{1}{2}\big)$, whose inverse is $\mathrm{diag}(1,1,2)$, and

$$P^{-1}[D]_{\mathcal{B}\mathcal{B}}P = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix}\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{2} \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix},$$

as found there. Scaling the third basis vector by $\frac{1}{2}$ divides the third column by 2 and multiplies the third row by 2.

Exercise 4.5.20. ROUTINE Let $A = \begin{pmatrix} 4 & -2 \\ 1 & 1 \end{pmatrix}$ and $\mathring{\mathcal{B}} = (1,1), (2,1)$, a basis of F^2. Compute $[T_A]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$ with Theorem 4.5.17, and check the result by computing $A(1,1)$ and $A(2,1)$ directly.

Solution on page 1333

Matrices of one map

Every pair of bases gives a matrix of T, and by the theorem they are all of the form GAH with G and H invertible. The converse also holds, because every invertible matrix is a change-of-coordinates matrix.

Corollary 4.5.21 (Matrices of one linear map). Let $T \in \mathrm{L}(V, W)$ with $\dim V = n \geq 1$ and $\dim W = m \geq 1$, let $\mathcal{B}$ and $\mathcal{C}$ be bases of V and W, and let $A = [T]_{\mathcal{C}\mathcal{B}}$. For $A' \in F^{m\times n}$, the following are equivalent.

(a) $A' = [T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}}$ for some bases $\mathring{\mathcal{B}}$ of V and $\mathring{\mathcal{C}}$ of W.
(b) $A' = GAH$ for some invertible $G \in F^{m\times m}$ and $H \in F^{n\times n}$.
(c) $\operatorname{rank} A' = \operatorname{rank} A$.

Proof. ROUTINE

Uses. Theorem 4.5.17 (Change of basis), Proposition 4.5.12 (Calculus of change of coordinates), Proposition 4.5.16 (Every invertible matrix changes coordinates), Proposition 4.3.1 (Invertible factors preserve rank), Theorem 3.5.27 (Rank normal form), Proposition 2.5.17 (Algebra of inverses)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. (a) ⇒ (b) is the theorem. For (b) ⇒ (a), realize H and G as change-of-coordinates matrices with Proposition 4.5.16.
Hint 2. For (c) ⇒ (b), bring both A and A' to the same rank normal form.
Sketch. (a) ⇒ (b): Theorem 4.5.17 with $G = [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}}$ and $H = [\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}$. (b) ⇒ (a): choose $\mathring{\mathcal{B}}$ with $[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}} = H$ and $\mathring{\mathcal{C}}$ with $[\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}} = G$, and apply the theorem. (b) ⇒ (c) is Proposition 4.3.1. (c) ⇒ (b): $G_1 A H_1 = N_r = G_2 A' H_2$, so $A' = G_2^{-1} G_1 A H_1 H_2^{-1}$.

We prove (a) ⇔ (b) and (b) ⇔ (c).

(a) ⇒ (b). By Theorem 4.5.17, $A' = [\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}} A [\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}$, and both outer factors are invertible (Proposition 4.5.12(b)).

(b) ⇒ (a). By Proposition 4.5.16(a) there is a basis $\mathring{\mathcal{B}}$ of V with $[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}} = H$, and by part (b) there is a basis $\mathring{\mathcal{C}}$ of W with $[\mathrm{id}_W]_{\mathring{\mathcal{C}}\mathcal{C}} = G$. By Theorem 4.5.17, $[T]_{\mathring{\mathcal{C}}\mathring{\mathcal{B}}} = GAH = A'$.

(b) ⇒ (c). This is Proposition 4.3.1.

(c) ⇒ (b). Let $r = \operatorname{rank} A = \operatorname{rank} A'$. By Theorem 3.5.27 there are invertible $G_1, G_2 \in F^{m\times m}$ and $H_1, H_2 \in F^{n\times n}$ with $G_1 A H_1 = N_r = G_2 A' H_2$. Then $A' = \left(G_2^{-1} G_1\right) A \left(H_1 H_2^{-1}\right)$, and both factors are invertible by Proposition 2.5.17. □

So when the domain and the target may carry unrelated bases, the matrix of T can be any matrix of rank $\operatorname{rank} T$, and nothing else about T is visible. Choosing the bases well, the matrix becomes as simple as possible.

Corollary 4.5.22 (Rank normal form for linear maps). Let $T \in \mathrm{L}(V, W)$, where V and W are nonzero and finite-dimensional, and let $r = \operatorname{rank} T$. There are bases $\mathcal{B}$ of V and $\mathcal{C}$ of W with

$$[T]_{\mathcal{C}\mathcal{B}} = N_r = \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}.$$

Proof (from the matrix version). ROUTINE

Uses. Corollary 4.5.21 (Matrices of one linear map), Proposition 4.2.15 (Rank through any matrix)
Hint 1. Start from any bases. What is the rank of the resulting matrix?
Hint 2. N_r has rank r; use (c) ⇒ (a) of Corollary 4.5.21.
Sketch. For any bases, $\operatorname{rank} [T]_{\mathcal{C}_0\mathcal{B}_0} = \operatorname{rank} T = r = \operatorname{rank} N_r$ (Proposition 4.2.15), so by Corollary 4.5.21, N_r is a matrix of T.

Choose any bases $\mathcal{B}_0$ and $\mathcal{C}_0$. By Proposition 4.2.15, $\operatorname{rank} [T]_{\mathcal{C}_0\mathcal{B}_0} = \operatorname{rank} T = r$, and $\operatorname{rank} N_r = r$. By Corollary 4.5.21, (c) ⇒ (a), there are bases $\mathcal{B}$ and $\mathcal{C}$ with $[T]_{\mathcal{C}\mathcal{B}} = N_r$. □

Proof (by building the bases). STANDARD

Uses. Theorem 4.1.16 (Extending to a basis), Theorem 4.2.11 (Rank–nullity), Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Definition 2.3.1 (Matrix of a linear map)
Techniques. Extend a basis of a subspace (Technique 4.1.18)
Hint 1. The last $n-r$ vectors of $\mathcal{B}$ must go to $\mathbf{0}$, and the first r must go to the first r vectors of $\mathcal{C}$. Where should the last $n-r$ vectors come from?
Hint 2. Extend a basis of $\ker T$ to a basis of V, putting the new vectors first. Their images form a basis of $\operatorname{im} T$; extend that to a basis of W.
Sketch. Extend a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of $\ker T$ to a basis $\mathbf{v}_1, \dots, \mathbf{v}_r, \mathbf{u}_1, \dots, \mathbf{u}_k$ of V. The images $T(\mathbf{v}_1), \dots, T(\mathbf{v}_r)$ span $\operatorname{im} T$, and $r = \dim \operatorname{im} T$ by rank–nullity, so they form a basis of $\operatorname{im} T$; extend them to a basis of W. Then $T(\mathbf{v}_j) = \mathbf{c}_j$ and $T(\mathbf{u}_i) = \mathbf{0}$, which is N_r.

Let $\mathbf{u}_1, \dots, \mathbf{u}_k$ be a basis of $\ker T$, and extend it to a basis of V (Theorem 4.1.16); list the new vectors first, so that $\mathcal{B} = \mathbf{v}_1, \dots, \mathbf{v}_s, \mathbf{u}_1, \dots, \mathbf{u}_k$. Since $T(\mathbf{u}_i) = \mathbf{0}$, the list $T(\mathcal{B})$, which spans $\operatorname{im} T$ (Proposition 2.6.22(d)), still spans $\operatorname{im} T$ when the zeros are deleted. So $T(\mathbf{v}_1), \dots, T(\mathbf{v}_s)$ spans $\operatorname{im} T$. By Theorem 4.2.11(b), $s = \dim V - k = \dim \operatorname{im} T = r$, so these r vectors span the r-dimensional space $\operatorname{im} T$, and they form a basis of it (Corollary 4.1.11(b)). Write $\mathbf{c}_j = T(\mathbf{v}_j)$ and extend $\mathbf{c}_1, \dots, \mathbf{c}_r$ to a basis $\mathcal{C}$ of W. Then the j-th column of $[T]_{\mathcal{C}\mathcal{B}}$ is $[\mathbf{c}_j]_{\mathcal{C}} = \mathbf{e}_j$ for $j \le r$, and the remaining columns are $[\mathbf{0}]_{\mathcal{C}} = \mathbf{0}$. So $[T]_{\mathcal{C}\mathcal{B}} = N_r$. □

The second proof is the one sketched after the second proof of rank–nullity (Section 4.2), and the first is Corollary 3.5.29 transported to abstract spaces. For operators, where the same basis must be used on both sides, much more survives. That is the subject of the next subsection.

4.5.4 Similarity

For $T \in \mathrm{L}(V)$ we compare $T(\mathbf{v})$ with $\mathbf{v}$, so we use one basis for both. By Theorem 4.5.17, the matrices of T in two bases are related by $[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = P^{-1}[T]_{\mathcal{B}\mathcal{B}}P$, with the same invertible P on both sides.

Definition 4.5.23 (Similar matrices). Matrices $A, B \in F^{n\times n}$ are **similar** if

$$B = S^{-1}AS$$

for some invertible $S \in F^{n\times n}$. We then write $A \sim B$.

The lecture writes the same condition as $B = QAQ^{-1}$; take $Q = S^{-1}$. To check a proposed S, it is easier to verify $AS = SB$ (and that S is invertible) than to compute S^{-1}.

Proposition 4.5.24 (Similarity is an equivalence relation). For all $A, B, C \in F^{n\times n}$: $A \sim A$; if $A \sim B$ then $B \sim A$; and if $A \sim B$ and $B \sim C$ then $A \sim C$.

Proof. ROUTINE

Uses. Definition 4.5.23 (Similar matrices), Proposition 2.5.17 (Algebra of inverses), Proposition 2.4.14 (Algebra of matrices)
Hint 1. Each claim asks for an invertible matrix. Try I_n, then S^{-1}, then a product.
Hint 2. If $B = S^{-1}AS$ and $C = R^{-1}BR$, substitute and regroup.
Sketch. $A = I^{-1}AI$. If $B = S^{-1}AS$, then $A = SBS^{-1} = (S^{-1})^{-1}BS^{-1}$. If also $C = R^{-1}BR$, then $C = R^{-1}S^{-1}ASR = (SR)^{-1}A(SR)$.

First, $A = I_n^{-1}AI_n$. If $B = S^{-1}AS$, multiplying by S on the left and S^{-1} on the right gives $A = SBS^{-1} = (S^{-1})^{-1}BS^{-1}$, and S^{-1} is invertible (Proposition 2.5.17(a)). If also $C = R^{-1}BR$, then by associativity (Proposition 2.4.14) and Proposition 2.5.17(b),

$$C = R^{-1}S^{-1}ASR = (SR)^{-1}A(SR),$$

and SR is invertible. □

The definition is a statement about matrices, but its meaning is a statement about operators.

Theorem 4.5.25 (Similar matrices are one operator in two bases). Let $A, B \in F^{n\times n}$ with $n \geq 1$. The following are equivalent.

(a) $A \sim B$.
(b) Whenever $\dim V = n$, $T \in \mathrm{L}(V)$, and $\mathcal{B}$ is a basis of V with $[T]_{\mathcal{B}\mathcal{B}} = A$, there is a basis $\mathring{\mathcal{B}}$ of V with $[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = B$.
(c) There are a vector space V with $\dim V = n$, an operator $T \in \mathrm{L}(V)$, and bases $\mathcal{B}$, $\mathring{\mathcal{B}}$ of V with $[T]_{\mathcal{B}\mathcal{B}} = A$ and $[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = B$.

Moreover, if $B = S^{-1}AS$, then $B = [T_A]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$, where $\mathring{\mathcal{B}}$ is the list of columns of S.

Proof. ROUTINE

Uses. Theorem 4.5.17 (Change of basis), Proposition 4.5.16 (Every invertible matrix changes coordinates), Proposition 4.5.12 (Calculus of change of coordinates), Proposition 2.3.16 (The matrix of T_A)
Techniques. Proving TFAE (Technique 2.7.1), Translate between maps and matrices (Technique 2.3.27)
Hint 1. Prove (a) ⇒ (b) ⇒ (c) ⇒ (a). Two of the three steps are Theorem 4.5.17 read in the two directions.
Hint 2. For (a) ⇒ (b), given $B = S^{-1}AS$, use Proposition 4.5.16 to find $\mathring{\mathcal{B}}$ with $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = S$. For (b) ⇒ (c), you need one example of V, T, $\mathcal{B}$: take the obvious one.
Sketch. (a) ⇒ (b): if $B = S^{-1}AS$, choose $\mathring{\mathcal{B}}$ with $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = S$; then $[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = S^{-1}AS = B$. (b) ⇒ (c): apply (b) to T_A on F^n with the standard basis. (c) ⇒ (a): Theorem 4.5.17 with $P = [\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$. For the last claim, the basis of F^n with $[\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}} = S$ is the list of columns of S.

We prove (a) ⇒ (b) ⇒ (c) ⇒ (a).

(a) ⇒ (b). Let $B = S^{-1}AS$, and let V, T, and $\mathcal{B}$ be as in (b). By Proposition 4.5.16(a), there is a basis $\mathring{\mathcal{B}}$ of V with $[\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}} = S$. By Theorem 4.5.17, $[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = S^{-1}[T]_{\mathcal{B}\mathcal{B}}S = S^{-1}AS = B$.

(b) ⇒ (c). Take $V = F^n$, $T = T_A$, and the standard basis $\mathcal{E}$; then $[T_A]_{\mathcal{E}\mathcal{E}} = A$ (Proposition 2.3.16), and (b) provides $\mathring{\mathcal{B}}$.

(c) ⇒ (a). Let $P = [\mathrm{id}]_{\mathcal{B}\mathring{\mathcal{B}}}$, which is invertible (Proposition 4.5.12(b)). By Theorem 4.5.17, $B = [T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = P^{-1}AP$.

For the last claim, apply the proof of (a) ⇒ (b) to T_A and $\mathcal{B} = \mathcal{E}$. By Proposition 4.5.16(a), the j-th vector of $\mathring{\mathcal{B}}$ is $\sum_i s_{ij}\mathbf{e}_i$, the j-th column of S. □

Intuition (Similarity is a change of viewpoint). Two similar matrices describe one operator, recorded in two coordinate systems, and S is the dictionary between them: its columns are the new basis, written in the old coordinates. So a question about similarity is a question about whether two matrices can be the same operator. Any property of the operator itself, defined without reference to a basis, must be shared by all of its matrices. That is how we will tell matrices apart.

Example 4.5.26 (A similarity and a non-similarity).

(a) Let F be a field with $2 \neq 0$, and let $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$. Then $A(1,1) = (2,2) = 2(1,1)$ and $A(1,-1) = (0,0)$. So in the basis $\mathring{\mathcal{B}} = (1,1), (1,-1)$, the operator T_A doubles the first basis vector and kills the second, and with $S = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$, the matrix whose columns are these vectors,

$$S^{-1}AS = \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}.$$

(Check: $AS = \begin{pmatrix} 2 & 0 \\ 2 & 0 \end{pmatrix} = S\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$, and S is invertible since $1\cdot(-1) - 1\cdot 1 = -2 \neq 0$.) Similar matrices need not share a single entry.

(a) Over $\mathbb{F}_2$, the same matrix $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ is not similar to $\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$, which is now the zero matrix: $S^{-1}0S = 0$ for every S, so the only matrix similar to 0 is 0. Whether two matrices are similar can depend on the field.

Similarity invariants

A **similarity invariant** is a quantity or property of square matrices that is the same for any two similar matrices. Here are the ones available so far.

Proposition 4.5.27 (Similarity invariants). Let $A, B \in F^{n\times n}$ with $A \sim B$. Then:

(a) $\operatorname{rank} A = \operatorname{rank} B$;
(b) $\operatorname{tr} A = \operatorname{tr} B$;
(c) $A^k \sim B^k$ for every $k \geq 0$; in particular $\operatorname{rank} A^k = \operatorname{rank} B^k$;
(d) $A - cI_n \sim B - cI_n$ for every $c \in F$; in particular $\operatorname{rank}(A - cI_n) = \operatorname{rank}(B - cI_n)$;
(e) A is invertible if and only if B is, and then $A^{-1} \sim B^{-1}$;
(f) $A^{\mathsf{T}} \sim B^{\mathsf{T}}$.

Proof (by matrix algebra). ROUTINE

Uses. Definition 4.5.23 (Similar matrices), Proposition 4.3.1 (Invertible factors preserve rank), Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.14 (Algebra of matrices), Proposition 2.5.17 (Algebra of inverses), Proposition 2.4.23 (Transpose of a product)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. Write $B = S^{-1}AS$. For (a), invertible factors do not change the rank. For (b), move a factor around the trace.
Hint 2. For (c), the inner factors telescope: $(S^{-1}AS)(S^{-1}AS) = S^{-1}A^2S$. For (d), $S^{-1}(cI)S = cI$. For (f), transpose $B = S^{-1}AS$.
Sketch. With $B = S^{-1}AS$: (a) Proposition 4.3.1. (b) $\operatorname{tr}\big(S^{-1}(AS)\big) = \operatorname{tr}\big((AS)S^{-1}\big) = \operatorname{tr} A$. (c) $B^k = S^{-1}A^kS$ by induction. (d) $S^{-1}(A - cI)S = B - cI$. (e) $B^{-1} = S^{-1}A^{-1}S$. (f) $B^{\mathsf{T}} = S^{\mathsf{T}}A^{\mathsf{T}}\big(S^{\mathsf{T}}\big)^{-1}$.

Write $B = S^{-1}AS$ with S invertible.

(a) By Proposition 4.3.1, $\operatorname{rank}\big(S^{-1}AS\big) = \operatorname{rank} A$.

(b) By Proposition 2.4.28 with the factors S^{-1} and AS,

$$\operatorname{tr} B = \operatorname{tr}\big(S^{-1}(AS)\big) = \operatorname{tr}\big((AS)S^{-1}\big) = \operatorname{tr} A.$$

(c) We show $B^k = S^{-1}A^kS$ by induction on k. For $k = 0$ both sides are I_n. If it holds for k, then

$$B^{k+1} = B^kB = \big(S^{-1}A^kS\big)\big(S^{-1}AS\big) = S^{-1}A^k\big(SS^{-1}\big)AS = S^{-1}A^{k+1}S.$$

So $A^k \sim B^k$, and their ranks agree by (a).

(d) $S^{-1}(A - cI_n)S = S^{-1}AS - cS^{-1}S = B - cI_n$ (Proposition 2.4.14), and the ranks agree by (a).

(e) If A is invertible, then B is a product of invertible matrices, hence invertible, with $B^{-1} = S^{-1}A^{-1}S$ (Proposition 2.5.17(b)). So $A^{-1} \sim B^{-1}$. The converse follows by symmetry, since $A = SBS^{-1}$.

(f) By Proposition 2.4.23 and Proposition 2.5.17(d), $B^{\mathsf{T}} = S^{\mathsf{T}}A^{\mathsf{T}}\big(S^{-1}\big)^{\mathsf{T}} = S^{\mathsf{T}}A^{\mathsf{T}}\big(S^{\mathsf{T}}\big)^{-1}$. With $R = \big(S^{\mathsf{T}}\big)^{-1}$, this is $B^{\mathsf{T}} = R^{-1}A^{\mathsf{T}}R$. □

The second proof uses Theorem 4.5.25: since A and B are matrices of one operator, anything defined from the operator alone is the same for both. It reaches (a), (c), (d), and (e), but not (b) or (f), because the trace and the transpose are defined through matrices.

Proof (through the operator). ROUTINE

Uses. Theorem 4.5.25 (Similar matrices are one operator in two bases), Proposition 4.2.15 (Rank through any matrix), Theorem 2.4.2 (The matrix of a composite), Proposition 2.4.12 (Matrices of sums and scalar multiples), Example 2.3.6 (The zero map and the identity map), Proposition 2.5.20 (Inverses and matrices)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. By Theorem 4.5.25, $A = [T]_{\mathcal{B}\mathcal{B}}$ and $B = [T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$ for a single operator T. What is the rank of a matrix of T?
Hint 2. Which operators have matrices A^k, $A - cI_n$, and A^{-1} in the basis $\mathcal{B}$? Apply Theorem 4.5.25 to them in the other direction.

Sketch. Let $A = [T]_{\mathcal{B}\mathcal{B}}$ and $B = [T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$. Then $\operatorname{rank} A = \operatorname{rank} T = \operatorname{rank} B$. Also A^k and B^k are the matrices of T^k in the two bases, $A - cI_n$ and $B - cI_n$ those of $T - c\mathrm{id}_V$, and A^{-1}, B^{-1} those of T^{-1} (which exists iff either matrix is invertible); so each pair is similar by the theorem.

By Theorem 4.5.25, (a) ⇒ (c), there are V, $T \in \mathrm{L}(V)$, and bases $\mathcal{B}$, $\mathring{\mathcal{B}}$ with $A = [T]_{\mathcal{B}\mathcal{B}}$ and $B = [T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$.

(a) By Proposition 4.2.15, $\operatorname{rank} A = \operatorname{rank} T = \operatorname{rank} B$.

(c) By Theorem 2.4.2 and induction on k, $\left[T^k\right]_{\mathcal{B}\mathcal{B}} = A^k$ and $\left[T^k\right]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = B^k$ (with $T^0 = \mathrm{id}_V$ and Example 2.3.6 for $k = 0$). So A^k and B^k are matrices of the single operator T^k, and they are similar by Theorem 4.5.25, (c) ⇒ (a).

(d) By Proposition 2.4.12 and Example 2.3.6, $A - cI_n$ and $B - cI_n$ are the matrices of $T - c\mathrm{id}_V$ in the two bases.

(e) By Proposition 2.5.20(b), A is invertible if and only if T is, if and only if B is; and then A^{-1} and B^{-1} are the matrices of T^{-1} in the two bases. □

Remark 4.5.28 (What the invariants cannot do). Equal invariants do not make matrices similar. The matrices

$$N = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

both have trace 0 and rank 2. But $N^3 = 0$, since N shifts $\mathbf{e}_1 \mapsto \mathbf{e}_2 \mapsto \mathbf{e}_3 \mapsto \mathbf{0}$, while $D^3 = D$ has rank 2. By (c), $\operatorname{rank} N^3 \neq \operatorname{rank} D^3$ rules out $N \sim D$. Similarly, I_2 and $J = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ have the same rank and trace, and J^k has rank 2 like I_2^k; but $\operatorname{rank}(J - I_2) = 1 \neq 0 = \operatorname{rank}(I_2 - I_2)$, so they are not similar. (More simply, the only matrix similar to I_n is I_n, since $S^{-1} I_n S = I_n$.)

The determinant is one more invariant (Proposition 5.4.17), and the characteristic polynomial, which contains both the trace and the determinant, is a stronger one (Section 7.3). None of these decides similarity on its own. Over $\mathbb{C}$, the ranks of $(A - cI_n)^k$ for all c and k do decide it; this is the content of the Jordan form (Section 10.3).

Technique 4.5.29 (Rule out similarity with an invariant). To show that A and B are not similar, find a similarity invariant on which they differ: trace, rank, rank of a power A^k, rank of $A - cI_n$ for a well-chosen c, and later the determinant and the characteristic polynomial. To show that they are similar, invariants are not enough: produce an S with $AS = SB$, usually by finding a basis in which the operator T_A has matrix B (Theorem 4.5.25).

Reach for the cheapest invariants first. Trace and rank take seconds. If they agree, look for a structural difference: is one matrix nilpotent, or a scalar multiple of I_n, or does $A - cI_n$ drop rank for some c where $B - cI_n$ does not? The canonical example is Remark 4.5.28.

Used in. Exercise 4.5.32, Exercise 4.5.44, Exercise 4.5.45, Exercise 4.8.4, Problem 4.13, Exercise 7.3.38, Exercise 7.4.43, Exercise 4.5.46, Exercise 7.6.43.

Invariants of an operator

Because the trace is a similarity invariant, it can be assigned to an operator, just as the rank was in Definition 4.2.14.

Definition 4.5.30 (Trace of an operator). Let V be finite-dimensional with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$. The **trace** of T is

$$\operatorname{tr} T = \operatorname{tr} [T]_{\mathcal{B}\mathcal{B}},$$

where $\mathcal{B}$ is any basis of V.

The definition does not depend on $\mathcal{B}$: by Theorem 4.5.17, the matrices of T in two bases are similar, and similar matrices have the same trace (Proposition 4.5.27(b)). In the same way, $\operatorname{rank}[T]_{\mathcal{B}\mathcal{B}} = \operatorname{rank} T$ for every basis (Proposition 4.2.15), and in Definition 5.4.18 the determinant joins them. For $V = F^n$ and the standard basis, $\operatorname{tr} T_A = \operatorname{tr} A$.

Example 4.5.31 (The trace of transposition). Let $T \in \mathrm{L}(F^{n\times n})$ be $T(X) = X^{\mathsf{T}}$. In the basis of matrix units U_{ij} (Proposition 1.6.7(b)), $T(U_{ij}) = U_{ji}$. The diagonal entry of $[T]$ in the position belonging to U_{ij} is the U_{ij}-coordinate of $T(U_{ij}) = U_{ji}$, which is 1 if $i = j$ and 0 otherwise. So

$$\operatorname{tr} T = n \quad (\text{that is}, n \cdot 1 \in F).$$

Over $\mathbb{R}$ there is a second basis to check this against. T fixes the symmetric matrices, a subspace of dimension $n(n+1)/2$, and negates the skew-symmetric ones, of dimension $n(n-1)/2$. In a basis made of a basis of each, $[T]$ is diagonal with $n(n+1)/2$ entries 1 and $n(n-1)/2$ entries -1, and its trace is again $n(n+1)/2 - n(n-1)/2 = n$.

Exercise 4.5.32. STANDARD Let $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \mathbb{Q}^{2\times 2}$. Decide which of the following matrices are similar to J. For each one that is, find S with $S^{-1}MS = J$.

(a) $M = I_2$.
(b) $M = \begin{pmatrix} 2 & 1 \\ -1 & 0 \end{pmatrix}$.
(c) $M = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$.

Solution on page 1333

4.5.5 Choosing a convenient basis

The change-of-basis formula also gives a proof technique: if a statement does not depend on the basis, we may prove it in whichever basis makes it easiest.

Technique 4.5.33 (Choose a convenient basis). Many statements about a linear map T (or a matrix A) are invariant under change of basis: they hold for one matrix of T if and only if they hold for all of them, or for A if and only if they hold for GAH (or for $S^{-1}AS$). To prove such a statement, first check this invariance, then choose bases in which the matrix is as simple as possible, prove the statement there, and transport the conclusion back.

For maps between two spaces, the best possible matrix is the rank normal form N_r (Corollary 4.5.22), and in matrix language this says: to prove something about A that survives $A \mapsto GAH$, assume $A = N_r$. For operators, the bases must agree on both sides, and the convenient bases come from the operator itself: bases adapted to a subspace that T preserves (below), bases of the form $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ (Exercise 4.5.50, Exercise 4.5.43), and later bases of eigenvectors (Section 7.4) and triangularizing bases (Section 7.5).
Used in. Exercise 4.5.41, Exercise 4.5.42, Exercise 4.5.43, Exercise 4.5.49, Exercise 4.5.50, Exercise 4.5.51, Exercise 4.5.52, Exercise 4.5.53, Exercise 4.8.12, Theorem 7.5.22, Problem 7.6, Problem 7.10, Problem 7.11, Proposition 8.2.2, Corollary 8.2.28, Exercise 8.3.43, Exercise 4.5.55.

Example 4.5.34 (A matrix with $AXA = A$). We show that for every $A \in F^{m\times n}$ there is $X \in F^{n\times m}$ with $AXA = A$. (Such an X is a generalized inverse of A; if A is invertible, $X = A^{-1}$ is the only choice.)

For $A = N_r$ the claim is easy: $X = N_r^{\mathsf{T}} \in F^{n\times m}$ works. By block multiplication (Theorem 2.4.34), $N_r N_r^{\mathsf{T}} = \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix} \in F^{m\times m}$, and then $N_r N_r^{\mathsf{T}} N_r = N_r$.

The statement survives $A \mapsto GAH$: if $N_r X N_r = N_r$ and $A = GN_rH$ with G and H invertible, then $X' = H^{-1}XG^{-1}$ satisfies

$$AX'A = GN_rHH^{-1}XG^{-1}GN_rH = G(N_rXN_r)H = GN_rH = A.$$

By Theorem 3.5.27, every A is GN_rH for some invertible G, H (namely, invert the factors in $G'AH' = N_r$). So every A has a generalized inverse, $X' = H^{-1}N_r^{\mathsf{T}}G^{-1}$.

In terms of maps: if $[T]_{\mathcal{C}\mathcal{B}} = N_r$ with $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ and $\mathcal{C} = \mathbf{c}_1, \ldots, \mathbf{c}_m$, let $S \in \mathrm{L}(W, V)$ send $\mathbf{c}_j \mapsto \mathbf{b}_j$ for $j \le r$ and $\mathbf{c}_j \mapsto \mathbf{0}$ for $j > r$. Then $TST = T$, as one checks on the basis $\mathcal{B}$. The matrix computation is this argument in coordinates.

Bases adapted to a subspace

For an operator, the convenient basis must work on both sides at once. The first source of such bases is a subspace that T maps into itself.

Proposition 4.5.35 (Preserved subspaces give block triangular matrices). Let $\dim V = n \ge 1$, $T \in \mathrm{L}(V)$, and $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ a basis of V. Let $1 \le k \le n$ and $U = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_k)$. Then $\operatorname{im}(T{\restriction_U}) \subseteq U$ if and only if

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$$

for some $A \in F^{k\times k}$, $B \in F^{k\times(n-k)}$, and $D \in F^{(n-k)\times(n-k)}$, where 0 is the zero block of size $(n-k)\times k$. In that case, $A = [T{\restriction_U}]_{\mathcal{B}_U\mathcal{B}_U}$, where $\mathcal{B}_U = \mathbf{b}_1, \ldots, \mathbf{b}_k$ and $T{\restriction_U}$ is regarded as an operator on U.

Proof. ROUTINE

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.14 (Coordinates), Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Definition 4.2.1 (Restriction)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. The j-th column of $[T]_{\mathcal{B}\mathcal{B}}$ holds the coefficients of $T(\mathbf{b}_j)$. When does a vector lie in U, in terms of its $\mathcal{B}$-coordinates?
Hint 2. $\operatorname{im}(T{\restriction_U})$ is spanned by $T(\mathbf{b}_1), \ldots, T(\mathbf{b}_k)$, so it lies in U exactly when each $T(\mathbf{b}_j)$ with $j \le k$ does.
Sketch. A vector lies in U exactly when its last $n-k$ coordinates are 0. The image of $T{\restriction_U}$ is spanned by $T(\mathbf{b}_1), \ldots, T(\mathbf{b}_k)$, so it lies in U exactly when the first k columns of $[T]_{\mathcal{B}\mathcal{B}}$ vanish below row k. Their top parts are then the coordinates of $T(\mathbf{b}_j)$ in $\mathcal{B}_U$, the columns of $[T{\restriction_U}]$.

A vector $\mathbf{v}$ lies in U if and only if its $\mathcal{B}$-coordinates $(c_1, \ldots, c_n)$ satisfy $c_{k+1} = \cdots = c_n = 0$: if they do, $\mathbf{v} = \sum_{i\le k} c_i\mathbf{b}_i \in U$; conversely, a vector of U is $\sum_{i\le k} c_i\mathbf{b}_i$, and by uniqueness of coordinates (Definition 1.6.14) these are its coordinates, with zeros after position k.

The list $\mathbf{b}_1, \ldots, \mathbf{b}_k$ is a basis of U, so $T(\mathbf{b}_1), \ldots, T(\mathbf{b}_k)$ spans $\operatorname{im}(T{\restriction_U})$ (Proposition 2.6.22(d), applied to $T{\restriction_U}$). Since U is a subspace, $\operatorname{im}(T{\restriction_U}) \subseteq U$ if and only if $T(\mathbf{b}_j) \in U$ for each $j \le k$, that is, if and only if the j-th column $[T(\mathbf{b}_j)]_{\mathcal{B}}$ of $[T]_{\mathcal{B}\mathcal{B}}$ has zeros in rows $k+1, \ldots, n$ for each $j \le k$. This is the block form.

In that case $T(\mathbf{b}_j) = \sum_{i\le k} a_{ij}\mathbf{b}_i$ for $j \le k$, where (a_{ij}) is the top left block. So the $\mathcal{B}_U$-coordinates of $T{\restriction_U}(\mathbf{b}_j)$ are the j-th column of A, and $A = [T{\restriction_U}]_{\mathcal{B}_U\mathcal{B}_U}$ (Definition 2.3.1). □

If also the span of the last $n-k$ basis vectors is mapped into itself, the same argument shows that the block B is zero, and $[T]_{\mathcal{B}\mathcal{B}}$ is block diagonal. Subspaces with $\operatorname{im}(T{\restriction_U}) \subseteq U$ are called invariant subspaces of T; they are studied in Section 7.2.

Technique 4.5.36 (Choose a basis adapted to a preserved subspace). If T maps a subspace U into itself, take a basis of U and extend it to a basis of V (Theorem 4.1.16). In this basis the matrix of T is block upper triangular (Proposition 4.5.35), the top left block is the matrix of T on U, and a question about T splits into a question about T on U and one about the bottom right block. If V is assembled from several preserved subspaces, list bases of each in turn, and the matrix becomes block diagonal.

Reach for it when you can see a subspace that T preserves: a kernel or image of something commuting with T, the span of a vector fixed or scaled by T, or the span of $\mathbf{v}, T\mathbf{v}, \ldots, T^k\mathbf{v}$. It is the first step of triangularization (Section 7.5) and of the Jordan form (Section 10.3).
Used in. Problem 4.4, Problem 4.12, Problem 4.13, Corollary 7.3.16, Exercise 7.3.41, Theorem 7.4.15, Lemma 7.5.11, Exercise 4.5.42.

Example 4.5.37 (The cyclic permutation of coordinates). Let $Z \in F^{3\times 3}$ be the matrix with $Z(x,y,z) = (z,x,y)$, so that $Z^3 = I_3$. Two subspaces are visibly preserved by T_Z: the line $U = \operatorname{span}(\mathbf{u}_1)$ with $\mathbf{u}_1 = (1,1,1)$, which Z fixes, and the plane $U' = \{(x,y,z) \mid x+y+z = 0\}$, since permuting the coordinates does not change their sum. Let $\mathbf{u}_2 = (1,-1,0)$ and $\mathbf{u}_3 = (0,1,-1)$, both in U'.

Suppose $3 \neq 0$ in F. Then $\mathcal{U} = \mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$ is a basis of F^3: if $a\mathbf{u}_1 + b\mathbf{u}_2 + c\mathbf{u}_3 = (a+b, a-b+c, a-c) = \mathbf{0}$, then $b = -a$ and $c = a$, so the middle entry is $3a = 0$, and $a = b = c = 0$. Now

$$Z\mathbf{u}_1 = \mathbf{u}_1, \quad Z\mathbf{u}_2 = (0,1,-1) = \mathbf{u}_3, \quad Z\mathbf{u}_3 = (-1,0,1) = -\mathbf{u}_2 - \mathbf{u}_3,$$

so

$$[T_Z]_{\mathcal{U}\mathcal{U}} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & R \end{pmatrix}, \quad R = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}.$$

The matrix is block diagonal because both U and $\operatorname{span}(\mathbf{u}_2, \mathbf{u}_3) = U'$ are preserved. The trace is $0 = 1 + \operatorname{tr} R$, as it must be, and $Z^3 = I_3$ becomes $R^3 = I_2$, which is easy to check by hand. Over $\mathbb{R}$, R turns out to be similar to the rotation by $2\pi/3$ (Exercise 4.5.43), which matches the picture of Z as a rotation of $\mathbb{R}^3$ about the line U.

If $3 = 0$ in F, then $\mathbf{u}_1 \in U'$, so U and U' no longer fill F^3; the list $\mathbf{u}_1, \mathbf{u}_2, \mathbf{e}_1$ still gives a block upper triangular matrix, but not a block diagonal one.

The normal forms ahead are all answers to one question: in the best basis, how simple can the matrix of an operator be? For maps between two spaces, Corollary 4.5.22 gave the complete answer. For operators the answer is diagonal when there is a basis of eigenvectors (Section 7.4), upper triangular over $\mathbb{C}$ (Section 7.5), and the Jordan form in general over $\mathbb{C}$ (Section 10.3).

Exercises

Exercise 4.5.38. ROUTINE Over $\mathbb{F}_3$, let $\mathcal{B} = (1,1,0), (0,1,1), (1,0,1)$ and $\mathring{\mathcal{B}} = (1,0,0), (1,1,0), (1,1,1)$.

(a) Show that $\mathcal{B}$ is a basis of $\mathbb{F}_3^3$, and compute $[\mathrm{id}]_{\mathcal{B}\mathcal{E}}$.
(b) Find $[(1,2,0)]_{\mathcal{B}}$.
(c) Compute $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}}$.
(d) Is the same list $\mathcal{B}$ a basis of $\mathbb{F}_2^3$?

Solution on page 1333

Exercise 4.5.39. ROUTINE Prove or disprove.

(a) Every change-of-coordinates matrix is invertible.
(b) If $A \sim B$, then A and B have the same diagonal entries, possibly in a different order.
(c) If $T \in \mathrm{L}(V,W)$ is injective and $\dim V = \dim W < \infty$, then T is an isomorphism.
(d) Two matrices in $F^{n\times n}$ with the same rank and the same trace are similar.
(e) If $\dim V = 2$ and $\dim \mathrm{L}(V,W) = 6$, then $W \cong F^3$.
(f) The only matrix similar to cI_n is cI_n.

Solution on page 1334

Exercise 4.5.40. STANDARD Let $a \in F$ and $n \geq 1$. In $F[x]_{\leq n}$, let $\mathcal{B} = 1, x, \ldots, x^n$ and $\mathcal{B}_a = 1, x-a, (x-a)^2, \ldots, (x-a)^n$. Index rows and columns from 0 to n.

(a) Show that $\mathcal{B}_a$ is a basis, and that the (i,j) entry of $[\mathrm{id}]_{\mathcal{B}_a\mathcal{B}}$ is $\binom{j}{i}a^{j-i}$ for $i \leq j$ and 0 for $i > j$.
(b) Find the entries of $[\mathrm{id}]_{\mathcal{B}\mathcal{B}_a}$ in the same way.
(c) Taking $F = \mathbb{Q}$ and $a = 1$, deduce that $\sum_{k=i}^{j}(-1)^{k-i}\binom{j}{k}\binom{k}{i}$ is 1 if $i = j$ and 0 if $i < j$.

Solution on page 1335

Exercise 4.5.41. STANDARD Let V and W be finite-dimensional with $\dim V = n \geq 1$ and $\dim W = m$, and let $\mathbf{v}_0 \in V$ be nonzero. Show that

$$K = \{T \in \mathrm{L}(V,W) \mid T(\mathbf{v}_0) = \mathbf{0}\}$$

is a subspace of $\mathrm{L}(V,W)$ of dimension $(n-1)m$. Give two proofs: one by choosing a basis of V that contains $\mathbf{v}_0$, and one by rank–nullity.

Solution on page 1335

Solution on page 1335

Exercise 4.5.42. HARD Let V and W be finite-dimensional with $\dim V = n \geq 1$ and $\dim W = m \geq 1$, and let $U \subseteq V$ and $U' \subseteq W$ be subspaces with $\dim U = k$ and $\dim U' = k'$. Show that

$$\{T \in \mathrm{L}(V,W) \mid \mathrm{im}(T{\restriction_U}) \subseteq U'\}$$

is a subspace of $\mathrm{L}(V,W)$ of dimension $mn - k(m-k')$. In particular, the operators $T \in \mathrm{L}(V)$ with $\mathrm{im}(T{\restriction_U}) \subseteq U$ form a subspace of $\mathrm{L}(V)$ of dimension $n^2 - k(n-k)$.

Solution on page 1336

Exercise 4.5.43. HARD For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, let $\delta(A) = ad - bc$.

(a) Show that if $A\mathbf{v} \in \mathrm{span}(\mathbf{v})$ for every $\mathbf{v} \in F^2$, then $A = cI_2$ for some $c \in F$.
(b) Suppose A is not a scalar multiple of I_2. Show that there is $\mathbf{v} \in F^2$ such that $\mathbf{v}, A\mathbf{v}$ is a basis of F^2, and that in this basis T_A has the matrix

$$C_A = \begin{pmatrix} 0 & -\delta(A) \\ 1 & \mathrm{tr}\, A \end{pmatrix}.$$

(c) Deduce that two matrices in $F^{2\times 2}$, neither a scalar multiple of I_2, with the same trace and the same value of δ, are similar.
(d) Show that $A \sim A^{\mathsf{T}}$ for every $A \in F^{2\times 2}$.
(e) Show that the matrix $R = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}$ of Example 4.5.37 is similar over $\mathbb{R}$ to the rotation matrix $\begin{pmatrix} \cos(2\pi/3) & -\sin(2\pi/3) \\ \sin(2\pi/3) & \cos(2\pi/3) \end{pmatrix}$.

Solution on page 1336

Exercise 4.5.44. HARD Keep the notation $\delta(A) = ad - bc$ of Exercise 4.5.43.

(a) Show that $\delta(XY) = \delta(X)\delta(Y)$ for all $X, Y \in F^{2\times 2}$, and deduce that δ is a similarity invariant.
(b) Show that every $A \in F^{2\times 2}$ is similar to exactly one matrix in the list consisting of cI_2 for $c \in F$ and $\begin{pmatrix} 0 & -d \\ 1 & t \end{pmatrix}$ for $t, d \in F$.
(c) Deduce that over $\mathbb{F}_q$ there are exactly $q^2 + q$ similarity classes of 2×2 matrices.

Solution on page 1337

Exercise 4.5.45. ROUTINE Find the error in the following argument, and show that its conclusion is false.

Claim. Any two matrices $A, B \in F^{n\times n}$ of the same rank r are similar.

Proof. By Theorem 3.5.27 there are invertible G, H, G', H' with $GAH = N_r = G'BH'$. Then $B = G'^{-1}GAHH'^{-1}$. Let $S = HH'^{-1}$, which is invertible. Then $B = \big(G'^{-1}G\big)AS$, a product of A with invertible matrices on both sides, so B is similar to A.

Solution on page 1337

Exercise 4.5.46. STANDARD Let $A, B, C, D \in F^{n\times n}$, $n \geq 2$. Prove or disprove.

(a) If $A \sim B$ and $C \sim D$, then $A + C \sim B + D$.
(b) If $A \sim B$, then $AC \sim BC$.
(c) If $A \sim B$, then $A + cI_n \sim B + cI_n$ for every $c \in F$.
(d) If $A^2 \sim B^2$, then $A \sim B$.

Solution on page 1338

Exercise 4.5.47. HARD Let $f : F^{n\times n} \to F$ be a linear map such that $f\big(S^{-1}AS\big) = f(A)$ for every $A \in F^{n\times n}$ and every invertible $S \in F^{n\times n}$. Show that $f = c\,\mathrm{tr}$ for some $c \in F$. That is, up to a scalar factor, the trace is the only linear similarity invariant.

Solution on page 1338

Exercise 4.5.48. STANDARD For $A, B \in F^{n\times n}$, let $T \in \mathrm{L}(F^{n\times n})$ be $T(X) = AXB$. Show that $\mathrm{tr}\,T = (\mathrm{tr}\,A)(\mathrm{tr}\,B)$. Deduce the traces of the operators $X \mapsto AX$, $X \mapsto XB$, and $X \mapsto AX - XA$.

Solution on page 1339

Exercise 4.5.49. STANDARD Let $\dim V = n \geq 1$, and let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$. Let $r = \mathrm{rank}\,P$.

(a) Show that P fixes every vector of $\mathrm{im}\,P$, that $\ker P \cap \mathrm{im}\,P = \{\mathbf{0}\}$, and that a basis of $\mathrm{im}\,P$ followed by a basis of $\ker P$ is a basis of V.
(b) Deduce that in this basis $[P] = N_r = \mathrm{diag}(1, \ldots, 1, 0, \ldots, 0)$, with r ones, and that $\mathrm{tr}\,P = r \cdot 1$.
(c) Show that two matrices $A, B \in F^{n\times n}$ with $A^2 = A$ and $B^2 = B$ are similar if and only if $\mathrm{rank}\,A = \mathrm{rank}\,B$.

Solution on page 1339

Exercise 4.5.50. STANDARD Let $\dim V = n \geq 1$, and let $N \in \mathrm{L}(V)$ satisfy $N^n = 0$ and $N^{n-1} \neq 0$. Let $J_n \in F^{n\times n}$ be the matrix with 1 in positions $(2,1), (3,2), \ldots, (n, n-1)$ and 0 elsewhere.

(a) Show that $[N]_{\mathcal{B}\mathcal{B}} = J_n$ for some basis $\mathcal{B}$ of V.
(b) Deduce that any two matrices $A, B \in F^{n\times n}$ with $A^n = B^n = 0$, $A^{n-1} \neq 0$, and $B^{n-1} \neq 0$ are similar.
(c) Show that $J_n \sim J_n^{\mathsf{T}}$.

Solution on page 1339

Exercise 4.5.51. HARD Let $n \geq 2$, let $A \in F^{n\times n}$ have rank 1, and let $t = \mathrm{tr}\,A$. Show that $A \sim tU_{11}$ if $t \neq 0$, and $A \sim U_{21}$ if $t = 0$. Conclude that two matrices of rank 1 are similar if and only if they have the same trace.

Solution on page 1340

Exercise 4.5.52. STANDARD Let F be a field with at least three elements. Show that every $A \in F^{n\times n}$ is the sum of two invertible matrices. Show that this fails for the matrix $(1) \in \mathbb{F}_2^{1\times 1}$.

Solution on page 1340

Exercise 4.5.53. CHALLENGE Show that for $n \geq 2$, every $A \in \mathbb{F}_2^{n\times n}$ is the sum of two invertible matrices.

Solution on page 1341

Exercise 4.5.54. STANDARD This exercise shows what goes wrong in infinite dimensions.

(a) Let $xF[x]$ be the subspace of polynomials in $F[x]$ whose constant coefficient is 0. Show that $S : F[x] \to xF[x]$, $S(p) = xp$, is an isomorphism. So $F[x]$ is isomorphic to a proper subspace of itself, and S, regarded as an operator on $F[x]$, is injective but not surjective.
(b) Explain why a finite-dimensional space is never isomorphic to a proper subspace of itself.
(c) Show that differentiation $D \in \mathrm{L}(\mathbb{R}[x])$ is surjective but not injective.
(d) Show that if $V \cong W$ and V is infinite-dimensional, then so is W.

Solution on page 1341

Exercise 4.5.55. STANDARD Let $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, the rotation by $\pi/2$.

(a) Show that R is similar over $\mathbb{C}$ to $\operatorname{diag}(i, -i)$, by finding $S \in \mathbb{C}^{2\times 2}$.
(b) Show that R is not similar over $\mathbb{R}$ to any diagonal matrix in $\mathbb{R}^{2\times 2}$.
(c) Show that R is similar over $\mathbb{R}$ to $-R$, and interpret the similarity geometrically.

Solution on page 1342

Exercise 4.5.56. ROUTINE Let $T \in \mathrm{L}(F^2)$ satisfy $T(1, 2) = (3, 6)$ and $T(1, 1) = (-1, -1)$. Use Theorem 4.5.17 to find $[T]_{\mathcal{E}\mathcal{E}}$. Check your answer, and compute $\operatorname{tr} T$ in two ways.

Solution on page 1342

4.6 Products and quotients BEYOND 21-242

A vector space can be built out of others in two basic ways. A *product* places several spaces side by side: a vector of $V \times W$ is a pair, one vector from each. A *quotient* goes the other way. It takes a subspace U of V and collapses it to a single point, so that two vectors of V become equal when they differ by an element of U. Recall from Corollary 2.6.31 that a linear map T slices its domain into parallel copies of $\ker T$ and sends each slice to one vector of $\operatorname{im} T$. The quotient $V/\ker T$ turns the set of slices into a vector space on which T becomes injective, and this is the first isomorphism theorem (Theorem 4.6.34). It gives a third proof of rank–nullity. Products, for their part, give the cleanest way to say when a sum of subspaces is direct.

Neither construction appears in the 21-242 lectures (they are in LADR, Section 3E). Quotients come back in Section 7.5, where they give a second route to triangularization, and in Section 13.1.

Throughout, V and W are vector spaces over F.

4.6.1 Product spaces

Definition 4.6.1 (Product space). Let $V_1, \ldots, V_m$ be vector spaces over F. Their **product** is the set of m-tuples

$$V_1 \times \cdots \times V_m = \{(\mathbf{v}_1, \ldots, \mathbf{v}_m) \mid \mathbf{v}_j \in V_j \text{ for } j = 1, \ldots, m\},$$

with the componentwise operations

$$(\mathbf{v}_1, \ldots, \mathbf{v}_m) + (\mathbf{w}_1, \ldots, \mathbf{w}_m) = (\mathbf{v}_1 + \mathbf{w}_1, \ldots, \mathbf{v}_m + \mathbf{w}_m),$$

$$a(\mathbf{v}_1, \ldots, \mathbf{v}_m) = (a\mathbf{v}_1, \ldots, a\mathbf{v}_m).$$

For a single space V we write $V^m = V \times \cdots \times V$ (m factors).

Proposition 4.6.2 (Products are vector spaces). $V_1 \times \cdots \times V_m$ is a vector space over F. Its zero vector is $(\mathbf{0}, \ldots, \mathbf{0})$, and $-(\mathbf{v}_1, \ldots, \mathbf{v}_m) = (-\mathbf{v}_1, \ldots, -\mathbf{v}_m)$.

Proof. ROUTINE

Uses. Definition 1.2.1 (Vector space), Definition 4.6.1 (Product space)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Two tuples are equal exactly when they are equal in every component.
Hint 2. Write out the jth component of both sides of each axiom. It is the same axiom in V_j.
Sketch. Every axiom is an identity between tuples, and its jth component is that axiom in V_j. The zero and the negatives are found the same way.

Sums and scalar multiples of tuples are tuples of the right kind, since each V_j is closed under its operations. Each vector space axiom is an identity between elements of the product, and two tuples are equal when they agree in every component. In the jth component, each axiom becomes the same axiom in V_j. For example, for $\mathbf{x} = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$ and $\mathbf{y} = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$, the jth components of $a(\mathbf{x} + \mathbf{y})$ and $a\mathbf{x} + a\mathbf{y}$ are $a(\mathbf{v}_j + \mathbf{w}_j)$ and $a\mathbf{v}_j + a\mathbf{w}_j$, which are equal by distributivity in V_j. The other identities (commutativity, associativity, the second distributive law, $(ab)\mathbf{x} = a(b\mathbf{x})$, and $1\mathbf{x} = \mathbf{x}$) are checked identically. Finally, $(\mathbf{v}_1, \ldots, \mathbf{v}_m) + (\mathbf{0}, \ldots, \mathbf{0}) = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$ and $(\mathbf{v}_1, \ldots, \mathbf{v}_m) + (-\mathbf{v}_1, \ldots, -\mathbf{v}_m) = (\mathbf{0}, \ldots, \mathbf{0})$, componentwise. □

Example 4.6.3 (Products).

(a) F^m is $F \times \cdots \times F$ (m factors); Definition 1.2.4 is the case $V_1 = \cdots = V_m = F$, with the tuples written as columns.

(b) An element of $F^2 \times F^3$ is a pair $((a, b), (c, d, e))$, which is not literally an element of F^5. But removing the inner parentheses, $((a, b), (c, d, e)) \mapsto (a, b, c, d, e)$, is a bijective linear map, so $F^2 \times F^3 \cong F^5$ (Definition 4.5.1). In the same way $F^n \times F^p \cong F^{n+p}$, and we identify the two whenever convenient.

(c) In $V \times W$, the subsets $V \times \{\mathbf{0}\}$ and $\{\mathbf{0}\} \times W$ are subspaces, and $V \times W = (V \times \{\mathbf{0}\}) \oplus (\{\mathbf{0}\} \times W)$: every $(\mathbf{v}, \mathbf{w})$ is $(\mathbf{v}, \mathbf{0}) + (\mathbf{0}, \mathbf{w})$, and this is the only way to write it as such a sum, since the components are forced.

Non-example 4.6.4 (Scaling only one component). Let $W \neq \{\mathbf{0}\}$. On the set $V \times W$ keep componentwise addition, but scale only the first component: $a \odot (\mathbf{v}, \mathbf{w}) = (a\mathbf{v}, \mathbf{w})$. This is not a vector space. In any vector space $0\mathbf{x} = \mathbf{0}$ (Proposition 1.2.32), but here $0 \odot (\mathbf{v}, \mathbf{w}) = (\mathbf{0}, \mathbf{w})$, which is not the zero vector $(\mathbf{0}, \mathbf{0})$ when $\mathbf{w} \neq \mathbf{0}$. (The axiom that fails is distributivity over scalar addition: $(1 + 1) \odot (\mathbf{v}, \mathbf{w})$ has second component $\mathbf{w}$, while $1 \odot (\mathbf{v}, \mathbf{w}) + 1 \odot (\mathbf{v}, \mathbf{w})$ has second component $\mathbf{w} + \mathbf{w}$.)

For each j there are two linear maps connecting V_j with the product. The **inclusion** $\iota_j : V_j \to V_1 \times \cdots \times V_m$ puts a vector in the jth slot and $\mathbf{0}$ in the others, and the **projection** $\mathrm{Pr}_j : V_1 \times \cdots \times V_m \to V_j$ reads off the jth component. Both are linear because the operations are componentwise, $\mathrm{Pr}_j \iota_j = \mathrm{id}_{V_j}$, and every vector of the product splits as

$$(\mathbf{v}_1, \ldots, \mathbf{v}_m) = \iota_1(\mathbf{v}_1) + \cdots + \iota_m(\mathbf{v}_m). \tag{4.6.1}$$

Theorem 4.6.5 (Dimension of a product). Suppose $V_1, \ldots, V_m$ are finite-dimensional. Then $V_1 \times \cdots \times V_m$ is finite-dimensional, and

$$\dim(V_1 \times \cdots \times V_m) = \dim V_1 + \cdots + \dim V_m.$$

More precisely, if $\mathcal{B}_j$ is a basis of V_j for each j, then the list obtained by concatenating $\iota_1(\mathcal{B}_1), \ldots, \iota_m(\mathcal{B}_m)$ is a basis of the product.

The first proof checks the basis directly. The second never checks a basis of the product: it peels off one factor with a surjection and counts the kernel by rank–nullity, which is how quotients will be measured below.

Proof (by building a basis). ROUTINE

> *Uses.* Definition 1.6.1 (Basis), Proposition 1.6.2 (Bases are independent spanning lists), (4.6.1), Theorem 1.5.5 (Independence is decided at zero)
> *Techniques.* Fix an arbitrary element and chase it (Technique 1.3.13)
> *Hint 1.* Take a basis $\mathbf{b}_{j,1}, \dots, \mathbf{b}_{j,n_j}$ of each V_j. Which vectors of the product would you guess form a basis?
> *Hint 2.* For spanning, use (4.6.1) and expand each $\mathbf{v}_j$ in its basis. For independence, look at the jth component of a linear relation.
> *Sketch.* By (4.6.1) and the linearity of ι_j, each tuple is a combination of the $\iota_j(\mathbf{b}_{j,i})$. The jth component of a relation $\sum_{j,i} c_{j,i}\iota_j(\mathbf{b}_{j,i}) = \mathbf{0}$ is $\sum_i c_{j,i}\mathbf{b}_{j,i} = \mathbf{0}$, so all $c_{j,i} = 0$.

Let $\mathcal{B}_j = \mathbf{b}_{j,1}, \dots, \mathbf{b}_{j,n_j}$ be a basis of V_j, so $n_j = \dim V_j$, and let $\mathcal{L}$ be the concatenation of the lists $\iota_j\big(\mathcal{B}_j\big)$. It has $n_1 + \cdots + n_m$ entries, so it suffices to show that $\mathcal{L}$ is a basis.

Spanning. Let $(\mathbf{v}_1, \dots, \mathbf{v}_m)$ be in the product, and write $\mathbf{v}_j = \sum_i c_{j,i}\mathbf{b}_{j,i}$. By (4.6.1) and the linearity of each ι_j,

$$(\mathbf{v}_1, \dots, \mathbf{v}_m) = \sum_{j=1}^{m} \iota_j(\mathbf{v}_j) = \sum_{j=1}^{m}\sum_{i=1}^{n_j} c_{j,i}\iota_j(\mathbf{b}_{j,i}).$$

Independence. Suppose $\sum_{j,i} c_{j,i}\iota_j(\mathbf{b}_{j,i}) = \mathbf{0}$. The jth component of $\iota_j(\mathbf{b}_{j,i})$ is $\mathbf{b}_{j,i}$, and the jth component of $\iota_k(\mathbf{b}_{k,i})$ is $\mathbf{0}$ for $k \neq j$. So the jth component of the relation reads $\sum_i c_{j,i}\mathbf{b}_{j,i} = \mathbf{0}$, and since $\mathcal{B}_j$ is independent, $c_{j,1} = \cdots = c_{j,n_j} = 0$. This holds for every j. □

Proof (by induction on m, with rank–nullity). STANDARD

> *Uses.* Theorem 4.2.11 (Rank–nullity), Proposition 4.2.6 (Injective maps preserve dimension), (4.6.1), Definition 1.6.23 (Finite-dimensional)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* For $m \geq 2$, the projection Pr_m onto the last factor is surjective. What is its kernel?
> *Hint 2.* The kernel of Pr_m consists of the tuples $(\mathbf{v}_1, \dots, \mathbf{v}_{m-1}, \mathbf{0})$, a copy of the product of the first $m-1$ factors. Apply rank–nullity, after checking that the product is finite-dimensional at all.
> *Sketch.* The vectors $\iota_j(\mathbf{b})$, $\mathbf{b}$ in a basis of V_j, span the product by (4.6.1), so it is finite-dimensional. Pr_m is surjective, and $(\mathbf{v}_1, \dots, \mathbf{v}_{m-1}) \mapsto (\mathbf{v}_1, \dots, \mathbf{v}_{m-1}, \mathbf{0})$ is injective with image $\ker \mathrm{Pr}_m$. Rank–nullity gives $\dim = \dim(V_1 \times \cdots \times V_{m-1}) + \dim V_m$, and induction finishes.

We prove the dimension formula by induction on m; the case $m = 1$ is trivial. Let $m \geq 2$ and $P = V_1 \times \cdots \times V_m$. By (4.6.1), the vectors $\iota_j(\mathbf{b})$, with $\mathbf{b}$ running through a basis of V_j and $j = 1, \dots, m$, span P (expand each $\mathbf{v}_j$ in its basis), so P is finite-dimensional. The projection $\mathrm{Pr}_m : P \to V_m$ is linear and surjective, since $\mathrm{Pr}_m\, \iota_m(\mathbf{v}) = \mathbf{v}$. Its kernel is the set of tuples whose last component is $\mathbf{0}$, which is the image of

$$J : V_1 \times \cdots \times V_{m-1} \to P, \quad (\mathbf{v}_1, \dots, \mathbf{v}_{m-1}) \mapsto (\mathbf{v}_1, \dots, \mathbf{v}_{m-1}, \mathbf{0}).$$

J is linear and injective, so by Proposition 4.2.6(a) and the induction hypothesis, $\dim \ker \mathrm{Pr}_m = \dim(V_1 \times \cdots \times V_{m-1}) = \dim V_1 + \cdots + \dim V_{m-1}$. By rank–nullity (Theorem 4.2.11),

$$\dim P = \dim \ker \mathrm{Pr}_m + \dim \operatorname{im} \mathrm{Pr}_m = (\dim V_1 + \cdots + \dim V_{m-1}) + \dim V_m,$$

as desired. (This proof gives the dimension only; the explicit basis is the first proof's.) □

Exercise 4.6.6. ROUTINE

(a) Show that if V' is a subspace of V and W' is a subspace of W, then $V' \times W'$ is a subspace of $V \times W$.

(b) Prove or disprove: every subspace of $V \times W$ is of the form $V' \times W'$ as in (a).

Solution on page 1343

Maps into and out of a product

A map into a product is the same as a list of maps into the factors, and a map out of a product is the same as a list of maps out of the factors.

Proposition 4.6.7 (Maps into and out of a product).

(a) Let $T_j \in \mathrm{L}\big(U, W_j\big)$ for $j = 1, \dots, m$. Then

$$(T_1, \dots, T_m) : U \to W_1 \times \cdots \times W_m, \quad \mathbf{u} \mapsto (T_1(\mathbf{u}), \dots, T_m(\mathbf{u})),$$

is linear, and every $T \in \mathrm{L}(U, W_1 \times \cdots \times W_m)$ equals $(T_1, \dots, T_m)$ for exactly one list of linear maps, namely $T_j = \mathrm{Pr}_j\, T$.

(b) Let $S_j \in \mathrm{L}\big(V_j, W\big)$ for $j = 1, \dots, m$. Then

$$V_1 \times \cdots \times V_m \to W, \quad (\mathbf{v}_1, \dots, \mathbf{v}_m) \mapsto S_1(\mathbf{v}_1) + \cdots + S_m(\mathbf{v}_m),$$

is linear, and every $S \in \mathrm{L}(V_1 \times \cdots \times V_m, W)$ is of this form for exactly one list of linear maps, namely $S_j = S\iota_j$.

Proof. ROUTINE

Uses. Theorem 2.1.3 (Checking linearity), Proposition 2.1.17 (Compositions of linear maps are linear), (4.6.1)
Techniques. Assemble linear maps from linear pieces (Technique 2.1.26), Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Linearity in both parts is a componentwise computation.
Hint 2. For the converse in (a), compare components of $T(\mathbf{u})$. In (b), apply S to (4.6.1).
Sketch. (a) The jth component of $(T_1, \dots, T_m)(a\mathbf{u} + \mathbf{u}')$ is $aT_j(\mathbf{u}) + T_j(\mathbf{u}')$. A map T into the product is determined by the components $\mathrm{Pr}_j\, T(\mathbf{u})$ of its values. (b) Linearity is a sum of linear computations, and applying S to (4.6.1) gives $S(\mathbf{v}_1, \dots, \mathbf{v}_m) = \sum_j S\iota_j(\mathbf{v}_j)$. Uniqueness: evaluate at $\iota_j(\mathbf{v})$.

(a) For $\mathbf{u}, \mathbf{u}' \in U$ and $a \in F$, the jth component of $(T_1, \dots, T_m)(a\mathbf{u} + \mathbf{u}')$ is $T_j(a\mathbf{u} + \mathbf{u}') = aT_j(\mathbf{u}) + T_j(\mathbf{u}')$, which is the jth component of $a(T_1, \dots, T_m)(\mathbf{u}) + (T_1, \dots, T_m)(\mathbf{u}')$. So the map is linear (Theorem 2.1.3). Now let $T \in \mathrm{L}(U, W_1 \times \cdots \times W_m)$. Each $\mathrm{Pr}_j\, T$ is linear (Proposition 2.1.17), and the jth component of $T(\mathbf{u})$ is $\mathrm{Pr}_j\, T(\mathbf{u})$, so $T = (\mathrm{Pr}_1\, T, \dots, \mathrm{Pr}_m\, T)$. Conversely, if $T = (T_1, \dots, T_m)$, then $T_j(\mathbf{u})$ is the jth component of $T(\mathbf{u})$, that is, $T_j = \mathrm{Pr}_j\, T$. So the list is unique.

(b) Write S' for the map defined by the S_j. For tuples $\mathbf{x} = \big(\mathbf{v}_j\big)_j$, $\mathbf{y} = \big(\mathbf{w}_j\big)_j$ and $a \in F$,

$$S'(a\mathbf{x} + \mathbf{y}) = \sum_{j=1}^{m} S_j\big(a\mathbf{v}_j + \mathbf{w}_j\big) = a\sum_{j=1}^{m} S_j\big(\mathbf{v}_j\big) + \sum_{j=1}^{m} S_j\big(\mathbf{w}_j\big) = aS'(\mathbf{x}) + S'(\mathbf{y}).$$

Also $S'\iota_j(\mathbf{v}) = S_j(\mathbf{v})$, since the other components of $\iota_j(\mathbf{v})$ are $\mathbf{0}$; so $S'\iota_j = S_j$, which shows that the list is determined by the map. Finally, let $S \in \mathrm{L}(V_1 \times \cdots \times V_m, W)$. Applying S to (4.6.1),

$$S(\mathbf{v}_1, \dots, \mathbf{v}_m) = \sum_{j=1}^{m} S\big(\iota_j(\mathbf{v}_j)\big) = \sum_{j=1}^{m} \big(S\iota_j\big)(\mathbf{v}_j),$$

so S is the map defined by the list $S\iota_1, \dots, S\iota_m$ of linear maps. □

The assignments $T \mapsto (\mathrm{Pr}_1\, T, \dots, \mathrm{Pr}_m\, T)$ and $S \mapsto (S\iota_1, \dots, S\iota_m)$ are linear, so the proposition says that

$$\mathrm{L}(U, W_1 \times \cdots \times W_m) \cong \mathrm{L}(U, W_1) \times \cdots \times \mathrm{L}(U, W_m), \quad \mathrm{L}(V_1 \times \cdots \times V_m, W) \cong \mathrm{L}(V_1, W) \times \cdots \times \mathrm{L}(V_m, W).$$

Combining the two for $F^n \times F^p = F^{n+p}$ and $F^m \times F^q = F^{m+q}$: a linear map $F^{n+p} \to F^{m+q}$ is the same as four maps $\mathrm{Pr}_i\, T\iota_j$, and its matrix is the block matrix whose blocks are their matrices (Definition 2.4.33).

4.6.2 Products and direct sums

A sum of subspaces is the image of a single linear map out of a product, and directness becomes injectivity of that map.

Definition 4.6.8 (Addition map). Let $U_1, \dots, U_m$ be subspaces of V. The **addition map** is

$$\Gamma : U_1 \times \cdots \times U_m \to V, \quad \Gamma(\mathbf{u}_1, \dots, \mathbf{u}_m) = \mathbf{u}_1 + \cdots + \mathbf{u}_m.$$

By Proposition 4.6.7(b), applied to the inclusions $U_j \to V$, the map Γ is linear, and by Definition 4.4.1 its image is $U_1 + \cdots + U_m$. More is true: for $\mathbf{v} \in V$, the elements of the fiber $\Gamma^{-1}(\mathbf{v})$ are exactly the decompositions $\mathbf{v} = \mathbf{u}_1 + \cdots + \mathbf{u}_m$ of $\mathbf{v}$ along $U_1, \dots, U_m$, each recorded as the tuple $(\mathbf{u}_1, \dots, \mathbf{u}_m)$ of its components.

Theorem 4.6.9 (Direct sums and the addition map). Let $U_1, \dots, U_m$ be subspaces of V. The sum $U_1 + \cdots + U_m$ is direct if and only if Γ is injective. In that case Γ is an isomorphism from $U_1 \times \cdots \times U_m$ onto $U_1 \oplus \cdots \oplus U_m$. In particular, if $V = U_1 \oplus \cdots \oplus U_m$, then $V \cong U_1 \times \cdots \times U_m$.

Proof. ROUTINE

Uses. Definition 4.4.4 (Direct sum), Definition 2.6.1 (Injective), Definition 4.6.8 (Addition map), Proposition 2.7.7 (Bijective linear maps are invertible)
Hint 1. What are the preimages of $\mathbf{v}$ under Γ?
Hint 2. The preimages of $\mathbf{v}$ are its decompositions. Vectors outside $\operatorname{im}\Gamma$ have no preimages at all.
Sketch. $\Gamma^{-1}(\mathbf{v})$ is the set of decompositions of $\mathbf{v}$. The sum is direct when every $\mathbf{v} \in \operatorname{im}\Gamma$ has exactly one, that is, when every $\mathbf{v} \in V$ has at most one preimage. That is injectivity. An injective linear map is an isomorphism onto its image.

By the remark before the theorem, the decompositions of $\mathbf{v}$ along $U_1, \dots, U_m$ correspond to the elements of $\Gamma^{-1}(\mathbf{v})$. By Definition 4.4.4, the sum is direct exactly when every $\mathbf{v} \in U_1 + \cdots + U_m = \operatorname{im}\Gamma$ has exactly one preimage. Vectors outside $\operatorname{im}\Gamma$ have none, and vectors in $\operatorname{im}\Gamma$ have at least one. So the sum is direct if and only if every $\mathbf{v} \in V$ has at most one preimage under Γ, which is injectivity (Definition 2.6.1). In that case Γ, regarded as a map onto $U_1 \oplus \cdots \oplus U_m$, is linear and bijective, hence an isomorphism (Proposition 2.7.7). □

By Theorem 2.6.11, injectivity of Γ means $\ker\Gamma = \{\mathbf{0}\}$: the only decomposition of $\mathbf{0}$ is the trivial one. That is criterion (II) of Theorem 4.4.7, now read as a statement about a kernel. The point of the reformulation is that kernels can be counted.

Corollary 4.6.10 (Dimension of a sum). Let $U_1, \dots, U_m$ be finite-dimensional subspaces of V. Then

$$\dim(U_1 + \cdots + U_m) \le \dim U_1 + \cdots + \dim U_m,$$

with equality if and only if the sum is direct.

Proof. ROUTINE

Uses. Theorem 4.6.5 (Dimension of a product), Theorem 4.2.11 (Rank–nullity), Theorem 4.6.9 (Direct sums and the addition map), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Apply rank–nullity to Γ.
Hint 2. The domain has dimension $\sum_j \dim U_j$ by Theorem 4.6.5, and the image is the sum. What does $\dim\ker\Gamma = 0$ mean?
Sketch. Rank–nullity for Γ gives $\dim(U_1 + \cdots + U_m) = \sum_j \dim U_j - \dim\ker\Gamma$. Equality holds iff $\ker\Gamma = \{\mathbf{0}\}$ iff Γ is injective iff the sum is direct.

The domain of Γ is finite-dimensional of dimension $\sum_j \dim U_j$ by Theorem 4.6.5, and $\operatorname{im}\Gamma = U_1 + \cdots + U_m$. By rank–nullity (Theorem 4.2.11),

$$\dim(U_1 + \cdots + U_m) = \dim U_1 + \cdots + \dim U_m - \dim\ker\Gamma \le \dim U_1 + \cdots + \dim U_m.$$

Equality holds if and only if $\dim\ker\Gamma = 0$, that is, $\ker\Gamma = \{\mathbf{0}\}$. By Theorem 2.6.11 and Theorem 4.6.9, this happens exactly when the sum is direct. □

So $\dim\ker\Gamma$ measures how far a sum is from being direct. For two subspaces the kernel can be named, and the count becomes the dimension formula of Theorem 4.4.19.

Proposition 4.6.11 (The kernel of the addition map). Let U and W be subspaces of V, and let $\Gamma : U \times W \to V$, $(\mathbf{u}, \mathbf{w}) \mapsto \mathbf{u} + \mathbf{w}$.

(a) $\ker \Gamma = \{(\mathbf{u}, -\mathbf{u}) \mid \mathbf{u} \in U \cap W\}$, and $\mathbf{u} \mapsto (\mathbf{u}, -\mathbf{u})$ is an isomorphism from $U \cap W$ onto $\ker \Gamma$.

(b) If U and W are finite-dimensional, then $\dim(U + W) = \dim U + \dim W - \dim(U \cap W)$.

Proof. ROUTINE

Uses. Proposition 4.6.7 (Maps into and out of a product), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.6.5 (Dimension of a product), Theorem 4.2.11 (Rank–nullity)
Techniques. Double containment (Technique 1.3.14), Dimension counting (Technique 4.2.24)
Hint 1. If $\mathbf{u} + \mathbf{w} = \mathbf{0}$, then $\mathbf{w} = -\mathbf{u}$. Which subspaces does $\mathbf{u}$ lie in?
Hint 2. For (b), apply rank–nullity to Γ, using (a) for the kernel and Theorem 4.6.5 for the domain.
Sketch. (a) $\mathbf{u} + \mathbf{w} = \mathbf{0}$ forces $\mathbf{u} = -\mathbf{w} \in U \cap W$ and $(\mathbf{u}, \mathbf{w}) = (\mathbf{u}, -\mathbf{u})$; conversely such pairs are killed. The map $\mathbf{u} \mapsto (\mathbf{u}, -\mathbf{u})$ is linear and injective with image $\ker \Gamma$. (b) $\dim U + \dim W = \dim \ker \Gamma + \dim(U + W)$ and $\dim \ker \Gamma = \dim(U \cap W)$.

(a) If $(\mathbf{u}, \mathbf{w}) \in \ker \Gamma$, then $\mathbf{w} = -\mathbf{u}$. So $\mathbf{u} = -\mathbf{w} \in W$, hence $\mathbf{u} \in U \cap W$ and $(\mathbf{u}, \mathbf{w}) = (\mathbf{u}, -\mathbf{u})$. Conversely, if $\mathbf{u} \in U \cap W$, then $(\mathbf{u}, -\mathbf{u}) \in U \times W$ and $\Gamma(\mathbf{u}, -\mathbf{u}) = \mathbf{0}$. This proves the description of $\ker \Gamma$. The map $\varphi : U \cap W \to U \times W$, $\varphi(\mathbf{u}) = (\mathbf{u}, -\mathbf{u})$, is linear by Proposition 4.6.7(a), it is injective because the first component of $\varphi(\mathbf{u})$ is $\mathbf{u}$, and its image is $\ker \Gamma$. So it is an isomorphism onto $\ker \Gamma$.

(b) $U \cap W$ is a subspace of the finite-dimensional space U, hence finite-dimensional (Proposition 4.1.21), and by (a) and Proposition 4.2.6(a), $\dim \ker \Gamma = \dim(U \cap W)$. The domain $U \times W$ has dimension $\dim U + \dim W$ (Theorem 4.6.5) and $\operatorname{im} \Gamma = U + W$. Rank–nullity (Theorem 4.2.11) gives

$$\dim U + \dim W = \dim(U \cap W) + \dim(U + W),$$

as desired. □

This proof builds no basis of $U + W$. It counts instead: the pairs in $U \times W$ that add up to $\mathbf{0}$ form a copy of $U \cap W$, and that copy is exactly what the naive count $\dim U + \dim W$ counts twice.

4.6.3 Cosets

Intuition (Collapsing a subspace to a point). Take $V = \mathbb{R}^2$ and let U be the line through $\mathbf{0}$ spanned by $(2, 1)$. The translates $\mathbf{v} + U$ are the lines parallel to U. They stack up across the plane like the rules on a sheet of paper, and every point of the plane lies on exactly one of them.

Now forget everything about a vector except which of these lines it lies on. Two vectors become indistinguishable exactly when they differ by an element of U, so the whole line U collapses to one point, and so does every line parallel to it. One point per line remains. The lines are labelled by a single number, the value $c = x - 2y$ that is constant along each of them, so the collapsed plane looks like a copy of $\mathbb{R}$ (Figure 4.6.1).

The quotient V/U is this collapsed space. Its elements are the lines themselves, and it becomes a vector space once we say how to add and scale lines.

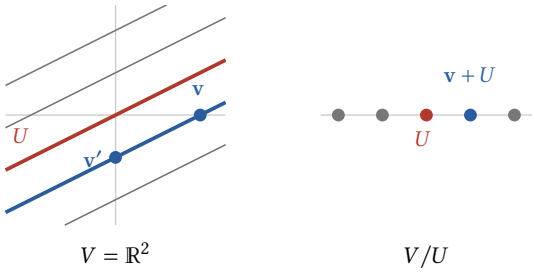

Figure 4.6.1. Left: the line $U = \operatorname{span}((2,1))$ (red) and some of its translates, the lines $x - 2y = c$. The vectors $\mathbf{v} = (2,0)$ and $\mathbf{v}' = (0,-1)$ lie on the same translate (blue), because $\mathbf{v} - \mathbf{v}' = (2,1) \in U$. Right: in V/U each line becomes a single point, drawn at position c; the line U becomes the origin.

Definition 4.6.12 (Coset). Let U be a subspace of V and $\mathbf{v} \in V$. The translate

$$\mathbf{v} + U = \{\mathbf{v} + \mathbf{u} \mid \mathbf{u} \in U\}$$

(Notation 3.1.17) is called a **coset** of U, and $\mathbf{v}$ is a **representative** of it.

A coset is a subset of V, and it has many representatives: by Lemma 4.6.14 below, every element of $\mathbf{v} + U$ is one. Cosets reappear in Section 4.7 as affine subspaces, where their geometry is studied in its own right.

Example 4.6.13 (Cosets).

(a) In $\mathbb{R}^2$ let $U = \operatorname{span}((2,1))$. The coset $(v_1, v_2) + U$ is the line $x - 2y = v_1 - 2v_2$. Indeed, its points $(v_1 + 2t, v_2 + t)$ satisfy $x - 2y = v_1 - 2v_2$; conversely, if $x - 2y = v_1 - 2v_2$, then $(x, y) = (v_1, v_2) + (y - v_2)(2,1)$.

(b) In $\mathbb{F}_2^3$ let $U = \operatorname{span}((1,1,0)) = \{(0,0,0), (1,1,0)\}$. The cosets of U are

$$U, \quad (1,0,0) + U = \{(1,0,0), (0,1,0)\}, \quad (0,0,1) + U = \{(0,0,1), (1,1,1)\}, \quad (1,0,1) + U = \{(1,0,1), (0,1,1)\}.$$

They have two elements each and split the eight vectors of $\mathbb{F}_2^3$ into four pairs.

(c) For $T \in \mathrm{L}(V, W)$, the nonempty fibers $T^{-1}(\mathbf{w})$ are exactly the cosets of $\ker T$ (Corollary 2.6.31). In particular the solution set of a consistent system $A\mathbf{x} = \mathbf{y}$ is a coset of $\ker T_A$ (Proposition 3.1.19).

(d) In $F[x]$ let $U = \{p \mid p(0) = 0\}$, the polynomials with constant term 0. Then $p + U = \{q \in F[x] \mid q(0) = p(0)\}$: if $q = p + u$ with $u \in U$, then $q(0) = p(0) + u(0) = p(0)$ (Proposition 1.2.18), and if $q(0) = p(0)$, then $q - p \in U$. So there is one coset for each scalar.

Lemma 4.6.14 (Equal cosets). Let U be a subspace of V and let $\mathbf{v}, \mathbf{w} \in V$. The following are equivalent.

(I) $\mathbf{v} + U = \mathbf{w} + U$.

(II) $\mathbf{v} - \mathbf{w} \in U$.

(III) $\mathbf{v} \in \mathbf{w} + U$.

(IV) $(\mathbf{v} + U) \cap (\mathbf{w} + U) \neq \emptyset$.

Proof. ROUTINE

Uses. Definition 4.6.12 (Coset), Definition 1.4.1 (Subspace)
Techniques. Proving TFAE (Technique 2.7.1), Double containment (Technique 1.3.14)
Hint 1. Prove the cycle (I) ⇒ (III) ⇒ (IV) ⇒ (II) ⇒ (I). Only the last step takes work.
Hint 2. For (II) ⇒ (I), write $\mathbf{v} + \mathbf{u} = \mathbf{w} + ((\mathbf{v} - \mathbf{w}) + \mathbf{u})$ to get $\mathbf{v} + U \subseteq \mathbf{w} + U$. For the other containment, note that $\mathbf{w} - \mathbf{v} \in U$ as well.
Sketch. (I) ⇒ (III): $\mathbf{v} = \mathbf{v} + \mathbf{0}$. (III) ⇒ (IV): $\mathbf{v}$ is in both cosets. (IV) ⇒ (II): a common element $\mathbf{v} + \mathbf{u} = \mathbf{w} + \mathbf{u}'$ gives $\mathbf{v} - \mathbf{w} = \mathbf{u}' - \mathbf{u} \in U$. (II) ⇒ (I): double containment, using that U is closed under addition and negation.

We prove (I) ⇒ (III) ⇒ (IV) ⇒ (II) ⇒ (I).

(I) ⇒ (III). $\mathbf{v} = \mathbf{v} + \mathbf{0} \in \mathbf{v} + U = \mathbf{w} + U$.

(III) ⇒ (IV). $\mathbf{v} \in \mathbf{v} + U$, and $\mathbf{v} \in \mathbf{w} + U$ by (III).

(IV) ⇒ (II). Let $\mathbf{x}$ be in both cosets, say $\mathbf{x} = \mathbf{v} + \mathbf{u} = \mathbf{w} + \mathbf{u}'$ with $\mathbf{u}, \mathbf{u}' \in U$. Then $\mathbf{v} - \mathbf{w} = \mathbf{u}' - \mathbf{u} \in U$.

(II) ⇒ (I). Let $\mathbf{z} = \mathbf{v} - \mathbf{w} \in U$. For $\mathbf{u} \in U$,

$$\mathbf{v} + \mathbf{u} = \mathbf{w} + (\mathbf{z} + \mathbf{u}) \in \mathbf{w} + U,$$

since $\mathbf{z} + \mathbf{u} \in U$. So $\mathbf{v} + U \subseteq \mathbf{w} + U$. Since $\mathbf{w} - \mathbf{v} = -\mathbf{z} \in U$, the same argument with $\mathbf{v}$ and $\mathbf{w}$ exchanged gives $\mathbf{w} + U \subseteq \mathbf{v} + U$. □

Corollary 4.6.15 (Cosets partition V). Let U be a subspace of V.

(a) Every $\mathbf{v} \in V$ lies in exactly one coset of U, namely $\mathbf{v} + U$.

(b) Two cosets of U are either equal or disjoint.

(c) $\mathbf{v} + U = U$ if and only if $\mathbf{v} \in U$.

Proof. ROUTINE

Uses. Lemma 4.6.14 (Equal cosets)
Hint. Each part is one implication of Lemma 4.6.14. For (c), write $U = \mathbf{0} + U$.
Sketch. (a) $\mathbf{v} \in \mathbf{v} + U$, and $\mathbf{v} \in \mathbf{w} + U$ forces $\mathbf{w} + U = \mathbf{v} + U$ by (III) ⇒ (I). (b) is (IV) ⇒ (I). (c) is (I) ⇔ (II) with $\mathbf{w} = \mathbf{0}$.

(a) $\mathbf{v} = \mathbf{v} + \mathbf{0} \in \mathbf{v} + U$. If also $\mathbf{v} \in \mathbf{w} + U$, then $\mathbf{v} + U = \mathbf{w} + U$ by (III) ⇒ (I) of Lemma 4.6.14.

(b) If two cosets are not disjoint, they are equal by (IV) ⇒ (I).

(c) $U = \mathbf{0} + U$, so by (I) ⇔ (II), $\mathbf{v} + U = U$ if and only if $\mathbf{v} - \mathbf{0} = \mathbf{v} \in U$. □

Remark 4.6.16 (Congruence modulo U). Write $\mathbf{v} \equiv \mathbf{w} (\mathrm{mod}\, U)$ when $\mathbf{v} - \mathbf{w} \in U$. This is an equivalence relation: it is reflexive because $\mathbf{0} \in U$, symmetric because U is closed under negation, and transitive because U is closed under addition. By Lemma 4.6.14 its equivalence classes are exactly the cosets of U. (Section A.3 treats equivalence relations in general, but nothing from there is needed here beyond Lemma 4.6.14.) Notice that each of the three properties used a different part of "U is a subspace".

Exercise 4.6.17. ROUTINE Let $U = \mathrm{span}((1,0,1),(0,1,1)) \subseteq \mathbb{R}^3$.

(a) Show that $U = \{(x,y,z) \mid z = x + y\}$, and that $\mathbf{v} + U$ is the plane $z - x - y = v_3 - v_1 - v_2$.

(b) Which of the cosets $(1,2,3) + U$, $(0,0,1) + U$, $(2,-1,2) + U$, and $(1,1,1) + U$ are equal?

Solution on page 1343

4.6.4 The quotient space

We want to add and scale cosets, and the only handle on a coset is a representative. So, as in the picture, add two lines by picking a point on each, adding the points, and taking the line through the sum:

$$(\mathbf{v} + U) + (\mathbf{w} + U) = (\mathbf{v} + \mathbf{w}) + U, \quad a(\mathbf{v} + U) = a\mathbf{v} + U.$$

The right sides are computed from the chosen representatives, and a coset has many. If two choices could produce different cosets, these formulas would not define operations at all. Figure 4.6.2 shows why they do: replacing $\mathbf{v}$ by $\mathbf{v}' = \mathbf{v} + \mathbf{u}$ and $\mathbf{w}$ by $\mathbf{w}' = \mathbf{w} + \mathbf{u}'$ changes the sum by $\mathbf{u} + \mathbf{u}' \in U$, which moves it along its line but not off it.

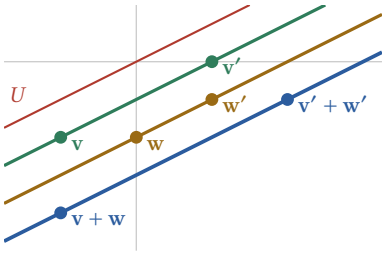

Figure 4.6.2. Adding cosets of $U = \operatorname{span}((2,1))$ (red) in $\mathbb{R}^2$. The green line is $x - 2y = 2$ and the ochre line is $x - 2y = 4$. The representatives $\mathbf{v}$ or $\mathbf{v}'$ of the green line and $\mathbf{w}$ or $\mathbf{w}'$ of the ochre line give different sums, $\mathbf{v} + \mathbf{w} = (-2, -4)$ and $\mathbf{v}' + \mathbf{w}' = (4, -1)$, but both lie on the blue line $x - 2y = 6$. So the sum of the green and ochre lines is the blue line, whichever points we pick.

Technique 4.6.18 (Check that a definition does not depend on the representative). Objects such as cosets are handled through representatives: a coset is named by any one of its elements, and a function on cosets is defined by a formula in that element, $f(\mathbf{v} + U) = g(\mathbf{v})$. Such a formula defines a function only if every name of the same coset gives the same value. So the first thing to prove about it is

$$\mathbf{v} + U = \mathbf{v}' + U \quad \Rightarrow \quad g(\mathbf{v}) = g(\mathbf{v}'),$$

which by Lemma 4.6.14 means: if $\mathbf{v} - \mathbf{v}' \in U$, then $g(\mathbf{v}) = g(\mathbf{v}')$. One says that f is **well defined**.

Mind the direction. Equal inputs must give equal outputs. The converse, that equal outputs force equal inputs, is injectivity, which is a different property that f may or may not have (Exercise 4.6.43).

Reach for it whenever an object is defined through a choice: of a representative, a basis, a preimage, an extension. The canonical example is Theorem 4.6.22. The same check appeared in Exercise 2.6.43, where a map was defined on preimages, and in Proposition 4.2.15, which shows that the rank of a matrix of T does not depend on the bases. It returns when the determinant of an operator is defined through any one of its matrices (Section 5.4).

Used in. Theorem 4.6.22, Exercise 4.6.24, Theorem 4.6.30, Theorem 4.6.34, Exercise 4.6.43, Theorem A.3.10, Exercise A.3.19, Exercise A.4.10.

Non-example 4.6.19 (A formula that defines no function). Let $U = \operatorname{span}((2,1)) \subseteq \mathbb{R}^2$. The formula $f((v_1, v_2) + U) = v_1$ does not define a function on the set of cosets: $(0,0) + U$ and $(2,1) + U$ are the same coset, since $(2,1) - (0,0) \in U$, but the formula gives 0 for the first name and 2 for the second. On the other hand, $g((v_1, v_2) + U) = v_1 - 2v_2$ is well defined: if $(v_1, v_2) - (v_1', v_2') = t(2,1)$, then $(v_1 - 2v_2) - (v_1' - 2v_2') = 2t - 2t = 0$. In the picture, g reads off the label c of the line $x - 2y = c$, which is a property of the line, while f reads off a property of a chosen point on it.

Definition 4.6.20 (Quotient space). Let U be a subspace of V. The **quotient** of V by U is the set of cosets

$$V/U = \{\mathbf{v} + U \mid \mathbf{v} \in V\},$$

with addition and scalar multiplication

$$(\mathbf{v} + U) + (\mathbf{w} + U) = (\mathbf{v} + \mathbf{w}) + U, \quad a(\mathbf{v} + U) = a\mathbf{v} + U.$$

By Theorem 4.6.22 these operations are well defined and make V/U a vector space over F. We read V/U as "V mod U".

Notation 4.6.21. When U is clear from context, we sometimes write $[\mathbf{v}]$ for $\mathbf{v} + U$. Then $[\mathbf{v}] = [\mathbf{w}]$ if and only if $\mathbf{v} - \mathbf{w} \in U$, and the operations read $[\mathbf{v}] + [\mathbf{w}] = [\mathbf{v} + \mathbf{w}]$ and $a[\mathbf{v}] = [a\mathbf{v}]$.

Theorem 4.6.22 (The quotient is a vector space). Let U be a subspace of V.

(a) The operations of Definition 4.6.20 are well defined: if $\mathbf{v}+U=\mathbf{v}'+U$ and $\mathbf{w}+U=\mathbf{w}'+U$, then

$$(\mathbf{v}+\mathbf{w})+U=(\mathbf{v}'+\mathbf{w}')+U \quad \text{and} \quad a\mathbf{v}+U=a\mathbf{v}'+U \quad \text{for all } a\in F.$$

(b) With these operations, V/U is a vector space over F. Its zero vector is $\mathbf{0}+U=U$, and $-(\mathbf{v}+U)=(-\mathbf{v})+U$.

Proof. STANDARD

Uses. Lemma 4.6.14 (Equal cosets), Definition 1.4.1 (Subspace), Definition 1.2.1 (Vector space)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18), Proving from axioms (Technique 1.1.7)
Hint 1. Translate the hypotheses with Lemma 4.6.14: $\mathbf{v}-\mathbf{v}'\in U$ and $\mathbf{w}-\mathbf{w}'\in U$. What must you show about the outputs?
Hint 2. Show that $(\mathbf{v}+\mathbf{w})-(\mathbf{v}'+\mathbf{w}')$ and $a\mathbf{v}-a\mathbf{v}'$ lie in U. Which properties of U does this use?
Hint 3. For (b), write every coset with a representative, use the definitions to turn each axiom into a computation in V, and use the axiom there.
Sketch. (a) $(\mathbf{v}+\mathbf{w})-(\mathbf{v}'+\mathbf{w}')=(\mathbf{v}-\mathbf{v}')+(\mathbf{w}-\mathbf{w}')\in U$ and $a\mathbf{v}-a\mathbf{v}'=a(\mathbf{v}-\mathbf{v}')\in U$, because U is closed under addition and scalar multiplication; conclude with Lemma 4.6.14. (b) Each axiom for cosets is the same axiom for representatives, e.g. $a((\mathbf{v}+U)+(\mathbf{w}+U))=(a\mathbf{v}+a\mathbf{w})+U=a(\mathbf{v}+U)+a(\mathbf{w}+U)$.

(a) By Lemma 4.6.14, the hypotheses say that $\mathbf{v}-\mathbf{v}'\in U$ and $\mathbf{w}-\mathbf{w}'\in U$. Since U is a subspace,

$$(\mathbf{v}+\mathbf{w})-(\mathbf{v}'+\mathbf{w}')=(\mathbf{v}-\mathbf{v}')+(\mathbf{w}-\mathbf{w}')\in U \quad \text{and} \quad a\mathbf{v}-a\mathbf{v}'=a(\mathbf{v}-\mathbf{v}')\in U.$$

By Lemma 4.6.14 again, $(\mathbf{v}+\mathbf{w})+U=(\mathbf{v}'+\mathbf{w}')+U$ and $a\mathbf{v}+U=a\mathbf{v}'+U$.

(b) By (a), the sum of two cosets and a scalar multiple of a coset are well-defined cosets. Each axiom is an identity between cosets. Writing each coset with a representative and applying the definitions turns both sides into cosets of vectors of V, which agree by the corresponding axiom in V. For instance, for $\mathbf{u},\mathbf{v},\mathbf{w}\in V$ and $a,b\in F$,

$$\begin{aligned}((\mathbf{u}+U)+(\mathbf{v}+U))+(\mathbf{w}+U)&=((\mathbf{u}+\mathbf{v})+\mathbf{w})+U=(\mathbf{u}+(\mathbf{v}+\mathbf{w}))+U\\&=(\mathbf{u}+U)+((\mathbf{v}+U)+(\mathbf{w}+U)),\\ a((\mathbf{v}+U)+(\mathbf{w}+U))&=a(\mathbf{v}+\mathbf{w})+U=(a\mathbf{v}+a\mathbf{w})+U=a(\mathbf{v}+U)+a(\mathbf{w}+U),\\ (a+b)(\mathbf{v}+U)&=(a+b)\mathbf{v}+U=(a\mathbf{v}+b\mathbf{v})+U=a(\mathbf{v}+U)+b(\mathbf{v}+U),\end{aligned}$$

and commutativity, $(ab)(\mathbf{v}+U)=a(b(\mathbf{v}+U))$, and $1(\mathbf{v}+U)=\mathbf{v}+U$ are checked the same way. Finally, $(\mathbf{v}+U)+(\mathbf{0}+U)=\mathbf{v}+U$ and $(\mathbf{v}+U)+((-\mathbf{v})+U)=\mathbf{0}+U$, so $\mathbf{0}+U=U$ is a zero vector and $(-\mathbf{v})+U$ is an additive inverse of $\mathbf{v}+U$. □

All the content is in (a), and (a) used exactly that U is closed under addition and under scalar multiplication. Part (b) is bookkeeping. Notice also that U, the subspace we collapsed, is now the origin of V/U.

Example 4.6.23 (Quotient spaces).

(a) Let $U = \operatorname{span}((2,1)) \subseteq \mathbb{R}^2$. By Non-example 4.6.19, $g : \mathbb{R}^2/U \to \mathbb{R}$, $g((v_1, v_2) + U) = v_1 - 2v_2$, is well defined. It is linear, since $g(a(\mathbf{v} + U) + (\mathbf{w} + U)) = g((a\mathbf{v} + \mathbf{w}) + U) = a(v_1 - 2v_2) + (w_1 - 2w_2)$. It is injective: if $v_1 - 2v_2 = 0$, then $\mathbf{v} = v_2(2,1) \in U$, so $\mathbf{v} + U = U$ is the zero coset. It is surjective, since $g((c,0) + U) = c$. So $\mathbb{R}^2/U \cong \mathbb{R}$, as Intuition (Collapsing a subspace to a point) predicted, and g is the coordinate across the stack of lines.

(b) Let $U = \operatorname{span}((1,1,0)) \subseteq \mathbb{F}_2^3$ as in Example 4.6.13(b). Then $\mathbb{F}_2^3/U$ has four elements. For instance $((1,0,0) + U) + ((0,0,1) + U) = (1,0,1) + U$, and with the other representatives $(0,1,0)$ and $(1,1,1)$ we get $(1,0,1) + U$ once more. With $(1,0,0)$ and $(1,1,1)$ we get $(0,1,1) + U$, which is the same coset, as it must be. Every element is its own negative, and Theorem 4.6.27 below gives $\dim\left(\mathbb{F}_2^3/U\right) = 2$.

(c) The extreme cases: V/V has the single element $\mathbf{0} + V = V$, so it is the zero space. In $V/\{\mathbf{0}\}$ each coset $\mathbf{v} + \{\mathbf{0}\} = \{\mathbf{v}\}$ has one element, and $\mathbf{v} \mapsto \{\mathbf{v}\}$ is an isomorphism $V \to V/\{\mathbf{0}\}$.

Exercise 4.6.24. ROUTINE Let $U = \operatorname{span}((1,1)) \subseteq \mathbb{R}^2$. Which of the following formulas define functions on $\mathbb{R}^2/U$? For those that do, decide whether the function is linear.

(a) $f(\mathbf{v} + U) = v_1 + v_2$.

(b) $f(\mathbf{v} + U) = v_1 - v_2$.

(c) $f(\mathbf{v} + U) = (v_1 - v_2)^2$.

(d) $S(\mathbf{v} + U) = (v_2, v_1) + U$.

(e) $S(\mathbf{v} + U) = (v_1, 0) + U$.

Solution on page 1343

The quotient map

Definition 4.6.25 (Quotient map). Let U be a subspace of V. The **quotient map** is $\pi : V \to V/U$, $\pi(\mathbf{v}) = \mathbf{v} + U$.

Proposition 4.6.26 (The quotient map). The quotient map $\pi : V \to V/U$ is linear and surjective, and $\ker \pi = U$.

Proof. ROUTINE

Uses. Definition 4.6.20 (Quotient space), Corollary 4.6.15 (Cosets partition V), Theorem 2.1.3 (Checking linearity)
Hint 1. Linearity is the definition of the operations on V/U, read backwards.
Hint 2. For the kernel, recall that the zero of V/U is U, and use Corollary 4.6.15(c).
Sketch. $\pi(a\mathbf{v} + \mathbf{w}) = (a\mathbf{v} + \mathbf{w}) + U = a(\mathbf{v} + U) + (\mathbf{w} + U)$. Every coset is π of its representatives. $\pi(\mathbf{v}) = U$ iff $\mathbf{v} \in U$.

For $\mathbf{v}, \mathbf{w} \in V$ and $a \in F$, the definition of the operations gives

$$\pi(a\mathbf{v} + \mathbf{w}) = (a\mathbf{v} + \mathbf{w}) + U = a(\mathbf{v} + U) + (\mathbf{w} + U) = a\pi(\mathbf{v}) + \pi(\mathbf{w}),$$

so π is linear (Theorem 2.1.3). Every element of V/U has the form $\mathbf{v} + U = \pi(\mathbf{v})$, so π is surjective. The zero of V/U is U (Theorem 4.6.22), and $\pi(\mathbf{v}) = U$ if and only if $\mathbf{v} \in U$ (Corollary 4.6.15(c)). So $\ker \pi = U$. □

In fact the operations on V/U were chosen to make π linear. One consequence: every subspace of every vector space is the kernel of some linear map. In finite dimensions Section 4.4 gets this from a complement; the quotient map gives it with no choices and no dimension hypothesis.

4.6.5 The dimension of a quotient

In the plane, collapsing a line leaves a line. In general, collapsing U should remove exactly $\dim U$ dimensions. The first proof below finds a basis of V/U inside a basis of V, and the second reads the count off rank–nullity for π.

Theorem 4.6.27 (Dimension of a quotient). Let V be finite-dimensional and let U be a subspace of V. Then V/U is finite-dimensional, and

$$\dim(V/U) = \dim V - \dim U.$$

More precisely, if $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}_1, \dots, \mathbf{v}_r$ is a basis of V such that $\mathbf{u}_1, \dots, \mathbf{u}_k$ is a basis of U, then $\mathbf{v}_1 + U, \dots, \mathbf{v}_r + U$ is a basis of V/U.

Proof (by extending a basis of U). STANDARD

Uses. Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis), Lemma 4.6.14 (Equal cosets), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Extend a basis of a subspace (Technique 4.1.18)
Hint 1. Bases of the required kind exist by Theorem 4.1.16. Why should the cosets $\mathbf{u}_i + U$ play no role?
Hint 2. Each $\mathbf{u}_i + U$ is the zero coset. For spanning, expand an arbitrary $\mathbf{v}$ in the basis and apply π.
Hint 3. For independence: $\sum_j b_j(\mathbf{v}_j + U) = U$ means $\sum_j b_j \mathbf{v}_j \in U = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$. Write that as a linear relation among the basis vectors of V.
Sketch. Extend a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of U to a basis of V. Since $\mathbf{v} - \sum_j b_j \mathbf{v}_j \in U$, every coset is $\sum_j b_j(\mathbf{v}_j + U)$. If $\sum_j b_j(\mathbf{v}_j + U) = U$, then $\sum_j b_j \mathbf{v}_j = \sum_i a_i \mathbf{u}_i$, a relation among basis vectors, so all $b_j = 0$. Hence $\dim(V/U) = r = \dim V - \dim U$.

By Proposition 4.1.21(a), U is finite-dimensional, so it has a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$, and by Theorem 4.1.16 this extends to a basis $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}_1, \dots, \mathbf{v}_r$ of V with $k + r = \dim V$. So it suffices to prove the second statement, for any such basis. Then $\dim(V/U) = r = \dim V - \dim U$.

Spanning. Let $\mathbf{v} \in V$ and write $\mathbf{v} = \sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{v}_j$. Then $\mathbf{v} - \sum_j b_j \mathbf{v}_j = \sum_i a_i \mathbf{u}_i \in U$, so by Lemma 4.6.14 and the definition of the operations,

$$\mathbf{v} + U = \left(\sum_{j=1}^{r} b_j \mathbf{v}_j \right) + U = \sum_{j=1}^{r} b_j (\mathbf{v}_j + U).$$

Independence. Suppose $\sum_j b_j(\mathbf{v}_j + U) = \mathbf{0} + U$, that is, $\left(\sum_j b_j \mathbf{v}_j\right) + U = U$. By Corollary 4.6.15(c), $\sum_j b_j \mathbf{v}_j \in U$, so $\sum_j b_j \mathbf{v}_j = \sum_i a_i \mathbf{u}_i$ for some scalars a_i. Then

$$\sum_{i=1}^{k} (-a_i) \mathbf{u}_i + \sum_{j=1}^{r} b_j \mathbf{v}_j = \mathbf{0}$$

is a linear relation among the vectors of a basis of V, so all its coefficients vanish (Theorem 1.5.5). In particular $b_1 = \cdots = b_r = 0$. □

Proof (by rank–nullity for the quotient map). ROUTINE

Uses. Proposition 4.6.26 (The quotient map), Theorem 4.2.11 (Rank–nullity), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Corollary 4.1.11 (Spanning lists are long)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. $\pi : V \to V/U$ is linear and surjective. What is its kernel?
Hint 2. Rank–nullity applies because V is finite-dimensional. For the basis statement, a spanning list of length $\dim(V/U)$ is a basis.
Sketch. π is surjective with kernel U, so rank–nullity gives $\dim V = \dim U + \dim(V/U)$, with $V/U = \operatorname{im}\pi$ finite-dimensional. The images $\pi(\mathbf{u}_i) = \mathbf{0}$ and $\pi(\mathbf{v}_j)$ span V/U, so the $r = \dim(V/U)$ cosets $\mathbf{v}_j + U$ span it, hence form a basis.

By Proposition 4.6.26, π is linear and surjective with $\ker \pi = U$. Since V is finite-dimensional, rank–nullity (Theorem 4.2.11(b)) says that $\operatorname{im}\pi = V/U$ is finite-dimensional and $\dim V = \dim U + \dim(V/U)$.

For the second statement, the list $\pi(\mathbf{u}_1), \dots, \pi(\mathbf{u}_k), \pi(\mathbf{v}_1), \dots, \pi(\mathbf{v}_r)$ spans $\operatorname{im}\pi = V/U$ (Proposition 2.1.16(a)). Its first k entries are $\mathbf{0}$, so $\mathbf{v}_1 + U, \dots, \mathbf{v}_r + U$ spans V/U as well. It has length $r = \dim V - \dim U = \dim(V/U)$, so it is a basis (Corollary 4.1.11(b)). □

The second proof is shorter, but it leans on rank–nullity. The first proof uses only the extension of bases, and that matters in Section 4.6.7, where the theorem is used to reprove rank–nullity.

The converse direction needs no finiteness assumption on V: a basis of U together with lifts of a basis of V/U is a basis of V. This is what makes quotients useful for induction on dimension, where a statement about V is split into statements about U and V/U.

Proposition 4.6.28 (Lifting a basis of a quotient). Let U be a subspace of V, let $\mathbf{u}_1, \dots, \mathbf{u}_k$ be a basis of U, and let $\mathbf{v}_1, \dots, \mathbf{v}_r \in V$ be such that $\mathbf{v}_1 + U, \dots, \mathbf{v}_r + U$ is a basis of V/U. Then $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}_1, \dots, \mathbf{v}_r$ is a basis of V. In particular, if U and V/U are finite-dimensional, then so is V, and $\dim V = \dim U + \dim(V/U)$.

Proof. STANDARD

Uses. Proposition 4.6.26 (The quotient map), Lemma 4.6.14 (Equal cosets), Corollary 1.6.24 (Bases exist in finite dimensions)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. For spanning, expand $\mathbf{v} + U$ in the basis of V/U and pull back with Lemma 4.6.14.
Hint 2. For independence, apply π to a linear relation. Which terms does it kill?
Sketch. If $\mathbf{v} + U = \sum_j b_j(\mathbf{v}_j + U)$, then $\mathbf{v} - \sum_j b_j \mathbf{v}_j \in U = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$. Applying π to a relation $\sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{v}_j = \mathbf{0}$ kills the $\mathbf{u}_i$ and leaves a relation among the $\mathbf{v}_j + U$, so all $b_j = 0$, and then all $a_i = 0$.

Spanning. Let $\mathbf{v} \in V$. Since $\mathbf{v}_1 + U, \dots, \mathbf{v}_r + U$ spans V/U, there are scalars b_j with

$$\mathbf{v} + U = \sum_{j=1}^{r} b_j(\mathbf{v}_j + U) = \left(\sum_{j=1}^{r} b_j \mathbf{v}_j\right) + U.$$

By Lemma 4.6.14, $\mathbf{v} - \sum_j b_j \mathbf{v}_j \in U$, so it equals $\sum_i a_i \mathbf{u}_i$ for some scalars a_i, and $\mathbf{v} = \sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{v}_j$.

Independence. Suppose $\sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{v}_j = \mathbf{0}$. Apply the linear map π. Since $\pi(\mathbf{u}_i) = \mathbf{0}$ (as $\ker \pi = U$), we get $\sum_j b_j(\mathbf{v}_j + U) = \mathbf{0} + U$, so all $b_j = 0$ because the cosets $\mathbf{v}_j + U$ are independent. Then $\sum_i a_i \mathbf{u}_i = \mathbf{0}$, so all $a_i = 0$.

For the last statement, U and V/U have bases (Corollary 1.6.24), and every element of V/U is a coset $\mathbf{v} + U$, so the basis of V/U has the form $\mathbf{v}_1 + U, \dots, \mathbf{v}_r + U$. By the first part, V has a basis of length $k + r$. □

Quotients and complements

A complement of U (Proposition 4.4.16) and the quotient V/U have the same dimension. They are related by the quotient map.

Proposition 4.6.29 (Complements and the quotient). Let U and W be subspaces of V, and let $\pi : V \to V/U$ be the quotient map. Then $\pi|_W : W \to V/U$ is injective if and only if $U \cap W = \{\mathbf{0}\}$, and surjective if and only if $U + W = V$. In particular, $\pi|_W$ is an isomorphism if and only if $V = U \oplus W$, so $V/U \cong W$ for every complement W of U.

Proof. STANDARD

Uses. Proposition 4.2.3 (Properties of restriction), Proposition 4.6.26 (The quotient map), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Lemma 4.6.14 (Equal cosets), Theorem 4.4.7 (Criteria for direct sums)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. The kernel of a restriction is the intersection of the subspace with the kernel (Proposition 4.2.3(c)).
Hint 2. $\pi|_W$ is surjective when every coset $\mathbf{v} + U$ contains a vector of W. Translate this with Lemma 4.6.14.
Sketch. $\ker \pi|_W = W \cap \ker \pi = W \cap U$. Surjectivity says that every $\mathbf{v}$ has some $\mathbf{w} \in W$ with $\mathbf{v} - \mathbf{w} \in U$, i.e. $\mathbf{v} \in U + W$. Both together say $V = U \oplus W$ (Theorem 4.4.7).

By Proposition 4.2.3(c) and $\ker \pi = U$, we have $\ker \pi|_W = W \cap U$, so $\pi|_W$ is injective if and only if $U \cap W = \{\mathbf{0}\}$ (Theorem 2.6.11).

The image of $\pi|_W$ consists of the cosets $\mathbf{w} + U$ with $\mathbf{w} \in W$. If $U + W = V$, then every $\mathbf{v}$ is $\mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in U$, $\mathbf{w} \in W$, and $\mathbf{v} + U = \mathbf{w} + U$ since $\mathbf{v} - \mathbf{w} \in U$; so $\pi|_W$ is surjective. Conversely, if it is surjective, then for every $\mathbf{v} \in V$ there is $\mathbf{w} \in W$ with $\mathbf{v} + U = \mathbf{w} + U$, so $\mathbf{v} - \mathbf{w} \in U$ (Lemma 4.6.14) and $\mathbf{v} = (\mathbf{v} - \mathbf{w}) + \mathbf{w} \in U + W$.

Hence $\pi|_W$ is bijective if and only if $U \cap W = \{\mathbf{0}\}$ and $U + W = V$, which by Theorem 4.4.7 says that $V = U \oplus W$. A bijective linear map is an isomorphism. □

Intuition (A complement is a choice; the quotient is not). The proposition says that a complement W meets every coset of U in exactly one vector. So a complement amounts to choosing one representative from each coset, in such a way that the chosen vectors form a subspace. In the plane, every line through $\mathbf{0}$ other than U meets each line parallel to U exactly once, and none of these lines is preferred. The quotient is the same space with the choice removed. This is why quotients, not complements, are the tool when a construction must not depend on choices, as in the first isomorphism theorem below, or when complements are hard to produce: in infinite dimensions their existence in general needs Zorn's lemma (Section A.4), while V/U always exists.

With Proposition 4.4.16(b) the proposition also gives a third proof of Theorem 4.6.27: $\dim(V/U) = \dim W = \dim V - \dim U$.

4.6.6 Linear maps out of a quotient

Intuition (Maps that kill U). A linear map out of V/U composed with π is a linear map out of V that sends all of U to $\mathbf{0}$, because π does. Conversely, let $T : V \to W$ be linear with $T(U) = \{\mathbf{0}\}$. If $\mathbf{v}$ and $\mathbf{v}'$ lie in the same coset, then $T(\mathbf{v}) - T(\mathbf{v}') = T(\mathbf{v} - \mathbf{v}') = \mathbf{0}$, so T is constant on each coset and makes sense as a function of the coset. So linear maps out of V/U are the same thing as linear maps out of V that vanish on U.

Theorem 4.6.30 (Universal property of the quotient). Let U be a subspace of V, let $\pi : V \to V/U$ be the quotient map, and let $T \in \mathrm{L}(V, W)$.

(a) If $U \subseteq \ker T$, there is exactly one linear map $\tilde{T} : V/U \to W$ with $\tilde{T} \circ \pi = T$, namely

$$\tilde{T}(\mathbf{v} + U) = T(\mathbf{v}).$$

Its image is $\operatorname{im} \tilde{T} = \operatorname{im} T$, and its kernel is $\ker \tilde{T} = \{\mathbf{v} + U \mid \mathbf{v} \in \ker T\}$.

(b) Conversely, for every $S \in \mathrm{L}(V/U, W)$ the map $S \circ \pi \in \mathrm{L}(V, W)$ vanishes on U.

The map $\tilde{T}$ is the **map induced by** T. The equation $\tilde{T} \circ \pi = T$ is often drawn as a triangle:

$$\begin{array}{ccc} V & \xrightarrow{\pi} & V/U \\ & \searrow^{T} & \downarrow \tilde{T} \\ & & W \end{array}$$

Proof. STANDARD

Uses. Proposition 4.6.26 (The quotient map), Lemma 4.6.14 (Equal cosets), Theorem 2.1.3 (Checking linearity), Definition 4.6.20 (Quotient space)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18), Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Uniqueness first: two maps S, S' with $S \circ \pi = S' \circ \pi$ agree at every $\pi(\mathbf{v})$. Why is that everything?
Hint 2. For existence, the formula $\tilde{T}(\mathbf{v} + U) = T(\mathbf{v})$ is forced. Check that it is well defined: if $\mathbf{v} - \mathbf{v}' \in U$, why is $T(\mathbf{v}) = T(\mathbf{v}')$?
Hint 3. Linearity: compute $\tilde{T}(a(\mathbf{v} + U) + (\mathbf{w} + U))$ by first combining the cosets. The image and kernel come from $\tilde{T}(\mathbf{v} + U) = T(\mathbf{v})$.
Sketch. Since π is surjective, $S \circ \pi = T$ determines S at every coset, which gives uniqueness and the formula. If $\mathbf{v} - \mathbf{v}' \in U \subseteq \ker T$, then $T(\mathbf{v}) = T(\mathbf{v}')$, so the formula is well defined; it is linear because $a(\mathbf{v} + U) + (\mathbf{w} + U) = (a\mathbf{v} + \mathbf{w}) + U$ and T is linear. The values of $\tilde{T}$ are the values of T, and $\tilde{T}(\mathbf{v} + U) = \mathbf{0}$ iff $\mathbf{v} \in \ker T$. (b) $S(\pi(\mathbf{u})) = S(\mathbf{0}) = \mathbf{0}$ for $\mathbf{u} \in U$.

(a) *Uniqueness.* If $S \circ \pi = T$, then $S(\mathbf{v} + U) = S(\pi(\mathbf{v})) = T(\mathbf{v})$ for every $\mathbf{v} \in V$. Every element of V/U is $\mathbf{v} + U$ for some $\mathbf{v}$ (Proposition 4.6.26), so S is determined by T: it must be given by the formula in the statement.

Well defined. Suppose $\mathbf{v}+U=\mathbf{v}'+U$. Then $\mathbf{v}-\mathbf{v}'\in U\subseteq\ker T$ (Lemma 4.6.14), so $T(\mathbf{v})-T(\mathbf{v}')=T(\mathbf{v}-\mathbf{v}')=\mathbf{0}$. Hence the formula defines a function $\tilde{T}:V/U\to W$.

Linear. For $\mathbf{v},\mathbf{w}\in V$ and $a\in F$,

$$\tilde{T}(a(\mathbf{v}+U)+(\mathbf{w}+U))=\tilde{T}((a\mathbf{v}+\mathbf{w})+U)=T(a\mathbf{v}+\mathbf{w})=a\tilde{T}(\mathbf{v}+U)+\tilde{T}(\mathbf{w}+U).$$

By construction $\tilde{T}(\pi(\mathbf{v}))=T(\mathbf{v})$, so $\tilde{T}\circ\pi=T$.

Image and kernel. The values of $\tilde{T}$ are the vectors $T(\mathbf{v})$, $\mathbf{v}\in V$, so $\operatorname{im}\tilde{T}=\operatorname{im}T$. And $\tilde{T}(\mathbf{v}+U)=\mathbf{0}$ if and only if $T(\mathbf{v})=\mathbf{0}$, so $\ker\tilde{T}=\{\mathbf{v}+U\mid\mathbf{v}\in\ker T\}$. (This is well stated: whether $\mathbf{v}\in\ker T$ does not depend on the representative, since $\ker T\supseteq U$.)

(b) $S\circ\pi$ is linear (Proposition 2.1.17), and for $\mathbf{u}\in U$, $(S\circ\pi)(\mathbf{u})=S(\mathbf{0}+U)=\mathbf{0}$, since $\mathbf{u}+U=\mathbf{0}+U$. □

So $T\mapsto\tilde{T}$ and $S\mapsto S\circ\pi$ are inverse bijections between the linear maps $V\to W$ that vanish on U and the linear maps $V/U\to W$. Note how the hypothesis $U\subseteq\ker T$ entered: it is exactly what the well-definedness check needed. When U is not inside $\ker T$, there is no induced map at all. This is the quotient version of Exercise 2.6.43, with π as the surjection.

Technique 4.6.31 (Pass to a quotient). When a construction only depends on vectors up to elements of a subspace U, replace V by V/U. By Theorem 4.6.30, a linear map that kills U is the same as a linear map on V/U, and by Theorem 4.6.27 and Proposition 4.6.28, dimensions split as $\dim V=\dim U+\dim(V/U)$. Two typical uses:

- *Make a map injective.* Dividing out exactly the kernel turns T into an injective map with the same image. This is the first isomorphism theorem (Theorem 4.6.34), and it is the standard way to show that some space is isomorphic to an image.
- *Split a problem in two.* If an operator T maps U into itself, it acts on U and on V/U (Proposition 4.6.32), and a statement about T often follows from the same statement for these two smaller operators, by induction on $\dim V$. Section 7.5 triangularizes operators this way.

The price is the well-definedness check (Technique 4.6.18) for every map defined on cosets.

Used in. Proposition 4.6.32, Theorem 4.6.34, Corollary 4.6.35, Exercise 4.6.37, Exercise 4.6.44, Exercise 4.6.45, Exercise 4.6.46, Exercise 4.6.47, Exercise 4.6.49, Exercise 4.6.50, Exercise 4.6.52, Exercise 4.6.53, Exercise 4.6.55, Exercise 4.8.14, Problem 4.18, Theorem 7.6.32, Exercise 4.6.42.

Operators on a quotient

Proposition 4.6.32 (Operators on a quotient). Let $T\in\mathrm{L}(V)$ and let U be a subspace of V with $T(\mathbf{u})\in U$ for every $\mathbf{u}\in U$ (that is, U is **invariant** under T; see Section 7.2).

(a) There is exactly one $T/U\in\mathrm{L}(V/U)$ with $(T/U)(\mathbf{v}+U)=T(\mathbf{v})+U$ for all $\mathbf{v}\in V$.

(b) Suppose V is finite-dimensional, let $\mathcal{C}=\mathbf{u}_1,\dots,\mathbf{u}_k$ be a basis of U, extend it to a basis $\mathcal{B}=\mathbf{u}_1,\dots,\mathbf{u}_k,\mathbf{v}_1,\dots,\mathbf{v}_r$ of V, and let $\mathcal{D}=\mathbf{v}_1+U,\dots,\mathbf{v}_r+U$ (a basis of V/U by Theorem 4.6.27). Regard $T|_U$ as an operator on U. Then

$$[T]_{\mathcal{B}\mathcal{B}}=\begin{pmatrix}[T|_U]_{\mathcal{C}\mathcal{C}} & B\\ 0 & [T/U]_{\mathcal{D}\mathcal{D}}\end{pmatrix}$$

for some $B\in F^{k\times r}$.

Proof. STANDARD

Uses. Theorem 4.6.30 (Universal property of the quotient), Proposition 4.6.26 (The quotient map), Proposition 2.1.17 (Compositions of linear maps are linear), Definition 2.3.1 (Matrix of a linear map), Definition 2.4.33 (Block matrix)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. For (a), apply Theorem 4.6.30 to the composite $\pi\circ T:V\to V/U$. What is its kernel?

Hint 2. For (b), read the matrix column by column. Where does $T(\mathbf{u}_j)$ live? Expand $T(\mathbf{v}_j)$ in $\mathcal{B}$ and apply π.
Sketch. (a) $\pi \circ T$ is linear and kills U, because $T(U) \subseteq U = \ker \pi$, so it induces T/U, which is unique by Theorem 4.6.30. (b) $T(\mathbf{u}_j) \in U$, so the first k columns have zeros below row k, and their top parts are the columns of $[T|_U]_{\mathcal{C}\mathcal{C}}$. If $T(\mathbf{v}_j) = \sum_i b_{ij}\mathbf{u}_i + \sum_i c_{ij}\mathbf{v}_i$, then $(T/U)(\mathbf{v}_j + U) = \sum_i c_{ij}(\mathbf{v}_i + U)$, so the lower right block is $[T/U]_{\mathcal{D}\mathcal{D}}$.

(a) The composite $\pi \circ T : V \to V/U$ is linear (Proposition 2.1.17). For $\mathbf{u} \in U$, $T(\mathbf{u}) \in U = \ker \pi$, so $(\pi \circ T)(\mathbf{u}) = \mathbf{0}$. By Theorem 4.6.30(a), there is exactly one linear $T/U : V/U \to V/U$ with $(T/U) \circ \pi = \pi \circ T$, that is, $(T/U)(\mathbf{v} + U) = T(\mathbf{v}) + U$.

(b) Column j of $[T]_{\mathcal{B}\mathcal{B}}$ is the coordinate vector of the image of the jth basis vector (Definition 2.3.1). For $j \le k$, the vector $T(\mathbf{u}_j)$ lies in U, so it is a combination of $\mathbf{u}_1, \dots, \mathbf{u}_k$ alone: its last r coordinates are 0, and its first k coordinates form column j of $[T|_U]_{\mathcal{C}\mathcal{C}}$. For $j \le r$, write

$$T(\mathbf{v}_j) = \sum_{i=1}^{k} b_{ij}\mathbf{u}_i + \sum_{i=1}^{r} c_{ij}\mathbf{v}_i.$$

Applying π, which kills the $\mathbf{u}_i$,

$$(T/U)(\mathbf{v}_j + U) = T(\mathbf{v}_j) + U = \sum_{i=1}^{r} c_{ij}(\mathbf{v}_i + U),$$

so (c_{ij}) is $[T/U]_{\mathcal{D}\mathcal{D}}$. Together these give the block form, with $B = (b_{ij})$. □

Example 4.6.33 (A shift and its quotient). Let $N \in \mathrm{L}(F^3)$ be the shift $N(\mathbf{e}_1) = \mathbf{0}$, $N(\mathbf{e}_2) = \mathbf{e}_1$, $N(\mathbf{e}_3) = \mathbf{e}_2$, and let $U = \operatorname{span}(\mathbf{e}_1)$, which N maps into itself (to $\{\mathbf{0}\}$). On F^3/U, with basis $\mathbf{e}_2 + U, \mathbf{e}_3 + U$,

$$(N/U)(\mathbf{e}_2 + U) = \mathbf{e}_1 + U = \mathbf{0} + U, \quad (N/U)(\mathbf{e}_3 + U) = \mathbf{e}_2 + U.$$

So N/U is the shift of a two-dimensional space, and in the standard basis

$$[N] = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad [N|_U] = (0), \quad B = (1 \;\; 0), \quad [N/U] = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Collapsing the last vector of the chain $\mathbf{e}_3 \mapsto \mathbf{e}_2 \mapsto \mathbf{e}_1 \mapsto \mathbf{0}$ leaves a chain one step shorter.

4.6.7 The first isomorphism theorem

Intuition (Each slice becomes one vector). Return to the slices of Corollary 2.6.31. A linear map T sends each coset of $\ker T$ to a single vector, and different cosets to different vectors. So T is a bijection from the set of cosets of $\ker T$ onto $\operatorname{im} T$. The quotient $V/\ker T$ makes that set of cosets into a vector space, and the bijection is linear.

Theorem 4.6.34 (First isomorphism theorem). Let $T \in \mathrm{L}(V, W)$. The map

$$\tilde{T} : V/\ker T \to \operatorname{im} T, \quad \tilde{T}(\mathbf{v} + \ker T) = T(\mathbf{v}),$$

is well defined and is an isomorphism. In particular, $V/\ker T \cong \operatorname{im} T$.

The first proof is an application of the universal property. The second proves well-definedness and injectivity at once, with a single chain of equivalences read in both directions.

Proof (by the universal property). ROUTINE
Uses. Theorem 4.6.30 (Universal property of the quotient), Proposition 2.7.7 (Bijective linear maps are invertible), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. Apply Theorem 4.6.30 with $U = \ker T$. What are the image and kernel of the induced map?
Hint 2. The kernel of $\tilde{T}$ is the set of cosets $\mathbf{v} + \ker T$ with $\mathbf{v} \in \ker T$. How many different cosets is that?

Sketch. With $U = \ker T$, Theorem 4.6.30 gives a linear $\tilde{T}$ with $\operatorname{im}\tilde{T} = \operatorname{im} T$ and $\ker\tilde{T} = \{\mathbf{v} + \ker T \mid \mathbf{v} \in \ker T\} = \{\ker T\}$, the zero coset. So $\tilde{T}$ is injective, and as a map onto $\operatorname{im} T$ it is bijective.

Apply Theorem 4.6.30(a) with $U = \ker T$; the hypothesis $U \subseteq \ker T$ holds trivially. It gives a well-defined linear map $\tilde{T} : V/\ker T \to W$ with $\tilde{T}(\mathbf{v} + \ker T) = T(\mathbf{v})$, image $\operatorname{im} T$, and kernel $\{\mathbf{v} + \ker T \mid \mathbf{v} \in \ker T\}$. For $\mathbf{v} \in \ker T$ we have $\mathbf{v} + \ker T = \ker T$, the zero vector of $V/\ker T$ (Corollary 4.6.15(c)). So $\ker\tilde{T}$ is the zero subspace and $\tilde{T}$ is injective (Theorem 2.6.11). Regarded as a map into $\operatorname{im} T$, it is also surjective, so it is a bijective linear map, hence an isomorphism (Proposition 2.7.7). □

Proof (by one chain of equivalences). ROUTINE

Uses. Lemma 4.6.14 (Equal cosets), Definition 2.6.5 (Kernel), Definition 4.6.20 (Quotient space), Proposition 2.7.7 (Bijective linear maps are invertible)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18)
Hint 1. For $\mathbf{v}, \mathbf{v}' \in V$, connect "$\mathbf{v} + \ker T = \mathbf{v}' + \ker T$" with "$T(\mathbf{v}) = T(\mathbf{v}')$" by a chain of equivalences.
Hint 2. Read the chain left to right: that is well-definedness. Read it right to left: that is injectivity.
Sketch. $\mathbf{v} + \ker T = \mathbf{v}' + \ker T$ iff $\mathbf{v} - \mathbf{v}' \in \ker T$ iff $T(\mathbf{v}) = T(\mathbf{v}')$. The forward implications make $\tilde{T}$ well defined, the backward ones make it injective. Linearity and surjectivity onto $\operatorname{im} T$ are immediate.

For $\mathbf{v}, \mathbf{v}' \in V$, by Lemma 4.6.14 and linearity,

$$\mathbf{v} + \ker T = \mathbf{v}' + \ker T \quad\Leftrightarrow\quad \mathbf{v} - \mathbf{v}' \in \ker T \quad\Leftrightarrow\quad T(\mathbf{v} - \mathbf{v}') = \mathbf{0} \quad\Leftrightarrow\quad T(\mathbf{v}) = T(\mathbf{v}').$$

Read from left to right, this says that the formula for $\tilde{T}$ gives the same value for every representative, so $\tilde{T}$ is well defined (Technique 4.6.18). Read from right to left, it says that $\tilde{T}$ is injective. Linearity is the computation

$$\tilde{T}(a(\mathbf{v} + \ker T) + (\mathbf{w} + \ker T)) = \tilde{T}((a\mathbf{v} + \mathbf{w}) + \ker T) = T(a\mathbf{v} + \mathbf{w}) = aT(\mathbf{v}) + T(\mathbf{w}),$$

and $\tilde{T}$ is onto $\operatorname{im} T$ because $T(\mathbf{v}) = \tilde{T}(\mathbf{v} + \ker T)$. So $\tilde{T}$ is a bijective linear map onto $\operatorname{im} T$, hence an isomorphism (Proposition 2.7.7). □

The second proof shows what is special about $U = \ker T$. For a subspace U strictly inside $\ker T$, the chain acquires a one-way step, "$\mathbf{v} - \mathbf{v}' \in U \Rightarrow \mathbf{v} - \mathbf{v}' \in \ker T$". The induced map is still well defined, but it is no longer injective.

Corollary 4.6.35 (Rank–nullity, a third proof). Let V be finite-dimensional and $T \in \mathrm{L}(V, W)$. Then $\operatorname{im} T$ is finite-dimensional, and

$$\dim V = \dim\ker T + \dim\operatorname{im} T.$$

Proof. ROUTINE

Uses. Theorem 4.6.34 (First isomorphism theorem), Theorem 4.6.27 (Dimension of a quotient), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. $\operatorname{im} T$ is isomorphic to a quotient of V. What is the dimension of that quotient?
Hint 2. Use the first proof of Theorem 4.6.27. Using the second would be circular.
Sketch. $V/\ker T$ is finite-dimensional of dimension $\dim V - \dim\ker T$ (Theorem 4.6.27, by extending a basis). The isomorphism $\tilde{T}$ carries it onto $\operatorname{im} T$, so $\operatorname{im} T$ is finite-dimensional of the same dimension.

By Proposition 4.1.21, $\ker T$ is a finite-dimensional subspace of V, and by Theorem 4.6.27 (first proof), $V/\ker T$ is finite-dimensional with $\dim(V/\ker T) = \dim V - \dim\ker T$. By Theorem 4.6.34, $\tilde{T}$ is an injective linear map on $V/\ker T$ with image $\operatorname{im} T$. By Proposition 4.2.6(a), $\operatorname{im} T$ is finite-dimensional and $\dim\operatorname{im} T = \dim(V/\ker T) = \dim V - \dim\ker T$. □

The second proof of Theorem 4.6.27 used rank–nullity, so citing it here would be circular; the first used only Theorem 4.1.16. Unwound, this proof is close to the proof of Theorem 4.2.11 by extending a basis of the kernel: the basis $\mathbf{v}_1 + \ker T, \ldots, \mathbf{v}_r + \ker T$ of $V/\ker T$ is carried by $\tilde{T}$ to $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_r)$, the basis of $\operatorname{im} T$

found there. What the quotient adds is that the space being counted, $V/\ker T$, no longer depends on the choice of the $\mathbf{v}_j$ (see Remark 4.2.12).

Example 4.6.36 (The first isomorphism theorem at work).

(a) *Evaluation.* For $c \in F$, the evaluation map $\mathrm{ev}_c : F[x] \to F$, $p \mapsto p(c)$ (Example 2.1.9), is linear and surjective (it sends the constant polynomial a to a). Its kernel is $U_c = \{p \mid p(c) = 0\}$. So $F[x]/U_c \cong F$, via $p + U_c \mapsto p(c)$: two polynomials lie in the same coset exactly when they agree at c. An infinite-dimensional space can have a one-dimensional quotient.

(b) *Trace.* The trace $\mathrm{tr} : F^{n\times n} \to F$ is linear and surjective, since $\mathrm{tr}(U_{11}) = 1$ for the matrix unit U_{11} (Lemma 2.4.24). So $F^{n\times n}/\ker \mathrm{tr} \cong F$, and by Theorem 4.6.27 the trace-zero matrices form a subspace of dimension $n^2 - 1$. The coset of A is determined by $\mathrm{tr}\, A$.

(c) *Fibers.* For $A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix}$ as in Figure 2.6.1, the cosets of $\ker T_A$ are the lines $x_1 + 2x_2 = t$, and $\widetilde{T_A}$ sends the line $x_1 + 2x_2 = t$ to $t(1, 1)$. So $\mathbb{R}^2/\ker T_A \cong \mathrm{span}((1, 1))$.

(d) *A quotient isomorphic to the whole space.* The backward shift $B : F[x] \to F[x]$,

$$B(a_0 + a_1 x + \cdots + a_n x^n) = a_1 + a_2 x + \cdots + a_n x^{n-1},$$

is linear (it acts on coefficient sequences by deleting the first entry) and surjective, since $B(xp) = p$. Its kernel is the set of constant polynomials, $\mathrm{span}(1)$. So $F[x]/\mathrm{span}(1) \cong F[x]$: dividing out a nonzero subspace gave back a space isomorphic to the original. In finite dimensions this is impossible, because $\dim(V/U) = \dim V - \dim U < \dim V$ when $U \neq \{\mathbf{0}\}$.

Exercise 4.6.37. STANDARD Let $U = \{p \in F[x] \mid p(1) = p(2) = 0\}$.

(a) Show that $F[x]/U \cong F^2$, and that $p + U = q + U$ if and only if $p(1) = q(1)$ and $p(2) = q(2)$.

(b) Show that $1 + U, x + U$ is a basis of $F[x]/U$, and write $x^2 + U$ in this basis. What does your answer say over $\mathbb{F}_2$?

Solution on page 1344

Exercises

Exercise 4.6.38. ROUTINE Let $V = F[x]_{\leq 2}$.

(a) Write down a basis of $V \times V$ and find $\dim(V \times V)$.

(b) Let $D = \{(p, q) \in V \times V \mid p(0) = q(1)\}$. Show that D is a subspace of $V \times V$, find $\dim D$, and find a basis of D.

Solution on page 1344

Exercise 4.6.39. STANDARD Let $T \in \mathrm{L}(V, W)$. The **graph** of T is $G_T = \{(\mathbf{v}, T(\mathbf{v})) \mid \mathbf{v} \in V\} \subseteq V \times W$.

(a) Show that G_T is a subspace of $V \times W$ and that $\mathbf{v} \mapsto (\mathbf{v}, T(\mathbf{v}))$ is an isomorphism $V \to G_T$.

(b) Show that $V \times W = G_T \oplus (\{\mathbf{0}\} \times W)$, and deduce that $(V \times W)/G_T \cong W$.

(c) Let G be any subspace of $V \times W$. Show that $G = G_S$ for some $S \in \mathrm{L}(V, W)$ if and only if $G \cap (\{\mathbf{0}\} \times W) = \{\mathbf{0}\}$ and every $\mathbf{v} \in V$ is the first component of some element of G.

Solution on page 1345

Exercise 4.6.40. ROUTINE For subsets $A, B \subseteq V$ and $a \in F$, let $A + B = \{\mathbf{x} + \mathbf{y} \mid \mathbf{x} \in A, \mathbf{y} \in B\}$ and $aA = \{a\mathbf{x} \mid \mathbf{x} \in A\}$. Let U be a subspace of V.

(a) Show that $(\mathbf{v}+U)+(\mathbf{w}+U)=(\mathbf{v}+\mathbf{w})+U$ as sets.

(b) Show that $a(\mathbf{v}+U)=a\mathbf{v}+U$ as sets when $a\neq 0$.

(c) Compute $0(\mathbf{v}+U)$, and explain why, when $U\neq\{\mathbf{0}\}$, these set operations do not make the set of cosets into a vector space, although they agree with the operations of Definition 4.6.20 whenever the result is a coset.

Solution on page 1345

Exercise 4.6.41. STANDARD Let U be a subspace of V, let $\mathbf{v}_1,\ldots,\mathbf{v}_k\in V$, and let $X=\operatorname{span}(\mathbf{v}_1,\ldots,\mathbf{v}_k)$.

(a) Show that $\mathbf{v}_1+U,\ldots,\mathbf{v}_k+U$ is linearly independent in V/U if and only if $\mathbf{v}_1,\ldots,\mathbf{v}_k$ is linearly independent and $X\cap U=\{\mathbf{0}\}$.

(b) Show that $\mathbf{v}_1+U,\ldots,\mathbf{v}_k+U$ spans V/U if and only if $X+U=V$.

(c) Conclude that $\mathbf{v}_1+U,\ldots,\mathbf{v}_k+U$ is a basis of V/U if and only if $\mathbf{v}_1,\ldots,\mathbf{v}_k$ is a basis of a complement of U.

Solution on page 1346

Exercise 4.6.42. STANDARD Let $V=F^{2\times 2}$ and $S=\left\{A\in V\;\middle|\;A^{\mathsf{T}}=A\right\}$.

(a) Show that $A+S\mapsto a_{12}-a_{21}$ is a well-defined isomorphism $V/S\to F$, where $A=\left(a_{ij}\right)$.

(b) Suppose $1+1\neq 0$ in F. Show that $K=\left\{A\;\middle|\;A^{\mathsf{T}}=-A\right\}$ is a complement of S.

(c) Show that over $\mathbb{F}_2$ the subspace K is not a complement of S, and find a complement.

Solution on page 1346

Exercise 4.6.43. STANDARD Let $T\in \mathrm{L}(V,W)$, and let U be a subspace of V with $\ker T\subseteq U$. A student defines $S:V/U\to W$ by $S(\mathbf{v}+U)=T(\mathbf{v})$, and argues:

"S is well defined: if $S(\mathbf{v}+U)=S(\mathbf{v}'+U)$, then $T(\mathbf{v})=T(\mathbf{v}')$, so $\mathbf{v}-\mathbf{v}'\in\ker T\subseteq U$, hence $\mathbf{v}+U=\mathbf{v}'+U$."

Find the error, and give an example with $V=W=\mathbb{R}^2$ in which the formula does not define a function on V/U. What hypothesis would make the definition correct?

Solution on page 1346

Exercise 4.6.44. STANDARD Let U be a subspace of V, where V may be infinite-dimensional.

(a) Show that $\dim(V/U)=1$ if and only if $U=\ker f$ for some nonzero linear map $f:V\to F$.

(b) Let $f,g:V\to F$ be nonzero linear maps. Show that $\ker f=\ker g$ if and only if $g=cf$ for some nonzero $c\in F$.

Solution on page 1347

Exercise 4.6.45. STANDARD Let $A\in F^{m\times n}$ and $B\in F^{p\times n}$. Show that $B=CA$ for some $C\in F^{p\times m}$ if and only if $\ker T_A\subseteq\ker T_B$.

Solution on page 1347

Exercise 4.6.46. HARD Let $T_1\in\mathrm{L}(V,W_1)$ and $T_2\in\mathrm{L}(V,W_2)$ be surjective, and let $T=(T_1,T_2):V\to W_1\times W_2$.

(a) Show that $\ker T = \ker T_1 \cap \ker T_2$.

(b) Show that T is surjective if and only if $\ker T_1 + \ker T_2 = V$.

(c) Let U, W be subspaces of V. Show that $V \to V/U \times V/W$, $\mathbf{v} \mapsto (\mathbf{v}+U, \mathbf{v}+W)$, has kernel $U \cap W$, and is surjective if and only if $U + W = V$. Deduce that if $U + W = V$, then $V/(U \cap W) \cong V/U \times V/W$.

Solution on page 1348

Exercise 4.6.47. STANDARD Let $U_1, \ldots, U_m$ be subspaces of V such that each V/U_i is finite-dimensional. Here V may be infinite-dimensional.

(a) Show that $V/(U_1 \cap \cdots \cap U_m)$ is finite-dimensional and

$$\dim(V/(U_1 \cap \cdots \cap U_m)) \leq \dim(V/U_1) + \cdots + \dim(V/U_m).$$

(b) Deduce that if V is finite-dimensional, then $\dim(U_1 \cap \cdots \cap U_m) \geq \dim U_1 + \cdots + \dim U_m - (m-1)\dim V$.

(c) Show that any two 4-dimensional subspaces and any 3-dimensional subspace of F^5 have a nonzero vector in common.

Solution on page 1348

Exercise 4.6.48. STANDARD Let $n \geq 1$, and let $Z \subseteq F^{n \times n}$ be the set of matrices whose row sums and column sums are all 0. Let $\mathbf{1} = (1, \ldots, 1) \in F^n$. Use the map

$$\Phi : F^{n \times n} \to F^n \times F^n, \quad \Phi(A) = \left(A\mathbf{1}, A^{\mathsf{T}}\mathbf{1}\right),$$

to show that Z is a subspace of dimension $(n-1)^2$.

Solution on page 1349

Exercise 4.6.49. STANDARD Let U and W be subspaces of V.

(a) Show that $\mathbf{w} \mapsto \mathbf{w} + U$ is a surjective linear map $W \to (U+W)/U$ with kernel $U \cap W$, and deduce the **second isomorphism theorem**: $W/(U \cap W) \cong (U+W)/U$.

(b) Use (a) and Theorem 4.6.27 to give another proof of Theorem 4.4.19.

Solution on page 1349

Exercise 4.6.50. HARD Let U be a subspace of V, and let $\pi : V \to V/U$ be the quotient map. For a subspace X of V with $U \subseteq X$, write $X/U = \{\mathbf{x} + U \mid \mathbf{x} \in X\} \subseteq V/U$.

(a) Show that X/U is a subspace of V/U and that $\pi^{-1}(X/U) = X$.

(b) Show that every subspace Y of V/U equals X/U for exactly one subspace X of V containing U.

(c) (*Third isomorphism theorem.*) Show that $(V/U)/(X/U) \cong V/X$ whenever $U \subseteq X \subseteq V$.

(d) If V is finite-dimensional, show that $\dim(X/U) = \dim X - \dim U$.

Solution on page 1349

Exercise 4.6.51. HARD Let U and W be subspaces of V. For each statement, decide whether it holds when V is finite-dimensional, and whether it holds for all V.

(a) If $U \neq \{\mathbf{0}\}$, then $V/U \ncong V$.

(b) If $V/U \cong V/W$, then $U \cong W$.

(c) If $U \cong W$, then $V/U \cong V/W$.

Solution on page 1350

Exercise 4.6.52. HARD Let V be finite-dimensional, $T \in \mathrm{L}(V)$, and U a subspace with $T(U) \subseteq U$. Write $T_U \in \mathrm{L}(U)$ for $T|_U$ regarded as an operator on U, and T/U for the induced operator on V/U (Proposition 4.6.32).

(a) Show that $\operatorname{rank} T \geq \operatorname{rank} T_U + \operatorname{rank}(T/U)$.

(b) Show that equality holds if and only if $\operatorname{im} T \cap U = T(U)$.

(c) Give an example where the inequality is strict. What does (a) say about block upper triangular matrices?

Solution on page 1351

Exercise 4.6.53. HARD Reprove Frobenius's rank inequality (Exercise 4.3.31(a)) with quotients: for $A \in F^{m\times n}$, $B \in F^{n\times p}$, and $C \in F^{p\times q}$,

$$\operatorname{rank}(AB) + \operatorname{rank}(BC) \leq \operatorname{rank} B + \operatorname{rank}(ABC).$$

Use the map $\operatorname{im} T_B/\operatorname{im} T_{BC} \to \operatorname{im} T_{AB}/\operatorname{im} T_{ABC}$ induced by T_A.

Solution on page 1351

Exercise 4.6.54. HARD Let F be a field with q elements, let V be an n-dimensional space over F, and let U be a subspace of dimension k. Fix one complement W_0 of U.

(a) For $S \in \mathrm{L}(W_0, U)$, show that $W_S = \{\mathbf{w} + S(\mathbf{w}) \mid \mathbf{w} \in W_0\}$ is a complement of U.

(b) Show that every complement of U is W_S for exactly one $S \in \mathrm{L}(W_0, U)$.

(c) Deduce that U has exactly $q^{k(n-k)}$ complements. How many lines in $\mathbb{F}_3^2$ are complements of a given line?

Solution on page 1352

Exercise 4.6.55. CHALLENGE Let U be a subspace of $F[x]$ with $U \neq \{\mathbf{0}\}$ and $xp \in U$ for every $p \in U$. Let d be the smallest degree of a nonzero element of U.

(a) Show that U contains a polynomial $p = x^d + c_{d-1}x^{d-1} + \cdots + c_1 x + c_0$, and that $F[x]_{\leq d-1}$ is a complement of U (read $F[x]_{\leq -1}$ as $\{\mathbf{0}\}$). Conclude that $\dim(F[x]/U) = d$.

(b) Suppose $d \geq 1$. Show that multiplication by x induces an operator X on $F[x]/U$ with $X(q+U) = xq + U$, and find the matrix of X in the basis $1+U, x+U, \ldots, x^{d-1}+U$.

Solution on page 1352

4.7 Affine geometry BEYOND 21-242

The solution set of a linear system $A\mathbf{x} = \mathbf{y}$ with $\mathbf{y} \neq \mathbf{0}$ is never a subspace, but by Proposition 3.1.19 it is the next best thing: the subspace $\ker T_A$, slid over so that it passes through one solution. Lines and planes that miss the origin are sets of this kind, and so is the screen of a computer, which has no preferred origin either. On such a set the sum of two points means nothing (the sum of two solutions of $A\mathbf{x} = \mathbf{y}$ solves $A\mathbf{x} =$

$2\mathbf{y}$), yet some combinations of points, such as midpoints, make perfect sense. This section finds out which combinations these are, and which maps respect them. Its last part, homogeneous coordinates, turns this affine geometry back into linear algebra one dimension up, which is how graphics software moves and projects three-dimensional scenes.

4.7.1 Affine subspaces

Recall the translate $\mathbf{v} + U = \{\mathbf{v} + \mathbf{u} \mid \mathbf{u} \in U\}$ of a subset $U \subseteq V$ (Notation 3.1.17).

Definition 4.7.1 (Affine subspace). Let V be a vector space over F. A subset $E \subseteq V$ is an **affine subspace** of V if $E = \mathbf{v} + U$ for some $\mathbf{v} \in V$ and some subspace U of V.

An affine subspace contains $\mathbf{v} = \mathbf{v} + \mathbf{0}$, so it is never empty. Some authors count $\emptyset$ as an affine subspace as well, which makes statements about intersections shorter; we will say "empty or an affine subspace" where it matters. We use the letters E, E', E_i for affine subspaces and keep A and B for matrices.

Example 4.7.2 (Affine subspaces).

(a) Every subspace U is an affine subspace, since $U = \mathbf{0} + U$. Every single point is one, since $\{\mathbf{v}\} = \mathbf{v} + \{\mathbf{0}\}$.

(b) If the system $A\mathbf{x} = \mathbf{y}$ has a solution $\mathbf{x}_0$, its solution set $\mathbf{x}_0 + \ker T_A$ is an affine subspace of F^n (Proposition 3.1.19). More generally, every nonempty fiber $T^{-1}(\mathbf{w})$ of a linear map $T : V \to W$ is one (Corollary 2.6.31).

(c) In $\mathbb{R}^2$, the line $x_1 + x_2 = 2$ is $(1, 1) + \operatorname{span}((1, -1))$.

(d) In $\mathbb{R}[x]$, the polynomials p with $p(1) = 1$ form the fiber over 1 of the linear map $p \mapsto p(1)$, so they form the affine subspace $1 + \{p \in \mathbb{R}[x] \mid p(1) = 0\}$. Here 1 is the constant polynomial.

The vector $\mathbf{v}$ in $E = \mathbf{v} + U$ is not determined by E, but the subspace U is, and every point of E can play the role of $\mathbf{v}$.

Proposition 4.7.3 (Direction and base points). Let $E = \mathbf{v} + U$ be an affine subspace of V.

(a) $U = \{\mathbf{a} - \mathbf{b} \mid \mathbf{a}, \mathbf{b} \in E\}$. In particular, if also $E = \mathbf{v}' + U'$ for some $\mathbf{v}' \in V$ and some subspace U', then $U' = U$.

(b) $E = \mathbf{a} + U$ for every $\mathbf{a} \in E$.

(c) For $\mathbf{w} \in V$, the conditions $\mathbf{w} + U = E$, $\mathbf{w} \in E$, and $\mathbf{w} - \mathbf{v} \in U$ are equivalent.

Proof. ROUTINE

Uses. Definition 4.7.1 (Affine subspace), Notation 3.1.17 (Translates), Definition 1.4.1 (Subspace)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For (a), write two points of E as $\mathbf{v} + \mathbf{u}$ and $\mathbf{v} + \mathbf{u}'$. For the reverse containment, write $\mathbf{u} \in U$ as a difference of two points of E.
Hint 2. For (b), write $\mathbf{a} = \mathbf{v} + \mathbf{u}_0$ and prove both containments, moving $\mathbf{u}_0$ from one side to the other.
Hint 3. For (c), go around the cycle of the three conditions; (a) and (b) do the work.
Sketch. (a) $(\mathbf{v} + \mathbf{u}) - (\mathbf{v} + \mathbf{u}') = \mathbf{u} - \mathbf{u}' \in U$, and $\mathbf{u} = (\mathbf{v} + \mathbf{u}) - (\mathbf{v} + \mathbf{0})$. The set of differences depends only on E, so it is U however E is written. (b) If $\mathbf{a} = \mathbf{v} + \mathbf{u}_0$, then $\mathbf{a} + \mathbf{u} = \mathbf{v} + (\mathbf{u}_0 + \mathbf{u})$ and $\mathbf{v} + \mathbf{u} = \mathbf{a} + (\mathbf{u} - \mathbf{u}_0)$. (c) $\mathbf{w} + U = E$ gives $\mathbf{w} = \mathbf{w} + \mathbf{0} \in E$; $\mathbf{w} \in E$ gives $\mathbf{w} - \mathbf{v} \in U$ by (a); and $\mathbf{w} - \mathbf{v} \in U$ gives $\mathbf{w} \in E$, so $\mathbf{w} + U = E$ by (b).

(a) The points of E are the vectors $\mathbf{v} + \mathbf{u}$ with $\mathbf{u} \in U$. For two of them, $(\mathbf{v} + \mathbf{u}) - (\mathbf{v} + \mathbf{u}') = \mathbf{u} - \mathbf{u}'$, which lies in U because U is a subspace. Conversely, every $\mathbf{u} \in U$ is the difference $(\mathbf{v} + \mathbf{u}) - (\mathbf{v} + \mathbf{0})$ of two points of E. So U equals the set D of differences of points of E. The set D is defined in terms of E alone, so if also $E = \mathbf{v}' + U'$, the same argument gives $U' = D = U$.

(b) Let $\mathbf{a} \in E$, say $\mathbf{a} = \mathbf{v} + \mathbf{u}_0$ with $\mathbf{u}_0 \in U$. For $\mathbf{u} \in U$,

$$\mathbf{a} + \mathbf{u} = \mathbf{v} + (\mathbf{u}_0 + \mathbf{u}) \in \mathbf{v} + U \quad \text{and} \quad \mathbf{v} + \mathbf{u} = \mathbf{a} + (\mathbf{u} - \mathbf{u}_0) \in \mathbf{a} + U,$$

because $\mathbf{u}_0 + \mathbf{u}$ and $\mathbf{u} - \mathbf{u}_0$ lie in U. So $\mathbf{a} + U = \mathbf{v} + U = E$.

(c) If $\mathbf{w} + U = E$, then $\mathbf{w} = \mathbf{w} + \mathbf{0} \in E$. If $\mathbf{w} \in E$, then $\mathbf{w} - \mathbf{v}$ is a difference of two points of E (as $\mathbf{v} = \mathbf{v} + \mathbf{0} \in E$), so it lies in U by (a). If $\mathbf{w} - \mathbf{v} \in U$, then $\mathbf{w} = \mathbf{v} + (\mathbf{w} - \mathbf{v}) \in E$, and $\mathbf{w} + U = E$ by (b). □

Technique 4.7.4 (Choose a base point). An affine subspace has no origin of its own, but by Proposition 4.7.3(b) any of its points can serve as one. Once a point $\mathbf{a} \in E$ is fixed, $\mathbf{x} \mapsto \mathbf{x} - \mathbf{a}$ carries E onto the subspace $U = E - \mathbf{a}$, and statements about E become statements about U, where linear algebra applies. Every point of E works equally well, so choose the most convenient one, such as a point that two affine subspaces have in common, or a fixed point of a map.

Reach for it whenever an affine question has a linear counterpart that you already know how to answer. The canonical example is Proposition 4.7.10. The same move drives Theorem 4.7.14, Proposition 4.7.17, and Theorem 4.7.37.

Used in. Corollary 4.7.6, Proposition 4.7.10, Theorem 4.7.14, Proposition 4.7.17, Proposition 4.7.20, Theorem 4.7.37, Proposition 4.7.38, Theorem 4.7.39, Theorem 8.4.31, Exercise 8.4.46.

Definition 4.7.5 (Direction, dimension, parallel). Let E be an affine subspace of V. The subspace U with $E = \mathbf{v} + U$, which is unique by Proposition 4.7.3(a), is the **direction** of E, written $\operatorname{dir} E$. If $\operatorname{dir} E$ is finite-dimensional, the **dimension** of E is $\dim E = \dim \operatorname{dir} E$. Affine subspaces of dimension 0, 1, and 2 are called **points**, **lines**, and **planes**; if $\dim V = n$, those of dimension $n - 1$ are called **hyperplanes**. Two affine subspaces E and E' of V are **parallel** if $\operatorname{dir} E = \operatorname{dir} E'$.

A subspace U has direction U, so its dimension is the same whether we regard it as a subspace or as an affine subspace. A line is a set $\mathbf{v} + \operatorname{span}(\mathbf{u}) = \{\mathbf{v} + t\mathbf{u} \mid t \in F\}$ with $\mathbf{u} \neq \mathbf{0}$.

Corollary 4.7.6 (Parallel affine subspaces are equal or disjoint). If E and E' are parallel affine subspaces of V, then $E = E'$ or $E \cap E' = \emptyset$. Given a subspace U of V, every $\mathbf{v} \in V$ lies in exactly one translate of U, namely $\mathbf{v} + U$.

Proof. ROUTINE

Uses. Proposition 4.7.3 (Direction and base points)
Techniques. Choose a base point (Technique 4.7.4)
Hint. Suppose some $\mathbf{c}$ lies in both. Use $\mathbf{c}$ as the base point of each.
Sketch. If $\mathbf{c} \in E \cap E'$, then $E = \mathbf{c} + U = E'$ by Proposition 4.7.3(b), where U is the common direction. For the second claim, $\mathbf{v} \in \mathbf{v} + U$, and a translate $\mathbf{w} + U$ containing $\mathbf{v}$ equals $\mathbf{v} + U$ by the same result.

Let $U = \operatorname{dir} E = \operatorname{dir} E'$. If $\mathbf{c} \in E \cap E'$, then $E = \mathbf{c} + U$ and $E' = \mathbf{c} + U$ by Proposition 4.7.3(b), so $E = E'$. For the second statement, $\mathbf{v} = \mathbf{v} + \mathbf{0} \in \mathbf{v} + U$, and if $\mathbf{v} \in \mathbf{w} + U$, then Proposition 4.7.3(b), applied to the affine subspace $\mathbf{w} + U$ and its point $\mathbf{v}$, gives $\mathbf{w} + U = \mathbf{v} + U$. □

So the translates of a subspace U cut V into disjoint parallel pieces, as the solution sets in Figure 3.1.4 do. They are the elements of the quotient space V/U (Definition 4.6.20), which treats each translate as a single vector.

Non-example 4.7.7 (Sets that are not affine subspaces).

(a) The unit circle $C = \left\{\mathbf{x} \in \mathbb{R}^2 \;\middle|\; x_1^2 + x_2^2 = 1\right\}$. If C were an affine subspace, then $(1,0) - (-1,0) = (2,0)$ would lie in $\operatorname{dir} C$ by Proposition 4.7.3(a), and $C = (1,0) + \operatorname{dir} C$ by (b). Then $(3,0) = (1,0) + (2,0) \in C$, which is false.

(b) The union E of the lines $x_2 = 0$ and $x_2 = 1$ in $\mathbb{R}^2$. If E were an affine subspace, then $(0,1) - (0,0) \in \operatorname{dir} E$, so $(0,0) + 2(0,1) = (0,2)$ would lie in E.

(c) The three-point set $\{(0,0), (1,0), (0,1)\} \subseteq \mathbb{F}_2^2$ (Exercise 3.1.48).

Solution sets, revisited

Proposition 3.1.19 says that consistent linear systems have affine solution sets. With dimension theory we can now say how large they are, and show that every affine subspace of F^n arises this way.

Theorem 4.7.8 (Affine subspaces of F^n are solution sets).

(a) Let $A \in F^{m\times n}$ and $\mathbf{y} \in F^m$. If the system $A\mathbf{x} = \mathbf{y}$ is consistent, its solution set is an affine subspace of F^n with direction $\ker T_A$ and dimension $n - \operatorname{rank} A$.

(b) Conversely, let E be an affine subspace of F^n of dimension k. Then E is the solution set of a system $A\mathbf{x} = \mathbf{y}$ with $A \in F^{(n-k)\times n}$, that is, of $n-k$ equations. No system of fewer than $n-k$ equations has solution set E.

Proof. STANDARD

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 4.2.23 (Dimension of solution sets), Proposition 4.4.16 (Complements exist), Theorem 4.4.19 (Dimension of a sum), Proposition 4.4.18 (Every subspace is a kernel and an image), Theorem 4.5.6 (Classification by dimension), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Theorem 4.2.7 (The image of T_A), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Particular plus homogeneous (Technique 3.1.18), Dimension counting (Technique 4.2.24)
Hint 1. (a) is Proposition 3.1.19 plus a dimension count.
Hint 2. For (b), write $E = \mathbf{v} + U$. It suffices to find $A \in F^{(n-k)\times n}$ with $\ker T_A = U$, and then to take $\mathbf{y} = A\mathbf{v}$.
Hint 3. Every subspace is a kernel (Proposition 4.4.18), but of an operator $F^n \to F^n$, whose image is a complement W of U. Follow it by an isomorphism $W \to F^{n-k}$.
Sketch. (a) The solution set is $\mathbf{x}_0 + \ker T_A$, and $\dim \ker T_A = n - \operatorname{rank} A$. (b) Let $E = \mathbf{v} + U$ and let W be a complement of U, so $\dim W = n - k$. Take $T \in \mathrm{L}(F^n)$ with $\ker T = U$ and $\operatorname{im} T = W$, and an isomorphism $\varphi : W \to F^{n-k}$. Then $\varphi \circ T$ has kernel U and equals T_A with $A \in F^{(n-k)\times n}$, and $A\mathbf{x} = A\mathbf{v}$ has solution set $\mathbf{v} + U = E$. With m equations, (a) gives $k = n - \operatorname{rank} A \geq n - m$.

(a) By Proposition 3.1.19, the solution set is $\mathbf{x}_0 + \ker T_A$ for any solution $\mathbf{x}_0$, an affine subspace with direction $\ker T_A$. By Corollary 4.2.23(a), $\dim \ker T_A = n - \operatorname{rank} A$.

(b) Write $E = \mathbf{v} + U$ with $U = \operatorname{dir} E$, so $\dim U = k$. By Proposition 4.4.16, U has a complement W in F^n. Since $U \cap W = \{\mathbf{0}\}$ and $U + W = F^n$, Theorem 4.4.19 gives $\dim W = n - k$. By Proposition 4.4.18 there is $T \in \mathrm{L}(F^n)$ with $\ker T = U$ and $\operatorname{im} T = W$, and by Theorem 4.5.6 there is an isomorphism $\varphi : W \to F^{n-k}$. The map $S : F^n \to F^{n-k}$, $S(\mathbf{x}) = \varphi(T(\mathbf{x}))$, is linear, and since φ is injective, $S(\mathbf{x}) = \mathbf{0}$ if and only if $T(\mathbf{x}) = \mathbf{0}$. So $\ker S = U$. By Proposition 2.3.17, $S = T_A$ for some $A \in F^{(n-k)\times n}$. Put $\mathbf{y} = A\mathbf{v}$. Then $\mathbf{v}$ solves $A\mathbf{x} = \mathbf{y}$, and by Proposition 3.1.19 the solution set is $\mathbf{v} + \ker T_A = \mathbf{v} + U = E$.

Finally, suppose E is the solution set of a system $A'\mathbf{x} = \mathbf{y}'$ with $A' \in F^{m\times n}$. By (a), $k = n - \operatorname{rank} A'$. Since $\operatorname{im} T_{A'}$ is a subspace of F^m, Theorem 4.2.7 and Proposition 4.1.21 give $\operatorname{rank} A' = \dim \operatorname{im} T_{A'} \leq m$. Hence $k \geq n - m$, that is, $m \geq n - k$. □

For $k = n - 1$ this says that the hyperplanes of F^n are exactly the solution sets of single equations $a_1x_1 + \cdots + a_nx_n = c$ with $(a_1, \ldots, a_n) \neq \mathbf{0}$. (Such an equation is consistent, since $x_j = c/a_j$ and $x_i = 0$ for $i \neq j$ solves it when $a_j \neq 0$, and its coefficient matrix has rank 1.)

Example 4.7.9 (A line in $\mathbb{R}^3$ as a solution set). Let E be the line through $(1, 2, 0)$ with direction $\operatorname{span}((1, 1, 1))$. By Theorem 4.7.8(b), two equations cut it out. We need $A \in \mathbb{R}^{2\times 3}$ of rank 2 with $(1, 1, 1) \in \ker T_A$. The rows (a_1, a_2, a_3) must satisfy $a_1 + a_2 + a_3 = 0$ and be independent, so take $(1, -1, 0)$ and $(0, 1, -1)$. Then $A(1, 2, 0) = (-1, 2)$, and E is the solution set of

$$x_1 - x_2 = -1, \quad x_2 - x_3 = 2.$$

Indeed, the solution set contains $(1, 2, 0)$, and its direction $\ker T_A$ contains $(1, 1, 1)$ and has dimension $3 - 2 = 1$, so it equals $\operatorname{span}((1, 1, 1))$ by Proposition 4.1.21(b).

Intersections

Proposition 4.7.10 (Intersections of affine subspaces). Let $(E_i)_{i\in I}$ be a family of affine subspaces of V, indexed by a nonempty set I. Then $\bigcap_{i\in I} E_i$ is either empty or an affine subspace with direction $\bigcap_{i\in I} \operatorname{dir} E_i$.

Proof. ROUTINE

Uses. Proposition 4.7.3 (Direction and base points), Proposition 1.4.16 (Intersections of subspaces)
Techniques. Choose a base point (Technique 4.7.4), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. If the intersection is nonempty, pick a point $\mathbf{c}$ in it. How does each E_i look when $\mathbf{c}$ is used as its base point?
Hint 2. $E_i = \mathbf{c} + \operatorname{dir} E_i$, so $\mathbf{x} \in E_i$ if and only if $\mathbf{x} - \mathbf{c} \in \operatorname{dir} E_i$.
Sketch. With $\mathbf{c}$ in the intersection, $E_i = \mathbf{c} + U_i$ for every i. So $\mathbf{x}$ lies in every E_i if and only if $\mathbf{x} - \mathbf{c}$ lies in every U_i, and the intersection is $\mathbf{c} + \bigcap U_i$, a translate of a subspace.

Suppose $\mathbf{c} \in \bigcap_{i\in I} E_i$, and let $U_i = \operatorname{dir} E_i$. By Proposition 4.7.3(b), $E_i = \mathbf{c} + U_i$ for every i. For $\mathbf{x} \in V$ we have $\mathbf{x} \in \mathbf{c} + U_i$ if and only if $\mathbf{x} - \mathbf{c} \in U_i$ (if $\mathbf{x} = \mathbf{c} + \mathbf{u}$, then $\mathbf{x} - \mathbf{c} = \mathbf{u}$; conversely $\mathbf{x} = \mathbf{c} + (\mathbf{x} - \mathbf{c})$). Hence $\mathbf{x}$ lies in every E_i if and only if $\mathbf{x} - \mathbf{c} \in \bigcap_i U_i$, that is,

$$\bigcap_{i\in I} E_i = \mathbf{c} + \bigcap_{i\in I} U_i.$$

By Proposition 1.4.16, $\bigcap_i U_i$ is a subspace, so the intersection is an affine subspace, and its direction is $\bigcap_i U_i$ by Proposition 4.7.3(a). □

The choice of base point was the whole proof: a point common to all the E_i lets us write all of them as translates from one origin. Without such a point the intersection can be empty even when the directions have a large intersection, as for two distinct parallel lines. In $\mathbb{R}^3$ two lines can also miss each other without being parallel, for example the x_1-axis and $(0,0,1) + \operatorname{span}(\mathbf{e}_2)$; such lines are called **skew**. Exercise 4.7.53 characterizes skew lines, and Exercise 4.7.52 explains why a plane has none.

4.7.2 Affine combinations

Intuition (Which combinations make sense without an origin). Suppose we only know positions relative to some reference point $\mathbf{p}$, as on a screen or in a scene: the point $\mathbf{v}$ has position $\mathbf{v} - \mathbf{p}$. Combining positions with coefficients c_i and converting the result back into a point gives

$$\mathbf{p} + \sum_i c_i(\mathbf{v}_i - \mathbf{p}) = \sum_i c_i \mathbf{v}_i + \left(1 - \sum_i c_i\right)\mathbf{p}.$$

For two reference points $\mathbf{p}$ and $\mathbf{p}'$ the results differ by $\left(1 - \sum_i c_i\right)(\mathbf{p} - \mathbf{p}')$, so the result does not depend on the reference point exactly when the coefficients add up to 1. These are the weighted averages of points. Combinations whose coefficients add up to 0 are meaningful in a different way: $\sum_i c_i(\mathbf{v}_i - \mathbf{p}) = \sum_i c_i \mathbf{v}_i$ does not depend on $\mathbf{p}$, and it is a displacement rather than a point, like the difference $\mathbf{v} - \mathbf{u}$.

Definition 4.7.11 (Affine combination). An **affine combination** of $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$ is a linear combination $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k$ whose coefficients satisfy $c_1 + \cdots + c_k = 1$.

Example 4.7.12 (Affine combinations).

(a) For $\mathbf{u}, \mathbf{v} \in V$ and $t \in F$, $(1-t)\mathbf{u} + t\mathbf{v} = \mathbf{u} + t(\mathbf{v} - \mathbf{u})$. If $\mathbf{u} \neq \mathbf{v}$, these points form the line through $\mathbf{u}$ and $\mathbf{v}$. When $1 + 1 \neq 0$ in F, the case $t = 1/2$ is the **midpoint** $\frac{1}{2}\mathbf{u} + \frac{1}{2}\mathbf{v}$.

(b) If $k \cdot 1 \neq 0$ in F, the **centroid** $\frac{1}{k}(\mathbf{v}_1 + \cdots + \mathbf{v}_k)$ is an affine combination. Over $\mathbb{F}_3$, three points have no centroid.

(c) $\mathbf{u} - \mathbf{v} + \mathbf{w}$, with coefficients $1, -1, 1$, is the fourth vertex of the parallelogram with consecutive vertices $\mathbf{u}, \mathbf{v}, \mathbf{w}$: its differences with $\mathbf{w}$ and with $\mathbf{u}$ are $\mathbf{u} - \mathbf{v}$ and $\mathbf{w} - \mathbf{v}$.

(d) If $A\mathbf{x}_i = \mathbf{y}$ for $i = 1, \ldots, k$ and $\sum_i c_i = 1$, then $A\big(\sum_i c_i \mathbf{x}_i\big) = \big(\sum_i c_i\big)\mathbf{y} = \mathbf{y}$. So affine combinations of solutions are solutions, while the sum of two solutions is not.

Lemma 4.7.13 (Affine combinations do not depend on the origin). Let $\mathbf{v}_1, \ldots, \mathbf{v}_k, \mathbf{p} \in V$ and $c_1, \ldots, c_k \in F$.

(a) If $c_1 + \cdots + c_k = 1$, then $\sum_i c_i \mathbf{v}_i = \mathbf{p} + \sum_i c_i(\mathbf{v}_i - \mathbf{p})$.

(b) If $c_1 + \cdots + c_k = 0$, then $\sum_i c_i \mathbf{v}_i = \sum_i c_i(\mathbf{v}_i - \mathbf{p})$.

Proof. ROUTINE

Uses. Lemma 1.3.9 (Arithmetic of linear combinations)
Hint. Expand $\sum_i c_i(\mathbf{v}_i - \mathbf{p})$.
Sketch. $\sum_i c_i(\mathbf{v}_i - \mathbf{p}) = \sum_i c_i \mathbf{v}_i - \big(\sum_i c_i\big)\mathbf{p}$; substitute $\sum_i c_i = 1$ or 0.

By distributivity and Lemma 1.3.9, $\sum_i c_i(\mathbf{v}_i - \mathbf{p}) = \sum_i c_i \mathbf{v}_i - \big(\sum_i c_i\big)\mathbf{p}$. If $\sum_i c_i = 1$, this is $\sum_i c_i \mathbf{v}_i - \mathbf{p}$, and adding $\mathbf{p}$ gives (a). If $\sum_i c_i = 0$, it is $\sum_i c_i \mathbf{v}_i$, which is (b). □

Subspaces are the nonempty sets closed under linear combinations. Affine subspaces have the analogous description.

Theorem 4.7.14 (Affine subspaces are the sets closed under affine combinations). A nonempty subset $E \subseteq V$ is an affine subspace if and only if every affine combination of elements of E lies in E.

Intuition. The forward direction is a base point computation with Lemma 4.7.13(a). For the converse, the base point tells us what the direction must be: if $E = \mathbf{p} + U$ with $\mathbf{p} \in E$, then $U = \{\mathbf{e} - \mathbf{p} \mid \mathbf{e} \in E\}$. So define U this way and check the subspace criterion. Each closure property of U should come from one affine combination in E.

Proof. STANDARD

Uses. Lemma 4.7.13 (Affine combinations do not depend on the origin), Proposition 4.7.3 (Direction and base points), Theorem 1.4.3 (Subspace criterion)
Techniques. Choose a base point (Technique 4.7.4)
Hint 1. For ($\Rightarrow$), write $E = \mathbf{p} + U$ and each $\mathbf{e}_i = \mathbf{p} + \mathbf{u}_i$, and apply Lemma 4.7.13(a).
Hint 2. For ($\Leftarrow$), fix $\mathbf{p} \in E$ and put $U = \{\mathbf{e} - \mathbf{p} \mid \mathbf{e} \in E\}$. Then $E = \mathbf{p} + U$, and it remains to show that U is a subspace.
Hint 3. $c(\mathbf{e} - \mathbf{p}) = (c\mathbf{e} + (1-c)\mathbf{p}) - \mathbf{p}$ and $(\mathbf{e} - \mathbf{p}) + (\mathbf{e}' - \mathbf{p}) = (\mathbf{e} + \mathbf{e}' - \mathbf{p}) - \mathbf{p}$. The vectors in parentheses are affine combinations of points of E.
Sketch. ($\Rightarrow$) $\sum_i c_i(\mathbf{p} + \mathbf{u}_i) = \mathbf{p} + \sum_i c_i \mathbf{u}_i \in \mathbf{p} + U$. ($\Leftarrow$) With $U = E - \mathbf{p}$: $\mathbf{0} = \mathbf{p} - \mathbf{p} \in U$, $c(\mathbf{e} - \mathbf{p}) = (c\mathbf{e} + (1-c)\mathbf{p}) - \mathbf{p} \in U$, and $(\mathbf{e} - \mathbf{p}) + (\mathbf{e}' - \mathbf{p}) = (\mathbf{e} + \mathbf{e}' - \mathbf{p}) - \mathbf{p} \in U$, because $c\mathbf{e} + (1-c)\mathbf{p}$ and $\mathbf{e} + \mathbf{e}' - \mathbf{p}$ are affine combinations of elements of E.

($\Rightarrow$) Let $E = \mathbf{p} + U$ be an affine subspace, let $\mathbf{e}_1, \ldots, \mathbf{e}_k \in E$, and let $\sum_i c_i = 1$. Since $\mathbf{p} = \mathbf{p} + \mathbf{0} \in E$, each $\mathbf{u}_i = \mathbf{e}_i - \mathbf{p}$ lies in U by Proposition 4.7.3(a). By Lemma 4.7.13(a),

$$\sum_i c_i \mathbf{e}_i = \mathbf{p} + \sum_i c_i \mathbf{u}_i \in \mathbf{p} + U = E.$$

($\Leftarrow$) Suppose E is nonempty and closed under affine combinations. Fix $\mathbf{p} \in E$ and put $U = \{\mathbf{e} - \mathbf{p} \mid \mathbf{e} \in E\}$. Then $E = \mathbf{p} + U$, since each $\mathbf{e} \in E$ equals $\mathbf{p} + (\mathbf{e} - \mathbf{p})$. We check the conditions of Theorem 1.4.3 for U.

$\mathbf{0} \in U$, since $\mathbf{0} = \mathbf{p} - \mathbf{p}$.

Scalar multiples. Let $\mathbf{e} \in E$ and $c \in F$. The vector $c\mathbf{e} + (1-c)\mathbf{p}$ is an affine combination of $\mathbf{e}, \mathbf{p} \in E$, so it lies in E, and

$$c(\mathbf{e} - \mathbf{p}) = (c\mathbf{e} + (1-c)\mathbf{p}) - \mathbf{p} \in U.$$

Sums. Let $\mathbf{e}, \mathbf{e}' \in E$. The vector $\mathbf{e} + \mathbf{e}' - \mathbf{p}$ is an affine combination of $\mathbf{e}, \mathbf{e}', \mathbf{p}$, with coefficients $1 + 1 - 1 = 1$, so it lies in E, and

$$(\mathbf{e} - \mathbf{p}) + (\mathbf{e}' - \mathbf{p}) = (\mathbf{e} + \mathbf{e}' - \mathbf{p}) - \mathbf{p} \in U.$$

So U is a subspace, and $E = \mathbf{p} + U$ is an affine subspace. □

Remark 4.7.15 (Two points or three). The proof used affine combinations of two points, for scalar multiples, and of three points, for sums. The three-point combination cannot be dropped in general. When $1 + 1 \neq 0$, Exercise 3.1.48 showed that closure under combinations of two points (the lines through pairs of points) already forces a nonempty set to be affine, by way of midpoints. Over $\mathbb{F}_2$, the only affine combinations of two points $\mathbf{u}, \mathbf{v}$ are $\mathbf{u}$ and $\mathbf{v}$ themselves. The set $\{(0,0), (1,0), (0,1)\}$ is closed under them, but $(1,0) + (0,1) - (0,0) = (1,1)$ is missing. Exercise 4.7.61 shows that over $\mathbb{F}_2$ three points always suffice.

Definition 4.7.16 (Affine hull). The **affine hull** $\operatorname{aff} S$ of a subset $S \subseteq V$ is the set of all affine combinations of finitely many elements of S. For a list, $\operatorname{aff}(\mathbf{v}_0, \ldots, \mathbf{v}_k) = \operatorname{aff}\{\mathbf{v}_0, \ldots, \mathbf{v}_k\}$.

The empty set has no affine combinations, because an empty list of coefficients adds up to 0, so $\operatorname{aff} \emptyset = \emptyset$.

Proposition 4.7.17 (The affine hull). Let $S \subseteq V$ be nonempty, and let $\mathbf{v}_0, \ldots, \mathbf{v}_k \in V$.

(a) $\operatorname{aff} S$ is an affine subspace containing S, and it is contained in every affine subspace that contains S.

(b) $\operatorname{aff}(\mathbf{v}_0, \ldots, \mathbf{v}_k) = \mathbf{v}_0 + \operatorname{span}(\mathbf{v}_1 - \mathbf{v}_0, \ldots, \mathbf{v}_k - \mathbf{v}_0)$. In particular, $\dim \operatorname{aff}(\mathbf{v}_0, \ldots, \mathbf{v}_k) \leq k$.

Proof. STANDARD

Uses. Theorem 4.7.14 (Affine subspaces are the sets closed under affine combinations), Lemma 4.7.13 (Affine combinations do not depend on the origin), Theorem 1.6.10 (Every spanning list contains a basis)
Techniques. Choose a base point (Technique 4.7.4)
Hint 1. For (a), show that an affine combination of affine combinations of elements of S is again one. List all the elements of S involved once, padding with zero coefficients.
Hint 2. For (b), use $\mathbf{v}_0$ as base point: Lemma 4.7.13(a) with $\mathbf{p} = \mathbf{v}_0$ rewrites $\sum_i c_i \mathbf{v}_i$.
Sketch. (a) If $\mathbf{w}_j = \sum_i a_{ij}\mathbf{s}_i$ with $\sum_i a_{ij} = 1$ and $\sum_j d_j = 1$, then $\sum_j d_j \mathbf{w}_j = \sum_i \big(\sum_j d_j a_{ij}\big)\mathbf{s}_i$, whose coefficients add up to $\sum_j d_j = 1$. So $\operatorname{aff} S$ is closed under affine combinations, hence affine by Theorem 4.7.14, and every affine subspace containing S is closed under them, hence contains $\operatorname{aff} S$. (b) By Lemma 4.7.13(a), $\sum_i c_i \mathbf{v}_i = \mathbf{v}_0 + \sum_{i \geq 1} c_i(\mathbf{v}_i - \mathbf{v}_0)$, and conversely $\mathbf{v}_0 + \sum_{i \geq 1} a_i(\mathbf{v}_i - \mathbf{v}_0) = \big(1 - \sum_i a_i\big)\mathbf{v}_0 + \sum_{i \geq 1} a_i \mathbf{v}_i$.

(a) Each $\mathbf{s} \in S$ is the affine combination $1\mathbf{s}$, so $S \subseteq \operatorname{aff} S$, and $\operatorname{aff} S$ is nonempty. Let $\mathbf{w}_1, \ldots, \mathbf{w}_m \in \operatorname{aff} S$ and $d_1 + \cdots + d_m = 1$. Each $\mathbf{w}_j$ is an affine combination of finitely many elements of S. Let $\mathbf{s}_1, \ldots, \mathbf{s}_N$ list all elements of S that occur in any of these combinations, and pad with zero coefficients, so that $\mathbf{w}_j = \sum_{i=1}^N a_{ij}\mathbf{s}_i$ with $\sum_i a_{ij} = 1$ for every j. Then

$$\sum_j d_j \mathbf{w}_j = \sum_{i=1}^N \left(\sum_j d_j a_{ij} \right) \mathbf{s}_i, \quad \text{and} \quad \sum_i \sum_j d_j a_{ij} = \sum_j d_j \sum_i a_{ij} = \sum_j d_j = 1.$$

So $\operatorname{aff} S$ is closed under affine combinations, and it is an affine subspace by Theorem 4.7.14. If E is an affine subspace with $S \subseteq E$, then E is closed under affine combinations by the same theorem, so it contains every affine combination of elements of S, that is, $\operatorname{aff} S \subseteq E$.

(b) If $c_0 + \cdots + c_k = 1$, then Lemma 4.7.13(a) with $\mathbf{p} = \mathbf{v}_0$ gives

$$\sum_{i=0}^{k} c_i \mathbf{v}_i = \mathbf{v}_0 + \sum_{i=1}^{k} c_i(\mathbf{v}_i - \mathbf{v}_0),$$

because the term with $i = 0$ is $c_0(\mathbf{v}_0 - \mathbf{v}_0) = \mathbf{0}$. So $\operatorname{aff}(\mathbf{v}_0, \ldots, \mathbf{v}_k) \subseteq \mathbf{v}_0 + \operatorname{span}(\mathbf{v}_1 - \mathbf{v}_0, \ldots, \mathbf{v}_k - \mathbf{v}_0)$. Conversely, for $a_1, \ldots, a_k \in F$,

$$\mathbf{v}_0 + \sum_{i=1}^{k} a_i(\mathbf{v}_i - \mathbf{v}_0) = (1 - a_1 - \cdots - a_k)\mathbf{v}_0 + a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k,$$

an affine combination of $\mathbf{v}_0, \ldots, \mathbf{v}_k$. Hence the two sets are equal. The direction $\operatorname{span}(\mathbf{v}_1 - \mathbf{v}_0, \ldots, \mathbf{v}_k - \mathbf{v}_0)$ is spanned by a list of length k, which contains a basis (Theorem 1.6.10), so its dimension is at most k. □

For two points $\mathbf{u} \neq \mathbf{v}$, (b) gives $\operatorname{aff}(\mathbf{u}, \mathbf{v}) = \mathbf{u} + \operatorname{span}(\mathbf{v} - \mathbf{u}) = \{(1 - t)\mathbf{u} + t\mathbf{v} \mid t \in F\}$, the line through them. Over $\mathbb{F}_2$ this line consists of $\mathbf{u}$ and $\mathbf{v}$ alone. Three points of $\mathbb{R}^3$ that do not lie on one line have a plane as their affine hull.

4.7.3 Affine independence and barycentric coordinates

Intuition (From linear to affine independence). By Proposition 4.7.17(b), $k + 1$ points have an affine hull of dimension at most k: two points span at most a line, three at most a plane. The points are in general position when they reach this bound, which by Proposition 4.7.17(b) means that the differences $\mathbf{v}_i - \mathbf{v}_0$ are linearly independent. That description singles out $\mathbf{v}_0$. For a definition that treats all points alike, imitate linear independence, which asks that the only linear relation be the trivial one (Theorem 1.5.5). For points, only relations whose coefficients add up to 0 are meaningful (the intuition at the start of Section 4.7.2), so we test only those.

Definition 4.7.18 (Affine independence). A list $\mathbf{v}_0, \ldots, \mathbf{v}_k$ in V is **affinely independent** if the only scalars $c_0, \ldots, c_k \in F$ with

$$c_0\mathbf{v}_0 + \cdots + c_k\mathbf{v}_k = \mathbf{0} \quad \text{and} \quad c_0 + \cdots + c_k = 0$$

are $c_0 = \cdots = c_k = 0$. Otherwise the list is **affinely dependent**, and a relation of this form with some $c_i \neq 0$ is an **affine dependence**.

Example 4.7.19 (Affine independence).

(a) A single point is affinely independent, since $c_0 = 0$ is forced by the coefficient sum. Two points $\mathbf{u}, \mathbf{v}$ are affinely independent if and only if $\mathbf{u} \neq \mathbf{v}$: a relation with coefficients $c, -c$ says $c(\mathbf{u} - \mathbf{v}) = \mathbf{0}$.

(b) The points $(0, 0), (1, 0), (0, 1)$ of $\mathbb{R}^2$ are affinely independent: $c_0(0, 0) + c_1(1, 0) + c_2(0, 1) = (c_1, c_2)$, so a relation has $c_1 = c_2 = 0$, and then $c_0 = 0$. The list is linearly dependent, since it contains $\mathbf{0}$.

(c) The points $(0, 0), (1, 1), (3, 3)$ are affinely dependent: $-2(0, 0) + 3(1, 1) - (3, 3) = \mathbf{0}$, and $-2 + 3 - 1 = 0$. They lie on one line.

An affine dependence is in particular a linear relation, so a linearly independent list is affinely independent; (b) shows that the converse fails. Unlike linear independence, affine independence does not change when all points are moved by the same vector $\mathbf{w}$: by Lemma 4.7.13(b) with $\mathbf{p} = -\mathbf{w}$, $\sum_i c_i(\mathbf{v}_i + \mathbf{w}) = \sum_i c_i\mathbf{v}_i$ whenever $\sum_i c_i = 0$.

Proposition 4.7.20 (Affine independence through differences). A list $\mathbf{v}_0, \ldots, \mathbf{v}_k$ in V is affinely independent if and only if $\mathbf{v}_1 - \mathbf{v}_0, \ldots, \mathbf{v}_k - \mathbf{v}_0$ is linearly independent.

Proof (translate the relations). ROUTINE

Uses. Definition 4.7.18 (Affine independence), Theorem 1.5.5 (Independence is decided at zero), Lemma 4.7.13 (Affine combinations do not depend on the origin)
Techniques. Choose a base point (Technique 4.7.4)
Hint 1. A linear relation among the differences, $\sum_{i\geq 1} a_i(\mathbf{v}_i - \mathbf{v}_0) = \mathbf{0}$, expands to a relation among $\mathbf{v}_0, \dots, \mathbf{v}_k$. What are its coefficients, and what is their sum?
Hint 2. Conversely, an affine dependence has $c_0 = -(c_1 + \cdots + c_k)$. Use Lemma 4.7.13(b) with $\mathbf{p} = \mathbf{v}_0$.
Sketch. $\sum_{i\geq 1} a_i(\mathbf{v}_i - \mathbf{v}_0) = \big(-\sum_i a_i\big)\mathbf{v}_0 + \sum_{i\geq 1} a_i\mathbf{v}_i$ has coefficient sum 0. So the linear relations among the differences are the affine relations among the points, read with $c_0 = -\sum_{i\geq 1} c_i$, and trivial ones correspond to trivial ones.

(⇒) Suppose $\mathbf{v}_0, \dots, \mathbf{v}_k$ is affinely independent, and let $\sum_{i=1}^{k} a_i(\mathbf{v}_i - \mathbf{v}_0) = \mathbf{0}$. Expanding,

$$(-a_1 - \cdots - a_k)\mathbf{v}_0 + a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0},$$

and the coefficients add up to 0. By affine independence they are all 0; in particular $a_1 = \cdots = a_k = 0$. So the differences are linearly independent by Theorem 1.5.5.

(⇐) Suppose the differences are linearly independent, and let $\sum_{i=0}^{k} c_i\mathbf{v}_i = \mathbf{0}$ with $\sum_{i=0}^{k} c_i = 0$. By Lemma 4.7.13(b) with $\mathbf{p} = \mathbf{v}_0$, $\sum_{i=0}^{k} c_i(\mathbf{v}_i - \mathbf{v}_0) = \mathbf{0}$, and the term with $i = 0$ is $\mathbf{0}$, so $\sum_{i=1}^{k} c_i(\mathbf{v}_i - \mathbf{v}_0) = \mathbf{0}$. Hence $c_1 = \cdots = c_k = 0$, and $c_0 = -(c_1 + \cdots + c_k) = 0$. □

The first approach singles out $\mathbf{v}_0$. The second treats all points alike, at the price of a larger space: it turns each point into a vector one dimension up, so that affine relations become linear relations. For a vector space V, the set $V \times F$ of pairs $(\mathbf{v}, a)$ with the componentwise operations $(\mathbf{v}, a) + (\mathbf{w}, b) = (\mathbf{v} + \mathbf{w}, a + b)$ and $c(\mathbf{v}, a) = (c\mathbf{v}, ca)$ is a vector space, because each axiom holds in each component separately. (Product spaces are studied in Section 4.6.) For $V = F^n$ it is F^{n+1}, with $(\mathbf{v}, a)$ the vector whose last entry is a.

Technique 4.7.21 (Homogenize: add a coordinate 1). To turn an affine problem into a linear one without choosing a base point, replace each point $\mathbf{v}$ by its lift $\hat{\mathbf{v}} = (\mathbf{v}, 1)$ in $V \times F$, or in F^{n+1} if $V = F^n$. Then

$$\sum_i c_i\hat{\mathbf{v}}_i = \left(\sum_i c_i\mathbf{v}_i, \sum_i c_i\right),$$

so the last coordinate records the coefficient sum. Affine combinations of points are the linear combinations of their lifts that land in the hyperplane "last coordinate 1", and affine dependences are the linear relations among the lifts. Row reduction, rank, and matrices then apply directly.

Reach for it when you want to treat all points symmetrically, or when you want affine maps to become matrix multiplication. The canonical example is the second approach to Proposition 4.7.20. Homogeneous coordinates (Section 4.7.6) apply the same idea to maps.
Used in. Proposition 4.7.20, Theorem 4.7.42, Exercise 4.7.58.

Proof (lift to one dimension higher). STANDARD

Uses. Definition 4.7.18 (Affine independence), Proposition 1.5.18 (Operations that preserve independence), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Homogenize: add a coordinate 1 (Technique 4.7.21)
Hint 1. Compute $\sum_i c_i(\mathbf{v}_i, 1)$ in $V \times F$. What does it say about affine dependences?
Hint 2. The lifts are linearly independent exactly when the points are affinely independent. Now subtract the first lift from the others; Proposition 1.5.18 says that independence does not change.
Sketch. $\sum_i c_i\hat{\mathbf{v}}_i = \big(\sum_i c_i\mathbf{v}_i, \sum_i c_i\big)$, so the points are affinely independent if and only if their lifts are linearly independent, if and only if (by Proposition 1.5.18(c)) $(\mathbf{v}_0, 1), (\mathbf{v}_1 - \mathbf{v}_0, 0), \dots, (\mathbf{v}_k - \mathbf{v}_0, 0)$ is. In a relation among these, the last coordinate forces the first coefficient to be 0, so this list is independent if and only if the differences are.

Let $\hat{\mathbf{v}}_i = (\mathbf{v}_i, 1) \in V \times F$. For $c_0, \dots, c_k \in F$,

$$\sum_{i=0}^{k} c_i\hat{\mathbf{v}}_i = \left(\sum_i c_i\mathbf{v}_i, \sum_i c_i\right),$$

so $\sum_i c_i \hat{\mathbf{v}}_i = \mathbf{0}$ if and only if $\sum_i c_i \mathbf{v}_i = \mathbf{0}$ and $\sum_i c_i = 0$. Thus the affine dependences of $\mathbf{v}_0, \dots, \mathbf{v}_k$ are exactly the nontrivial linear relations of $\hat{\mathbf{v}}_0, \dots, \hat{\mathbf{v}}_k$, and the points are affinely independent if and only if their lifts are linearly independent.

Replacing $\hat{\mathbf{v}}_i$ by $\hat{\mathbf{v}}_i + (-1)\hat{\mathbf{v}}_0$ for $i = 1, \dots, k$, one at a time, does not change linear independence (Proposition 1.5.18(c)). The new list is

$$(\mathbf{v}_0, 1), (\mathbf{u}_1, 0), \dots, (\mathbf{u}_k, 0), \quad \text{where } \mathbf{u}_i = \mathbf{v}_i - \mathbf{v}_0.$$

If $a_0(\mathbf{v}_0, 1) + \sum_{i=1}^{k} a_i(\mathbf{u}_i, 0) = \mathbf{0}$, the last coordinate gives $a_0 = 0$, and then $\sum_i a_i \mathbf{u}_i = \mathbf{0}$. So if $\mathbf{u}_1, \dots, \mathbf{u}_k$ is independent, every such relation is trivial. Conversely, a relation $\sum_i a_i \mathbf{u}_i = \mathbf{0}$ gives the relation $0(\mathbf{v}_0, 1) + \sum_i a_i(\mathbf{u}_i, 0) = \mathbf{0}$, so if the new list is independent, all $a_i = 0$. Hence the new list is independent if and only if the differences are, and chaining the equivalences proves the proposition. □

The second approach also gives a mechanical test. For points of F^n, $\mathbf{v}_0, \dots, \mathbf{v}_k$ is affinely independent if and only if the $(n+1) \times (k+1)$ matrix with columns $\hat{\mathbf{v}}_0, \dots, \hat{\mathbf{v}}_k$ has linearly independent columns, which row reduction decides (Theorem 3.5.12).

Theorem 4.7.22 (Characterizations of affine independence). Let $\mathbf{v}_0, \dots, \mathbf{v}_k \in V$. The following are equivalent.

(I) $\mathbf{v}_0, \dots, \mathbf{v}_k$ is affinely independent.

(II) $\mathbf{v}_1 - \mathbf{v}_0, \dots, \mathbf{v}_k - \mathbf{v}_0$ is linearly independent.

(III) $\dim \operatorname{aff}(\mathbf{v}_0, \dots, \mathbf{v}_k) = k$.

(IV) Every point of $\operatorname{aff}(\mathbf{v}_0, \dots, \mathbf{v}_k)$ is an affine combination of $\mathbf{v}_0, \dots, \mathbf{v}_k$ in exactly one way.

(V) No $\mathbf{v}_j$ lies in the affine hull of the other entries of the list.

Proof. STANDARD

Uses. Proposition 4.7.20 (Affine independence through differences), Proposition 4.7.17 (The affine hull), Proposition 1.6.2 (Bases are independent spanning lists), Corollary 4.1.11 (Spanning lists are long)
Techniques. Proving TFAE (Technique 2.7.1), Uniqueness via two candidates (Technique 1.1.8), Contrapositive (Technique 1.5.4)
Hint 1. (I) ⇔ (II) is Proposition 4.7.20. For (II) ⇔ (III), compute the direction of the affine hull with Proposition 4.7.17(b).
Hint 2. For (I) ⇔ (IV), subtract two representations of the same point. What do the coefficients of the difference add up to?
Hint 3. For (I) ⇔ (V), solve an affine dependence for a $\mathbf{v}_j$ with $c_j \neq 0$, and check that the new coefficients add up to 1.
Sketch. The direction of the hull is spanned by the k differences, so it has dimension k exactly when they are a basis of it, that is, independent. Two representations of one point differ by an affine dependence, and conversely an affine dependence added to $\mathbf{v}_0 = 1\mathbf{v}_0$ gives a second representation of $\mathbf{v}_0$. If $\mathbf{v}_j = \sum_{i \neq j} c_i \mathbf{v}_i$ with $\sum c_i = 1$, moving $\mathbf{v}_j$ across gives an affine dependence; if $\sum c_i \mathbf{v}_i = \mathbf{0}$, $\sum c_i = 0$, and $c_j \neq 0$, then $\mathbf{v}_j = \sum_{i \neq j}(-c_i/c_j)\mathbf{v}_i$, and these coefficients add up to 1.

We prove (I) ⇔ (II), (II) ⇔ (III), (I) ⇔ (IV), and (I) ⇔ (V).

(I) ⇔ (II) is Proposition 4.7.20.

(II) ⇔ (III). By Proposition 4.7.17(b), the direction of $\operatorname{aff}(\mathbf{v}_0, \dots, \mathbf{v}_k)$ is $D = \operatorname{span}(\mathbf{v}_1 - \mathbf{v}_0, \dots, \mathbf{v}_k - \mathbf{v}_0)$, which is spanned by a list of length k. If this list is independent, it is a basis of D (Proposition 1.6.2), so $\dim D = k$. If $\dim D = k$, the spanning list of length k is a basis of D by Corollary 4.1.11(b), hence independent.

(I) ⇒ (IV). Suppose $\mathbf{p} = \sum_i c_i \mathbf{v}_i = \sum_i c_i' \mathbf{v}_i$ with $\sum_i c_i = \sum_i c_i' = 1$. Subtracting, $\sum_i (c_i - c_i')\mathbf{v}_i = \mathbf{0}$ and $\sum_i (c_i - c_i') = 0$. By (I), $c_i = c_i'$ for all i.

(IV) ⇒ (I). Suppose $\sum_i c_i \mathbf{v}_i = \mathbf{0}$ with $\sum_i c_i = 0$. Then

$$\mathbf{v}_0 = 1\mathbf{v}_0 + 0\mathbf{v}_1 + \cdots + 0\mathbf{v}_k = (1 + c_0)\mathbf{v}_0 + c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k$$

are two affine combinations (their coefficients add up to 1 and to $1+0=1$) that represent the point $\mathbf{v}_0$ of the affine hull. By (IV) they have the same coefficients, so $c_0 = \cdots = c_k = 0$.

(I) ⇔ (V). We show that (I) fails if and only if (V) fails. If $\mathbf{v}_j = \sum_{i\neq j} c_i\mathbf{v}_i$ with $\sum_{i\neq j} c_i = 1$, then $\sum_{i\neq j} c_i\mathbf{v}_i + (-1)\mathbf{v}_j = \mathbf{0}$ is an affine dependence: its coefficients add up to $1-1=0$, and the coefficient of $\mathbf{v}_j$ is $-1\neq 0$. Conversely, let $\sum_i c_i\mathbf{v}_i = \mathbf{0}$ with $\sum_i c_i = 0$ and $c_j \neq 0$. Then

$$\mathbf{v}_j = \sum_{i\neq j}\left(-\frac{c_i}{c_j}\right)\mathbf{v}_i, \quad \text{and} \quad \sum_{i\neq j}\left(-\frac{c_i}{c_j}\right) = -\frac{1}{c_j}\sum_{i\neq j} c_i = -\frac{1}{c_j}(-c_j) = 1,$$

so $\mathbf{v}_j$ lies in the affine hull of the other entries. □

Condition (V) is the affine form of the linear dependence lemma (Lemma 1.5.10), and (IV) is the affine form of unique coordinates. For $k=0$, (V) holds because the other entries form an empty list, whose affine hull is empty.

Corollary 4.7.23 (Affinely independent lists are short). If $\dim V = n$, then every affinely independent list in V has at most $n+1$ entries. In particular, any $n+2$ points of V are affinely dependent.

Proof. ROUTINE

Uses. Proposition 4.7.20 (Affine independence through differences), Theorem 4.1.10 (Independent lists are short)
Hint. Pass to the differences.
Sketch. If $\mathbf{v}_0,\dots,\mathbf{v}_k$ is affinely independent, the k differences $\mathbf{v}_i - \mathbf{v}_0$ are linearly independent in an n-dimensional space, so $k \le n$.

If $\mathbf{v}_0,\dots,\mathbf{v}_k$ is affinely independent, the k vectors $\mathbf{v}_i - \mathbf{v}_0$ are linearly independent by Proposition 4.7.20, so $k \le n$ by Theorem 4.1.10(a), and the list has $k+1 \le n+1$ entries. A list of $n+2$ points has $k = n+1 > n$, so it is affinely dependent. □

Exercise 4.7.24. ROUTINE Decide whether each list is affinely independent. If it is not, find an affine dependence.

(a) $(1,2,3),(2,3,4),(4,5,6)$ in $\mathbb{R}^3$.

(b) $(1,0,0),(0,1,0),(0,0,1),(1,1,1)$ in $\mathbb{R}^3$.

(c) The same four points, read in $\mathbb{F}_2^3$.

Solution on page 1353

Definition 4.7.25 (Affine frame, barycentric coordinates). Let E be an affine subspace of V. An **affine frame** of E is an affinely independent list $\mathbf{v}_0,\dots,\mathbf{v}_k$ with $\operatorname{aff}(\mathbf{v}_0,\dots,\mathbf{v}_k) = E$. Given an affine frame, each $\mathbf{p}\in E$ can be written as

$$\mathbf{p} = t_0\mathbf{v}_0 + \cdots + t_k\mathbf{v}_k, \quad t_0 + \cdots + t_k = 1,$$

in exactly one way (Theorem 4.7.22(IV)). The scalars $(t_0,\dots,t_k)$ are the **barycentric coordinates** of $\mathbf{p}$ with respect to $\mathbf{v}_0,\dots,\mathbf{v}_k$.

The name comes from physics: if masses $t_0,\dots,t_k \ge 0$ with total 1 sit at $\mathbf{v}_0,\dots,\mathbf{v}_k$, their center of mass, or barycenter, is $\sum_i t_i\mathbf{v}_i$.

Remark 4.7.26 (Frames exist, and coordinates are coordinates). Let $E = \mathbf{p} + U$ with $\dim U = k$, and let $\mathbf{u}_1,\dots,\mathbf{u}_k$ be a basis of U. Then $\mathbf{p}, \mathbf{p}+\mathbf{u}_1,\dots,\mathbf{p}+\mathbf{u}_k$ is an affine frame of E: its differences are the $\mathbf{u}_i$, which are independent, and its affine hull is $\mathbf{p} + \operatorname{span}(\mathbf{u}_1,\dots,\mathbf{u}_k) = E$ by Proposition 4.7.17(b). Conversely, every affine frame of E has $\dim E + 1$ entries, by Theorem 4.7.22(III).

Barycentric coordinates are ordinary coordinates in disguise. By Lemma 4.7.13(a), $\mathbf{p} = \sum_{i=0}^{k} t_i \mathbf{v}_i$ with $\sum_i t_i = 1$ if and only if

$$\mathbf{p} - \mathbf{v}_0 = t_1(\mathbf{v}_1 - \mathbf{v}_0) + \cdots + t_k(\mathbf{v}_k - \mathbf{v}_0) \quad \text{and} \quad t_0 = 1 - t_1 - \cdots - t_k.$$

So $(t_1, \ldots, t_k) = [\mathbf{p} - \mathbf{v}_0]_{\mathcal{B}}$ for the basis $\mathcal{B} = \mathbf{v}_1 - \mathbf{v}_0, \ldots, \mathbf{v}_k - \mathbf{v}_0$ of $\operatorname{dir} E$, and t_0 is determined by the others.

Example 4.7.27 (Barycentric coordinates in a triangle). Let $\mathbf{v}_0 = (1,1)$, $\mathbf{v}_1 = (5,2)$, $\mathbf{v}_2 = (2,5)$ in $\mathbb{R}^2$. The differences $(4,1)$ and $(1,4)$ are independent, so the three points form an affine frame of $\mathbb{R}^2$, a triangle. For $\mathbf{p} = (3,3)$, Remark 4.7.26 asks for $\mathbf{p} - \mathbf{v}_0 = (2,2) = t_1(4,1) + t_2(1,4)$, that is, $4t_1 + t_2 = 2$ and $t_1 + 4t_2 = 2$. So $t_1 = t_2 = \frac{2}{5}$ and $t_0 = \frac{1}{5}$:

$$(3,3) = \frac{1}{5}(1,1) + \frac{2}{5}(5,2) + \frac{2}{5}(2,5).$$

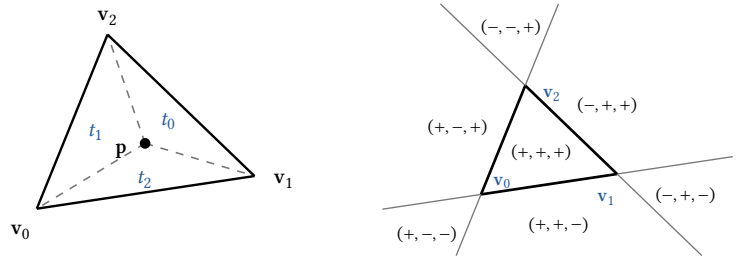
For $\mathbf{q} = (6,0)$, the equations $4t_1 + t_2 = 5$ and $t_1 + 4t_2 = -1$ give $t_1 = \frac{7}{5}$, $t_2 = -\frac{3}{5}$, and $t_0 = \frac{1}{5}$. Check: $\frac{1}{5}(1,1) + \frac{7}{5}(5,2) - \frac{3}{5}(2,5) = \frac{1}{5}(1 + 35 - 6, 1 + 14 - 15) = (6,0)$.

Homogenizing (Technique 4.7.21) gives the same numbers in one step: (t_0, t_1, t_2) is the unique solution of

$$\begin{pmatrix} 1 & 5 & 2 \\ 1 & 2 & 5 \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} t_0 \\ t_1 \\ t_2 \end{pmatrix} = \begin{pmatrix} 3 \\ 3 \\ 1 \end{pmatrix},$$

whose columns are the lifts $\hat{\mathbf{v}}_i$.

Intuition (Reading barycentric coordinates off a picture). In a triangle in $\mathbb{R}^2$, the coordinate t_0 vanishes exactly on the line through $\mathbf{v}_1$ and $\mathbf{v}_2$ (the points whose representation does not use $\mathbf{v}_0$), equals 1 at $\mathbf{v}_0$, and changes at a constant rate as $\mathbf{p}$ moves, because by Remark 4.7.26 it is an affine function of $\mathbf{p}$. So t_0 measures how far $\mathbf{p}$ has traveled from the line $\mathbf{v}_1\mathbf{v}_2$ toward $\mathbf{v}_0$, as a fraction of the height of $\mathbf{v}_0$ above that line. It is positive on the side of $\mathbf{v}_0$ and negative on the other side, and the three edge lines cut the plane into seven regions with seven sign patterns (Figure 4.7.1, right). For $\mathbf{p}$ inside the triangle, the triangles $\mathbf{p}\mathbf{v}_1\mathbf{v}_2$ and $\mathbf{v}_0\mathbf{v}_1\mathbf{v}_2$ share the base $\mathbf{v}_1\mathbf{v}_2$, so the height description says that t_0 is the ratio of their areas (left). In Example 4.7.27, $\mathbf{q}$ has $t_2 < 0$, and indeed it lies on the far side of the line $\mathbf{v}_0\mathbf{v}_1$ from $\mathbf{v}_2$.



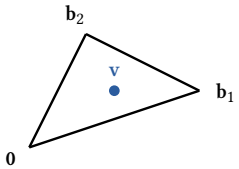


Figure 4.7.1. Barycentric coordinates in a triangle. Left: the point $\mathbf{p}$ with barycentric coordinates $(0.3, 0.4, 0.3)$; for a point inside the triangle, t_i is the fraction of the area taken by the small triangle opposite $\mathbf{v}_i$. Right: the signs of (t_0, t_1, t_2) in the seven regions cut out by the lines through the edges.

When $\mathbf{v}_0 = \mathbf{0}$, Remark 4.7.26 says that (t_1, t_2) are the coordinates of $\mathbf{p}$ in the basis $\mathbf{v}_1, \mathbf{v}_2$, so the change-of-basis component of Section 4.5 also shows barycentric coordinates. Read its two basis vectors as two vertices of a triangle whose third vertex is $\mathbf{0}$.

The triangle with vertices $\mathbf{0}$, $\mathbf{b}_1 = (3,1)$, $\mathbf{b}_2 = (1,2)$ is half of a cell of the $\mathcal{B}$-grid. The point $\mathbf{v} = (1.5,1) = 0.4\mathbf{b}_1 + 0.3\mathbf{b}_2$ has $\mathcal{B}$-coordinates $(t_1,t_2) = (0.4,0.3)$, so its barycentric coordinates with respect to $\mathbf{0},\mathbf{b}_1,\mathbf{b}_2$ are $(0.3,0.4,0.3)$, with $t_0 = 1 - t_1 - t_2$. In the interactive version, drag $\mathbf{v}$: it lies in the triangle exactly when $t_1 \geq 0$, $t_2 \geq 0$, and $t_1 + t_2 \leq 1$. When $\mathbf{b}_1$ and $\mathbf{b}_2$ become parallel, the three points are affinely dependent and the coordinates are undefined. (Interactive in the web version.)

If $(k+1)\cdot 1 \neq 0$ in F, the point whose barycentric coordinates are all $1/(k+1)$ is the centroid $\frac{1}{k+1}(\mathbf{v}_0 + \cdots + \mathbf{v}_k)$. Over $\mathbb{F}_3$ a triangle has no centroid, and Exercise 4.7.57 shows what its medians do instead.

4.7.4 Convexity and simplices

Over $\mathbb{R}$ we can ask for barycentric coordinates to be nonnegative, which describes the solid triangle rather than the plane it spans. Throughout this subsection V is a real vector space; everything works verbatim over $\mathbb{Q}$.

Definition 4.7.28 (Convex combination, convex set, convex hull). Let V be a real vector space. A **convex combination** of $\mathbf{v}_1,\ldots,\mathbf{v}_k$ is an affine combination $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k$ with $c_i \geq 0$ for all i. A subset $C \subseteq V$ is **convex** if $(1-t)\mathbf{u} + t\mathbf{v} \in C$ for all $\mathbf{u},\mathbf{v} \in C$ and $t \in [0,1]$, that is, if C contains the segment $[\mathbf{u},\mathbf{v}] = \{(1-t)\mathbf{u} + t\mathbf{v} \mid t \in [0,1]\}$ between any two of its points. The **convex hull** $\operatorname{conv} S$ of $S \subseteq V$ is the set of all convex combinations of finitely many elements of S.

Example 4.7.29 (Convex sets). Affine subspaces are convex, by Theorem 4.7.14. So is every half-space $H = \{\mathbf{x} \in \mathbb{R}^n \mid a_1x_1 + \cdots + a_nx_n \geq c\}$: writing $\alpha(\mathbf{x}) = a_1x_1 + \cdots + a_nx_n$, if $\alpha(\mathbf{u}) \geq c$ and $\alpha(\mathbf{v}) \geq c$, then $\alpha((1-t)\mathbf{u} + t\mathbf{v}) = (1-t)\alpha(\mathbf{u}) + t\alpha(\mathbf{v}) \geq (1-t)c + tc = c$ for $t \in [0,1]$. An intersection of convex sets is convex, so the solution set of any system of linear inequalities is convex; these are the feasible regions of linear programming. The union of the two coordinate axes in $\mathbb{R}^2$ is not convex, since the midpoint of $(1,0)$ and $(0,1)$ is missing.

Proposition 4.7.30 (Convex sets and convex hulls). Let V be a real vector space, and let $S \subseteq V$.

(a) A subset $C \subseteq V$ is convex if and only if every convex combination of elements of C lies in C.

(b) $\operatorname{conv} S$ is convex, contains S, and is contained in every convex subset of V that contains S.

Proof. STANDARD

Uses. Definition 4.7.28 (Convex combination, convex set, convex hull), Proposition 4.7.17 (The affine hull)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. ($\Leftarrow$) of (a) is the case of two points. For ($\Rightarrow$), induct on the number k of points, splitting off the last one.
Hint 2. If $c_k < 1$, write $\sum_i c_i\mathbf{v}_i = (1-c_k)\mathbf{q} + c_k\mathbf{v}_k$, where $\mathbf{q}$ is a convex combination of $\mathbf{v}_1,\ldots,\mathbf{v}_{k-1}$.
Hint 3. For (b), copy the proof of Proposition 4.7.17(a): over a common list, a convex combination of two convex combinations is a convex combination.
Sketch. Induct on k. For $k=1$ the combination is $\mathbf{v}_1$. If $c_k = 1$, the other coefficients are 0 and the point is $\mathbf{v}_k$. Otherwise $\mathbf{q} = \sum_{i<k}(c_i/(1-c_k))\mathbf{v}_i$ is a convex combination of $k-1$ points, so $\mathbf{q} \in C$, and the point is $(1-c_k)\mathbf{q} + c_k\mathbf{v}_k \in C$. For (b), $(1-t)\sum_i a_i\mathbf{s}_i + t\sum_i b_i\mathbf{s}_i = \sum_i((1-t)a_i + tb_i)\mathbf{s}_i$ is a convex combination.

(a) If C contains every convex combination of its elements, then in particular it contains $(1-t)\mathbf{u} + t\mathbf{v}$ for $\mathbf{u},\mathbf{v} \in C$ and $t \in [0,1]$, so C is convex. Conversely, let C be convex. We show by induction on $k \geq 1$ that every convex combination $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k$ of elements of C lies in C. For $k = 1$, $c_1 = 1$ and the combination

is $\mathbf{v}_1 \in C$. Let $k \geq 2$, and assume the claim for $k-1$. If $c_k = 1$, then $c_1 + \cdots + c_{k-1} = 0$ with all $c_i \geq 0$, so $c_1 = \cdots = c_{k-1} = 0$ and the combination is $\mathbf{v}_k \in C$. Otherwise $s = 1 - c_k = c_1 + \cdots + c_{k-1} > 0$, and

$$\mathbf{q} = \frac{c_1}{s}\mathbf{v}_1 + \cdots + \frac{c_{k-1}}{s}\mathbf{v}_{k-1}$$

is a convex combination of $k-1$ elements of C (its coefficients are nonnegative and add up to $s/s = 1$), so $\mathbf{q} \in C$ by the induction hypothesis. Then

$$c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k = s\mathbf{q} + c_k\mathbf{v}_k = (1 - c_k)\mathbf{q} + c_k\mathbf{v}_k,$$

which lies in C because C is convex and $c_k \in [0, 1]$.

(b) Each $\mathbf{s} \in S$ is the convex combination $1\mathbf{s}$, so $S \subseteq \operatorname{conv} S$. Let $\mathbf{u}, \mathbf{v} \in \operatorname{conv} S$ and $t \in [0, 1]$. As in the proof of Proposition 4.7.17(a), write $\mathbf{u} = \sum_i a_i\mathbf{s}_i$ and $\mathbf{v} = \sum_i b_i\mathbf{s}_i$ over one list $\mathbf{s}_1, \ldots, \mathbf{s}_N$ of elements of S, padding with zero coefficients. Then

$$(1 - t)\mathbf{u} + t\mathbf{v} = \sum_i ((1 - t)a_i + tb_i)\mathbf{s}_i,$$

and the coefficients are nonnegative and add up to $(1 - t) + t = 1$. So $\operatorname{conv} S$ is convex. If C is convex and $S \subseteq C$, then C contains every convex combination of elements of S by (a), that is, $\operatorname{conv} S \subseteq C$. □

Definition 4.7.31 (Simplex). Let $\mathbf{v}_0, \ldots, \mathbf{v}_k$ be affinely independent in a real vector space V. The **k-simplex** with **vertices** $\mathbf{v}_0, \ldots, \mathbf{v}_k$ is

$$\operatorname{conv}(\mathbf{v}_0, \ldots, \mathbf{v}_k) = \{t_0\mathbf{v}_0 + \cdots + t_k\mathbf{v}_k \mid t_i \geq 0 \text{ for all } i,\ t_0 + \cdots + t_k = 1\}.$$

Indexing the coordinates of $\mathbb{R}^{k+1}$ from 0, the **standard k-simplex** is

$$\Delta^k = \left\{(t_0, \ldots, t_k) \in \mathbb{R}^{k+1} \;\middle|\; t_i \geq 0 \text{ for all } i,\ t_0 + \cdots + t_k = 1\right\},$$

the simplex whose vertices are the standard basis vectors of $\mathbb{R}^{k+1}$.

A 0-simplex is a point, a 1-simplex is a segment, a 2-simplex is a solid triangle, and a 3-simplex is a solid tetrahedron. The points of Δ^k are the probability vectors with $k+1$ entries. For instance, a classifier that assigns probabilities to $k+1$ classes outputs a point of Δ^k, and stochastic matrices (Section 11.1) have columns in Δ^{n-1}.

Proposition 4.7.32 (Barycentric coordinates on a simplex). Let σ be the k-simplex with vertices $\mathbf{v}_0, \ldots, \mathbf{v}_k$. The map $\beta : \Delta^k \to \sigma$, $\beta(t_0, \ldots, t_k) = t_0\mathbf{v}_0 + \cdots + t_k\mathbf{v}_k$, is a bijection. Equivalently, a point of $\operatorname{aff}(\mathbf{v}_0, \ldots, \mathbf{v}_k)$ lies in σ if and only if all of its barycentric coordinates are nonnegative, and β^{-1} sends a point of σ to its barycentric coordinates.

Proof. ROUTINE

Uses. Definition 4.7.31 (Simplex), Theorem 4.7.22 (Characterizations of affine independence), Definition 4.7.25 (Affine frame, barycentric coordinates)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Surjectivity is the definition of σ.
Hint 2. Injectivity is the uniqueness of barycentric coordinates, Theorem 4.7.22(IV).
Sketch. β is onto $\sigma = \operatorname{conv}(\mathbf{v}_0, \ldots, \mathbf{v}_k)$ by definition, and two tuples with the same image are two affine combinations representing one point, so they are equal by Theorem 4.7.22(IV). A point lies in σ exactly when its unique coordinate tuple lies in Δ^k.

By the definition of σ, β is surjective. If $\beta(\mathbf{t}) = \beta(\mathbf{t}')$ for $\mathbf{t}, \mathbf{t}' \in \Delta^k$, then $\sum_i t_i\mathbf{v}_i$ and $\sum_i t_i'\mathbf{v}_i$ are affine combinations representing the same point, so $\mathbf{t} = \mathbf{t}'$ by Theorem 4.7.22(IV). Hence β is a bijection. A point $\mathbf{p} \in \operatorname{aff}(\mathbf{v}_0, \ldots, \mathbf{v}_k)$ has unique barycentric coordinates $\mathbf{t}$, and $\mathbf{p} \in \sigma$ if and only if $\mathbf{p} = \beta(\mathbf{t}')$ for some $\mathbf{t}' \in \Delta^k$. By uniqueness this happens if and only if $\mathbf{t} \in \Delta^k$, that is, if and only if all $t_i \geq 0$. □

In Example 4.7.27, $\mathbf{p} = (3,3)$ lies in the triangle, since its coordinates $\left(\frac{1}{5}, \frac{2}{5}, \frac{2}{5}\right)$ are positive, and $\mathbf{q} = (6,0)$ does not. Renderers test whether a pixel lies in a triangle exactly this way. They also use the coordinates to shade it: if the vertices carry colors $\mathbf{c}_0, \mathbf{c}_1, \mathbf{c}_2 \in \mathbb{R}^3$ (red, green, and blue intensities), the pixel at $\mathbf{p}$ gets $t_0\mathbf{c}_0 + t_1\mathbf{c}_1 + t_2\mathbf{c}_2$. This is the unique affine map $\mathbb{R}^2 \to \mathbb{R}^3$ with the prescribed values at the vertices (Theorem 4.7.39 below), and the same formula interpolates depths and texture coordinates.

Carathéodory's theorem

A point of $\operatorname{conv} S$ may be given as a convex combination of many points of S. In $\mathbb{R}^2$, though, every point of a convex polygon lies in a triangle formed by three of its vertices. In general a long convex combination can be shortened: when the points it uses are affinely dependent, the dependence gives a way to change the coefficients without changing the point or the coefficient sum, and we change them until one coefficient reaches 0.

Technique 4.7.33 (Slide along a dependence). Suppose $\mathbf{p} = \sum_i c_i\mathbf{v}_i$, where the coefficients are subject to constraints, such as $c_i \geq 0$ and $\sum_i c_i = 1$, and the $\mathbf{v}_i$ satisfy a relation $\sum_i d_i\mathbf{v}_i = \mathbf{0}$ that respects the equality constraints (here $\sum_i d_i = 0$). Then $\mathbf{p} = \sum_i (c_i - \lambda d_i)\mathbf{v}_i$ for every scalar λ, and the equality constraints still hold. Increase λ from 0 until the first inequality constraint becomes tight. At that extremal λ some coefficient is 0, and its vector can be dropped. Repeat as long as a relation exists.

Reach for it to show that a representation can be chosen short, for instance using independent vectors only. It refines the argument of Theorem 1.6.10, where a redundant vector is simply discarded, to situations where the coefficients must keep their signs. The canonical example is Carathéodory's theorem (Theorem 4.7.34).

Used in. Theorem 4.7.34, Exercise 4.7.59.

Theorem 4.7.34 (Carathéodory). Let V be a real vector space with $\dim V = n$, and let $S \subseteq V$. Every point of $\operatorname{conv} S$ is a convex combination of at most $n+1$ elements of S.

Proof. HARD

Uses. Definition 4.7.28 (Convex combination, convex set, convex hull), Corollary 4.7.23 (Affinely independent lists are short), Definition 4.7.18 (Affine independence)
Techniques. Slide along a dependence (Technique 4.7.33), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Take a representation $\mathbf{p} = \sum_{i=1}^{m} c_i\mathbf{v}_i$ with m as small as possible. Then all $c_i > 0$. If $m \geq n+2$, what does Corollary 4.7.23 give?
Hint 2. An affine dependence $\sum_i d_i\mathbf{v}_i = \mathbf{0}$, $\sum_i d_i = 0$, has some $d_i > 0$. Subtract λ times it from the representation.
Hint 3. Take $\lambda = \min\{c_i/d_i \mid d_i > 0\}$.
Sketch. Choose a representation $\mathbf{p} = \sum_{i=1}^{m} c_i\mathbf{v}_i$ with m minimal, so every $c_i > 0$. If $m \geq n+2$, the $\mathbf{v}_i$ are affinely dependent: $\sum_i d_i\mathbf{v}_i = \mathbf{0}$, $\sum_i d_i = 0$, and some $d_i > 0$. With $\lambda = \min_{d_i>0} c_i/d_i$, the coefficients $c_i - \lambda d_i$ are nonnegative, add up to 1, represent $\mathbf{p}$, and one of them is 0, contradicting minimality.

Let $\mathbf{p} \in \operatorname{conv} S$. Among all ways of writing $\mathbf{p}$ as a convex combination of finitely many elements of S, choose one, $\mathbf{p} = c_1\mathbf{v}_1 + \cdots + c_m\mathbf{v}_m$, with m as small as possible. Every c_i is positive, since a term with $c_j = 0$ could be deleted. Suppose, for contradiction, that $m \geq n+2$. By Corollary 4.7.23, the list $\mathbf{v}_1, \ldots, \mathbf{v}_m$ is affinely dependent: there are $d_1, \ldots, d_m$, not all 0, with

$$d_1\mathbf{v}_1 + \cdots + d_m\mathbf{v}_m = \mathbf{0}, \quad d_1 + \cdots + d_m = 0.$$

Since the d_i add up to 0 and are not all 0, at least one of them is positive. Let

$$\lambda = \min\left\{\frac{c_i}{d_i} \;\middle|\; d_i > 0\right\},$$

attained at $i = j$. Then $\lambda > 0$. Put $c_i' = c_i - \lambda d_i$. Then

$$\sum_i c_i' \mathbf{v}_i = \sum_i c_i \mathbf{v}_i - \lambda \sum_i d_i \mathbf{v}_i = \mathbf{p}, \quad \sum_i c_i' = \sum_i c_i - \lambda \sum_i d_i = 1.$$

If $d_i \le 0$, then $c_i' \ge c_i > 0$; if $d_i > 0$, then $c_i/d_i \ge \lambda$, so $c_i' = d_i(c_i/d_i - \lambda) \ge 0$. So $\mathbf{p} = \sum_i c_i' \mathbf{v}_i$ is a convex combination, and $c_j' = c_j - (c_j/d_j)d_j = 0$. Deleting the jth term represents $\mathbf{p}$ as a convex combination of $m-1$ elements of S, contradicting the minimality of m. Hence $m \le n+1$. □

The bound $n+1$ cannot be lowered. Let S be the vertex set of an n-simplex. Its centroid has all $n+1$ barycentric coordinates positive, while a convex combination of fewer vertices has a zero coordinate, so by the uniqueness in Proposition 4.7.32 the centroid is not a convex combination of fewer than $n+1$ points of S.

4.7.5 Affine maps

In Section 2.1, the maps $\mathbf{v} \mapsto L(\mathbf{v}) + \mathbf{b}$ were the basic non-examples of linear maps (Non-example 2.1.12), and Proposition 2.1.13 showed that, when $\mathbf{b} \neq \mathbf{0}$, they respect exactly the affine combinations. They are the maps of affine geometry.

Definition 4.7.35 (Affine map). Let V and W be vector spaces over F. A map $f : V \to W$ is **affine** if there are $L \in \mathrm{L}(V, W)$ and $\mathbf{b} \in W$ with $f(\mathbf{v}) = L(\mathbf{v}) + \mathbf{b}$ for all $\mathbf{v} \in V$. We then write $f = L + \mathbf{b}$.

The pair is determined by f: $f(\mathbf{0}) = L(\mathbf{0}) + \mathbf{b} = \mathbf{b}$, and then $L(\mathbf{v}) = f(\mathbf{v}) - f(\mathbf{0})$. We call L the **linear part** of f.

Example 4.7.36 (Affine maps).

(a) Linear maps ($\mathbf{b} = \mathbf{0}$), constant maps ($L = 0$), and translations $\tau_{\mathbf{b}}(\mathbf{v}) = \mathbf{v} + \mathbf{b}$ (with $L = \mathrm{id}_V$) are affine.

(b) The rotation of $\mathbb{R}^2$ by the angle θ about a point $\mathbf{a}$ moves $\mathbf{a}$ to the origin, rotates, and moves back:

$$f(\mathbf{v}) = \mathbf{a} + R_\theta(\mathbf{v} - \mathbf{a}) = R_\theta \mathbf{v} + (\mathbf{a} - R_\theta \mathbf{a}),$$

where R_θ is the rotation about $\mathbf{0}$ (Section 2.1). Its linear part is R_θ wherever the center is. Likewise the scaling by c about $\mathbf{a}$ is $\mathbf{v} \mapsto \mathbf{a} + c(\mathbf{v} - \mathbf{a}) = c\mathbf{v} + (1-c)\mathbf{a}$.

(c) The map $x \mapsto x^2$ on $\mathbb{R}$ is not affine, since it sends $0, 1, 2$ to $0, 1, 4$, and 1 is the midpoint of 0 and 2 while 1 is not the midpoint of 0 and 4. (Affine maps preserve midpoints, by the next theorem.)

Theorem 4.7.37 (Affine maps preserve affine combinations). Let $f : V \to W$ be a map. The following are equivalent.

(I) f is affine.

(II) $f(c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k) = c_1 f(\mathbf{v}_1) + \cdots + c_k f(\mathbf{v}_k)$ for all $k \ge 1$, all $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$, and all $c_1, \ldots, c_k \in F$ with $c_1 + \cdots + c_k = 1$.

(III) For every $\mathbf{p} \in V$, the map $g_{\mathbf{p}} : V \to W$, $g_{\mathbf{p}}(\mathbf{v}) = f(\mathbf{p} + \mathbf{v}) - f(\mathbf{p})$, is linear.

(IV) For some $\mathbf{p} \in V$, the map $g_{\mathbf{p}}$ is linear.

In that case $g_{\mathbf{p}}$ is the linear part of f for every $\mathbf{p}$.

Intuition. Condition (II) says that f commutes with weighted averages. Condition (III) says that f becomes linear once positions are measured from $\mathbf{p}$ in V and from $f(\mathbf{p})$ in W. The definition measures from $\mathbf{0}$; the theorem says that $\mathbf{0}$ is not special. To get from (II) to (III), express $\mathbf{p} + \mathbf{u} + \mathbf{v}$ and $\mathbf{p} + c\mathbf{v}$ as affine combinations of $\mathbf{p}$, $\mathbf{p} + \mathbf{u}$, and $\mathbf{p} + \mathbf{v}$.

Proof. STANDARD

Uses. Proposition 2.1.13 (Which combinations an affine map respects), Theorem 2.1.3 (Checking linearity)

Techniques. Proving TFAE (Technique 2.7.1), Choose a base point (Technique 4.7.4)
Hint 1. (I) ⇒ (II) is Proposition 2.1.13.
Hint 2. For (II) ⇒ (III): $\mathbf{p}+\mathbf{u}+\mathbf{v} = (\mathbf{p}+\mathbf{u})+(\mathbf{p}+\mathbf{v})-\mathbf{p}$ and $\mathbf{p}+c\mathbf{v} = c(\mathbf{p}+\mathbf{v})+(1-c)\mathbf{p}$.
Hint 3. For (IV) ⇒ (I), write $f(\mathbf{v}) = f(\mathbf{p}+(\mathbf{v}-\mathbf{p}))$.
Sketch. Applying f to $\mathbf{p}+\mathbf{u}+\mathbf{v} = (\mathbf{p}+\mathbf{u})+(\mathbf{p}+\mathbf{v})-\mathbf{p}$ and to $\mathbf{p}+c\mathbf{v} = c(\mathbf{p}+\mathbf{v})+(1-c)\mathbf{p}$ and subtracting $f(\mathbf{p})$ gives additivity and homogeneity of $g_{\mathbf{p}}$. Conversely, $f(\mathbf{v}) = g_{\mathbf{p}}(\mathbf{v}-\mathbf{p})+f(\mathbf{p}) = g_{\mathbf{p}}(\mathbf{v}) + \big(f(\mathbf{p})-g_{\mathbf{p}}(\mathbf{p})\big)$. If $f = L+\mathbf{b}$, then $g_{\mathbf{p}}(\mathbf{v}) = L(\mathbf{p}+\mathbf{v})-L(\mathbf{p}) = L(\mathbf{v})$.

We prove (I) ⇒ (II) ⇒ (III) ⇒ (IV) ⇒ (I).

(I) ⇒ (II). If $f = L+\mathbf{b}$, then by Proposition 2.1.13, $f\big(\sum_i c_i\mathbf{v}_i\big) - \sum_i c_i f(\mathbf{v}_i) = \big(1-\sum_i c_i\big)\mathbf{b} = \mathbf{0}$ when $\sum_i c_i = 1$.

(II) ⇒ (III). Fix $\mathbf{p}$ and write $g = g_{\mathbf{p}}$. For $\mathbf{u},\mathbf{v}\in V$, the vector $\mathbf{p}+\mathbf{u}+\mathbf{v} = 1(\mathbf{p}+\mathbf{u})+1(\mathbf{p}+\mathbf{v})+(-1)\mathbf{p}$ is an affine combination, as $1+1-1=1$. By (II), $f(\mathbf{p}+\mathbf{u}+\mathbf{v}) = f(\mathbf{p}+\mathbf{u})+f(\mathbf{p}+\mathbf{v})-f(\mathbf{p})$, and subtracting $f(\mathbf{p})$ from both sides gives

$$g(\mathbf{u}+\mathbf{v}) = (f(\mathbf{p}+\mathbf{u})-f(\mathbf{p}))+(f(\mathbf{p}+\mathbf{v})-f(\mathbf{p})) = g(\mathbf{u})+g(\mathbf{v}).$$

For $c\in F$, $\mathbf{p}+c\mathbf{v} = c(\mathbf{p}+\mathbf{v})+(1-c)\mathbf{p}$, so by (II), $f(\mathbf{p}+c\mathbf{v}) = cf(\mathbf{p}+\mathbf{v})+(1-c)f(\mathbf{p})$, and

$$g(c\mathbf{v}) = cf(\mathbf{p}+\mathbf{v})-cf(\mathbf{p}) = cg(\mathbf{v}).$$

So g is linear by Theorem 2.1.3.

(III) ⇒ (IV) holds because V is nonempty.

(IV) ⇒ (I). Let $g = g_{\mathbf{p}}$ be linear. For $\mathbf{v}\in V$,

$$f(\mathbf{v}) = f(\mathbf{p}+(\mathbf{v}-\mathbf{p})) = g(\mathbf{v}-\mathbf{p})+f(\mathbf{p}) = g(\mathbf{v})+(f(\mathbf{p})-g(\mathbf{p})).$$

So $f = g+\mathbf{b}$ with $\mathbf{b} = f(\mathbf{p})-g(\mathbf{p})$, and f is affine.

Finally, if $f = L+\mathbf{b}$, then for every $\mathbf{p}$ and $\mathbf{v}$, $g_{\mathbf{p}}(\mathbf{v}) = (L(\mathbf{p}+\mathbf{v})+\mathbf{b})-(L(\mathbf{p})+\mathbf{b}) = L(\mathbf{v})$, so $g_{\mathbf{p}} = L$. □

Compare Exercise 2.1.39, which assumed only that f respects affine combinations of two points and needed $1+1\neq 0$ to recover additivity. The three-point combination with coefficients $1,1,-1$ makes the division by 2 unnecessary, exactly as in the proof of Theorem 4.7.14.

Proposition 4.7.38 (Affine maps and affine subspaces). Let $f = L+\mathbf{b}: V\to W$ be affine.

(a) If $g = M+\mathbf{c}: W\to X$ is affine, then $g\circ f$ is affine, and $(g\circ f)(\mathbf{v}) = ML(\mathbf{v})+(M(\mathbf{b})+\mathbf{c})$.

(b) f is bijective if and only if L is. In that case f^{-1} is affine, and $f^{-1}(\mathbf{w}) = L^{-1}(\mathbf{w})-L^{-1}(\mathbf{b})$.

(c) If E is an affine subspace of V, then $f(E)$ is an affine subspace of W with direction $\operatorname{im}(L\restriction_{\operatorname{dir}E})$. If E is finite-dimensional, then $\dim f(E)\le\dim E$.

(d) If E' is an affine subspace of W, then $f^{-1}(E')$ is empty or an affine subspace of V with direction $\{\mathbf{u}\in V \mid L(\mathbf{u})\in\operatorname{dir}E'\}$.

Proof. STANDARD

Uses. Definition 4.7.35 (Affine map), Proposition 2.1.17 (Compositions of linear maps are linear), Proposition 2.7.7 (Bijective linear maps are invertible), Proposition 4.7.3 (Direction and base points), Proposition 2.6.8 (Kernels and images are subspaces), Theorem 4.2.11 (Rank–nullity), Theorem 1.4.3 (Subspace criterion)
Techniques. Choose a base point (Technique 4.7.4)
Hint 1. (a) is a computation. For (b), write $f = \tau_{\mathbf{b}}\circ L$, where $\tau_{\mathbf{b}}$ is the translation by $\mathbf{b}$, a bijection.
Hint 2. For (c) and (d), choose base points: $\mathbf{p}\in E$ for (c), and a point $\mathbf{q}\in f^{-1}(E')$, if there is one, for (d). The key identity is $f(\mathbf{p}+\mathbf{u}) = f(\mathbf{p})+L(\mathbf{u})$.
Sketch. (a) $M(L(\mathbf{v})+\mathbf{b})+\mathbf{c}$. (b) $\tau_{\mathbf{b}}$ is a bijection with inverse $\tau_{-\mathbf{b}}$, so $f = \tau_{\mathbf{b}}\circ L$ is bijective if and only if L is, and then $f^{-1} = L^{-1}\circ\tau_{-\mathbf{b}}$. (c) $f(\mathbf{p}+U) = f(\mathbf{p})+L(U)$, and $\dim L(U)\le\dim U$ by rank–nullity. (d) With $\mathbf{q}\in f^{-1}(E')$, $f(\mathbf{v})\in E'$ if and only if $L(\mathbf{v}-\mathbf{q}) = f(\mathbf{v})-f(\mathbf{q})\in\operatorname{dir}E'$.

(a) $g(f(\mathbf{v})) = M(L(\mathbf{v})+\mathbf{b})+\mathbf{c} = ML(\mathbf{v})+(M(\mathbf{b})+\mathbf{c})$, and ML is linear by Proposition 2.1.17.

(b) The translation $\tau_{\mathbf{b}} : W \to W, \mathbf{w} \mapsto \mathbf{w} + \mathbf{b}$, is a bijection with inverse $\tau_{-\mathbf{b}}$, and $f = \tau_{\mathbf{b}} \circ L$. If L is bijective, so is f; if f is bijective, so is $L = \tau_{-\mathbf{b}} \circ f$. In that case $f^{-1} = L^{-1} \circ \tau_{-\mathbf{b}}$, that is, $f^{-1}(\mathbf{w}) = L^{-1}(\mathbf{w} - \mathbf{b}) = L^{-1}(\mathbf{w}) - L^{-1}(\mathbf{b})$, and L^{-1} is linear by Proposition 2.7.7. So f^{-1} is affine.

(c) Let $E = \mathbf{p} + U$. For $\mathbf{u} \in U$, $f(\mathbf{p} + \mathbf{u}) = L(\mathbf{p}) + L(\mathbf{u}) + \mathbf{b} = f(\mathbf{p}) + L(\mathbf{u})$. Hence $f(E) = f(\mathbf{p}) + L(U)$, where $L(U) = \operatorname{im}(L|_U)$ is a subspace of W (Proposition 2.6.8, applied to $L|_U$). So $f(E)$ is an affine subspace with direction $\operatorname{im}(L|_U)$. If U is finite-dimensional, rank–nullity for $L|_U$ (Theorem 4.2.11) gives $\dim \operatorname{im}(L|_U) \le \dim U$.

(d) Let $U' = \operatorname{dir} E'$ and $U'' = \{\mathbf{u} \in V \mid L(\mathbf{u}) \in U'\}$. Then U'' is a subspace: $L(\mathbf{0}) = \mathbf{0} \in U'$, and if $L(\mathbf{u}), L(\mathbf{u}') \in U'$ and $c \in F$, then $L(\mathbf{u} + \mathbf{u}') = L(\mathbf{u}) + L(\mathbf{u}') \in U'$ and $L(c\mathbf{u}) = cL(\mathbf{u}) \in U'$. Suppose $f^{-1}(E')$ is nonempty, and let $\mathbf{q} \in f^{-1}(E')$. By Proposition 4.7.3(b), $E' = f(\mathbf{q}) + U'$, so for $\mathbf{v} \in V$ we have $f(\mathbf{v}) \in E'$ if and only if $f(\mathbf{v}) - f(\mathbf{q}) \in U'$. Since $f(\mathbf{v}) - f(\mathbf{q}) = L(\mathbf{v} - \mathbf{q})$, this holds if and only if $\mathbf{v} - \mathbf{q} \in U''$. Hence $f^{-1}(E') = \mathbf{q} + U''$. □

Over $\mathbb{R}$, condition (II) of Theorem 4.7.37 applied to convex combinations shows that an affine map sends segments onto segments, convex sets to convex sets, and $\operatorname{conv} S$ onto $\operatorname{conv} f(S)$. It also preserves ratios along a line: if $\mathbf{p} = (1-t)\mathbf{a} + t\mathbf{b}$, then $f(\mathbf{p}) = (1-t)f(\mathbf{a}) + tf(\mathbf{b})$, so midpoints go to midpoints. Lengths and angles are not preserved (think of a shear), which is why affine geometry has parallel lines and ratios along a line but no distances.

Theorem 4.7.39 (Affine maps are determined by a frame). Let $\mathbf{v}_0, \dots, \mathbf{v}_n$ be an affine frame of V, and let $\mathbf{w}_0, \dots, \mathbf{w}_n \in W$ be arbitrary. There is exactly one affine map $f : V \to W$ with $f(\mathbf{v}_i) = \mathbf{w}_i$ for $i = 0, \dots, n$, namely

$$f(t_0\mathbf{v}_0 + \cdots + t_n\mathbf{v}_n) = t_0\mathbf{w}_0 + \cdots + t_n\mathbf{w}_n \quad \text{whenever } t_0 + \cdots + t_n = 1.$$

Proof. STANDARD

Uses. Theorem 4.7.37 (Affine maps preserve affine combinations), Definition 4.7.25 (Affine frame, barycentric coordinates), Proposition 4.7.17 (The affine hull), Theorem 4.7.22 (Characterizations of affine independence), Theorem 2.2.1 (Linear maps are determined by a basis)
Techniques. Choose a base point (Technique 4.7.4), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. Uniqueness: every point is an affine combination of the $\mathbf{v}_i$, and affine maps preserve affine combinations.
Hint 2. Existence: use $\mathbf{v}_0$ as base point. The differences $\mathbf{v}_i - \mathbf{v}_0$ form a basis of V. Which linear map should be the linear part?
Sketch. Every point has barycentric coordinates, and Theorem 4.7.37(II) forces the formula, which gives uniqueness. For existence, the differences $\mathbf{v}_i - \mathbf{v}_0$ are independent and span V, so there is a linear L with $L(\mathbf{v}_i - \mathbf{v}_0) = \mathbf{w}_i - \mathbf{w}_0$; then $f(\mathbf{v}) = \mathbf{w}_0 + L(\mathbf{v} - \mathbf{v}_0)$ is affine and sends $\mathbf{v}_i$ to $\mathbf{w}_i$.

Uniqueness and the formula. Let f be affine with $f(\mathbf{v}_i) = \mathbf{w}_i$ for all i. Every $\mathbf{v} \in V = \operatorname{aff}(\mathbf{v}_0, \dots, \mathbf{v}_n)$ has barycentric coordinates, $\mathbf{v} = \sum_i t_i\mathbf{v}_i$ with $\sum_i t_i = 1$, and by Theorem 4.7.37(II), $f(\mathbf{v}) = \sum_i t_i f(\mathbf{v}_i) = \sum_i t_i\mathbf{w}_i$. So f is determined by the $\mathbf{w}_i$ and is given by the formula.

Existence. By Proposition 4.7.17(b), $V = \mathbf{v}_0 + D$ with $D = \operatorname{span}(\mathbf{v}_1 - \mathbf{v}_0, \dots, \mathbf{v}_n - \mathbf{v}_0)$. For every $\mathbf{x} \in V$, $\mathbf{v}_0 + \mathbf{x} \in V$, so $\mathbf{x} \in D$; hence $D = V$. By Theorem 4.7.22(II), the differences are linearly independent, so they form a basis of V. By Theorem 2.2.1 there is a linear map $L : V \to W$ with $L(\mathbf{v}_i - \mathbf{v}_0) = \mathbf{w}_i - \mathbf{w}_0$ for $i = 1, \dots, n$. Define

$$f(\mathbf{v}) = \mathbf{w}_0 + L(\mathbf{v} - \mathbf{v}_0) = L(\mathbf{v}) + (\mathbf{w}_0 - L(\mathbf{v}_0)),$$

an affine map. Then $f(\mathbf{v}_0) = \mathbf{w}_0$, and $f(\mathbf{v}_i) = \mathbf{w}_0 + (\mathbf{w}_i - \mathbf{w}_0) = \mathbf{w}_i$ for $i \ge 1$. □

Example 4.7.40 (Mapping one triangle onto another). The affine map $f : \mathbb{R}^2 \to \mathbb{R}^2$ with $f(0,0) = (1,1)$, $f(1,0) = (5,2)$, $f(0,1) = (2,5)$ has translation part $f(\mathbf{0}) = (1,1)$ and linear part L with $L(\mathbf{e}_1) = (4,1)$ and $L(\mathbf{e}_2) = (1,4)$:

$$f(\mathbf{x}) = \begin{pmatrix} 4 & 1 \\ 1 & 4 \end{pmatrix}\mathbf{x} + \begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

By Theorem 4.7.39, f sends the point with barycentric coordinates (t_0, t_1, t_2) with respect to $\mathbf{0}, \mathbf{e}_1, \mathbf{e}_2$, which is (t_1, t_2), to the point with the same barycentric coordinates with respect to the triangle of Example 4.7.27. For instance $f\left(\frac{2}{5}, \frac{2}{5}\right) = \left(\frac{8}{5} + \frac{2}{5} + 1, \frac{2}{5} + \frac{8}{5} + 1\right) = (3, 3)$, matching the coordinates $\left(\frac{1}{5}, \frac{2}{5}, \frac{2}{5}\right)$ of $(3, 3)$ found there. Texture mapping works this way: the renderer finds the affine map from a triangle in the texture image to a triangle on the screen.

4.7.6 Homogeneous coordinates

A graphics program moves objects by rotations, scalings, and translations, composed in long chains, and applies the result to every vertex of the scene. Composites of linear maps are products of matrices, which can be computed once and reused. A translation is not linear, so a chain such as "rotate about a point, then translate" is not a single matrix in $F^{n\times n}$. Homogenizing (Technique 4.7.21) repairs this.

Definition 4.7.41 (Homogeneous coordinates). For $\mathbf{x} \in F^n$, let $\hat{\mathbf{x}} = \begin{pmatrix} \mathbf{x} \\ 1 \end{pmatrix} \in F^{n+1}$. A **vector of homogeneous coordinates** of $\mathbf{x}$ is any vector $c\hat{\mathbf{x}} = (c\mathbf{x}, c)$ with $c \in F$, $c \neq 0$. Conversely, a vector $(\mathbf{z}, c) \in F^{n+1}$ with $\mathbf{z} \in F^n$ and $c \neq 0$ is a vector of homogeneous coordinates of exactly one point of F^n, namely $c^{-1}\mathbf{z}$.

The last claim holds because $(\mathbf{z}, c) = c'(\mathbf{x}, 1)$ forces $c' = c$ and $\mathbf{x} = c^{-1}\mathbf{z}$. For example, $(6, -3, 9, 3)$ and $(2, -1, 3, 1)$ are both vectors of homogeneous coordinates of $(2, -1, 3) \in \mathbb{R}^3$. The vectors of homogeneous coordinates of $\mathbf{x}$ are the nonzero vectors on the line $\operatorname{span}(\hat{\mathbf{x}})$ through $\mathbf{0}$ in F^{n+1}, so $\mathbf{x} \mapsto \operatorname{span}(\hat{\mathbf{x}})$ matches the points of F^n with the lines through $\mathbf{0}$ in F^{n+1} that are not contained in the hyperplane $x_{n+1} = 0$. Vectors with last coordinate 0 represent no point of F^n; the aside at the end of the section says what they represent instead.

Theorem 4.7.42 (Affine maps as matrices). Let $f : F^n \to F^m$ be affine, $f(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$ with $A \in F^{m\times n}$ and $\mathbf{b} \in F^m$, and let

$$M_f = \begin{pmatrix} A & \mathbf{b} \\ 0 & 1 \end{pmatrix} \in F^{(m+1)\times(n+1)},$$

where 0 is the $1 \times n$ zero row.

(a) $M_f\hat{\mathbf{x}} = \widehat{f(\mathbf{x})}$ for every $\mathbf{x} \in F^n$, and M_f is the only matrix in $F^{(m+1)\times(n+1)}$ with this property.

(b) $f \mapsto M_f$ is a bijection from the set of affine maps $F^n \to F^m$ onto the set of matrices in $F^{(m+1)\times(n+1)}$ whose last row is $(0, \ldots, 0, 1)$.

(c) If $g : F^m \to F^l$ is affine, then $M_{g\circ f} = M_g M_f$.

(d) If $m = n$, then f is bijective if and only if M_f is invertible, and in that case $M_{f^{-1}} = M_f^{-1}$.

Proof. STANDARD

Uses. Theorem 2.4.34 (Block multiplication), Proposition 4.7.38 (Affine maps and affine subspaces), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Corollary 2.2.6 (Agreeing on a spanning list), Theorem 2.3.20 (Linear maps correspond to matrices), Corollary 3.5.25 (The invertible matrix theorem)
Techniques. Homogenize: add a coordinate 1 (Technique 4.7.21), Block decomposition (Technique 2.4.35)
Hint 1. Multiply in blocks (Theorem 2.4.34), splitting $n + 1$ as n and 1, and $m + 1$ as m and 1.
Hint 2. For uniqueness in (a), the vectors $\hat{\mathbf{x}}$ span F^{n+1}: look at $\hat{\mathbf{0}}$ and the $\hat{\mathbf{e}}_j$.
Hint 3. (c) is block multiplication together with Proposition 4.7.38(a). For (d), apply (c) to f and f^{-1}; for the converse, apply M_f to $(\mathbf{a}, 0)$ with $A\mathbf{a} = \mathbf{0}$.

Sketch. Block multiplication gives $M_f\hat{\mathbf{x}} = (A\mathbf{x}+\mathbf{b}, 1)$. Since $\hat{\mathbf{0}} = \mathbf{e}_{n+1}$ and $\hat{\mathbf{e}}_j - \hat{\mathbf{0}} = \mathbf{e}_j$, the $\hat{\mathbf{x}}$ span F^{n+1}, so a matrix is determined by its products with them. $M_gM_f = \left(\begin{smallmatrix} BA & B\mathbf{b}+\mathbf{c} \\ 0 & 1 \end{smallmatrix}\right) = M_{g\circ f}$. If f is bijective, $M_{f^{-1}}M_f = M_{\mathrm{id}} = I_{n+1}$ and likewise in the other order. If M_f is invertible and $A\mathbf{a} = \mathbf{0}$, then $M_f(\mathbf{a}, 0) = \mathbf{0}$, so $\mathbf{a} = \mathbf{0}$ and A is invertible.

(a) By Theorem 2.4.34, with blocks of sizes $m, 1$ and $n, 1$,

$$M_f\hat{\mathbf{x}} = \begin{pmatrix} A & \mathbf{b} \\ 0 & 1 \end{pmatrix}\begin{pmatrix} \mathbf{x} \\ 1 \end{pmatrix} = \begin{pmatrix} A\mathbf{x}+\mathbf{b} \\ 0\mathbf{x}+1 \end{pmatrix} = \begin{pmatrix} f(\mathbf{x}) \\ 1 \end{pmatrix} = \widehat{f(\mathbf{x})}.$$

For uniqueness, note that $\hat{\mathbf{0}} = \mathbf{e}_{n+1}$ and $\hat{\mathbf{e}}_j - \hat{\mathbf{0}} = \mathbf{e}_j$ for $j \le n$, so the vectors $\hat{\mathbf{x}}$ span F^{n+1}. If $N\hat{\mathbf{x}} = M_f\hat{\mathbf{x}}$ for all $\mathbf{x}$, then the linear maps T_N and T_{M_f} agree on a spanning list, so they are equal (Corollary 2.2.6), and $N = M_f$ (Theorem 2.3.20).

(b) By Proposition 2.3.17, the linear part of an affine map $F^n \to F^m$ is T_A for exactly one $A \in F^{m\times n}$, so each affine map is $\mathbf{x} \mapsto A\mathbf{x}+\mathbf{b}$ for exactly one pair $(A, \mathbf{b})$, since the linear part and $\mathbf{b} = f(\mathbf{0})$ are determined by f. The matrices with last row $(0, \ldots, 0, 1)$ are exactly the $\left(\begin{smallmatrix} A & \mathbf{b} \\ 0 & 1 \end{smallmatrix}\right)$ with $A \in F^{m\times n}$ and $\mathbf{b} \in F^m$, and each of them determines $(A, \mathbf{b})$. So $f \mapsto M_f$ is a bijection.

(c) Let $g(\mathbf{y}) = B\mathbf{y}+\mathbf{c}$. By Theorem 2.4.34,

$$M_gM_f = \begin{pmatrix} B & \mathbf{c} \\ 0 & 1 \end{pmatrix}\begin{pmatrix} A & \mathbf{b} \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} BA & B\mathbf{b}+\mathbf{c} \\ 0 & 1 \end{pmatrix},$$

and by Proposition 4.7.38(a), $g \circ f$ is $\mathbf{x} \mapsto BA\mathbf{x} + (B\mathbf{b}+\mathbf{c})$. So $M_gM_f = M_{g\circ f}$.

(d) Note that $M_{\mathrm{id}} = \left(\begin{smallmatrix} I_n & \mathbf{0} \\ 0 & 1 \end{smallmatrix}\right) = I_{n+1}$. If f is bijective, then f^{-1} is affine (Proposition 4.7.38(b)), and by (c), $M_{f^{-1}}M_f = M_{f^{-1}\circ f} = I_{n+1}$ and $M_fM_{f^{-1}} = I_{n+1}$. So M_f is invertible with inverse $M_{f^{-1}}$. Conversely, suppose M_f is invertible, and let $A\mathbf{a} = \mathbf{0}$ with $\mathbf{a} \in F^n$. Then $M_f\left(\begin{smallmatrix} \mathbf{a} \\ 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} A\mathbf{a} \\ 0 \end{smallmatrix}\right) = \mathbf{0}$, so $(\mathbf{a}, 0) = \mathbf{0}$ and $\mathbf{a} = \mathbf{0}$. Hence $\ker T_A = \{\mathbf{0}\}$, A is invertible by Corollary 3.5.25, and f is bijective by Proposition 4.7.38(b). □

The translation by $\mathbf{a}$ has matrix $\left(\begin{smallmatrix} I_n & \mathbf{a} \\ 0 & 1 \end{smallmatrix}\right)$. On F^{n+1} it is a linear map, a shear that slides the hyperplane $x_{n+1} = 1$ along itself by $\mathbf{a}$ and fixes the hyperplane $x_{n+1} = 0$. For $n = 1$: the map $(x, y) \mapsto (x + ay, y)$ of F^2 is linear and moves the line $y = 1$, a copy of F, by a. So translations, which are not linear on F^n, become linear one dimension up.

Exercise 4.7.43. ROUTINE Let $A \in F^{n\times n}$ be invertible and $\mathbf{b} \in F^n$. Verify by block multiplication that

$$\begin{pmatrix} A & \mathbf{b} \\ 0 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} A^{-1} & -A^{-1}\mathbf{b} \\ 0 & 1 \end{pmatrix}.$$

Use it to invert the matrix of the translation by $\mathbf{a}$, and the matrix $\left(\begin{smallmatrix} 0 & -1 & 3 \\ 1 & 0 & 1 \\ 0 & 0 & 1 \end{smallmatrix}\right)$.

Solution on page 1353

Example 4.7.44 (Rotation about a point). Let f be the rotation of $\mathbb{R}^2$ by $90°$ counterclockwise about $\mathbf{a} = (1, 2)$, and $R = R_{\pi/2} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. By Example 4.7.36, $f = \tau_{\mathbf{a}} \circ R \circ \tau_{-\mathbf{a}}$, so by Theorem 4.7.42(c),

$$M_f = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 & 3 \\ 1 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

The last column is $\mathbf{a} - R\mathbf{a} = (1, 2) - (-2, 1) = (3, 1)$. As a check, $M_f\widehat{(1, 2)} = (0 - 2 + 3, 1 + 0 + 1, 1)$, so the center is fixed, and $M_f\widehat{(2, 2)} = (1, 3, 1)$: the point one unit to the right of $\mathbf{a}$ goes to the point one unit above it.

The order of the factors matters. The product

$$\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 & -2 \\ 1 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}$$

is the matrix of "translate by $\mathbf{a}$, then rotate about $\mathbf{0}$", which is $\mathbf{x} \mapsto R\mathbf{x} + R\mathbf{a}$, a rotation about a different center.

In three dimensions the same matrices are 4×4. A renderer stores each object once, in coordinates convenient for that object, and places it in the scene by a product $M = M_k \cdots M_1$ of rotations, scalings, and translations, computed once per object. Each vertex then costs one 4×4 matrix–vector product, which is why graphics processors are built around 4×4 matrix arithmetic. In the product, M_1 acts first.

Perspective projection

The projection $(x, y, z) \mapsto (x, y, 0)$ onto the xy-plane is linear, but it draws distant objects as large as near ones. A camera, or an eye, projects through a point instead. Fix $d \neq 0$, the **center** $\mathbf{c} = (0, 0, d)$, and the image plane $z = 0$. The **perspective projection** π sends $\mathbf{v} = (x, y, z)$ to the point where the line through $\mathbf{c}$ and $\mathbf{v}$ meets the image plane (Figure 4.7.2).

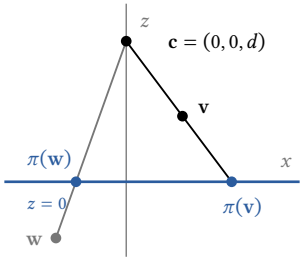

Figure 4.7.2. The perspective projection seen from the side, with the image plane $z = 0$ drawn as the horizontal line. The point $\mathbf{v}$ between the plane and the center is projected outward; the point $\mathbf{w}$ behind the plane is projected inward, so distant points come closer together.

The points of the line through $\mathbf{c}$ and $\mathbf{v}$ are $\mathbf{c} + s(\mathbf{v} - \mathbf{c})$ for $s \in \mathbb{R}$. The third coordinate of such a point is $d + s(z - d)$, which is 0 if and only if $s(d - z) = d$. If $z = d$, there is no such s: the line is parallel to the image plane, or $\mathbf{v} = \mathbf{c}$, and $\mathbf{v}$ has no image. Otherwise $s = d/(d - z)$, and the first two coordinates are sx and sy, so

$$\pi(x, y, z) = \left(\frac{x}{1 - z/d}, \frac{y}{1 - z/d}, 0 \right) \quad (z \neq d).$$

The same formula covers points on the far side of the image plane from the center, and points on the far side of the center from the image plane, where $s < 0$.

The map π is not affine. With $d = 1$, $\pi(0, 0, 0) = \mathbf{0}$ and $\pi\left(1, 0, \frac{1}{2}\right) = (2, 0, 0)$, but the midpoint $\left(\frac{1}{2}, 0, \frac{1}{4}\right)$ goes to $\left(\frac{2}{3}, 0, 0\right)$, not to the midpoint $(1, 0, 0)$ of the images. So by Theorem 4.7.37 no matrix M_f represents π. Even so:

Proposition 4.7.45 (Perspective projection in homogeneous coordinates). Let $d \neq 0$ and

$$P = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1/d & 1 \end{pmatrix}.$$

For every $\mathbf{v} = (x, y, z) \in \mathbb{R}^3$ with $z \neq d$, $P\hat{\mathbf{v}} = (x, y, 0, 1 - z/d)$, and this is a vector of homogeneous coordinates of $\pi(\mathbf{v})$.

Proof. ROUTINE

Uses. Definition 2.3.8 (Matrix–vector product), Definition 4.7.41 (Homogeneous coordinates)
Hint 1. Compute $P\hat{\mathbf{v}}$ row by row.
Hint 2. Which point does a vector $(\mathbf{z}, c)$ with $c \neq 0$ represent?
Sketch. The rows of P give x, y, 0, and $-z/d + 1$. The last entry is nonzero because $z \neq d$, and dividing by it gives $\pi(\mathbf{v})$.

Multiplying the rows of P by $\hat{\mathbf{v}} = (x, y, z, 1)$ gives x, y, 0, and $-z/d + 1$. Since $z \neq d$, the last entry $c = 1 - z/d$ is nonzero, and by Definition 4.7.41 the vector represents the point $c^{-1}(x, y, 0) = \pi(\mathbf{v})$. □

The nonlinearity has moved into the freedom of Definition 4.7.41: $P\hat{\mathbf{v}}$ does not have last coordinate 1, and the division by the last coordinate, performed once at the very end, supplies it. The matrix P has rank 3, so the depth z is lost. Renderers therefore use the third row $(0, 0, 1, 0)$ instead of $(0, 0, 0, 0)$, which keeps the number $z/(1 - z/d) = dz/(d - z)$ as a third coordinate. Its derivative in z is $d^2/(d - z)^2 > 0$, so on each side of the plane $z = d$ it increases with z, and it still tells which of two points that project to the same pixel is nearer to the camera.

For a center off the z-axis, or another image plane, conjugate by translations and rotations as in Example 4.7.44; Exercise 4.7.49 carries this out. Under π, parallel lines in space usually stop being parallel, as the rails of a track do in a photograph, and Exercise 4.7.50 finds where their images meet.

ASIDE: *Projective space*

By Definition 4.7.41, a point $\mathbf{x}$ of F^n is the same thing as a line through $\mathbf{0}$ in F^{n+1}, namely $\operatorname{span}(\hat{\mathbf{x}})$, and every line through $\mathbf{0}$ that is not contained in the hyperplane $H = \{x_{n+1} = 0\}$ arises this way exactly once. The **projective space** $\mathbb{P}^n(F)$ is the set of all lines through $\mathbf{0}$ in F^{n+1}, that is, of all 1-dimensional subspaces. Its elements are the points of F^n together with the lines inside H, called **points at infinity**. A point at infinity $\operatorname{span}((\mathbf{w}, 0))$, with $\mathbf{w} \neq \mathbf{0}$, corresponds to a direction in F^n. Over $\mathbb{R}$, the points $\mathbf{x} + s\mathbf{w}$ of a line have the vectors of homogeneous coordinates $(\mathbf{x} + s\mathbf{w}, 1)$ and $\left(s^{-1}\mathbf{x} + \mathbf{w}, s^{-1}\right)$ for $s \neq 0$, and the latter tend to $(\mathbf{w}, 0)$ as $s \to \infty$. So all lines with direction $\operatorname{span}(\mathbf{w})$ share one point at infinity, and in Exercise 4.7.50 the vanishing point of a family of parallel lines is the image of their common point at infinity under P.

A **projective line** is a 2-dimensional subspace of F^{n+1}, viewed as the set of lines through $\mathbf{0}$ that it contains. In the projective plane $\mathbb{P}^2(F)$, two distinct projective lines $U \neq W$ meet in exactly one point: $W \not\subseteq U$ by Proposition 4.1.21(b), so $U + W$ is larger than U and equals F^3, and Theorem 4.4.19 gives $\dim(U \cap W) = 2 + 2 - 3 = 1$. In particular, two parallel lines of F^2, completed by their common point at infinity, meet there. An invertible matrix in $F^{(n+1)\times(n+1)}$ permutes the 1-dimensional subspaces of F^{n+1}, so it acts on $\mathbb{P}^n(F)$, and nonzero multiples of a matrix act in the same way. These are the **projective transformations**. They send projective lines to projective lines, but unlike affine maps they can move points at infinity into F^n, which is how a photograph can show a horizon. Over a field with q elements, $\mathbb{P}^2$ has $\left(q^3 - 1\right)/(q - 1) = q^2 + q + 1$ points; for $q = 2$ it is the seven-point Fano plane.

Exercises

Exercise 4.7.46. ROUTINE Decide which of the following sets are affine subspaces. For each one that is, find its direction and, if it is finite, its dimension.

(a) The solution set in $\mathbb{R}^3$ of $x_1 + x_2 + x_3 = 1$ and $x_1 - x_3 = 2$.

(b) The set of $p \in \mathbb{R}[x]$ with $p(0) = 1$ and $p(1) = 3$.

(c) The set of $\mathbf{x} \in \mathbb{R}^2$ with $x_1 x_2 = 0$.

(d) The set of $(x_1, x_2) \in \mathbb{F}_3^2$ with $x_2 = x_1^2$.

Solution on page 1354

Exercise 4.7.47. ROUTINE Let $\mathbf{v}_0 = (0,0)$, $\mathbf{v}_1 = (4,0)$, $\mathbf{v}_2 = (1,3)$ in $\mathbb{R}^2$. Find the barycentric coordinates of $\mathbf{p} = (2,1)$, $\mathbf{q} = (3,2)$, and $\mathbf{r} = (-1,1)$ with respect to $\mathbf{v}_0, \mathbf{v}_1, \mathbf{v}_2$, and decide which of the three points lie in the triangle $\operatorname{conv}(\mathbf{v}_0, \mathbf{v}_1, \mathbf{v}_2)$. For each point outside, name the edge line it lies beyond.

Solution on page 1354

Exercise 4.7.48. ROUTINE Work in $\mathbb{R}^2$ with homogeneous coordinates.

(a) Write the 3×3 matrices of the translation T by $(2,-1)$, the rotation R by $90°$ counterclockwise about $\mathbf{0}$, and the scaling S by the factor 3 about $(1,1)$.

(b) Compute $M_T M_R$ and $M_R M_T$, and describe each product as a map of $\mathbb{R}^2$.

(c) Which point of $\mathbb{R}^2$ has $(6,-3,3)$ as a vector of homogeneous coordinates? Give a vector of homogeneous coordinates of the same point with last entry 2.

Solution on page 1355

Exercise 4.7.49. STANDARD Let $d \neq 0$ and $c_1, c_2 \in \mathbb{R}$, and let $\pi_{\mathbf{c}}$ be the perspective projection onto the plane $z = 0$ with center $\mathbf{c} = (c_1, c_2, d)$.

(a) Show that for $\mathbf{v} = (x, y, z)$ with $z \neq d$,

$$\pi_{\mathbf{c}}(\mathbf{v}) = \left(\frac{dx - c_1 z}{d - z}, \frac{dy - c_2 z}{d - z}, 0 \right).$$

(b) Let $\mathbf{a} = (c_1, c_2, 0)$ and let π be the projection with center $(0,0,d)$. Show that $\pi_{\mathbf{c}} = \tau_{\mathbf{a}} \circ \pi \circ \tau_{-\mathbf{a}}$.

(c) Compute the 4×4 matrix $M_{\tau_{\mathbf{a}}} P M_{\tau_{-\mathbf{a}}}$, with P as in Proposition 4.7.45, and check that it sends $\hat{\mathbf{v}}$ to a vector of homogeneous coordinates of $\pi_{\mathbf{c}}(\mathbf{v})$.

Solution on page 1355

Exercise 4.7.50. STANDARD Let $d \neq 0$, and let π and P be as in Proposition 4.7.45. Let $\mathbf{v} = (v_1, v_2, v_3)$ with $v_3 \neq d$, and let $\mathbf{w} = (w_1, w_2, w_3) \neq \mathbf{0}$.

(a) Suppose $w_3 \neq 0$, and let $\mathbf{q}_{\mathbf{w}} = (-dw_1/w_3, -dw_2/w_3, 0)$. Show that $P\begin{pmatrix} \mathbf{w} \\ 0 \end{pmatrix}$ is a vector of homogeneous coordinates of $\mathbf{q}_{\mathbf{w}}$, and that for every $s \in \mathbb{R}$ with $v_3 + sw_3 \neq d$, the point $\pi(\mathbf{v} + s\mathbf{w})$ lies on $\operatorname{aff}(\pi(\mathbf{v}), \mathbf{q}_{\mathbf{w}})$. Conclude that the images of all lines with direction $\operatorname{span}(\mathbf{w})$ lie on lines (or points) through the single point $\mathbf{q}_{\mathbf{w}}$, the **vanishing point** of the direction $\mathbf{w}$.

(b) Suppose $w_3 = 0$. Show that π maps the line $\mathbf{v} + \operatorname{span}(\mathbf{w})$ onto the line $\pi(\mathbf{v}) + \operatorname{span}((w_1, w_2, 0))$. So lines parallel to the image plane have parallel images.

Solution on page 1356

Exercise 4.7.51. STANDARD Prove or disprove: if E_1 and E_2 are affine subspaces of V and $E_1 \cup E_2$ is an affine subspace, then $E_1 \subseteq E_2$ or $E_2 \subseteq E_1$. Does the answer depend on F?

Solution on page 1356

Exercise 4.7.52. STANDARD Let $\dim V = n \geq 2$, and let H and H' be hyperplanes in V. Show that either H and H' are parallel, or $H \cap H'$ is an affine subspace of dimension $n - 2$. Deduce that two lines in a plane are parallel or meet in exactly one point.

Solution on page 1357

Exercise 4.7.53. STANDARD Let $\mathbf{u}, \mathbf{w} \in V$ be nonzero, let $\mathbf{p}, \mathbf{q} \in V$, and let $\ell_1 = \mathbf{p} + \operatorname{span}(\mathbf{u})$ and $\ell_2 = \mathbf{q} + \operatorname{span}(\mathbf{w})$. Show that ℓ_1 and ℓ_2 are disjoint and not parallel if and only if $\mathbf{u}, \mathbf{w}, \mathbf{q} - \mathbf{p}$ is linearly independent. Deduce that if $\dim V = 2$, there are no skew lines in V.

Solution on page 1357

Exercise 4.7.54. ROUTINE Find a system of linear equations whose solution set is $\operatorname{aff}((1,0,2,1),(2,1,1,1),(0,1,3,2))$ in $\mathbb{R}^4$. How many equations are needed?

Solution on page 1358

Exercise 4.7.55. HARD Let $f : \mathbb{Q}^n \to \mathbb{Q}^m$ satisfy

$$f\Big(\frac{1}{2}\mathbf{u} + \frac{1}{2}\mathbf{v}\Big) = \frac{1}{2}f(\mathbf{u}) + \frac{1}{2}f(\mathbf{v}) \quad \text{for all } \mathbf{u}, \mathbf{v} \in \mathbb{Q}^n.$$

Show that f is affine. (Over $\mathbb{R}$ the same hypothesis does not imply that f is affine; the counterexamples need a basis of $\mathbb{R}$ over $\mathbb{Q}$, see Section 15.1.)

Solution on page 1358

Exercise 4.7.56. ROUTINE Find the error in the following argument, and decide which half of the claim is true.

Claim. A list $\mathbf{v}_0, \dots, \mathbf{v}_k$ in V is affinely independent if and only if it is linearly independent.

Proof. An affine dependence is a linear relation, so if the list is linearly independent, it is affinely independent. Conversely, let $\sum_i c_i \mathbf{v}_i = \mathbf{0}$ be a linear relation, and put $s = \sum_i c_i$. Replacing c_0 by $c_0 - s$ gives coefficients that add up to 0, so an affinely independent list has $c_0 - s = c_1 = \cdots = c_k = 0$. Then $s = c_0$, so $c_0 = c_0 + c_1 + \cdots + c_k$ is consistent only if all $c_i = 0$.

Solution on page 1359

Exercise 4.7.57. HARD Let $\mathbf{v}_0, \mathbf{v}_1, \mathbf{v}_2$ be affinely independent in V. When $1 + 1 \neq 0$, the **median** from $\mathbf{v}_i$ is the line through $\mathbf{v}_i$ and the midpoint $\mathbf{m}_i$ of the other two vertices.

(a) Suppose $2 \neq 0$ and $3 \neq 0$ in F. Show that the three medians are distinct lines that all pass through the centroid $\mathbf{g} = \frac{1}{3}(\mathbf{v}_0 + \mathbf{v}_1 + \mathbf{v}_2)$, and that $\mathbf{g}$ is their only common point.

(b) Now let $F = \mathbb{F}_3$ and $V = \mathbb{F}_3^2$. Show that the three medians are parallel and pairwise disjoint, and that together they contain every point of $\mathbb{F}_3^2$.

Solution on page 1359

Exercise 4.7.58. STANDARD

(a) Find the affine map $f : \mathbb{R}^2 \to \mathbb{R}^2$ with $f(0,0) = (2,1)$, $f(1,0) = (4,2)$, $f(0,1) = (1,3)$, and its matrix M_f.

(b) Find the affine map $g : \mathbb{R}^2 \to \mathbb{R}^2$ with $g(1,1) = (2,1)$, $g(3,1) = (4,2)$, $g(1,2) = (1,3)$.

(c) Let $\mathbf{a}_0, \mathbf{a}_1, \mathbf{a}_2$ be affinely independent in $\mathbb{R}^2$, let $\mathbf{b}_0, \mathbf{b}_1, \mathbf{b}_2 \in \mathbb{R}^2$, and let $\hat{A}, \hat{B} \in \mathbb{R}^{3\times 3}$ have columns $\hat{\mathbf{a}}_i$ and $\hat{\mathbf{b}}_i$. Show that $\hat{A}$ is invertible and that the affine map with $\mathbf{a}_i \mapsto \mathbf{b}_i$ has matrix $\hat{B}\hat{A}^{-1}$. Check (b) this way.

Solution on page 1360

Exercise 4.7.59. HARD (Radon's theorem.) Let $\mathbf{v}_1, \dots, \mathbf{v}_{n+2} \in \mathbb{R}^n$. Show that the index set $\{1, \dots, n+2\}$ can be split into two disjoint nonempty parts I and J with

$$\operatorname{conv}\{\mathbf{v}_i \mid i \in I\} \cap \operatorname{conv}\{\mathbf{v}_j \mid j \in J\} \neq \emptyset.$$

Find such a split for the four points $(0,0),(2,0),(0,2),(1,1)$ of $\mathbb{R}^2$, and for $(0,0),(4,0),(0,4),(1,1)$.

Solution on page 1361

Exercise 4.7.60. STANDARD A function $h : \mathbb{R}^n \to \mathbb{R}$ of the form $h(\mathbf{x}) = w_1x_1 + \cdots + w_nx_n + b$ is an affine map, and the rule "label $\mathbf{x}$ by the sign of $h(\mathbf{x})$" is a **linear classifier**, a single neuron of a neural network (Section 16.6).

(a) Show that no affine $h : \mathbb{R}^2 \to \mathbb{R}$ has $h(0,0) > 0$, $h(1,1) > 0$, $h(1,0) < 0$, and $h(0,1) < 0$. (The labels of these four points form the "exclusive or" pattern.)

(b) Show that after adding the feature x_1x_2, that is, after replacing each point $\mathbf{x}$ by $\varphi(\mathbf{x}) = (x_1, x_2, x_1x_2) \in \mathbb{R}^3$, there is an affine $h' : \mathbb{R}^3 \to \mathbb{R}$ with $h' \circ \varphi$ positive at $(0,0),(1,1)$ and negative at $(1,0),(0,1)$.

Solution on page 1361

Exercise 4.7.61. STANDARD Show that a nonempty subset $S \subseteq \mathbb{F}_2^n$ is an affine subspace if and only if $\mathbf{u} + \mathbf{v} + \mathbf{w} \in S$ for all $\mathbf{u}, \mathbf{v}, \mathbf{w} \in S$. Use this to decide whether $\{(0,0,0),(1,1,0),(1,0,1),(0,1,1)\}$ and $\{(1,0,0),(0,1,0),(0,0,1),(1,1,1)\}$ are affine subspaces of $\mathbb{F}_2^3$.

Solution on page 1361

Exercise 4.7.62. STANDARD

(a) Using 3×3 matrices, compute the composite of the rotation by $90°$ counterclockwise about $(0,0)$ followed by the rotation by $90°$ counterclockwise about $(1,0)$. Show that it is a rotation by $180°$, and find its center.

(b) More generally, let $f(\mathbf{v}) = R_\theta\mathbf{v} + \mathbf{b}$ be an affine map of $\mathbb{R}^2$ whose linear part is the rotation by an angle θ that is not a multiple of 2π. Show that f has exactly one fixed point $\mathbf{c}$, and that f is the rotation by θ about $\mathbf{c}$.

Solution on page 1362

Exercise 4.7.63. STANDARD Let F be a field with q elements, and let $0 \le k \le n$.

(a) Show that the number of k-dimensional affine subspaces of F^n is q^{n-k} times the number of k-dimensional subspaces of F^n.

(b) Count the lines in $\mathbb{F}_3^2$ and the planes in $\mathbb{F}_2^3$.

Solution on page 1362

Exercise 4.7.64. HARD Let V and W be real vector spaces, and let $f : V \to W$ satisfy

$$f((1-t)\mathbf{u} + t\mathbf{v}) = (1-t)f(\mathbf{u}) + tf(\mathbf{v}) \quad \text{for all } \mathbf{u}, \mathbf{v} \in V \text{ and } t \in [0,1].$$

That is, f maps each segment onto a segment, at constant speed. Show that f is affine.

Solution on page 1363

Exercise 4.7.65. STANDARD A point $\mathbf{p}$ of a convex set C is an **extreme point** of C if $\mathbf{p} = (1-t)\mathbf{a} + t\mathbf{b}$ with $\mathbf{a}, \mathbf{b} \in C$ and $t \in (0,1)$ implies $\mathbf{a} = \mathbf{b} = \mathbf{p}$. Show that the extreme points of a simplex are exactly its vertices. Conclude that a simplex determines its set of vertices.

Solution on page 1363

4.8 Proof patterns

Chapter 4 attaches a number to every finite-dimensional space, and most of its proofs either compute such a number or use one to force a conclusion: a list that is too long has a relation, and an injective operator on a finite-dimensional space is onto. This section sorts the chapter's arguments by the question they answer, solves two problems in three ways each to compare the moves, and lists the errors that the chapter's exercises warn against. The exercises at the end practice one move at a time, and the problem set (Problems for Chapter 4) mixes them with earlier chapters.

4.8.1 Relations and independent lists

There are three ways to get information about a list from its length.

- *Too many vectors* (Technique 4.1.30). More than $\dim V$ vectors in V satisfy a nontrivial relation. Nobody computes the relation; it exists, and often that is all we need: every square matrix satisfies a nonzero polynomial (Proposition 4.1.31), the inverse of an injective operator is a polynomial in it (Exercise 4.1.56), and a statement about subsets of $\{1, \dots, n\}$ follows from a relation among $n+1$ vectors (Exercise 4.1.57). The smaller the space that contains the vectors, the shorter the relation, so it pays to look for a small one. The powers of an upper triangular 2×2 matrix stay in a space of dimension 3, not 4 (Exercise 4.8.4(a)).
- *The right length.* A list of length $\dim V$ is a basis as soon as it is independent or spanning (Theorem 4.1.10(b), Corollary 4.1.11(b)), so half of the definition of a basis comes for free (Example 4.1.12). The same count squeezes the dimension of a subspace between an independent list inside it and a vector outside it (Example 4.1.22).
- *Kill terms* (Technique 4.1.25). To show that a particular list is independent, apply an operator to a relation so that all but one term dies. Counting says nothing about a particular list; this move does.

The canonical use of the third move is the nilpotent chain (Proposition 4.1.26): if $T^k\mathbf{v} \neq \mathbf{0}$ and $T^{k+1}\mathbf{v} = \mathbf{0}$, then $\mathbf{v}, T\mathbf{v}, \dots, T^k\mathbf{v}$ is independent. It returns in every later chapter about operators, so here is why it works. The hypothesis $T^{k+1}\mathbf{v} = \mathbf{0}$ is what makes T^k kill every term except the first, and without it the argument collapses (Exercise 4.8.5). Nothing about $\dim V$ is used, so the fact holds on $F[x]$ as well. And it is a statement about one vector at a time, which is what lets it combine with counting: an independent list in V has at most $\dim V$ entries, so when T is nilpotent, every vector dies within $\dim V$ steps, and that is Corollary 4.1.27. When $k+1 = \dim V$, the chain is a basis in which T is the shift (Exercise 4.5.50), and the vectors $\mathbf{w}$ whose chains span the same space are easy to describe (Exercise 4.8.8). In Section 7.2 the same proof runs with T replaced by $N = T - \lambda\,\mathrm{id}$ (Proposition 7.2.37). The last nonzero vector $N^k\mathbf{v}$ is then an eigenvector, and the span of the chain is the smallest subspace that contains $\mathbf{v}$ and is mapped into itself by T (Corollary 7.2.38). Chains glued together are the Jordan bases of Section 10.3, and whether several chains can be glued is decided by their last vectors alone (Exercise 7.2.51).

Example 4.8.1 (A nilpotent operator dies within n steps, three ways). Let $\dim V = n$, and let $T \in \mathrm{L}(V)$ satisfy $T^m = 0$ for some $m \geq 1$. We show $T^n = 0$.

Chains. Let $\mathbf{v} \neq \mathbf{0}$, and let k be the largest index with $T^k\mathbf{v} \neq \mathbf{0}$; it exists and $k < m$, since $T^m\mathbf{v} = \mathbf{0}$. By Proposition 4.1.26, $\mathbf{v}, T\mathbf{v}, \dots, T^k\mathbf{v}$ is an independent list of length $k+1$, so $k+1 \leq n$ (Theorem 4.1.10(a)), and $T^n\mathbf{v} = T^{n-k-1}\big(T^{k+1}\mathbf{v}\big) = \mathbf{0}$. This is the proof of Corollary 4.1.27.

Kernels. The kernels $\ker T^0 \subseteq \ker T \subseteq \ker T^2 \subseteq \cdots$ grow, and once two consecutive ones are equal, all later ones are equal (Exercise 4.2.51(b)). Let k be the first index with $\ker T^k = \ker T^{k+1}$; it exists, since the dimensions of the kernels are at most n and cannot increase forever. Before k every step is strict and raises the dimension by at least 1, so $k \leq \dim \ker T^k \leq n$. After k nothing changes, so $\ker T^k = \ker T^j$ for $j = \max(k, m)$, which contains $\ker T^m = V$. Hence $T^k = 0$ and $T^n = T^{n-k}T^k = 0$.

Restriction and induction on $\dim V$. We induct on n, assuming the statement for all spaces of dimension less than n. For $n = 0$ there is nothing to prove. Let $n \geq 1$. If T were injective, every power of T would

be injective, which is false for $T^m = 0$ on $V \neq \{\mathbf{0}\}$. So $\dim\ker T \geq 1$, and $U = \operatorname{im} T$ has $\dim U \leq n-1$ by Theorem 4.2.11. The operator T maps U into itself, and its restriction $T_U \in \mathrm{L}(U)$ satisfies $T_U^m = 0$. By the induction hypothesis, applied to U, $T_U^{\dim U} = 0$, so $T_U^{n-1} = 0$, and for every $\mathbf{v}$,

$$T^n\mathbf{v} = T^{n-1}(T\mathbf{v}) = T_U^{n-1}(T\mathbf{v}) = \mathbf{0}.$$

The chain proof works one vector at a time, and when $T^{n-1} \neq 0$ it produces a basis. The kernel proof never looks at a vector. It only counts, and the numbers it counts, $\dim\ker T^k - \dim\ker T^{k-1}$, are the data from which the Jordan form is built (Exercise 4.2.52, Section 10.3). The restriction proof is an induction on the dimension, which is the shape of the triangularization proofs of Section 7.5, and it proves a little more: $\operatorname{rank} T^k \leq n-k$ for $k \leq n$. A fourth version runs the chain argument in a quotient, relative to a subspace that T maps into itself (Exercise 4.8.14). The bound n cannot be lowered, as the shift on F^n shows.

Practice: Exercise 4.8.4, Exercise 4.8.8, and Exercise 4.8.9.

4.8.2 Rank–nullity and restriction

Rank–nullity says that the kernel and the image of one map have complementary dimensions, so whichever is easier to find gives the other (Technique 4.2.24). Sometimes the image is easy, because the map is visibly onto a space of known dimension; this is how kernels of nonzero functionals were found to be hyperplanes (Example 4.2.25). Sometimes the kernel is easy, because degrees or a leading coefficient force it to be small, and then the image is everything (Example 4.2.28). The cleanest instance is Corollary 4.2.18: between spaces of the same finite dimension, uniqueness of solutions gives existence (Example 4.2.19). Counting also produces vectors that nobody constructs, in an intersection of large subspaces (Proposition 4.2.26) or in the kernel of a map into a smaller space (Corollary 4.2.21). For matrix equations that are linear in the unknown matrix, the same count applies to the map $X \mapsto AX - XA$ or its relatives (Technique 4.2.29).

When only part of the domain matters, restrict first and then count (Technique 4.2.5). The restriction $T{\restriction_U}$ has kernel $U \cap \ker T$, so

$$\dim\operatorname{im}(T{\restriction_U}) = \dim U - \dim(U \cap \ker T)$$

(Exercise 4.2.44), and with $U = \operatorname{im} S$ this is the exact rank of a composite, Proposition 4.3.5. Restriction to a hyperplane is a small model of the whole move (Exercise 4.8.7). Two cautions. A restriction is a map $U \to W$, and it is an operator on U only when T maps U into itself, as T does with $\operatorname{im} T$ in the third proof of Example 4.8.1. And none of this counting means anything when the dimensions are infinite (Exercise 4.8.6).

4.8.3 Rank inequalities

An inequality between ranks is almost always a containment of subspaces followed by a count. For a product, the two easy containments are $\operatorname{im}(AB) \subseteq \operatorname{im} A$ and $\ker B \subseteq \ker(AB)$; the first bounds $\operatorname{rank}(AB)$ by $\operatorname{rank} A$, and the second, through rank–nullity, by $\operatorname{rank} B$ (Theorem 4.3.3, Remark 4.3.9). For an exact count, restrict A to $\operatorname{im} B$:

$$\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A)$$

((4.3.1)), and every lower bound for $\operatorname{rank}(AB)$ is an upper bound for the subtracted term. The transpose exchanges rows and columns without changing the rank (Theorem 4.3.8), so each statement about column spaces has a mirror statement about row spaces. Sums are handled by images, $\operatorname{im}(A+B) \subseteq \operatorname{im} A + \operatorname{im} B$ (Proposition 4.3.20), or by counting rank-one pieces (Corollary 4.3.24, Technique 4.3.17). Finally, several matrices can be packed into one block matrix, whose rank does not change under invertible block row and column operations (Proposition 4.3.1). The block method needs one fact about block triangular matrices.

Lemma 4.8.2 (Ranks of block triangular matrices). Let $X \in F^{p\times q}$, $Y \in F^{p\times s}$, $Y' \in F^{r\times q}$, and $Z \in F^{r\times s}$.

(a) $\operatorname{rank}\begin{pmatrix} X & Y \\ 0 & Z \end{pmatrix} \geq \operatorname{rank} X + \operatorname{rank} Z$ and $\operatorname{rank}\begin{pmatrix} X & 0 \\ Y' & Z \end{pmatrix} \geq \operatorname{rank} X + \operatorname{rank} Z$.
(b) $\operatorname{rank}\begin{pmatrix} X & 0 \\ 0 & Z \end{pmatrix} = \operatorname{rank} X + \operatorname{rank} Z$.

Proof. STANDARD

Uses. Theorem 4.2.7 (The image of T_A), Proposition 2.6.18 (The column space is spanned by the columns), Theorem 1.5.5 (Independence is decided at zero), Theorem 4.1.10 (Independent lists are short), Theorem 4.3.8 (Row rank equals column rank), Proposition 4.4.2 (Sums are the smallest containing subspaces), Theorem 4.4.13 (Bases and dimension of a sum)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Take $\operatorname{rank} X$ independent columns of X and $\operatorname{rank} Z$ independent columns of Z, and look at the corresponding columns of the block matrix.
Hint 2. In a relation among these columns, read the bottom block first: the columns coming from X have zero bottom part. For the lower triangular matrix, transpose.
Sketch. (a) Let $\mathbf{x}_j$ ($j \in J$) be $\operatorname{rank} X$ independent columns of X and $\mathbf{z}_k$ ($k \in K$) be $\operatorname{rank} Z$ independent columns of Z. The columns $(\mathbf{x}_j, \mathbf{0})$ and $(\mathbf{y}_k, \mathbf{z}_k)$ of $\left(\begin{smallmatrix} X & Y \\ 0 & Z \end{smallmatrix}\right)$ are independent: the bottom block of a relation kills the coefficients of the $\mathbf{z}_k$, and then the top block kills the rest. Transposing gives the lower triangular case. (b) With $Y = 0$, the column space lies in the sum of the column spaces of $\left(\begin{smallmatrix} X \\ 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 \\ Z \end{smallmatrix}\right)$, of dimension at most $\operatorname{rank} X + \operatorname{rank} Z$.

(a) Write $M = \left(\begin{smallmatrix} X & Y \\ 0 & Z \end{smallmatrix}\right)$, and write vectors of F^{p+r} as pairs $(\mathbf{a}, \mathbf{b})$ with $\mathbf{a} \in F^p$ and $\mathbf{b} \in F^r$. By Theorem 4.2.7, X has a set J of $a = \operatorname{rank} X$ columns $\mathbf{x}_j$ that are independent, and Z has a set K of $b = \operatorname{rank} Z$ columns $\mathbf{z}_k$ that are independent. The corresponding columns of M are $(\mathbf{x}_j, \mathbf{0})$ for $j \in J$ and $(\mathbf{y}_k, \mathbf{z}_k)$ for $k \in K$, where $\mathbf{y}_k$ is the column of Y above $\mathbf{z}_k$. Suppose

$$\sum_{j \in J} \alpha_j (\mathbf{x}_j, \mathbf{0}) + \sum_{k \in K} \beta_k (\mathbf{y}_k, \mathbf{z}_k) = (\mathbf{0}, \mathbf{0}).$$

The bottom block reads $\sum_k \beta_k \mathbf{z}_k = \mathbf{0}$, so every $\beta_k = 0$. Then the top block reads $\sum_j \alpha_j \mathbf{x}_j = \mathbf{0}$, so every $\alpha_j = 0$. So M has $a + b$ independent columns in its column space, and $\operatorname{rank} M \geq a + b$ (Proposition 2.6.18, Theorem 4.1.10(a)). For the lower triangular matrix,

$$\begin{pmatrix} X & 0 \\ Y' & Z \end{pmatrix}^{\mathsf{T}} = \begin{pmatrix} X^{\mathsf{T}} & Y'^{\mathsf{T}} \\ 0 & Z^{\mathsf{T}} \end{pmatrix},$$

and by Theorem 4.3.8 and the first case its rank is at least $\operatorname{rank} X^{\mathsf{T}} + \operatorname{rank} Z^{\mathsf{T}} = \operatorname{rank} X + \operatorname{rank} Z$.

(b) By (a) the rank is at least $\operatorname{rank} X + \operatorname{rank} Z$. Every column of $\left(\begin{smallmatrix} X & 0 \\ 0 & Z \end{smallmatrix}\right)$ is a column of $\left(\begin{smallmatrix} X \\ 0 \end{smallmatrix}\right)$ or of $\left(\begin{smallmatrix} 0 \\ Z \end{smallmatrix}\right)$, so the column space is contained in the sum of their column spaces (Proposition 4.4.2), which have dimensions $\operatorname{rank} X$ and $\operatorname{rank} Z$. By Theorem 4.4.13(a), its dimension is at most $\operatorname{rank} X + \operatorname{rank} Z$. □

Example 4.8.3 (Sylvester's inequality, three ways). Let $A \in F^{m \times n}$ and $B \in F^{n \times p}$. We show $\operatorname{rank}(AB) \geq \operatorname{rank} A + \operatorname{rank} B - n$.

By restriction. By (4.3.1), $\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A)$, and the subtracted space lies in $\ker A$, which has dimension $n - \operatorname{rank} A$. So $\operatorname{rank}(AB) \geq \operatorname{rank} B - (n - \operatorname{rank} A)$. This is the solution of Exercise 4.3.30(a).

By kernels. A vector $\mathbf{x} \in F^p$ lies in $\ker(AB)$ exactly when $B\mathbf{x} \in \ker A$. So T_B restricts to a linear map $R : \ker(AB) \to \ker A$, whose kernel is $\ker(AB) \cap \ker B = \ker B$. Rank–nullity for R gives

$$\dim \ker(AB) = \dim \ker B + \dim \operatorname{im} R \leq \dim \ker B + \dim \ker A,$$

and rank–nullity for AB, B, and A turns this into $p - \operatorname{rank}(AB) \leq (p - \operatorname{rank} B) + (n - \operatorname{rank} A)$, which is the claim.

By blocks. Let $M = \left(\begin{smallmatrix} B & I_n \\ 0 & A \end{smallmatrix}\right) \in F^{(n+m) \times (p+n)}$. By Lemma 4.8.2(a), $\operatorname{rank} M \geq \operatorname{rank} B + \operatorname{rank} A$. Clear the blocks with block row and column operations (Theorem 2.4.34):

$$\begin{pmatrix} I_n & 0 \\ -A & I_m \end{pmatrix}\begin{pmatrix} B & I_n \\ 0 & A \end{pmatrix}\begin{pmatrix} I_p & 0 \\ -B & I_n \end{pmatrix} = \begin{pmatrix} B & I_n \\ -AB & 0 \end{pmatrix}\begin{pmatrix} I_p & 0 \\ -B & I_n \end{pmatrix} = \begin{pmatrix} 0 & I_n \\ -AB & 0 \end{pmatrix}.$$

The outer factors are invertible, with inverses obtained by changing the signs of A and B, so M has the rank of the last matrix (Proposition 4.3.1). Exchanging its two block columns is multiplication by an invertible permutation matrix and gives $\begin{pmatrix} I_n & 0 \\ 0 & -AB \end{pmatrix}$, of rank $n + \operatorname{rank}(AB)$ by Lemma 4.8.2(b). So $n + \operatorname{rank}(AB) \geq \operatorname{rank} A + \operatorname{rank} B$.

The restriction proof is the most informative. It identifies the rank lost in the product, $\operatorname{rank} B - \operatorname{rank}(AB) = \dim(\operatorname{im} B \cap \ker A)$, and the slack in Sylvester's bound, $\dim \ker A - \dim(\operatorname{im} B \cap \ker A)$, so it also gives the equality case, $\ker A \subseteq \operatorname{im} B$ (Exercise 4.8.10). The kernel proof proves the inequality $\dim \ker(AB) \leq \dim \ker A + \dim \ker B$, which makes sense for linear maps between any spaces as long as the two kernels are finite-dimensional, and it is the ingredient of the index formula in Problem 4.18. The block proof is mechanical: once the right block matrix is written down, everything is multiplication, and the same computation proves Frobenius's inequality (Exercise 4.8.13). Its price is that the dimension argument hides inside Lemma 4.8.2, and the proof does not say where the rank goes.

Practice: Exercise 4.8.10, Exercise 4.8.13, and Exercise 4.8.11.

4.8.4 Sums and direct sums

To show that a sum $U_1 + \cdots + U_k$ is direct, show that $\mathbf{0}$ has only the trivial decomposition, by sorting the terms of an equation into the summands they belong to (Technique 4.4.8). For two subspaces this is the single condition $U \cap W = \{\mathbf{0}\}$. For more, the induction of Technique 4.4.10 needs each U_k to meet the sum of the previous ones trivially, and pairwise intersections are not enough (Non-example 4.4.6). In finite dimension there are two shortcuts. Counting: the sum is direct exactly when bases of the summands concatenate to an independent list, that is, when the dimensions add up (Theorem 4.4.13, Technique 4.4.14), and for $V = U \oplus W$ any two of $U \cap W = \{\mathbf{0}\}$, $U + W = V$, and $\dim U + \dim W = \dim V$ suffice (Proposition 4.4.21). Idempotents: an operator P with $P^2 = P$ splits $V = \operatorname{im} P \oplus \ker P$ with no computation (Technique 4.4.28). In Problem 4.12 the decomposition $F^n = \operatorname{im} A \oplus \ker A$ comes from a rank count instead (Exercise 4.2.50), and AB then turns out to be the idempotent that splits it.

The formula $\dim(U + W) = \dim U + \dim W - \dim(U \cap W)$ received three proofs in Section 4.4.5, and the discussion after them compares them. Extending a basis of $U \cap W$ produces a basis of $U + W$; choosing a complement of $U \cap W$ inside U reduces the formula to the direct case; rank–nullity for a map onto $U + W$ is the one that computes. Read from the point of view of this section, they are Technique 4.1.18, Technique 4.4.14, and Technique 4.2.24, and a fourth proof uses quotients (Exercise 4.6.49). A fifth method, a single row reduction that produces bases of both $U + W$ and $U \cap W$, is Problem 4.6.

4.8.5 Choosing a basis, and transporting

Extend a basis (Technique 4.1.18) when a subspace U must be compared with the whole space or a map must be prescribed on U and left free elsewhere. Complements (Proposition 4.4.16), extensions of maps (Proposition 4.1.19), and functionals separating a vector from a subspace all come from one extended basis.

Choose a convenient basis (Technique 4.5.33) after checking that the statement does not depend on the basis. For statements that survive $A \mapsto GAH$ with G and H invertible, the convenient matrix is the rank normal form $\begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$ (Corollary 4.5.22), as in Exercise 4.8.12. For statements about operators that survive similarity, the basis has to be the same on both sides, and the useful bases come from the operator: a basis adapted to a subspace that T maps into itself (Technique 4.5.36), or a chain $\mathbf{v}, T\mathbf{v}, \ldots$. For instance, an idempotent P of rank r has, in a basis of $\operatorname{im} P$ followed by a basis of $\ker P$, the matrix $\begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$, so $\operatorname{tr} P = r * 1$ in one line, and its commutant can be read off the same matrix (Problem 4.4). The proof of $\operatorname{tr} P = r *$

1 through a column–row factorization (Exercise 4.3.43) chooses no basis of V, but it computes where this proof only looks.

Transport along an isomorphism (Technique 4.5.7) when the space is made of polynomials, matrices, or maps and the question concerns only the linear structure. Coordinates make every n-dimensional space into F^n, and $\mathrm{L}(V,W)$ into $F^{m\times n}$ (Theorem 4.5.8). Only linear notions survive the trip. The degree of a polynomial, the product of two matrices, and the rank of a matrix seen as a vector of $F^{m\times n}$ mean nothing in F^n, and in infinite dimension an isomorphism can even land in a proper subspace (Exercise 4.5.54). To show that two matrices are not similar, transport nothing: compare invariants (Technique 4.5.29).

Practice: Exercise 4.8.12 and Exercise 4.8.4(e).

4.8.6 Quotients and affine arguments BEYOND 21-242

Quotients and affine geometry (Section 4.6, Section 4.7) are not part of 21-242.

A complement of U is a choice, and the quotient V/U is the canonical object that every complement is isomorphic to (Proposition 4.6.29, Intuition (A complement is a choice; the quotient is not)). So proofs that choose a complement can usually be rewritten with a quotient, and the result no longer depends on the choice: rank–nullity becomes the first isomorphism theorem (Corollary 4.6.35), the dimension formula becomes the second (Exercise 4.6.49), and Frobenius's inequality has a quotient proof (Exercise 4.6.53) next to the block proof of Exercise 4.8.13. The price is one check before anything else, that every definition on V/U is independent of the representative (Technique 4.6.18). The second use of quotients is to split an operator that maps U into itself into a piece on U and a piece on V/U (Proposition 4.6.32) and to induct on the dimension (Technique 4.6.31). Applied to the nilpotent chain, this gives a version of Proposition 4.1.26 relative to a subspace (Exercise 4.8.14). Quotients also make sense of rank–nullity in infinite dimension, where $\dim V$ is not a number but the index $\dim\ker T - \dim(W/\operatorname{im} T)$ can be (Problem 4.18).

In affine geometry, a point of an affine subspace can serve as the origin (Technique 4.7.4), or every point can be given an extra coordinate 1 (Technique 4.7.21). The first is shorter when one point is special, and the second treats all points alike. The affine version of too many vectors is that $n+2$ points of an n-dimensional space are affinely dependent (Corollary 4.7.23), and splitting an affine dependence by the signs of its coefficients gives Radon's theorem (Exercise 4.7.59), Carathéodory's theorem (Technique 4.7.33), and Helly's theorem (Problem 4.15).

4.8.7 Reading the chapter's proofs

Where finite dimension enters. The exchange lemma compares an independent list with a finite spanning list, and everything about dimension rests on it (Lemma 4.1.2). Extending an independent list to a basis terminates because independent lists are short (Theorem 4.1.16). Rank–nullity is an equation between numbers, and its corollary that injective operators are surjective fails on $F[x]$ (Example 2.6.4). On the other hand, Proposition 4.1.26 and the restriction formula for $\operatorname{im}(TS)$ use no dimension at all, and the inequality $\dim\ker(AB) \le \dim\ker A + \dim\ker B$ needs only finite-dimensional kernels. For each result, ask which of its steps needed finite dimension.

Inequalities come with their equality cases. Each inequality of the chapter came from a containment of subspaces and a count, and Proposition 4.1.21(b) says that equality of dimensions turns a containment into an equality. So the equality case can be read off the proof. $\operatorname{rank}(TS) = \operatorname{rank} S$ exactly when $\operatorname{im} S \cap \ker T = \{\mathbf{0}\}$ (Proposition 4.3.5), Sylvester's inequality is an equality exactly when $\ker A \subseteq \operatorname{im} B$ (Exercise 4.8.10), and $\dim(U+W) = \dim U + \dim W$ exactly when $U \cap W = \{\mathbf{0}\}$. A proof that drops the subspace it is bounding, instead of writing it down, loses its equality case.

Existence without construction. Counting proves that a relation, a nonzero vector, or a solution exists, and says nothing about what it is: Proposition 4.1.31, Proposition 4.2.26, Corollary 4.2.18. Often the count also

says where to look and how many unknowns to use, after which a small computation finds the object (Exercise 4.1.33, Example 4.2.28).

The field is part of the data. $\mathbb{C}^n$ has dimension $2n$ over $\mathbb{R}$ (Remark 4.1.6, Exercise 4.2.37), and $1 + 1 = 0$ in $\mathbb{F}_2$ makes some sums direct over $\mathbb{Q}$ and not over $\mathbb{F}_2$ (Problem 4.6). The rank of a matrix with rational entries is the same over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$, since Gauss–Jordan elimination never leaves $\mathbb{Q}$ and the reduced form is unique (Theorem 3.3.17). For an integer matrix read modulo a prime p, the rank can only drop, so a rank computed modulo p is a lower bound over $\mathbb{Q}$ (Problem 4.17), and it can drop (Exercise 4.2.36).

4.8.8 Common errors

Most of these appear in the chapter as find-the-error exercises.

- *Pairwise for all at once.* Subspaces that meet pairwise in $\{\mathbf{0}\}$ need not form a direct sum (Non-example 4.4.6, Exercise 4.4.37), and there is no inclusion–exclusion formula for three subspaces (Remark 4.4.22, Exercise 4.4.39).
- *Bases that are not adapted.* A basis of V need not contain a basis of a subspace (Exercise 4.1.48), and bases of U and W need not contain a basis of $U \cap W$ (Exercise 4.4.38). Adapted bases have to be built, by extending a basis of the smaller space.
- *A subspace of the wrong space.* The columns of $\operatorname{rref}(A)$ that span its column space are not columns of A, and $\operatorname{im}(\operatorname{rref}(A)) \neq \operatorname{im} A$ in general (Non-example 4.2.8, Exercise 4.3.35). Containments such as $\ker(AB) \subseteq \ker A + \ker B$ compare subspaces of spaces that are different, or are false even when they are the same space (Exercise 4.8.11).
- *Order of factors.* $\operatorname{rank}(AB) \neq \operatorname{rank}(BA)$ in general, even for square matrices (Example 4.3.4, Exercise 4.3.36), although the difference is limited (Problem 4.11).
- *One invariant for all.* Equal ranks do not make matrices similar (Exercise 4.5.45), and equal traces do not either.
- *Infinite dimension.* Rank–nullity, injective if and only if surjective, and "a subspace of the same dimension is everything" all need finite dimension (Exercise 4.8.6, Exercise 4.5.54).
- *A missing hypothesis in a chain.* $T^k\mathbf{v} \neq \mathbf{0}$ alone does not make $\mathbf{v}, \ldots, T^k\mathbf{v}$ independent (Exercise 4.8.5).
- *Extending the wrong list.* A basis whose last vectors map to a basis of the image does not have its first vectors in the kernel (Exercise 4.2.45).
- *Uniqueness of choices that are not unique.* Complements are not unique (Example 4.4.17), so "the complement" of a subspace means nothing. In quotients, well-definedness is the implication from equal cosets to equal values, not its converse (Exercise 4.6.43), and affine independence is not linear independence (Exercise 4.7.56).

Exercises

Exercise 4.8.4. ROUTINE Prove or disprove each statement with the shortest argument you can, and name the move you used.

(a) For every upper triangular $A \in F^{2\times 2}$ there are $c_0, c_1, c_2, c_3 \in F$, not all 0, with $c_0 I_2 + c_1 A + c_2 A^2 + c_3 A^3 = 0$.

(b) There are $A \in F^{2\times 3}$ and $B \in F^{3\times 2}$ with $BA = I_3$.

(c) Any two 4-dimensional subspaces of F^7 have a nonzero vector in common.

(d) If $T \in \mathrm{L}(F^5)$ satisfies $T^3 = 0$, then $\operatorname{rank} T \leq 3$.

(e) For every $A \in F^{2\times 2}$, the matrices A and $A + I_2$ are not similar. (The answer depends on F: decide for which fields it holds.)

Solution on page 1364

Exercise 4.8.5. ROUTINE Find the error in the following argument, and show that the claim is false.

Claim. Let $T \in \mathrm{L}(V)$, $\mathbf{v} \in V$, and $k \geq 1$ with $T^k\mathbf{v} \neq \mathbf{0}$. Then $\mathbf{v}, T\mathbf{v}, \ldots, T^k\mathbf{v}$ is linearly independent.

Proof. Suppose $a_0\mathbf{v} + a_1T\mathbf{v} + \cdots + a_kT^k\mathbf{v} = \mathbf{0}$. Applying T^k, every term except the first becomes a vector $T^{k+j}\mathbf{v}$ with $j \geq 1$, which is $\mathbf{0}$. So $a_0T^k\mathbf{v} = \mathbf{0}$, and $a_0 = 0$. Applying T^{k-1} to the remaining relation gives $a_1 = 0$ in the same way, and so on.

Solution on page 1364

Exercise 4.8.6. ROUTINE Find the error in the following argument, and show that the claim is false.

Claim. Every injective operator $T \in \mathrm{L}(V)$ is surjective.

Proof. Since T is injective, $\ker T = \{\mathbf{0}\}$. By rank–nullity, $\dim \operatorname{im} T = \dim V - \dim \ker T = \dim V$. So $\operatorname{im} T$ is a subspace of V of the same dimension as V, and therefore $\operatorname{im} T = V$.

Solution on page 1365

Exercise 4.8.7. ROUTINE Let V be finite-dimensional with $\dim V = n \geq 1$, let $T \in \mathrm{L}(V, W)$, and let H be a subspace of V with $\dim H = n - 1$.

(a) Show that $\operatorname{rank}(T\restriction_H)$ is $\operatorname{rank} T$ or $\operatorname{rank} T - 1$, and that it is $\operatorname{rank} T - 1$ if and only if $\ker T \subseteq H$.

(b) Let $A \in F^{m\times n}$ with $n \geq 2$, and let A' be A with column j deleted. Show that $\operatorname{rank} A' = \operatorname{rank} A - 1$ if column j is not a linear combination of the other columns, and $\operatorname{rank} A' = \operatorname{rank} A$ otherwise. Prove this twice: from (a), and directly from the column spaces.

(c) Deduce that deleting k rows and l columns of a matrix, so that at least one row and one column remain, lowers its rank by at most $k + l$.

Solution on page 1365

Exercise 4.8.8. STANDARD Let $T \in \mathrm{L}(V)$, $\mathbf{v} \in V$, and $k \geq 0$ with $T^k\mathbf{v} \neq \mathbf{0}$ and $T^{k+1}\mathbf{v} = \mathbf{0}$, and let $W = \operatorname{span}\big(\mathbf{v}, T\mathbf{v}, \ldots, T^k\mathbf{v}\big)$.

(a) Let $\mathbf{w} = a_0\mathbf{v} + a_1T\mathbf{v} + \cdots + a_kT^k\mathbf{v}$. Show that $\mathbf{w}, T\mathbf{w}, \ldots, T^k\mathbf{w}$ is a basis of W if and only if $a_0 \neq 0$.

(b) Let F have q elements. How many $\mathbf{w} \in W$ satisfy $W = \operatorname{span}\big(\mathbf{w}, T\mathbf{w}, \ldots, T^k\mathbf{w}\big)$?

Solution on page 1366

Exercise 4.8.9. STANDARD Let $n \geq 1$, and let $S \subseteq F^{n\times n}$ be a subspace with $I_n \in S$ and $XY \in S$ for all $X, Y \in S$. Let $A \in S$ be invertible.

(a) Show that $A^{-1} \in S$ by finding a relation among $I_n, A, A^2, \ldots, A^d$, where $d = \dim S$.

(b) Show again that $A^{-1} \in S$, by applying rank–nullity to the map $S \to S$, $X \mapsto AX$.

(c) Deduce that the inverse of an invertible upper triangular matrix is upper triangular.

Solution on page 1366

Exercise 4.8.10. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{n\times p}$.

(a) Show that $\operatorname{rank}(AB) = \operatorname{rank} A + \operatorname{rank} B - n$ if and only if $\ker A \subseteq \operatorname{im} B$.

(b) Suppose $AB = 0$. Show that $\operatorname{rank} A + \operatorname{rank} B \leq n$, with equality if and only if $\operatorname{im} B = \ker A$.

(c) Let $N \in F^{n\times n}$. Show that $\operatorname{rank}\big(N^2\big) = 2\operatorname{rank} N - n$ if and only if $\ker N \subseteq \operatorname{im} N$, and check this on the shift N with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$ for $j \geq 2$.

Solution on page 1367

Exercise 4.8.11. STANDARD Find the error in the following argument. Is the claim true? Give matrices for which the false step fails, and repair the argument.

Claim. For $A, B \in F^{n\times n}$, $\dim\ker(AB) \le \dim\ker A + \dim\ker B$, and hence $\operatorname{rank}(AB) \ge \operatorname{rank} A + \operatorname{rank} B - n$.

Proof. If $AB\mathbf{x} = \mathbf{0}$, then A kills $B\mathbf{x}$, so either $B\mathbf{x} = \mathbf{0}$ or A kills $\mathbf{x}$. Hence $\ker(AB) \subseteq \ker A \cup \ker B \subseteq \ker A + \ker B$, and by Theorem 4.4.19, $\dim\ker(AB) \le \dim(\ker A + \ker B) \le \dim\ker A + \dim\ker B$. Rank–nullity for AB, A, and B gives the second inequality.

Solution on page 1367

Exercise 4.8.12. HARD Let $A \in F^{m\times n}$ have rank r, and let

$$\Sigma_A = \{X \in F^{n\times m} \mid AXA = A\}.$$

(a) Show that Σ_A is nonempty, and that $\Sigma_A = X_0 + K$ for any $X_0 \in \Sigma_A$, where $K = \{X \mid AXA = 0\}$ is a subspace of $F^{n\times m}$ with $\dim K = mn - r^2$.

(b) Let F have q elements. How many X satisfy $AXA = A$?

(c) For $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \in \mathbb{Q}^{2\times 2}$, describe Σ_A.

Solution on page 1368

Exercise 4.8.13. HARD (*Frobenius's inequality by blocks.*) Let $A \in F^{m\times n}$, $B \in F^{n\times p}$, and $C \in F^{p\times q}$, and let

$$M = \begin{pmatrix} AB & 0 \\ B & BC \end{pmatrix} \in F^{(m+n)\times(p+q)}.$$

(a) Compute $\begin{pmatrix} I_m & -A \\ 0 & I_n \end{pmatrix} M \begin{pmatrix} I_p & -C \\ 0 & I_q \end{pmatrix}$.

(b) Deduce $\operatorname{rank}(AB) + \operatorname{rank}(BC) \le \operatorname{rank} B + \operatorname{rank}(ABC)$.

(c) Recover Sylvester's inequality as a special case.

Solution on page 1369

Exercise 4.8.14. STANDARD BEYOND 21-242 Let $T \in \mathrm{L}(V)$, and let U be a subspace of V with $T(\mathbf{u}) \in U$ for all $\mathbf{u} \in U$. Let $\mathbf{v} \in V$ and $k \ge 0$ with $T^k\mathbf{v} \notin U$ and $T^{k+1}\mathbf{v} \in U$.

(a) Show that the cosets $\mathbf{v} + U, T\mathbf{v} + U, \dots, T^k\mathbf{v} + U$ are linearly independent in V/U. Deduce that $\mathbf{v}, T\mathbf{v}, \dots, T^k\mathbf{v}$ is linearly independent and that its span meets U only in $\mathbf{0}$.

(b) Let V be finite-dimensional, and suppose $T^m(V) \subseteq U$ for some $m \ge 1$. Show that $T^d(V) \subseteq U$, where $d = \dim V - \dim U$. Which earlier result is the case $U = \{\mathbf{0}\}$?

Solution on page 1369

Problems for Chapter 4

These problems combine the sections of Chapter 4 with each other and with Chapters 1–3. The first three are review prompts: state a main result, prove it without looking, and then answer a question that the text did not ask. The rest are ordered roughly by difficulty. Problems marked "Beyond 21-242" use the quotients, affine geometry, or subspace counting of the sections marked the same way, and problems of

kind "competition" are harder than anything the course expects. Section 4.8 compares the techniques these problems call for.

Review: state and prove

Problem 4.1. STANDARD

(a) State Theorem 4.2.11(b).

(b) Prove it by extending a basis of $\ker T$ to a basis of V.

(c) Give a second proof that lifts a basis of $\operatorname{im} T$ instead: choose $\mathbf{v}_1, \dots, \mathbf{v}_r \in V$ such that $T(\mathbf{v}_1), \dots, T(\mathbf{v}_r)$ is a basis of $\operatorname{im} T$, and show that a basis of $\ker T$ followed by $\mathbf{v}_1, \dots, \mathbf{v}_r$ is a basis of V. Deduce that if V is any vector space and $T \in \mathrm{L}(V, W)$ has finite-dimensional kernel and image, then V is finite-dimensional. In particular, an operator on an infinite-dimensional space has an infinite-dimensional kernel or an infinite-dimensional image.

Solution on page 1370

Problem 4.2. STANDARD For $A \in F^{m\times n}$, sets $I \subseteq \{1, \dots, m\}$ and $J \subseteq \{1, \dots, n\}$ with $|I| = |J| = k$, let $A_{IJ} \in F^{k\times k}$ be the submatrix formed by the entries a_{ij} with $i \in I$ and $j \in J$.

(a) State Theorem 4.3.8.

(b) Prove it.

(c) Let $r = \operatorname{rank} A \geq 1$, let the rows of A with indices in I be linearly independent, and let the columns with indices in J be linearly independent, where $|I| = |J| = r$. Show that A_{IJ} is invertible. Deduce that for $A \neq 0$, $\operatorname{rank} A$ is the largest k for which A has an invertible $k \times k$ submatrix.

Solution on page 1370

Problem 4.3. STANDARD

(a) State Proposition 4.1.26 and Corollary 4.1.27.

(b) Prove both.

(c) Under the hypotheses of Proposition 4.1.26, let $W = \operatorname{span}\left(\mathbf{v}, T\mathbf{v}, \dots, T^k\mathbf{v}\right)$. Show that for $1 \leq j \leq k+1$,

$$\ker T^j \cap W = \operatorname{span}\left(T^{k-j+1}\mathbf{v}, \dots, T^k\mathbf{v}\right),$$

so that $\dim\left(\ker T^j \cap W\right) = j$.

Solution on page 1371

Synthesis problems

Problem 4.4. STANDARD Let $P \in F^{n\times n}$ satisfy $P^2 = P$, let $r = \operatorname{rank} P$, and let $\delta : F^{n\times n} \to F^{n\times n}$ be $\delta(X) = PX - XP$.

(a) Show that $\dim \ker \delta = r^2 + (n-r)^2$.

(b) Show that $\operatorname{rank} \delta = 2r(n-r)$, and that $Z \in \operatorname{im} \delta$ if and only if $PZP = 0$ and $(I_n - P)Z(I_n - P) = 0$.

(c) Show that $F^{n\times n} = \ker \delta \oplus \operatorname{im} \delta$, and that the component of X in $\ker \delta$ is $PXP + (I_n - P)X(I_n - P)$.

Solution on page 1372

Problem 4.5. STANDARD Let $S \in \mathrm{L}(F[x])$ be the shift $S(p) = p(x+1)$ (Exercise 2.1.32), and $\Delta = S - \mathrm{id}$. You may use the binomial theorem $(x+c)^j = \sum_{i=0}^{j} \binom{j}{i} c^{j-i} x^i$ in $F[x]$, and that $S^j(p) = p(x+j)$.

(a) Let $n \geq 0$, and suppose that $n! = 1 \cdot 2 \cdots n$ is nonzero in F. Show that for every $p \in F[x]$ of degree exactly n, the translates $p(x), p(x+1), \ldots, p(x+n)$ form a basis of $F[x]_{\leq n}$.

(b) Write 1 as a combination of $x^2, (x+1)^2, (x+2)^2$ over $\mathbb{Q}$.

(c) Let p be a prime. Show that over $\mathbb{F}_p$ the translates $(x+j)^p$, $j \in \mathbb{F}_p$, span a 2-dimensional space. So (a) fails over $\mathbb{F}_p$ for $n = p$.

Solution on page 1373

Problem 4.6. STANDARD (*Zassenhaus's algorithm.*) Let $U = \mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$ and $W = \mathrm{span}(\mathbf{w}_1, \ldots, \mathbf{w}_l)$ be subspaces of F^n. Form the matrix $M \in F^{(k+l)\times 2n}$ whose rows are $(\mathbf{u}_i, \mathbf{u}_i)$ for $i = 1, \ldots, k$ and $(\mathbf{w}_j, \mathbf{0})$ for $j = 1, \ldots, l$, written as rows of length $2n$, and let $R = \mathrm{rref}(M)$.

(a) Show that the row space of M is $Z = \{(\mathbf{u}+\mathbf{w}, \mathbf{u}) \mid \mathbf{u} \in U, \mathbf{w} \in W\}$, and that $(\mathbf{a}, \mathbf{b}) \mapsto \mathbf{a}$ maps Z onto $U + W$ with kernel $\{(\mathbf{0}, \mathbf{u}) \mid \mathbf{u} \in U \cap W\}$.

(b) Show that the left halves of the nonzero rows of R whose left half is nonzero form a basis of $U + W$, and that the right halves of the remaining nonzero rows form a basis of $U \cap W$.

(c) Run the algorithm in F^4 with $\mathbf{u}_1 = (1,1,0,0)$, $\mathbf{u}_2 = (0,1,1,0)$, $\mathbf{w}_1 = (0,0,1,1)$, $\mathbf{w}_2 = (1,0,0,-1)$, for $F = \mathbb{F}_2$, and decide what happens for $F = \mathbb{Q}$.

Solution on page 1374

Problem 4.7. STANDARD Let $A, B \in F^{n\times n}$ satisfy $A^2 = A$ and $B^2 = B$.

(a) Suppose $I_n - A - B$ is invertible. Show that A and B are similar, so in particular $\mathrm{rank}\, A = \mathrm{rank}\, B$.

(b) Show by an example that (a) fails without the invertibility hypothesis.

(c) Suppose $AB = BA = 0$. Show that $A + B$ is idempotent and that $\mathrm{rank}(A+B) = \mathrm{rank}\, A + \mathrm{rank}\, B$.

Solution on page 1375

Problem 4.8. STANDARD Let $\dim V = n \geq 1$, and let $N \in \mathrm{L}(V)$ satisfy $N^k = 0$ for some $k \geq 1$. By Exercise 4.2.52, the jumps $d_j = \dim\ker N^j - \dim\ker N^{j-1}$ satisfy $d_1 \geq d_2 \geq \cdots$, and $\dim\ker N \geq n/k$.

(a) Prove $\dim\ker N \geq n/k$ again, by iterating Sylvester's inequality.

(b) Suppose k divides n and $\dim\ker N = n/k$. Show that $\dim\ker N^j = jn/k$ for $0 \leq j \leq k$; in particular $N^{k-1} \neq 0$. Find such an N.

(c) Suppose $\dim\ker N = 1$. Show that $N^{n-1} \neq 0$, and deduce that V has a basis $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$.

Solution on page 1375

Problem 4.9. STANDARD Let $k \geq 2$, let $V_1, \ldots, V_k$ be finite-dimensional, and let $T_i \in \mathrm{L}(V_i, V_{i+1})$ for $i = 1, \ldots, k-1$. The sequence $V_1 \xrightarrow{T_1} V_2 \xrightarrow{T_2} \cdots \xrightarrow{T_{k-1}} V_k$ is **exact** if T_1 is injective, T_{k-1} is surjective, and $\mathrm{im}\, T_{i-1} = \ker T_i$ for $2 \leq i \leq k-1$.

(a) Show that for an exact sequence, $\sum_{i=1}^{k} (-1)^i \dim V_i = 0$.

(b) What does (a) say for $k = 2$ and $k = 3$?

(c) Let $n_1, \ldots, n_k \geq 0$, and let $r_0 = 0$ and $r_i = n_i - r_{i-1}$ for $i = 1, \ldots, k$. Show that there is an exact sequence with $\dim V_i = n_i$ for all i if and only if $r_i \geq 0$ for all i and $r_k = 0$.

Solution on page 1376

Problem 4.10. STANDARD BEYOND 21-242 Let F have q elements, let $\dim V = n$, and for $0 \le r \le n$ let $N_q(n,r)$ be the number of independent lists of length r in V (Corollary 4.1.35).

(a) Let U and W be subspaces of V with $\dim U + \dim W = n$, and let $r = \dim W$. Show that exactly $N_q(r,r)$ operators $T \in \mathrm{L}(V)$ satisfy $\ker T = U$ and $\operatorname{im} T = W$.

(b) Show that the number of $T \in \mathrm{L}(V)$ with $T^2 = T$ and $\operatorname{rank} T = r$ is

$$N_q \frac{n,r}{N_q}(r,r) \cdot q^{r(n-r)},$$

and check the total over all r against Problem 2.8(b) for $n = 2$ when q is a prime.

(c) Show that the number of $T \in \mathrm{L}(V)$ of rank r is $N_q(n,r)^2 / N_q(r,r)$, and check that the counts for $n = q = 2$ add up to $|\mathrm{L}(V)|$.

Solution on page 1377

Problem 4.11. HARD Let $A, B \in F^{n\times n}$.

(a) Show that $\operatorname{rank}(BA) \ge 2\operatorname{rank}(AB) - n$.

(b) Deduce that $|\operatorname{rank}(AB) - \operatorname{rank}(BA)| \le \lfloor n/2 \rfloor$.

(c) Show that the bound in (b) is attained for every $n \ge 1$.

Solution on page 1378

Problem 4.12. HARD Let $A, B \in F^{n\times n}$ satisfy $A^2B = A$, and let $r = \operatorname{rank} A$.

(a) Show that $\operatorname{rank} A^2 = \operatorname{rank} A$, and deduce that $F^n = \operatorname{im} A \oplus \ker A$.

(b) Show that $(AB - BA)^2 = 0$.

(c) Show that $\operatorname{rank}(AB - BA) \le \min(r, n-r)$, and that for every k with $2k \le n$ there are such A and B with $\operatorname{rank}(AB - BA) = k$.

Solution on page 1378

Problem 4.13. HARD Let $n \ge 1$, and call $N \in F^{n\times n}$ nilpotent if $N^m = 0$ for some $m \ge 1$.

(a) Show that every nilpotent N is similar to a strictly upper triangular matrix, and deduce that $\operatorname{tr} N = 0$.

(b) Show that the nilpotent matrices span the subspace $\{X \in F^{n\times n} \mid \operatorname{tr} X = 0\}$.

(c) Show that the matrices P with $P^2 = P$ span all of $F^{n\times n}$.

Solution on page 1379

Problem 4.14. HARD BEYOND 21-242 Let F have q elements, let $\dim V = n$, let U be a subspace of dimension k, and let $0 \le j \le n-k$. With N_q as in Corollary 4.1.35, show that the number of j-dimensional subspaces W of V with $W \cap U = \{\mathbf{0}\}$ is

$$q^{jk} \cdot N_q \frac{n-k,j}{N_q}(j,j).$$

Check the cases $j = n-k$ and $j = 1$, and the example of lines and planes in $\mathbb{F}_2^3$ meeting a fixed line only in $\mathbf{0}$.

Solution on page 1380

Problem 4.15. HARD BEYOND 21-242 (*Helly's theorem.*) Let V be a real vector space with $\dim V = n$, and let $C_1, \ldots, C_m$ be convex subsets of V with $m \geq n+1$.

(a) Suppose that every $n+1$ of the sets have a common point. Show that all m of them have a common point.

(b) Let $n \geq 1$. Show that "$n+1$" cannot be replaced by "n" in (a).

Solution on page 1381

Problem 4.16. HARD Let $A \in \mathbb{R}^{3\times 2}$ and $B \in \mathbb{R}^{2\times 3}$ satisfy

$$AB = M = \begin{pmatrix} 8 & 2 & -2 \\ 2 & 5 & 4 \\ -2 & 4 & 5 \end{pmatrix}.$$

(a) Show that $BA = 9I_2$.

(b) Find such A and B.

Solution on page 1381

Problem 4.17. HARD For $n \geq 1$, let $M_n \in \mathbb{Q}^{(2n+1)\times(2n+1)}$ be the matrix with $M_n^{\mathsf{T}} = -M_n$ in which every entry in the first n diagonals below the main diagonal is 1 and every other entry below the main diagonal is -1. Find $\operatorname{rank} M_n$.

Solution on page 1382

Problem 4.18. CHALLENGE BEYOND 21-242 For vector spaces V and W, possibly infinite-dimensional, call $T \in \mathrm{L}(V,W)$ **Fredholm** if $\ker T$ and $W/\operatorname{im} T$ are finite-dimensional, and define its **index** $\operatorname{ind} T = \dim\ker T - \dim(W/\operatorname{im} T)$.

(a) Show that if V and W are finite-dimensional, every $T \in \mathrm{L}(V,W)$ is Fredholm with $\operatorname{ind} T = \dim V - \dim W$.

(b) Let M and D be multiplication by x and differentiation on $\mathbb{Q}[x]$. Show that M and D are Fredholm, and compute their indices.

(c) Let $T \in \mathrm{L}(U,V)$ and $S \in \mathrm{L}(V,W)$ be Fredholm. Show that ST is Fredholm and $\operatorname{ind}(ST) = \operatorname{ind} S + \operatorname{ind} T$. Check this for DM and MD on $\mathbb{Q}[x]$.

Solution on page 1383

Chapter 5

Determinants

The determinant from its axioms: permutations, existence and uniqueness, invertibility, multiplicativity, and cofactor expansion.

5.1 What a determinant should be

A square matrix $A \in F^{n\times n}$ gives a linear map $T_A : F^n \to F^n$. Over $\mathbb{R}$ we can watch T_A act on a region of the plane or of space: it stretches the region, shears it, and possibly turns it over. Two features of this action are recorded by a single number, the determinant $\det A$. Its absolute value is the factor by which T_A scales areas (or volumes), and its sign says whether T_A reverses orientation. We will not start from a formula for $\det A$. Instead, this section lists the properties that a signed area must have, takes them as axioms, and shows that for 2×2 matrices they leave exactly one possibility, $ad - bc$. The same axioms determine $\det A$ for $n \times n$ matrices as well, but the proof needs permutations (Section 5.2) and is given in Section 5.3.

5.1.1 Signed area

Let $A \in \mathbb{R}^{2\times 2}$ have columns $\mathbf{a}_1 = A\mathbf{e}_1$ and $\mathbf{a}_2 = A\mathbf{e}_2$. By linearity, $T_A(s\mathbf{e}_1 + t\mathbf{e}_2) = s\mathbf{a}_1 + t\mathbf{a}_2$, so T_A sends the unit square

$$Q = \{s\mathbf{e}_1 + t\mathbf{e}_2 \mid 0 \le s, t \le 1\}$$

onto the parallelogram

$$P(\mathbf{a}_1, \mathbf{a}_2) = \{s\mathbf{a}_1 + t\mathbf{a}_2 \mid 0 \le s, t \le 1\}.$$

The same computation shows that T_A sends each small grid square $\mathbf{p} + hQ$ onto the parallelogram $A\mathbf{p} + hP(\mathbf{a}_1, \mathbf{a}_2)$. So T_A multiplies the area of every grid square by the same factor, the area of $P(\mathbf{a}_1, \mathbf{a}_2)$, and approximating a region by grid squares suggests that T_A multiplies every area by this factor. (Making the approximation precise is a matter for analysis. We use the picture only as motivation; Section 9.2 returns to it.)

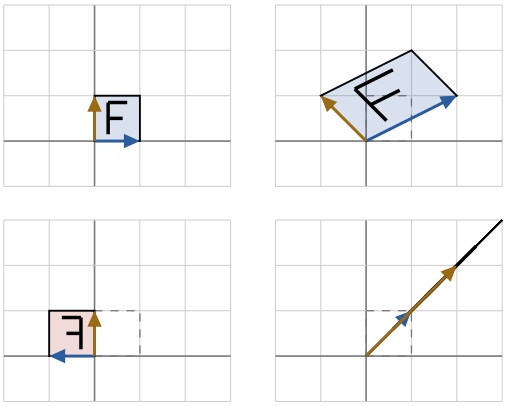

Figure 5.1.1. The unit square (dashed) and a letter F drawn in it, under four linear maps; the arrows are the images of $\mathbf{e}_1$ and $\mathbf{e}_2$. Top row: I_2, and $A = \begin{pmatrix} 2 & -1 \\ 1 & 1 \end{pmatrix}$, which triples areas. Bottom row: $R = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$, which preserves areas but reverses orientation, and $B = \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix}$, which flattens the square. Blue shading means orientation is preserved, red that it is reversed.

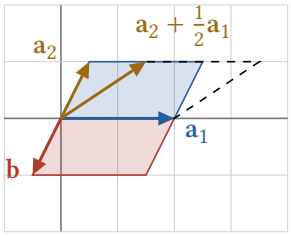
Figure 5.1.1 shows four examples. The map T_A triples areas. The reflection T_R preserves areas but draws the F backwards, and no rotation of the plane turns a backwards F into an F. The map T_B squashes the square onto a segment, so it multiplies areas by 0. This matches the fact that B is not invertible: its second column is twice its first, so its columns are linearly dependent.



To tell T_R apart from the identity we use orientation. In Q, turning from $\mathbf{e}_1$ to $\mathbf{e}_2$ is a counterclockwise turn through an angle between 0 and π. Under T_A this is still true of the turn from $\mathbf{a}_1 = (2, 1)$ to $\mathbf{a}_2 = (-1, 1)$, but under T_R the turn from $\mathbf{a}_1 = (-1, 0)$ to $\mathbf{a}_2 = (0, 1)$ is clockwise. We say that T_A **preserves orientation** and T_R **reverses** it. Accordingly, the **signed area** of $P(\mathbf{a}_1, \mathbf{a}_2)$ is its area when the turn from $\mathbf{a}_1$ to $\mathbf{a}_2$ is counterclockwise, the negative of its area when the turn is clockwise, and 0 when $\mathbf{a}_1$ and $\mathbf{a}_2$ lie on one line through the origin. The determinant of a real 2×2 matrix should be the signed area of the parallelogram spanned by its columns. Its absolute value is then the area scaling factor of T_A, and its sign tells whether T_A preserves orientation.

Intuition (Signed area is linear in each column). Write $S(\mathbf{a}_1, \mathbf{a}_2)$ for the signed area of $P(\mathbf{a}_1, \mathbf{a}_2)$. We do not yet have a formula for S, but three of its properties can be read off from pictures.

- $S(\mathbf{e}_1, \mathbf{e}_2) = 1$, since $P(\mathbf{e}_1, \mathbf{e}_2)$ is the unit square.
- $S(\mathbf{v}, \mathbf{v}) = 0$ for every $\mathbf{v}$, since $P(\mathbf{v}, \mathbf{v})$ is a segment.
- S is linear in each argument when the other argument is fixed.

The first two are clear. For the third, compute area as base times height. Fix $\mathbf{a}_1 \neq \mathbf{0}$ as the base, and let ℓ be the line through $\mathbf{0}$ and $\mathbf{a}_1$. The area of $P(\mathbf{a}_1, \mathbf{a}_2)$ is the length of $\mathbf{a}_1$ times the distance from $\mathbf{a}_2$ to ℓ. Count that distance as positive when $\mathbf{a}_2$ lies on the side of ℓ that $\mathbf{a}_1$ turns toward when it turns counterclockwise, and negative on the other side. With this signed height $h(\mathbf{a}_2)$, the signed area is the length of $\mathbf{a}_1$ times $h(\mathbf{a}_2)$. If $\mathbf{a}_1$ points along the positive x-axis, then $h(x, y) = y$, a linear function of (x, y). Rotating the whole picture changes neither areas nor orientations, so h is linear whatever the direction of $\mathbf{a}_1$, and so is $S(\mathbf{a}_1, \cdot)$. Finally, reversing the order of $\mathbf{a}_1$ and $\mathbf{a}_2$ reverses the direction of the turn, so $S(\mathbf{a}_2, \mathbf{a}_1) = -S(\mathbf{a}_1, \mathbf{a}_2)$, and linearity in the second argument gives linearity in the first.

Two special cases are worth seeing. Adding a multiple of $\mathbf{a}_1$ to $\mathbf{a}_2$ slides $\mathbf{a}_2$ parallel to ℓ, which changes neither the base nor the height, so $S(\mathbf{a}_1, \mathbf{a}_2 + c\mathbf{a}_1) = S(\mathbf{a}_1, \mathbf{a}_2)$. Moving $\mathbf{a}_2$ across ℓ changes the sign of S. Try both below.

Drag $A\mathbf{e}_2$, or focus it and use the arrow keys. Sliding it parallel to $A\mathbf{e}_1$ leaves the signed area unchanged, and moving it across the line through $A\mathbf{e}_1$ flips the sign; the letter F in the square is mirrored exactly when the sign is negative. The formula for the signed area in terms of the entries comes out of the axioms in Theorem 5.1.13. (Interactive in the web version.)

The signs are what make linearity possible. Unsigned area is not linear in either argument: $P(\mathbf{e}_1, \mathbf{e}_2)$ and $P(-\mathbf{e}_1, \mathbf{e}_2)$ both have area 1, but $P(\mathbf{e}_1 + (-\mathbf{e}_1), \mathbf{e}_2) = P(\mathbf{0}, \mathbf{e}_2)$ has area 0, which is not $1 + 1$. With signs, $S(\mathbf{e}_1, \mathbf{e}_2) + S(-\mathbf{e}_1, \mathbf{e}_2) = 1 + (-1) = 0$, as linearity requires. So any function that agrees with area up to sign and is linear in each argument must take negative values, and the sign it carries is the orientation.

5.1.2 The determinant axioms

The three properties of S make no reference to area or to $\mathbb{R}$, and they make sense for n vectors in F^n over any field. We take them as the definition. For a function D on $F^{n\times n}$ and a matrix A with columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, we write $D(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ for $D(A)$. This lets us treat D as a function of n vectors in F^n, the columns of its argument.

Definition 5.1.1 (Determinant function). Let $n \geq 1$, and let $D : F^{n\times n} \to F$.

- D is **normalized** if $D(I_n) = 1$, that is, $D(\mathbf{e}_1, \ldots, \mathbf{e}_n) = 1$.
- D is **alternating** if $D(A) = 0$ whenever two columns of A are equal, that is, whenever $\mathbf{a}_i = \mathbf{a}_j$ for some $i \neq j$.
- D is **multilinear** if it is linear in each column when the other columns are held fixed. That is, for each $j \in [n]$ and all fixed $\mathbf{a}_i$ with $i \neq j$, the map $F^n \to F$ given by

$$\mathbf{x} \mapsto D\big(\mathbf{a}_1, \ldots, \mathbf{a}_{j-1}, \mathbf{x}, \mathbf{a}_{j+1}, \ldots, \mathbf{a}_n\big)$$

  is linear. Concretely,

$$D(\ldots, c\mathbf{x} + \mathbf{y}, \ldots) = cD(\ldots, \mathbf{x}, \ldots) + D(\ldots, \mathbf{y}, \ldots)$$

  for all $\mathbf{x}, \mathbf{y} \in F^n$ and $c \in F$, where the dots stand for the same fixed columns in all three places.

A **determinant function** on $F^{n\times n}$ is a function $D : F^{n\times n} \to F$ that is normalized, alternating, and multilinear. These three conditions are the **determinant axioms**.

So a determinant function is what the motivation asks for: the unit cube has volume 1, a parallelepiped with two equal edges is flat and has volume 0, and signed volume is linear in each edge. In Section 5.3 we prove that for every n there is exactly one determinant function on $F^{n\times n}$ (Theorem 5.3.4). It is called the **determinant** and written det. Until then, D denotes a function satisfying some of the axioms, and each result below says which ones it uses. Several results need only multilinearity and alternation, so they apply to functions such as $D = 0$ as well.

Example 5.1.2 ($n = 1$). A 1×1 matrix is a scalar, so $D : F \to F$. The alternating condition is empty, since there is only one column. Multilinearity says that D is linear, so $D(a) = D(a \cdot 1) = aD(1)$ for every a, and normalization says $D(1) = 1$. Hence $D(a) = a$ is the only determinant function on $F^{1\times 1}$, and it is one.

Non-example 5.1.3 (One axiom at a time). Write $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, whose columns are (a, c) and (b, d). Each function below satisfies two of the axioms and fails the third.

(a) $D(A) = ad$ is normalized, and it is multilinear: for a fixed second column, $(a, c) \mapsto da$ is linear, and for a fixed first column, $(b, d) \mapsto ad$ is linear. It is not alternating, since $D\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} = 1$.

(b) $D = 0$ is alternating and multilinear but not normalized.

(c) Over $\mathbb{R}$, the unsigned area $D(A) = |ad - bc|$ is normalized and alternating (if the columns are equal, then $ad - bc = ac - ca = 0$). It is not multilinear: $D(-\mathbf{e}_1, \mathbf{e}_2) = 1$, while linearity in the first column would force $D(-\mathbf{e}_1, \mathbf{e}_2) = -D(\mathbf{e}_1, \mathbf{e}_2) = -1$.

So none of the three axioms follows from the other two.

Remark 5.1.4. Multilinear does not mean linear. A multilinear D is linear in one column at a time, and scaling the whole matrix scales every column, so $D(cA) = c^n D(A)$, not $cD(A)$. Similarly $D(A + B)$ is usually not $D(A) + D(B)$; Exercise 5.1.21 has an example.

> **Exercise 5.1.5.** ROUTINE Let $D : F^{n\times n} \to F$ be multilinear. Show that $D(cA) = c^n D(A)$ for every $c \in F$ and $A \in F^{n\times n}$. In particular $D(-A) = (-1)^n D(A)$, and $D(A) = 0$ whenever A has a zero column.

Solution on page 1384

Remark 5.1.6. We state the axioms for columns because the columns of A are the vectors $A\mathbf{e}_j$, so they describe what T_A does to the standard basis. The same axioms for rows would serve equally well, and Theorem 5.4.14 shows that they lead to the same function.

Multilinearity and alternation also make sense for a function $f : V \times \cdots \times V \to F$ of k vectors in any vector space V. A multilinear such f is a *k-linear form* on V, and an *alternating* k-linear form if it is also alternating. The proofs of Proposition 5.1.10 and Proposition 5.1.17 below use nothing about columns of matrices, so those results hold for alternating k-linear forms with the same proofs. Section 13.4 develops this point of view and uses it to define the determinant of an operator without choosing a basis.

5.1.3 Swapping columns

The axioms say nothing directly about what happens when two columns are interchanged. In the plane, interchanging $\mathbf{a}_1$ and $\mathbf{a}_2$ reverses the direction of the turn from one to the other, so we expect the sign of D to flip. Proving this is our first use of the basic move for multilinear functions.

> **Technique 5.1.7** (Expand by multilinearity). If an argument of a multilinear function is a sum, split it: linearity in slot j turns $D(\ldots, \sum_k c_k \mathbf{x}_k, \ldots)$ into $\sum_k c_k D(\ldots, \mathbf{x}_k, \ldots)$. Doing this in several slots turns one value of D into a sum over all ways of choosing one term in each slot, so m terms in each of r slots give m^r terms. Usually the terms are standard basis vectors, or other vectors on which D is known, and the expansion reduces $D(A)$ to finitely many known values. When D is also alternating, every term that uses the same vector in two slots vanishes, and typically most of the sum disappears.
>
> Reach for it when you need a value of a multilinear function on general inputs and you know its values on special ones, much as a linear map is determined by its values on a basis (Technique 2.2.7). The canonical example is the 2×2 determinant (Theorem 5.1.13). In Section 5.3 the same expansion, carried out in all n columns, produces a formula for D on $F^{n\times n}$.

> *Used in.* Lemma 5.1.8, Proposition 5.1.10, Theorem 5.1.13, Proposition 5.1.17, Exercise 5.1.20, Exercise 5.1.33, Exercise 5.1.37, Exercise 5.1.38, Exercise 5.1.40, Exercise 5.2.44, Lemma 5.3.2, Theorem 5.3.3, Exercise 5.3.26, Theorem 5.5.3, Theorem 5.5.14, Theorem 5.5.27, Exercise 5.5.48, Exercise 5.5.52, Exercise 5.6.8, Problem 5.3, Problem 5.6, Proposition 6.1.22, Proposition 6.1.29, Corollary 6.3.6, Exercise 7.3.53, Exercise 6.1.44, Exercise 6.1.57, Exercise 6.3.56.

The simplest expansion has just two terms, one of which vanishes.

Lemma 5.1.8 (Column replacement). Let $D : F^{n\times n} \to F$ be multilinear and alternating, let $i \neq j$, and let $c \in F$. If A' is obtained from A by adding c times column j to column i, then $D(A') = D(A)$.

Proof. ROUTINE

Uses. Definition 5.1.1 (Determinant function)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Column i of A' is a sum, $\mathbf{a}_i + c\mathbf{a}_j$. Expand $D(A')$ in column i.
Hint 2. One of the two terms is $D(A)$. In the other, which vector appears in two columns?
Sketch. Linearity in column i gives $D(A') = D(A) + cD(A'')$, where A'' is A with column i replaced by $\mathbf{a}_j$. Then A'' has equal columns i and j, so $D(A'') = 0$.

Let A'' be the matrix obtained from A by replacing column i with $\mathbf{a}_j$. The matrices A, A', and A'' agree outside column i, where they have $\mathbf{a}_i$, $\mathbf{a}_i + c\mathbf{a}_j$, and $\mathbf{a}_j$. By linearity in column i,

$$D(A') = D(A) + cD(A'').$$

Columns i and j of A'' are both $\mathbf{a}_j$, and $i \neq j$, so $D(A'') = 0$ because D is alternating. Hence $D(A') = D(A)$.□

This is the algebraic form of the shear in Intuition (Signed area is linear in each column): sliding one edge of a parallelogram parallel to another edge does not change its signed area. Section 5.4 combines this lemma with the other column operations to compute determinants by elimination.

Definition 5.1.9 (Antisymmetric). A function $D : F^{n\times n} \to F$ is **antisymmetric** if interchanging two columns negates its value: whenever A' is obtained from A by interchanging columns i and j for some $i \neq j$, we have $D(A') = -D(A)$.

For instance, $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto ad - bc$ is antisymmetric, since interchanging the columns gives $bc - ad$. The function $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto ad$ is not: interchanging the columns of I_2 changes its value from 1 to 0, not to -1.

Every result in this subsection fixes all columns except two, so we set up a shorthand. Fix $i \neq j$ and the columns $\mathbf{a}_k$ for $k \notin \{i, j\}$, and for $\mathbf{x}, \mathbf{y} \in F^n$ let $f(\mathbf{x}, \mathbf{y})$ be the value of D at the matrix with $\mathbf{x}$ in column i, $\mathbf{y}$ in column j, and $\mathbf{a}_k$ in every other column k. If D is multilinear, then f is linear in each of $\mathbf{x}$ and $\mathbf{y}$ when the other is fixed; if D is alternating, then $f(\mathbf{x}, \mathbf{x}) = 0$; and D is antisymmetric exactly when $f(\mathbf{y}, \mathbf{x}) = -f(\mathbf{x}, \mathbf{y})$ for every such choice of i, j, and the fixed columns.

Proposition 5.1.10 (Alternating implies antisymmetric). If $D : F^{n\times n} \to F$ is multilinear and alternating, then D is antisymmetric.

Proof (by expanding). ROUTINE

Uses. Definition 5.1.1 (Determinant function), Definition 5.1.9 (Antisymmetric)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Only columns i and j change, so work with the two-variable function f above. You want $f(\mathbf{y}, \mathbf{x}) = -f(\mathbf{x}, \mathbf{y})$.
Hint 2. Alternation only says something when two columns are equal. Which matrix with two equal columns involves both $\mathbf{x}$ and $\mathbf{y}$?
Hint 3. Expand $0 = f(\mathbf{x} + \mathbf{y}, \mathbf{x} + \mathbf{y})$ in both slots.
Sketch. Expanding $0 = f(\mathbf{x} + \mathbf{y}, \mathbf{x} + \mathbf{y})$ gives four terms. Alternation kills $f(\mathbf{x}, \mathbf{x})$ and $f(\mathbf{y}, \mathbf{y})$, leaving $f(\mathbf{x}, \mathbf{y}) + f(\mathbf{y}, \mathbf{x}) = 0$.

Fix $i \neq j$ and the other columns, and let f be as above. Let $\mathbf{x}, \mathbf{y} \in F^n$. Since D is alternating, $f(\mathbf{x} + \mathbf{y}, \mathbf{x} + \mathbf{y}) = 0$. Expanding by linearity in the first slot and then in the second,

$$\begin{aligned} 0 &= f(\mathbf{x}, \mathbf{x} + \mathbf{y}) + f(\mathbf{y}, \mathbf{x} + \mathbf{y}) \\ &= f(\mathbf{x}, \mathbf{x}) + f(\mathbf{x}, \mathbf{y}) + f(\mathbf{y}, \mathbf{x}) + f(\mathbf{y}, \mathbf{y}) \\ &= f(\mathbf{x}, \mathbf{y}) + f(\mathbf{y}, \mathbf{x}), \end{aligned}$$

where the last step uses $f(\mathbf{x},\mathbf{x}) = f(\mathbf{y},\mathbf{y}) = 0$, again because D is alternating. Hence $f(\mathbf{y},\mathbf{x}) = -f(\mathbf{x},\mathbf{y})$. As i, j, the other columns, $\mathbf{x}$, and $\mathbf{y}$ were arbitrary, D is antisymmetric. □

The second proof avoids the four-term expansion. It performs the swap with moves whose effect on D we already know: three column replacements, which do not change D (Lemma 5.1.8), and one sign change. In the plane, the three replacements are shears, and together they rotate the pair $(\mathbf{x},\mathbf{y})$ to $(\mathbf{y},-\mathbf{x})$.

Proof (by column replacements). ROUTINE

> *Uses.* Lemma 5.1.8 (Column replacement), Definition 5.1.1 (Determinant function), Definition 5.1.9 (Antisymmetric)
> *Hint 1.* Lemma 5.1.8 says that $f(\mathbf{x}+c\mathbf{y},\mathbf{y}) = f(\mathbf{x},\mathbf{y})$ and $f(\mathbf{x},\mathbf{y}+c\mathbf{x}) = f(\mathbf{x},\mathbf{y})$. Try to reach $f(\mathbf{y},\pm\mathbf{x})$ by such moves.
> *Hint 2.* Start with $f(\mathbf{x},\mathbf{y}) = f(\mathbf{x}+\mathbf{y},\mathbf{y})$. Now subtract the first slot from the second.
> *Sketch.* Three column replacements take $(\mathbf{x},\mathbf{y})$ to $(\mathbf{x}+\mathbf{y},\mathbf{y})$, then to $(\mathbf{x}+\mathbf{y},-\mathbf{x})$, then to $(\mathbf{y},-\mathbf{x})$. None of them changes f, and pulling out the factor -1 gives $f(\mathbf{x},\mathbf{y}) = -f(\mathbf{y},\mathbf{x})$.

Fix $i \neq j$ and the other columns, let f be as above, and let $\mathbf{x},\mathbf{y} \in F^n$. Each of the first three steps below adds a multiple of one slot to the other, so it does not change f by Lemma 5.1.8:

$$\begin{aligned} f(\mathbf{x},\mathbf{y}) &= f(\mathbf{x}+\mathbf{y},\mathbf{y}) && \text{(add slot 2 to slot 1)} \\ &= f(\mathbf{x}+\mathbf{y},\mathbf{y}-(\mathbf{x}+\mathbf{y})) = f(\mathbf{x}+\mathbf{y},-\mathbf{x}) && \text{(subtract slot 1 from slot 2)} \\ &= f(\mathbf{x}+\mathbf{y}+(-\mathbf{x}),-\mathbf{x}) = f(\mathbf{y},-\mathbf{x}) && \text{(add slot 2 to slot 1)} \\ &= -f(\mathbf{y},\mathbf{x}) && \text{(linearity in slot 2).} \end{aligned}$$

So $f(\mathbf{y},\mathbf{x}) = -f(\mathbf{x},\mathbf{y})$, and D is antisymmetric. □

The first proof is the more economical one. The second shows that a swap is built from shears and a single reflection, which is how Section 5.4 analyzes column operations.

Antisymmetry looks like a reasonable alternative axiom: it is exactly the orientation reversal we observed in the plane. For multilinear functions the two conditions are equivalent over most fields, by Proposition 5.1.11 below. But the converse fails over fields in which $1+1=0$ (as soon as $n \geq 2$), and that failure is why we did not choose antisymmetry.

Proposition 5.1.11 (Antisymmetric implies alternating when $1+1 \neq 0$). Suppose $1+1 \neq 0$ in F. If $D : F^{n\times n} \to F$ is antisymmetric, then D is alternating. Consequently, a multilinear function on $F^{n\times n}$ is alternating if and only if it is antisymmetric.

Proof. ROUTINE

> *Uses.* Definition 5.1.9 (Antisymmetric), Proposition 1.1.17 (No zero divisors), Proposition 5.1.10 (Alternating implies antisymmetric)
> *Hint 1.* Suppose columns i and j of A are equal. What does interchanging them do to A?
> *Hint 2.* It does not change A, so antisymmetry gives $D(A) = -D(A)$. Rewrite this as $(1+1)D(A) = 0$.
> *Sketch.* If $\mathbf{a}_i = \mathbf{a}_j$ with $i \neq j$, interchanging these columns leaves A unchanged, so $D(A) = -D(A)$ and $(1+1)D(A) = 0$. Since $1+1 \neq 0$, $D(A) = 0$. The "consequently" combines this with Proposition 5.1.10.

Let $A \in F^{n\times n}$ with $\mathbf{a}_i = \mathbf{a}_j$ for some $i \neq j$. Interchanging columns i and j of A gives A again, so antisymmetry gives $D(A) = -D(A)$. Adding $D(A)$ to both sides, $D(A) + D(A) = 0$, that is, $(1+1)D(A) = 0$ by distributivity. Since $1+1 \neq 0$ and a field has no zero divisors (Proposition 1.1.17), $D(A) = 0$. So D is alternating.

For the last sentence: a multilinear alternating function is antisymmetric by Proposition 5.1.10, and an antisymmetric function is alternating by what we just proved. □

Note that this direction does not use multilinearity at all. The condition $1+1 \neq 0$ says that $\operatorname{char} F \neq 2$ (Definition 1.1.28). It holds over $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{F}_p$ for odd p, and fails over $\mathbb{F}_2$, where $-1 = 1$ and antisymmetry says only that interchanging two columns changes nothing.

Example 5.1.12 (Antisymmetric but not alternating, over $\mathbb{F}_2$). On $\mathbb{F}_2^{2\times 2}$, define

$$D\begin{pmatrix} a & b \\ c & d \end{pmatrix} = ad + bc + ab.$$

For a fixed second column (b, d), the map $(a, c) \mapsto ad + bc + ab = (d + b)a + bc$ is linear, and for a fixed first column, $(b, d) \mapsto (c + a)b + ad$ is linear, so D is multilinear. Interchanging the columns gives $bc + ad + ba$, the same value, and since $-1 = 1$ in $\mathbb{F}_2$ this means D is antisymmetric. Also $D(I_2) = 1 + 0 + 0 = 1$. But D is not alternating, since $D\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} = 0 + 0 + 1 = 1$.

So over $\mathbb{F}_2$ the axioms "normalized, antisymmetric, multilinear" are satisfied by at least two different functions: this D, and $ad - bc = ad + bc$, which we will see is a determinant function (Theorem 5.1.13). With alternation in place of antisymmetry, the 2×2 case has exactly one solution over every field. This is the reason the definition uses alternation, and an instance of the warning in Aside (Characteristic) that arguments dividing by $1 + 1$ fail in characteristic 2.

5.1.4 The 2×2 determinant

We now show that the axioms determine D completely on $F^{2\times 2}$.

Intuition (Strategy). The axioms tell us the value of D on very few matrices: $D(\mathbf{e}_1, \mathbf{e}_1) = D(\mathbf{e}_2, \mathbf{e}_2) = 0$ by alternation, $D(\mathbf{e}_2, \mathbf{e}_1) = -D(\mathbf{e}_1, \mathbf{e}_2)$ by Proposition 5.1.10, and $D(\mathbf{e}_1, \mathbf{e}_2) = D(I_2) = 1$ by normalization. Multilinearity lets us reach every other matrix from these four. Write each column as a combination of $\mathbf{e}_1$ and $\mathbf{e}_2$ and expand (Technique 5.1.7): $D(A)$ becomes a combination of the four known values, with coefficients that are products of entries of A. Since the expansion uses only multilinearity and alternation, we keep $D(I_2)$ as an unknown until the end; this gives a stronger statement for free.

Theorem 5.1.13 (The 2×2 determinant).

(a) Let $D : F^{2\times 2} \to F$ be multilinear and alternating. Then for all $a, b, c, d \in F$,

$$D\begin{pmatrix} a & b \\ c & d \end{pmatrix} = (ad - bc)D(I_2).$$

(b) The function $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto ad - bc$ is a determinant function on $F^{2\times 2}$.

Consequently, there is exactly one determinant function on $F^{2\times 2}$, namely $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto ad - bc$.

Proof, part 1 of 2: the axioms force $ad - bc$. STANDARD

Uses. Definition 5.1.1 (Determinant function), Proposition 5.1.10 (Alternating implies antisymmetric), Definition 1.6.8 (Standard bases)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Write each column of A as a linear combination of $\mathbf{e}_1$ and $\mathbf{e}_2$.
Hint 2. Expand $D(a\mathbf{e}_1 + c\mathbf{e}_2, b\mathbf{e}_1 + d\mathbf{e}_2)$ by multilinearity, first in column 1, then in column 2. You get four terms.
Hint 3. The four terms involve $D(\mathbf{e}_1, \mathbf{e}_1)$, $D(\mathbf{e}_1, \mathbf{e}_2)$, $D(\mathbf{e}_2, \mathbf{e}_1)$, and $D(\mathbf{e}_2, \mathbf{e}_2)$. Evaluate them with alternation and Proposition 5.1.10.
Sketch. The columns are $a\mathbf{e}_1 + c\mathbf{e}_2$ and $b\mathbf{e}_1 + d\mathbf{e}_2$. Expanding gives $abD(\mathbf{e}_1, \mathbf{e}_1) + adD(\mathbf{e}_1, \mathbf{e}_2) + cbD(\mathbf{e}_2, \mathbf{e}_1) + cdD(\mathbf{e}_2, \mathbf{e}_2)$. Alternation kills the first and last terms, and antisymmetry turns $D(\mathbf{e}_2, \mathbf{e}_1)$ into $-D(\mathbf{e}_1, \mathbf{e}_2) = -D(I_2)$.

(a) Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Its columns are $a\mathbf{e}_1 + c\mathbf{e}_2$ and $b\mathbf{e}_1 + d\mathbf{e}_2$. By linearity in the first column,

$$D(A) = aD(\mathbf{e}_1, b\mathbf{e}_1 + d\mathbf{e}_2) + cD(\mathbf{e}_2, b\mathbf{e}_1 + d\mathbf{e}_2),$$

and by linearity in the second column,

$$D(A) = abD(\mathbf{e}_1, \mathbf{e}_1) + adD(\mathbf{e}_1, \mathbf{e}_2) + cbD(\mathbf{e}_2, \mathbf{e}_1) + cdD(\mathbf{e}_2, \mathbf{e}_2).$$

Since D is alternating, $D(\mathbf{e}_1, \mathbf{e}_1) = D(\mathbf{e}_2, \mathbf{e}_2) = 0$. By Proposition 5.1.10, $D(\mathbf{e}_2, \mathbf{e}_1) = -D(\mathbf{e}_1, \mathbf{e}_2)$, and $D(\mathbf{e}_1, \mathbf{e}_2) = D(I_2)$. Therefore

$$D(A) = adD(I_2) - bcD(I_2) = (ad - bc)D(I_2),$$

as desired.

Part (a) shows that there is at most one determinant function on $F^{2\times 2}$: if $D(I_2) = 1$, then $D(A) = ad - bc$. It remains to check that this candidate satisfies the axioms. For $n = 2$ this is a direct computation. For general n the analogous check is the existence half of Theorem 5.3.4, and it is where permutations enter.

Proof, part 2 of 2: $ad - bc$ satisfies the axioms. ROUTINE

> *Uses.* Definition 5.1.1 (Determinant function), Definition 2.1.1 (Linear map)
> *Hint 1.* Check the three axioms separately. For multilinearity, fix one column and look at $ad - bc$ as a function of the entries of the other column.
> *Hint 2.* For a fixed second column (b, d), the value is $da - bc$, which is a fixed linear combination of the entries a and c of the first column.
> *Sketch.* For a fixed second column, $(a, c) \mapsto da - bc$ is linear; for a fixed first column, $(b, d) \mapsto ad - cb$ is linear. Equal columns give $ac - ca = 0$, and I_2 gives $1 \cdot 1 - 0 \cdot 0 = 1$.

(b) Let $\Delta\begin{pmatrix} a & b \\ c & d \end{pmatrix} = ad - bc$.

Normalized. $\Delta(I_2) = 1 \cdot 1 - 0 \cdot 0 = 1$.

Alternating. If the two columns are equal, then $b = a$ and $d = c$, so $\Delta = ac - ac = 0$.

Multilinear. Fix the second column (b, d). For first columns (a, c) and (a', c') and $s \in F$,

$$\begin{aligned}\Delta\begin{pmatrix} sa + a' & b \\ sc + c' & d \end{pmatrix} &= (sa + a')d - b(sc + c') \\ &= s(ad - bc) + (a'd - bc') = s\Delta\begin{pmatrix} a & b \\ c & d \end{pmatrix} + \Delta\begin{pmatrix} a' & b \\ c' & d \end{pmatrix},\end{aligned}$$

so Δ is linear in the first column. Similarly, for a fixed first column (a, c),

$$a(sd + d') - (sb + b')c = s(ad - bc) + (ad' - b'c),$$

so Δ is linear in the second column. Hence Δ is a determinant function.

Finally, if D is any determinant function on $F^{2\times 2}$, then $D(I_2) = 1$ and (a) gives $D = \Delta$. So Δ is the only one.□

Definition 5.1.14 (The 2×2 determinant). For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$, the **determinant** of A is $\det A = ad - bc$. By Theorem 5.1.13 it is the unique determinant function on $F^{2\times 2}$, and every multilinear alternating $D : F^{2\times 2} \to F$ is a scalar multiple of it: $D = D(I_2)\det$.

For the matrices of Figure 5.1.1, $\det A = 2 \cdot 1 - (-1) \cdot 1 = 3$, $\det R = -1$, and $\det B = 1 \cdot 2 - 2 \cdot 1 = 0$, as the pictures suggested. In general, the formula is the signed area of the motivation.

Example 5.1.15 (det is signed area). Let $\mathbf{a}_1, \mathbf{a}_2 \in \mathbb{R}^2$ be nonzero, and write them in polar form, $\mathbf{a}_1 = r(\cos\alpha, \sin\alpha)$ and $\mathbf{a}_2 = s(\cos\beta, \sin\beta)$ with $r, s > 0$. Then

$$\det(\mathbf{a}_1, \mathbf{a}_2) = rs(\cos\alpha \sin\beta - \sin\alpha \cos\beta) = rs\sin(\beta - \alpha).$$

The parallelogram $P(\mathbf{a}_1, \mathbf{a}_2)$ has base r and height $s|\sin(\beta - \alpha)|$, so $|\det(\mathbf{a}_1, \mathbf{a}_2)|$ is its area. Also $\sin(\beta - \alpha) > 0$ exactly when $\beta - \alpha$ lies strictly between 0 and π modulo 2π, that is, when $\mathbf{a}_2$ is reached from $\mathbf{a}_1$ by a counterclockwise turn of less than a half-turn. So $\det(\mathbf{a}_1, \mathbf{a}_2)$ is the signed area $S(\mathbf{a}_1, \mathbf{a}_2)$ of Intuition (Signed area is linear in each column). (If $\mathbf{a}_1$ or $\mathbf{a}_2$ is $\mathbf{0}$, both are 0.) Together with part (b) of Theorem 5.1.13, this proves the three properties of signed area that we read off from pictures. The general statement that $|\det A|$ is the factor by which T_A scales volume needs a theory of volume; see Section 9.2.

Exercise 5.1.16. ROUTINE Let $A = \begin{pmatrix} 3 & 5 \\ 4 & 2 \end{pmatrix}$. Compute $\det A$ when A is regarded as a matrix over $\mathbb{Q}$, over $\mathbb{F}_7$, and over $\mathbb{F}_2$ (reading each integer as its remainder). For which primes p is $\det A = 0$ over $\mathbb{F}_p$?

Solution on page 1384

Intuition (What the proof did, and where it leads). The expansion in Theorem 5.1.13 produced one term for each way of choosing $\mathbf{e}_1$ or $\mathbf{e}_2$ in each column. The two terms that chose the same vector twice died, and the two survivors correspond to the two orders of $\mathbf{e}_1, \mathbf{e}_2$: the identity order, with value $D(I_2)$, and the swapped order, with value $-D(I_2)$.

For an $n \times n$ matrix, write column j as $\sum_i a_{ij}\mathbf{e}_i$ and expand all n columns. This gives n^n terms, each a product of entries times some $D\big(\mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_n}\big)$. Alternation kills every term with a repeated index, leaving one term for each ordering $i_1, \ldots, i_n$ of $1, \ldots, n$. Each surviving value can be computed by interchanging columns until the order is $1, \ldots, n$, picking up a factor -1 per interchange. For example, two interchanges sort $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1$:

$$D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1) = -D(\mathbf{e}_1, \mathbf{e}_3, \mathbf{e}_2) = D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3).$$

Two questions remain. First, could one ordering be sorted both by an even and by an odd number of interchanges? If so, the axioms would force $D(I_n) = -D(I_n)$, so $D(I_n) = 0$ when $1 + 1 \neq 0$, and no determinant function could exist. Second, does the formula produced by the expansion actually satisfy the axioms? Section 5.2 answers the first question (no), and Section 5.3 answers the second (yes).

5.1.5 Dependent columns

In Figure 5.1.1, the dependent columns of B span a flat parallelogram, and its signed area is 0. The same holds in every dimension: if the columns of A are linearly dependent, then one column is a combination of the others, and expanding that column (Technique 5.1.7) produces only terms with a repeated column.

Proposition 5.1.17 (Dependent columns). Let $D : F^{n\times n} \to F$ be multilinear and alternating. If the columns of $A \in F^{n\times n}$ are linearly dependent, then $D(A) = 0$.

Proof (by expanding). ROUTINE

Uses. Definition 1.5.1 (Linear independence), Definition 5.1.1 (Determinant function), Exercise 5.1.5
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Use a nontrivial dependence relation to write one column $\mathbf{a}_k$ as a linear combination of the other columns.
Hint 2. Expand $D(A)$ in column k. Each term has some $\mathbf{a}_j$ with $j \neq k$ in column k. Where else does $\mathbf{a}_j$ appear?
Sketch. Some $\mathbf{a}_k$ equals $\sum_{j\neq k} b_j\mathbf{a}_j$. Linearity in column k gives $D(A) = \sum_{j\neq k} b_j D\big(A_j\big)$, where A_j has $\mathbf{a}_j$ in columns j and k. Each $D\big(A_j\big)$ is 0.

Since the columns are linearly dependent, there are scalars $c_1, \ldots, c_n$, not all 0, with $c_1\mathbf{a}_1 + \cdots + c_n\mathbf{a}_n = \mathbf{0}$. Choose k with $c_k \neq 0$. Then

$$\mathbf{a}_k = \sum_{j\neq k} b_j\mathbf{a}_j, \quad \text{where } b_j = -c_k^{-1}c_j.$$

If $n = 1$, the sum is empty, so $\mathbf{a}_1 = \mathbf{0}$ and $D(A) = 0$ by Exercise 5.1.5. Otherwise, for $j \neq k$ let A_j be the matrix obtained from A by replacing column k with $\mathbf{a}_j$. By linearity in column k,

$$D(A) = \sum_{j\neq k} b_j D\big(A_j\big).$$

For each $j \neq k$, columns j and k of A_j are both $\mathbf{a}_j$, so $D\big(A_j\big) = 0$ because D is alternating. Hence $D(A) = 0$. □

The second proof replaces the expansion by an invariance argument: change A, without changing $D(A)$, until D is obviously 0.

Proof (by column replacement). ROUTINE

> *Uses.* Definition 1.5.1 (Linear independence), Lemma 5.1.8 (Column replacement), Exercise 5.1.5
> *Hint 1.* Again write $\mathbf{a}_k = \sum_{j \neq k} b_j \mathbf{a}_j$.
> *Hint 2.* Use Lemma 5.1.8 to subtract $b_j \mathbf{a}_j$ from column k, one j at a time. What is column k at the end?
> *Sketch.* Subtracting $b_j \mathbf{a}_j$ from column k for each $j \neq k$ does not change D and turns column k into $\mathbf{0}$. A matrix with a zero column has $D = 0$.

As in the first proof, write $\mathbf{a}_k = \sum_{j \neq k} b_j \mathbf{a}_j$. For each $j \neq k$ in turn, add $-b_j$ times column j to column k. Columns other than k never change, so each step adds $-b_j \mathbf{a}_j$ to column k, and by Lemma 5.1.8 it does not change the value of D. After all the steps, column k is $\mathbf{a}_k - \sum_{j \neq k} b_j \mathbf{a}_j = \mathbf{0}$. So $D(A)$ equals the value of D at a matrix with a zero column, which is 0 by Exercise 5.1.5. □

The first proof is self-contained. The second generalizes better in practice: computing $D(A)$ by column operations that either preserve D or change it in a known way, until the matrix is simple, is how determinants are evaluated in Section 5.4.

Corollary 5.1.18 (Non-invertible matrices). Let $D : F^{n \times n} \to F$ be multilinear and alternating. If $A \in F^{n \times n}$ is not invertible, then $D(A) = 0$. Equivalently, if $D(A) \neq 0$, then A is invertible.

Proof. ROUTINE

> *Uses.* Proposition 5.1.17 (Dependent columns), Corollary 3.5.25 (The invertible matrix theorem), Theorem 3.5.12 (First Fundamental Theorem, completed)
> *Hint 1.* Relate invertibility of a square matrix to linear independence of its columns.
> *Hint 2.* For $A \in F^{n \times n}$, Theorem 3.5.12 says the columns are independent if and only if $\operatorname{rank} A = n$, and Corollary 3.5.25 says A is invertible if and only if $\operatorname{rank} A = n$.
> *Sketch.* If A is not invertible, then $\operatorname{rank} A \neq n$ (Corollary 3.5.25), so the columns of A are dependent (Theorem 3.5.12), and $D(A) = 0$ by Proposition 5.1.17.

Suppose $A \in F^{n \times n}$ is not invertible. By Corollary 3.5.25, $\operatorname{rank} A \neq n$. By Theorem 3.5.12, the columns of A are then not linearly independent. So $D(A) = 0$ by Proposition 5.1.17. The second statement is the contrapositive of the first. □

The converse is false for $D = 0$, which is multilinear and alternating but vanishes on every matrix. So any proof that $\det A \neq 0$ for invertible A must use normalization. For $n = 2$ it follows from the formula (Exercise 5.1.25), and for general n it is Theorem 5.4.7.

Exercises

Exercise 5.1.19. ROUTINE For each function $D : \mathbb{Q}^{2 \times 2} \to \mathbb{Q}$ below, where $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, decide which of the three determinant axioms it satisfies. Then decide which of your answers change if $\mathbb{Q}$ is replaced by $\mathbb{F}_2$.

(a) $D(A) = a + d$.

(b) $D(A) = ab - cd$.

(c) $D(A) = bc - ad$.

(d) $D(A) = (a - b)(d - c)$.

Solution on page 1384

Exercise 5.1.20. ROUTINE Suppose D is a determinant function on $F^{3 \times 3}$. Using only the axioms and the results of this section, find $D(A)$ for

(a) $A = \begin{pmatrix} 0 & 0 & 2 \\ 0 & 3 & 0 \\ 5 & 0 & 0 \end{pmatrix}$, (b) $A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}$, (c) $A = \begin{pmatrix} 1 & 2 & 3 \\ 0 & 1 & 4 \\ 0 & 0 & 1 \end{pmatrix}$.

Solution on page 1385

Exercise 5.1.21. ROUTINE Find the error in the following argument.

Claim. If D is a determinant function on $F^{n\times n}$, then $D(A+B) = D(A) + D(B)$ for all $A, B \in F^{n\times n}$.

Proof. Column j of $A+B$ is $\mathbf{a}_j + \mathbf{b}_j$. Since D is linear in each column,

$$D(A+B) = D(\mathbf{a}_1 + \mathbf{b}_1, ..., \mathbf{a}_n + \mathbf{b}_n) = D(\mathbf{a}_1, ..., \mathbf{a}_n) + D(\mathbf{b}_1, ..., \mathbf{b}_n) = D(A) + D(B).$$

Solution on page 1385

Exercise 5.1.22. ROUTINE Find the error in the following argument.

Claim. If $D : F^{n\times n} \to F$ is multilinear and alternating and $D(A) = 0$, then the columns of A are linearly dependent.

Proof. By Proposition 5.1.17, a matrix with dependent columns has $D(A) = 0$. Here $D(A) = 0$, so the columns of A are dependent.

Solution on page 1385

Exercise 5.1.23. ROUTINE Let $a, b, c, d > 0$ be real numbers with $ad > bc$. Figure 5.1.2 shows the parallelogram P spanned by (a, c) and (b, d) inside the rectangle $[0, a+b] \times [0, c+d]$.

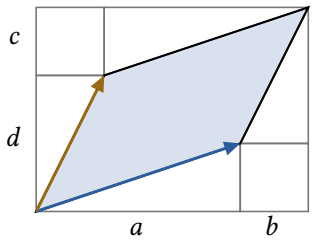

Figure 5.1.2. The parallelogram spanned by (a, c) and (b, d), drawn for $(a, b, c, d) = (3, 1, 1, 2)$. The rest of the rectangle splits into four right triangles and two rectangles.

(a) By computing the areas of the other pieces, show that P has area $ad - bc$.

(b) Explain why the hypothesis $ad > bc$ means that the turn from (a, c) to (b, d) is counterclockwise, so that the answer agrees with the signed area $\det\begin{pmatrix} a & b \\ c & d \end{pmatrix}$.

Solution on page 1386

Exercise 5.1.24. ROUTINE The **permanent** of $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is $\operatorname{per} A = ad + bc$.

(a) Show that per is normalized and multilinear, and that interchanging the two columns of A does not change per A.

(b) For which fields F is per a determinant function on $F^{2\times 2}$?

Solution on page 1386

Exercise 5.1.25. STANDARD Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in F^{2\times 2}$.

(a) Show that $\det A = 0$ if and only if the columns of A are linearly dependent.

(b) Deduce that A is invertible if and only if $\det A \neq 0$, and that in this case

$$A^{-1} = \frac{1}{\det A}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.$$

Solution on page 1386

Exercise 5.1.26. ROUTINE

(a) Compute $\det\begin{pmatrix} 1+i & 2 \\ i & 1-i \end{pmatrix}$ over $\mathbb{C}$.

(b) Find all $z \in \mathbb{C}$ for which the columns of $\begin{pmatrix} z & i \\ i & z \end{pmatrix}$ are linearly dependent, and for each such z write down a dependence relation.

Solution on page 1387

Exercise 5.1.27. STANDARD Show that $\det(AB) = \det A \det B$ for all $A, B \in F^{2\times 2}$.

Solution on page 1387

Solution on page 1387

Exercise 5.1.28. ROUTINE For $\theta \in \mathbb{R}$, let $R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$ be the rotation by θ, and for $t \in \mathbb{R}$ let $S_t = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}$. Show that

$$\det(R_\theta A) = \det A = \det(AS_t) \quad \text{for all } A \in \mathbb{R}^{2\times 2},$$

and explain what each equality says about the parallelogram spanned by the columns of A.

Solution on page 1388

Exercise 5.1.29. STANDARD Find all multilinear alternating functions $D : F^{2\times 2} \to F$ with $D\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} = 6$ when (a) $F = \mathbb{Q}$; (b) $F = \mathbb{F}_2$; (c) $F = \mathbb{F}_3$.

Solution on page 1388

Exercise 5.1.30. STANDARD For which fields F is the function $A \mapsto (\det A)^2$ a determinant function on $F^{2\times 2}$?

Solution on page 1388

Exercise 5.1.31. STANDARD Prove or disprove each statement.

(a) If $D : F^{2\times 2} \to F$ is multilinear and alternating and $D(A) = 0$ for some invertible A, then $D = 0$.

(b) If $D : \mathbb{R}^{2\times 2} \to \mathbb{R}$ is alternating and $D(cA) = c^2 D(A)$ for all $c \in \mathbb{R}$ and all A, then D is a scalar multiple of det.

(c) If $D : F^{3\times 3} \to F$ is multilinear and alternating, then $D(\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3) = D(\mathbf{a}_2, \mathbf{a}_3, \mathbf{a}_1)$ for all $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3 \in F^3$.

Solution on page 1389

Exercise 5.1.32. STANDARD For $\mathbf{x}, \mathbf{y} \in F^3$, define the **cross product**

$$\mathbf{x} \times \mathbf{y} = (x_2y_3 - x_3y_2, x_3y_1 - x_1y_3, x_1y_2 - x_2y_1),$$

and define $D : F^{3\times 3} \to F$ by

$$D(\mathbf{x}, \mathbf{y}, \mathbf{z}) = (\mathbf{x} \times \mathbf{y})_1 z_1 + (\mathbf{x} \times \mathbf{y})_2 z_2 + (\mathbf{x} \times \mathbf{y})_3 z_3.$$

Show that D is a determinant function on $F^{3\times 3}$. (Over $\mathbb{R}$ this is the scalar triple product. So determinant functions exist for $n = 3$; Section 5.3 treats all n.)

Solution on page 1389

Exercise 5.1.33. STANDARD Let $A = \begin{pmatrix} 1 & 0 & 2 \\ 3 & 1 & 0 \\ 0 & 4 & 1 \end{pmatrix}$, and let $D : F^{3\times 3} \to F$ be multilinear and alternating.

(a) Show that $D(A) = 25D(I_3)$ by expanding each column in the standard basis.

(b) Regard A as a matrix over $\mathbb{F}_5$. Find a nontrivial linear dependence among its columns, and explain why this is consistent with (a).

(c) Regard A as a matrix over $\mathbb{Q}$. Show that A is invertible. (A determinant function on $\mathbb{Q}^{3\times 3}$ exists by Exercise 5.1.32.)

Solution on page 1389

Exercise 5.1.34. STANDARD Let Alt_n be the set of multilinear alternating functions $F^{n\times n} \to F$.

(a) Show that Alt_n is a subspace of the vector space of all functions $F^{n\times n} \to F$.

(b) Show that $\mathrm{Alt}_2 = \mathrm{span}(\det)$, and that $\dim \mathrm{Alt}_2 = 1$.

Solution on page 1390

Exercise 5.1.35. STANDARD Let $D : F^{n\times n} \to F$ be multilinear, and suppose that $D(A) = 0$ whenever two *adjacent* columns of A are equal, that is, whenever $\mathbf{a}_i = \mathbf{a}_{i+1}$ for some i. Show that D is alternating.

Solution on page 1390

Exercise 5.1.36. STANDARD Let $k > n$, and let $f : F^n \times \cdots \times F^n \to F$ (with k factors) be multilinear and alternating, in the sense of Remark 5.1.6. Show that $f = 0$. Interpret the result geometrically for $k = 3$ and $n = 2$.

Solution on page 1391

Exercise 5.1.37. STANDARD For $\mathbf{x}, \mathbf{y} \in F^3$ and $1 \le i < j \le 3$, let $f_{ij}(\mathbf{x}, \mathbf{y}) = x_i y_j - x_j y_i$.

(a) Show that f_{12}, f_{13}, and f_{23} are multilinear and alternating functions of two vectors in F^3.

(b) Show that they are linearly independent, as elements of the vector space of functions $F^3 \times F^3 \to F$.

(c) Show that every multilinear alternating $f : F^3 \times F^3 \to F$ satisfies $f = \sum_{i<j} f(\mathbf{e}_i, \mathbf{e}_j) f_{ij}$.

So for two vectors in F^3 there is a three-dimensional space of "signed areas", not a single one up to scaling. This is one reason determinants are only defined for square matrices.

Solution on page 1391

Exercise 5.1.38. STANDARD

(a) Show that $\det(A + tI_2) = t^2 + (\operatorname{tr} A)t + \det A$ for all $A \in F^{2\times 2}$ and $t \in F$.

(b) Let $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, the rotation by $\pi/2$. Find all $t \in \mathbb{C}$ for which $A + tI_2$ is not invertible over $\mathbb{C}$, and all $t \in \mathbb{R}$ for which it is not invertible over $\mathbb{R}$.

Solution on page 1392

Exercise 5.1.39. STANDARD Let p be a prime.

(a) Count the matrices $A \in \mathbb{F}_p^{2\times 2}$ with $\det A \neq 0$.

(b) For $p = 3$, show that exactly half of them have $\det A = 1$.

(c) How many $A \in \mathbb{F}_2^{2\times 2}$ have $\det A = 1$?

Solution on page 1392

Exercise 5.1.40. HARD Let $n \geq 2$, and let $D : F^{n\times n} \to F$ be multilinear and alternating. Write $\mathbf{a}_{n+1} = \mathbf{a}_1$.

(a) Show that when $n = 3$,

$$D(\mathbf{a}_1 + \mathbf{a}_2, \mathbf{a}_2 + \mathbf{a}_3, \mathbf{a}_3 + \mathbf{a}_1) = 2D(\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3).$$

(b) Show that in general

$$D(\mathbf{a}_1 + \mathbf{a}_2, \mathbf{a}_2 + \mathbf{a}_3, \ldots, \mathbf{a}_n + \mathbf{a}_{n+1}) = \left(1 + (-1)^{n-1}\right) D(\mathbf{a}_1, \ldots, \mathbf{a}_n).$$

(c) For even n, explain the answer to (b) directly by finding a linear dependence among the columns $\mathbf{a}_k + \mathbf{a}_{k+1}$.

Solution on page 1392

Exercise 5.1.41. HARD Let $D : F^{n\times n} \to F$ satisfy the following two conditions.

(i) Scaling a column scales D: $D(\ldots, c\mathbf{x}, \ldots) = cD(\ldots, \mathbf{x}, \ldots)$ for every column position, every $c \in F$, and all fixed other columns.

(ii) Column replacement preserves D: if A' is obtained from A by adding a multiple of one column to a different column, then $D(A') = D(A)$.

Show that D is multilinear and alternating. Since conversely every multilinear alternating function satisfies (i) and (ii) (by Lemma 5.1.8), multilinearity and alternation may be replaced by (i) and (ii) in the definition of a determinant function. These are the two properties of volume that are visible in the shear picture.

Solution on page 1393

Exercise 5.1.42. CHALLENGE Let $D : \mathbb{R}^{2\times 2} \to \mathbb{R}$ satisfy $D(AB) = D(A)D(B)$ for all A, B, and $D\begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix} = t$ for all $t \in \mathbb{R}$. Show that $D = \det$.

Solution on page 1394

5.2 Permutations

Let $D : F^{n\times n} \to F$ be multilinear and alternating. In Intuition (What the proof did, and where it leads) we wrote column j of A as $\sum_i a_{ij}\mathbf{e}_i$ and expanded $D(A)$ in all n columns. A term of the expansion chooses one index in each column, so it is indexed by a function $f : [n] \to [n]$, and it equals

$$a_{f(1)1}a_{f(2)2}\cdots a_{f(n)n} D\left(\mathbf{e}_{f(1)}, \mathbf{e}_{f(2)}, \ldots, \mathbf{e}_{f(n)}\right).$$

Alternation kills the term whenever f takes some value twice, so only the bijections f survive. This section studies these bijections, the permutations of $[n]$. To evaluate a surviving value $D\left(\mathbf{e}_{f(1)}, \ldots, \mathbf{e}_{f(n)}\right)$ we interchange two columns at a time until they are in order, and each interchange contributes a factor

-1. The main result, Theorem 5.2.18, says that the parity of the number of interchanges does not depend on how we sort. This gives every permutation σ a sign $\operatorname{sgn}(\sigma) = \pm 1$, and Theorem 5.2.31 shows that $D\big(\mathbf{e}_{\sigma(1)}, \dots, \mathbf{e}_{\sigma(n)}\big) = \operatorname{sgn}(\sigma) D(I_n)$.

5.2.1 Permutations

Throughout, $n \geq 1$ and $[n] = \{1, 2, \dots, n\}$.

Definition 5.2.1 (Permutation). A **permutation** of $[n]$ is a bijection $\sigma : [n] \to [n]$. The set of all permutations of $[n]$ is denoted S_n.

Since $[n]$ is finite, a function $f : [n] \to [n]$ is injective if and only if it is surjective, and hence if and only if it is bijective (Section A.1). So f is a permutation exactly when the list $f(1), f(2), \dots, f(n)$ has no repeated entries, and then this list contains each element of $[n]$ exactly once. In this sense a permutation is a rearrangement of $1, 2, \dots, n$. We record a permutation in **two-line notation**, writing each i above its image:

$$\sigma = \begin{pmatrix} 1 & 2 & \cdots & n \\ \sigma(1) & \sigma(2) & \cdots & \sigma(n) \end{pmatrix}.$$

The bottom row is the rearrangement.

Example 5.2.2 (S_1, S_2, and S_3). S_1 contains only the identity map of $[1]$, and S_2 contains the identity and the permutation $\left(\begin{smallmatrix} 1 & 2 \\ 2 & 1 \end{smallmatrix}\right)$, which interchanges 1 and 2. The six elements of S_3 are

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix},$$
$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix}.$$

In the expansion of a 3×3 determinant these are the six orderings of $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ whose terms survive alternation. For instance, the fourth gives the term $a_{21}a_{32}a_{13}D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1)$.

Non-example 5.2.3 (A function that is not a permutation). Define $f : [3] \to [3]$ by $f(1) = 2$, $f(2) = 2$, and $f(3) = 1$. Then f is not injective, so $f \notin S_3$. In the expansion of $D(A)$ for $A \in F^{3\times 3}$, the term indexed by f is $a_{21}a_{22}a_{13}D(\mathbf{e}_2, \mathbf{e}_2, \mathbf{e}_1)$, which is 0 because $\mathbf{e}_2$ appears in two columns. Every function that is not injective is killed in the same way.

Proposition 5.2.4 (Counting permutations). S_n has exactly $n!$ elements.

Proof. ROUTINE

Uses. Definition 5.2.1 (Permutation), injective maps $[n] \to [n]$ are bijective (Section A.1)
Hint 1. A permutation is determined by the list $\sigma(1), \dots, \sigma(n)$. Given the first k entries, how many choices are there for the next?
Hint 2. Show by induction on k that there are $n(n-1)\cdots(n-k+1)$ lists of k distinct elements of $[n]$.
Sketch. The permutations correspond to the lists of n distinct elements of $[n]$. There are n choices for the first entry, then $n-1$ for the second, and so on, which gives $n!$ lists; induction on the length makes this precise.

A permutation σ is determined by the list $\sigma(1), \dots, \sigma(n)$, and by the remark above, the lists that arise are exactly the lists of n distinct elements of $[n]$. We show by induction on k, for $0 \leq k \leq n$, that there are $n(n-1)\cdots(n-k+1)$ lists of k distinct elements of $[n]$, with the empty product 1 for $k = 0$ (the empty list). This is clear for $k = 0$. If $k < n$, a list of $k+1$ distinct elements consists of a list of k distinct elements followed by one of the $n-k$ elements not in it, and different choices give different lists. So there are $n(n-1)\cdots(n-k+1)\cdot(n-k)$ such lists. Taking $k = n$ gives $n!$. □

The factorial grows quickly: S_{10} already has $3,628,800$ elements. So an expansion over S_n is a tool for proving things about determinants, not for computing them; Section 5.4 computes determinants by elimination.

Composition and inverses

Permutations are functions $[n] \to [n]$, so we can compose them. We write $\sigma\tau$ for the composite $\sigma \circ \tau$, so that $(\sigma\tau)(i) = \sigma(\tau(i))$ for $i \in [n]$: first τ, then σ. We write id for the identity permutation, σ^k for the composite of k copies of σ, and $\sigma^0 = \mathrm{id}$.

Proposition 5.2.5 (Composition and inverses). Let $\sigma, \tau, \rho \in S_n$.

(a) $\mathrm{id} \in S_n$, $\sigma\tau \in S_n$, and $\sigma^{-1} \in S_n$.

(b) $(\sigma\tau)\rho = \sigma(\tau\rho)$, $\sigma\,\mathrm{id} = \mathrm{id}\,\sigma = \sigma$, and $\sigma\sigma^{-1} = \sigma^{-1}\sigma = \mathrm{id}$.

(c) $(\sigma\tau)^{-1} = \tau^{-1}\sigma^{-1}$.

Proof. ROUTINE

Uses. Definition 5.2.1 (Permutation), composition of functions is associative; inverse functions (Section A.1)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. A function is a bijection exactly when it has a two-sided inverse. Find one for $\sigma\tau$.
Hint 2. Try $\tau^{-1}\sigma^{-1}$, and regroup using associativity of composition.
Sketch. The identity and σ^{-1} are bijections. Regrouping gives $(\sigma\tau)(\tau^{-1}\sigma^{-1}) = \sigma\sigma^{-1} = \mathrm{id}$ and $(\tau^{-1}\sigma^{-1})(\sigma\tau) = \mathrm{id}$, so $\sigma\tau$ is a bijection with inverse $\tau^{-1}\sigma^{-1}$. Part (b) is associativity of composition and the definition of an inverse function.

(a) The identity map is a bijection, and the inverse of a bijection σ is a bijection, with inverse σ. Since composition of functions is associative,

$$(\sigma\tau)(\tau^{-1}\sigma^{-1}) = \sigma(\tau\tau^{-1})\sigma^{-1} = \sigma\sigma^{-1} = \mathrm{id}, \quad (\tau^{-1}\sigma^{-1})(\sigma\tau) = \tau^{-1}(\sigma^{-1}\sigma)\tau = \tau^{-1}\tau = \mathrm{id}.$$

So $\sigma\tau$ has a two-sided inverse, and it is a bijection.

(b) These are the associativity of composition and the defining properties of the identity map and of the inverse function.

(c) By the computation in (a), $\tau^{-1}\sigma^{-1}$ is a two-sided inverse of $\sigma\tau$. A bijection has only one inverse function (if g and g' are both inverses of f, then $g = g(fg') = (gf)g' = g'$), so $(\sigma\tau)^{-1} = \tau^{-1}\sigma^{-1}$. □

Remark 5.2.6. Parts (a) and (b) say that S_n with composition is a *group*: a set with an associative operation that has an identity element and inverses. It is called the *symmetric group* of degree n. We will not need any group theory, but Section 14.1 develops this point of view.

Example 5.2.7 (Composing and inverting). Let

$$\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}, \quad \tau = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 1 & 5 & 3 & 4 \end{pmatrix}.$$

To compute $(\sigma\tau)(i)$, apply τ first: $(\sigma\tau)(1) = \sigma(\tau(1)) = \sigma(2) = 5$, $(\sigma\tau)(2) = \sigma(1) = 3$, and so on. We get

$$\sigma\tau = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 5 & 3 & 2 & 4 & 1 \end{pmatrix}, \quad \tau\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 5 & 4 & 3 & 2 & 1 \end{pmatrix}.$$

So $\sigma\tau \neq \tau\sigma$: composition of permutations is not commutative. To invert σ, read the two-line notation from the bottom up. Since σ sends $1,2,3,4,5$ to $3,5,4,1,2$, its inverse sends $3,5,4,1,2$ to $1,2,3,4,5$; sorting the columns,

$$\sigma^{-1} = \begin{pmatrix} 3 & 5 & 4 & 1 & 2 \\ 1 & 2 & 3 & 4 & 5 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 5 & 1 & 3 & 2 \end{pmatrix}.$$

Sums over S_n appear throughout this chapter. The following fact lets us substitute $\rho\sigma$, $\sigma\rho$, or σ^{-1} for the summation variable σ.

Proposition 5.2.8 (Reindexing sums over S_n). Fix $\rho \in S_n$. Each of the maps $S_n \to S_n$ given by $\sigma \mapsto \rho\sigma$, by $\sigma \mapsto \sigma\rho$, and by $\sigma \mapsto \sigma^{-1}$ is a bijection. Consequently, for every function $g : S_n \to F$,

$$\sum_{\sigma \in S_n} g(\sigma) = \sum_{\sigma \in S_n} g(\rho\sigma) = \sum_{\sigma \in S_n} g(\sigma\rho) = \sum_{\sigma \in S_n} g\big(\sigma^{-1}\big).$$

Proof. ROUTINE

Uses. Proposition 5.2.5 (Composition and inverses)
Hint 1. To show that $\sigma \mapsto \rho\sigma$ is a bijection, write down its inverse.
Hint 2. For the sums: if $\varphi : S_n \to S_n$ is a bijection, how do the terms of $\sum_\sigma g(\varphi(\sigma))$ compare with those of $\sum_\sigma g(\sigma)$?
Sketch. The inverses are $\sigma \mapsto \rho^{-1}\sigma$, $\sigma \mapsto \sigma\rho^{-1}$, and $\sigma \mapsto \sigma^{-1}$ itself. If φ is a bijection of S_n, then $\sum_\sigma g(\varphi(\sigma))$ has the same terms as $\sum_\sigma g(\sigma)$ in a different order.

By Proposition 5.2.5, $\rho^{-1}(\rho\sigma) = \sigma$ and $\rho\big(\rho^{-1}\sigma\big) = \sigma$ for every $\sigma \in S_n$, so $\sigma \mapsto \rho^{-1}\sigma$ is a two-sided inverse of $\sigma \mapsto \rho\sigma$. In the same way $\sigma \mapsto \sigma\rho^{-1}$ is a two-sided inverse of $\sigma \mapsto \sigma\rho$, and $\sigma \mapsto \sigma^{-1}$ is its own inverse because $\big(\sigma^{-1}\big)^{-1} = \sigma$. So all three maps are bijections.

Now let $\varphi : S_n \to S_n$ be a bijection. As σ runs through S_n, the element $\varphi(\sigma)$ runs through S_n and takes each value exactly once. So the sum $\sum_\sigma g(\varphi(\sigma))$ has exactly the terms of $\sum_\sigma g(\sigma)$, in another order, and since addition in F is commutative and associative, the two sums are equal. Applying this to the three bijections gives the displayed equalities. □

Exercise 5.2.9. ROUTINE Let $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 1 & 3 \end{pmatrix}$. Compute σ^2, σ^3, and σ^{-1}, and find the least $m \geq 1$ with $\sigma^m = \mathrm{id}$.

Solution on page 1394

5.2.2 Transpositions and cycles

In Intuition (What the proof did, and where it leads) we sorted the columns of $D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1)$ by interchanging two columns at a time. The permutations that interchange two elements are the building blocks of this section.

Definition 5.2.10 (Transposition). Let $k, l \in [n]$ with $k \neq l$. The **transposition** $\tau = (k\ l)$ is the permutation that interchanges k and l and fixes everything else:

$$\tau(k) = l, \quad \tau(l) = k, \quad \tau(i) = i \text{ for } i \notin \{k, l\}.$$

It is an **adjacent transposition** if $l = k + 1$.

Transpositions are also called **swaps**. Note that $(k\ l) = (l\ k)$, and that interchanging twice changes nothing: $(k\ l)^2 = \mathrm{id}$, so $(k\ l)^{-1} = (k\ l)$.

Remark 5.2.11 (Composing with a transposition). Let $\sigma \in S_n$ and $\tau = (k\ l)$. Then $(\sigma\tau)(k) = \sigma(l)$, $(\sigma\tau)(l) = \sigma(k)$, and $(\sigma\tau)(i) = \sigma(i)$ for all other i. So the bottom row of $\sigma\tau$ is the bottom row of σ with the entries in *positions* k and l interchanged. On the other hand, $\tau\sigma$ applies τ to every entry of the bottom row of σ, so its bottom row is that of σ with the *values* k and l interchanged. For example, with $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}$,

$$\sigma(2\ 4) = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 1 & 4 & 5 & 2 \end{pmatrix}, \quad (2\ 4)\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 2 & 1 & 4 \end{pmatrix}.$$

Either way, the bottom row changes by interchanging two of its entries.

Every rearrangement of $1, \ldots, n$ can be sorted by interchanging two entries at a time, so we expect every permutation to be a product of transpositions. To turn this into a proof we need a measure of progress. Say that σ **moves** i if $\sigma(i) \neq i$, and let $m(\sigma)$ be the number of points that σ moves. If $\sigma(k) = j$ with $j \neq k$, then $(k\ j)\sigma$ sends k to k, so composing with one transposition fixes at least one more point. It may fix two, if also $\sigma(j) = k$, so the measure drops by an amount we do not control. This calls for strong induction.

Technique 5.2.12 (Strong induction and well-ordering). To prove a statement $P(m)$ for every integer $m \geq 0$, it suffices to prove $P(m)$ for each m under the assumption that $P(k)$ holds for every $k < m$. When $m = 0$ there is nothing to assume, so the argument must handle that case outright, but no separate base case is needed. Reach for strong induction when a reduction step replaces an object by a smaller one but you cannot say by how much it shrinks, so that induction from $m - 1$ to m does not apply. Often the main decision is the measure of size, such as the number of points a permutation moves or the degree of a polynomial.

An equivalent form is the **well-ordering principle**: every nonempty set of nonnegative integers has a least element. It justifies arguments that begin "let k be the least positive integer such that ...", and proofs by minimal counterexample. The canonical example is Proposition 5.2.13, by induction on the number of moved points. Section A.2 compares the forms of induction, and Section 7.1 uses strong induction on the degree to divide polynomials.

Used in. Proposition 5.2.13, Proposition 5.2.16, Lemma 5.3.14, Theorem 7.1.14, Proposition 7.5.8, Theorem 7.5.13, Lemma 8.2.4, Exercise A.2.9, Exercise 7.1.68.

Proposition 5.2.13 (Products of transpositions). Every permutation $\sigma \in S_n$ is a product of transpositions: there are transpositions $\tau_1, \ldots, \tau_r \in S_n$, with $r \geq 0$, such that $\sigma = \tau_1 \tau_2 \cdots \tau_r$. (For $\sigma = \mathrm{id}$ we take $r = 0$, the empty product.)

Proof. STANDARD

Uses. Definition 5.2.10 (Transposition), Proposition 5.2.5 (Composition and inverses)
Techniques. Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Measure progress by the number $m(\sigma)$ of points that σ moves. Can you compose σ with one transposition so that the result fixes more points?
Hint 2. If $\sigma(k) = j \neq k$, look at $\rho = (k\ j)\sigma$. Which points does ρ fix?
Hint 3. ρ fixes k and every point that σ fixes, so $m(\rho) < m(\sigma)$, but possibly $m(\rho) = m(\sigma) - 2$. Use strong induction, and recover σ from ρ using $(k\ j)^2 = \mathrm{id}$.
Sketch. Strong induction on $m(\sigma)$. If $\sigma = \mathrm{id}$, take the empty product. Otherwise pick k with $\sigma(k) = j \neq k$. Then $\rho = (k\ j)\sigma$ fixes k and every point fixed by σ (a fixed point i of σ cannot be j, by injectivity), so $m(\rho) < m(\sigma)$. Write ρ as a product of transpositions, and $\sigma = (k\ j)\rho$.

We prove by strong induction on $m \geq 0$ that every $\sigma \in S_n$ with $m(\sigma) = m$ is a product of transpositions. Let $\sigma \in S_n$ with $m(\sigma) = m$, and assume the statement for all permutations that move fewer than m points.

If $m = 0$, then $\sigma = \mathrm{id}$, the empty product. Otherwise choose k with $\sigma(k) \neq k$, let $j = \sigma(k)$, and let $\tau = (k\ j)$ and $\rho = \tau\sigma$. Then $\rho(k) = \tau(j) = k$. Now let i be a point fixed by σ. Then $i \neq k$, since σ moves k. Also $i \neq j$: otherwise $\sigma(j) = j = \sigma(k)$ with $j \neq k$, contradicting injectivity of σ. So τ fixes i, and $\rho(i) = \tau(\sigma(i)) = \tau(i) = i$. Thus ρ fixes every point that σ fixes, and it also fixes k, which σ moves. Hence $m(\rho) \leq m - 1$.

By the induction hypothesis, $\rho = \tau_1 \cdots \tau_r$ for some transpositions τ_i. Since $\tau^2 = \mathrm{id}$, we get $\sigma = \tau^2\sigma = \tau\rho = \tau\tau_1 \cdots \tau_r$, a product of transpositions. □

Example 5.2.14 (Sorting by transpositions). Run the proof on $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}$, always choosing the least moved point k. By Remark 5.2.11, composing with a transposition on the left interchanges two values in the bottom row. Since $\sigma(1) = 3$, the first step interchanges the values 1 and 3, then the values 2 and 5, then 3 and 4:

$$(1\ 3)\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 1 & 5 & 4 & 3 & 2 \end{pmatrix},$$

$$(2\ 5)(1\ 3)\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 1 & 2 & 4 & 3 & 5 \end{pmatrix},$$

$$(3\ 4)(2\ 5)(1\ 3)\sigma = \mathrm{id}.$$

Multiplying on the left by $(1\ 3)(2\ 5)(3\ 4)$, the inverse of $(3\ 4)(2\ 5)(1\ 3)$, gives $\sigma = (1\ 3)(2\ 5)(3\ 4)$.

Cycles

Following where a permutation sends one element at a time gives a more economical notation. For $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}$ we have $1 \mapsto 3 \mapsto 4 \mapsto 1$ and $2 \mapsto 5 \mapsto 2$: the elements of $[5]$ travel around two loops.

Definition 5.2.15 (Cycle). Let $k \geq 2$, and let $a_1, \ldots, a_k \in [n]$ be distinct. The **cycle** $(a_1\ a_2\ \ldots\ a_k) \in S_n$ is the permutation that sends

$$a_1 \mapsto a_2 \mapsto \cdots \mapsto a_k \mapsto a_1$$

and fixes every element of $[n]$ outside $\{a_1, \ldots, a_k\}$. Its **length** is k, and we also call it a k-**cycle**. Two cycles $(a_1\ \ldots\ a_k)$ and $(b_1\ \ldots\ b_l)$ are **disjoint** if $\{a_1, \ldots, a_k\} \cap \{b_1, \ldots, b_l\} = \emptyset$.

A 2-cycle is a transposition. A k-cycle has k names, one for each starting point: $(a_1\ a_2\ \ldots\ a_k) = (a_2\ \ldots\ a_k\ a_1)$. Its inverse runs the loop backwards, $(a_1\ a_2\ \ldots\ a_k)^{-1} = (a_k\ \ldots\ a_2\ a_1)$. Disjoint cycles γ and δ commute. Indeed, if γ moves x, then δ fixes both x and $\gamma(x)$, so $\gamma\delta(x) = \gamma(x) = \delta\gamma(x)$; the case where δ moves x is symmetric, and if neither moves x, both sides are x. Cycles that are not disjoint need not commute: $(1\ 2)(2\ 3) = (1\ 2\ 3)$, while $(2\ 3)(1\ 2) = (1\ 3\ 2)$.

Proposition 5.2.16 (Cycle decomposition). Let $\sigma \in S_n$. For $i \in [n]$, the **orbit** of i under σ is $O(i) = \{\sigma^m(i) \mid m \geq 0\}$.

(a) There is a least positive integer k with $\sigma^k(i) = i$. For this k, the elements $i, \sigma(i), \ldots, \sigma^{k-1}(i)$ are distinct, and they are all the elements of $O(i)$.

(b) Any two orbits are equal or disjoint.

(c) σ is the product of the cycles $\big(i\ \sigma(i)\ \ldots\ \sigma^{k-1}(i)\big)$, one for each orbit with $k \geq 2$ elements, and these cycles are pairwise disjoint.

Proof. STANDARD

Uses. Definition 5.2.15 (Cycle), Proposition 5.2.5 (Composition and inverses)
Techniques. Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Follow $i, \sigma(i), \sigma^2(i), \ldots$. These lie in the finite set $[n]$, so two of them coincide. Why does that force some positive power of σ to fix i?
Hint 2. If $\sigma^p(i) = \sigma^q(i)$ with $p < q$, apply σ^{-1} p times. Then take the least k with $\sigma^k(i) = i$; a repetition among $i, \ldots, \sigma^{k-1}(i)$ would produce a smaller one.
Hint 3. For (b), if $j = \sigma^p(i)$, show that i is also of the form $\sigma^q(j)$. For (c), check the product at each $x \in [n]$: only the cycle of the orbit of x moves x.
Sketch. Finiteness gives $\sigma^p(i) = \sigma^q(i)$ with $p < q$, and cancelling σ^p gives $\sigma^{q-p}(i) = i$. Taking k least makes $i, \ldots, \sigma^{k-1}(i)$ distinct, and division with remainder shows that every $\sigma^m(i)$ is among them. If $j = \sigma^p(i)$, then $i = \sigma^{k-p}(j)$, so each of i, j is in the orbit of the other and the orbits agree. On each orbit σ acts as the corresponding cycle, and cycles of different orbits move disjoint sets of points, so their product agrees with σ everywhere.

(a) The elements $i, \sigma(i), \sigma^2(i), \ldots$ all lie in the finite set $[n]$, so $\sigma^p(i) = \sigma^q(i)$ for some $0 \leq p < q$. Applying σ^{-1} to both sides p times gives $\sigma^{q-p}(i) = i$, with $q - p \geq 1$. So the set of positive integers m with $\sigma^m(i) = i$ is nonempty, and by the well-ordering principle it has a least element k. If $\sigma^p(i) = \sigma^q(i)$ with $0 \leq p < q \leq k - 1$, the same argument gives $\sigma^{q-p}(i) = i$ with $0 < q - p < k$, contradicting the choice of k. So $i, \sigma(i), \ldots, \sigma^{k-1}(i)$

are distinct. Finally, let $m \geq 0$, and write $m = qk + r$ with $q \geq 0$ and $0 \leq r < k$. Since $\sigma^k(i) = i$, applying σ^k q times to i gives i, so $\sigma^m(i) = \sigma^r\left(\sigma^{qk}(i)\right) = \sigma^r(i)$. Hence $O(i) = \left\{i, \sigma(i), \ldots, \sigma^{k-1}(i)\right\}$.

(b) Let $j \in O(i)$. By (a), $j = \sigma^p(i)$ with $0 \leq p < k$, where k is as in (a). For every $m \geq 0$, $\sigma^m(j) = \sigma^{m+p}(i) \in O(i)$, so $O(j) \subseteq O(i)$. Also $\sigma^{k-p}(j) = \sigma^k(i) = i$, so $i \in O(j)$, and the same argument with the roles of i and j exchanged gives $O(i) \subseteq O(j)$. So $O(j) = O(i)$ whenever $j \in O(i)$. If two orbits $O(i)$ and $O(i')$ have a common element j, then $O(i) = O(j) = O(i')$.

(c) Let $O_1, \ldots, O_t$ be the distinct orbits with at least two elements. For each s choose $i_s \in O_s$, let $k_s = |O_s|$, and let $\gamma_s = \left(i_s\ \sigma(i_s)\ \ldots\ \sigma^{k_s-1}(i_s)\right)$. By (a), the entries of γ_s are distinct, so γ_s is a cycle, and the set of its entries is O_s. By (b), $\gamma_1, \ldots, \gamma_t$ are pairwise disjoint. We show that $\sigma = \gamma_1 \cdots \gamma_t$ by evaluating both sides at each $x \in [n]$.

If x lies in none of $O_1, \ldots, O_t$, then its orbit $O(x)$ has one element, so $\sigma(x) = x$; and every γ_s fixes x, so the product does too. Otherwise $x \in O_s$ for exactly one s, say $x = \sigma^p(i_s)$ with $0 \leq p < k_s$. Then $\gamma_s(x) = \sigma^{p+1}(i_s) = \sigma(x)$; for $p = k_s - 1$ this reads $\gamma_s(x) = i_s = \sigma^{k_s}(i_s) = \sigma(x)$. Every other $\gamma_{s'}$ fixes the elements of O_s, in particular x and $\sigma(x)$. So when we apply $\gamma_1 \cdots \gamma_t$ to x, the factors to the right of γ_s fix x, then γ_s sends x to $\sigma(x)$, and the factors to the left of γ_s fix $\sigma(x)$. Hence $(\gamma_1 \cdots \gamma_t)(x) = \sigma(x)$. □

Writing σ as a product of disjoint cycles, with the fixed points omitted, is **cycle notation**. To find it, start at the least element, follow it around its loop until it returns, and then start again at the least element not yet used. For example,

$$\begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix} = (1\ 3\ 4)(2\ 5), \quad \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 1 & 5 & 3 & 4 \end{pmatrix} = (1\ 2)(3\ 5\ 4).$$

We write $c(\sigma)$ for the number of orbits of σ, counting each fixed point as an orbit with one element. So $c(\mathrm{id}) = n$, and $c((1\ 3\ 4)(2\ 5)) = 2$ in S_5, while $c((1\ 2)(3\ 4\ 5)) = 3$ in S_6, the orbits being $\{1, 2\}$, $\{3, 4, 5\}$, and $\{6\}$.

Lemma 5.2.17 (Cycles as products of transpositions). Let $k \geq 2$ and let $a_1, \ldots, a_k \in [n]$ be distinct. Then

$$(a_1\ a_2\ \ldots\ a_k) = (a_1\ a_2)(a_2\ a_3)\cdots(a_{k-1}\ a_k).$$

In particular, a k-cycle is a product of $k - 1$ transpositions.

Proof. ROUTINE

Uses. Definition 5.2.15 (Cycle), Definition 5.2.10 (Transposition)
Hint 1. Evaluate the right side at each point. The rightmost factor acts first.
Hint 2. Follow a_i for $i < k$: which factors move it, and in what order? Then follow a_k.
Sketch. For $i < k$, the factors to the right of $(a_i\ a_{i+1})$ do not involve a_i, that factor sends a_i to a_{i+1}, and the factors to its left do not involve a_{i+1}. The point a_k is sent to a_{k-1}, then a_{k-2}, and so on down to a_1. Points outside $\{a_1, \ldots, a_k\}$ are fixed.

Let $\pi = (a_1\ a_2)(a_2\ a_3)\cdots(a_{k-1}\ a_k)$. To compute $\pi(x)$ we apply the factors from right to left, starting with $(a_{k-1}\ a_k)$.

If $x \notin \{a_1, \ldots, a_k\}$, every factor fixes x, so $\pi(x) = x$. Let $1 \leq i < k$. The factors applied before $(a_i\ a_{i+1})$ are the $\left(a_j\ a_{j+1}\right)$ with $j > i$, which do not involve a_i; then $(a_i\ a_{i+1})$ sends a_i to a_{i+1}; and the factors applied after it are the $\left(a_j\ a_{j+1}\right)$ with $j < i$, which do not involve a_{i+1}. So $\pi(a_i) = a_{i+1}$. Finally, $(a_{k-1}\ a_k)$ sends a_k to a_{k-1}, then $(a_{k-2}\ a_{k-1})$ sends it to a_{k-2}, and so on, until $(a_1\ a_2)$ sends a_2 to a_1. So $\pi(a_k) = a_1$. Thus π agrees with $(a_1\ \ldots\ a_k)$ at every point. □

With Proposition 5.2.16, the lemma gives a second proof of Proposition 5.2.13, and this one counts. If the orbits of σ with at least two elements have sizes $k_1, \ldots, k_t$, then σ is a product of $\sum_s (k_s - 1)$ transpositions. The orbits partition $[n]$ and $c(\sigma) - t$ of them are fixed points, so $k_1 + \cdots + k_t + (c(\sigma) - t) = n$, and the number of transpositions is

$$\sum_{s=1}^{t}(k_s - 1) = n - c(\sigma).$$

For $\sigma = (1\ 3\ 4)(2\ 5)$ this gives $\sigma = (1\ 3)(3\ 4)(2\ 5)$, with $5 - 2 = 3$ transpositions.

5.2.3 Parity

A permutation has many factorizations into transpositions. Since $(1\ 2)^2 = \mathrm{id}$, the identity is both the empty product and a product of two transpositions. A direct check shows that

$$(1\ 3) = (1\ 2)(2\ 3)(1\ 2),$$

so $(1\ 3)$ is a product of one transposition and also of three. Substituting this into $\sigma = (1\ 3)(3\ 4)(2\ 5)$ writes that σ as a product of five transpositions as well as of three. In each example the lengths have the same parity, and Theorem 5.2.18 below says that this always happens. Determinants depend on it: if some σ were a product of an even number of transpositions and also of an odd number, then sorting the columns of $D\left(\mathbf{e}_{\sigma(1)}, \ldots, \mathbf{e}_{\sigma(n)}\right)$ in two ways would give both $D(I_n)$ and $-D(I_n)$. So $D(I_n) = 0$ whenever $1 + 1 \neq 0$, and no determinant function would exist.

Theorem 5.2.18 (Parity is well defined). Let $\sigma \in S_n$, and suppose that $\sigma = \tau_1 \cdots \tau_r$ and $\sigma = \tau'_1 \cdots \tau'_s$, where all τ_i and τ'_j are transpositions. Then r and s are both even or both odd. In particular, the identity is not a product of an odd number of transpositions.

Intuition (Looking for an invariant). Comparing two factorizations directly is hopeless, since nothing relates the transpositions in one of them to those in the other. Instead, look for a quantity $Q(\sigma)$ that is computed from σ alone, without reference to any factorization, and that changes sign whenever we multiply by one more transposition:

$$Q(\rho\tau) = -Q(\rho) \quad \text{for every } \rho \in S_n \text{ and every transposition } \tau.$$

If $\sigma = \tau_1 \cdots \tau_r$, applying this r times gives $Q(\sigma) = (-1)^r Q(\mathrm{id})$. So if Q takes values in $\mathbb{Q}$ (or in any field in which $1 \neq -1$) and $Q(\mathrm{id}) \neq 0$, then $(-1)^r = Q(\sigma)/Q(\mathrm{id})$ is determined by σ, and all factorizations of σ have lengths of the same parity.

An obvious candidate is $Q(\sigma) = D\left(\mathbf{e}_{\sigma(1)}, \ldots, \mathbf{e}_{\sigma(n)}\right)$ for a determinant function D. It does change sign, by Proposition 5.1.10 and Remark 5.2.11. But we do not know yet that a determinant function exists for $n \geq 3$, and the proof of existence in Section 5.3 uses this theorem. So we need a Q that we can write down explicitly. Approach 1 below uses a product of differences, and Approach 2 counts the pairs that σ puts out of order.

Technique 5.2.19 (Parity via an invariant). To show that the number of steps in a process has a determined parity, attach to each state a quantity that every step changes in a controlled way: it is multiplied by -1, or it changes by an odd integer. After r steps the quantity has been multiplied by $(-1)^r$, or has changed by an amount of the same parity as r, so the parity of r is determined by the initial and final states, whichever steps were taken. The same idea shows that a state cannot be reached: find a quantity that every allowed move preserves and that differs between the two states.

Reach for it when a statement is about parity, or about which configurations can be reached by repeating moves of one kind: swaps, slides, rotations. The canonical example is Lemma 5.2.20, where a product of differences $x_j - x_i$ changes sign under every transposition of the variables. Exercise 5.2.47 applies it to a classic puzzle, and Section 8.4 uses the sign of the determinant to separate rotations from reflections.
Used in. Lemma 5.2.20, Lemma 5.2.22, Theorem 5.2.18, Exercise 5.2.47, Exercise 8.4.44, Exercise 5.2.48.

Approach 1: a product of differences

For $\mathbf{x} = (x_1, \ldots, x_n) \in F^n$, let

$$\Delta(\mathbf{x}) = \prod_{1 \le i < j \le n} (x_j - x_i).$$

For instance, $\Delta(x_1, x_2, x_3) = (x_2 - x_1)(x_3 - x_1)(x_3 - x_2)$. By Proposition 1.1.17, $\Delta(\mathbf{x}) \neq 0$ exactly when the entries of $\mathbf{x}$ are distinct. (This product reappears as the Vandermonde determinant in Theorem 5.5.21.) For $\sigma \in S_n$, write

$$\mathbf{x}^\sigma = \left(x_{\sigma(1)}, x_{\sigma(2)}, \ldots, x_{\sigma(n)}\right)$$

for the vector whose i-th entry is $x_{\sigma(i)}$, that is, the entries of $\mathbf{x}$ rearranged by σ.

Take $n = 3$ and $\tau = (1\ 2)$. Then $\mathbf{x}^\tau = (x_2, x_1, x_3)$, and

$$\Delta(\mathbf{x}^\tau) = (x_1 - x_2)(x_3 - x_2)(x_3 - x_1) = -(x_2 - x_1)(x_3 - x_1)(x_3 - x_2) = -\Delta(\mathbf{x}).$$

The factor $x_2 - x_1$ changed sign, and the two factors involving x_3 traded places. The same happens for every transposition.

Lemma 5.2.20 (A transposition negates Δ). Let $n \ge 2$, let $\tau \in S_n$ be a transposition, and let $\mathbf{x} \in F^n$. Then $\Delta(\mathbf{x}^\tau) = -\Delta(\mathbf{x})$.

Proof. STANDARD

Uses. Definition 5.2.10 (Transposition), Proposition 1.1.16 (Sign rules)
Techniques. Parity via an invariant (Technique 5.2.19)
Hint 1. Write $\tau = (k\ l)$ with $k < l$ and $\mathbf{y} = \mathbf{x}^\tau$, so $y_k = x_l$, $y_l = x_k$, and $y_i = x_i$ otherwise. Sort the factors $y_j - y_i$ of $\Delta(\mathbf{y})$ according to how many of i, j lie in $\{k, l\}$.
Hint 2. Factors that avoid k and l are unchanged, and the factor for the pair (k, l) changes sign. Every other factor involves exactly one of k, l, together with a third index m.
Hint 3. For each $m \notin \{k, l\}$, multiply the two factors that involve m. Show that their product is unchanged, separately in the cases $m < k$, $k < m < l$, and $m > l$.
Sketch. With $\tau = (k\ l)$, $k < l$, and $\mathbf{y} = \mathbf{x}^\tau$, the factors of $\Delta(\mathbf{y})$ not involving k or l are those of $\Delta(\mathbf{x})$, and $y_l - y_k = -(x_l - x_k)$. For each $m \notin \{k, l\}$ the two factors involving m trade places, with two sign changes when $k < m < l$, so their product is unchanged. So exactly one sign changes overall.

Write $\tau = (k\ l)$ with $k < l$, and let $\mathbf{y} = \mathbf{x}^\tau$. Then $y_k = x_{\tau(k)} = x_l$, $y_l = x_k$, and $y_i = x_i$ for $i \notin \{k, l\}$. Each factor $y_j - y_i$ (where $i < j$) of $\Delta(\mathbf{y})$ belongs to exactly one of the following groups, and we compare each group with the corresponding factors of $\Delta(\mathbf{x})$.

Factors with $i, j \notin \{k, l\}$. Here $y_j - y_i = x_j - x_i$.

The factor with $(i, j) = (k, l)$. Here $y_l - y_k = x_k - x_l = -(x_l - x_k)$.

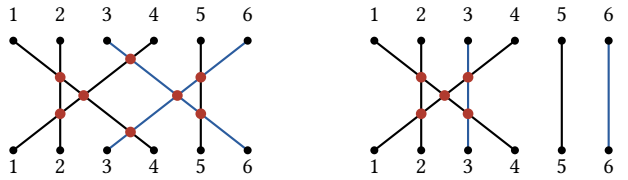
The two factors involving a fixed $m \notin \{k, l\}$. These are the factors for the pairs $\{m, k\}$ and $\{m, l\}$. Let $P_m(\mathbf{x})$ be the product of the corresponding two factors of $\Delta(\mathbf{x})$, each of the form $x_j - x_i$ with $i < j$.

- If $m < k$, then $P_m(\mathbf{y}) = (y_k - y_m)(y_l - y_m) = (x_l - x_m)(x_k - x_m) = P_m(\mathbf{x})$.
- If $k < m < l$, then $P_m(\mathbf{y}) = (y_m - y_k)(y_l - y_m) = (x_m - x_l)(x_k - x_m)$. Pulling a factor -1 out of each difference (Proposition 1.1.16), this equals $(x_l - x_m)(x_m - x_k) = P_m(\mathbf{x})$.
- If $m > l$, then $P_m(\mathbf{y}) = (y_m - y_k)(y_m - y_l) = (x_m - x_l)(x_m - x_k) = P_m(\mathbf{x})$.

Multiplying over all groups and reordering factors by commutativity, $\Delta(\mathbf{y}) = -\Delta(\mathbf{x})$, as desired. □

Approach 2: counting inversions

The second approach measures how far the bottom row of σ is from being sorted.



Definition 5.2.21 (Inversion). An **inversion** of $\sigma \in S_n$ is a pair (i, j) with $1 \le i < j \le n$ and $\sigma(i) > \sigma(j)$. We write $\mathrm{inv}(\sigma)$ for the number of inversions of σ.

In the bottom row of the two-line notation, an inversion is a pair of positions whose entries are out of order, the larger entry coming first. For $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}$ the inversions are

$$(1,4), (1,5), (2,3), (2,4), (2,5), (3,4), (3,5),$$

coming from $3 > 1, 3 > 2, 5 > 4, 5 > 1, 5 > 2, 4 > 1$, and $4 > 2$. So $\mathrm{inv}(\sigma) = 7$. The identity has no inversions, the adjacent transposition $(k\ k+1)$ has exactly one, namely $(k, k+1)$, and the reversal $i \mapsto n+1-i$ has all $n(n-1)/2$ pairs as inversions.

There is a picture. Join each i on a top row to $\sigma(i)$ on a bottom row by a straight segment. Two segments starting at $i < j$ cross exactly when they end in the opposite order, that is, when $\sigma(i) > \sigma(j)$. So $\mathrm{inv}(\sigma)$ is the number of crossings, counted pair by pair. Figure 5.2.1 shows this for a permutation $\pi \in S_6$ with 8 inversions, together with the effect of multiplying it by a transposition on the right.

π, with 8 crossings $\qquad$ $\pi(3\ 6)$, with 5 crossings

Figure 5.2.1. Left: $\pi = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 4 & 2 & 6 & 1 & 5 & 3 \end{pmatrix}$, drawn by joining i on the top row to $\pi(i)$ on the bottom row. Each crossing (dot) is an inversion. Right: $\pi(3\ 6)$, in which the strands from 3 and 6 (blue) have exchanged their endpoints. The two blue strands no longer cross. Of the strands that start between 3 and 6, the one from 4 still crosses one blue strand, and the one from 5 has lost both of its crossings with blue strands. The strands from 1 and 2 cross as many blue strands as before. The total dropped by $1 + 2 = 3$, an odd number.

Lemma 5.2.22 (A transposition changes inv by an odd number). Let $\sigma \in S_n$ and let τ be a transposition. Then $\mathrm{inv}(\sigma\tau) - \mathrm{inv}(\sigma)$ is odd. If τ is an adjacent transposition, then $\mathrm{inv}(\sigma\tau) = \mathrm{inv}(\sigma) \pm 1$.

Proof. STANDARD

Uses. Definition 5.2.21 (Inversion), Remark 5.2.11 (Composing with a transposition)
Techniques. Parity via an invariant (Technique 5.2.19)
Hint 1. Write $\tau = (k\ l)$ with $k < l$. By Remark 5.2.11, the bottom row of $\sigma\tau$ is that of σ with the entries in positions k and l interchanged. Which pairs of positions can change status?
Hint 2. The pair (k, l) always changes status. For a third position m, look at the two pairs that m forms with k and with l, and consider $m < k$, $k < m < l$, and $m > l$ separately.
Hint 3. When $k < m < l$, let N and N' be the numbers of inverted pairs among the two pairs, before and after. Show that $N + N' = 2$.
Sketch. Let $\tau = (k\ l)$, $k < l$. The bottom rows of σ and $\sigma\tau$ differ by interchanging the entries a_k and a_l at positions k and l. Pairs avoiding k and l keep their status, and (k, l) flips. If $m < k$ or $m > l$, the two pairs formed by m with k and l make the same two comparisons, of a_m with a_k and with a_l, before and after. If $k < m < l$, the number N of inverted pairs among them becomes $2 - N$. So the total changes by ± 1 plus an even number. For adjacent k, l there is no m in between.

Write $\tau = (k\ l)$ with $k < l$, and let $a_i = \sigma(i)$ and $b_i = (\sigma\tau)(i)$. By Remark 5.2.11, $b_k = a_l$, $b_l = a_k$, and $b_i = a_i$ for $i \notin \{k, l\}$. For positions $i < j$, say the pair (i, j) is *inverted in a* if $a_i > a_j$, and *inverted in b* if $b_i > b_j$; so $\mathrm{inv}(\sigma)$ and $\mathrm{inv}(\sigma\tau)$ count the pairs inverted in a and in b. We compare them group by group.

Pairs (i, j) with $i, j \notin \{k, l\}$. These have the same entries in a and b, so the same status.

The pair (k,l). It is inverted in b if and only if $a_l > a_k$, that is, if and only if it is not inverted in a. So this pair contributes $+1$ or -1 to $\operatorname{inv}(\sigma\tau) - \operatorname{inv}(\sigma)$.

The two pairs that a fixed $m \notin \{k,l\}$ *forms with* k *and with* l. If $m < k$, then in a the pair (m,k) is inverted if and only if $a_m > a_k$, and (m,l) if and only if $a_m > a_l$; in b, the pair (m,k) is inverted if and only if $a_m > a_l$, and (m,l) if and only if $a_m > a_k$. These are the same two conditions, so the number of inverted pairs among the two is the same in a and in b. The case $m > l$ is the same with the inequalities reversed. If $k < m < l$, the pairs are (k,m) and (m,l). In a they are inverted if and only if $a_k > a_m$ and $a_m > a_l$, respectively, and in b if and only if $a_l > a_m$ and $a_m > a_k$. Let N and N' be the numbers of these pairs that are inverted in a and in b. Since the entries are distinct, exactly one of $a_k > a_m$ and $a_m > a_k$ holds, and exactly one of $a_m > a_l$ and $a_l > a_m$ holds. Hence $N + N' = 2$, and $N' - N = 2 - 2N$ is even.

Adding up, $\operatorname{inv}(\sigma\tau) - \operatorname{inv}(\sigma)$ is ± 1 plus a sum of even numbers, so it is odd. If $l = k+1$, there is no m with $k < m < l$, so the pair (k,l) is the only group that contributes to $\operatorname{inv}(\sigma\tau) - \operatorname{inv}(\sigma)$, and $\operatorname{inv}(\sigma\tau) = \operatorname{inv}(\sigma) \pm 1$. □

Two proofs of the theorem

Each lemma supplies the quantity Q of Intuition (Looking for an invariant): $Q(\sigma) = \Delta(\mathbf{x}^\sigma)$ for a fixed $\mathbf{x}$ with distinct entries, and $Q(\sigma) = (-1)^{\operatorname{inv}(\sigma)}$.

Proof of Theorem 5.2.18 (via the product of differences). STANDARD

> *Uses.* Lemma 5.2.20 (A transposition negates Δ), Proposition 5.2.13 (Products of transpositions)
> *Techniques.* Parity via an invariant (Technique 5.2.19)
> *Hint 1.* Lemma 5.2.20 says what one transposition does to Δ. What does a product of r transpositions do?
> *Hint 2.* You will need that rearranging by ρ and then by τ is rearranging by $\rho\tau$: check that $(\mathbf{x}^\rho)^\tau = \mathbf{x}^{\rho\tau}$.
> *Hint 3.* Show $\Delta(\mathbf{x}^\sigma) = (-1)^r\Delta(\mathbf{x})$ by induction on r, then evaluate at a vector with $\Delta(\mathbf{x}) \neq 0$ over a field in which $1 \neq -1$.
> *Sketch.* Since $(\mathbf{x}^\rho)^\tau = \mathbf{x}^{\rho\tau}$, Lemma 5.2.20 and induction on r give $\Delta(\mathbf{x}^\sigma) = (-1)^r\Delta(\mathbf{x})$ whenever σ is a product of r transpositions. Take $\mathbf{x} = (1,2,\ldots,n) \in \mathbb{Q}^n$, so $\Delta(\mathbf{x}) \neq 0$. Then two factorizations of lengths r and s give $(-1)^r\Delta(\mathbf{x}) = (-1)^s\Delta(\mathbf{x})$, so $(-1)^r = (-1)^s$.

Let F be any field and $\mathbf{x} \in F^n$. First, for $\rho, \pi \in S_n$, the i-th entry of $(\mathbf{x}^\rho)^\pi$ is the $\pi(i)$-th entry of $\mathbf{x}^\rho$, which is $x_{\rho(\pi(i))}$. So

$$(\mathbf{x}^\rho)^\pi = \mathbf{x}^{\rho\pi}.$$

We show by induction on $r \geq 0$ that if $\sigma = \tau_1 \cdots \tau_r$ is a product of r transpositions, then $\Delta(\mathbf{x}^\sigma) = (-1)^r\Delta(\mathbf{x})$. For $r = 0$, $\sigma = \mathrm{id}$ and $\mathbf{x}^{\mathrm{id}} = \mathbf{x}$. For $r \geq 1$ there is a transposition in S_n, so $n \geq 2$. Let $\rho = \tau_1 \cdots \tau_{r-1}$, so that $\sigma = \rho\tau_r$ and, by the induction hypothesis, $\Delta(\mathbf{x}^\rho) = (-1)^{r-1}\Delta(\mathbf{x})$. Applying Lemma 5.2.20 to the vector $\mathbf{x}^\rho$,

$$\Delta(\mathbf{x}^\sigma) = \Delta\big((\mathbf{x}^\rho)^{\tau_r}\big) = -\Delta(\mathbf{x}^\rho) = (-1)^r\Delta(\mathbf{x}).$$

Now take $F = \mathbb{Q}$ and $\mathbf{x} = (1,2,\ldots,n)$. Then $\Delta(\mathbf{x}) = \prod_{i<j}(j-i)$ is a product of positive integers (the empty product 1 if $n = 1$), so $\Delta(\mathbf{x}) \neq 0$. If $\sigma = \tau_1 \cdots \tau_r = \tau'_1 \cdots \tau'_s$, then

$$(-1)^r\Delta(\mathbf{x}) = \Delta(\mathbf{x}^\sigma) = (-1)^s\Delta(\mathbf{x}),$$

and dividing by $\Delta(\mathbf{x})$ gives $(-1)^r = (-1)^s$. Since $1 \neq -1$ in $\mathbb{Q}$, the integers r and s have the same parity. □

Proof of Theorem 5.2.18 (by counting inversions). ROUTINE

> *Uses.* Lemma 5.2.22 (A transposition changes inv by an odd number), Definition 5.2.21 (Inversion)
> *Techniques.* Parity via an invariant (Technique 5.2.19)
> *Hint 1.* Start from the identity, which has no inversions, and multiply by the transpositions one at a time on the right.
> *Hint 2.* Show by induction on r that if $\sigma = \tau_1 \cdots \tau_r$, then $\operatorname{inv}(\sigma) - r$ is even.
> *Sketch.* $\operatorname{inv}(\mathrm{id}) = 0$, and by Lemma 5.2.22 each additional factor on the right changes inv by an odd number. So $\operatorname{inv}(\tau_1 \cdots \tau_r) \equiv r$ modulo 2, and any two factorizations of σ have lengths with the parity of $\operatorname{inv}(\sigma)$.

We show by induction on $r \geq 0$ that if $\sigma = \tau_1 \cdots \tau_r$ with transpositions τ_i, then $\operatorname{inv}(\sigma) - r$ is even. For $r = 0$, $\sigma = \mathrm{id}$ and $\operatorname{inv}(\mathrm{id}) = 0$. For $r \geq 1$, let $\rho = \tau_1 \cdots \tau_{r-1}$, so that $\sigma = \rho\tau_r$. Then

$$\operatorname{inv}(\sigma) - r = (\operatorname{inv}(\sigma) - \operatorname{inv}(\rho)) + (\operatorname{inv}(\rho) - (r-1)) - 1.$$

The first term is odd by Lemma 5.2.22 and the second is even by the induction hypothesis, so the sum is even.

Hence if $\sigma = \tau_1 \cdots \tau_r = \tau'_1 \cdots \tau'_s$, both r and s have the same parity as $\operatorname{inv}(\sigma)$. □

Intuition (Comparing the two proofs). Both proofs follow Technique 5.2.19, and the invariants are closer than they look. With $\mathbf{x} = (1, \ldots, n)$, the factor $\sigma(j) - \sigma(i)$ of $\Delta(\mathbf{x}^\sigma)$ is negative exactly when (i, j) is an inversion, and the absolute values $|\sigma(j) - \sigma(i)|$ are the numbers $j - i$ in another order (as $\{i, j\}$ runs over all two-element sets, so does $\{\sigma(i), \sigma(j)\}$). So $\Delta(\mathbf{x}^\sigma) = (-1)^{\operatorname{inv}(\sigma)}\Delta(\mathbf{x})$. The arguments are still different. Approach 1 never asks which factors are negative. Its lemma is an algebraic identity, valid for every vector over every field, and the sign falls out of regrouping. That is the pattern of Theorem 5.2.31 below, where an alternating function plays the role of Δ. Approach 2 is combinatorial and gives a formula you can read off from the two-line notation. Its sharper statement for adjacent transpositions also shows that $\operatorname{inv}(\sigma)$ is the number of interchanges of neighbors that sorting σ requires (Exercise 5.2.43).

A third proof counts orbits instead. By Lemma 5.2.17, σ is a product of $n - c(\sigma)$ transpositions, and one can show that multiplying by a transposition changes c by exactly 1. Exercise 5.2.50 works this out.

5.2.4 The sign of a permutation

Definition 5.2.23 (Sign of a permutation). A permutation $\sigma \in S_n$ is **even** if it is a product of an even number of transpositions, and **odd** if it is a product of an odd number of transpositions. The **sign** of σ is $\operatorname{sgn}(\sigma) = 1$ if σ is even and $\operatorname{sgn}(\sigma) = -1$ if σ is odd.

By Proposition 5.2.13 every permutation is even or odd, and by Theorem 5.2.18 it is not both. So sgn is well defined, and

$$\operatorname{sgn}(\sigma) = (-1)^r \quad \text{whenever } \sigma \text{ is a product of } r \text{ transpositions.}$$

The sign is an integer, 1 or -1. When it multiplies an element of a field F, we read it as 1 or -1 in F; if $1 + 1 = 0$ in F, these are the same element.

Corollary 5.2.24 (Formulas for the sign). Let $\sigma \in S_n$.

(a) $\operatorname{sgn}(\sigma) = (-1)^{\operatorname{inv}(\sigma)}$.

(b) For every field F and every $\mathbf{x} \in F^n$, $\Delta(\mathbf{x}^\sigma) = \operatorname{sgn}(\sigma)\Delta(\mathbf{x})$. In particular,

$$\operatorname{sgn}(\sigma) = \prod_{1 \le i < j \le n} \frac{\sigma(j) - \sigma(i)}{j - i}.$$

Proof. ROUTINE

Uses. Theorem 5.2.18 (Parity is well defined), Definition 5.2.23 (Sign of a permutation), Proposition 5.2.13 (Products of transpositions)
Hint 1. Both proofs of Theorem 5.2.18 established more than the theorem. What did each show about a product of r transpositions?
Hint 2. For the product formula, take $F = \mathbb{Q}$ and $\mathbf{x} = (1, 2, \ldots, n)$ in (b).
Sketch. Write $\sigma = \tau_1 \cdots \tau_r$. The second proof showed $\operatorname{inv}(\sigma) \equiv r$, and the first showed $\Delta(\mathbf{x}^\sigma) = (-1)^r\Delta(\mathbf{x})$ for every $\mathbf{x}$ over every field. Both say the claimed formulas, since $(-1)^r = \operatorname{sgn}(\sigma)$. With $\mathbf{x} = (1, \ldots, n)$, (b) becomes the product formula after dividing by $\Delta(\mathbf{x}) \neq 0$.

Write $\sigma = \tau_1 \cdots \tau_r$ with transpositions τ_i (Proposition 5.2.13), so that $\operatorname{sgn}(\sigma) = (-1)^r$.

(a) The second proof of Theorem 5.2.18 showed that $\operatorname{inv}(\sigma) - r$ is even, so $(-1)^{\operatorname{inv}(\sigma)} = (-1)^r = \operatorname{sgn}(\sigma)$.

(b) The first proof showed that $\Delta(\mathbf{x}^\sigma) = (-1)^r \Delta(\mathbf{x})$ for every field F and every $\mathbf{x} \in F^n$, which is the first claim. Taking $F = \mathbb{Q}$ and $\mathbf{x} = (1, 2, \ldots, n)$, we have $\Delta(\mathbf{x}^\sigma) = \prod_{i<j}(\sigma(j) - \sigma(i))$ and $\Delta(\mathbf{x}) = \prod_{i<j}(j - i) \neq 0$, and dividing gives the product formula. □

For $\sigma = (1\ 3\ 4)(2\ 5) = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}$ we found $\mathrm{inv}(\sigma) = 7$ and $\sigma = (1\ 3)(3\ 4)(2\ 5)$. Both give $\mathrm{sgn}(\sigma) = -1$, as they must. Table 5.2.1 lists the signs of the six permutations of $[3]$.

σ	Cycles	$\mathrm{inv}(\sigma)$	$\mathrm{sgn}(\sigma)$
$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}$	id	0	1
$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}$	$(2\ 3)$	1	-1
$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}$	$(1\ 2)$	1	-1
$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}$	$(1\ 2\ 3)$	2	1
$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix}$	$(1\ 3\ 2)$	2	1
$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix}$	$(1\ 3)$	3	-1

Table 5.2.1. The six permutations of $[3]$. The three even ones are the identity and the two 3-cycles; the three odd ones are the transpositions.

Proposition 5.2.25 (Multiplicativity of the sign).

(a) $\mathrm{sgn}(\mathrm{id}) = 1$, and $\mathrm{sgn}(\tau) = -1$ for every transposition τ.

(b) $\mathrm{sgn}(\sigma\rho) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\rho)$ for all $\sigma, \rho \in S_n$.

(c) $\mathrm{sgn}(\sigma^{-1}) = \mathrm{sgn}(\sigma)$ for all $\sigma \in S_n$.

Proof. ROUTINE

Uses. Definition 5.2.23 (Sign of a permutation), Theorem 5.2.18 (Parity is well defined), Proposition 5.2.5 (Composition and inverses)
Hint 1. Use the definition: factor σ and ρ into transpositions. What is a factorization of $\sigma\rho$?
Hint 2. For (c), apply (b) to $\sigma\sigma^{-1} = \mathrm{id}$.
Sketch. Concatenating factorizations of σ (with r factors) and ρ (with s factors) gives one of $\sigma\rho$ with $r + s$ factors, so $\mathrm{sgn}(\sigma\rho) = (-1)^{r+s}$. Then $\mathrm{sgn}(\sigma)\,\mathrm{sgn}(\sigma^{-1}) = \mathrm{sgn}(\mathrm{id}) = 1$.

(a) The identity is the product of zero transpositions, and a transposition is a product of one.

(b) Write $\sigma = \tau_1 \cdots \tau_r$ and $\rho = \tau'_1 \cdots \tau'_s$ with transpositions τ_i, τ'_j. Then $\sigma\rho = \tau_1 \cdots \tau_r \tau'_1 \cdots \tau'_s$ is a product of $r + s$ transpositions, so by Definition 5.2.23 (which is legitimate by Theorem 5.2.18),

$$\mathrm{sgn}(\sigma\rho) = (-1)^{r+s} = (-1)^r (-1)^s = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\rho).$$

(c) By (b) and (a), $\mathrm{sgn}(\sigma)\,\mathrm{sgn}(\sigma^{-1}) = \mathrm{sgn}(\sigma\sigma^{-1}) = \mathrm{sgn}(\mathrm{id}) = 1$. Multiplying both sides by $\mathrm{sgn}(\sigma)$ and using $\mathrm{sgn}(\sigma)^2 = 1$ gives $\mathrm{sgn}(\sigma^{-1}) = \mathrm{sgn}(\sigma)$. □

With the definition through transpositions, (b) takes one line. Proving it directly from the inversion count is harder (Exercise 5.2.49). This is the reason to define sgn through transpositions and to treat $(-1)^{\mathrm{inv}(\sigma)}$ as a way of computing it. In the language of Section 14.1, (b) says that sgn is a homomorphism from S_n to the group $\{1, -1\}$ under multiplication. For example, if σ is odd, then σ^{-1} is odd by (c), while σ^2 is even since $\mathrm{sgn}(\sigma^2) = \mathrm{sgn}(\sigma)^2 = 1$.

Proposition 5.2.26 (Sign of a cycle). A k-cycle has sign $(-1)^{k-1}$. More generally, $\mathrm{sgn}(\sigma) = (-1)^{n-c(\sigma)}$ for every $\sigma \in S_n$, where $c(\sigma)$ is the number of orbits of σ.

Proof. ROUTINE

Uses. Lemma 5.2.17 (Cycles as products of transpositions), Proposition 5.2.16 (Cycle decomposition), Definition 5.2.23 (Sign of a permutation)
Hint 1. Lemma 5.2.17 writes a k-cycle as a product of how many transpositions?
Hint 2. For general σ, combine Proposition 5.2.16 with the count $n - c(\sigma)$ that follows Lemma 5.2.17.
Sketch. A k-cycle is a product of $k-1$ transpositions. Decomposing σ into the cycles of its orbits and each cycle into transpositions writes σ as a product of $n - c(\sigma)$ transpositions.

By Lemma 5.2.17 a k-cycle is a product of $k-1$ transpositions, so its sign is $(-1)^{k-1}$. For general σ, Proposition 5.2.16 and Lemma 5.2.17 write σ as a product of $n - c(\sigma)$ transpositions, as computed after Lemma 5.2.17. So $\operatorname{sgn}(\sigma) = (-1)^{n-c(\sigma)}$. □

So a cycle of odd length is an even permutation and a cycle of even length is odd. For $\sigma = (1\ 3\ 4)(2\ 5) \in S_5$, $c(\sigma) = 2$, and again $\operatorname{sgn}(\sigma) = (-1)^3 = -1$.

Proposition 5.2.27 (Half of all permutations are even). For $n \geq 2$, exactly $n!/2$ elements of S_n are even and $n!/2$ are odd. Equivalently, $\sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) = 0$.

Proof. ROUTINE

Uses. Proposition 5.2.8 (Reindexing sums over S_n), Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.2.4 (Counting permutations)
Hint 1. Find a bijection from the even permutations to the odd ones.
Hint 2. Multiply by a fixed transposition, say $(1\ 2)$, on the right.
Sketch. $\varphi(\sigma) = \sigma(1\ 2)$ is a bijection of S_n that reverses signs, and $\varphi \circ \varphi = \mathrm{id}$, so it restricts to a bijection from the even permutations to the odd ones. With $|S_n| = n!$ the two sets have $n!/2$ elements each.

Let $\tau = (1\ 2)$, which exists since $n \geq 2$, and let $\varphi : S_n \to S_n$ be $\varphi(\sigma) = \sigma\tau$, a bijection by Proposition 5.2.8. By Proposition 5.2.25, $\operatorname{sgn}(\varphi(\sigma)) = -\operatorname{sgn}(\sigma)$, so φ maps the set S_n^+ of even permutations into the set S_n^- of odd permutations, and S_n^- into S_n^+. Since $\tau^2 = \mathrm{id}$, we have $\varphi(\varphi(\sigma)) = \sigma$, so the restrictions $S_n^+ \to S_n^-$ and $S_n^- \to S_n^+$ of φ are inverse to each other. Hence $|S_n^+| = |S_n^-|$. As every permutation is even or odd but not both, $|S_n^+| + |S_n^-| = n!$ by Proposition 5.2.4, so each set has $n!/2$ elements, and $\sum_\sigma \operatorname{sgn}(\sigma) = |S_n^+| - |S_n^-| = 0$. □

Pairing each σ with $\sigma(k\ l)$, which has the opposite sign, is the standard way to make the terms of a sum over S_n cancel in pairs.

Exercise 5.2.28. ROUTINE

(a) Show that σ^2 and $\sigma\rho\sigma^{-1}\rho^{-1}$ are even for all $\sigma, \rho \in S_n$.

(b) Deduce that $(1\ 2)$ is not the square of any permutation, and that neither is $(1\ 2)(3\ 4\ 5)$.

Solution on page 1395

5.2.5 Permutation matrices

We return to the values that survive in the expansion of Intuition (What the proof did, and where it leads). They are values of D at matrices whose columns are the standard basis vectors in some order.

Definition 5.2.29 (Permutation matrix). For $\sigma \in S_n$, the **permutation matrix** $E_\sigma \in F^{n \times n}$ is the matrix with columns $\mathbf{e}_{\sigma(1)}, \mathbf{e}_{\sigma(2)}, \ldots, \mathbf{e}_{\sigma(n)}$. That is, its (i, j) entry is 1 if $i = \sigma(j)$, and 0 otherwise.

Each column of E_σ is a standard basis vector, and since σ is a bijection, each standard basis vector is exactly one of the columns. So E_σ has exactly one entry 1 in each row and in each column, and zeros elsewhere. We have $E_{\mathrm{id}} = I_n$, and for a transposition $(k\ l)$, $E_{(k\ l)}$ is I_n with columns k and l interchanged, which is the elementary matrix that interchanges rows k and l (Definition 3.2.2). For example, in S_3,

$$E_{(1\,2\,3)} = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad E_{(1\,3\,2)} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \quad E_{(1\,3)} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

The first has columns $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1$, because (1 2 3) sends $1, 2, 3$ to $2, 3, 1$.

Proposition 5.2.30 (Algebra of permutation matrices). Let $\sigma, \rho \in S_n$, and let $A \in F^{m\times n}$ have columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$.

(a) AE_σ is the matrix with columns $\mathbf{a}_{\sigma(1)}, \ldots, \mathbf{a}_{\sigma(n)}$.

(b) $E_\sigma E_\rho = E_{\sigma\rho}$.

(c) E_σ is invertible, and $E_\sigma^{-1} = E_{\sigma^{-1}} = E_\sigma^{\mathsf{T}}$.

Proof. ROUTINE

Uses. Definition 5.2.29 (Permutation matrix), Definition 2.4.1 (Matrix product), Definition 2.3.8 (Matrix–vector product), Definition 2.5.12 (Invertible), Definition 2.4.21 (Transpose)
Hint 1. Column j of a product AB is A times column j of B, and $A\mathbf{e}_k$ is column k of A.
Hint 2. For (b), apply (a) with $A = E_\sigma$. For (c), use (b) with $\rho = \sigma^{-1}$, and compare entries for the transpose.
Sketch. Column j of AE_σ is $A\mathbf{e}_{\sigma(j)} = \mathbf{a}_{\sigma(j)}$. With $A = E_\sigma$, column j of $E_\sigma E_\rho$ is column $\rho(j)$ of E_σ, which is $\mathbf{e}_{\sigma(\rho(j))}$. Then $E_\sigma E_{\sigma^{-1}} = E_{\mathrm{id}} = I_n = E_{\sigma^{-1}} E_\sigma$, and the (i,j) entry of E_σ^{T} is 1 exactly when $j = \sigma(i)$, that is, $i = \sigma^{-1}(j)$.

(a) By Definition 2.4.1, column j of AE_σ is A times column j of E_σ, which is $A\mathbf{e}_{\sigma(j)} = \mathbf{a}_{\sigma(j)}$.

(b) Apply (a) with $A = E_\sigma$, whose columns are $\mathbf{e}_{\sigma(1)}, \ldots, \mathbf{e}_{\sigma(n)}$: column j of $E_\sigma E_\rho$ is column $\rho(j)$ of E_σ, which is $\mathbf{e}_{\sigma(\rho(j))} = \mathbf{e}_{(\sigma\rho)(j)}$. So $E_\sigma E_\rho = E_{\sigma\rho}$.

(c) By (b), $E_\sigma E_{\sigma^{-1}} = E_{\mathrm{id}} = I_n$ and $E_{\sigma^{-1}} E_\sigma = E_{\mathrm{id}} = I_n$, so $E_{\sigma^{-1}}$ is a two-sided inverse of E_σ. For the transpose, the (i,j) entry of E_σ^{T} is the (j,i) entry of E_σ, which is 1 if $j = \sigma(i)$ and 0 otherwise. Since $j = \sigma(i)$ if and only if $i = \sigma^{-1}(j)$, this is the (i,j) entry of $E_{\sigma^{-1}}$. □

Part (a) says that multiplying by E_σ on the right rearranges the columns, putting column $\sigma(j)$ in position j. Multiplication of a vector on the left goes the other way: $E_\sigma \mathbf{x} = \sum_j x_j \mathbf{e}_{\sigma(j)}$, so the entry x_j moves to position $\sigma(j)$, and $E_\sigma \mathbf{x} = \mathbf{x}^{\sigma^{-1}}$ in the notation of Approach 1: a product of differences. Keep the two descriptions apart.

Intuition. Write $\sigma = \tau_1 \cdots \tau_r$ with transpositions τ_i. By Proposition 5.2.30, $AE_\sigma = AE_{\tau_1} \cdots E_{\tau_r}$, so the columns of AE_σ are obtained from those of A by r interchanges of two columns, and each interchange negates D. So $D(AE_\sigma) = (-1)^r D(A)$. The right side involves a factorization of σ, and Theorem 5.2.18 is exactly what makes it independent of the factorization.

Theorem 5.2.31 (Alternating functions and permutations). Let $D : F^{n\times n} \to F$ be multilinear and alternating, and let $\sigma \in S_n$. For all $\mathbf{a}_1, \ldots, \mathbf{a}_n \in F^n$,

$$D\big(\mathbf{a}_{\sigma(1)}, \mathbf{a}_{\sigma(2)}, \ldots, \mathbf{a}_{\sigma(n)}\big) = \operatorname{sgn}(\sigma) D(\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n).$$

That is, $D(AE_\sigma) = \operatorname{sgn}(\sigma) D(A)$ for every $A \in F^{n\times n}$. In particular $D(E_\sigma) = \operatorname{sgn}(\sigma) D(I_n)$, and if D is a determinant function, then $D(E_\sigma) = \operatorname{sgn}(\sigma)$.

Proof. STANDARD

Uses. Proposition 5.1.10 (Alternating implies antisymmetric), Proposition 5.2.13 (Products of transpositions), Definition 5.2.23 (Sign of a permutation), Proposition 5.2.30 (Algebra of permutation matrices)
Hint 1. Factor σ into transpositions and induct on the number r of factors.
Hint 2. If $\sigma = \rho\tau$ with $\tau = (k\ l)$, put $\mathbf{b}_i = \mathbf{a}_{\rho(i)}$. How is the list $\mathbf{a}_{\sigma(1)}, \ldots, \mathbf{a}_{\sigma(n)}$ related to $\mathbf{b}_1, \ldots, \mathbf{b}_n$?
Hint 3. It is the same list with the entries in positions k and l interchanged. Use Proposition 5.1.10.

Sketch. By induction on r, if σ is a product of r transpositions then $D\big(\mathbf{a}_{\sigma(1)},\dots\big) = (-1)^r D(\mathbf{a}_1,\dots)$: writing $\sigma = \rho\tau$ with $\tau = (k\ l)$ and $\mathbf{b}_i = \mathbf{a}_{\rho(i)}$, the list $\mathbf{a}_{\sigma(i)} = \mathbf{b}_{\tau(i)}$ is $\mathbf{b}$ with positions k and l interchanged, which negates D. Since $(-1)^r = \operatorname{sgn}(\sigma)$, done. The matrix forms follow from Proposition 5.2.30.

We show by induction on $r \geq 0$: if σ is a product of r transpositions, then for all $\mathbf{a}_1,\dots,\mathbf{a}_n \in F^n$,

$$D\big(\mathbf{a}_{\sigma(1)},\dots,\mathbf{a}_{\sigma(n)}\big) = (-1)^r D(\mathbf{a}_1,\dots,\mathbf{a}_n).$$

For $r = 0$, $\sigma = \mathrm{id}$ and there is nothing to prove. For $r \geq 1$, write $\sigma = \rho\tau$, where ρ is a product of $r-1$ transpositions and $\tau = (k\ l)$. Put $\mathbf{b}_i = \mathbf{a}_{\rho(i)}$ for $i \in [n]$. Then $\mathbf{a}_{\sigma(i)} = \mathbf{a}_{\rho(\tau(i))} = \mathbf{b}_{\tau(i)}$. Since τ interchanges k and l and fixes everything else, the list $\mathbf{b}_{\tau(1)},\dots,\mathbf{b}_{\tau(n)}$ is the list $\mathbf{b}_1,\dots,\mathbf{b}_n$ with the entries in positions k and l interchanged. By Proposition 5.1.10 and then the induction hypothesis,

$$D\big(\mathbf{a}_{\sigma(1)},\dots,\mathbf{a}_{\sigma(n)}\big) = -D(\mathbf{b}_1,\dots,\mathbf{b}_n) = -D\big(\mathbf{a}_{\rho(1)},\dots,\mathbf{a}_{\rho(n)}\big) = (-1)^r D(\mathbf{a}_1,\dots,\mathbf{a}_n).$$

By Proposition 5.2.13, every σ is a product of some number r of transpositions, and $(-1)^r = \operatorname{sgn}(\sigma)$ by Definition 5.2.23. This proves the displayed identity. By Proposition 5.2.30, the columns of AE_σ are $\mathbf{a}_{\sigma(1)},\dots,\mathbf{a}_{\sigma(n)}$, so $D(AE_\sigma) = \operatorname{sgn}(\sigma)D(A)$. Taking $A = I_n$ gives $D(E_\sigma) = \operatorname{sgn}(\sigma)D(I_n)$, and a determinant function has $D(I_n) = 1$. □

This answers the first question raised in Intuition (What the proof did, and where it leads): each surviving value is determined, $D\big(\mathbf{e}_{\sigma(1)},\dots,\mathbf{e}_{\sigma(n)}\big) = \operatorname{sgn}(\sigma)D(I_n)$, however we sort. Substituting into the expansion expresses $D(A)$ as $D(I_n)$ times a sum, over $\sigma \in S_n$, of signed products of entries of A. Section 5.3 carries out this substitution (Theorem 5.3.3) and answers the second question by checking that the resulting formula satisfies the axioms.

Remark 5.2.32 (Two comments on the theorem). (1) If $1 + 1 = 0$ in F, then $\operatorname{sgn}(\sigma) = 1$ in F for every σ, and the theorem says that $D(AE_\sigma) = D(A)$: rearranging the columns does not change D at all. This matches Example 5.1.12, where interchanging two columns changed nothing over $\mathbb{F}_2$.

(2) The induction in the proof does not use Theorem 5.2.18. So if we had, over $\mathbb{Q}$, a multilinear alternating $D : \mathbb{Q}^{n\times n} \to \mathbb{Q}$ with $D(I_n) \neq 0$, constructed without permutations, then two factorizations of σ of lengths r and s would give $(-1)^r D(I_n) = D(E_\sigma) = (-1)^s D(I_n)$, a third proof of Theorem 5.2.18. In this sense the parity theorem is exactly what the existence of determinants requires. The construction in Section 5.3 uses sgn, so it cannot be used this way (Exercise 5.2.38).

Exercises

Exercise 5.2.33. ROUTINE Let

$$\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 2 & 5 & 6 & 1 & 3 & 4 \end{pmatrix}, \quad \tau = (1\ 4)(2\ 6) \in S_6.$$

Compute $\sigma\tau$, $\tau\sigma$, and σ^{-1}, in two-line and in cycle notation, and find the signs of σ, τ, $\sigma\tau$, $\tau\sigma$, and σ^{-1}.

Solution on page 1395

Exercise 5.2.34. ROUTINE

(a) Let $1 \leq k < l \leq n$. Show that $\operatorname{inv}((k\ l)) = 2(l-k) - 1$.

(b) Find inv of the n-cycle $(1\ 2\ \dots\ n)$, and check the result against Proposition 5.2.26.

(c) Let $\omega \in S_n$ be the reversal, $\omega(i) = n + 1 - i$. Compute $\operatorname{sgn}(\omega)$ in two ways, from $\operatorname{inv}(\omega)$ and from the cycle notation of ω, and deduce that $(-1)^{n(n-1)/2} = (-1)^{\lfloor n/2 \rfloor}$. For which n is ω even?

Solution on page 1395

Exercise 5.2.35. ROUTINE Find the error in the following argument.

Claim. If $\sigma \in S_n$ and τ is a transposition, then $\operatorname{inv}(\sigma\tau) = \operatorname{inv}(\sigma) \pm 1$.

Proof. By Remark 5.2.11, the bottom row of $\sigma\tau$ is that of σ with two entries interchanged. Interchanging two entries changes their relative order and nothing else. So exactly one pair of positions changes from inverted to not inverted, or the other way.

Solution on page 1396

Exercise 5.2.36. STANDARD Let $\sigma \in S_n$.

(a) Let $A \in F^{n\times m}$. Show that row $\sigma(i)$ of $E_\sigma A$ is row i of A, for every i.

(b) Let $A \in F^{n\times n}$. Show that the $(\sigma(i), \sigma(j))$ entry of $E_\sigma A E_\sigma^{\mathsf{T}}$ is a_{ij}, for all i, j.

(c) The *adjacency matrix* of a graph with vertices $1, \ldots, n$ is the $n \times n$ matrix with (i, j) entry 1 if i and j are joined by an edge, and 0 otherwise. Explain what (b) says about adjacency matrices when the vertices of a graph are renamed by σ.

Solution on page 1396

Exercise 5.2.37. STANDARD Prove or disprove each statement, for all n and all $\sigma, \tau \in S_n$.

(a) The product of two odd permutations is odd.

(b) If $\sigma^2 = \mathrm{id}$, then σ is the identity or a transposition.

(c) $\operatorname{inv}\left(\sigma^{-1}\right) = \operatorname{inv}(\sigma)$.

(d) $\operatorname{inv}(\sigma\tau) = \operatorname{inv}(\sigma) + \operatorname{inv}(\tau)$.

(e) $\operatorname{sgn}\left(\sigma\tau\sigma^{-1}\right) = \operatorname{sgn}(\tau)$.

Solution on page 1397

Exercise 5.2.38. STANDARD Find the errors in the following argument.

Claim. Theorem 5.2.18.

Proof. Let det be the determinant function on $F^{n\times n}$ (Theorem 5.3.4). If $\sigma = \tau_1 \cdots \tau_r$ is a product of transpositions, then by Proposition 5.2.30 the columns of E_σ are obtained from those of I_n by r interchanges of two columns, and each interchange multiplies det by -1 (Proposition 5.1.10). So $\det E_\sigma = (-1)^r \det I_n = (-1)^r$. Since $\det E_\sigma$ depends only on σ, so does $(-1)^r$, and the parity of r is determined by σ.

Solution on page 1397

Exercise 5.2.39. STANDARD

(a) Let $\sigma \in S_n$ and let $(a_1\ \ldots\ a_k)$ be a cycle. Show that

$$\sigma(a_1\ a_2\ \ldots\ a_k)\sigma^{-1} = (\sigma(a_1)\ \sigma(a_2)\ \ldots\ \sigma(a_k)).$$

(b) Let $n \geq 2$ and $k \neq l$ in $[n]$. Show that $(k\ l) = \rho(1\ 2)\rho^{-1}$ for some $\rho \in S_n$.

(c) Compute $\sigma(1\ 2\ 3)(4\ 5)\sigma^{-1}$ for $\sigma = (1\ 5\ 2)(3\ 4)$ without multiplying permutations.

Solution on page 1398

Exercise 5.2.40. STANDARD Let $n \geq 3$. Show that every even permutation in S_n is a product of 3-cycles. Conclude that a permutation is even if and only if it is a product of 3-cycles.

Solution on page 1398

Exercise 5.2.41. STANDARD The **order** of $\sigma \in S_n$ is the least $m \geq 1$ with $\sigma^m = \mathrm{id}$.

(a) Show that the order of a k-cycle is k, and that if $\sigma = \gamma_1 \cdots \gamma_t$ is a product of disjoint cycles of lengths $k_1, \ldots, k_t$, then the order of σ is the least common multiple of $k_1, \ldots, k_t$.

(b) Let $\sigma = (1\ 2\ 3)(4\ 5\ 6\ 7) \in S_7$. Find the least $m \geq 1$ with $E_\sigma^m = I_7$.

Solution on page 1398

Exercise 5.2.42. STANDARD

(a) Find $\sigma \in S_5$ with $\sigma^2 = (1\ 2\ 3\ 4\ 5)$.

(b) Find $\sigma \in S_4$ with $\sigma^2 = (1\ 2)(3\ 4)$.

(c) Show that there is no $\sigma \in S_n$ (for any $n \geq 5$) with $\sigma^2 = (1\ 2)(3\ 4\ 5)$.

Solution on page 1399

Exercise 5.2.43. STANDARD Show that $\mathrm{inv}(\sigma)$ is the least number of adjacent transpositions whose product is σ. That is, σ is a product of $\mathrm{inv}(\sigma)$ adjacent transpositions, and not of fewer.

Solution on page 1399

Exercise 5.2.44. STANDARD A matrix is **monomial** if it has exactly one nonzero entry in each row and in each column.

(a) Let $A \in F^{n\times n}$ be monomial. Show that there are $\sigma \in S_n$ and nonzero $c_1, \ldots, c_n \in F$ such that column j of A is $c_j \mathbf{e}_{\sigma(j)}$. Deduce that if $D : F^{n\times n} \to F$ is multilinear and alternating, then $D(A) = \mathrm{sgn}(\sigma) c_1 c_2 \cdots c_n D(I_n)$.

(b) Over $\mathbb{C}$, find $D(A)$ in terms of $D(I_4)$ for

$$A = \begin{pmatrix} 0 & 2 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ i & 0 & 0 & 0 \\ 0 & 0 & 1-i & 0 \end{pmatrix}.$$

(c) Over $\mathbb{F}_3$, find $D(B)$ in terms of $D(I_3)$ for $B = \begin{pmatrix} 0 & 2 & 0 \\ 0 & 0 & 2 \\ 2 & 0 & 0 \end{pmatrix}$.

Solution on page 1400

Exercise 5.2.45. STANDARD

(a) Let $2 \leq k \leq n$. Show that S_n contains exactly $n!/((n-k)!\,k)$ cycles of length k.

(b) Sort the 24 elements of S_4 by their cycle notation: the identity, transpositions, 3-cycles, 4-cycles, and products of two disjoint transpositions. Count each kind, and use the counts to check Proposition 5.2.27 for $n = 4$.

Solution on page 1400

Exercise 5.2.46. HARD Let $n \geq 2$, let F be a field, and let $f : S_n \to F$ satisfy $f(\sigma) \neq 0$ and $f(\sigma\rho) = f(\sigma) f(\rho)$ for all $\sigma, \rho \in S_n$. Show that either $f(\sigma) = 1$ for all σ, or $f(\sigma) = \mathrm{sgn}(\sigma)$ for all σ.

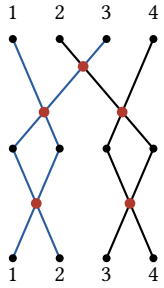
Solution on page 1401

Exercise 5.2.47 (The 15 puzzle). HARD In the 15 puzzle, fifteen square tiles numbered $1, \ldots, 15$ and one empty space sit in a 4×4 frame. A move slides a tile that shares an edge with the empty space into it.

In the solved position the tiles read $1, \ldots, 15$ row by row, from the top left, with the empty space in the bottom right corner. Show that no sequence of moves turns the solved position into the position in which tiles 14 and 15 are interchanged and all other tiles, and the empty space, are where they were.

Solution on page 1401

Exercise 5.2.48. HARD The numbers $1, \ldots, n$ (where $n \geq 3$) are written in a row in some order. A move chooses three consecutive entries x, y, z and replaces them by z, x, y. For which starting orders can the row be sorted into $1, 2, \ldots, n$ by a sequence of moves?



Solution on page 1401

Exercise 5.2.49. HARD This exercise proves $\operatorname{sgn}(\sigma\rho) = \operatorname{sgn}(\sigma)\operatorname{sgn}(\rho)$ directly from inversions, without using Theorem 5.2.18.

For a two-element set $\{i, j\} \subseteq [n]$, say that $\pi \in S_n$ **reverses** $\{i, j\}$ if $\pi(i) - \pi(j)$ and $i - j$ have opposite signs. So $\operatorname{inv}(\pi)$ is the number of two-element subsets that π reverses.

(a) Show that $\sigma\rho$ reverses $\{i, j\}$ if and only if exactly one of the following holds: ρ reverses $\{i, j\}$; σ reverses $\{\rho(i), \rho(j)\}$.

(b) Deduce that $\operatorname{inv}(\sigma\rho) - \operatorname{inv}(\sigma) - \operatorname{inv}(\rho)$ is even. Figure 5.2.2 shows an example.

ρ (top) followed by σ (bottom)

Figure 5.2.2. Stacking the diagrams of $\rho = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 1 & 3 \end{pmatrix}$ and $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 4 & 3 \end{pmatrix}$ gives a diagram of $\sigma\rho = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 3 & 2 & 4 \end{pmatrix}$. The blue strands from 1 and 3 cross once in each half, so they end in their original order. There are $3 + 2 = 5$ crossings but only $\operatorname{inv}(\sigma\rho) = 1$ inversion, and $5 - 1$ is even.

(c) Use (b) and Exercise 5.2.34 to give another proof of Theorem 5.2.18.

Solution on page 1402

Exercise 5.2.50. HARD BEYOND 21-242 This exercise gives a third proof of Theorem 5.2.18, by counting orbits. Recall that $c(\sigma)$ is the number of orbits of σ, fixed points included.

(a) Let $\sigma \in S_n$ and let $\tau = (a\ b)$. Show that if a and b lie in the same orbit of σ, then $c(\sigma\tau) = c(\sigma) + 1$, and otherwise $c(\sigma\tau) = c(\sigma) - 1$.

(b) Deduce that if σ is a product of r transpositions, then $c(\sigma) - (n - r)$ is even, and use this to prove Theorem 5.2.18 and $\operatorname{sgn}(\sigma) = (-1)^{n-c(\sigma)}$ without Lemma 5.2.20 or Lemma 5.2.22.

(c) Show that the least number of transpositions whose product is σ is $n - c(\sigma)$.

Solution on page 1403

Exercise 5.2.51. CHALLENGE BEYOND 21-242 Let p be an odd prime and let $a \in \mathbb{F}_p$ with $a \neq 0$. Multiplication by a permutes the nonzero elements $1, 2, \ldots, p-1$ of $\mathbb{F}_p$; let $\mu_a \in S_{p-1}$ be the permutation with $\mu_a(k) = ak$, the product computed in $\mathbb{F}_p$.

(a) Show that $a^{p-1} = 1$ in $\mathbb{F}_p$.

(b) Show that $\operatorname{sgn}(\mu_a) = a^{(p-1)/2}$, where the right side is computed in $\mathbb{F}_p$ and is therefore 1 or -1. (This is **Zolotarev's lemma**.)

(c) Check (b) for $p = 7$ and $a = 2, 3$ by finding the cycle notation of μ_2 and μ_3.

Solution on page 1403

5.3 Existence and uniqueness

Theorem 5.1.13 showed that the determinant axioms leave exactly one function on $F^{2\times 2}$. Intuition (What the proof did, and where it leads) outlined the same argument for $n \times n$ matrices and left two questions open. The first, whether an ordering of $\mathbf{e}_1, \ldots, \mathbf{e}_n$ could be sorted both by an even and by an odd number of interchanges, was settled in Section 5.2: it cannot (Theorem 5.2.18), and $D\big(\mathbf{e}_{\sigma(1)}, \ldots, \mathbf{e}_{\sigma(n)}\big) = \operatorname{sgn}(\sigma) D(I_n)$ (Theorem 5.2.31). The second, whether the resulting formula satisfies the axioms, is answered here, and this section finishes the argument. Carrying out the expansion shows that a determinant function must be given by an explicit formula, the Leibniz formula, so there is at most one. Checking that the formula satisfies the axioms shows that there is one. The formula has $n!$ terms and is a poor way to compute, but it displays $\det A$ as an explicit function of the entries of A, and the rest of the section reads several facts off it: the 3×3 formula, the determinants of triangular and block-diagonal matrices, and the fact that $\det A$ is a polynomial in the entries.

Throughout, $A \in F^{n\times n}$ has entries a_{ij} and columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, so that $\mathbf{a}_j = \sum_{i=1}^{n} a_{ij}\mathbf{e}_i$.

5.3.1 The axioms force a formula

Intuition (Strategy). As in the 2×2 case, we break $D(A)$ into values of D at matrices of 0s and 1s. Write each column in the standard basis and expand by multilinearity in every column (Technique 5.1.7). Each column contributes n terms, so there are n^n terms, one for each way of choosing a row index in every column. Written with n nested sums, $\sum_{i_1} \cdots \sum_{i_n}$, this quickly becomes unreadable. The better bookkeeping indexes a choice of row indices by a single object: a function $f : [n] \to [n]$, where $f(j)$ is the row chosen in column j. Alternation then kills every term whose f takes some value twice, the survivors are indexed by permutations, and Theorem 5.2.31 evaluates them.

Notation 5.3.1. We write $[n]^{[n]}$ for the set of all functions $f : [n] \to [n]$. It has n^n elements, since each of $f(1), \ldots, f(n)$ can be any element of $[n]$. For $f \in [n]^{[n]}$, let $E_f \in F^{n\times n}$ be the matrix with columns $\mathbf{e}_{f(1)}, \mathbf{e}_{f(2)}, \ldots, \mathbf{e}_{f(n)}$. When $f = \sigma$ is a permutation, E_σ is the permutation matrix of Definition 5.2.29.

For example, the function $f : [3] \to [3]$ of Non-example 5.2.3, with $f(1) = f(2) = 2$ and $f(3) = 1$, gives the matrix E_f with columns $\mathbf{e}_2, \mathbf{e}_2, \mathbf{e}_1$.

Lemma 5.3.2 (Expanding every column). Let $D : F^{n\times n} \to F$ be multilinear. Then for every $A \in F^{n\times n}$,

$$D(A) = \sum_{f \in [n]^{[n]}} a_{f(1)1} a_{f(2)2} \cdots a_{f(n)n} D\big(E_f\big).$$

Proof. STANDARD

Uses. Definition 5.1.1 (Determinant function), Definition 1.6.8 (Standard bases), induction on the number k of expanded columns
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Expand one column at a time. After the first k columns have been expanded, what does a single term look like?
Hint 2. For $0 \le k \le n$ and $g : [k] \to [n]$, let A_g be the matrix with columns $\mathbf{e}_{g(1)}, \dots, \mathbf{e}_{g(k)}, \mathbf{a}_{k+1}, \dots, \mathbf{a}_n$. Prove by induction on k that $D(A) = \sum_g a_{g(1)1} \cdots a_{g(k)k} D\big(A_g\big)$, the sum running over all $g : [k] \to [n]$.
Hint 3. For the inductive step, expand column $k+1$ of A_g as $\sum_i a_{i,k+1}\mathbf{e}_i$. A function $[k+1] \to [n]$ is the same thing as a function $g : [k] \to [n]$ together with a value $i \in [n]$ at $k+1$.
Sketch. Induct on the number k of columns already expanded. The statement for k writes $D(A)$ as the sum, over $g : [k] \to [n]$, of $a_{g(1)1} \cdots a_{g(k)k}$ times D at the matrix whose first k columns are $\mathbf{e}_{g(1)}, \dots, \mathbf{e}_{g(k)}$ and whose other columns are those of A. Expanding column $k+1$ of each such matrix by linearity gives the statement for $k+1$, because extending g by a value at $k+1$ produces each function $[k+1] \to [n]$ exactly once. For $k = n$ these matrices are the E_f.

For $0 \le k \le n$ and a function $g : [k] \to [n]$, let A_g be the matrix with columns $\mathbf{e}_{g(1)}, \dots, \mathbf{e}_{g(k)}, \mathbf{a}_{k+1}, \dots, \mathbf{a}_n$. For $k = 0$ there is exactly one function $g : \varnothing \to [n]$, and $A_g = A$. We show by induction on k that

$$D(A) = \sum_{g:[k]\to[n]} a_{g(1)1} \cdots a_{g(k)k} D\big(A_g\big),$$

the sum running over all functions $g : [k] \to [n]$. For $k = 0$ the sum has the single term $D(A)$, whose coefficient is the empty product 1.

Suppose the identity holds for some $k < n$, and fix $g : [k] \to [n]$. For $i \in [n]$, let $g_i : [k+1] \to [n]$ agree with g on $[k]$ and send $k+1$ to i. Column $k+1$ of A_g is $\mathbf{a}_{k+1} = \sum_{i=1}^{n} a_{i,k+1}\mathbf{e}_i$, and replacing it by $\mathbf{e}_i$ gives A_{g_i}. So by linearity in column $k+1$,

$$D\big(A_g\big) = \sum_{i=1}^{n} a_{i,k+1} D\big(A_{g_i}\big).$$

Substituting this into the identity for k,

$$D(A) = \sum_{g:[k]\to[n]} \sum_{i=1}^{n} a_{g(1)1} \cdots a_{g(k)k} a_{i,k+1} D\big(A_{g_i}\big).$$

Every function $h : [k+1] \to [n]$ equals g_i for exactly one pair (g, i), namely $g = h|_{[k]}$ and $i = h(k+1)$, and the coefficient of that term is $a_{h(1)1} \cdots a_{h(k+1),k+1}$. So the double sum equals $\sum_h a_{h(1)1} \cdots a_{h(k+1),k+1} D(A_h)$, the sum over all $h : [k+1] \to [n]$, which is the identity for $k+1$. For $k = n$ we have $A_f = E_f$, and the identity is the claim. □

The lemma uses only multilinearity: it is Technique 5.1.7 carried out in all n columns at once. Alternation now removes most of the n^n terms.

Theorem 5.3.3 (The Leibniz formula). Let $D : F^{n\times n} \to F$ be multilinear and alternating. Then for every $A \in F^{n\times n}$,

$$D(A) = D(I_n) \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n}.$$

In particular, every determinant function D on $F^{n\times n}$ satisfies

$$D(A) = \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n}.$$

Proof. ROUTINE

Uses. Lemma 5.3.2 (Expanding every column), Definition 5.1.1 (Determinant function), Definition 5.2.1 (Permutation), Theorem 5.2.31 (Alternating functions and permutations), an injective function $[n] \to [n]$ is a bijection (Section A.1)
Techniques. Expand by multilinearity (Technique 5.1.7)

Hint 1. Start from Lemma 5.3.2. For which f does alternation force $D\big(E_f\big) = 0$?
Hint 2. If f is not injective, two columns of E_f are the same standard basis vector. The injective functions $[n] \to [n]$ are exactly the permutations.
Hint 3. For a permutation σ, Theorem 5.2.31 gives $D(E_\sigma)$.
Sketch. By Lemma 5.3.2, $D(A) = \sum_f a_{f(1)1} \cdots a_{f(n)n} D\big(E_f\big)$. If $f(p) = f(q)$ with $p \neq q$, then E_f has two equal columns and $D\big(E_f\big) = 0$. The remaining f are injective, hence permutations, and $D(E_\sigma) = \operatorname{sgn}(\sigma) D(I_n)$.

By Lemma 5.3.2,

$$D(A) = \sum_{f \in [n]^{[n]}} a_{f(1)1} \cdots a_{f(n)n} D\big(E_f\big).$$

Suppose f is not injective, say $f(p) = f(q)$ with $p \neq q$. Then columns p and q of E_f are both $\mathbf{e}_{f(p)}$, so $D\big(E_f\big) = 0$ because D is alternating, and the term of f is 0. An injective function from the finite set $[n]$ to itself is a bijection, so the remaining terms are indexed by the permutations $\sigma \in S_n$. For these, $D(E_\sigma) = \operatorname{sgn}(\sigma) D(I_n)$ by Theorem 5.2.31. Hence

$$D(A) = \sum_{\sigma \in S_n} a_{\sigma(1)1} \cdots a_{\sigma(n)n} \operatorname{sgn}(\sigma) D(I_n),$$

which is the claim after pulling out the common factor $D(I_n)$. If D is a determinant function, then $D(I_n) = 1$. □

For $n = 2$, the permutations are id and (1 2), with signs 1 and -1, and the formula reads $D(A) = (a_{11}a_{22} - a_{21}a_{12})D(I_2)$. This is part (a) of Theorem 5.1.13. For $n = 1$ it reads $D(a) = aD(1)$, as in Example 5.1.2.

Theorem 5.3.3 proves uniqueness: any two determinant functions on $F^{n \times n}$ are given by the same formula, so they are equal. It does not prove existence. Its hypothesis is that D is multilinear and alternating, and its conclusion describes such a D if there is one. For $n = 2$ we checked separately that $ad - bc$ satisfies the axioms (part (b) of Theorem 5.1.13). For general n that check is the next subsection.

5.3.2 The formula satisfies the axioms

By Theorem 5.3.3, if a determinant function on $F^{n \times n}$ exists, it is the function $L : F^{n \times n} \to F$ given by

$$L(A) = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n}. \tag{5.3.1}$$

(The name L is temporary, until we know that L is a determinant function.) For $\sigma \in S_n$ we write

$$t_\sigma(A) = \operatorname{sgn}(\sigma) a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n}$$

for the term of σ, so that $L(A) = \sum_\sigma t_\sigma(A)$. Realize that $t_\sigma(A)$ contains exactly one entry from each column of A, namely $a_{\sigma(j)j}$ from column j. This makes normalization and multilinearity routine to check. Alternation is the delicate axiom: when two columns of A are equal, no single term needs to vanish, and the terms have to cancel against each other.

Theorem 5.3.4 (Existence and uniqueness of the determinant). Let $n \geq 1$. The function L of (5.3.1) is a determinant function on $F^{n \times n}$, and it is the only one. Moreover, every multilinear alternating function $D : F^{n \times n} \to F$ satisfies $D(A) = D(I_n)L(A)$ for all $A \in F^{n \times n}$.

Proof, part 1 of 3: uniqueness. ROUTINE

Uses. Theorem 5.3.3 (The Leibniz formula), Definition 5.1.1 (Determinant function)
Hint 1. This half is already done. Which result expresses every multilinear alternating D through the formula (5.3.1)?
Hint 2. Theorem 5.3.3 says that $D(A) = D(I_n)L(A)$. What is $D(I_n)$ for a determinant function?
Sketch. By Theorem 5.3.3, every multilinear alternating D equals $D(I_n)L$, and a determinant function has $D(I_n) = 1$, so it equals L.

Let D be multilinear and alternating. By Theorem 5.3.3, $D(A) = D(I_n)L(A)$ for every A, which is the last sentence of the theorem. If D is a determinant function, then $D(I_n) = 1$, so $D = L$. Hence there is at most one determinant function, and if there is one, it is L. It remains to show that L is a determinant function.

Proof, part 2 of 3: L is normalized and multilinear. ROUTINE
