Hint 2. In the second case, subtract from $\mathbf{x}$ the vector obtained by swapping coordinates i and j. Then move the result around with other permutations to get every $\mathbf{e}_k - \mathbf{e}_l$ into U.
Hint 3. The vectors $\mathbf{e}_k - \mathbf{e}_n$ span Z. If U is bigger than Z, pick $\mathbf{u} \in U$ with nonzero coordinate sum and write any $\mathbf{y}$ as an element of Z plus a multiple of $\mathbf{u}$.
Sketch. If all vectors of U are constant, $U \subseteq \operatorname{span}(\mathbf{s})$, so $U = \{\mathbf{0}\}$ or $\operatorname{span}(\mathbf{s})$. Otherwise some $\mathbf{x} \in U$ has $x_i \neq x_j$; subtracting its swap gives $(x_i - x_j)(\mathbf{e}_i - \mathbf{e}_j) \in U$, and permuting gives every $\mathbf{e}_k - \mathbf{e}_l \in U$, so $Z = \operatorname{span}(\mathbf{e}_1 - \mathbf{e}_n, \ldots, \mathbf{e}_{n-1} - \mathbf{e}_n) \subseteq U$. If some $\mathbf{u} \in U$ has coordinate sum $\sigma \neq 0$, then $\mathbf{y} = (\mathbf{y} - (\tau/\sigma)\mathbf{u}) + (\tau/\sigma)\mathbf{u} \in U$, where τ is the coordinate sum of $\mathbf{y}$. (b) Exactly when $n * 1 = 0$ in F.

For a bijection π of $\{1, \ldots, n\}$ and $\mathbf{x} \in F^n$, write $\pi\mathbf{x} = \left(x_{\pi(1)}, \ldots, x_{\pi(n)}\right)$; so U is symmetric if $\pi\mathbf{x} \in U$ for all $\mathbf{x} \in U$ and all π. The sum of the coordinates of $\mathbf{x}$ is denoted $\Sigma(\mathbf{x})$; it does not change under permutations.

(a) The four subspaces are symmetric: for $\{\mathbf{0}\}$ and F^n there is nothing to check, $\pi(c\mathbf{s}) = c\mathbf{s}$, and $\Sigma(\pi\mathbf{x}) = \Sigma(\mathbf{x})$. Note that Z is a subspace by Example 1.4.8. Now let U be a symmetric subspace.

Case 1: every $\mathbf{x} \in U$ has all coordinates equal. Then $U \subseteq \operatorname{span}(\mathbf{s})$. If $U \neq \{\mathbf{0}\}$, it contains some $c\mathbf{s}$ with $c \neq 0$, hence $\mathbf{s} = c^{-1}(c\mathbf{s})$, hence $\operatorname{span}(\mathbf{s})$ by Proposition 1.4.14(b). So $U = \{\mathbf{0}\}$ or $U = \operatorname{span}(\mathbf{s})$.

Case 2: some $\mathbf{x} \in U$ has $x_i \neq x_j$ for some $i \neq j$. Let $\mathbf{y}$ be $\mathbf{x}$ with coordinates i and j swapped. Then $\mathbf{y} \in U$, and $\mathbf{x} - \mathbf{y}$ has i-th coordinate $x_i - x_j$, j-th coordinate $x_j - x_i$, and all others 0:

$$\mathbf{x} - \mathbf{y} = (x_i - x_j)(\mathbf{e}_i - \mathbf{e}_j) \in U.$$

Multiplying by $(x_i - x_j)^{-1}$ gives $\mathbf{e}_i - \mathbf{e}_j \in U$. Now let $k \neq l$, and choose a bijection π of $\{1, \ldots, n\}$ with $\pi(k) = i$ and $\pi(l) = j$. Then $\pi(\mathbf{e}_i - \mathbf{e}_j)$ has k-th coordinate 1, l-th coordinate -1, and all others 0; that is, $\mathbf{e}_k - \mathbf{e}_l \in U$.

Every $\mathbf{z} \in Z$ satisfies $z_n = -(z_1 + \cdots + z_{n-1})$, so

$$\mathbf{z} = z_1(\mathbf{e}_1 - \mathbf{e}_n) + \cdots + z_{n-1}(\mathbf{e}_{n-1} - \mathbf{e}_n),$$

as both sides have the same first $n-1$ coordinates and the same n-th coordinate. So $Z \subseteq \operatorname{span}(\mathbf{e}_1 - \mathbf{e}_n, \ldots, \mathbf{e}_{n-1} - \mathbf{e}_n) \subseteq U$ by Proposition 1.4.14(b). If $U = Z$, we are done. Otherwise there is $\mathbf{u} \in U$ with $\sigma = \Sigma(\mathbf{u}) \neq 0$. For any $\mathbf{y} \in F^n$, let $\tau = \Sigma(\mathbf{y})$. Then $\Sigma(\mathbf{y} - (\tau/\sigma)\mathbf{u}) = \tau - (\tau/\sigma)\sigma = 0$, so

$$\mathbf{y} = (\mathbf{y} - (\tau/\sigma)\mathbf{u}) + (\tau/\sigma)\mathbf{u} \in Z + U \subseteq U.$$

Hence $U = F^n$.

(b) $\operatorname{span}(\mathbf{s}) \subseteq Z$ if and only if $\mathbf{s} \in Z$, that is, $\Sigma(\mathbf{s}) = n * 1 = 0$ in F (in the notation of Exercise 1.2.45). This happens exactly when $\operatorname{char} F$ divides n; over $\mathbb{F}_2$ with n even, for example. In that case the four subspaces form a chain $\{\mathbf{0}\} \subseteq \operatorname{span}(\mathbf{s}) \subseteq Z \subseteq F^n$. For $F = \mathbb{F}_2$ and $n = 2$, $\operatorname{span}(\mathbf{s}) = Z = \{\mathbf{0}, (1,1)\}$, so there are only three symmetric subspaces.

Solution to Exercise 1.4.42

Uses. Proposition 1.4.20 (Unions of two subspaces), Lemma 1.4.19 (Adding a vector outside a subspace), Example 1.4.12 (The subspaces of $\mathbb{F}_2^2$), Corollary 1.2.36 (Cancelling scalars and vectors)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. For (a), use the lines of Example 1.4.12. For (b), let $U = U_1 \cup U_2 \cup U_3$, and suppose no U_i equals U. First show that U_1 is not contained in $U_2 \cup U_3$.
Hint 2. Pick $\mathbf{u} \in U_1$ outside $U_2 \cup U_3$ and $\mathbf{v} \in U$ outside U_1. Consider the vectors $\mathbf{v} + \lambda\mathbf{u}$ for $\lambda \in F$. Which of the U_i can contain them?
Hint 3. None lies in U_1, and U_2 contains at most one of them: if it contains two, it contains their difference, a nonzero multiple of $\mathbf{u}$.
Sketch. (a) The three lines of $\mathbb{F}_2^2$. (b) Suppose no U_i is all of $U = U_1 \cup U_2 \cup U_3$. If $U_1 \subseteq U_2 \cup U_3$, then $U = U_2 \cup U_3$, and Proposition 1.4.20 gives a contradiction; so pick $\mathbf{u} \in U_1$ outside $U_2 \cup U_3$, and $\mathbf{v} \in U \setminus U_1$. The vectors $\mathbf{v} + \lambda\mathbf{u}$, $\lambda \in F$, are at least three distinct vectors of U, none in U_1 (Lemma 1.4.19), and at most one in each of U_2, U_3. Contradiction.

(a) By Example 1.4.12, the lines $\{\mathbf{0}, (1,0)\}$, $\{\mathbf{0}, (0,1)\}$, $\{\mathbf{0}, (1,1)\}$ are subspaces of $\mathbb{F}_2^2$, and their union is $\mathbb{F}_2^2$. Each contains exactly one nonzero vector, and these are different, so no line contains another.

(b) Let $U = U_1 \cup U_2 \cup U_3$, a subspace by hypothesis. One of the U_i contains the other two if and only if it equals U, so suppose, to the contrary, that $U_i \neq U$ for each i.

First, $U_1 \not\subseteq U_2 \cup U_3$. Otherwise $U = U_2 \cup U_3$ is a subspace, so by Proposition 1.4.20 one of U_2, U_3 contains the other and equals U, contrary to our assumption. So we may pick $\mathbf{u} \in U_1$ with $\mathbf{u} \notin U_2$ and $\mathbf{u} \notin U_3$. In particular $\mathbf{u} \neq \mathbf{0}$. Since $U_1 \neq U$, we may also pick $\mathbf{v} \in U$ with $\mathbf{v} \notin U_1$.

For $\lambda \in F$, the vector $\mathbf{v} + \lambda\mathbf{u}$ lies in the subspace U. It does not lie in U_1, by Lemma 1.4.19, since $\lambda\mathbf{u} \in U_1$ and $\mathbf{v} \notin U_1$. Suppose U_2 contained $\mathbf{v} + \lambda\mathbf{u}$ and $\mathbf{v} + \mu\mathbf{u}$ with $\lambda \neq \mu$. Then it would contain their difference $(\lambda - \mu)\mathbf{u}$, and hence $\mathbf{u} = (\lambda - \mu)^{-1}(\lambda - \mu)\mathbf{u}$, which is false. So U_2 contains at most one of the vectors $\mathbf{v} + \lambda\mathbf{u}$, and likewise U_3. These vectors are distinct for distinct λ, by Corollary 1.2.36(b), since $\mathbf{u} \neq \mathbf{0}$, and F has at least three elements. So at least three distinct vectors of U lie in $U_2 \cup U_3$, which contains at most two of them, and none of them lies in U_1. This contradicts $U = U_1 \cup U_2 \cup U_3$.

Part (a) shows that the hypothesis on F is needed. The proof needs three values of λ to outnumber U_2 and U_3; over $\mathbb{F}_2$ there are only two.

Solution to Exercise 1.4.43

Uses. Lemma 1.4.19 (Adding a vector outside a subspace), Exercise 1.4.33, Corollary 1.2.36 (Cancelling scalars and vectors)
Hint 1. Suppose $V = U_1 \cup \cdots \cup U_n$, and choose such a covering with n as small as possible. Why is U_1 then not contained in $U_2 \cup \cdots \cup U_n$?
Hint 2. Pick $\mathbf{u} \in U_1$ outside the other U_j, and $\mathbf{v} \notin U_1$. Count how many of the vectors $\mathbf{v} + \lambda\mathbf{u}$, $\lambda \in F$, each U_j can contain.
Sketch. (a) Take a counterexample with n minimal. Then $n \geq 2$ and $U_1 \not\subseteq U_2 \cup \cdots \cup U_n$; pick $\mathbf{u}$ in U_1 only, and $\mathbf{v} \notin U_1$. The $|F| \geq n$ distinct vectors $\mathbf{v} + \lambda\mathbf{u}$ avoid U_1, and each U_j with $j \geq 2$ contains at most one of them, so at most $n-1$ are covered. (b) An infinite field has at least n elements for every n. (c) F^2 is the union of its $q+1$ lines.

(a) Suppose the statement fails, and among all coverings $V = U_1 \cup \cdots \cup U_n$ of V by proper subspaces with $n \le |F|$, choose one with n as small as possible. Then $n \ge 2$, since $U_1 \ne V$. If $U_1 \subseteq U_2 \cup \cdots \cup U_n$, then $V = U_2 \cup \cdots \cup U_n$ is a covering by $n-1 \le |F|$ proper subspaces, contradicting minimality. So we may pick $\mathbf{u} \in U_1$ with $\mathbf{u} \notin U_j$ for all $j \ge 2$; in particular $\mathbf{u} \ne \mathbf{0}$. Since $U_1 \ne V$, we may also pick $\mathbf{v} \in V$ with $\mathbf{v} \notin U_1$.

Consider the vectors $\mathbf{v} + \lambda\mathbf{u}$ for $\lambda \in F$. They are distinct, by Corollary 1.2.36(b), since $\mathbf{u} \ne \mathbf{0}$, so there are $|F| \ge n$ of them. None lies in U_1, by Lemma 1.4.19, since $\lambda\mathbf{u} \in U_1$ and $\mathbf{v} \notin U_1$. For $j \ge 2$, U_j contains at most one of them: if $\mathbf{v} + \lambda\mathbf{u}$ and $\mathbf{v} + \mu\mathbf{u}$ lie in U_j with $\lambda \ne \mu$, then so does $(\lambda - \mu)^{-1}((\mathbf{v} + \lambda\mathbf{u}) - (\mathbf{v} + \mu\mathbf{u})) = \mathbf{u}$, which is false. So at most $n-1$ of these at least n vectors lie in $U_1 \cup \cdots \cup U_n = V$, a contradiction.

(b) If F is infinite, it has at least n elements for every n, so (a) applies to every finite collection of proper subspaces.

(c) By Exercise 1.4.33, F^2 has $q+1$ lines, each a proper subspace with $q < q^2$ elements. Every nonzero $\mathbf{v} \in F^2$ lies on the line $\operatorname{span}(\mathbf{v})$, and $\mathbf{0}$ lies on every line, so F^2 is the union of the $q+1$ lines. Since $q+1 > q$, this does not contradict (a), and it shows that the bound $n \le |F|$ in (a) cannot be relaxed to $n \le |F| + 1$.

Solution to Exercise 1.4.44

> *Uses.* Proposition 1.4.14 (The span is the smallest subspace containing a list), Example 1.4.8 (One equation in F^n), Corollary 1.3.19 (Equal spans)
> *Techniques.* Double containment (Technique 1.3.14)
> *Hint 1.* By Proposition 1.4.14, the smallest subspace containing a list is its span.
> *Hint 2.* For (a), both vectors satisfy $x_3 = 0$. For the reverse containment, solve $a + b = x_1$ and $a - b = x_2$. For (b), add and subtract the two polynomials.
> *Sketch.* (a) $\operatorname{span}((1,1,0),(1,-1,0)) = \{x_3 = 0\}$: the plane is a subspace containing both vectors, and $(x_1, x_2, 0) = \frac{x_1+x_2}{2}(1,1,0) + \frac{x_1-x_2}{2}(1,-1,0)$. (b) $\operatorname{span}(1+x^2, 1-x^2) = \operatorname{span}(1, x^2) = \{a + bx^2 \mid a, b \in \mathbb{R}\}$.

By Proposition 1.4.14, the smallest subspace containing the entries of a list is the span of the list.

(a) Let $P = \{\mathbf{x} \in \mathbb{R}^3 \mid x_3 = 0\}$, a subspace by Example 1.4.8. Both vectors lie in P, so $\operatorname{span}((1,1,0),(1,-1,0)) \subseteq P$ by Proposition 1.4.14(b). Conversely, for $(x_1, x_2, 0) \in P$,

$$\frac{x_1 + x_2}{2}(1,1,0) + \frac{x_1 - x_2}{2}(1,-1,0) = (x_1, x_2, 0).$$

So the smallest subspace is the plane $x_3 = 0$.

(b) Since $1 = \frac{1}{2}\big((1+x^2) + (1-x^2)\big)$ and $x^2 = \frac{1}{2}\big((1+x^2) - (1-x^2)\big)$, and conversely $1 \pm x^2$ are combinations of 1 and x^2, Corollary 1.3.19 gives

$$\operatorname{span}(1+x^2, 1-x^2) = \operatorname{span}(1, x^2) = \{a + bx^2 \mid a, b \in \mathbb{R}\}.$$

Section 1.5

Solution to Exercise 1.5.8

> *Uses.* Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.1.17 (No zero divisors)
> *Hint 1.* Expand $a(\mathbf{v} + \mathbf{w}) + b(\mathbf{v} - \mathbf{w})$ as a linear combination of $\mathbf{v}, \mathbf{w}$, and use that $\mathbf{v}, \mathbf{w}$ has only the trivial relation.
> *Hint 2.* You get $a + b = 0$ and $a - b = 0$. Add them. When does $(1+1)a = 0$ force $a = 0$?
> *Sketch.* Expanding, the combination with coefficients a, b of the new list is the combination with coefficients $a + b$, $a - b$ of $\mathbf{v}, \mathbf{w}$. So a relation of the new list gives $a + b = a - b = 0$, hence $(1+1)a = 0$ and $(1+1)b = 0$. If $1 + 1 \ne 0$, then $a = b = 0$. If $1 + 1 = 0$, then $(\mathbf{v} + \mathbf{w}) + (\mathbf{v} - \mathbf{w}) = (1+1)\mathbf{v} = \mathbf{0}$ is a dependence relation.

By Lemma 1.3.9, for $a, b \in F$,

$$a(\mathbf{v} + \mathbf{w}) + b(\mathbf{v} - \mathbf{w}) = (a + b)\mathbf{v} + (a - b)\mathbf{w}.$$

Suppose that $1+1 \neq 0$, and that the left side is $\mathbf{0}$. Since $\mathbf{v}, \mathbf{w}$ is independent, Theorem 1.5.5 gives $a+b=0$ and $a-b=0$. Adding and subtracting these equations gives $(1+1)a=0$ and $(1+1)b=0$, so $a=b=0$ by Proposition 1.1.17. Hence $\mathbf{v}+\mathbf{w}, \mathbf{v}-\mathbf{w}$ is independent.

Suppose that $1+1=0$. Taking $a=b=1$, the right side is $(1+1)\mathbf{v}+0\mathbf{w}=\mathbf{0}$. So $1,1$ is a dependence relation, and the list is dependent. In fact $-1=1$, so $\mathbf{v}-\mathbf{w}=\mathbf{v}+\mathbf{w}$, and the list repeats an entry.

Solution to Exercise 1.5.12

Uses. Lemma 1.5.10 (Linear dependence lemma), Definition 1.3.10 (Span), Corollary 1.3.20 (Operations that preserve the span)
Hint 1. Go through $j=1,\ldots,5$ in order. For $j=2$, compare $\mathbf{v}_2$ with $\mathbf{v}_1$.
Hint 2. Once you know that $\mathbf{v}_2$ is redundant, $\operatorname{span}(\mathbf{v}_1,\mathbf{v}_2,\mathbf{v}_3)=\operatorname{span}(\mathbf{v}_1,\mathbf{v}_3)$, whose elements are $(a,a+b,b)$. Test $\mathbf{v}_4$ and $\mathbf{v}_5$ against this description.
Sketch. $j=2$, since $\mathbf{v}_2=2\mathbf{v}_1$, and $j=4$, since $\mathbf{v}_4=\mathbf{v}_1+\mathbf{v}_3$, with relations $2\mathbf{v}_1-\mathbf{v}_2=\mathbf{0}$ and $\mathbf{v}_1+\mathbf{v}_3-\mathbf{v}_4=\mathbf{0}$. No other j works: $\mathbf{v}_1\neq\mathbf{0}$, $\mathbf{v}_3$ is not a multiple of $\mathbf{v}_1$, and $\operatorname{span}(\mathbf{v}_1,\ldots,\mathbf{v}_4)=\{(a,a+b,b)\}$ does not contain $(0,0,1)$.

$j=1$: $\mathbf{v}_1\neq\mathbf{0}$, so $\mathbf{v}_1\notin\operatorname{span}(())=\{\mathbf{0}\}$.

$j=2$: $\mathbf{v}_2=2\mathbf{v}_1$. The relation $2\mathbf{v}_1+(-1)\mathbf{v}_2=\mathbf{0}$, with zero coefficients on the other entries, has largest nonzero index 2.

$j=3$: By Corollary 1.3.20(c), $\operatorname{span}(\mathbf{v}_1,\mathbf{v}_2)=\operatorname{span}(\mathbf{v}_1)$, whose elements $(a,a,0)$ have third coordinate 0. So $\mathbf{v}_3=(0,1,1)$ is not in it.

$j=4$: $\mathbf{v}_1+\mathbf{v}_3=(1,2,1)=\mathbf{v}_4$. The relation $\mathbf{v}_1+\mathbf{v}_3+(-1)\mathbf{v}_4=\mathbf{0}$ has largest nonzero index 4.

$j=5$: By Corollary 1.3.20(a) and (c), deleting $\mathbf{v}_2$ and $\mathbf{v}_4$ shows $\operatorname{span}(\mathbf{v}_1,\ldots,\mathbf{v}_4)=\operatorname{span}(\mathbf{v}_1,\mathbf{v}_3)$, which consists of the vectors $a(1,1,0)+b(0,1,1)=(a,a+b,b)$. For $(0,0,1)$ we would need $a=0$, $b=1$, and $a+b=0$, which is impossible. So $\mathbf{v}_5\notin\operatorname{span}(\mathbf{v}_1,\ldots,\mathbf{v}_4)$.

Hence $j=2$ and $j=4$ are the indices that work.

Solution to Exercise 1.5.16

Uses. Proposition 1.5.15 (Short lists, zeros, and repeats), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Which step turns a linear combination of two vectors into a multiple of one of them?
Hint 2. Test the claim on $(1,0),(0,1),(1,1)$ in $\mathbb{R}^2$.
Sketch. A combination of $\mathbf{v}_2$ and $\mathbf{v}_3$ with both coefficients nonzero need not be a multiple of either. The list $(1,0),(0,1),(1,1)$ satisfies the hypothesis but has the relation $(1,0)+(0,1)-(1,1)=\mathbf{0}$.

The error is the step "so $\mathbf{v}_1$ is a scalar multiple of $\mathbf{v}_2$ or of $\mathbf{v}_3$". It holds when $a_2=0$ or $a_3=0$, but a linear combination of $\mathbf{v}_2$ and $\mathbf{v}_3$ with both coefficients nonzero is in general a multiple of neither.

The claim is false. In $\mathbb{R}^2$, no two of $(1,0)$, $(0,1)$, $(1,1)$ are multiples of each other: their coordinates show that $(0,1)$ and $(1,1)$ are not multiples of $(1,0)$, and so on. But $(1,0)+(0,1)+(-1)(1,1)=\mathbf{0}$ is a dependence relation. For two vectors the claim is correct (Proposition 1.5.15(d)), and the argument above is a valid proof in that case.

Solution to Exercise 1.5.22

Uses. Proposition 1.5.15 (Short lists, zeros, and repeats), Theorem 1.5.5 (Independence is decided at zero), Definition 1.1.29 (Complex numbers), Proposition 1.5.21 (Real lists in $\mathbb{C}^m$)
Hint 1. Over $\mathbb{C}$, is the second vector a complex multiple of the first? Compare first coordinates to find the only candidate.
Hint 2. Over $\mathbb{R}$, write $a(1,1+i)+b(1-i,2)=\mathbf{0}$ with a,b real, and take the real and imaginary parts of the first coordinate.
Sketch. $(1-i)(1,1+i)=(1-i,2)$, so the list is dependent over $\mathbb{C}$. Over $\mathbb{R}$, the first coordinate $a+b-bi$ of a relation must vanish, which forces $b=0$ and $a=0$. No contradiction: the vectors are not real.

Over $\mathbb{C}$:

$$(1-i)(1,1+i)=(1-i,(1-i)(1+i))=\left(1-i,1-i^2\right)=(1-i,2).$$

So the second vector is a multiple of the first, and the list is dependent by Proposition 1.5.15(d).

Over $\mathbb{R}$: let $a, b \in \mathbb{R}$ with $a(1, 1+i) + b(1-i, 2) = \mathbf{0}$. The first coordinate is $a + b(1-i) = (a+b) + (-b)i$, which is 0 only if $a + b = 0$ and $-b = 0$, by Definition 1.1.29. So $a = b = 0$, and the list is independent over $\mathbb{R}$.

This does not contradict Proposition 1.5.21, which concerns lists of vectors with real coordinates. Here the coordinates $1 + i$ and $1 - i$ are not real.

Solution to Exercise 1.5.28

Uses. Theorem 1.5.5 (Independence is decided at zero), Lemma 1.5.10 (Linear dependence lemma), Proposition 1.5.15 (Short lists, zeros, and repeats)
Hint 1. Write $a\mathbf{v}_1 + b\mathbf{v}_2 + c\mathbf{v}_3 = \mathbf{0}$ as three equations in a, b, c, one per coordinate, and eliminate.
Hint 2. In (b), the equations can be solved from the top down. In (c), add up the three vectors.
Sketch. (a) Dependent: $\mathbf{v}_1 - 2\mathbf{v}_2 + \mathbf{v}_3 = \mathbf{0}$, and only $j = 3$ works. (b) Independent: the relation reads $(a, a+b, a+b+c) = \mathbf{0}$. (c) Dependent: $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 = \mathbf{0}$, and only $j = 3$ works.

(a) The relation $a(1, 2, 3) + b(4, 5, 6) + c(7, 8, 9) = \mathbf{0}$ reads

$$a + 4b + 7c = 0, \quad 2a + 5b + 8c = 0, \quad 3a + 6b + 9c = 0.$$

Subtracting twice the first equation from the second gives $-3b - 6c = 0$, so $b = -2c$, and then the first gives $a = -4b - 7c = c$. The third equation then holds: $3c - 12c + 9c = 0$. Taking $c = 1$ gives the dependence relation $\mathbf{v}_1 - 2\mathbf{v}_2 + \mathbf{v}_3 = \mathbf{0}$, so the list is dependent. Here $j = 1$ fails as $\mathbf{v}_1 \neq \mathbf{0}$, and $j = 2$ fails as $(4, 5, 6)$ is not a multiple of $(1, 2, 3)$ (the multiplier would have to be 4 and $5/2$). The relation gives $j = 3$: $\mathbf{v}_3 = -\mathbf{v}_1 + 2\mathbf{v}_2$.

(b) A relation reads

$$a(1, 1, 1) + b(0, 1, 1) + c(0, 0, 1) = (a, a+b, a+b+c) = \mathbf{0},$$

which gives $a = 0$, then $b = 0$, then $c = 0$. So the list is independent.

(c) The three vectors add up to $(1 + 0 - 1, -1 + 1 + 0, 0 - 1 + 1) = \mathbf{0}$, so 1, 1, 1 is a dependence relation. Here $\mathbf{v}_1 \neq \mathbf{0}$, and $\mathbf{v}_2 = (0, 1, -1)$ is not a multiple of $(1, -1, 0)$, since a multiple $t(1, -1, 0)$ with first coordinate 0 has $t = 0$. So only $j = 3$ works, with $\mathbf{v}_3 = -\mathbf{v}_1 - \mathbf{v}_2$.

Solution to Exercise 1.5.29

Uses. Theorem 1.5.5 (Independence is decided at zero), Proposition 1.1.17 (No zero divisors), Proposition 1.5.15 (Short lists, zeros, and repeats)
Hint 1. The relation $a(1, 1, 1) + b(1, 2, 3) + c(1, 4, 9) = \mathbf{0}$ gives one equation per coordinate. The t-th coordinates of the three vectors are $1, t, t^2$.
Hint 2. Eliminate a, then b. You should reach $2c = 0$. Which primes make $2 = 0$?
Sketch. The equations $a + b + c = 0$, $a + 2b + 4c = 0$, $a + 3b + 9c = 0$ reduce to $b + 3c = 0$ and $2c = 0$, using only operations valid in every field. If $2 \neq 0$ (every $p \neq 2$, and $\mathbb{Q}$), the list is independent. In $\mathbb{F}_2^3$ the list is $(1, 1, 1), (1, 0, 1), (1, 0, 1)$, which repeats an entry.

Reading the coordinates of $a(1, 1, 1) + b(1, 2, 3) + c(1, 4, 9) = \mathbf{0}$ one at a time gives

$$a + b + c = 0, \quad a + 2b + 4c = 0, \quad a + 3b + 9c = 0.$$

Subtracting the first equation from the other two gives $b + 3c = 0$ and $2b + 8c = 0$, and subtracting twice the first of these from the second gives $2c = 0$. These steps are valid over every field.

If $2 \neq 0$ in F, then $c = 0$ by Proposition 1.1.17, so $b = -3c = 0$ and $a = -b - c = 0$, and the list is independent by Theorem 1.5.5. This is the case for $F = \mathbb{Q}$ and $F = \mathbb{F}_p$ with p odd.

If $p = 2$, then $2 = 0$ and $4 = 0$ and $3 = 9 = 1$ in $\mathbb{F}_2$, so the list is $(1, 1, 1), (1, 0, 1), (1, 0, 1)$. It repeats an entry, so it is dependent (Proposition 1.5.15(c)).

So the list is independent in $\mathbb{F}_p^3$ exactly for $p \neq 2$, and it is independent in $\mathbb{Q}^3$.

Solution to Exercise 1.5.30

Uses. Lemma 1.5.10 (Linear dependence lemma), Proposition 1.5.14 (Appending a vector), Example 1.5.11 (Which entries are redundant)
Hint 1. Is the largest index with a nonzero coefficient necessarily k? What if $a_k = 0$?
Hint 2. For (b), compare with Proposition 1.5.14.
Sketch. (a) j is the largest index with $a_j \neq 0$, which is k only if $a_k \neq 0$. Counterexample: $(1,0),(2,0),(0,1)$ in $\mathbb{R}^2$. (b) This is the contrapositive of the backward direction of Proposition 1.5.14.

(a) The step "$j = k$" is wrong. The index j is the largest one with $a_j \neq 0$, and nothing prevents $a_k = 0$. The claim itself is false: in $\mathbb{R}^2$, the list $(1,0),(2,0),(0,1)$ is dependent (Example 1.5.11), but $(0,1) \notin \operatorname{span}((1,0),(2,0))$, since every vector of that span has second coordinate 0.

(b) Suppose that $\mathbf{v}_1, \ldots, \mathbf{v}_{k-1}$ is independent and that $\mathbf{v}_k \notin \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$. Then $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is independent by Proposition 1.5.14. Taking the contrapositive: if $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is dependent, then $\mathbf{v}_k \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$. In terms of the argument in (a): if $a_k = 0$, the relation would be a nontrivial relation of the independent list $\mathbf{v}_1, \ldots, \mathbf{v}_{k-1}$, which is impossible, so here $j = k$ is correct.

Solution to Exercise 1.5.31

Uses. Corollary 1.5.13 (Independence, one entry at a time), Corollary 1.3.20 (Operations that preserve the span)
Hint 1. By Corollary 1.3.20(b), $S_{j-1} \subseteq S_j$ always. When are they equal?
Hint 2. Corollary 1.3.20(c) says $S_j = S_{j-1}$ exactly when $\mathbf{v}_j \in S_{j-1}$. Now use Corollary 1.5.13.
Sketch. $S_{j-1} \subseteq S_j$, with equality if and only if $\mathbf{v}_j \in S_{j-1}$ (Corollary 1.3.20(c)). So the chain is strict exactly when $\mathbf{v}_j \notin S_{j-1}$ for all j, which is independence by Corollary 1.5.13.

For $1 \leq j \leq k$, the list $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$ is a sublist of $\mathbf{v}_1, \ldots, \mathbf{v}_j$, so $S_{j-1} \subseteq S_j$ by Corollary 1.3.20(b). By Corollary 1.3.20(c), applied to the list $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$ and the vector $\mathbf{v}_j$, we have $S_j = S_{j-1}$ if and only if $\mathbf{v}_j \in S_{j-1}$. So $S_{j-1} \subsetneq S_j$ if and only if $\mathbf{v}_j \notin \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$. The chain is strict at every step if and only if this holds for every j, which by Corollary 1.5.13 is exactly the independence of $\mathcal{L}$.

Solution to Exercise 1.5.32

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.9 (Function spaces), Example 1.5.26 (Trigonometric functions)
Hint 1. For (a), recall a double-angle formula. For (b), evaluate a relation at points where the sines are simple, such as $\pi/2$, $\pi/3$, and $\pi/4$.
Hint 2. For (c), evaluate at $t = 1$ and $t = -1$. Which of these points is available in $\mathbb{R}^{[0,\infty)}$?
Sketch. (a) Dependent: $1 + \cos 2t - 2\cos^2 t = 0$. (b) Independent: evaluating $a \sin t + b \sin 2t + c \sin 3t = 0$ at $\pi/2$, $\pi/3$, $\pi/4$ gives $a = c$, $b = -a$, and $\left(\sqrt{2} - 1\right)a = 0$. (c) Independent in $\mathbb{R}^{\mathbb{R}}$ (evaluate at ± 1); dependent in $\mathbb{R}^{[0,\infty)}$, where $|t| = t$.

(a) Dependent. By the double-angle formula $\cos 2t = 2\cos^2 t - 1$, the relation with coefficients $1, 1, -2$ holds: $1 + \cos 2t - 2\cos^2 t = 0$ for every t.

(b) Independent. Suppose $a \sin t + b \sin 2t + c \sin 3t = 0$ for all t. At $t = \pi/2$: $\sin(\pi/2) = 1$, $\sin \pi = 0$, and $\sin(3\pi/2) = -1$, so $a - c = 0$. At $t = \pi/3$: $\sin(\pi/3) = \sin(2\pi/3) = \sqrt{3}/2$ and $\sin \pi = 0$, so $\left(\sqrt{3}/2\right)(a + b) = 0$ and $b = -a$. At $t = \pi/4$: $\sin(\pi/4) = \sin(3\pi/4) = \sqrt{2}/2$ and $\sin(\pi/2) = 1$, so

$$\frac{\sqrt{2}}{2}a + b + \frac{\sqrt{2}}{2}c = 0.$$

Substituting $b = -a$ and $c = a$ gives $\left(\sqrt{2} - 1\right)a = 0$, so $a = 0$, and then $b = c = 0$.

(c) In $\mathbb{R}^{\mathbb{R}}$, suppose $at + b|t| = 0$ for all t. At $t = 1$, $a + b = 0$; at $t = -1$, $-a + b = 0$. So $a = b = 0$, and the list is independent. In $\mathbb{R}^{[0,\infty)}$, the two functions are equal, since $|t| = t$ for $t \geq 0$, so the list repeats an entry and is dependent. The relation $1 \cdot t + (-1)|t| = 0$ holds on $[0,\infty)$ but not at $t = -1$: whether functions are independent depends on their domain.

Solution to Exercise 1.5.33

Uses. Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Exercise 1.3.34, Corollary 1.3.19 (Equal spans)
Hint 1. If $a_j = 0$, then $\mathbf{w}$ is a combination of the other entries of $\mathcal{L}'$. Write down a relation.

Hint 2. If $a_j \neq 0$, take a relation $\sum_{i\neq j} b_i\mathbf{v}_i + b_j\mathbf{w} = \mathbf{0}$, substitute for $\mathbf{w}$, and collect the coefficients of $\mathbf{v}_1, \ldots, \mathbf{v}_k$.
Sketch. If $a_j = 0$: $\sum_{i\neq j} a_i\mathbf{v}_i - \mathbf{w} = \mathbf{0}$ is a nontrivial relation of $\mathcal{L}'$. If $a_j \neq 0$: a relation of $\mathcal{L}'$ becomes $\sum_{i\neq j}\big(b_i + b_j a_i\big)\mathbf{v}_i + b_j a_j\mathbf{v}_j = \mathbf{0}$, so $b_j a_j = 0$, whence $b_j = 0$, and then all $b_i = 0$. For the spans, solve for $\mathbf{v}_j$.

Suppose $a_j = 0$. Then $\mathbf{w} = \sum_{i\neq j} a_i\mathbf{v}_i$, and the linear combination of $\mathcal{L}'$ with coefficient a_i on $\mathbf{v}_i$ for $i \neq j$ and -1 on $\mathbf{w}$ represents $\mathbf{w} - \mathbf{w} = \mathbf{0}$. It is nontrivial, so $\mathcal{L}'$ is dependent.

Suppose $a_j \neq 0$. Let $\sum_{i\neq j} b_i\mathbf{v}_i + b_j\mathbf{w} = \mathbf{0}$. Substituting $\mathbf{w} = \sum_i a_i\mathbf{v}_i$ and collecting coefficients with Lemma 1.3.9,

$$\sum_{i\neq j}\big(b_i + b_j a_i\big)\mathbf{v}_i + \big(b_j a_j\big)\mathbf{v}_j = \mathbf{0}.$$

Since $\mathcal{L}$ is independent, all these coefficients are 0 (Theorem 1.5.5). From $b_j a_j = 0$ and $a_j \neq 0$ we get $b_j = 0$, and then $b_i = b_i + b_j a_i = 0$ for $i \neq j$. So $\mathcal{L}'$ is independent.

For the spans, $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, and since $a_j \neq 0$,

$$\mathbf{v}_j = a_j^{-1}\mathbf{w} + \sum_{i\neq j}\big(-a_j^{-1}a_i\big)\mathbf{v}_i \in \operatorname{span}(\mathcal{L}').$$

So each list lies in the span of the other, and $\operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{L})$ by Corollary 1.3.19. (Compare Exercise 1.3.34, which made the same exchange using only spans.)

Solution to Exercise 1.5.34

Uses. Proposition 1.5.15 (Short lists, zeros, and repeats), Example 1.5.11 (Which entries are redundant), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Look for counterexamples in $\mathbb{R}^2$ among $\mathbf{e}_1$, $\mathbf{e}_2$, $\mathbf{e}_1 + \mathbf{e}_2$, and repeated vectors.
Hint 2. Exactly one statement is true. For it, write down a relation in which the last entry has coefficient -1.
Sketch. (a) False: $\mathbf{u} = \mathbf{w} = \mathbf{e}_1$, $\mathbf{v} = \mathbf{e}_2$. (b) False: $(1,0), (2,0), (0,1)$. (c) False: $\mathcal{L} = \mathcal{M} = \mathbf{e}_1$. (d) True: $\mathbf{v}_1 + \cdots + \mathbf{v}_k - (\mathbf{v}_1 + \cdots + \mathbf{v}_k) = \mathbf{0}$ has coefficient -1 on the last entry. (e) False: $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$.

Write $\mathbf{e}_1 = (1,0)$ and $\mathbf{e}_2 = (0,1)$ in $\mathbb{R}^2$.

(a) False. Take $\mathbf{u} = \mathbf{w} = \mathbf{e}_1$ and $\mathbf{v} = \mathbf{e}_2$. Then $\mathbf{u}, \mathbf{v}$ and $\mathbf{v}, \mathbf{w}$ are $\mathbf{e}_1, \mathbf{e}_2$ and $\mathbf{e}_2, \mathbf{e}_1$, which are independent (Example 1.5.2, and neither is a multiple of the other). But $\mathbf{u}, \mathbf{w} = \mathbf{e}_1, \mathbf{e}_1$ repeats an entry (Proposition 1.5.15(c)).

(b) False. The list $(1,0), (2,0), (0,1)$ is dependent, but $(0,1) \notin \operatorname{span}((1,0), (2,0))$ (Example 1.5.11).

(c) False. Take $\mathcal{L} = \mathcal{M} = \mathbf{e}_1$, which is independent by Proposition 1.5.15(b). The concatenation $\mathbf{e}_1, \mathbf{e}_1$ repeats an entry.

(d) True. The linear combination with coefficient 1 on each $\mathbf{v}_i$ and -1 on the last entry represents $(\mathbf{v}_1 + \cdots + \mathbf{v}_k) - (\mathbf{v}_1 + \cdots + \mathbf{v}_k) = \mathbf{0}$, and it is nontrivial. (Independence of $\mathbf{v}_1, \ldots, \mathbf{v}_k$ was not needed. For $k = 0$ the list is the single vector $\mathbf{0}$, the empty sum.)

(e) False. Take $\mathbf{u} = \mathbf{e}_1$, $\mathbf{v} = \mathbf{e}_2$, and $\mathbf{w} = (1,1)$. Then $\mathbf{w}$ is on neither axis, but $\mathbf{u} + \mathbf{v} - \mathbf{w} = \mathbf{0}$. Avoiding the two lines spanned by $\mathbf{u}$ and $\mathbf{v}$ is much weaker than avoiding $\operatorname{span}(\mathbf{u}, \mathbf{v})$, which is what Proposition 1.5.14 requires.

Solution to Exercise 1.5.35

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.17 (Evaluation), Proposition 1.2.18 (Degree and evaluation versus the operations), Proposition 1.1.17 (No zero divisors), Proposition 1.5.15 (Short lists, zeros, and repeats)
Hint 1. Evaluate each p_i at 0, 1, and 2. Each polynomial vanishes at two of these points.
Hint 2. If $ap_1 + bp_2 + cp_3 = \mathbf{0}$, evaluate at 0, 1, 2 using Proposition 1.2.18(c). For the case $1 + 1 = 0$, rewrite the three polynomials with $2 = 0$ and $3 = 1$.
Sketch. $p_1(0) = 2$, $p_2(1) = -1$, $p_3(2) = 2$, and each p_i vanishes at the other two points. A relation evaluated at $0, 1, 2$ gives $2a = 0$, $-b = 0$, $2c = 0$, so if $2 \neq 0$ the list is independent. If $2 = 0$, then $p_1 = x^2 + x = p_3$, a repeated entry.

By Definition 1.2.17,

$$\begin{aligned} p_1(0) &= 2, \quad p_1(1) = 1-3+2 = 0, \quad p_1(2) = 4-6+2 = 0, \\ p_2(0) &= 0, \quad p_2(1) = 1-2 = -1, \qquad\quad p_2(2) = 4-4 = 0, \\ p_3(0) &= 0, \quad p_3(1) = 1-1 = 0, \qquad\quad p_3(2) = 4-2 = 2. \end{aligned}$$

Suppose that $1+1 \neq 0$, and that $ap_1 + bp_2 + cp_3 = \mathbf{0}$. The zero polynomial has value 0 everywhere, so by Proposition 1.2.18(c), evaluating at 0, 1, 2 gives

$$2a = 0, \quad -b = 0, \quad 2c = 0.$$

Since $2 = 1+1 \neq 0$, Proposition 1.1.17 gives $a = c = 0$, and $b = 0$. So the list is independent by Theorem 1.5.5.

Suppose that $1+1 = 0$. Then $2 = 0$, $3 = 1$, and $-1 = 1$ in F, so

$$p_1 = x^2 + x, \quad p_2 = x^2, \quad p_3 = x^2 + x.$$

The list repeats an entry, so it is dependent (Proposition 1.5.15(c)). The evaluation argument breaks down because the values $p_1(0) = p_3(2) = 2$ vanish when $2 = 0$, so the equations at 0 and 2 become $0 = 0$, and only $b = 0$ remains.

Solution to Exercise 1.5.36

Uses. Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.1.17 (No zero divisors)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. Expand $\sum_i a_i \mathbf{w}_i$ in terms of the $\mathbf{v}_i$. Each $\mathbf{v}_i$ occurs in exactly two of the $\mathbf{w}$'s.
Hint 2. Independence of the $\mathbf{v}_i$ gives $a_i + a_{i-1} = 0$ for every i, with $a_0 = a_n$. So the signs alternate around the cycle. What happens when you get back to the start?
Hint 3. Try $n = 2, 3, 4$ first, and over $\mathbb{F}_2$.
Sketch. With $a_0 = a_n$, $\sum a_i \mathbf{w}_i = \sum_i (a_{i-1} + a_i)\mathbf{v}_i$, so a relation means $a_i = -a_{i-1}$ for all i, that is, $a_i = (-1)^{i-1} a_1$ and $\left(1 + (-1)^{n-1}\right) a_1 = 0$. For n even, $a_i = (-1)^{i-1}$ is a nontrivial relation. For n odd, the condition is $(1+1)a_1 = 0$. Answer: independent exactly when n is odd and $1 + 1 \neq 0$.

Let $a_1, \ldots, a_n \in F$, and set $a_0 = a_n$. The vector $\mathbf{v}_i$ occurs in $\mathbf{w}_{i-1}$ and in $\mathbf{w}_i$ (in $\mathbf{w}_n$ and $\mathbf{w}_1$ for $i = 1$), each time with coefficient 1. So by Lemma 1.3.9,

$$\sum_{i=1}^{n} a_i \mathbf{w}_i = \sum_{i=1}^{n} (a_{i-1} + a_i)\mathbf{v}_i.$$

Since the $\mathbf{v}_i$ are independent, $a_1, \ldots, a_n$ is a linear relation of $\mathbf{w}_1, \ldots, \mathbf{w}_n$ if and only if $a_i = -a_{i-1}$ for $2 \leq i \leq n$ and $a_1 = -a_n$. The first $n-1$ conditions say that $a_i = (-1)^{i-1} a_1$ for all i, and then the last one says $a_1 = -(-1)^{n-1} a_1$, that is,

$$\left(1 + (-1)^{n-1}\right) a_1 = 0.$$

If n is even, $(-1)^{n-1} = -1$, so the last condition always holds, and $a_i = (-1)^{i-1}$ is a nontrivial relation. The list is dependent, over every field.

If n is odd, the last condition is $(1+1)a_1 = 0$. If $1 + 1 \neq 0$, it forces $a_1 = 0$ (Proposition 1.1.17), hence every $a_i = 0$, and the list is independent by Theorem 1.5.5. If $1 + 1 = 0$, then $a_1 = 1$ satisfies it, giving the nontrivial relation $a_i = (-1)^{i-1} = 1$ (as $-1 = 1$). Indeed,

$$\mathbf{w}_1 + \cdots + \mathbf{w}_n = (1+1)(\mathbf{v}_1 + \cdots + \mathbf{v}_n) = \mathbf{0}.$$

So $\mathbf{w}_1, \ldots, \mathbf{w}_n$ is independent exactly when n is odd and $1 + 1 \neq 0$ in F. For $n = 2$ the list is $\mathbf{v}_1 + \mathbf{v}_2, \mathbf{v}_2 + \mathbf{v}_1$, which repeats an entry, as it must.

Solution to Exercise 1.5.37

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.1.29 (Complex numbers), Proposition 1.2.19 (Restriction of scalars)
Hint 1. For real a_j, b_j, rewrite $a_j\mathbf{v}_j + b_j(i\mathbf{v}_j)$ as a single complex multiple of $\mathbf{v}_j$.
Hint 2. Complex relations of $\mathbf{v}_1, \dots, \mathbf{v}_k$ and real relations of the doubled list correspond to each other, via $c_j = a_j + b_j i$.
Sketch. By (A6) and (A8), $a_j\mathbf{v}_j + b_j(i\mathbf{v}_j) = (a_j + b_j i)\mathbf{v}_j$. So real coefficients $a_1, b_1, \dots, a_k, b_k$ form a relation of the doubled list if and only if $a_1 + b_1 i, \dots, a_k + b_k i$ form a complex relation of the original list, and one is trivial exactly when the other is.

For $a_j, b_j \in \mathbb{R}$, (A6) gives $b_j(i\mathbf{v}_j) = (b_j i)\mathbf{v}_j$, and then (A8) gives $a_j\mathbf{v}_j + (b_j i)\mathbf{v}_j = (a_j + b_j i)\mathbf{v}_j$. Hence

$$\sum_{j=1}^{k}\bigl(a_j\mathbf{v}_j + b_j(i\mathbf{v}_j)\bigr) = \sum_{j=1}^{k}(a_j + b_j i)\mathbf{v}_j. \tag{C.1.1}$$

(⇒) Suppose that $\mathbf{v}_1, \dots, \mathbf{v}_k$ is independent over $\mathbb{C}$, and that real numbers $a_1, b_1, \dots, a_k, b_k$ form a relation of the doubled list. By (C.1.1), the complex numbers $a_j + b_j i$ form a relation of $\mathbf{v}_1, \dots, \mathbf{v}_k$, so $a_j + b_j i = 0$, that is, $a_j = b_j = 0$ (Definition 1.1.29).

(⇐) Suppose that the doubled list is independent over $\mathbb{R}$, and that $c_1, \dots, c_k \in \mathbb{C}$ form a relation of $\mathbf{v}_1, \dots, \mathbf{v}_k$. Write $c_j = a_j + b_j i$ with $a_j, b_j \in \mathbb{R}$. By (C.1.1), the real numbers $a_1, b_1, \dots, a_k, b_k$ form a relation of the doubled list, so they are all 0, and every $c_j = 0$.

In the language of Section 4.1: if $\mathbf{v}_1, \dots, \mathbf{v}_n$ is a basis of V over $\mathbb{C}$, the doubled list is a basis over $\mathbb{R}$, so the real dimension of V is twice its complex dimension.

Solution to Exercise 1.5.38

Uses. Definition 1.3.10 (Span), Definition 1.1.29 (Complex numbers), Definition 1.2.4 (The space F^n), Proposition 1.5.21 (Real lists in $\mathbb{C}^m$)
Hint 1. Every $\mathbf{z} \in \mathbb{C}^m$ can be written as $\mathbf{x} + i\mathbf{y}$ with $\mathbf{x}, \mathbf{y} \in \mathbb{R}^m$, by taking real and imaginary parts coordinatewise.
Hint 2. For (⇐), write a real vector as a complex combination of $\mathcal{L}$ and take real parts coordinate by coordinate, as in the proof of Proposition 1.5.21.
Sketch. (⇒) Write $\mathbf{z} = \mathbf{x} + i\mathbf{y}$, expand $\mathbf{x} = \sum a_j\mathbf{v}_j$ and $\mathbf{y} = \sum b_j\mathbf{v}_j$ over $\mathbb{R}$; then $\mathbf{z} = \sum(a_j + b_j i)\mathbf{v}_j$. (⇐) If $\mathbf{x} \in \mathbb{R}^m$ equals $\sum c_j\mathbf{v}_j$ with $c_j = a_j + b_j i$, then comparing real parts in each coordinate gives $\mathbf{x} = \sum a_j\mathbf{v}_j$.

Write v_{jt} for the t-th coordinate of $\mathbf{v}_j$, a real number.

(⇒) Suppose $\mathcal{L}$ spans $\mathbb{R}^m$, and let $\mathbf{z} \in \mathbb{C}^m$ have coordinates $z_t = x_t + y_t i$ with $x_t, y_t \in \mathbb{R}$. Let $\mathbf{x} = (x_1, \dots, x_m)$ and $\mathbf{y} = (y_1, \dots, y_m)$ in $\mathbb{R}^m$, and write $\mathbf{x} = \sum_j a_j\mathbf{v}_j$ and $\mathbf{y} = \sum_j b_j\mathbf{v}_j$ with $a_j, b_j \in \mathbb{R}$. Then for each t,

$$\sum_{j=1}^{k}(a_j + b_j i)v_{jt} = \sum_{j=1}^{k} a_j v_{jt} + \left(\sum_{j=1}^{k} b_j v_{jt}\right) i = x_t + y_t i = z_t,$$

so $\mathbf{z} = \sum_j(a_j + b_j i)\mathbf{v}_j \in \operatorname{span}_{\mathbb{C}}(\mathcal{L})$.

(⇐) Suppose $\mathcal{L}$ spans $\mathbb{C}^m$, and let $\mathbf{x} \in \mathbb{R}^m$. Then $\mathbf{x} = \sum_j c_j\mathbf{v}_j$ for some $c_j = a_j + b_j i$ in $\mathbb{C}$. In coordinate t,

$$x_t = \sum_{j=1}^{k} a_j v_{jt} + \left(\sum_{j=1}^{k} b_j v_{jt}\right) i.$$

Both sums are real, and x_t is real, so comparing real parts (Definition 1.1.29) gives $x_t = \sum_j a_j v_{jt}$. Hence $\mathbf{x} = \sum_j a_j\mathbf{v}_j$ with real coefficients, and $\mathbf{x} \in \operatorname{span}_{\mathbb{R}}(\mathcal{L})$.

Together with Proposition 1.5.21, this shows that $\mathcal{L}$ is a basis of $\mathbb{R}^m$ if and only if it is a basis of $\mathbb{C}^m$ (Section 1.6).

Solution to Exercise 1.5.39

Uses. Theorem 1.5.5 (Independence is decided at zero), Example 1.2.20 (Real and rational scalars)
Hint 1. Suppose $a\ln 2 + b\ln 3 + c\ln 5 = 0$ with $a, b, c \in \mathbb{Q}$. Clear denominators to make the coefficients integers.
Hint 2. Exponentiate: $2^A 3^B 5^C = 1$ with integers A, B, C. Move the factors with negative exponents to the other side.

Sketch. Multiply a relation by a common denominator to get $A\ln 2 + B\ln 3 + C\ln 5 = 0$ with $A, B, C \in \mathbb{Z}$, so $2^A 3^B 5^C = 1$. Collecting negative exponents on the right gives two factorizations of one positive integer into primes, and uniqueness forces $A = B = C = 0$.

Suppose $a\ln 2 + b\ln 3 + c\ln 5 = 0$ with $a, b, c \in \mathbb{Q}$. Let $N \geq 1$ be a common denominator, so that $A = Na$, $B = Nb$, $C = Nc$ are integers, and $A\ln 2 + B\ln 3 + C\ln 5 = 0$. Exponentiating, $2^A 3^B 5^C = e^0 = 1$. For an integer n, write $n^+ = \max(n, 0)$ and $n^- = \max(-n, 0)$, so that $n = n^+ - n^-$ and at most one of n^+, n^- is nonzero. Multiplying by $2^{A^-} 3^{B^-} 5^{C^-}$,

$$2^{A^+} 3^{B^+} 5^{C^+} = 2^{A^-} 3^{B^-} 5^{C^-}.$$

Both sides are positive integers. By unique factorization, the exponent of 2 on the two sides agrees, so $A^+ = A^-$; since one of them is 0, both are, and $A = 0$. Likewise $B = C = 0$. Hence $a = b = c = 0$, and the list is independent by Theorem 1.5.5.

The same argument shows that $\ln p_1, \ldots, \ln p_k$ is independent over $\mathbb{Q}$ for any distinct primes $p_1, \ldots, p_k$. Since there are infinitely many primes, $\mathbb{R}$ over $\mathbb{Q}$ contains independent lists of every length, which is another way to see that no finite list spans it (Exercise 1.3.45, Section 4.1).

Solution to Exercise 1.5.40

Uses. Exercise 1.3.44, Example 1.5.19 (The same vectors over two fields), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. Group a relation $a + b\sqrt{2} + c\sqrt{3} + d\sqrt{6} = 0$ as $\alpha + \beta\sqrt{3} = 0$ with $\alpha = a + b\sqrt{2}$ and $\beta = c + d\sqrt{2}$.
Hint 2. If $\beta \neq 0$, then $\sqrt{3} = -\alpha/\beta$. Rationalize the denominator: multiply numerator and denominator by $c - d\sqrt{2}$.
Hint 3. Check that $c^2 - 2d^2 \neq 0$ when $(c, d) \neq (0, 0)$, so that $-\alpha/\beta$ lies in $\operatorname{span}\left(1, \sqrt{2}\right)$.
Sketch. Write the relation as $\left(a + b\sqrt{2}\right) + \left(c + d\sqrt{2}\right)\sqrt{3} = 0$. If $c + d\sqrt{2} \neq 0$, then $c^2 - 2d^2 \neq 0$, and $\sqrt{3} = -\left(a + b\sqrt{2}\right)\left(c - d\sqrt{2}\right)/\left(c^2 - 2d^2\right)$ is of the form $r + s\sqrt{2}$ with $r, s \in \mathbb{Q}$, contradicting Exercise 1.3.44. So $c + d\sqrt{2} = 0$, hence $c = d = 0$, and then $a = b = 0$.

Suppose $a + b\sqrt{2} + c\sqrt{3} + d\sqrt{6} = 0$ with $a, b, c, d \in \mathbb{Q}$. Since $\sqrt{6} = \sqrt{2}\sqrt{3}$, this reads

$$\left(a + b\sqrt{2}\right) + \left(c + d\sqrt{2}\right)\sqrt{3} = 0.$$

Suppose $c + d\sqrt{2} \neq 0$. Then $(c, d) \neq (0, 0)$, and $c^2 - 2d^2 \neq 0$: otherwise $d \neq 0$ (as $c^2 = 2d^2$ with $d = 0$ forces $c = 0$) and $(c/d)^2 = 2$, making $\sqrt{2}$ or $-\sqrt{2}$ rational. So $c - d\sqrt{2} \neq 0$ as well, since $\left(c + d\sqrt{2}\right)\left(c - d\sqrt{2}\right) = c^2 - 2d^2$. Hence

$$\sqrt{3} = -\frac{a + b\sqrt{2}}{c + d\sqrt{2}} = -\frac{\left(a + b\sqrt{2}\right)\left(c - d\sqrt{2}\right)}{c^2 - 2d^2} = -\frac{ac - 2bd}{c^2 - 2d^2} - \frac{bc - ad}{c^2 - 2d^2}\sqrt{2},$$

using

$$\left(a + b\sqrt{2}\right)\left(c - d\sqrt{2}\right) = (ac - 2bd) + (bc - ad)\sqrt{2}.$$

Both coefficients on the right are rational, so $\sqrt{3} \in \operatorname{span}\left(1, \sqrt{2}\right)$ over $\mathbb{Q}$, contradicting Exercise 1.3.44.

So $c + d\sqrt{2} = 0$. Since $1, \sqrt{2}$ is independent over $\mathbb{Q}$ (Example 1.5.19(b)), $c = d = 0$. The relation becomes $a + b\sqrt{2} = 0$, and for the same reason $a = b = 0$. By Theorem 1.5.5, the list is independent.

Solution to Exercise 1.5.41

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.1.19 (Integers modulo n), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$)
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. Prove the contrapositive of (a). Starting from a nontrivial rational relation, clear denominators to get integer coefficients.
Hint 2. Divide the integer coefficients by their greatest common divisor. Then not all of them are divisible by p, so reducing the relation modulo p gives a nontrivial relation over $\mathbb{F}_p$.

Sketch. (a) A nontrivial relation over $\mathbb{Q}$ can be scaled to have integer coefficients $n_1, \dots, n_k$ with greatest common divisor 1. Reducing each coordinate equation $\sum_j n_j v_{jt} = 0$ modulo p gives a relation over $\mathbb{F}_p$, which is nontrivial because p does not divide every n_j. (b) The list (2) in $\mathbb{Q}^1$ is independent, but its reduction modulo 2 is (0).

(a) We prove the contrapositive. Suppose that $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k = \mathbf{0}$ with $c_j \in \mathbb{Q}$ not all 0. Multiplying by a common denominator of the c_j gives a relation with integer coefficients, not all 0; dividing these by their greatest common divisor gives a relation with integer coefficients $n_1, \dots, n_k$ whose greatest common divisor is 1. In particular, p does not divide some n_j.

Write v_{jt} for the t-th coordinate of $\mathbf{v}_j$. For each t, $\sum_j n_j v_{jt} = 0$ is an equation between integers. Reducing modulo p is compatible with sums and products (Definition 1.1.19, Lemma 1.1.21), so $\sum_j \overline{n}_j \overline{v}_{jt} = \overline{0}$ in $\mathbb{F}_p$, where bars denote remainders modulo p. That is, $\overline{n}_1, \dots, \overline{n}_k$ is a linear relation of $\overline{\mathbf{v}}_1, \dots, \overline{\mathbf{v}}_k$ in $\mathbb{F}_p^m$. It is nontrivial, since $\overline{n}_j \neq 0$ for the j with $p \nmid n_j$. So the reduced list is dependent.

(b) The list (2) of length one in $\mathbb{Q}^1$ is independent, since $(2) \neq \mathbf{0}$ (Proposition 1.5.15(b)). Its reduction modulo 2 is (0), which is dependent. For a list of length two: $(1,1), (1,-1)$ is independent in $\mathbb{Q}^2$ (neither vector is a multiple of the other), but modulo 2 both vectors reduce to $(1,1)$.

Part (a) gives a quick test: to show that an integer list is independent over $\mathbb{Q}$, it suffices to check independence over a small field such as $\mathbb{F}_2$, where there are only finitely many relations to try.

Solution to Exercise 1.5.42

Uses. Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.19 (Restriction of scalars), Example 1.2.6 (Small fields), Theorem 1.6.10 (Every spanning list contains a basis), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Hint 1. One direction holds because a relation over K is a relation over E. For the other, take a relation $\sum_j c_j\mathbf{v}_j = \mathbf{0}$ with $c_j \in E$.
Hint 2. The coefficients $c_1, \dots, c_k$ are vectors of the K-vector space E. By Theorem 1.6.10, some sublist $r_1, \dots, r_s$ of $c_1, \dots, c_k$ is K-independent and has the same K-span.
Hint 3. Write $c_j = \sum_l q_{jl} r_l$ with $q_{jl} \in K$, substitute into each coordinate of the relation, and use K-independence of the r_l, then of $\mathcal{L}$.
Sketch. (Independence over E implies independence over K.) A K-relation is an E-relation. (Independence over K implies independence over E.) Given an E-relation $\sum c_j\mathbf{v}_j = \mathbf{0}$, choose a K-independent sublist $r_1, \dots, r_s$ of $c_1, \dots, c_k$ with the same K-span, and write $c_j = \sum_l q_{jl} r_l$ with $q_{jl} \in K$. In coordinate t, $0 = \sum_l \big(\sum_j q_{jl} v_{jt}\big) r_l$ with coefficients in K, so $\sum_j q_{jl} v_{jt} = 0$ for all l, t: each $q_{1l}, \dots, q_{kl}$ is a K-relation of $\mathcal{L}$, hence trivial. So every $c_j = 0$.

The operations of K^m are those of E^m restricted to vectors and scalars from K. Write $v_{jt} \in K$ for the t-th coordinate of $\mathbf{v}_j$.

Independence over E implies independence over K. A relation $a_1, \dots, a_k \in K$ of $\mathcal{L}$ in K^m is also a relation in E^m, so it is trivial.

Independence over K implies independence over E. Suppose $\mathcal{L}$ is independent over K, and let $c_1, \dots, c_k \in E$ with $\sum_j c_j\mathbf{v}_j = \mathbf{0}$ in E^m. The field E is a vector space over itself (Example 1.2.6), hence over K (Proposition 1.2.19), with scalar multiplication the product in E. Let W be the K-span of $c_1, \dots, c_k$ in E. It is a K-vector space (Proposition 1.4.14), and $c_1, \dots, c_k$ spans it, so by Theorem 1.6.10 some sublist $r_1, \dots, r_s$ of $c_1, \dots, c_k$ is a basis of W over K. In particular, $r_1, \dots, r_s$ is K-independent, and each c_j lies in its K-span: $c_j = \sum_{l=1}^{s} q_{jl} r_l$ with $q_{jl} \in K$.

Fix a coordinate t. The t-th coordinate of the relation is, after expanding and regrouping in the field E,

$$0 = \sum_{j=1}^{k} c_j v_{jt} = \sum_{j=1}^{k} \sum_{l=1}^{s} q_{jl} r_l v_{jt} = \sum_{l=1}^{s} \left(\sum_{j=1}^{k} q_{jl} v_{jt} \right) r_l.$$

Each coefficient $\sum_j q_{jl} v_{jt}$ lies in K. Since $r_1, \dots, r_s$ is K-independent, all these coefficients are 0. As this holds for every t, we get $\sum_j q_{jl}\mathbf{v}_j = \mathbf{0}$ in K^m for each l. Since $\mathcal{L}$ is K-independent, $q_{jl} = 0$ for all j and l. Therefore $c_j = \sum_l q_{jl} r_l = 0$ for every j, and $\mathcal{L}$ is independent over E by Theorem 1.5.5.

For $K = \mathbb{R}$ and $E = \mathbb{C}$, this is Proposition 1.5.21. There the list $1, i$ played the role of $r_1, \dots, r_s$, chosen once and for all; here the list depends on the relation, which is what makes the argument work when E has no finite spanning list over K (Remark 1.5.23).

Solution to Exercise 1.5.43

Uses. Definition 1.5.1 (Linear independence), Definition 1.3.10 (Span), Exercise 1.3.39, Proposition 1.5.14 (Appending a vector), Corollary 1.5.17 (Sublists), induction on k
Hint 1. In (a), consider the map sending a list of coefficients $a_1, \dots, a_k$ to the vector it represents. It maps F^k onto $\operatorname{span}(\mathcal{L})$. What does independence say about it?
Hint 2. For (b), build an independent list one entry at a time with Proposition 1.5.14. Given an independent list of length j, how many vectors lie outside its span?
Sketch. (a) The map $F^k \to \operatorname{span}(\mathcal{L})$, coefficients $\mapsto$ represented vector, is onto by definition, and injective exactly when $\mathcal{L}$ is independent; a map from a set with q^k elements onto a set is injective iff the target has q^k elements. (b) By Proposition 1.5.14, an independent list of length $j+1$ is an independent list of length j followed by a vector outside its span, which has q^j elements by (a): $q^n - q^j$ choices. (c) $7 \cdot 6 \cdot 4 = 168$ and 0.

(a) Let $\mathcal{L} = \mathbf{v}_1, \dots, \mathbf{v}_k$, and let $\varphi : F^k \to \operatorname{span}(\mathcal{L})$ send $(a_1, \dots, a_k)$ to $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. By Definition 1.3.10, φ is surjective, and by Definition 1.5.1, $\mathcal{L}$ is independent exactly when every vector of $\operatorname{span}(\mathcal{L})$ has one preimage, that is, when φ is injective. The set F^k has q^k elements. A surjection from a set with q^k elements onto a finite set is injective if and only if the target also has q^k elements. So $\mathcal{L}$ is independent if and only if $|\operatorname{span}(\mathcal{L})| = q^k$.

(b) Let N_k be the number of independent lists of length k in F^n; we show $N_k = \prod_{i=0}^{k-1}\left(q^n - q^i\right)$ by induction on k. For $k = 0$, the empty list is independent, so $N_0 = 1$, the empty product. Let $k \geq 0$. By Corollary 1.5.17 and Proposition 1.5.14, an independent list of length $k+1$ is the same thing as an independent list $\mathcal{L}$ of length k followed by a vector $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$. For each of the N_k choices of $\mathcal{L}$, the span has q^k elements by (a), so there are $q^n - q^k$ choices of $\mathbf{w}$. Hence $N_{k+1} = N_k\left(q^n - q^k\right)$, which completes the induction. As soon as $k > n$, the product contains the factor $q^n - q^n = 0$.

(c) For $q = 2$, $n = 3$, $k = 3$: $(8-1)(8-2)(8-4) = 7 \cdot 6 \cdot 4 = 168$. For $k = 4$ the product contains the factor $8 - 2^3 = 0$, so there are none: no list of length 4 in $\mathbb{F}_2^3$ is independent. Over a finite field this counting argument already proves that an independent list in F^n has length at most n, a fact that Section 4.1 proves over every field (Theorem 4.1.10).

Solution to Exercise 1.5.44

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.9 (Function spaces), Proposition 1.1.17 (No zero divisors)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Suppose the list is dependent, and choose a dependence relation $c_1, \dots, c_k$ with as few nonzero coefficients as possible. A relation says $\sum_i c_i\lambda_i^m = 0$ for every $m \geq 0$.
Hint 2. Shift: the same identity holds with $m+1$ in place of m. Subtract λ_{i_0} times the original identity, where $c_{i_0} \neq 0$.
Hint 3. The new relation has coefficients $c_i\left(\lambda_i - \lambda_{i_0}\right)$. It has fewer nonzero coefficients, so it is trivial. What does that say about c_i for $i \neq i_0$?
Sketch. Take a dependence relation $\sum c_i\lambda_i^m = 0$ (all m) with the fewest nonzero coefficients, and i_0 with $c_{i_0} \neq 0$. Then $\sum_i c_i\left(\lambda_i - \lambda_{i_0}\right)\lambda_i^m = 0$ for all m, a relation with fewer nonzero coefficients (the i_0 one vanishes), hence trivial. Since $\lambda_i \neq \lambda_{i_0}$, $c_i = 0$ for $i \neq i_0$, and then the $m = 0$ term gives $c_{i_0} = 0$, a contradiction.

The m-th term of $\mathbf{s}_\lambda$ is λ^m (with $\lambda^0 = 1$). So scalars $c_1, \dots, c_k$ form a linear relation of the list exactly when

$$\sum_{i=1}^{k} c_i\lambda_i^m = 0 \quad \text{for every } m \geq 0.$$

Suppose the list is dependent. Among its dependence relations, choose one, $c_1, \dots, c_k$, with the fewest nonzero coefficients, and fix i_0 with $c_{i_0} \neq 0$. Applying the identity with $m+1$ in place of m, and subtracting λ_{i_0} times the identity for m,

$$\sum_{i=1}^{k} c_i\big(\lambda_i - \lambda_{i_0}\big)\lambda_i^m = \sum_{i=1}^{k} c_i\lambda_i^{m+1} - \lambda_{i_0}\sum_{i=1}^{k} c_i\lambda_i^m = 0 \quad \text{for every } m \geq 0.$$

So $d_i = c_i\big(\lambda_i - \lambda_{i_0}\big)$ is a linear relation. Every i with $d_i \neq 0$ has $c_i \neq 0$, and $d_{i_0} = 0$ while $c_{i_0} \neq 0$. So d has fewer nonzero coefficients than c, and by the choice of c it is not a dependence relation: it is trivial. For $i \neq i_0$, $\lambda_i - \lambda_{i_0} \neq 0$, so $d_i = 0$ forces $c_i = 0$ (Proposition 1.1.17). The relation c thus reads $c_{i_0}\lambda_{i_0}^m = 0$ for all m, and at $m = 0$ this gives $c_{i_0} = 0$, a contradiction. So the list is independent.

Shifting a sequence multiplies $\mathbf{s}_\lambda$ by λ, just as differentiation multiplies $t \mapsto e^{\lambda t}$ by λ; the argument is the first proof of Example 1.5.27, done once for all k. A variant of the argument, by induction on k instead of a minimal relation, shows that the truncated vectors $\big(1, \lambda_i, \lambda_i^2, \ldots, \lambda_i^{k-1}\big) \in F^k$, $1 \leq i \leq k$, are independent. This is the Vandermonde determinant in disguise (Theorem 5.5.21).

Solution to Exercise 1.5.45

Uses. Theorem 1.5.5 (Independence is decided at zero), $e^{-st} \to 0$ as $t \to \infty$, for $s > 0$
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Follow the second proof of Example 1.5.27. In a dependence relation, which term dominates as $t \to \infty$?
Hint 2. Among the i with $c_i \neq 0$, take the one with the largest λ_i, divide by $e^{\lambda_i t}$, and let $t \to \infty$.
Sketch. Suppose $\sum c_i e^{\lambda_i t} = 0$ for all t with some $c_i \neq 0$, and let $\mu = \lambda_{i_0}$ be the largest λ_i with $c_i \neq 0$. Dividing by $e^{\mu t}$ gives $c_{i_0} + \sum c_i e^{(\lambda_i - \mu)t} = 0$, the sum over the other i with $c_i \neq 0$, all of which have $\lambda_i - \mu < 0$. Letting $t \to \infty$ gives $c_{i_0} = 0$, a contradiction.

Suppose, to the contrary, that $\sum_{i=1}^{k} c_i e^{\lambda_i t} = 0$ for all $t \in \mathbb{R}$, with not all $c_i = 0$. Let $I = \{i \mid c_i \neq 0\}$, and choose $i_0 \in I$ with $\mu = \lambda_{i_0}$ as large as possible; since the λ_i are distinct, $\lambda_i < \mu$ for all $i \in I$ other than i_0. Dropping the terms with $c_i = 0$ and multiplying by $e^{-\mu t}$,

$$c_{i_0} + \sum_{i \in I, i \neq i_0} c_i e^{(\lambda_i - \mu)t} = 0 \quad \text{for all } t.$$

Each exponent $\lambda_i - \mu$ in the sum is negative, so each term tends to 0 as $t \to \infty$, and the left side tends to c_{i_0}. Since it is 0 for every t, $c_{i_0} = 0$, contradicting $i_0 \in I$. So the functions are independent.

In the language of Aside (Independent sets), the set of all functions $t \mapsto e^{\lambda t}$ with $\lambda \in \mathbb{R}$ is linearly independent, and it is uncountable. The first proof of Example 1.5.27, organized as in Exercise 1.5.44 with d/dt in place of the shift, also works.

Solution to Exercise 1.5.46

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.4 (The space F^n), Example 1.1.4 (The field with two elements)
Hint 1. For $\mathbf{x}, \mathbf{y} \in \mathbb{F}_2^n$, let $\mathbf{x} \cdot \mathbf{y} = x_1 y_1 + \cdots + x_n y_n \in \mathbb{F}_2$. What is $\mathbf{x}_C \cdot \mathbf{x}_D$ in terms of the clubs C and D?
Hint 2. Take a relation $\sum_j a_j \mathbf{x}_{C_j} = \mathbf{0}$ and take the dot product of both sides with $\mathbf{x}_{C_i}$. Which terms survive?
Sketch. $\mathbf{x}_C \cdot \mathbf{x}_D$ is the parity of $|C \cap D|$, so $\mathbf{x}_{C_i} \cdot \mathbf{x}_{C_j}$ is 1 if $i = j$ and 0 otherwise. The dot product satisfies $\big(\sum_j a_j \mathbf{x}_j\big) \cdot \mathbf{y} = \sum_j a_j(\mathbf{x}_j \cdot \mathbf{y})$. Dotting a relation with $\mathbf{x}_{C_i}$ leaves $a_i = 0$.

For $\mathbf{x}, \mathbf{y} \in \mathbb{F}_2^n$, define $\mathbf{x} \cdot \mathbf{y} = x_1 y_1 + \cdots + x_n y_n \in \mathbb{F}_2$. By the coordinatewise operations and distributivity in $\mathbb{F}_2$, $(\mathbf{x} + \mathbf{x}') \cdot \mathbf{y} = \mathbf{x} \cdot \mathbf{y} + \mathbf{x}' \cdot \mathbf{y}$ and $(a\mathbf{x}) \cdot \mathbf{y} = a(\mathbf{x} \cdot \mathbf{y})$, so by induction on the number of terms,

$$\left(\sum_{j=1}^{k} a_j \mathbf{x}_j\right) \cdot \mathbf{y} = \sum_{j=1}^{k} a_j(\mathbf{x}_j \cdot \mathbf{y}),$$

and $\mathbf{0} \cdot \mathbf{y} = 0$. For clubs C and D, the product $(\mathbf{x}_C)_t(\mathbf{x}_D)_t$ is 1 if $t \in C \cap D$ and 0 otherwise, so $\mathbf{x}_C \cdot \mathbf{x}_D$ is the sum of $|C \cap D|$ ones in $\mathbb{F}_2$, which is 1 if $|C \cap D|$ is odd and 0 if it is even (Example 1.1.4). By hypothesis, writing $\mathbf{x}_j = \mathbf{x}_{C_j}$,

$$\mathbf{x}_i \cdot \mathbf{x}_i = 1, \quad \mathbf{x}_j \cdot \mathbf{x}_i = 0 \quad (j \neq i).$$

Now suppose $\sum_j a_j \mathbf{x}_j = \mathbf{0}$, and fix i. Taking the dot product of both sides with $\mathbf{x}_i$,

$$0 = \mathbf{0} \cdot \mathbf{x}_i = \sum_{j=1}^{k} a_j(\mathbf{x}_j \cdot \mathbf{x}_i) = a_i.$$

So every $a_i = 0$, and the list is independent by Theorem 1.5.5.

Taking a dot product with $\mathbf{x}_i$ eliminated every term of the relation but one, the idea of Technique 4.1.25. Once we know that an independent list in $\mathbb{F}_2^n$ has length at most n (Exercise 1.5.43, Theorem 4.1.10), it follows that the town has at most n clubs.

Solution to Exercise 1.5.47

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.9 (Function spaces)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. For a function g, a point s, and $h > 0$, consider $\Delta_h g(s) = g(s+h) - 2g(s) + g(s-h)$. What is it for $g(t) = c + dt$?
Hint 2. If h is smaller than the distance from a_i to every other a_l, compute $\Delta_h f_l(a_i)$ for $l \neq i$ and for $l = i$.
Sketch. The operation $\Delta_h g(s) = g(s+h) - 2g(s) + g(s-h)$ respects linear combinations, kills affine functions, and kills $|t - a_l|$ at $s = a_i$ when $l \neq i$ and h is small (the function is affine near a_i). But $\Delta_h f_i(a_i) = 2h$. Applying it to a relation at $s = a_i$ gives $2hb_i = 0$. Once all $b_i = 0$, evaluating $c + dt = 0$ at $t = 0, 1$ gives $c = d = 0$.

For a function $g : \mathbb{R} \to \mathbb{R}$, a point s, and $h > 0$, let $\Delta_h g(s) = g(s+h) - 2g(s) + g(s-h)$. If $g = \sum_r c_r g_r$, then $\Delta_h g(s) = \sum_r c_r \Delta_h g_r(s)$, since the pointwise operations let us expand and regroup.

Affine functions. For $g(t) = c + dt$,

$$\Delta_h g(s) = (c + ds + dh) - 2(c + ds) + (c + ds - dh) = 0.$$

The functions f_l near a_i. Fix i, and let $h > 0$ be smaller than $|a_l - a_i|$ for every $l \neq i$. For $l \neq i$, the interval $[a_i - h, a_i + h]$ lies entirely on one side of a_l, so on it $f_l(t) = \varepsilon(t - a_l)$ for a fixed sign $\varepsilon \in \{1, -1\}$. This is an affine function of t, so $\Delta_h f_l(a_i) = 0$ by the previous computation. For $l = i$, $\Delta_h f_i(a_i) = |h| - 2 \cdot 0 + |-h| = 2h$.

Now suppose that $c + dt + \sum_{l=1}^{n} b_l f_l(t) = 0$ for all t. Applying Δ_h at $s = a_i$, with h as above, every term but one vanishes, and we get $2hb_i = 0$, so $b_i = 0$. This holds for every i, so $c + dt = 0$ for all t. At $t = 0$ this gives $c = 0$, and at $t = 1$ it gives $d = 0$. By Theorem 1.5.5, the list is independent.

The operation Δ_h at a_i measures the kink of a function at a_i; only f_i has a kink there. This is the move of Technique 4.1.25 with a "second difference" as the operator.

Solution to Exercise 1.5.48

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.4 (The space F^n), a sum of nonnegative real numbers is 0 only if every term is 0
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, let $\mathbf{x} \cdot \mathbf{y} = x_1 y_1 + \cdots + x_n y_n$. What is $\mathbf{x}_A \cdot \mathbf{x}_B$? Given a relation $\sum_i c_i \mathbf{x}_{A_i} = \mathbf{0}$, take the dot product of the left side with itself.
Hint 2. You should get $0 = \sum_i c_i^2 |A_i| + \lambda \sum_{i \neq j} c_i c_j$. Rewrite $\sum_{i \neq j} c_i c_j$ using $\left(\sum_i c_i\right)^2$, and check that every resulting term is nonnegative.
Hint 3. Each $|A_i| \geq \lambda$. Can two of the sets have exactly λ elements?
Sketch. With $\mathbf{x}_i = \mathbf{x}_{A_i}$, $\mathbf{x}_i \cdot \mathbf{x}_j = |A_i \cap A_j|$. Dotting a relation $\mathbf{u} = \sum c_i \mathbf{x}_i = \mathbf{0}$ with itself gives $0 = \sum_i c_i^2(|A_i| - \lambda) + \lambda\left(\sum_i c_i\right)^2$, a sum of nonnegative terms, so each vanishes: $\sum_i c_i = 0$, and $c_i = 0$ unless $|A_i| = \lambda$. Two sets with λ elements would both equal their intersection, so at most one c_i survives, and $\sum_i c_i = 0$ kills it.

For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, let $\mathbf{x} \cdot \mathbf{y} = x_1 y_1 + \cdots + x_n y_n$. By the coordinatewise operations and the arithmetic of $\mathbb{R}$, $\mathbf{x} \cdot \mathbf{y} = \mathbf{y} \cdot \mathbf{x}$, and the dot product respects linear combinations in each argument: expanding and regrouping finite sums,

$$\left(\sum_i c_i \mathbf{x}_i\right) \cdot \left(\sum_j c_j \mathbf{x}_j\right) = \sum_i \sum_j c_i c_j (\mathbf{x}_i \cdot \mathbf{x}_j).$$

Write $\mathbf{x}_i = \mathbf{x}_{A_i}$. The product of the t-th coordinates of $\mathbf{x}_i$ and $\mathbf{x}_j$ is 1 if $t \in A_i \cap A_j$ and 0 otherwise, so $\mathbf{x}_i \cdot \mathbf{x}_j = |A_i \cap A_j|$. This is λ for $i \neq j$, and $|A_i|$ for $i = j$.

Suppose $\mathbf{u} = \sum_i c_i \mathbf{x}_i = \mathbf{0}$ with $c_i \in \mathbb{R}$. Then $\mathbf{u} \cdot \mathbf{u} = 0$, and by the display,

$$0 = \sum_i c_i^2 |A_i| + \lambda \sum_{i \neq j} c_i c_j = \sum_i c_i^2 (|A_i| - \lambda) + \lambda \left(\sum_i c_i \right)^2,$$

using $\left(\sum_i c_i\right)^2 = \sum_i c_i^2 + \sum_{i \neq j} c_i c_j$. Since $m \geq 2$, each A_i meets some other A_j in λ elements, so $|A_i| \geq \lambda$. So every term on the right is a nonnegative real number, and since they add up to 0, each of them is 0. As $\lambda \geq 1$, this gives $\sum_i c_i = 0$, and $c_i = 0$ for every i with $|A_i| > \lambda$.

At most one i has $|A_i| = \lambda$. Indeed, if $|A_i| = |A_j| = \lambda$ with $i \neq j$, then $A_i \cap A_j$ is a subset of A_i with as many elements as A_i, so $A_i \cap A_j = A_i$; likewise $A_i \cap A_j = A_j$. Then $A_i = A_j$, contradicting distinctness. So all c_i vanish except possibly one, and that one equals $\sum_i c_i = 0$. Hence the list is independent by Theorem 1.5.5.

The hypotheses are needed: with $\lambda = 0$, the sets $\emptyset, \{1\}$ give the dependent list $\mathbf{0}, \mathbf{e}_1$. Once we know that an independent list in $\mathbb{R}^n$ has at most n entries (Theorem 4.1.10), it follows that $m \leq n$. This is Fisher's inequality from combinatorics, and the dot product trick is the one of Exercise 1.5.46, with positivity over $\mathbb{R}$ in place of parity over $\mathbb{F}_2$.

Section 1.6

Solution to Exercise 1.6.6

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Exercise 1.3.32, Proposition 1.5.24 (Distinct degrees)
Hint 1. By Proposition 1.6.2, check spanning and independence separately. One of them is already done in Section 1.3.
Hint 2. The three polynomials are nonzero and have different degrees.
Sketch. The list spans W by Exercise 1.3.32. Its entries have degrees $1, 2, 3$, so it is independent by Proposition 1.5.24.

Each entry has degree at most 3 and value $1 - 1 = 0$ at 1, so the list lies in W, and it spans W by Exercise 1.3.32. Its entries are nonzero polynomials of the distinct degrees 1, 2, and 3, so it is linearly independent by Proposition 1.5.24. By Proposition 1.6.2, it is a basis of W.

Solution to Exercise 1.6.12

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Proposition 1.5.15 (Short lists, zeros, and repeats), Exercise 1.3.37, Corollary 1.5.17 (Sublists)
Hint 1. Sort the sublists by length. A sublist of length 0 or 1 cannot span $\mathbb{R}^2$. Why?
Hint 2. Every sublist of length 3 or 4 has a dependence relation; find one in each case. For length 2, use Proposition 1.5.15(d) and Exercise 1.3.37.
Sketch. Five sublists: all pairs except $(1,1), (2,2)$. Length 0 and 1: the span is $\{\mathbf{0}\}$ or a set of multiples of one vector, which misses $\mathbf{e}_1$ or $\mathbf{e}_2$. Length 3 and 4: each contains a dependent sublist, since $(2,2) = 2(1,1)$ and $(1,1) = (1,0) + (0,1)$ and $(2,2) = 2(1,0) + 2(0,1)$. Length 2: $(1,1), (2,2)$ is dependent, and the other five pairs $(a,b), (c,d)$ have $ad - bc \neq 0$.

Length 0 or 1. The span of () is $\{\mathbf{0}\}$. The span of a single vector $\mathbf{v}$ consists of its multiples. If both $\mathbf{e}_1 = (1,0)$ and $\mathbf{e}_2 = (0,1)$ were multiples of $\mathbf{v} = (a,b)$, say $\mathbf{e}_1 = c\mathbf{v}$ and $\mathbf{e}_2 = d\mathbf{v}$, then $ca = 1$ and $cb = 0$ would give $c \neq 0$ and $b = 0$, while $db = 1$ would give $b \neq 0$. So no sublist of length 0 or 1 spans $\mathbb{R}^2$.

Length 3 or 4. The four sublists of length 3 have the dependence relations

$$\begin{aligned} &2(1,1) - (2,2) = \mathbf{0} && \text{for } (1,0), (1,1), (2,2) \text{ and for } (1,1), (2,2), (0,1), \\ &(1,0) - (1,1) + (0,1) = \mathbf{0} && \text{for } (1,0), (1,1), (0,1), \\ &2(1,0) - (2,2) + 2(0,1) = \mathbf{0} && \text{for } (1,0), (2,2), (0,1). \end{aligned}$$

The whole list contains the dependent sublist $(1,1), (2,2)$, so it is dependent by Corollary 1.5.17. None of these is a basis.

Length 2. The pair $(1,1), (2,2)$ is dependent. For each of the other five pairs $(a,b), (c,d)$, namely

$$(1,0), (1,1) \quad (1,0), (2,2) \quad (1,0), (0,1) \quad (1,1), (0,1) \quad (2,2), (0,1),$$

the number $ad - bc$ is $1, 2, 1, 1, 2$ respectively, which is nonzero. So each of them spans $\mathbb{R}^2$ by Exercise 1.3.37(a). Neither vector of the pair is a multiple of the other: a multiple of $(1, 0)$ has second coordinate 0, a multiple of $(0, 1)$ has first coordinate 0, and a multiple of $(1, 1)$ or $(2, 2)$ has equal coordinates. So each pair is independent by Proposition 1.5.15(d). By Proposition 1.6.2, these five sublists are exactly the bases of $\mathbb{R}^2$ contained in $\mathcal{L}$.

Solution to Exercise 1.6.18

Uses. Exercise 1.3.33, Proposition 1.5.24 (Distinct degrees), Proposition 1.6.2 (Bases are independent spanning lists), (1.6.1), Proposition 1.2.18 (Degree and evaluation versus the operations)
Hint 1. For (a), the entries have degrees $0, 1, 2$. Use Exercise 1.3.33 and Proposition 1.5.24.
Hint 2. For (b), by (1.6.1) it suffices to expand the combination with the proposed coefficients and check that it gives $a + bx + cx^2$.
Hint 3. For (c), evaluate $p = \alpha + \beta(x - 1) + \gamma\big(x^2 - 2x + 1\big)$ at 1.
Sketch. (a) Degrees $0, 1, 2$: spanning by Exercise 1.3.33, independence by Proposition 1.5.24. (b) Expanding $(a + b + c) + (b + 2c)(x - 1) + c\big(x^2 - 2x + 1\big)$ gives $a + bx + cx^2$. (c) Evaluation respects linear combinations, and the second and third entries of $\mathcal{T}$ vanish at 1.

(a) The entries of $\mathcal{T}$ have degrees 0, 1, and 2. So $\mathcal{T}$ spans $F[x]_{\leq 2}$ by Exercise 1.3.33(a), and it is independent by Proposition 1.5.24. By Proposition 1.6.2, it is a basis.

(b) Expanding,

$$\begin{aligned}(a + b + c) \cdot 1 + (b + 2c)(x - 1) + c\big(x^2 - 2x + 1\big) &= (a + b + c - b - 2c + c) + (b + 2c - 2c)x + cx^2 \\ &= a + bx + cx^2.\end{aligned}$$

By (1.6.1), $\big[a + bx + cx^2\big]_{\mathcal{T}} = (a + b + c, b + 2c, c)$.

(c) Write $[p]_{\mathcal{T}} = (\alpha, \beta, \gamma)$, so $p = \alpha + \beta(x - 1) + \gamma\big(x^2 - 2x + 1\big)$. By Proposition 1.2.18(c), evaluation at 1 respects sums and scalar multiples, so

$$p(1) = \alpha + \beta(1 - 1) + \gamma(1 - 2 + 1) = \alpha.$$

(In (b), this is the identity $p(1) = a + b + c$.) Similarly, over $\mathbb{R}$ the second coordinate $b + 2c$ is the derivative of p at 1. These are the first terms of the Taylor expansion of p around 1.

Solution to Exercise 1.6.22

Uses. Definition 1.6.14 (Coordinates), (1.6.1)
Hint 1. Which vector of V has $\mathcal{B}$-coordinates $\mathbf{e}_j$?
Hint 2. Compute $\big[\mathbf{v}_j\big]_{\mathcal{C}}$ using the hypothesis, and read it in reverse.
Sketch. $\big[\mathbf{v}_j\big]_{\mathcal{C}} = \big[\mathbf{v}_j\big]_{\mathcal{B}} = \mathbf{e}_j$, so $\mathbf{v}_j = \mathbf{w}_j$ by (1.6.1).

Fix j. Since $\mathbf{v}_j$ is represented by the combination of $\mathcal{B}$ with coefficient 1 on $\mathbf{v}_j$ and 0 elsewhere, $\big[\mathbf{v}_j\big]_{\mathcal{B}} = \mathbf{e}_j$. By hypothesis $\big[\mathbf{v}_j\big]_{\mathcal{C}} = \mathbf{e}_j$ as well, which by Definition 1.6.14 means $\mathbf{v}_j = 0\mathbf{w}_1 + \cdots + 1\mathbf{w}_j + \cdots + 0\mathbf{w}_n = \mathbf{w}_j$. This holds for every j, and the lists have the same length, so $\mathcal{B} = \mathcal{C}$.

Solution to Exercise 1.6.27

Uses. Definition 1.6.1 (Basis), Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.1.17 (No zero divisors), Example 1.4.11 (Matrices)
Hint 1. For (a), solve $a(1, 2, 0) + b(0, 1, 2) + c(2, 0, 1) = (x, y, z)$ by expressing a in terms of c, then b, and substituting into the last equation. Which element of F do you need to divide by?
Hint 2. For (b), look for a way to write $2 + x + x^2$ using the other two entries. For (c), which matrices can a combination of these three be?
Sketch. (a) The equations give $9c = 4x - 2y + z$, and cyclically for a and b. If $3 \neq 0$ in F, there is exactly one solution, so the list is a basis. If $3 = 0$, the three vectors add up to $(3, 3, 3) = \mathbf{0}$. (b) No: $2 + x + x^2 = 2\big(1 + x^2\big) + \big(x - x^2\big)$. (c) No: the combinations are the symmetric matrices, and U_{12} is not symmetric. The list is a basis of the symmetric matrices, though.

(a) For $(x, y, z) \in F^3$, the equation $a(1, 2, 0) + b(0, 1, 2) + c(2, 0, 1) = (x, y, z)$ reads

$$a + 2c = x, \quad 2a + b = y, \quad 2b + c = z.$$

Any solution has $a = x - 2c$, then $b = y - 2a = y - 2x + 4c$, and then the third equation becomes $2y - 4x + 8c + c = z$, that is,

$$9c = 4x - 2y + z.$$

Suppose $3 \neq 0$ in F. Then $9 = 3 \cdot 3 \neq 0$ by Proposition 1.1.17, so $c = (4x - 2y + z)/9$, and then

$$a = \frac{x + 4y - 2z}{9}, \quad b = \frac{-2x + y + 4z}{9}.$$

So there is at most one solution. These values are a solution: for instance $a + 2c = (x + 4y - 2z + 8x - 4y + 2z)/9 = x$, and the other two equations check the same way, as the formulas are cyclic shifts of each other. So every vector of F^3 has exactly one representation, and the list is a basis (Definition 1.6.1).

Suppose $3 = 0$ in F, as in $\mathbb{F}_3$. Then $(1, 2, 0) + (0, 1, 2) + (2, 0, 1) = (3, 3, 3) = \mathbf{0}$ is a dependence relation, so the list is not a basis.

(b) Not a basis: $2\left(1 + x^2\right) + \left(x - x^2\right) = 2 + x + x^2$, so $2\left(1 + x^2\right) + \left(x - x^2\right) - \left(2 + x + x^2\right) = \mathbf{0}$ is a dependence relation.

(c) Not a basis. Every linear combination

$$aU_{11} + b(U_{12} + U_{21}) + dU_{22} = \begin{pmatrix} a & b \\ b & d \end{pmatrix}$$

has equal off-diagonal entries, so U_{12} is not in the span, and the list does not span $\mathbb{R}^{2\times 2}$. (The display also shows that each symmetric matrix $\left(\begin{smallmatrix} a & b \\ b & d \end{smallmatrix}\right)$ is represented by exactly one combination, so the list is a basis of the subspace S of symmetric matrices of Example 1.4.11.)

Solution to Exercise 1.6.28

Uses. Definition 1.6.1 (Basis), Definition 1.6.14 (Coordinates), (1.6.1)
Hint 1. Solve for the coefficients directly. In (a), the combination $a(1, 1, 1) + b(0, 1, 1) + c(0, 0, 1)$ is $(a, a + b, a + b + c)$.
Hint 2. In (b), write the combination with coefficients $\alpha, \beta, \gamma, \delta$ as a single matrix and solve from the bottom right entry up.
Sketch. (a) $(a, a + b, a + b + c) = (x, y, z)$ has the unique solution $(x, y - x, z - y)$, which is $[(x, y, z)]_{\mathcal{B}}$; and $\mathbf{v} = (1, 1 + 2, 1 + 2 + 3) = (1, 3, 6)$. (b) The combination is $\left(\begin{smallmatrix} \alpha+\beta+\gamma+\delta & \beta+\gamma+\delta \\ \gamma+\delta & \delta \end{smallmatrix}\right)$, so $[A]_{\mathcal{C}} = (p - q, q - r, r - s, s)$.

(a) The combination with coefficients a, b, c represents $(a, a + b, a + b + c)$. This equals (x, y, z) if and only if $a = x$, $b = y - x$, and $c = z - y$. So each vector has exactly one representation, $\mathcal{B}$ is a basis, and

$$[(x, y, z)]_{\mathcal{B}} = (x, y - x, z - y).$$

By (1.6.1), the vector with coordinates $(1, 2, 3)$ is $1(1, 1, 1) + 2(0, 1, 1) + 3(0, 0, 1) = (1, 3, 6)$.

(b) The combination with coefficients $\alpha, \beta, \gamma, \delta$ represents

$$\begin{pmatrix} \alpha + \beta + \gamma + \delta & \beta + \gamma + \delta \\ \gamma + \delta & \delta \end{pmatrix}.$$

This equals $\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right)$ if and only if $\delta = s$, $\gamma = r - s$, $\beta = q - r$, and $\alpha = p - q$. So every $A \in F^{2\times 2}$ has exactly one representation, $\mathcal{C}$ is a basis, and $[A]_{\mathcal{C}} = (p - q, q - r, r - s, s)$.

Solution to Exercise 1.6.29

Uses. Proposition 1.6.20 (Coordinates translate questions about V into F^n), Definition 1.6.1 (Basis)
Hint 1. By Proposition 1.6.20, the list is a basis exactly when $(1, 0, 1), (0, 1, 1), (1, 1, c)$ is a basis of $\mathbb{R}^3$.
Hint 2. Solve $a(1, 0, 1) + b(0, 1, 1) + d(1, 1, c) = (x, y, z)$. You will need to divide by $c - 2$.

Sketch. The coordinate vectors are $(1,0,1),(0,1,1),(1,1,c)$. The equations $a+d=x$, $b+d=y$, $a+b+cd=z$ give $(c-2)d=z-x-y$, which has a unique solution for every right side exactly when $c\neq 2$. For $c=2$, $1+x+2x^2=\left(1+x^2\right)+\left(x+x^2\right)$.

In the standard basis $1, x, x^2$ the coordinate vectors are $(1,0,1)$, $(0,1,1)$, and $(1,1,c)$. By Proposition 1.6.20(c), the polynomials form a basis of $\mathbb{R}[x]_{\leq 2}$ if and only if these columns form a basis of $\mathbb{R}^3$. The equation $a(1,0,1)+b(0,1,1)+d(1,1,c)=(x,y,z)$ reads

$$a+d=x,\quad b+d=y,\quad a+b+cd=z.$$

Any solution has $a=x-d$ and $b=y-d$, and then the last equation becomes $(c-2)d=z-x-y$.

If $c\neq 2$, this forces $d=(z-x-y)/(c-2)$, and then a and b are determined; conversely, these values solve all three equations. So every column has exactly one representation, and the list is a basis.

If $c=2$, the columns satisfy $(1,0,1)+(0,1,1)-(1,1,2)=\mathbf{0}$, so they are dependent, and so are the polynomials: $1+x+2x^2=\left(1+x^2\right)+\left(x+x^2\right)$. So the list is a basis exactly when $c\neq 2$.

Solution to Exercise 1.6.30

Uses. Lemma 1.5.10 (Linear dependence lemma), Example 1.5.11 (Which entries are redundant), Theorem 1.6.10 (Every spanning list contains a basis)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. The inductive hypothesis is about *spanning* lists of length k. Is $\mathbf{v}_1,\ldots,\mathbf{v}_k$ one?
Hint 2. Test the step on the dependent spanning list $(1,0),(2,0),(0,1)$ of $\mathbb{R}^2$.
Sketch. The inductive hypothesis applies only to lists that span V, and deleting the last entry of a dependent spanning list can destroy spanning: $(1,0),(2,0),(0,1)$ spans $\mathbb{R}^2$, but $(1,0),(2,0)$ does not. The repair deletes the entry $\mathbf{v}_j$ given by Lemma 1.5.10, which keeps the span equal to V.

(a) The inductive hypothesis is a statement about lists of length k that span V. The argument applies it to $\mathbf{v}_1,\ldots,\mathbf{v}_k$ without checking that this list spans V, and it need not. In $\mathbb{R}^2$, the list $(1,0),(2,0),(0,1)$ spans $\mathbb{R}^2$ and is dependent (Example 1.5.11), but deleting its last entry leaves $(1,0),(2,0)$, whose span is the first axis. The claim itself is true (Theorem 1.6.10); only the choice of the deleted entry is wrong.

(b) Since $\mathcal{L}$ is dependent, Lemma 1.5.10 gives an index j such that deleting $\mathbf{v}_j$ from $\mathcal{L}$ does not change the span. The resulting list has length k and spans $\operatorname{span}(\mathcal{L})=V$, so the inductive hypothesis applies to it, and the rest of the argument goes through. (In the example, the lemma deletes $(2,0)$.)

Solution to Exercise 1.6.31

Uses. Definition 1.6.14 (Coordinates), (1.6.1), Non-example 1.6.4 (One property without the other)
Hint 1. How many linear combinations of $\mathcal{L}$ represent $\mathbf{0}$? What does "the coefficients" refer to?
Hint 2. For (b), consider $\Phi(a,b,d)=a(1,0)+b(0,1)+d(1,1)$. Then $\Phi(c(\mathbf{v}))=\mathbf{v}$. Which two elements of $\mathbb{R}^3$ does Φ send to $\mathbf{0}$?
Sketch. (a) $\mathcal{L}$ is dependent, so a vector has many representations, and "the" coefficients do not name one column; the proof's step "so the coordinates of $\mathbf{x}+\mathbf{y}$ are a_i+b_i" needs the backward direction of (1.6.1), which uses uniqueness. (b) $\Phi\circ c$ is the identity, so c is injective. Both $(0,0,0)$ and $(1,1,-1)$ represent $\mathbf{0}$, but $c(\mathbf{0})$ is only one of them, and the other is $c(\mathbf{v})$ for no $\mathbf{v}$.

(a) The list $\mathcal{L}$ is dependent (Non-example 1.6.4), so a vector of $\mathbb{R}^2$ is represented by many linear combinations of $\mathcal{L}$; for instance $(1,1)$ has coefficients $(1,1,0)$ and $(0,0,1)$. So "the coefficients" does not specify a column, and the student has not defined a function. In the proof of Proposition 1.6.19(a), the step that fails is the last one: from "$\mathbf{x}+\mathbf{y}=\sum(a_i+b_i)\mathbf{v}_i$" it concludes that (a_i+b_i) *is* the coordinate vector of $\mathbf{x}+\mathbf{y}$. That is the backward direction of (1.6.1), which holds because a basis allows only one representation. For $\mathcal{L}$ the column (a_i+b_i) is one representation among many, and it need not be the one the student's rule picks for $\mathbf{x}+\mathbf{y}$.

(b) Let $\Phi:\mathbb{R}^3\to\mathbb{R}^2$, $\Phi(a,b,d)=a(1,0)+b(0,1)+d(1,1)$. The hypothesis on c says $\Phi(c(\mathbf{v}))=\mathbf{v}$ for every $\mathbf{v}\in\mathbb{R}^2$. If $c(\mathbf{v})=c(\mathbf{v}')$, then $\mathbf{v}=\Phi(c(\mathbf{v}))=\Phi(c(\mathbf{v}'))=\mathbf{v}'$, so c is injective.

Now $\Phi(0,0,0) = \mathbf{0}$ and $\Phi(1,1,-1) = (1,0) + (0,1) - (1,1) = \mathbf{0}$. Let $\mathbf{a}$ be whichever of these two columns differs from $c(\mathbf{0})$. If $\mathbf{a} = c(\mathbf{v})$ for some $\mathbf{v}$, then $\mathbf{v} = \Phi(c(\mathbf{v})) = \Phi(\mathbf{a}) = \mathbf{0}$, so $\mathbf{a} = c(\mathbf{0})$, contradicting the choice of $\mathbf{a}$. So $\mathbf{a}$ is not a value of c, and c is not surjective. By contrast, the coordinate map of a basis is a bijection (Proposition 1.6.16).

Solution to Exercise 1.6.32

Uses. Definition 1.6.1 (Basis), Definition 1.6.8 (Standard bases), Proposition 1.1.17 (No zero divisors), Theorem 1.4.3 (Subspace criterion)
Hint 1. A symmetric matrix is determined by its entries on and above the diagonal. For each position (i,j) with $i < j$, use $U_{ij} + U_{ji}$.
Hint 2. For (b), what does $a_{ii} = -a_{ii}$ say when $1 + 1 \neq 0$? For (c), what is -1 in $\mathbb{F}_2$?
Sketch. (a) U_{ii} $(1 \leq i \leq n)$ and $U_{ij} + U_{ji}$ $(i < j)$: a combination with coefficients c has entries c_{ii} on the diagonal and c_{ij} in both positions (i,j) and (j,i), so each symmetric A is represented exactly by $c =$ its entries on and above the diagonal. Count $n + n(n-1)/2$. (b) $(1+1)a_{ii} = 0$ forces a zero diagonal; use $U_{ij} - U_{ji}$, $i < j$. (c) In $\mathbb{F}_2$, $-a = a$, so $K = S$, with the basis from (a).

(a) Consider the list consisting of the U_{ii} for $1 \leq i \leq n$ and the $U_{ij} + U_{ji}$ for $1 \leq i < j \leq n$, in any fixed order. Each entry is symmetric. A linear combination with coefficient c_{ii} on U_{ii} and c_{ij} on $U_{ij} + U_{ji}$ is the matrix with diagonal entries c_{ii} and with c_{ij} in both positions (i,j) and (j,i) for $i < j$. So it equals a given $A \in S$ if and only if $c_{ij} = a_{ij}$ for all $i \leq j$; these values work because $a_{ji} = a_{ij}$. Every $A \in S$ is represented by exactly one combination, and the list is a basis of S (Definition 1.6.1). Its length is $n + n(n-1)/2 = n(n+1)/2$.

(b) The set K is a subspace by Theorem 1.4.3: the zero matrix satisfies $0 = -0$, and the conditions $a_{ji} = -a_{ij}$ are preserved by entrywise sums and scalar multiples. For $A \in K$, the condition with $j = i$ gives $a_{ii} = -a_{ii}$, that is, $(1+1)a_{ii} = 0$, so $a_{ii} = 0$ by Proposition 1.1.17. Consider the matrices $U_{ij} - U_{ji}$ for $i < j$, which lie in K. A combination with coefficients c_{ij} has zero diagonal, c_{ij} in position (i,j), and $-c_{ij}$ in position (j,i), for $i < j$. It equals $A \in K$ if and only if $c_{ij} = a_{ij}$ for all $i < j$: the diagonal entries of A are 0, and $a_{ji} = -a_{ij}$. So this list of length $n(n-1)/2$ is a basis of K.

(c) In $\mathbb{F}_2$, $-a = a$ for every a, so the condition $a_{ji} = -a_{ij}$ is the condition $a_{ji} = a_{ij}$, and $K = S$. A basis is the one from (a), of length $n(n+1)/2$. The argument of (b) breaks down because $(1+1)a_{ii} = 0$ holds for every a_{ii}; for instance $U_{11} \in K$.

Solution to Exercise 1.6.33

Uses. Definition 1.6.1 (Basis), (1.6.1), Definition 1.6.8 (Standard bases), Theorem 1.4.3 (Subspace criterion)
Hint 1. A matrix in Z is determined by its top-left 2×2 block. Express the entries in row 3 and column 3 in terms of that block.
Hint 2. Compute every entry of $\sum_{k,l \leq 2} c_{kl} Z_{kl}$. Its top-left block is (c_{kl}).
Sketch. Each Z_{kl} lies in Z. The combination $\sum c_{kl} Z_{kl}$ has top-left block (c_{kl}), so at most one combination represents a given A, with $c_{kl} = a_{kl}$. That one works: its entries in column 3, row 3, and the corner are $-(c_{k1} + c_{k2})$, $-(c_{1l} + c_{2l})$, and $\sum c_{kl}$, and for $A \in Z$ the zero row and column sums give exactly these values.

First, Z is a subspace of $F^{3\times 3}$: the zero matrix lies in it, and if every row and column of A and of B sums to 0, the same holds for $A + B$ and cA, since sums of entries respect the entrywise operations (Theorem 1.4.3). Each Z_{kl} lies in Z: its nonzero entries are 1 in positions (k,l) and $(3,3)$ and -1 in positions $(k,3)$ and $(3,l)$, so every row and every column contains either no nonzero entry or one 1 and one -1.

Let $M = \sum_{k,l \in \{1,2\}} c_{kl} Z_{kl}$. Its entry in position (k,l) with $k,l \leq 2$ is c_{kl}, its entry $(k,3)$ is $-(c_{k1} + c_{k2})$, its entry $(3,l)$ is $-(c_{1l} + c_{2l})$, and its entry $(3,3)$ is $c_{11} + c_{12} + c_{21} + c_{22}$.

Now let $A \in Z$. If $M = A$, comparing the top-left blocks gives $c_{kl} = a_{kl}$, so at most one combination represents A. Conversely, take $c_{kl} = a_{kl}$. Since rows 1 and 2 of A sum to 0, $a_{k3} = -(a_{k1} + a_{k2})$, which is the $(k,3)$ entry of M. Since columns 1 and 2 sum to 0, $a_{3l} = -(a_{1l} + a_{2l})$, the $(3,l)$ entry of M. Since row 3 sums to 0,

$$a_{33} = -(a_{31} + a_{32}) = (a_{11} + a_{21}) + (a_{12} + a_{22}),$$

the $(3,3)$ entry of M. So $M = A$. Every $A \in Z$ is represented by exactly one linear combination, the list is a basis of Z (Definition 1.6.1), and by (1.6.1) the coordinates of A are $(a_{11}, a_{12}, a_{21}, a_{22})$.

Solution to Exercise 1.6.34

> *Uses.* Exercise 1.3.33, Proposition 1.5.24 (Distinct degrees), Example 1.4.9 (Polynomials), Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 1.3.18 (Comparing spans), Example 1.3.11 (Small spans)
> *Hint 1.* For (a), see Exercise 1.3.33 and Proposition 1.5.24. For (b), which subspace contains every p_k?
> *Hint 2.* For (c), start with x^n and add x^n to each lower power of x.
> *Sketch.* (a) Spanning by Exercise 1.3.33, independence by Proposition 1.5.24. (b) All p_k lie in the subspace $F[x]_{\leq n-1}$, so their span does too, and x^n is missing. (c) $x^n, x^n+1, x^n+x, \ldots, x^n+x^{n-1}$: each $x^k = \left(x^n + x^k\right) - x^n$ is in the span, and in a relation the coefficient of x^k for $k < n$ is the coefficient of $x^n + x^k$.

(a) The list spans $F[x]_{\leq n}$ by Exercise 1.3.33(a). Its entries are nonzero (they have degrees $k \geq 0$) and have distinct degrees, so it is independent by Proposition 1.5.24. So it is a basis.

(b) Each p_k has degree at most n and not equal to n, so $p_k \in F[x]_{\leq n-1}$, a subspace (Example 1.4.9). By Proposition 1.4.14(b), $\operatorname{span}(p_0, \ldots, p_n) \subseteq F[x]_{\leq n-1}$, which does not contain x^n. So the list does not span $F[x]_{\leq n}$.

(c) Let $q_n = x^n$ and $q_k = x^n + x^k$ for $0 \leq k < n$, and consider $q_n, q_0, q_1, \ldots, q_{n-1}$. Each entry has degree n, since $k < n$.

Spanning. $x^n = q_n$ and $x^k = q_k - q_n$ for $k < n$, so $1, x, \ldots, x^n$ lie in the span, and the span is $F[x]_{\leq n}$ by Proposition 1.3.18 and Example 1.3.11.

Independence. Suppose that $cq_n + \sum_{k=0}^{n-1} c_k q_k = \mathbf{0}$. The left side is

$$(c + c_0 + \cdots + c_{n-1})x^n + c_0 + c_1 x + \cdots + c_{n-1}x^{n-1}.$$

Its coefficient of x^k for $k < n$ is c_k, so every $c_k = 0$, and then its coefficient of x^n is $c = 0$. So the list is a basis. Degrees alone therefore do not decide whether a list is a basis: (a) is a sufficient condition, not a necessary one.

Solution to Exercise 1.6.35

> *Uses.* Proposition 1.6.2 (Bases are independent spanning lists), Corollary 1.5.13 (Independence, one entry at a time), Proposition 1.5.18 (Operations that preserve independence), Definition 1.5.1 (Linear independence), Example 1.6.11 (Sifting a list of polynomials)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* Test (a) with the standard basis of $\mathbb{R}^2$ and a line that is not an axis. For (b), the first entry of $\mathcal{C}$ comes after all of $\mathcal{B}$.
> *Hint 2.* For (d), what does "at most one" say about vectors outside the span? For (e), look at Example 1.6.11.
> *Sketch.* (a) False: $U = \operatorname{span}((1,1))$ in $\mathbb{R}^2$ contains no sublist of $\mathbf{e}_1, \mathbf{e}_2$ that spans it. (b) True: $\mathcal{C} \neq ()$ and its first entry lies in $\operatorname{span}(\mathcal{B}) = V$, so Corollary 1.5.13 makes $\mathcal{B}, \mathcal{C}$ dependent. (c) True: scaling by nonzero scalars preserves span and independence (Proposition 1.5.18(b)). (d) False: "at most one" is independence; $\mathbf{e}_1$ in $\mathbb{R}^2$. (e) False: $(1,0), (0,1), (1,1)$ contains three bases of $\mathbb{R}^2$.

(a) False. In $\mathbb{R}^2$, let $\mathcal{B} = \mathbf{e}_1, \mathbf{e}_2$ and $U = \operatorname{span}((1,1))$. The sublists of $\mathcal{B}$ are $()$, $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathcal{B}$. The last three contain $\mathbf{e}_1$ or $\mathbf{e}_2$, which are not in U (they are not multiples of $(1,1)$), so they are not lists in U at all; and $()$ spans $\{\mathbf{0}\} \neq U$.

(b) True. Since $V \neq \{\mathbf{0}\}$, neither $\mathcal{B}$ nor $\mathcal{C}$ is the empty list (it spans only $\{\mathbf{0}\}$). Let $\mathbf{w}$ be the first entry of $\mathcal{C}$. In $\mathcal{B}, \mathcal{C}$ the entries before $\mathbf{w}$ are those of $\mathcal{B}$, and $\mathbf{w} \in V = \operatorname{span}(\mathcal{B})$. So $\mathcal{B}, \mathcal{C}$ is dependent by Corollary 1.5.13, and it is not a basis.

(c) True. Replacing $\mathbf{v}_j$ by $c_j \mathbf{v}_j$ with $c_j \neq 0$ preserves both the span and independence (Proposition 1.5.18(b)). Doing this for $j = 1, \ldots, n$ in turn produces a list that spans V and is independent, which is a basis by Proposition 1.6.2.

(d) False. Every vector outside $\operatorname{span}(\mathcal{L})$ is represented by no combination, so the hypothesis says exactly that every vector of $\operatorname{span}(\mathcal{L})$ is represented by at most one combination, which is independence (Definition 1.5.1). Independent lists need not span: in $\mathbb{R}^2$, the list $\mathbf{e}_1$ satisfies the hypothesis and is not a basis.

(e) False. In $\mathbb{R}^2$, the spanning list $(1,0),(0,1),(1,1)$ has the three sublists $(1,0),(0,1)$ and $(1,0),(1,1)$ and $(0,1),(1,1)$, each of which is a basis (check spanning and independence as in Example 1.6.3(a)). See also Example 1.6.11.

Solution to Exercise 1.6.36

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Corollary 1.3.19 (Equal spans), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.6.16 (The coordinate map is a bijection), Exercise 1.3.34
Hint 1. If $a_j = 0$, then $\mathbf{w}$ is a combination of the other entries of $\mathcal{B}'$. If $a_j \neq 0$, solve $\mathbf{w} = \sum a_i \mathbf{v}_i$ for $\mathbf{v}_j$.
Hint 2. For independence when $a_j \neq 0$, substitute $\mathbf{w} = \sum_i a_i \mathbf{v}_i$ into a relation of $\mathcal{B}'$ and use the independence of $\mathcal{B}$.
Hint 3. For (b), which column is $[\mathbf{0}]_{\mathcal{B}}$?
Sketch. If $a_j = 0$, then $\mathbf{w} = \sum_{i\neq j} a_i \mathbf{v}_i$, which gives a relation of $\mathcal{B}'$ with coefficient -1 on $\mathbf{w}$. If $a_j \neq 0$, then $\mathbf{v}_j = a_j^{-1}\big(\mathbf{w} - \sum_{i\neq j} a_i \mathbf{v}_i\big)$, so $\mathcal{B}'$ spans V; and a relation $\sum_{i\neq j} c_i \mathbf{v}_i + c\mathbf{w} = \mathbf{0}$ becomes $\sum_{i\neq j}(c_i + ca_i)\mathbf{v}_i + ca_j \mathbf{v}_j = \mathbf{0}$, so $ca_j = 0$, $c = 0$, and then all $c_i = 0$. (b) $[\mathbf{w}]_{\mathcal{B}} \neq \mathbf{0}$ since the coordinate map is injective, so some $a_j \neq 0$.

(a) Write $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_n\mathbf{v}_n$.

Suppose $a_j = 0$. Then $\mathbf{w} = \sum_{i\neq j} a_i \mathbf{v}_i$, and the combination of $\mathcal{B}'$ with coefficients a_i on $\mathbf{v}_i$ $(i \neq j)$ and -1 on $\mathbf{w}$ represents $\mathbf{0}$. It is nontrivial, so $\mathcal{B}'$ is dependent and not a basis.

Suppose $a_j \neq 0$. *Spanning.* Solving for $\mathbf{v}_j$,

$$\mathbf{v}_j = a_j^{-1}\mathbf{w} + \sum_{i\neq j}\big(-a_j^{-1}a_i\big)\mathbf{v}_i \in \operatorname{span}(\mathcal{B}').$$

The other entries of $\mathcal{B}$ are entries of $\mathcal{B}'$, so $\mathcal{B} \subseteq \operatorname{span}(\mathcal{B}')$, and also $\mathcal{B}' \subseteq V = \operatorname{span}(\mathcal{B})$. By Corollary 1.3.19, $\operatorname{span}(\mathcal{B}') = \operatorname{span}(\mathcal{B}) = V$. (This is also Exercise 1.3.34, after moving $\mathbf{v}_j$ to the end; its hypothesis that $\mathbf{w}$ is not in the span of the other entries holds because $a_j \neq 0$ and coordinates are unique.) *Independence.* Suppose $\sum_{i\neq j} c_i \mathbf{v}_i + c\mathbf{w} = \mathbf{0}$. Substituting for $\mathbf{w}$ and collecting terms,

$$\sum_{i\neq j}(c_i + ca_i)\mathbf{v}_i + ca_j\mathbf{v}_j = \mathbf{0}.$$

Since $\mathcal{B}$ is independent, $ca_j = 0$, so $c = 0$ because $a_j \neq 0$, and then $c_i = c_i + ca_i = 0$ for all $i \neq j$. So $\mathcal{B}'$ is independent, and it is a basis by Proposition 1.6.2.

(b) Since $[\mathbf{0}]_{\mathcal{B}} = \mathbf{0}$ and the coordinate map is injective (Proposition 1.6.16), $\mathbf{w} \neq \mathbf{0}$ implies $[\mathbf{w}]_{\mathcal{B}} \neq \mathbf{0}$, so $a_j \neq 0$ for some j. By (a), replacing $\mathbf{v}_j$ with $\mathbf{w}$ gives a basis. Repeating such replacements is the idea behind the exchange lemma of Section 4.1 (Lemma 4.1.2).

Solution to Exercise 1.6.37

Uses. Definition 1.6.1 (Basis), (1.6.1), Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 1.6.16 (The coordinate map is a bijection)
Hint 1. If $f = [\cdot]_{\mathcal{C}}$ with $\mathcal{C} = \mathbf{c}_1, \ldots, \mathbf{c}_n$, then $f(\mathbf{c}_j) = \mathbf{e}_j$. So there is only one candidate for $\mathcal{C}$.
Hint 2. Let $\mathbf{c}_j = f^{-1}(\mathbf{e}_j)$. To show $\mathcal{C}$ is a basis, write $f(\mathbf{v}) = (a_1, \ldots, a_n) = \sum a_i \mathbf{e}_i$ and apply f^{-1}, using that f respects linear combinations.
Sketch. Uniqueness: $[\mathbf{c}_j]_{\mathcal{C}} = \mathbf{e}_j$ forces $\mathbf{c}_j = f^{-1}(\mathbf{e}_j)$. Existence: with this $\mathcal{C}$, $f(\sum b_i \mathbf{c}_i) = \sum b_i \mathbf{e}_i = (b_1, \ldots, b_n)$. Since f is injective, $\sum b_i \mathbf{c}_i = \mathbf{v}$ holds exactly when $(b_1, \ldots, b_n) = f(\mathbf{v})$; so each $\mathbf{v}$ has exactly one representation, with coefficients $f(\mathbf{v})$.

Uniqueness. Suppose $\mathcal{C} = \mathbf{c}_1, \ldots, \mathbf{c}_n$ is a basis with $f(\mathbf{v}) = [\mathbf{v}]_{\mathcal{C}}$ for all $\mathbf{v}$. Then $f(\mathbf{c}_j) = [\mathbf{c}_j]_{\mathcal{C}} = \mathbf{e}_j$, so $\mathbf{c}_j = f^{-1}(\mathbf{e}_j)$ for each j. So $\mathcal{C}$ is determined by f.

Existence. Let $\mathbf{c}_j = f^{-1}(\mathbf{e}_j)$ and $\mathcal{C} = \mathbf{c}_1, \ldots, \mathbf{c}_n$. For all $b_1, \ldots, b_n \in F$, since f respects linear combinations,

$$f(b_1\mathbf{c}_1 + \cdots + b_n\mathbf{c}_n) = b_1\mathbf{e}_1 + \cdots + b_n\mathbf{e}_n = (b_1, \ldots, b_n).$$

Let $\mathbf{v} \in V$. Since f is injective, $\sum_i b_i \mathbf{c}_i = \mathbf{v}$ holds if and only if $f\left(\sum_i b_i \mathbf{c}_i\right) = f(\mathbf{v})$, that is, if and only if $(b_1, \ldots, b_n) = f(\mathbf{v})$. So exactly one linear combination of $\mathcal{C}$ represents $\mathbf{v}$, namely the one with coefficients $f(\mathbf{v})$. Hence $\mathcal{C}$ is a basis (Definition 1.6.1) and $[\mathbf{v}]_{\mathcal{C}} = f(\mathbf{v})$ (Definition 1.6.14).

Conversely, every coordinate map is a bijection that respects linear combinations, by Proposition 1.6.16 and Proposition 1.6.19(c). In the language of Section 4.5, the coordinate maps $V \to F^n$ are the isomorphisms $V \to F^n$.

Solution to Exercise 1.6.38

Uses. Exercise 1.5.43, Proposition 1.6.2 (Bases are independent spanning lists), Proposition 1.6.7 (Standard bases)
Hint 1. By Exercise 1.5.43(a), an independent list of length k spans a set of exactly q^k elements. How many elements does F^n have?
Hint 2. For (b), (a) turns the count of bases into the count of independent lists of length n, which Exercise 1.5.43(b) computes.
Sketch. (a) If $\mathcal{L}$ is independent of length k, then $|\operatorname{span}(\mathcal{L})| = q^k$, while $|F^n| = q^n$. So an independent list spans F^n exactly when $q^k = q^n$, that is, $k = n$. (b) $(q^n - 1)(q^n - q)\cdots\left(q^n - q^{n-1}\right)$. For $\mathbb{F}_2^2$ this is $3 \cdot 2 = 6$: the ordered pairs of distinct vectors among $(1,0), (0,1), (1,1)$.

(a) F^n has q^n elements. Let $\mathcal{L}$ be an independent list of length k. By Exercise 1.5.43(a), $\operatorname{span}(\mathcal{L})$ has q^k elements. Since $\operatorname{span}(\mathcal{L}) \subseteq F^n$, it equals F^n if and only if $q^k = q^n$, which holds if and only if $k = n$, because $q \geq 2$. So an independent list spans F^n exactly when its length is n. By Proposition 1.6.2, the bases of F^n are the independent lists of length n.

(b) By (a) and Exercise 1.5.43(b), F^n has exactly

$$(q^n - 1)(q^n - q)\left(q^n - q^2\right)\cdots\left(q^n - q^{n-1}\right)$$

bases. For $q = 2$ and $n = 2$ this is $(4-1)(4-2) = 6$. An independent list of length 2 in $\mathbb{F}_2^2$ consists of a nonzero vector and a vector outside its span; the span of a nonzero $\mathbf{v}$ is $\{\mathbf{0}, \mathbf{v}\}$. So the bases are the ordered pairs of distinct vectors from $(1,0), (0,1), (1,1)$:

$$\begin{array}{lll} (1,0),(0,1) & (0,1),(1,0) & (1,0),(1,1) \\ (1,1),(1,0) & (0,1),(1,1) & (1,1),(0,1). \end{array}$$

Part (a) shows that over a finite field every basis of F^n has length n. Section 4.1 proves this over every field (Theorem 4.1.1), where counting elements is not available.

Solution to Exercise 1.6.39

Uses. Theorem 1.4.3 (Subspace criterion), Definition 1.6.1 (Basis), (1.6.1), Proposition 1.6.2 (Bases are independent spanning lists), induction on k
Hint 1. For (a), check the subspace criterion one condition at a time. For the second claim, prove by induction on k that $s_k = s_{k+1} = 0$.
Hint 2. For (b), given $\mathbf{s} \in V$, the sequence $\mathbf{s} - s_0\mathbf{g} - s_1\mathbf{f}$ lies in V. What are its first two terms?
Hint 3. For (c), $\varphi^{k+2} = \varphi^k\varphi^2 = \varphi^k(\varphi + 1)$. To represent $\mathbf{s}$, choose α, β with $\alpha + \beta = s_0$ and $\alpha\varphi + \beta\psi = s_1$, and argue as in (b).
Sketch. (a) The recurrence is preserved by sums and multiples, and the zero sequence satisfies it; if $s_0 = s_1 = 0$, induction gives $s_k = 0$ for all k. (b) $\mathbf{s} - s_0\mathbf{g} - s_1\mathbf{f} \in V$ starts $0, 0$, so it is $\mathbf{0}$; and a combination $c\mathbf{g} + d\mathbf{f}$ starts c, d, so the coefficients are forced. (c) $\mathbf{a}, \mathbf{b} \in V$ because $\varphi^2 = \varphi + 1$ and $\psi^2 = \psi + 1$. Since $\varphi \neq \psi$, the system $\alpha + \beta = s_0$, $\alpha\varphi + \beta\psi = s_1$ has exactly one solution, and by (a) the coefficients represent $\mathbf{s}$. For $\mathbf{f}$: $\alpha = 1/\sqrt{5}$, $\beta = -1/\sqrt{5}$.

(a) The zero sequence satisfies $0 = 0 + 0$. If $\mathbf{s}, \mathbf{t} \in V$ and $c \in \mathbb{R}$, then $s_{k+2} + t_{k+2} = (s_{k+1} + t_{k+1}) + (s_k + t_k)$ and $cs_{k+2} = cs_{k+1} + cs_k$ for all k, since the operations of $\mathbb{R}^X$ are termwise. So V is a subspace by Theorem 1.4.3. Now let $\mathbf{s} \in V$ with $s_0 = s_1 = 0$. We show by induction on k that $s_k = s_{k+1} = 0$. For $k = 0$ this is the hypothesis. If $s_k = s_{k+1} = 0$, then $s_{k+2} = s_{k+1} + s_k = 0$, so $s_{k+1} = s_{k+2} = 0$. Hence $s_k = 0$ for all k, and $\mathbf{s} = \mathbf{0}$.

(b) (The sequences $\mathbf{g}$ and $\mathbf{f}$ exist and are unique: choose the first two terms and define the rest by the recurrence.) Let $\mathbf{s} \in V$ and $c, d \in \mathbb{R}$. The combination $c\mathbf{g} + d\mathbf{f}$ has first two terms c and d. So if it represents

$\mathbf{s}$, then $c = s_0$ and $d = s_1$. Conversely, $\mathbf{t} = \mathbf{s} - s_0\mathbf{g} - s_1\mathbf{f}$ lies in V, since V is a subspace, and $t_0 = s_0 - s_0 = 0$, $t_1 = s_1 - s_1 = 0$. By (a), $\mathbf{t} = \mathbf{0}$, that is, $\mathbf{s} = s_0\mathbf{g} + s_1\mathbf{f}$. So $\mathbf{s}$ is represented by exactly one combination, $\mathbf{g}, \mathbf{f}$ is a basis of V, and $[\mathbf{s}]_{(\mathbf{g},\mathbf{f})} = (s_0, s_1)$.

(c) Since $\varphi^2 = \varphi + 1$, we get $\varphi^{k+2} = \varphi^k\varphi^2 = \varphi^{k+1} + \varphi^k$ for all k, so $\mathbf{a} \in V$; likewise $\mathbf{b} \in V$. Let $\mathbf{s} \in V$. A combination $\alpha\mathbf{a} + \beta\mathbf{b}$ has first two terms $\alpha + \beta$ and $\alpha\varphi + \beta\psi$. The system

$$\alpha + \beta = s_0, \quad \alpha\varphi + \beta\psi = s_1$$

has exactly one solution, because $\varphi - \psi = \sqrt{5} \neq 0$: subtracting ψ times the first equation from the second gives $\alpha = (s_1 - \psi s_0)/\sqrt{5}$, and then $\beta = s_0 - \alpha$. For these α, β, the sequence $\mathbf{s} - \alpha\mathbf{a} - \beta\mathbf{b}$ lies in V and starts with $0, 0$, so it is $\mathbf{0}$ by (a). For any other α, β, the combination differs from $\mathbf{s}$ in one of the first two terms. So $\mathbf{s}$ has exactly one representation, and $\mathbf{a}, \mathbf{b}$ is a basis of V.

For $\mathbf{f}$, $s_0 = 0$ and $s_1 = 1$ give $\alpha = 1/\sqrt{5}$ and $\beta = -1/\sqrt{5}$. So $[\mathbf{f}]_{(\mathbf{a},\mathbf{b})} = \left(1/\sqrt{5}, -1/\sqrt{5}\right)$, which means $\mathbf{f} = (\mathbf{a} - \mathbf{b})/\sqrt{5}$. Comparing k-th terms, $f_k = \left(\varphi^k - \psi^k\right)/\sqrt{5}$.

The same space has two useful bases. In $\mathbf{g}, \mathbf{f}$ the coordinates are the initial values, and in $\mathbf{a}, \mathbf{b}$ the recurrence acts on each basis vector by a single multiplication, which is what makes the closed formula possible. Choosing such a basis is the idea of diagonalization (Section 7.4).

Solution to Exercise 1.6.40

Uses. Exercise 1.6.33, Theorem 1.4.3 (Subspace criterion), Definition 1.6.1 (Basis), (1.6.1), Proposition 1.3.18 (Comparing spans), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Hint 1. For (a), if $A \in S$ has common sum s, what are the row and column sums of $A - sI$?
Hint 2. For uniqueness in (a), compute the first row sum of $c_0 I + \sum c_{kl} Z_{kl}$; then use the uniqueness in Exercise 1.6.33.
Hint 3. For (c), it is enough to write I and the four Z_{kl} as combinations of permutation matrices. Each Z_{kl} is a difference of two of them. For the relation, add up the three permutation matrices that place the 1 of row 1 in different columns "cyclically".
Sketch. (a) Line sums are preserved by sums and scalar multiples, so S is a subspace. For $A \in S$ with sum s, $A - sI \in Z$, so $A = sI + \sum (A - sI)_{kl} Z_{kl}$ by Exercise 1.6.33. Conversely, the first row sum of $c_0 I + \sum c_{kl} Z_{kl}$ is c_0, which forces $c_0 = s$, and then the c_{kl} are the $\mathcal{Z}$-coordinates of $A - sI$. (b) $s(J) = 3$, so $[J] = (3, -2, 1, 1, -2)$; $J \in Z$ iff $3 = 0$ in F. (c) With T_k the permutation matrix fixing position k and C, C' the two cyclic ones: $Z_{11} = I - T_2$, $Z_{22} = I - T_1$, $Z_{12} = T_3 - C'$, $Z_{21} = T_3 - C$. Relation: $I + C + C' = J = T_1 + T_2 + T_3$.

(a) *Subspace.* The zero matrix lies in S with $s = 0$. If $A, B \in S$ and $c \in F$, then every row and column of $A + B$ sums to $s(A) + s(B)$, and every row and column of cA sums to $cs(A)$, because sums of entries respect the entrywise operations. So S is a subspace by Theorem 1.4.3. The matrix I lies in S with $s(I) = 1$, and each Z_{kl} lies in $Z \subseteq S$.

Existence. Let $A \in S$ with $s = s(A)$. Every row and column of $A - sI$ sums to $s - s = 0$, so $A - sI \in Z$. By Exercise 1.6.33,

$$A - sI = \sum_{k,l \in \{1,2\}} (A - sI)_{kl} Z_{kl},$$

where $(A - sI)_{kl}$ is $a_{kl} - s$ for $k = l$ and a_{kl} for $k \neq l$. So A is represented with the coefficients claimed.

Uniqueness. Suppose $A = c_0 I + \sum_{k,l} c_{kl} Z_{kl}$. Every row of a matrix in Z sums to 0, so the first row of the right side sums to c_0, and hence $c_0 = s$. Then $\sum_{k,l} c_{kl} Z_{kl} = A - sI$, and the uniqueness in Exercise 1.6.33 gives $c_{kl} = (A - sI)_{kl}$. So every $A \in S$ has exactly one representation, $I, \mathcal{Z}$ is a basis of S, and the coordinates are as stated ((1.6.1)).

(b) Every row and column of J sums to $3 = 1 + 1 + 1$, so $J \in S$ with $s(J) = 3$, and by (a)

$$[J]_{(I,\mathcal{Z})} = (3, \quad 1 - 3, \quad 1, \quad 1, \quad 1 - 3) = (3, -2, 1, 1, -2).$$

The matrix J lies in Z exactly when its line sums are 0, that is, when $3 = 0$ in F, as in $\mathbb{F}_3$. In that case its first coordinate is 0, and its coordinates are $(0, 1, 1, 1, 1)$.

(c) Each permutation matrix lies in S, with every line sum equal to 1. There are six of them: I; the two "cyclic" ones

$$C = U_{12} + U_{23} + U_{31}, \quad C' = U_{13} + U_{21} + U_{32};$$

and the three that keep exactly one 1 of I in place,

$$T_1 = U_{11} + U_{23} + U_{32}, \quad T_2 = U_{13} + U_{22} + U_{31}, \quad T_3 = U_{12} + U_{21} + U_{33}.$$

Comparing entries,

$$Z_{11} = I - T_2, \quad Z_{22} = I - T_1, \quad Z_{12} = T_3 - C', \quad Z_{21} = T_3 - C.$$

For instance, $I - T_2 = (U_{11} + U_{22} + U_{33}) - (U_{13} + U_{22} + U_{31}) = U_{11} - U_{13} - U_{31} + U_{33} = Z_{11}$. So the basis $I, \mathcal{Z}$ of S lies in the span of the permutation matrices, and $S \subseteq$ that span by Proposition 1.3.18. Conversely, the permutation matrices lie in the subspace S, so their span is contained in S (Proposition 1.4.14). Hence they span S.

The matrices I, C, C' have their 1's in disjoint positions covering all nine, and so do T_1, T_2, T_3. Hence

$$I + C + C' = J = T_1 + T_2 + T_3,$$

and $I + C + C' - T_1 - T_2 - T_3 = 0$ is a dependence relation, with coefficient 1 on I, over every field. So six matrices span S, which has a basis of length 5, and they are dependent; Section 4.1 shows that this had to happen.

Solution to Exercise 1.6.41

Uses. Proposition 1.2.19 (Restriction of scalars), Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.1 (Vector space), Lemma 1.3.9 (Arithmetic of linear combinations)
Hint 1. For spanning, write $\mathbf{v} = \sum_j a_j \mathbf{v}_j$ with $a_j \in E$, and then write each a_j as a K-combination of the α_i.
Hint 2. For independence, group a K-relation $\sum_{i,j} b_{ij}\alpha_i \mathbf{v}_j = \mathbf{0}$ as $\sum_j \big(\sum_i b_{ij}\alpha_i\big)\mathbf{v}_j = \mathbf{0}$. Use independence over E, then over K.
Sketch. Spanning: $\mathbf{v} = \sum_j a_j \mathbf{v}_j$ with $a_j = \sum_i b_{ij}\alpha_i$, $b_{ij} \in K$, so $\mathbf{v} = \sum_{i,j} b_{ij}(\alpha_i \mathbf{v}_j)$ by (A6) and (A8). Independence: a K-relation regroups as $\sum_j c_j \mathbf{v}_j = \mathbf{0}$ with $c_j = \sum_i b_{ij}\alpha_i \in E$; independence of the $\mathbf{v}_j$ over E gives each $c_j = 0$, and independence of the α_i over K gives each $b_{ij} = 0$. (b) $(1, 0), (i, 0), (0, 1), (0, i)$, and coordinates $(1, 2, 3, -1)$.

Scalar multiplication of K on V is that of E, restricted to K, and the same holds on E, where it is multiplication in E. So the vector space axioms of V over E apply whenever the scalars lie in K or E.

(a) *Spanning.* Let $\mathbf{v} \in V$. Since $\mathbf{v}_1, \ldots, \mathbf{v}_n$ spans V over E, $\mathbf{v} = \sum_j a_j \mathbf{v}_j$ with $a_j \in E$. Since $\alpha_1, \ldots, \alpha_m$ spans E over K, each $a_j = \sum_i b_{ij}\alpha_i$ with $b_{ij} \in K$. By (A8) and (A6) in the E-vector space V,

$$a_j \mathbf{v}_j = \left(\sum_{i=1}^{m} b_{ij}\alpha_i\right)\mathbf{v}_j = \sum_{i=1}^{m} b_{ij}\big(\alpha_i \mathbf{v}_j\big),$$

so $\mathbf{v} = \sum_{j=1}^{n}\sum_{i=1}^{m} b_{ij}\big(\alpha_i \mathbf{v}_j\big)$ is a K-linear combination of the list.

Independence. Suppose that $\sum_{j=1}^{n}\sum_{i=1}^{m} b_{ij}\big(\alpha_i \mathbf{v}_j\big) = \mathbf{0}$ with all $b_{ij} \in K$. Regrouping with the same axioms, $\sum_j c_j \mathbf{v}_j = \mathbf{0}$, where $c_j = \sum_i b_{ij}\alpha_i \in E$. Since $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is independent over E, every $c_j = 0$ (Theorem 1.5.5). So for each j, $\sum_i b_{ij}\alpha_i = 0$ is a K-relation of $\alpha_1, \ldots, \alpha_m$, and independence over K gives $b_{ij} = 0$ for all i. So the list is independent over K, and it is a basis by Proposition 1.6.2.

(b) Take $K = \mathbb{R}$, $E = \mathbb{C}$ with basis $1, i$ (Example 1.6.5), and $V = \mathbb{C}^2$ with the standard basis $\mathbf{e}_1, \mathbf{e}_2$ over $\mathbb{C}$. The basis of (a) is

$$(1, 0), \quad (i, 0), \quad (0, 1), \quad (0, i).$$

Since $(1+2i, 3-i) = 1(1,0) + 2(i,0) + 3(0,1) + (-1)(0,i)$ with real coefficients, its coordinates are $(1,2,3,-1)$ by (1.6.1). In general, the coordinates of a vector of $\mathbb{C}^n$ in this basis over $\mathbb{R}$ list the real and imaginary parts of its entries.

Solution to Exercise 1.6.42

Uses. Exercise 1.5.43, Proposition 1.6.2 (Bases are independent spanning lists), Definition 1.2.9 (Function spaces), Proposition 1.3.18 (Comparing spans)
Hint 1. Count: V has 2^{2^n} elements, and the list has length 2^n. By Exercise 1.5.43(a), it is enough to show that the list spans V.
Hint 2. For $\mathbf{a} \in X$, let $\delta_{\mathbf{a}}$ be 1 at $\mathbf{a}$ and 0 elsewhere. Every f is a combination of the $\delta_{\mathbf{a}}$. Show that $\delta_{\mathbf{a}}(\mathbf{y}) = \prod_{i=1}^{n}(y_i + a_i + 1)$.
Hint 3. Expand that product of n binomials. Each term is a constant times $\prod_{i\in S} y_i$ for some S.
Sketch. Every $f = \sum_{\mathbf{a}} f(\mathbf{a})\delta_{\mathbf{a}}$. In $\mathbb{F}_2$, $y_i + a_i + 1 = 1$ exactly when $y_i = a_i$, so $\delta_{\mathbf{a}}(\mathbf{y}) = \prod_i((a_i+1)+y_i)$, and expanding gives $\sum_S\big(\prod_{i\notin S}(a_i+1)\big)m_S(\mathbf{y})$. So the m_S span V. The span of a list of length 2^n then has 2^{2^n} elements, so by Exercise 1.5.43(a) the list is independent, hence a basis. The coordinates in this basis give the unique expression.

Write $N = 2^n$ for the number of subsets S, and fix a listing $m_{S_1}, \dots, m_{S_N}$. The space V has 2^N elements, since a function $X \to \mathbb{F}_2$ chooses one of two values at each of the N points of X.

Spanning. For $\mathbf{a} \in X$, let $\delta_{\mathbf{a}} \in V$ be 1 at $\mathbf{a}$ and 0 elsewhere. Every $f \in V$ satisfies $f = \sum_{\mathbf{a}\in X} f(\mathbf{a})\delta_{\mathbf{a}}$, since both sides take the value $f(\mathbf{y})$ at each $\mathbf{y}$ (only the term with $\mathbf{a} = \mathbf{y}$ contributes). So by Proposition 1.3.18 it suffices to show that each $\delta_{\mathbf{a}}$ lies in the span of the m_S.

In $\mathbb{F}_2$, the element $y_i + a_i + 1$ is 1 if $y_i = a_i$ and 0 if $y_i \neq a_i$ (as $a_i + a_i = 0$ and $1 + 1 = 0$). A product of elements of $\mathbb{F}_2$ is 1 exactly when every factor is 1, so

$$\delta_{\mathbf{a}}(\mathbf{y}) = \prod_{i=1}^{n}((a_i + 1) + y_i) \quad \text{for all } \mathbf{y} \in X.$$

Expanding a product of n sums $(u_i + y_i)$ by distributivity (induction on n) gives the sum, over all subsets $S \subseteq \{1, \dots, n\}$, of the products that take y_i from the factors with $i \in S$ and u_i from the others:

$$\prod_{i=1}^{n}(u_i + y_i) = \sum_{S\subseteq\{1,\dots,n\}}\left(\prod_{i\notin S} u_i\right)\left(\prod_{i\in S} y_i\right).$$

With $u_i = a_i + 1$, this says that $\delta_{\mathbf{a}} = \sum_S c_S m_S$ with $c_S = \prod_{i\notin S}(a_i + 1) \in \mathbb{F}_2$, an identity of functions because it holds at every $\mathbf{y}$. So the list spans V.

Independence. By Exercise 1.5.43(a), a list of length N over $\mathbb{F}_2$ is independent if and only if its span has exactly 2^N elements. Our list has length N, and its span is V, which has 2^N elements. So the list is independent, and it is a basis by Proposition 1.6.2.

The deduction. For $f \in V$, Definition 1.6.1 gives exactly one list of coefficients $c_S \in \mathbb{F}_2$ with $f = \sum_S c_S m_S$. Over $\mathbb{F}_2$ a coefficient is 0 or 1, so this says that f is the sum of the m_S with $c_S = 1$, and the set of these S is uniquely determined. For instance, for $n = 2$, the function that is 1 exactly at $(0,0)$ is $\delta_{(0,0)} = (1 + y_1)(1 + y_2) = 1 + y_1 + y_2 + y_1y_2$. This unique expression is the *algebraic normal form* of a Boolean function.

Section 1.7

Solution to Exercise 1.7.5

Uses. Corollary 1.3.19 (Equal spans), Proposition 1.4.14 (The span is the smallest subspace containing a list), Theorem 1.4.3 (Subspace criterion), Proposition 1.2.18 (Degree and evaluation versus the operations), Definition 1.2.17 (Evaluation)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. In (a) both sides are spans, so Corollary 1.3.19 reduces the equality to six memberships. In (b) the left side is a subspace.

Hint 2. For (a), write $\mathbf{v}_1$ and $\mathbf{v}_2$ in terms of the new list. For (b), $\operatorname{span}(1, x^2 - x) \subseteq W$ follows from Proposition 1.4.14(b); for the other containment, write $p = a + bx + cx^2$ and see what $p(0) = p(1)$ says about b and c.
Sketch. (a) The new entries are visibly combinations of the old ones, and $\mathbf{v}_3 = \mathbf{v}_3$, $\mathbf{v}_2 = (\mathbf{v}_2 - \mathbf{v}_3) + \mathbf{v}_3$, $\mathbf{v}_1 = (\mathbf{v}_1 - \mathbf{v}_2) + (\mathbf{v}_2 - \mathbf{v}_3) + \mathbf{v}_3$. (b) The left side W is a subspace containing 1 and $x^2 - x$, so it contains their span. Conversely $p = a + bx + cx^2 \in W$ means $b + c = 0$, so $p = a \cdot 1 + c(x^2 - x)$.

(a) Both sides are spans, so by Corollary 1.3.19 it suffices to check that each list lies in the span of the other. Each of $\mathbf{v}_1 - \mathbf{v}_2, \mathbf{v}_2 - \mathbf{v}_3, \mathbf{v}_3$ is a linear combination of $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$, with coefficients $1, -1, 0$, then $0, 1, -1$, then $0, 0, 1$. In the other direction,

$$\begin{aligned} \mathbf{v}_3 &= \mathbf{v}_3, \\ \mathbf{v}_2 &= (\mathbf{v}_2 - \mathbf{v}_3) + \mathbf{v}_3, \\ \mathbf{v}_1 &= (\mathbf{v}_1 - \mathbf{v}_2) + (\mathbf{v}_2 - \mathbf{v}_3) + \mathbf{v}_3. \end{aligned}$$

Neither containment needs a generic element; the constructions are the last two lines, and there are only finitely many of them.

(b) Let W be the left side. First, W is a subspace of $F[x]_{\leq 2}$: the zero polynomial has $\mathbf{0}(0) = \mathbf{0}(1) = 0$, and if $p(0) = p(1)$ and $q(0) = q(1)$, then $(p + q)(0) = p(0) + q(0) = p(1) + q(1) = (p + q)(1)$ and $(ap)(0) = ap(0) = ap(1) = (ap)(1)$ by Proposition 1.2.18(c). So Theorem 1.4.3 applies.

$\operatorname{span}(1, x^2 - x) \subseteq W$. The constant 1 takes the value 1 at 0 and at 1, and $x^2 - x$ takes the value 0 at both. So both entries lie in the subspace W, and their span does by Proposition 1.4.14(b). This half is a finite check.

$W \subseteq \operatorname{span}(1, x^2 - x)$. Let $p = a + bx + cx^2 \in W$. By Definition 1.2.17, $p(0) = a$ and $p(1) = a + b + c$, so $p(0) = p(1)$ gives $b + c = 0$, that is, $b = -c$. Hence

$$p = a + (-c)x + cx^2 = a \cdot 1 + c(x^2 - x) \in \operatorname{span}(1, x^2 - x).$$

This half is the construction: it produces coefficients for a generic element of W. The argument works over every field.

Solution to Exercise 1.7.6

Uses. Proposition 1.2.30 (Additive arithmetic), Proposition 1.2.34 (Negatives and the scalar -1), Definition 1.2.1 (Vector space), Exercise 1.2.37, Proposition 1.2.32 (The scalar zero)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Try small cases and small fields (Technique 1.2.38)
Hint 1. Rewrite the equation so that all occurrences of $\mathbf{m}$ are on one side. You should get $\mathbf{m} + \mathbf{m} = \mathbf{u} + \mathbf{w}$.
Hint 2. By (A5) and (A8), $\mathbf{m} + \mathbf{m} = (1 + 1)\mathbf{m}$. When can you divide by $1 + 1$?
Sketch. Adding $\mathbf{m} + \mathbf{u}$ to both sides shows that the equation is equivalent to $(1 + 1)\mathbf{m} = \mathbf{u} + \mathbf{w}$. If $1 + 1 \neq 0$, this has exactly one solution, $\mathbf{m} = (1 + 1)^{-1}(\mathbf{u} + \mathbf{w})$. If $1 + 1 = 0$, the left side is always $\mathbf{0}$, so there is a solution exactly when $\mathbf{u} + \mathbf{w} = \mathbf{0}$, that is, $\mathbf{w} = -\mathbf{u} = \mathbf{u}$, and then every $\mathbf{m}$ works.

We first rewrite the equation. If $\mathbf{m} - \mathbf{u} = \mathbf{w} - \mathbf{m}$, then adding $\mathbf{m} + \mathbf{u}$ to both sides and regrouping with (A1)–(A4) gives $\mathbf{m} + \mathbf{m} = \mathbf{w} + \mathbf{u}$. Conversely, if $\mathbf{m} + \mathbf{m} = \mathbf{w} + \mathbf{u}$, then adding $-\mathbf{m} - \mathbf{u}$ to both sides gives back the original equation. So the equation is equivalent to $\mathbf{m} + \mathbf{m} = \mathbf{u} + \mathbf{w}$, and by (A5) and (A8), $\mathbf{m} + \mathbf{m} = 1\mathbf{m} + 1\mathbf{m} = (1 + 1)\mathbf{m}$. So it is equivalent to

$$(1 + 1)\mathbf{m} = \mathbf{u} + \mathbf{w}.$$

(a) If $1 + 1 \neq 0$, this equation has exactly one solution, $\mathbf{m} = (1 + 1)^{-1}(\mathbf{u} + \mathbf{w})$, by Exercise 1.2.37(a), applied with $a = 1 + 1$, with $\mathbf{0}$ in place of its $\mathbf{u}$, and with $\mathbf{u} + \mathbf{w}$ in place of its $\mathbf{w}$. Over $\mathbb{R}$ this is the midpoint $(\mathbf{u} + \mathbf{w})/2$. Uniqueness here is the two-candidate argument in disguise: two solutions $\mathbf{m}, \mathbf{m}'$ satisfy $(1 + 1)\mathbf{m} = (1 + 1)\mathbf{m}'$, and the nonzero scalar $1 + 1$ cancels.

(b) Over $\mathbb{F}_2$, $1 + 1 = 0$, so the left side is $0\mathbf{m} = \mathbf{0}$ for every $\mathbf{m}$ (Proposition 1.2.32). The equation becomes $\mathbf{0} = \mathbf{u} + \mathbf{w}$, which holds for all $\mathbf{m}$ or for none. It holds exactly when $\mathbf{w} = -\mathbf{u}$ (Proposition 1.2.30(a)), and $-\mathbf{u} = (-1)\mathbf{u} = 1\mathbf{u} = \mathbf{u}$ by Proposition 1.2.34, since $-1 = 1$ in $\mathbb{F}_2$. So there is a solution only if $\mathbf{w} = \mathbf{u}$, and then

every $\mathbf{m}$ is one. If $V \neq \{\mathbf{0}\}$, choosing $\mathbf{u} \neq \mathbf{w}$ gives no solution and choosing $\mathbf{u} = \mathbf{w}$ gives more than one, so the hypothesis $1 + 1 \neq 0$ in (a) cannot be dropped.

Solution to Exercise 1.7.7

Uses. Definition 1.5.3 (Linear relation), Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.2.32 (The scalar zero), Proposition 1.5.15 (Short lists, zeros, and repeats)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), if $c_j = 0$, what does the relation say about the list with $\mathbf{v}_j$ deleted?
Hint 2. For (b), the two relations are two candidates; compare them after making one coefficient agree. Subtract (d_1/c_1) times the first relation from the second, and apply (a) to the result.
Sketch. (a) If $c_j = 0$, dropping the j-th term gives a nontrivial relation of the sublist without $\mathbf{v}_j$, which is independent. (b) With $\lambda = d_1/c_1$, the coefficients $d_i - \lambda c_i$ form a linear relation whose first coefficient is 0; by (a) it is not a dependence relation, so it is trivial. (c) $(1,0), (0,1), (1,1)$, whose relations are $\lambda, \lambda, -\lambda$.

(a) Let $c_1, \dots, c_n$ be a dependence relation, and suppose $c_j = 0$ for some j. The term $c_j\mathbf{v}_j = 0\mathbf{v}_j = \mathbf{0}$ can be dropped, so the coefficients c_i, $i \neq j$, form a linear relation of the sublist obtained by deleting $\mathbf{v}_j$. Not all of them are 0, since $c_j = 0$ and the relation is nontrivial. So that sublist, of length $n - 1$, is dependent by Theorem 1.5.5, contrary to the hypothesis. Hence all $c_i \neq 0$.

(b) Let c and d be dependence relations. By (a), $c_1 \neq 0$, so we may set $\lambda = d_1/c_1$. By Lemma 1.3.9,

$$\sum_{i=1}^{n}(d_i - \lambda c_i)\mathbf{v}_i = \sum_{i=1}^{n} d_i\mathbf{v}_i - \lambda \sum_{i=1}^{n} c_i\mathbf{v}_i = \mathbf{0} - \lambda\mathbf{0} = \mathbf{0},$$

so the scalars $e_i = d_i - \lambda c_i$ form a linear relation. Its first coefficient is $e_1 = d_1 - (d_1/c_1)c_1 = 0$. By (a), a dependence relation has no zero coefficient, so e is not a dependence relation: it is the trivial relation. Hence $d_i = \lambda c_i$ for every i.

(c) Take $(1,0), (0,1), (1,1)$. It is dependent, since $(1,0) + (0,1) - (1,1) = \mathbf{0}$, and no entry is a multiple of another, so each sublist of length 2 is independent by Proposition 1.5.15(d). By (b), every linear relation is a multiple of $1, 1, -1$, and conversely each $\lambda, \lambda, -\lambda$ is a relation, by Lemma 1.3.9(b). So the relations are $\lambda, \lambda, -\lambda$ for $\lambda \in \mathbb{R}$ (with $\lambda = 0$ giving the trivial relation).

So for such a list the relations form a single line through the trivial relation. This is the uniqueness-by-subtraction pattern: two candidates, normalized so that one coordinate agrees, differ by a solution of a problem that has only the zero solution.

Solution to Exercise 1.7.8

Uses. Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.2.34 (Negatives and the scalar -1)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. For ($\Leftarrow$), take a nontrivial relation and solve it for one entry. Which choice of entry leaves only *later* entries on the other side?
Hint 2. Let i be the smallest index with $a_i \neq 0$. For ($\Rightarrow$), turn $\mathbf{v}_j = \sum_{l>j} b_l\mathbf{v}_l$ into a relation.
Sketch. ($\Leftarrow$) In a nontrivial relation, let i be the smallest index with $a_i \neq 0$. The earlier terms vanish, so $\mathbf{v}_i = \sum_{l>i}(-a_l/a_i)\mathbf{v}_l \in \operatorname{span}(\mathbf{v}_{i+1}, \dots, \mathbf{v}_k)$, a contradiction. ($\Rightarrow$) If $\mathbf{v}_j = \sum_{l>j} b_l\mathbf{v}_l$, the coefficients $0, \dots, 0, -1, b_{j+1}, \dots, b_k$ form a nontrivial relation.

($\Leftarrow$) Suppose the condition holds, and suppose for contradiction that $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ with not all $a_l = 0$. Let i be the *smallest* index with $a_i \neq 0$. Then $a_l = 0$ for $l < i$, and those terms vanish, so

$$a_i\mathbf{v}_i + \sum_{l=i+1}^{k} a_l\mathbf{v}_l = \mathbf{0}, \quad \text{hence} \quad \mathbf{v}_i = \sum_{l=i+1}^{k}\left(-\frac{a_l}{a_i}\right)\mathbf{v}_l,$$

by the computation in the proof of Lemma 1.5.10. So $\mathbf{v}_i \in \operatorname{span}(\mathbf{v}_{i+1}, \dots, \mathbf{v}_k)$; if $i = k$, the sum is empty and this says $\mathbf{v}_k = \mathbf{0} \in \operatorname{span}(())$. Either way the condition fails for $j = i$, a contradiction. By Theorem 1.5.5 the list is independent.

(⇒) We prove the contrapositive. Suppose $\mathbf{v}_j = b_{j+1}\mathbf{v}_{j+1} + \cdots + b_k\mathbf{v}_k$ for some j. The linear combination with coefficients 0 on $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$, -1 on $\mathbf{v}_j$, and b_l on $\mathbf{v}_l$ for $l > j$ represents $-\mathbf{v}_j + \mathbf{v}_j = \mathbf{0}$, by Proposition 1.2.34 and Lemma 1.3.9. Its coefficient on $\mathbf{v}_j$ is $-1 \neq 0$, so the list is dependent.

The proof of Lemma 1.5.10 chose the largest index to get earlier entries on the other side. Choosing the smallest gets later ones. Which extreme to choose is decided by which side the conclusion wants.

Solution to Exercise 1.7.9

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.2.9 (Function spaces), Proposition 1.1.17 (No zero divisors)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. In a nontrivial relation $\sum a_l f_l = \mathbf{0}$, choose the smallest index i with $a_i \neq 0$, and evaluate the relation at t_i.
Hint 2. For (b), list the functions as $1, r_0, \ldots, r_{n-1}$ and choose the points $-1, 1, 2, \ldots, n$.
Sketch. (a) Evaluating at t_i kills the terms with $l < i$ (their coefficients vanish) and with $l > i$ (as $f_l(t_i) = 0$), leaving $a_i f_i(t_i) = 0$, so $a_i = 0$. (b) With $g_0 = 1$, $g_{i+1} = r_i$ and points $s_0 = -1$, $s_{i+1} = i + 1$: $g_m(s_m) = 1$, and $r_i(s_j) = 0$ for $j \leq i$ because $s_j \leq i$.

(a) Suppose $a_1 f_1 + \cdots + a_n f_n = \mathbf{0}$, the zero function, and suppose for contradiction that some $a_l \neq 0$. Let i be the smallest index with $a_i \neq 0$. A relation among functions holds at every point (Definition 1.2.9), so at t_i,

$$\sum_{l=1}^{n} a_l f_l(t_i) = 0.$$

For $l < i$ we have $a_l = 0$, and for $l > i$ we have $f_l(t_i) = 0$ by hypothesis (as $i < l$). So the sum is $a_i f_i(t_i)$, and $a_i f_i(t_i) = 0$ with $f_i(t_i) \neq 0$ forces $a_i = 0$ (Proposition 1.1.17), a contradiction. By Theorem 1.5.5 the list is independent.

(b) Write $g_0 = 1$ and $g_{i+1} = r_i$ for $0 \leq i \leq n-1$, and choose the points $s_0 = -1$ and $s_{i+1} = i + 1$. We check the hypotheses of (a) for the list $g_0, \ldots, g_n$ and the points $s_0, \ldots, s_n$. First, $g_0(s_0) = 1 \neq 0$ and $g_{i+1}(s_{i+1}) = r_i(i + 1) = \max(0, 1) = 1 \neq 0$. Next, let $j < i + 1$, that is, $j \leq i$. Then $s_j = -1$ or $s_j = j$, so $s_j \leq i$ and $s_j - i \leq 0$, which gives $g_{i+1}(s_j) = r_i(s_j) = \max(0, s_j - i) = 0$. (For g_0 there is nothing to check, since no index is smaller than 0.) By (a), with the indices shifted by one, $1, r_0, \ldots, r_{n-1}$ is independent.

The pattern is a triangular one: each function is invisible at the points before its own, so evaluating at the points in order reads off one coefficient at a time.

Solution to Exercise 1.7.10

Uses. Exercise 1.3.28
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Run the inductive step with $k = 1$. Which vectors are in the two shorter lists?
Hint 2. For the corrected statement, start the induction at $k = 2$ and check that the step from k to $k + 1$ is valid when $k \geq 2$.
Sketch. For $k = 1$ the shorter lists are $\mathbf{v}_1$ and $\mathbf{v}_2$, which share no entry, so "$\mathbf{v}_2$ lies on both lines" is false; the step from 1 to 2 fails. The claim is false for $(1, 0), (0, 1)$. With base case $k = 2$ (the hypothesis), the step is valid for $k \geq 2$, because then the two shorter lists share $\mathbf{v}_2$, and a nonzero $\mathbf{v}_2 \in \operatorname{span}(\mathbf{u})$ has $\operatorname{span}(\mathbf{v}_2) = \operatorname{span}(\mathbf{u})$.

The error. The inductive step uses the vector $\mathbf{v}_2$ as a common entry of the lists $\mathbf{v}_1, \ldots, \mathbf{v}_k$ and $\mathbf{v}_2, \ldots, \mathbf{v}_{k+1}$. When $k = 1$ these lists are $\mathbf{v}_1$ and $\mathbf{v}_2$, which have no entry in common, and $\mathbf{v}_2$ is not in the first. So the step from $k = 1$ to $k = 2$ is invalid. The base case and the steps from k to $k + 1$ for $k \geq 2$ are fine, but without the step from 1 to 2 the induction proves nothing beyond $k = 1$.

The claim is false. In $\mathbb{R}^2$, suppose $(1, 0) = a\mathbf{u}$ and $(0, 1) = b\mathbf{u}$. Both vectors are nonzero, so $a, b \neq 0$, and $(0, 1) = b\mathbf{u} = (b/a)(1, 0)$, whose second coordinate is 0. This is a contradiction, so $(1, 0)$ and $(0, 1)$ lie on no common line.

The corrected statement. Suppose every two of the nonzero vectors $\mathbf{v}_1, \ldots, \mathbf{v}_k$ lie on a common line; we show by induction on $k \geq 2$ that all of them do (for $k = 1$ there is nothing to prove). For $k = 2$ this is the hypothesis. Suppose it holds for lists of length $k \geq 2$ satisfying the hypothesis, and let $\mathbf{v}_1, \ldots, \mathbf{v}_{k+1}$ satisfy

it. Both shorter lists satisfy it as well, so the argument above gives $\mathbf{u}$ and $\mathbf{u}'$. Since $k \geq 2$, the vector $\mathbf{v}_2$ is an entry of both shorter lists. It lies in $\operatorname{span}(\mathbf{u})$, say $\mathbf{v}_2 = c\mathbf{u}$, and $c \neq 0$ because $\mathbf{v}_2 \neq \mathbf{0}$. So $\operatorname{span}(\mathbf{v}_2) = \operatorname{span}(\mathbf{u})$ by Exercise 1.3.28(b); likewise $\operatorname{span}(\mathbf{v}_2) = \operatorname{span}(\mathbf{u}')$. Hence $\mathbf{v}_{k+1} \in \operatorname{span}(\mathbf{u}') = \operatorname{span}(\mathbf{u})$, and all the vectors lie on the line $\operatorname{span}(\mathbf{u})$.

When an inductive step combines two shorter lists through a shared entry, check that the shared entry exists for the smallest k at which the step is used.

Solution to Exercise 1.7.11

> *Uses.* Definition 1.3.4 (Linear combination), Lemma 1.3.9 (Arithmetic of linear combinations), Theorem 1.5.5 (Independence is decided at zero), Theorem 1.6.10 (Every spanning list contains a basis), Corollary 1.5.13 (Independence, one entry at a time)
> *Techniques.* Induction on the length of a list (Technique 1.6.9), Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* Over $\mathbb{F}_2$, a subset I is the same thing as a list of coefficients in $\{0,1\}$, that is, a linear combination of $\mathcal{L}$. So $Z(\mathcal{L})$ counts the linear relations of $\mathcal{L}$.
> *Hint 2.* Split the zero-sum subsets of $\{1,\dots,k+1\}$ according to whether they contain $k+1$. Those that do correspond to linear combinations of $\mathcal{L}$ representing $\mathbf{w}$. Fix one such representation and add relations to it.
> *Hint 3.* For (b), induct on k. Sifting reads from left to right, so sifting $\mathcal{L}, \mathbf{w}$ deletes what sifting $\mathcal{L}$ deletes, plus $\mathbf{w}$ exactly when $\mathbf{w} \in \operatorname{span}(\mathcal{L})$.
> *Sketch.* Subsets of $\{1,\dots,k\}$ are linear combinations of $\mathcal{L}$ over $\mathbb{F}_2$. A zero-sum subset of $\{1,\dots,k+1\}$ either avoids $k+1$ ($Z(\mathcal{L})$ of them) or is $J \cup \{k+1\}$ with $\sum_J \mathbf{v}_j = -\mathbf{w} = \mathbf{w}$. The representations of $\mathbf{w}$ number 0 if $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, and otherwise as many as the relations, since $c \mapsto a + c$ is a bijection from relations to representations for any fixed representation a. For (b), induct on k with $Z(()) = 1 = 2^0$.

Over $\mathbb{F}_2$ the only scalars are 0 and 1, so a linear combination of $\mathcal{L}$ is a list of coefficients in $\{0,1\}$, and it represents $\sum_{i \in I} \mathbf{v}_i$, where I is the set of positions with coefficient 1. This is a bijection between subsets of $\{1,\dots,k\}$ and linear combinations of $\mathcal{L}$. In particular, $Z(\mathcal{L})$ is the number of linear relations of $\mathcal{L}$, and for $\mathbf{w} \in V$ the number $N(\mathbf{w})$ of linear combinations of $\mathcal{L}$ representing $\mathbf{w}$ is the number of I with $\sum_{i \in I} \mathbf{v}_i = \mathbf{w}$.

(a) Split the subsets $I' \subseteq \{1,\dots,k+1\}$ with $\sum_{i \in I'} \mathbf{v}_i = \mathbf{0}$ (writing $\mathbf{v}_{k+1} = \mathbf{w}$) into those that do not contain $k+1$ and those that do. The first kind are the zero-sum subsets of $\{1,\dots,k\}$, and there are $Z(\mathcal{L})$ of them. The second kind are the sets $J \cup \{k+1\}$ with $J \subseteq \{1,\dots,k\}$ and $\sum_{j \in J} \mathbf{v}_j + \mathbf{w} = \mathbf{0}$, that is, $\sum_{j \in J} \mathbf{v}_j = -\mathbf{w} = \mathbf{w}$ (over $\mathbb{F}_2$, $-\mathbf{w} = (-1)\mathbf{w} = \mathbf{w}$). There are $N(\mathbf{w})$ of them.

If $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, then $N(\mathbf{w}) = 0$. If $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, fix one representation $a_1, \dots, a_k$ of $\mathbf{w}$. For a linear relation c, the coefficients $a + c$ represent $\mathbf{w} + \mathbf{0} = \mathbf{w}$ (Lemma 1.3.9). Conversely, for a representation b of $\mathbf{w}$, the coefficients $b - a$ represent $\mathbf{w} - \mathbf{w} = \mathbf{0}$. These two maps are inverse to each other, so $N(\mathbf{w})$ equals the number of relations, $Z(\mathcal{L})$. Hence $Z(\mathcal{L}, \mathbf{w}) = Z(\mathcal{L}) + N(\mathbf{w})$ is $Z(\mathcal{L})$ or $2Z(\mathcal{L})$, as claimed.

(b) For a list $\mathcal{M}$, write $d(\mathcal{M})$ for the number of entries that sifting deletes from it. We show $Z(\mathcal{L}) = 2^{d(\mathcal{L})}$ by induction on k. For $k = 0$, the only subset is $\emptyset$, whose sum is $\mathbf{0}$, so $Z(()) = 1 = 2^0$, and sifting deletes nothing. Suppose the claim holds for lists of length k, and consider $\mathcal{L}, \mathbf{w}$. Sifting decides about each entry by looking only at the entries before it, so on the first k entries, sifting $\mathcal{L}, \mathbf{w}$ makes the same decisions as sifting $\mathcal{L}$. It deletes $\mathbf{w}$ exactly when $\mathbf{w} \in \operatorname{span}(\mathcal{L})$. So $d(\mathcal{L}, \mathbf{w}) = d(\mathcal{L})$ if $\mathbf{w} \notin \operatorname{span}(\mathcal{L})$, and $d(\mathcal{L}) + 1$ otherwise, and by (a) and the inductive hypothesis, $Z(\mathcal{L}, \mathbf{w}) = 2^{d(\mathcal{L}, \mathbf{w})}$ in both cases.

Finally, $Z(\mathcal{L}) = 1$ means that the trivial relation is the only one, which is independence (Theorem 1.5.5). Equivalently $d = 0$: sifting deletes nothing exactly when no entry lies in the span of the earlier ones, which is independence by Corollary 1.5.13.

Solution to Exercise 1.7.12

> *Uses.* Theorem 1.5.5 (Independence is decided at zero), Proposition 1.5.15 (Short lists, zeros, and repeats), Lemma 1.3.9 (Arithmetic of linear combinations), Definition 1.3.10 (Span), Proposition 1.3.17 (A list lies in its span)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* Take V as small as possible and both lists of length one.

Hint 2. In your counterexample, the two spans share a nonzero vector. For (c), a vector in both spans gives a relation of $\mathcal{L}, \mathcal{M}$, and a relation of $\mathcal{L}, \mathcal{M}$ gives a vector in both spans.
Sketch. (a) $\mathcal{L} = \mathcal{M} = \mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$: each is independent, but $\mathbf{v}, \mathbf{v}$ is not. (b) The spans share $\mathbf{v}$; conjecture that a common nonzero vector is the only obstruction. (c) If $\mathbf{x} = \sum a_i \mathbf{u}_i = \sum b_j \mathbf{w}_j$, then $a, -b$ is a relation of $\mathcal{L}, \mathcal{M}$, trivial by independence, so $\mathbf{x} = \mathbf{0}$. Conversely a relation $\sum a_i \mathbf{u}_i + \sum b_j \mathbf{w}_j = \mathbf{0}$ gives $\sum a_i \mathbf{u}_i = \sum(-b_j)\mathbf{w}_j$ in both spans, hence $\mathbf{0}$, and independence of each list kills the coefficients.

(a) Let V be any nonzero vector space, $\mathbf{v} \neq \mathbf{0}$, and $\mathcal{L} = \mathcal{M} = \mathbf{v}$. Each list is independent by Proposition 1.5.15(b), but $\mathcal{L}, \mathcal{M} = \mathbf{v}, \mathbf{v}$ has a repeated entry and is dependent by Proposition 1.5.15(c). No counterexample is smaller: lists of length 0 add nothing, and in the zero space every nonempty list is dependent. (The same counterexample settles Exercise 1.5.34(c).)

(b) The two spans are both span($\mathbf{v}$), and they share the nonzero vector $\mathbf{v}$. Any counterexample must be like this: a relation among the concatenation that involves both lists produces a vector that both lists can represent. This suggests that concatenating independent lists can fail only when their spans share a nonzero vector, which is (c).

(c) Write $\mathcal{L} = \mathbf{u}_1, ..., \mathbf{u}_k$ and $\mathcal{M} = \mathbf{w}_1, ..., \mathbf{w}_m$.

(⇒) Suppose $\mathcal{L}, \mathcal{M}$ is independent, and let $\mathbf{x} \in \text{span}(\mathcal{L}) \cap \text{span}(\mathcal{M})$, say $\mathbf{x} = \sum_i a_i \mathbf{u}_i = \sum_j b_j \mathbf{w}_j$. By Lemma 1.3.9, the coefficients $a_1, ..., a_k, -b_1, ..., -b_m$ represent $\mathbf{x} - \mathbf{x} = \mathbf{0}$, so they form a linear relation of $\mathcal{L}, \mathcal{M}$. It is trivial, so every $a_i = 0$ and $\mathbf{x} = \mathbf{0}$. Since $\mathbf{0}$ lies in both spans (Proposition 1.3.17), the intersection is $\{\mathbf{0}\}$.

(⇐) Suppose $\text{span}(\mathcal{L}) \cap \text{span}(\mathcal{M}) = \{\mathbf{0}\}$, and let $\sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{w}_j = \mathbf{0}$. Then

$$\mathbf{x} = \sum_{i=1}^{k} a_i \mathbf{u}_i = \sum_{j=1}^{m} (-b_j)\mathbf{w}_j$$

lies in both spans, so $\mathbf{x} = \mathbf{0}$. Since $\mathcal{L}$ is independent, $\sum_i a_i \mathbf{u}_i = \mathbf{0}$ forces all $a_i = 0$, and since $\mathcal{M}$ is independent, $\sum_j (-b_j)\mathbf{w}_j = \mathbf{0}$ forces all $b_j = 0$. So the relation is trivial, and $\mathcal{L}, \mathcal{M}$ is independent by Theorem 1.5.5.

For two subspaces, the condition $\text{span}(\mathcal{L}) \cap \text{span}(\mathcal{M}) = \{\mathbf{0}\}$ characterizes direct sums (Section 4.4).

Solution to Exercise 1.7.13

Uses. Theorem 1.4.3 (Subspace criterion), Definition 1.2.1 (Vector space)
Techniques. Proving a disjunction (Technique 1.7.4), Try small cases and small fields (Technique 1.2.38)
Hint 1. Assume that $\mathbf{v} + \mathbf{w} \in U$, and show that $\mathbf{v} - \mathbf{w} \notin U$.
Hint 2. If both were in U, so would be their sum. What is it? For (b), try the smallest possible V and U.
Sketch. If $\mathbf{v} + \mathbf{w} \in U$ and also $\mathbf{v} - \mathbf{w} \in U$, then their sum $(1+1)\mathbf{v}$ lies in U, and so does $(1+1)^{-1}(1+1)\mathbf{v} = \mathbf{v}$, a contradiction. Over $\mathbb{F}_2$: $V = \mathbb{F}_2, U = \{0\}, \mathbf{v} = \mathbf{w} = 1$, where $\mathbf{v} + \mathbf{w} = \mathbf{v} - \mathbf{w} = 0 \in U$.

(a) Assume that $\mathbf{v} + \mathbf{w} \in U$; we show that $\mathbf{v} - \mathbf{w} \notin U$. Suppose instead that $\mathbf{v} - \mathbf{w} \in U$. Since U is closed under addition (Theorem 1.4.3), it contains

$$(\mathbf{v} + \mathbf{w}) + (\mathbf{v} - \mathbf{w}) = \mathbf{v} + \mathbf{v} = (1+1)\mathbf{v},$$

using (A1)–(A4) to cancel $\mathbf{w}$, then (A5) and (A8). Since $1 + 1 \neq 0$, closure under scalar multiplication gives $(1+1)^{-1}((1+1)\mathbf{v}) = \mathbf{v} \in U$ by (A6) and (A5), contradicting $\mathbf{v} \notin U$. So $\mathbf{v} - \mathbf{w} \notin U$, and the disjunction holds.

(b) Take $V = \mathbb{F}_2$, regarded as a vector space over itself, $U = \{0\}$, and $\mathbf{v} = \mathbf{w} = 1$. Then $\mathbf{v} \notin U$, but $\mathbf{v} + \mathbf{w} = 1 + 1 = 0 \in U$ and $\mathbf{v} - \mathbf{w} = 0 \in U$. The proof of (a) breaks exactly at the division by $1 + 1$.

Solution to Exercise 1.7.14

Uses. Definition 1.2.1 (Vector space), Proposition 1.2.27 (Uniqueness of the zero vector), Proposition 1.2.32 (The scalar zero), Example 1.2.39 (When does $\mathbf{v} = -\mathbf{v}$ force $\mathbf{v} = \mathbf{0}$?)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. The scalar multiplication is unknown, so look for a consequence of the axioms that involves only the addition. Example 1.2.39 computed $\mathbf{v} + \mathbf{v} = (1+1)\mathbf{v}$.

Hint 2. Split into the cases $1+1=0$ and $1+1\neq 0$ in F. In the second case, consider the vector $(1+1)^{-1}\odot 1$, where $1\in\mathbb{Z}$.
Sketch. Write $e=1+1\in F$. In every vector space, $\mathbf{v}+\mathbf{v}=e\mathbf{v}$. If $e=0$, then $\mathbf{v}+\mathbf{v}=\mathbf{0}$ for all $\mathbf{v}$, but $1+1=2\neq 0$ in $\mathbb{Z}$. If $e\neq 0$, then $\mathbf{x}=e^{-1}\odot 1$ satisfies $\mathbf{x}+\mathbf{x}=e\odot\left(e^{-1}\odot 1\right)=1$, but no integer x has $x+x=1$.

Suppose, for contradiction, that some field F and some scalar multiplication $\odot$ make $\mathbb{Z}$, with its usual addition, a vector space over F. Its zero vector is the integer 0, the unique element with $n+0=n$ for all n. Write $e=1+1\in F$. For every integer n, by (A5) and (A8),

$$n+n=1\odot n+1\odot n=(1+1)\odot n=e\odot n.$$

Case $e=0$. Then $n+n=0\odot n=0$ for every n, by Proposition 1.2.32. But $1+1=2\neq 0$ in $\mathbb{Z}$.

Case $e\neq 0$. Let $x=e^{-1}\odot 1\in\mathbb{Z}$. By the display, (A6), and (A5),

$$x+x=e\odot\left(e^{-1}\odot 1\right)=\left(ee^{-1}\right)\odot 1=1\odot 1=1.$$

But $x+x=2x$ is even for every integer x, so it is not 1.

Both cases are impossible, so no such F and $\odot$ exist. The argument never examined a particular scalar multiplication. It used a consequence of the axioms, $\mathbf{v}+\mathbf{v}=(1+1)\mathbf{v}$, that every candidate must satisfy and that mentions the scalar multiplication only through the field, and it showed that the addition of $\mathbb{Z}$ is incompatible with both possible values of $1+1$.

Solution to Exercise 1.7.15

Uses. Theorem 1.4.25 (The subspaces of F^2), Definition 1.3.10 (Span)
Techniques. Try small cases and small fields (Technique 1.2.38), Finding counterexamples and minimal examples (Technique 1.4.18), Double containment (Technique 1.3.14)
Hint 1. Test the smallest subspace first.
Hint 2. By Theorem 1.4.25, the other subspaces are F^2 and the lines $\operatorname{span}((p,q))$ with $(p,q)\neq\mathbf{0}$. For a line, the equation $qx-py=0$ is a natural guess; prove the equality by double containment, splitting into the cases $p\neq 0$ and $p=0$.
Sketch. False for $\{\mathbf{0}\}$: if $(a,b)=\mathbf{0}$ the solution set is F^2, and otherwise it contains $(-b,a)\neq\mathbf{0}$. True for every other subspace: F^2 is the solution set of $0x+0y=0$, and $\operatorname{span}((p,q))$ is that of $qx-py=0$. Every multiple of (p,q) satisfies the equation, and a solution (x,y) is $(x/p)(p,q)$ if $p\neq 0$, or $(y/q)(p,q)$ if $p=0$.

The claim is false, and the smallest subspace is the counterexample. Let $a,b\in F$ and let S be the solution set of $ax+by=0$. If $a=b=0$, then $S=F^2$. Otherwise $(-b,a)\neq\mathbf{0}$ and $a(-b)+ba=0$, so S contains a nonzero vector. Either way $S\neq\{\mathbf{0}\}$, so $\{\mathbf{0}\}$ is not the solution set of a single equation. (It is the solution set of the two equations $x=0$ and $y=0$.)

Every other subspace is. By Theorem 1.4.25, the subspaces other than $\{\mathbf{0}\}$ are F^2, which is the solution set of $0x+0y=0$, and the lines $L=\operatorname{span}((p,q))$ with $(p,q)\neq\mathbf{0}$. We show that $L=S$ for the equation $qx-py=0$, by double containment.

$L\subseteq S$. A vector of L is (cp,cq) for some $c\in F$, and $q(cp)-p(cq)=0$.

$S\subseteq L$. Let (x,y) satisfy $qx=py$. If $p\neq 0$, then $y=qx/p$, and $(x,y)=(x/p)(p,q)\in L$. If $p=0$, then $q\neq 0$, and $qx=0$ forces $x=0$; then $(x,y)=(0,y)=(y/q)(0,q)=(y/q)(p,q)\in L$.

Problems for Chapter 1

Solution to Problem 1.1

Uses. Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Proposition 1.1.17 (No zero divisors), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Proposition 1.1.13 (Solving $a+x=b$ and $ax=b$), Bézout's identity and the Euclidean algorithm
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. Only multiplicative inverses are in question (Lemma 1.1.21). For a composite $n=rs$, look at $r\cdot s$.
Hint 2. For a prime p and $0<a<p$, Bézout gives $ax+py=1$. For (b), run the Euclidean algorithm on 101 and 17, and then substitute back.

Sketch. (a) $\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime. If $n = rs$ with $1 < r, s < n$, then $rs = 0$ is a product of nonzero elements; if $n = p$ is prime and $0 < a < p$, then $\gcd(a, p) = 1$, and Bézout's $ax + py = 1$ makes $x \bmod p$ an inverse of a. (b) $101 = 5 \cdot 17 + 16$ and $17 = 16 + 1$, so $1 = 6 \cdot 17 - 101$, and $17^{-1} = 6$. Then $17x = 2$, so $x = 12$.

(a) *Statement.* For an integer $n \geq 2$, $\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime (Proposition 1.1.24).

Proof. By Lemma 1.1.21, $\mathbb{Z}/n\mathbb{Z}$ satisfies every field axiom except possibly the existence of multiplicative inverses, so it is a field exactly when every nonzero element has an inverse.

($\Rightarrow$) We prove the contrapositive. If n is not prime, write $n = rs$ with $1 < r, s < n$. Then r and s are nonzero elements of $\mathbb{Z}/n\mathbb{Z}$ with $r \cdot_n s = n \bmod n = 0$. A field has no zero divisors (Proposition 1.1.17), so $\mathbb{Z}/n\mathbb{Z}$ is not a field.

($\Leftarrow$) Let $n = p$ be prime and $a \in \{1, \ldots, p-1\}$. The only positive divisors of p are 1 and p, and $p \nmid a$, so $\gcd(a, p) = 1$. By Bézout's identity, $ax + py = 1$ for some integers x, y. Let $b = x \bmod p$. By Lemma 1.1.21(a),

$$a \cdot_p b = (ax) \bmod p = (1 - py) \bmod p = 1,$$

so b is an inverse of a.

(b) The Bézout proof computes inverses: run the Euclidean algorithm and substitute back. Here

$$101 = 5 \cdot 17 + 16, \quad 17 = 1 \cdot 16 + 1,$$

so

$$1 = 17 - 16 = 17 - (101 - 5 \cdot 17) = 6 \cdot 17 - 101.$$

Hence $17 \cdot 6 = 102 = 101 + 1$, and $17^{-1} = 6$ in $\mathbb{F}_{101}$. By Proposition 1.1.13, $17x + 3 = 5$ holds exactly when $17x = 2$, that is, $x = 6 \cdot 2 = 12$. Check: $17 \cdot 12 + 3 = 207 = 2 \cdot 101 + 5$.

The counting proof of Proposition 1.1.24 shows that 17 has an inverse without producing it; using it to find 17^{-1} would mean trying the candidates one by one.

Solution to Problem 1.2

Uses. Definition 1.2.1 (Vector space), Proposition 1.2.30 (Additive arithmetic), Proposition 1.2.28 (Uniqueness of additive inverses), Proposition 1.2.33 (The zero vector), Proposition 1.2.32 (The scalar zero), Example 1.2.25 (Changing one operation on $\mathbb{R}^2$)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. For (a), it suffices to show $a(-\mathbf{w}) = -(a\mathbf{w})$. Compute $a\mathbf{w} + a(-\mathbf{w})$ with (A7). You will need $a\mathbf{0} = \mathbf{0}$: which of the two proofs of Proposition 1.2.33 avoids (A8)?
Hint 2. For (b), show $(-b)\mathbf{v} = -(b\mathbf{v})$ by computing $b\mathbf{v} + (-b)\mathbf{v}$ with (A8). For (c), look at Example 1.2.25.
Sketch. (a) The first proof of Proposition 1.2.33 uses (A7), (A3), and cancellation, so $a\mathbf{0} = \mathbf{0}$ without (A8). Then $a\mathbf{w} + a(-\mathbf{w}) = a(\mathbf{w} + (-\mathbf{w})) = a\mathbf{0} = \mathbf{0}$, so $a(-\mathbf{w}) = -(a\mathbf{w})$, and (A7) gives the identity. (b) $b\mathbf{v} + (-b)\mathbf{v} = (b + (-b))\mathbf{v} = 0\mathbf{v} = \mathbf{0}$ by (A8) and Proposition 1.2.32, which itself uses (A8); then (A8) again. (c) On $\mathbb{R}^2$ with $a \odot (x, y) = (ax, y)$: $(2 - 1) \odot (0, 1) = (0, 1)$, but $2 \odot (0, 1) - 1 \odot (0, 1) = \mathbf{0}$.

(a) We use only (A1)–(A7) and facts proved from them. Cancellation (Proposition 1.2.30(b)) and uniqueness of negatives (Proposition 1.2.28) use only (A1)–(A4). The first proof of Proposition 1.2.33 uses (A7), (A3), and cancellation, so $a\mathbf{0} = \mathbf{0}$ holds without (A8). Now

$$\begin{aligned} a\mathbf{w} + a(-\mathbf{w}) &= a(\mathbf{w} + (-\mathbf{w})) && \text{(A7)} \\ &= a\mathbf{0} = \mathbf{0} && \text{(A4, then } a\mathbf{0} = \mathbf{0}\text{)}, \end{aligned}$$

so $a(-\mathbf{w})$ is an additive inverse of $a\mathbf{w}$, and $a(-\mathbf{w}) = -(a\mathbf{w})$ by Proposition 1.2.28. Hence, by (A7),

$$a(\mathbf{v} - \mathbf{w}) = a(\mathbf{v} + (-\mathbf{w})) = a\mathbf{v} + a(-\mathbf{w}) = a\mathbf{v} + (-(a\mathbf{w})) = a\mathbf{v} - a\mathbf{w}.$$

(b) First,

$$b\mathbf{v} + (-b)\mathbf{v} = (b + (-b))\mathbf{v} \quad \text{(A8)}$$

$$= 0\mathbf{v} = \mathbf{0} \qquad \text{(@prop:vs-zero-mul)},$$

so $(-b)\mathbf{v} = -(b\mathbf{v})$ by Proposition 1.2.28. Then by (A8),

$$(a-b)\mathbf{v} = (a+(-b))\mathbf{v} = a\mathbf{v} + (-b)\mathbf{v} = a\mathbf{v} - b\mathbf{v}.$$

The proof uses (A8) twice directly, and once more through Proposition 1.2.32, whose proof starts from $(0+0)\mathbf{v} = 0\mathbf{v} + 0\mathbf{v}$. Besides (A8) it uses (A1)–(A4) through Proposition 1.2.28 and cancellation.

(c) By Example 1.2.25(b), $\mathbb{R}^2$ with its usual addition and $a \odot (x, y) = (ax, y)$ satisfies every axiom except (A8). There,

$$(2-1) \odot (0,1) = 1 \odot (0,1) = (0,1),$$

while $2 \odot (0,1) - 1 \odot (0,1) = (0,1) - (0,1) = (0,0)$. So $(a-b) \odot \mathbf{v} \neq a \odot \mathbf{v} - b \odot \mathbf{v}$ for $a = 2$, $b = 1$, $\mathbf{v} = (0,1)$. Every step of (b) that invokes (A8) fails here, and so do the derived facts $0 \odot \mathbf{v} = \mathbf{0}$ and $(-b) \odot \mathbf{v} = -(b \odot \mathbf{v})$: for instance $0 \odot (0,1) = (0,1)$, and $(-1) \odot (0,1) = (0,1) \neq (0,-1)$. Part (a), whose proof avoided (A8), still holds in this structure, as it must.

Solution to Problem 1.3

> *Uses.* Definition 1.5.1 (Linear independence), Definition 1.5.3 (Linear relation), Theorem 1.5.5 (Independence is decided at zero), Lemma 1.3.9 (Arithmetic of linear combinations), Proposition 1.2.34 (Negatives and the scalar -1), Proposition 1.5.15 (Short lists, zeros, and repeats)
> *Techniques.* Contrapositive (Technique 1.5.4), Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* For (a), one direction is the definition applied to $\mathbf{0}$. For the other, two different representations of one vector can be subtracted.
> *Hint 2.* For (b), fix the representation a of $\mathbf{w}$. If c is a linear relation, what does $a + c$ represent?
> *Hint 3.* For (c), compare $(1,0)$ and $(1,0),(2,0)$ in $\mathbb{R}^2$, with $\mathbf{w} = (0,1)$.
> *Sketch.* (a) Independence (every vector of the span has exactly one representation) applied to $\mathbf{0}$ gives the test at zero. Conversely, two different representations of $\mathbf{w}$ subtract to a nontrivial relation. (b) If c is a relation, then $a + c$ represents $\mathbf{w}$, so $a + c = a$ and $c = 0$. (c) Neither: $\mathbf{w} = (0,1)$ is outside the spans of the independent list $(1,0)$ and of the dependent list $(1,0),(2,0)$.

(a) *Statement.* $\mathcal{L}$ is linearly independent if every vector of $\operatorname{span}(\mathcal{L})$ is represented by exactly one linear combination of $\mathcal{L}$ (Definition 1.5.1). The test at zero: $\mathcal{L}$ is independent if and only if $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ implies $a_1 = \cdots = a_k = 0$.

Proof. If $\mathcal{L}$ is independent, then $\mathbf{0} \in \operatorname{span}(\mathcal{L})$ is represented by the trivial relation, and by nothing else, so every relation is trivial. Conversely, we prove the contrapositive: suppose $\mathcal{L}$ is dependent, so that some $\mathbf{w}$ has two different representations, with coefficients a_i and b_i. By Lemma 1.3.9 and $-\mathbf{x} = (-1)\mathbf{x}$ (Proposition 1.2.34),

$$\sum_{i=1}^{k}(a_i - b_i)\mathbf{v}_i = \sum_{i=1}^{k} a_i\mathbf{v}_i - \sum_{i=1}^{k} b_i\mathbf{v}_i = \mathbf{w} - \mathbf{w} = \mathbf{0},$$

and $a_j - b_j \neq 0$ for some j. So the test at zero fails.

(b) Let $a_1, \ldots, a_k$ be the unique representation of $\mathbf{w}$, and let $c_1, \ldots, c_k$ be any linear relation of $\mathcal{L}$. By Lemma 1.3.9, the coefficients $a_i + c_i$ represent $\mathbf{w} + \mathbf{0} = \mathbf{w}$. By uniqueness, $a_i + c_i = a_i$ for every i, so $c_i = 0$. Every relation is trivial, and $\mathcal{L}$ is independent by (a).

So uniqueness at a single vector of the span forces uniqueness everywhere. This is the reason the test can be run at $\mathbf{0}$: any vector of the span would do, and $\mathbf{0}$ is the one whose representation we always know.

(c) Neither. In $\mathbb{R}^2$ let $\mathbf{w} = (0,1)$. The list $(1,0)$ is independent (Proposition 1.5.15(b)), the list $(1,0),(2,0)$ is dependent (Proposition 1.5.15(d)), and $\mathbf{w}$ lies in neither span, since both spans consist of vectors with second coordinate 0. A vector outside the span says something about spanning, not about independence.

Solution to Problem 1.4

Uses. Lemma 1.5.10 (Linear dependence lemma), Theorem 1.5.5 (Independence is decided at zero), Corollary 1.3.20 (Operations that preserve the span)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Start from a nontrivial relation. Solving it for one entry requires that entry's coefficient to be nonzero; the choice of *which* entry decides what is on the other side.
Hint 2. For the deletion statement, Corollary 1.3.20(c) says that appending a vector already in the span does not change the span.
Hint 3. In (c), the spans involved are the first axis, the second axis, and $\mathbb{R}^2$.
Sketch. (a) With j largest, the terms after j vanish, so $\mathbf{v}_j = \sum_{l<j}(-a_l/a_j)\mathbf{v}_l$. If $\mathbf{v}_j$ lies in the span of the earlier entries, it lies in the span of the list without it, so appending it back changes nothing (Corollary 1.3.20(c)), and the result is a reordering of $\mathcal{L}$. (b) With i smallest, $\mathbf{v}_i = \sum_{l>i}(-a_l/a_i)\mathbf{v}_l$, a combination of later entries. (c) Only $j = 3$, and only $i = 2$.

(a) *Statement.* If $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ is linearly dependent, then $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$ for some j, and for every such j, deleting $\mathbf{v}_j$ from $\mathcal{L}$ does not change the span (Lemma 1.5.10).

Proof. By Theorem 1.5.5 there is a relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$ with some $a_l \neq 0$. Let j be the largest index with $a_j \neq 0$. The terms with index above j are $\mathbf{0}$, so $a_1\mathbf{v}_1 + \cdots + a_j\mathbf{v}_j = \mathbf{0}$, and since $a_j \neq 0$,

$$\mathbf{v}_j = \sum_{l=1}^{j-1}\left(-\frac{a_l}{a_j}\right)\mathbf{v}_l \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}),$$

where for $j = 1$ the sum is empty and the statement is $\mathbf{v}_1 = \mathbf{0}$. Now let j be any index with $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$, and let $\mathcal{L}'$ be $\mathcal{L}$ without $\mathbf{v}_j$. Then $\mathbf{v}_j \in \operatorname{span}(\mathcal{L}')$, since $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$ is a sublist of $\mathcal{L}'$ (Corollary 1.3.20(b)). By Corollary 1.3.20(c), $\operatorname{span}(\mathcal{L}', \mathbf{v}_j) = \operatorname{span}(\mathcal{L}')$, and $\mathcal{L}', \mathbf{v}_j$ is a reordering of $\mathcal{L}$, so its span is $\operatorname{span}(\mathcal{L})$ by Corollary 1.3.20(a).

(b) With i the smallest index with $a_i \neq 0$, the terms before i vanish, so $a_i\mathbf{v}_i + a_{i+1}\mathbf{v}_{i+1} + \cdots + a_k\mathbf{v}_k = \mathbf{0}$, and

$$\mathbf{v}_i = \sum_{l=i+1}^{k}\left(-\frac{a_l}{a_i}\right)\mathbf{v}_l \in \operatorname{span}(\mathbf{v}_{i+1}, \ldots, \mathbf{v}_k).$$

So a dependent list also has an entry in the span of the entries *after* it. The extremal choice decides the side: the largest index leaves earlier entries, the smallest leaves later ones.

(c) Write $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3 = (1, 0), (0, 1), (0, 2)$.

Earlier entries. $\mathbf{v}_1 \neq \mathbf{0}$, so $j = 1$ fails. $\operatorname{span}(\mathbf{v}_1)$ is the first axis, which does not contain $\mathbf{v}_2$, so $j = 2$ fails. $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2) = \mathbb{R}^2$ contains $\mathbf{v}_3$, so $j = 3$ works.

Later entries. $\operatorname{span}(\mathbf{v}_2, \mathbf{v}_3)$ is the second axis, which does not contain $\mathbf{v}_1$, so $i = 1$ fails. $\mathbf{v}_2 = (1/2)\mathbf{v}_3$, so $i = 2$ works. $\operatorname{span}(()) = \{\mathbf{0}\}$ and $\mathbf{v}_3 \neq \mathbf{0}$, so $i = 3$ fails.

The two versions of the lemma pick out different redundant entries, here $\mathbf{v}_3$ and $\mathbf{v}_2$. Deleting either one leaves a basis of $\mathbb{R}^2$.

Solution to Problem 1.5

Uses. Theorem 1.4.25 (The subspaces of F^2), Exercise 1.3.28, Definition 1.6.1 (Basis), (1.6.1), Exercise 1.3.37, Proposition 1.5.15 (Short lists, zeros, and repeats), Proposition 1.6.2 (Bases are independent spanning lists)
Hint 1. A nonzero vector (a, b) with $a \neq 0$ lies on the same line as $(1, b/a)$. Inverses in $\mathbb{F}_5$: $2^{-1} = 3$, $3^{-1} = 2$, $4^{-1} = 4$.
Hint 2. For (b), solve $a(1, 2) + b(1, 3) = (x, y)$ for arbitrary (x, y). For (c), a list $\mathbf{u}, \mathbf{v}$ in $\mathbb{F}_5^2$ is a basis exactly when $\mathbf{u} \neq \mathbf{0}$ and $\mathbf{v} \notin \operatorname{span}(\mathbf{u})$.
Sketch. (a) The six lines are $\operatorname{span}((1, c))$ for $c \in \mathbb{F}_5$ and $\operatorname{span}((0, 1))$; $(2, 3) = 2(1, 4)$. (b) The equations $a + b = x$, $2a + 3b = y$ force $b = y - 2x$ and $a = 3x - y$, which work; so $[(x, y)]_{\mathcal{B}} = (3x - y, y - 2x)$ and $[(2, 3)]_{\mathcal{B}} = (3, 4)$. (c) 4 choices of first entry, then $25 - 5 = 20$ choices outside its line: 80.

(a) By Theorem 1.4.25, the lines are the sets $\operatorname{span}(\mathbf{v})$ with $\mathbf{v} \neq \mathbf{0}$, and $\operatorname{span}(\mathbf{v}) = \operatorname{span}(c\mathbf{v})$ for $c \neq 0$ (Exercise 1.3.28(b)). If $\mathbf{v} = (a, b)$ with $a \neq 0$, then $\operatorname{span}(\mathbf{v}) = \operatorname{span}((1, b/a))$; if $a = 0$, then $b \neq 0$ and $\operatorname{span}(\mathbf{v}) =$

$\operatorname{span}((0,1))$. The lines $\operatorname{span}((1,c))$, $c \in \mathbb{F}_5$, are different from each other and from $\operatorname{span}((0,1))$, since the only multiple of $(1,c)$ with first coordinate 1 is $(1,c)$ itself, and $\operatorname{span}((0,1))$ contains no vector with first coordinate 1. So the six lines are

$$\operatorname{span}((1,0)), \quad \operatorname{span}((1,1)), \quad \operatorname{span}((1,2)), \quad \operatorname{span}((1,3)), \quad \operatorname{span}((1,4)), \quad \operatorname{span}((0,1)).$$

For $(2,3)$: $3/2 = 3 \cdot 2^{-1} = 3 \cdot 3 = 9 = 4$, so $(2,3) = 2(1,4)$ lies on $\operatorname{span}((1,4))$.

(b) For $(x,y) \in \mathbb{F}_5^2$, the equation $a(1,2) + b(1,3) = (x,y)$ reads $a + b = x$ and $2a + 3b = y$. Subtracting twice the first equation from the second gives $b = y - 2x$, and then $a = x - b = 3x - y$. Conversely these values satisfy both equations: $a + b = x$, and $2a + 3b = 6x - 2y + 3y - 6x = y$. So every (x,y) has exactly one representation, $\mathcal{B}$ is a basis (Definition 1.6.1), and by (1.6.1),

$$[(x,y)]_{\mathcal{B}} = (3x - y, y - 2x).$$

For $(2,3)$: $3 \cdot 2 - 3 = 3$ and $3 - 4 = -1 = 4$, so $[(2,3)]_{\mathcal{B}} = (3,4)$. Check: $3(1,2) + 4(1,3) = (7,18) = (2,3)$ in $\mathbb{F}_5^2$.

(c) A list $\mathbf{u}, \mathbf{v}$ in $\mathbb{F}_5^2$ with $\mathbf{u} \neq \mathbf{0}$ spans $\mathbb{F}_5^2$ exactly when $\mathbf{v} \notin \operatorname{span}(\mathbf{u})$ (Exercise 1.3.37(b)), and then it is also independent by Proposition 1.5.14, since the list $\mathbf{u}$ is independent (Proposition 1.5.15(b)). So it is a basis exactly when $\mathbf{u} \neq \mathbf{0}$ and $\mathbf{v} \notin \operatorname{span}(\mathbf{u})$ (Proposition 1.6.2). The first entry is one of the 4 nonzero vectors of $\operatorname{span}((1,2))$, and its span is that line, which has 5 elements. So there are $25 - 5 = 20$ choices for the second entry, and $4 \cdot 20 = 80$ bases in all.

Solution to Problem 1.6

> *Uses.* Definition 1.2.17 (Evaluation), Proposition 1.5.24 (Distinct degrees), Proposition 1.6.2 (Bases are independent spanning lists), Proposition 1.4.24 (The sum of two subspaces), Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 1.6.7 (Standard bases)
> *Hint 1.* Write $p = a + bx + cx^2 + dx^3$. Then $p(1) = a + b + c + d$ and $p(-1) = a - b + c - d$. Add and subtract.
> *Hint 2.* For $U + W$, find $1, x, x^2, x^3$ in $U + W$. The vectors $x - 1 \in U$ and $x + 1 \in W$ are a good start. Over $\mathbb{F}_2$, what is -1?
> *Sketch.* (a) $p(1) = p(-1) = 0$ if and only if $a + c = 0$ and $b + d = 0$ (this uses $1 + 1 \neq 0$), so $U \cap W = \operatorname{span}\big(1 - x^2, x - x^3\big)$, a basis by distinct degrees. $U + W$ contains $(x + 1) - (x - 1) = 2$, hence 1, then x, $x^2 = \big(x^2 - 1\big) + 1$, $x^3 = \big(x^3 - 1\big) + 1$. (b) Over $\mathbb{F}_2$, $-1 = 1$, so $U = W = U \cap W = U + W = \operatorname{span}\big(1 + x, 1 + x^2, 1 + x^3\big)$, a proper subspace.

Write $p = a + bx + cx^2 + dx^3$. By Definition 1.2.17, $p(1) = a + b + c + d$ and $p(-1) = a - b + c - d$.

(a) If $a + c = 0$ and $b + d = 0$, then $p(1) = (a + c) + (b + d) = 0$ and $p(-1) = (a + c) - (b + d) = 0$. Conversely, if $p(1) = p(-1) = 0$, then adding and subtracting gives $(1 + 1)(a + c) = 0$ and $(1 + 1)(b + d) = 0$, so $a + c = 0$ and $b + d = 0$ because $1 + 1 \neq 0$ (Proposition 1.1.17). Hence $p \in U \cap W$ exactly when $c = -a$ and $d = -b$, that is,

$$p = a\big(1 - x^2\big) + b\big(x - x^3\big).$$

So $U \cap W = \operatorname{span}\big(1 - x^2, x - x^3\big)$. The two polynomials are nonzero of degrees 2 and 3, so they are independent (Proposition 1.5.24), and they form a basis of $U \cap W$ (Proposition 1.6.2).

For $U + W$: the polynomials $x - 1$, $x^2 - 1$, $x^3 - 1$ vanish at 1 and lie in U, and $x + 1$ vanishes at -1 and lies in W. The sum $U + W$ is a subspace containing U and W (Proposition 1.4.24), so it contains

$$(x + 1) - (x - 1) = 1 + 1,$$

hence $1 = (1 + 1)^{-1}(1 + 1)$, and then $x = (x - 1) + 1$, $x^2 = \big(x^2 - 1\big) + 1$, and $x^3 = \big(x^3 - 1\big) + 1$. These span $F[x]_{\leq 3}$ (Proposition 1.6.7), so $U + W = F[x]_{\leq 3}$ by Proposition 1.4.14(b).

(b) Over $\mathbb{F}_2$, $-1 = 1$, so $p(-1) = p(1)$ for every p, and $U = W$. Hence $U \cap W = U + W = U$. Since $-(b + c + d) = b + c + d$ over $\mathbb{F}_2$, $p \in U$ exactly when $a = b + c + d$, that is,

$$p = b(1 + x) + c\big(1 + x^2\big) + d\big(1 + x^3\big).$$

So $U = \operatorname{span}\big(1+x, 1+x^2, 1+x^3\big)$, and this list is a basis of U by distinct degrees. The subspace $U + W = U$ is proper, since $1 \notin U$. Over $\mathbb{F}_2$, the two conditions are one condition, and the computation in (a) broke exactly where it divided by $1+1$.

Solution to Problem 1.7

> *Uses.* Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero), (1.6.1), the addition and double-angle formulas
> *Hint 1.* For independence, evaluate a relation $a + b\cos t + c\sin t = 0$ at $t = 0$, π, and $\pi/2$.
> *Hint 2.* For (b), use $\cos(s+u) = \cos s\cos u - \sin s\sin u$, $\cos t = 1 - 2\sin^2(t/2)$, and $\sin t = 2\sin(t/2)\cos(t/2)$. For (c), the same three evaluations force the coefficients; test a fourth point.
> *Sketch.* (a) The list spans V by definition; evaluating at 0, π, $\pi/2$ gives $a+b = a-b = a+c = 0$. (b) $\big(0, 1/2, -\sqrt{3}/2\big)$, $(1/2, -1/2, 0)$, and $(1, 0, 1)$. (c) No: if $\cos^2 t = a + b\cos t + c\sin t$, the points 0, π, $\pi/2$ force $a = 1$, $b = 0$, $c = -1$, and $t = -\pi/2$ gives $0 = 2$.

(a) The list spans V by definition. Suppose $a + b\cos t + c\sin t = 0$ for all t. At $t = 0$ this gives $a + b = 0$, at $t = \pi$ it gives $a - b = 0$, so $a = b = 0$, and at $t = \pi/2$ it gives $a + c = 0$, so $c = 0$. The list is independent (Theorem 1.5.5), hence a basis of V (Proposition 1.6.2).

(b) By (1.6.1), it suffices to write each function as a combination of $1, \cos, \sin$, valid for every t.

- $\cos(t+\pi/3) = \cos(\pi/3)\cos t - \sin(\pi/3)\sin t = (1/2)\cos t - \big(\sqrt{3}/2\big)\sin t$, with coordinates $\big(0, 1/2, -\sqrt{3}/2\big)$.
- $\cos t = 1 - 2\sin^2(t/2)$, so $\sin^2(t/2) = 1/2 - (1/2)\cos t$, with coordinates $(1/2, -1/2, 0)$.
- $(\cos(t/2) + \sin(t/2))^2 = \cos^2(t/2) + \sin^2(t/2) + 2\sin(t/2)\cos(t/2) = 1 + \sin t$, with coordinates $(1, 0, 1)$.

(c) No. Suppose $\cos^2 t = a + b\cos t + c\sin t$ for all t. At $t = 0$ and $t = \pi$ we get $1 = a + b$ and $1 = a - b$, so $a = 1$ and $b = 0$. At $t = \pi/2$ we get $0 = a + c$, so $c = -1$. So the only candidate is $1 - \sin t$. But at $t = -\pi/2$, $\cos^2 t = 0$ while $1 - \sin t = 2$. Hence $t \mapsto \cos^2 t$ is not in V. Three evaluations determined the only possible coefficients, and a fourth refuted them.

Solution to Problem 1.8

> *Uses.* Definition 1.1.32 (Subfield), Proposition 1.2.19 (Restriction of scalars), Theorem 1.4.3 (Subspace criterion), Definition 1.2.4 (The space F^n), Definition 1.1.29 (Complex numbers)
> *Hint 1.* Closure of K^n under scalars from K comes from closure of K under products. For the failure over F, pick $c \in F$ outside K.
> *Hint 2.* For (b), take a nonzero $\mathbf{v} \in U$ and a coordinate $v_i \neq 0$. Which multiples of $\mathbf{v}$ lie in K^n?
> *Hint 3.* For (c), check the subspace criterion directly. In $\mathbb{C}^2$, compare $\operatorname{span}((1,i))$ and $\operatorname{span}((1,1))$.
> *Sketch.* (a) K^n contains $\mathbf{0}$ and is closed under sums and K-multiples coordinatewise; but $c\mathbf{e}_1 \notin K^n$ for $c \in F \setminus K$. (b) If $\mathbf{v} \in U$ is nonzero with $v_i \neq 0$, then $\big(cv_i^{-1}\big)\mathbf{v} \in U \subseteq K^n$ has i-th coordinate c, so every $c \in F$ lies in K. (c) Sums and K-multiples of vectors in $U \cap K^n$ stay in both sets. $\operatorname{span}((1,i)) \cap \mathbb{R}^2 = \{\mathbf{0}\}$, while $\operatorname{span}((1,1)) \cap \mathbb{R}^2$ contains $(1,1)$.

(a) K^n contains $\mathbf{0}$, since $0 \in K$. For $\mathbf{x}, \mathbf{y} \in K^n$ and $a \in K$, the coordinates $x_i + y_i$ and ax_i lie in K, because K is closed under the operations of F (Definition 1.1.32). So K^n is a subspace of the K-vector space F^n by Theorem 1.4.3. Over F it is not closed under scalar multiplication: choose $c \in F$ with $c \notin K$; then $\mathbf{e}_1 \in K^n$, but $c\mathbf{e}_1 = (c, 0, \ldots, 0) \notin K^n$.

(b) $\{\mathbf{0}\}$ is such a subspace. Let U be a subspace of the F-vector space F^n with $U \subseteq K^n$, and suppose for contradiction that U contains some $\mathbf{v} \neq \mathbf{0}$. Choose i with $v_i \neq 0$. For any $c \in F$, the vector $\big(cv_i^{-1}\big)\mathbf{v}$ lies in U, hence in K^n, and its i-th coordinate is $cv_i^{-1}v_i = c$. So $c \in K$ for every $c \in F$, that is, $F = K$, a contradiction.

(c) $U \cap K^n$ contains $\mathbf{0}$. Let $\mathbf{x}, \mathbf{y} \in U \cap K^n$ and $a \in K$. Then $\mathbf{x} + \mathbf{y} \in U$ and $a\mathbf{x} \in U$, because U is closed under sums and under multiples by scalars of F, and $a \in K \subseteq F$. Also $\mathbf{x} + \mathbf{y} \in K^n$ and $a\mathbf{x} \in K^n$, by the computation in (a). So $U \cap K^n$ is a subspace of the K-vector space K^n by Theorem 1.4.3.

Now let $F = \mathbb{C}$, $K = \mathbb{R}$, $n = 2$. For $U = \operatorname{span}((1,i))$, a vector $c(1,i) = (c, ci)$ lies in $\mathbb{R}^2$ only if $c \in \mathbb{R}$ and $ci \in \mathbb{R}$. Writing $ci = 0 + ci$ (Definition 1.1.29), the second condition forces $c = 0$. So $U \cap \mathbb{R}^2 = \{\mathbf{0}\}$, although U is a line in $\mathbb{C}^2$. For $U = \operatorname{span}((1,1))$, the intersection $U \cap \mathbb{R}^2$ contains $(1,1)$; in fact it is $\{(c,c) \mid c \in \mathbb{R}\}$, the real line through $(1,1)$.

By (b), $U \cap \mathbb{R}^2$ is never all of U unless $U = \{\mathbf{0}\}$.

Solution to Problem 1.9

> *Uses.* Proposition 1.2.22 (Transport of structure), Proposition 1.2.19 (Restriction of scalars), Proposition 1.5.15 (Short lists, zeros, and repeats), Theorem 1.5.5 (Independence is decided at zero), unique factorization of positive integers into primes
> *Hint 1.* The zero vector satisfies $x \oplus \mathbf{0} = x$, that is, $x \cdot \mathbf{0} = x$. A linear combination $a \odot 2 \oplus b \odot 3$ is the real number $2^a 3^b$.
> *Hint 2.* Over $\mathbb{Q}$, a relation reads $2^a 3^b = 1$ with a, b rational. Clear denominators by raising to a suitable integer power, and use unique factorization.
> *Sketch.* (a) The zero vector is 1, so $1, 2$ is dependent. $4 = 2 \odot 2$ and $3 = (\log_2 3) \odot 2$, so $2, 4$ and $2, 3$ are dependent over $\mathbb{R}$. (b) If $2^{m/N} 3^{n/N} = 1$ with integers m, n and $N \geq 1$, then $2^m 3^n = 1$, so $m = n = 0$ by unique factorization. $2 \oplus 3 \oplus (-1) \odot 6 = 1$ and $2 \odot 2 \oplus (-1) \odot 4 = 1$. (c) $5 = 2^a 3^b$ with rational a, b would give $5^N = 2^m 3^n$ after raising to the power N.

(a) The zero vector is 1, since $x \oplus 1 = x \cdot 1 = x$ for all $x \in P$. So $1, 2$ is dependent: it contains the zero vector (Proposition 1.5.15(c)). Next, $2 \odot 2 = 2^2 = 4$, so 4 is a scalar multiple of 2, and $2, 4$ is dependent (Proposition 1.5.15(d)). Finally, $(\log_2 3) \odot 2 = 2^{\log_2 3} = 3$, so $2, 3$ is dependent as well. In fact any two vectors x, y of P are dependent over $\mathbb{R}$: if $x = 1$, the list contains the zero vector, and if $x \neq 1$, then $y = (\ln y / \ln x) \odot x$ is a multiple of x.

(b) A linear combination over $\mathbb{Q}$ represents $a \odot 2 \oplus b \odot 3 = 2^a 3^b$. Suppose $2^a 3^b = 1$ with $a, b \in \mathbb{Q}$. Write $a = m/N$ and $b = n/N$ with integers m, n and $N \geq 1$. Raising to the power N gives $2^m 3^n = 1$, that is,

$$2^{m^+} 3^{n^+} = 2^{m^-} 3^{n^-},$$

where $m^+ = \max(m, 0)$ and $m^- = \max(-m, 0)$, and similarly for n. Both sides are positive integers, so by unique factorization the exponents of 2 agree and the exponents of 3 agree: $m^+ = m^-$ and $n^+ = n^-$. One of m^+, m^- is always 0, so $m = 0$, and likewise $n = 0$. Hence $a = b = 0$, and $2, 3$ is independent over $\mathbb{Q}$ by Theorem 1.5.5.

On the other hand, $1 \odot 2 \oplus 1 \odot 3 \oplus (-1) \odot 6 = 2 \cdot 3 \cdot 6^{-1} = 1$, the zero vector, so $2, 3, 6$ is dependent over $\mathbb{Q}$. And $2 \odot 2 \oplus (-1) \odot 4 = 4 \cdot 4^{-1} = 1$, so $2, 4$ is dependent over $\mathbb{Q}$ too.

(c) Suppose $5 = 2^a 3^b$ with $a = m/N$, $b = n/N$ as before. Raising to the power N gives $5^N = 2^m 3^n$, so $5^N 2^{m^-} 3^{n^-} = 2^{m^+} 3^{n^+}$. The prime 5 divides the left side and not the right side, contradicting unique factorization. So $5 \notin \operatorname{span}(2, 3)$ over $\mathbb{Q}$.

In this structure 1 is the zero vector, so "a list containing 1" is the analogue of a list containing $\mathbf{0}$. Under the bijection $\ln : P \to \mathbb{R}$ the problem becomes a statement about $\ln 2$, $\ln 3$, and $\ln 5$ over $\mathbb{Q}$, which is Exercise 1.5.39.

Solution to Problem 1.10

> *Uses.* Proposition 1.5.15 (Short lists, zeros, and repeats), Proposition 1.5.14 (Appending a vector), Corollary 1.5.17 (Sublists), Proposition 1.4.24 (The sum of two subspaces), Proposition 1.4.14 (The span is the smallest subspace containing a list), Example 1.6.5 ($\mathbb{C}$ over $\mathbb{R}$ and over $\mathbb{C}$), Exercise 1.5.8
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* For (a), use Proposition 1.5.15(d): if one of $\mathbf{u}, \mathbf{w}$ were a multiple of the other, where would it lie?
> *Hint 2.* Test (b) over $\mathbb{F}_2$. For (c), treat independent and dependent $\mathcal{L}$ separately. For (d), (e), and (f), try $V = \mathbb{C}$, a list containing $\mathbf{0}$, and the subspace $U + W$.
> *Sketch.* (a) True: $\mathbf{u} = c\mathbf{w}$ would put $\mathbf{u}$ in W, and $\mathbf{w} = c\mathbf{u}$ would put $\mathbf{w}$ in U. (b) False over $\mathbb{F}_2$: the axes of $\mathbb{F}_2^2$ with $\mathbf{u} = \mathbf{e}_1$, $\mathbf{w} = \mathbf{e}_2$ give $\mathbf{u} + \mathbf{w} = \mathbf{u} - \mathbf{w}$. (c) True: the set is $\operatorname{span}(\mathcal{L})$ if $\mathcal{L}$ is independent, and V otherwise. (d) False: 1 spans $\mathbb{C}$ over $\mathbb{C}$, not over $\mathbb{R}$. (e) False: $\mathcal{L} = \mathbf{0}$. (f) True: $U + W$ is a subspace containing the entries.

(a) True. By Proposition 1.5.15(d), if $\mathbf{u}, \mathbf{w}$ were dependent, one would be a multiple of the other. If $\mathbf{u} = c\mathbf{w}$, then $\mathbf{u} \in W$, since W is closed under scalar multiplication; if $\mathbf{w} = c\mathbf{u}$, then $\mathbf{w} \in U$. Both contradict the hypotheses.

(b) False. Over $\mathbb{F}_2$, let $V = \mathbb{F}_2^2$, $U = \operatorname{span}(\mathbf{e}_1)$, $W = \operatorname{span}(\mathbf{e}_2)$, $\mathbf{u} = \mathbf{e}_1$, $\mathbf{w} = \mathbf{e}_2$. The hypotheses hold, but $\mathbf{u} - \mathbf{w} = \mathbf{u} + \mathbf{w}$ because $-1 = 1$, so the list repeats an entry and is dependent (Proposition 1.5.15(c)). (If $1 + 1 \neq 0$, the statement is true, by (a) and Exercise 1.5.8.)

(c) True. If $\mathcal{L}$ is independent, then by Proposition 1.5.14, $\mathcal{L}, \mathbf{v}$ is dependent exactly when $\mathbf{v} \in \operatorname{span}(\mathcal{L})$, so the set is $\operatorname{span}(\mathcal{L})$, a subspace (Proposition 1.4.14). If $\mathcal{L}$ is dependent, then $\mathcal{L}, \mathbf{v}$ has the dependent sublist $\mathcal{L}$ for every $\mathbf{v}$, so it is dependent (Corollary 1.5.17), and the set is V.

(d) False. The list 1 spans $\mathbb{C}$ over $\mathbb{C}$, but over $\mathbb{R}$ its span is $\mathbb{R} \neq \mathbb{C}$ (Example 1.6.5).

(e) False. For $\mathcal{L} = \mathbf{0}$, the list of length one, $\operatorname{span}(\mathcal{L}) = \{\mathbf{0}\}$, so $\operatorname{span}(\mathcal{L}) \cap U = \{\mathbf{0}\}$ for every U, but $\mathcal{L}$ is dependent (Proposition 1.5.15(b)).

(f) True. $U + W$ is a subspace containing U and W (Proposition 1.4.24), so it contains every entry of $\mathcal{L}$, and hence $\operatorname{span}(\mathcal{L})$ by Proposition 1.4.14(b).

Solution to Problem 1.11

Uses. Theorem 1.6.10 (Every spanning list contains a basis), Corollary 1.5.13 (Independence, one entry at a time), Exercise 1.3.36, Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. Which entries come before $\mathbf{w}_j$ in the concatenation? Try $U = \operatorname{span}(\mathbf{e}_1)$ and $W = \mathbb{R}^2$ with $\mathcal{M} = \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$.
Hint 2. For (b), the entries of $\mathcal{L}$ come first, and $\mathcal{L}$ is independent. For (c), write $\mathbf{w}_j$ as a combination of the earlier entries and move the $\mathbf{w}$-terms to the left.
Sketch. (a) The entries before $\mathbf{w}_j$ include $\mathbf{w}_1, \ldots, \mathbf{w}_{j-1}$, whose span need not lie in U. With $\mathcal{L} = \mathbf{e}_1$ and $\mathcal{M} = \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$ in $\mathbb{R}^2$, sifting deletes $\mathbf{e}_1 + \mathbf{e}_2 \notin U$. (b) The first k entries form the independent list $\mathcal{L}$, so none lies in the span of earlier ones; the kept entries are independent and span $\operatorname{span}(\mathcal{L}, \mathcal{M}) = U + W$. (c) $\mathbf{w}_j = \sum a_i \mathbf{u}_i + \sum_{l<j} b_l \mathbf{w}_l$ gives $\mathbf{w}_j - \mathbf{y} = \sum a_i \mathbf{u}_i \in U \cap W$ with $\mathbf{y} = \sum_{l<j} b_l \mathbf{w}_l$, and it is nonzero because $\mathcal{M}$ is independent.

(a) The error is "these are the entries of $\mathcal{L}$". The entries before $\mathbf{w}_j$ in $\mathcal{L}, \mathcal{M}$ are $\mathbf{u}_1, \ldots, \mathbf{u}_k$ *and* $\mathbf{w}_1, \ldots, \mathbf{w}_{j-1}$, and the span of these need not lie in U. For a counterexample, take $V = \mathbb{R}^2$, $U = \operatorname{span}(\mathbf{e}_1)$ with basis $\mathcal{L} = \mathbf{e}_1$, and $W = \mathbb{R}^2$ with basis $\mathcal{M} = \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$. Sifting $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$ keeps $\mathbf{e}_1$ (it is nonzero), keeps $\mathbf{e}_2$ (it is not a multiple of $\mathbf{e}_1$), and deletes $\mathbf{e}_1 + \mathbf{e}_2 \in \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$. But $\mathbf{e}_1 + \mathbf{e}_2 \notin U$, so the deleted entry is not in $U \cap W = U$.

(b) For $j \leq k$, the entry $\mathbf{u}_j$ is preceded only by $\mathbf{u}_1, \ldots, \mathbf{u}_{j-1}$. Since $\mathcal{L}$ is independent, $\mathbf{u}_j \notin \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_{j-1})$ by Corollary 1.5.13, so $\mathbf{u}_j$ is kept. By Theorem 1.6.10 (third proof), the kept entries form an independent list with the same span as $\mathcal{L}, \mathcal{M}$, which is $\operatorname{span}(\mathcal{L}) + \operatorname{span}(\mathcal{M}) = U + W$ by Exercise 1.3.36. So they form a basis of $U + W$ (Proposition 1.6.2).

(c) If $\mathbf{w}_j$ is deleted, then $\mathbf{w}_j \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{w}_1, \ldots, \mathbf{w}_{j-1})$, say

$$\mathbf{w}_j = \sum_{i=1}^{k} a_i \mathbf{u}_i + \sum_{l=1}^{j-1} b_l \mathbf{w}_l.$$

Let $\mathbf{y} = \sum_{l<j} b_l \mathbf{w}_l$. Then $\mathbf{w}_j - \mathbf{y} = \sum_i a_i \mathbf{u}_i$ lies in U, and it lies in W because $\mathbf{w}_j$ and $\mathbf{y}$ do. It is nonzero: otherwise $\mathbf{w}_j - \sum_{l<j} b_l \mathbf{w}_l = \mathbf{0}$ would be a nontrivial relation of $\mathcal{M}$ (the coefficient of $\mathbf{w}_j$ is 1), contradicting the independence of $\mathcal{M}$.

So each deleted entry produces a nonzero vector of $U \cap W$, though not necessarily the entry itself. Showing that these vectors form a basis of $U \cap W$ gives one route to the formula of Section 4.4 relating the sizes of bases of $U, W, U + W$, and $U \cap W$.

Solution to Problem 1.12

Uses. Theorem 1.5.5 (Independence is decided at zero), Example 1.5.19 (The same vectors over two fields), Definition 1.1.32 (Subfield), Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 1.1.17 (No zero divisors)
Hint 1. First, $1, t$ is independent over $\mathbb{Q}$ because $t \notin \mathbb{Q}$. Given $a + bt + ct^2 = 0$, multiply by t (using $t^3 = 2$) and combine the two equations to eliminate t^2.

Hint 2. Eliminating t^2 leaves $\big(2c^2 - ab\big) + \big(ac - b^2\big)t = 0$, so $ab = 2c^2$ and $b^2 = ac$. If $c \neq 0$, compute b^3.
Hint 3. For (c), expand with $t^3 = 2$ and $t^4 = 2t$. For inverses, show that $\alpha \neq 0$ forces $\alpha\beta \neq 0$; if $\alpha\beta = 0$ then $\beta = 0$, and (a) turns this into equations like those in the previous hint.
Sketch. (a) From $a + bt + ct^2 = 0$ and $2c + at + bt^2 = 0$, eliminating t^2 gives $\big(2c^2 - ab\big) + \big(ac - b^2\big)t = 0$, so $ab = 2c^2$ and $b^2 = ac$. Then $b^3 = abc = 2c^3$, so $c = 0$ (else $(b/c)^3 = 2$), then $b = 0$, $a = 0$. (b) Expand with $t^3 = 2$. (c) Expanding, the coefficients of t and t^2 cancel. If $\alpha \neq 0$ and $N = \alpha\beta = 0$, then $\beta = 0$, so $a^2 = 2bc$, $ab = 2c^2$, $b^2 = ac$, which force $a = b = c = 0$ as in (a). So $\alpha^{-1} = \beta/N \in K$.

Throughout, $t^3 = 2$ and $t^4 = 2t$. Since $t \notin \mathbb{Q}$, the list $1, t$ is independent over $\mathbb{Q}$: if $q + rt = 0$ with $r \neq 0$, then $t = -q/r \in \mathbb{Q}$; so $r = 0$, and then $q = 0$ (as in Example 1.5.19(b)).

(a) Suppose $a + bt + ct^2 = 0$ with $a, b, c \in \mathbb{Q}$. Multiplying by t gives $2c + at + bt^2 = 0$. Now c times the second equation minus b times the first eliminates t^2:

$$c\big(2c + at + bt^2\big) - b\big(a + bt + ct^2\big) = \big(2c^2 - ab\big) + \big(ac - b^2\big)t = 0.$$

By independence of $1, t$, we get $ab = 2c^2$ and $b^2 = ac$. Suppose $c \neq 0$. Then $b^3 = b \cdot b^2 = abc = (ab)c = 2c^3$, so $(b/c)^3 = 2$ with $b/c \in \mathbb{Q}$, which is impossible. So $c = 0$. Then $b^2 = ac = 0$ gives $b = 0$, and the original equation gives $a = 0$. By Theorem 1.5.5, $1, t, t^2$ is independent over $\mathbb{Q}$.

(b) For $\alpha = a + bt + ct^2$ and $\alpha' = a' + b't + c't^2$ in K, expanding and using $t^3 = 2$, $t^4 = 2t$,

$$\alpha\alpha' = (aa' + 2bc' + 2cb') + (ab' + ba' + 2cc')t + (ac' + bb' + ca')t^2 \in K.$$

(c) Write $\beta = A + Bt + Ct^2$ with $A = a^2 - 2bc$, $B = 2c^2 - ab$, $C = b^2 - ac$. By the formula in (b), the coefficients of $\alpha\beta$ are

$$\begin{aligned} aA + 2bC + 2cB &= a^3 - 2abc + 2b^3 - 2abc + 4c^3 - 2abc = a^3 + 2b^3 + 4c^3 - 6abc, \\ aB + bA + 2cC &= 2ac^2 - a^2b + a^2b - 2b^2c + 2b^2c - 2ac^2 = 0, \\ aC + bB + cA &= ab^2 - a^2c + 2bc^2 - ab^2 + a^2c - 2bc^2 = 0. \end{aligned}$$

So $\alpha\beta = N$, where $N = a^3 + 2b^3 + 4c^3 - 6abc \in \mathbb{Q}$.

Now K contains 0 and 1, and it is closed under addition and negation because it is a span, hence a subspace of the $\mathbb{Q}$-vector space $\mathbb{R}$ (Proposition 1.4.14). It is closed under multiplication by (b). For inverses, let $\alpha \in K$ be nonzero. We claim $N \neq 0$. If $N = 0$, then $\alpha\beta = 0$ with $\alpha \neq 0$, so $\beta = 0$ (Proposition 1.1.17), and by (a) all its coefficients vanish:

$$a^2 = 2bc, \quad ab = 2c^2, \quad b^2 = ac.$$

The last two are the equations of (a), which force $c = 0$ and $b = 0$, and then $a^2 = 0$ gives $a = 0$. So $\alpha = 0$, a contradiction. Hence $N \neq 0$, and

$$\alpha^{-1} = N^{-1}\beta = N^{-1}A + N^{-1}Bt + N^{-1}Ct^2 \in K.$$

By Definition 1.1.32, K is a subfield of $\mathbb{R}$.

For instance, $(1 + t)^{-1}$: here $a = b = 1$, $c = 0$, so $N = 1 + 2 = 3$ and $\beta = 1 - t + t^2$; indeed $(1 + t)\big(1 - t + t^2\big) = 1 + t^3 = 3$.

Solution to Problem 1.13

Uses. Exercise 1.5.43, Proposition 1.5.14 (Appending a vector), Proposition 1.4.14 (The span is the smallest subspace containing a list), Exercise 1.3.28, Proposition 1.5.15 (Short lists, zeros, and repeats)
Hint 1. For (a), imitate the proof of Theorem 1.4.25: pick vectors of U one at a time, each outside the span of the previous ones. Three independent vectors span q^3 elements. The four kinds have different sizes.
Hint 2. Lines: each nonzero vector lies on exactly one line, and each line has $q - 1$ nonzero vectors.
Hint 3. Planes: count independent lists of length 2 in F^3 in two ways. Each spans exactly one plane, and each plane contains $\big(q^2 - 1\big)\big(q^2 - q\big)$ of them, all spanning it.

Sketch. (a) For $U \neq \{\mathbf{0}\}$, choose $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{w} \in U \setminus \operatorname{span}(\mathbf{v})$ if possible, then $\mathbf{x} \in U \setminus \operatorname{span}(\mathbf{v}, \mathbf{w})$ if possible; the lists stay independent (Proposition 1.5.14), and $\operatorname{span}(\mathbf{v}, \mathbf{w}, \mathbf{x})$ has q^3 elements, so it is F^3. Sizes $1 < q < q^2 < q^3$ separate the kinds. (b) Lines: $(q^3-1)/(q-1) = q^2+q+1$. Planes: $(q^3-1)(q^3-q)/((q^2-1)(q^2-q)) = q^2+q+1$. Total $2q^2+2q+4$, which is 16 for $q = 2$.

(a) The four kinds are subspaces, since spans are (Proposition 1.4.14). Let U be a subspace of F^3 other than $\{\mathbf{0}\}$, and choose $\mathbf{v} \in U$ with $\mathbf{v} \neq \mathbf{0}$; then $\operatorname{span}(\mathbf{v}) \subseteq U$ by Proposition 1.4.14(b). If $U = \operatorname{span}(\mathbf{v})$, it is a line. Otherwise choose $\mathbf{w} \in U$ with $\mathbf{w} \notin \operatorname{span}(\mathbf{v})$. The list $\mathbf{v}$ is independent (Proposition 1.5.15(b)), so $\mathbf{v}, \mathbf{w}$ is independent by Proposition 1.5.14, and $\operatorname{span}(\mathbf{v}, \mathbf{w}) \subseteq U$. If equality holds, U is a plane. Otherwise choose $\mathbf{x} \in U$ with $\mathbf{x} \notin \operatorname{span}(\mathbf{v}, \mathbf{w})$. Then $\mathbf{v}, \mathbf{w}, \mathbf{x}$ is independent by Proposition 1.5.14, so its span has q^3 elements (Exercise 1.5.43(a)). That span is contained in F^3, which also has q^3 elements, so it equals F^3, and $F^3 \subseteq U$. So U is one of the four kinds.

By Exercise 1.5.43(a), a line has q elements and a plane has q^2; also $|\{\mathbf{0}\}| = 1$ and $|F^3| = q^3$. Since $q \geq 2$, the numbers $1 < q < q^2 < q^3$ are different, so no subspace is of two kinds.

(b) *Lines.* Every nonzero vector $\mathbf{v}$ lies on the line $\operatorname{span}(\mathbf{v})$, and on no other: if $\mathbf{v} \in \operatorname{span}(\mathbf{u})$ with $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{v} = c\mathbf{u}$ with $c \neq 0$, so $\operatorname{span}(\mathbf{v}) = \operatorname{span}(\mathbf{u})$ (Exercise 1.3.28(b)). So the lines split the $q^3 - 1$ nonzero vectors of F^3 into disjoint groups, each consisting of the $q - 1$ nonzero vectors of one line. Hence there are

$$\frac{q^3-1}{q-1} = q^2+q+1$$

lines.

Planes. We count the independent lists $\mathbf{v}, \mathbf{w}$ of length 2 in F^3 in two ways. By Exercise 1.5.43(b), there are $(q^3-1)(q^3-q)$ of them. On the other hand, each of them spans exactly one plane, namely $\operatorname{span}(\mathbf{v}, \mathbf{w})$. Fix a plane P. An independent list $\mathbf{v}, \mathbf{w}$ with both entries in P has a span with q^2 elements contained in P, which has q^2 elements, so it spans P. The number of such lists is $(q^2-1)(q^2-q)$: there are $q^2 - 1$ choices of $\mathbf{v} \in P$ with $\mathbf{v} \neq \mathbf{0}$, and then, by Proposition 1.5.14, the choices for $\mathbf{w}$ are the $q^2 - q$ vectors of P outside $\operatorname{span}(\mathbf{v})$. So each plane is spanned by exactly $(q^2-1)(q^2-q)$ independent lists, and the number of planes is

$$\frac{(q^3-1)(q^3-q)}{(q^2-1)(q^2-q)} = \frac{(q^3-1)q(q^2-1)}{(q^2-1)q(q-1)} = \frac{q^3-1}{q-1} = q^2+q+1.$$

All subspaces. $1 + (q^2+q+1) + (q^2+q+1) + 1 = 2q^2+2q+4$. For $q = 2$ this is 16: one zero subspace, seven lines with 2 elements each, seven planes with 4 elements each, and $\mathbb{F}_2^3$ itself.

Over a finite field, counting elements did the work that dimension does in general: a subspace containing an independent list of length 3 is all of F^3 because it is too big to be anything else. That lines and planes come in equal numbers is not an accident; it is explained by duality (Section 13.1).

Solution to Problem 1.14

Uses. Proposition 1.2.30 (Additive arithmetic), Theorem 1.4.3 (Subspace criterion), Proposition 1.4.14 (The span is the smallest subspace containing a list), Example 1.4.8 (One equation in F^n)
Hint 1. Pick $\mathbf{v} \notin U$, and for each scalar a consider the set $a\mathbf{v} + U = \{a\mathbf{v} + \mathbf{u} \mid \mathbf{u} \in U\}$.
Hint 2. These q sets each have $|U|$ elements. Show that they are pairwise disjoint.
Sketch. (a) For $\mathbf{v} \notin U$, the q sets $a\mathbf{v} + U$ have $|U|$ elements each and are disjoint: $a\mathbf{v} + \mathbf{u} = b\mathbf{v} + \mathbf{u}'$ with $a \neq b$ would give $\mathbf{v} = (a-b)^{-1}(\mathbf{u}' - \mathbf{u}) \in U$. So $q|U| \leq q^n$. (b) $\operatorname{span}(S)$ is a subspace with more than q^{n-1} elements, so it is not proper. (c) The subspace $x_1 = 0$.

(a) Since U is proper, choose $\mathbf{v} \in F^n$ with $\mathbf{v} \notin U$. For $a \in F$, let $a\mathbf{v} + U = \{a\mathbf{v} + \mathbf{u} \mid \mathbf{u} \in U\}$. The map $\mathbf{u} \mapsto a\mathbf{v} + \mathbf{u}$ from U to $a\mathbf{v} + U$ is surjective by definition and injective by cancellation (Proposition 1.2.30(b)), so $a\mathbf{v} + U$ has exactly $|U|$ elements.

The q sets $a\mathbf{v}+U$, $a\in F$, are pairwise disjoint. Suppose $a\mathbf{v}+\mathbf{u}=b\mathbf{v}+\mathbf{u}'$ with $\mathbf{u},\mathbf{u}'\in U$ and $a\neq b$. Then $(a-b)\mathbf{v}=\mathbf{u}'-\mathbf{u}\in U$, and since $a-b\neq 0$, $\mathbf{v}=(a-b)^{-1}(\mathbf{u}'-\mathbf{u})\in U$ by closure under scalar multiplication (Theorem 1.4.3), a contradiction.

So F^n contains q disjoint sets of $|U|$ elements each, and $q|U|\le |F^n|=q^n$. Hence $|U|\le q^{n-1}$.

(b) Let $\mathcal{L}$ be a list whose entries run through the elements of S. By Proposition 1.4.14(a), $\operatorname{span}(\mathcal{L})$ is a subspace of F^n containing every element of S, so it has more than q^{n-1} elements. By (a) it is not a proper subspace, so $\operatorname{span}(\mathcal{L})=F^n$.

(c) Let $S=\{\mathbf{x}\in F^n \mid x_1=0\}$. It is a subspace (Example 1.4.8), so the span of any list running through S is S itself (Proposition 1.4.14), and $S\neq F^n$ since $\mathbf{e}_1\notin S$. Its elements are determined by the free coordinates $x_2,\dots,x_n$, so $|S|=q^{n-1}$.

So a subset of F^n that contains more than a $1/q$ fraction of all vectors spans F^n. The sets $a\mathbf{v}+U$ in (a) are translates of U, which Section 4.6 studies as the elements of the quotient space F^n/U.

Solution to Problem 1.15

Uses. Proposition 1.4.14 (The span is the smallest subspace containing a list), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.6.2 (Bases are independent spanning lists), (1.6.1), the binomial theorem, continuity of polynomial functions
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. For (a), expand $(1-t)^{n-k}$ by the binomial theorem.
Hint 2. For (b), if m is the smallest index with $c_m\neq 0$, divide the relation by t^m for $t\neq 0$, and let $t\to 0$.
Hint 3. For (c), write $t^j=t^j(t+(1-t))^{n-j}$ and expand.
Sketch. (a) $b_k(t)=\sum_i\binom{n-k}{i}(-1)^i t^{k+i}$. (b) If $\sum c_k b_k=0$ and m is the smallest index with $c_m\neq 0$, then $\sum_{k\ge m}c_k t^{k-m}(1-t)^{n-k}=0$ for $t\neq 0$; this is a polynomial function, continuous at 0, whose value at 0 is c_m. So $c_m=0$, a contradiction. (c) $t^j=\sum_i\binom{n-j}{i}b_{j+i}(t)$. (d) $1=\sum_k\binom{n}{k}b_k$ and $t=\sum_{k\ge 1}\binom{n-1}{k-1}b_k$.

(a) By the binomial theorem, for every real t,

$$b_k(t)=t^k\sum_{i=0}^{n-k}\binom{n-k}{i}(-t)^i=\sum_{i=0}^{n-k}\binom{n-k}{i}(-1)^i t^{k+i}.$$

So b_k is a linear combination of $t^k,\dots,t^n$, and $b_k\in V_n$.

(b) Suppose $c_0b_0+\cdots+c_nb_n=\mathbf{0}$, the zero function, and suppose for contradiction that some $c_k\neq 0$. Let m be the smallest index with $c_m\neq 0$. Then for every real t,

$$\sum_{k=m}^{n}c_k t^k(1-t)^{n-k}=0,$$

and dividing by t^m for $t\neq 0$ gives $g(t)=0$ for all $t\neq 0$, where

$$g(t)=\sum_{k=m}^{n}c_k t^{k-m}(1-t)^{n-k}=c_m(1-t)^{n-m}+\sum_{k=m+1}^{n}c_k t^{k-m}(1-t)^{n-k}.$$

The function g is a polynomial function, hence continuous, so $g(0)=\lim_{t\to 0}g(t)=0$. But every term of the second sum vanishes at $t=0$, since $k-m\ge 1$, so $g(0)=c_m$. Hence $c_m=0$, a contradiction. By Theorem 1.5.5, $b_0,\dots,b_n$ is independent.

(c) For $0\le j\le n$ and every real t, since $t+(1-t)=1$,

$$t^j=t^j(t+(1-t))^{n-j}=\sum_{i=0}^{n-j}\binom{n-j}{i}t^{j+i}(1-t)^{n-j-i}=\sum_{i=0}^{n-j}\binom{n-j}{i}b_{j+i}(t).$$

So each t^j lies in $\operatorname{span}(b_0,\dots,b_n)$, and $V_n\subseteq\operatorname{span}(b_0,\dots,b_n)$ by Proposition 1.4.14(b). With (a), the two spans are equal, so $b_0,\dots,b_n$ spans V_n; with (b), it is a basis of V_n (Proposition 1.6.2).

(d) Taking $j = 0$ and $j = 1$ in (c),

$$1 = \sum_{k=0}^{n} \binom{n}{k} b_k, \quad t = \sum_{k=1}^{n} \binom{n-1}{k-1} b_k.$$

By (1.6.1), the coordinates of 1 are $\left(\binom{n}{0}, \binom{n}{1}, \ldots, \binom{n}{n}\right)$, and those of t are $\left(0, \binom{n-1}{0}, \binom{n-1}{1}, \ldots, \binom{n-1}{n-1}\right)$.

The proof of (b) is the extremal argument of Proposition 1.5.24 and Example 1.5.27, read at $t = 0$ instead of at $t = \infty$: near 0, the term with the smallest power of t dominates. These functions are the Bernstein basis of V_n.

Solution to Problem 1.16

Uses. Definition 1.1.28 (Characteristic), Exercise 1.1.48, Definition 1.1.32 (Subfield), Corollary 1.1.14 (Cancellation), Example 1.2.6 (Small fields), Proposition 1.2.19 (Restriction of scalars), Corollary 1.6.24 (Bases exist in finite dimensions), Proposition 1.6.16 (The coordinate map is a bijection), an injective map from a finite set to itself is surjective
Hint 1. For (a), the elements $m * 1$ for $m = 1, 2, 3, \ldots$ cannot all be different in a finite field.
Hint 2. For (b), every $m * 1$ with $m \geq 0$ equals $r * 1$ for the remainder r of m mod p. For inverses inside K, use the counting argument of Proposition 1.1.24: multiplication by $a \neq 0$ is injective on K.
Hint 3. For (c), regard F as a vector space over K. Why is it finite-dimensional, and what does a basis of length n say about the number of elements?
Sketch. (a) $m * 1 = m' * 1$ with $m < m'$ gives $(m' - m) * 1 = 0$, so $\operatorname{char} F > 0$, hence prime. (b) The p listed elements are distinct by minimality of p, and K is the set of all $m * 1$, which is closed under sums and products; $-(m * 1) = (p - m) * 1$; and $x \mapsto ax$ is an injection of the finite set K into itself, hence onto, so a has an inverse in K. (c) F is a K-vector space, spanned by the list of all its elements, so it has a basis of some length $n \geq 1$, and the coordinate map is a bijection $F \to K^n$.

(a) The elements $1 * 1, 2 * 1, 3 * 1, \ldots$ lie in the finite set F, so two of them coincide: $m * 1 = m' * 1$ with $1 \leq m < m'$. Subtracting $m * 1$ from both sides gives $(m' - m) * 1 = 0$ with $m' - m \geq 1$. So $\operatorname{char} F$ is positive (Definition 1.1.28), and by Exercise 1.1.48 it is a prime p.

(b) *K has p elements.* If $m * 1 = m' * 1$ with $0 \leq m < m' \leq p - 1$, then $(m' - m) * 1 = 0$ with $0 < m' - m < p$, contradicting the minimality of p. So the p listed elements are distinct.

K contains every $m * 1$. For an integer $m \geq 0$, write $m = sp + r$ with $0 \leq r \leq p - 1$. Grouping the m ones into s blocks of p and one block of r writes $m * 1$ as a sum of s copies of $p * 1$ plus $r * 1$. Since $p * 1 = 0$, this gives $m * 1 = r * 1 \in K$.

Closure. $0 = 0 * 1$ and $1 = 1 * 1$ lie in K. For $m, m' \geq 0$, $(m * 1) + (m' * 1) = (m + m') * 1 \in K$, and $(m * 1)(m' * 1) = (mm') * 1 \in K$, by distributivity (expand the product of the two sums of ones into mm' products $1 \cdot 1 = 1$). For $1 \leq m \leq p - 1$, $(m * 1) + ((p - m) * 1) = p * 1 = 0$, so $-(m * 1) = (p - m) * 1 \in K$, and $-0 = 0$. Finally, let $a \in K$ be nonzero. The map $K \to K$, $x \mapsto ax$, maps into K by closure, and it is injective by cancellation in F (Corollary 1.1.14). An injective map from a finite set to itself is surjective, so $ab = 1$ for some $b \in K$, and $a^{-1} = b \in K$. By Definition 1.1.32, K is a subfield of F.

(c) F is a vector space over itself (Example 1.2.6), hence over its subfield K (Proposition 1.2.19). Let $\mathcal{L}$ be a list whose entries are all the elements of F. Every $\alpha \in F$ equals $1 \cdot \alpha$, a linear combination of $\mathcal{L}$ over K, so $\mathcal{L}$ spans F over K, and F is finite-dimensional over K. By Corollary 1.6.24, F has a basis $\alpha_1, \ldots, \alpha_n$ over K, and $n \geq 1$ because $F \neq \{0\}$ (the empty list spans only $\{0\}$). By Proposition 1.6.16, the coordinate map is a bijection $F \to K^n$, so $|F| = |K^n| = p^n$.

Since 6 is not a power of a prime, no field has 6 elements. On the other hand, Exercise 1.1.56 constructs a field with $4 = 2^2$ elements; there, $K = \{0, 1\}$ and $1, \alpha$ is a basis over K.

Solution to Problem 1.17

Uses. Theorem 1.5.5 (Independence is decided at zero), Corollary 1.5.17 (Sublists), Proposition 1.5.15 (Short lists, zeros, and repeats), Definition 1.2.9 (Function spaces), Lemma 1.3.9 (Arithmetic of linear combinations)
Techniques. Induction on the length of a list (Technique 1.6.9), Uniqueness via two candidates (Technique 1.1.8)

Hint 1. The backward direction is immediate. For the forward direction, induct on n, applying the inductive hypothesis to $f_1, \dots, f_n$ inside $f_1, \dots, f_{n+1}$.
Hint 2. Given good points $t_1, \dots, t_n$ for $f_1, \dots, f_n$, look at the n equations in the $n+1$ unknowns $a_1, \dots, a_{n+1}$. Show that they have at most one solution with $a_{n+1} = 1$.
Hint 3. If every choice of t_{n+1} failed, each failure would produce a solution with $a_{n+1} = 1$, and by uniqueness they would all be the same solution $\mathbf{s}$. What relation among the f_i would $\mathbf{s}$ give?
Sketch. ($\Leftarrow$) A relation holds at every point, in particular at the t_j. ($\Rightarrow$) Induction on n. For $n = 1$, pick t_1 with $f_1(t_1) \neq 0$. For the step, take good points $t_1, \dots, t_n$ for $f_1, \dots, f_n$. A solution of the n equations in $n+1$ unknowns with $a_{n+1} = 0$ is 0, so two solutions with $a_{n+1} = 1$ agree (subtract them). If no t worked as t_{n+1}, each t would give a nontrivial solution, rescaled to $a_{n+1} = 1$, hence equal to one fixed $\mathbf{s}$; then $\sum s_i f_i(t) = 0$ for all t, a nontrivial relation.

($\Leftarrow$) Suppose such points exist, and let $a_1 f_1 + \cdots + a_n f_n = \mathbf{0}$. A relation among functions holds at every point (Definition 1.2.9), in particular at $t_1, \dots, t_n$, so all $a_i = 0$. The list is independent by Theorem 1.5.5.

($\Rightarrow$) We induct on n. For brevity, call points $t_1, \dots, t_n$ *good* for $f_1, \dots, f_n$ if the system above has only the zero solution.

Base case. If f_1 is independent, then $f_1 \neq \mathbf{0}$ (Proposition 1.5.15(b)), so $f_1(t_1) \neq 0$ for some $t_1 \in X$, and $a_1 f_1(t_1) = 0$ forces $a_1 = 0$.

Inductive step. Let $f_1, \dots, f_{n+1}$ be independent. Its sublist $f_1, \dots, f_n$ is independent (Corollary 1.5.17), so by the inductive hypothesis there are good points $t_1, \dots, t_n$ for it. Consider the system of n equations in $n+1$ unknowns

$$\sum_{i=1}^{n+1} a_i f_i(t_j) = 0 \quad (j = 1, \dots, n),$$

which we call (E). Two observations. First, a solution of (E) with $a_{n+1} = 0$ is zero, because then $a_1, \dots, a_n$ solves the system for $f_1, \dots, f_n$ at good points. Second, at most one solution has $a_{n+1} = 1$: if $\mathbf{a}$ and $\mathbf{a}'$ are two such solutions, their difference solves (E) (subtract the equations) and has last coordinate 0, so it is zero by the first observation.

Now suppose, for contradiction, that no point $t \in X$ is good as a last point, that is, for every $t \in X$ the points $t_1, \dots, t_n, t$ are not good for $f_1, \dots, f_{n+1}$. Then for every t there is a nonzero $\mathbf{a}(t) \in F^{n+1}$ solving (E) together with $\sum_i a_i f_i(t) = 0$. By the first observation, its last coordinate is nonzero, and dividing by it gives a solution with last coordinate 1 that still satisfies the equation at t. By the second observation, this rescaled solution is the same vector $\mathbf{s}$ for every t. (Here $X \neq \emptyset$, because $f_1 \neq \mathbf{0}$.) So $s_{n+1} = 1$ and

$$s_1 f_1(t) + \cdots + s_{n+1} f_{n+1}(t) = 0 \quad \text{for every } t \in X,$$

that is, $s_1 f_1 + \cdots + s_{n+1} f_{n+1} = \mathbf{0}$ is a nontrivial relation. This contradicts the independence of $f_1, \dots, f_{n+1}$. Hence some $t_{n+1} \in X$ makes $t_1, \dots, t_{n+1}$ good, completing the induction.

The uniqueness step is the subtraction pattern of Section 1.7.2: two normalized solutions differ by a solution of a problem that has only the zero solution.

Solution to Problem 1.18

Uses. Definition 1.2.17 (Evaluation), Proposition 1.2.18 (Degree and evaluation versus the operations), Example 1.4.9 (Polynomials), Proposition 7.1.22 (Counting roots), Proposition 1.1.17 (No zero divisors), Definition 1.2.9 (Function spaces), Proposition 1.4.14 (The span is the smallest subspace containing a list), a surjection between finite sets of the same size is injective
Hint 1. The answer is: exactly the finite fields. For an infinite field, find a function that a polynomial cannot imitate, for instance one that vanishes at all but one point.
Hint 2. For a finite field, it suffices to produce, for each $c \in F$, the function δ_c that is 1 at c and 0 elsewhere. Try $t \mapsto \prod_{e \neq c}(t - e)$.
Hint 3. Products like this are polynomial functions: if g is the polynomial function of $\sum a_k x^k$, then $t \mapsto tg(t)$ is that of $\sum a_k x^{k+1}$. For uniqueness, count: how many polynomials of degree less than q, and how many functions?

Sketch. Infinite F: if δ_0 were the polynomial function of p, then p would have infinitely many roots, so $p = \mathbf{0}$, but $p(0) = 1$. Finite F with q elements: the functions of polynomials of degree at most d form a subspace P_d of F^F, and $g \mapsto (t \mapsto (t-e)g(t))$ maps P_d into P_{d+1}. So $h_c(t) = \prod_{e \neq c}(t-e)$ lies in P_{q-1}, $h_c(c) \neq 0$, and $\delta_c = h_c(c)^{-1}h_c$. Every $f = \sum_c f(c)\delta_c$. The map from $F[x]_{\leq q-1}$, with q^q elements, onto the q^q functions is then a bijection.

The answer: exactly the finite fields.

Infinite fields fail. Let F be infinite, and let $\delta_0 : F \to F$ be 1 at 0 and 0 elsewhere. Suppose δ_0 is the polynomial function of $p \in F[x]$. Then $p(c) = 0$ for every $c \neq 0$, so p has infinitely many roots. By Proposition 7.1.22, $p = \mathbf{0}$, and then $p(0) = 0 \neq 1 = \delta_0(0)$. So δ_0 is not a polynomial function.

Finite fields work. Let F have q elements, and for $d \geq 0$ let $P_d \subseteq F^F$ be the set of polynomial functions of polynomials in $F[x]_{\leq d}$.

Step 1: P_d is a subspace of F^F. It contains the zero function (of $\mathbf{0}$), and by Proposition 1.2.18(c), the sum of the functions of $p, p' \in F[x]_{\leq d}$ is the function of $p + p'$, and a times the function of p is the function of ap; both polynomials lie in $F[x]_{\leq d}$, which is a subspace (Example 1.4.9).

Step 2: multiplying by $t - d$. Let $g \in P_d$ be the function of $p = \sum_{k=0}^{d} a_k x^k$, and let $e \in F$. The polynomial $p^+ = \sum_{k=0}^{d} a_k x^{k+1}$ lies in $F[x]_{\leq d+1}$, and its value at t is $\sum_k a_k t^{k+1} = tg(t)$. So the function $t \mapsto (t-e)g(t) = tg(t) - eg(t)$ is the function of $p^+ - ep \in F[x]_{\leq d+1}$, by Proposition 1.2.18(c). That is, it lies in P_{d+1}.

Step 3: the functions δ_c. Fix $c \in F$, and let $h_c(t) = \prod_{e \neq c}(t-e)$, a product of $q-1$ factors. Starting from the constant function $1 \in P_0$ and applying Step 2 once for each factor, $h_c \in P_{q-1}$. At $t = c$ every factor is nonzero, so $h_c(c) \neq 0$ by Proposition 1.1.17; at $t \neq c$ the factor $t - t$ appears, so $h_c(t) = 0$. Hence $\delta_c = h_c(c)^{-1}h_c$, the function that is 1 at c and 0 elsewhere, lies in the subspace P_{q-1}.

Step 4: every function. For $f : F \to F$, the functions f and $\sum_{c \in F} f(c)\delta_c$ agree at every point t, since only the term with $c = t$ is nonzero there. So $f \in \operatorname{span}(\delta_c \mid c \in F) \subseteq P_{q-1}$ by Proposition 1.4.14(b). Every function is the polynomial function of some polynomial of degree at most $q-1$.

Step 5: uniqueness. The map $F[x]_{\leq q-1} \to F^F$ sending a polynomial to its function is surjective by Step 4. A polynomial of degree at most $q-1$ is determined by its q coefficients $a_0, \ldots, a_{q-1}$, so $F[x]_{\leq q-1}$ has q^q elements, and F^F has q^q elements as well. A surjection between finite sets of the same size is injective, so different polynomials of degree less than q have different functions.

For $F = \mathbb{F}_2$ this recovers Aside (Polynomials versus polynomial functions): $x^2 + x$ and $\mathbf{0}$ have the same function, and only one of them has degree less than 2.

Solution to Problem 1.19

Uses. Proposition 1.5.15 (Short lists, zeros, and repeats), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.30 (Additive arithmetic)
Hint 1. Translate the condition. Over $\mathbb{F}_2$ the only coefficients are 0 and 1, so a sublist $\mathbf{x}, \mathbf{y}, \mathbf{z}$ of distinct nonzero vectors is dependent exactly when $\mathbf{x} + \mathbf{y} + \mathbf{z} = \mathbf{0}$.
Hint 2. So the entries form a set S of nonzero vectors in which no sum of two different elements lies in S. Fix $\mathbf{s} \in S$ and compare S with $\mathbf{s} + S = \{\mathbf{s} + \mathbf{x} \mid \mathbf{x} \in S\}$.
Hint 3. For the construction, look at the vectors whose first coordinate is 1.
Sketch. The answer is 2^{n-1}. The condition says: the entries are nonzero, distinct, and $\mathbf{x} + \mathbf{y} \notin S$ for distinct $\mathbf{x}, \mathbf{y}$ in the set S of entries. For $\mathbf{s} \in S$, the sets S and $\mathbf{s} + S$ have k elements each and are disjoint, so $2k \leq 2^n$. The 2^{n-1} vectors with $x_1 = 1$ work, since a sum of two of them has $x_1 = 0$.

The answer is $k = 2^{n-1}$.

Translating the condition. Let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ be a list in $\mathbb{F}_2^n$. Its sublists of length 1 are independent exactly when every entry is nonzero (Proposition 1.5.15(b)). Given that, a sublist $\mathbf{v}_i, \mathbf{v}_j$ of length 2 is dependent exactly when $\mathbf{v}_i = \mathbf{v}_j$: over $\mathbb{F}_2$ the nontrivial relations are $\mathbf{v}_i = \mathbf{0}$, $\mathbf{v}_j = \mathbf{0}$, and $\mathbf{v}_i + \mathbf{v}_j = \mathbf{0}$, the last meaning $\mathbf{v}_i = \mathbf{v}_j$. Given that the entries are nonzero and distinct, a sublist $\mathbf{v}_i, \mathbf{v}_j, \mathbf{v}_l$ of length 3 is dependent exactly when $\mathbf{v}_i + \mathbf{v}_j + \mathbf{v}_l = \mathbf{0}$, since a nontrivial relation with one or two coefficients equal to 1 would make an entry

zero or two entries equal. So the condition holds exactly when the entries are nonzero and distinct, and the set S of entries, which has k elements, satisfies

$$\mathbf{x}+\mathbf{y}\notin S \quad \text{for all distinct } \mathbf{x},\mathbf{y}\in S.$$

(Indeed $\mathbf{x}+\mathbf{y}=\mathbf{z}$ is the same as $\mathbf{x}+\mathbf{y}+\mathbf{z}=\mathbf{0}$, and such a $\mathbf{z}\in S$ would differ from $\mathbf{x}$ and $\mathbf{y}$, as $\mathbf{x},\mathbf{y}\neq\mathbf{0}$.)

Upper bound. If $k=0$ there is nothing to prove. Otherwise fix $\mathbf{s}\in S$, and let $\mathbf{s}+S=\{\mathbf{s}+\mathbf{x}\mid\mathbf{x}\in S\}$. It has k elements, because $\mathbf{x}\mapsto\mathbf{s}+\mathbf{x}$ is injective (Proposition 1.2.30(b)). It is disjoint from S: suppose $\mathbf{s}+\mathbf{x}=\mathbf{y}$ with $\mathbf{x},\mathbf{y}\in S$. If $\mathbf{x}=\mathbf{s}$, then $\mathbf{y}=\mathbf{s}+\mathbf{s}=\mathbf{0}\notin S$. If $\mathbf{x}\neq\mathbf{s}$, then $\mathbf{s}+\mathbf{x}\notin S$ by the condition. Either way we have a contradiction. So S and $\mathbf{s}+S$ are disjoint subsets of $\mathbb{F}_2^n$ with k elements each, and $2k\le 2^n$, that is, $k\le 2^{n-1}$.

Construction. Let S be the set of 2^{n-1} vectors of $\mathbb{F}_2^n$ with first coordinate 1, listed in any order. They are nonzero and distinct. The sum of two of them has first coordinate $1+1=0$, so it is not in S. By the translation, every sublist of length at most 3 is independent.

So the largest k is 2^{n-1}. For $n=3$, the four vectors $(1,0,0),(1,1,0),(1,0,1),(1,1,1)$ have every three independent, while any five distinct nonzero vectors of $\mathbb{F}_2^3$ contain three with sum $\mathbf{0}$.

Section 2.1

Solution to Exercise 2.1.5

Uses. Theorem 2.1.3 (Checking linearity), Definition 1.2.1 (Vector space)
Hint 1. (a) is two of the vector space axioms of W.
Hint 2. (b) Every $x\in F$ is a scalar multiple of the single vector $1\in F$: $x=x\cdot 1$. Apply homogeneity.
Sketch. (a) $(x+y)\mathbf{w}=x\mathbf{w}+y\mathbf{w}$ and $(ax)\mathbf{w}=a(x\mathbf{w})$. (b) $T(x)=T(x\cdot 1)=xT(1)$.

(a) For $x,y,a\in F$, the vector space axioms of W give $(x+y)\mathbf{w}=x\mathbf{w}+y\mathbf{w}$ and $(ax)\mathbf{w}=a(x\mathbf{w})$. So the map is additive and homogeneous, hence linear by Theorem 2.1.3.

(b) Let $T\in\mathrm{L}(F,W)$ and $\mathbf{w}=T(1)$. For $x\in F$, the element $x=x\cdot 1$ is the scalar x times the vector $1\in F$, so homogeneity gives $T(x)=T(x\cdot 1)=xT(1)=x\mathbf{w}$. Taking $W=F$, every $T\in\mathrm{L}(F)$ is $x\mapsto ax$ with $a=T(1)$, and these maps are linear by (a).

Solution to Exercise 2.1.15

Uses. Example 2.1.7 (Maps $F^n\to F^m$ given by linear formulas), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Theorem 2.1.3 (Checking linearity)
Hint 1. Test $T(\mathbf{0})$ first, then $T(-\mathbf{v})$ or $T(2\mathbf{v})$. These catch most nonlinear formulas.
Hint 2. In (d) there are only two scalars, so homogeneity says very little. Test additivity on $\mathbf{e}_1$ and $\mathbf{e}_2$.
Sketch. (a) Linear: it is T_A with $A=\begin{pmatrix}0&1\\1&-3\end{pmatrix}$. (b) Not linear: $T(\mathbf{0})=(1,0)$. (c) Not linear: $T(-1)=(-1,1)\neq -T(1)$. (d) Homogeneous but not additive: $T(1,0)+T(0,1)=0\neq 1=T(1,1)$.

(a) Linear: $T=T_A$ for $A=\begin{pmatrix}0&1\\1&-3\end{pmatrix}$, so Example 2.1.7 applies.

(b) Not linear: $T(0,0)=(1,0)\neq\mathbf{0}$, contradicting Proposition 2.1.4.

(c) Not linear: $T(-1)=(-1,1)$, while $(-1)T(1)=(-1,-1)$, so T is not homogeneous. (Note that $T(0)=\mathbf{0}$, so the first test does not detect this one.)

(d) Not linear. Homogeneity does hold: the only scalars are 0 and 1, and $T(0\mathbf{v})=T(0,0)=0=0T(\mathbf{v})$ and $T(1\mathbf{v})=1T(\mathbf{v})$. But additivity fails: $T(1,0)+T(0,1)=0+0=0$, while $T(1,1)=1$.

Solution to Exercise 2.1.20

Uses. Proposition 2.1.17 (Compositions of linear maps are linear)
Hint. ST means "first T, then S", so it is a map $\mathbb{R}^2\to\mathbb{R}^2$. Substitute the coordinates of $T(u,v)$ into the formula for S.
Sketch. $ST(u,v)=(u+v,u+2v)$ and $TS(x,y,z)=(x-z,2y+2z,x+y)$.

$ST:\mathbb{R}^2\to\mathbb{R}^2$ is

$$(ST)(u,v)=S(u-v,2v,u)=((u-v)+2v,2v+u)=(u+v,u+2v),$$

and $TS : \mathbb{R}^3 \to \mathbb{R}^3$ is

$$(TS)(x, y, z) = T(x + y, y + z) = ((x + y) - (y + z), 2(y + z), x + y) = (x - z, 2y + 2z, x + y).$$

The two composites have different domains, so here the question whether $ST = TS$ does not even arise.

Solution to Exercise 2.1.25

Uses. Proposition 2.1.24 (Algebra of composition), Notation 2.1.18
Hint 1. Compute $T^2(x, y) = T(T(x, y))$ and add $T(x, y)$.
Hint 2. For the second part, expand $T(T + \mathrm{id})$ with Proposition 2.1.24.
Sketch. $T^2(x, y) = (x - y, 2y - x)$, and adding $(y, x - y)$ gives (x, y). Then $T(T + \mathrm{id}) = T^2 + T = \mathrm{id}$ and $(T + \mathrm{id})T = T^2 + T = \mathrm{id}$ by parts (b) and (c) of Proposition 2.1.24.

We have $T^2(x, y) = T(y, x - y) = (x - y, y - (x - y)) = (x - y, 2y - x)$, so

$$\big(T^2 + T\big)(x, y) = (x - y + y, 2y - x + x - y) = (x, y).$$

That is, $T^2 + T = \mathrm{id}$. By parts (b) and (c) of Proposition 2.1.24, $T(T + \mathrm{id}) = T^2 + T\,\mathrm{id} = T^2 + T = \mathrm{id}$ and $(T + \mathrm{id})T = T^2 + \mathrm{id}\,T = T^2 + T = \mathrm{id}$. So applying $T + \mathrm{id}$ undoes T, in either order; invertibility is the subject of Section 2.5.

Solution to Exercise 2.1.28

Uses. Definition 2.1.21 (Pointwise operations), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space), Theorem 2.1.3 (Checking linearity)
Hint. The vectors of $\mathrm{L}(V, W)$ are maps, and they are added and scaled pointwise. Evaluate $aS + T$ at $\mathbf{v}_0$.
Sketch. $(aS + T)(\mathbf{v}_0) = aS(\mathbf{v}_0) + T(\mathbf{v}_0)$ by the definition of the operations.

Write $E(T) = T(\mathbf{v}_0)$. For $S, T \in \mathrm{L}(V, W)$ and $a \in F$, the definition of the operations on $\mathrm{L}(V, W)$ gives

$$E(aS + T) = (aS + T)(\mathbf{v}_0) = aS(\mathbf{v}_0) + T(\mathbf{v}_0) = aE(S) + E(T).$$

So E is linear by Theorem 2.1.3. Note that the linearity of S and T played no role; the same computation shows that evaluation at a point is linear on W^X for any set X.

Solution to Exercise 2.1.29

Uses. Example 2.1.7 (Maps $F^n \to F^m$ given by linear formulas), Example 2.1.9 (Maps of polynomials), Non-example 2.1.14 (Complex conjugation)
Techniques. Assemble linear maps from linear pieces (Technique 2.1.26)
Hint 1. Entrywise operations make $F^{2\times 2}$ look like F^4. Which of the formulas are sums of constant multiples of the entries?
Hint 2. For (b), try two matrices with a single nonzero entry each, on the diagonal. For (e) over $\mathbb{C}$, compare $T(i \cdot 1)$ with $i \cdot T(1)$.
Sketch. (a), (c), and (d) are linear: (a) and (c) are linear formulas in the entries, and (d) is $\mathrm{id} + D$. (b) is not additive: the two diagonal matrices with a single 1 each map to 0, while their sum, the identity matrix, maps to 1. (e) is $\mathbb{R}$-linear, being $(a, b) \mapsto (b, a)$ in coordinates, but not $\mathbb{C}$-linear: $T(i) = 1$ while $iT(1) = -1$.

(a) Linear. The entries of $cA + B$ are $ca_{ij} + b_{ij}$, so the map sends $cA + B$ to $(ca_{11} + b_{11}) + (ca_{22} + b_{22}) = c(a_{11} + a_{22}) + (b_{11} + b_{22})$.

(b) Not linear, over any field. Let A have $a_{11} = 1$ and all other entries 0, and let B have $b_{22} = 1$ and all other entries 0. Both map to 0, but $A + B$ has diagonal entries 1, 1 and off-diagonal entries 0, so it maps to $1 \neq 0$. The map is not additive.

(c) Linear. Listing the entries as $(a_{11}, a_{12}, a_{21}, a_{22})$, the map is $(a, b, c, d) \mapsto (a, c, b, d)$, a linear formula as in Example 2.1.7 (each output coordinate is one input coordinate), and the operations of $F^{2\times 2}$ are those of F^4 in these coordinates.

(d) Linear: the map is $\mathrm{id}_{F[x]} + D$, a sum of linear maps (Technique 2.1.26).

(e) Write $T(z) = i\bar{z}$. For $z = a + bi$, $T(z) = i(a - bi) = b + ai$. Over $\mathbb{R}$, in the coordinates (a, b) this is $(a, b) \mapsto (b, a)$, which is linear (it is the reflection across the line $y = x$). Over $\mathbb{C}$ it is not homogeneous: $T(i \cdot 1) = T(i) = i \cdot (-i) = 1$, while $i \cdot T(1) = i \cdot i = -1$.

Solution to Exercise 2.1.30

Uses. Example 2.1.7 (Maps $F^n \to F^m$ given by linear formulas), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Hint 1. A function $\mathbb{F}_2^2 \to \mathbb{F}_2$ is a choice of one of two values at each of the four points of $\mathbb{F}_2^2$.
Hint 2. A linear T satisfies $T(x, y) = xT(\mathbf{e}_1) + yT(\mathbf{e}_2)$. How many choices are there for the pair $(T(\mathbf{e}_1), T(\mathbf{e}_2))$, and does each choice give a linear map?
Sketch. $2^4 = 16$ functions, of which $2^3 = 8$ send $\mathbf{0}$ to 0. A linear map is $(x, y) \mapsto \alpha x + \beta y$ with $(\alpha, \beta) = (T(\mathbf{e}_1), T(\mathbf{e}_2))$, and every such formula is linear, so there are 4: 0, x, y, and $x + y$.

$\mathbb{F}_2^2$ has 4 elements and $\mathbb{F}_2$ has 2, so there are $2^4 = 16$ functions $\mathbb{F}_2^2 \to \mathbb{F}_2$. Those with $T(\mathbf{0}) = 0$ are free only at the other three points, so there are $2^3 = 8$ of them.

If T is linear, then since $(x, y) = x\mathbf{e}_1 + y\mathbf{e}_2$,

$$T(x, y) = xT(\mathbf{e}_1) + yT(\mathbf{e}_2) = \alpha x + \beta y, \quad \text{where } \alpha = T(\mathbf{e}_1),\ \beta = T(\mathbf{e}_2).$$

So T is determined by $(\alpha, \beta) \in \mathbb{F}_2^2$, and there are at most 4 linear maps. Conversely, each formula $(x, y) \mapsto \alpha x + \beta y$ is linear by Example 2.1.7. So there are exactly 4 linear maps: $(x, y) \mapsto 0$, x, y, and $x + y$.

So half of the functions that fix $\mathbf{0}$ are not linear. They are $(x, y) \mapsto xy$, $x + xy$, $y + xy$, and $x + y + xy$.

Solution to Exercise 2.1.31

Uses. Proposition 2.1.16 (Linear maps preserve spans and linear relations)
Hint 1. Proposition 2.1.16 says that $T(\mathcal{L})$ spans $\operatorname{im}\left(T\restriction_{\operatorname{span}\mathcal{L}}\right)$. When is that all of W?
Hint 2. For counterexamples, try the zero map and a coordinate projection $\mathbb{R}^2 \to \mathbb{R}$.
Sketch. (a) False: the zero map $\mathbb{R} \to \mathbb{R}$ and $\mathcal{L} = 1$. (b) False: $(x, y) \mapsto x$ from $\mathbb{R}^2$ to $\mathbb{R}$ and $\mathcal{L} = \mathbf{e}_1$. (c) True: $W = \operatorname{span} T(\mathcal{L}) = \operatorname{im}\left(T\restriction_{\operatorname{span}\mathcal{L}}\right) \subseteq \operatorname{im} T \subseteq W$.

(a) False. Let $T : \mathbb{R} \to \mathbb{R}$ be the zero map and $\mathcal{L}$ the list 1, which spans $\mathbb{R}$. Then $T(\mathcal{L})$ is the list 0, which spans $\{0\} \neq \mathbb{R}$.

(b) False. Let $T : \mathbb{R}^2 \to \mathbb{R}$, $T(x, y) = x$, and $\mathcal{L} = \mathbf{e}_1$. Then $T(\mathcal{L})$ is the list 1, which spans $\mathbb{R}$, but $\mathcal{L}$ does not span $\mathbb{R}^2$: every element of $\operatorname{span}(\mathbf{e}_1)$ has second coordinate 0.

(c) True. By Proposition 2.1.16, $W = \operatorname{span} T(\mathcal{L}) = \operatorname{im}\left(T\restriction_{\operatorname{span}\mathcal{L}}\right) \subseteq \operatorname{im} T \subseteq W$, so $\operatorname{im} T = W$.

Solution to Exercise 2.1.32

Uses. Theorem 2.1.3 (Checking linearity), Definition 1.2.13 (Polynomials)
Hint 1. Write $cp + r$ in terms of the coefficients of p and r, using the same n for both.
Hint 2. Substituting q into $\sum_k (ca_k + b_k)x^k$ gives $\sum_k (ca_k + b_k)q^k$. Split it using the vector space axioms of $F[x]$.
Sketch. With $p = \sum a_k x^k$ and $r = \sum b_k x^k$, $cp + r = \sum (ca_k + b_k)x^k$, so $C_q(cp + r) = \sum (ca_k + b_k)q^k = c\sum a_k q^k + \sum b_k q^k$.

Let $p = \sum_{k=0}^n a_k x^k$ and $r = \sum_{k=0}^n b_k x^k$, padding with zero coefficients so that both use the same n. (Padding does not change $p(q)$, since the added terms are $0 \cdot q^k = 0$.) For $c \in F$, $cp + r = \sum_k (ca_k + b_k)x^k$, so

$$C_q(cp + r) = \sum_{k=0}^{n} (ca_k + b_k)q^k = c\sum_{k=0}^{n} a_k q^k + \sum_{k=0}^{n} b_k q^k = cC_q(p) + C_q(r),$$

by distributivity and the other vector space axioms of $F[x]$. By Theorem 2.1.3, C_q is linear.

Solution to Exercise 2.1.33

Uses. Theorem 2.1.3 (Checking linearity), Example 2.1.6 (Zero, identity, and scaling maps)
Hint 1. Apply L_q to the polynomial x, and to the polynomial $2x$. What does homogeneity say?
Hint 2. $L_q(x) = q$ and $L_q(2x) = q(2x)$. If $q = \sum b_k x^k$, then $q(2x) = \sum 2^k b_k x^k$. Compare coefficients with $2q$.
Sketch. L_q is linear exactly when $q = cx$ for some $c \in \mathbb{R}$. If L_q is linear, $q(2x) = L_q(2x) = 2L_q(x) = 2q$, so $\left(2^k - 2\right)b_k = 0$ for every k, and $b_k = 0$ unless $k = 1$. Conversely $L_{cx}(p) = cp$ is a scaling map.

The answer is $q = cx$ with $c \in \mathbb{R}$.

If $q = cx$, then $L_q(p) = cp$, which is linear (Example 2.1.6). Conversely, suppose L_q is linear, and write $q = b_0 + b_1x + \cdots + b_nx^n$. Then $L_q(x) = q$ and

$$L_q(2x) = q(2x) = \sum_{k=0}^{n} b_k(2x)^k = \sum_{k=0}^{n} 2^k b_k x^k.$$

By homogeneity, $L_q(2x) = 2L_q(x) = \sum_k 2b_kx^k$. Comparing coefficients, $\big(2^k - 2\big)b_k = 0$ for every k. For $k \neq 1$ we have $2^k - 2 \neq 0$ (it is -1 for $k = 0$ and at least 2 for $k \geq 2$), so $b_k = 0$. Hence $q = b_1x$.

The test used the scalar 2, which is 0 in $\mathbb{F}_2$, so over $\mathbb{F}_2$ the condition $L_q(2x) = 2L_q(x)$ says nothing. Indeed over $\mathbb{F}_2$ the answer is different: for $q = x^2$, the map $p \mapsto p^2$ turns out to be linear (try it).

Solution to Exercise 2.1.34

Uses. Example 2.1.9 (Maps of polynomials), Proposition 1.1.17 (No zero divisors), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
Hint 1. $D\big(\sum a_kx^k\big) = \sum ka_kx^{k-1}$, so $D(p) = 0$ if and only if $ka_k = 0$ for every $k \geq 1$.
Hint 2. In $\mathbb{F}_q$ for a prime q, $ka_k = (k \cdot 1)a_k$, and $k \cdot 1 = 0$ exactly when q divides k.
Sketch. $D(p) = 0$ if and only if $ka_k = 0$ for all $k \geq 1$. Over $\mathbb{F}_2$ this means $a_k = 0$ for odd k, so p is a polynomial in x^2. Over $\mathbb{F}_3$, p is a polynomial in x^3. Over $\mathbb{R}$, p is constant.

Let $p = a_0 + a_1x + \cdots + a_nx^n$. Then $D(p) = \sum_{k=1}^{n} ka_kx^{k-1}$, which is 0 if and only if $ka_k = 0$ for every $1 \leq k \leq n$. Here $ka_k = (k \cdot 1)a_k$, where $k \cdot 1$ is the sum of k ones in F. By Proposition 1.1.17, $ka_k = 0$ if and only if $k \cdot 1 = 0$ or $a_k = 0$.

In $\mathbb{F}_q$ for a prime q, the sum of k ones is $k \bmod q$, which is 0 exactly when q divides k. So over $\mathbb{F}_2$, $D(p) = 0$ if and only if $a_k = 0$ for every odd k, that is, $p = b_0 + b_1x^2 + b_2x^4 + \cdots$ for some $b_i \in \mathbb{F}_2$. For example $D\big(x^2 + 1\big) = 2x = 0$. Over $\mathbb{F}_3$, $D(p) = 0$ if and only if $a_k = 0$ whenever 3 does not divide k, that is, $p = b_0 + b_1x^3 + b_2x^6 + \cdots$. Over $\mathbb{R}$, $k \cdot 1 = k \neq 0$ for $k \geq 1$, so $D(p) = 0$ if and only if $p = a_0$ is constant.

Solution to Exercise 2.1.35

Uses. Theorem 2.1.3 (Checking linearity)
Hint. How many terms does the sum $x + x + \cdots + x$ have? For which c does that make sense?
Sketch. Writing cx as a sum of c copies of x only makes sense for positive integers c. The argument proves $T(nx) = nT(x)$ for $n = 1, 2, 3, \ldots$ and nothing about $c = 1/2$ or $c = \sqrt{2}$.

The first step writes cx as a sum of c copies of x, which only makes sense when c is a positive integer. For such $c = n$ the argument is correct: by induction on n, using additivity, $T(nx) = T((n-1)x + x) = T((n-1)x) + T(x) = nT(x)$. But it says nothing about $c = 1/2$ or $c = \sqrt{2}$, and homogeneity requires $T(cx) = cT(x)$ for every real c.

The gap is not a technicality. The conclusion $T(cx) = cT(x)$ can be rescued for rational c with a further idea (Exercise 2.1.37), but over $\mathbb{R}$ the claim is false: there are additive maps $\mathbb{R} \to \mathbb{R}$ that are not linear (Aside (Additive maps that are not linear)).

Solution to Exercise 2.1.36

Uses. Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Non-example 2.1.14 (Complex conjugation), Definition 1.1.19 (Integers modulo n)
Hint 1. In $\mathbb{F}_p$, every element is $1 + 1 + \cdots + 1$ for some number of terms.
Hint 2. If $c = 1 + \cdots + 1$ (n terms), then $c\mathbf{v} = \mathbf{v} + \cdots + \mathbf{v}$. Apply additivity $n - 1$ times. Do not forget $c = 0$.
Hint 3. For (b), look at the non-examples in this section.
Sketch. (a) True. Each $c \in \mathbb{F}_p$ is $n \cdot 1$ for some $0 \leq n < p$, so $c\mathbf{v}$ is a sum of n copies of $\mathbf{v}$ and additivity gives $T(c\mathbf{v}) = cT(\mathbf{v})$; the case $n = 0$ is $T(\mathbf{0}) = \mathbf{0}$, which holds for additive maps. (b) False: complex conjugation $\mathbb{C} \to \mathbb{C}$ is additive but not $\mathbb{C}$-linear.

(a) True. Let $c \in \mathbb{F}_p = \{0, 1, \ldots, p-1\}$, and let n be c regarded as an integer. In $\mathbb{F}_p$ the sum of n ones is $n \bmod p = c$. If $n = 0$, then $T(0\mathbf{v}) = T(\mathbf{0}) = \mathbf{0} = 0T(\mathbf{v})$, where $T(\mathbf{0}) = \mathbf{0}$ holds for additive maps by the second proof of Proposition 2.1.4. If $n \geq 1$, distributivity and $1\mathbf{v} = \mathbf{v}$ give $c\mathbf{v} = (1 + \cdots + 1)\mathbf{v} = \mathbf{v} + \cdots + \mathbf{v}$ (n terms), and additivity, applied $n - 1$ times, gives

$$T(c\mathbf{v}) = T(\mathbf{v} + \cdots + \mathbf{v}) = T(\mathbf{v}) + \cdots + T(\mathbf{v}) = (1 + \cdots + 1)T(\mathbf{v}) = cT(\mathbf{v}).$$

So T is homogeneous, hence linear.

(b) False. Complex conjugation $\mathbb{C} \to \mathbb{C}$ is additive but not $\mathbb{C}$-linear (Non-example 2.1.14).

Solution to Exercise 2.1.37

Uses. Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Exercise 2.1.35
Hint 1. First show $T(n\mathbf{v}) = nT(\mathbf{v})$ for every integer n, positive, zero, or negative.
Hint 2. For $c = m/n$ with $n \geq 1$, let $\mathbf{w} = c\mathbf{v}$. Then $n\mathbf{w} = m\mathbf{v}$. Apply T and use the integer case on both sides.
Sketch. For integers $n \geq 0$, $T(n\mathbf{v}) = nT(\mathbf{v})$ by induction, and $T(-\mathbf{u}) = -T(\mathbf{u})$ extends this to $n < 0$. If $c = m/n$, then $n(c\mathbf{v}) = m\mathbf{v}$, so $nT(c\mathbf{v}) = mT(\mathbf{v})$; divide by n.

Integers. We first show $T(n\mathbf{v}) = nT(\mathbf{v})$ for every $\mathbf{v} \in V$ and every integer n. For $n = 0$ this is $T(\mathbf{0}) = \mathbf{0}$, which holds for additive maps by the second proof of Proposition 2.1.4. If it holds for some $n \geq 0$, then $T((n+1)\mathbf{v}) = T(n\mathbf{v} + \mathbf{v}) = nT(\mathbf{v}) + T(\mathbf{v}) = (n+1)T(\mathbf{v})$. So it holds for all $n \geq 0$. For $n < 0$, the second proof of Proposition 2.1.4 also shows $T(-\mathbf{u}) = -T(\mathbf{u})$ for additive T, so $T(n\mathbf{v}) = T(-((-n)\mathbf{v})) = -((-n)T(\mathbf{v})) = nT(\mathbf{v})$.

Rationals. Let $c = m/n$ with $m, n \in \mathbb{Z}$ and $n \geq 1$, and put $\mathbf{w} = c\mathbf{v}$. Then $n\mathbf{w} = (nc)\mathbf{v} = m\mathbf{v}$, so by the integer case

$$nT(\mathbf{w}) = T(n\mathbf{w}) = T(m\mathbf{v}) = mT(\mathbf{v}).$$

Multiplying by $1/n \in \mathbb{Q}$ gives $T(c\mathbf{v}) = T(\mathbf{w}) = (m/n)T(\mathbf{v}) = cT(\mathbf{v})$. So T is homogeneous, hence linear.

Solution to Exercise 2.1.38

Uses. Proposition 1.1.17 (No zero divisors)
Hint 1. Homogeneity only relates $T(\mathbf{v})$ to the values of T on the line $\operatorname{span}(\mathbf{v})$. It says nothing about how different lines through $\mathbf{0}$ interact.
Hint 2. Let T be a linear function on the x-axis and 0 off the x-axis.
Sketch. $T(x, y) = x$ if $y = 0$, and $T(x, y) = 0$ if $y \neq 0$. Scaling by $c \neq 0$ keeps a point on or off the x-axis, which gives homogeneity. But $T(1,1) + T(0,-1) = 0 \neq 1 = T(1,0)$.

Define $T(x, y) = x$ if $y = 0$, and $T(x, y) = 0$ if $y \neq 0$.

Homogeneity. Let $c \in F$ and $(x, y) \in F^2$. If $c = 0$, then $T(c(x, y)) = T(0, 0) = 0 = cT(x, y)$. Let $c \neq 0$. If $y = 0$, then $T(cx, 0) = cx = cT(x, 0)$. If $y \neq 0$, then $cy \neq 0$ by Proposition 1.1.17, so $T(cx, cy) = 0 = c \cdot 0 = cT(x, y)$.

Additivity fails. $T(1,1) + T(0,-1) = 0 + 0 = 0$, since $1 \neq 0$ and $-1 \neq 0$, while $T((1,1) + (0,-1)) = T(1,0) = 1$.

Homogeneity is a condition on each line through $\mathbf{0}$ separately, and additivity is what ties different lines together.

Solution to Exercise 2.1.39

Uses. Theorem 2.1.3 (Checking linearity), Exercise 2.1.15
Hint 1. For homogeneity, use the pair of coefficients a and $1 - a$, with $\mathbf{0}$ as the second vector.
Hint 2. For additivity, write $\mathbf{u} + \mathbf{v} = (1+1)(h\mathbf{u} + h\mathbf{v})$ with $h = (1+1)^{-1}$, and note that $h + h = 1$.
Hint 3. For (b), what does the hypothesis say when the only scalars are 0 and 1?
Sketch. (a) $T(a\mathbf{u}) = T(a\mathbf{u} + (1-a)\mathbf{0}) = aT(\mathbf{u})$. With $h = (1+1)^{-1}$, homogeneity and the hypothesis with $a = b = h$ give $T(\mathbf{u} + \mathbf{v}) = (1+1)T(h\mathbf{u} + h\mathbf{v}) = (1+1)(hT(\mathbf{u}) + hT(\mathbf{v})) = T(\mathbf{u}) + T(\mathbf{v})$. (b) Over $\mathbb{F}_2$, $a + b = 1$ forces $\{a, b\} = \{0, 1\}$, and the hypothesis is empty. So $(x, y) \mapsto xy$ on $\mathbb{F}_2^2$ satisfies it but is not linear.

(a) *Homogeneity.* For $a \in F$ and $\mathbf{u} \in V$, the coefficients a and $1 - a$ add up to 1, so

$$T(a\mathbf{u}) = T(a\mathbf{u} + (1-a)\mathbf{0}) = aT(\mathbf{u}) + (1-a)T(\mathbf{0}) = aT(\mathbf{u}).$$

Additivity. Since $1 + 1 \neq 0$, it has an inverse $h = (1+1)^{-1}$, and $h + h = (1+1)h = 1$. For $\mathbf{u}, \mathbf{v} \in V$ we have $(1+1)(h\mathbf{u} + h\mathbf{v}) = \mathbf{u} + \mathbf{v}$, so by homogeneity and then the hypothesis with $a = b = h$,

$$T(\mathbf{u} + \mathbf{v}) = (1+1)T(h\mathbf{u} + h\mathbf{v}) = (1+1)(hT(\mathbf{u}) + hT(\mathbf{v})) = T(\mathbf{u}) + T(\mathbf{v}).$$

By Theorem 2.1.3, T is linear.

(b) In $\mathbb{F}_2$, $a+b=1$ holds only for $(a,b)=(1,0)$ and $(0,1)$, and then the hypothesis reads $T(\mathbf{u})=T(\mathbf{u})$ or $T(\mathbf{v})=T(\mathbf{v})$, which is always true. So every T with $T(\mathbf{0})=\mathbf{0}$ satisfies the hypotheses. For example $T:\mathbb{F}_2^2\to\mathbb{F}_2$, $T(x,y)=xy$, does, and it is not linear (Exercise 2.1.15).

Solution to Exercise 2.1.40

Uses. Example 2.1.7 (Maps $F^n\to F^m$ given by linear formulas)
Hint 1. $ST=0$ means that S sends every vector of the form $T(\mathbf{v})$ to $\mathbf{0}$. Choose T with all its values on a line, and S that kills that line.
Hint 2. Try $S(x,y)=(x,0)$, the projection onto the x-axis, and a T whose values lie on the y-axis.
Sketch. $S(x,y)=(x,0)$ and $T(x,y)=(0,x)$: then $ST(x,y)=S(0,x)=\mathbf{0}$, while $TS(x,y)=(0,x)$. The same T answers (b): $T^2(x,y)=T(0,x)=\mathbf{0}$.

Let $S(x,y)=(x,0)$ and $T(x,y)=(0,x)$; both are linear by Example 2.1.7.

(a) $(ST)(x,y)=S(0,x)=(0,0)$ for all (x,y), so $ST=0$. But $(TS)(x,y)=T(x,0)=(0,x)$, so $(TS)(\mathbf{e}_1)=\mathbf{e}_2\neq\mathbf{0}$ and $TS\neq 0$.

(b) The same T works: $T(\mathbf{e}_1)=\mathbf{e}_2\neq\mathbf{0}$, and $T^2(x,y)=T(0,x)=(0,0)$. Geometrically, T moves everything onto the y-axis and sends the y-axis to $\mathbf{0}$.

Solution to Exercise 2.1.41

Uses. Example 2.1.11 (Rotations, projections, and reflections), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Hint 1. Test the claim on a projection from Example 2.1.11.
Hint 2. Which step would be valid for numbers but not for linear maps? Can a linear map send a nonzero vector to $\mathbf{0}$ without being 0?
Sketch. The step "$P(\mathbf{w})=\mathbf{0}$ implies $P=0$ or $\mathbf{w}=\mathbf{0}$" is false. The projection $P(x,y)=(x,0)$ satisfies $P^2=P$ and is neither 0 nor id; there $P(P(\mathbf{v})-\mathbf{v})=P(0,-y)=\mathbf{0}$ with $(0,-y)\neq\mathbf{0}$ for $y\neq 0$.

The claim is false: $P(x,y)=(x,0)$ (the projection Pr_ℓ of Example 2.1.11 onto the x-axis) satisfies $P^2(x,y)=P(x,0)=(x,0)=P(x,y)$, and P is neither 0 nor $\mathrm{id}_{\mathbb{R}^2}$.

The error is the step "since P is linear, either $P=0$ or $P(\mathbf{v})-\mathbf{v}=\mathbf{0}$". It treats $P(\mathbf{w})=\mathbf{0}$ like a product of numbers equal to 0, but a linear map can send a nonzero vector to $\mathbf{0}$ without being the zero map. In the example, $P(\mathbf{v})-\mathbf{v}=(0,-y)$, which is nonzero when $y\neq 0$, and $P(0,-y)=\mathbf{0}$. The vectors that a linear map sends to $\mathbf{0}$ are studied in Section 2.6.

Solution to Exercise 2.1.42

Uses. Example 2.1.11 (Rotations, projections, and reflections), Example 2.1.27 (Maps assembled from linear pieces), Proposition 2.1.24 (Algebra of composition)
Techniques. Assemble linear maps from linear pieces (Technique 2.1.26)
Hint 1. Write $P(x,y)=s(\cos\theta,\sin\theta)$ with $s=x\cos\theta+y\sin\theta$, and apply P to the point $s(\cos\theta,\sin\theta)$.
Hint 2. Expand $(2P-\mathrm{id})(2P-\mathrm{id})$ as you would expand $(2p-1)^2$, but justify each step by a part of Proposition 2.1.24.
Sketch. (a) P applied to $s(\cos\theta,\sin\theta)$ gives $s(\cos^2\theta+\sin^2\theta)(\cos\theta,\sin\theta)=P(x,y)$. (b) $S^2=4P^2-2P-2P+\mathrm{id}=\mathrm{id}$ and $SP=2P^2-P=P=PS$. Reflecting twice returns every point; a point and its mirror image have the same foot on ℓ; points of ℓ are fixed by S.

(a) Let $\mathbf{u}=(\cos\theta,\sin\theta)$ and $s=x\cos\theta+y\sin\theta$, so $P(x,y)=s\mathbf{u}$. By linearity of P, $P(s\mathbf{u})=sP(\mathbf{u})$, and by the formula,

$$P(\mathbf{u})=(\cos\theta\cdot\cos\theta+\sin\theta\cdot\sin\theta)\mathbf{u}=\mathbf{u}.$$

So $P(P(x,y))=s\mathbf{u}=P(x,y)$, that is, $P^2=P$.

(b) Using parts (c), (d), and (b) of Proposition 2.1.24,

$$\begin{aligned}S^2=(2P-\mathrm{id})(2P-\mathrm{id})&=(2P)(2P)-(2P)\,\mathrm{id}-\mathrm{id}\,(2P)+\mathrm{id}\,\mathrm{id}\\&=4P^2-2P-2P+\mathrm{id}=4P-4P+\mathrm{id}=\mathrm{id},\end{aligned}$$

where we used $P^2=P$. Similarly,

$$SP = (2P - \mathrm{id})P = 2P^2 - P = P, \quad PS = P(2P - \mathrm{id}) = 2P^2 - P = P.$$

Geometrically, $S^2 = \mathrm{id}$ says that reflecting twice returns every point to where it started. $PS = P$ says that a point and its mirror image have the same foot of perpendicular on ℓ. $SP = P$ says that S fixes every point of ℓ, since the values of P are exactly the points of ℓ.

Solution to Exercise 2.1.43

Uses. Example 2.1.11 (Rotations, projections, and reflections), Proposition 2.1.17 (Compositions of linear maps are linear)
Hint 1. Substitute the formula for $R_\beta(x, y)$ into the formula for R_α, and collect the coefficients of x and y.
Hint 2. The coefficients come out as $\cos\alpha\cos\beta - \sin\alpha\sin\beta$ and similar expressions. Recognize them with the angle addition formulas. For the reflections, the angles are 2α and 2β.
Sketch. The first coordinate of $R_\alpha R_\beta(x, y)$ is $x(\cos\alpha\cos\beta - \sin\alpha\sin\beta) - y(\sin\alpha\cos\beta + \cos\alpha\sin\beta) = x\cos(\alpha+\beta) - y\sin(\alpha+\beta)$, and the second is similar. For reflections, the coefficients become $\cos 2\alpha\cos 2\beta + \sin 2\alpha\sin 2\beta = \cos(2\alpha - 2\beta)$ and $\sin 2\alpha\cos 2\beta - \cos 2\alpha\sin 2\beta = \sin(2\alpha - 2\beta)$.

Rotations. Write $(u, v) = R_\beta(x, y) = (x\cos\beta - y\sin\beta, x\sin\beta + y\cos\beta)$. Then $R_\alpha R_\beta(x, y) = (u\cos\alpha - v\sin\alpha, u\sin\alpha + v\cos\alpha)$. The first coordinate is

$$x(\cos\alpha\cos\beta - \sin\alpha\sin\beta) - y(\cos\alpha\sin\beta + \sin\alpha\cos\beta) = x\cos(\alpha+\beta) - y\sin(\alpha+\beta),$$

and the second is

$$x(\sin\alpha\cos\beta + \cos\alpha\sin\beta) + y(\cos\alpha\cos\beta - \sin\alpha\sin\beta) = x\sin(\alpha+\beta) + y\cos(\alpha+\beta).$$

So $R_\alpha R_\beta = R_{\alpha+\beta}$.

Reflections. Write $(u, v) = S_\beta(x, y) = (x\cos 2\beta + y\sin 2\beta, x\sin 2\beta - y\cos 2\beta)$. Then $S_\alpha S_\beta(x, y) = (u\cos 2\alpha + v\sin 2\alpha, u\sin 2\alpha - v\cos 2\alpha)$. The first coordinate is

$$x(\cos 2\alpha\cos 2\beta + \sin 2\alpha\sin 2\beta) + y(\cos 2\alpha\sin 2\beta - \sin 2\alpha\cos 2\beta) = x\cos(2\alpha - 2\beta) - y\sin(2\alpha - 2\beta),$$

and the second is

$$x(\sin 2\alpha\cos 2\beta - \cos 2\alpha\sin 2\beta) + y(\sin 2\alpha\sin 2\beta + \cos 2\alpha\cos 2\beta) = x\sin(2\alpha - 2\beta) + y\cos(2\alpha - 2\beta).$$

So $S_\alpha S_\beta = R_{2(\alpha-\beta)}$.

Geometrically: reflecting across one line and then across another is a rotation about their intersection point by twice the angle from the first line to the second. In particular, reflecting twice across the same line ($\alpha = \beta$) gives $R_0 = \mathrm{id}$. Also, two reflections never compose to a reflection: R_φ sends $\mathbf{e}_1, \mathbf{e}_2$ to $(\cos\varphi, \sin\varphi), (-\sin\varphi, \cos\varphi)$, and S_γ sends them to $(\cos 2\gamma, \sin 2\gamma), (\sin 2\gamma, -\cos 2\gamma)$, so $R_\varphi = S_\gamma$ would force $\cos\varphi = \cos 2\gamma = -\cos 2\gamma$ and $\sin\varphi = \sin 2\gamma = -\sin 2\gamma$, hence $\cos\varphi = \sin\varphi = 0$, which is impossible.

Solution to Exercise 2.1.44

Uses. Definition 1.4.1 (Subspace), Theorem 1.4.3 (Subspace criterion), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space)
Hint 1. A subspace contains the zero vector. What is the zero vector of $\mathrm{L}(V, W)$, and where does it send $\mathbf{v}_0$?
Hint 2. If $\mathbf{w}_0 = \mathbf{0}$, check closure directly, or note that the set is where the linear map $T \mapsto T(\mathbf{v}_0)$ of Exercise 2.1.28 takes the value $\mathbf{0}$.
Sketch. The zero map sends $\mathbf{v}_0$ to $\mathbf{0}$, so it lies in the set only if $\mathbf{w}_0 = \mathbf{0}$. If $\mathbf{w}_0 = \mathbf{0}$, then $(cS + T)(\mathbf{v}_0) = cS(\mathbf{v}_0) + T(\mathbf{v}_0) = \mathbf{0}$ for S, T in the set.

Call the set U. The zero vector of $\mathrm{L}(V, W)$ is the zero map (Proposition 2.1.23), which sends $\mathbf{v}_0$ to $\mathbf{0}$.

If $\mathbf{w}_0 \neq \mathbf{0}$, the zero map is not in U, so U is not a subspace.

If $\mathbf{w}_0 = \mathbf{0}$, the zero map is in U. For $S, T \in U$ and $c \in F$,

$$(cS + T)(\mathbf{v}_0) = cS(\mathbf{v}_0) + T(\mathbf{v}_0) = c\mathbf{0} + \mathbf{0} = \mathbf{0},$$

Taking $c = 1$ shows that U is closed under addition, and taking $T = 0$ shows that it is closed under scalar multiplication. So U is a subspace by Theorem 1.4.3.

Solution to Exercise 2.1.45

Uses. Proposition 2.1.24 (Algebra of composition), Theorem 1.4.3 (Subspace criterion), Notation 2.1.18
Hint 1. Every step is an application of Proposition 2.1.24. For (a), expand $A(cS+T)$ and $(cS+T)A$.
Hint 2. For (b), move A across ST one factor at a time, using associativity.
Hint 3. For (c), id_V and A commute with A. Use (b) and induction for the powers, then (a).
Sketch. (a) $A0 = 0 = 0A$, and $A(cS+T) = cAS + AT = cSA + TA = (cS+T)A$. (b) $AST = SAT = STA$. (c) $\mathrm{id}_V, A \in C(A)$, so every $A^k \in C(A)$ by (b), and linear combinations stay in $C(A)$ by (a).

(a) The zero map commutes with A: $(A0)(\mathbf{v}) = A(\mathbf{0}) = \mathbf{0} = (0A)(\mathbf{v})$ by Proposition 2.1.4. If $S, T \in C(A)$ and $c \in F$, then by parts (c) and (d) of Proposition 2.1.24,

$$A(cS+T) = c(AS) + AT = c(SA) + TA = (cS+T)A.$$

With $c = 1$ this shows that $C(A)$ is closed under addition, and with $T = 0$ that it is closed under scalar multiplication. So $C(A)$ is a subspace by Theorem 1.4.3.

(b) By associativity, $A(ST) = (AS)T = (SA)T = S(AT) = S(TA) = (ST)A$.

(c) $\mathrm{id}_V A = A = A\mathrm{id}_V$, and $AA = AA$, so $\mathrm{id}_V, A \in C(A)$. If $A^k \in C(A)$, then $A^{k+1} = A^k A \in C(A)$ by (b), so by induction every $A^k \in C(A)$. Since $C(A)$ is a subspace, it contains $a_0\mathrm{id}_V + a_1 A + \cdots + a_n A^n$.

Solution to Exercise 2.1.46

Uses. Example 2.1.9 (Maps of polynomials), Proposition 2.1.24 (Algebra of composition), Notation 2.1.18
Hint 1. (a) Apply both sides to $p = \sum_j a_j x^j$ and compare coefficients.
Hint 2. (b) Induct on k. First check, using only Proposition 2.1.24, that $DM^{k+1} - M^{k+1}D = \big(DM^k - M^kD\big)M + M^k(DM - MD)$.
Sketch. (a) $DM(p) = \sum (j+1)a_j x^j$ and $MD(p) = \sum j a_j x^j$, so the difference is p. (b) By the identity in the hint, the induction hypothesis, and (a), $DM^{k+1} - M^{k+1}D = kM^{k-1}M + M^k = (k+1)M^k$. Applied to p, (b) is the product rule $D\big(x^k p\big) = kx^{k-1}p + x^k D(p)$.

(a) Let $p = \sum_{j=0}^n a_j x^j$. Then $M(p) = \sum_{j=0}^n a_j x^{j+1}$, so $(DM)(p) = \sum_{j=0}^n (j+1)a_j x^j$, while $(MD)(p) = x\sum_{j=1}^n j a_j x^{j-1} = \sum_{j=0}^n j a_j x^j$ (the term $j=0$ is 0). Since $(j+1)a_j - j a_j = a_j$,

$$(DM - MD)(p) = \sum_{j=0}^n a_j x^j = p.$$

(b) We induct on k. For $k = 1$ this is (a), since $M^0 = \mathrm{id}$. Suppose $DM^k - M^kD = kM^{k-1}$ for some $k \geq 1$. By Proposition 2.1.24,

$$\big(DM^k - M^kD\big)M + M^k(DM - MD) = DM^{k+1} - M^kDM + M^kDM - M^{k+1}D = DM^{k+1} - M^{k+1}D.$$

By the induction hypothesis and (a), the left side is $kM^{k-1}M + M^k\,\mathrm{id} = kM^k + M^k = (k+1)M^k$, as desired.

Applied to p, (b) says $D\big(x^k p\big) - x^k D(p) = kx^{k-1}p$, that is, $D\big(x^k p\big) = kx^{k-1}p + x^k D(p)$: the product rule for the product of x^k and p. Exercise 2.1.49 proves the product rule in general.

Solution to Exercise 2.1.47

Uses. Non-example 2.1.14 (Complex conjugation), Exercise 2.1.5, Proposition 2.1.17 (Compositions of linear maps are linear), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space)
Techniques. Assemble linear maps from linear pieces (Technique 2.1.26)
Hint 1. An $\mathbb{R}$-linear map $T : \mathbb{C} \to \mathbb{C}$ satisfies $T(a+bi) = aT(1) + bT(i)$ for $a, b \in \mathbb{R}$. So it is determined by $T(1)$ and $T(i)$.
Hint 2. The map $z \mapsto \alpha z + \beta\overline{z}$ is $\mathbb{R}$-linear. Make its values at 1 and i equal $T(1)$ and $T(i)$: solve $\alpha + \beta = T(1)$ and $(\alpha - \beta)i = T(i)$.
Sketch. Both T and $z \mapsto \alpha z + \beta\overline{z}$ are $\mathbb{R}$-linear, so they agree everywhere as soon as they agree at 1 and i, which means $\alpha + \beta = T(1)$ and $\alpha - \beta = -iT(i)$. This system has the unique solution $\alpha = (T(1) - iT(i))/2$, $\beta = (T(1) + iT(i))/2$. Then $\beta = 0$ if and only if $T(i) = iT(1)$, which holds when T is $\mathbb{C}$-linear; and $\beta = 0$ makes $T(z) = \alpha z$ $\mathbb{C}$-linear.

(a) For $a, b \in \mathbb{R}$, $\mathbb{R}$-linearity gives $T(a+bi) = aT(1) + bT(i)$, so an $\mathbb{R}$-linear map $\mathbb{C} \to \mathbb{C}$ is determined by its values at 1 and i. For $\alpha, \beta \in \mathbb{C}$, the map $T_{\alpha,\beta}(z) = \alpha z + \beta\overline{z}$ is $\mathbb{R}$-linear. Indeed, multiplication by a complex number is $\mathbb{C}$-linear (Exercise 2.1.5), hence $\mathbb{R}$-linear, and conjugation is $\mathbb{R}$-linear (Non-example 2.1.14). So

$z \mapsto \beta\overline{z}$, the composite of conjugation and multiplication by β, is $\mathbb{R}$-linear by Proposition 2.1.17, and the sum of two $\mathbb{R}$-linear maps is $\mathbb{R}$-linear by Proposition 2.1.23. (Here β is not a scalar of the real vector space of $\mathbb{R}$-linear maps, so $z \mapsto \beta\overline{z}$ is a composite, not a scalar multiple.) Its values are $T_{\alpha,\beta}(1) = \alpha + \beta$ and $T_{\alpha,\beta}(i) = (\alpha - \beta)i$.

So $T = T_{\alpha,\beta}$ if and only if $\alpha + \beta = T(1)$ and $(\alpha - \beta)i = T(i)$, that is, $\alpha - \beta = -iT(i)$. Adding and subtracting these two equations shows that they hold if and only if

$$\alpha = \frac{T(1) - iT(i)}{2}, \quad \beta = \frac{T(1) + iT(i)}{2}.$$

So α and β exist and are unique.

(b) From the formula, $\beta = 0$ if and only if $T(1) + iT(i) = 0$; multiplying by $-i$, this says $T(i) = iT(1)$. If T is $\mathbb{C}$-linear, then $T(i) = T(i \cdot 1) = iT(1)$. Conversely, if $\beta = 0$, then $T(z) = \alpha z$, which is $\mathbb{C}$-linear by Exercise 2.1.5.

Solution to Exercise 2.1.48

Uses. Proposition 1.2.35 (Zero products), Theorem 1.5.5 (Independence is decided at zero), Definition 2.1.1 (Linear map)
Hint 1. For each nonzero $\mathbf{v}$ there is a scalar $\lambda_{\mathbf{v}}$ with $T(\mathbf{v}) = \lambda_{\mathbf{v}}\mathbf{v}$, and it is unique. The task is to show that $\lambda_{\mathbf{v}}$ does not depend on $\mathbf{v}$.
Hint 2. Take nonzero $\mathbf{u}, \mathbf{v}$. If the list $\mathbf{u}, \mathbf{v}$ is linearly independent, expand $T(\mathbf{u} + \mathbf{v})$ in two ways and compare coefficients.
Hint 3. If $\mathbf{u}, \mathbf{v}$ is dependent, then $\mathbf{v} = c\mathbf{u}$ for some c; compute $T(\mathbf{v})$ directly.
Sketch. Write $T(\mathbf{v}) = \lambda_{\mathbf{v}}\mathbf{v}$ for $\mathbf{v} \neq \mathbf{0}$. If $\mathbf{u}, \mathbf{v}$ is independent, then $\lambda_{\mathbf{u}+\mathbf{v}}(\mathbf{u} + \mathbf{v}) = \lambda_{\mathbf{u}}\mathbf{u} + \lambda_{\mathbf{v}}\mathbf{v}$, and comparing coefficients gives $\lambda_{\mathbf{u}} = \lambda_{\mathbf{u}+\mathbf{v}} = \lambda_{\mathbf{v}}$. If $\mathbf{v} = c\mathbf{u}$, then $T(\mathbf{v}) = c\lambda_{\mathbf{u}}\mathbf{u} = \lambda_{\mathbf{u}}\mathbf{v}$. So all $\lambda_{\mathbf{v}}$ are equal.

If $V = \{\mathbf{0}\}$, any λ works. Otherwise, for each $\mathbf{v} \neq \mathbf{0}$ choose $\lambda_{\mathbf{v}} \in F$ with $T(\mathbf{v}) = \lambda_{\mathbf{v}}\mathbf{v}$. It is unique: if $\lambda\mathbf{v} = \mu\mathbf{v}$, then $(\lambda - \mu)\mathbf{v} = \mathbf{0}$, so $\lambda = \mu$ by Proposition 1.2.35. We show $\lambda_{\mathbf{u}} = \lambda_{\mathbf{v}}$ for all nonzero $\mathbf{u}, \mathbf{v} \in V$.

Case 1: the list $\mathbf{u}, \mathbf{v}$ is linearly independent. Then $\mathbf{u} + \mathbf{v} \neq \mathbf{0}$ (otherwise $1\mathbf{u} + 1\mathbf{v} = \mathbf{0}$ would be a nontrivial relation), and

$$\lambda_{\mathbf{u}+\mathbf{v}}\mathbf{u} + \lambda_{\mathbf{u}+\mathbf{v}}\mathbf{v} = T(\mathbf{u} + \mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v}) = \lambda_{\mathbf{u}}\mathbf{u} + \lambda_{\mathbf{v}}\mathbf{v}.$$

So $(\lambda_{\mathbf{u}+\mathbf{v}} - \lambda_{\mathbf{u}})\mathbf{u} + (\lambda_{\mathbf{u}+\mathbf{v}} - \lambda_{\mathbf{v}})\mathbf{v} = \mathbf{0}$, and by Theorem 1.5.5 both coefficients are 0. Hence $\lambda_{\mathbf{u}} = \lambda_{\mathbf{u}+\mathbf{v}} = \lambda_{\mathbf{v}}$.

Case 2: the list $\mathbf{u}, \mathbf{v}$ is linearly dependent. By Theorem 1.5.5 there are $a, b \in F$, not both 0, with $a\mathbf{u} + b\mathbf{v} = \mathbf{0}$. If $b = 0$, then $a \neq 0$ and $a\mathbf{u} = \mathbf{0}$ would force $\mathbf{u} = \mathbf{0}$ by Proposition 1.2.35; so $b \neq 0$, and $\mathbf{v} = c\mathbf{u}$ with $c = -a/b$. Then

$$T(\mathbf{v}) = cT(\mathbf{u}) = c\lambda_{\mathbf{u}}\mathbf{u} = \lambda_{\mathbf{u}}(c\mathbf{u}) = \lambda_{\mathbf{u}}\mathbf{v},$$

so $\lambda_{\mathbf{v}} = \lambda_{\mathbf{u}}$ by uniqueness.

So all the $\lambda_{\mathbf{v}}$ equal a common value λ, and $T(\mathbf{v}) = \lambda\mathbf{v}$ for every $\mathbf{v} \neq \mathbf{0}$. Since also $T(\mathbf{0}) = \mathbf{0} = \lambda\mathbf{0}$, we get $T = \lambda \mathrm{id}_V$.

Solution to Exercise 2.1.49

Uses. Example 2.1.9 (Maps of polynomials), Proposition 2.1.17 (Compositions of linear maps are linear), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. For (a), fix q. Both sides of $D(pq) = D(p)q + pD(q)$ are linear in p, so it is enough to check them for $p = x^j$. Then fix $p = x^j$ and argue the same way in q.
Hint 2. For (b), first find $T(1)$ by applying the rule to $1 = 1 \cdot 1$. Then compute $T(x^n)$ by induction, writing $x^{n+1} = x^n \cdot x$.
Hint 3. You should get $T(x^n) = nx^{n-1}T(x)$. Two linear maps that agree on every x^n agree on every polynomial.
Sketch. (a) For a fixed q, $p \mapsto D(pq)$, $p \mapsto D(p)q$, and $p \mapsto pD(q)$ are linear (composites of D and multiplication maps), so it suffices to take $p = x^j$, and likewise $q = x^k$; there $(j + k)x^{j+k-1} = jx^{j-1}x^k + x^j kx^{k-1}$. (b) $T(1) = T(1) + T(1)$ gives $T(1) = 0$, and induction gives $T(x^n) = nx^{n-1}r$ with $r = T(x)$. So T and $p \mapsto rD(p)$ agree on monomials, hence everywhere. Conversely rD is a derivation by (a).

For $s \in F[x]$ let $M_s : F[x] \to F[x]$ be multiplication by s, $M_s(p) = sp$. It is linear, since $s(cp+q) = c(sp) + sq$ in $F[x]$. We use one observation twice: if two linear maps $F[x] \to F[x]$ agree on every monomial x^j, they agree on every $p = \sum_j a_j x^j$, since by linearity both send p to $\sum_j a_j$ times the common value at x^j. (This is the idea of Technique 2.2.7.)

(a) Fix q. The maps $p \mapsto D(pq) = \big(DM_q\big)(p)$, $p \mapsto D(p)q = \big(M_q D\big)(p)$, and $p \mapsto pD(q) = M_{D(q)}(p)$ are linear, so $p \mapsto D(p)q + pD(q)$ is linear too. Hence it suffices to prove $D\big(x^j q\big) = D\big(x^j\big)q + x^j D(q)$ for every $j \geq 0$. Now fix j; by the same argument with the roles of p and q exchanged, it suffices to take $q = x^k$. For $j, k \geq 0$,

$$D\big(x^j x^k\big) = (j+k)x^{j+k-1} = jx^{j-1}x^k + x^j \cdot kx^{k-1} = D\big(x^j\big)x^k + x^j D\big(x^k\big),$$

where a term with coefficient 0 is read as 0 (so that $jx^{j-1} = 0$ when $j = 0$, matching $D(1) = 0$).

(b) Let T be a derivation and $r = T(x)$. From $1 = 1 \cdot 1$, $T(1) = T(1) \cdot 1 + 1 \cdot T(1) = T(1) + T(1)$, so $T(1) = 0$. We claim $T(x^n) = nx^{n-1}r$ for all $n \geq 1$. For $n = 1$ this is the definition of r. If it holds for n, then

$$T\big(x^{n+1}\big) = T(x^n \cdot x) = T(x^n)x + x^n T(x) = nx^n r + x^n r = (n+1)x^n r.$$

So $T(x^n) = rD(x^n)$ for all $n \geq 0$ (for $n = 0$ both sides are 0). The maps T and $M_r D$ are linear and agree on every monomial, so $T(p) = rD(p)$ for all p.

Conversely, $p \mapsto rD(p)$ is linear, being $M_r D$, and by (a) and commutativity of multiplication in $F[x]$,

$$rD(pq) = r(D(p)q + pD(q)) = (rD(p))q + p(rD(q)).$$

So it is a derivation, with value $rD(x) = r$ at x.

Solution to Exercise 2.1.50

> *Uses.* Example 2.1.9 (Maps of polynomials), Proposition 2.1.24 (Algebra of composition), Exercise 2.1.45
> *Hint 1.* Work with $e_n = x^n/n!$ for $n \geq 0$. Then $D(e_n) = e_{n-1}$ for $n \geq 1$ and $D(e_0) = 0$, and every polynomial is a combination of the e_n in exactly one way.
> *Hint 2.* Write $T(e_n) = \sum_j b_{n,j} e_j$. Apply $DT = TD$ to e_0 to see that $T(e_0)$ is constant, and to e_n to get $b_{n,j+1} = b_{n-1,j}$.
> *Hint 3.* Let $c_k = b_{k,0}$, the constant term of $T(e_k)$. Show by induction on n that $T(e_n) = c_0 e_n + c_1 e_{n-1} + \cdots + c_n e_0$, and note that $e_{n-k} = D^k(e_n)$.
> *Sketch.* With $e_n = x^n/n!$, D shifts e_n to e_{n-1}. Writing $T(e_n) = \sum_j b_{n,j} e_j$, the relation $DT(e_n) = T(e_{n-1})$ gives $b_{n,j+1} = b_{n-1,j}$, and $DT(e_0) = 0$ gives $b_{0,j} = 0$ for $j \geq 1$. By induction, $b_{n,j} = c_{n-j}$ for $j \leq n$ and 0 for $j > n$, where $c_k = b_{k,0}$. So $T(e_n) = \sum_{k \leq n} c_k e_{n-k} = \sum_{k \leq n} c_k D^k(e_n)$, and linearity extends this to all p.

Setup. For $n \geq 0$ let $e_n = x^n/n! \in \mathbb{F}[x]$; dividing by $n!$ is allowed since $n! \neq 0$ in $\mathbb{R}$ and $\mathbb{C}$. Then $D(e_0) = 0$ and $D(e_n) = nx^{n-1}/n! = e_{n-1}$ for $n \geq 1$, so $D^k(e_n) = e_{n-k}$ for $k \leq n$ and $D^k(e_n) = 0$ for $k > n$. A polynomial $\sum_j a_j x^j$ equals $\sum_j \big(j! a_j\big) e_j$, and comparing coefficients of x^j shows that this is the only way to write it as a combination of the e_j.

For each n write $T(e_n) = \sum_{j \geq 0} b_{n,j} e_j$, with only finitely many $b_{n,j}$ nonzero, and let $c_k = b_{k,0}$. We claim that for every $n \geq 0$,

$$b_{n,j} = c_{n-j} \quad \text{for } 0 \leq j \leq n, \quad \text{and} \quad b_{n,j} = 0 \quad \text{for } j > n. \tag{C.1.2}$$

The case $n = 0$. Since $DT = TD$, $D(T(e_0)) = T(D(e_0)) = T(0) = 0$. But $D(T(e_0)) = \sum_{j \geq 1} b_{0,j} e_{j-1}$, and by uniqueness of coefficients $b_{0,j} = 0$ for all $j \geq 1$. Also $b_{0,0} = c_0$ by definition.

The induction step. Let $n \geq 1$ and suppose the claim holds for $n-1$. Then

$$\sum_{j \geq 0} b_{n,j+1} e_j = D(T(e_n)) = T(D(e_n)) = T(e_{n-1}) = \sum_{j \geq 0} b_{n-1,j} e_j,$$

so $b_{n,j+1} = b_{n-1,j}$ for all $j \geq 0$. For $0 \leq j \leq n-1$ this gives $b_{n,j+1} = c_{n-1-j} = c_{n-(j+1)}$, and for $j \geq n$ it gives $b_{n,j+1} = 0$. Together with $b_{n,0} = c_n$, this is (C.1.2) for n.

Conclusion. By (C.1.2),

$$T(e_m) = \sum_{j=0}^{m} c_{m-j} e_j = \sum_{k=0}^{m} c_k e_{m-k} = \sum_{k=0}^{n} c_k D^k(e_m) \quad \text{for every } n \geq m,$$

since $e_{m-k} = D^k(e_m)$ for $k \leq m$ and $D^k(e_m) = 0$ for $k > m$. Now let $\deg p \leq n$, and write $p = \sum_{m=0}^{n} a_m e_m$. By linearity of T and of each D^k,

$$T(p) = \sum_{m=0}^{n} a_m \sum_{k=0}^{n} c_k D^k(e_m) = \sum_{k=0}^{n} c_k D^k\left(\sum_{m=0}^{n} a_m e_m\right) = \sum_{k=0}^{n} c_k D^k(p).$$

Converse. Given scalars $c_0, c_1, \ldots$, define $T(p) = \sum_{k=0}^{n} c_k D^k(p)$ for any $n \geq \deg p$. For $p, q \in \mathbb{F}[x]$ and $a \in \mathbb{F}$, choose one n at least $\deg p$ and $\deg q$; then $T(ap+q) = \sum_{k \leq n} c_k D^k(ap+q) = aT(p) + T(q)$, because each D^k is linear. Since $\deg D(p) \leq \deg p$,

$$T(D(p)) = \sum_{k=0}^{n} c_k D^{k+1}(p) = D\left(\sum_{k=0}^{n} c_k D^k(p)\right) = D(T(p)).$$

So T is linear and commutes with D. (Compare Exercise 2.1.45: when $c_k = 0$ for large k, T is a polynomial in D.)

Solution to Exercise 2.1.51

> *Uses.* Exercise 2.1.37, every real number is a limit of a sequence of rational numbers
> *Hint 1.* Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$. By Exercise 2.1.37, T is $\mathbb{Q}$-linear. What is $T(q)$ for rational q?
> *Hint 2.* Approximate a real x by rationals and use continuity.
> *Sketch.* T is $\mathbb{Q}$-linear, so $T(q) = T(q \cdot 1) = qT(1)$ for $q \in \mathbb{Q}$. If $q_n \to x$ with $q_n \in \mathbb{Q}$, continuity gives $T(x) = \lim T(q_n) = \lim q_n T(1) = xT(1)$.

Regard $\mathbb{R}$ as a vector space over $\mathbb{Q}$. Since T is additive, Exercise 2.1.37 shows that T is $\mathbb{Q}$-linear, so $T(q) = T(q \cdot 1) = qT(1)$ for every $q \in \mathbb{Q}$. Let $x \in \mathbb{R}$, and choose rationals q_n with $q_n \to x$. Since T is continuous,

$$T(x) = \lim_{n \to \infty} T(q_n) = \lim_{n \to \infty} q_n T(1) = xT(1).$$

So T is the map $x \mapsto ax$ with $a = T(1)$, which is $\mathbb{R}$-linear by Exercise 2.1.5.

Section 2.2

Solution to Exercise 2.2.5

> *Uses.* Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.1 (Basis)
> *Hint 1.* First check that $(1,1), (1,2)$ is a basis of $\mathbb{R}^2$ by solving $(x,y) = a(1,1) + b(1,2)$ for a and b.
> *Hint 2.* Then $T(x,y) = aT(1,1) + bT(1,2) = a$.
> *Sketch.* Solving gives $a = 2x - y$ and $b = y - x$, uniquely, so the list is a basis and $T(x,y) = a = 2x - y$. Then $T(3,5) = 1$.

The equations $a + b = x$ and $a + 2b = y$ give $b = y - x$ by subtraction, and then $a = x - b = 2x - y$. Conversely these values satisfy both equations, so every (x,y) is a combination of $(1,1), (1,2)$ in exactly one way, and the list is a basis of $\mathbb{R}^2$. By Theorem 2.2.1 there is exactly one such T, and by (2.2.1),

$$T(x,y) = (2x - y) \cdot 1 + (y - x) \cdot 0 = 2x - y.$$

Check: $T(1,1) = 1$ and $T(1,2) = 0$. Finally, $T(3,5) = 6 - 5 = 1$.

Solution to Exercise 2.2.9

> *Uses.* Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space), Proposition 2.1.17 (Compositions of linear maps are linear)
> *Techniques.* Check it on a basis (Technique 2.2.7)
> *Hint 1.* Both sides are linear maps, so it suffices to compare them at each $\mathbf{v}_i$.
> *Hint 2.* Compute $T^2(\mathbf{v}_i) = T(\mathbf{v}_i + \mathbf{v}_1) = T(\mathbf{v}_i) + T(\mathbf{v}_1)$.
> *Sketch.* $T^2(\mathbf{v}_i) = (\mathbf{v}_i + \mathbf{v}_1) + 2\mathbf{v}_1 = \mathbf{v}_i + 3\mathbf{v}_1$, and $(3T - 2\,\mathrm{id})(\mathbf{v}_i) = 3\mathbf{v}_i + 3\mathbf{v}_1 - 2\mathbf{v}_i$ is the same vector.

Both T^2 and $3T - 2\mathrm{id}_V$ are linear (Proposition 2.1.17, Proposition 2.1.23), so by Corollary 2.2.6 it suffices to show that they agree at each $\mathbf{v}_i$. For every i,

$$T^2(\mathbf{v}_i) = T(\mathbf{v}_i + \mathbf{v}_1) = T(\mathbf{v}_i) + T(\mathbf{v}_1) = (\mathbf{v}_i + \mathbf{v}_1) + 2\mathbf{v}_1 = \mathbf{v}_i + 3\mathbf{v}_1,$$

and

$$(3T - 2\mathrm{id}_V)(\mathbf{v}_i) = 3(\mathbf{v}_i + \mathbf{v}_1) - 2\mathbf{v}_i = \mathbf{v}_i + 3\mathbf{v}_1.$$

(For $i = 1$ both computations give $4\mathbf{v}_1$.) So $T^2 = 3T - 2\mathrm{id}_V$.

Solution to Exercise 2.2.21

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.1 (Basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations)
Hint 1. (a) Solve $(x, y) = a(1, 2) + b(2, 1)$ for a and b in $\mathbb{F}_5$. You will need 3^{-1} in $\mathbb{F}_5$.
Hint 2. (b) Compare $(2, 1)$ with $2 \cdot (1, 2)$ in $\mathbb{F}_3^2$.
Sketch. (a) Solving gives $b = 4x + 3y$ and $a = 3x + 4y$, uniquely, so the list is a basis and $T(x, y) = a(1, 0) + b(0, 1) = (3x + 4y, 4x + 3y)$. (b) In $\mathbb{F}_3^2$, $(2, 1) = 2(1, 2)$, so a linear T would have $T(2, 1) = (2, 0) \neq (0, 1)$.

(a) Consider the equations $a + 2b = x$ and $2a + b = y$ over $\mathbb{F}_5$. Subtracting twice the first from the second gives $-3b = y - 2x$, that is, $3b = 2x - y$. Since $3 \cdot 2 = 6 = 1$ in $\mathbb{F}_5$, $3^{-1} = 2$, so

$$b = 2(2x - y) = 4x - 2y = 4x + 3y, \quad a = x - 2b = x - 8x - 6y = 3x + 4y.$$

Conversely, these values satisfy both equations: $a + 2b = 11x + 10y = x$ and $2a + b = 10x + 11y = y$ in $\mathbb{F}_5$. So every vector has exactly one representation, and $(1, 2), (2, 1)$ is a basis of $\mathbb{F}_5^2$. By Theorem 2.2.1 there is exactly one such T, and by (2.2.1)

$$T(x, y) = a(1, 0) + b(0, 1) = (3x + 4y, 4x + 3y).$$

Check: $T(1, 2) = (11, 10) = (1, 0)$ and $T(2, 1) = (10, 11) = (0, 1)$ in $\mathbb{F}_5^2$.

(b) In $\mathbb{F}_3^2$, $2 \cdot (1, 2) = (2, 4) = (2, 1)$. A linear T would therefore satisfy $T(2, 1) = 2T(1, 2) = (2, 0)$, which is not $(0, 1)$. So no such T exists. Here $(1, 2), (2, 1)$ is linearly dependent, and the prescribed values do not satisfy the relation $(2, 1) - 2 \cdot (1, 2) = \mathbf{0}$.

Solution to Exercise 2.2.22

Uses. Algorithm 2.2.15 (Deciding whether a linear map with prescribed values exists), Proposition 2.2.14 (Prescribing values on any list), Proposition 2.1.16 (Linear maps preserve spans and linear relations)
Hint 1. Follow Algorithm 2.2.15: look for a linear relation among the given vectors, then ask whether they span the domain.
Hint 2. (a) $(2, 4) = 2(1, 2)$. (b) $(1, 1, 2)$ is the sum of the other two vectors; do these span $\mathbb{R}^3$? (c) $(3, 1) = 2(1, 1) + (1, -1)$. (d) Add the three vectors in $\mathbb{F}_2^3$.
Sketch. (a) No: $T(2, 4)$ would be $2T(1, 2) = (2, 0)$. (b) Exists, since the relation is respected, but is not unique, since the vectors span only a plane. (c) Exists and is unique: $T(x, y) = x + y$. (d) No: the three vectors add up to $\mathbf{0}$ in $\mathbb{F}_2^3$, but the values add up to 1.

(a) No. Since $(2, 4) = 2(1, 2)$, a linear T would have $T(2, 4) = 2T(1, 2) = (2, 0) \neq (2, 1)$.

(b) Exists, but is not unique. Let $\mathbf{u}_1 = (1, 0, 1)$ and $\mathbf{u}_2 = (0, 1, 1)$. They are independent, since $a\mathbf{u}_1 + b\mathbf{u}_2 = (a, b, a + b)$ is $\mathbf{0}$ only for $a = b = 0$. The third vector is $(1, 1, 2) = \mathbf{u}_1 + \mathbf{u}_2$, and the values satisfy the same relation: $(1, 1) + (2, 0) = (3, 1)$. The list does not span $\mathbb{R}^3$, since every vector $(a, b, a + b)$ of the span has third coordinate equal to the sum of the first two, and $\mathbf{e}_3$ does not. Adding $\mathbf{e}_3$ gives a basis: $(x, y, z) = a\mathbf{u}_1 + b\mathbf{u}_2 + c\mathbf{e}_3$ exactly when $a = x$, $b = y$, and $c = z - x - y$. By Proposition 2.2.14, a map exists and is not unique. Explicitly, for each $\mathbf{c} \in \mathbb{R}^2$,

$$T(x, y, z) = x(1, 1) + y(2, 0) + (z - x - y)\mathbf{c}$$

has the prescribed values and $T(\mathbf{e}_3) = \mathbf{c}$.

(c) Exists and is unique. The vectors $(1,1),(1,-1)$ form a basis of $\mathbb{R}^2$ (Example 2.2.3), and $(3,1) = 2(1,1) + (1,-1)$. The values satisfy the same relation, $2 \cdot 2 + 0 = 4$, so by Remark 2.2.12 a map exists, and it is unique because the list spans $\mathbb{R}^2$. Explicitly, $T(x,y) = x + y$, which gives $T(1,1) = 2$, $T(1,-1) = 0$, and $T(3,1) = 4$.

(d) No. In $\mathbb{F}_2^3$,

$$(1,1,0) + (0,1,1) + (1,0,1) = (2,2,2) = \mathbf{0},$$

so by Proposition 2.1.16 a linear T would satisfy $T(1,1,0) + T(0,1,1) + T(1,0,1) = 0$. But $1+1+1 = 1$ in $\mathbb{F}_2$.

Solution to Exercise 2.2.23

Uses. Proposition 2.2.20 (Linear maps out of $F[x]$), Example 2.1.10 (Integration), Example 2.1.9 (Maps of polynomials), Proposition 2.1.17 (Compositions of linear maps are linear), Proposition 1.2.18 (Degree and evaluation versus the operations)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. In each part, show that the proposed map is linear and has the right values on monomials; then Proposition 2.2.20 says it is the map in question.
Hint 2. $\int_0^1 t^n \, dt = 1/(n+1)$, and $p \mapsto p'(1)$ is the composite of differentiation and evaluation at 1.
Sketch. (a) $p \mapsto \int_0^1 p$ is linear and sends x^n to $1/(n+1)$. (b) $p \mapsto p'(1)$ is linear, being evaluation at 1 after D, and sends x^n to $n \cdot 1^{n-1} = n$. By uniqueness in Proposition 2.2.20, these are T and U. $U\left(x^2 + x\right) = 2 + 1 = 3$, which is 3, 1, and 0 in $\mathbb{R}$, $\mathbb{F}_2$, and $\mathbb{F}_3$.

(a) Let $I(p) = \int_0^1 p(t) \, dt$. Evaluation respects the operations of $\mathbb{R}[x]$, $(cp+q)(t) = cp(t) + q(t)$ (Proposition 1.2.18), so by the linearity of the integral (Example 2.1.10), $I(cp+q) = cI(p) + I(q)$, and I is linear. Since $I(x^n) = \int_0^1 t^n \, dt = 1/(n+1)$, the maps I and T are linear and agree on every monomial, so $I = T$ by the uniqueness part of Proposition 2.2.20.

(b) Let $U'(p) = p'(1)$, that is, $U' = \mathrm{ev}_1 \circ D$ with ev_1 the evaluation at 1 and D the formal derivative. Both are linear (Example 2.1.9), so U' is linear (Proposition 2.1.17). We have $U'(1) = \mathrm{ev}_1(0) = 0$, and $U'(x^n) = \mathrm{ev}_1\left(nx^{n-1}\right) = n \cdot 1^{n-1} = n$ for $n \geq 1$. So U' and U agree on every monomial, and $U' = U$ by Proposition 2.2.20.

Finally, $U\left(x^2 + x\right) = 2 + 1 = 3 \cdot 1$. This is 3 over $\mathbb{R}$, 1 over $\mathbb{F}_2$, and 0 over $\mathbb{F}_3$. Over $\mathbb{F}_3$, indeed, $D\left(x^2 + x\right) = 2x + 1$ and $2 + 1 = 0$.

Solution to Exercise 2.2.24

Uses. Proposition 2.2.11 (Prescribing values on a spanning list), Non-example 2.2.10 (A spanning list that is not independent)
Hint 1. Does $T(\mathbf{v})$ depend on which scalars were chosen?
Hint 2. Try $V = W = \mathbb{R}$, the spanning list $1, 1$, and the values $0, 1$.
Sketch. $T(\mathbf{v})$ depends on the chosen representation, and the proof silently uses other representations: the trivial one for $\mathbf{v}_i$, and $\sum_i (ca_i + b_i)\mathbf{v}_i$ for $c\mathbf{u} + \mathbf{v}$. Counterexample: the list $1, 1$ in $\mathbb{R}$ with values $0, 1$. The claim becomes true under (2.2.2).

The definition of T involves a choice of scalars for each $\mathbf{v}$, and when $\mathbf{v}$ has several representations, different choices can give different values. The proof then treats $T(\mathbf{v})$ as if it could be computed from any representation. It computes $T(\mathbf{v}_i)$ from the representation with $a_i = 1$, which need not be the one chosen for $\mathbf{v}_i$, and it computes $T(c\mathbf{u} + \mathbf{v})$ from the representation $\sum_i (ca_i + b_i)\mathbf{v}_i$, which need not be the one chosen for $c\mathbf{u} + \mathbf{v}$. Both steps are valid only if the value does not depend on the representation, and that is exactly what can fail.

The claim is false. In $V = W = \mathbb{R}$, the list $1, 1$ spans $\mathbb{R}$. With $\mathbf{w}_1 = 0$ and $\mathbf{w}_2 = 1$, a linear T would need $T(1) = 0$ and $T(1) = 1$. The argument becomes correct under the extra hypothesis (2.2.2), which is exactly what makes the value independent of the representation; the first proof of Proposition 2.2.11 is the repaired version.

Solution to Exercise 2.2.25

Uses. Proposition 2.1.16 (Linear maps preserve spans and linear relations), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Techniques. Check it on a basis (Technique 2.2.7)

Hint 1. Technique 2.2.7 applies to equations between linear maps and to statements that reduce to them. Which of these statements are of that kind?
Hint 2. For (a) and (c), try $T(x,y) = (x, 2y)$ and $T(x,y) = x - y$ on $\mathbb{R}^2$ with the standard basis.
Sketch. (a) False: $T(x,y) = (x,2y)$ scales $\mathbf{e}_1$ and $\mathbf{e}_2$, but $T(1,1) = (1,2)$. (b) True: $T(V) = \operatorname{span} T(\mathcal{B}) \subseteq U$. (c) False: $(x,y) \mapsto x - y$ kills $(1,1)$. (d) True: $T\big(\sum_i a_i \mathbf{v}_i\big) = \big(\sum_i a_i\big) T(\mathbf{v}_1)$.

(a) False. On $\mathbb{R}^2$ with the standard basis, $T(x,y) = (x,2y)$ satisfies $T(\mathbf{e}_1) = \mathbf{e}_1$ and $T(\mathbf{e}_2) = 2\mathbf{e}_2$. But $T(1,1) = (1,2)$, which is not in $\operatorname{span}((1,1))$, since multiples of $(1,1)$ have equal coordinates. The condition "$T(\mathbf{v}) \in \operatorname{span}(\mathbf{v})$" is not an equation between linear maps, so it does not pass from a basis to all vectors.

(b) True. By Proposition 2.1.16, $T(V) = T(\operatorname{span} \mathcal{B}) = \operatorname{span}(T(\mathbf{v}_1), \ldots, T(\mathbf{v}_n))$. Since U is a subspace containing every $T(\mathbf{v}_i)$, it contains their span (Proposition 1.4.14).

(c) False. Let $T : \mathbb{R}^2 \to \mathbb{R}$, $T(x,y) = x - y$. Then $T(\mathbf{e}_1) = 1$ and $T(\mathbf{e}_2) = -1$ are nonzero, but $T(1,1) = 0$.

(d) True. Let $\mathbf{w}$ be the common value. For $\mathbf{v} = \sum_i a_i \mathbf{v}_i$, linearity gives $T(\mathbf{v}) = \sum_i a_i \mathbf{w} = (a_1 + \cdots + a_n)\mathbf{w} \in \operatorname{span}(\mathbf{w})$.

Solution to Exercise 2.2.26

Uses. Theorem 2.2.1 (Linear maps are determined by a basis)
Hint 1. The theorem gives three maps, one for each pair of vectors. Why should they be the same map?
Hint 2. Write $(1,1)$ as a combination of $(1,2)$ and $(2,1)$.
Sketch. The three maps given by the theorem need not coincide, and the last sentence does not follow. The linear map with $T(1,2) = T(2,1) = 1$ is unique, namely $T(x,y) = (x+y)/3$, so $T(1,1)$ is forced to be $2/3$. Hence $c = 2/3$ only, and the claim is false.

(a) The argument produces, for each of the three pairs, a linear map that takes the two prescribed values on that pair. These are three maps, and nothing in the argument shows that they are the same map, or that any one of them takes all three values. The first sentence is true, but the conclusion does not follow from it, and (b) shows that the claim is false.

(b) The vectors $(1,2), (2,1)$ form a basis of $\mathbb{R}^2$: the equations $a + 2b = x$ and $2a + b = y$ have the unique solution $a = (2y - x)/3$, $b = (2x - y)/3$. By Theorem 2.2.1, there is exactly one linear T_0 with $T_0(1,2) = T_0(2,1) = 1$, namely

$$T_0(x,y) = a + b = \frac{x+y}{3}.$$

Any T with $T(1,2) = T(2,1) = 1$ equals T_0, so $T(1,1) = T_0(1,1) = 2/3$. Hence $c = 2/3$ is the only possible value, and for it T_0 works. In particular no linear map has $T(1,1) = 1$. Equivalently, $(1,1) = \frac{1}{3}(1,2) + \frac{1}{3}(2,1)$, and the prescribed values violate this relation unless $c = 2/3$.

Solution to Exercise 2.2.27

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.1 (Basis), Proposition 1.2.19 (Restriction of scalars), Non-example 2.1.14 (Complex conjugation)
Hint 1. (a) Solve $(z_1, z_2) = a(1,i) + b(1,-i)$ for $a, b \in \mathbb{C}$.
Hint 2. (b) Over $\mathbb{C}$, how is $(i,-1)$ related to $(1,i)$?
Hint 3. (c) Over $\mathbb{R}$ the scalar i is not available. Extend $(1,i), (i,-1)$ to a basis of $\mathbb{C}^2$ over $\mathbb{R}$ by adding $(0,1)$ and $(0,i)$.
Sketch. (a) $a = (z_1 - iz_2)/2$ and $b = (z_1 + iz_2)/2$, uniquely, so $T(z_1,z_2) = ((z_1 - iz_2)/2, (z_1 + iz_2)/2)$. (b) $(i,-1) = i(1,i)$, so $T(i,-1)$ would be $(i,0)$. (c) $(1,i), (i,-1), (0,1), (0,i)$ is a basis over $\mathbb{R}$; apply Theorem 2.2.1 over $\mathbb{R}$.

(a) The equation $(z_1, z_2) = a(1,i) + b(1,-i)$ means $a + b = z_1$ and $i(a - b) = z_2$, that is, $a - b = -iz_2$. Adding and subtracting,

$$a = \frac{z_1 - iz_2}{2}, \quad b = \frac{z_1 + iz_2}{2},$$

and these values satisfy both equations. So $(1,i), (1,-i)$ is a basis of $\mathbb{C}^2$, and by Theorem 2.2.1 there is exactly one such T:

$$T(z_1, z_2) = a(1,0) + b(0,1) = \left(\frac{z_1 - iz_2}{2}, \frac{z_1 + iz_2}{2}\right).$$

Check: at $(1,i)$, $z_1 - iz_2 = 1 - i^2 = 2$ and $z_1 + iz_2 = 1 + i^2 = 0$, so $T(1,i) = (1,0)$; similarly $T(1,-i) = (0,1)$.

(b) Since $i \cdot i = -1$, we have $(i,-1) = i(1,i)$. A $\mathbb{C}$-linear T would satisfy $T(i,-1) = iT(1,i) = (i,0)$, which is not $(0,1)$.

(c) Over $\mathbb{R}$ we show that $(1,i),(i,-1),(0,1),(0,i)$ is a basis of $\mathbb{C}^2$. For $a,b,c,d \in \mathbb{R}$,

$$a(1,i) + b(i,-1) + c(0,1) + d(0,i) = (a + bi, (c-b) + (a+d)i).$$

This equals a given (z_1, z_2) exactly when $a + bi = z_1$ and $(c-b) + (a+d)i = z_2$. Comparing real and imaginary parts, the first equation determines a and b, and then the second determines c and d. So there is exactly one solution, and the list is a basis of $\mathbb{C}^2$ over $\mathbb{R}$. By Theorem 2.2.1 over the field $\mathbb{R}$, there is an $\mathbb{R}$-linear T with $T(1,i) = (1,0)$, $T(i,-1) = (0,1)$, and, say, $T(0,1) = T(0,i) = \mathbf{0}$. By (b), T is not $\mathbb{C}$-linear. As with complex conjugation (Non-example 2.1.14), whether a map is linear depends on the field of scalars.

Solution to Exercise 2.2.28

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Corollary 2.2.6 (Agreeing on a spanning list)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
Hint 1. Find a basis of $\mathbb{R}^3$ consisting of two vectors of U and $(1,1,1)$. Try $(1,-1,0)$ and $(0,1,-1)$.
Hint 2. Express (x,y,z) in that basis. The coefficient of $(1,1,1)$ is $(x+y+z)/3$.
Hint 3. For $T^2 = T$, compare both sides on your basis.
Sketch. $\mathbf{u}_1 = (1,-1,0)$ and $\mathbf{u}_2 = (0,1,-1)$ span U, and with $\mathbf{u}_3 = (1,1,1)$ they form a basis of $\mathbb{R}^3$, in which (x,y,z) has $\mathbf{u}_3$-coefficient $s = (x+y+z)/3$. The conditions force $\mathbf{u}_1 \mapsto \mathbf{u}_1$, $\mathbf{u}_2 \mapsto \mathbf{u}_2$, $\mathbf{u}_3 \mapsto \mathbf{0}$, so $T(\mathbf{v}) = \mathbf{v} - s\mathbf{u}_3$. Both T^2 and T fix $\mathbf{u}_1, \mathbf{u}_2$ and kill $\mathbf{u}_3$.

Let $\mathbf{u}_1 = (1,-1,0)$, $\mathbf{u}_2 = (0,1,-1)$, and $\mathbf{u}_3 = (1,1,1)$. For $(x,y,z) \in \mathbb{R}^3$,

$$a\mathbf{u}_1 + b\mathbf{u}_2 + c\mathbf{u}_3 = (a + c, -a + b + c, -b + c).$$

Setting this equal to (x,y,z) and adding the three coordinates gives $3c = x + y + z$. The first and third coordinates then give $a = x - c$ and $b = c - z$, and the second holds automatically, since $-a + b + c = 3c - x - z = y$. So the unique solution is

$$c = \frac{x+y+z}{3}, \quad a = x - c, \quad b = c - z,$$

and $\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$ is a basis of $\mathbb{R}^3$. Both $\mathbf{u}_1$ and $\mathbf{u}_2$ lie in U, and if $(x,y,z) \in U$ then $c = 0$, so $U = \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$.

Uniqueness. Any T with the required properties satisfies $T(\mathbf{u}_1) = \mathbf{u}_1$, $T(\mathbf{u}_2) = \mathbf{u}_2$, and $T(\mathbf{u}_3) = \mathbf{0}$, and by Theorem 2.2.1 only one linear map does.

Existence. Let T be that linear map. For $\mathbf{u} = a\mathbf{u}_1 + b\mathbf{u}_2 \in U$, $T(\mathbf{u}) = a\mathbf{u}_1 + b\mathbf{u}_2 = \mathbf{u}$, and $T(1,1,1) = \mathbf{0}$. For a general vector $\mathbf{v} = (x,y,z) = a\mathbf{u}_1 + b\mathbf{u}_2 + c\mathbf{u}_3$,

$$T(\mathbf{v}) = a\mathbf{u}_1 + b\mathbf{u}_2 = \mathbf{v} - c\mathbf{u}_3 = (x - s, y - s, z - s), \quad \text{where } s = \frac{x+y+z}{3}.$$

So T subtracts from each coordinate the average of the three coordinates.

$T^2 = T$. Both sides are linear. For $i = 1,2$, $T^2(\mathbf{u}_i) = T(\mathbf{u}_i) = \mathbf{u}_i$, and $T^2(\mathbf{u}_3) = T(\mathbf{0}) = \mathbf{0} = T(\mathbf{u}_3)$. By Corollary 2.2.6, $T^2 = T$.

Solution to Exercise 2.2.29

Uses. Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.1.24 (Algebra of composition), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. All three statements are identities between linear maps, or follow from one. Check them on $\mathbf{v}_1, \ldots, \mathbf{v}_n$.
Hint 2. T moves each basis vector one step around the cycle $\mathbf{v}_1 \to \mathbf{v}_2 \to \cdots \to \mathbf{v}_n \to \mathbf{v}_1$. Where is $\mathbf{v}_i$ after k steps?

Hint 3. $N(\mathbf{v}_i)$ is the sum of the vectors that $\mathbf{v}_i$ visits in its first $n-1$ steps, together with $\mathbf{v}_i$ itself.
Sketch. With indices read mod n, $T^k(\mathbf{v}_i) = \mathbf{v}_{i+k}$. So $T^n(\mathbf{v}_i) = \mathbf{v}_i$, and $N(\mathbf{v}_i) = \mathbf{v}_i + \mathbf{v}_{i+1} + \cdots + \mathbf{v}_{i+n-1} = \mathbf{s}$, since these are all n basis vectors once each. Linearity gives (b). Since $T(\mathbf{s}) = \mathbf{s}$, TN and NT also send every $\mathbf{v}_i$ to $\mathbf{s}$.

For an integer j, write $\mathbf{v}_j$ for $\mathbf{v}_r$, where $r \in \{1, \ldots, n\}$ and $r \equiv j \pmod{n}$. With this convention $T(\mathbf{v}_j) = \mathbf{v}_{j+1}$ for every integer j, and by induction on k, $T^k(\mathbf{v}_i) = \mathbf{v}_{i+k}$ for all $k \geq 0$. All maps below are linear by Proposition 2.1.17 and Proposition 2.1.23.

(a) $T^n(\mathbf{v}_i) = \mathbf{v}_{i+n} = \mathbf{v}_i$ for each i. So T^n and id_V agree on a basis, and $T^n = \mathrm{id}_V$ by Corollary 2.2.6.

(b) For each i,

$$N(\mathbf{v}_i) = \sum_{k=0}^{n-1} T^k(\mathbf{v}_i) = \sum_{k=0}^{n-1} \mathbf{v}_{i+k} = \mathbf{s},$$

because the n consecutive integers $i, i+1, \ldots, i+n-1$ cover each residue mod n exactly once. By linearity, $N\left(\sum_i a_i \mathbf{v}_i\right) = \sum_i a_i \mathbf{s} = (a_1 + \cdots + a_n)\mathbf{s}$.

(c) $T(\mathbf{s}) = \sum_i T(\mathbf{v}_i) = \sum_i \mathbf{v}_{i+1} = \mathbf{s}$, the same n vectors in another order. So $TN(\mathbf{v}_i) = T(\mathbf{s}) = \mathbf{s} = N(\mathbf{v}_i)$, and $NT(\mathbf{v}_i) = N(\mathbf{v}_{i+1}) = \mathbf{s} = N(\mathbf{v}_i)$. By Corollary 2.2.6, $TN = NT = N$. (Alternatively, by Proposition 2.1.24 and (a), $TN = T + T^2 + \cdots + T^n = T + \cdots + T^{n-1} + \mathrm{id}_V = N$, and likewise $NT = T + T^2 + \cdots + T^n = N$.)

Solution to Exercise 2.2.30

Uses. Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.1.24 (Algebra of composition), Exercise 2.1.5
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. $\mathbf{e}_1$ and $R(\mathbf{e}_1) = \mathbf{e}_2$ form a basis of $\mathbb{R}^2$, so T is determined by $T(\mathbf{e}_1)$ and $T(R(\mathbf{e}_1))$.
Hint 2. If $TR = RT$, then $T(R(\mathbf{e}_1)) = R(T(\mathbf{e}_1))$. Write $T(\mathbf{e}_1) = (a, b)$ and compare T with $a\,\mathrm{id} + bR$ at $\mathbf{e}_1$ and $\mathbf{e}_2$.
Sketch. If $TR = RT$ and $T(\mathbf{e}_1) = (a, b)$, then $T(\mathbf{e}_2) = T(R\mathbf{e}_1) = R(a, b) = (-b, a)$. The map $a\,\mathrm{id} + bR$ also sends $\mathbf{e}_1 \mapsto (a, b)$ and $\mathbf{e}_2 \mapsto (-b, a)$, so it equals T. Conversely $a\,\mathrm{id} + bR$ commutes with R by Proposition 2.1.24. Under $(x, y) \leftrightarrow x + yi$, R is multiplication by i and $a\,\mathrm{id} + bR$ is multiplication by $a + bi$.

Suppose $TR = RT$, and let $T(\mathbf{e}_1) = (a, b)$. Since $R(\mathbf{e}_1) = \mathbf{e}_2$,

$$T(\mathbf{e}_2) = T(R(\mathbf{e}_1)) = R(T(\mathbf{e}_1)) = R(a, b) = (-b, a).$$

On the other hand, $(a\,\mathrm{id} + bR)(\mathbf{e}_1) = (a, 0) + b(0, 1) = (a, b)$ and $(a\,\mathrm{id} + bR)(\mathbf{e}_2) = (0, a) + b(-1, 0) = (-b, a)$. So T and $a\,\mathrm{id} + bR$ are linear maps that agree on the basis $\mathbf{e}_1, \mathbf{e}_2$, and $T = a\,\mathrm{id} + bR$ by Corollary 2.2.6.

Conversely, by Proposition 2.1.24, $(a\,\mathrm{id} + bR)R = aR + bR^2 = R(a\,\mathrm{id} + bR)$.

Identify $(x, y) \in \mathbb{R}^2$ with $x + yi \in \mathbb{C}$. Then $R(x, y) = (-y, x)$ corresponds to $-y + xi = i(x + yi)$, so R is multiplication by i, and $a\,\mathrm{id} + bR$ is multiplication by $a + bi$. So the $\mathbb{R}$-linear maps of the plane that commute with the quarter turn are exactly the multiplications by complex numbers, which are the $\mathbb{C}$-linear maps $\mathbb{C} \to \mathbb{C}$ (Exercise 2.1.5).

Solution to Exercise 2.2.31

Uses. Corollary 2.2.18 (Linear maps correspond to lists of vectors), Example 2.2.3 (Building maps from a convenient basis)
Hint 1. By Corollary 2.2.18, choosing T is the same as freely choosing the images of the vectors of a basis. Pick a basis that contains $(1, 1)$.
Hint 2. For (b), when is $(1, 1), (1, -1)$ a basis of $\mathbb{F}_p^2$? What happens when $p = 2$?
Sketch. (a) $(1, 1), (1, 0)$ is a basis; $T(1, 1)$ has p allowed values and $T(1, 0)$ has p^2, so there are p^3 maps. (b) For odd p, $(1, 1), (1, -1)$ is a basis, giving $p \cdot p = p^2$. For $p = 2$, $(1, -1) = (1, 1)$, the two conditions coincide, and the answer is $2^3 = 8$.

(a) The list $(1, 1), (1, 0)$ is a basis of $\mathbb{F}_p^2$, since $(x, y) = a(1, 1) + b(1, 0)$ exactly when $a = y$ and $b = x - y$. By Corollary 2.2.18, $T \mapsto (T(1, 1), T(1, 0))$ is a bijection from $\mathrm{L}\left(\mathbb{F}_p^2\right)$ onto the pairs of vectors in $\mathbb{F}_p^2$. The condition restricts $T(1, 1)$ to $\mathrm{span}((1, 1)) = \left\{(c, c) \;\middle|\; c \in \mathbb{F}_p\right\}$, which has p elements, and leaves $T(1, 0)$ free among p^2 vectors. So there are $p \cdot p^2 = p^3$ such maps.

(b) If p is odd, then $1+1 \neq 0$ in $\mathbb{F}_p$, so $(1,1),(1,-1)$ is a basis of $\mathbb{F}_p^2$ (Example 2.2.3). The conditions restrict $T(1,1)$ to the p vectors (c,c) and $T(1,-1)$ to the p vectors $(c,-c)$, which are distinct for distinct c. So there are p^2 such maps.

If $p=2$, then $-1=1$ in $\mathbb{F}_2$, so $(1,-1)=(1,1)$ and the second condition is the first one again. By (a) the answer is $2^3=8$.

Solution to Exercise 2.2.32

Uses. Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.35 (Zero products), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Hint 1. (a) Suppose $a_1\mathbf{v}_1+\cdots+a_n\mathbf{v}_n=\mathbf{0}$. Choose the $\mathbf{w}_i$ so that applying T to this relation isolates a_j.
Hint 2. Take $\mathbf{w}_j$ to be a nonzero vector of W and all other $\mathbf{w}_i=\mathbf{0}$.
Hint 3. (b) $\mathcal{L}$ is a basis of span $\mathcal{L}$.
Sketch. (a) If $\sum_i a_i\mathbf{v}_i=\mathbf{0}$, pick $\mathbf{w}\neq\mathbf{0}$ and let T send $\mathbf{v}_j\mapsto\mathbf{w}$ and the other $\mathbf{v}_i\mapsto\mathbf{0}$. Then $\mathbf{0}=T\big(\sum_i a_i\mathbf{v}_i\big)=a_j\mathbf{w}$, so $a_j=0$. (b) $\mathcal{L}$ spans span $\mathcal{L}$ and is independent, so it is a basis; apply Theorem 2.2.1.

(a) Suppose $a_1\mathbf{v}_1+\cdots+a_n\mathbf{v}_n=\mathbf{0}$, and fix j. Choose $\mathbf{w}\in W$ with $\mathbf{w}\neq\mathbf{0}$, and apply the hypothesis with $\mathbf{w}_j=\mathbf{w}$ and $\mathbf{w}_i=\mathbf{0}$ for $i\neq j$. The resulting linear T gives

$$\mathbf{0}=T(\mathbf{0})=T\left(\sum_{i=1}^{n}a_i\mathbf{v}_i\right)=\sum_{i=1}^{n}a_iT(\mathbf{v}_i)=a_j\mathbf{w}.$$

Since $\mathbf{w}\neq\mathbf{0}$, Proposition 1.2.35 gives $a_j=0$. As j was arbitrary, every $a_i=0$, and $\mathcal{L}$ is linearly independent by Theorem 1.5.5. (The hypothesis $W\neq\{\mathbf{0}\}$ is needed: every list has the zero map into $\{\mathbf{0}\}$.)

(b) The span of $\mathcal{L}$ is a subspace of V (Proposition 1.4.14), hence a vector space, and $\mathcal{L}$ spans it. If $\mathcal{L}$ is linearly independent, it is therefore a basis of span $\mathcal{L}$, and Theorem 2.2.1 gives the map. To get a map on all of V, one needs to extend from span $\mathcal{L}$ to V, which is possible under the hypothesis of Proposition 2.2.14.

Solution to Exercise 2.2.33

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.14 (Coordinates), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.1.23 (L(V,W) is a vector space)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. (a) is Theorem 2.2.1 with $W=F$. Use (2.2.1) to evaluate $\varphi_i(a_1\mathbf{v}_1+\cdots+a_n\mathbf{v}_n)$.
Hint 2. (c) Both sides are linear maps $V\to F$. Compare them on the basis.
Sketch. (a) $\varphi_i\big(\sum_j a_j\mathbf{v}_j\big)=\sum_j a_j\varphi_i(\mathbf{v}_j)=a_i$. (b) is the definition of coordinates, rewritten with (a). (c) Both sides send $\mathbf{v}_k$ to $\varphi(\mathbf{v}_k)$, since $\varphi_i(\mathbf{v}_k)$ is 1 for $i=k$ and 0 otherwise.

(a) By Theorem 2.2.1 with $W=F$, there is exactly one linear φ_i with the prescribed values on $\mathcal{B}$. By (2.2.1),

$$\varphi_i(a_1\mathbf{v}_1+\cdots+a_n\mathbf{v}_n)=\sum_{j=1}^{n}a_j\varphi_i(\mathbf{v}_j)=a_i,$$

so $\varphi_i(\mathbf{v})$ is the i-th coordinate of $\mathbf{v}$ (Definition 1.6.14).

(b) By definition of coordinates, $\mathbf{v}=c_1\mathbf{v}_1+\cdots+c_n\mathbf{v}_n$ with $(c_1,\ldots,c_n)=[\mathbf{v}]_{\mathcal{B}}$, and $c_i=\varphi_i(\mathbf{v})$ by (a).

(c) Let $\psi=\varphi(\mathbf{v}_1)\varphi_1+\cdots+\varphi(\mathbf{v}_n)\varphi_n$, which is linear by Proposition 2.1.23. For each k,

$$\psi(\mathbf{v}_k)=\sum_{i=1}^{n}\varphi(\mathbf{v}_i)\varphi_i(\mathbf{v}_k)=\varphi(\mathbf{v}_k),$$

since only the term $i=k$ survives. So ψ and φ agree on a basis, and $\psi=\varphi$ by Corollary 2.2.6.

Solution to Exercise 2.2.34

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Corollary 2.2.6 (Agreeing on a spanning list), Theorem 1.5.5 (Independence is decided at zero), Definition 2.1.21 (Pointwise operations)
Techniques. Check it on a basis (Technique 2.2.7)

Hint 1. Each E_{ij} exists and is unique by Theorem 2.2.1. For independence, apply a vanishing combination $\sum_{i,j} c_{ij}E_{ij}$ to a basis vector $\mathbf{v}_k$.
Hint 2. For spanning, given T, write $T(\mathbf{v}_j) = a_{1j}\mathbf{w}_1 + \cdots + a_{mj}\mathbf{w}_m$, and compare T with $\sum_{i,j} a_{ij}E_{ij}$ on the basis of V.
Sketch. $\left(\sum_{i,j} c_{ij}E_{ij}\right)(\mathbf{v}_k) = \sum_i c_{ik}\mathbf{w}_i$. If the combination is 0, independence of the $\mathbf{w}_i$ gives every $c_{ik} = 0$. Given T with $T(\mathbf{v}_j) = \sum_i a_{ij}\mathbf{w}_i$, the map $\sum_{i,j} a_{ij}E_{ij}$ agrees with T at every $\mathbf{v}_k$, so it equals T.

By Theorem 2.2.1 each E_{ij} exists and is unique. For scalars c_{ij} and each k, the operations on $\mathrm{L}(V, W)$ are pointwise (Definition 2.1.21), so

$$\left(\sum_{i,j} c_{ij}E_{ij}\right)(\mathbf{v}_k) = \sum_{i,j} c_{ij}E_{ij}(\mathbf{v}_k) = \sum_{i=1}^{m} c_{ik}\mathbf{w}_i, \tag{C.1.3}$$

because $E_{ij}(\mathbf{v}_k) = \mathbf{0}$ unless $j = k$.

Independence. Suppose $\sum_{i,j} c_{ij}E_{ij} = 0$. Evaluating at $\mathbf{v}_k$ and using (C.1.3) gives $\sum_i c_{ik}\mathbf{w}_i = \mathbf{0}$. Since $\mathbf{w}_1, \ldots, \mathbf{w}_m$ is linearly independent, $c_{ik} = 0$ for every i (Theorem 1.5.5). This holds for every k, so all $c_{ij} = 0$, and the list is linearly independent by Theorem 1.5.5.

Spanning. Let $T \in \mathrm{L}(V, W)$. Since the $\mathbf{w}_i$ span W, there are scalars a_{ij} with $T(\mathbf{v}_j) = a_{1j}\mathbf{w}_1 + \cdots + a_{mj}\mathbf{w}_m$ for each j. By (C.1.3), $\left(\sum_{i,j} a_{ij}E_{ij}\right)(\mathbf{v}_k) = \sum_i a_{ik}\mathbf{w}_i = T(\mathbf{v}_k)$ for every k. So $T = \sum_{i,j} a_{ij}E_{ij}$ by Corollary 2.2.6.

The coefficients a_{ij} in the last step are the entries of the matrix of T (Section 2.3).

Solution to Exercise 2.2.35

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Definition 1.6.14 (Coordinates), Corollary 1.5.17 (Sublists), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. Decide what P and S should do to each basis vector, then apply Theorem 2.2.1.
Hint 2. Let P fix each $\mathbf{u}_i$ and kill each $\mathbf{x}_j$; let S kill each $\mathbf{u}_i$ and fix each $\mathbf{x}_j$.
Hint 3. For (b), compute $S\left(\sum_i a_i\mathbf{u}_i + \sum_j b_j\mathbf{x}_j\right)$, and use that $\mathbf{x}_1, \ldots, \mathbf{x}_r$ is linearly independent. For (c), use the basis $(1, 2, 3), \mathbf{e}_2, \mathbf{e}_3$.
Sketch. $P : \mathbf{u}_i \mapsto \mathbf{u}_i$, $\mathbf{x}_j \mapsto \mathbf{0}$ gives $P\left(\sum_i a_i\mathbf{u}_i + \sum_j b_j\mathbf{x}_j\right) = \sum_i a_i\mathbf{u}_i$. $S : \mathbf{u}_i \mapsto \mathbf{0}$, $\mathbf{x}_j \mapsto \mathbf{x}_j$ gives $S(\mathbf{v}) = \sum_j b_j\mathbf{x}_j$, which is $\mathbf{0}$ iff every $b_j = 0$ iff $\mathbf{v} \in U$. For $U = \mathrm{span}((1, 2, 3))$: $P(x, y, z) = (x, 2x, 3x)$ and $S(x, y, z) = (0, y - 2x, z - 3x)$.

Each $\mathbf{v} \in V$ has exactly one representation $\mathbf{v} = \sum_i a_i\mathbf{u}_i + \sum_j b_j\mathbf{x}_j$.

(a) Let P be the linear map with $P(\mathbf{u}_i) = \mathbf{u}_i$ and $P(\mathbf{x}_j) = \mathbf{0}$ (Theorem 2.2.1). Then $P(\mathbf{v}) = \sum_i a_i\mathbf{u}_i \in U$, so $P(V) \subseteq U$. If $\mathbf{u} \in U$, write $\mathbf{u} = \sum_i c_i\mathbf{u}_i$; then $P(\mathbf{u}) = \sum_i c_i\mathbf{u}_i = \mathbf{u}$. In particular every $\mathbf{u} \in U$ equals $P(\mathbf{u}) \in P(V)$, so $P(V) = U$.

(b) Let S be the linear map with $S(\mathbf{u}_i) = \mathbf{0}$ and $S(\mathbf{x}_j) = \mathbf{x}_j$. Then $S(\mathbf{v}) = \sum_j b_j\mathbf{x}_j$. If $S(\mathbf{v}) = \mathbf{0}$, then every $b_j = 0$, because $\mathbf{x}_1, \ldots, \mathbf{x}_r$ is linearly independent, being a sublist of a basis (Corollary 1.5.17, Theorem 1.5.5); so $\mathbf{v} = \sum_i a_i\mathbf{u}_i \in U$. Conversely, if $\mathbf{v} = \sum_i c_i\mathbf{u}_i \in U$, then $S(\mathbf{v}) = \sum_i c_i S(\mathbf{u}_i) = \mathbf{0}$. So the vectors sent to $\mathbf{0}$ are exactly those of U.

(c) The single vector $(1, 2, 3)$ is a basis of U: it spans U, and it is linearly independent because it is nonzero. Together with $\mathbf{e}_2$ and $\mathbf{e}_3$ it forms a basis of $\mathbb{R}^3$, since

$$(x, y, z) = a(1, 2, 3) + b\mathbf{e}_2 + c\mathbf{e}_3 \quad \Longleftrightarrow \quad a = x, \quad b = y - 2x, \quad c = z - 3x.$$

So the constructions give

$$P(x, y, z) = x(1, 2, 3) = (x, 2x, 3x), \quad S(x, y, z) = (y - 2x)\mathbf{e}_2 + (z - 3x)\mathbf{e}_3 = (0, y - 2x, z - 3x).$$

As a check, $S(x, y, z) = \mathbf{0}$ exactly when $y = 2x$ and $z = 3x$, that is, when $(x, y, z) = x(1, 2, 3)$.

Solution to Exercise 2.2.36

Uses. Proposition 2.1.16 (Linear maps preserve spans and linear relations), Proposition 1.4.14 (The span is the smallest subspace containing a list), Exercise 2.2.25
Techniques. Check it on a basis (Technique 2.2.7)

Hint 1. Let $U_k = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$ for $0 \le k \le n$, with $U_0 = \{\mathbf{0}\}$. Show that $T(U_k) \subseteq U_{k-1}$.
Hint 2. For $T(U_k) \subseteq U_{k-1}$, check where T sends the spanning list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ of U_k (part (b) of Exercise 2.2.25).
Hint 3. Then show by induction on k that T^k sends every vector of U_k to $\mathbf{0}$.
Sketch. With $U_k = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$, each $T(\mathbf{v}_j)$ with $j \le k$ lies in $U_{j-1} \subseteq U_{k-1}$, so $T(U_k) \subseteq U_{k-1}$. Each application of T lowers the index by one, so $T^k(U_k) \subseteq U_0 = \{\mathbf{0}\}$, and $k = n$ gives $T^n = 0$.

For $0 \le k \le n$, let $U_k = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$, so that $U_0 = \{\mathbf{0}\}$, $U_0 \subseteq U_1 \subseteq \cdots \subseteq U_n = V$, and each U_k is a subspace.

Claim: $T(U_k) \subseteq U_{k-1}$ **for** $1 \le k \le n$**.** For $j \le k$, the hypothesis gives $T(\mathbf{v}_j) \in U_{j-1} \subseteq U_{k-1}$ (for $j = 1$, $T(\mathbf{v}_1) = \mathbf{0} \in U_0$). So U_{k-1} is a subspace containing $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)$, and by Proposition 2.1.16 and Proposition 1.4.14,

$$T(U_k) = \operatorname{span}(T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)) \subseteq U_{k-1}.$$

Claim: $T^k(\mathbf{u}) = \mathbf{0}$ **for every** $\mathbf{u} \in U_k$**, for** $0 \le k \le n$**.** We induct on k. For $k = 0$, $U_0 = \{\mathbf{0}\}$ and $T^0(\mathbf{0}) = \mathbf{0}$. Suppose the claim holds for some $k < n$, and let $\mathbf{u} \in U_{k+1}$. Then $T(\mathbf{u}) \in U_k$ by the first claim, so $T^{k+1}(\mathbf{u}) = T^k(T(\mathbf{u})) = \mathbf{0}$.

Taking $k = n$, $T^n(\mathbf{v}) = \mathbf{0}$ for every $\mathbf{v} \in U_n = V$, that is, $T^n = 0$. (In the language of Section 2.3, the matrix of T in this basis is strictly upper triangular.)

Solution to Exercise 2.2.37

Uses. Proposition 2.2.11 (Prescribing values on a spanning list), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Section A.1
Hint 1. For ($\Longrightarrow$), apply S to a relation of $\mathcal{L}$; for the reverse implication between relations, use that S is injective.
Hint 2. For ($\Longleftarrow$), Proposition 2.2.11 gives a linear $S : \operatorname{span}\mathcal{L} \to W$ with $S(\mathbf{v}_i) = \mathbf{w}_i$. What is its image? Why is it injective?
Hint 3. If $S(\sum_i a_i\mathbf{v}_i) = S(\sum_i b_i\mathbf{v}_i)$, then $\sum_i (a_i - b_i)\mathbf{w}_i = \mathbf{0}$.
Sketch. If S exists, relations of $\mathcal{L}$ map to relations of $\mathcal{M}$, and if $\sum_i a_i\mathbf{w}_i = \mathbf{0}$ then $S(\sum_i a_i\mathbf{v}_i) = \mathbf{0} = S(\mathbf{0})$, so injectivity gives $\sum_i a_i\mathbf{v}_i = \mathbf{0}$. Conversely, Proposition 2.2.11 gives S on $\operatorname{span}\mathcal{L}$; its image is $\operatorname{span}\mathcal{M}$, and if $S(\mathbf{u}) = S(\mathbf{u}')$, the difference of coefficient lists is a relation of $\mathcal{M}$, hence of $\mathcal{L}$, so $\mathbf{u} = \mathbf{u}'$. In the example both lists have exactly the relations $a = b = -c$, so S exists.

($\Longrightarrow$). Let S be such a map. If $\sum_i a_i\mathbf{v}_i = \mathbf{0}$, then $\sum_i a_i\mathbf{w}_i = \sum_i a_i S(\mathbf{v}_i) = S(\sum_i a_i\mathbf{v}_i) = S(\mathbf{0}) = \mathbf{0}$ (Proposition 2.1.4). If $\sum_i a_i\mathbf{w}_i = \mathbf{0}$, then $S(\sum_i a_i\mathbf{v}_i) = \mathbf{0} = S(\mathbf{0})$, and since S is injective, $\sum_i a_i\mathbf{v}_i = \mathbf{0}$.

($\Longleftarrow$). The subspace $\operatorname{span}\mathcal{L}$ is a vector space spanned by $\mathcal{L}$, and every relation of $\mathcal{L}$ is a relation of $\mathcal{M}$, which is (2.2.2). By Proposition 2.2.11, applied with $\operatorname{span}\mathcal{L}$ in place of V, there is a linear $S : \operatorname{span}\mathcal{L} \to W$ with $S(\mathbf{v}_i) = \mathbf{w}_i$. By Proposition 2.1.16, $S(\operatorname{span}\mathcal{L}) = \operatorname{span}(S(\mathbf{v}_1), \ldots, S(\mathbf{v}_k)) = \operatorname{span}\mathcal{M}$, so S is a surjective linear map $\operatorname{span}\mathcal{L} \to \operatorname{span}\mathcal{M}$. It is injective: if $\mathbf{u} = \sum_i a_i\mathbf{v}_i$ and $\mathbf{u}' = \sum_i b_i\mathbf{v}_i$ satisfy $S(\mathbf{u}) = S(\mathbf{u}')$, then

$$\sum_{i=1}^{k} (a_i - b_i)\mathbf{w}_i = S(\mathbf{u}) - S(\mathbf{u}') = \mathbf{0},$$

which is a relation of $\mathcal{M}$, hence of $\mathcal{L}$: $\sum_i (a_i - b_i)\mathbf{v}_i = \mathbf{0}$, that is, $\mathbf{u} = \mathbf{u}'$. So S is bijective (Section A.1).

The example. For $\mathcal{L}$: $a(1,0) + b(0,1) + c(1,1) = (a + c, b + c)$, which is $\mathbf{0}$ exactly when $a = b = -c$. For $\mathcal{M}$: $a(1,1) + b(1,-1) + c(2,0) = (a + b + 2c, a - b)$, which is $\mathbf{0}$ exactly when $a = b$ and $2a + 2c = 0$, that is, when $a = b = -c$. The two lists have the same relations, so such an S exists. Here $\operatorname{span}\mathcal{L} = \operatorname{span}\mathcal{M} = \mathbb{R}^2$, and S is the linear map with $S(\mathbf{e}_1) = (1,1)$ and $S(\mathbf{e}_2) = (1,-1)$; indeed $S(1,1) = (2,0)$.

Solution to Exercise 2.2.38

Uses. Proposition 2.2.11 (Prescribing values on a spanning list), Proposition 1.2.35 (Zero products), Definition 1.1.28 (Characteristic)
Hint 1. The list $\mathbf{v}_1, \ldots, \mathbf{v}_{n+1}$ spans F^n, so Proposition 2.2.11 applies. Find all linear relations among $\mathbf{v}_1, \ldots, \mathbf{v}_{n+1}$.
Hint 2. Every relation is a multiple of $\mathbf{s} - \mathbf{e}_1 - \cdots - \mathbf{e}_n = \mathbf{0}$. So T exists if and only if $\mathbf{v}_{\sigma(n+1)} = \mathbf{v}_{\sigma(1)} + \cdots + \mathbf{v}_{\sigma(n)}$.
Hint 3. If $\sigma(n+1) = k \le n$, then $\mathbf{v}_{\sigma(1)}, \ldots, \mathbf{v}_{\sigma(n)}$ are $\mathbf{s}$ and the $\mathbf{e}_j$ with $j \ne k$, in some order.
Sketch. $\sum_i a_i\mathbf{e}_i + b\mathbf{s} = \mathbf{0}$ iff $a_i = -b$ for all i, so all relations are multiples of one, and T exists iff $\mathbf{v}_{\sigma(n+1)} = \sum_{i \le n} \mathbf{v}_{\sigma(i)}$. If σ fixes $n+1$, the right side is $\mathbf{s}$: fine. If $\sigma(n+1) = k \le n$, the right side is $\mathbf{s} + \sum_{j \ne k} \mathbf{e}_j = \mathbf{e}_k + 2\sum_{j \ne k} \mathbf{e}_j$, which equals $\mathbf{e}_k$ iff $1 + 1 = 0$. So: all $(n+1)!$ permutations if $1 + 1 = 0$, otherwise exactly the $n!$ that fix $n+1$.

The relations. For scalars $a_1, \dots, a_n, b$,

$$a_1\mathbf{e}_1 + \cdots + a_n\mathbf{e}_n + b\mathbf{s} = (a_1 + b, \dots, a_n + b),$$

which is $\mathbf{0}$ exactly when $a_i = -b$ for every i. So the linear relations of the list are exactly the multiples, by $b \in F$, of the relation $\mathbf{s} - \mathbf{e}_1 - \cdots - \mathbf{e}_n = \mathbf{0}$.

The criterion. The list contains the standard basis, so it spans F^n. Given σ, put $\mathbf{w}_i = \mathbf{v}_{\sigma(i)}$. A list satisfies all multiples of a relation as soon as it satisfies the relation itself, so (2.2.2) holds exactly when $\mathbf{w}_{n+1} - \mathbf{w}_1 - \cdots - \mathbf{w}_n = \mathbf{0}$. By Proposition 2.2.11, T exists if and only if

$$\mathbf{v}_{\sigma(n+1)} = \mathbf{v}_{\sigma(1)} + \cdots + \mathbf{v}_{\sigma(n)}. \tag{C.1.4}$$

Case $\sigma(n+1) = n+1$. Then σ permutes $\{1, \dots, n\}$, and the right side of (C.1.4) is $\mathbf{e}_1 + \cdots + \mathbf{e}_n = \mathbf{s} = \mathbf{v}_{n+1}$. So T exists; it permutes the standard basis.

Case $\sigma(n+1) = k \le n$. Then $\{\sigma(1), \dots, \sigma(n)\} = \{1, \dots, n+1\} \setminus \{k\}$, so with $2 = 1 + 1$ the right side of (C.1.4) is

$$\mathbf{s} + \sum_{j \le n, j \ne k} \mathbf{e}_j = \mathbf{e}_k + 2 \sum_{j \le n, j \ne k} \mathbf{e}_j.$$

Since $n \ge 2$, there is some $j \ne k$, and the vector $\sum_{j \ne k} \mathbf{e}_j$ is nonzero. By Proposition 1.2.35, (C.1.4) holds if and only if $2 = 0$.

Answer. If $1 + 1 \ne 0$ in F, exactly the $n!$ permutations with $\sigma(n+1) = n+1$ are realized by linear maps. If $1 + 1 = 0$ (characteristic 2, Definition 1.1.28), all $(n+1)!$ permutations are. The reason is visible in the relation: when $1 + 1 = 0$ it reads $\mathbf{e}_1 + \cdots + \mathbf{e}_n + \mathbf{s} = \mathbf{0}$, which is symmetric in all $n + 1$ vectors.

Solution to Exercise 2.2.39

> *Uses.* Proposition 2.2.20 (Linear maps out of $F[x]$), Exercise 2.1.32, Proposition 1.1.17 (No zero divisors), Definition 1.2.16 (Degree)
> *Techniques.* Check it on a basis (Technique 2.2.7)
> *Hint 1.* Let $e = f(1)$. Apply the condition to $1 = 1 \cdot 1$. What can e be?
> *Hint 2.* If $e = 1$, put $q = f(x)$. Compute $f(x^n)$ and compare f with the substitution map $p \mapsto p(q)$ on monomials.
> *Hint 3.* To show that $p \mapsto p(q)$ is multiplicative, fix r and note that both sides of $(pr)(q) = p(q)r(q)$ are linear in p, so it suffices to take $p = x^j$. Then fix j and argue the same way in r.
> *Sketch.* $e = f(1)$ satisfies $e^2 = e$, and comparing degrees gives $e \in \{0, 1\}$. If $e = 0$, then $f(p) = f(p)e = 0$. If $e = 1$ and $q = f(x)$, then $f(x^n) = q^n$, so f is the substitution map $C_q : p \mapsto p(q)$ by Proposition 2.2.20. Conversely C_q is linear, and multiplicative because both sides of $C_q(pr) = C_q(p)C_q(r)$ are linear in each of p and r and agree on monomials. Answer: $f = 0$ or $f = C_q$ for some $q \in F[x]$.

For $q \in F[x]$ let $C_q : F[x] \to F[x]$, $p \mapsto p(q)$, be the substitution map, which is linear by Exercise 2.1.32 and satisfies $C_q(x^n) = q^n$. We show that the maps with the property are $f = 0$ and the maps C_q.

The value $e = f(1)$. We have $e = f(1 \cdot 1) = f(1)f(1) = e^2$. Suppose $e \ne 0$, with degree d and leading coefficient $c \ne 0$ (Definition 1.2.16). In e^2, the coefficient of x^{2d} is $c^2 \ne 0$ (Proposition 1.1.17) and all higher coefficients are 0, so $\deg e^2 = 2d$. From $e^2 = e$ we get $2d = d$, so $d = 0$, and $e = c$ is a nonzero constant with $c^2 = c$, that is, $c(c-1) = 0$. Hence $c = 1$. So $e = 0$ or $e = 1$.

If $e = 0$. For every p, $f(p) = f(p \cdot 1) = f(p)e = 0$, so $f = 0$, which is linear and multiplicative.

If $e = 1$. Let $q = f(x)$. Then $f(x^n) = q^n$ for every $n \ge 0$, by induction: $f(x^0) = f(1) = 1 = q^0$, and $f(x^{n+1}) = f(x^n x) = f(x^n)f(x) = q^n q = q^{n+1}$. So f and C_q are linear maps that agree on every monomial, and $f = C_q$ by Proposition 2.2.20.

Each C_q is multiplicative. Fix $r \in F[x]$. The maps $p \mapsto C_q(pr)$ and $p \mapsto C_q(p)C_q(r)$ are linear in p: the first is C_q composed with multiplication by r, the second is multiplication by $C_q(r)$ composed with C_q, and multiplication by a fixed polynomial is linear by distributivity. By Proposition 2.2.20 it suffices to compare

them at $p = x^j$. Now fix j. The maps $r \mapsto C_q(x^j r)$ and $r \mapsto q^j C_q(r)$ are linear in r for the same reason, so it suffices to compare them at $r = x^k$:

$$C_q\big(x^j x^k\big) = C_q\big(x^{j+k}\big) = q^{j+k} = q^j q^k = C_q\big(x^j\big) C_q\big(x^k\big).$$

So $C_q(pr) = C_q(p)C_q(r)$ for all p, r.

Answer. The linear maps f with $f(pq) = f(p)f(q)$ are the zero map and the substitution maps $p \mapsto p(q)$, one for each $q \in F[x]$. Different q give different maps, since $C_q(x) = q$.

Solution to Exercise 2.2.40

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 1.6.14 (Coordinates), Theorem 2.2.1 (Linear maps are determined by a basis), Corollary 2.2.6 (Agreeing on a spanning list)
Techniques. Check it on a basis (Technique 2.2.7), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. (a) If $a_j = 0$, find a nontrivial linear relation among the n vectors other than $\mathbf{v}_j$.
Hint 2. (b) Write $T(\mathbf{v}_i) = \lambda_i \mathbf{v}_i$ and compute $T(\mathbf{v}_{n+1})$ in two ways. Compare coordinates in the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$.
Hint 3. (c) Write $\mathbf{w}_{n+1} = \sum_i b_i \mathbf{w}_i$ with all $b_i \neq 0$, and define T on the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ by $T(\mathbf{v}_i) = (b_i/a_i)\mathbf{w}_i$. For uniqueness, argue as in (b).
Sketch. (a) If $a_j = 0$, then $\mathbf{v}_{n+1} - \sum_{i \neq j} a_i \mathbf{v}_i = \mathbf{0}$ is a nontrivial relation among the n vectors other than $\mathbf{v}_j$, which form a basis. (b) $T(\mathbf{v}_{n+1}) = \sum_i a_i \lambda_i \mathbf{v}_i = \lambda_{n+1} \sum_i a_i \mathbf{v}_i$, so $a_i \lambda_i = a_i \lambda_{n+1}$, and $a_i \neq 0$ gives $\lambda_i = \lambda_{n+1}$. (c) The map $\mathbf{v}_i \mapsto (b_i/a_i)\mathbf{w}_i$ sends $\mathbf{v}_{n+1}$ to $\mathbf{w}_{n+1}$. If $T'(\mathbf{v}_i) = c_i' \mathbf{w}_i$, comparing coordinates of $T'(\mathbf{v}_{n+1})$ forces $c_i' = c_{n+1}' b_i/a_i$, so $T' = c_{n+1}' T$.

By hypothesis, deleting any one vector from $\mathbf{v}_1, \ldots, \mathbf{v}_{n+1}$ leaves a basis of V; in particular $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis.

(a) Write $\mathbf{v}_{n+1} = a_1 \mathbf{v}_1 + \cdots + a_n \mathbf{v}_n$, with unique coefficients. Suppose $a_j = 0$ for some j. Then

$$1 \cdot \mathbf{v}_{n+1} - \sum_{i \leq n,\, i \neq j} a_i \mathbf{v}_i = \mathbf{0}$$

is a linear relation, with the nonzero coefficient 1, among the vectors of the list obtained by deleting $\mathbf{v}_j$. That list is a basis, hence linearly independent, which contradicts Theorem 1.5.5. So every $a_i \neq 0$.

(b) Write $T(\mathbf{v}_i) = \lambda_i \mathbf{v}_i$ for $i = 1, \ldots, n+1$. Then

$$\sum_{i=1}^{n} a_i \lambda_i \mathbf{v}_i = \sum_{i=1}^{n} a_i T(\mathbf{v}_i) = T(\mathbf{v}_{n+1}) = \lambda_{n+1} \mathbf{v}_{n+1} = \sum_{i=1}^{n} \lambda_{n+1} a_i \mathbf{v}_i.$$

By uniqueness of coordinates in the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ (Definition 1.6.14), $a_i \lambda_i = a_i \lambda_{n+1}$, and since $a_i \neq 0$ by (a), $\lambda_i = \lambda_{n+1}$. With $\lambda = \lambda_{n+1}$, T and $\lambda \mathrm{id}_V$ agree on the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$, so $T = \lambda \mathrm{id}_V$ by Corollary 2.2.6.

(c) By (a) applied to the $\mathbf{w}_i$, $\mathbf{w}_{n+1} = b_1 \mathbf{w}_1 + \cdots + b_n \mathbf{w}_n$ with every $b_i \neq 0$.

Existence. By Theorem 2.2.1, let $T : V \to W$ be the linear map with $T(\mathbf{v}_i) = (b_i/a_i)\mathbf{w}_i$ for $i = 1, \ldots, n$. Then

$$T(\mathbf{v}_{n+1}) = \sum_{i=1}^{n} a_i \left(\frac{b_i}{a_i}\right) \mathbf{w}_i = \sum_{i=1}^{n} b_i \mathbf{w}_i = \mathbf{w}_{n+1}.$$

So $T(\mathbf{v}_i) = c_i \mathbf{w}_i$ with $c_i = b_i/a_i \neq 0$ for $i \leq n$ and $c_{n+1} = 1$.

Uniqueness up to scalars. Let $T' : V \to W$ be linear with $T'(\mathbf{v}_i) = c_i' \mathbf{w}_i$, all $c_i' \neq 0$. Then

$$\sum_{i=1}^{n} a_i c_i' \mathbf{w}_i = T'(\mathbf{v}_{n+1}) = c_{n+1}' \mathbf{w}_{n+1} = \sum_{i=1}^{n} c_{n+1}' b_i \mathbf{w}_i,$$

and comparing coordinates in the basis $\mathbf{w}_1, \ldots, \mathbf{w}_n$ gives $c_i' = c_{n+1}' b_i/a_i$ for $i \leq n$. So $T'(\mathbf{v}_i) = c_{n+1}' T(\mathbf{v}_i)$ for $i \leq n$, and $T' = c_{n+1}' T$ by Corollary 2.2.6. Every such map is therefore a nonzero multiple of T, and any two of them are multiples of each other.

In projective geometry, (c) says that any two frames of $n+1$ points in general position are related by a projective transformation, which is unique.

Section 2.3

Solution to Exercise 2.3.7

Uses. Definition 2.3.1 (Matrix of a linear map), Notation 2.3.2 (The standard basis $\mathcal{E}$), Example 2.1.9 (Maps of polynomials)
Hint 1. Each coordinate of $T(p)$ is an evaluation, so T is linear. The columns of $[T]_{\mathcal{E}\mathcal{B}}$ are $T(1)$ and $T(x)$.
Hint 2. For $\mathring{\mathcal{B}}$, compute $T(1-x)$ and $T(x)$. You should also check that $\mathring{\mathcal{B}}$ is a basis.
Sketch. $T(1)=(1,1)$ and $T(x)=(0,1)$, so $[T]_{\mathcal{E}\mathcal{B}}=\left(\begin{smallmatrix}1&0\\1&1\end{smallmatrix}\right)$. $T(1-x)=(1,0)$ and $T(x)=(0,1)$, so $[T]_{\mathcal{E}\mathring{\mathcal{B}}}=I_2$.

The coordinates of $T(p)$ are $\mathrm{ev}_0(p)$ and $\mathrm{ev}_1(p)$, which are linear in p (Example 2.1.9), so $T(cp+q)=cT(p)+T(q)$ coordinate by coordinate, and T is linear. By Notation 2.3.2, the columns of $[T]_{\mathcal{E}\mathcal{B}}$ are $T(1)=(1,1)$ and $T(x)=(0,1)$:

$$[T]_{\mathcal{E}\mathcal{B}}=\begin{pmatrix}1&0\\1&1\end{pmatrix}.$$

The list $\mathring{\mathcal{B}}$ is a basis: $c(1-x)+dx=c+(d-c)x$ equals $a+bx$ exactly when $c=a$ and $d=a+b$. Since $T(1-x)=(1,0)$ and $T(x)=(0,1)$,

$$[T]_{\mathcal{E}\mathring{\mathcal{B}}}=\begin{pmatrix}1&0\\0&1\end{pmatrix}=I_2.$$

The same map has two different matrices. In the second basis the coordinates of p are exactly its values at 0 and 1.

Solution to Exercise 2.3.14

Uses. Definition 2.3.8 (Matrix–vector product), Proposition 2.3.11 (Entries of $A\mathbf{x}$)
Hint 1. By columns: 2 times the first column, plus 1 times the second, plus 4 times the third. Reduce modulo 5 at the end.
Hint 2. By rows: each entry pairs one row with the vector. In (b), $i\cdot i=-1$.
Sketch. (a) Both ways give $(16,12)$, which is $(1,2)$ in $\mathbb{F}_5^2$. By rows, $2+2+12=16$ and $8+0+4=12$. (b) $i(1,-i)+(i,2)=(2i,3)$, and by rows $i+i=2i$ and $-i^2+2=3$.

(a) By columns, in $\mathbb{F}_5^2$,

$$2\begin{pmatrix}1\\4\end{pmatrix}+1\begin{pmatrix}2\\0\end{pmatrix}+4\begin{pmatrix}3\\1\end{pmatrix}=\begin{pmatrix}2+2+12\\8+0+4\end{pmatrix}=\begin{pmatrix}16\\12\end{pmatrix}=\begin{pmatrix}1\\2\end{pmatrix}.$$

By rows, the first entry is $1\cdot 2+2\cdot 1+3\cdot 4=16=1$ and the second is $4\cdot 2+0\cdot 1+1\cdot 4=12=2$.

(b) By columns,

$$i\begin{pmatrix}1\\-i\end{pmatrix}+1\begin{pmatrix}i\\2\end{pmatrix}=\begin{pmatrix}i\\1\end{pmatrix}+\begin{pmatrix}i\\2\end{pmatrix}=\begin{pmatrix}2i\\3\end{pmatrix},$$

using $i(-i)=-i^2=1$. By rows, the entries are $1\cdot i+i\cdot 1=2i$ and $(-i)\cdot i+2\cdot 1=1+2=3$.

Solution to Exercise 2.3.18

Uses. Proposition 2.3.17 (Every linear map $F^n\to F^m$ is some T_A), Definition 2.3.8 (Matrix–vector product)
Hint 1. By Proposition 2.3.17, the columns of A are $T(\mathbf{e}_1),\ldots,T(\mathbf{e}_n)$. No formula for the entries is needed.
Hint 2. In (c) the target is $\mathbb{R}=\mathbb{R}^1$, so A has one row. In (d), $T(1,1)=A(1,1)$ is the sum of the two columns.
Sketch. (a) Columns $\mathbf{e}_2,\mathbf{e}_3,\mathbf{e}_1$. (b) Columns $\mathbf{e}_1,\mathbf{e}_2,\mathbf{0}$. (c) $\left(\begin{smallmatrix}1&1&1\end{smallmatrix}\right)$. (d) $\left(\begin{smallmatrix}1&0\\1&1\end{smallmatrix}\right)$, and $T(1,1)=(1,1)+(0,1)=(1,0)$.

By Proposition 2.3.17, A is the matrix with columns $T(\mathbf{e}_1),\ldots,T(\mathbf{e}_n)$.

(a) $T(\mathbf{e}_1)=(0,1,0)$, $T(\mathbf{e}_2)=(0,0,1)$, and $T(\mathbf{e}_3)=(1,0,0)$, so $A=\begin{pmatrix}0&0&1\\1&0&0\\0&1&0\end{pmatrix}$.

(b) $T(\mathbf{e}_1)=\mathbf{e}_1$, $T(\mathbf{e}_2)=\mathbf{e}_2$, and $T(\mathbf{e}_3)=\mathbf{0}$, so $A=\begin{pmatrix}1&0&0\\0&1&0\\0&0&0\end{pmatrix}$.

(c) $T(\mathbf{e}_1)=T(\mathbf{e}_2)=T(\mathbf{e}_3)=1$, so A is the 1×3 matrix $\left(\begin{smallmatrix}1&1&1\end{smallmatrix}\right)$.

(d) $A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$. By Definition 2.3.8, $T(1,1) = A(1,1) = (1,1) + (0,1) = (1,2) = (1,0)$ in $\mathbb{F}_2^2$. So T swaps $(1,0)$ and $(1,1)$ and fixes $(0,1)$.

Solution to Exercise 2.3.21

Uses. Definition 2.3.1 (Matrix of a linear map), Theorem 2.3.20 (Linear maps correspond to matrices), Theorem 2.2.1 (Linear maps are determined by a basis)
Hint 1. The columns say what $T(1)$ and $T(x)$ are, in $\mathcal{C}$-coordinates. Turn them back into polynomials.
Hint 2. Then $T(a+bx) = aT(1) + bT(x)$. For $[T]_{\mathcal{BB}}$, write $T(1)$ and $T(x)$ in the basis $1, x$.
Sketch. $T(1) = 1\cdot 1 + 0\cdot(1+x) = 1$ and $T(x) = 2\cdot 1 + 1\cdot(1+x) = 3+x$. So $T(a+bx) = (a+3b) + bx$ and $[T]_{\mathcal{BB}} = \begin{pmatrix} 1 & 3 \\ 0 & 1 \end{pmatrix}$.

$\mathcal{C}$ is a basis, since $a + bx = (a-b)\cdot 1 + b(1+x)$, and these are the only possible coefficients. By Definition 2.3.1, the first column says $T(1) = 1\cdot 1 + 0\cdot(1+x) = 1$, and the second says $T(x) = 2\cdot 1 + 1\cdot(1+x) = 3 + x$. By linearity,

$$T(a+bx) = aT(1) + bT(x) = (a+3b) + bx.$$

(By Theorem 2.3.20, this is the only operator with the given matrix.) In the basis $\mathcal{B}$, $T(1) = 1$ has coordinates $(1,0)$ and $T(x) = 3 + x$ has coordinates $(3,1)$, so

$$[T]_{\mathcal{BB}} = \begin{pmatrix} 1 & 3 \\ 0 & 1 \end{pmatrix}.$$

Solution to Exercise 2.3.26

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 2.3.5 (Identity matrix), Definition 1.6.14 (Coordinates)
Hint 1. The j-th column of $[\mathrm{id}_V]_{\mathcal{CB}}$ is $[\mathbf{v}_j]_{\mathcal{C}}$. When is it $\mathbf{e}_j$?
Hint 2. A vector with $\mathcal{C}$-coordinates $\mathbf{e}_j$ is $0\mathbf{w}_1 + \cdots + 1\mathbf{w}_j + \cdots + 0\mathbf{w}_n$.
Sketch. The j-th column is $[\mathbf{v}_j]_{\mathcal{C}}$, and $[\mathbf{v}_j]_{\mathcal{C}} = \mathbf{e}_j$ if and only if $\mathbf{v}_j = \mathbf{w}_j$. So all columns agree with those of I_n if and only if $\mathbf{v}_j = \mathbf{w}_j$ for all j.

By Definition 2.3.1, the j-th column of $[\mathrm{id}_V]_{\mathcal{CB}}$ is $[\mathbf{v}_j]_{\mathcal{C}}$, and the j-th column of I_n is $\mathbf{e}_j$. Since a vector is determined by its coordinates (Definition 1.6.14), $[\mathbf{v}_j]_{\mathcal{C}} = \mathbf{e}_j$ holds if and only if

$$\mathbf{v}_j = 0\mathbf{w}_1 + \cdots + 1\mathbf{w}_j + \cdots + 0\mathbf{w}_n = \mathbf{w}_j.$$

So $[\mathrm{id}_V]_{\mathcal{CB}} = I_n$ if and only if $\mathbf{v}_j = \mathbf{w}_j$ for every j.

Solution to Exercise 2.3.29

Uses. Definition 2.3.1 (Matrix of a linear map), Theorem 2.3.9 (The matrix of a map computes the map), Definition 2.3.8 (Matrix–vector product)
Hint 1. First find a formula for the $\mathcal{C}$-coordinates (a,b,c) of a vector (x,y,z) by solving for a, b, c.
Hint 2. The columns of $[T]_{\mathcal{CB}}$ are the $\mathcal{C}$-coordinates of $T(1,1)$ and $T(1,-1)$. For (b), $(3,1) = 2(1,1) + (1,-1)$.
Sketch. $[(x,y,z)]_{\mathcal{C}} = (x-y, y-z, z)$. $T(1,1) = (2,0,2)$ and $T(1,-1) = (0,2,2)$ give $[T]_{\mathcal{CB}} = \begin{pmatrix} 2 & -2 \\ -2 & 0 \\ 2 & 2 \end{pmatrix}$. For $\mathbf{v} = (3,1)$, $[\mathbf{v}]_{\mathcal{B}} = (2,1)$, and both sides equal $(2,-4,6)$.

Since

$$a(1,0,0) + b(1,1,0) + c(1,1,1) = (a+b+c, b+c, c),$$

the $\mathcal{C}$-coordinates of (x,y,z) are $c = z$, $b = y - z$, and $a = x - y$:

$$[(x,y,z)]_{\mathcal{C}} = (x-y, y-z, z).$$

(a) $T(1,1) = (2,0,2)$ has $\mathcal{C}$-coordinates $(2,-2,2)$, and $T(1,-1) = (0,2,2)$ has $\mathcal{C}$-coordinates $(-2,0,2)$. So

$$[T]_{\mathcal{CB}} = \begin{pmatrix} 2 & -2 \\ -2 & 0 \\ 2 & 2 \end{pmatrix}.$$

(b) Since $(3,1) = 2(1,1) + 1(1,-1)$, $[\mathbf{v}]_{\mathcal{B}} = (2,1)$, and

$$[T]_{\mathcal{CB}}[\mathbf{v}]_{\mathcal{B}} = 2\begin{pmatrix}2\\-2\\2\end{pmatrix} + 1\begin{pmatrix}-2\\0\\2\end{pmatrix} = \begin{pmatrix}2\\-4\\6\end{pmatrix}.$$

On the other side, $T(3,1) = (4,2,6)$, whose $\mathcal{C}$-coordinates are $(4-2, 2-6, 6) = (2,-4,6)$. The two sides agree.

Solution to Exercise 2.3.30

Uses. Theorem 2.3.9 (The matrix of a map computes the map), Example 2.3.24 (The identity in two bases)
Hint 1. Check the answer: is $4(1,1) + 2(1,-1)$ equal to $(3,1)$?
Hint 2. By Theorem 2.3.9, $[\mathrm{id}]_{\mathcal{EB}}$ multiplies $\mathcal{B}$-coordinates and produces $\mathcal{E}$-coordinates. Which matrix goes the other way?
Sketch. $[\mathrm{id}]_{\mathcal{EB}}[\mathbf{v}]_{\mathcal{B}} = [\mathbf{v}]_{\mathcal{E}}$, so this matrix turns $\mathcal{B}$-coordinates into standard coordinates, not the reverse. The correct matrix is $[\mathrm{id}]_{\mathcal{BE}} = \frac{1}{2}\begin{pmatrix}1 & 1\\1 & -1\end{pmatrix}$, which gives $[\mathbf{v}]_{\mathcal{B}} = (2,1)$.

The answer is wrong: $4(1,1) + 2(1,-1) = (6,2) \neq (3,1)$. By Theorem 2.3.9, $[\mathrm{id}]_{\mathcal{EB}}[\mathbf{w}]_{\mathcal{B}} = [\mathbf{w}]_{\mathcal{E}}$ for every $\mathbf{w}$, so $[\mathrm{id}]_{\mathcal{EB}}$ takes $\mathcal{B}$-coordinates as input and produces standard coordinates. The computation feeds it standard coordinates. What it actually produced is the vector whose $\mathcal{B}$-coordinates are $(3,1)$, namely $3(1,1) + (1,-1) = (4,2)$.

To go from standard coordinates to $\mathcal{B}$-coordinates, use $[\mathrm{id}]_{\mathcal{BE}} = \frac{1}{2}\begin{pmatrix}1 & 1\\1 & -1\end{pmatrix}$ (Example 2.3.24):

$$[\mathbf{v}]_{\mathcal{B}} = [\mathrm{id}]_{\mathcal{BE}}[\mathbf{v}]_{\mathcal{E}} = \frac{1}{2}\begin{pmatrix}1 & 1\\1 & -1\end{pmatrix}\begin{pmatrix}3\\1\end{pmatrix} = \begin{pmatrix}2\\1\end{pmatrix}.$$

Check: $2(1,1) + (1,-1) = (3,1)$. The subscripts are a guide: in $[\mathrm{id}]_{\mathcal{CB}}[\mathbf{v}]_{\mathcal{B}}$ the inner two must match.

Solution to Exercise 2.3.31

Uses. Example 2.2.3 (Building maps from a convenient basis), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A)
Hint 1. When is $(1,1), (1,-1)$ a basis of F^2? Look at Example 2.2.3.
Hint 2. Over $\mathbb{F}_2$, $-1 = 1$. Try $A = \begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}$.
Sketch. $(1,1), (1,-1)$ is a basis only when $1 + 1 \neq 0$. Over $\mathbb{F}_2$ the two vectors coincide, and $A = \begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}$ satisfies both hypotheses without being I_2. When $1 + 1 \neq 0$ the argument is correct.

The error is the claim that $(1,1), (1,-1)$ is a basis of F^2 for every field. It is a basis when $1 + 1 \neq 0$ (Example 2.2.3), but over $\mathbb{F}_2$ we have $-1 = 1$, so the two vectors are equal and the list is linearly dependent. Then the hypothesis says only that $A(1,1) = (1,1)$, and the claim fails: over $\mathbb{F}_2$,

$$\begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}\begin{pmatrix}1\\1\end{pmatrix} = \begin{pmatrix}1\\1\end{pmatrix},$$

so $A = \begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}$ satisfies both hypotheses and $A \neq I_2$. In general $(1,-1) = (1,1)$ exactly when $1 + 1 = 0$. When $1 + 1 \neq 0$ the argument is correct as written, by Corollary 2.2.6 and Proposition 2.3.17.

Solution to Exercise 2.3.32

Uses. Definition 2.3.1 (Matrix of a linear map), Theorem 2.3.9 (The matrix of a map computes the map), Proposition 2.3.11 (Entries of $A\mathbf{x}$), Theorem 2.3.20 (Linear maps correspond to matrices)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Expand $(x+1)^k$ for $k = 0, 1, 2, 3$. Over $\mathbb{F}_2$, reduce the binomial coefficients modulo 2.
Hint 2. $p(x+1) = p(x)$ means $T(p) = p$, that is, $A[p]_{\mathcal{B}} = [p]_{\mathcal{B}}$ with $A = [T]_{\mathcal{BB}}$. Write out the four entries of $A(a,b,c,d)$ and compare.
Sketch. The columns are the coefficients of 1, $1 + x$, $1 + 2x + x^2$, $1 + 3x + 3x^2 + x^3$. Over $\mathbb{F}_2$ the condition $A(a,b,c,d) = (a,b,c,d)$ reads $b + c + d = 0$ and $d = 0$, so $p = a + b(x + x^2)$. Over $\mathbb{Q}$ it reads $b + c + d = 0$, $2c + 3d = 0$, $3d = 0$, so p is constant.

(a) $T(1) = 1$, $T(x) = 1 + x$, $T(x^2) = 1 + 2x + x^2$, and $T(x^3) = 1 + 3x + 3x^2 + x^3$. Their coordinate vectors are the columns, so over $\mathbb{Q}$ and over $\mathbb{F}_2$ (where $2 = 0$ and $3 = 1$) respectively

$$[T]_{\mathcal{BB}} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad [T]_{\mathcal{BB}} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

The entries are the binomial coefficients of Pascal's triangle, reduced modulo 2 in the second case.

(b) Let A be the matrix over $\mathbb{F}_2$, and $[p]_{\mathcal{B}} = (a, b, c, d)$. By Theorem 2.3.9 and since coordinates determine vectors, $T(p) = p$ if and only if $A(a, b, c, d) = (a, b, c, d)$. By Proposition 2.3.11,

$$A \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} a + b + c + d \\ b + d \\ c + d \\ d \end{pmatrix},$$

so the condition is $b + c + d = 0$ and $d = 0$, that is, $d = 0$ and $c = b$ (in $\mathbb{F}_2$, $b + c = 0$ means $c = b$). So the solutions are the four polynomials $p = a + b(x + x^2)$ with $a, b \in \mathbb{F}_2$. Check: $(x + 1) + (x + 1)^2 = x + 1 + x^2 + 1 = x + x^2$ over $\mathbb{F}_2$.

(c) Over $\mathbb{Q}$ the condition $A(a, b, c, d) = (a, b, c, d)$ reads

$$a + b + c + d = a, \quad b + 2c + 3d = b, \quad c + 3d = c, \quad d = d,$$

so $3d = 0$, then $2c = 0$, then $b = 0$: only the constant polynomials satisfy $p(x + 1) = p(x)$. The difference between the two fields is the entry 2 in row 2, column 3: over $\mathbb{Q}$ it forces $c = 0$, and over $\mathbb{F}_2$ it vanishes, which lets $x + x^2$ through.

Solution to Exercise 2.3.33

Uses. Definition 2.3.1 (Matrix of a linear map), Theorem 2.3.9 (The matrix of a map computes the map), Definition 1.6.1 (Basis), Definition 1.2.17 (Evaluation)
Hint 1. (a) The columns are $T(1)$, $T(x)$, $T(x^2)$. (b) The condition says $T(p_j) = \mathbf{e}_{j+1}$: each p_j is 1 at j and 0 at the other two points. Build it from the factors x, $x - 1$, $x - 2$.
Hint 2. To prove that p_0, p_1, p_2 is a basis, show that $q - (q(0)p_0 + q(1)p_1 + q(2)p_2)$ vanishes at $0, 1, 2$, and that the only $r = a + bx + cx^2$ vanishing at $0, 1, 2$ is $r = \mathbf{0}$.
Hint 3. (d) Over $\mathbb{F}_2$, $2 = 0$. Compare the first and third coordinates of $T(p)$.
Sketch. (a) $\left(\begin{smallmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 2 & 4 \end{smallmatrix}\right)$. (b) $p_0 = (x - 1)(x - 2)/2$, $p_1 = -x(x - 2)$, $p_2 = x(x - 1)/2$. Every q equals $\sum_j q(j)p_j$, because the difference vanishes at $0, 1, 2$ and $r(0) = r(1) = r(2) = 0$ forces $r = \mathbf{0}$ when $2 \neq 0$; the coefficients are unique because evaluating $\sum c_j p_j$ at k gives c_k. (c) $[T(q)]_{\mathcal{E}} = I_3[q]_{\mathring{\mathcal{B}}}$. (d) Every value $T(p) = (p(0), p(1), p(0))$ has equal first and third coordinates, but $\mathbf{e}_1$ does not.

(a) $T(1) = (1, 1, 1)$, $T(x) = (0, 1, 2)$, and $T(x^2) = (0, 1, 4)$, so

$$[T]_{\mathcal{EB}} = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 2 & 4 \end{pmatrix}.$$

(b) We need $T(p_j) = \mathbf{e}_{j+1}$, that is, $p_j(k) = 1$ if $k = j$ and 0 otherwise, for $j, k \in \{0, 1, 2\}$. Let

$$p_0 = \frac{1}{2}(x - 1)(x - 2) = \frac{1}{2}(x^2 - 3x + 2),$$
$$p_1 = -x(x - 2) = -x^2 + 2x,$$
$$p_2 = \frac{1}{2}x(x - 1) = \frac{1}{2}(x^2 - x).$$

Evaluating the expanded forms: p_0 takes the values $1, 0, 0$ at $0, 1, 2$ (at 2: $(4 - 6 + 2)/2 = 0$), p_1 takes $0, 1, 0$, and p_2 takes $0, 0, 1$.

Spanning. Let $q \in F[x]_{\leq 2}$ and $r = q - (q(0)p_0 + q(1)p_1 + q(2)p_2)$. Evaluation is linear, so $r(k) = q(k) - q(k) = 0$ for $k = 0, 1, 2$. Write $r = a + bx + cx^2$. Then $r(0) = a = 0$, $r(1) = b + c = 0$, and $r(2) = 2b + 4c = 0$. Substituting $b = -c$ into the last equation gives $2c = 0$, so $c = 0$ because $2 \neq 0$, and then $b = 0$. Hence $r = \mathbf{0}$ and $q = q(0)p_0 + q(1)p_1 + q(2)p_2$.

Uniqueness. If $q = c_0p_0 + c_1p_1 + c_2p_2$, evaluating at k gives $q(k) = c_k$. So the coefficients are determined by q, and $\mathring{\mathcal{B}}$ is a basis (Definition 1.6.1). By construction, $[T]_{\mathcal{E}\mathring{\mathcal{B}}} = I_3$.

(c) By Theorem 2.3.9 and Proposition 2.3.13(c),

$$(q(0), q(1), q(2)) = [T(q)]_{\mathcal{E}} = I_3[q]_{\mathring{\mathcal{B}}} = [q]_{\mathring{\mathcal{B}}}.$$

(This is also visible in the uniqueness argument.) In this basis, the coordinates of a polynomial are its values.

(d) Over $\mathbb{F}_2$, $2 = 0$, so $T(p) = (p(0), p(1), p(0))$ for every p: the first and third coordinates of every value of T agree. If $[T]_{\mathcal{E}\mathring{\mathcal{B}}} = I_3$, then $T(p_0) = \mathbf{e}_1 = (1, 0, 0)$, whose first and third coordinates differ. So no such basis exists. Correspondingly, the first and third rows of $[T]_{\mathcal{E}\mathcal{B}} = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 0 & 0 \end{pmatrix}$ are equal over $\mathbb{F}_2$.

Solution to Exercise 2.3.34

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.1 (Basis), Proposition 1.2.35 (Zero products)
Hint 1. Every value of T is a multiple of $(1, 2)$: $T(x, y) = (x + y)(1, 2)$. For (a) you need $T(\mathbf{v}_1) = \mathbf{w}_1$ and $T(\mathbf{v}_2) = \mathbf{0}$.
Hint 2. For (b), the matrix would force $T(\mathbf{v}_1) = \mathbf{v}_1$. Then $\mathbf{v}_1$ is a value of T. Compute T on a multiple of $(1, 2)$.
Sketch. (a) $\mathcal{B} = (1, 0), (1, -1)$ and $\mathcal{C} = (1, 2), (0, 1)$: $T(1, 0) = (1, 2)$ and $T(1, -1) = \mathbf{0}$. (b) $T(\mathbf{v}_1) = \mathbf{v}_1$ forces $\mathbf{v}_1 = c(1, 2)$, but $T(c(1, 2)) = 3c(1, 2)$, so $2\mathbf{v}_1 = \mathbf{0}$. (c) $\mathcal{B} = (1, 2), (1, -1)$ gives $\begin{pmatrix} 3 & 0 \\ 0 & 0 \end{pmatrix}$.

Note that $T(x, y) = (x + y)(1, 2)$, so every value of T is a multiple of $(1, 2)$, and $T(1, 2) = 3(1, 2)$.

(a) We need $T(\mathbf{v}_1) = \mathbf{w}_1$ and $T(\mathbf{v}_2) = \mathbf{0}$. Take $\mathcal{B} = (1, 0), (1, -1)$, a basis since $(x, y) = (x + y)(1, 0) - y(1, -1)$ with no other coefficients possible. Then $T(1, 0) = (1, 2)$ and $T(1, -1) = (0, 0)$. Take $\mathcal{C} = (1, 2), (0, 1)$, a basis since $(x, y) = x(1, 2) + (y - 2x)(0, 1)$ with no other coefficients possible. Then $[T(1, 0)]_{\mathcal{C}} = (1, 0)$ and $[T(1, -1)]_{\mathcal{C}} = (0, 0)$, so $[T]_{\mathcal{C}\mathcal{B}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

(b) Suppose $\mathcal{B} = \mathbf{v}_1, \mathbf{v}_2$ is a basis with $[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. The first column says $T(\mathbf{v}_1) = \mathbf{v}_1$. So $\mathbf{v}_1$ is a value of T, hence $\mathbf{v}_1 = c(1, 2)$ for some $c \in \mathbb{R}$, and then $T(\mathbf{v}_1) = cT(1, 2) = 3c(1, 2) = 3\mathbf{v}_1$. So $3\mathbf{v}_1 = \mathbf{v}_1$, that is, $2\mathbf{v}_1 = \mathbf{0}$, and $\mathbf{v}_1 = \mathbf{0}$ by Proposition 1.2.35. But a basis does not contain $\mathbf{0}$, a contradiction.

(c) Let $\mathcal{B} = (1, 2), (1, -1)$. It is a basis: $a(1, 2) + b(1, -1) = (x, y)$ exactly when $a = (x + y)/3$ and $b = (2x - y)/3$. Since $T(1, 2) = 3(1, 2)$ and $T(1, -1) = \mathbf{0}$,

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 3 & 0 \\ 0 & 0 \end{pmatrix}.$$

With two bases the nonzero entry can be scaled to 1, as in (a); with one basis the factor 3 by which T stretches the line through $(1, 2)$ cannot be changed. Such factors are the eigenvalues of Section 7.2.

Solution to Exercise 2.3.35

Uses. Definition 2.3.1 (Matrix of a linear map), Exercise 2.1.5, Non-example 2.1.14 (Complex conjugation), Theorem 2.3.20 (Linear maps correspond to matrices)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. The columns are the $\mathcal{B}$-coordinates of $M_z(1) = z$ and $M_z(i) = zi$.
Hint 2. For (c), a $\mathbb{C}$-linear map $\mathbb{C} \to \mathbb{C}$ is multiplication by some complex number (Exercise 2.1.5), and it is in particular $\mathbb{R}$-linear, so it has a matrix with respect to $\mathcal{B}$.

Sketch. (a) $z = a + bi$ and $zi = -b + ai$ give $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$. (b) $\overline{1} = 1$ and $\overline{i} = -i$ give $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. (c) A $\mathbb{C}$-linear T is M_z for $z = T(1)$, so its matrix has the form in (a); conversely $\begin{pmatrix} a & -b \\ b & a \end{pmatrix} = [M_{a+bi}]_{\mathcal{BB}}$.

(a) M_z is $\mathbb{R}$-linear (it is even $\mathbb{C}$-linear, Exercise 2.1.5), so it has a matrix with respect to $\mathcal{B}$. Since $M_z(1) = a + bi$ and $M_z(i) = (a + bi)i = -b + ai$,

$$[M_z]_{\mathcal{BB}} = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}.$$

For $z = \cos\theta + i\sin\theta$ this is the rotation matrix of Example 2.3.3: multiplying by a complex number of modulus 1 rotates the plane.

(b) Conjugation is $\mathbb{R}$-linear (Non-example 2.1.14), with $\overline{1} = 1$ and $\overline{i} = -i$, so its matrix is $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$.

(c) Let $T : \mathbb{C} \to \mathbb{C}$ be $\mathbb{C}$-linear. By Exercise 2.1.5, $T = M_z$ with $z = T(1)$, and T is in particular $\mathbb{R}$-linear. Writing $z = a + bi$, part (a) gives $[T]_{\mathcal{BB}} = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$. Conversely, $\begin{pmatrix} a & -b \\ b & a \end{pmatrix} = [M_{a+bi}]_{\mathcal{BB}}$ by (a), and M_{a+bi} is $\mathbb{C}$-linear. By Theorem 2.3.20, each such matrix is the matrix of exactly one $\mathbb{R}$-linear map, so the matrices of the form $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ are exactly the matrices of the $\mathbb{C}$-linear maps. The matrix of conjugation in (b) is not of this form, consistent with Non-example 2.1.14.

Solution to Exercise 2.3.36

Uses. Theorem 2.3.20 (Linear maps correspond to matrices), Example 2.3.6 (The zero map and the identity map), Example 2.3.23 (Maps of the plane in adapted bases), Definition 2.3.1 (Matrix of a linear map)
Hint 1. Only (b) is true. For (a), (c), and (d), look at Example 2.3.23 and at maps that send one basis to another.
Hint 2. For (e), what would the two columns say about the vectors of $\mathcal{B}$?
Sketch. (a) False: $[S_\ell]_{\mathcal{UU}} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ is also the standard matrix of the reflection across the x-axis. (b) True: $[T]_{\mathcal{BB}} = [0]_{\mathcal{BB}}$, so $T = 0$ by Theorem 2.3.20. (c) False: $T = 2\,\mathrm{id}$ with $\mathcal{C} = 2\mathbf{v}_1, \ldots, 2\mathbf{v}_n$. (d) False: S_ℓ in $\mathcal{U}$ and in $\mathcal{E}$. (e) False: both columns equal means $\mathbf{v}_1 = \mathbf{v}_2$.

(a) False. Let ℓ be the line $y = 2x$ and $\mathcal{U}$ as in Example 2.3.23. Then $[S_\ell]_{\mathcal{UU}} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$, which is also $[S]_{\mathcal{EE}}$ for the reflection $S(x, y) = (x, -y)$ across the x-axis. But $S_\ell \neq S$, since $S_\ell(1, 2) = (1, 2)$ and $S(1, 2) = (1, -2)$.

(b) True. The zero map also has the zero matrix (Example 2.3.6), so $[T]_{\mathcal{BB}} = [0]_{\mathcal{BB}}$, and $T = 0$ by Theorem 2.3.20(a).

(c) False. Take $V = \mathbb{R}$ with $\mathcal{B} = 1$ and $\mathcal{C} = 2$, and $T = 2\mathrm{id}_{\mathbb{R}}$. Then $T(1) = 2 = 1 \cdot 2$, so $[T]_{\mathcal{CB}} = (1) = I_1$, but $T \neq \mathrm{id}$. In general, $[T]_{\mathcal{CB}} = I_n$ says exactly that $T(\mathbf{v}_j) = \mathbf{w}_j$ for each j, which describes the map sending one basis to the other.

(d) False. With $\mathcal{U}$ as in (a), $[S_\ell]_{\mathcal{UU}} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ is diagonal, but $[S_\ell]_{\mathcal{EE}} = \frac{1}{5}\begin{pmatrix} -3 & 4 \\ 4 & 3 \end{pmatrix}$ is not (Example 2.3.19).

(e) False. The columns of $[\mathrm{id}]_{\mathcal{CB}}$ are $[\mathbf{v}_1]_{\mathcal{C}}$ and $[\mathbf{v}_2]_{\mathcal{C}}$. If both are $(1, 1)$, then $\mathbf{v}_1 = \mathbf{w}_1 + \mathbf{w}_2 = \mathbf{v}_2$, so $\mathcal{B}$ contains a vector twice and is linearly dependent, which is impossible for a basis.

Solution to Exercise 2.3.37

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.14 (Coordinates), Definition 1.6.1 (Basis)
Hint 1. Changing $\mathcal{B}$ changes which vectors T is applied to, so it acts on the columns. Changing $\mathcal{C}$ changes the coordinates of every value, so it acts on the rows.
Hint 2. For (d) and (e), take $T(\mathbf{v}_j) = \sum_l a_{lj}\mathbf{w}_l$ and rewrite the right side in the new basis. In (e), $\mathbf{w}_k = (\mathbf{w}_k + c\mathbf{w}_i) - c\mathbf{w}_i$.
Sketch. (a) Columns j and k swap. (b) Column j is multiplied by c. (c) Rows i and k swap. (d) Row i is multiplied by c^{-1}, since $a\mathbf{w}_i = (ac^{-1})(c\mathbf{w}_i)$. (e) Row i becomes row i minus c times row k, since $a\mathbf{w}_k = a(\mathbf{w}_k + c\mathbf{w}_i) - ac\mathbf{w}_i$.

The modified lists are bases. Reordering a list does not change which combinations represent a vector, only the order of the terms, so (a) and (c) give bases. For (b),

$$\sum_l a_l\mathbf{v}_l = \sum_{l \neq j} a_l\mathbf{v}_l + (a_j c^{-1})(c\mathbf{v}_j),$$

so a vector has a representation in the new list exactly when it has one in the old, and the coefficients correspond one to one; the same goes for (d). For (e), write $\mathbf{w}'_k = \mathbf{w}_k + c\mathbf{w}_i$ and $\mathbf{w}'_l = \mathbf{w}_l$ for $l \neq k$. Then

$$\sum_l b_l \mathbf{w}'_l = \sum_l b_l \mathbf{w}_l + c b_k \mathbf{w}_i,$$

so the combination with coefficients (b_l) in the new list equals the combination with coefficients (a_l) in the old list, where $a_l = b_l$ for $l \neq i$ and $a_i = b_i + cb_k$. This correspondence between coefficient lists is a bijection (its inverse is $b_l = a_l$ for $l \neq i$ and $b_i = a_i - ca_k$), so every vector has exactly one representation in the new list.

(a) The columns of the new matrix are $[T(\mathbf{v}_l)]_{\mathcal{C}}$ in the new order, so columns j and k of A are swapped.

(b) The new j-th column is $\big[T\big(c\mathbf{v}_j\big)\big]_{\mathcal{C}} = c\big[T\big(\mathbf{v}_j\big)\big]_{\mathcal{C}}$ by linearity of T and of coordinates, so column j is multiplied by c; the other columns are unchanged.

(c) The coordinates of a vector with respect to the reordered basis are its old coordinates reordered in the same way. So in every column, the entries in positions i and k are swapped: rows i and k of A are swapped.

(d) For each j,

$$T\big(\mathbf{v}_j\big) = \sum_{l \neq i} a_{lj}\mathbf{w}_l + \big(a_{ij}c^{-1}\big)(c\mathbf{w}_i),$$

so in the new basis the coordinates of $T\big(\mathbf{v}_j\big)$ are the old ones with the i-th entry multiplied by c^{-1}. Row i of A is multiplied by c^{-1}, not by c.

(e) For each j, substituting $\mathbf{w}_k = \mathbf{w}'_k - c\mathbf{w}_i$,

$$T\big(\mathbf{v}_j\big) = \sum_{l \neq k} a_{lj}\mathbf{w}_l + a_{kj}\big(\mathbf{w}'_k - c\mathbf{w}_i\big) = \sum_{l \neq i,k} a_{lj}\mathbf{w}'_l + \big(a_{ij} - ca_{kj}\big)\mathbf{w}'_i + a_{kj}\mathbf{w}'_k.$$

So row i of A is replaced by row i minus c times row k, and the other rows are unchanged.

In the language of Section 3.2: changing the basis of the target performs row operations on the matrix, and changing the basis of the domain performs column operations. Note that in (d) and (e) the row operation undoes the operation on the basis, with the roles of the indices exchanged in (e): adding c times $\mathbf{w}_i$ to $\mathbf{w}_k$ subtracts c times row k from row i.

Solution to Exercise 2.3.38

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.14 (Coordinates), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. Column k of $[T]_{\mathcal{BB}}$ is $[T(\mathbf{v}_k)]_{\mathcal{B}}$. Upper triangular means that its entries below position k vanish.
Hint 2. For (ii) $\Rightarrow$ (iii), $T(V_k)$ is spanned by $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)$, and each of these lies in $V_j \subseteq V_k$ for some $j \leq k$.
Sketch. (i) $\Leftrightarrow$ (ii): $a_{ik} = 0$ for all $i > k$ says that $T(\mathbf{v}_k) = \sum_{i \leq k} a_{ik}\mathbf{v}_i \in V_k$, and conversely, by uniqueness of coordinates. (ii) $\Rightarrow$ (iii): $T(V_k) = \operatorname{span}(T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)) \subseteq V_k$. (iii) $\Rightarrow$ (ii): $\mathbf{v}_k \in V_k$.

(i) $\Leftrightarrow$ (ii). Fix k. The k-th column of $[T]_{\mathcal{BB}}$ is $[T(\mathbf{v}_k)]_{\mathcal{B}} = (a_{1k}, \ldots, a_{nk})$, so $T(\mathbf{v}_k) = \sum_{i=1}^{n} a_{ik}\mathbf{v}_i$. If $a_{ik} = 0$ for all $i > k$, then $T(\mathbf{v}_k) = \sum_{i \leq k} a_{ik}\mathbf{v}_i \in V_k$. Conversely, if $T(\mathbf{v}_k) \in V_k$, then $T(\mathbf{v}_k) = \sum_{i \leq k} c_i\mathbf{v}_i$ for some scalars, which is a representation in terms of $\mathcal{B}$ with coefficients 0 for $i > k$. By uniqueness of coordinates (Definition 1.6.14), $a_{ik} = 0$ for $i > k$. Applying this for every k gives the equivalence.

(ii) $\Rightarrow$ (iii). For $j \leq k$, $T\big(\mathbf{v}_j\big) \in V_j \subseteq V_k$. By Proposition 2.1.16, $T(V_k) = \operatorname{span}(T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k))$, and this is contained in the subspace V_k by Proposition 1.4.14.

(iii) $\Rightarrow$ (ii). $\mathbf{v}_k \in V_k$, so $T(\mathbf{v}_k) \in T(V_k) \subseteq V_k$.

For example, $[D]_{\mathcal{BB}}$ in Example 2.3.4 is upper triangular, because D maps polynomials of degree at most k to polynomials of degree at most k. Upper-triangular matrices of operators return in Section 7.5.

Solution to Exercise 2.3.39

Uses. Definition 2.3.1 (Matrix of a linear map), Example 2.1.9 (Maps of polynomials), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
Hint 1. Read off what $[D]_{\mathcal{BB}} = N$ says about $D(\mathbf{v}_1), \ldots, D(\mathbf{v}_4)$. What is $D(D(D(\mathbf{v}_4)))$?
Hint 2. Over $\mathbb{F}_2$, compute $D\big(D\big(x^k\big)\big)$; over $\mathbb{F}_3$, compute $D\big(D\big(D\big(x^k\big)\big)\big)$. Products of two, or of three, consecutive integers are divisible by 2, or by 3.
Hint 3. Over $\mathbb{Q}$ and $\mathbb{F}_5$, try to scale the monomials so that each one differentiates to the previous one.
Sketch. $[D]_{\mathcal{BB}} = N$ means $D(\mathbf{v}_1) = \mathbf{0}$ and $D(\mathbf{v}_k) = \mathbf{v}_{k-1}$, so $D^3(\mathbf{v}_4) = \mathbf{v}_1 \neq \mathbf{0}$ and $D^2(\mathbf{v}_3) = \mathbf{v}_1 \neq \mathbf{0}$. Over $\mathbb{F}_2$, $D^2 = 0$ since $k(k-1)$ is even; over $\mathbb{F}_3$, $D^3 = 0$ since $k(k-1)(k-2)$ is divisible by 3. So no basis exists there. Over $\mathbb{Q}$ and $\mathbb{F}_5$, $6 \neq 0$ and $1, x, x^2/2, x^3/6$ works.

The k-th column of N is $\mathbf{0}$ for $k = 1$ and $\mathbf{e}_{k-1}$ for $k = 2, 3, 4$. So $[D]_{\mathcal{BB}} = N$ for $\mathcal{B} = \mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \mathbf{v}_4$ means exactly that

$$D(\mathbf{v}_1) = \mathbf{0}, \quad D(\mathbf{v}_2) = \mathbf{v}_1, \quad D(\mathbf{v}_3) = \mathbf{v}_2, \quad D(\mathbf{v}_4) = \mathbf{v}_3.$$

In that case $D(D(\mathbf{v}_3)) = \mathbf{v}_1$ and $D(D(D(\mathbf{v}_4))) = \mathbf{v}_1$, and $\mathbf{v}_1 \neq \mathbf{0}$ because it belongs to a basis.

$\mathbb{F}_2$: no. For $k \geq 2$, $D\big(D\big(x^k\big)\big) = k(k-1)x^{k-2}$, and $k(k-1)$ is even, so it is 0 in $\mathbb{F}_2$. Also $D(D(1)) = D(D(x)) = \mathbf{0}$. So the linear maps $D \circ D$ and 0 agree on the basis $1, x, x^2, x^3$, and $D \circ D = 0$ (Corollary 2.2.6). This contradicts $D(D(\mathbf{v}_3)) = \mathbf{v}_1 \neq \mathbf{0}$.

$\mathbb{F}_3$: no. For $k \geq 3$, $D\big(D\big(D\big(x^k\big)\big)\big) = k(k-1)(k-2)x^{k-3}$, and one of three consecutive integers is divisible by 3, so the coefficient is 0 in $\mathbb{F}_3$. For $k \leq 2$, $D\big(D\big(D\big(x^k\big)\big)\big) = \mathbf{0}$ as well. As before, $D \circ D \circ D = 0$, contradicting $D(D(D(\mathbf{v}_4))) = \mathbf{v}_1 \neq \mathbf{0}$.

$\mathbb{Q}$ and $\mathbb{F}_5$: yes. In both fields $2 \neq 0$ and $6 \neq 0$ (in $\mathbb{F}_5$, $6 = 1$). Let

$$\mathcal{B} = 1, x, \frac{1}{2}x^2, \frac{1}{6}x^3.$$

It is a basis of $F[x]_{\leq 3}$, since

$$a + bx + cx^2 + dx^3 = a \cdot 1 + bx + 2c \cdot \frac{1}{2}x^2 + 6d \cdot \frac{1}{6}x^3,$$

and these coefficients are the only possible ones. Also $D(1) = \mathbf{0}$, $D(x) = 1$, $D\big(\frac{1}{2}x^2\big) = x$, and $D\big(\frac{1}{6}x^3\big) = \frac{1}{2}x^2$, so $[D]_{\mathcal{BB}} = N$. Over $\mathbb{F}_5$, $\frac{1}{2} = 3$ and $\frac{1}{6} = 1$, so the basis is $1, x, 3x^2, x^3$; for instance $D\big(x^3\big) = 3x^2$.

So the answer depends on the field: the property $D \circ D \circ D \neq 0$, which every operator with matrix N has, holds over $\mathbb{Q}$ and $\mathbb{F}_5$ and fails over $\mathbb{F}_2$ and $\mathbb{F}_3$.

Solution to Exercise 2.3.40

Uses. Definition 2.3.1 (Matrix of a linear map), Example 2.3.6 (The zero map and the identity map), Theorem 2.3.20 (Linear maps correspond to matrices), Exercise 2.3.37
Hint 1. One direction is quick: what is $[\lambda \mathrm{id}_V]_{\mathcal{BB}}$? For the other, fix one basis $\mathcal{B}$ with matrix A, and compare A with the matrix in a cleverly modified basis.
Hint 2. For $i \neq j$, replace $\mathbf{v}_j$ by $\mathbf{v}_j + \mathbf{v}_i$. How do the coordinates of a vector change? (See Exercise 2.3.37.)
Hint 3. In the new basis, a vector's coordinates are the old ones except that the i-th becomes (old i-th) minus (old j-th). Compare the entries in row i of the two matrices, first in a column $k \neq j$, then in column j.
Sketch. $[\lambda\ \mathrm{id}]_{\mathcal{BB}} = \lambda I_n$ for every $\mathcal{B}$. Conversely, let $A = [T]_{\mathcal{BB}}$ and let $\mathcal{B}'$ be $\mathcal{B}$ with $\mathbf{v}_j$ replaced by $\mathbf{v}_j + \mathbf{v}_i$. The $\mathcal{B}'$-coordinates of a vector are its $\mathcal{B}$-coordinates with the i-th entry replaced by (entry i) $-$ (entry j). Entry (i,k) of $[T]_{\mathcal{B}'\mathcal{B}'}$ for $k \neq j$ is $a_{ik} - a_{jk}$, so $a_{jk} = 0$. Entry (i,j) is $a_{ij} + a_{ii} - a_{jj} - a_{ji}$, so $a_{ii} = a_{jj}$. Hence $A = \lambda I_n$ and $T = \lambda\ \mathrm{id}$.

If $T = \lambda \mathrm{id}_V$. Then $T\big(\mathbf{v}_j\big) = \lambda \mathbf{v}_j$, whose coordinate vector is $\lambda \mathbf{e}_j$, so $[T]_{\mathcal{BB}} = \lambda I_n$ for every basis $\mathcal{B}$ of length n.

Conversely, suppose all the matrices $[T]_{\mathcal{BB}}$ with $\mathcal{B}$ of length n are equal. Fix a basis $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ and let $A = [T]_{\mathcal{BB}}$. If $n = 1$, then $A = (\lambda)$ for some λ, so $T(\mathbf{v}_1) = \lambda \mathbf{v}_1$, and $T = \lambda \mathrm{id}_V$ because both are linear and agree on the basis.

Let $n \geq 2$, and fix $i \neq j$. Let $\mathcal{B}'$ be $\mathcal{B}$ with $\mathbf{v}_j$ replaced by $\mathbf{v}_j + \mathbf{v}_i$; it is a basis of length n by Exercise 2.3.37(e) (with $c = 1$). Since $\mathbf{v}_j = \big(\mathbf{v}_j + \mathbf{v}_i\big) - \mathbf{v}_i$, a vector $\mathbf{y} = \sum_l c_l \mathbf{v}_l$ equals

$$\mathbf{y} = \sum_{l \neq i,j} c_l \mathbf{v}_l + (c_i - c_j)\mathbf{v}_i + c_j(\mathbf{v}_j + \mathbf{v}_i).$$

So $[\mathbf{y}]_{\mathcal{B}'}$ is $[\mathbf{y}]_{\mathcal{B}}$ with the i-th entry replaced by $c_i - c_j$.

Column $k \neq j$. The k-th vector of $\mathcal{B}'$ is $\mathbf{v}_k$, and $T(\mathbf{v}_k) = \sum_l a_{lk}\mathbf{v}_l$. So the (i,k) entry of $[T]_{\mathcal{B}'\mathcal{B}'}$ is $a_{ik} - a_{jk}$. Since this matrix equals A, $a_{ik} - a_{jk} = a_{ik}$, that is, $a_{jk} = 0$. Since $n \geq 2$, for every j there is some $i \neq j$, so $a_{jk} = 0$ whenever $j \neq k$: A is diagonal.

Column j. The j-th vector of $\mathcal{B}'$ is $\mathbf{v}_j + \mathbf{v}_i$, and $T(\mathbf{v}_j + \mathbf{v}_i) = \sum_l (a_{lj} + a_{li})\mathbf{v}_l$. So the (i,j) entry of $[T]_{\mathcal{B}'\mathcal{B}'}$ is $(a_{ij} + a_{ii}) - (a_{jj} + a_{ji}) = a_{ii} - a_{jj}$, using that A is diagonal. It must equal $a_{ij} = 0$, so $a_{ii} = a_{jj}$.

So $A = \lambda I_n$ with $\lambda = a_{11}$. Since $[\lambda \mathrm{id}_V]_{\mathcal{B}\mathcal{B}} = \lambda I_n$ as well, $T = \lambda \mathrm{id}_V$ by Theorem 2.3.20.

Solution to Exercise 2.3.41

Uses. Definition 2.3.8 (Matrix–vector product), Proposition 2.3.11 (Entries of $A\mathbf{x}$)
Hint 1. Pressing button j adds the j-th column of A to $\mathbf{s}$. Over $\mathbb{F}_2$, adding a vector twice adds nothing.
Hint 2. Switching everything off means solving $A\mathbf{x} = \mathbf{s}$. Set $x_0 = x_{n+1} = 0$, so that every equation reads $x_{i-1} + x_i + x_{i+1} = s_i$. Once x_1 is chosen, the equations for $i = 1, \ldots, n-1$ determine $x_2, \ldots, x_n$ one at a time.
Hint 3. Compare the two sequences obtained from $x_1 = 0$ and $x_1 = 1$. Their sum satisfies $d_{i+1} = d_i + d_{i-1}$ with $d_0 = 0$, $d_1 = 1$, which is periodic: $0, 1, 1, 0, 1, 1, \ldots$.
Sketch. (a) Each press of button j adds column $\mathbf{a}_j$; addition in $\mathbb{F}_2^n$ is commutative and $\mathbf{a}_j + \mathbf{a}_j = \mathbf{0}$, so the total change is $\sum_j x_j \mathbf{a}_j = A\mathbf{x}$. (b) Solving $A\mathbf{x} = \mathbf{s}$ by choosing x_1 and propagating, the last equation becomes $x_{n+1} = 0$. The two choices of x_1 give values of x_{n+1} differing by d_{n+1}, where d is $0, 1, 1$ repeated. If $3 \nmid n+1$, exactly one choice works for each $\mathbf{s}$. If $3 \mid n+1$, either both or neither work, so each solvable $\mathbf{s}$ has two solutions $\mathbf{x}$, only 2^{n-1} of the 2^n configurations are solvable, and some configuration cannot be switched off.

(a) Pressing button j switches exactly the lamps i with $|i - j| \leq 1$, that is, it adds to $\mathbf{s}$ the vector $\mathbf{a}_j$ with 1 in these positions, which is the j-th column of A. A sequence of presses adds the corresponding columns, and since addition in $\mathbb{F}_2^n$ is commutative, the order does not matter. Since $\mathbf{a}_j + \mathbf{a}_j = \mathbf{0}$ in $\mathbb{F}_2^n$, pressing button j a total of m_j times adds $\mathbf{a}_j$ if m_j is odd and nothing if it is even. So the configuration becomes $\mathbf{s} + \sum_j x_j \mathbf{a}_j = \mathbf{s} + A\mathbf{x}$ (Definition 2.3.8).

(b) By (a), $\mathbf{s}$ can be switched off exactly when $\mathbf{s} + A\mathbf{x} = \mathbf{0}$ for some $\mathbf{x} \in \mathbb{F}_2^n$, that is, when $A\mathbf{x} = \mathbf{s}$ (in $\mathbb{F}_2$, $-\mathbf{s} = \mathbf{s}$). By Proposition 2.3.11, with the convention $x_0 = x_{n+1} = 0$, this system reads

$$x_{i-1} + x_i + x_{i+1} = s_i \quad (i = 1, \ldots, n).$$

Propagation. Given $\mathbf{s}$ and a choice of $x_1 \in \mathbb{F}_2$, set $x_0 = 0$ and define $x_2, x_3, \ldots, x_{n+1}$ by $x_{i+1} = s_i + x_{i-1} + x_i$ for $i = 1, \ldots, n$. For $i \leq n-1$ this is forced by the i-th equation, and the last step defines a number x_{n+1}. The sequence $x_1, \ldots, x_n$ is a solution if and only if the n-th equation also holds with $x_{n+1} = 0$, that is, if and only if the propagated value x_{n+1} is 0. Every solution arises this way from its own x_1. So for each $\mathbf{s}$, the solutions correspond to those $x_1 \in \{0, 1\}$ whose propagated x_{n+1} is 0.

Comparing the two choices. Let x and x' be the sequences propagated from $x_1 = 0$ and $x'_1 = 1$, and let $d_i = x_i + x'_i$. Then $d_0 = 0$, $d_1 = 1$, and $d_{i+1} = d_{i-1} + d_i$, since the s_i cancel. So $d = 0, 1, 1, 0, 1, 1, 0, \ldots$, and $d_i = 0$ exactly when 3 divides i.

If $3 \nmid n+1$, then $x_{n+1} + x'_{n+1} = d_{n+1} = 1$, so exactly one of x_{n+1}, x'_{n+1} is 0, and $A\mathbf{x} = \mathbf{s}$ has exactly one solution. Every configuration can be switched off.

If $3 \mid n+1$, then $x_{n+1} = x'_{n+1}$, so for each $\mathbf{s}$ the system has either two solutions or none. Each of the 2^n vectors $\mathbf{x}$ solves the system for exactly one $\mathbf{s}$, namely $\mathbf{s} = A\mathbf{x}$. So the solvable configurations number $2^n/2 = 2^{n-1} < 2^n$, and some configuration cannot be switched off. Finally, 3 divides $n+1$ exactly when $n = 3k+2$ for some integer $k \geq 0$.

For example, for $n = 2$ the matrix is $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$, both buttons switch both lamps, and the configuration $(1, 0)$ cannot be switched off.

Solution to Exercise 2.3.42

> *Uses.* Example 2.3.28 (Translating in both directions), Theorem 2.3.9 (The matrix of a map computes the map), Proposition 2.3.11 (Entries of $A\mathbf{x}$)
> *Techniques.* Translate between maps and matrices (Technique 2.3.27)
> *Hint 1.* $\Delta(x^3) = (x+1)^3 - x^3 = 1 + 3x + 3x^2$. The other columns are as in Example 2.3.28, with an extra zero row.
> *Hint 2.* Solve $[\Delta](a,b,c,d) = (0,0,1,0)$ from the bottom up.
> *Sketch.* The new column is $(1,3,3,0)$. The system $b+c+d=0$, $2c+3d=0$, $3d=1$ gives $d=1/3$, $c=-1/2$, $b=1/6$, a free, so $p = a + x(x-1)(2x-1)/6$. Telescoping gives $\sum_{k=0}^{n-1} k^2 = n(n-1)(2n-1)/6$.

With $\mathcal{B} = 1, x, x^2, x^3$, we have $\Delta(1) = \mathbf{0}$, $\Delta(x) = 1$, $\Delta(x^2) = 1 + 2x$, and $\Delta(x^3) = 1 + 3x + 3x^2$, so

$$[\Delta]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 0 & 0 & 2 & 3 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

For $p = a + bx + cx^2 + dx^3$, the equation $\Delta(p) = x^2$ becomes $[\Delta]_{\mathcal{B}\mathcal{B}}(a,b,c,d) = (0,0,1,0)$ (Theorem 2.3.9), that is,

$$b + c + d = 0, \quad 2c + 3d = 0, \quad 3d = 1.$$

So $d = 1/3$, $c = -1/2$, $b = 1/2 - 1/3 = 1/6$, and a is arbitrary:

$$p = a + \frac{x}{6} - \frac{x^2}{2} + \frac{x^3}{3} = a + \frac{x(x-1)(2x-1)}{6}.$$

(Indeed $x(x-1)(2x-1) = 2x^3 - 3x^2 + x$.)

For $q(t) = t(t-1)(2t-1)/6$ and every number t,

$$q(t+1) - q(t) = \frac{t((t+1)(2t+1) - (t-1)(2t-1))}{6} = \frac{t \cdot 6t}{6} = t^2.$$

Summing over $t = 0, 1, \ldots, n-1$, the right side telescopes:

$$\sum_{k=0}^{n-1} k^2 = q(n) - q(0) = \frac{n(n-1)(2n-1)}{6}.$$

For $n = 3$: $0 + 1 + 4 = 5 = (3 \cdot 2 \cdot 5)/6$.

Solution to Exercise 2.3.43

> *Uses.* Definition 2.3.8 (Matrix–vector product), Proposition 2.3.11 (Entries of $A\mathbf{x}$), Proposition 2.3.13 (Linearity of the product)
> *Hint 1.* The map s is linear. Apply it to $A\mathbf{x} = \sum_j x_j \mathbf{a}_j$.
> *Hint 2.* For the converse in (a), take $\mathbf{x} = \mathbf{e}_j$. For (b), use the row-times-column rule.
> *Sketch.* (a) $s(A\mathbf{x}) = \sum_j x_j s(\mathbf{a}_j)$, which is $s(\mathbf{x})$ when every $s(\mathbf{a}_j) = 1$; conversely $s(\mathbf{a}_j) = s(A\mathbf{e}_j) = s(\mathbf{e}_j) = 1$. (b) The i-th entry of $A(1,\ldots,1)$ is the i-th row sum. (c) The entries $\sum_j a_{ij} x_j$ are sums of products of nonnegative numbers, and they add up to 1 by (a).

The map $s : F^k \to F$ is linear, since

$$s(c\mathbf{y} + \mathbf{z}) = \sum_i (cy_i + z_i) = cs(\mathbf{y}) + s(\mathbf{z}).$$

(a) Let $\mathbf{a}_1, \ldots, \mathbf{a}_n$ be the columns of A. By Definition 2.3.8 and linearity of s,

$$s(A\mathbf{x}) = s(x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n) = x_1 s(\mathbf{a}_1) + \cdots + x_n s(\mathbf{a}_n).$$

If $s(\mathbf{a}_j) = 1$ for every j, this is $x_1 + \cdots + x_n = s(\mathbf{x})$. Conversely, if $s(A\mathbf{x}) = s(\mathbf{x})$ for all $\mathbf{x}$, take $\mathbf{x} = \mathbf{e}_j$: by Proposition 2.3.13(c), $s(\mathbf{a}_j) = s(A\mathbf{e}_j) = s(\mathbf{e}_j) = 1$.

(b) By Proposition 2.3.11, the i-th entry of $A(1,\dots,1)$ is $a_{i1}+\cdots+a_{in}$, the sum of the entries of row i. So $A(1,\dots,1)=c(1,\dots,1)$ if and only if every row sum is c.

(c) By Proposition 2.3.11, the i-th entry of $A\mathbf{x}$ is $\sum_j a_{ij}x_j$, a sum of products of nonnegative numbers, hence nonnegative. By (a), the entries of $A\mathbf{x}$ add up to $s(\mathbf{x})=1$. Vectors with nonnegative entries adding up to 1 are probability distributions, and matrices as in (c) describe how they evolve in a Markov chain (Section 11.1).

Solution to Exercise 2.3.44

Uses. Proposition 2.2.20 (Linear maps out of $F[x]$), Definition 1.2.13 (Polynomials), Example 2.1.9 (Maps of polynomials)
Hint 1. Column j lists the coefficients of the polynomial $T(x^j)$. For the converse, use Proposition 2.2.20.
Hint 2. For (c), write $p=\sum_j c_j x^j$ and apply T term by term. For (d), try an evaluation, viewed as a map into constants.
Sketch. (a) $T(x^j)$ is a polynomial, so its coefficients are eventually 0. Given a column-finite array, $\mathbf{w}_j=\sum_i a_{ij}x^i$ is a polynomial, and Proposition 2.2.20 gives exactly one T with $T(x^j)=\mathbf{w}_j$. (b) D: $a_{j-1,j}=j$; M: $a_{j+1,j}=1$; all else 0. (c) Expand $T(p)=\sum_j c_j T(x^j)$ and collect the coefficient of each x^i. (d) $p\mapsto p(1)$, regarded as a constant polynomial, has row 0 equal to $1,1,1,\dots$.

(a) Column j consists of the coefficients of the polynomial $T(x^j)$, and only finitely many coefficients of a polynomial are nonzero (Definition 1.2.13). Conversely, let (a_{ij}) be an array whose columns have finitely many nonzero entries. Then $\mathbf{w}_j=\sum_i a_{ij}x^i$ is a polynomial for each j, and by Proposition 2.2.20 there is exactly one $T\in \mathrm{L}(F[x])$ with $T(x^j)=\mathbf{w}_j$ for every j. Its matrix is the given array, and any operator with this matrix sends each x^j to $\mathbf{w}_j$, so it is this T.

(b) $D(x^j)=jx^{j-1}$ for $j\geq 1$ and $D(1)=\mathbf{0}$, so the matrix of D has the entries $a_{j-1,j}=j$ for $j\geq 1$, just above the diagonal, and zeros elsewhere. Multiplication by x sends x^j to x^{j+1}, so its matrix has $a_{j+1,j}=1$ just below the diagonal, and zeros elsewhere.

(c) Let $p=\sum_{j=0}^{d} c_j x^j$, with $c_j=0$ for $j>d$. By linearity,

$$T(p)=\sum_{j=0}^{d} c_j T(x^j)=\sum_{j=0}^{d} c_j \sum_i a_{ij}x^i=\sum_i\left(\sum_{j=0}^{d} a_{ij}c_j\right)x^i.$$

So the i-th coefficient of $T(p)$ is $\sum_j a_{ij}c_j$, in which the terms with $j>d$ are 0. This is the row-times-column rule of Proposition 2.3.11 for infinite matrices whose columns are finite.

(d) Let $T(p)=p(1)$, regarded as a constant polynomial. It is linear (Example 2.1.9), and $T(x^j)=1$ for every j, so row 0 of its matrix is $1,1,1,\dots$. Rows can be infinite; only the columns must be finite.

Solution to Exercise 2.3.45

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.1 (Basis), Theorem 2.3.9 (The matrix of a map computes the map), Corollary 2.2.6 (Agreeing on a spanning list)
Hint 1. (a) The columns are $T(1,0)$ and $T(0,1)$.
Hint 2. (b) Compute $T(1,i)$ and $T(1,-i)$ and express them in terms of $(1,i)$ and $(1,-i)$.
Sketch. (a) $\begin{pmatrix}1 & i\\ i & -1\end{pmatrix}$. (b) $(z,w)=a(1,i)+b(1,-i)$ has the unique solution $a=(z-iw)/2$, $b=(z+iw)/2$. $T(1,i)=\mathbf{0}$ and $T(1,-i)=(2,2i)=2(1,i)$, so $[T]_{\mathcal{BB}}=\begin{pmatrix}0 & 2\\ 0 & 0\end{pmatrix}$. So T sends $(1,-i)$ to a multiple of $(1,i)$ and $(1,i)$ to $\mathbf{0}$, hence $T\circ T=0$.

(a) $T(1,0)=(1,i)$ and $T(0,1)=(i,-1)$, so $[T]_{\mathcal{EE}}=\begin{pmatrix}1 & i\\ i & -1\end{pmatrix}$.

(b) The equation $(z,w)=a(1,i)+b(1,-i)$ means $a+b=z$ and $i(a-b)=w$, that is, $a-b=-iw$. Adding and subtracting, $a=(z-iw)/2$ and $b=(z+iw)/2$, and these values do satisfy both equations. So every vector has exactly one representation, and $\mathcal{B}$ is a basis. Now

$$T(1,i)=\left(1+i^2,i-i\right)=(0,0),\quad T(1,-i)=\left(1-i^2,i+i\right)=(2,2i)=2(1,i),$$

so

$$[T]_{\mathcal{BB}}=\begin{pmatrix}0 & 2\\ 0 & 0\end{pmatrix}.$$

So T kills $(1,i)$ and sends $(1,-i)$ into $\operatorname{span}((1,i))$. Hence $T\big(T(\mathbf{v}_j)\big) = \mathbf{0}$ for both basis vectors, and $T \circ T = 0$ by Corollary 2.2.6. Directly,

$$T(T(z,w)) = (z + iw + i(iz - w), i(z + iw) - (iz - w)) = (0,0).$$

The standard matrix hides this; the basis $\mathcal{B}$ shows it.

Solution to Exercise 2.3.46

Uses. Example 2.1.11 (Rotations, projections, and reflections), Exercise 2.1.43, Definition 2.3.1 (Matrix of a linear map), Example 2.3.3 (Matrices with respect to standard bases)
Hint 1. (a) Compare $a\mathbf{u}_1 + b\mathbf{u}_2$ with the formula for $R_\varphi(a,b)$. For the basis property, R_φ is undone by $R_{-\varphi}$ (Exercise 2.1.43).
Hint 2. The formula for S_α shows that S_α sends the unit vector at angle β to the unit vector at angle $2\alpha - \beta$, and R_θ adds θ to the angle. Write down the angles of the images of $\mathbf{u}_1$ (angle φ) and $\mathbf{u}_2$ (angle $\varphi + \pi/2$), and use (a).
Sketch. (a) Expanding gives $a\mathbf{u}_1 + b\mathbf{u}_2 = R_\varphi(a,b)$, and since $R_{-\varphi}R_\varphi = \mathrm{id} = R_\varphi R_{-\varphi}$, $(a,b) = R_{-\varphi}(\mathbf{y})$ is the unique coefficient vector for $\mathbf{y}$; $R_{-\varphi}$ subtracts φ from the angle. (b) $R_\theta(\mathbf{u}_1)$ and $R_\theta(\mathbf{u}_2)$ have angles $\varphi + \theta$ and $\varphi + \pi/2 + \theta$, hence coordinates $(\cos\theta, \sin\theta)$ and $(-\sin\theta, \cos\theta)$. (c) $S_\alpha(\mathbf{u}_1)$ and $S_\alpha(\mathbf{u}_2)$ have angles $2\alpha - \varphi$ and $2\alpha - \varphi - \pi/2$, hence coordinates $(\cos 2\gamma, \sin 2\gamma)$ and $(\sin 2\gamma, -\cos 2\gamma)$ with $\gamma = \alpha - \varphi$.

(a) By the formula for R_φ in Example 2.1.11,

$$a\mathbf{u}_1 + b\mathbf{u}_2 = (a\cos\varphi - b\sin\varphi, a\sin\varphi + b\cos\varphi) = R_\varphi(a,b).$$

By Exercise 2.1.43, $R_\varphi R_{-\varphi} = R_{-\varphi}R_\varphi = R_0 = \mathrm{id}$. So for $\mathbf{y} \in \mathbb{R}^2$, the coefficients $(a,b) = R_{-\varphi}(\mathbf{y})$ work, since R_φ undoes $R_{-\varphi}$. They are the only ones: if $R_\varphi(a,b) = \mathbf{y}$, then applying $R_{-\varphi}$ gives $(a,b) = R_{-\varphi}(\mathbf{y})$. Hence $\mathcal{U}$ is a basis and $[\mathbf{y}]_\mathcal{U} = R_{-\varphi}(\mathbf{y})$. Rotation by $-\varphi$ subtracts φ from the polar angle (Example 2.1.11), so

$$[(r\cos\beta, r\sin\beta)]_\mathcal{U} = (r\cos(\beta - \varphi), r\sin(\beta - \varphi)).$$

(b) The vector $\mathbf{u}_1$ has angle φ and $\mathbf{u}_2 = (\cos(\varphi + \pi/2), \sin(\varphi + \pi/2))$ has angle $\varphi + \pi/2$, both of length 1. Rotation adds θ to the angle, so by (a),

$$[R_\theta(\mathbf{u}_1)]_\mathcal{U} = (\cos\theta, \sin\theta), \quad [R_\theta(\mathbf{u}_2)]_\mathcal{U} = (\cos(\theta + \pi/2), \sin(\theta + \pi/2)) = (-\sin\theta, \cos\theta).$$

These are the columns of $[R_\theta]_{\mathcal{E}\mathcal{E}}$ (Example 2.3.3).

(c) From the formula in Example 2.1.11 and the angle subtraction formulas,

$$S_\alpha(\cos\beta, \sin\beta) = (\cos\beta\cos 2\alpha + \sin\beta\sin 2\alpha, \cos\beta\sin 2\alpha - \sin\beta\cos 2\alpha) = (\cos(2\alpha - \beta), \sin(2\alpha - \beta)).$$

So $S_\alpha(\mathbf{u}_1)$ has angle $2\alpha - \varphi$ and $S_\alpha(\mathbf{u}_2)$ has angle $2\alpha - \varphi - \pi/2$. With $\gamma = \alpha - \varphi$, part (a) gives the coordinates

$$[S_\alpha(\mathbf{u}_1)]_\mathcal{U} = (\cos 2\gamma, \sin 2\gamma), \quad [S_\alpha(\mathbf{u}_2)]_\mathcal{U} = (\cos(2\gamma - \pi/2), \sin(2\gamma - \pi/2)) = (\sin 2\gamma, -\cos 2\gamma).$$

By the formula for S_γ, these are $S_\gamma(\mathbf{e}_1)$ and $S_\gamma(\mathbf{e}_2)$, the columns of $\big[S_\gamma\big]_{\mathcal{E}\mathcal{E}}$.

In words: in coordinates rotated by φ, a rotation looks the same, and the reflection across the line at angle α looks like the reflection across the line at angle $\alpha - \varphi$, the angle of the mirror measured from $\mathbf{u}_1$ instead of from $\mathbf{e}_1$. Taking $\varphi = \alpha$ puts $\mathbf{u}_1$ on the mirror, and then $[S_\alpha]_{\mathcal{U}\mathcal{U}} = [S_0]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$, as in Example 2.3.23.

Solution to Exercise 2.3.47

Uses. Proposition 2.3.11 (Entries of $A\mathbf{x}$), the triangle inequality $|z + w| \le |z| + |w|$ in $\mathbb{C}$, Section B.1
Hint 1. Suppose $A\mathbf{x} = \mathbf{0}$ with $\mathbf{x} \neq \mathbf{0}$. Look at the equation coming from a cleverly chosen row.
Hint 2. Choose i with $|x_i|$ as large as possible. The i-th entry of $A\mathbf{x}$ gives $a_{ii}x_i = -\sum_{j \neq i} a_{ij}x_j$. Estimate both sides.
Sketch. If $\mathbf{x} \neq \mathbf{0}$, pick i with $|x_i|$ maximal, so $|x_i| > 0$. Row i of $A\mathbf{x} = \mathbf{0}$ and the triangle inequality give $|a_{ii}||x_i| \le \sum_{j \neq i} |a_{ij}||x_j|$. Bounding each $|x_j|$ by $|x_i|$ makes the right side smaller than $|a_{ii}||x_i|$, a contradiction.

Suppose $A\mathbf{x} = \mathbf{0}$ and $\mathbf{x} \neq \mathbf{0}$. Choose i with $|x_i| \ge |x_j|$ for all j; then $|x_i| > 0$. By Proposition 2.3.11, the i-th entry of $A\mathbf{x}$ is $\sum_j a_{ij}x_j = 0$, so $a_{ii}x_i = -\sum_{j \neq i} a_{ij}x_j$. Taking absolute values and using the triangle inequality,

$$|a_{ii}||x_i| = \left|\sum_{j\neq i} a_{ij}x_j\right| \leq \sum_{j\neq i}|a_{ij}||x_j| \leq \left(\sum_{j\neq i}|a_{ij}|\right)|x_i| < |a_{ii}||x_i|,$$

where the last step uses the hypothesis and $|x_i| > 0$. This is a contradiction, so $\mathbf{x} = \mathbf{0}$.

The proof chose an extremal coordinate, the largest one in absolute value, so that a single row of A could be played against all the others. In the language of Section 2.6 the conclusion says that T_A is injective, and since A is square it is then invertible (Corollary 3.5.25).

Solution to Exercise 2.3.48

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.1 (Basis), Definition 1.2.16 (Degree), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Corollary 2.2.6 (Agreeing on a spanning list), binomial coefficients: $\binom{p}{k}$ is divisible by p for $0 < k < p$

Hint 1. (a) $\deg b_k = k$, which gives the basis property. For the matrix, prove the polynomial identity $b_k(x+1) = b_k + b_{k-1}$ by pulling out the common factor $x(x-1)\cdots(x-k+2)$.

Hint 2. (b), "if": for $k \leq n < p$, the integer $k!$ is not divisible by p, so it is invertible in $\mathbb{F}_p$ and (a) goes through. "Only if": what does $[T]_{\mathcal{B}\mathcal{B}} = J$ say about $T(\mathbf{v}_k)$? Compute $T^r(\mathbf{v}_s)$ by induction on r.

Hint 3. You should find $T^r(\mathbf{v}_s) = \sum_k \binom{r}{k}\mathbf{v}_{s-k}$. Take $r = s = p$, and compare with $T^p(f) = f(x+p)$.

Sketch. (a) The b_k have degrees $0, 1, \ldots, n$, so they form a basis. Pulling out the common factor $x(x-1)\cdots(x-k+2)$ shows $b_k(x+1) - b_k = b_{k-1}$, so $T(b_k) = b_k + b_{k-1}$ and $T(b_0) = b_0$: the matrix is J. (b) If $n < p$, the same construction works in $\mathbb{F}_p$. If $n \geq p$ and $[T]_{\mathcal{B}\mathcal{B}} = J$ with $\mathcal{B} = \mathbf{v}_0, \ldots, \mathbf{v}_n$, then $T(\mathbf{v}_k) = \mathbf{v}_k + \mathbf{v}_{k-1}$, and by induction $T^p(\mathbf{v}_p) = \sum_k \binom{p}{k}\mathbf{v}_{p-k} = \mathbf{v}_p + \mathbf{v}_0$ in characteristic p. But $T^p(f) = f(x+p) = f$, so $\mathbf{v}_0 = \mathbf{0}$, a contradiction.

Throughout, index the basis vectors from 0, so that column k of J (for $k = 0, \ldots, n$) is $\mathbf{e}_k$ for $k = 0$ and $\mathbf{e}_{k-1} + \mathbf{e}_k$ for $k \geq 1$, where $\mathbf{e}_0, \ldots, \mathbf{e}_n$ is the standard basis of F^{n+1}. So $[T]_{\mathcal{B}\mathcal{B}} = J$ for $\mathcal{B} = \mathbf{v}_0, \ldots, \mathbf{v}_n$ means

$$T(\mathbf{v}_0) = \mathbf{v}_0, \quad T(\mathbf{v}_k) = \mathbf{v}_k + \mathbf{v}_{k-1} \quad (1 \leq k \leq n). \tag{C.1.5}$$

Polynomials of degrees $0, 1, \ldots, n$. Let $q_0, \ldots, q_n \in F[x]_{\leq n}$ with $\deg q_k = k$. They span $F[x]_{\leq n}$: by induction on k, every x^k is in their span, since x^k minus a suitable multiple of q_k has degree less than k. They are linearly independent: in a relation $\sum_k c_k q_k = \mathbf{0}$ with some $c_k \neq 0$, let k be the largest index with $c_k \neq 0$; then the coefficient of x^k on the left is c_k times the leading coefficient of q_k, which is nonzero. So $q_0, \ldots, q_n$ is a basis (Definition 1.6.1).

(a) Over $\mathbb{Q}$, b_k is a product of k factors of degree 1 divided by $k!$, so $\deg b_k = k$, and $\mathcal{B}$ is a basis by the paragraph above. For $k \geq 1$, write $P = x(x-1)\cdots(x-k+2)$ (with $P = 1$ when $k = 1$), so that $b_k = P(x-k+1)/k!$ and $b_{k-1} = P/(k-1)!$. Substituting $x+1$ for x in b_k gives $(x+1)P/k!$. Hence

$$b_k(x+1) - b_k = \frac{P((x+1)-(x-k+1))}{k!} = \frac{kP}{k!} = \frac{P}{(k-1)!} = b_{k-1}.$$

So $T(b_k) = b_k + b_{k-1}$ for $k \geq 1$, and $T(b_0) = b_0$. This is (C.1.5), so $[T]_{\mathcal{B}\mathcal{B}} = J$.

(b) *If $n < p$.* For $k \leq n < p$, the integer $k!$ is a product of integers between 1 and $p-1$, none divisible by the prime p, so $k! \neq 0$ in $\mathbb{F}_p$ and it is invertible (Proposition 1.1.24). So $b_0, \ldots, b_n$ are defined in $\mathbb{F}_p[x]$, and the computation in (a) uses only the field operations and division by $k!$. It goes through unchanged, and gives a basis with $[T]_{\mathcal{B}\mathcal{B}} = J$.

If $n \geq p$. Suppose $\mathcal{B} = \mathbf{v}_0, \ldots, \mathbf{v}_n$ is a basis satisfying (C.1.5). Set $\mathbf{v}_k = \mathbf{0}$ for $k < 0$, so that $T(\mathbf{v}_k) = \mathbf{v}_k + \mathbf{v}_{k-1}$ for all $k \leq n$ (for $k < 0$ both sides are $\mathbf{0}$). We claim that for all $r \geq 0$ and $0 \leq s \leq n$,

$$T^r(\mathbf{v}_s) = \sum_{k=0}^{r}\binom{r}{k}\mathbf{v}_{s-k}.$$

For $r = 0$ both sides are $\mathbf{v}_s$. If it holds for r, then by linearity

$$T^{r+1}(\mathbf{v}_s) = \sum_{k=0}^{r} \binom{r}{k} (\mathbf{v}_{s-k} + \mathbf{v}_{s-k-1}) = \sum_{k=0}^{r+1} \left(\binom{r}{k} + \binom{r}{k-1} \right) \mathbf{v}_{s-k} = \sum_{k=0}^{r+1} \binom{r+1}{k} \mathbf{v}_{s-k},$$

with the conventions $\binom{r}{-1} = \binom{r}{r+1} = 0$ and Pascal's rule. Now take $r = s = p$, which is allowed since $p \leq n$. For $0 < k < p$, $\binom{p}{k}$ is divisible by p, so it is 0 in $\mathbb{F}_p$, and

$$T^p(\mathbf{v}_p) = \mathbf{v}_p + \mathbf{v}_0.$$

On the other hand, substituting $x + 1$ a total of p times gives $T^p(f) = f(x + p \cdot 1) = f(x)$, since $p \cdot 1 = 0$ in $\mathbb{F}_p$. So $T^p(\mathbf{v}_p) = \mathbf{v}_p$, and $\mathbf{v}_0 = \mathbf{0}$, which is impossible for a vector of a basis. Hence no such basis exists.

For example, over $\mathbb{F}_2$ with $n = 2$: $T^2 = \mathrm{id}$, while a basis as above would give $T^2(\mathbf{v}_2) = \mathbf{v}_2 + 2\mathbf{v}_1 + \mathbf{v}_0 = \mathbf{v}_2 + \mathbf{v}_0$.

Section 2.4

Solution to Exercise 2.4.6

Uses. Definition 2.4.1 (Matrix product), Definition 2.3.8 (Matrix–vector product)
Hint 1. Compute column by column: column j of AB is A times column j of B. Or use the entry formula: row i of A against column j of B.
Hint 2. Work with integers and reduce modulo 5 at the end. In (b), use $i^2 = -1$.
Sketch. (a) $AB = \begin{pmatrix} 2 & 7 \\ 10 & 10 \end{pmatrix} = \begin{pmatrix} 2 & 2 \\ 0 & 0 \end{pmatrix}$ and $BA = \begin{pmatrix} 5 & 5 & 4 \\ 9 & 3 & 12 \\ 4 & 3 & 4 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 4 \\ 4 & 3 & 2 \\ 4 & 3 & 4 \end{pmatrix}$ in $\mathbb{F}_5$. A^2 needs $3 = 2$ and B^2 needs $2 = 3$, so neither is defined. (b) $\begin{pmatrix} 2i & 2 \\ 2 & -2i \end{pmatrix}$ and $\begin{pmatrix} i & 1 \\ 1 & -i \end{pmatrix}$.

(a) By columns, $A(2, 0, 1) = 2(1, 3) + (0, 4) = (2, 10)$ and $A(1, 3, 1) = (1, 3) + 3(2, 1) + (0, 4) = (7, 10)$. Reducing modulo 5,

$$AB = \begin{pmatrix} 2 & 2 \\ 0 & 0 \end{pmatrix}.$$

The columns of BA are $B(1, 3) = (2 + 3, 0 + 9, 1 + 3)$, $B(2, 1) = (4 + 1, 0 + 3, 2 + 1)$, and $B(0, 4) = (0 + 4, 0 + 12, 0 + 4)$, so

$$BA = \begin{pmatrix} 5 & 5 & 4 \\ 9 & 3 & 12 \\ 4 & 3 & 4 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 4 \\ 4 & 3 & 2 \\ 4 & 3 & 4 \end{pmatrix} \quad \text{in } \mathbb{F}_5.$$

A product XY needs as many columns in X as rows in Y. A is 2×3, so AA is not defined, and B is 3×2, so BB is not defined either.

(b) By the entry formula, the first product has entries $1 \cdot i + i \cdot 1 = 2i$, $1 \cdot 1 + i(-i) = 2$, $0 \cdot i + 2 \cdot 1 = 2$, and $0 \cdot 1 + 2(-i) = -2i$, and the second has entries i, $i^2 + 2 = 1$, 1, and $i - 2i = -i$:

$$\begin{pmatrix} 1 & i \\ 0 & 2 \end{pmatrix} \begin{pmatrix} i & 1 \\ 1 & -i \end{pmatrix} = \begin{pmatrix} 2i & 2 \\ 2 & -2i \end{pmatrix},$$

$$\begin{pmatrix} i & 1 \\ 1 & -i \end{pmatrix} \begin{pmatrix} 1 & i \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} i & 1 \\ 1 & -i \end{pmatrix}.$$

The two products differ.

Solution to Exercise 2.4.11

Uses. Proposition 2.4.8 (Four views of the product), Proposition 2.3.13 (Linearity of the product)
Hint 1. Use the column view for statements about columns of AB, and the row view for rows.
Hint 2. Column j of AB is $AB_{\cdot,j}$, and $\mathbf{x} \mapsto A\mathbf{x}$ is linear. For (c), you need a nonzero column $\mathbf{b}$ with $A\mathbf{b} = \mathbf{0}$.

Sketch. (a) $(AB)_{\cdot,j} = A\mathbf{0} = \mathbf{0}$, and $(AB)_{i,\cdot} = A_{i,\cdot}B$ is a combination of rows of B with all coefficients 0. (b) Apply the linear map $\mathbf{x} \mapsto A\mathbf{x}$ to the relation. (c) $A = \begin{pmatrix}1 & 1\end{pmatrix}$ and $B = \begin{pmatrix}1\\-1\end{pmatrix}$ give $AB = (0)$.

(a) By the column view (Proposition 2.4.8(b)), $(AB)_{\cdot,j} = AB_{\cdot,j} = A\mathbf{0} = \mathbf{0}$. By the row view (Proposition 2.4.8(c)), $(AB)_{i,\cdot} = a_{i1}B_{1,\cdot} + \cdots + a_{im}B_{m,\cdot}$, and every coefficient a_{ik} is 0, so this row is zero.

(b) By the column view and the linearity of $\mathbf{x} \mapsto A\mathbf{x}$ (Proposition 2.3.13),

$$\begin{aligned}(AB)_{\cdot,3} &= A\big(B_{\cdot,1} + 2B_{\cdot,2}\big) = AB_{\cdot,1} + 2AB_{\cdot,2}\\ &= (AB)_{\cdot,1} + 2(AB)_{\cdot,2}.\end{aligned}$$

In words: every linear relation among the columns of B also holds among the columns of AB.

(c) We need a nonzero column $\mathbf{b}$ with $A\mathbf{b} = \mathbf{0}$. Take $A = \begin{pmatrix}1 & 1\end{pmatrix} \in \mathbb{R}^{1\times 2}$ and $B = \begin{pmatrix}1\\-1\end{pmatrix} \in \mathbb{R}^{2\times 1}$. Then $AB = (1 - 1) = (0)$, a zero column, while B has none. A square example: $\begin{pmatrix}1 & 1\\1 & 1\end{pmatrix}\begin{pmatrix}1 & 2\\-1 & -2\end{pmatrix} = \begin{pmatrix}0 & 0\\0 & 0\end{pmatrix}$.

Solution to Exercise 2.4.17

Uses. Proposition 2.4.14 (Algebra of matrices), Definition 1.2.7 (Matrices)
Hint 1. Expand $(A + B)(A + B)$ with both distributive laws. Do not reorder any product.
Hint 2. Subtract $A^2 + AB + B^2$ from both expressions and compare what is left.
Sketch. Distributivity gives $(A + B)^2 = A^2 + AB + BA + B^2$. This equals $A^2 + AB + AB + B^2$ exactly when $BA = AB$, by cancelling in the vector space $F^{n\times n}$.

By the two distributive laws of Proposition 2.4.14,

$$\begin{aligned}(A + B)(A + B) &= A(A + B) + B(A + B)\\ &= A^2 + AB + BA + B^2.\end{aligned}$$

So $(A + B)^2 = A^2 + 2AB + B^2$ holds if and only if $A^2 + AB + BA + B^2 = A^2 + AB + AB + B^2$. Adding $-\big(A^2 + AB + B^2\big)$ to both sides in the vector space $F^{n\times n}$, this holds if and only if $BA = AB$. The familiar identity from high school algebra secretly uses commutativity.

Solution to Exercise 2.4.20

Uses. Proposition 2.4.8 (Four views of the product), Definition 2.3.8 (Matrix–vector product)
Hint 1. By the column view, $AB = 0$ means $A\mathbf{b} = \mathbf{0}$ for each column $\mathbf{b}$ of B. Start from an A that kills some nonzero vector.
Hint 2. Try $A = \begin{pmatrix}1 & 2\\1 & 2\end{pmatrix}$. Which vectors does it kill? Build B from such columns, and then compute BA.
Sketch. $A = \begin{pmatrix}1 & 2\\1 & 2\end{pmatrix}$ kills $(2, -1)$, so $B = \begin{pmatrix}2 & 2\\-1 & -1\end{pmatrix}$ gives $AB = 0$, while $BA = \begin{pmatrix}4 & 8\\-2 & -4\end{pmatrix} \neq 0$.

By the column view (Proposition 2.4.8(b)), $AB = 0$ means that A sends each column of B to $\mathbf{0}$. Let $A = \begin{pmatrix}1 & 2\\1 & 2\end{pmatrix}$. By Definition 2.3.8, $A(x, y) = (x + 2y, x + 2y)$, so $A(2, -1) = \mathbf{0}$. Let $B = \begin{pmatrix}2 & 2\\-1 & -1\end{pmatrix}$, whose columns are both $(2, -1)$. Then $AB = 0$, and

$$\begin{aligned}BA &= \begin{pmatrix}2 + 2 & 4 + 4\\-1 - 1 & -2 - 2\end{pmatrix}\\ &= \begin{pmatrix}4 & 8\\-2 & -4\end{pmatrix} \neq 0.\end{aligned}$$

No entry of A or B is 0.

Solution to Exercise 2.4.25

Uses. Proposition 2.4.23 (Transpose of a product), Proposition 2.4.22 (Transpose is a linear involution)
Hint 1. Take the transpose of each expression with Proposition 2.4.23, and use $\big(A^{\mathsf{T}}\big)^{\mathsf{T}} = A$.
Hint 2. For symmetric A and B, $(AB)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}} = BA$.
Sketch. (a) $\big(A^{\mathsf{T}}A\big)^{\mathsf{T}} = A^{\mathsf{T}}\big(A^{\mathsf{T}}\big)^{\mathsf{T}} = A^{\mathsf{T}}A$, and likewise for AA^{T}. (b) $(AB)^{\mathsf{T}} = BA$, so transposing swaps AB and BA: $AB + BA$ is fixed, $AB - BA$ changes sign, and AB is fixed exactly when $AB = BA$.

(a) By Proposition 2.4.23 and Proposition 2.4.22, $\left(A^{\mathsf{T}}A\right)^{\mathsf{T}} = A^{\mathsf{T}}\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A^{\mathsf{T}}A$ and $\left(AA^{\mathsf{T}}\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^{\mathsf{T}}A^{\mathsf{T}} = AA^{\mathsf{T}}$.

(b) Since $A^{\mathsf{T}} = A$ and $B^{\mathsf{T}} = B$, Proposition 2.4.23 gives $(AB)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}} = BA$, and likewise $(BA)^{\mathsf{T}} = AB$. By linearity of transposition (Proposition 2.4.22),

$$(AB + BA)^{\mathsf{T}} = BA + AB,$$
$$(AB - BA)^{\mathsf{T}} = BA - AB = -(AB - BA).$$

Finally AB is symmetric if and only if $AB = (AB)^{\mathsf{T}} = BA$.

Solution to Exercise 2.4.32

Uses. Proposition 2.4.28 (Cyclicity of the trace), Lemma 2.4.24 (Matrix units)
Hint 1. Proposition 2.4.28 says $\operatorname{tr}(XY) = \operatorname{tr}(YX)$, an equality of two numbers. Does it say $XY = YX$?
Hint 2. For a counterexample, try $A = \mathbf{e}_1\mathbf{e}_2^{\mathsf{T}}$, $B = \mathbf{e}_2\mathbf{e}_1^{\mathsf{T}}$, and $C = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$ in $F^{2\times 2}$.
Sketch. The step $\operatorname{tr}((AB)C) = \operatorname{tr}((BA)C)$ replaces AB by BA inside a product, which needs $AB = BA$; cyclicity only gives $\operatorname{tr}(XY) = \operatorname{tr}(YX)$. With the matrix units above, $ABC = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$ has trace 1 and $BAC = 0$.

The error is in the step $\operatorname{tr}((AB)C) = \operatorname{tr}((BA)C)$. Proposition 2.4.28 says that $\operatorname{tr}(XY) = \operatorname{tr}(YX)$ for two matrices X and Y. With $X = AB$ and $Y = C$ it gives $\operatorname{tr}(ABC) = \operatorname{tr}(CAB)$, a rotation. It does not say that AB and BA are equal, or that they can be exchanged inside a longer product; the argument used $\operatorname{tr}(AB) = \operatorname{tr}(BA)$ as if it were $AB = BA$.

The conclusion is false. In $F^{2\times 2}$, let $A = \mathbf{e}_1\mathbf{e}_2^{\mathsf{T}}$, $B = \mathbf{e}_2\mathbf{e}_1^{\mathsf{T}}$, and $C = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$. By Lemma 2.4.24(c), $AB = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$ and $BA = \mathbf{e}_2\mathbf{e}_2^{\mathsf{T}}$, so

$$ABC = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}} = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}},$$
$$BAC = \mathbf{e}_2\mathbf{e}_2^{\mathsf{T}}\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}} = 0.$$

Hence $\operatorname{tr}(ABC) = 1 \neq 0 = \operatorname{tr}(BAC)$. In matrices: $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$, $C = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

Solution to Exercise 2.4.37

Uses. Theorem 2.4.34 (Block multiplication), Proposition 2.4.14 (Algebra of matrices)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Multiply with Theorem 2.4.34, using sizes p, q for rows and columns of both factors.
Hint 2. Induct on k: $M^{k+1} = M^k M$.
Sketch. $\begin{pmatrix} I & Y \\ 0 & I \end{pmatrix}\begin{pmatrix} I & Z \\ 0 & I \end{pmatrix} = \begin{pmatrix} I & Z+Y \\ 0 & I \end{pmatrix}$ by block multiplication. Induction gives $M^k = \begin{pmatrix} I & kX \\ 0 & I \end{pmatrix}$, and $Y = X$, $Z = -X$ gives I.

Let $Y, Z \in F^{p\times q}$, and partition both factors below with sizes p, q. By Theorem 2.4.34 and Proposition 2.4.14(b), the blocks of the product are $I_pI_p + Y0 = I_p$, $I_pZ + YI_q = Z + Y$, $0I_p + I_q0 = 0$, and $0Z + I_qI_q = I_q$:

$$\begin{pmatrix} I_p & Y \\ 0 & I_q \end{pmatrix}\begin{pmatrix} I_p & Z \\ 0 & I_q \end{pmatrix} = \begin{pmatrix} I_p & Z+Y \\ 0 & I_q \end{pmatrix}.$$

For $k = 1$ the claim is $M = M$. If $M^k = \begin{pmatrix} I_p & kX \\ 0 & I_q \end{pmatrix}$, then by the formula $M^{k+1} = M^kM = \begin{pmatrix} I_p & X+kX \\ 0 & I_q \end{pmatrix} = \begin{pmatrix} I_p & (k+1)X \\ 0 & I_q \end{pmatrix}$. Taking $Y = X$ and $Z = -X$ gives $\begin{pmatrix} I_p & X \\ 0 & I_q \end{pmatrix}\begin{pmatrix} I_p & -X \\ 0 & I_q \end{pmatrix} = \begin{pmatrix} I_p & 0 \\ 0 & I_q \end{pmatrix} = I_{p+q}$. In the language of maps, M adds X times the last q coordinates to the first p coordinates, and the second factor subtracts it again.

Solution to Exercise 2.4.41

Uses. Definition 2.3.1 (Matrix of a linear map), Theorem 2.4.2 (The matrix of a composite), Proposition 2.4.28 (Cyclicity of the trace), Example 2.1.9 (Maps of polynomials)
Hint 1. The columns of $[D]_{\mathcal{B}_2\mathcal{B}_3}$ are the coordinates of $D(1), D(x), D\left(x^2\right), D\left(x^3\right)$ in $\mathcal{B}_2$; the columns of $[M]_{\mathcal{B}_3\mathcal{B}_2}$ are those of x, x^2, x^3 in $\mathcal{B}_3$.

Hint 2. By Theorem 2.4.2, $[DM] = [D][M]$ and $[MD] = [M][D]$. Compute column by column. Then compute $\left(x \cdot x^k\right)'$ and $x\left(x^k\right)'$ directly.
Sketch. $[D] = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}$ and $[M]$ has columns $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4$. Then $[DM] = \operatorname{diag}(1,2,3)$ and $[MD] = \operatorname{diag}(0,1,2,3)$, matching $\left(x^{k+1}\right)' = (k+1)x^k$ and $x\left(x^k\right)' = kx^k$. Both traces are 6, as Proposition 2.4.28 predicts for a 3×4 and a 4×3 matrix.

(a) $D(1) = \mathbf{0}$, $D(x) = 1$, $D\left(x^2\right) = 2x$, and $D\left(x^3\right) = 3x^2$, and $M(1) = x$, $M(x) = x^2$, $M\left(x^2\right) = x^3$, so

$$[D]_{\mathcal{B}_2\mathcal{B}_3} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix},$$

$$[M]_{\mathcal{B}_3\mathcal{B}_2} = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

(b) By Theorem 2.4.2, $[DM]_{\mathcal{B}_2\mathcal{B}_2} = [D]_{\mathcal{B}_2\mathcal{B}_3}[M]_{\mathcal{B}_3\mathcal{B}_2}$. Its columns are $[D]$ times the columns $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4$ of $[M]$, which are columns $2, 3, 4$ of $[D]$:

$$[DM]_{\mathcal{B}_2\mathcal{B}_2} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}.$$

Similarly $[MD]_{\mathcal{B}_3\mathcal{B}_3} = [M]_{\mathcal{B}_3\mathcal{B}_2}[D]_{\mathcal{B}_2\mathcal{B}_3}$ has columns $[M]\mathbf{0} = \mathbf{0}$, $[M](1,0,0) = \mathbf{e}_2$, $[M](0,2,0) = 2\mathbf{e}_3$, and $[M](0,0,3) = 3\mathbf{e}_4$:

$$[MD]_{\mathcal{B}_3\mathcal{B}_3} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}.$$

Directly, $DM\left(x^k\right) = \left(x^{k+1}\right)' = (k+1)x^k$ for $k = 0, 1, 2$, and $MD\left(x^k\right) = x \cdot kx^{k-1} = kx^k$ for $k = 0, 1, 2, 3$, which are the diagonal entries found above.

(c) Both traces are $1 + 2 + 3 = 6 = 0 + 1 + 2 + 3$, although the matrices have different sizes. This is Proposition 2.4.28 for the 3×4 matrix $[D]$ and the 4×3 matrix $[M]$. Note also that $[DM] - [MD]$ is not defined, since the sizes differ; on all of $F[x]$, $DM - MD = \mathrm{id}$ (Exercise 2.4.51).

Solution to Exercise 2.4.42

Uses. Example 2.4.10 (Diagonal matrices), Proposition 2.4.8 (Four views of the product), Proposition 1.1.17 (No zero divisors)
Hint 1. (a) is the row view and the column view of Example 2.4.10, read entry by entry.
Hint 2. $DX = XD$ means $(d_i - d_j)x_{ij} = 0$ for all i, j. When does this force $x_{ij} = 0$?
Sketch. (a) DX scales row i by d_i; XD scales column j by d_j. (b) $XD = DX$ iff $(d_i - d_j)x_{ij} = 0$ for all i, j; with distinct d's this forces $x_{ij} = 0$ for $i \neq j$. (c) The condition kills exactly the entries x_{ij} with $d_i \neq d_j$, so X is block diagonal with blocks of sizes $2, 1$.

(a) By Example 2.4.10, row i of DX is $d_i X_{i,\cdot}$ and column j of XD is $d_j X_{\cdot,j}$. Reading off the (i,j) entries gives $(DX)_{ij} = d_i x_{ij}$ and $(XD)_{ij} = x_{ij} d_j$.

(b) By (a), $DX = XD$ if and only if $d_i x_{ij} = x_{ij} d_j$, that is, $(d_i - d_j)x_{ij} = 0$, for all i, j. For $i = j$ this always holds. For $i \neq j$, $d_i - d_j \neq 0$, so it holds if and only if $x_{ij} = 0$ (Proposition 1.1.17). So X commutes with D exactly when all its off-diagonal entries vanish.

(c) Here $d_1 = d_2 = 1$ and $d_3 = 0$. The condition $(d_i - d_j)x_{ij} = 0$ is automatic when $d_i = d_j$, that is, for $i, j \in \{1, 2\}$ and for $i = j = 3$, and it forces $x_{ij} = 0$ when exactly one of i, j equals 3, since then $d_i - d_j = \pm 1 \neq 0$. So the matrices commuting with $\operatorname{diag}(1, 1, 0)$ are

$$X = \begin{pmatrix} x_{11} & x_{12} & 0 \\ x_{21} & x_{22} & 0 \\ 0 & 0 & x_{33} \end{pmatrix},$$

with the five remaining entries arbitrary. These are the block diagonal matrices with blocks of sizes 2 and 1, matching the blocks on which $\operatorname{diag}(1,1,0)$ is a scalar matrix.

Solution to Exercise 2.4.43

Uses. Lemma 2.4.24 (Matrix units), Proposition 2.4.14 (Algebra of matrices)
Hint 1. Use only a few upper triangular matrices: the matrix units $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ with $i \le j$.
Hint 2. Commuting with $\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ says $A_{\cdot,i}\mathbf{e}_i^{\mathsf{T}} = \mathbf{e}_i A_{i,\cdot}$. The left side is zero outside column i, the right side zero outside row i. What does that force?
Hint 3. Once A is diagonal, compare $A\big(\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}\big)$ with $\big(\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}\big)A$.
Sketch. Commuting with $\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ gives $A_{\cdot,i}\mathbf{e}_i^{\mathsf{T}} = \mathbf{e}_i A_{i,\cdot}$; comparing entries outside position (i,i), column i and row i of A vanish off the diagonal, so A is diagonal. Then $A\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}} = a_{11}\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}$ and $\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}A = a_{jj}\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}$ give $a_{jj} = a_{11}$.

If. cI_n commutes with every matrix, since $(cI_n)X = cX = X(cI_n)$ by Proposition 2.4.14.

Only if. Suppose A commutes with every upper triangular matrix. Fix i. The matrix unit $\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ is upper triangular, and by associativity and Lemma 2.4.24(b),

$$A\big(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\big) = A_{\cdot,i}\mathbf{e}_i^{\mathsf{T}}, \quad \big(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\big)A = \mathbf{e}_i A_{i,\cdot}.$$

The first matrix has (k,l) entry $a_{ki}\delta_{li}$: it is zero outside column i, where it equals column i of A. The second has (k,l) entry $\delta_{ki}a_{il}$: it is zero outside row i, where it equals row i of A. Comparing the entries in positions (k,i) with $k \ne i$ gives $a_{ki} = 0$, and comparing those in positions (i,l) with $l \ne i$ gives $a_{il} = 0$. As i was arbitrary, A is diagonal, so $A\mathbf{e}_j = a_{jj}\mathbf{e}_j$ and $\mathbf{e}_j^{\mathsf{T}}A = a_{jj}\mathbf{e}_j^{\mathsf{T}}$ for every j.

Now let $2 \le j \le n$. The matrix unit $\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}$ is upper triangular, and

$$A\big(\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}\big) = (A\mathbf{e}_1)\mathbf{e}_j^{\mathsf{T}} = a_{11}\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}},$$
$$\big(\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}\big)A = \mathbf{e}_1\big(\mathbf{e}_j^{\mathsf{T}}A\big) = a_{jj}\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}}.$$

These are equal, and $\mathbf{e}_1\mathbf{e}_j^{\mathsf{T}} \ne 0$, so $a_{jj} = a_{11}$. Hence $A = a_{11}I_n$.

Solution to Exercise 2.4.44

Uses. Proposition 2.4.8 (Four views of the product), Definition 2.4.21 (Transpose), Exercise 2.4.25, Proposition 2.4.36 (Products of upper triangular matrices), Example 2.4.18 ($AB \ne BA$), Proposition 1.1.17 (No zero divisors)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. (a), (b), and (c) are false; look among 2×2 matrices with entries 0 and 1. For (a), think of a reflection.
Hint 2. (d) Compute the diagonal entries of $A^{\mathsf{T}}A$. (e) Use Proposition 2.4.36.
Sketch. (a) False: $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)^2 = I_2$. (b) False: $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. (c) False: with $A = \mathbf{e}_1\mathbf{e}_2^{\mathsf{T}}$, $B = \mathbf{e}_2\mathbf{e}_1^{\mathsf{T}}$, $(AB)^2 = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$ but $A^2 = 0$. (d) True over $\mathbb{R}$: $\big(A^{\mathsf{T}}A\big)_{jj} = \sum_i a_{ij}^2$. False over $\mathbb{C}$ and $\mathbb{F}_2$: $A = \left(\begin{smallmatrix} 1 & 0 \\ i & 0 \end{smallmatrix}\right)$, resp. $\left(\begin{smallmatrix} 1 & 0 \\ 1 & 0 \end{smallmatrix}\right)$. (e) True: $\big(A^2\big)_{ii} = a_{ii}^2$.

We give the counterexamples for $n = 2$. For $n > 2$, those in (b), (c), and (d) can be placed in the top left corner of an $n \times n$ zero matrix (Theorem 2.4.34), and the one in (a) in the top left corner of I_n.

(a) False. $A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ swaps $\mathbf{e}_1$ and $\mathbf{e}_2$, so $A^2 = I_2$, but $A \ne \pm I_2$ (in $\mathbb{F}_2$, where $-I_2 = I_2$, still $A \ne I_2$). Geometrically, A is the reflection across the line $y = x$. For $n > 2$, the matrix that swaps $\mathbf{e}_1$ and $\mathbf{e}_2$ and fixes the other $\mathbf{e}_j$ works.

(b) False. $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ are symmetric, but $AB = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ is not. By Exercise 2.4.25, AB is symmetric exactly when $AB = BA$.

(c) False. With $A = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$ (Example 2.4.18), $AB = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, so $(AB)^2 = AB \ne 0$, while $A^2 = 0$ gives $A^2B^2 = 0$. In general $(AB)^2 = ABAB$, and this equals $AABB$ when $AB = BA$.

(d) True over $\mathbb{R}$. By Proposition 2.4.8(a) and Definition 2.4.21, the (j,j) entry of $A^{\mathsf{T}}A$ is $\sum_i \left(A^{\mathsf{T}}\right)_{ji} a_{ij} = \sum_i a_{ij}^2$. If $A^{\mathsf{T}}A = 0$, then for each j this sum of squares of real numbers is 0, so every $a_{ij} = 0$.

Over $\mathbb{C}$ it is false: for $A = \begin{pmatrix} 1 & 0 \\ i & 0 \end{pmatrix}$, $A^{\mathsf{T}}A = \begin{pmatrix} 1 & i \\ 0 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ i & 0 \end{pmatrix} = \begin{pmatrix} 1+i^2 & 0 \\ 0 & 0 \end{pmatrix} = 0$. Over $\mathbb{F}_2$, $A = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ gives $A^{\mathsf{T}}A = \begin{pmatrix} 1+1 & 0 \\ 0 & 0 \end{pmatrix} = 0$. The real proof used that a sum of squares vanishes only if each term does, which fails in both fields. Over $\mathbb{C}$ the cure is to conjugate, using A^*A (Section 6.1).

(e) True. By Proposition 2.4.36, A^2 is upper triangular with diagonal entries a_{ii}^2. If $A^2 = 0$, then $a_{ii}^2 = 0$, so $a_{ii} = 0$ by Proposition 1.1.17.

Solution to Exercise 2.4.45

Uses. Proposition 2.4.8 (Four views of the product), Proposition 1.1.17 (No zero divisors)
Hint 1. Compute A^2. Its off-diagonal entries are $b(a+d)$ and $c(a+d)$.
Hint 2. If $a+d \neq 0$, then $b = c = 0$; what do the diagonal entries then force? For (b), count the pairs (b,c) with $bc = -a^2$, separately for $a = 0$ and $a \neq 0$.
Sketch. $A^2 = \begin{pmatrix} a^2+bc & b(a+d) \\ c(a+d) & d^2+bc \end{pmatrix}$. If $a+d \neq 0$ then $b = c = 0$ and $a^2 = d^2 = 0$, so $a = d = 0$, a contradiction; so $d = -a$, and then all four conditions reduce to $a^2 + bc = 0$. (b) For $a = 0$: $bc = 0$ has $2p-1$ solutions. For each of the $p-1$ nonzero a: $bc = -a^2 \neq 0$ has $p-1$ solutions. Total $2p - 1 + (p-1)^2 = p^2$.

(a) By the entry formula,

$$A^2 = \begin{pmatrix} a^2+bc & b(a+d) \\ c(a+d) & d^2+bc \end{pmatrix}.$$

Suppose $A^2 = 0$. If $a+d \neq 0$, the off-diagonal entries give $b = c = 0$ (Proposition 1.1.17), and then the diagonal entries give $a^2 = d^2 = 0$, so $a = d = 0$, contradicting $a+d \neq 0$. Hence $a+d = 0$, and then $a^2 + bc = 0$ is the $(1,1)$ entry. Conversely, if $d = -a$ and $a^2 + bc = 0$, then the off-diagonal entries are 0, the $(1,1)$ entry is 0, and the $(2,2)$ entry is $d^2 + bc = a^2 + bc = 0$.

(b) By (a), such A correspond to triples $(a,b,c) \in \mathbb{F}_p^3$ with $bc = -a^2$, with $d = -a$. If $a = 0$, we need $bc = 0$, that is, $b = 0$ or $c = 0$: there are $p + p - 1 = 2p - 1$ such pairs. If $a \neq 0$, then $-a^2 \neq 0$, so $b \neq 0$ and $c = -a^2 b^{-1}$ is determined by b: there are $p-1$ pairs. With $p-1$ nonzero values of a, the total is

$$(2p-1) + (p-1)^2 = p^2.$$

For $p = 2$ the four matrices are 0, $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$, and $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$.

Solution to Exercise 2.4.46

Uses. Notation 2.4.16 (Powers of a matrix), Proposition 2.4.8 (Four views of the product), Theorem 2.4.2 (The matrix of a composite), Example 2.4.5 (Composites through their matrices)
Hint 1. (a) Induct on k, computing $J^{k+1} = J^k J$ with the entry formula.
Hint 2. (b) Take $\lambda = 1$ and $k = p$. (c) Over $\mathbb{R}$, think of a rotation. Over $\mathbb{F}_2$, try $A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$.
Sketch. (a) $J^k J = \begin{pmatrix} \lambda^{k+1} & \lambda^k + k\lambda^k \\ 0 & \lambda^{k+1} \end{pmatrix}$. (b) $p * 1 = 0$ in $\mathbb{F}_p$. (c) Over $\mathbb{F}_2$, $\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}^2 = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}^3 = I_2$. Over $\mathbb{R}$, the rotation by $2\pi/3$, $\left[R_{2\pi/3}\right] = \frac{1}{2}\begin{pmatrix} -1 & -\sqrt{3} \\ \sqrt{3} & -1 \end{pmatrix}$.

(a) For $k = 1$ the formula reads $J = J$, since $1 * 1 = 1$ and $\lambda^0 = 1$. If it holds for k, then

$$J^{k+1} = J^k J = \begin{pmatrix} \lambda^k & k\lambda^{k-1} \\ 0 & \lambda^k \end{pmatrix}\begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix}.$$

By the entry formula, this product has diagonal entries λ^{k+1}, lower left entry 0, and upper right entry $\lambda^k \cdot 1 + k\lambda^{k-1} \cdot \lambda = (k+1)\lambda^k$, which is the formula for $k+1$.

(b) With $\lambda = 1$ and $k = p$, (a) gives $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^p = \begin{pmatrix} 1 & p*1 \\ 0 & 1 \end{pmatrix} = I_2$, since $p * 1 = 0$ in $\mathbb{F}_p$. The map $(x,y) \mapsto (x+y, y)$ of $\mathbb{F}_p^2$ adds y to the first coordinate, and doing so p times adds $p * y = 0$.

(c) Over $\mathbb{F}_2$, let $A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$. Then, using $1 + 1 = 0$,

$$A^2 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix},$$
$$A^3 = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Over $\mathbb{R}$, let $A' = \left[R_{2\pi/3}\right]_{\mathcal{E}\mathcal{E}} = \frac{1}{2}\begin{pmatrix} -1 & -\sqrt{3} \\ \sqrt{3} & -1 \end{pmatrix}$. By Theorem 2.4.2 and Example 2.4.5(b), $A'^3 = \left[R_{2\pi/3}^3\right] = [R_{2\pi}] = I_2$, and $A' \neq I_2$.

Solution to Exercise 2.4.47

Uses. Notation 2.4.16 (Powers of a matrix), Proposition 2.4.8 (Four views of the product), Proposition 2.4.14 (Algebra of matrices)
Hint 1. (a) Induct on k, with $Q^{k+1} = Q^k Q$.
Hint 2. (b) Compare the $(1,2)$ entries of Q^{m+n} and $Q^m Q^n$.
Sketch. (a) $Q^k Q = \begin{pmatrix} f_{k+1}+f_k & f_{k+1} \\ f_k+f_{k-1} & f_k \end{pmatrix}$. (b) $(Q^{m+n})_{12} = f_{m+n}$ and $(Q^m Q^n)_{12} = f_{m+1}f_n + f_m f_{n-1}$. Put $m = n$.

(a) For $k = 1$, $\begin{pmatrix} f_2 & f_1 \\ f_1 & f_0 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} = Q$. If the formula holds for k, then

$$\begin{aligned} Q^{k+1} = Q^k Q &= \begin{pmatrix} f_{k+1} & f_k \\ f_k & f_{k-1} \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \\ &= \begin{pmatrix} f_{k+1}+f_k & f_{k+1} \\ f_k + f_{k-1} & f_k \end{pmatrix} \\ &= \begin{pmatrix} f_{k+2} & f_{k+1} \\ f_{k+1} & f_k \end{pmatrix}. \end{aligned}$$

(b) By Notation 2.4.16, $Q^{m+n} = Q^m Q^n$. The $(1,2)$ entry of the left side is f_{m+n} by (a), and by the entry formula the $(1,2)$ entry of the right side is

$$\begin{aligned} &(Q^m)_{11}(Q^n)_{12} + (Q^m)_{12}(Q^n)_{22} \\ &\quad = f_{m+1}f_n + f_m f_{n-1}. \end{aligned}$$

With $m = n$ this is $f_{2n} = f_{n+1}f_n + f_n f_{n-1} = f_n(f_{n+1} + f_{n-1})$. For example, $f_{10} = f_5(f_6 + f_4) = 5(8+3) = 55$. Linear recurrences in general are treated with matrix powers in Section 15.2.

Solution to Exercise 2.4.48

Uses. Proposition 2.4.8 (Four views of the product), Proposition 2.4.23 (Transpose of a product)
Hint 1. The first three equalities are correct. In the entry formula $(XY)_{ij} = \sum_k x_{ik}y_{kj}$, which index of each factor is the summation index?
Hint 2. In $\left(A^{\mathsf{T}}\right)_{kj}\left(B^{\mathsf{T}}\right)_{ik}$, the summation index k is the *first* index of the A^{T} factor. Reorder the two factors.
Sketch. The last step misreads the index pattern. After reordering the factors, the sum is $\sum_k \left(B^{\mathsf{T}}\right)_{ik}\left(A^{\mathsf{T}}\right)_{kj}$, which is the (i,j) entry of $B^{\mathsf{T}}A^{\mathsf{T}}$, not of $A^{\mathsf{T}}B^{\mathsf{T}}$. The correct conclusion is $(AB)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}}$.

Everything up to the last equality is correct. In a product $(XY)_{ij} = \sum_k x_{ik}y_{kj}$, the row index i belongs to the left factor, the column index j to the right factor, and the summation index is the column index of the left factor and the row index of the right one. In $\sum_k \left(A^{\mathsf{T}}\right)_{kj}\left(B^{\mathsf{T}}\right)_{ik}$, the factor carrying i is B^{T} and the factor carrying j is A^{T}. Since scalars commute,

$$\begin{aligned} \sum_k \left(A^{\mathsf{T}}\right)_{kj}\left(B^{\mathsf{T}}\right)_{ik} &= \sum_k \left(B^{\mathsf{T}}\right)_{ik}\left(A^{\mathsf{T}}\right)_{kj} \\ &= \left(B^{\mathsf{T}}A^{\mathsf{T}}\right)_{ij}. \end{aligned}$$

So the computation actually proves Proposition 2.4.23. The claimed identity is false: with $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ as in Example 2.4.19, we have $(AB)^{\mathsf{T}} = 0^{\mathsf{T}} = 0$, while $A^{\mathsf{T}}B^{\mathsf{T}} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.

Solution to Exercise 2.4.49

Uses. Lemma 2.4.24 (Matrix units), Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.4.14 (Algebra of matrices)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. (a) Rotate inside the trace: $\operatorname{tr}\left(A\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\right) = \operatorname{tr}\left(\mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_j\right)$, a 1×1 matrix.
Hint 2. (c) Choose B so that $\operatorname{tr}(BX)$ and $\varphi(X)$ agree on the matrix units $X = \mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}$. Uniqueness is (b) applied to a difference.
Sketch. (a) By cyclicity, $\operatorname{tr}\left(A\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\right) = \operatorname{tr}\left(\mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_j\right) = a_{ij}$. (b) Take $X = \mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}$. (c) Let $b_{ij} = \varphi\left(\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\right)$; then $X \mapsto \operatorname{tr}(BX)$ is linear and agrees with φ on the matrix units, which span. If $\operatorname{tr}(BX) = \operatorname{tr}(B'X)$ for all X, then $\operatorname{tr}((B - B')X) = 0$ for all X, so $B = B'$ by (b).

(a) By Proposition 2.4.28 with the factors $A\mathbf{e}_j \in F^{m\times 1}$ and $\mathbf{e}_i^{\mathsf{T}} \in F^{1\times m}$, and by Lemma 2.4.24(b),

$$\operatorname{tr}\left((A\mathbf{e}_j)\mathbf{e}_i^{\mathsf{T}}\right) = \operatorname{tr}\left(\mathbf{e}_i^{\mathsf{T}}(A\mathbf{e}_j)\right) = \mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_j = a_{ij}.$$

(b) Taking $X = \mathbf{e}_j\mathbf{e}_i^{\mathsf{T}} \in F^{n\times m}$ in the hypothesis and using (a) gives $a_{ij} = 0$ for all i, j.

(c) Define $B \in F^{m\times n}$ by $b_{ij} = \varphi\left(\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\right)$. The map $\psi(X) = \operatorname{tr}(BX)$ is linear, by Proposition 2.4.14 and Proposition 2.4.27, and by (a) applied to B, $\psi\left(\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\right) = b_{ij} = \varphi\left(\mathbf{e}_j\mathbf{e}_i^{\mathsf{T}}\right)$. The matrix units span $F^{n\times m}$ (Lemma 2.4.24(a)), so $\psi = \varphi$ by Corollary 2.2.6. If also $\varphi(X) = \operatorname{tr}(B'X)$ for all X, then $\operatorname{tr}((B - B')X) = 0$ for all X, and $B = B'$ by (b). So the linear maps $F^{n\times m} \to F$ correspond exactly to the matrices of $F^{m\times n}$; this is a first example of duality (Section 13.1).

Solution to Exercise 2.4.50

Uses. Lemma 2.4.24 (Matrix units), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.4.27 (The trace is linear)
Techniques. Check it on a basis (Technique 2.2.7), Cyclicity of trace (Technique 2.4.29)
Hint 1. It is enough to compute φ on the matrix units $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$. Write each one as a product XY for which YX is simpler.
Hint 2. For $i \neq j$, $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}} = \left(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\right)\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right)$, and the product in the other order is 0. For the diagonal units, compare $\left(\mathbf{e}_i\mathbf{e}_1^{\mathsf{T}}\right)\left(\mathbf{e}_1\mathbf{e}_i^{\mathsf{T}}\right)$ with the product in the other order.
Sketch. For $i \neq j$, write $\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}} = XY$ with $X = \mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ and $Y = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$; then $YX = 0$, so $\varphi\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right) = \varphi(YX) = 0$. Writing $\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ and $\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$ as the two products of $\mathbf{e}_i\mathbf{e}_1^{\mathsf{T}}$ and $\mathbf{e}_1\mathbf{e}_i^{\mathsf{T}}$ shows that φ takes the same value c on all diagonal units. So φ and $c\operatorname{tr}$ agree on the matrix units.

We compute φ on the matrix units, using Lemma 2.4.24(c) throughout. For $i \neq j$,

$$\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}} = \left(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\right)\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right),$$
$$\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right)\left(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\right) = \delta_{ji}\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}} = 0,$$

so the hypothesis gives $\varphi\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right) = \varphi(0) = 0$. For the diagonal units,

$$\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}} = \left(\mathbf{e}_i\mathbf{e}_1^{\mathsf{T}}\right)\left(\mathbf{e}_1\mathbf{e}_i^{\mathsf{T}}\right),$$
$$\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}} = \left(\mathbf{e}_1\mathbf{e}_i^{\mathsf{T}}\right)\left(\mathbf{e}_i\mathbf{e}_1^{\mathsf{T}}\right),$$

so $\varphi\left(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\right) = \varphi\left(\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}\right)$ for every i; call this value c. On the other hand $\operatorname{tr}\left(\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\right) = \delta_{ij}$. So the linear maps φ and $c\operatorname{tr}$ (Proposition 2.4.27) agree on every matrix unit. The matrix units span $F^{n\times n}$ (Lemma 2.4.24(a)), so $\varphi = c\operatorname{tr}$ by Corollary 2.2.6.

Solution to Exercise 2.4.51

Uses. Example 2.1.9 (Maps of polynomials), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space), Proposition 2.1.17 (Compositions of linear maps are linear), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.4.30 ($AB - BA \neq I$), Definition 1.2.16 (Degree)
Hint 1. (a) Both sides are linear, so check on the monomials x^k, which span $F[x]$.
Hint 2. (b) Proposition 2.4.30 is about $n \times n$ matrices. (c) If $U \neq \{\mathbf{0}\}$, take a nonzero $p \in U$ of the largest degree among a finite spanning list, and apply M.

Sketch. (a) $(DM - MD)\big(x^k\big) = (k+1)x^k - kx^k = x^k$. (b) $F[x]$ has no finite basis, so D and M are not given by square matrices; the trace argument needs a finite size. (c) Every element of U has degree at most the largest degree d in a finite spanning list; if $U \neq \{\mathbf{0}\}$ it contains an element of degree exactly d, and M of it has degree $d+1$.

(a) Both $DM - MD$ and id are linear (Proposition 2.1.23, Proposition 2.1.17). For $k \geq 0$,

$$\begin{aligned}(DM - MD)\big(x^k\big) &= D\big(x^{k+1}\big) - xD\big(x^k\big)\\ &= (k+1)x^k - kx^k = x^k,\end{aligned}$$

where for $k = 0$ the second term is $xD(1) = \mathbf{0}$. The monomials span $F[x]$, so $DM - MD = \mathrm{id}$ by Corollary 2.2.6. (This is the product rule $(xp)' = p + xp'$.)

(b) Proposition 2.4.30 is a statement about $n \times n$ matrices, that is, about operators on F^n, and its proof takes the trace, a finite sum of diagonal entries. The maps D and M act on $F[x]$, which is spanned by no finite list (every finite list of polynomials has a largest degree). So they have no $n \times n$ matrices, and there is no trace to take. Part (c) shows that we also cannot cut $F[x]$ down to a finite-dimensional piece on which M acts.

(c) Suppose $U = \operatorname{span}(p_1, \ldots, p_r)$ with $M(U) \subseteq U$ and $U \neq \{\mathbf{0}\}$. We may drop the p_i that are $\mathbf{0}$, so all are nonzero, and $r \geq 1$. Let d be the largest of $\deg p_1, \ldots, \deg p_r$. Every element of U is a combination of the p_i, so every nonzero element of U has degree at most d, and p_i has degree d for some i. But $M(p_i) = xp_i \in U$ has degree $d+1$, a contradiction. So $U = \{\mathbf{0}\}$. (The same argument shows that $F[x]$ itself is not spanned by finitely many polynomials.)

Solution to Exercise 2.4.52

Uses. Proposition 2.4.30 ($AB - BA \neq I$), Theorem 2.4.34 (Block multiplication), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.3.13 (Linearity of the product)
Techniques. Block decomposition (Technique 2.4.35), Cyclicity of trace (Technique 2.4.29)
Hint 1. (a) A and B are the matrices of differentiation and of multiplication by x on polynomials of degree less than p, in the basis $1, x, \ldots, x^{p-1}$, with x^p replaced by 0. Compute $(AB - BA)\mathbf{e}_k$, treating $k = p$ separately.
Hint 2. (b) One direction is Proposition 2.4.30: over $\mathbb{F}_p$, $n * 1 = 0$ exactly when $p \mid n$. For the other, put n/p copies of the matrices from (a) on the diagonal of a block diagonal matrix.
Sketch. (a) For $k < p$, $AB\mathbf{e}_k = A\mathbf{e}_{k+1} = k\mathbf{e}_k$ and $BA\mathbf{e}_k = (k-1)\mathbf{e}_k$, so the difference is $\mathbf{e}_k$. For $k = p$, $AB\mathbf{e}_p = \mathbf{0}$ and $BA\mathbf{e}_p = (p-1)\mathbf{e}_p$, so the difference is $(1-p)\mathbf{e}_p = \mathbf{e}_p$. (b) If $p \nmid n$ then $n * 1 \neq 0$ in $\mathbb{F}_p$. If $n = pq$, let $X = \operatorname{diag}(A, \ldots, A)$ and $Y = \operatorname{diag}(B, \ldots, B)$ (q blocks); block multiplication gives $XY - YX = \operatorname{diag}\big(I_p, \ldots, I_p\big) = I_n$.

(a) We compare $(AB - BA)\mathbf{e}_k$ with $\mathbf{e}_k$ for each k; by Proposition 2.3.13(c) these are the columns of the two matrices. Note that $BA\mathbf{e}_k = B((k-1)\mathbf{e}_{k-1}) = (k-1)\mathbf{e}_k$ for $2 \leq k \leq p$, and $BA\mathbf{e}_1 = B\mathbf{0} = \mathbf{0} = (1-1)\mathbf{e}_1$, so $BA\mathbf{e}_k = (k-1)\mathbf{e}_k$ for all k. For $1 \leq k \leq p-1$, $AB\mathbf{e}_k = A\mathbf{e}_{k+1} = k\mathbf{e}_k$, so

$$(AB - BA)\mathbf{e}_k = k\mathbf{e}_k - (k-1)\mathbf{e}_k = \mathbf{e}_k.$$

For $k = p$, $AB\mathbf{e}_p = A\mathbf{0} = \mathbf{0}$, so $(AB - BA)\mathbf{e}_p = -(p-1)\mathbf{e}_p$, which is $\mathbf{e}_p$ because $-(p-1) = 1 - p = 1$ in $\mathbb{F}_p$. So $AB - BA = I_p$. For $p = 2$ these are the matrices $A = \left(\begin{smallmatrix}0 & 1\\ 0 & 0\end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix}0 & 0\\ 1 & 0\end{smallmatrix}\right)$ of Remark 2.4.31.

(b) If $p \nmid n$, then $n * 1 = n \bmod p \neq 0$ in $\mathbb{F}_p$, and Proposition 2.4.30 says that no such X, Y exist. Conversely, suppose $n = pq$. Let X and Y be the block diagonal matrices with q diagonal blocks, all equal to A, respectively all equal to B, partitioned with sizes $p, \ldots, p$. By Theorem 2.4.34, XY and YX are block diagonal with diagonal blocks AB, respectively BA, so $XY - YX$ is block diagonal with diagonal blocks $AB - BA = I_p$. That is the matrix I_n.

Solution to Exercise 2.4.53

Uses. Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear), Proposition 2.4.14 (Algebra of matrices)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. It suffices to write C^k as a commutator $AX - XA$ for some X, since commutators have trace 0.
Hint 2. $C^k = C^{k-1}(AB - BA) = C^{k-1}AB - C^{k-1}BA$. Move A past C^{k-1} in the first term.

Sketch. Since C commutes with A, so does C^{k-1}. Expanding $C^k = C^{k-1}(AB - BA)$ and moving A to the front of the first term gives $C^k = AX - XA$ with $X = C^{k-1}B$, so $\operatorname{tr}\big(C^k\big) = 0$ by cyclicity.

Since $AC = CA$, induction gives $AC^{k-1} = C^{k-1}A$ for every $k \geq 1$ (for $k = 1$, $C^0 = I_n$). By distributivity and associativity (Proposition 2.4.14),

$$\begin{aligned} C^k &= C^{k-1}(AB - BA) \\ &= \big(C^{k-1}A\big)B - C^{k-1}BA \\ &= A\big(C^{k-1}B\big) - \big(C^{k-1}B\big)A. \end{aligned}$$

So with $X = C^{k-1}B$, Proposition 2.4.27 and Proposition 2.4.28 give $\operatorname{tr}\big(C^k\big) = \operatorname{tr}(AX) - \operatorname{tr}(XA) = 0$. Over $\mathbb{C}$, the vanishing of every $\operatorname{tr}\big(C^k\big)$ forces C to be nilpotent, a result known as Jacobson's lemma; that last step needs eigenvalues (Section 7.3).

Solution to Exercise 2.4.54

Uses. Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear), Proposition 2.4.23 (Transpose of a product), Proposition 2.4.8 (Four views of the product), Exercise 2.4.25
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. The equality case suggests looking at $C = AB - BA$. What is C^{T}?
Hint 2. Expand $\operatorname{tr}\big(C^2\big)$ and use cyclicity to bring each of the four terms to $\operatorname{tr}(ABAB)$ or $\operatorname{tr}\big(A^2B^2\big)$.
Hint 3. For a real skew-symmetric C, $\operatorname{tr}\big(C^2\big) = -\operatorname{tr}\big(C^{\mathsf{T}}C\big)$, and $\operatorname{tr}\big(C^{\mathsf{T}}C\big)$ is a sum of squares of entries.
Sketch. $C = AB - BA$ is skew-symmetric. Cyclicity gives $\operatorname{tr}\big(C^2\big) = 2\operatorname{tr}(ABAB) - 2\operatorname{tr}\big(A^2B^2\big)$. Also $\operatorname{tr}\big(C^2\big) = -\operatorname{tr}\big(C^{\mathsf{T}}C\big) = -\sum_{i,j} c_{ij}^2 \leq 0$, with equality iff $C = 0$.

Let $C = AB - BA$. By Exercise 2.4.25, C is skew-symmetric: $C^{\mathsf{T}} = -C$. Expanding,

$$C^2 = ABAB - ABBA - BAAB + BABA.$$

By Proposition 2.4.28, rotating the factors gives $\operatorname{tr}(ABBA) = \operatorname{tr}(AABB)$, $\operatorname{tr}(BAAB) = \operatorname{tr}(AABB)$, and $\operatorname{tr}(BABA) = \operatorname{tr}(ABAB)$. So by Proposition 2.4.27,

$$\operatorname{tr}\big(C^2\big) = 2\operatorname{tr}(ABAB) - 2\operatorname{tr}\big(A^2B^2\big).$$

On the other hand $C^2 = -C^{\mathsf{T}}C$, and by the entry formula the (j,j) entry of $C^{\mathsf{T}}C$ is $\sum_i c_{ij}^2$. Hence

$$\operatorname{tr}\big(C^2\big) = -\operatorname{tr}\big(C^{\mathsf{T}}C\big) = -\sum_{i,j} c_{ij}^2 \leq 0,$$

with equality if and only if every $c_{ij} = 0$, that is, $AB = BA$. Combining the two expressions for $\operatorname{tr}\big(C^2\big)$ gives $\operatorname{tr}(ABAB) \leq \operatorname{tr}\big(A^2B^2\big)$, with equality exactly when $AB = BA$.

Solution to Exercise 2.4.55

Uses. Theorem 2.4.34 (Block multiplication), Proposition 2.4.14 (Algebra of matrices), Notation 2.4.16 (Powers of a matrix)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. (a) Induct on k. Compute $N^{k+1} = N^kN$ by blocks; the top right block is $A^kX + X_kD$.
Hint 2. (b) $N^{2k} = N^kN^k$, and N^k has zero diagonal blocks.
Sketch. (a) By blocks, N^kN has diagonal blocks A^{k+1}, D^{k+1} and top right block $A^kX + X_kD$, and $X_kD = \sum_{i=0}^{k-1} A^iXD^{k-i}$, so the top right block is X_{k+1}. (b) $N^k = \left(\begin{smallmatrix} 0 & X_k \\ 0 & 0 \end{smallmatrix}\right)$, and $\left(\begin{smallmatrix} 0 & Y \\ 0 & 0 \end{smallmatrix}\right)^2 = 0$.

(a) For $k = 1$, $X_1 = A^0XD^0 = X$. Suppose the formula holds for k. By Theorem 2.4.34,

$$\begin{aligned} N^{k+1} = N^kN &= \begin{pmatrix} A^k & X_k \\ 0 & D^k \end{pmatrix}\begin{pmatrix} A & X \\ 0 & D \end{pmatrix} \\ &= \begin{pmatrix} A^{k+1} & A^kX + X_kD \\ 0 & D^{k+1} \end{pmatrix}, \end{aligned}$$

and by distributivity

$$A^kX + X_kD = A^kXD^0 + \sum_{i=0}^{k-1} A^iXD^{k-i}$$

$$= \sum_{i=0}^{k} A^iXD^{k-i} = X_{k+1}.$$

(b) If $A^k = 0$ and $D^k = 0$, then $N^k = \begin{pmatrix} 0 & X_k \\ 0 & 0 \end{pmatrix}$, and by block multiplication

$$N^{2k} = N^kN^k = \begin{pmatrix} 0 & X_k \\ 0 & 0 \end{pmatrix}\begin{pmatrix} 0 & X_k \\ 0 & 0 \end{pmatrix} = 0,$$

since each block of the product is a sum of terms with a zero factor. So a block upper triangular matrix whose diagonal blocks are nilpotent is nilpotent. The bound $2k$ cannot be improved to k in general: for $p = q = 1$, $A = D = 0$, and $X = 1$, $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has $A^1 = D^1 = 0$ but $N^1 \neq 0$.

Solution to Exercise 2.4.56

Uses. Definition 2.4.38 (Adjacency matrix), Proposition 2.4.39 (Powers count walks)
Hint 1. A has a 1 in positions $(1,2)$, $(2,3)$, $(3,1)$, and $(1,1)$.
Hint 2. By Proposition 2.4.39, the answers are $\left(A^3\right)_{11}$ and $\operatorname{tr}\left(A^3\right)$. Check them by listing walks.
Sketch. $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}$ and $A^3 = \begin{pmatrix} 2 & 1 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{pmatrix}$. The two walks of length 3 from 1 to 1 are $1,1,1,1$ and $1,2,3,1$, and $\operatorname{tr}\left(A^3\right) = 4$.

(a)

$$A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \quad A^2 = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 1 & 0 \end{pmatrix},$$

$$A^3 = A^2A = \begin{pmatrix} 2 & 1 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{pmatrix}.$$

(b) By Proposition 2.4.39 there are $\left(A^3\right)_{11} = 2$ walks of length 3 from 1 to 1: they are $1,1,1,1$ (the loop three times) and $1,2,3,1$ (around the triangle). In all there are $\operatorname{tr}\left(A^3\right) = 2 + 1 + 1 = 4$ closed walks of length 3: the two above, and $2,3,1,2$ and $3,1,2,3$.

Solution to Exercise 2.4.57

Uses. Proposition 2.4.39 (Powers count walks), Proposition 2.4.8 (Four views of the product), Proposition 2.4.14 (Algebra of matrices), Definition 2.4.26 (Trace)
Hint 1. (a) Every entry of J^2 is a sum of n products $1 \cdot 1$.
Hint 2. (b) Induct on k. Expand $\left(a_kJ + (-1)^kI\right)(J - I)$ with (a), and check that the coefficient of J satisfies $a_{k+1} = (n-1)a_k + (-1)^k$.
Sketch. (a) Each entry of J^2 is a sum of n ones. (b) Multiplying $a_kJ + (-1)^kI$ by $J - I$ and using $J^2 = nJ$ gives coefficient $(n-1)a_k + (-1)^k$ on J and $(-1)^{k+1}$ on I; the formula for a_k satisfies this recursion. (c) Off the diagonal, $\left(A^k\right)_{ij} = a_k$; the trace is $na_k + n(-1)^k$, which simplifies to $(n-1)^k + (n-1)(-1)^k$.

(a) By the entry formula, $\left(J^2\right)_{ij} = \sum_{k=1}^{n} 1 \cdot 1 = n$, so $J^2 = nJ$.

(b) For $k = 1$, $a_1 = (n - 1 + 1)/n = 1$, and $A = J - I_n = a_1J + (-1)^1I_n$. If $A^k = a_kJ + (-1)^kI_n$, then by Proposition 2.4.14 and (a),

$$A^{k+1} = \left(a_kJ + (-1)^kI_n\right)(J - I_n)$$

$$= a_knJ - a_kJ + (-1)^kJ - (-1)^kI_n$$

$$= \Big((n-1)a_k + (-1)^k\Big)J + (-1)^{k+1}I_n.$$

It remains to show that the coefficient of J is a_{k+1}. Write $b_k = na_k = (n-1)^k - (-1)^k$. Then $n\Big((n-1)a_k + (-1)^k\Big) = (n-1)b_k + n(-1)^k$, and

$$\begin{aligned}&(n-1)b_k + n(-1)^k\\ &= (n-1)^{k+1} - (n-1)(-1)^k + n(-1)^k\\ &= (n-1)^{k+1} + (-1)^k = b_{k+1}.\end{aligned}$$

Dividing by n gives $(n-1)a_k + (-1)^k = a_{k+1}$.

(c) By Proposition 2.4.39 and (b), for $i \neq j$ there are $\big(A^k\big)_{ij} = a_k = \Big((n-1)^k - (-1)^k\Big)/n$ walks of length k from i to j, and the number of closed walks of length k is

$$\begin{aligned}\operatorname{tr}\big(A^k\big) &= na_k + n(-1)^k\\ &= (n-1)^k - (-1)^k + n(-1)^k\\ &= (n-1)^k + (n-1)(-1)^k.\end{aligned}$$

For instance, the triangle ($n = 3$) has $2^3 - 2 = 6$ closed walks of length 3, the two directions around it from each of the three vertices. As a check, a_k is an integer, since $n-1$ and -1 leave the same remainder modulo n, so n divides $(n-1)^k - (-1)^k$.

Section 2.5

Solution to Exercise 2.5.9

Uses. Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence), Proposition 2.4.8 (Four views of the product), Proposition 2.3.13 (Linearity of the product)
Hint 1. If column j is zero, then $A\mathbf{e}_j = \mathbf{0} = A\mathbf{0}$. What does that say about T_A?
Hint 2. If row i is zero, then row i of AC is zero for every C, by the row view. Compare with row i of I_m.
Sketch. (a) $A\mathbf{e}_j = \mathbf{0} = A\mathbf{0}$ with $\mathbf{e}_j \neq \mathbf{0}$, so T_A is not injective, and Proposition 2.5.4 rules out a left inverse. (b) Row i of AC is row i of A times C, which is zero, while row i of I_m is $\mathbf{e}_i^{\mathsf{T}} \neq 0$.

(a) Suppose column j of A is zero. By Proposition 2.3.13, $A\mathbf{e}_j$ is column j of A, so $A\mathbf{e}_j = \mathbf{0} = A\mathbf{0}$ although $\mathbf{e}_j \neq \mathbf{0}$. Hence T_A is not injective, and by Proposition 2.5.4, A has no left inverse. (Directly: for every $B \in F^{n\times m}$, $(BA)\mathbf{e}_j = B\big(A\mathbf{e}_j\big) = \mathbf{0}$, whereas $I_n\mathbf{e}_j = \mathbf{e}_j$.)

(b) Suppose row i of A is zero, and let $C \in F^{n\times m}$. By the row view (Proposition 2.4.8(c)), row i of AC is a combination of the rows of C with the entries of row i of A as coefficients, so it is zero. Row i of I_m has a 1 in position i, so $AC \neq I_m$. (In the language of Proposition 2.5.5: every vector $A\mathbf{x}$ has i-th entry 0, so $\mathbf{e}_i$ is not a value of T_A.)

Solution to Exercise 2.5.19

Uses. Definition 2.5.12 (Invertible), Proposition 2.5.17 (Algebra of inverses), Definition 2.4.1 (Matrix product)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Multiply out both products in (a).
Hint 2. By Proposition 2.5.17(b), $(AB)^{-1} = B^{-1}A^{-1}$, so it is enough to compute the two products of inverses and identify which one it is.
Sketch. (a) Both products are I_2 in each case. (b) $B^{-1}A^{-1} = \begin{pmatrix}1 & -1\\ -1 & 2\end{pmatrix} = (AB)^{-1}$, with $AB = \begin{pmatrix}2 & 1\\ 1 & 1\end{pmatrix}$, while $A^{-1}B^{-1} = \begin{pmatrix}2 & -1\\ -1 & 1\end{pmatrix}$ is the inverse of $BA = \begin{pmatrix}1 & 1\\ 1 & 2\end{pmatrix}$.

(a) $\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}\begin{pmatrix}1 & -1\\ 0 & 1\end{pmatrix} = \begin{pmatrix}1 & -1+1\\ 0 & 1\end{pmatrix} = I_2$ and $\begin{pmatrix}1 & -1\\ 0 & 1\end{pmatrix}\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix} = \begin{pmatrix}1 & 1-1\\ 0 & 1\end{pmatrix} = I_2$. Similarly $\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}\begin{pmatrix}1 & 0\\ -1 & 1\end{pmatrix} = \begin{pmatrix}1 & 0\\ 1-1 & 1\end{pmatrix} = I_2$, and the product in the other order is I_2 as well.

(b) We have $AB = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$ and

$$\begin{aligned} B^{-1}A^{-1} &= \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}, \\ A^{-1}B^{-1} &= \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix}. \end{aligned}$$

By Proposition 2.5.17(b), $(AB)^{-1} = B^{-1}A^{-1} = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$; as a check, $\begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix} = \begin{pmatrix} 2-1 & -2+2 \\ 1-1 & -1+2 \end{pmatrix} = I_2$. The product $A^{-1}B^{-1}$ is different; it is $(BA)^{-1}$, the inverse of $BA = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$.

Solution to Exercise 2.5.22

Uses. Definition 2.3.1 (Matrix of a linear map), Proposition 2.5.20 (Inverses and matrices), Definition 2.4.1 (Matrix product)
Techniques. Translate between maps and matrices (Technique 2.3.27), Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. The columns of $[S]_{\mathcal{BB}}$ are the coordinates of $S(1) = 1$, $S(x) = x - 1$, and $S\left(x^2\right) = (x-1)^2 = x^2 - 2x + 1$.
Hint 2. Multiply $[T][S]$ and $[S][T]$. If both are I_3, then by Proposition 2.5.20(a), S is a two-sided inverse of T.
Sketch. $[S]_{\mathcal{BB}} = \begin{pmatrix} 1 & -1 & 1 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{pmatrix}$. Both products $[T][S]$ and $[S][T]$ are I_3, so by Proposition 2.5.20(a), S is a left and a right inverse of T.

From $S(1) = 1$, $S(x) = -1 + x$, and $S\left(x^2\right) = 1 - 2x + x^2$,

$$[S]_{\mathcal{BB}} = \begin{pmatrix} 1 & -1 & 1 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{pmatrix}.$$

By the entry formula,

$$\begin{aligned} [T][S] &= \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 & 1 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & -1+1 & 1-2+1 \\ 0 & 1 & -2+2 \\ 0 & 0 & 1 \end{pmatrix} = I_3, \end{aligned}$$

and

$$\begin{aligned} [S][T] &= \begin{pmatrix} 1 & -1 & 1 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & 1-1 & 1-2+1 \\ 0 & 1 & 2-2 \\ 0 & 0 & 1 \end{pmatrix} = I_3, \end{aligned}$$

where $[T]$ and $[S]$ abbreviate the matrices in the basis $\mathcal{B}$. So $[S]_{\mathcal{BB}}$ is a left and a right inverse of $[T]_{\mathcal{BB}}$. By Proposition 2.5.20(a), S is a left and a right inverse of T, so T is invertible with $T^{-1} = S$. Shifting by 1 and then by -1 changes nothing, as expected; the matrices let us confirm it without composing substitutions.

Solution to Exercise 2.5.30

Uses. Definition 2.5.1 (Left inverse), Definition 2.5.2 (Right inverse), Corollary 2.5.11 (Many one-sided inverses), Proposition 2.4.8 (Four views of the product)
Hint 1. A left inverse is a row $(b_1 \;\; b_2 \;\; b_3)$ with $b_1 + 2b_2 - b_3 = 1$. Solve for b_3.
Hint 2. For a right inverse $(c_1 \;\; c_2 \;\; c_3)$, the 3×3 product $\mathbf{a}(c_1 \;\; c_2 \;\; c_3)$ has (i,j) entry $a_i c_j$. Compare the entries in positions $(1,2)$ and $(2,2)$ with those of I_3.
Sketch. (a) The rows $(s \;\; t \;\; s+2t-1)$ for $s,t \in \mathbb{Q}$. (b) $\mathbf{a}(c_1 \;\; c_2 \;\; c_3) = I_3$ would need $c_2 = 0$ (position $(1,2)$) and $2c_2 = 1$ (position $(2,2)$). Alternatively, $(1 \;\; 0 \;\; 0)$ and $(0 \;\; 0 \;\; -1)$ are two different left inverses, so Corollary 2.5.11 applies.

(a) A left inverse is a matrix $B = (b_1 \;\; b_2 \;\; b_3) \in \mathbb{Q}^{1\times 3}$ with $B\mathbf{a} = I_1$, that is, $b_1 + 2b_2 - b_3 = 1$. For any $b_1 = s$ and $b_2 = t$ this determines $b_3 = s + 2t - 1$. So the left inverses of $\mathbf{a}$ are the rows

$$(s \;\; t \;\; s + 2t - 1) \quad (s, t \in \mathbb{Q}).$$

For instance $s = 1, t = 0$ gives $(1 \;\; 0 \;\; 0)$, $s = t = 0$ gives $(0 \;\; 0 \;\; -1)$, and $s = 1/6, t = 1/3$ gives $(1/6 \;\; 1/3 \;\; -1/6)$.

(b) A right inverse would be $C = (c_1 \;\; c_2 \;\; c_3) \in \mathbb{Q}^{1\times 3}$ with $\mathbf{a}C = I_3$. The product $\mathbf{a}C$ has (i,j) entry $a_i c_j$ (Proposition 2.4.8(a)). Position $(1,2)$ gives $1 \cdot c_2 = 0$, and position $(2,2)$ gives $2c_2 = 1$, which contradict each other. So there is no right inverse.

Alternatively, by (a), $(1 \;\; 0 \;\; 0)$ and $(0 \;\; 0 \;\; -1)$ are two different left inverses of $\mathbf{a}$, and by Corollary 2.5.11 a matrix with two different left inverses has no right inverse.

Solution to Exercise 2.5.31

Uses. Proposition 2.5.28 (Inverse of a 2×2 matrix)
Hint 1. Compute $\Delta = ad - bc$ in each case and apply Proposition 2.5.28.
Hint 2. In (b), $\Delta = 18 - 10 = 8$, which is 1 in $\mathbb{F}_7$. In (c), $\Delta = t^2 - 4$.
Sketch. (a) $\Delta = 2 - i^2 = 3$, so the inverse is $\frac{1}{3}\begin{pmatrix} 2 & -i \\ -i & 1 \end{pmatrix}$. (b) $\Delta = 1$, so the inverse is $\begin{pmatrix} 6 & -5 \\ -2 & 3 \end{pmatrix} = \begin{pmatrix} 6 & 2 \\ 5 & 3 \end{pmatrix}$. (c) Over $\mathbb{R}$, $t \neq \pm 2$. Over $\mathbb{F}_5$, $t^2 \neq 4$, so $t \in \{0, 1, 4\}$.

(a) $\Delta = 1 \cdot 2 - i \cdot i = 2 + 1 = 3$, so by Proposition 2.5.28

$$\begin{pmatrix} 1 & i \\ i & 2 \end{pmatrix}^{-1} = \frac{1}{3}\begin{pmatrix} 2 & -i \\ -i & 1 \end{pmatrix}.$$

Check: $\begin{pmatrix} 1 & i \\ i & 2 \end{pmatrix}\begin{pmatrix} 2 & -i \\ -i & 1 \end{pmatrix} = \begin{pmatrix} 2-i^2 & -i+i \\ 2i-2i & -i^2+2 \end{pmatrix} = \begin{pmatrix} 3 & 0 \\ 0 & 3 \end{pmatrix}$.

(b) $\Delta = 3 \cdot 6 - 5 \cdot 2 = 8 = 1$ in $\mathbb{F}_7$, so the inverse is $\begin{pmatrix} 6 & -5 \\ -2 & 3 \end{pmatrix} = \begin{pmatrix} 6 & 2 \\ 5 & 3 \end{pmatrix}$. Check:

$$\begin{pmatrix} 3 & 5 \\ 2 & 6 \end{pmatrix}\begin{pmatrix} 6 & 2 \\ 5 & 3 \end{pmatrix} = \begin{pmatrix} 18 + 25 & 6 + 15 \\ 12 + 30 & 4 + 18 \end{pmatrix} = \begin{pmatrix} 43 & 21 \\ 42 & 22 \end{pmatrix},$$

which is I_2 modulo 7 since $43 = 42 + 1$ and $22 = 21 + 1$.

(c) Here $\Delta = t^2 - 4$. By Proposition 2.5.28 the matrix is invertible exactly when $t^2 \neq 4$. Over $\mathbb{R}$ this means $t \neq \pm 2$, and then the inverse is $(t^2 - 4)^{-1}\begin{pmatrix} t & -1 \\ -4 & t \end{pmatrix}$. In $\mathbb{F}_5$ the squares of $0, 1, 2, 3, 4$ are $0, 1, 4, 4, 1$, so $t^2 = 4$ exactly for $t \in \{2, 3\}$, and the matrix is invertible for $t \in \{0, 1, 4\}$.

Solution to Exercise 2.5.32

Uses. Corollary 2.5.6 (One-sided cancellation), Proposition 2.5.17 (Algebra of inverses), Exercise 2.5.9, Notation 2.4.16 (Powers of a matrix)
Hint 1. (a) and (c) are cancellations: write the hypothesis as $AX = AY$.
Hint 2. (b) Powers of an invertible matrix are invertible. Is the zero matrix invertible?
Hint 3. (d) Compute AA^{k-1} and $A^{k-1}A$.
Sketch. (a) $AB = A0$, and A can be cancelled. (b) If A were invertible, so would be $A^k = 0$, but 0 has a zero column. (c) $AA = AI_n$; cancel. (d) $AA^{k-1} = A^{k-1}A = A^k = I_n$.

(a) $AB = 0 = A0$, and A is left-invertible, so $B = 0$ by Corollary 2.5.6.

(b) If A were invertible, then A^k would be invertible by Proposition 2.5.17(b) and induction. But $A^k = 0$, whose columns are all zero, and a matrix with a zero column has no left inverse (Exercise 2.5.9). So A is not invertible.

(c) $AA = A = AI_n$, so $A = I_n$ by Corollary 2.5.6.

(d) By Notation 2.4.16, $AA^{k-1} = A^k = I_n$ and $A^{k-1}A = A^k = I_n$ (for $k = 1$, $A^0 = I_n$ and $A = I_n$). So A^{k-1} is a two-sided inverse of A.

Solution to Exercise 2.5.33

Uses. Definition 2.5.12 (Invertible), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. (a) Fix $\mathbf{w} \in W$ and write it as $T(\mathbf{v})$. Compute $T(S(\mathbf{w}))$.
Hint 2. (b) Fix $\mathbf{v}$. Show that $T(S(T(\mathbf{v}))) = T(\mathbf{v})$, and use injectivity.
Sketch. (a) For $\mathbf{w} = T(\mathbf{v})$: $TS(\mathbf{w}) = T(ST(\mathbf{v})) = T(\mathbf{v}) = \mathbf{w}$. (b) $T(ST(\mathbf{v})) = (TS)(T(\mathbf{v})) = T(\mathbf{v})$, so $ST(\mathbf{v}) = \mathbf{v}$ by injectivity. (c) One direction is (a) or (b); the other is Proposition 2.5.5 or Proposition 2.5.4.

(a) Let $\mathbf{w} \in W$. Since T is surjective, $\mathbf{w} = T(\mathbf{v})$ for some $\mathbf{v} \in V$. Then

$$\begin{aligned} T(S(\mathbf{w})) &= T(S(T(\mathbf{v}))) \\ &= T((ST)(\mathbf{v})) = T(\mathbf{v}) = \mathbf{w}. \end{aligned}$$

As $\mathbf{w}$ was arbitrary, $TS = \mathrm{id}_W$.

(b) Let $\mathbf{v} \in V$. Then $T(S(T(\mathbf{v}))) = (TS)(T(\mathbf{v})) = T(\mathbf{v})$. Since T is injective, $S(T(\mathbf{v})) = \mathbf{v}$. As $\mathbf{v}$ was arbitrary, $ST = \mathrm{id}_V$.

(c) Let S be a left inverse of T. If T is surjective, then by (a) S is also a right inverse, so T is invertible. Conversely, an invertible map has a right inverse and is therefore surjective (Proposition 2.5.5). The second statement follows in the same way from (b) and Proposition 2.5.4.

Solution to Exercise 2.5.34

Uses. Definition 2.5.12 (Invertible), Definition 2.5.2 (Right inverse), Theorem 2.5.10 (Left and right inverses agree), Example 2.5.27 (An invertible product of non-invertible factors)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. What does $AB = I_m$ say about B, according to the definitions? What does "$B = A^{-1}$" require?
Hint 2. Try $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$.
Hint 3. If A also has some left inverse, what does Theorem 2.5.10 say?
Sketch. $AB = I_m$ only says that B is a right inverse of A; the step "$B = A^{-1}$" assumes that A is invertible, which is what the claim was supposed to deliver. With $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, $AB = I_1$ but $BA = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. If A also has a left inverse C, then $C = B$ by Theorem 2.5.10, so $BA = CA = I_n$.

The error is the step "$B = A^{-1}$". By Definition 2.5.2, $AB = I_m$ says only that B is a right inverse of A. The inverse A^{-1} is a matrix that is a left and a right inverse at the same time (Definition 2.5.12), and nothing in the hypothesis says that A has an inverse on the left. The argument assumes, in the notation A^{-1}, the very fact $BA = I_n$ that it set out to prove.

The conclusion is false: as in Example 2.5.27, $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ satisfy $AB = (1) = I_1$, but $BA = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \neq I_2$.

It becomes true if A is also assumed to be left-invertible. If $CA = I_n$, then $C = B$ by Theorem 2.5.10, so $BA = CA = I_n$. For square matrices no extra hypothesis is needed (Theorem 3.5.23), but that is a deeper fact, and the argument above does not prove it. For maps from a space to itself it fails without finite dimension: $DJ = \mathrm{id}$ but $JD \neq \mathrm{id}$ on $\mathbb{Q}[x]$ (Example 2.5.24).

Solution to Exercise 2.5.35

Uses. Definition 2.5.12 (Invertible), Theorem 2.5.10 (Left and right inverses agree), Proposition 2.5.17 (Algebra of inverses), Exercise 2.5.9
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. (a) Try $B = -A$. (b) From an inverse X of A^2, build a left and a right inverse of A separately.
Hint 2. (c) Use Proposition 2.5.17(d). (d) Write down a candidate left inverse that involves $\left(A^{\mathsf{T}}A\right)^{-1}$.
Hint 3. (e) The field matters. Try a column $A \in \mathbb{F}_2^{2\times 1}$ or $A \in \mathbb{C}^{2\times 1}$ with $A^{\mathsf{T}}A = 0$.
Sketch. (a) False: $I_n + (-I_n) = 0$. (b) True: if $XA^2 = A^2X = I_n$, then XA is a left inverse and AX a right inverse of A. (c) True: $\left(A^{-1}\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^{-1} = A^{-1}$. (d) True: $\left(A^{\mathsf{T}}A\right)^{-1}A^{\mathsf{T}}$ is a left inverse. (e) False: $A = \begin{pmatrix}1\\1\end{pmatrix}$ over $\mathbb{F}_2$, or $\begin{pmatrix}1\\i\end{pmatrix}$ over $\mathbb{C}$, is left-invertible with $A^{\mathsf{T}}A = 0$.

(a) False. I_n and $-I_n$ are invertible (each is its own inverse), but $I_n + (-I_n) = 0$ has a zero column and is not invertible (Exercise 2.5.9). This works over every field, including $\mathbb{F}_2$, where $-I_n = I_n$.

(b) True. Let $X = \left(A^2\right)^{-1}$, so $XA^2 = A^2X = I_n$. Then $(XA)A = XA^2 = I_n$, so XA is a left inverse of A, and $A(AX) = A^2X = I_n$, so AX is a right inverse of A. By Theorem 2.5.10, A is invertible (and $XA = AX = A^{-1}$).

(c) True. By Proposition 2.5.17(d) and $A^{\mathsf{T}} = A$, $\left(A^{-1}\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^{-1} = A^{-1}$.

(d) True. Let $X = \left(A^{\mathsf{T}}A\right)^{-1} \in F^{n\times n}$. Then $\left(XA^{\mathsf{T}}\right)A = X\left(A^{\mathsf{T}}A\right) = I_n$, so $XA^{\mathsf{T}} \in F^{n\times m}$ is a left inverse of A.

(e) False. Over $\mathbb{F}_2$, let $A = \begin{pmatrix}1\\1\end{pmatrix}$. It is left-invertible, with left inverse $\begin{pmatrix}1 & 0\end{pmatrix}$, but $A^{\mathsf{T}}A = 1 + 1 = 0$ is not invertible. Over $\mathbb{C}$, $A = \begin{pmatrix}1\\i\end{pmatrix}$ has the left inverse $\begin{pmatrix}1 & 0\end{pmatrix}$ and $A^{\mathsf{T}}A = 1 + i^2 = 0$. Over $\mathbb{R}$ the statement is true. By positivity of sums of squares, $A^{\mathsf{T}}A\mathbf{x} = \mathbf{0}$ forces $A\mathbf{x} = \mathbf{0}$ (Section 6.5), hence $\mathbf{x} = \mathbf{0}$ when A is left-invertible. So the square matrix $A^{\mathsf{T}}A$ defines an injective map, and that makes it invertible (Section 3.5).

Solution to Exercise 2.5.36

Uses. Definition 2.5.1 (Left inverse), Proposition 2.4.8 (Four views of the product), Corollary 2.5.11 (Many one-sided inverses), Proposition 2.4.23 (Transpose of a product)
Hint 1. By the row view, $BA = I_2$ means: row 1 of B times A is $\begin{pmatrix}1 & 0\end{pmatrix}$ and row 2 of B times A is $\begin{pmatrix}0 & 1\end{pmatrix}$. Treat the two rows separately.
Hint 2. A row $\begin{pmatrix}r_1 & r_2 & r_3\end{pmatrix}$ times A is $\begin{pmatrix}r_1+r_3 & r_1+r_2\end{pmatrix}$.
Hint 3. For (c), transpose $BA = I_2$.
Sketch. $\begin{pmatrix}r_1 & r_2 & r_3\end{pmatrix}A = \begin{pmatrix}r_1+r_3 & r_1+r_2\end{pmatrix}$. Row 1 of B must be $\begin{pmatrix}t & -t & 1-t\end{pmatrix}$ and row 2 must be $\begin{pmatrix}s & 1-s & -s\end{pmatrix}$, with $s,t \in \mathbb{F}_p$ free: p^2 left inverses. Since $p^2 \geq 4 > 1$, there is no right inverse. C is a right inverse of A^{T} iff C^{T} is a left inverse of A, so A^{T} has p^2 right inverses.

(a) By the row view (Proposition 2.4.8(c)), $BA = I_2$ means that row 1 of B times A is $\begin{pmatrix}1 & 0\end{pmatrix}$ and row 2 of B times A is $\begin{pmatrix}0 & 1\end{pmatrix}$, and the two rows can be chosen independently. For a row $\mathbf{r} = \begin{pmatrix}r_1 & r_2 & r_3\end{pmatrix}$, the row view gives $\mathbf{r}A = r_1\begin{pmatrix}1 & 1\end{pmatrix} + r_2\begin{pmatrix}0 & 1\end{pmatrix} + r_3\begin{pmatrix}1 & 0\end{pmatrix} = \begin{pmatrix}r_1+r_3 & r_1+r_2\end{pmatrix}$. So $\mathbf{r}A = \begin{pmatrix}1 & 0\end{pmatrix}$ means $r_3 = 1 - r_1$ and $r_2 = -r_1$, giving the p rows $\begin{pmatrix}t & -t & 1-t\end{pmatrix}$ with $t \in \mathbb{F}_p$. And $\mathbf{r}A = \begin{pmatrix}0 & 1\end{pmatrix}$ means $r_3 = -r_1$ and $r_2 = 1 - r_1$, giving the p rows $\begin{pmatrix}s & 1-s & -s\end{pmatrix}$. Hence the left inverses are

$$B_{t,s} = \begin{pmatrix} t & -t & 1-t \\ s & 1-s & -s \end{pmatrix} \quad (s,t \in \mathbb{F}_p),$$

and there are p^2 of them.

(b) No. Since $p^2 \geq 4$, A has two different left inverses, so it has no right inverse by Corollary 2.5.11.

(c) By Proposition 2.4.23, $(BA)^{\mathsf{T}} = A^{\mathsf{T}}B^{\mathsf{T}}$, and $I_2^{\mathsf{T}} = I_2$. Since transposing is a bijection (Proposition 2.4.22), $BA = I_2$ if and only if $A^{\mathsf{T}}B^{\mathsf{T}} = I_2$. So C is a right inverse of A^{T} exactly when C^{T} is a left inverse of A, and A^{T} has p^2 right inverses.

Solution to Exercise 2.5.37

Uses. Theorem 2.5.10 (Left and right inverses agree), Definition 2.5.12 (Invertible)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. The equation $ST = \mathrm{id}_V$ also says something about S: on which side is T an inverse of S?

Hint 2. If $RS = \mathrm{id}_W$, then S has a left inverse R and a right inverse T. Apply Theorem 2.5.10 to S.
Sketch. $ST = \mathrm{id}_V$ says that T is a right inverse of S. If S also has a left inverse R, then $R = T$ by Theorem 2.5.10, so $TS = RS = \mathrm{id}_W$ and S is a two-sided inverse of T. Conversely, if T is invertible, then $S = T^{-1}$ and T is a left inverse of S.

Note first that $ST = \mathrm{id}_V$ says that T is a right inverse of S.

Suppose S has a left inverse $R \in \mathrm{L}(V, W)$, so $RS = \mathrm{id}_W$. Then S has the left inverse R and the right inverse T, so $R = T$ by Theorem 2.5.10, applied to S. Hence $TS = RS = \mathrm{id}_W$. Together with $ST = \mathrm{id}_V$, this shows that S is a two-sided inverse of T, so T is invertible and $T^{-1} = S$.

Conversely, suppose T is invertible. By Theorem 2.5.10, its only left inverse is T^{-1}, so $S = T^{-1}$. Then $TS = TT^{-1} = \mathrm{id}_W$, so T is a left inverse of S.

Solution to Exercise 2.5.38

Uses. Proposition 2.1.24 (Algebra of composition), Notation 2.1.18, Definition 2.5.12 (Invertible), Proposition 2.4.14 (Algebra of matrices)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Move $a_0\mathrm{id}_V$ to the other side and factor T out of what remains, on the left and on the right.
Hint 2. With $Q = a_kT^{k-1} + \cdots + a_1\mathrm{id}_V$, both TQ and QT equal $a_kT^k + \cdots + a_1T = -a_0\mathrm{id}_V$.
Hint 3. For A^3, multiply $A^2 - A + I_2 = 0$ by $A + I_2$.
Sketch. (a) With $Q = a_kT^{k-1} + \cdots + a_1\mathrm{id}_V$, distributivity and $TT^j = T^jT = T^{j+1}$ give $TQ = QT = -a_0\mathrm{id}_V$, so $-a_0^{-1}Q$ is a two-sided inverse. (b) $A^2 = \left(\begin{smallmatrix} 0 & 1 \\ -1 & -1 \end{smallmatrix}\right)$, so $A^2 - A + I_2 = 0$, and (a) gives $A^{-1} = I_2 - A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 1 \end{smallmatrix}\right)$. Then $0 = (A + I_2)\big(A^2 - A + I_2\big) = A^3 + I_2$.

(a) Let $Q = a_kT^{k-1} + \cdots + a_2T + a_1\mathrm{id}_V$. By the distributive laws in Proposition 2.1.24 and $TT^j = T^jT = T^{j+1}$ (Notation 2.1.18),

$$\begin{aligned} TQ = QT &= a_kT^k + \cdots + a_2T^2 + a_1T \\ &= -a_0\mathrm{id}_V, \end{aligned}$$

where the last step is the hypothesis. Multiplying by the scalar $-a_0^{-1}$ (Proposition 2.1.24(d)) gives

$$T\big(-a_0^{-1}Q\big) = \big(-a_0^{-1}Q\big)T = \mathrm{id}_V.$$

So $-a_0^{-1}Q$ is a two-sided inverse of T, and T is invertible with $T^{-1} = -a_0^{-1}Q$.

(b) By the entry formula, $A^2 = \left(\begin{smallmatrix} 1{-}1 & 1{+}0 \\ -1{+}0 & -1{+}0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 1 \\ -1 & -1 \end{smallmatrix}\right)$, so

$$\begin{aligned} A^2 - A + I_2 = &\begin{pmatrix} 0 & 1 \\ -1 & -1 \end{pmatrix} - \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix} \\ &+ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = 0. \end{aligned}$$

The relation has $a_2 = 1$, $a_1 = -1$, $a_0 = 1$, so by (a) (in its matrix form, with the same proof), $A^{-1} = -(A - I_2) = I_2 - A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 1 \end{smallmatrix}\right)$. Check: $A(I_2 - A) = A - A^2 = \left(\begin{smallmatrix} 1{-}0 & 1{-}1 \\ -1{+}1 & 0{+}1 \end{smallmatrix}\right) = I_2$. Finally,

$$\begin{aligned} 0 &= (A + I_2)\big(A^2 - A + I_2\big) \\ &= A^3 - A^2 + A + A^2 - A + I_2 \\ &= A^3 + I_2, \end{aligned}$$

so $A^3 = -I_2$. In particular $A^6 = I_2$.

Solution to Exercise 2.5.39

Uses. Proposition 2.1.24 (Algebra of composition), Notation 2.1.18, Definition 2.5.12 (Invertible), Example 2.1.19 (Composites)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Multiply $(\mathrm{id} - N)\big(\mathrm{id} + N + \cdots + N^{k-1}\big)$ out. Most terms cancel in pairs.

Hint 2. For $\mathrm{id}+N$, apply the first part to $-N$. For (b), write the matrix as I_3+N with N strictly upper triangular, and compute N^2 and N^3.
Hint 3. For (c), $D^4=0$ on $F[x]_{\le 3}$.
Sketch. (a) The product telescopes to $\mathrm{id}-N^k=\mathrm{id}$, in either order. $\mathrm{id}+N=\mathrm{id}-(-N)$ and $(-N)^k=(-1)^kN^k=0$. (b) With $N=\begin{pmatrix}0&a&b\\0&0&c\\0&0&0\end{pmatrix}$, $N^2=\begin{pmatrix}0&0&ac\\0&0&0\\0&0&0\end{pmatrix}$ and $N^3=0$, so the inverse is $I_3-N+N^2=\begin{pmatrix}1&-a&ac-b\\0&1&-c\\0&0&1\end{pmatrix}$. (c) $(\mathrm{id}+D)^{-1}=\mathrm{id}-D+D^2-D^3$, which sends x^3 to x^3-3x^2+6x-6.

(a) Let $G=\mathrm{id}+N+\cdots+N^{k-1}$. By the distributive laws in Proposition 2.1.24,

$$\begin{aligned}(\mathrm{id}-N)G&=\left(\mathrm{id}+N+\cdots+N^{k-1}\right)\\&\quad-\left(N+N^2+\cdots+N^k\right)\\&=\mathrm{id}-N^k=\mathrm{id},\end{aligned}$$

and in the same way $G(\mathrm{id}-N)=\mathrm{id}-N^k=\mathrm{id}$. So $\mathrm{id}-N$ is invertible with inverse G. Since $(-N)^k=(-1)^kN^k=0$, the same applies to $-N$, so $\mathrm{id}+N=\mathrm{id}-(-N)$ is invertible, with inverse $\mathrm{id}-N+N^2-\cdots+(-1)^{k-1}N^{k-1}$.

(b) The matrix is I_3+N with $N=\begin{pmatrix}0&a&b\\0&0&c\\0&0&0\end{pmatrix}$. By the entry formula, $N^2=\begin{pmatrix}0&0&ac\\0&0&0\\0&0&0\end{pmatrix}$ and $N^3=N^2N=0$. By (a) applied to $-N$,

$$\begin{aligned}(I_3+N)^{-1}&=I_3-N+N^2\\&=\begin{pmatrix}1&-a&ac-b\\0&1&-c\\0&0&1\end{pmatrix}.\end{aligned}$$

Check, first row of the product of the matrix with this inverse: $(1,-a+a,(ac-b)-ac+b)=(1,0,0)$; the other rows are similar.

(c) Each application of D lowers the degree of a nonconstant polynomial and sends constants to 0 (Example 2.1.19), so $D^4=0$ on $F[x]_{\le 3}$. By (a), $\mathrm{id}+D$ is invertible with inverse $\mathrm{id}-D+D^2-D^3$. Applied to x^3:

$$(\mathrm{id}+D)^{-1}\left(x^3\right)=x^3-3x^2+6x-6.$$

Check: $(\mathrm{id}+D)\left(x^3-3x^2+6x-6\right)=\left(x^3-3x^2+6x-6\right)+\left(3x^2-6x+6\right)=x^3$.

Solution to Exercise 2.5.40

Uses. Theorem 2.4.34 (Block multiplication), Proposition 2.5.28 (Inverse of a 2×2 matrix), Definition 2.5.12 (Invertible), Proposition 2.4.14 (Algebra of matrices)
Techniques. Guess the inverse, then check both products (Technique 2.5.16), Block decomposition (Technique 2.4.35)
Hint 1. Multiply M by the candidate on both sides with Theorem 2.4.34, partitioning with sizes p,q.
Hint 2. To find the candidate yourself, solve $\begin{pmatrix}A&X\\0&D\end{pmatrix}\begin{pmatrix}P&Q\\0&S\end{pmatrix}=I$ block by block.
Hint 3. For (b), take $p=2$, $q=1$, $A=\begin{pmatrix}1&2\\1&3\end{pmatrix}$, $X=\begin{pmatrix}1\\0\end{pmatrix}$, $D=(2)$.
Sketch. By blocks, MN has diagonal blocks $AA^{-1}=I_p$ and $DD^{-1}=I_q$ and top right block $-AA^{-1}XD^{-1}+XD^{-1}=0$; NM has top right block $A^{-1}X-A^{-1}XD^{-1}D=0$. (b) $A^{-1}=\begin{pmatrix}3&-2\\-1&1\end{pmatrix}$, $D^{-1}=(1/2)$, and $-A^{-1}XD^{-1}=\begin{pmatrix}-3/2\\1/2\end{pmatrix}$.

(a) Let N be the proposed inverse, partitioned with sizes p,q like M. By Theorem 2.4.34, the four blocks of MN are

$$\begin{aligned}AA^{-1}+X\cdot 0&=I_p,\\A\left(-A^{-1}XD^{-1}\right)+XD^{-1}&=0,\\0\cdot A^{-1}+D\cdot 0&=0,\end{aligned}$$

$$0 \cdot \left(-A^{-1}XD^{-1}\right) + DD^{-1} = I_q,$$

so $MN = I_{p+q}$. In the same way, the blocks of NM are $A^{-1}A = I_p$, then $A^{-1}X + \left(-A^{-1}XD^{-1}\right)D = A^{-1}X - A^{-1}X = 0$, then 0, and $D^{-1}D = I_q$, so $NM = I_{p+q}$. Hence N is a two-sided inverse of M.

(b) Take $A = \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix}$, $X = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, and $D = (2)$. By Proposition 2.5.28, $\Delta = 3 - 2 = 1$ and $A^{-1} = \begin{pmatrix} 3 & -2 \\ -1 & 1 \end{pmatrix}$, and $D^{-1} = (1/2)$. Then

$$\begin{aligned} -A^{-1}XD^{-1} &= -\frac{1}{2}\begin{pmatrix} 3 & -2 \\ -1 & 1 \end{pmatrix}\begin{pmatrix} 1 \\ 0 \end{pmatrix} \\ &= \begin{pmatrix} -3/2 \\ 1/2 \end{pmatrix}, \end{aligned}$$

so

$$\begin{pmatrix} 1 & 2 & 1 \\ 1 & 3 & 0 \\ 0 & 0 & 2 \end{pmatrix}^{-1} = \begin{pmatrix} 3 & -2 & -3/2 \\ -1 & 1 & 1/2 \\ 0 & 0 & 1/2 \end{pmatrix}.$$

Check, row by row against the original: $(3 - 2, -2 + 2, -3/2 + 1 + 1/2) = (1, 0, 0)$ for the first row of the product, and similarly for the others.

Solution to Exercise 2.5.41

Uses. Example 2.1.9 (Maps of polynomials), Proposition 2.2.20 (Linear maps out of $F[x]$), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence), Corollary 2.2.6 (Agreeing on a spanning list)
Hint 1. M shifts coefficients up by one place, and L shifts them down, discarding a_0.
Hint 2. A left inverse S must satisfy $S\left(x^{k+1}\right) = S\left(M\left(x^k\right)\right) = x^k$ for all $k \geq 0$. What about $S(1)$?
Hint 3. A linear map out of $F[x]$ can take arbitrary values on the monomials (Proposition 2.2.20).
Sketch. (a) $L(M(p)) = p$ and $M(L(p)) = p - a_0$. M has no right inverse since 1 is not a value of M, and L has no left inverse since $L(1) = 0 = L(0)$. (b) A left inverse is determined by $S\left(x^{k+1}\right) = x^k$ and the free choice $S(1) = q \in F[x]$: the left inverses are $S_q(p) = L(p) + a_0 q$, one for each $q \in F[x]$.

(a) For $p = a_0 + a_1 x + \cdots + a_n x^n$, $M(p) = a_0 x + a_1 x^2 + \cdots + a_n x^{n+1}$, whose coefficients, shifted down by one place, are $a_0, \ldots, a_n$. So $L(M(p)) = p$, that is, $LM = \mathrm{id}$. In the other order, $M(L(p)) = a_1 x + \cdots + a_n x^n = p - a_0$, so $ML \neq \mathrm{id}$: it kills the constant term.

Every value of M has constant term 0, so 1 is not a value of M, and M is not surjective. By Proposition 2.5.5, M has no right inverse. Since $L(1) = 0 = L(0)$, L is not injective, so it has no left inverse by Proposition 2.5.4.

(b) Let $S \in \mathrm{L}(F[x])$ with $SM = \mathrm{id}$. Then $S\left(x^{k+1}\right) = S\left(M\left(x^k\right)\right) = x^k$ for every $k \geq 0$, so S agrees with L on $x, x^2, x^3, \ldots$, while $q = S(1)$ is unconstrained. Conversely, for any $q \in F[x]$, Proposition 2.2.20 gives a linear map S_q with $S_q(1) = q$ and $S_q\left(x^{k+1}\right) = x^k$, namely

$$S_q(p) = a_0 q + L(p),$$

where a_0 is the constant term of p. Then $S_q M$ and id agree on every monomial, since $S_q\left(M\left(x^k\right)\right) = S_q\left(x^{k+1}\right) = x^k$, so $S_q M = \mathrm{id}$ by Corollary 2.2.6. Conversely, a left inverse S agrees with S_q for $q = S(1)$ on every monomial, so $S = S_q$, again by Corollary 2.2.6. So the left inverses of M are exactly the maps S_q, one for each $q \in F[x]$, and $S_0 = L$. (Since there are many, Corollary 2.5.11 gives another proof that M has no right inverse.)

Solution to Exercise 2.5.42

Uses. Example 2.5.24 (Differentiation has a right inverse but no left inverse), Example 2.1.9 (Maps of polynomials), Proposition 2.5.5 (Right inverses give existence), Definition 1.2.17 (Evaluation), Proposition 2.1.17 (Compositions of linear maps are linear)

Hint 1. Start from J of Example 2.5.24. Adding a constant to $J(p)$ does not change its derivative. Which constant makes the value at 1 vanish?
Hint 2. For (b), the coefficient of x^{p-1} in $D\left(\sum a_k x^k\right)$ is pa_p, computed in $\mathbb{F}_p$.
Sketch. (a) $R(p) = J(p) - (J(p))(1)$, the antiderivative vanishing at 1; it is linear because evaluation at 1 is linear, and $DR = DJ = \mathrm{id}$. (b) The coefficient of x^{p-1} in $D\left(\sum a_k x^k\right) = \sum k a_k x^{k-1}$ is $p * a_p = 0$. So D is not surjective, and Proposition 2.5.5 rules out a right inverse.

(a) Let J be the antiderivative of Example 2.5.24 and define

$$R(p) = J(p) - (J(p))(1),$$

where the scalar $(J(p))(1)$ is subtracted as a constant polynomial. So $R(p)$ is the antiderivative of p that vanishes at 1. The map $p \mapsto (J(p))(1)$ is the composite of J with evaluation at 1, both linear (Example 2.1.9, Proposition 2.1.17), so R is linear. The subtracted term is a constant polynomial, so its derivative is 0, and $D(R(p)) = D(J(p)) = p$. So R is a right inverse of D, and $(R(p))(1) = (J(p))(1) - (J(p))(1) = 0$. For example, $R(x) = x^2/2 - 1/2$.

(b) By Example 2.1.9, $D\left(\sum_{k=0}^{n} a_k x^k\right) = \sum_{k=1}^{n} (k * a_k) x^{k-1}$, so the coefficient of x^{p-1} in $D(f)$ comes only from $k = p$ and equals $p * a_p = (p * 1)a_p = 0$ in $\mathbb{F}_p$ (it is 0 outright if $n < p$). So no polynomial has derivative x^{p-1}: D is not surjective, and by Proposition 2.5.5 it has no right inverse. Over $\mathbb{Q}$, $x^{p-1} = D(x^p/p)$, and the division by p is exactly what $\mathbb{F}_p$ cannot do.

Solution to Exercise 2.5.43

Uses. Proposition 2.5.28 (Inverse of a 2×2 matrix), Proposition 1.1.17 (No zero divisors), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
Hint 1. Count the complement: quadruples (a, b, c, d) with $ad = bc$. Group them by the common value $t = ad = bc$.
Hint 2. The equation $ad = 0$ has $2p - 1$ solutions (a, d), and for $t \neq 0$ the equation $ad = t$ has $p - 1$ solutions.
Sketch. By Proposition 2.5.28, A is invertible iff $ad \neq bc$. The number of (a, b, c, d) with $ad = bc = t$ is $(2p-1)^2$ for $t = 0$ and $(p-1)^2$ for each of the $p - 1$ nonzero t. So $(2p-1)^2 + (p-1)^3$ matrices are not invertible, and p^4 minus this is $p^4 - p^3 - p^2 + p = (p^2 - 1)(p^2 - p)$.

By Proposition 2.5.28, $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is invertible if and only if $ad \neq bc$. We count the matrices with $ad = bc$, grouping them by the common value t.

For $t = 0$: by Proposition 1.1.17, $ad = 0$ means $a = 0$ or $d = 0$, which holds for $p + p - 1 = 2p - 1$ pairs (a, d). Likewise there are $2p - 1$ pairs (b, c) with $bc = 0$, so $(2p-1)^2$ quadruples.

For $t \neq 0$: $ad = t$ forces $a \neq 0$, and then $d = ta^{-1}$ is determined, so there are $p - 1$ pairs (a, d), and likewise $p - 1$ pairs (b, c). That gives $(p-1)^2$ quadruples for each of the $p - 1$ nonzero values of t.

So $(2p-1)^2 + (p-1)^3$ matrices are not invertible. Expanding $(2p-1)^2 = 4p^2 - 4p + 1$ and $(p-1)^3 = p^3 - 3p^2 + 3p - 1$, the number of invertible ones is

$$\begin{aligned} & p^4 - (2p-1)^2 - (p-1)^3 \\ &= p^4 - p^3 - p^2 + p \\ &= (p^2 - 1)(p^2 - p). \end{aligned}$$

For $p = 2$ this is $3 \cdot 2 = 6$:

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix},$$
$$\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}.$$

The factored form $(p^2 - 1)(p^2 - p)$ suggests another count: $p^2 - 1$ choices of a nonzero first column, then $p^2 - p$ choices of a second column that is not a multiple of the first. That count is justified by the

Fundamental Theorems (Theorem 2.7.8), which say that A is invertible exactly when its columns form a basis.

Solution to Exercise 2.5.44

Uses. Proposition 2.4.28 (Cyclicity of the trace), Definition 2.4.26 (Trace), Definition 1.1.28 (Characteristic), Definition 2.5.12 (Invertible)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. Take the trace of $AA^{-1} = I_m$ and of $A^{-1}A = I_n$.
Hint 2. Proposition 2.4.28 applies to an $m \times n$ matrix times an $n \times m$ matrix. What is $\operatorname{tr} I_k$?
Sketch. (a) $m * 1 = \operatorname{tr} I_m = \operatorname{tr}(AA^{-1}) = \operatorname{tr}(A^{-1}A) = \operatorname{tr} I_n = n * 1$. In characteristic 0, $m * 1 = n * 1$ forces $m = n$. (b) If $BA = I_n$, then $n * 1 = \operatorname{tr}(BA) = \operatorname{tr}(AB) = m * 1$. (c) In $\mathbb{F}_2$, $m * 1 = n * 1$ whenever m and n have the same parity, so the trace cannot tell $m = 1$ from $n = 3$.

(a) The trace of I_k is $1 + \cdots + 1 = k * 1$. Since $A \in F^{m\times n}$ and $A^{-1} \in F^{n\times m}$, Proposition 2.4.28 gives

$$\begin{aligned} m * 1 = \operatorname{tr} I_m &= \operatorname{tr}\left(AA^{-1}\right) \\ &= \operatorname{tr}\left(A^{-1}A\right) = \operatorname{tr} I_n = n * 1. \end{aligned}$$

Suppose F has characteristic 0 and, say, $m > n$. Then $(m-n) * 1 = m * 1 - n * 1 = 0$ with $m - n \geq 1$, contradicting Definition 1.1.28. So $m = n$.

(b) If $BA = I_n$, then $n * 1 = \operatorname{tr}(BA) = \operatorname{tr}(AB) = \operatorname{tr} I_m = m * 1$ by Proposition 2.4.28, contradicting the hypothesis. So $BA \neq I_n$. For instance, over $\mathbb{Q}$, whenever $AB = I_m$ with A not square, BA is not the identity.

(c) In $\mathbb{F}_2$, $k * 1$ is 0 for even k and 1 for odd k, so the trace only sees the parity of the size. For $m = 1$ and $n = 3$ the argument gives $1 = 1$, no contradiction. Invertible matrices over $\mathbb{F}_2$, and over every field, are nevertheless square (Corollary 3.5.15), but the proof needs rank.

Solution to Exercise 2.5.45

Uses. Proposition 2.4.23 (Transpose of a product), Proposition 2.4.22 (Transpose is a linear involution), Proposition 2.5.17 (Algebra of inverses)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. Transpose the equation $BA = I_n$.
Hint 2. Transposing is a bijection, so $X = Y$ if and only if $X^{\mathsf{T}} = Y^{\mathsf{T}}$.
Sketch. $(BA)^{\mathsf{T}} = A^{\mathsf{T}}B^{\mathsf{T}}$ and $I_n^{\mathsf{T}} = I_n$, and transposing is injective, so $BA = I_n$ iff $A^{\mathsf{T}}B^{\mathsf{T}} = I_n$. The second claim follows since $B \mapsto B^{\mathsf{T}}$ is a bijection $F^{n\times m} \to F^{m\times n}$. Two-sided: apply both one-sided statements, and use $\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A$.

By Proposition 2.4.23 and Proposition 2.4.22, $(BA)^{\mathsf{T}} = A^{\mathsf{T}}B^{\mathsf{T}}$ and $I_n^{\mathsf{T}} = I_n$. Transposing is a bijection (Proposition 2.4.22), so two matrices are equal if and only if their transposes are. Hence

$$\begin{aligned} BA = I_n \quad &\Longleftrightarrow \quad (BA)^{\mathsf{T}} = I_n^{\mathsf{T}} \\ &\Longleftrightarrow \quad A^{\mathsf{T}}B^{\mathsf{T}} = I_n, \end{aligned}$$

that is, B is a left inverse of A if and only if B^{T} is a right inverse of A^{T}.

If A is left-invertible, with left inverse B, then B^{T} is a right inverse of A^{T}. Conversely, if C is a right inverse of A^{T}, then $B = C^{\mathsf{T}}$ satisfies $B^{\mathsf{T}} = C$, so B is a left inverse of A. The same argument with the roles of the two sides exchanged shows that A is right-invertible if and only if A^{T} is left-invertible. Combining the two, A is invertible if and only if A^{T} is; this is Proposition 2.5.17(d) together with its converse, which follows by applying it to A^{T}, since $\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A$.

Solution to Exercise 2.5.46

Uses. Proposition 2.4.8 (Four views of the product), Exercise 2.5.38, Proposition 1.1.17 (No zero divisors)
Hint 1. (a) is a direct computation. (b) The relation has constant term $ad - bc$.
Hint 2. (c) $A^{-1} = A$ means $A^2 = I_2$. Combine with (a): $(1 + \Delta)I_2 = (a + d)A$, where $\Delta = ad - bc$. What if $a + d \neq 0$?
Hint 3. If $a + d \neq 0$, then A is a scalar matrix. Otherwise $d = -a$ and $\Delta = -1$; count the triples (a, b, c) with $a^2 + bc = 1$, splitting according to whether $a^2 = 1$.

Sketch. (a) Compute A^2 and subtract. (b) With $\Delta \neq 0$, Exercise 2.5.38 gives $A^{-1} = -\Delta^{-1}(A-(a+d)I_2) = \Delta^{-1}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$. (c) Besides $\pm I_2$, the solutions are exactly the A with $d=-a$ and $a^2+bc=1$. For $a=\pm 1$, $bc=0$ has $2p-1$ solutions; for the other $p-2$ values, $bc = 1-a^2 \neq 0$ has $p-1$. Total $2+2(2p-1)+(p-2)(p-1) = p^2+p+2$.

(a) By the entry formula,

$$A^2 = \begin{pmatrix} a^2+bc & ab+bd \\ ca+dc & cb+d^2 \end{pmatrix},$$

$$(a+d)A = \begin{pmatrix} a^2+ad & ab+bd \\ ac+cd & ad+d^2 \end{pmatrix},$$

so $A^2-(a+d)A = \begin{pmatrix} bc-ad & 0 \\ 0 & bc-ad \end{pmatrix} = -(ad-bc)I_2$, which is the claim.

(b) Let $\Delta = ad-bc \neq 0$ and $t = a+d$. The relation of (a) reads $A^2 - tA + \Delta I_2 = 0$, with $a_2 = 1$, $a_1 = -t$, and $a_0 = \Delta \neq 0$. By Exercise 2.5.38 (in matrix form),

$$\begin{aligned} A^{-1} &= -\Delta^{-1}(A - tI_2) = \Delta^{-1}(tI_2 - A) \\ &= \Delta^{-1}\begin{pmatrix} a+d-a & -b \\ -c & a+d-d \end{pmatrix} \\ &= \frac{1}{\Delta}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}. \end{aligned}$$

(c) $A^{-1} = A$ means $A^2 = I_2$. Let $t = a+d$ and $\Delta = ad-bc$. By (a), $A^2 = tA - \Delta I_2$, so $A^2 = I_2$ if and only if $tA = (1+\Delta)I_2$.

If $t \neq 0$, this says $A = t^{-1}(1+\Delta)I_2$ is a scalar matrix λI_2, and $A^2 = I_2$ means $\lambda^2 = 1$, so $\lambda = \pm 1$ (since $(\lambda-1)(\lambda+1)=0$, Proposition 1.1.17). Both I_2 and $-I_2$ satisfy $A^2 = I_2$, and they are different because p is odd.

If $t = 0$, the condition becomes $(1+\Delta)I_2 = 0$, that is, $\Delta = -1$. With $d=-a$, $\Delta = -a^2-bc$, so the condition is $a^2+bc=1$. Conversely every such A has $t=0$ and $\Delta=-1$, so $A^2 = tA - \Delta I_2 = I_2$. These matrices are not $\pm I_2$, whose traces are $\pm 2 \neq 0$.

It remains to count the triples $(a,b,c) \in \mathbb{F}_p^3$ with $bc = 1-a^2$. The equation $a^2=1$ has exactly the two solutions $a=\pm 1$; for each, $bc=0$ has $2p-1$ solutions. For each of the other $p-2$ values of a, $1-a^2 \neq 0$, so $b \neq 0$ and $c = (1-a^2)b^{-1}$: $p-1$ solutions. The total is

$$\begin{aligned} &2 + 2(2p-1) + (p-2)(p-1) \\ &= 2 + 4p - 2 + p^2 - 3p + 2 \\ &= p^2 + p + 2. \end{aligned}$$

For $p=3$ this gives 14 matrices. Over $\mathbb{F}_2$ the count is different, because $I_2 = -I_2$ there: of the six invertible matrices listed in Exercise 2.5.43, exactly four satisfy $A^2 = I_2$.

Solution to Exercise 2.5.47

Uses. Proposition 2.4.14 (Algebra of matrices), Definition 2.5.12 (Invertible)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Where does the formula come from? Pretend the matrices are numbers and expand $1/(1-ba)$ as a geometric series: $1+ba+baba+\cdots = 1+b(1+ab+abab+\cdots)a$. Then forget the heuristic and verify.
Hint 2. Write $C = (I_m - AB)^{-1}$. In $(I_n - BA)(I_n + BCA)$, collect the terms of the form $B(\cdots)A$.
Hint 3. The bracket you get is $C - I_m - ABC = (I_m - AB)C - I_m$.
Sketch. With $C = (I_m-AB)^{-1}$: $(I_n-BA)(I_n+BCA) = I_n + B[C - I_m - ABC]A = I_n + B[(I_m-AB)C - I_m]A = I_n$, and $(I_n+BCA)(I_n-BA) = I_n + B[C - I_m - CAB]A = I_n + B[C(I_m-AB) - I_m]A = I_n$. (b) is (a) with $m=1$, $B=\mathbf{u}$, $A=-\mathbf{v}^{\mathsf{T}}$.

(a) Let $C = (I_m - AB)^{-1}$, so $(I_m-AB)C = C(I_m-AB) = I_m$. By the distributive and associative laws (Proposition 2.4.14),

$$\begin{aligned}&(I_n - BA)(I_n + BCA)\\&= I_n + BCA - BA - BABCA\\&= I_n + B(C - I_m - ABC)A\\&= I_n + B((I_m - AB)C - I_m)A\\&= I_n + B(I_m - I_m)A = I_n,\end{aligned}$$

and similarly

$$\begin{aligned}&(I_n + BCA)(I_n - BA)\\&= I_n - BA + BCA - BCABA\\&= I_n + B(C - I_m - CAB)A\\&= I_n + B(C(I_m - AB) - I_m)A = I_n.\end{aligned}$$

So $I_n + BCA$ is a two-sided inverse of $I_n - BA$.

(b) Apply (a) with $m = 1$, $B = \mathbf{u} \in F^{n\times 1}$, and $A = -\mathbf{v}^{\mathsf{T}} \in F^{1\times n}$. Then $I_n - BA = I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}$, and $I_1 - AB = 1 + \mathbf{v}^{\mathsf{T}}\mathbf{u}$, a 1×1 matrix, which is invertible exactly when it is nonzero. By (a),

$$\begin{aligned}&\left(I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right)^{-1}\\&= I_n + \mathbf{u}\left(1 + \mathbf{v}^{\mathsf{T}}\mathbf{u}\right)^{-1}\left(-\mathbf{v}^{\mathsf{T}}\right)\\&= I_n - \left(1 + \mathbf{v}^{\mathsf{T}}\mathbf{u}\right)^{-1}\mathbf{u}\mathbf{v}^{\mathsf{T}}.\end{aligned}$$

The point of (a) is that inverting the $n \times n$ matrix $I_n - BA$ reduces to inverting the $m \times m$ matrix $I_m - AB$, which in (b) is a single number.

Solution to Exercise 2.5.48

Uses. Proposition 2.1.24 (Algebra of composition), Theorem 2.5.10 (Left and right inverses agree), Example 2.5.24 (Differentiation has a right inverse but no left inverse)
Hint 1. Expand $(\mathrm{id} - S)(\mathrm{id} - T)$ and use the hypothesis.
Hint 2. By (a), $\mathrm{id} - T$ is a right inverse of $\mathrm{id} - S$. If $\mathrm{id} - S$ is invertible, then $\mathrm{id} - T$ is its inverse, so the product in the other order is also id. Expand that product.
Hint 3. For (c), you need $\mathrm{id} - S$ and $\mathrm{id} - T$ that are one-sided inverses of each other but not two-sided. Use D and J.
Sketch. (a) $(\mathrm{id} - S)(\mathrm{id} - T) = \mathrm{id} - S - T + ST = \mathrm{id}$. (b) Then $\mathrm{id} - T = (\mathrm{id} - S)^{-1}$ by Theorem 2.5.10, so $(\mathrm{id} - T)(\mathrm{id} - S) = \mathrm{id}$, which expands to $TS = S + T = ST$. (c) $S = \mathrm{id} - D$ and $T = \mathrm{id} - J$: $ST = 2\,\mathrm{id} - D - J + DJ = S + T$, while $TS - ST = JD - DJ = JD - \mathrm{id} \neq 0$.

(a) By Proposition 2.1.24 and the hypothesis,

$$\begin{aligned}(\mathrm{id} - S)(\mathrm{id} - T) &= \mathrm{id} - T - S + ST\\&= \mathrm{id} - T - S + S + T = \mathrm{id}.\end{aligned}$$

(b) By (a), $\mathrm{id} - T$ is a right inverse of $\mathrm{id} - S$. If $\mathrm{id} - S$ is invertible, then by Theorem 2.5.10 its right inverse $\mathrm{id} - T$ is its inverse, so also $(\mathrm{id} - T)(\mathrm{id} - S) = \mathrm{id}$. Expanding, $\mathrm{id} - S - T + TS = \mathrm{id}$, so $TS = S + T = ST$.

(c) Let $D, J \in \mathrm{L}(\mathbb{Q}[x])$ be as in Example 2.5.24, so $DJ = \mathrm{id}$ and $JD \neq \mathrm{id}$. Let $S = \mathrm{id} - D$ and $T = \mathrm{id} - J$. Then

$$\begin{aligned}ST &= (\mathrm{id} - D)(\mathrm{id} - J) = \mathrm{id} - J - D + DJ\\&= 2\,\mathrm{id} - D - J = S + T,\end{aligned}$$

while

$$\begin{aligned}TS &= (\mathrm{id} - J)(\mathrm{id} - D) = \mathrm{id} - D - J + JD\\&= ST + (JD - \mathrm{id}).\end{aligned}$$

Since $JD(1) = 0 \neq 1$, $JD - \mathrm{id} \neq 0$, so $TS \neq ST$. Here $\mathrm{id} - S = D$ has the right inverse $\mathrm{id} - T = J$ but is not invertible, which is exactly the hypothesis of (b) failing.

Solution to Exercise 2.5.49

Uses. Theorem 2.5.10 (Left and right inverses agree), Notation 2.4.16 (Powers of a matrix), Proposition 2.4.14 (Algebra of matrices), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Too many vectors force a dependence (Technique 4.1.30)
Hint 1. (a) First show $AB^k = B^{k-1}$ for $k \geq 1$, then induct on r.
Hint 2. (b) The matrices $I_n, B, \ldots, B^{n^2}$ are dependent. Take a nontrivial relation $\sum c_k B^k = 0$, let r be the smallest index with $c_r \neq 0$, and multiply the relation on the left by A^r.
Hint 3. After multiplying by A^r, the relation reads $c_r I_n + c_{r+1}B + c_{r+2}B^2 + \cdots = 0$. Solve for I_n and factor out B.
Hint 4. (c) B now has a left inverse and a right inverse.
Sketch. (a) $AB^k = (AB)B^{k-1} = B^{k-1}$, and induction on r. (b) Take a nontrivial relation $\sum_{k=r}^{N} c_k B^k = 0$ with $c_r \neq 0$ and multiply by A^r: $\sum_{k=r}^{N} c_k B^{k-r} = 0$, so $I_n = BQ$ with $Q = -c_r^{-1} \sum_{k=r+1}^{N} c_k B^{k-r-1}$. (c) A is a left inverse of B and Q a right inverse, so $A = Q$ by Theorem 2.5.10 and $BA = BQ = I_n$.

(a) For $k \geq 1$, $AB^k = (AB)B^{k-1} = B^{k-1}$ by associativity. We induct on r; for $r = 0$ the claim is $B^k = B^k$. If $A^r B^k = B^{k-r}$ for all $k \geq r$, and $k \geq r+1$, then

$$A^{r+1}B^k = A\left(A^r B^k\right) = AB^{k-r} = B^{k-r-1},$$

using $k - r \geq 1$.

(b) The $n^2 + 1$ matrices $I_n, B, B^2, \ldots, B^{n^2}$ are linearly dependent, so there are $c_0, \ldots, c_{n^2} \in F$, not all 0, with $\sum_{k=0}^{n^2} c_k B^k = 0$ (Theorem 1.5.5). Let r be the smallest index with $c_r \neq 0$, so the relation is $\sum_{k=r}^{n^2} c_k B^k = 0$. Multiplying on the left by A^r and using (a),

$$c_r I_n + c_{r+1}B + c_{r+2}B^2 + \cdots + c_{n^2}B^{n^2-r} = 0.$$

Let $Q = -c_r^{-1}\left(c_{r+1}I_n + c_{r+2}B + \cdots + c_{n^2}B^{n^2-r-1}\right)$, an empty sum being 0. Solving for I_n gives $I_n = BQ$. So Q is a right inverse of B, and it is a linear combination of powers of B.

(c) $AB = I_n$ says that A is a left inverse of B, and by (b), Q is a right inverse of B. By Theorem 2.5.10, $A = Q$, so $BA = BQ = I_n$.

This proves the square case of Theorem 3.5.23 using only that $F^{n\times n}$ is finite-dimensional, and finite dimension is essential. On $\mathbb{Q}[x]$, with $DJ = \mathrm{id}$, the argument breaks down at (b), because the powers of J are linearly independent.

Section 2.6

Solution to Exercise 2.6.10

Uses. Definition 2.6.5 (Kernel), Definition 2.6.6 (Image), Definition 1.3.10 (Span)
Hint 1. For the kernel, set the value equal to $\mathbf{0}$ and solve. For the image, write a general value as a linear combination of fixed vectors.
Hint 2. (a) Every value is a multiple of $(1, -2)$. (b) A value (a, b, c) of S satisfies $b = a + c$. (c) $\mathrm{ev}_1(a + bx) = a + b$.
Sketch. (a) $T(x, y) = (x - y)(1, -2)$: kernel $\mathrm{span}((1, 1))$, image $\mathrm{span}((1, -2))$, neither injective nor surjective. (b) $S(x, y) = \mathbf{0}$ forces $x = y = 0$; the image is $\{(a, b, c) \mid b = a + c\}$, which misses $(0, 1, 0)$; injective, not surjective. (c) Kernel $\mathrm{span}(1 - x)$, image F; surjective, not injective.

(a) $T(x, y) = (x - y, -2(x - y)) = (x - y)(1, -2)$. This is $\mathbf{0}$ if and only if $x = y$, so $\ker T = \mathrm{span}((1, 1))$, and $\mathrm{im}\, T = \{t(1, -2) \mid t \in \mathbb{R}\} = \mathrm{span}((1, -2))$, since $x - y$ takes every real value. As $(1, 1) \neq \mathbf{0}$ lies in the kernel, T is not injective, and as $(1, 0)$ is not a multiple of $(1, -2)$, T is not surjective.

(b) If $S(x, y) = \mathbf{0}$, then $x = 0$ and $y = 0$, so $\ker S = \{\mathbf{0}\}$ and S is injective (by definition: $S(x, y) = S(x', y')$ forces $x = x'$ and $y = y'$ from the first and last entries). Every value $(a, b, c) = (x, x + y, y)$ satisfies $b = a + c$, and conversely each $(a, a + c, c)$ equals $S(a, c)$. So $\mathrm{im}\, S = \left\{(a, b, c) \in F^3 \;\middle|\; b = a + c\right\} = \mathrm{span}((1, 1, 0), (0, 1, 1))$. It does not contain $(0, 1, 0)$, so S is not surjective.

(c) $\mathrm{ev}_1(a+bx) = a+b$. This is 0 if and only if $b = -a$, so $\ker \mathrm{ev}_1 = \{a - ax \mid a \in F\} = \mathrm{span}(1-x)$, and ev_1 is not injective. Every $c \in F$ equals $\mathrm{ev}_1(c)$, so $\operatorname{im} \mathrm{ev}_1 = F$ and ev_1 is surjective.

Solution to Exercise 2.6.16

Uses. Theorem 2.6.11 (Injectivity is decided at **0**), Definition 2.6.5 (Kernel)
Techniques. Test injectivity at **0** (Technique 2.6.12)
Hint 1. In each part, use the kernel: suppose the value is **0** and deduce that the input is **0**, or find a nonzero input with value **0**.
Hint 2. (b) If $p = a_0 + \cdots + a_d x^d$ with $a_d \neq 0$, the coefficient of x^{d+1} in $xp + p$ is a_d. (c) If $T \neq 0$, pick $\mathbf{v}$ with $T(\mathbf{v}) \neq \mathbf{0}$ and look at $T(\mathbf{v})$.
Sketch. (a) $T(x,y) = \mathbf{0}$ gives $x = 0$ and then $y = 0$. (b) For $p \neq 0$ of degree d, $T(p)$ has coefficient $a_d \neq 0$ at x^{d+1}. (c) If $T = 0$, any nonzero vector is in the kernel; otherwise $T(\mathbf{v}) \neq \mathbf{0}$ for some $\mathbf{v}$, and $T(T(\mathbf{v})) = \mathbf{0}$.

(a) If $T(x,y) = \mathbf{0}$, the first entry gives $x = 0$, and then the second gives $y = 0$. So $\ker T = \{\mathbf{0}\}$, and T is injective by Theorem 2.6.11. No division was needed, so this holds over every field.

(b) Let $p = a_0 + a_1 x + \cdots + a_d x^d$ with $a_d \neq 0$. Then $xp + p = a_0 + (a_0 + a_1)x + \cdots + (a_{d-1} + a_d)x^d + a_d x^{d+1}$, whose coefficient of x^{d+1} is $a_d \neq 0$. So $T(p) \neq \mathbf{0}$ for every $p \neq \mathbf{0}$, that is, $\ker T = \{\mathbf{0}\}$, and T is injective.

(c) Suppose $V \neq \{\mathbf{0}\}$. If $T = 0$, then every nonzero vector of V lies in $\ker T$. Otherwise there is $\mathbf{v}$ with $\mathbf{w} = T(\mathbf{v}) \neq \mathbf{0}$, and $T(\mathbf{w}) = T^2(\mathbf{v}) = \mathbf{0}$, so $\mathbf{w}$ is a nonzero vector of $\ker T$. In either case $\ker T \neq \{\mathbf{0}\}$, and T is not injective.

Solution to Exercise 2.6.26

Uses. Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Proposition 1.5.15 (Short lists, zeros, and repeats), Proposition 1.5.24 (Distinct degrees), Example 2.1.9 (Maps of polynomials)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. $x \cdot x^k = x^{k+1}$, whose derivative is $(k+1)x^k$.
Hint 2. So $T_c\left(x^k\right) = (k+1-c)x^k$. When is the list $(1-c)1, (2-c)x, (3-c)x^2$ independent, and when does it span?
Sketch. $T_c\left(x^k\right) = (k+1-c)x^k$. If $1-c$, $2-c$, $3-c$ are all nonzero, the values are nonzero multiples of $1, x, x^2$, so they form a basis and T_c is bijective. If one of them is 0, the list of values contains 0 (not injective) and its span misses the corresponding monomial (not surjective). Over $\mathbb{Q}$: bijective iff $c \notin \{1,2,3\}$, otherwise neither. Over $\mathbb{F}_2$ and $\mathbb{F}_3$ the set $\{1,2,3\}$ is all of F, so T_c is never injective or surjective; over $\mathbb{F}_5$ it is bijective iff $c \in \{0,4\}$.

(a) For $k = 0, 1, 2$, $D\left(x \cdot x^k\right) = D\left(x^{k+1}\right) = (k+1)x^k$, so $T_c\left(x^k\right) = (k+1-c)x^k$:

$$T_c(1) = (1-c)1, \quad T_c(x) = (2-c)x, \quad T_c\left(x^2\right) = (3-c)x^2.$$

(b) and **(c)**. Let $\mathcal{B} = 1, x, x^2$. Suppose first that $1-c$, $2-c$, and $3-c$ are all nonzero. Then $T_c(\mathcal{B})$ consists of nonzero multiples of 1, x, and x^2, which have distinct degrees, so it is linearly independent (Proposition 1.5.24). It also spans $F[x]_{\leq 2}$, since $x^k = (k+1-c)^{-1} T_c\left(x^k\right)$ for each k. By Proposition 2.6.22, T_c is injective and surjective.

Now suppose $k+1-c = 0$ for some $k \in \{0,1,2\}$. Then $T_c\left(x^k\right) = \mathbf{0}$, so $T_c(\mathcal{B})$ contains **0** and is linearly dependent (Proposition 1.5.15), and T_c is not injective. Every value of T_c is a combination of the other two monomials, so its coefficient of x^k is 0; hence $x^k \notin \operatorname{im} T_c$ and T_c is not surjective.

So T_c is bijective if $c \notin \{1,2,3\}$ and neither injective nor surjective if $c \in \{1,2,3\}$, where $1, 2, 3$ are read in F. Over $\mathbb{Q}$ these are three distinct values. Over $\mathbb{F}_2$, $\{1,2,3\} = \{1,0,1\} = \mathbb{F}_2$, and over $\mathbb{F}_3$, $\{1,2,3\} = \{1,2,0\} = \mathbb{F}_3$, so in both cases T_c is neither injective nor surjective for every c. Over $\mathbb{F}_5$, $\{1,2,3\}$ leaves $c \in \{0,4\}$, and these are the values for which T_c is bijective.

Solution to Exercise 2.6.33

Uses. Corollary 2.6.31 (Fibers are translates of the kernel), Example 2.6.19 (Computing a null space and a column space)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. The third column minus the first is $(2,5)$. Is there a simpler combination of columns that gives $(1,3)$?
Hint 2. Once you have one solution $\mathbf{x}_0$, every solution is $\mathbf{x}_0 + \mathbf{z}$ with $\mathbf{z} \in \ker T_A = \mathrm{span}((-2,1,0))$.
Sketch. $(1,3) = (3,7) - 2(1,2)$, so $\mathbf{x}_0 = (-2,0,1)$ is a solution. All solutions: $(-2-2t, t, 1)$ for $t \in F$.

The columns are $(1,2)$, $(2,4)$, and $(3,7)$, and $(3,7) - 2(1,2) = (1,3)$. So $\mathbf{x}_0 = (-2,0,1)$ satisfies $A\mathbf{x}_0 = (1,3)$. By Example 2.6.19(a), $\ker T_A = \operatorname{span}((-2,1,0))$, so by Corollary 2.6.31(b) the solutions are exactly

$$(-2,0,1) + t(-2,1,0) = (-2-2t, t, 1), \quad t \in F.$$

As a check, $(-2-2t) + 2t + 3 = 1$ and $2(-2-2t) + 4t + 7 = 3$.

Solution to Exercise 2.6.34

Uses. Definition 2.6.5 (Kernel), Proposition 2.6.18 (The column space is spanned by the columns), Corollary 1.3.20 (Operations that preserve the span), Corollary 2.6.31 (Fibers are translates of the kernel)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. $T(x,y,z) = x(1,0,1) + y(1,1,0) + z(0,1,-1)$. Is one of these three vectors a combination of the other two?
Hint 2. Every value (a,b,c) of T satisfies one linear equation. Find it by eliminating x, y, and z from $a = x + y$, $b = y + z$, $c = x - z$.
Sketch. The kernel is $\operatorname{span}((1,-1,1))$. Since $(0,1,-1) = (1,1,0) - (1,0,1)$, $\operatorname{im} T = \operatorname{span}((1,0,1),(1,1,0)) = \{(a,b,c) \mid a - b - c = 0\}$. So $(1,2,3) \notin \operatorname{im} T$ and $(2,1,1) = T(1,1,0) \in \operatorname{im} T$, with preimages $(1+t, 1-t, t)$.

(a) $T(x,y,z) = \mathbf{0}$ means $x + y = 0$, $y + z = 0$, and $x - z = 0$. The first two give $y = -x$ and $z = x$, and then the third holds. So $\ker T = \{(t,-t,t) \mid t \in \mathbb{R}\} = \operatorname{span}((1,-1,1))$.

T is T_A for the matrix with columns $\mathbf{a}_1 = (1,0,1)$, $\mathbf{a}_2 = (1,1,0)$, and $\mathbf{a}_3 = (0,1,-1) = \mathbf{a}_2 - \mathbf{a}_1$, so by Proposition 2.6.18 and Corollary 1.3.20(c), $\operatorname{im} T = \operatorname{span}(\mathbf{a}_1, \mathbf{a}_2)$. Every value $(a,b,c) = (x+y, y+z, x-z)$ satisfies $a - b - c = 0$. Conversely, if $a - b - c = 0$, then

$$(a-b)\mathbf{a}_1 + b\mathbf{a}_2 = (a, b, a-b) = (a,b,c).$$

So $\operatorname{im} T = \left\{(a,b,c) \in \mathbb{R}^3 \;\middle|\; a - b - c = 0\right\}$, a plane.

(b) Since $1 - 2 - 3 = -4 \neq 0$, $(1,2,3) \notin \operatorname{im} T$. Since $2 - 1 - 1 = 0$, $(2,1,1) \in \operatorname{im} T$, and by the computation above $(2,1,1) = \mathbf{a}_1 + \mathbf{a}_2 = T(1,1,0)$. By Corollary 2.6.31, its preimages are

$$(1,1,0) + t(1,-1,1) = (1+t, 1-t, t), \quad t \in \mathbb{R}.$$

As a check, $T(1+t, 1-t, t) = (2,1,1)$.

Solution to Exercise 2.6.35

Uses. Proposition 2.6.18 (The column space is spanned by the columns), Definition 2.3.8 (Matrix–vector product), Proposition 1.2.35 (Zero products), Corollary 2.6.31 (Fibers are translates of the kernel)
Hint 1. $i(1,i) = (i,-1)$. What is $(1+i)(1,i)$?
Hint 2. Then $A\mathbf{x} = (x_1 + ix_2 + (1+i)x_3)(1,i)$, which is $\mathbf{0}$ exactly when the scalar factor is 0.
Sketch. The columns are $(1,i)$, $i(1,i)$, and $(1+i)(1,i)$, so $\operatorname{im} T_A = \operatorname{span}((1,i))$. $A\mathbf{x} = \mathbf{0}$ iff $x_1 = -ix_2 - (1+i)x_3$, so $\ker T_A = \operatorname{span}((-i,1,0),(-1-i,0,1))$. Neither injective nor surjective. $(1+i, i-1)$ is the third column, so the solutions are $\mathbf{e}_3 + \ker T_A$.

(a) The columns are $\mathbf{a}_1 = (1,i)$, $\mathbf{a}_2 = (i,-1) = i(1,i)$, and $\mathbf{a}_3 = (1+i, i-1) = (1+i)(1,i)$, since $(1+i)i = i + i^2 = i - 1$. By Proposition 2.6.18, $\operatorname{im} T_A = \operatorname{span}((1,i), i(1,i), (1+i)(1,i)) = \operatorname{span}((1,i))$.

(b) By Definition 2.3.8, $A\mathbf{x} = x_1\mathbf{a}_1 + x_2\mathbf{a}_2 + x_3\mathbf{a}_3 = (x_1 + ix_2 + (1+i)x_3)(1,i)$. Since $(1,i) \neq \mathbf{0}$, this is $\mathbf{0}$ if and only if $x_1 = -ix_2 - (1+i)x_3$ (Proposition 1.2.35). So

$$\ker T_A = \{(-is - (1+i)t, s, t) \mid s,t \in \mathbb{C}\} = \operatorname{span}((-i,1,0),(-1-i,0,1)).$$

(c) T_A is not injective, since $(-i,1,0)$ is a nonzero vector of its kernel. It is not surjective: $(1,0) \notin \operatorname{span}((1,i))$, since $c(1,i) = (1,0)$ would need $c = 1$ and $ci = 0$. Finally, $(1+i, i-1) = \mathbf{a}_3 = A\mathbf{e}_3$, so by Corollary 2.6.31 the solutions of $A\mathbf{x} = (1+i, i-1)$ are

$$\mathbf{e}_3 + s(-i,1,0) + t(-1-i,0,1) = (-is - (1+i)t, s, 1+t), \quad s,t \in \mathbb{C}.$$

Solution to Exercise 2.6.36

Uses. Definition 2.1.21 (Pointwise operations), Definition 2.6.5 (Kernel), Definition 2.6.6 (Image), Proposition 1.4.24 (The sum of two subspaces)

Techniques. Fix an arbitrary element and chase it (Technique 1.3.13), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. $(S+T)(\mathbf{v}) = S(\mathbf{v}) + T(\mathbf{v})$ by definition of the sum of maps.
Hint 2. For (c), try $T = -S$.
Sketch. (a) If $S(\mathbf{v}) = T(\mathbf{v}) = \mathbf{0}$, then $(S+T)(\mathbf{v}) = \mathbf{0}$. (b) $(S+T)(\mathbf{v}) = S(\mathbf{v}) + T(\mathbf{v}) \in \operatorname{im} S + \operatorname{im} T$. (c) With $V = W \neq \{\mathbf{0}\}$, $S = \mathrm{id}$, and $T = -\mathrm{id}$: $\ker S \cap \ker T = \{\mathbf{0}\}$ but $\ker(S+T) = V$, and $\operatorname{im}(S+T) = \{\mathbf{0}\}$ but $\operatorname{im} S + \operatorname{im} T = V$.

Recall that $(S+T)(\mathbf{v}) = S(\mathbf{v}) + T(\mathbf{v})$ (Definition 2.1.21).

(a) If $\mathbf{v} \in \ker S \cap \ker T$, then $(S+T)(\mathbf{v}) = \mathbf{0} + \mathbf{0} = \mathbf{0}$.

(b) For every $\mathbf{v} \in V$, $(S+T)(\mathbf{v}) = S(\mathbf{v}) + T(\mathbf{v})$ with $S(\mathbf{v}) \in \operatorname{im} S$ and $T(\mathbf{v}) \in \operatorname{im} T$, so it lies in $\operatorname{im} S + \operatorname{im} T$.

(c) Let $V = W$ be any nonzero space, $S = \mathrm{id}_V$, and $T = -\mathrm{id}_V$. Then $\ker S \cap \ker T = \{\mathbf{0}\}$, while $S + T = 0$ has kernel $V \neq \{\mathbf{0}\}$. And $\operatorname{im}(S+T) = \{\mathbf{0}\}$, while $\operatorname{im} S + \operatorname{im} T = V + V = V$.

Solution to Exercise 2.6.37

Uses. Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Definition 2.6.5 (Kernel), Definition 2.6.6 (Image)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Test injectivity at $\mathbf{0}$ (Technique 2.6.12)
Hint 1. (a) Look for two different bijections of F^2. (b) Try $N(x,y) = (y,0)$.
Hint 2. (c) If $\mathbf{w} = P(\mathbf{v})$, then $P(\mathbf{w}) = P^2(\mathbf{v}) = \mathbf{w}$. (d) What is the kernel of the restriction? (e) Look at Example 2.6.4.
Sketch. (a) False: id and the swap $(x,y) \mapsto (y,x)$ on F^2. (b) False: for $N(x,y) = (y,0)$, $\ker N = \operatorname{im} N = \operatorname{span}(\mathbf{e}_1)$. (c) True: $\mathbf{w} \in \operatorname{im} P$ gives $P(\mathbf{w}) = \mathbf{w}$, and $\mathbf{w} \in \ker P$ gives $P(\mathbf{w}) = \mathbf{0}$. (d) True: $\ker(T|_U) = U \cap \ker T = \{\mathbf{0}\}$. (e) False: $P(x,y) = x$.

(a) False. On F^2, let $S = \mathrm{id}$ and $T(x,y) = (y,x)$. Both have kernel $\{\mathbf{0}\}$ and image F^2, since each is its own inverse ($T^2 = \mathrm{id}$), but $S(\mathbf{e}_1) = \mathbf{e}_1 \neq \mathbf{e}_2 = T(\mathbf{e}_1)$.

(b) False. Let $N : F^2 \to F^2$, $N(x,y) = (y,0)$. Then $N(x,y) = \mathbf{0}$ if and only if $y = 0$, so $\ker N = \operatorname{span}(\mathbf{e}_1)$, and the values of N are the vectors $(y,0)$, so $\operatorname{im} N = \operatorname{span}(\mathbf{e}_1)$ as well. Their intersection is $\operatorname{span}(\mathbf{e}_1) \neq \{\mathbf{0}\}$.

(c) True. Let $\mathbf{w} \in \ker P \cap \operatorname{im} P$, say $\mathbf{w} = P(\mathbf{v})$. Then $\mathbf{w} = P(\mathbf{v}) = P^2(\mathbf{v}) = P(\mathbf{w}) = \mathbf{0}$, the last step because $\mathbf{w} \in \ker P$.

(d) True. The restriction is linear, and its kernel is $\{\mathbf{u} \in U \mid T(\mathbf{u}) = \mathbf{0}\} = U \cap \ker T = U \cap \{\mathbf{0}\} = \{\mathbf{0}\}$, by Theorem 2.6.11 applied to T. Applying Theorem 2.6.11 to $T|_U$, it is injective. (Directly: if $\mathbf{u}, \mathbf{u}' \in U$ and $T(\mathbf{u}) = T(\mathbf{u}')$, then $\mathbf{u} = \mathbf{u}'$.)

(e) False. $P : F^2 \to F$, $P(x,y) = x$, is surjective but not injective (Example 2.6.4(b)).

Solution to Exercise 2.6.38

Uses. Definition 2.6.5 (Kernel), Definition 2.6.6 (Image)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Decide what T does to the standard basis. Which basis vectors should be sent to $\mathbf{0}$, and where should the others go so that their values fill up exactly the kernel?
Hint 2. In F^2: kill $\mathbf{e}_1$ and send $\mathbf{e}_2$ to $\mathbf{e}_1$. In F^4: kill $\mathbf{e}_1, \mathbf{e}_2$ and send $\mathbf{e}_3 \mapsto \mathbf{e}_1$, $\mathbf{e}_4 \mapsto \mathbf{e}_2$.
Hint 3. For (c), $T(\mathbf{v}) \in \operatorname{im} T$ for every $\mathbf{v}$. For the converse, try $T = 0$.
Sketch. (a) $T(x,y) = (y,0)$: kernel and image are $\operatorname{span}(\mathbf{e}_1)$. (b) $T(x_1,x_2,x_3,x_4) = (x_3,x_4,0,0)$: kernel and image are $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$. (c) $T(\mathbf{v}) \in \operatorname{im} T = \ker T$ gives $T^2(\mathbf{v}) = \mathbf{0}$; the zero map on F has $T^2 = 0$, kernel F, and image $\{0\}$.

(a) Let $T(x,y) = (y,0)$. As in Exercise 2.6.37(b), $\ker T = \operatorname{im} T = \operatorname{span}(\mathbf{e}_1)$.

(b) Let $T(x_1,x_2,x_3,x_4) = (x_3,x_4,0,0)$. Then $T(\mathbf{x}) = \mathbf{0}$ if and only if $x_3 = x_4 = 0$, so $\ker T = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$. The values of T are the vectors $(a,b,0,0)$ with $a, b \in F$, each of which occurs (take $x_3 = a$, $x_4 = b$), so $\operatorname{im} T = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ as well.

(c) Let $\ker T = \operatorname{im} T$ and $\mathbf{v} \in V$. Then $T(\mathbf{v}) \in \operatorname{im} T = \ker T$, so $T^2(\mathbf{v}) = T(T(\mathbf{v})) = \mathbf{0}$. Hence $T^2 = 0$. The converse fails: the zero map T on F satisfies $T^2 = 0$, but $\ker T = F$ and $\operatorname{im} T = \{0\}$.

No $T \in \mathrm{L}(F^3)$ has $\ker T = \operatorname{im} T$. Rank–nullity (Theorem 4.2.11) gives $\dim \ker T + \dim \operatorname{im} T = 3$, which is impossible if the two dimensions are equal.

Solution to Exercise 2.6.39

Uses. Proposition 2.6.15 (Kernels and images of composites), Proposition 1.4.24 (The sum of two subspaces), Proposition 2.6.8 (Kernels and images are subspaces)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. By Proposition 2.6.15, $\ker S \subseteq \ker(TS)$ and $\operatorname{im}(TS) \subseteq \operatorname{im} T$ always hold, so only one containment is at stake in each part.
Hint 2. (a) If $T(S(\mathbf{u})) = \mathbf{0}$, then $S(\mathbf{u})$ lies in $\ker T \cap \operatorname{im} S$. (b) If $T(\mathbf{v}) = T(S(\mathbf{u}))$, then $\mathbf{v} - S(\mathbf{u}) \in \ker T$.
Sketch. (a) "If": $\mathbf{u} \in \ker(TS)$ puts $S(\mathbf{u})$ in $\ker T \cap \operatorname{im} S = \{\mathbf{0}\}$. "Only if": for $\mathbf{v} = S(\mathbf{u}) \in \ker T$, $\mathbf{u} \in \ker(TS) = \ker S$, so $\mathbf{v} = \mathbf{0}$. (b) "If": for $\mathbf{v} = S(\mathbf{u}) + \mathbf{z}$ with $\mathbf{z} \in \ker T$, $T(\mathbf{v}) = TS(\mathbf{u})$. "Only if": $T(\mathbf{v}) = TS(\mathbf{u})$ for some $\mathbf{u}$, so $\mathbf{v} = S(\mathbf{u}) + (\mathbf{v} - S(\mathbf{u}))$. (c) Take $U = V$ and $S = T$.

(a) By Proposition 2.6.15(a), $\ker S \subseteq \ker(TS)$ always. Suppose $\ker T \cap \operatorname{im} S = \{\mathbf{0}\}$, and let $\mathbf{u} \in \ker(TS)$. Then $S(\mathbf{u}) \in \operatorname{im} S$ and $T(S(\mathbf{u})) = \mathbf{0}$, so $S(\mathbf{u}) \in \ker T \cap \operatorname{im} S = \{\mathbf{0}\}$, and $\mathbf{u} \in \ker S$. Conversely, suppose $\ker(TS) = \ker S$, and let $\mathbf{v} \in \ker T \cap \operatorname{im} S$, say $\mathbf{v} = S(\mathbf{u})$. Then $T(S(\mathbf{u})) = T(\mathbf{v}) = \mathbf{0}$, so $\mathbf{u} \in \ker(TS) = \ker S$, and $\mathbf{v} = S(\mathbf{u}) = \mathbf{0}$.

(b) By Proposition 2.6.15(b), $\operatorname{im}(TS) \subseteq \operatorname{im} T$ always. Suppose $\operatorname{im} S + \ker T = V$, and let $\mathbf{v} \in V$. Write $\mathbf{v} = S(\mathbf{u}) + \mathbf{z}$ with $\mathbf{u} \in U$ and $\mathbf{z} \in \ker T$. Then $T(\mathbf{v}) = T(S(\mathbf{u})) + T(\mathbf{z}) = T(S(\mathbf{u})) \in \operatorname{im}(TS)$. So $\operatorname{im} T \subseteq \operatorname{im}(TS)$. Conversely, suppose $\operatorname{im}(TS) = \operatorname{im} T$, and let $\mathbf{v} \in V$. Then $T(\mathbf{v}) \in \operatorname{im} T = \operatorname{im}(TS)$, so $T(\mathbf{v}) = T(S(\mathbf{u}))$ for some $\mathbf{u} \in U$. The vector $\mathbf{z} = \mathbf{v} - S(\mathbf{u})$ satisfies $T(\mathbf{z}) = \mathbf{0}$, and $\mathbf{v} = S(\mathbf{u}) + \mathbf{z} \in \operatorname{im} S + \ker T$. So $V \subseteq \operatorname{im} S + \ker T$, and the other containment holds because $\operatorname{im} S + \ker T$ is a subspace of V (Proposition 2.6.8, Proposition 1.4.24).

(c) Apply (a) and (b) with $U = V$ and $S = T$, so that $TS = T^2$.

Solution to Exercise 2.6.40

Uses. Proposition 2.6.22 (Testing injectivity and surjectivity on a basis), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Can a linear combination of nonzero vectors with nonzero coefficients be $\mathbf{0}$?
Hint 2. Try $T : F^2 \to F$, $T(x, y) = x + y$, with the standard basis.
Sketch. The step "none of the $T(\mathbf{v}_i)$ is $\mathbf{0}$, so every $a_i = 0$" confuses "nonzero entries" with "linearly independent". $T(x, y) = x + y$ has $T(\mathbf{e}_1) = T(\mathbf{e}_2) = 1 \neq 0$ but $T(1, -1) = 0$. Correct version: T is injective iff $T(\mathcal{B})$ is linearly independent (Proposition 2.6.22(a)).

The error is the step "none of the vectors $T(\mathbf{v}_i)$ is $\mathbf{0}$, so every coefficient a_i must be 0". A linear combination of nonzero vectors can vanish with nonzero coefficients; what the step needs is that $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_n)$ is linearly independent (Theorem 1.5.5), and nonzero entries do not guarantee that.

The claim is false. Let $T : F^2 \to F$, $T(x, y) = x + y$, with the standard basis. Then $T(\mathbf{e}_1) = T(\mathbf{e}_2) = 1 \neq 0$, but $T(1, -1) = 0$ with $(1, -1) \neq \mathbf{0}$, so T is not injective.

The correct statement is Proposition 2.6.22(a): T is injective if and only if $T(\mathcal{B})$ is linearly independent. The hypothesis of the claim only says that each one-entry list $T(\mathbf{v}_i)$ is linearly independent.

Solution to Exercise 2.6.41

Uses. Example 2.1.9 (Maps of polynomials), Definition 2.6.5 (Kernel), Definition 2.6.6 (Image)
Hint 1. Write $p = a + bx + cx^2 + dx^3$, so $D(p) = b + 2cx + 3dx^2$, and reduce the coefficients 2 and 3 in each field.
Hint 2. For (c), $D^2\left(x^k\right) = k(k-1)x^{k-2}$, and $k(k-1)$ is always even.
Sketch. (a) Over $\mathbb{F}_2$, $D(p) = b + dx^2$, so $\ker D = \operatorname{span}\left(1, x^2\right) = \operatorname{im} D$. (b) Over $\mathbb{F}_3$, $D(p) = b + 2cx$, so $\ker D = \operatorname{span}\left(1, x^3\right)$ and $\operatorname{im} D = \operatorname{span}(1, x)$; they are not equal. (c) $D^2\left(\sum a_k x^k\right) = \sum k(k-1)a_k x^{k-2}$, and $k(k-1) * 1 = 0$ in $\mathbb{F}_2$.

Write $p = a + bx + cx^2 + dx^3$, so that $D(p) = b + 2cx + 3dx^2$ (Example 2.1.9).

(a) In $\mathbb{F}_2$, $2 = 0$ and $3 = 1$, so $D(p) = b + dx^2$. This is $\mathbf{0}$ if and only if $b = d = 0$, so $\ker D = \left\{a + cx^2 \;\middle|\; a, c \in \mathbb{F}_2\right\} = \operatorname{span}\left(1, x^2\right)$. The values $b + dx^2$, with b, d arbitrary, form $\operatorname{span}\left(1, x^2\right)$ as well. So $\ker D = \operatorname{im} D$.

(b) In $\mathbb{F}_3$, $3 = 0$, so $D(p) = b + 2cx$. Since $2 \neq 0$ in $\mathbb{F}_3$, this is $\mathbf{0}$ if and only if $b = c = 0$, so $\ker D = \operatorname{span}\left(1, x^3\right)$. Every $e + fx$ is a value, namely $D\left(ex + 2fx^2\right)$, because $2 \cdot 2f = 4f = f$ in $\mathbb{F}_3$. So $\operatorname{im} D = \operatorname{span}(1, x)$. These are not equal, since $x^3 \in \ker D$ but $x^3 \notin \operatorname{im} D$. They share the constants.

(c) For $f = \sum_k a_k x^k \in \mathbb{F}_2[x]$, applying the formula for D twice gives $D^2(f) = \sum_{k\geq 2}(k(k-1) * 1)a_k x^{k-2}$. One of k and $k-1$ is even, so $k(k-1) * 1 = 0$ in $\mathbb{F}_2$, and $D^2(f) = 0$. In particular $\operatorname{im} D \subseteq \ker D$ on $\mathbb{F}_2[x]$, which is what made (a) possible.

Solution to Exercise 2.6.42

Uses. Definition 2.6.1 (Injective), Definition 2.6.6 (Image), Proposition 2.6.15 (Kernels and images of composites), Definition 2.1.1 (Linear map)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For each $\mathbf{u} \in U$, the vector $S(\mathbf{u})$ lies in $\operatorname{im} T$. How many $\mathbf{v} \in V$ satisfy $T(\mathbf{v}) = S(\mathbf{u})$?
Hint 2. Define $R(\mathbf{u})$ to be that vector. To prove that R is linear, apply T to $R(a\mathbf{u} + \mathbf{u}')$ and to $aR(\mathbf{u}) + R(\mathbf{u}')$, and use injectivity.
Hint 3. For (b), compute $\operatorname{im}(TR)$ with Proposition 2.6.15(b).
Sketch. Since T is injective and $S(\mathbf{u}) \in \operatorname{im} T$, there is exactly one $\mathbf{v}$ with $T(\mathbf{v}) = S(\mathbf{u})$; call it $R(\mathbf{u})$. Then $TR = S$, and $T(R(a\mathbf{u} + \mathbf{u}')) = S(a\mathbf{u} + \mathbf{u}') = T(aR(\mathbf{u}) + R(\mathbf{u}'))$, so R is linear by injectivity. If $TR' = S$, then $T(R'(\mathbf{u})) = S(\mathbf{u})$ forces $R'(\mathbf{u}) = R(\mathbf{u})$. (b) $TR = S$ gives $\operatorname{im} S = \operatorname{im}(TR) \subseteq \operatorname{im} T$.

(a) *Existence.* Let $\mathbf{u} \in U$. Since $S(\mathbf{u}) \in \operatorname{im} S \subseteq \operatorname{im} T$, there is some $\mathbf{v} \in V$ with $T(\mathbf{v}) = S(\mathbf{u})$, and since T is injective there is only one. Let $R(\mathbf{u})$ be this vector. This defines a function $R : U \to V$ with $T(R(\mathbf{u})) = S(\mathbf{u})$ for every $\mathbf{u}$, that is, $TR = S$. To see that R is linear, let $\mathbf{u}, \mathbf{u}' \in U$ and $a \in F$. Since T and S are linear,

$$T(aR(\mathbf{u}) + R(\mathbf{u}')) = aS(\mathbf{u}) + S(\mathbf{u}') = S(a\mathbf{u} + \mathbf{u}') = T(R(a\mathbf{u} + \mathbf{u}')).$$

As T is injective, $R(a\mathbf{u} + \mathbf{u}') = aR(\mathbf{u}) + R(\mathbf{u}')$.

Uniqueness. If $R' : U \to V$ also satisfies $TR' = S$, then $T(R'(\mathbf{u})) = S(\mathbf{u}) = T(R(\mathbf{u}))$ for every $\mathbf{u}$, so $R'(\mathbf{u}) = R(\mathbf{u})$ by injectivity. Hence $R' = R$.

(b) If $TR = S$ for some linear R, then $\operatorname{im} S = \operatorname{im}(TR) \subseteq \operatorname{im} T$ by Proposition 2.6.15(b). So without $\operatorname{im} S \subseteq \operatorname{im} T$ there is no such R at all.

Solution to Exercise 2.6.43

Uses. Definition 2.6.2 (Surjective), Definition 2.6.5 (Kernel), Proposition 2.6.15 (Kernels and images of composites), Definition 2.1.1 (Linear map)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. If $RT = S$, then $R(T(\mathbf{v})) = S(\mathbf{v})$, so there is only one candidate: for $\mathbf{w} \in W$, pick any $\mathbf{v}$ with $T(\mathbf{v}) = \mathbf{w}$ and set $R(\mathbf{w}) = S(\mathbf{v})$.
Hint 2. The danger is that $R(\mathbf{w})$ might depend on the choice of $\mathbf{v}$. If $T(\mathbf{v}) = T(\mathbf{v}') = \mathbf{w}$, where does $\mathbf{v} - \mathbf{v}'$ lie?
Hint 3. For linearity, if $T(\mathbf{v}) = \mathbf{w}$ and $T(\mathbf{v}') = \mathbf{w}'$, then $a\mathbf{v} + \mathbf{v}'$ is an allowed choice for $a\mathbf{w} + \mathbf{w}'$.
Sketch. For $\mathbf{w} \in W$ choose $\mathbf{v}$ with $T(\mathbf{v}) = \mathbf{w}$ and put $R(\mathbf{w}) = S(\mathbf{v})$. Another choice $\mathbf{v}'$ has $\mathbf{v} - \mathbf{v}' \in \ker T \subseteq \ker S$, so $S(\mathbf{v}) = S(\mathbf{v}')$: R is well defined. Choosing $a\mathbf{v} + \mathbf{v}'$ for $a\mathbf{w} + \mathbf{w}'$ shows that R is linear, and $R(T(\mathbf{v})) = S(\mathbf{v})$ by construction. Uniqueness: $R'T = RT$ and T surjective give $R' = R$. (b) If $RT = S$, then $\ker T \subseteq \ker(RT) = \ker S$.

(a) *Definition of R.* Let $\mathbf{w} \in W$. Since T is surjective, there is some $\mathbf{v} \in V$ with $T(\mathbf{v}) = \mathbf{w}$, and we would like to set $R(\mathbf{w}) = S(\mathbf{v})$. For this to make sense, the value must not depend on which preimage $\mathbf{v}$ we pick. If $T(\mathbf{v}) = T(\mathbf{v}') = \mathbf{w}$, then $T(\mathbf{v} - \mathbf{v}') = \mathbf{0}$, so $\mathbf{v} - \mathbf{v}' \in \ker T \subseteq \ker S$, and $S(\mathbf{v}) - S(\mathbf{v}') = S(\mathbf{v} - \mathbf{v}') = \mathbf{0}$. So $S(\mathbf{v})$ is the same for every preimage $\mathbf{v}$ of $\mathbf{w}$, and $R(\mathbf{w}) = S(\mathbf{v})$, for any such $\mathbf{v}$, defines a function $R : W \to U$.

R is linear. Let $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$, and choose $\mathbf{v}, \mathbf{v}'$ with $T(\mathbf{v}) = \mathbf{w}$ and $T(\mathbf{v}') = \mathbf{w}'$. Then $T(a\mathbf{v} + \mathbf{v}') = a\mathbf{w} + \mathbf{w}'$, so $a\mathbf{v} + \mathbf{v}'$ is a preimage of $a\mathbf{w} + \mathbf{w}'$, and

$$R(a\mathbf{w} + \mathbf{w}') = S(a\mathbf{v} + \mathbf{v}') = aS(\mathbf{v}) + S(\mathbf{v}') = aR(\mathbf{w}) + R(\mathbf{w}').$$

$RT = S$. For $\mathbf{v} \in V$, the vector $\mathbf{v}$ is a preimage of $T(\mathbf{v})$, so $R(T(\mathbf{v})) = S(\mathbf{v})$.

Uniqueness. If $R'T = S$ as well, then $R'(T(\mathbf{v})) = R(T(\mathbf{v}))$ for every $\mathbf{v} \in V$. Every $\mathbf{w} \in W$ is $T(\mathbf{v})$ for some $\mathbf{v}$, so $R' = R$.

(b) If $RT = S$ for some linear R, then $\ker T \subseteq \ker(RT) = \ker S$ by Proposition 2.6.15(a).

The construction is the general pattern for defining a map on W through a surjection T: define it on preimages, and check that the result does not depend on the choice. Since the preimages of $\mathbf{w}$ form the fiber $T^{-1}(\mathbf{w})$, a translate of $\ker T$ (Corollary 2.6.31), the check is exactly that S is constant on translates of $\ker T$, which is what $\ker T \subseteq \ker S$ says. The same pattern defines the maps out of quotient spaces in Section 4.6.

Solution to Exercise 2.6.44

Uses. Corollary 2.6.31 (Fibers are translates of the kernel)
Hint 1. By Corollary 2.6.31, V is the disjoint union of the fibers $T^{-1}(\mathbf{w})$ over $\mathbf{w} \in \operatorname{im} T$. How many elements does each fiber have?
Hint 2. For (b), $\left|\mathbb{F}_p^n\right| = p^n$. What are $|\ker T|$ and $|\operatorname{im} T|$ when T is injective? When it is surjective?
Sketch. (a) The fibers over the $|\operatorname{im} T|$ vectors of $\operatorname{im} T$ partition V, and each is in bijection with $\ker T$, so $|V| = |\operatorname{im} T| \cdot |\ker T|$. (b) Injective: $|\ker T| = 1$, so $p^n = |\operatorname{im} T| \leq p^m$. Surjective: $p^n = |\ker T| p^m \geq p^m$.

(a) By Corollary 2.6.31(c), V is the disjoint union of the fibers $T^{-1}(\mathbf{w})$ with $\mathbf{w} \in \operatorname{im} T$, and by part (b) of that corollary each of these fibers is in bijection with $\ker T$, so it has $|\ker T|$ elements. Since V is finite, so are $\ker T$ and $\operatorname{im} T$, and adding up the sizes of the fibers gives

$$|V| = \sum_{\mathbf{w} \in \operatorname{im} T} \left|T^{-1}(\mathbf{w})\right| = |\operatorname{im} T| \cdot |\ker T|.$$

(b) $\mathbb{F}_p^n$ has p^n elements. If T is injective, then $\ker T = \{\mathbf{0}\}$, so by (a) $|\operatorname{im} T| = p^n$. Since $\operatorname{im} T \subseteq \mathbb{F}_p^m$, $p^n \leq p^m$, and $n \leq m$. If T is surjective, then $\operatorname{im} T = \mathbb{F}_p^m$, so $p^n = |\ker T| \cdot p^m \geq p^m$, and $n \geq m$.

Part (b) is the "moreover" clause of the Fundamental Theorems over $\mathbb{F}_p$. Over other fields it needs a different argument (Section 3.5). Section 4.2 proves $\dim V = \dim \ker T + \dim \operatorname{im} T$ over every field; over $\mathbb{F}_p$ this is equivalent to (a), because a space of dimension d over $\mathbb{F}_p$ has p^d elements.

Solution to Exercise 2.6.45

Uses. Corollary 2.6.24 (The columns decide), Theorem 1.4.25 (The subspaces of F^2), Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 2.3.16 (The matrix of T_A), Proposition 2.6.18 (The column space is spanned by the columns)
Hint 1. By Corollary 2.6.24, count the matrices $A \in \mathbb{F}_p^{2\times 3}$ whose three columns span $\mathbb{F}_p^2$. It is easier to count the complement.
Hint 2. By Theorem 1.4.25, if the columns do not span $\mathbb{F}_p^2$, their span is $\{\mathbf{0}\}$ or a line. How many lines through $\mathbf{0}$ does $\mathbb{F}_p^2$ have, and how many column triples lie in a given line?
Hint 3. Each line has $p-1$ nonzero vectors, distinct lines share only $\mathbf{0}$, and $\mathbb{F}_p^2$ has p^2-1 nonzero vectors.
Sketch. Count triples of columns that do not span: their span is $\{\mathbf{0}\}$ or one of the $p+1$ lines. All three columns lie in a given line in p^3 ways, and a triple other than the zero triple lies in at most one line. So $1 + (p+1)\left(p^3-1\right)$ triples fail to span, and $p^6 - 1 - (p+1)\left(p^3-1\right) = p^6 - p^4 - p^3 + p = \left(p^3-1\right)\left(p^3-p\right)$ succeed.

The maps T_A with $A \in \mathbb{F}_p^{2\times 3}$ are all the linear maps $\mathbb{F}_p^3 \to \mathbb{F}_p^2$, each exactly once. By Corollary 2.6.24(b), T_A is surjective if and only if the columns $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$ span $\mathbb{F}_p^2$. There are p^6 matrices in all, so we count those whose columns do not span $\mathbb{F}_p^2$.

Lines. By Theorem 1.4.25, the span of the columns is $\{\mathbf{0}\}$, a line $\operatorname{span}(\mathbf{v})$ with $\mathbf{v} \neq \mathbf{0}$, or $\mathbb{F}_p^2$. A line $\operatorname{span}(\mathbf{v})$ consists of the p vectors $c\mathbf{v}$, $c \in \mathbb{F}_p$, which are distinct since $\mathbf{v} \neq \mathbf{0}$; so it has $p-1$ nonzero vectors. Two different lines share only $\mathbf{0}$: if $\mathbf{u} \neq \mathbf{0}$ lies on $\operatorname{span}(\mathbf{v})$, then $\mathbf{u} = c\mathbf{v}$ with $c \neq 0$, and $\operatorname{span}(\mathbf{u}) = \operatorname{span}(\mathbf{v})$ by Theorem 1.4.25. So the p^2-1 nonzero vectors of $\mathbb{F}_p^2$ are split among the lines, $p-1$ to a line, and there are $\left(p^2-1\right)/(p-1) = p+1$ lines.

Counting. The columns fail to span $\mathbb{F}_p^2$ exactly when all three lie in a common line (this includes the zero matrix, whose columns lie in every line). For a fixed line there are p^3 choices of three columns in it, one of which is the zero triple. A triple with a nonzero column $\mathbf{a}_j$ lies only in the line $\operatorname{span}(\mathbf{a}_j)$, so it is counted once. Hence the number of matrices whose columns do not span is

$$1 + (p+1)\left(p^3-1\right) = p^4 + p^3 - p,$$

and the number of surjective maps is

$$p^6 - p^4 - p^3 + p = \big(p^3 - 1\big)\big(p^3 - p\big).$$

For $p = 2$ this is $7 \cdot 6 = 42$ of the 64 linear maps $\mathbb{F}_2^3 \to \mathbb{F}_2^2$.

The factored form has its own meaning: $\big(p^3 - 1\big)\big(p^3 - p\big)$ is the number of ways to choose a nonzero first row and then a second row that is not a multiple of it, so it counts the 2×3 matrices with linearly independent rows. That the two counts agree is a first sign that row rank equals column rank (Section 4.3).

Solution to Exercise 2.6.46

Uses. Proposition 2.4.22 (Transpose is a linear involution), Definition 2.4.21 (Transpose), Definition 2.6.5 (Kernel), Definition 2.6.6 (Image)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Transposition is linear and $\big(A^{\mathsf{T}}\big)^{\mathsf{T}} = A$ (Proposition 2.4.22). For (b), compute $\Phi(A)^{\mathsf{T}}$, and for the converse try $A = 2^{-1}B$.
Hint 2. For (c), the (i, j) entry of $\Phi(A)$ over $\mathbb{F}_2$ is $a_{ij} + a_{ji}$. Given a symmetric B with zero diagonal, try A = the part of B strictly below the diagonal.
Sketch. (a) $\Phi(A) = 0$ iff $A^{\mathsf{T}} = A$. (b) $\Phi(A)^{\mathsf{T}} = -\Phi(A)$, and $\Phi(B/2) = B$ for skew-symmetric B. (c) Over $\mathbb{F}_2$, $\Phi(A) = A + A^{\mathsf{T}}$ is symmetric with diagonal entries $2a_{ii} = 0$; conversely $B = L + L^{\mathsf{T}} = \Phi(L)$ for the strictly lower part L of B. Over $\mathbb{F}_2$ skew-symmetric means symmetric, and I_n is symmetric but not in $\operatorname{im}\Phi$.

(a) By Proposition 2.4.22, $(cA + B)^{\mathsf{T}} = cA^{\mathsf{T}} + B^{\mathsf{T}}$, so

$$\Phi(cA + B) = cA + B - cA^{\mathsf{T}} - B^{\mathsf{T}} = c\Phi(A) + \Phi(B).$$

And $\Phi(A) = 0$ if and only if $A^{\mathsf{T}} = A$, that is, A is symmetric.

(b) For every A, $\Phi(A)^{\mathsf{T}} = A^{\mathsf{T}} - A = -\Phi(A)$, so $\operatorname{im}\Phi$ consists of skew-symmetric matrices. Conversely, let $B^{\mathsf{T}} = -B$. Since $2 = 1 + 1 \neq 0$,

$$\Phi\big(2^{-1}B\big) = 2^{-1}B - 2^{-1}B^{\mathsf{T}} = 2^{-1}B + 2^{-1}B = B.$$

So $\operatorname{im}\Phi$ is the set of skew-symmetric matrices.

(c) Over $\mathbb{F}_2$, $-1 = 1$, so $\Phi(A) = A + A^{\mathsf{T}}$, whose (i, j) entry is $a_{ij} + a_{ji}$. This is symmetric in i and j, and on the diagonal it is $a_{ii} + a_{ii} = 0$. Conversely, let B be symmetric with zero diagonal, and let L have entries $l_{ij} = b_{ij}$ for $i > j$ and $l_{ij} = 0$ for $i \leq j$. The (i, j) entry of $\Phi(L) = L + L^{\mathsf{T}}$ is $l_{ij} + l_{ji}$, which is b_{ij} if $i > j$, $b_{ji} = b_{ij}$ if $i < j$, and $0 = b_{ii}$ if $i = j$. So $\Phi(L) = B$, and $\operatorname{im}\Phi$ is exactly the set of symmetric matrices with zero diagonal.

Over $\mathbb{F}_2$, $B^{\mathsf{T}} = -B$ says the same thing as $B^{\mathsf{T}} = B$, so every symmetric matrix is skew-symmetric. In particular I_n is skew-symmetric, but its diagonal entries are 1, so $I_n \notin \operatorname{im}\Phi$. So the conclusion of (b) fails over $\mathbb{F}_2$, and the image is a proper subset of $\ker\Phi$.

Solution to Exercise 2.6.47

Uses. Proposition 2.4.14 (Algebra of matrices), Definition 2.6.5 (Kernel), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Hint 1. $\mathbf{x} \in \ker T_{I_n - BA}$ means $BA\mathbf{x} = \mathbf{x}$. Compute $AB(A\mathbf{x})$ by regrouping.
Hint 2. For (b), compose the two maps from (a) in both orders: $B(A\mathbf{x}) = BA\mathbf{x}$ and $A(B\mathbf{y}) = AB\mathbf{y}$.
Hint 3. For (c), a bijection between the two kernels matches $\{\mathbf{0}\}$ with $\{\mathbf{0}\}$.
Sketch. (a) If $BA\mathbf{x} = \mathbf{x}$, then $AB(A\mathbf{x}) = A(BA\mathbf{x}) = A\mathbf{x}$; symmetrically for $\mathbf{y}$. (b) On the kernels, $B(A\mathbf{x}) = BA\mathbf{x} = \mathbf{x}$ and $A(B\mathbf{y}) = AB\mathbf{y} = \mathbf{y}$, so the maps are mutually inverse. (c) The bijection sends $\mathbf{0}$ to $\mathbf{0}$, so one kernel is $\{\mathbf{0}\}$ iff the other is.

(a) Let $\mathbf{x} \in \ker T_{I_n - BA}$, that is, $\mathbf{x} - BA\mathbf{x} = \mathbf{0}$, or $BA\mathbf{x} = \mathbf{x}$. By associativity (Proposition 2.4.14),

$$AB(A\mathbf{x}) = A(BA\mathbf{x}) = A\mathbf{x},$$

so $(I_m - AB)(A\mathbf{x}) = \mathbf{0}$, and $A\mathbf{x} \in \ker T_{I_m - AB}$. In the same way, if $AB\mathbf{y} = \mathbf{y}$, then $BA(B\mathbf{y}) = B(AB\mathbf{y}) = B\mathbf{y}$, so $B\mathbf{y} \in \ker T_{I_n - BA}$.

(b) By (a), $f(\mathbf{x}) = A\mathbf{x}$ maps $K_1 = \ker T_{I_n - BA}$ into $K_2 = \ker T_{I_m - AB}$, and $g(\mathbf{y}) = B\mathbf{y}$ maps K_2 into K_1. For $\mathbf{x} \in K_1$, $g(f(\mathbf{x})) = BA\mathbf{x} = \mathbf{x}$, and for $\mathbf{y} \in K_2$, $f(g(\mathbf{y})) = AB\mathbf{y} = \mathbf{y}$. So f and g are inverse bijections between K_1 and K_2.

(c) The bijection f sends $\mathbf{0}$ to $\mathbf{0}$, so $K_1 = \{\mathbf{0}\}$ if and only if $K_2 = \{\mathbf{0}\}$. By Theorem 2.6.11, $T_{I_n - BA}$ is injective if and only if $T_{I_m - AB}$ is.

Compare Exercise 2.5.47, which produces an explicit inverse. In the language of Section 7.2, (b) says that AB and BA have "the same" eigenvectors for the eigenvalue 1; the same argument works for every nonzero eigenvalue.

Solution to Exercise 2.6.48

Uses. Example 2.6.7 (First kernels and images), Example 2.1.11 (Rotations, projections, and reflections), Proposition 2.5.28 (Inverse of a 2×2 matrix), Proposition 2.5.20 (Inverses and matrices), Definition 2.5.12 (Invertible)
Hint 1. By Example 2.6.7(d), every $\mathbf{v} = (x, y)$ is $\mathbf{v} = \alpha\mathbf{u} + \beta\mathbf{u}^\perp$ with $\alpha = x\cos\theta + y\sin\theta$, $\beta = y\cos\theta - x\sin\theta$, and $\mathbf{u}^\perp = (-\sin\theta, \cos\theta)$, and $\mathrm{Pr}_\ell(\mathbf{v}) = \alpha\mathbf{u}$.
Hint 2. So $(\mathrm{Pr}_\ell - \mathrm{id})(\mathbf{v}) = -\beta\mathbf{u}^\perp$. Express (b) and (c) through Pr_ℓ. For (d), use Proposition 2.5.28.
Sketch. With $\mathbf{v} = \alpha\mathbf{u} + \beta\mathbf{u}^\perp$: $(\mathrm{Pr}_\ell - \mathrm{id})(\mathbf{v}) = -\beta\mathbf{u}^\perp$, so kernel ℓ and image $\ell^\perp$. (b) $S_\ell - \mathrm{id} = 2(\mathrm{Pr}_\ell - \mathrm{id})$: same. (c) $S_\ell + \mathrm{id} = 2\,\mathrm{Pr}_\ell$: kernel $\ell^\perp$, image ℓ. (d) $ad - bc = (\cos\varphi - 1)^2 + \sin^2\varphi = 2 - 2\cos\varphi \neq 0$, so $R_\varphi - \mathrm{id}$ is invertible: kernel $\{\mathbf{0}\}$, image $\mathbb{R}^2$.

Write $c = \cos\theta$, $s = \sin\theta$, and $\mathbf{u}^\perp = (-s, c)$. By Example 2.6.7(d), every $\mathbf{v} = (x, y)$ satisfies $\mathbf{v} = \alpha\mathbf{u} + \beta\mathbf{u}^\perp$ with $\alpha = xc + ys$ and $\beta = yc - xs$, and $\mathrm{Pr}_\ell(\mathbf{v}) = \alpha\mathbf{u}$. Note that $\mathbf{v} = t\mathbf{u}$ gives $\beta = tsc - tcs = 0$, and $\mathbf{v} = t\mathbf{u}^\perp$ gives $\beta = tc^2 + ts^2 = t$.

(a) $(\mathrm{Pr}_\ell - \mathrm{id})(\mathbf{v}) = \alpha\mathbf{u} - \mathbf{v} = -\beta\mathbf{u}^\perp$. This is $\mathbf{0}$ if and only if $\beta = 0$, that is, $\mathbf{v} = \alpha\mathbf{u} \in \ell$; and every vector of ℓ has $\beta = 0$. So $\ker(\mathrm{Pr}_\ell - \mathrm{id}) = \ell$. Every value is a multiple of $\mathbf{u}^\perp$, and $(\mathrm{Pr}_\ell - \mathrm{id})\big(-t\mathbf{u}^\perp\big) = t\mathbf{u}^\perp$, so $\mathrm{im}(\mathrm{Pr}_\ell - \mathrm{id}) = \ell^\perp$.

(b) $S_\ell - \mathrm{id} = 2\,\mathrm{Pr}_\ell - 2\,\mathrm{id} = 2(\mathrm{Pr}_\ell - \mathrm{id})$. Multiplying a map by the nonzero scalar 2 changes neither its kernel nor its image, so the kernel is ℓ and the image is $\ell^\perp$: the reflection fixes ℓ and moves every other vector by a multiple of $\mathbf{u}^\perp$.

(c) $S_\ell + \mathrm{id} = 2\,\mathrm{Pr}_\ell$, so by Example 2.6.7(d) its kernel is $\ker \mathrm{Pr}_\ell = \ell^\perp$ and its image is $\mathrm{im}\,\mathrm{Pr}_\ell = \ell$.

(d) By Example 2.1.11, $R_\varphi - \mathrm{id}$ has matrix $\begin{pmatrix} \cos\varphi - 1 & -\sin\varphi \\ \sin\varphi & \cos\varphi - 1 \end{pmatrix}$, with $ad - bc = (\cos\varphi - 1)^2 + \sin^2\varphi = 2 - 2\cos\varphi$. Since φ is not a multiple of 2π, $\cos\varphi \neq 1$, so this is nonzero, and the matrix is invertible by Proposition 2.5.28, so $R_\varphi - \mathrm{id}$ is invertible (Proposition 2.5.20(c)). An invertible map is bijective, so $\ker\big(R_\varphi - \mathrm{id}\big) = \{\mathbf{0}\}$ and $\mathrm{im}\big(R_\varphi - \mathrm{id}\big) = \mathbb{R}^2$. Geometrically, a nontrivial rotation fixes only the origin.

Solution to Exercise 2.6.49

Uses. Definition 2.6.5 (Kernel), Proposition 2.1.24 (Algebra of composition), Proposition 1.2.35 (Zero products)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Look for the three pieces as combinations of $\mathbf{v}$, $T(\mathbf{v})$, and $T^2(\mathbf{v})$. The piece in $\ker T$ must be killed by T, and $T\big(\mathbf{v} - T^2(\mathbf{v})\big) = T(\mathbf{v}) - T^3(\mathbf{v}) = \mathbf{0}$.
Hint 2. Try $\mathbf{v}_\pm = 2^{-1}\big(T^2(\mathbf{v}) \pm T(\mathbf{v})\big)$. Where do these come from? When $2 \neq 0$, the identity $1 = \big(1 - x^2\big) + \big(x^2 + x\big)/2 + \big(x^2 - x\big)/2$ splits 1 along the roots $0, 1, -1$ of $x^3 - x$: each term is 1 at one root and 0 at the other two.
Hint 3. For (b), suppose $\mathbf{v}_0 + \mathbf{v}_+ + \mathbf{v}_- = \mathbf{0}$ and apply T, then T again.
Sketch. (a) $\mathbf{v}_0 = \mathbf{v} - T^2\mathbf{v}$, $\mathbf{v}_\pm = 2^{-1}\big(T^2\mathbf{v} \pm T\mathbf{v}\big)$; these add up to $\mathbf{v}$, and $T^3 = T$ shows $T\mathbf{v}_0 = \mathbf{0}$ and $T\mathbf{v}_\pm = \pm\mathbf{v}_\pm$. (b) If the three pieces add to $\mathbf{0}$, applying T gives $\mathbf{v}_+ - \mathbf{v}_- = \mathbf{0}$, and applying T twice gives $\mathbf{v}_+ + \mathbf{v}_- = \mathbf{0}$; as $2 \neq 0$, all pieces are $\mathbf{0}$. (c) $A^2 = I$ over $\mathbb{F}_2$, so $A^3 = A$, but $\ker T_A = \{\mathbf{0}\}$ and $\ker T_{A-I} = \ker T_{A+I} = \mathrm{span}(\mathbf{e}_1)$, which do not add up to $\mathbb{F}_2^2$.

(a) Write $T\mathbf{v}$ for $T(\mathbf{v})$, and let

$$\mathbf{v}_0 = \mathbf{v} - T^2\mathbf{v}, \quad \mathbf{v}_+ = 2^{-1}\big(T^2\mathbf{v} + T\mathbf{v}\big), \quad \mathbf{v}_- = 2^{-1}\big(T^2\mathbf{v} - T\mathbf{v}\big).$$

Then $\mathbf{v}_0 + \mathbf{v}_+ + \mathbf{v}_- = \mathbf{v} - T^2\mathbf{v} + T^2\mathbf{v} = \mathbf{v}$. Using $T^3 = T$,

$$T\mathbf{v}_0 = T\mathbf{v} - T^3\mathbf{v} = \mathbf{0},$$

$$T\mathbf{v}_+ = 2^{-1}\big(T^3\mathbf{v} + T^2\mathbf{v}\big) = 2^{-1}\big(T\mathbf{v} + T^2\mathbf{v}\big) = \mathbf{v}_+,$$
$$T\mathbf{v}_- = 2^{-1}\big(T^3\mathbf{v} - T^2\mathbf{v}\big) = 2^{-1}\big(T\mathbf{v} - T^2\mathbf{v}\big) = -\mathbf{v}_-.$$

So $\mathbf{v}_0 \in \ker T$, $\mathbf{v}_+ \in \ker(T - \mathrm{id})$, and $\mathbf{v}_- \in \ker(T + \mathrm{id})$.

(b) It suffices to show that if $\mathbf{z}_0 + \mathbf{z}_+ + \mathbf{z}_- = \mathbf{0}$ with $\mathbf{z}_0 \in \ker T$ and $T\mathbf{z}_\pm = \pm\mathbf{z}_\pm$, then all three are $\mathbf{0}$: the difference of two decompositions of $\mathbf{v}$ is such a decomposition of $\mathbf{0}$, since each of the three kernels is a subspace. Applying T gives $\mathbf{z}_+ - \mathbf{z}_- = \mathbf{0}$, and applying T once more gives $\mathbf{z}_+ + \mathbf{z}_- = \mathbf{0}$. Adding, $2\mathbf{z}_+ = \mathbf{0}$, so $\mathbf{z}_+ = \mathbf{0}$ because $2 \neq 0$ (Proposition 1.2.35). Then $\mathbf{z}_- = \mathbf{0}$, and $\mathbf{z}_0 = \mathbf{0}$.

(c) Over $\mathbb{F}_2$, $A^2 = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = I_2$, so $A^3 = A$. Since A is invertible, $\ker T_A = \{\mathbf{0}\}$. Also $-1 = 1$, so $A - I_2 = A + I_2 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, whose kernel is $\mathrm{span}(\mathbf{e}_1)$. Every sum $\mathbf{v}_0 + \mathbf{v}_+ + \mathbf{v}_-$ as in (a) therefore lies in $\mathrm{span}(\mathbf{e}_1)$, and $\mathbf{e}_2$ has no such decomposition.

The polynomial identity in the second hint is Lagrange interpolation (Proposition 3.4.27) at the points $0, 1, -1$. Decompositions of this kind, along the roots of a polynomial that T satisfies, are the subject of Section 7.4.

Solution to Exercise 2.6.50

> *Uses.* Proposition 1.4.20 (Unions of two subspaces), Proposition 2.6.8 (Kernels and images are subspaces), Proposition 1.2.35 (Zero products)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18), Induction on the length of a list (Technique 1.6.9)
> *Hint 1.* (a) asks for a vector outside $\ker S \cup \ker T$. When can a union of two subspaces be all of V?
> *Hint 2.* (b) $\mathbb{F}_2^2$ has three lines through $\mathbf{0}$.
> *Hint 3.* (c) Induct on k. Given $\mathbf{v}$ that works for $T_1, \ldots, T_{k-1}$ and $\mathbf{u}$ with $T_k(\mathbf{u}) \neq \mathbf{0}$, look at the line $\mathbf{v} + t\mathbf{u}$, $t \in F$. For how many t can $T_i(\mathbf{v} + t\mathbf{u}) = \mathbf{0}$?
> *Sketch.* (a) $\ker S$ and $\ker T$ are proper subspaces, and if their union were V it would be a subspace, so one contains the other (Proposition 1.4.20) and equals V. (b) x, y, $x + y$. (c) Induct: for each $i \leq k$, $T_i(\mathbf{v} + t\mathbf{u}) = T_i(\mathbf{v}) + tT_i(\mathbf{u})$ vanishes for at most one t, since two such t would give $T_i(\mathbf{u}) = \mathbf{0}$ and then $T_i(\mathbf{v}) = \mathbf{0}$. So at most k values of t are bad, and F is infinite.

(a) Since $S \neq 0$ and $T \neq 0$, the kernels $\ker S$ and $\ker T$ are subspaces of V (Proposition 2.6.8) different from V. Suppose $\ker S \cup \ker T = V$. Then the union is a subspace, so by Proposition 1.4.20 one kernel contains the other, and the union is the larger kernel. That kernel would be V, a contradiction. So some $\mathbf{v}$ lies in neither kernel.

(b) Let $T_1(x, y) = x$, $T_2(x, y) = y$, and $T_3(x, y) = x + y$. Then $(0, 0)$ lies in every kernel, $(1, 0) \in \ker T_2$, $(0, 1) \in \ker T_1$, and $(1, 1) \in \ker T_3$, since $1 + 1 = 0$. These are all the vectors of $\mathbb{F}_2^2$.

(c) We induct on k. For $k = 1$, $T_1 \neq 0$ means that $T_1(\mathbf{v}) \neq \mathbf{0}$ for some $\mathbf{v}$. Let $k \geq 2$, and suppose by induction that $\mathbf{v}$ satisfies $T_i(\mathbf{v}) \neq \mathbf{0}$ for $i = 1, \ldots, k-1$. Choose $\mathbf{u}$ with $T_k(\mathbf{u}) \neq \mathbf{0}$, and consider the vectors $\mathbf{v} + t\mathbf{u}$ for $t \in F$.

Claim: for each $i \in \{1, \ldots, k\}$, there is at most one $t \in F$ with $T_i(\mathbf{v} + t\mathbf{u}) = \mathbf{0}$. Suppose $t \neq t'$ both work. Then

$$\mathbf{0} = T_i(\mathbf{v} + t\mathbf{u}) - T_i(\mathbf{v} + t'\mathbf{u}) = (t - t')T_i(\mathbf{u}),$$

so $T_i(\mathbf{u}) = \mathbf{0}$ by Proposition 1.2.35, and then $T_i(\mathbf{v}) = T_i(\mathbf{v} + t\mathbf{u}) = \mathbf{0}$. For $i = k$ this contradicts $T_k(\mathbf{u}) \neq \mathbf{0}$, and for $i < k$ it contradicts $T_i(\mathbf{v}) \neq \mathbf{0}$.

So at most k values of t are excluded. Since F is infinite, some t is not excluded, and $\mathbf{v} + t\mathbf{u}$ is the required vector.

The proof of (c) only needs F to have more than k elements at the kth step, so the statement holds for k maps over any field with more than k elements; (b) shows that some such bound is needed. Every proper subspace U of a finite-dimensional space V is the kernel of a nonzero operator on V (Exercise 2.2.35).

Applied to such operators, (c) says that over an infinite field a finite-dimensional vector space is never the union of finitely many proper subspaces.

Solution to Exercise 2.6.51

Uses. Theorem 1.4.3 (Subspace criterion), Notation 2.6.30 (Preimages), Proposition 1.4.24 (The sum of two subspaces), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. (a) is the proof of Proposition 2.6.8 with $\{\mathbf{0}\}$ replaced by U and V replaced by X.
Hint 2. (c) If $T(\mathbf{v}) = T(\mathbf{x})$ with $\mathbf{x} \in X$, then $\mathbf{v} - \mathbf{x} \in \ker T$.
Sketch. (a) $T(\mathbf{0}) = \mathbf{0}$, and $T(\mathbf{x} + \mathbf{x}') = T(\mathbf{x}) + T(\mathbf{x}')$, $T(a\mathbf{x}) = aT(\mathbf{x})$ give closure for both sets; $\ker T = T^{-1}(\mathbf{0}) \subseteq T^{-1}(U)$. (b) A value $T(\mathbf{v})$ with $T(\mathbf{v}) \in U$ lies in $U \cap \operatorname{im} T$, and $\mathbf{w} = T(\mathbf{v}) \in U$ comes from $\mathbf{v} \in T^{-1}(U)$. (c) $T(\mathbf{x} + \mathbf{z}) = T(\mathbf{x})$ for $\mathbf{z} \in \ker T$, and $T(\mathbf{v}) = T(\mathbf{x})$ gives $\mathbf{v} = \mathbf{x} + (\mathbf{v} - \mathbf{x})$.

(a) $\operatorname{im}(T\restriction_X)$ contains $T(\mathbf{0}) = \mathbf{0}$ (Proposition 2.1.4), and for $\mathbf{x}, \mathbf{x}' \in X$ and $a \in F$, $T(\mathbf{x}) + T(\mathbf{x}') = T(\mathbf{x} + \mathbf{x}')$ and $aT(\mathbf{x}) = T(a\mathbf{x})$ lie in $\operatorname{im}(T\restriction_X)$ because $\mathbf{x} + \mathbf{x}', a\mathbf{x} \in X$. So $\operatorname{im}(T\restriction_X)$ is a subspace by Theorem 1.4.3. Similarly, $T(\mathbf{0}) = \mathbf{0} \in U$, so $\mathbf{0} \in T^{-1}(U)$, and if $T(\mathbf{v}), T(\mathbf{v}') \in U$, then $T(\mathbf{v} + \mathbf{v}') = T(\mathbf{v}) + T(\mathbf{v}') \in U$ and $T(a\mathbf{v}) = aT(\mathbf{v}) \in U$. So $T^{-1}(U)$ is a subspace. Since $\mathbf{0} \in U$, $\ker T = T^{-1}(\mathbf{0}) \subseteq T^{-1}(U)$.

(b) An element of $\operatorname{im}\left(T\restriction_{T^{-1}(U)}\right)$ has the form $T(\mathbf{v})$ with $T(\mathbf{v}) \in U$, so it lies in U and in $\operatorname{im} T$. Conversely, if $\mathbf{w} \in U \cap \operatorname{im} T$, then $\mathbf{w} = T(\mathbf{v})$ for some $\mathbf{v}$, and $T(\mathbf{v}) = \mathbf{w} \in U$ means $\mathbf{v} \in T^{-1}(U)$, so $\mathbf{w} \in \operatorname{im}\left(T\restriction_{T^{-1}(U)}\right)$.

(c) If $\mathbf{x} \in X$ and $\mathbf{z} \in \ker T$, then $T(\mathbf{x} + \mathbf{z}) = T(\mathbf{x}) \in \operatorname{im}(T\restriction_X)$, so $\mathbf{x} + \mathbf{z} \in T^{-1}(\operatorname{im}(T\restriction_X))$. Conversely, if $T(\mathbf{v}) \in \operatorname{im}(T\restriction_X)$, then $T(\mathbf{v}) = T(\mathbf{x})$ for some $\mathbf{x} \in X$, so $\mathbf{z} = \mathbf{v} - \mathbf{x} \in \ker T$, and $\mathbf{v} = \mathbf{x} + \mathbf{z} \in X + \ker T$.

By (b), $\operatorname{im}\left(T\restriction_{T^{-1}(U)}\right) = U$ exactly when $U \subseteq \operatorname{im} T$, and by (c), $T^{-1}(\operatorname{im}(T\restriction_X)) = X$ exactly when $\ker T \subseteq X$. So taking images and preimages are inverse operations between the subspaces of V containing $\ker T$ and the subspaces of $\operatorname{im} T$.

Solution to Exercise 2.6.52

Uses. Definition 2.6.5 (Kernel), Definition 2.6.6 (Image), Proposition 2.1.24 (Algebra of composition)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For $\mathbf{v} \in \ker T$, compute $T(S(\mathbf{v}))$ using $TS = ST$. For $\mathbf{w} = T(\mathbf{v})$, rewrite $S(\mathbf{w})$ as a value of T.
Hint 2. For (b), T commutes with $T - \lambda \operatorname{id}$. For (c), use a swap and a projection on F^2.
Sketch. (a) $T(S(\mathbf{v})) = S(T(\mathbf{v})) = S(\mathbf{0}) = \mathbf{0}$, and $S(T(\mathbf{v})) = T(S(\mathbf{v})) \in \operatorname{im} T$. (b) $T(T - \lambda \operatorname{id}) = T^2 - \lambda T = (T - \lambda \operatorname{id})T$. (c) $S(x, y) = (y, x)$ and $T(x, y) = (x, 0)$: $\ker T = \operatorname{span}(\mathbf{e}_2)$, but $S(\mathbf{e}_2) = \mathbf{e}_1 \notin \ker T$.

(a) If $\mathbf{v} \in \ker T$, then $T(S(\mathbf{v})) = S(T(\mathbf{v})) = S(\mathbf{0}) = \mathbf{0}$, so $S(\mathbf{v}) \in \ker T$. If $\mathbf{w} = T(\mathbf{v}) \in \operatorname{im} T$, then $S(\mathbf{w}) = S(T(\mathbf{v})) = T(S(\mathbf{v})) \in \operatorname{im} T$.

(b) By Proposition 2.1.24, $T(T - \lambda \operatorname{id}) = T^2 - \lambda T = (T - \lambda \operatorname{id})T$. Apply (a) with $T - \lambda \operatorname{id}$ in place of T and T in place of S.

(c) On F^2, let $S(x, y) = (y, x)$ and $T(x, y) = (x, 0)$. Then $\ker T = \operatorname{span}(\mathbf{e}_2)$ and $\operatorname{im} T = \operatorname{span}(\mathbf{e}_1)$, but $S(\mathbf{e}_2) = \mathbf{e}_1 \notin \ker T$ and $S(\mathbf{e}_1) = \mathbf{e}_2 \notin \operatorname{im} T$. Indeed $ST(x, y) = (0, x)$ while $TS(x, y) = (y, 0)$.

In the language of Section 7.2, (b) says that eigenspaces of T are invariant under T, and (a) that they are invariant under everything that commutes with T.

Section 2.7

Solution to Exercise 2.7.6

Uses. Proposition 2.5.4 (Left inverses give uniqueness), Definition 2.6.1 (Injective), Definition 2.4.1 (Matrix product)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Prove (i) ⇒ (ii) ⇒ (iii) ⇒ (i). The last step is Proposition 2.5.4.
Hint 2. For (ii) ⇒ (iii), some entry a_k of $\mathbf{a}$ is nonzero. Find a row $\mathbf{c}$ that reads off a_k and divides by it.
Sketch. (i) ⇒ (ii): $T_{\mathbf{a}}(1) = \mathbf{a}$ and $T_{\mathbf{a}}(0) = \mathbf{0}$, so $\mathbf{a} = \mathbf{0}$ would contradict injectivity. (ii) ⇒ (iii): if $a_k \neq 0$, the row $\mathbf{c} = a_k^{-1}\mathbf{e}_k^{\mathsf{T}}$ has $\mathbf{ca} = a_k^{-1}a_k = 1$. (iii) ⇒ (i): left-invertible maps are injective. The construction is (ii) ⇒ (iii).

We prove (i) ⇒ (ii) ⇒ (iii) ⇒ (i).

(i) ⇒ (ii). $T_{\mathbf{a}}(1) = \mathbf{a}$ and $T_{\mathbf{a}}(0) = \mathbf{0}$. If $\mathbf{a} = \mathbf{0}$, these are two different inputs with the same value, so $T_{\mathbf{a}}$ would not be injective (Definition 2.6.1).

(ii) ⇒ (iii). Since $\mathbf{a} \neq \mathbf{0}$, some entry a_k is nonzero. Let $\mathbf{c} \in F^{1\times m}$ be the row with entry a_k^{-1} in position k and 0 elsewhere. By Definition 2.4.1, $\mathbf{ca} = a_k^{-1}a_k = 1$.

(iii) ⇒ (i). If $\mathbf{ca} = 1$, then $T_{\mathbf{c}}$ is a left inverse of $T_{\mathbf{a}}$, since $\mathbf{c}(x\mathbf{a}) = x(\mathbf{ca}) = x$. So $T_{\mathbf{a}}$ is injective by Proposition 2.5.4.

The step (ii) ⇒ (iii) produces the left inverse, so it is the case $n = 1$ of the construction in part 3. Run on the single column $\mathbf{a}$, that construction appends every $\mathbf{e}_i$ except $\mathbf{e}_k$ for the *last* index k with $a_k \neq 0$, and it produces exactly the row $\mathbf{c} = a_k^{-1}\mathbf{e}_k^{\mathsf{T}}$.

Solution to Exercise 2.7.13

> *Uses.* Proposition 2.5.28 (Inverse of a 2×2 matrix), Proposition 2.5.20 (Inverses and matrices), Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.7.8 (Third Fundamental Theorem)
> *Hint 1.* Treat the two cases $ad - bc \neq 0$ and $ad - bc = 0$ separately. In each case, Proposition 2.5.28 tells you which inverses A has.
> *Hint 2.* If $ad - bc = 0$, A has no left inverse. Which condition of Theorem 2.7.2 fails, and what does that say about (I)?
> *Sketch.* If $\Delta = ad - bc \neq 0$, then A is invertible, so T_A is invertible and hence injective and surjective (Theorem 2.7.8). If $\Delta = 0$, then A has no left and no right inverse, so neither does T_A; (V) fails in Theorem 2.7.2 and Theorem 2.7.4, so (I) fails in both: T_A is neither injective nor surjective. In both cases the three statements have the same truth value.

Let $\Delta = ad - bc$. By Proposition 2.5.20(c), A has a left inverse, a right inverse, or an inverse exactly when T_A does.

If $\Delta \neq 0$, then A is invertible by Proposition 2.5.28(a), so T_A is invertible, and by Theorem 2.7.8 it is bijective. So all three statements hold.

If $\Delta = 0$, then by Proposition 2.5.28(b), A has neither a left nor a right inverse, so neither does T_A. Condition (V) of Theorem 2.7.2 fails, so (I) fails: T_A is not injective. Condition (V) of Theorem 2.7.4 fails, so T_A is not surjective. So all three statements fail.

The second case used (I) ⇒ (V) in both theorems, in contrapositive form. Without the constructions of this section, we would only know that A has no inverse on either side.

Solution to Exercise 2.7.15

> *Uses.* Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.4.2 (The matrix of a composite), Proposition 2.5.26 (One-sided inverses of composites)
> *Techniques.* Proving TFAE (Technique 2.7.1)
> *Hint 1.* Translate "the columns span" into a condition of Theorem 2.7.4 in which products are easy to handle.
> *Hint 2.* Use (I): $T_{AB} = T_A \circ T_B$. Or use (V): right inverses of a product.
> *Sketch.* By Theorem 2.7.4, T_A and T_B are surjective. $T_{AB} = T_A \circ T_B$ is then surjective: given $\mathbf{y}$, pick $\mathbf{z}$ with $A\mathbf{z} = \mathbf{y}$ and $\mathbf{x}$ with $B\mathbf{x} = \mathbf{z}$. So the columns of AB span F^m.

By Theorem 2.7.4, (III) ⇒ (I), $T_A : F^n \to F^m$ and $T_B : F^p \to F^n$ are surjective. Let $\mathbf{y} \in F^m$. There is $\mathbf{z} \in F^n$ with $A\mathbf{z} = \mathbf{y}$, and then $\mathbf{x} \in F^p$ with $B\mathbf{x} = \mathbf{z}$, so $(AB)\mathbf{x} = A(B\mathbf{x}) = \mathbf{y}$. Thus T_{AB} is surjective, and by (I) ⇒ (III) for AB, the columns of AB span F^m.

Alternatively, by (V), there are $C \in F^{n\times m}$ and $D \in F^{p\times n}$ with $AC = I_m$ and $BD = I_n$. Then $(AB)(DC) = A(BD)C = AC = I_m$ (Proposition 2.5.26(a)), so AB has a right inverse, which is (V) for AB.

Solution to Exercise 2.7.19

> *Uses.* Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.7.8 (Third Fundamental Theorem)
> *Techniques.* Proving TFAE (Technique 2.7.1)
> *Hint 1.* For injectivity, look for a nonzero vector in the kernel, or show that there is none. For surjectivity, try to solve $A\mathbf{x} = \mathbf{y}$ for a general $\mathbf{y}$, or find a condition that every value $A\mathbf{x}$ satisfies.
> *Hint 2.* (b) Compare the second entry of $A\mathbf{x}$ with i times the first. (d) Try $\mathbf{x} = (1, 1, 1)$.

Sketch. (a) Every column is a multiple of $(1,2)$: $(2,-1,0) \in \ker$ and $(1,0) \notin \operatorname{im}$, so no theorem applies. (b) $A(x,y) = (x+iy, ix-y, y)$ is $\mathbf{0}$ only for $x = y = 0$, and its second entry is always i times the first; only the first theorem applies. (c) $A\mathbf{x} = \mathbf{y}$ has the unique solution $x_1 = y_2$, $x_2 = y_1 + y_2$; all three apply. (d) $A\mathbf{x} = \mathbf{y}$ is solved by $(y_1 + y_2, y_2, 0)$, and $(1,1,1) \in \ker$; only the second applies.

(a) The columns are $(1,2)$, $2(1,2)$, and $3(1,2)$. So $A(2,-1,0) = 2(1,2) - 2(1,2) = \mathbf{0}$, and condition (IV) of Theorem 2.7.2 fails. Every value $A\mathbf{x}$ is a multiple of $(1,2)$, and $(1,0)$ is not ($t(1,2) = (1,0)$ forces $t = 1$ and $2t = 0$), so condition (I) of Theorem 2.7.4 fails. Since T_A is not injective, Theorem 2.7.8 fails as well.

(b) $A(x,y) = (x+iy, ix-y, y)$. If this is $\mathbf{0}$, the third entry gives $y = 0$ and then the first gives $x = 0$, so (IV) of Theorem 2.7.2 holds. The second entry is $ix - y = i(x+iy)$, i times the first, for every (x,y). The vector $(0,1,0)$ fails this, so it is not a value, and Theorem 2.7.4 and Theorem 2.7.8 fail.

(c) Over $\mathbb{F}_2$, $A\mathbf{x} = \mathbf{y}$ reads $x_1 + x_2 = y_1$, $x_1 = y_2$, whose only solution is $x_1 = y_2$, $x_2 = y_1 - y_2 = y_1 + y_2$. So (II) of Theorem 2.7.8 holds, and all three theorems apply. The inverse is $\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$; check: $\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = I_2$ in $\mathbb{F}_2$.

(d) Over $\mathbb{F}_3$, $A\mathbf{x} = \mathbf{y}$ reads $x_1 + 2x_2 = y_1$, $x_2 + 2x_3 = y_2$. Taking $x_3 = 0$ gives the solution $(y_1 - 2y_2, y_2, 0) = (y_1 + y_2, y_2, 0)$, so (II) of Theorem 2.7.4 holds. But $A(1,1,1) = (1+2, 1+2) = (0,0)$ in $\mathbb{F}_3$, so (IV) of Theorem 2.7.2 fails, and with it Theorem 2.7.8.

Solution to Exercise 2.7.20

Uses. Corollary 2.7.16 (The Fundamental Theorems for linear maps), Theorem 2.7.8 (Third Fundamental Theorem), Definition 2.3.1 (Matrix of a linear map)
Hint 1. Compute the matrix in the bases $1, x, x^2$ and $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$, or directly the values on $p = a + bx + cx^2$.
Hint 2. For (b), $(Dp)(1) = b + 2c$. What happens when $2 = 0$ in F?
Sketch. (a) $T(a + bx + cx^2) = (a, b, a+b+c)$, and $T(p) = (y_1, y_2, y_3)$ has the unique solution $a = y_1$, $b = y_2$, $c = y_3 - y_1 - y_2$; so $T^{-1}(\mathbf{y}) = y_1 + y_2 x + (y_3 - y_1 - y_2)x^2$. (b) $U(a + bx + cx^2) = (a, b, b + 2c)$. If $2 \neq 0$, solve uniquely with $c = 2^{-1}(y_3 - y_2)$; if $2 = 0$, then $U(x^2) = \mathbf{0}$, so U is not injective.

Write $p = a + bx + cx^2$, so that $Dp = b + 2cx$.

(a) $T(p) = (a, b, a+b+c)$, and the matrix of T in the bases $1, x, x^2$ and $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ has columns $T(1) = (1,0,1)$, $T(x) = (0,1,1)$, $T(x^2) = (0,0,1)$. The equation $T(p) = (y_1, y_2, y_3)$, that is, $[T](a,b,c) = (y_1, y_2, y_3)$, has exactly one solution,

$$a = y_1, \quad b = y_2, \quad c = y_3 - y_1 - y_2.$$

No division occurred, so this holds over every field. By Theorem 2.7.8, (II) $\Rightarrow$ (III), the columns of $[T]$ form a basis of F^3, and by Corollary 2.7.16(c), T is invertible, with

$$T^{-1}(y_1, y_2, y_3) = y_1 + y_2 x + (y_3 - y_1 - y_2)x^2.$$

Check: this polynomial has value y_1 at 0, derivative y_2 at 0, and value $y_1 + y_2 + y_3 - y_1 - y_2 = y_3$ at 1.

(b) $U(p) = (a, b, b + 2c)$. If $2 \neq 0$ in F, then $U(p) = (y_1, y_2, y_3)$ has exactly one solution, $a = y_1$, $b = y_2$, $c = 2^{-1}(y_3 - y_2)$, and as in (a), U is invertible. If $2 = 0$, that is, if F has characteristic 2, then $U(x^2) = (0,0,0)$, so U is not injective (Theorem 2.6.11) and not invertible. So U is invertible exactly when $1 + 1 \neq 0$ in F.

Solution to Exercise 2.7.21

Uses. Corollary 2.6.24 (The columns decide), Example 2.7.5 (A tall matrix)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Proving TFAE (Technique 2.7.1)
Hint 1. Draw the four statements as points and the proved implications as arrows. Can you get from (i) to (iii)?
Hint 2. For a counterexample, look for a map that is injective but not surjective, such as the one in Example 2.7.5.
Sketch. The proof only links (i) with (ii) and (iii) with (iv); no implication connects the two pairs. The claim is false: $A = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ gives an injective $T_A(x) = (x, 0)$ that is not surjective.

The two equivalences are correct, but they form two separate groups: no proved implication leads from (i) or (ii) to (iii) or (iv), or back. So nothing has been shown about, say, (i) versus (iii).

The claim is in fact false. For $A = \begin{pmatrix}1\\0\end{pmatrix} \in F^{2\times 1}$, $T_A(x) = (x, 0)$ is injective, since $(x, 0) = \mathbf{0}$ forces $x = 0$, but not surjective, since $(0, 1)$ is not a value. Example 2.7.5 is another example. (For square matrices the claim is true, but its proof needs Section 3.5; see Corollary 3.5.25.)

Solution to Exercise 2.7.22

> *Uses.* Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Corollary 2.5.11 (Many one-sided inverses), Proposition 2.5.20 (Inverses and matrices), Proposition 2.6.15 (Kernels and images of composites), Theorem 2.4.2 (The matrix of a composite), Example 2.5.27 (An invertible product of non-invertible factors)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* (a) and (c) are false; look for small non-square matrices.
> *Hint 2.* (b) Two different left inverses rule out a right inverse (Corollary 2.5.11). Which theorem turns "no right inverse" into a statement about surjectivity?
> *Hint 3.* (d) $T_{AB} = T_A \circ T_B$. What does Proposition 2.6.15(c) say?
> *Sketch.* (a) False: $A = \begin{pmatrix}1\\0\end{pmatrix}$. (b) True: no right inverse, so by Theorem 2.7.4, (I) $\Rightarrow$ (V), T_A is not surjective. (c) False: $A = \begin{pmatrix}1 & 0\end{pmatrix}$, $B = \begin{pmatrix}1\\0\end{pmatrix}$, $AB = (1)$. (d) True: $T_A \circ T_B$ bijective makes T_A surjective and T_B injective; translate with (I) $\Leftrightarrow$ (III).

(a) False. For $A = \begin{pmatrix}1\\0\end{pmatrix} \in F^{2\times 1}$, $Ax = (x, 0) = \mathbf{0}$ only for $x = 0$, but $Ax = (0, 1)$ has no solution.

(b) True. By Corollary 2.5.11, a matrix with two different left inverses has no right inverse, and by Proposition 2.5.20(c) neither does T_A. So condition (V) of Theorem 2.7.4 fails, and therefore so does (I): T_A is not surjective. This uses the implication (I) $\Rightarrow$ (V) of Theorem 2.7.4.

(c) False. With $A = \begin{pmatrix}1 & 0\end{pmatrix}$ and $B = \begin{pmatrix}1\\0\end{pmatrix}$, $AB = (1) = I_1$, so $T_{AB} = \mathrm{id}_F$ is bijective, but $T_A(x, y) = x$ is not injective and $T_B(x) = (x, 0)$ is not surjective (Example 2.5.27).

(d) True. $T_{AB} = T_A \circ T_B$ by Theorem 2.4.2. Since this composite is injective, T_B is injective, and since it is surjective, T_A is surjective (Proposition 2.6.15(c)). By Theorem 2.7.2 and Theorem 2.7.4, (I) $\Rightarrow$ (III), the columns of B are linearly independent and the columns of A span F^m.

Solution to Exercise 2.7.23

> *Uses.* Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence), Definition 2.5.12 (Invertible)
> *Techniques.* Proving TFAE (Technique 2.7.1)
> *Hint 1.* (iv) is the strongest statement, so make it the hub: prove that (i) and (ii) each imply (iv), and that (iv) implies the rest.
> *Hint 2.* For (i) $\Rightarrow$ (iv), compute $P(P\mathbf{v} - \mathbf{v})$. For (ii) $\Rightarrow$ (iv), write a vector as $P\mathbf{w}$ and apply P.
> *Sketch.* (iv) $\Rightarrow$ (iii) $\Rightarrow$ (i) and (iii) $\Rightarrow$ (ii) hold for every operator. (i) $\Rightarrow$ (iv): $P(P\mathbf{v} - \mathbf{v}) = P^2\mathbf{v} - P\mathbf{v} = \mathbf{0}$, so $P\mathbf{v} = \mathbf{v}$. (ii) $\Rightarrow$ (iv): if $\mathbf{v} = P\mathbf{w}$, then $P\mathbf{v} = P^2\mathbf{w} = P\mathbf{w} = \mathbf{v}$.

We prove (iv) $\Rightarrow$ (iii), (iii) $\Rightarrow$ (i), (iii) $\Rightarrow$ (ii), (i) $\Rightarrow$ (iv), and (ii) $\Rightarrow$ (iv). From each statement one can reach (iv) and from (iv) every statement, so this suffices.

(iv) $\Rightarrow$ (iii). id_V is invertible, with inverse id_V.

(iii) $\Rightarrow$ (i) and (iii) $\Rightarrow$ (ii). An invertible map has a left inverse and a right inverse (Definition 2.5.12), so it is injective (Proposition 2.5.4) and surjective (Proposition 2.5.5).

(i) $\Rightarrow$ (iv). Let $\mathbf{v} \in V$. Then $P(P\mathbf{v} - \mathbf{v}) = P^2\mathbf{v} - P\mathbf{v} = P\mathbf{v} - P\mathbf{v} = \mathbf{0}$, so $P\mathbf{v} - \mathbf{v} \in \ker P = \{\mathbf{0}\}$ (Theorem 2.6.11). Hence $P\mathbf{v} = \mathbf{v}$ for every $\mathbf{v}$, that is, $P = \mathrm{id}_V$.

(ii) $\Rightarrow$ (iv). Let $\mathbf{v} \in V$. Since P is surjective, $\mathbf{v} = P\mathbf{w}$ for some $\mathbf{w}$, and $P\mathbf{v} = P^2\mathbf{w} = P\mathbf{w} = \mathbf{v}$. So $P = \mathrm{id}_V$.

No basis was used, so the result holds in every vector space. Without the hypothesis $P^2 = P$, (i) and (ii) are not equivalent for operators on $F[x]$ (Example 2.6.4(e)).

Solution to Exercise 2.7.24

> *Uses.* Definition 2.5.1 (Left inverse), Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.6.18 (The column space is spanned by the columns)

Hint 1. Compare the domain of R with the domain that Definition 2.5.1 requires of a left inverse of $T_A : F^n \to F^m$.
Hint 2. To repair the argument, R has to be extended from $\operatorname{im} T_A$ to a linear map on all of F^m. The columns of A form a basis of $\operatorname{im} T_A$. What does part 3 of the proof of Theorem 2.7.2 do with them?
Sketch. A left inverse of T_A must be a linear map $F^m \to F^n$, but R is defined only on the subspace $\operatorname{im} T_A$, which is all of F^m only when T_A is surjective. Repair: the columns form a basis of $\operatorname{im} T_A$; complete them to a basis of F^m and extend R by prescribing values on the added vectors, as in part 3 of the proof of Theorem 2.7.2.

Everything up to the last sentence is correct: T_A, regarded as a map onto its image, is a linear bijection, and its inverse $R : \operatorname{im} T_A \to F^n$ is linear. The error is the conclusion. By Definition 2.5.1, a left inverse of $T_A : F^n \to F^m$ is a linear map $F^m \to F^n$, defined on all of F^m, while R is defined only on $\operatorname{im} T_A$. These agree only when $\operatorname{im} T_A = F^m$, that is, when T_A is also surjective. For example, for $A = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, R is defined on the x-axis of F^2 and says nothing about $(0, 1)$.

Repair. The map R has to be extended linearly to F^m. Since T_A is injective, the columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$ are linearly independent (Theorem 2.7.2), and they span $\operatorname{im} T_A$ (Proposition 2.6.18), so they are a basis of $\operatorname{im} T_A$, and $R(\mathbf{a}_j) = \mathbf{e}_j$. Complete them to a basis $\mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_t}$ of F^m as in part 3 of the proof of Theorem 2.7.2, and let $S : F^m \to F^n$ be the linear map with $S(\mathbf{a}_j) = \mathbf{e}_j$ and $S(\mathbf{e}_{i_s}) = \mathbf{0}$ (Theorem 2.2.1). Then S agrees with R on the basis $\mathbf{a}_1, \ldots, \mathbf{a}_n$ of $\operatorname{im} T_A$, hence on all of $\operatorname{im} T_A$, and $S(T_A(\mathbf{x})) = R(T_A(\mathbf{x})) = \mathbf{x}$. So S is a left inverse.

Solution to Exercise 2.7.25

Uses. Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Exercise 2.5.45, Proposition 2.5.20 (Inverses and matrices), Proposition 2.4.22 (Transpose is a linear involution)
Hint 1. Which condition of the Fundamental Theorems behaves well under transposition?
Hint 2. Condition (V): $CA = I_n$ if and only if $A^{\mathsf{T}}C^{\mathsf{T}} = I_n$ (Exercise 2.5.45).
Sketch. (a) Columns of A independent $\Leftrightarrow$ A has a left inverse C (Theorem 2.7.2) $\Leftrightarrow$ A^{T} has the right inverse C^{T} $\Leftrightarrow$ the columns of A^{T} span F^n (Theorem 2.7.4). (b) Apply (a) to A^{T}, using $\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A$.

(a) By Theorem 2.7.2, (III) $\Leftrightarrow$ (V), the columns of A are linearly independent if and only if T_A has a left inverse, which by Proposition 2.5.20(c) means that $CA = I_n$ for some $C \in F^{n\times m}$. By Exercise 2.5.45, $CA = I_n$ if and only if $A^{\mathsf{T}}C^{\mathsf{T}} = I_n$. So A has a left inverse if and only if $A^{\mathsf{T}} \in F^{n\times m}$ has a right inverse, that is, if and only if $T_{A^{\mathsf{T}}}$ has a right inverse (Proposition 2.5.20(c)), which by Theorem 2.7.4, (V) $\Leftrightarrow$ (III), happens if and only if the columns of A^{T} span F^n. These columns are the rows of A.

(b) Apply (a) to A^{T}: the columns of A^{T} are linearly independent if and only if the columns of $\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A$ span F^m (Proposition 2.4.22). The columns of A^{T} are the rows of A.

Solution to Exercise 2.7.26

Uses. Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 2.3.16 (The matrix of T_A), Theorem 2.7.2 (First Fundamental Theorem), Proposition 1.5.14 (Appending a vector), Proposition 1.5.15 (Short lists, zeros, and repeats), Corollary 1.5.17 (Sublists), Proposition 1.2.35 (Zero products), Exercise 2.7.25
Hint 1. Every linear map $\mathbb{F}_p^2 \to \mathbb{F}_p^3$ is T_A for exactly one $A \in \mathbb{F}_p^{3\times 2}$. Count the matrices whose two columns are independent.
Hint 2. The first column must be nonzero, and the second must avoid the span of the first. How many vectors does $\operatorname{span}(\mathbf{a}_1)$ contain?
Hint 3. For (b), $A \mapsto A^{\mathsf{T}}$ is a bijection from $\mathbb{F}_p^{3\times 2}$ to $\mathbb{F}_p^{2\times 3}$.
Sketch. By Theorem 2.7.2, count pairs $\mathbf{a}_1, \mathbf{a}_2$ in $\mathbb{F}_p^3$ that are independent: $\mathbf{a}_1 \neq \mathbf{0}$ ($p^3 - 1$ choices) and $\mathbf{a}_2 \notin \operatorname{span}(\mathbf{a}_1)$, which has p elements ($p^3 - p$ choices). (b) By Exercise 2.7.25, T_A is injective iff $T_{A^{\mathsf{T}}}$ is surjective, and transposition is a bijection between the two sets of matrices.

(a) Every linear map $\mathbb{F}_p^2 \to \mathbb{F}_p^3$ is T_A for exactly one $A \in \mathbb{F}_p^{3\times 2}$ (Theorem 2.3.20, Proposition 2.3.16), and by Theorem 2.7.2, T_A is injective if and only if the columns $\mathbf{a}_1, \mathbf{a}_2$ are linearly independent. This holds if and only if $\mathbf{a}_1 \neq \mathbf{0}$ and $\mathbf{a}_2 \notin \operatorname{span}(\mathbf{a}_1)$: if the pair is independent, so is its sublist $\mathbf{a}_1$ (Corollary 1.5.17), so $\mathbf{a}_1 \neq \mathbf{0}$ (Proposition 1.5.15(b)), and then $\mathbf{a}_2 \notin \operatorname{span}(\mathbf{a}_1)$ by Proposition 1.5.14; the converse is Proposition 1.5.15(b) and Proposition 1.5.14 again. There are $p^3 - 1$ choices of $\mathbf{a}_1 \neq \mathbf{0}$. For each, $\operatorname{span}(\mathbf{a}_1) = \left\{ t\mathbf{a}_1 \;\middle|\; t \in \mathbb{F}_p \right\}$ has exactly p elements, since $t\mathbf{a}_1 = t'\mathbf{a}_1$ gives $(t - t')\mathbf{a}_1 = \mathbf{0}$ and hence $t = t'$ (Proposition 1.2.35). So there are $p^3 - p$ choices of $\mathbf{a}_2$, and $\left(p^3 - 1\right)\left(p^3 - p\right)$ injective maps in all.

(b) By Exercise 2.7.25(a), the columns of $A \in \mathbb{F}_p^{3\times 2}$ are independent if and only if the columns of $A^{\mathsf{T}} \in \mathbb{F}_p^{2\times 3}$ span $\mathbb{F}_p^2$, that is, T_A is injective if and only if $T_{A^{\mathsf{T}}}$ is surjective. Since $A \mapsto A^{\mathsf{T}}$ is a bijection $\mathbb{F}_p^{3\times 2} \to \mathbb{F}_p^{2\times 3}$ (it is its own inverse), it matches the injective maps $\mathbb{F}_p^2 \to \mathbb{F}_p^3$ with the surjective maps $\mathbb{F}_p^3 \to \mathbb{F}_p^2$ one to one. So the two counts agree.

Solution to Exercise 2.7.27

Uses. Theorem 2.7.2 (First Fundamental Theorem), Proposition 2.4.23 (Transpose of a product), Definition 2.4.1 (Matrix product), Exercise 2.4.44
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. By Theorem 2.7.2, the claim is that $A^{\mathsf{T}}A\mathbf{x} = \mathbf{0}$ forces $\mathbf{x} = \mathbf{0}$. Multiply $A^{\mathsf{T}}A\mathbf{x} = \mathbf{0}$ on the left by $\mathbf{x}^{\mathsf{T}}$.
Hint 2. $\mathbf{x}^{\mathsf{T}}A^{\mathsf{T}}A\mathbf{x} = (A\mathbf{x})^{\mathsf{T}}(A\mathbf{x})$ is the sum of the squares of the entries of $A\mathbf{x}$. When does such a sum vanish?
Sketch. (a) True: if $A^{\mathsf{T}}A\mathbf{x} = \mathbf{0}$, then $0 = \mathbf{x}^{\mathsf{T}}A^{\mathsf{T}}A\mathbf{x} = \sum_i (A\mathbf{x})_i^2$, so $A\mathbf{x} = \mathbf{0}$ and $\mathbf{x} = \mathbf{0}$. (b) False: $A = \begin{pmatrix}1\\ i\end{pmatrix}$ gives $A^{\mathsf{T}}A = \begin{pmatrix}1 + i^2\end{pmatrix} = (0)$. (c) False: $A = \begin{pmatrix}1\\ 1\end{pmatrix}$ gives $A^{\mathsf{T}}A = (1 + 1) = (0)$.

By Theorem 2.7.2, (III) $\Leftrightarrow$ (IV), the columns of $A^{\mathsf{T}}A$ are independent if and only if $A^{\mathsf{T}}A\mathbf{x} = \mathbf{0}$ only for $\mathbf{x} = \mathbf{0}$, and likewise for A.

(a) True. Let $A^{\mathsf{T}}A\mathbf{x} = \mathbf{0}$, and put $\mathbf{z} = A\mathbf{x} \in \mathbb{R}^m$. By Proposition 2.4.23, $\mathbf{x}^{\mathsf{T}}A^{\mathsf{T}} = (A\mathbf{x})^{\mathsf{T}} = \mathbf{z}^{\mathsf{T}}$, so

$$0 = \mathbf{x}^{\mathsf{T}}\left(A^{\mathsf{T}}A\mathbf{x}\right) = \mathbf{z}^{\mathsf{T}}\mathbf{z} = z_1^2 + \cdots + z_m^2,$$

where the left side is the 1×1 matrix $\mathbf{x}^{\mathsf{T}}\mathbf{0} = (0)$, read as a number. A sum of squares of real numbers is 0 only if every term is, so $\mathbf{z} = A\mathbf{x} = \mathbf{0}$, and $\mathbf{x} = \mathbf{0}$ because the columns of A are independent.

(b) False. Let $A = \begin{pmatrix}1\\ i\end{pmatrix} \in \mathbb{C}^{2\times 1}$. Its single column is nonzero, hence independent, but $A^{\mathsf{T}}A = (1 \cdot 1 + i \cdot i) = (0)$, whose column is $\mathbf{0}$.

(c) False. Let $A = \begin{pmatrix}1\\ 1\end{pmatrix} \in \mathbb{F}_2^{2\times 1}$. Then $A^{\mathsf{T}}A = (1 + 1) = (0)$.

The proof of (a) breaks down exactly where sums of squares can vanish without each term vanishing, as in Exercise 2.4.44(d). Over $\mathbb{C}$, replacing A^{T} by the conjugate transpose repairs it (Section 6.5).

Solution to Exercise 2.7.28

Uses. Theorem 2.7.8 (Third Fundamental Theorem), Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem)
Hint 1. Solve $A_c\mathbf{x} = (a, b, d)$ by hand: express x_2 through x_3 using the second equation, then x_1 through x_3 using the first, and substitute into the third.
Hint 2. You should reach $\left(1 + c^3\right)x_3 = d - ca + c^2b$. If $1 + c^3 = 0$, try $x_3 = 1$ for a vector in the kernel.
Sketch. The system is equivalent to $x_2 = b - cx_3$, $x_1 = a - cb + c^2x_3$, $\left(1 + c^3\right)x_3 = d - ca + c^2b$. If $1 + c^3 \neq 0$ there is exactly one solution, so A_c is invertible. If $1 + c^3 = 0$, then $\left(c^2, -c, 1\right)$ is a nonzero kernel vector and $(0, 0, 1)$ is not a value. Not invertible exactly for: $c = -1$ over $\mathbb{R}$; $c = -1, \left(1 \pm i\sqrt{3}\right)/2$ over $\mathbb{C}$; $c = 3, 5, 6$ over $\mathbb{F}_7$.

(a) The system $A_c\mathbf{x} = (a, b, d)$ is

$$x_1 + cx_2 = a, \quad x_2 + cx_3 = b, \quad cx_1 + x_3 = d.$$

The second equation says $x_2 = b - cx_3$; given this, the first says $x_1 = a - cx_2 = a - cb + c^2x_3$; given both, the third says $c\left(a - cb + c^2x_3\right) + x_3 = d$, that is,

$$\left(1 + c^3\right)x_3 = d - ca + c^2b.$$

So the system is equivalent to these three equations for x_2, x_1, and x_3.

If $1 + c^3 \neq 0$, the last equation determines x_3, and then x_2 and x_1 are determined. So the system has exactly one solution for every right-hand side, which is (II) of Theorem 2.7.8, and A_c is invertible.

If $1 + c^3 = 0$, take $(a, b, d) = (0, 0, 1)$: the last equation reads $0 = 1$, so $(0, 0, 1)$ is not a value, and T_{A_c} is not surjective. Take $(a, b, d) = \mathbf{0}$ and $x_3 = 1$: then $\mathbf{x} = \left(c^2, -c, 1\right)$ is a nonzero solution of $A_c\mathbf{x} = \mathbf{0}$ (check: $c^2 - c^2 = 0$, $-c + c = 0$, $c^3 + 1 = 0$), so T_{A_c} is not injective.

(b) Over $\mathbb{R}$, $c^3 = -1$ only for $c = -1$. Over $\mathbb{C}$, $c^3 + 1 = (c+1)\left(c^2 - c + 1\right)$, so $c = -1$ or $c = \left(1 \pm i\sqrt{3}\right)/2$. Over $\mathbb{F}_7$, the cubes of $0, 1, \ldots, 6$ are $0, 1, 1, 6, 1, 6, 6$ (for instance $3^3 = 27 = 3 \cdot 7 + 6$), so $c^3 = -1 = 6$ exactly for $c = 3, 5, 6$.

Solution to Exercise 2.7.29

Uses. Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.7.8 (Third Fundamental Theorem), Theorem 2.5.10 (Left and right inverses agree), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.5.20 (Inverses and matrices), Definition 2.4.1 (Matrix product), Exercise 2.5.45
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. If A is invertible, every one-sided inverse equals A^{-1} (Theorem 2.5.10). For the converse in (a), show that a left-invertible A with T_A not surjective has at least two left inverses.
Hint 2. Use the construction in part 3 of the proof of Theorem 2.7.2. If the columns do not span F^m, at least one standard basis vector $\mathbf{e}_{i_1}$ is appended, and the value of the left inverse there can be chosen in two ways.
Hint 3. For (b), if $AB = I_m$ and $A\mathbf{z} = \mathbf{0}$ with $\mathbf{z} \neq \mathbf{0}$, change one column of B by $\mathbf{z}$.
Sketch. If A is invertible, every one-sided inverse equals A^{-1}. (a) If A has exactly one left inverse, then T_A is injective. If it were not surjective, completing the columns to a basis $\mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_t}$ would append $t \geq 1$ vectors, and $S\left(\mathbf{e}_{i_1}\right) = \mathbf{0}$ or $\mathbf{e}_1$ would give two left inverses. So T_A is bijective. (b) If $AB = I_m$ and $\mathbf{z} \neq \mathbf{0}$ lies in $\ker T_A$, then adding $\mathbf{z}$ to the first column of B gives a second right inverse. So a unique right inverse forces T_A to be injective as well as surjective.

By Proposition 2.5.20(c), $C \mapsto T_C$ matches the left (right) inverses of A with the left (right) inverses of T_A, so we may count either.

If A is invertible, then every left inverse C equals A^{-1} by Theorem 2.5.10, since A^{-1} is a right inverse; likewise every right inverse equals A^{-1}. This proves "if" in (a) and (b).

(a) Suppose A has exactly one left inverse. Then T_A has a left inverse, so by Theorem 2.7.2 the columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$ are linearly independent. Suppose, for contradiction, that T_A is not surjective. Complete the columns to a basis $\mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_t}$ of F^m as in part 3 of the proof of Theorem 2.7.2. Since the columns do not span F^m (Theorem 2.7.4), $t \geq 1$. By Theorem 2.2.1 there are linear maps $S, S' : F^m \to F^n$ with

$$S\left(\mathbf{a}_j\right) = S'\left(\mathbf{a}_j\right) = \mathbf{e}_j \quad (j = 1, \ldots, n),$$
$$S\left(\mathbf{e}_{i_s}\right) = S'\left(\mathbf{e}_{i_s}\right) = \mathbf{0} \quad (s \geq 2),$$

and $S\left(\mathbf{e}_{i_1}\right) = \mathbf{0}$, $S'\left(\mathbf{e}_{i_1}\right) = \mathbf{e}_1$. Both are left inverses of T_A, by the computation in part 3 of the proof of Theorem 2.7.2, and $S \neq S'$ since $\mathbf{e}_1 \neq \mathbf{0}$. This contradicts uniqueness. So T_A is injective and surjective, and by Theorem 2.7.8, T_A and hence A are invertible.

(b) Suppose A has exactly one right inverse B. Then T_A is surjective (Theorem 2.7.4). Suppose, for contradiction, that T_A is not injective, and let $\mathbf{z} \neq \mathbf{0}$ with $A\mathbf{z} = \mathbf{0}$. Let B' be B with $\mathbf{z}$ added to its first column. By Definition 2.4.1, the columns of AB' are those of $AB = I_m$, except the first, which is $A(\mathbf{b}_1 + \mathbf{z}) = A\mathbf{b}_1 + \mathbf{0} = \mathbf{e}_1$. So $AB' = I_m$ and $B' \neq B$, a contradiction. So T_A is bijective, and A is invertible by Theorem 2.7.8.

Transposing gives a second route to (a): $C \mapsto C^{\mathsf{T}}$ matches the left inverses of A with the right inverses of A^{T} (Exercise 2.5.45), and A is invertible if and only if A^{T} is, so (a) for A is (b) for A^{T}. Done directly, the two parts are not symmetric in difficulty: a second right inverse comes from a single vector of the kernel, while a second left inverse needs the columns to be completed to a basis.

Solution to Exercise 2.7.30

Uses. Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence), Theorem 2.7.8 (Third Fundamental Theorem), Theorem 2.5.10 (Left and right inverses agree), Proposition 2.5.20 (Inverses and matrices)
Hint 1. $AB = I_m$ says that A is a left inverse of B and B is a right inverse of A. What does each of these say about injectivity or surjectivity?
Hint 2. In (a), T_B is injective and surjective. Apply Theorem 2.7.8, and then Theorem 2.5.10 to compare A with B^{-1}.
Sketch. (a) A is a left inverse of B, so T_B is injective; with surjectivity, B is invertible by Theorem 2.7.8, and the left inverse A equals B^{-1}, so $BA = I_n$. (b) B is a right inverse of A, so T_A is surjective; with injectivity, A is invertible and $B = A^{-1}$.

(a) Since $AB = I_m$, T_A is a left inverse of T_B, so T_B is injective (Proposition 2.5.4). It is also surjective, so by Theorem 2.7.8 it is invertible, and by Proposition 2.5.20(c) so is B. Now A is a left inverse and B^{-1} a right inverse of B, so $A = B^{-1}$ by Theorem 2.5.10, and $BA = BB^{-1} = I_n$.

(b) Since $AB = I_m$, T_B is a right inverse of T_A, so T_A is surjective (Proposition 2.5.5). It is also injective, so A is invertible as in (a). Then B is a right inverse and A^{-1} a left inverse of A, so $B = A^{-1}$, and $BA = A^{-1}A = I_n$.

Solution to Exercise 2.7.31

Uses. Definition 2.4.1 (Matrix product), Proposition 2.4.14 (Algebra of matrices), Definition 2.5.12 (Invertible), Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. (a) Every entry of J^2 is a sum of n products $1 \cdot 1$.
Hint 2. (b) Multiply $(J - I_n)\big((n-1)^{-1}J - I_n\big)$ out with (a). Both factors are combinations of J and I_n, so they commute.
Hint 3. (c) Apply A to the vector $\mathbf{1}$ with all entries 1. For surjectivity, add up the entries of $A\mathbf{x}$.
Sketch. (a) Each entry of J^2 is $\sum_k 1 \cdot 1 = n$. (b) $(J - I)\big((n-1)^{-1}J - I\big) = (n-1)^{-1}(n-1)J - J + I = I$, and the factors commute. (c) $A\mathbf{1} = (n-1)\mathbf{1} = \mathbf{0}$, and the entries of $A\mathbf{x}$ add up to $(n-1)(x_1 + \cdots + x_n) = 0$, so $\mathbf{e}_1$ is not a value. (d) $n - 1 = 4$, so A is invertible over $\mathbb{F}_p$ exactly for $p \neq 2$.

(a) By Definition 2.4.1, the (i, j) entry of J^2 is $\sum_{k=1}^{n} 1 \cdot 1 = n$, which is the (i, j) entry of nJ.

(b) Let $B = (n-1)^{-1}J - I_n$. By Proposition 2.4.14 and (a),

$$\begin{aligned} AB &= (n-1)^{-1}J^2 - J - (n-1)^{-1}J + I_n \\ &= (n-1)^{-1}(n-1)J - J + I_n = I_n. \end{aligned}$$

The same expansion gives $BA = I_n$, since J commutes with itself and with I_n. So A is invertible with $A^{-1} = B$ (Definition 2.5.12).

(c) Let $\mathbf{1} \in F^n$ have every entry 1. Each entry of $A\mathbf{1}$ is the sum of the $n - 1$ off-diagonal entries of a row, which is $n - 1 = 0$. So $\mathbf{1}$ is a nonzero vector of $\ker T_A$, and T_A is not injective (Theorem 2.7.2). For $\mathbf{x} \in F^n$ with $s = x_1 + \cdots + x_n$, the ith entry of $A\mathbf{x}$ is $s - x_i$, so the entries of $A\mathbf{x}$ add up to $ns - s = (n-1)s = 0$. The vector $\mathbf{e}_1$, whose entries add up to 1, is therefore not a value, and T_A is not surjective (Theorem 2.7.4).

(d) Here $n - 1 = 4$, which is 0 in $\mathbb{F}_p$ exactly when $p = 2$. So A is invertible over $\mathbb{F}_p$ for every odd prime p, by (b), and not over $\mathbb{F}_2$, by (c).

Solution to Exercise 2.7.32

Uses. Theorem 1.5.5 (Independence is decided at zero), Corollary 1.5.17 (Sublists), Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Proposition 2.5.4 (Left inverses give uniqueness), induction on m
Hint 1. For the inductive step, look at the last entries $c_1, \ldots, c_{m+1}$ of the vectors $\mathbf{v}_1, \ldots, \mathbf{v}_{m+1} \in F^m$. If they are all 0, the vectors live in a copy of F^{m-1}.
Hint 2. If some last entry is nonzero, say $c_{m+1} \neq 0$, subtract multiples of $\mathbf{v}_{m+1}$ from the others to make their last entries 0. Apply the inductive hypothesis to m of the resulting vectors, viewed in F^{m-1}.
Hint 3. For (b), a surjective T_A has a right inverse B, and T_B is injective.
Sketch. (a) $m = 1$: two scalars a, b satisfy a nontrivial relation. Step: if all last entries vanish, drop them and apply the hypothesis to $\mathbf{v}_1, \ldots, \mathbf{v}_m$. Otherwise, with $c_{m+1} \neq 0$, the vectors $\mathbf{u}_i = \mathbf{v}_i - (c_i/c_{m+1})\mathbf{v}_{m+1}$, $i \leq m$, have last entry 0, so they satisfy a nontrivial relation, which expands to one among the $\mathbf{v}_i$ with some coefficient of $\mathbf{v}_i$, $i \leq m$, nonzero. (b) Independent columns in F^m number at most m. A right inverse $B \in F^{n \times m}$ of A has A as a left inverse, so $T_B : F^m \to F^n$ is injective and $m \leq n$.

(a) *Base case* $m = 1$. Two vectors of $F^1 = F$ are scalars a, b. If $a = 0$, then $1 \cdot a + 0 \cdot b = 0$ is a nontrivial relation; otherwise $b \cdot a + (-a) \cdot b = 0$ is one, since $-a \neq 0$.

Inductive step. Let $m \geq 2$, assume the claim for $m - 1$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_{m+1} \in F^m$. Let c_i be the last entry of $\mathbf{v}_i$. For a vector of F^m with last entry 0, write $\overline{\mathbf{u}} \in F^{m-1}$ for the vector of its first $m - 1$ entries. If $\mathbf{u}_1, \ldots, \mathbf{u}_k \in F^m$ all have last entry 0, then a relation $\sum_i a_i \overline{\mathbf{u}}_i = \mathbf{0}$ in F^{m-1} implies $\sum_i a_i \mathbf{u}_i = \mathbf{0}$ in F^m, since the last entries vanish anyway.

Case 1: all $c_i = 0$. The m vectors $\overline{\mathbf{v}}_1, \ldots, \overline{\mathbf{v}}_m \in F^{m-1}$ satisfy a nontrivial relation by the inductive hypothesis, hence so do $\mathbf{v}_1, \ldots, \mathbf{v}_m$, and adding $0 \cdot \mathbf{v}_{m+1}$ gives a nontrivial relation among all $m+1$ vectors.

Case 2: some $c_k \neq 0$. Reordering the list does not affect dependence, so we may assume $c_{m+1} \neq 0$. For $i = 1, \ldots, m$ let $\mathbf{u}_i = \mathbf{v}_i - (c_i/c_{m+1})\mathbf{v}_{m+1}$, whose last entry is $c_i - c_i = 0$. By the inductive hypothesis applied to $\overline{\mathbf{u}}_1, \ldots, \overline{\mathbf{u}}_m \in F^{m-1}$, there are $a_1, \ldots, a_m$, not all 0, with $\sum_{i=1}^{m} a_i \mathbf{u}_i = \mathbf{0}$. Expanding,

$$a_1\mathbf{v}_1 + \cdots + a_m\mathbf{v}_m - \left(\sum_{i=1}^{m} a_i c_i/c_{m+1}\right)\mathbf{v}_{m+1} = \mathbf{0},$$

a relation among $\mathbf{v}_1, \ldots, \mathbf{v}_{m+1}$ in which some a_i with $i \leq m$ is nonzero. So the list is dependent (Theorem 1.5.5).

(b) If T_A is injective, its n columns are linearly independent in F^m (Theorem 2.7.2). If $n > m$, the first $m+1$ columns would be an independent sublist (Corollary 1.5.17) of $m+1$ vectors in F^m, contradicting (a). So $n \leq m$.

If T_A is surjective, it has a right inverse by Theorem 2.7.4, (I) $\Rightarrow$ (V), that is, $AB = I_m$ for some $B \in F^{n\times m}$. Then A is a left inverse of B, so $T_B : F^m \to F^n$ is injective (Proposition 2.5.4), and by the first part, $m \leq n$.

If A is invertible, T_A is both, so $n \leq m$ and $n \geq m$.

Solution to Exercise 2.7.33

Uses. Theorem 2.7.2 (First Fundamental Theorem), Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.7.8 (Third Fundamental Theorem), Proposition 2.5.20 (Inverses and matrices), Proposition 2.4.14 (Algebra of matrices)
Hint 1. Use condition (V). If $CA = I_n$, find a left inverse of GAH built from C, G^{-1}, and H^{-1}.
Hint 2. For the converse, write $A = G^{-1}(GAH)H^{-1}$ and apply the first direction with G^{-1} and H^{-1}.
Sketch. If $CA = I_n$, then $\big(H^{-1}CG^{-1}\big)(GAH) = H^{-1}(CA)H = I_n$; if $AC = I_m$, then $(GAH)\big(H^{-1}CG^{-1}\big) = I_m$. By (I) $\Leftrightarrow$ (V) of the first two theorems, injectivity and surjectivity pass from A to GAH, and back since $A = G^{-1}(GAH)H^{-1}$. Then apply Theorem 2.7.8.

By Proposition 2.5.20(c) and Theorem 2.7.2, (I) $\Leftrightarrow$ (V), T_A is injective if and only if $CA = I_n$ for some $C \in F^{n\times m}$. If so, then by Proposition 2.4.14,

$$\begin{aligned}\big(H^{-1}CG^{-1}\big)(GAH) &= H^{-1}C\big(G^{-1}G\big)AH \\ &= H^{-1}(CA)H = H^{-1}H = I_n,\end{aligned}$$

so GAH has a left inverse and T_{GAH} is injective. Likewise, if $AC = I_m$, then $(GAH)\big(H^{-1}CG^{-1}\big) = G(AC)G^{-1} = I_m$, so by Theorem 2.7.4, (V) $\Rightarrow$ (I), T_{GAH} is surjective whenever T_A is.

For the converses, apply what we just proved to the matrix GAH and the invertible matrices G^{-1} and H^{-1}: since $A = G^{-1}(GAH)H^{-1}$, injectivity and surjectivity pass from GAH back to A. Finally, by Theorem 2.7.8 and Proposition 2.5.20(c), a matrix is invertible if and only if its map is injective and surjective, so GAH is invertible if and only if A is.

Solution to Exercise 2.7.34

Uses. Proposition 2.4.14 (Algebra of matrices), Proposition 2.4.8 (Four views of the product), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Theorem 2.7.8 (Third Fundamental Theorem), Proposition 2.7.7 (Bijective linear maps are invertible), Proposition 2.5.4 (Left inverses give uniqueness), Proposition 2.5.5 (Right inverses give existence), Proposition 2.5.20 (Inverses and matrices)
Hint 1. By the column view of the product, column k of AX is $A\mathbf{x}_k$, where $\mathbf{x}_k$ is column k of X. So $AX = Y$ is p separate systems $A\mathbf{x}_k = \mathbf{y}_k$.
Hint 2. For "only if" in (b), turn a nonzero $\mathbf{v} \in \ker T_A$ into a nonzero matrix X with $AX = 0$. For "only if" in (c), solve $AX = Y$ for a Y whose first column is a given $\mathbf{y}$.
Sketch. (a) $A(cX + Y) = cAX + AY$. (b) If T_A is injective and $AX = 0$, every column of X is in $\ker T_A = \{\mathbf{0}\}$. If $A\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$, the matrix with first column $\mathbf{v}$ and other columns $\mathbf{0}$ is a nonzero element of $\ker L_A$. (c) Solve column by column;

conversely, the first column of a solution of $AX = (\mathbf{y}, \mathbf{0}, \ldots, \mathbf{0})$ solves $A\mathbf{x} = \mathbf{y}$. (d) Combine (b), (c), Theorem 2.7.8, and Proposition 2.7.7.

Write $\mathbf{x}_1, \ldots, \mathbf{x}_p$ for the columns of $X \in F^{n\times p}$. By Proposition 2.4.8, column k of AX is $A\mathbf{x}_k$.

(a) By Proposition 2.4.14, $A(cX + Y) = cAX + AY$ for $X, Y \in F^{n\times p}$ and $c \in F$, so L_A is linear.

(b) Suppose T_A is injective, and $AX = 0$. Then $A\mathbf{x}_k = \mathbf{0}$ for every k, so every $\mathbf{x}_k = \mathbf{0}$, and $X = 0$. So $\ker L_A = \{0\}$, and L_A is injective (Theorem 2.6.11). Conversely, suppose T_A is not injective, and let $\mathbf{v} \neq \mathbf{0}$ with $A\mathbf{v} = \mathbf{0}$. Let X have first column $\mathbf{v}$ and all other columns $\mathbf{0}$ (this uses $p \geq 1$). Then $X \neq 0$ and $AX = 0$, so L_A is not injective.

(c) Suppose T_A is surjective, and let $Y \in F^{m\times p}$ have columns $\mathbf{y}_1, \ldots, \mathbf{y}_p$. Choose $\mathbf{x}_k$ with $A\mathbf{x}_k = \mathbf{y}_k$, and let X have columns $\mathbf{x}_1, \ldots, \mathbf{x}_p$; then $AX = Y$. Conversely, suppose L_A is surjective, and let $\mathbf{y} \in F^m$. Some X satisfies $AX = Y$, where Y has first column $\mathbf{y}$ and all other columns $\mathbf{0}$. Comparing first columns, $A\mathbf{x}_1 = \mathbf{y}$. So T_A is surjective.

(d) A linear map is invertible if and only if it is bijective (Proposition 2.7.7, Proposition 2.5.4, Proposition 2.5.5). By (b) and (c), L_A is bijective if and only if T_A is, which by Theorem 2.7.8 and Proposition 2.5.20(c) holds if and only if A is invertible.

Solution to Exercise 2.7.35

Uses. Theorem 2.7.2 (First Fundamental Theorem), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
Hint 1. By Theorem 2.7.2, it suffices to show that $A\mathbf{x} = \mathbf{0}$ with $\mathbf{x} \in \mathbb{Q}^n$ forces $\mathbf{x} = \mathbf{0}$. Suppose not. Can you make $\mathbf{x}$ an integer vector?
Hint 2. Clear denominators, then divide by the largest power of p that divides every entry. The result is an integer solution with some entry not divisible by p. Now reduce modulo p.
Hint 3. (b) Take $p = 2$. (c) A 1×1 example suffices.
Sketch. If $A\mathbf{x} = \mathbf{0}$ with $\mathbf{x} \in \mathbb{Q}^n$ nonzero, scale $\mathbf{x}$ to an integer vector, not all of whose entries are divisible by p. Reducing each equation $\sum_j a_{ij}x_j = 0$ modulo p (Lemma 1.1.21) gives $\overline{A}\overline{\mathbf{x}} = \mathbf{0}$ with $\overline{\mathbf{x}} \neq \mathbf{0}$, contradicting Theorem 2.7.2 over $\mathbb{F}_p$. (b) With $p = 2$, $\overline{A} = I_n$. (c) $A = (p)$.

(a) By Theorem 2.7.2, (III) $\Leftrightarrow$ (IV), over $\mathbb{Q}$ and over $\mathbb{F}_p$, it suffices to show: if $\overline{A}\mathbf{z} = \mathbf{0}$ has only the solution $\mathbf{z} = \mathbf{0}$ in $\mathbb{F}_p^n$, then $A\mathbf{x} = \mathbf{0}$ has only the solution $\mathbf{x} = \mathbf{0}$ in $\mathbb{Q}^n$.

Suppose, for contradiction, that $A\mathbf{x} = \mathbf{0}$ for some nonzero $\mathbf{x} \in \mathbb{Q}^n$. Multiplying $\mathbf{x}$ by the product of the denominators of its entries, we may assume that $\mathbf{x} \in \mathbb{Z}^n$, still nonzero. Some entry x_k is a nonzero integer, and $p^e \mid x_k$ only for $p^e \leq |x_k|$, so there is a largest $e \geq 0$ such that p^e divides every entry of $\mathbf{x}$. Dividing by p^e, we may assume that $\mathbf{x} \in \mathbb{Z}^n$, $A\mathbf{x} = \mathbf{0}$, and some entry of $\mathbf{x}$ is not divisible by p.

For each i, $\sum_{j=1}^n a_{ij}x_j = 0$ in $\mathbb{Z}$. Reduction modulo p respects sums and products (Lemma 1.1.21(a)), so $\sum_j \overline{a}_{ij}\overline{x}_j = \overline{0} = 0$ in $\mathbb{F}_p$, where $\overline{a}$ is the remainder of a modulo p. That is, $\overline{A}\overline{\mathbf{x}} = \mathbf{0}$, where $\overline{\mathbf{x}} \in \mathbb{F}_p^n$ has entries $\overline{x}_j$. Since some x_j is not divisible by p, $\overline{x}_j \neq 0$, so $\overline{\mathbf{x}} \neq \mathbf{0}$. This contradicts the hypothesis on $\overline{A}$.

(b) With $p = 2$, an odd integer has remainder 1 and an even one remainder 0, so $\overline{A} = I_n$, whose columns $\mathbf{e}_1, \ldots, \mathbf{e}_n$ are independent over $\mathbb{F}_2$. By (a), the columns of A are independent over $\mathbb{Q}$.

(c) $A = (p) \in \mathbb{Z}^{1\times 1}$ has a nonzero column, which is independent over $\mathbb{Q}$, but $\overline{A} = (0)$.

For (b), Section 3.5 shows that a square matrix with independent columns is invertible (Corollary 3.5.25), so these matrices are invertible over $\mathbb{Q}$.

Section 2.8

Solution to Exercise 2.8.5

Uses. Proposition 2.4.14 (Algebra of matrices), Proposition 2.4.22 (Transpose is a linear involution), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space), Proposition 2.1.17 (Compositions of linear maps are linear), Exercise 2.1.32, Definition 2.4.26 (Trace), Lemma 2.4.24 (Matrix units)

Techniques. Assemble linear maps from linear pieces (Technique 2.1.26), Try small cases and small fields (Technique 1.2.38)
Hint 1. (a) and (b) are built from maps you already know to be linear. For (c), the formula is a product of entries, which suggests testing homogeneity with a scalar c. Which scalars satisfy $c^2 = c$?
Hint 2. For (c) over $\mathbb{F}_2$, expand $\operatorname{tr}(X^2) = \sum_i \sum_k x_{ik}x_{ki}$ and pair the term for (i,k) with the term for (k,i).
Sketch. (a) A difference of the composite $X \mapsto AX \mapsto AXB$ and the transpose, all linear. (b) $C_{x+1} - 2\,\mathrm{id} + C_{x-1}$, with the substitution maps of Exercise 2.1.32. (c) Over $\mathbb{F}_2$, the off-diagonal terms of $\operatorname{tr}(X^2)$ cancel in pairs and $x_{ii}^2 = x_{ii}$, so $\operatorname{tr}(X^2) = \operatorname{tr} X$, which is linear. Over any other field pick $c \notin \{0,1\}$; then $\operatorname{tr}\left(\left(c\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}\right)^2\right) = c^2 \neq c$.

(a) Linear. The maps $X \mapsto AX$ and $X \mapsto XB$ are linear by Proposition 2.4.14(c) and (d), so their composite $X \mapsto AXB$ is linear (Proposition 2.1.17). The transpose is linear by Proposition 2.4.22, and a difference of linear maps is linear (Proposition 2.1.23).

(b) Linear. For $q \in F[x]$, the substitution $C_q : p \mapsto p(q)$ is linear (Exercise 2.1.32), so the map is $C_{x+1} - 2\mathrm{id}_{F[x]} + C_{x-1}$, a combination of linear maps.

(c) Write $\varphi(X) = \operatorname{tr}(X^2)$. By the entry formula,

$$\varphi(X) = \sum_{i=1}^{n} \left(X^2\right)_{ii} = \sum_{i=1}^{n}\sum_{k=1}^{n} x_{ik}x_{ki} = \sum_{i=1}^{n} x_{ii}^2 + \sum_{i<k}(x_{ik}x_{ki} + x_{ki}x_{ik}).$$

Over $\mathbb{F}_2$. Each pair in the last sum is $(1+1)x_{ik}x_{ki} = 0$, and $c^2 = c$ for both elements c of $\mathbb{F}_2$. So $\varphi(X) = \sum_i x_{ii} = \operatorname{tr} X$, and φ is linear by Proposition 2.4.27.

Over any other field. F has an element c with $c \neq 0$ and $c \neq 1$. Let $X = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$, the matrix unit with a single 1 in position $(1,1)$, so $X^2 = X$ by Lemma 2.4.24(c). Then $\varphi(cX) = \operatorname{tr}(c^2X^2) = c^2$, while $c\varphi(X) = c$. Since $c^2 - c = c(c-1) \neq 0$, φ is not homogeneous, so it is not linear.

Over $\mathbb{F}_2$ the squares collapse, since $c^2 = c$ for both scalars, and the cross terms cancel in pairs; a product of two different inputs, such as $(x,y) \mapsto xy$, is still not linear there (Exercise 2.1.15(d)). So the rule of thumb in Technique 2.1.26, that a product of inputs is a candidate for a counterexample, has exceptions over small fields, which is a reason to test them separately (Technique 1.2.38).

Solution to Exercise 2.8.6

Uses. Lemma 2.4.24 (Matrix units), Proposition 2.4.27 (The trace is linear), Proposition 2.4.14 (Algebra of matrices), Corollary 2.2.6 (Agreeing on a spanning list)
Techniques. Check it on a basis (Technique 2.2.7), Compute entry by entry (Technique 2.4.15)
Hint 1. Both sides of (a) are linear functions of A. By Lemma 2.4.24(c), $U_{ij}U_{kl} = \delta_{jk}U_{il}$.
Hint 2. Entry by entry: $U_{ij}AU_{ji} = \mathbf{e}_i\left(\mathbf{e}_j^{\mathsf{T}}A\mathbf{e}_j\right)\mathbf{e}_i^{\mathsf{T}}$, and the middle factor is a scalar. For (b), move A to the right in each term.
Sketch. (a) On units: $U_{ij}U_{kl}U_{ji} = \delta_{jk}\delta_{lj}U_{ii}$, which sums to $\delta_{kl}I_n = (\operatorname{tr} U_{kl})I_n$; both sides are linear in A and the units form a basis. Entrywise: $U_{ij}AU_{ji} = a_{jj}U_{ii}$, which sums to $\left(\sum_j a_{jj}\right)\left(\sum_i U_{ii}\right) = (\operatorname{tr} A)I_n$. (b) If A commutes with U_{ij}, the term is $U_{ij}U_{ji}A = U_{ii}A$, and the sum is n copies of I_nA.

(a) *On the matrix units.* The map $A \mapsto \sum_{i,j} U_{ij}AU_{ji}$ is a sum of maps $A \mapsto U_{ij}AU_{ji}$, each linear by Proposition 2.4.14(c) and (d), and $A \mapsto (\operatorname{tr} A)I_n$ is linear by Proposition 2.4.27. The matrix units form a basis of $F^{n\times n}$ (Lemma 2.4.24(a)), so by Corollary 2.2.6 it suffices to take $A = U_{kl}$. By Lemma 2.4.24(c), applied twice,

$$U_{ij}U_{kl}U_{ji} = \delta_{jk}U_{il}U_{ji} = \delta_{jk}\delta_{lj}U_{ii}.$$

Summing over j leaves only $j = k$, with the factor δ_{lk}, and summing over i then gives $\delta_{kl}\sum_i U_{ii} = \delta_{kl}I_n$. On the other side, $\operatorname{tr} U_{kl} = \delta_{kl}$. The two sides agree.

Entry by entry. By associativity and Lemma 2.4.24(b),

$$U_{ij}AU_{ji} = \mathbf{e}_i\left(\mathbf{e}_j^{\mathsf{T}}A\mathbf{e}_j\right)\mathbf{e}_i^{\mathsf{T}} = a_{jj}U_{ii}.$$

So the sum is $\sum_i \sum_j a_{jj}U_{ii} = \left(\sum_j a_{jj}\right)\left(\sum_i U_{ii}\right) = (\operatorname{tr} A)I_n$.

The second proof is shorter here, because each term collapses to a single entry of A. The first uses nothing but the multiplication table of the matrix units, and it is the version to use when the terms do not collapse so visibly.

(b) If A commutes with every matrix, then $U_{ij}AU_{ji} = U_{ij}U_{ji}A = U_{ii}A$, since $U_{ij}U_{ji} = \delta_{jj}U_{ii} = U_{ii}$. By (a),

$$(\operatorname{tr} A)I_n = \sum_{j=1}^{n}\sum_{i=1}^{n} U_{ii}A = \sum_{j=1}^{n} I_nA = (n * 1)A.$$

If $n * 1 \neq 0$, then $A = (n * 1)^{-1}(\operatorname{tr} A)I_n$ is a scalar multiple of I_n. Conversely cI_n commutes with every matrix, since $(cI_n)X = cX = X(cI_n)$ by Proposition 2.4.14(b) and (d).

Solution to Exercise 2.8.7

Uses. Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Definition 2.6.5 (Kernel), Definition 2.6.6 (Image), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4), Test injectivity at $\mathbf{0}$ (Technique 2.6.12)
Hint 1. Complete $(1,1,0,0), (0,0,1,1)$ to a basis of $\mathbb{Q}^4$ with two standard basis vectors. Send the first two vectors to $\mathbf{0}$ and the other two to the spanning vectors of L.
Hint 2. For (b), look for a nonzero vector in $K \cap L$. What does $T^2 = T$ do to a vector that is both a value of T and in $\ker T$?
Sketch. (a) $\mathbf{k}_1 = (1,1,0,0)$, $\mathbf{k}_2 = (0,0,1,1)$, $\mathbf{e}_1, \mathbf{e}_3$ is a basis; let T kill $\mathbf{k}_1, \mathbf{k}_2$ and send $\mathbf{e}_1, \mathbf{e}_3$ to $\mathbf{l}_1 = (1,0,1,0)$, $\mathbf{l}_2 = (0,1,0,1)$. Then $T(x) = (x_1 - x_2)\mathbf{l}_1 + (x_3 - x_4)\mathbf{l}_2$, a vector is killed exactly when its coefficients on $\mathbf{e}_1$ and $\mathbf{e}_3$ vanish, so $\ker T = K$, and $\operatorname{im} T = \operatorname{span}(\mathbf{l}_1, \mathbf{l}_2) = L$. (b) $\mathbf{u} = (1,1,1,1) = \mathbf{k}_1 + \mathbf{k}_2 = \mathbf{l}_1 + \mathbf{l}_2$. If $\mathbf{u} = T(\mathbf{w})$ and $T^2 = T$, then $\mathbf{u} = T(T(\mathbf{w})) = T(\mathbf{u}) = \mathbf{0}$.

(a) Let $\mathbf{k}_1 = (1,1,0,0)$, $\mathbf{k}_2 = (0,0,1,1)$, $\mathbf{l}_1 = (1,0,1,0)$, and $\mathbf{l}_2 = (0,1,0,1)$. The list $\mathbf{k}_1, \mathbf{k}_2, \mathbf{e}_1, \mathbf{e}_3$ is a basis of $\mathbb{Q}^4$: the equation

$$(x_1, x_2, x_3, x_4) = a\mathbf{k}_1 + b\mathbf{k}_2 + c\mathbf{e}_1 + d\mathbf{e}_3 = (a + c, a, b + d, b)$$

has exactly one solution, $a = x_2$, $b = x_4$, $c = x_1 - x_2$, $d = x_3 - x_4$. By Theorem 2.2.1 there is a linear map T with

$$T(\mathbf{k}_1) = T(\mathbf{k}_2) = \mathbf{0}, \quad T(\mathbf{e}_1) = \mathbf{l}_1, \quad T(\mathbf{e}_3) = \mathbf{l}_2,$$

and (2.2.1) gives

$$T(x_1, x_2, x_3, x_4) = (x_1 - x_2)\mathbf{l}_1 + (x_3 - x_4)\mathbf{l}_2 = (x_1 - x_2, x_3 - x_4, x_1 - x_2, x_3 - x_4).$$

Kernel. T kills $\mathbf{k}_1$ and $\mathbf{k}_2$, so it kills K. Conversely, if $T(\mathbf{v}) = \mathbf{0}$ for $\mathbf{v} = a\mathbf{k}_1 + b\mathbf{k}_2 + c\mathbf{e}_1 + d\mathbf{e}_3$, then $c\mathbf{l}_1 + d\mathbf{l}_2 = (c, d, c, d) = \mathbf{0}$, so $c = d = 0$ and $\mathbf{v} \in K$.

Image. By Proposition 2.1.16, $\operatorname{im} T$ is spanned by the values on the basis, $\mathbf{0}, \mathbf{0}, \mathbf{l}_1, \mathbf{l}_2$, so $\operatorname{im} T = L$.

The standard matrix has the columns $T(\mathbf{e}_j)$:

$$[T]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 \end{pmatrix}.$$

(b) The vector $\mathbf{u} = (1,1,1,1)$ is $\mathbf{k}_1 + \mathbf{k}_2 \in K$ and $\mathbf{l}_1 + \mathbf{l}_2 \in L$. Let T have kernel K and image L, and suppose $T^2 = T$. Since $\mathbf{u} \in \operatorname{im} T$, $\mathbf{u} = T(\mathbf{w})$ for some $\mathbf{w}$, and then

$$\mathbf{u} = T(\mathbf{w}) = T(T(\mathbf{w})) = T(\mathbf{u}) = \mathbf{0},$$

because $\mathbf{u} \in \ker T$. This is a contradiction. The construction in (a) needed nothing about how K and L sit relative to each other, but an operator with $T^2 = T$ fixes its image pointwise, so its kernel and image can share only $\mathbf{0}$.

Solution to Exercise 2.8.8

Uses. Example 2.1.9 (Maps of polynomials), Proposition 2.2.20 (Linear maps out of $F[x]$), Notation 2.4.16 (Powers of a matrix), Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 2.1.24 (Algebra of composition)
Techniques. Check it on a basis (Technique 2.2.7), Translate between maps and matrices (Technique 2.3.27)
Hint 1. D^p is linear, so it is enough to compute $D^p\left(x^k\right)$. Show by induction on j that $D^j\left(x^k\right) = k(k-1)\cdots(k-j+1)x^{k-j}$ for $j \le k$, and $D^j\left(x^k\right) = \mathbf{0}$ for $j > k$.
Hint 2. Among p consecutive integers, one is divisible by p. For (b), translate $D^p = 0$ into a statement about matrices with Notation 2.4.16. For (c), expand $(\mathrm{id} + D)^p$.
Sketch. (a) For $k < p$, $D^p\left(x^k\right) = \mathbf{0}$ because D kills constants; for $k \ge p$, $D^p\left(x^k\right) = k(k-1)\cdots(k-p+1)x^{k-p}$, and the integer coefficient is a product of p consecutive integers, hence divisible by p. So D^p vanishes on the monomials. (b) D maps $\mathbb{F}_p[x]_{\le n}$ into itself, and N^p is the matrix of the restriction of D^p, which is 0. Over $\mathbb{Q}$, $D^n(x^n) = n! \neq 0$. (c) $(\mathrm{id} + D)^p = \mathrm{id} + D^p = \mathrm{id}$, so $(\mathrm{id} + D)^{p-1}$ is a two-sided inverse.

(a) By Example 2.1.9, $D\left(x^k\right) = (k * 1)x^{k-1}$ for $k \ge 1$ and $D(1) = \mathbf{0}$. By induction on j,

$$D^j\left(x^k\right) = (k(k-1)\cdots(k-j+1) * 1)x^{k-j} \quad (j \le k), \quad D^j\left(x^k\right) = \mathbf{0} \quad (j > k):$$

one more application of D multiplies by the current exponent $k-j$ and lowers it by one, and once the constant $D^k\left(x^k\right) = k! * 1$ is reached, the next application gives $\mathbf{0}$. Now take $j = p$. If $k < p$, then $D^p\left(x^k\right) = \mathbf{0}$. If $k \ge p$, the integer $k(k-1)\cdots(k-p+1)$ is a product of p consecutive integers, one of which is divisible by p, so its image in $\mathbb{F}_p$ is 0 and $D^p\left(x^k\right) = \mathbf{0}$. So the linear map D^p agrees with 0 on every monomial, and $D^p = 0$ by the uniqueness in Proposition 2.2.20.

(b) D lowers degrees, so it maps $V = \mathbb{F}_p[x]_{\le n}$ into itself; call the restriction D_V. Then D_V^p is the restriction of $D^p = 0$, so $D_V^p = 0$. By Notation 2.4.16, $N^p = \left[D_V^p\right]_{\mathcal{BB}} = [0]_{\mathcal{BB}} = 0$, where $\mathcal{B} = 1, x, \ldots, x^n$.

Over $\mathbb{Q}$, the computation in (a) gives $D^n(x^n) = n! \neq 0$, so $D_V^n \neq 0$, and its matrix N^n is not 0 by Theorem 2.3.20. (In both cases $N^{n+1} = 0$, since D_V^{n+1} kills every polynomial of degree at most n.) So over $\mathbb{F}_p$ with $p \le n$, the matrix N dies earlier than the size forces it to.

(c) The operators id and D commute, so the binomial theorem gives

$$(\mathrm{id} + D)^p = \sum_{k=0}^{p} \binom{p}{k} D^k = \mathrm{id} + D^p = \mathrm{id},$$

because the coefficients $\binom{p}{k}$ with $0 < k < p$ are 0 in $\mathbb{F}_p$, and $D^p = 0$ by (a). Hence

$$(\mathrm{id} + D)(\mathrm{id} + D)^{p-1} = (\mathrm{id} + D)^{p-1}(\mathrm{id} + D) = (\mathrm{id} + D)^p = \mathrm{id},$$

and by Technique 2.5.16, $\mathrm{id} + D$ is invertible with inverse $(\mathrm{id} + D)^{p-1}$. This agrees with the inverse $\mathrm{id} - D + D^2 - \cdots$ found in Example 2.8.4, as it must, since an inverse is unique: over $\mathbb{F}_p$ the series stops at D^{p-1} for every polynomial.

Solution to Exercise 2.8.9

Uses. Theorem 2.4.34 (Block multiplication), Exercise 2.5.39, Proposition 2.4.14 (Algebra of matrices)
Techniques. Block decomposition (Technique 2.4.35), Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. $N = \begin{pmatrix} 0 & A & B \\ 0 & 0 & C \\ 0 & 0 & 0 \end{pmatrix}$. Only one block of N^2 is nonzero.
Hint 2. Since $N^3 = 0$, the geometric series $I - N + N^2$ is a candidate for M^{-1}. Check the sizes of AC and CA.
Sketch. N^2 has the single nonzero block AC in position $(1,3)$, and $N^3 = 0$. So $(I+N)\left(I - N + N^2\right) = I + N^3 = I$ in both orders, and $M^{-1} = \begin{pmatrix} I_p & -A & AC-B \\ 0 & I_q & -C \\ 0 & 0 & I_r \end{pmatrix}$. The product CA is defined only when $r = p$, and the corner of M^{-1} is $p \times r$, which AC is.

(a) $M = I + N$ with

$$N = \begin{pmatrix} 0 & A & B \\ 0 & 0 & C \\ 0 & 0 & 0 \end{pmatrix}.$$

By Theorem 2.4.34, the (I, J) block of N^2 is $\sum_K N_{IK} N_{KJ}$, and a term is nonzero only if $I < K < J$. So the only nonzero block of N^2 is in position $(1, 3)$, and it equals $N_{12} N_{23} = AC$:

$$N^2 = \begin{pmatrix} 0 & 0 & AC \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

The only nonzero block row of N^2 is the first, and its only nonzero block sits in block column 3, which multiplies the third block row of N, which is zero. So $N^3 = N^2 N = 0$. Since I commutes with N,

$$(I + N)\big(I - N + N^2\big) = I - N + N^2 + N - N^2 + N^3 = I,$$

and the product in the other order is the same expansion. By Technique 2.5.16 (this is Exercise 2.5.39 with $k = 3$),

$$M^{-1} = I - N + N^2 = \begin{pmatrix} I_p & -A & AC - B \\ 0 & I_q & -C \\ 0 & 0 & I_r \end{pmatrix}.$$

(b) $AC - B$ is correct. The product CA is defined only when $r = p$, since C has r columns and A has p rows, and even then it is not the right block. As a check, the $(1, 3)$ block of MM^{-1} is

$$I_p(AC - B) + A(-C) + BI_r = AC - B - AC + B = 0,$$

which works because AC appears twice in the same order. In the scalar formula the order did not matter, and that is exactly the information the scalar formula loses.

Solution to Exercise 2.8.10

> *Uses.* Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 1.2.18 (Degree and evaluation versus the operations), Example 2.6.29 (Evaluation at 0, and multiplication by x), Example 2.1.19 (Composites), Proposition 2.1.24 (Algebra of composition)
> *Techniques.* Test injectivity at $\mathbf{0}$ (Technique 2.6.12), Guess the inverse, then check both products (Technique 2.5.16)
> *Hint 1.* (a) Compare degrees for injectivity. For surjectivity, evaluate a value $(M - c\,\mathrm{id})(q)$ at c.
> *Hint 2.* (b) $D - c\,\mathrm{id} = -c\big(\mathrm{id} - c^{-1}D\big)$. Expand $1/(1 - t)$ as a geometric series, and use that D^{d+1} kills polynomials of degree at most d.
> *Sketch.* (a) For $q \neq \mathbf{0}$ of degree d, xq has degree $d + 1$ and cq degree at most d, so $(M - c\,\mathrm{id})(q) \neq \mathbf{0}$. Every value vanishes at c, and 1 does not. (b) $S = -\sum_{k\geq 0} c^{-k-1} D^k$, a finite sum on each polynomial; $(D - c\,\mathrm{id})S$ and $S(D - c\,\mathrm{id})$ telescope to id. (c) Both maps are injective by the kernel test, but only one is surjective.

(a) *Injective.* Let $q \neq \mathbf{0}$ have degree d. Then xq has degree $d + 1$ and cq has degree at most d, so their degrees differ and $(M - c\,\mathrm{id})(q) = xq - cq$ has degree $d + 1$ (Proposition 1.2.18(a)). In particular it is not $\mathbf{0}$, and $M - c\,\mathrm{id}$ is injective by Theorem 2.6.11.

Not surjective. Every value $(M - c\,\mathrm{id})(q) = xq - cq$ vanishes at c (Example 2.6.29). The constant polynomial 1 does not, so it is not a value.

(b) Since $D - c\,\mathrm{id} = -c\big(\mathrm{id} - c^{-1}D\big)$ and $1/(1 - t) = 1 + t + t^2 + \cdots$, the candidate is

$$S = -c^{-1} \sum_{k\geq 0} c^{-k} D^k = -\sum_{k\geq 0} c^{-k-1} D^k.$$

On a polynomial of degree at most d only the terms with $k \leq d$ can be nonzero, since D^{d+1} kills it (Example 2.1.19(a)). So define $S(f) = -\sum_{k=0}^{d} c^{-k-1} D^k(f)$ for any $d \geq \deg f$; the choice of d does not matter, and on $F[x]_{\leq d}$, S agrees with a linear combination of powers of D, so S is linear. For $\deg f \leq d$,

$$(D - c\,\mathrm{id})(S(f)) = -\sum_{k=0}^{d} c^{-k-1} D^{k+1}(f) + \sum_{k=0}^{d} c^{-k} D^{k}(f)$$
$$= f - c^{-d-1} D^{d+1}(f) = f,$$

since the two sums cancel except for the term $k = 0$ of the second and the term $k = d$ of the first. The same computation gives $S((D - c\,\mathrm{id})(f)) = f$, because $(D - c\,\mathrm{id})(f)$ also has degree at most d. By Technique 2.5.16, $D - c\,\mathrm{id}$ is invertible and $(D - c\,\mathrm{id})^{-1} = -\sum_{k\geq 0} c^{-k-1} D^{k}$.

(c) The kernel test proves that $D - c\,\mathrm{id}$ is injective for $c \neq 0$: if $D(f) = cf$ with $f \neq \mathbf{0}$, the left side has smaller degree than the right. But it proves the same about $M - c\,\mathrm{id}$, which is not surjective. On $F[x]$ injectivity does not imply surjectivity, so a second argument was needed, and the guessed inverse supplied both halves at once.

Solution to Exercise 2.8.11

Uses. Proposition 2.4.14 (Algebra of matrices), Lemma 2.4.24 (Matrix units), Example 2.3.28 (Translating in both directions), Exercise 2.3.40, Proposition 2.3.16 (The matrix of T_A), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Example 2.3.6 (The zero map and the identity map), Proposition 2.4.12 (Matrices of sums and scalar multiples)
Techniques. Proving TFAE (Technique 2.7.1), Compute entry by entry (Technique 2.4.15)
Hint 1. Use (i) as a hub. Which spokes are already in the chapter? Look at Example 2.3.28(b) and Exercise 2.3.40.
Hint 2. For (iii) ⇒ (i), compute both sides of $AU_{ij} = U_{ij}A$: one has only column j nonzero, the other only row i.
Sketch. Hub at (i). The cycle (i) ⇒ (ii) ⇒ (iii) ⇒ (i): scalars commute with everything, (iii) is a special case of (ii), and AU_{ij} has column j equal to column i of A while $U_{ij}A$ has row i equal to row j of A, which forces $a_{ki} = 0$ for $k \neq i$ and $a_{ii} = a_{jj}$. (i) ⇔ (iv) is Example 2.3.28(b) plus a one-line converse. (i) ⇔ (v): since $[T_A]_{\mathcal{E}\mathcal{E}} = A$, (v) says that the matrix of T_A is the same in every basis, which is Exercise 2.3.40.

We use (i) as a hub. Each spoke is either a citation or a short computation.

(i) ⇒ (ii) ⇒ (iii) ⇒ (i). If $A = \lambda I_n$, then $AX = \lambda X = XA$ by Proposition 2.4.14(b) and (d). (iii) is the special case $X = U_{ij}$ of (ii). For (iii) ⇒ (i), fix i and j. By associativity and Lemma 2.4.24(b),

$$AU_{ij} = (A\mathbf{e}_i)\mathbf{e}_j^{\mathsf{T}}, \quad U_{ij}A = \mathbf{e}_i\big(\mathbf{e}_j^{\mathsf{T}}A\big).$$

The first matrix has column j equal to column i of A and every other column zero. The second has row i equal to row j of A and every other row zero. If they are equal, then column j of the first, $A_{\cdot,i}$, is zero outside row i, so $a_{ki} = 0$ for $k \neq i$; and comparing the entries in position (i, j) gives $a_{ii} = a_{jj}$. As i and j range over all indices, A is diagonal with all diagonal entries equal to a_{11}, so $A = a_{11}I_n$.

(i) ⇔ (iv). If $A = \lambda I_n$, then $A\mathbf{x} = \lambda\mathbf{x} \in \mathrm{span}(\mathbf{x})$. The converse is Example 2.3.28(b).

(i) ⇔ (v). By Proposition 2.3.16, $[T_A]_{\mathcal{E}\mathcal{E}} = A$, so (v) says that $[T_A]_{\mathcal{B}\mathcal{B}}$ is the same matrix for every basis $\mathcal{B}$ of length n. By Exercise 2.3.40, this holds if and only if $T_A = \lambda\,\mathrm{id}$ for some λ, that is, $T_A = T_{\lambda I_n}$, which by Proposition 2.3.17 means $A = \lambda I_n$. (For the direction (i) ⇒ (v) one can also compute directly: $[\lambda\,\mathrm{id}]_{\mathcal{B}\mathcal{B}} = \lambda I_n$ by Example 2.3.6 and Proposition 2.4.12.)

Every condition is connected to the hub in both directions, so all five are equivalent. Only one arrow, (iii) ⇒ (i), needed new work; the others were earlier results read as statements about A.

Solution to Exercise 2.8.12

Uses. Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear), Definition 2.4.26 (Trace), Definition 2.4.21 (Transpose)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. Take the trace of both sides. The left side has trace 0.
Hint 2. $\mathrm{tr}\big(AA^{\mathsf{T}}\big) = \sum_{j,k} a_{jk}^2$. Over $\mathbb{R}$ this is a sum of squares. Over $\mathbb{C}$ and $\mathbb{F}_2$, find A with $AA^{\mathsf{T}} = -I_n$.
Sketch. (a) $\mathrm{tr}(AB - BA) = 0$ by cyclicity, while $\mathrm{tr}\big(AA^{\mathsf{T}} + I_n\big) = \sum_{j,k} a_{jk}^2 + n \geq n > 0$. (b) $A = iI_n$ over $\mathbb{C}$ and $A = I_n$ over $\mathbb{F}_2$ give $AA^{\mathsf{T}} = -I_n$, so with $B = 0$ both sides are 0. (c) Over $\mathbb{R}$ a sum of squares is 0 only if every term is. Over $\mathbb{C}$, $A = \left(\begin{smallmatrix} 1 & i \\ 0 & 0 \end{smallmatrix}\right)$; over $\mathbb{F}_2$, $A = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$.

The (j,j) entry of AA^{T} is $\sum_k a_{jk}\left(A^{\mathsf{T}}\right)_{kj} = \sum_k a_{jk}^2$, so

$$\operatorname{tr}\left(AA^{\mathsf{T}}\right) = \sum_{j=1}^{n}\sum_{k=1}^{n} a_{jk}^2.$$

(a) By Proposition 2.4.27 and Proposition 2.4.28, $\operatorname{tr}(AB-BA) = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$. Over $\mathbb{R}$, every $a_{jk}^2 \geq 0$, so $\operatorname{tr}\left(AA^{\mathsf{T}} + I_n\right) = \operatorname{tr}\left(AA^{\mathsf{T}}\right) + n \geq n > 0$. The two sides have different traces, so they are not equal.

(b) Over $\mathbb{C}$, let $A = iI_n$ and $B = 0$. Then $AB - BA = 0$ and $AA^{\mathsf{T}} + I_n = i^2 I_n + I_n = 0$. Over $\mathbb{F}_2$, let $A = I_n$ and $B = 0$; then $AA^{\mathsf{T}} + I_n = (1+1)I_n = 0 = AB - BA$.

(c) Over $\mathbb{R}$, a sum of squares of real numbers is 0 only if every square is 0, so $\operatorname{tr}\left(AA^{\mathsf{T}}\right) = 0$ gives every $a_{jk} = 0$. Over $\mathbb{C}$, $A = \begin{pmatrix} 1 & i \\ 0 & 0 \end{pmatrix}$ has $\operatorname{tr}\left(AA^{\mathsf{T}}\right) = 1^2 + i^2 = 0$. Over $\mathbb{F}_2$, $A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ has $\operatorname{tr}\left(AA^{\mathsf{T}}\right) = 1 + 1 = 0$.

The trace argument used one fact beyond cyclicity, the positivity of sums of real squares, and (c) shows exactly where that fact lives. The same positivity drives the inner products of Section 6.1, where $\operatorname{tr}\left(A^{\mathsf{T}}A\right)$ is the squared length of A.

Solution to Exercise 2.8.13

Uses. Theorem 2.4.2 (The matrix of a composite), Definition 2.3.1 (Matrix of a linear map), Example 2.5.21 (Change of coordinates is invertible)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Write $T = \mathrm{id} \circ T \circ \mathrm{id}$ and apply Theorem 2.4.2 with the bases chosen so that the inner subscripts match.
Hint 2. Which way does $P = [\mathrm{id}]_{\mathcal{EB}}$ convert coordinates? Check the answer by computing $T(\mathbf{b}_1)$ and $T(\mathbf{b}_2)$ in $\mathcal{B}$-coordinates.
Sketch. $[T]_{\mathcal{BB}} = [\mathrm{id}]_{\mathcal{BE}}[T]_{\mathcal{EE}}[\mathrm{id}]_{\mathcal{EB}} = P^{-1}[T]_{\mathcal{EE}}P = \begin{pmatrix} -1 & 0 \\ 1 & 1 \end{pmatrix}$. The computation multiplied in the wrong order: P converts $\mathcal{B}$-coordinates to standard ones, so it must act first. Directly, $T(\mathbf{b}_1) = (0,1) = -\mathbf{b}_1 + \mathbf{b}_2$ and $T(\mathbf{b}_2) = \mathbf{b}_2$.

The error. By Theorem 2.4.2, applied to $T = \mathrm{id} \circ T \circ \mathrm{id}$ with the bases arranged so that the inner subscripts match,

$$[T]_{\mathcal{BB}} = [\mathrm{id}]_{\mathcal{BE}}[T]_{\mathcal{EE}}[\mathrm{id}]_{\mathcal{EB}} = P^{-1}[T]_{\mathcal{EE}}P,$$

where $[\mathrm{id}]_{\mathcal{BE}} = P^{-1}$ by Example 2.5.21. The matrix $P = [\mathrm{id}]_{\mathcal{EB}}$ converts $\mathcal{B}$-coordinates into standard coordinates, so it is applied first, on the right; the computation put it on the left. In $P[T]_{\mathcal{EE}}P^{-1}$ the subscripts do not match: the factor $P = [\mathrm{id}]_{\mathcal{EB}}$ expects $\mathcal{B}$-coordinates, but it receives the standard coordinates produced by $[T]_{\mathcal{EE}}$.

The correct matrix.

$$P^{-1}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}P = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 1 & 1 \end{pmatrix}.$$

As a check, $T(\mathbf{b}_1) = (0,1) = -\mathbf{b}_1 + \mathbf{b}_2$ and $T(\mathbf{b}_2) = (1,1) = \mathbf{b}_2$, whose $\mathcal{B}$-coordinates $(-1,1)$ and $(0,1)$ are the columns found.

The wrong answer is not meaningless: $P[T]_{\mathcal{EE}}P^{-1}$ is the matrix of T in the basis $(1,0),(-1,1)$ formed by the columns of P^{-1}. That is one way to see that the error produces a plausible-looking matrix, which is why checking one column directly is worth the effort.

Solution to Exercise 2.8.14

Uses. Proposition 2.5.17 (Algebra of inverses), Proposition 2.4.14 (Algebra of matrices), Exercise 2.5.19
Techniques. Guess the inverse, then check both products (Technique 2.5.16), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Associativity moves parentheses. Does it move factors past each other?
Hint 2. $(AB)^{-1} = B^{-1}A^{-1}$ always. When is $B^{-1}A^{-1} = A^{-1}B^{-1}$? Invert both sides.

Sketch. Associativity gives $(AB)\left(A^{-1}B^{-1}\right) = ABA^{-1}B^{-1}$; replacing BA^{-1} by $A^{-1}B$ needs commutativity. With $A = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$, $A^{-1}B^{-1} = \left(\begin{smallmatrix}2 & -1\\ -1 & 1\end{smallmatrix}\right) \neq \left(\begin{smallmatrix}1 & -1\\ -1 & 2\end{smallmatrix}\right) = (AB)^{-1}$. The conclusion holds exactly when $AB = BA$: $(AB)^{-1} = B^{-1}A^{-1}$, and $B^{-1}A^{-1} = A^{-1}B^{-1}$ iff, inverting both sides, $AB = BA$.

The error. Associativity regroups a product but keeps the order of its factors: $(AB)\left(A^{-1}B^{-1}\right) = ABA^{-1}B^{-1}$. The step to $AA^{-1}BB^{-1}$ moves A^{-1} past B, which requires $BA^{-1} = A^{-1}B$.

The claim is false. Take $A = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$, as in Exercise 2.5.19. There, $(AB)^{-1} = B^{-1}A^{-1} = \left(\begin{smallmatrix}1 & -1\\ -1 & 2\end{smallmatrix}\right)$, while $A^{-1}B^{-1} = \left(\begin{smallmatrix}2 & -1\\ -1 & 1\end{smallmatrix}\right)$.

When it holds. By Proposition 2.5.17(d), the matrix version of (b), $(AB)^{-1} = B^{-1}A^{-1}$ always. So the conclusion holds if and only if $B^{-1}A^{-1} = A^{-1}B^{-1}$. By the same result together with Proposition 2.5.17(a), both sides are invertible, with inverses AB and BA, and two invertible matrices are equal exactly when their inverses are. So the conclusion holds if and only if $AB = BA$. In particular it holds for every pair when $n = 1$, and fails for some pair whenever $n \geq 2$ (put the example above in the top left corner).

Solution to Exercise 2.8.15

Uses. Corollary 2.5.6 (One-sided cancellation), Exercise 2.5.41, Exercise 2.5.33, Theorem 3.5.23 (One-sided inverses of square matrices)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Which property of T allows cancelling it on the right (Corollary 2.5.6)? Does T have it?
Hint 2. Try $V = F[x]$ and $T = M$, multiplication by x, with the left inverse L of Exercise 2.5.41.
Sketch. Cancelling T on the right requires T to be right-invertible, which is what the argument is trying to prove. On $F[x]$, $LM = \mathrm{id}$ but $ML(1) = \mathbf{0}$, and M is not surjective, so it has no right inverse. If T is surjective, then $(TS - \mathrm{id})T = 0$ says that $TS - \mathrm{id}$ vanishes on $\operatorname{im} T = V$, and the argument is correct (Exercise 2.5.33(a)).

The error. By Corollary 2.5.6(b), T can be cancelled on the right when T is right-invertible. That is exactly what the argument is trying to prove, so the cancellation assumes the conclusion. The first two steps are fine; only the cancellation is not.

The claim is false. Let $V = F[x]$, let M be multiplication by x, and let $L(a_0 + a_1x + \cdots + a_nx^n) = a_1 + a_2x + \cdots + a_nx^{n-1}$. Then $LM = \mathrm{id}_{F[x]}$ (Exercise 2.5.41), so M has a left inverse. But M is not surjective, since every value xq has constant term 0, so M has no right inverse (Proposition 2.5.5) and is not invertible. Indeed $(ML - \mathrm{id})(1) = M(\mathbf{0}) - 1 = -1 \neq \mathbf{0}$, although $(ML - \mathrm{id})M = M(LM) - M = 0$.

A repair. Suppose in addition that T is surjective. Then $(TS - \mathrm{id}_V)T = 0$ says that $TS - \mathrm{id}_V$ vanishes at every $T(\mathbf{v})$, that is, on $\operatorname{im} T = V$, so $TS = \mathrm{id}_V$. This is Exercise 2.5.33(a). For $V = F^n$ the claim itself is true (Theorem 3.5.23), but the argument above does not prove it, because it never uses that V is finite-dimensional.

Problems for Chapter 2

Solution to Problem 2.1

Uses. Definition 2.6.1 (Injective), Definition 2.6.5 (Kernel), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.5.15 (Short lists, zeros, and repeats), Definition 2.1.1 (Linear map)
Techniques. Test injectivity at $\mathbf{0}$ (Technique 2.6.12), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For the theorem, $T(\mathbf{v}) = T(\mathbf{v}')$ should become a statement about $\mathbf{v} - \mathbf{v}'$. For the proposition, pull a relation among the $T(\mathbf{v}_i)$ back through T.
Hint 2. For (c), list the facts about T that the proof used: $T(\mathbf{0}) = \mathbf{0}$ and $T(\mathbf{v} - \mathbf{v}') = T(\mathbf{v}) - T(\mathbf{v}')$. Over $\mathbb{F}_2$, a function with $T(\mathbf{0}) = 0$ is automatically homogeneous.
Sketch. (b) If T is injective and $T(\mathbf{v}) = \mathbf{0} = T(\mathbf{0})$, then $\mathbf{v} = \mathbf{0}$; if $\ker T = \{\mathbf{0}\}$ and $T(\mathbf{v}) = T(\mathbf{v}')$, then $T(\mathbf{v} - \mathbf{v}') = \mathbf{0}$. For independence: $\sum a_iT(\mathbf{v}_i) = \mathbf{0}$ gives $\sum a_i\mathbf{v}_i \in \ker T$; conversely a nonzero $\mathbf{v} \in \ker T$ is an independent list with dependent image. (c) Additivity alone gives $T(\mathbf{0}) = \mathbf{0}$ and $T(\mathbf{v} - \mathbf{v}') = T(\mathbf{v}) - T(\mathbf{v}')$. Over $\mathbb{F}_2$, $T(\mathbf{0}) = 0$ and $T(\mathbf{v}) = 1$ otherwise is homogeneous, has only $\mathbf{0}$ in its kernel, and has $T(\mathbf{e}_1) = T(\mathbf{e}_2)$.

(a) Theorem 2.6.11: a linear map $T \in \mathrm{L}(V,W)$ is injective if and only if $\ker T = \{\mathbf{0}\}$. Proposition 2.6.14: $T \in \mathrm{L}(V,W)$ is injective if and only if T sends every linearly independent list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ in V to a linearly independent list $T(\mathbf{v}_1), \ldots, T(\mathbf{v}_k)$.

(b) *The theorem.* Suppose T is injective, and let $\mathbf{v} \in \ker T$. Then $T(\mathbf{v}) = \mathbf{0} = T(\mathbf{0})$ by Proposition 2.1.4, so $\mathbf{v} = \mathbf{0}$. Conversely, suppose $\ker T = \{\mathbf{0}\}$, and let $T(\mathbf{v}) = T(\mathbf{v}')$. By Proposition 2.1.4, $T(\mathbf{v} - \mathbf{v}') = T(\mathbf{v}) - T(\mathbf{v}') = \mathbf{0}$, so $\mathbf{v} - \mathbf{v}' \in \ker T$, that is, $\mathbf{v} = \mathbf{v}'$.

The proposition. Suppose T is injective, let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ be independent, and let $\sum_i a_i T(\mathbf{v}_i) = \mathbf{0}$. By linearity, $T\left(\sum_i a_i \mathbf{v}_i\right) = \mathbf{0}$, so $\sum_i a_i \mathbf{v}_i \in \ker T = \{\mathbf{0}\}$, and independence gives every $a_i = 0$. So the image list is independent (Theorem 1.5.5). Conversely, suppose T is not injective. By the theorem there is $\mathbf{v} \neq \mathbf{0}$ in $\ker T$. The list $\mathbf{v}$ is independent (Proposition 1.5.15(b)), but its image is the list $\mathbf{0}$, which is dependent (Proposition 1.5.15(c)).

(c) *Additive maps.* The proof of the theorem used two facts: $T(\mathbf{0}) = \mathbf{0}$, and $T(\mathbf{v} - \mathbf{v}') = T(\mathbf{v}) - T(\mathbf{v}')$. Both follow from additivity alone. First, $T(\mathbf{0}) = T(\mathbf{0} + \mathbf{0}) = T(\mathbf{0}) + T(\mathbf{0})$, and adding $-T(\mathbf{0})$ gives $T(\mathbf{0}) = \mathbf{0}$. Next, $T(\mathbf{v}') + T(-\mathbf{v}') = T(\mathbf{0}) = \mathbf{0}$, so $T(-\mathbf{v}') = -T(\mathbf{v}')$, and then $T(\mathbf{v} - \mathbf{v}') = T(\mathbf{v}) + T(-\mathbf{v}') = T(\mathbf{v}) - T(\mathbf{v}')$. With these two facts the proof runs word for word, so an additive map is injective if and only if it sends only $\mathbf{0}$ to $\mathbf{0}$.

Homogeneous maps. Define $T : \mathbb{F}_2^2 \to \mathbb{F}_2$ by $T(\mathbf{0}) = 0$ and $T(\mathbf{v}) = 1$ for $\mathbf{v} \neq \mathbf{0}$. The only scalars are 0 and 1, and $T(0\mathbf{v}) = T(\mathbf{0}) = 0 = 0 \cdot T(\mathbf{v})$ and $T(1\mathbf{v}) = T(\mathbf{v}) = 1 \cdot T(\mathbf{v})$, so T is homogeneous. By construction $T(\mathbf{v}) = 0$ only for $\mathbf{v} = \mathbf{0}$. But $T(\mathbf{e}_1) = T(\mathbf{e}_2) = 1$ with $\mathbf{e}_1 \neq \mathbf{e}_2$, so T is not injective. It is not additive either, since $T(\mathbf{e}_1) + T(\mathbf{e}_2) = 0 \neq 1 = T(\mathbf{e}_1 + \mathbf{e}_2)$, and additivity is the half of linearity that the kernel test needs.

Solution to Problem 2.2

Uses. Definition 2.3.1 (Matrix of a linear map), Theorem 2.3.9 (The matrix of a map computes the map), Definition 2.4.1 (Matrix product), Proposition 2.3.16 (The matrix of T_A), Proposition 2.1.24 (Algebra of composition), Example 2.5.21 (Change of coordinates is invertible), Exercise 2.5.32, Exercise 2.3.26
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. For (b), compare the j-th columns. For associativity, read each matrix as the standard matrix of T_A, T_B, T_C.
Hint 2. For (c), try $T = \mathrm{id}_V$. Then $P = [\mathrm{id}_V]_{\mathcal{C}\mathcal{B}}$ satisfies $P^2 = P$, and P is invertible.
Sketch. (b) Column j of $[TS]_{\mathcal{C}\mathcal{A}}$ is $\left[T\left(S(\mathbf{u}_j)\right)\right]_{\mathcal{C}} = [T]_{\mathcal{C}\mathcal{B}}\left[S(\mathbf{u}_j)\right]_{\mathcal{B}}$, which is $[T]_{\mathcal{C}\mathcal{B}}$ times column j of $[S]_{\mathcal{B}\mathcal{A}}$. With standard bases, $(AB)C$ and $A(BC)$ are the matrices of $(T_A T_B)T_C$ and $T_A(T_B T_C)$, which are the same function. (c) If $\mathcal{B} = \mathcal{C}$ this is (a). Conversely, $T = \mathrm{id}$ gives $P^2 = P$ for the invertible $P = [\mathrm{id}]_{\mathcal{C}\mathcal{B}}$, so $P = I_n$, so $\mathcal{B} = \mathcal{C}$.

(a) Let U, V, W have bases $\mathcal{A} = \mathbf{u}_1, \ldots, \mathbf{u}_n$, $\mathcal{B}$, and $\mathcal{C}$. For $S \in \mathrm{L}(U,V)$ and $T \in \mathrm{L}(V,W)$,

$$[TS]_{\mathcal{C}\mathcal{A}} = [T]_{\mathcal{C}\mathcal{B}}[S]_{\mathcal{B}\mathcal{A}}.$$

(b) By Definition 2.3.1, column j of $[TS]_{\mathcal{C}\mathcal{A}}$ is $\left[T\left(S(\mathbf{u}_j)\right)\right]_{\mathcal{C}}$. By Theorem 2.3.9, applied to T at the vector $S(\mathbf{u}_j)$, this is $[T]_{\mathcal{C}\mathcal{B}}\left[S(\mathbf{u}_j)\right]_{\mathcal{B}}$, and $\left[S(\mathbf{u}_j)\right]_{\mathcal{B}}$ is column j of $[S]_{\mathcal{B}\mathcal{A}}$. By Definition 2.4.1, $[T]_{\mathcal{C}\mathcal{B}}$ times column j of $[S]_{\mathcal{B}\mathcal{A}}$ is column j of $[T]_{\mathcal{C}\mathcal{B}}[S]_{\mathcal{B}\mathcal{A}}$. The two matrices have the same columns.

Associativity. Let $A \in F^{\ell \times m}$, $B \in F^{m \times n}$, $C \in F^{n \times p}$, and use standard bases throughout, so that $[T_X]_{\mathcal{E}\mathcal{E}} = X$ for every matrix X (Proposition 2.3.16). Applying (a) twice,

$$[(T_A T_B)T_C]_{\mathcal{E}\mathcal{E}} = [T_A T_B]_{\mathcal{E}\mathcal{E}} C = (AB)C, \quad [T_A(T_B T_C)]_{\mathcal{E}\mathcal{E}} = A[T_B T_C]_{\mathcal{E}\mathcal{E}} = A(BC).$$

Composition of functions is associative (Proposition 2.1.24(a)), so $(T_A T_B)T_C = T_A(T_B T_C)$, and the two matrices are equal.

(c) If $\mathcal{B} = \mathcal{C}$, then (a) with $S = T$ and all three bases equal to $\mathcal{B}$ gives $[T]_{\mathcal{B}\mathcal{B}}[T]_{\mathcal{B}\mathcal{B}} = \left[T^2\right]_{\mathcal{B}\mathcal{B}}$.

Conversely, suppose the identity holds for every T, and take $T = \mathrm{id}_V$. With $P = [\mathrm{id}_V]_{\mathcal{C}\mathcal{B}}$ it reads $P^2 = [\mathrm{id}_V]_{\mathcal{C}\mathcal{B}} = P$. The matrix P is invertible, with inverse $[\mathrm{id}_V]_{\mathcal{B}\mathcal{C}}$ (Example 2.5.21), so $P^2 = P$ forces $P = I_n$ (Exercise 2.5.32(c)). By Exercise 2.3.26, $\mathcal{B} = \mathcal{C}$.

In the product $[T]_{\mathcal{C}\mathcal{B}}[T]_{\mathcal{C}\mathcal{B}}$, the right factor produces $\mathcal{C}$-coordinates and the left factor expects $\mathcal{B}$-coordinates. Part (c) says that this mismatch is harmless only when the two bases coincide.

Solution to Problem 2.3

> *Uses.* Theorem 2.7.4 (Second Fundamental Theorem), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.4.8 (Four views of the product), Theorem 2.4.2 (The matrix of a composite), Non-example 2.7.10 (Choices that are not linear), Corollary 2.6.31 (Fibers are translates of the kernel), Exercise 2.6.44
> *Techniques.* Construct a map by choosing it on a basis (Technique 2.2.4), Check it on a basis (Technique 2.2.7)
> *Hint 1.* For (b), pick $\mathbf{x}_i$ with $A\mathbf{x}_i = \mathbf{e}_i$, and let B have columns $\mathbf{x}_1, \dots, \mathbf{x}_m$.
> *Hint 2.* For (c), a right inverse is a choice of one solution of $A\mathbf{x} = \mathbf{e}_i$ for each i. How many solutions does each of these equations have? Use Corollary 2.6.31 and Exercise 2.6.44.
> *Sketch.* (b) With $A\mathbf{x}_i = \mathbf{e}_i$, the matrix B with columns $\mathbf{x}_i$ has $AB = I_m$ by the column view, so T_B is a right inverse. Choices made one $\mathbf{y}$ at a time need not fit together linearly (Non-example 2.7.10(b)); choices on a basis always extend. (c) $AC = I_m$ means $A\mathbf{c}_i = \mathbf{e}_i$ for each column. Each such equation has $|\ker T_A| = p^n/p^m$ solutions, and the m columns are chosen independently: $(p^{n-m})^m$.

(a) Theorem 2.7.4: for $A \in F^{m\times n}$ the following are equivalent. (I) T_A is surjective. (II) For every $\mathbf{y} \in F^m$, $A\mathbf{x} = \mathbf{y}$ has at least one solution. (III) The columns of A span F^m. (IV) $\operatorname{im} T_A = F^m$. (V) T_A has a right inverse, a linear map $S : F^m \to F^n$ with $T_A \circ S = \mathrm{id}_{F^m}$.

(b) Assume (II). For $i = 1, \dots, m$ choose $\mathbf{x}_i \in F^n$ with $A\mathbf{x}_i = \mathbf{e}_i$, and let $B \in F^{n\times m}$ have columns $\mathbf{x}_1, \dots, \mathbf{x}_m$. By the column view (Proposition 2.4.8(b)), column i of AB is $A\mathbf{x}_i = \mathbf{e}_i$, so $AB = I_m$. By Theorem 2.4.2(b), $T_A \circ T_B = T_{AB} = \mathrm{id}_{F^m}$, so $S = T_B$ is a right inverse. In the language of Theorem 2.2.1, S is the linear map with $S(\mathbf{e}_i) = \mathbf{x}_i$, and $T_A \circ S$ agrees with id on the standard basis.

The choices are made on a basis because only there do they automatically fit together. A choice of one solution for each $\mathbf{y}$ separately is a function $F^m \to F^n$, but usually not a linear one (Non-example 2.7.10(b)). Once $\mathbf{x}_1, \dots, \mathbf{x}_m$ are chosen, the extension sends $\mathbf{y} = \sum_i y_i \mathbf{e}_i$ to $\sum_i y_i \mathbf{x}_i$, which is a solution of $A\mathbf{x} = \mathbf{y}$ by linearity: no further choice is made.

(c) By the column view, $C \in \mathbb{F}_p^{n\times m}$ satisfies $AC = I_m$ if and only if its columns satisfy $A\mathbf{c}_i = \mathbf{e}_i$ for $i = 1, \dots, m$. The solutions of $A\mathbf{x} = \mathbf{e}_i$ form the fiber $T_A^{-1}(\mathbf{e}_i)$, which is nonempty since T_A is surjective, and is a translate of $\ker T_A$ (Corollary 2.6.31(b)); so it has $|\ker T_A|$ elements. By Exercise 2.6.44(a),

$$p^n = \left|\mathbb{F}_p^n\right| = |\ker T_A| \cdot |\operatorname{im} T_A| = |\ker T_A| \cdot p^m,$$

so $|\ker T_A| = p^{n-m}$. The m columns are chosen independently, so there are $(p^{n-m})^m = p^{m(n-m)}$ right inverses.

In Exercise 2.5.36(c), T_{A^T} is surjective for the matrix $A^\mathsf{T} \in \mathbb{F}_p^{2\times 3}$ there, and it has p^2 right inverses; the formula gives $p^{2(3-2)} = p^2$. A square surjective A has exactly one right inverse, as it must (Theorem 3.5.23).

Solution to Problem 2.4

> *Uses.* Proposition 2.4.14 (Algebra of matrices), Proposition 2.4.23 (Transpose of a product), Proposition 2.4.22 (Transpose is a linear involution), Lemma 2.4.24 (Matrix units), Definition 2.3.1 (Matrix of a linear map), Proposition 2.4.12 (Matrices of sums and scalar multiples), Proposition 2.4.27 (The trace is linear), Exercise 2.2.34
> *Techniques.* Compute entry by entry (Technique 2.4.15), Check it on a basis (Technique 2.2.7)
> *Hint 1.* The diagonal entry of $[\Phi]_{ll}$ belonging to U_{ij} is the U_{ij}-coordinate of $\Phi(U_{ij})$, which is the (i,j) entry of $\Phi(U_{ij})$.
> *Hint 2.* For (c), compute $L_{U_{ij},U_{kl}}(X) = U_{ij}XU_{kl}$. Which matrix unit does it send where?
> *Sketch.* (a) Distributivity, associativity, and $\left(AX^\mathsf{T}B\right)^\mathsf{T} = B^\mathsf{T}XA^\mathsf{T}$. (b) $\left(AU_{ij}B\right)_{ij} = \left(\mathbf{e}_i^\mathsf{T}A\mathbf{e}_i\right)\left(\mathbf{e}_j^\mathsf{T}B\mathbf{e}_j\right) = a_{ii}b_{jj}$, which sums to $\operatorname{tr} A \operatorname{tr} B$; $\tau(U_{ij}) = U_{ji}$ contributes δ_{ij}, so $\operatorname{tr}\tau = n * 1$; $C_A = L_{A,I_n} - L_{I_n,A}$ has trace 0. (c) $U_{ij}XU_{kl} = x_{jk}U_{il}$, so $L_{U_{ij},U_{kl}}$ sends U_{jk} to U_{il} and the other units to 0; these n^4 maps form the basis of Exercise 2.2.34. In particular $X^\mathsf{T} = \sum_{i,j} U_{ij}XU_{ij}$.

(a) $L_{A,B}$ is linear by Proposition 2.4.14(c) and (d). For every X, associativity gives

$$L_{A,B}\big(L_{C,D}(X)\big) = A(CXD)B = (AC)X(DB) = L_{AC,DB}(X),$$

and by Proposition 2.4.23 and Proposition 2.4.22,

$$\tau\big(L_{A,B}(\tau(X))\big) = \big(AX^{\mathsf{T}}B\big)^{\mathsf{T}} = B^{\mathsf{T}}\big(X^{\mathsf{T}}\big)^{\mathsf{T}}A^{\mathsf{T}} = B^{\mathsf{T}}XA^{\mathsf{T}}.$$

(b) By Lemma 2.4.24(a), the coordinates of a matrix with respect to $\mathcal{U}$ are its entries. So the diagonal entry of $[\Phi]_{\mathcal{U}\mathcal{U}}$ in the position of U_{ij} is the (i,j) entry of $\Phi\big(U_{ij}\big)$, whatever order $\mathcal{U}$ is listed in, and $\operatorname{tr}\Phi$ is the sum of these entries over all (i,j). For $\Phi = L_{A,B}$, by Lemma 2.4.24(b),

$$\big(AU_{ij}B\big)_{ij} = \mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}B\mathbf{e}_j = a_{ii}b_{jj},$$

and $\sum_{i,j} a_{ii}b_{jj} = (\operatorname{tr}A)(\operatorname{tr}B)$.

For τ, $\tau\big(U_{ij}\big) = U_{ji}$, whose (i,j) entry is δ_{ij}. So $\operatorname{tr}\tau = \sum_{i,j}\delta_{ij} = n * 1$.

For $C_A = L_{A,I_n} - L_{I_n,A}$, Proposition 2.4.12 and Proposition 2.4.27 give $\operatorname{tr}C_A = (\operatorname{tr}A)(n*1) - (n*1)(\operatorname{tr}A) = 0$.

(c) For all indices, associativity and Lemma 2.4.24(b) give

$$L_{U_{ij},U_{kl}}(X) = \mathbf{e}_i\big(\mathbf{e}_j^{\mathsf{T}}X\mathbf{e}_k\big)\mathbf{e}_l^{\mathsf{T}} = x_{jk}U_{il}.$$

So $L_{U_{ij},U_{kl}}$ sends U_{jk} to U_{il} and every other matrix unit to 0. These are the maps of Exercise 2.2.34 for $V = W = F^{n\times n}$ with the basis $\mathcal{U}$ on both sides: as (i,j,k,l) runs over all quadruples, the pair $\big(U_{jk},U_{il}\big)$ runs over all pairs of matrix units exactly once. By that exercise they form a basis of $\mathrm{L}(F^{n\times n})$. Every Φ is therefore a combination $\sum c_{ijkl}L_{U_{ij},U_{kl}} = \sum L_{c_{ijkl}U_{ij},U_{kl}}$, a sum of maps of the form $L_{A,B}$.

The transpose sends U_{jk} to U_{kj}, so it is the sum of the maps with $i = k$ and $l = j$:

$$X^{\mathsf{T}} = \sum_{j=1}^{n}\sum_{k=1}^{n} U_{kj}XU_{kj}.$$

Directly, $U_{kj}XU_{kj} = x_{jk}U_{kj}$, and summing gives the matrix with (k,j) entry x_{jk}. As a check against (b), $\operatorname{tr}\tau = \sum_{j,k}\big(\operatorname{tr}U_{kj}\big)^2 = \sum_k 1 = n*1$. So the transpose is a sum of n^2 maps $X\mapsto AXB$, although for $n\geq 2$ it is not one of them: if $X^{\mathsf{T}} = AXB$ for all X, then $U_{11} = (A\mathbf{e}_1)\big(\mathbf{e}_1^{\mathsf{T}}B\big)$ and $U_{21} = (A\mathbf{e}_1)\big(\mathbf{e}_2^{\mathsf{T}}B\big)$, by taking $X = U_{11}$ and $X = U_{12}$. Comparing first columns, $A\mathbf{e}_1 \neq \mathbf{0}$ would be a multiple of both $\mathbf{e}_1$ and $\mathbf{e}_2$, which is impossible since they are independent.

Solution to Problem 2.5

> *Uses.* Example 2.1.9 (Maps of polynomials), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space), Proposition 2.1.17 (Compositions of linear maps are linear), Exercise 2.1.32
> *Techniques.* Check it on a basis (Technique 2.2.7), Guess the inverse, then check both products (Technique 2.5.16)
> *Hint 1.* Both sides of (a) are linear on $\mathbb{Q}[x]_{\leq n}$, so compare them on x^m. Compute $D^k(x^m)$ first.
> *Hint 2.* $D^k(x^m)/k! = \binom{m}{k}x^{m-k}$ for $k\leq m$. For (c) with $n\geq p$, apply both sides to x^p.
> *Sketch.* (a) $D^k(x^m) = m(m-1)\cdots(m-k+1)x^{m-k}$ for $k\leq m$ and $\mathbf{0}$ for $k>m$, so $\sum_k c^kD^k(x^m)/k! = \sum_{k\leq m}\binom{m}{k}c^kx^{m-k} = (x+c)^m$. (b) $S_1S_{-1} = S_{-1}S_1 = \mathrm{id}$, so $S_1^{-1} = S_{-1} = \sum(-1)^kD^k/k!$. (c) For $k\leq n<p$, $k!$ is invertible in $\mathbb{F}_p$ and (a) goes through. For $n\geq p$, $D(x^p) = \mathbf{0}$, so the right side sends x^p to a_0x^p, while $S_1(x^p) = (x+1)^p = x^p+1$.

Throughout, by induction on k, $D^k(x^m) = (m(m-1)\cdots(m-k+1)*1)x^{m-k}$ for $k\leq m$, and $D^k(x^m) = \mathbf{0}$ for $k>m$ (Example 2.1.9).

(a) S_c maps $\mathbb{Q}[x]_{\leq n}$ into itself, since $(x+c)^m$ has degree m, and so does every D^k. Both sides of the claim are linear (Proposition 2.1.23, Proposition 2.1.17), so by Corollary 2.2.6 it suffices to compare them on x^m for $0\leq m\leq n$. For $k\leq m$, $m(m-1)\cdots(m-k+1)/k! = \binom{m}{k}$, and the terms with $k>m$ vanish, so

$$\sum_{k=0}^{n}\frac{c^k}{k!}D^k(x^m) = \sum_{k=0}^{m}\binom{m}{k}c^kx^{m-k} = (x+c)^m = S_c(x^m).$$

(b) $S_1S_{-1} = S_{-1}S_1 = S_0 = \mathrm{id}$, and both maps preserve $\mathbb{Q}[x]_{\leq n}$. By Technique 2.5.16, S_1 is invertible on $\mathbb{Q}[x]_{\leq n}$ with inverse S_{-1}, and by (a) with $c=-1$,

$$S_1^{-1} = \sum_{k=0}^{n} \frac{(-1)^k}{k!} D^k.$$

(c) *The case $n < p$.* For $k \le n < p$, the scalar $k! * 1$ is a product of the nonzero elements $1, 2, \ldots, k$ of $\mathbb{F}_p$, so it is invertible. The integer identity $m(m-1)\cdots(m-k+1) = k!\binom{m}{k}$ holds in $\mathbb{F}_p$ after reduction, so $(k!)^{-1} D^k(x^m) = \binom{m}{k} x^{m-k}$, and the computation of (a) with $c = 1$ goes through unchanged.

The case $n \ge p$. Suppose $S_1 = \sum_{k=0}^{r} a_k D^k$ on $\mathbb{F}_p[x]_{\le n}$. The polynomial x^p lies in this space. Since $D(x^p) = (p * 1)x^{p-1} = \mathbf{0}$, every $D^k(x^p)$ with $k \ge 1$ is $\mathbf{0}$, and the right side sends x^p to $a_0 x^p$. On the other hand, the coefficients $\binom{p}{k}$ with $0 < k < p$ are 0 in $\mathbb{F}_p$, so

$$S_1(x^p) = (x+1)^p = x^p + 1.$$

So $x^p + 1 = a_0 x^p$, and the constant terms give $1 = 0$, a contradiction.

Over $\mathbb{F}_p$ the derivative cannot see x^p, but the shift moves it. So Taylor's formula is a statement about fields in which the factorials can be inverted, and it fails exactly when the space contains x^p.

Solution to Problem 2.6

> *Uses.* Proposition 2.2.20 (Linear maps out of $F[x]$), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Example 2.6.27 (Differentiation on $F[x]$), Exercise 2.1.49
> *Techniques.* Check it on a basis (Technique 2.2.7)
> *Hint 1.* If $TM = MT$, then $TM^k = M^k T$. Apply this to the polynomial 1.
> *Hint 2.* For (c), write T as multiplication by q and expand $D(qf)$ with the product rule. What does $TD = DT$ say about $D(q)$?
> *Sketch.* (a) $T\big(x^k\big) = T\big(M^k(1)\big) = M^k(T(1)) = x^k q$, and two linear maps that agree on the monomials are equal; conversely $q(xf) = x(qf)$. (b) $qf = \mathbf{0}$ with $q, f \ne \mathbf{0}$ is impossible by degrees; if T is onto, $qg = 1$ forces $\deg q = 0$. (c) $D(qf) = D(q)f + qD(f)$, so T commutes with D iff $D(q)f = \mathbf{0}$ for all f, iff $D(q) = \mathbf{0}$. So $T = c$ id in characteristic 0, and over $\mathbb{F}_p$, T is multiplication by a polynomial in x^p.

(a) If $T(f) = qf$ for all f, then $T(1) = q$ and $T(Mf) = qxf = xqf = M(T(f))$ by commutativity. Conversely, suppose $TM = MT$. By induction, $TM^k = M^k T$ for every $k \ge 0$: if $TM^k = M^k T$, then $TM^{k+1} = \big(TM^k\big)M = M^k TM = M^k MT$. With $q = T(1)$,

$$T\big(x^k\big) = T\big(M^k(1)\big) = M^k(T(1)) = x^k q.$$

Multiplication by q is linear, by distributivity and $c(qf) = q(cf)$, and it agrees with T on every monomial. By the uniqueness in Proposition 2.2.20, $T(f) = qf$ for all f.

(b) If $q = \mathbf{0}$, then $T = 0$, which is not injective. If $q \ne \mathbf{0}$ and $f \ne \mathbf{0}$, then $\deg(qf) = \deg q + \deg f \ge 0$, so $qf \ne \mathbf{0}$; by Theorem 2.6.11, T is injective.

If $q = c$ is a nonzero constant, then $T = c$ id is surjective. Conversely, if T is surjective, then $1 = qg$ for some g. Both q and g are nonzero, so $\deg q + \deg g = \deg 1 = 0$, which forces $\deg q = 0$: q is a nonzero constant. For instance, multiplication by x is injective but not surjective, as in Example 2.6.4(e).

(c) By (a), T commutes with M exactly when it is multiplication by some q. For such T, the product rule gives $D(T(f)) = D(qf) = D(q)f + qD(f) = D(q)f + T(D(f))$. So $DT = TD$ if and only if $D(q)f = \mathbf{0}$ for every f. Taking $f = 1$ shows that this forces $D(q) = \mathbf{0}$, and conversely $D(q) = \mathbf{0}$ makes it hold. So the operators commuting with M and D are the multiplications by the polynomials in $\ker D$, which Example 2.6.27 computed.

- If F has characteristic 0, $\ker D$ consists of the constants, so $T = c$ id for some $c \in F$.
- If $F = \mathbb{F}_p$, $\ker D$ consists of the polynomials $b_0 + b_1 x^p + b_2 x^{2p} + \cdots$, so T is multiplication by a polynomial in x^p. For instance $f \mapsto x^p f$ commutes with D, because $D(x^p) = (p * 1)x^{p-1} = \mathbf{0}$.

Solution to Problem 2.7

Uses. Proposition 3.4.27 (Lagrange's formula), Definition 3.4.26 (Lagrange polynomials), Proposition 1.2.18 (Degree and evaluation versus the operations), Example 2.1.9 (Maps of polynomials), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space), Corollary 2.2.6 (Agreeing on a spanning list)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. Lagrange's formula (Proposition 3.4.27) writes every $f \in V$ as $\sum f(c_i)L_i$. For the second claim, compare both sides on the basis $L_0, \dots, L_n$.
Hint 2. In (b), the scalars are $w_i = \varphi(L_i)$ for $\varphi(f) = f'(0)$, and $f'(0)$ is the coefficient of x in f. Find L_0, L_1, L_2 by checking values. For (c), find a cubic that vanishes at $0, 1, 2$.
Sketch. (a) $f = \sum f(c_i)L_i$ by Proposition 3.4.27, and evaluating a relation $\sum a_i L_i = \mathbf{0}$ at c_k gives $a_k = 0$. Both φ and $\sum \varphi(L_i)\,\mathrm{ev}_{c_i}$ send L_k to $\varphi(L_k)$, so they agree; a relation $\sum a_i\,\mathrm{ev}_{c_i} = 0$ applied to L_k gives $a_k = 0$. (b) $L_0 = 1 - \frac{3}{2}x + \frac{1}{2}x^2$, $L_1 = 2x - x^2$, $L_2 = -\frac{1}{2}x + \frac{1}{2}x^2$, so $f'(0) = -\frac{3}{2}f(0) + 2f(1) - \frac{1}{2}f(2)$; over $\mathbb{F}_3$, $f'(0) = 2f(1) + f(2)$. (c) $f = x^3 - 3x^2 + 2x$ vanishes at $0, 1, 2$ and has $f'(0) = 2$.

(a) *Basis.* Let $f \in V$. By Proposition 3.4.27 with $d_i = f(c_i)$, the polynomial $\sum_i f(c_i)L_i$ is the unique element of V with the values $f(c_0), \dots, f(c_n)$, and f is such an element, so $f = \sum_i f(c_i)L_i$. Hence the L_i span V. If $\sum_i a_i L_i = \mathbf{0}$, then evaluating at c_k, which is linear (Proposition 1.2.18(c)), gives $a_k = 0$. So $L_0, \dots, L_n$ is a basis of V, and the coordinates of f in it are $(f(c_0), \dots, f(c_n))$.

The formula. Each ev_{c_i} is linear (Example 2.1.9), so $\psi = \sum_i \varphi(L_i)\,\mathrm{ev}_{c_i}$ is linear (Proposition 2.1.23). On a basis vector,

$$\psi(L_k) = \sum_{i=0}^{n} \varphi(L_i)L_k(c_i) = \varphi(L_k),$$

since only the term $i = k$ survives. By Corollary 2.2.6, $\psi = \varphi$. So the evaluations span $\mathrm{L}(V,F)$. If $\sum_i a_i\,\mathrm{ev}_{c_i}$ is the zero map, applying it to L_k gives $a_k = 0$. So $\mathrm{ev}_{c_0}, \dots, \mathrm{ev}_{c_n}$ is a basis of $\mathrm{L}(V,F)$, and the coefficients of φ in it are the values $\varphi(L_i)$.

(b) Since $2 \neq 0$, the points $0, 1, 2$ are distinct. The polynomials

$$L_0 = 1 - \frac{3}{2}x + \frac{1}{2}x^2, \quad L_1 = 2x - x^2, \quad L_2 = -\frac{1}{2}x + \frac{1}{2}x^2$$

have the required values: L_0 takes the values $1, 1 - \frac{3}{2} + \frac{1}{2} = 0, 1 - 3 + 2 = 0$ at $0, 1, 2$; L_1 takes $0, 1, 4 - 4 = 0$; and L_2 takes $0, 0, -1 + 2 = 1$. By the uniqueness in Definition 3.4.26, these are the Lagrange polynomials. The map $\varphi(f) = f'(0) = \mathrm{ev}_0(D(f))$ is linear, and for $f = a + bx + cx^2$, $D(f) = b + 2cx$, so $f'(0) = b$ is the coefficient of x. By (a), the formula holds with $w_i = \varphi(L_i)$, and with no other scalars, since the evaluations are independent:

$$f'(0) = -\frac{3}{2}f(0) + 2f(1) - \frac{1}{2}f(2).$$

Over $\mathbb{F}_3$, $2^{-1} = 2$, so $-\frac{3}{2} = 0$ and $-\frac{1}{2} = -2 = 1$, and the formula reads $f'(0) = 2f(1) + f(2)$. As a check over $\mathbb{F}_3$: for $f = 1, x, x^2$ the right side is $2 + 1 = 0$, $2 + 2 = 1$, $2 + 4 = 0$, which are the coefficients of x.

(c) Let $f = x^3 - 3x^2 + 2x$. Then $f(0) = 0$, $f(1) = 1 - 3 + 2 = 0$, $f(2) = 8 - 12 + 4 = 0$, and $f'(0) = 2$, the coefficient of x. Any formula $f'(0) = w_0 f(0) + w_1 f(1) + w_2 f(2)$ would give $2 = 0$. The three values cannot see a cubic that vanishes at all three points; on $\mathbb{Q}[x]_{\leq 3}$ the evaluations at three points span only a part of $\mathrm{L}\big(\mathbb{Q}[x]_{\leq 3}, \mathbb{Q}\big)$.

Solution to Problem 2.8

Uses. Exercise 2.5.46, Proposition 2.5.28 (Inverse of a 2×2 matrix), Proposition 2.4.14 (Algebra of matrices)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. Write $t = a + d$ and $\Delta = ad - bc$, so $A^2 = tA - \Delta I_2$. If $A^2 = A$, then $(t-1)A = \Delta I_2$. Split into $t \neq 1$ and $t = 1$.
Hint 2. For (b), count the triples (a,b,c) with $bc = a(1-a)$, separating $a \in \{0,1\}$ from the other $p-2$ values. For (c), the inverse map is $S \mapsto (S + I_n)/2$.
Sketch. (a) If $t \neq 1$, A is a scalar λI_2 with $\lambda^2 = \lambda$; if $t = 1$, $\Delta I_2 = 0$. (b) $bc = a(1-a)$ has $2p - 1$ solutions for $a \in \{0,1\}$ and $p - 1$ for each other a: $2(2p-1) + (p-2)(p-1) + 2 = p^2 + p + 2$. (c) $(2P - I_n)^2 = 4\big(P^2 - P\big) + I_n$ and $((S + I_n)/2)^2 =$

> $(S+I_n)/2$ when $S^2=I_n$. (d) Over $\mathbb{F}_2$, $A^2=tA+\Delta I_2$ with $t,\Delta\in\mathbb{F}_2$; four involutions; $\Delta=1$ invertible, $(t,\Delta)=(0,0)$ square-zero, $(1,0)$ idempotent. Over $\mathbb{F}_3$, $\left(\begin{smallmatrix}2&0\\0&0\end{smallmatrix}\right)$ is none of these.

Write $t=a+d$ and $\Delta=ad-bc$, so that $A^2=tA-\Delta I_2$.

(a) Suppose $A^2=A$. Then $A=tA-\Delta I_2$, that is, $(t-1)A=\Delta I_2$. If $t\neq 1$, then $A=(t-1)^{-1}\Delta I_2=\lambda I_2$ for a scalar λ, and $A^2=A$ gives $\lambda^2=\lambda$, so $\lambda\in\{0,1\}$ and $A=0$ or $A=I_2$. If $t=1$, then $\Delta I_2=0$, so $\Delta=0$. Conversely, 0 and I_2 are idempotent, and if $t=1$ and $\Delta=0$, then $A^2=A-0=A$. (The three cases do not overlap: $\operatorname{tr}0=0$ and $\operatorname{tr}I_2=1+1$, and neither is 1.)

(b) By (a), we count the A with $d=1-a$ and $bc=a(1-a)$, and add 2. Fix $a\in\mathbb{F}_p$.

- If $a\in\{0,1\}$, the condition is $bc=0$, which has $2p-1$ solutions ($b=0$ with c arbitrary, or $c=0$ with $b\neq 0$).
- Otherwise $k=a(1-a)\neq 0$, and $bc=k$ has $p-1$ solutions: b is any nonzero element and $c=kb^{-1}$.

The total is $2(2p-1)+(p-2)(p-1)+2=4p-2+p^2-3p+2+2=p^2+p+2$. For $p=2$ there are no values of the second kind, and the count is 8.

(c) Write $2=1+1$. If $P^2=P$, then by Proposition 2.4.14

$$(2P-I_n)^2=4P^2-4P+I_n=I_n.$$

If $S^2=I_n$, then $P=2^{-1}(S+I_n)$ satisfies $P^2=4^{-1}\left(S^2+2S+I_n\right)=4^{-1}(2S+2I_n)=P$. The maps $P\mapsto 2P-I_n$ and $S\mapsto 2^{-1}(S+I_n)$ are inverse to each other, so the first is a bijection. For an odd prime p, (b) therefore counts the $S\in\mathbb{F}_p^{2\times 2}$ with $S^2=I_2$, which are the matrices with $S^{-1}=S$, and Exercise 2.5.46(c) found p^2+p+2 of them as well.

(d) Over $\mathbb{F}_2$, $-1=1$, so $A^2=tA+\Delta I_2$. If $S^2=I_2$, then $tS=(1+\Delta)I_2$. If $t=1$, then $S=(1+\Delta)I_2$ is 0 or I_2, and both have trace 0, a contradiction. So $t=0$, and then $(1+\Delta)I_2=0$ gives $\Delta=1$. Conversely, $t=0$ and $\Delta=1$ give $S^2=I_2$. These are the matrices with $d=a$ and $a+bc=1$: for $a=0$, $b=c=1$; for $a=1$, $bc=0$. So there are 4:

$$I_2,\quad \begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \begin{pmatrix}1&1\\0&1\end{pmatrix},\quad \begin{pmatrix}1&0\\1&1\end{pmatrix},$$

against 8 idempotents. The bijection of (c) fails because $2P-I_2=I_2$ for every P.

Every $A\in\mathbb{F}_2^{2\times 2}$ has $t,\Delta\in\{0,1\}$. If $\Delta=1$, A is invertible (Proposition 2.5.28(a)). If $\Delta=0$, then $A^2=tA$, which is 0 for $t=0$ and A for $t=1$. Over $\mathbb{F}_3$, $A=\left(\begin{smallmatrix}2&0\\0&0\end{smallmatrix}\right)$ has $\Delta=0$, so it is not invertible (Proposition 2.5.28(b)), and $A^2=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$, which is neither 0 nor A.

Solution to Problem 2.9

> *Uses.* Proposition 2.4.14 (Algebra of matrices), Lemma 2.4.24 (Matrix units), Proposition 2.4.28 (Cyclicity of the trace)
> *Techniques.* Cyclicity of trace (Technique 2.4.29)
> *Hint 1.* Write out $(BA)^{k+1}=BABA\cdots BA$ and regroup by associativity, or induct on k.
> *Hint 2.* For (c), try matrix units: $U_{ij}U_{kl}=\delta_{jk}U_{il}$. For (d), apply cyclicity to $A\cdot\left(B(AB)^{k-1}\right)$.
> *Sketch.* (a) Induction: $(BA)^{k+2}=B(AB)^kABA=B(AB)^{k+1}A$. (b) If $(AB)^k=0$, then $(BA)^{k+1}=0$; swap the roles of A and B. (c) $A=U_{11}$, $B=U_{21}$: $AB=0$, $BA=U_{21}$. (d) $\operatorname{tr}\left((AB)^k\right)=\operatorname{tr}\left(A\left(B(AB)^{k-1}\right)\right)=\operatorname{tr}\left(B(AB)^{k-1}A\right)=\operatorname{tr}\left((BA)^k\right)$.

(a) For $k=0$ both sides are BA. If the identity holds for k, then by associativity

$$(BA)^{k+2}=(BA)^{k+1}(BA)=B(AB)^kABA=B(AB)^k(AB)A=B(AB)^{k+1}A.$$

(b) If $(AB)^k=0$, then $(BA)^{k+1}=B0A=0$ by (a), so BA is nilpotent. Exchanging the roles of A and B (the identity of (a) holds with A and B swapped, by the same proof), if BA is nilpotent, so is AB.

(c) Let $A=U_{11}$ and $B=U_{21}$, with $U_{ij}=\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}\in F^{2\times 2}$. By Lemma 2.4.24(c), $AB=U_{11}U_{21}=0$ and $BA=U_{21}U_{11}=U_{21}\neq 0$. Here $(AB)^1=0$ while $(BA)^1\neq 0$, and $(BA)^2=0$, as (b) predicts.

(d) For $k \geq 1$, by Proposition 2.4.28 applied to the product of A and $B(AB)^{k-1}$, and then (a),

$$\operatorname{tr}\Big((AB)^k\Big) = \operatorname{tr}\Big(A\Big(B(AB)^{k-1}\Big)\Big) = \operatorname{tr}\Big(B(AB)^{k-1}A\Big) = \operatorname{tr}\Big((BA)^k\Big).$$

So AB and BA cannot be told apart by the traces of their powers, although they may have different sizes and, as (c) shows, different nilpotency exponents.

Solution to Problem 2.10

Uses. Exercise 2.5.39, Proposition 2.5.17 (Algebra of inverses), Proposition 2.1.24 (Algebra of composition), Lemma 2.4.24 (Matrix units)
Techniques. Guess the inverse, then check both products (Technique 2.5.16), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. (a) If $N_1^a = 0$ and $N_2^b = 0$, expand $(N_1 + N_2)^{a+b-1}$. (b) Try $U_{12} + U_{21}$.
Hint 2. (c) Factor $G + N = G\big(\mathrm{id} + G^{-1}N\big)$. Show that G^{-1} commutes with N, so that $G^{-1}N$ is nilpotent.
Sketch. (a) Every term $N_1^j N_2^{a+b-1-j}$ has $j \geq a$ or $a + b - 1 - j \geq b$. (b) $(U_{12} + U_{21})^2 = I_2$. (c) $G^{-1}N = NG^{-1}$, so $\big(G^{-1}N\big)^k = G^{-k}N^k = 0$, $\mathrm{id} + G^{-1}N$ is invertible by Exercise 2.5.39, and $(G+N)^{-1} = \sum_{j<k}(-1)^j G^{-j-1}N^j$. (d) $G = U_{12} + U_{21}$, $N = -U_{12}$: $G + N = U_{21}$.

(a) Let $N_1^a = 0$ and $N_2^b = 0$, with $N_1N_2 = N_2N_1$. By the binomial theorem,

$$(N_1 + N_2)^{a+b-1} = \sum_{j=0}^{a+b-1} \binom{a+b-1}{j} N_1^j N_2^{a+b-1-j}.$$

In each term, either $j \geq a$, and then $N_1^j = 0$, or $j \leq a-1$, and then $a + b - 1 - j \geq b$ and $N_2^{a+b-1-j} = 0$. So every term is 0.

(b) U_{12} and U_{21} satisfy $U_{12}^2 = U_{21}^2 = 0$ by Lemma 2.4.24(c), but $S = U_{12} + U_{21} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ satisfies $S^2 = U_{11} + U_{22} = I_2$, so it is invertible, and it is not nilpotent: S^k is I_2 or S. So the set of nilpotent matrices is not closed under addition. (Here $U_{12}U_{21} \neq U_{21}U_{12}$, so (a) does not apply.)

(c) Multiplying $GN = NG$ by G^{-1} on both sides gives $NG^{-1} = G^{-1}N$. So G^{-1} and N commute, and by induction $\big(G^{-1}N\big)^j = G^{-j}N^j$. If $N^k = 0$, then $N' = G^{-1}N$ satisfies $N'^k = 0$. By Exercise 2.5.39(a), applied to the nilpotent operator $-N'$, $\mathrm{id} + N'$ is invertible with inverse $\sum_{j=0}^{k-1}(-N')^j$. Now $G + N = G(\mathrm{id} + N')$ is a composite of invertible maps, so it is invertible (Proposition 2.5.17(b)), with

$$(G+N)^{-1} = (\mathrm{id} + N')^{-1}G^{-1} = \sum_{j=0}^{k-1}(-1)^j G^{-j}N^jG^{-1} = \sum_{j=0}^{k-1}(-1)^j G^{-j-1}N^j.$$

(d) Let $G = U_{12} + U_{21} \in F^{2\times 2}$, which is invertible by (b), and $N = -U_{12}$, which satisfies $N^2 = 0$. Then $G + N = U_{21}$ has a zero row, so it has no right inverse (Exercise 2.5.9(b)) and is not invertible. Indeed $GN = -U_{22}$ and $NG = -U_{11}$, so G and N do not commute.

In (c) the commutation is what lets the geometric series of Technique 2.5.16 run: without it, $\big(G^{-1}N\big)^j$ is not $G^{-j}N^j$, and $G^{-1}N$ need not be nilpotent at all.

Solution to Problem 2.11

Uses. Proposition 2.4.8 (Four views of the product), Proposition 2.3.13 (Linearity of the product), Proposition 2.4.14 (Algebra of matrices)
Hint 1. By the column view, column j of XN is $X\big(N\mathbf{e}_j\big)$. Which $N\mathbf{e}_j$ gives $\mathbf{x}_{j+1}$?
Hint 2. $N\mathbf{e}_j = \mathbf{e}_{j+1}$ for $j < n$ and $N\mathbf{e}_n = \mathbf{0}$. Compute $N^k\mathbf{e}_j$, and use $\big(XNX^{-1}\big)^k = XN^kX^{-1}$.
Sketch. (a) N has columns $\mathbf{e}_2, \ldots, \mathbf{e}_n, \mathbf{0}$, so $XN\mathbf{e}_j = X\mathbf{e}_{j+1} = \mathbf{x}_{j+1}$. (b) $X^{-1}Y = N$, and $N^k\mathbf{e}_j = \mathbf{e}_{j+k}$ when $j + k \leq n$ and $\mathbf{0}$ otherwise, so $N^n = 0$ and $N^{n-1}\mathbf{e}_1 = \mathbf{e}_n$. Also $YX^{-1} = XNX^{-1}$ has k-th power XN^kX^{-1}, which is 0 exactly when $N^k = 0$.

(a) Let $N \in F^{n\times n}$ have columns $\mathbf{e}_2, \ldots, \mathbf{e}_n, \mathbf{0}$, so $N\mathbf{e}_j = \mathbf{e}_{j+1}$ for $j < n$ and $N\mathbf{e}_n = \mathbf{0}$. By the column view (Proposition 2.4.8(b)) and Proposition 2.3.13(c), column j of XN is $X\big(N\mathbf{e}_j\big)$, which is $X\mathbf{e}_{j+1} = \mathbf{x}_{j+1}$ for $j < n$ and $X\mathbf{0} = \mathbf{0}$ for $j = n$. So $XN = Y$.

(b) $X^{-1}Y = N$. By induction on k, $N^k\mathbf{e}_j = \mathbf{e}_{j+k}$ if $j+k \le n$, and $N^k\mathbf{e}_j = \mathbf{0}$ otherwise. So $N^n\mathbf{e}_j = \mathbf{0}$ for every j, that is, $N^n = 0$, while $N^{n-1}\mathbf{e}_1 = \mathbf{e}_n \neq \mathbf{0}$, so $N^{n-1} \neq 0$.

$YX^{-1} = XNX^{-1}$. By induction, $\left(XNX^{-1}\right)^k = XN^kX^{-1}$: the inner factors $X^{-1}X$ cancel. So $\left(YX^{-1}\right)^n = X0X^{-1} = 0$. If $\left(YX^{-1}\right)^{n-1} = XN^{n-1}X^{-1}$ were 0, then $N^{n-1} = X^{-1}\left(XN^{n-1}X^{-1}\right)X = 0$, which is false.

The problem looks like a statement about X, but X only changes coordinates: both products are the shift N, seen in two different bases.

Solution to Problem 2.12

Uses. Lemma 2.4.24 (Matrix units), Proposition 1.4.14 (The span is the smallest subspace containing a list), Theorem 1.4.3 (Subspace criterion), Theorem 2.4.34 (Block multiplication), Proposition 2.6.8 (Kernels and images are subspaces), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. If $X \in W$ has a nonzero entry x_{jk}, multiply X on both sides by matrix units to isolate it: compute $U_{ij}XU_{kl}$.
Hint 2. For (c), show that $\ker\psi$ satisfies the hypothesis of (a).
Sketch. (a) $U_{ij}XU_{kl} = x_{jk}U_{il}$, so a nonzero entry x_{jk} puts every U_{il} in W, and the units span. (b) $A\left(\mathbf{x}\mathbf{e}_1^{\mathsf{T}}\right) = (A\mathbf{x})\mathbf{e}_1^{\mathsf{T}} \in W_1$, but $U_{11}U_{12} = U_{12} \notin W_1$. (c) $\ker\psi$ is a subspace with $\psi(AX) = \psi(A)\psi(X) = 0$ and $\psi(XA) = 0$ for $X \in \ker\psi$; it is not everything since $\psi \neq 0$, so it is $\{0\}$. Example: $\psi(X) = \begin{pmatrix} X & 0 \\ 0 & X \end{pmatrix}$.

(a) Suppose $W \neq \{0\}$, and let $X \in W$ have an entry $x_{jk} \neq 0$. For any i, l, the hypothesis applied twice gives $U_{ij}X \in W$ and then $U_{ij}XU_{kl} \in W$. By associativity and Lemma 2.4.24(b),

$$U_{ij}XU_{kl} = \mathbf{e}_i\left(\mathbf{e}_j^{\mathsf{T}}X\mathbf{e}_k\right)\mathbf{e}_l^{\mathsf{T}} = x_{jk}U_{il}.$$

Since W is a subspace, $U_{il} = x_{jk}^{-1}\left(x_{jk}U_{il}\right) \in W$. So W contains every matrix unit, and the matrix units span $F^{n\times n}$ (Lemma 2.4.24(a)), so $W = F^{n\times n}$ by Proposition 1.4.14(b).

(b) The matrices of W_1 are the $\mathbf{x}\mathbf{e}_1^{\mathsf{T}}$ with $\mathbf{x} \in F^n$, and they form a subspace (Theorem 1.4.3). For $A \in F^{n\times n}$, $A\left(\mathbf{x}\mathbf{e}_1^{\mathsf{T}}\right) = (A\mathbf{x})\mathbf{e}_1^{\mathsf{T}} \in W_1$. But $U_{11} \in W_1$ and $U_{11}U_{12} = U_{12}$, whose second column is $\mathbf{e}_1 \neq \mathbf{0}$, so $U_{12} \notin W_1$. So for one-sided closure there are more subspaces than $\{0\}$ and $F^{n\times n}$; in (a), the proof multiplied by matrix units on both sides, and closure on the right is exactly what W_1 lacks.

(c) $\ker\psi$ is a subspace of $F^{n\times n}$ (Proposition 2.6.8). If $X \in \ker\psi$ and $A \in F^{n\times n}$, then $\psi(AX) = \psi(A)\psi(X) = \psi(A)0 = 0$ and $\psi(XA) = \psi(X)\psi(A) = 0$, so $AX, XA \in \ker\psi$. By (a), $\ker\psi = \{0\}$ or $\ker\psi = F^{n\times n}$. The second would mean $\psi = 0$. So $\ker\psi = \{0\}$, and ψ is injective (Theorem 2.6.11).

For an example, let $\psi(X) = \begin{pmatrix} X & 0 \\ 0 & X \end{pmatrix} \in F^{2n\times 2n}$. It is linear, nonzero, and multiplicative, since block diagonal matrices multiply block by block (Theorem 2.4.34).

Solution to Problem 2.13

Uses. Theorem 2.4.34 (Block multiplication), Proposition 2.4.14 (Algebra of matrices), Proposition 1.2.19 (Restriction of scalars), Definition 2.3.1 (Matrix of a linear map), Proposition 2.5.20 (Inverses and matrices), Theorem 2.7.8 (Third Fundamental Theorem), Definition 2.4.26 (Trace)
Techniques. Block decomposition (Technique 2.4.35), Translate between maps and matrices (Technique 2.3.27)
Hint 1. Expand $(X+iY)(X'+iY')$ by distributivity, and compare with the block product $\rho(Z)\rho(W)$.
Hint 2. The $\mathcal{B}_m$-coordinates of $\mathbf{u}+i\mathbf{v}$, with $\mathbf{u}, \mathbf{v} \in \mathbb{R}^m$, are $(\mathbf{u}, \mathbf{v})$. For (c), use (b) and Proposition 2.5.20.
Sketch. (a) $ZW = (XX'-YY') + i(XY'+YX')$, and block multiplication gives $\rho(Z)\rho(W) = \begin{pmatrix} XX'-YY' & -(XY'+YX') \\ YX'+XY' & XX'-YY' \end{pmatrix}$. (b) $Z\mathbf{e}_j = X\mathbf{e}_j + iY\mathbf{e}_j$ has coordinates $\left(X\mathbf{e}_j, Y\mathbf{e}_j\right)$, column j of $\rho(Z)$; $Z\left(i\mathbf{e}_j\right) = -Y\mathbf{e}_j + iX\mathbf{e}_j$ gives column $n+j$. (c) If Z is invertible, $\rho(Z)\rho\left(Z^{-1}\right) = \rho(I_n) = I_{2n}$ in both orders. If $\rho(Z)$ is invertible, then T_Z is invertible as an $\mathbb{R}$-linear map, so it is bijective, and a bijective T_Z means Z is invertible. (d) $\operatorname{tr} X + \operatorname{tr} X$.

(a) Let $W = X' + iY'$. Matrix multiplication over $\mathbb{C}$ distributes, and real scalars and i pass through products (Proposition 2.4.14), so

$$ZW = (XX'-YY') + i(XY'+YX'),$$

with $XX'-YY'$ and $XY'+YX'$ real. By block multiplication (Theorem 2.4.34),

$$\rho(Z)\rho(W) = \begin{pmatrix} XX' - YY' & -XY' - YX' \\ YX' + XY' & -YY' + XX' \end{pmatrix} = \rho(ZW).$$

The real and imaginary parts of $Z + Z'$ and of cZ for real c are the sums and real multiples of those of Z and Z', so ρ is $\mathbb{R}$-linear. Finally $I_n = I_n + i0$, so $\rho(I_n) = \begin{pmatrix} I_n & 0 \\ 0 & I_n \end{pmatrix} = I_{2n}$.

(b) Every $\mathbf{z} \in \mathbb{C}^n$ can be written $\mathbf{z} = \mathbf{u} + i\mathbf{v}$ with $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$ in exactly one way (real and imaginary parts), and then

$$\mathbf{z} = u_1\mathbf{e}_1 + \cdots + u_n\mathbf{e}_n + v_1(i\mathbf{e}_1) + \cdots + v_n(i\mathbf{e}_n).$$

So $\mathcal{B}_n$ is a basis of $\mathbb{C}^n$ over $\mathbb{R}$, and the $\mathcal{B}_n$-coordinates of $\mathbf{u} + i\mathbf{v}$ are $(\mathbf{u}, \mathbf{v}) \in \mathbb{R}^{2n}$. The map T_Z is $\mathbb{C}$-linear, so in particular $\mathbb{R}$-linear. Its matrix has as column j the coordinates of $Z\mathbf{e}_j = X\mathbf{e}_j + iY\mathbf{e}_j$, which are $\big(X\mathbf{e}_j, Y\mathbf{e}_j\big)$, column j of $\rho(Z)$; and as column $n + j$ the coordinates of $Z\big(i\mathbf{e}_j\big) = iX\mathbf{e}_j - Y\mathbf{e}_j$, which are $\big(-Y\mathbf{e}_j, X\mathbf{e}_j\big)$, column $n + j$ of $\rho(Z)$. So $[T_Z]_{\mathcal{B}_m\mathcal{B}_n} = \rho(Z)$.

(c) If Z is invertible, then by (a), $\rho(Z)\rho\big(Z^{-1}\big) = \rho(I_n) = I_{2n}$, and likewise in the other order, so $\rho(Z)$ is invertible with inverse $\rho\big(Z^{-1}\big)$.

Conversely, suppose $\rho(Z)$ is invertible. By (b) and Proposition 2.5.20(b), the $\mathbb{R}$-linear map $T_Z : \mathbb{C}^n \to \mathbb{C}^n$ is invertible, so it is a bijection. Bijectivity is a property of the function, not of the field of scalars, so T_Z is bijective as a $\mathbb{C}$-linear map too, and Z is invertible by Theorem 2.7.8, (I) ⇒ (V), and Proposition 2.5.20(c).

(d) The diagonal of $\rho(Z)$ consists of the diagonal of X twice, so $\operatorname{tr}\rho(Z) = 2\operatorname{tr} X = 2\operatorname{Re}(\operatorname{tr} Z)$.

For $n = 1$, $\rho(a + bi) = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ is the matrix of multiplication by $a + bi$ found in Exercise 2.3.35(a).

Solution to Problem 2.14

> *Uses.* Proposition 2.4.14 (Algebra of matrices), Proposition 2.6.15 (Kernels and images of composites), Example 2.6.4 (Injective, surjective, both, neither), Definition 2.4.26 (Trace), Lemma 2.4.24 (Matrix units), Definition 2.5.12 (Invertible)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18), Try small cases and small fields (Technique 1.2.38)
> *Hint 1.* (a) Expand, using $PQ = QP$ to collect terms; or note that $I_n - (P + Q - PQ) = (I_n - P)(I_n - Q)$. (b) and (c): look for counterexamples on $F[x]$ and over $\mathbb{F}_p$.
> *Hint 2.* (d) Try $P = U_{11}$ and an idempotent Q that shares its first column. (e) First show that S is injective, then cancel it.
> *Sketch.* (a) True: $I_n - (P + Q - PQ) = (I_n - P)(I_n - Q)$, a product of commuting idempotents. (b) False: multiplication by x on $F[x]$ has $\ker M = \ker M^2 = \{\mathbf{0}\}$ but $x \in \operatorname{im} M \setminus \operatorname{im} M^2$. (c) False over $\mathbb{F}_p$: I_p. (d) False: $P = U_{11}$ and $Q = U_{11} + U_{12}$ are idempotent, but $(P + Q)^2 = 4U_{11} + 2U_{12} \neq P + Q$. (e) True: TS injective makes S injective; $S(TS - \mathrm{id}) = (ST)S - S = 0$, so $TS = \mathrm{id}$.

(a) True. Write $R = P + Q - PQ$; then $I_n - R = (I_n - P)(I_n - Q)$ by distributivity. The matrices $I_n - P$ and $I_n - Q$ are idempotent ($(I_n - P)^2 = I_n - 2P + P^2 = I_n - P$) and commute, since P and Q do. A product EF of commuting idempotents is idempotent: $(EF)^2 = EFEF = EEFF = EF$. So $I_n - R$ is idempotent, and then so is $R = I_n - (I_n - R)$, by the same computation as for $I_n - P$.

(b) False. Let $V = F[x]$ and $T = M$, multiplication by x. It is injective (Example 2.6.4(e)), so M^2 is injective as well, and $\ker M = \ker M^2 = \{\mathbf{0}\}$. But $x = M(1) \in \operatorname{im} M$, while every element x^2q of $\operatorname{im} M^2$ has coefficient 0 at x, so $x \notin \operatorname{im} M^2$. (When V has a finite basis the statement is true; it follows from rank–nullity, Section 4.2.)

(c) False. Let p be a prime and $A = I_p \in \mathbb{F}_p^{p\times p}$. Then $\operatorname{tr}\big(A^k\big) = \operatorname{tr} I_p = p * 1 = 0$ for every k, but $A^k = I_p \neq 0$. Over $\mathbb{C}$ the statement is true, but its proof needs eigenvalues; the counterexample shows that some property of the field must enter.

(d) False. Let $P = U_{11}$ and $Q = U_{11} + U_{12}$, padded with zeros to size n. By Lemma 2.4.24(c), $P^2 = P$ and $Q^2 = U_{11} + U_{12} = Q$, since $U_{12}U_{11} = U_{12}U_{12} = 0$. But $P + Q = 2U_{11} + U_{12}$ and

$$(P + Q)^2 = 4U_{11} + 2U_{12},$$

whose entry in position $(1,2)$ is 2, while that of $P+Q$ is 1. Since $2 \neq 1$ in every field, $P+Q$ is not idempotent. When $PQ = QP = 0$, on the other hand, $(P+Q)^2 = P^2 + Q^2 = P + Q$; part (a) is another repair.

(e) True. Since TS is injective, so is S (Proposition 2.6.15(c)). Using $ST = \mathrm{id}_V$,

$$S(TS - \mathrm{id}_W) = (ST)S - S = S - S = 0.$$

So for every $\mathbf{w} \in W$, $S((TS - \mathrm{id}_W)(\mathbf{w})) = \mathbf{0}$, and injectivity of S gives $(TS - \mathrm{id}_W)(\mathbf{w}) = \mathbf{0}$. Hence $TS = \mathrm{id}_W$, and together with $ST = \mathrm{id}_V$, S is a two-sided inverse of T (Definition 2.5.12). Here S is cancelled on the left, which is legitimate because S is injective; compare Exercise 2.8.15, where the cancellation was not justified.

Solution to Problem 2.15

> *Uses.* Corollary 2.2.18 (Linear maps correspond to lists of vectors), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Exercise 1.5.43, Exercise 2.6.44, Proposition 1.5.14 (Appending a vector), Problem 1.13, Proposition 1.5.15 (Short lists, zeros, and repeats)
> *Techniques.* Construct a map by choosing it on a basis (Technique 2.2.4), Test injectivity at $\mathbf{0}$ (Technique 2.6.12)
> *Hint 1.* $\mathbf{u}, \mathbf{e}_2, \mathbf{e}_3$ is a basis of $\mathbb{F}_p^3$. A linear map is the same thing as a list of values on it (Corollary 2.2.18).
> *Hint 2.* In (b), $\ker T = \ell$ exactly when $T(\mathbf{e}_2), T(\mathbf{e}_3)$ is independent. In (c), $|\ker T| = p^3/p^2$ by Exercise 2.6.44.
> *Sketch.* (a) T is determined by $T(\mathbf{u}) = \mathbf{0}$ and free values $T(\mathbf{e}_2), T(\mathbf{e}_3) \in \mathbb{F}_p^2$: p^4 maps. (b) $a\mathbf{u} + b\mathbf{e}_2 + c\mathbf{e}_3 \in \ker T$ iff $bT(\mathbf{e}_2) + cT(\mathbf{e}_3) = \mathbf{0}$; so $\ker T = \ell$ iff the two values are independent, and there are $(p^2-1)(p^2-p)$ independent pairs; two independent vectors span $\mathbb{F}_p^2$, so T is onto. (c) $|\ker T| = p$, and a nonzero $\mathbf{v} \in \ker T$ has $|\mathrm{span}(\mathbf{v})| = p$. Each of the $p^2 + p + 1$ lines is the kernel of $(p^2-1)(p^2-p)$ maps, by (b) after completing $\mathbf{v}$ to a basis. Total $(p^2+p+1)(p^2-1)(p^2-p) = (p^3-1)(p^3-p)$.

(a) The list $\mathbf{u}, \mathbf{e}_2, \mathbf{e}_3$ is a basis of $\mathbb{F}_p^3$: the equation $(x,y,z) = a\mathbf{u} + b\mathbf{e}_2 + c\mathbf{e}_3 = (a, a+b, a+c)$ has exactly one solution, $a = x, b = y - x, c = z - x$. By Corollary 2.2.18, a linear map $T : \mathbb{F}_p^3 \to \mathbb{F}_p^2$ is determined by the list $T(\mathbf{u}), T(\mathbf{e}_2), T(\mathbf{e}_3)$, and every list occurs. The condition fixes $T(\mathbf{u}) = \mathbf{0}$ and leaves the other two values free, so there are $(p^2)^2 = p^4$ such maps.

(b) Let $T(\mathbf{u}) = \mathbf{0}$, and write $\mathbf{w}_2 = T(\mathbf{e}_2)$, $\mathbf{w}_3 = T(\mathbf{e}_3)$. For $\mathbf{v} = a\mathbf{u} + b\mathbf{e}_2 + c\mathbf{e}_3$, $T(\mathbf{v}) = b\mathbf{w}_2 + c\mathbf{w}_3$.

If $\mathbf{w}_2, \mathbf{w}_3$ is independent, then $T(\mathbf{v}) = \mathbf{0}$ forces $b = c = 0$, so $\ker T \subseteq \ell$, and $\ell \subseteq \ker T$ since $T(\mathbf{u}) = \mathbf{0}$. If the pair is dependent, a nontrivial relation $b\mathbf{w}_2 + c\mathbf{w}_3 = \mathbf{0}$ gives $\mathbf{v} = b\mathbf{e}_2 + c\mathbf{e}_3 = (0, b, c) \in \ker T$. This vector is nonzero and not in ℓ, since the only multiple (a,a,a) of $\mathbf{u}$ with first entry 0 is $\mathbf{0}$. So $\ker T = \ell$ if and only if $\mathbf{w}_2, \mathbf{w}_3$ is independent. By Exercise 1.5.43(b), $\mathbb{F}_p^2$ contains exactly $(p^2-1)(p^2-p)$ independent lists of length 2, and each gives one T by (a).

For such a T, the span of the independent list $\mathbf{w}_2, \mathbf{w}_3$ has p^2 elements (Exercise 1.5.43(a)), so it is all of $\mathbb{F}_p^2$, and $\mathrm{im}\, T \supseteq \mathrm{span}(\mathbf{w}_2, \mathbf{w}_3) = \mathbb{F}_p^2$ (Proposition 2.1.16). So T is surjective.

(c) Let $T : \mathbb{F}_p^3 \to \mathbb{F}_p^2$ be surjective. By Exercise 2.6.44(a), $p^3 = |\ker T| \cdot |\mathrm{im}\, T| = |\ker T| \cdot p^2$, so $|\ker T| = p$. In particular $\ker T$ contains some $\mathbf{v} \neq \mathbf{0}$. The p multiples $a\mathbf{v}$ are distinct (if $a\mathbf{v} = a'\mathbf{v}$ then $(a - a')\mathbf{v} = \mathbf{0}$, so $a = a'$) and lie in $\ker T$, so $\ker T = \mathrm{span}(\mathbf{v})$, a line.

Conversely, fix a line $\mathrm{span}(\mathbf{v})$. By Proposition 1.5.14, appending to the list $\mathbf{v}$ each standard basis vector that is not in the span of the list so far gives an independent list whose span contains every $\mathbf{e}_i$, hence a basis of $\mathbb{F}_p^3$. It has exactly 3 vectors, since an independent list of length k spans p^k vectors (Exercise 1.5.43(a)). The argument of (a) and (b), with this basis in place of $\mathbf{u}, \mathbf{e}_2, \mathbf{e}_3$, shows that exactly $(p^2-1)(p^2-p)$ maps have kernel $\mathrm{span}(\mathbf{v})$, and that they are surjective.

So the surjective maps are sorted by their kernels, which are exactly the lines. By Problem 1.13(b), $\mathbb{F}_p^3$ has $(p^3-1)/(p-1) = p^2 + p + 1$ lines, so the number of surjective maps is

$$(p^2+p+1)(p^2-1)(p^2-p) = \frac{p^3-1}{p-1} \cdot (p^2-1) \cdot p(p-1) = (p^3-1)(p^3-p),$$

in agreement with Exercise 2.6.45, which counted them through their columns instead.

Solution to Problem 2.16

Uses. Theorem 3.5.27 (Rank normal form), Theorem 2.4.34 (Block multiplication), Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear)
Techniques. Cyclicity of trace (Technique 2.4.29), Block decomposition (Technique 2.4.35)
Hint 1. By Theorem 3.5.27, $P = G^{-1}N_kH^{-1}$ with G, H invertible. Set $M = H^{-1}G^{-1}$ and rewrite $P^2 = P$ as an equation involving N_kMN_k.
Hint 2. Partition M with a $k \times k$ block M_{11} in the corner, and compute N_kMN_k by blocks. Then $\operatorname{tr} P = \operatorname{tr}(N_kM)$ by cyclicity.
Sketch. (a) $P^2 = G^{-1}N_kMN_kH^{-1}$, so $P^2 = P$ means $N_kMN_k = N_k$. By blocks, $N_kMN_k = \left(\begin{smallmatrix} M_{11} & 0 \\ 0 & 0 \end{smallmatrix}\right)$, so $M_{11} = I_k$, and $\operatorname{tr} P = \operatorname{tr}\left(G^{-1}N_kH^{-1}\right) = \operatorname{tr}(N_kM) = \operatorname{tr} M_{11} = k * 1$. (b) Same, with $N_kMN_k = 0$, so $M_{11} = 0$. (c) Take traces: $\sum_i \operatorname{rank} P_i = \operatorname{tr} I_n = n$ in $\mathbb{Q}$. Over $\mathbb{F}_2$, $I_1 + I_1 + I_1 = I_1$.

(a) By Theorem 3.5.27 there are invertible $G, H \in F^{n\times n}$ with $GPH = N_k$, so $P = G^{-1}N_kH^{-1}$. If $k = 0$, then $N_0 = 0$, so $P = 0$ and $\operatorname{tr} P = 0$. Let $k \geq 1$. Let $M = H^{-1}G^{-1}$. Then

$$P^2 = G^{-1}N_kH^{-1}G^{-1}N_kH^{-1} = G^{-1}N_kMN_kH^{-1},$$

and multiplying $P^2 = P$ by G on the left and H on the right gives $N_kMN_k = N_k$. Partition $M = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}$ with $M_{11} \in F^{k\times k}$, matching $N_k = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix}$. By block multiplication,

$$N_kM = \begin{pmatrix} M_{11} & M_{12} \\ 0 & 0 \end{pmatrix}, \quad N_kMN_k = \begin{pmatrix} M_{11} & 0 \\ 0 & 0 \end{pmatrix}.$$

So $M_{11} = I_k$. By cyclicity (Proposition 2.4.28), applied to G^{-1} and N_kH^{-1},

$$\operatorname{tr} P = \operatorname{tr}\left(N_kH^{-1}G^{-1}\right) = \operatorname{tr}(N_kM) = \operatorname{tr} M_{11} = \operatorname{tr} I_k = k * 1.$$

(When $k = n$ the blocks other than M_{11} are empty and the same computation applies.)

(b) Let $k = \operatorname{rank} A$. If $k = 0$, then $A = G^{-1}N_0H^{-1} = 0$. Otherwise write $A = G^{-1}N_kH^{-1}$ and $M = H^{-1}G^{-1}$ as in (a). Now $A^2 = 0$ gives $N_kMN_k = 0$, so $M_{11} = 0$, and $\operatorname{tr} A = \operatorname{tr}(N_kM) = \operatorname{tr} M_{11} = 0$.

(c) Let $k_i = \operatorname{rank} P_i$. By Proposition 2.4.27 and (a),

$$n = \operatorname{tr} I_n = \operatorname{tr} P_1 + \cdots + \operatorname{tr} P_r = k_1 + \cdots + k_r$$

in $\mathbb{Q}$, where the k_i are integers; so $k_1 + \cdots + k_r = n$. Over $\mathbb{F}_2$, take $n = 1$, $r = 3$, and $P_1 = P_2 = P_3 = I_1$: they are idempotent, their sum is $(1 + 1 + 1)I_1 = I_1$, and their ranks add up to $3 \neq 1$. Part (a) still holds there, but the trace only records $3 * 1 = 1$.

The trace of an idempotent counts the dimension of the space it projects onto, but only modulo the characteristic. In particular, over $\mathbb{Q}$ an idempotent with trace 0 is 0, and over $\mathbb{F}_2$, I_2 is a nonzero idempotent with trace 0.

Solution to Problem 2.17

Uses. Proposition 2.4.14 (Algebra of matrices), Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear), Lemma 2.4.24 (Matrix units)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. Expand $(A + B)^k$ as a sum of 2^k products $W_1W_2\cdots W_k$ with each $W_t \in \{A, B\}$. The products with only A or only B give A^k and B^k. Show that every other product has trace 0.
Hint 2. A product that contains both letters has, reading cyclically (so that W_k is followed by W_1), some A immediately followed by a B. Rotate the product with Proposition 2.4.28 so that this pair becomes adjacent.
Sketch. (a) In a mixed word some A is cyclically followed by B: otherwise every letter after an A is an A, and going around the cycle all letters are A. If the pair is inside the word, the product contains $AB = 0$. If it is $W_k = A$, $W_1 = B$, then $\operatorname{tr}(W_1\cdots W_k) = \operatorname{tr}(W_kW_1\cdots W_{k-1})$, which contains AB. (b) $A = U_{11}$, $B = U_{21}$: $(A + B)^2 = U_{11} + U_{21}$, but $A^2 + B^2 = U_{11}$.

(a) By distributivity (Proposition 2.4.14), $(A + B)^k$ is the sum, over all 2^k choices of $W_1, \ldots, W_k \in \{A, B\}$, of the products $W_1W_2\cdots W_k$. The choice with every $W_t = A$ gives A^k, and the choice with every $W_t = B$ gives B^k. By Proposition 2.4.27 it suffices to show that every other product has trace 0.

Consider a product in which both A and B occur, and read the indices cyclically, so that position k is followed by position 1. Some A is followed by a B: if every A were followed by an A, then starting from any position holding A and moving forward around the cycle, every position would hold A, contradicting the presence of B. So there is a t with $W_t = A$ and $W_{t+1} = B$, where W_{k+1} means W_1.

- If $t < k$, the product contains the adjacent factors $W_t W_{t+1} = AB = 0$, so it is 0 by associativity, and its trace is 0.
- If $t = k$, then $W_k = A$ and $W_1 = B$. By Proposition 2.4.28, applied to $X = W_1 \cdots W_{k-1}$ and $Y = W_k$,

$$\operatorname{tr}(W_1 \cdots W_k) = \operatorname{tr}(W_k W_1 \cdots W_{k-1}),$$

  and the product on the right contains $W_k W_1 = AB = 0$. Its trace is 0.

So $\operatorname{tr}\big((A+B)^k\big) = \operatorname{tr}\big(A^k\big) + \operatorname{tr}\big(B^k\big)$.

(b) Let $A = U_{11}$ and $B = U_{21}$, with $U_{ij} = \mathbf{e}_i \mathbf{e}_j^{\mathsf{T}} \in F^{2\times 2}$. By Lemma 2.4.24(c), $AB = 0$, $BA = U_{21}$, $A^2 = U_{11}$, and $B^2 = 0$. So

$$(A+B)^2 = A^2 + AB + BA + B^2 = U_{11} + U_{21} \neq U_{11} = A^2 + B^2.$$

The extra term BA has trace 0, as (a) requires. The trace cannot see a cyclic rotation of the factors, and one rotation is all it takes to bring an A next to a B.

Solution to Problem 2.18

Uses. Proposition 2.4.8 (Four views of the product), Definition 2.4.21 (Transpose), Proposition 2.5.4 (Left inverses give uniqueness), Exercise 2.6.44
Techniques. Test injectivity at **0** (Technique 2.6.12)
Hint 1. Record club j as the vector $\mathbf{v}_j \in \mathbb{F}_2^n$ with 1 in position r exactly when resident r is a member. Then $\mathbf{v}_i^{\mathsf{T}} \mathbf{v}_j$ is the number of common members, modulo 2.
Hint 2. Let $M \in \mathbb{F}_2^{n\times k}$ have columns $\mathbf{v}_1, \ldots, \mathbf{v}_k$. Compute $M^{\mathsf{T}} M$. What does a left inverse say about $T_M : \mathbb{F}_2^k \to \mathbb{F}_2^n$?
Sketch. (a) The entries of $M^{\mathsf{T}} M$ are $\mathbf{v}_i^{\mathsf{T}} \mathbf{v}_j$, which are 1 on the diagonal (odd sizes) and 0 off it (even intersections), so $M^{\mathsf{T}} M = I_k$. Then T_M is injective, and an injective linear map $\mathbb{F}_2^k \to \mathbb{F}_2^n$ has $k \le n$ (Exercise 2.6.44). (b) The n one-member clubs. (c) Pair the residents as $\{1,2\}, \{3,4\}, \{5,6\}$, and take the 7 nonempty unions of pairs; the Gram matrix is now 0, and the argument collapses.

(a) Number the residents $1, \ldots, n$, and for club j let $\mathbf{v}_j \in \mathbb{F}_2^n$ have r-th entry 1 if resident r belongs to club j and 0 otherwise. For any clubs i and j,

$$\mathbf{v}_i^{\mathsf{T}} \mathbf{v}_j = \sum_{r=1}^{n} (\mathbf{v}_i)_r (\mathbf{v}_j)_r$$

adds a 1 for each common member, so it is the number of common members, reduced modulo 2. By hypothesis this is 1 for $i = j$ and 0 for $i \neq j$.

Let $M \in \mathbb{F}_2^{n\times k}$ have columns $\mathbf{v}_1, \ldots, \mathbf{v}_k$. The (i,j) entry of $M^{\mathsf{T}} M$ is row i of M^{T}, which is $\mathbf{v}_i^{\mathsf{T}}$, times column j of M (Proposition 2.4.8(a)), so $M^{\mathsf{T}} M = I_k$. Thus M^{T} is a left inverse of M, and $T_M : \mathbb{F}_2^k \to \mathbb{F}_2^n$ is injective (Proposition 2.5.4). By Exercise 2.6.44(b), $k \le n$.

(b) Let club j consist of resident j alone, for $j = 1, \ldots, n$. Each club has one member and two different clubs share none.

(c) Split six residents into the pairs $\{1,2\}, \{3,4\}, \{5,6\}$, and let the clubs be the 7 nonempty unions of these pairs:

$$\{1,2\}, \quad \{3,4\}, \quad \{5,6\}, \quad \{1,2,3,4\}, \quad \{1,2,5,6\}, \quad \{3,4,5,6\}, \quad \{1,\ldots,6\}.$$

Each is a union of pairs, so it has an even number of members, and the intersection of two of them is again a union of pairs (those they share), so it is even as well. That is $7 > 6$ clubs. In the vector language every

$\mathbf{v}_i^{\mathsf{T}}\mathbf{v}_j$ is now 0, so $M^{\mathsf{T}}M = 0$ and there is no left inverse to be had: the oddness of the clubs is what made the vectors independent.

This is the Oddtown theorem. For the even version, one can show that at most $2^{\lfloor n/2 \rfloor}$ clubs are possible, counting the empty club, but the proof needs more than this chapter.

Solution to Problem 2.19

Uses. Proposition 2.4.14 (Algebra of matrices), Proposition 2.5.4 (Left inverses give uniqueness), Lemma 2.4.24 (Matrix units)
Techniques. Test injectivity at **0** (Technique 2.6.12)
Hint 1. Multiply $A^2 + B^2$ by a nonzero matrix built from A and B, and use both hypotheses.
Hint 2. Expand $(A^2 + B^2)(A - B)$. For (b), use block diagonal matrices whose first block is the same and whose second blocks are different matrices with square 0.
Sketch. (a) No. $(A^2 + B^2)(A - B) = (A^3 - B^3) - (A^2B - B^2A) = 0$ and $A - B \neq 0$; a nonzero column $\mathbf{x}$ of $A - B$ has $(A^2 + B^2)\mathbf{x} = \mathbf{0}$, so $A^2 + B^2$ is not injective. (b) $A = U_{11} + U_{23}$, $B = U_{11} + U_{32}$ in $\mathbb{R}^{3\times 3}$: $A^2 = B^2 = A^3 = B^3 = U_{11}$, $A^2B = B^2A = U_{11}$, and $A^2 + B^2 = 2U_{11}$.

(a) No. By distributivity,

$$(A^2 + B^2)(A - B) = A^3 - A^2B + B^2A - B^3 = (A^3 - B^3) - (A^2B - B^2A) = 0.$$

Since $A \neq B$, some column $\mathbf{x}$ of $A - B$ is nonzero, and by the column view $(A^2 + B^2)\mathbf{x}$ is the corresponding column of 0. So $T_{A^2+B^2}$ is not injective, and $A^2 + B^2$ has no left inverse (Proposition 2.5.4), let alone an inverse. The argument works over every field.

(b) Let $A = U_{11} + U_{23}$ and $B = U_{11} + U_{32}$ in $\mathbb{R}^{3\times 3}$. By Lemma 2.4.24(c), U_{11} kills U_{23} and U_{32} on both sides, and $U_{23}^2 = U_{32}^2 = 0$. So $A^2 = B^2 = U_{11}$, hence $A^3 = U_{11}A = U_{11} = B^3$, and $A^2B = U_{11}B = U_{11} = U_{11}A = B^2A$. Also $A \neq B$. But $A^2 + B^2 = 2U_{11} \neq 0$.

This is Problem A2 of the 1991 Putnam Competition. The idea is to find a product with $A^2 + B^2$ that the hypotheses kill, which is the zero-divisor phenomenon of Example 2.4.19 put to work.

Solution to Problem 2.20

Uses. Problem 2.9, Proposition 2.5.28 (Inverse of a 2×2 matrix), Exercise 2.5.46, Exercise 2.5.32, Lemma 2.4.24 (Matrix units), Theorem 2.4.34 (Block multiplication)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Try small cases and small fields (Technique 1.2.38)
Hint 1. (a) By Problem 2.9(a), $(BA)^3 = B(AB)^2A = 0$. So $N = BA$ is a 2×2 matrix with $N^3 = 0$. What does Exercise 2.5.46(a) say about such an N?
Hint 2. N is not invertible, so $ad - bc = 0$ and $N^2 = (\operatorname{tr} N)N$. For (b), look for 3×3 examples among sums of two matrix units, with AB a single matrix unit of square 0 and BA a path of length 2.
Sketch. (a) $N = BA$ has $N^3 = 0$, so N is not invertible and its $ad - bc$ is 0; then $N^2 = tN$ with $t = \operatorname{tr} N$, so $0 = N^3 = t^2N$, and either $t = 0$ or $N = 0$. In both cases $N^2 = tN = 0$. (b) $A = U_{11} + U_{22}$, $B = U_{12} + U_{31}$: $AB = U_{12}$, $(AB)^2 = 0$, but $BA = U_{12} + U_{31}$ and $(BA)^2 = U_{32}$. Pad with zero blocks for $n > 3$.

(a) Let $N = BA$. By Problem 2.9(a) with $k = 2$, $N^3 = B(AB)^2A = B0A = 0$. So N is not invertible (Exercise 2.5.32(b)), and by Proposition 2.5.28(a), $\Delta = ad - bc = 0$ for its entries. By Exercise 2.5.46(a), $N^2 = tN - \Delta I_2 = tN$, where $t = \operatorname{tr} N$. Then

$$0 = N^3 = tN^2 = t^2N.$$

If $t \neq 0$, this gives $N = 0$; otherwise $t = 0$. Either way $N^2 = tN = 0$, that is, $BABA = 0$.

(b) Let $n = 3$, $A = U_{11} + U_{22}$, and $B = U_{12} + U_{31}$, where $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$. By Lemma 2.4.24(c),

$$AB = U_{11}U_{12} = U_{12}, \quad (AB)^2 = U_{12}U_{12} = 0,$$

since the other three products of units vanish. On the other side,

$$BA = U_{12}U_{22} + U_{31}U_{11} = U_{12} + U_{31}, \quad (BA)^2 = U_{31}U_{12} = U_{32} \neq 0.$$

Explicitly,

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

For $n > 3$, use the block diagonal matrices $\begin{pmatrix} A & 0 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} B & 0 \\ 0 & 0 \end{pmatrix}$ in $F^{n\times n}$; by Theorem 2.4.34 their products are computed in the top left 3×3 block, so the same identities hold there.

In size 2 a matrix with $N^3 = 0$ already has $N^2 = 0$, and that is what (a) used. In size 3, BA is still nilpotent by Problem 2.9, but it can take three steps to die, as $U_{12} + U_{31}$ does: $\mathbf{e}_2 \mapsto \mathbf{e}_1 \mapsto \mathbf{e}_3 \mapsto \mathbf{0}$. This is Problem A5 of the 1990 Putnam Competition.

Section 3.1

Solution to Exercise 3.1.7

Uses. Proposition 3.1.5 (Three faces of a linear system), Definition 3.1.4 (Coefficient matrix; matrix and vector forms)
Hint 1. Row i of A lists the coefficients of x_1, x_2, x_3 in equation i, with 0 for a missing unknown.
Hint 2. To test a vector, substitute it into each equation, or compute $A\mathbf{x}$ and compare with $\mathbf{y}$.
Sketch. A has rows $(1, 0, -1)$, $(0, 1, 2)$, $(1, 1, 0)$ and $\mathbf{y} = (2, -1, 1)$. Then $A(2, -1, 0) = (2, -1, 1)$, a solution, and $A(3, -3, 1) = (2, -1, 0)$, not a solution.

The matrix and vector forms are

$$\begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & 2 \\ 1 & 1 & 0 \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}, \quad x_1\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix} + x_2\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} + x_3\begin{pmatrix} -1 \\ 2 \\ 0 \end{pmatrix} = \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}.$$

For $\mathbf{x} = (2, -1, 0)$, the left sides are $2 - 0 = 2$, $-1 + 0 = -1$, and $2 - 1 = 1$, so $(2, -1, 0)$ is a solution. For $\mathbf{x} = (3, -3, 1)$, the first two equations hold ($3 - 1 = 2$ and $-3 + 2 = -1$), but $3 + (-3) = 0 \neq 1$, so $(3, -3, 1)$ is not a solution.

Solution to Exercise 3.1.11

Uses. Technique 3.1.9 (Undetermined coefficients), Definition 1.2.13 (Polynomials)
Techniques. Undetermined coefficients (Technique 3.1.9)
Hint 1. Expand the right side and collect the coefficients of x^2, x, and 1.
Hint 2. Two polynomials are equal exactly when their coefficients agree, which gives three equations.
Sketch. The right side is $(c_1 + c_2)x^2 + (2c_1 - 2c_2)x + (c_1 + c_2 + c_3)$, so the system is $c_1 + c_2 = 1$, $2c_1 - 2c_2 = 0$, $c_1 + c_2 + c_3 = 0$, with unique solution $(1/2, 1/2, -1)$.

Expanding, $c_1(x + 1)^2 + c_2(x - 1)^2 + c_3 = (c_1 + c_2)x^2 + (2c_1 - 2c_2)x + (c_1 + c_2 + c_3)$. Comparing coefficients with $x^2 = 1x^2 + 0x + 0$ gives the system

$$c_1 + c_2 = 1, \quad 2c_1 - 2c_2 = 0, \quad c_1 + c_2 + c_3 = 0.$$

The second equation gives $c_1 = c_2$, and then the first gives $c_1 = c_2 = 1/2$; the third gives $c_3 = -1$. Conversely, $(1/2, 1/2, -1)$ satisfies all three equations. So the system has exactly one solution, and

$$x^2 = \frac{1}{2}(x + 1)^2 + \frac{1}{2}(x - 1)^2 - 1.$$

Solution to Exercise 3.1.21

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 3.1.16 (Homogeneous solution sets are subspaces)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. The difference of two solutions of the same system lies in the kernel.
Hint 2. Use linearity of T_A for the second question, and Proposition 3.1.19 for the third.
Sketch. $\mathbf{z} = (1, 2, 0) - (0, 1, 1) = (1, 1, -1) \in \ker T_A$, and it is nonzero. $A(2, 4, 0) = 2(3, 1) = (6, 2)$. The vectors $(1, 2, 0) + t(1, 1, -1)$, $t \in \mathbb{R}$, all solve $A\mathbf{x} = (3, 1)$.

Put $\mathbf{z} = (1,2,0) - (0,1,1) = (1,1,-1)$. Then $A\mathbf{z} = (3,1) - (3,1) = \mathbf{0}$, so $\mathbf{z}$ is a nonzero vector of $\ker T_A$. Next, $A(2,4,0) = 2A(1,2,0) = 2(3,1) = (6,2)$, so $(2,4,0)$ solves $A\mathbf{x} = (6,2)$. Finally, $\ker T_A$ is a subspace (Corollary 3.1.16), so $t\mathbf{z} \in \ker T_A$ for every $t \in \mathbb{R}$, and by Proposition 3.1.19 every vector $(1,2,0) + t(1,1,-1) = (1+t, 2+t, -t)$ is a solution of $A\mathbf{x} = (3,1)$. These vectors are distinct for distinct t (compare third entries), so there are infinitely many.

Solution to Exercise 3.1.28

Uses. Definition 3.1.1 (Linear system), Definition 3.1.4 (Coefficient matrix; matrix and vector forms), Definition 3.1.12 (Augmented matrix), Corollary 3.1.23 (Lines through solutions)
Hint 1. Move every term involving an unknown to the left and every constant to the right. Is each term then a scalar times a single unknown?
Hint 2. Coefficients may be any real numbers, including $\sin 1$ and π. A product of two unknowns is not allowed.
Sketch. (a), (c), and (d) are linear; rearranged they read $x_1 - 2x_2 + x_3 = 1$, $-4x_1 + x_3 = 0$; then $(\sin 1)x_1 + ex_2 - \pi x_3 = 0$; then $3x_1 - x_2 = -3$, $x_2 + x_3 = \sqrt{2}$. (b) contains the product x_1x_2.

Adding the same expression to both sides of an equation does not change its solutions, so we may move terms freely.

(a) Linear. Rearranged, the system is $x_1 - 2x_2 + x_3 = 1$, $-4x_1 + x_3 = 0$, so

$$A = \begin{pmatrix} 1 & -2 & 1 \\ -4 & 0 & 1 \end{pmatrix}, \quad (A \mid \mathbf{y}) = \left(\begin{array}{ccc|c} 1 & -2 & 1 & 1 \\ -4 & 0 & 1 & 0 \end{array}\right).$$

(b) Not linear: the term x_1x_2 is a product of two unknowns. In fact its solution set, the points with $x_3 = 1$ and $x_1 = 0$ or $x_2 = 0$, is not the solution set of any linear system: it contains $(1,0,1)$ and $(0,1,1)$ but not $\left(\frac{1}{2}, \frac{1}{2}, 1\right)$, which lies on the line through them, contrary to Corollary 3.1.23.

(c) Linear: one equation $(\sin 1)x_1 + ex_2 - \pi x_3 = 0$, so

$$A = (\sin 1 \;\; e \;\; -\pi), \quad (A \mid \mathbf{y}) = (\sin 1 \;\; e \;\; -\pi \mid 0).$$

(d) Linear. Rearranged, the system is $3x_1 - x_2 = -3$, $x_2 + x_3 = \sqrt{2}$, so

$$A = \begin{pmatrix} 3 & -1 & 0 \\ 0 & 1 & 1 \end{pmatrix}, \quad (A \mid \mathbf{y}) = \left(\begin{array}{ccc|c} 3 & -1 & 0 & -3 \\ 0 & 1 & 1 & \sqrt{2} \end{array}\right).$$

Solution to Exercise 3.1.29

Uses. Technique 3.1.9 (Undetermined coefficients), Proposition 3.1.5 (Three faces of a linear system), Proposition 3.1.19 (Solution sets are translates of the kernel)
Techniques. Particular plus homogeneous (Technique 3.1.18), Undetermined coefficients (Technique 3.1.9)
Hint 1. The combinations $c_1\mathbf{a}_1 + c_2\mathbf{a}_2 + c_3\mathbf{a}_3 = \mathbf{y}$ are the solutions of a linear system with augmented matrix $(\mathbf{a}_1\mathbf{a}_2\mathbf{a}_3 \mid \mathbf{y})$. Eliminate.
Hint 2. Notice $\mathbf{a}_3 = \mathbf{a}_1 + \mathbf{a}_2$. For (b), look for a linear condition that all three columns satisfy.
Sketch. Elimination reduces (a) to $c_1 + c_3 = 3$, $c_2 + c_3 = -1$, so the combinations are $(3-t)\mathbf{a}_1 + (-1-t)\mathbf{a}_2 + t\mathbf{a}_3$. In (b) elimination produces $0 = 1$; equivalently, every column satisfies $y_1 - 2y_2 + y_3 = 0$ and $(1,0,0)$ does not.

(a) We want all (c_1, c_2, c_3) with $c_1\mathbf{a}_1 + c_2\mathbf{a}_2 + c_3\mathbf{a}_3 = (1,5,9)$. The augmented matrix is

$$\left(\begin{array}{ccc|c} 1 & 2 & 3 & 1 \\ 2 & 1 & 3 & 5 \\ 3 & 0 & 3 & 9 \end{array}\right).$$

Subtracting 2 times row 1 from row 2 and 3 times row 1 from row 3 gives rows $(0,-3,-3 \mid 3)$ and $(0,-6,-6 \mid 6)$. Subtracting 2 times the new row 2 from the new row 3 gives the zero row, and scaling row 2 by $-1/3$ gives $(0,1,1 \mid -1)$. Finally, subtracting 2 times this row from row 1 gives $(1,0,1 \mid 3)$. So the system is equivalent to $c_1 + c_3 = 3$, $c_2 + c_3 = -1$, and its solutions are $(c_1, c_2, c_3) = (3-t, -1-t, t)$ for $t \in \mathbb{R}$. That is,

$$(1,5,9) = (3-t)\mathbf{a}_1 + (-1-t)\mathbf{a}_2 + t\mathbf{a}_3 \quad (t \in \mathbb{R}),$$

and these are all the ways. This matches Proposition 3.1.19: $(3,-1,0)$ is one solution, and the homogeneous solutions are the multiples of $(-1,-1,1)$, reflecting $\mathbf{a}_3 = \mathbf{a}_1 + \mathbf{a}_2$.

(b) The same row operations applied to $(\mathbf{a}_1\mathbf{a}_2\mathbf{a}_3 \mid (1,0,0))$ give the rows $(1,2,3 \mid 1)$, $(0,-3,-3 \mid -2)$, $(0,-6,-6 \mid -3)$, and then the last row becomes $(0,0,0 \mid 1)$. So every solution would satisfy $0 = 1$, and there is none. Here is a second argument, from the column picture. Each column satisfies $y_1 - 2y_2 + y_3 = 0$: $1 - 4 + 3 = 0$, $2 - 2 + 0 = 0$, and $3 - 6 + 3 = 0$. This condition is preserved by sums and scalar multiples, so every linear combination of the columns satisfies it. But $(1,0,0)$ gives $1 \neq 0$.

Solution to Exercise 3.1.30

Uses. Corollary 3.1.25 (Counting solutions over a finite field), Corollary 3.1.24 (No, one, or infinitely many solutions)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. Solve the second equation for x_1. In $\mathbb{F}_3$, $-2 = 1$.
Hint 2. Then the first equation determines x_3 in terms of x_2, and x_2 is free. For the count, also solve the homogeneous system.
Sketch. Over $\mathbb{F}_3$: $x_1 = x_2$ and $x_3 = 1 + x_2$, giving $(0,0,1)$, $(1,1,2)$, $(2,2,0)$. The homogeneous solutions are (t,t,t), also three. Over $\mathbb{R}$: $(-2s, s, 1+s)$, infinitely many.

Over $\mathbb{F}_3$, the second equation says $x_1 = -2x_2 = x_2$. Substituting into the first, $x_3 = 1 - 2x_2 = 1 + x_2$. Conversely, for each $t \in \mathbb{F}_3$ the vector $(t, t, 1+t)$ satisfies both equations: $t + t + 1 + t = 1 + 3t = 1$ and $t + 2t = 3t = 0$. So the solutions are

$$(0,0,1), \quad (1,1,2), \quad (2,2,0).$$

The homogeneous system $x_1 + x_2 + x_3 = 0$, $x_1 + 2x_2 = 0$ gives $x_1 = x_2$ and $x_3 = -2x_2 = x_2$ in the same way, so its solutions are $(0,0,0)$, $(1,1,1)$, $(2,2,2)$: three, as Corollary 3.1.25 predicts.

Over $\mathbb{R}$, the same steps give $x_1 = -2x_2$ and $x_3 = 1 - x_1 - x_2 = 1 + x_2$, so the solutions are $(-2s, s, 1+s)$ for $s \in \mathbb{R}$. There are infinitely many, in line with Corollary 3.1.24.

Solution to Exercise 3.1.31

Uses. Definition 3.1.1 (Linear system)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. Once $x_1, \ldots, x_{n-1}$ are chosen, how many choices of x_n work?
Hint 2. For (b), encode a subset $X \subseteq \{1, \ldots, n\}$ as the vector $\mathbf{x} \in \mathbb{F}_2^n$ with $x_i = 1$ exactly when $i \in X$. What is $x_1 + \cdots + x_n$ in $\mathbb{F}_2$?
Sketch. The map $\mathbf{x} \mapsto (x_1, \ldots, x_{n-1})$ is a bijection from the solution set onto $\mathbb{F}_p^{n-1}$, since $x_n = c - x_1 - \cdots - x_{n-1}$ is forced. For (b), $x_1 + \cdots + x_n$ in $\mathbb{F}_2$ is the parity of $|X|$, so the even subsets correspond to the solutions of $x_1 + \cdots + x_n = 0$ over $\mathbb{F}_2$.

(a) If $\mathbf{x}$ is a solution, then $x_n = c - x_1 - \cdots - x_{n-1}$. Conversely, for any $x_1, \ldots, x_{n-1} \in \mathbb{F}_p$, this choice of x_n gives a solution. So $\mathbf{x} \mapsto (x_1, \ldots, x_{n-1})$ is a bijection from the solution set onto $\mathbb{F}_p^{n-1}$, which has p^{n-1} elements.

(b) Encode $X \subseteq \{1, \ldots, n\}$ as $\mathbf{x} \in \mathbb{F}_2^n$ with $x_i = 1$ if $i \in X$ and $x_i = 0$ otherwise; this is a bijection between subsets and vectors. The sum $x_1 + \cdots + x_n$ computed in $\mathbb{F}_2$ is the remainder of $|X|$ on division by 2 (Lemma 1.1.21), so $|X|$ is even exactly when $x_1 + \cdots + x_n = 0$ in $\mathbb{F}_2$. By (a) with $p = 2$ and $c = 0$, there are 2^{n-1} such vectors.

Solution to Exercise 3.1.31

Uses. Corollary 3.1.25 (Counting solutions over a finite field)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. Every $\mathbf{x} \in \mathbb{F}_p^n$ solves exactly one of the p equations $x_1 + \cdots + x_n = c$, $c \in \mathbb{F}_p$.
Hint 2. Each of these equations is consistent. What does Corollary 3.1.25 say about the sizes of their solution sets?
Sketch. The p solution sets partition $\mathbb{F}_p^n$, and each has the size of the homogeneous solution set, since each equation is consistent ($c\mathbf{e}_1$ is a solution). So each has $p^n/p = p^{n-1}$ elements.

(a) Every $\mathbf{x} \in \mathbb{F}_p^n$ solves exactly one of the equations $x_1 + \cdots + x_n = c$ with $c \in \mathbb{F}_p$, namely the one with $c = x_1 + \cdots + x_n$. So the p solution sets S_c partition $\mathbb{F}_p^n$. Each equation is consistent, since $c\mathbf{e}_1 = (c, 0, \ldots, 0)$ is a solution, so by Corollary 3.1.25 every S_c has as many elements as S_0. Hence $p\,|S_0| = p^n$, and $|S_c| = |S_0| = p^{n-1}$ for every c.

(b) As in the first approach, the even subsets correspond to S_0 over $\mathbb{F}_2$, which has 2^{n-1} elements. In this language the argument says something familiar: toggling whether $1 \in X$ (that is, adding $\mathbf{e}_1$) is a bijection between even and odd subsets.

Solution to Exercise 3.1.32

Uses. Proposition 1.1.17 (No zero divisors), Corollary 3.1.24 (No, one, or infinitely many solutions)
Hint 1. Subtract the second equation from the first and factor: $(1-k)(x_1-x_2)=0$.
Hint 2. Split into the cases $k=1$ and $k\neq 1$. In the second case $x_1=x_2$; substitute back. Which value of k is then special?
Sketch. Any solution satisfies $(1-k)(x_1-x_2)=0$. If $k=1$ both equations are $x_1+x_2=1$. If $k\neq 1$, then $x_1=x_2$ and $(1+k)x_1=1$: no solution if $k=-1$, else $x_1=x_2=1/(1+k)$. The argument works in any field; over $\mathbb{F}_3$, $k=1$ gives 3 solutions, $k=2=-1$ none, $k=0$ one.

The algebra below is valid over any field, so we do it once. Suppose (x_1,x_2) is a solution. Subtracting the equations gives $(1-k)x_1-(1-k)x_2=0$, that is, $(1-k)(x_1-x_2)=0$.

Case $k=1$. Both equations read $x_1+x_2=1$, so the solution set is $\{(1-t,t)\mid t\in F\}$, one solution for each $t\in F$.

Case $k\neq 1$. Then $1-k\neq 0$, so $x_1=x_2$ by Proposition 1.1.17, and either equation becomes $(1+k)x_1=1$. If $k=-1$, this says $0=1$, so there is no solution. If $k\neq -1$, then $x_1=x_2=1/(1+k)$. Conversely, this pair is a solution, since $(1+k)/(1+k)=1$ in both equations. So there is exactly one solution.

(a) Over $\mathbb{R}$: infinitely many solutions for $k=1$, none for $k=-1$, and exactly one, $(1/(1+k),1/(1+k))$, otherwise.

(b) Over $\mathbb{F}_3$: for $k=1$ there are exactly 3 solutions, $(1,0)$, $(0,1)$, $(2,2)$; for $k=2=-1$ there are none; for $k=0$ there is exactly one, $(1,1)$.

Solution to Exercise 3.1.33

Uses. Proposition 3.1.8 (Systems and the map T_A), Definition 2.3.15 (The linear map of a matrix), Proposition 2.6.8 (Kernels and images are subspaces)
Hint 1. For (a), add solutions and scale them.
Hint 2. For (b), the set of $\mathbf{y}$ for which the system is consistent is $\operatorname{im} T_A$, a subspace. Is its complement closed under addition? Try $\mathbf{y}_2=-\mathbf{y}_1$.
Sketch. (a) True: if $A\mathbf{u}=\mathbf{y}_1$ and $A\mathbf{v}=\mathbf{y}_2$, then $A(\mathbf{u}+\mathbf{v})=\mathbf{y}_1+\mathbf{y}_2$ and $A(c\mathbf{u})=c\mathbf{y}_1$. (b) False: with $A=\begin{pmatrix}1\\0\end{pmatrix}$, both $(0,1)$ and $(0,-1)$ are outside $\operatorname{im} T_A$, but their sum $\mathbf{0}$ is not.

(a) True. Let $A\mathbf{u}=\mathbf{y}_1$ and $A\mathbf{v}=\mathbf{y}_2$. Since T_A is linear, $A(\mathbf{u}+\mathbf{v})=A\mathbf{u}+A\mathbf{v}=\mathbf{y}_1+\mathbf{y}_2$ and $A(c\mathbf{u})=cA\mathbf{u}=c\mathbf{y}_1$. In other words, by Proposition 3.1.8 the consistent right-hand sides form $\operatorname{im} T_A$, which is a subspace (Proposition 2.6.8).

(b) False. Over any field, let $A=\begin{pmatrix}1\\0\end{pmatrix}\in F^{2\times 1}$, $\mathbf{y}_1=(0,1)$, and $\mathbf{y}_2=(0,-1)$. For every $x\in F$, $Ax=(x,0)$ has second entry 0, so both systems are inconsistent. But $\mathbf{y}_1+\mathbf{y}_2=\mathbf{0}$, and $A\mathbf{x}=\mathbf{0}$ is consistent.

Solution to Exercise 3.1.34

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 3.1.22 (Uniqueness depends only on A)
Hint 1. Reread the hypothesis of Proposition 3.1.19. What does it assume about $\mathbf{x}_0$?
Hint 2. Look for a matrix with more rows than columns.
Sketch. The proposition needs a solution $\mathbf{x}_0$ to exist, and the argument never shows one does. For $A=\begin{pmatrix}1\\1\end{pmatrix}$, $Ax=0$ forces $x=0$, but $Ax=(1,0)$ has no solution.

Proposition 3.1.19 describes the solution set *given* a solution $\mathbf{x}_0$. The argument uses $\mathbf{x}_0$ without showing that the system is consistent, so it only proves that $A\mathbf{x}=\mathbf{y}$ has *at most* one solution, which is Corollary 3.1.22.

The claim itself is false. Let $A=\begin{pmatrix}1\\1\end{pmatrix}\in\mathbb{R}^{2\times 1}$. Then $Ax=(x,x)$, so $Ax=\mathbf{0}$ only for $x=0$. But $Ax=(1,0)$ would need $x=1$ and $x=0$, so it has no solution.

Solution to Exercise 3.1.35

Uses. Definition 3.1.1 (Linear system)
Hint 1. Is $(2, 1)$ a solution of the original system?
Hint 2. Each new equation is a combination of the old ones, so no solution is lost. Can the old equations be recovered from the two new ones?
Sketch. The two replacements were made at the same time, and the second used the old first equation, which no longer appears in the new system. The new equations are negatives of each other and only say $x_2 = 1$; the original system cannot be recovered from them. The original solution set is $\{(1, 1)\}$, so the points $(t, 1)$ with $t \neq 1$ were gained and nothing was lost.

The original system has the unique solution $(1, 1)$: adding the equations gives $2x_1 = 2$, so $x_1 = 1$, and then $x_2 = 1$. The student's answer contains $(2, 1)$, which is not a solution, since $2 - 1 \neq 0$.

Every solution of the old system satisfies both new equations, because each new equation is a combination of the old ones. So no solution is lost, and the student's set does contain $(1, 1)$. The problem is the other direction. The two new equations, $2x_2 = 2$ and $-2x_2 = -2$, are negatives of each other and together say only $x_2 = 1$. The equation $x_1 + x_2 = 2$ cannot be recovered from them, so solutions are gained: all $(t, 1)$ with $t \neq 1$.

The error is performing two replacements simultaneously when the second one uses the equation that the first one replaces. Replacing an equation E_i by $E_i - E_j$ is reversible only while E_j is still present: then $E_i = \big(E_i - E_j\big) + E_j$. Done one at a time, the operations are harmless. Replacing the first equation by the first minus the second gives $2x_2 = 2$, $x_1 - x_2 = 0$, and then subtracting the new first equation from the second gives $2x_2 = 2$, $x_1 - 3x_2 = -2$, whose only solution is $(1, 1)$.

Solution to Exercise 3.1.36

Uses. Definition 3.1.1 (Linear system)
Hint 1. A plane can contain lines in many directions. Must a plane that contains the direction of L be parallel to one of the planes through L?
Hint 2. Try three planes that all contain lines parallel to the x_3-axis, for example planes whose equations do not involve x_3.
Sketch. The step "parallel to neither plane, hence not parallel to L" is unjustified. Counterexample: $x_1 = 0$, $x_2 = 0$, $x_1 + x_2 = 1$. No two coefficient vectors are proportional, but a common point would have $0 + 0 = 1$.

The unjustified step is "the third plane is parallel to neither of the first two, so it is not parallel to L". Being parallel to a line is much weaker than being parallel to a plane: a plane is parallel to L when it contains lines in the direction of L, and many non-parallel planes do. If the third plane is parallel to L and does not contain it, it misses L entirely.

Counterexample: the planes $x_1 = 0$, $x_2 = 0$, and $x_1 + x_2 = 1$. Their coefficient vectors $(1, 0, 0)$, $(0, 1, 0)$, $(1, 1, 0)$ are pairwise not proportional, so no two of the planes are parallel. The first two meet in the x_3-axis L, and the third contains the lines $\{(1, 0, t) \mid t \in \mathbb{R}\}$ and $\{(0, 1, t) \mid t \in \mathbb{R}\}$, both parallel to L. A common point would satisfy $x_1 = 0$, $x_2 = 0$, and $x_1 + x_2 = 1$, which gives $0 = 1$. So there is none. This is the configuration of Figure 3.1.3.

Solution to Exercise 3.1.37

Uses. Technique 3.1.9 (Undetermined coefficients), Proposition 3.1.19 (Solution sets are translates of the kernel)
Techniques. Undetermined coefficients (Technique 3.1.9), Particular plus homogeneous (Technique 3.1.18)
Hint 1. Write $p = a + bx + cx^2$. Each condition $p(t) = v$ is a linear equation in a, b, c.
Hint 2. For (b), the answer to (a) is one particular solution. Find the cubics q with $q(-1) = q(0) = q(1) = 0$.
Sketch. (a) $a - b + c = 2$, $a = 1$, $a + b + c = 4$ give $p = 1 + x + 2x^2$, uniquely. (b) The homogeneous conditions force $a = c = 0$ and $d = -b$, so the solutions are $1 + x + 2x^2 + t\big(x^3 - x\big)$.

(a) Write $p = a + bx + cx^2$. The conditions are the linear system

$$a - b + c = 2, \quad a = 1, \quad a + b + c = 4.$$

With $a = 1$, the first and third equations become $-b + c = 1$ and $b + c = 3$; adding and subtracting gives $c = 2$ and $b = 1$. Conversely $p = 1 + x + 2x^2$ satisfies $p(-1) = 2$, $p(0) = 1$, $p(1) = 4$. So $p = 1 + x + 2x^2$ is the only such polynomial.

(b) Write $q = a + bx + cx^2 + dx^3$. The conditions are linear in (a, b, c, d), and $q = 1 + x + 2x^2$ is one solution by (a). The homogeneous conditions $q(-1) = q(0) = q(1) = 0$ read $a - b + c - d = 0$, $a = 0$, $a + b + c + d = 0$. Then $-b + c - d = 0$ and $b + c + d = 0$; adding gives $c = 0$, and then $d = -b$. So the homogeneous solutions are $bx - bx^3 = -b\big(x^3 - x\big)$, the multiples of $x^3 - x = (x + 1)x(x - 1)$. By Proposition 3.1.19, applied to the linear map $q \mapsto (q(-1), q(0), q(1))$ from $\mathbb{R}[x]_{\leq 3}$ to $\mathbb{R}^3$, the solutions are exactly

$$q = 1 + x + 2x^2 + t\big(x^3 - x\big), \quad t \in \mathbb{R}.$$

The kernel consists of the cubics vanishing at the three points. Section 3.4 shows that through $n + 1$ points with distinct first coordinates there is always exactly one polynomial of degree at most n.

Solution to Exercise 3.1.38

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Definition 3.1.14 (Homogeneous system)
Techniques. Undetermined coefficients (Technique 3.1.9), Particular plus homogeneous (Technique 3.1.18)
Hint 1. At A the arrivals are $300 + x_4$ and the departures are x_1. Write the other three balances similarly.
Hint 2. Solve for x_1, x_2, x_3 in terms of x_4. For (b), add the four equations written as "arrivals minus departures $= 0$".
Hint 3. The homogeneous solutions are the flows (t, t, t, t): cars circling the loop. For (c), which t are allowed?
Sketch. The balances give $x_1 = 300 + x_4$, $x_2 = x_1 - 200$, $x_3 = x_2 + 100$, $x_3 = x_4 + 200$, so the solutions are $(300 + t, 100 + t, 200 + t, t)$. The four balances sum to $0 = 0$ because each road leaves one intersection and enters another and the external flows cancel. Nonnegativity means $t \geq 0$, so the minima $300, 100, 200, 0$ all occur at $t = 0$.

(a) Balancing arrivals and departures at each intersection:

$$\begin{aligned} A: &\quad 300 + x_4 = x_1, \\ B: &\quad x_1 = x_2 + 200, \\ C: &\quad x_2 + 100 = x_3, \\ D: &\quad x_3 = x_4 + 200. \end{aligned}$$

Suppose (x_1, x_2, x_3, x_4) is a solution and put $t = x_4$. Then A gives $x_1 = 300 + t$, B gives $x_2 = 100 + t$, and C gives $x_3 = 200 + t$. Conversely, for every $t \in \mathbb{R}$ the vector $(300 + t, 100 + t, 200 + t, t)$ satisfies A, B, C by construction, and also D, since $200 + t = t + 200$. So the solution set is

$$(300, 100, 200, 0) + \operatorname{span}((1, 1, 1, 1)).$$

In the language of Proposition 3.1.19, the homogeneous solutions (t, t, t, t) are traffic circling the loop, which changes no balance.

(b) Write each balance as "arrivals minus departures $= 0$". Each road variable x_i appears once with a plus sign, at the intersection where the road ends, and once with a minus sign, where it starts. The external terms are $300 - 200 + 100 - 200 = 0$. So the sum of the four equations is $0 = 0$, and any one of them is the negative of the sum of the other three. (So the system is really three equations in four unknowns, and the computation in (a) shows that its homogeneous solutions form the line $\operatorname{span}((1, 1, 1, 1))$.)

(c) The flows are nonnegative exactly when $t \geq 0$, as then $300 + t$, $100 + t$, and $200 + t$ are positive too. So the smallest possible flows are $x_1 = 300$, $x_2 = 100$, $x_3 = 200$, $x_4 = 0$, and all four occur together at $t = 0$, when no traffic uses the road from D to A.

Solution to Exercise 3.1.39

Uses. Technique 3.1.9 (Undetermined coefficients), Corollary 3.1.16 (Homogeneous solution sets are subspaces)
Techniques. Undetermined coefficients (Technique 3.1.9)
Hint 1. Write one equation per element: for copper in (a), $a = c$. Count oxygen carefully: $Cu(NO_3)_2$ contains six oxygen atoms.

Hint 2. In (a), express everything in terms of a. In (b) there are two equations in four unknowns; express a and b in terms of c and d.
Sketch. (a) Cu: $a = c$; H: $b = 2e$; N: $b = 2c + d$; O: $3b = 6c + d + e$. The solutions are the multiples of $(3, 8, 3, 2, 4)$. (b) H: $a = c + d$; O: $2b = c + 2d$; so $(a, b, c, d) = (c/2)(2, 1, 2, 0) + d(1, 1, 0, 1)$.

(a) Counting atoms of each element on both sides gives the homogeneous system

$$\text{Cu} : a = c, \quad \text{H} : b = 2e, \quad \text{N} : b = 2c + d, \quad \text{O} : 3b = 6c + d + e.$$

Suppose (a, b, c, d, e) is a solution. Then $c = a$, and the nitrogen equation gives $d = b - 2a = 2e - 2a$. The oxygen equation becomes $6e = 6a + (2e - 2a) + e$, that is, $3e = 4a$. So $e = 4a/3$, $b = 8a/3$, and $d = 2a/3$, which means

$$(a, b, c, d, e) = \frac{a}{3}(3, 8, 3, 2, 4).$$

Conversely, $(3, 8, 3, 2, 4)$ satisfies all four equations: $3 = 3$, $8 = 8$, $8 = 6 + 2$, and $24 = 18 + 2 + 4$. Since the solution set is a subspace (Corollary 3.1.16), all multiples are solutions too. So the balancings are the multiples of $(3, 8, 3, 2, 4)$, and the smallest positive integer one is

$$3\ \text{Cu} + 8\text{HNO}_3 \to 3\text{Cu}(\text{NO}_3)_2 + 2\ \text{NO} + 4\text{H}_2\text{O}.$$

A balancing with positive integer entries is $(a/3)(3, 8, 3, 2, 4)$ with a a positive integer. Its fourth entry $2a/3$ is an integer and $\gcd(2, 3) = 1$, so $3 \mid a$ and $a \geq 3$. Hence $a = 3$ gives the smallest one.

(b) The system is $2a = 2c + 2d$ (hydrogen) and $2b = c + 2d$ (oxygen). So any solution has $a = c + d$ and $b = c/2 + d$, and

$$(a, b, c, d) = \left(c + d, \frac{c}{2} + d, c, d\right) = \frac{c}{2}(2, 1, 2, 0) + d(1, 1, 0, 1).$$

Conversely, $(2, 1, 2, 0)$ and $(1, 1, 0, 1)$ both satisfy the two equations, so all their combinations do. Chemically, every balanced version of this equation is a mixture of the two independent reactions $2\text{H}_2 + \text{O}_2 \to 2\text{H}_2\text{O}$ and $\text{H}_2 + \text{O}_2 \to \text{H}_2\text{O}_2$. The solution set is a plane rather than a line, so balancing alone cannot determine the proportions.

Solution to Exercise 3.1.40

Uses. Proposition 3.1.5 (Three faces of a linear system), Definition 2.4.1 (Matrix product)
Techniques. Undetermined coefficients (Technique 3.1.9)
Hint 1. Pressing a light twice does nothing, and the order of presses does not matter. Why? So only the parity of the number of presses of each light matters.
Hint 2. Column j of A records which lights pressing j toggles. For (b), entry (i, j) of A^2 counts the lights toggled both by pressing i and by pressing j (A is symmetric), modulo 2.
Hint 3. If $A^2 = I$, then $A\mathbf{x} = \mathbf{y}$ implies $\mathbf{x} = A\mathbf{y}$.
Sketch. Light i ends in state $y_i + \sum_j a_{ij}x_j$, so all lights end off exactly when $A\mathbf{x} = \mathbf{y}$ (over $\mathbb{F}_2$, $-\mathbf{y} = \mathbf{y}$). Here A has rows $(1, 1, 1, 0)$, $(1, 1, 0, 1)$, $(1, 0, 1, 1)$, $(0, 1, 1, 1)$; each row has three ones and any two rows share two, so $A^2 = I$. Then $A\mathbf{x} = \mathbf{y}$ if and only if $\mathbf{x} = A\mathbf{y}$. For light 1 alone: press 1, 2, 3.

(a) The final state of a light depends only on how many times it is toggled, and only on that number's parity. So the order of presses is irrelevant, pressing a light twice is the same as not pressing it, and a strategy is the vector $\mathbf{x} \in \mathbb{F}_2^4$ with $x_j = 1$ exactly when light j is pressed (an odd number of times). Let $a_{ij} = 1$ if pressing light j toggles light i, and $a_{ij} = 0$ otherwise. Starting from the pattern $\mathbf{y}$, light i ends in state $y_i + a_{i1}x_1 + \cdots + a_{i4}x_4$ in $\mathbb{F}_2$. All lights end off exactly when $A\mathbf{x} + \mathbf{y} = \mathbf{0}$, that is, $A\mathbf{x} = -\mathbf{y} = \mathbf{y}$, as $-1 = 1$ in $\mathbb{F}_2$. Light 1 toggles lights 1, 2, 3, light 2 toggles 1, 2, 4, light 3 toggles 1, 3, 4, and light 4 toggles 2, 3, 4, so

$$A = \begin{pmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 \end{pmatrix}.$$

(b) A is symmetric, so entry (i,j) of A^2 is $\sum_k a_{ik}a_{kj} = \sum_k a_{ik}a_{jk}$, the number of positions where rows i and j both have a 1, reduced mod 2. Each row has three 1s, so the diagonal entries are $3 = 1$. Any two different rows have exactly two 1s in common (for instance, rows 1 and 2 share positions 1 and 2), so the off-diagonal entries are $2 = 0$. Hence $A^2 = I_4$.

Now let $\mathbf{y}$ be any pattern. If $A\mathbf{x} = \mathbf{y}$, then $\mathbf{x} = A^2\mathbf{x} = A\mathbf{y}$. Conversely, $\mathbf{x} = A\mathbf{y}$ satisfies $A\mathbf{x} = A^2\mathbf{y} = \mathbf{y}$. So $A\mathbf{x} = \mathbf{y}$ has exactly one solution, $\mathbf{x} = A\mathbf{y}$: every pattern can be switched off, in exactly one way.

(c) For light 1 alone, $\mathbf{y} = \mathbf{e}_1$ and $\mathbf{x} = A\mathbf{e}_1 = (1,1,1,0)$: press lights 1, 2, and 3. Light 1 is toggled three times and each other light twice. By symmetry, to switch off a single lit corner, press it and its two neighbors.

Solution to Exercise 3.1.41

Uses. Technique 3.1.9 (Undetermined coefficients), Corollary 3.1.16 (Homogeneous solution sets are subspaces), Proposition 1.4.14 (The span is the smallest subspace containing a list), Proposition 3.1.19 (Solution sets are translates of the kernel)
Techniques. Undetermined coefficients (Technique 3.1.9), Double containment (Technique 1.3.14)
Hint 1. For (a), look for an equation $a_1x_1 + a_2x_2 + a_3x_3 = 0$ satisfied by both spanning vectors. That is a linear system in a_1, a_2, a_3.
Hint 2. Having found a candidate, prove that its solution set equals the span by double containment.
Hint 3. For (b), the line is $(1,0,2) + \operatorname{span}((1,1,-1))$. Find two equations whose left sides vanish at $(1,1,-1)$, and choose the right sides so that $(1,0,2)$ is a solution.
Sketch. (a) $a_1 + 2a_2 = 0$ and $a_2 + a_3 = 0$ give $(2,-1,1)$; the solutions of $2x_1 - x_2 + x_3 = 0$ are $x_1(1,2,0) + x_3(0,1,1)$. (b) $x_1 - x_2 = 1$, $x_2 + x_3 = 2$; its solutions are $(1,0,2) + s(1,1,-1)$.

(a) An equation $a_1x_1 + a_2x_2 + a_3x_3 = 0$ is satisfied by $(1,2,0)$ and $(0,1,1)$ exactly when $a_1 + 2a_2 = 0$ and $a_2 + a_3 = 0$. One solution of this system is $(a_1,a_2,a_3) = (2,-1,1)$. We claim that the solution set S of

$$2x_1 - x_2 + x_3 = 0$$

is $U = \operatorname{span}((1,2,0),(0,1,1))$.

$U \subseteq S$: both spanning vectors are solutions, since $2 - 2 + 0 = 0$ and $0 - 1 + 1 = 0$, and S is a subspace (Corollary 3.1.16), so S contains their span (Proposition 1.4.14).

$S \subseteq U$: if $2x_1 - x_2 + x_3 = 0$, then $x_2 = 2x_1 + x_3$, so

$$(x_1,x_2,x_3) = (x_1, 2x_1 + x_3, x_3) = x_1(1,2,0) + x_3(0,1,1) \in U.$$

(b) The line is $(1,0,2) + \operatorname{span}((1,1,-1))$, since $(2,1,1) - (1,0,2) = (1,1,-1)$. By Proposition 3.1.19, it suffices to find a system that has $(1,0,2)$ as a solution and whose homogeneous solution set is $\operatorname{span}((1,1,-1))$. The left sides $x_1 - x_2$ and $x_2 + x_3$ both vanish at $(1,1,-1)$, and at $(1,0,2)$ they equal 1 and 2. So consider

$$x_1 - x_2 = 1, \quad x_2 + x_3 = 2.$$

Any solution has $x_2 = x_1 - 1$ and $x_3 = 2 - x_2 = 3 - x_1$, so

$$(x_1,x_2,x_3) = (x_1, x_1 - 1, 3 - x_1) = (1,0,2) + (x_1 - 1)(1,1,-1),$$

a point of the line. Conversely, $(1,0,2) + s(1,1,-1) = (1+s, s, 2-s)$ satisfies $(1+s) - s = 1$ and $s + (2-s) = 2$. So the solution set is exactly the line.

Solution to Exercise 3.1.42

Uses. Corollary 3.1.23 (Lines through solutions)
Hint 1. By Corollary 3.1.23, a solution set that contains $\mathbf{u}$ and $\mathbf{v}$ contains $\mathbf{u} + t(\mathbf{v} - \mathbf{u})$ for every $t \in F$. Find two points of S_F.
Hint 2. In $\mathbb{F}_2$, what is x^2 for each x? In $\mathbb{F}_3$, list S_F by trying all nine points.
Sketch. (a) False: $(0,0),(1,0) \in S_{\mathbb{R}}$, but $(2,0) \notin S_{\mathbb{R}}$. (b) True: $x^2 = x$ for all $x \in \mathbb{F}_2$, so $S_{\mathbb{F}_2} = \mathbb{F}_2^2$, the solution set of $0x_1 + 0x_2 = 0$. (c) False: $S_{\mathbb{F}_3} = \{0,1\}^2$ contains $(0,0)$ and $(1,0)$ but not $(2,0)$.

In all three cases $(0,0)$ and $(1,0)$ lie in S_F, since $0 = 0$ and $1 = 1$. If S_F were the solution set of a linear system, then by Corollary 3.1.23 it would contain $(0,0) + t((1,0) - (0,0)) = (t,0)$ for every $t \in F$.

(a) False. $(2,0) \notin S_{\mathbb{R}}$, since $4 \neq 2$.

(b) True. In $\mathbb{F}_2$, $0^2 = 0$ and $1^2 = 1$, so $x^2 = x$ for every x, and every point of $\mathbb{F}_2^2$ satisfies the equation. So $S_{\mathbb{F}_2} = \mathbb{F}_2^2$, which is the solution set of the linear equation $0x_1 + 0x_2 = 0$.

(c) False. In $\mathbb{F}_3$, $x^2 - x$ equals $0, 0, 2$ for $x = 0, 1, 2$. So $(2,0) \notin S_{\mathbb{F}_3}$, since $\left(2^2 - 2\right) + \left(0^2 - 0\right) = 2 \neq 0$. (In fact $S_{\mathbb{F}_3} = \{(0,0),(0,1),(1,0),(1,1)\}$, as $2 + 2 = 4 = 1 \neq 0$ rules out $(2,2)$.)

Solution to Exercise 3.1.43

Uses. Definition 2.3.15 (The linear map of a matrix), Definition 2.3.8 (Matrix–vector product), Definition 2.4.1 (Matrix product), Definition 2.5.2 (Right inverse), Definition 1.6.8 (Standard bases)
Hint 1. Write $\mathbf{y} = y_1\mathbf{e}_1 + \cdots + y_m\mathbf{e}_m$ and use linearity of T_A.
Hint 2. The jth column of AB is $A\mathbf{b}_j$.
Sketch. $A(y_1\mathbf{b}_1 + \cdots + y_m\mathbf{b}_m) = y_1\mathbf{e}_1 + \cdots + y_m\mathbf{e}_m = \mathbf{y}$. The columns of AB are $A\mathbf{b}_j = \mathbf{e}_j$, so $AB = I_m$, and $T_A \circ T_B = \mathrm{id}$ since $A(B\mathbf{y}) = \mathbf{y}$.

(a) Let $\mathbf{y} = (y_1, \ldots, y_m) = y_1\mathbf{e}_1 + \cdots + y_m\mathbf{e}_m$. Since T_A is linear,

$$A(y_1\mathbf{b}_1 + \cdots + y_m\mathbf{b}_m) = y_1A\mathbf{b}_1 + \cdots + y_mA\mathbf{b}_m = y_1\mathbf{e}_1 + \cdots + y_m\mathbf{e}_m = \mathbf{y}.$$

So $\mathbf{x} = y_1\mathbf{b}_1 + \cdots + y_m\mathbf{b}_m$ is a solution.

(b) The jth column of AB is $A\mathbf{b}_j = \mathbf{e}_j$ (Definition 2.4.1), which is the jth column of I_m. So $AB = I_m$. The solution in (a) is $\mathbf{x} = B\mathbf{y}$, by Definition 2.3.8, so $T_A(T_B(\mathbf{y})) = A(B\mathbf{y}) = \mathbf{y}$ for every $\mathbf{y} \in F^m$. That is, $T_A \circ T_B = \mathrm{id}_{F^m}$, and the linear map T_B is a right inverse of T_A. This is one direction of the equivalence between solvability for every $\mathbf{y}$ and right invertibility in Theorem 2.7.4, with an explicit right inverse: it suffices to solve the m systems $A\mathbf{x} = \mathbf{e}_i$.

Solution to Exercise 3.1.44

Uses. Corollary 3.1.23 (Lines through solutions), Proposition 1.2.35 (Zero products)
Hint 1. Let $\mathbf{u} \neq \mathbf{v}$ be solutions. Corollary 3.1.23 gives a solution for each $t \in F$.
Hint 2. Show that $t \mapsto \mathbf{u} + t(\mathbf{v} - \mathbf{u})$ is injective. Then compare sizes.
Sketch. If $\mathbf{u} \neq \mathbf{v}$ are solutions, $t \mapsto \mathbf{u} + t(\mathbf{v} - \mathbf{u})$ is an injective map from F into the solution set, so the solution set has at least $|F|$ elements. With exactly two solutions this gives $|F| \leq 2$, and $|F| \geq 2$ since $0 \neq 1$.

(b) Let $\mathbf{u} \neq \mathbf{v}$ be solutions, and define $\varphi : F \to S$, where S is the solution set, by $\varphi(t) = \mathbf{u} + t(\mathbf{v} - \mathbf{u})$. This lands in S by Corollary 3.1.23. It is injective: if $\varphi(t) = \varphi(t')$, then $(t - t')(\mathbf{v} - \mathbf{u}) = \mathbf{0}$, and $\mathbf{v} - \mathbf{u} \neq \mathbf{0}$ gives $t = t'$ by Proposition 1.2.35. So $|S| \geq |F|$.

(a) If S has exactly two elements, then F is finite, since $\varphi : F \to S$ is injective, and $|F| \leq |S| = 2$ by the argument in (b). Every field has at least two elements, 0 and 1, so $|F| = 2$.

Solution to Exercise 3.1.45

Uses. Notation 3.1.17 (Translates), Definition 1.4.1 (Subspace), Proposition 3.1.19 (Solution sets are translates of the kernel)
Techniques. Double containment (Technique 1.3.14)
Hint 1. Since $\mathbf{0} \in U'$, the vector $\mathbf{v}'$ lies in $\mathbf{v} + U$. What does that say about $\mathbf{v}' - \mathbf{v}$?
Hint 2. Take $\mathbf{u}' \in U'$. Then $\mathbf{v}' + \mathbf{u}' \in \mathbf{v} + U$; subtract $\mathbf{v}$ and use that U is closed under subtraction. Then swap the roles of the two translates.
Sketch. $\mathbf{v}' = \mathbf{v}' + \mathbf{0} \in \mathbf{v} + U$, so $\mathbf{w} = \mathbf{v}' - \mathbf{v} \in U$. For $\mathbf{u}' \in U'$, $\mathbf{v}' + \mathbf{u}' = \mathbf{v} + \mathbf{u}$ with $\mathbf{u} \in U$, so $\mathbf{u}' = \mathbf{u} - \mathbf{w} \in U$. By symmetry $U \subseteq U'$. For (b), write the common solution set as $\mathbf{x}_0 + \ker T_A = \mathbf{x}_0 + \ker T_B$.

(a) Since $\mathbf{0} \in U'$, we have $\mathbf{v}' = \mathbf{v}' + \mathbf{0} \in \mathbf{v}' + U' = \mathbf{v} + U$, so $\mathbf{v}' = \mathbf{v} + \mathbf{w}$ for some $\mathbf{w} \in U$; that is, $\mathbf{v}' - \mathbf{v} = \mathbf{w} \in U$. By the symmetric argument, $\mathbf{v} - \mathbf{v}' \in U'$.

$U' \subseteq U$: let $\mathbf{u}' \in U'$. Then $\mathbf{v}' + \mathbf{u}' \in \mathbf{v}' + U' = \mathbf{v} + U$, so $\mathbf{v}' + \mathbf{u}' = \mathbf{v} + \mathbf{u}$ for some $\mathbf{u} \in U$. Hence $\mathbf{u}' = \mathbf{u} - (\mathbf{v}' - \mathbf{v}) = \mathbf{u} - \mathbf{w}$, which lies in U because U is a subspace.

$U \subseteq U'$: the same argument with the roles of $(\mathbf{v}, U)$ and $(\mathbf{v}', U')$ exchanged, using $\mathbf{v} - \mathbf{v}' \in U'$.

(b) Let S be the common solution set and $\mathbf{x}_0 \in S$. By Proposition 3.1.19, $\mathbf{x}_0 + \ker T_A = S = \mathbf{x}_0 + \ker T_B$, and $\ker T_A$, $\ker T_B$ are subspaces of F^n. By (a), $\ker T_A = \ker T_B$.

(c) Take $A = I_2$, $\mathbf{y} = (1,1)$, and $B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, $\mathbf{z} = (1,2)$. The first system says $x_1 = 1$, $x_2 = 1$. The second says $x_1 = 1$ and $x_1 + x_2 = 2$, which also forces $(x_1, x_2) = (1,1)$, and $(1,1)$ satisfies it. Both solution sets are $\{(1,1)\}$, and both kernels are $\{\mathbf{0}\}$.

Solution to Exercise 3.1.46

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Proposition 3.1.8 (Systems and the map T_A)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. $(1, 1, \ldots, 1)$ is a particular solution. Find the homogeneous solutions.
Hint 2. In the homogeneous system, $x_{i+1} = -x_i$ for each i, so $x_{k+1} = (-1)^k x_1$. Go once around the cycle: what does $x_n + x_1 = 0$ say?
Sketch. The homogeneous solutions have $x_{k+1} = (-1)^k x_1$, and the last equation gives $\big((-1)^{n-1} + 1\big)x_1 = 0$. For n odd this forces $x_1 = 0$, so $(1, \ldots, 1)$ is the unique solution; for n even the kernel is spanned by $(1, -1, 1, \ldots, -1)$. Over $\mathbb{F}_2$, $2 = 0$ and the equations say $x_1 = x_2 = \cdots = x_n$: two solutions.

Over $\mathbb{R}$, $(1, 1, \ldots, 1)$ is a solution. By Proposition 3.1.19, we need the solutions of the homogeneous system $x_i + x_{i+1} = 0$ $(1 \le i \le n-1)$, $x_n + x_1 = 0$. In such a solution, $x_{i+1} = -x_i$ for $i \le n-1$, so by induction $x_{k+1} = (-1)^k x_1$ for $0 \le k \le n-1$. The last equation then reads $(-1)^{n-1} x_1 + x_1 = 0$. Conversely, a vector with $x_{k+1} = (-1)^k x_1$ satisfies the first $n-1$ equations, and it satisfies the last one exactly when $\big((-1)^{n-1} + 1\big)x_1 = 0$.

If n is odd, this says $2x_1 = 0$, so $x_1 = 0$ and the kernel is $\{\mathbf{0}\}$. The unique solution is $(1, 1, \ldots, 1)$.

If n is even, it says $0 = 0$, so the kernel is spanned by $(1, -1, 1, -1, \ldots, 1, -1)$, and the solutions are

$$(1 + t, 1 - t, 1 + t, 1 - t, \ldots, 1 + t, 1 - t), \quad t \in \mathbb{R}.$$

Over $\mathbb{F}_2$, the right-hand sides are $2 = 0$ and $-x_i = x_i$, so the system says $x_{i+1} = x_i$ for all i (and $x_1 = x_n$). The solutions are $(0, \ldots, 0)$ and $(1, \ldots, 1)$, for every n. Over $\mathbb{R}$ the parity of n mattered only through $2x_1 = 0 \Rightarrow x_1 = 0$, which is exactly the step that fails in characteristic 2.

Solution to Exercise 3.1.47

Uses. Corollary 3.1.22 (Uniqueness depends only on A), Proposition 3.1.8 (Systems and the map T_A)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. By Corollary 3.1.22, it suffices to show that the homogeneous system, with all $b_q = 0$, has only the trivial solution.
Hint 2. In a homogeneous solution, let M be the largest u_p, and suppose $M > 0$. At a point where $u_p = M$, the average of four numbers that are all at most M equals M. What does that force?
Hint 3. Walk from a maximizing point to the right until you leave G. The first point outside G is a boundary point.
Sketch. Take a homogeneous solution, extended by $u_q = 0$ on ∂G, so each u_p is the average of its four neighbors. If $M = \max u_p > 0$ is attained at p, all four neighbors of p equal M. Walking right from p, every point of G along the way has value M, and the first point outside G is a boundary point adjacent to a point with value M, so its value 0 equals M, a contradiction. So $\max \le 0$; applying this to $-u$ gives $\min \ge 0$. Hence $u = \mathbf{0}$, and Corollary 3.1.22 finishes.

By Corollary 3.1.22, it suffices to show that the homogeneous system, the one with every $b_q = 0$, has only the trivial solution. Let $\big(u_p\big)_{p \in G}$ be a solution of the homogeneous system, and set $u_q = 0$ for $q \in \partial G$. Every neighbor of a point of G lies in G or in ∂G, so the equations say

$$u_p = \frac{1}{4} \sum_{q \sim p} u_q \quad \text{for every } p \in G,$$

the sum running over all four neighbors of p.

Suppose, for contradiction, that $M = \max_{p \in G} u_p > 0$ (the maximum exists because G is finite and, being the index set of the unknowns, nonempty). Then every u_q with $q \in G \cup \partial G$ is at most M. We first show: *if $p \in G$ and $u_p = M$, then all four neighbors of p have value M.* Indeed, $4M = 4u_p = \sum_{q \sim p} u_q$ is a sum of four numbers each at most M, so if one of them were less than M, the sum would be less than $4M$.

Pick $p_0 \in G$ with $u_{p_0} = M$, and consider the points $p_k = p_0 + (k, 0)$ for $k = 0, 1, 2, \ldots$. Since G is finite, some p_k lies outside G; let k be the smallest such index, so $k \geq 1$ and $p_0, \ldots, p_{k-1} \in G$. By the claim and induction, $u_{p_0} = u_{p_1} = \cdots = u_{p_{k-1}} = M$, and then $u_{p_k} = M$ too, since p_k is a neighbor of p_{k-1}. But $p_k \notin G$ is adjacent to $p_{k-1} \in G$, so $p_k \in \partial G$ and $u_{p_k} = 0 < M$. This contradiction shows $u_p \leq 0$ for all $p \in G$.

The vector $\left(-u_p\right)_{p \in G}$ also solves the homogeneous system, so the same argument gives $-u_p \leq 0$ for all p. Hence $u_p = 0$ for all $p \in G$: the homogeneous system has only the trivial solution, and the original system has at most one solution.

The system has as many equations as unknowns. For such square systems, Section 3.5 shows that "at most one solution for every right-hand side" implies "exactly one", so the equilibrium temperatures always exist and are unique.

Solution to Exercise 3.1.48

Uses. Definition 1.4.1 (Subspace), Theorem 1.4.3 (Subspace criterion), Notation 3.1.17 (Translates), Definition 1.1.28 (Characteristic)
Hint 1. Fix $\mathbf{v} \in S$ and let $U = \{\mathbf{s} - \mathbf{v} \mid \mathbf{s} \in S\}$, so $S = \mathbf{v} + U$. Check the subspace conditions for U.
Hint 2. Scalar multiples: $\mathbf{v} + t(\mathbf{s} - \mathbf{v}) \in S$. Sums are harder: first show that the midpoint $\frac{1}{2}\mathbf{s} + \frac{1}{2}\mathbf{s}'$ of two points of S lies in S; this step needs $2 \neq 0$.
Hint 3. For (b), over $\mathbb{F}_2$ the only values of t are 0 and 1. For the second part, a translate of a subspace by $\mathbf{v}$ contains $\mathbf{v}$; subtract it and count.
Sketch. With $U = S - \mathbf{v}$: $\mathbf{0} \in U$; $t(\mathbf{s} - \mathbf{v}) = (\mathbf{v} + t(\mathbf{s} - \mathbf{v})) - \mathbf{v} \in U$; the midpoint $\mathbf{m} = \mathbf{s} + \frac{1}{2}(\mathbf{s}' - \mathbf{s}) \in S$, and $(\mathbf{s} - \mathbf{v}) + (\mathbf{s}' - \mathbf{v}) = 2(\mathbf{m} - \mathbf{v}) \in U$. In (b), the line through two points of $\mathbb{F}_2^2$ is just those two points; a translate $\mathbf{v} + U$ with three elements would make U a subspace of $\mathbb{F}_2^2$ with three elements, but $\mathbf{u}, \mathbf{u}' \in U$ distinct and nonzero force a fourth element $\mathbf{u} + \mathbf{u}'$.

(a) Fix $\mathbf{v} \in S$ and put $U = \{\mathbf{s} - \mathbf{v} \mid \mathbf{s} \in S\}$, so that $S = \mathbf{v} + U$. We check that U is a subspace.

$\mathbf{0} \in U$, as $\mathbf{0} = \mathbf{v} - \mathbf{v}$.

Scalar multiples. Let $\mathbf{s} \in S$ and $t \in F$. By line-closedness with $\mathbf{u} = \mathbf{v}$, the point $\mathbf{v} + t(\mathbf{s} - \mathbf{v})$ lies in S, so $t(\mathbf{s} - \mathbf{v}) \in U$.

Sums. Let $\mathbf{s}, \mathbf{s}' \in S$. Since $2 = 1 + 1 \neq 0$, the scalar $\frac{1}{2}$ exists, and $\mathbf{m} = \mathbf{s} + \frac{1}{2}(\mathbf{s}' - \mathbf{s})$ lies in S. Then $\mathbf{m} - \mathbf{v} \in U$, and by the previous step $2(\mathbf{m} - \mathbf{v}) \in U$. But

$$2(\mathbf{m} - \mathbf{v}) = 2\mathbf{s} + (\mathbf{s}' - \mathbf{s}) - 2\mathbf{v} = (\mathbf{s} - \mathbf{v}) + (\mathbf{s}' - \mathbf{v}).$$

So U is closed under addition, and U is a subspace by Theorem 1.4.3. Hence $S = \mathbf{v} + U$ is a translate of a subspace.

(b) Over $\mathbb{F}_2$, t is 0 or 1, and $\mathbf{u} + t(\mathbf{v} - \mathbf{u})$ is then $\mathbf{u}$ or $\mathbf{v}$. So every subset of $\mathbb{F}_2^n$ is line-closed, in particular $S = \{(0, 0), (1, 0), (0, 1)\}$.

Suppose $S = \mathbf{v} + U$ for a subspace U. Then $U = \{\mathbf{s} - \mathbf{v} \mid \mathbf{s} \in S\}$ has exactly three elements, since $\mathbf{s} \mapsto \mathbf{s} - \mathbf{v}$ is injective. One of them is $\mathbf{0}$; call the other two $\mathbf{u} \neq \mathbf{u}'$, both nonzero. Since U is a subspace, $\mathbf{u} + \mathbf{u}' \in U$. But $\mathbf{u} + \mathbf{u}' \neq \mathbf{0}$, since otherwise $\mathbf{u}' = -\mathbf{u} = \mathbf{u}$ in characteristic 2; and $\mathbf{u} + \mathbf{u}' \neq \mathbf{u}$ and $\neq \mathbf{u}'$, since $\mathbf{u}'$ and $\mathbf{u}$ are nonzero. So U has a fourth element, a contradiction.

Part (b) shows that line-closedness is too weak a condition in characteristic 2. The right notion uses combinations of more than two points; see Section 4.7.

Solution to Exercise 3.1.49

Uses. Corollary 3.1.16 (Homogeneous solution sets are subspaces), Proposition 3.1.5 (Three faces of a linear system)
Hint 1. Fix the masses $\mathbf{w} = (w_1, \ldots, w_{13})$ and, for each i, one valid split. Encode the splits as a 13×13 matrix A with $A\mathbf{w} = \mathbf{0}$. What else lies in $\ker T_A$?
Hint 2. $(1, 1, \ldots, 1) \in \ker T_A$, and $\ker T_A$ is a subspace. Show that all entries of an integer vector in $\ker T_A$ have the same parity.

Hint 3. Subtract the smallest mass from all masses, then keep dividing by 2. Why must this stop, and what does that force?
Sketch. Row i of A has 0 in position i, $+1$ on one group and -1 on the other, so $A\mathbf{w} = \mathbf{0}$ and $A\mathbf{1} = \mathbf{0}$. For an integer $\mathbf{v} \in \ker T_A$, row i gives $\sum_{j\neq i} v_j \equiv 0 \bmod 2$, so every v_i has the parity of $\sum_j v_j$. Among nonzero integer vectors in $\ker T_A$ with nonnegative entries and a zero entry, take one with the smallest maximum entry; its entries are all even, and halving it gives a smaller one. So $\mathbf{w} - (\min_j w_j)\mathbf{1} = \mathbf{0}$.

Let $\mathbf{w} = (w_1, \ldots, w_{13}) \in \mathbb{Z}^{13}$ be the masses. For each i, fix a split of the other twelve weights into two groups of six with equal total mass, and let $A \in \mathbb{Q}^{13\times 13}$ have (i, j) entry 0 if $j = i$, $+1$ if weight j is in the first group of the split for i, and -1 if it is in the second. Then row i of $A\mathbf{w} = \mathbf{0}$ says that the two groups balance, so $\mathbf{w} \in \ker T_A$. Each row of A has six entries $+1$ and six entries -1, so $\mathbf{1} = (1, \ldots, 1) \in \ker T_A$ as well. By Corollary 3.1.16, $\ker T_A$ is a subspace of $\mathbb{Q}^{13}$.

Parity. Let $\mathbf{v} \in \ker T_A$ have integer entries, and let $N = v_1 + \cdots + v_{13}$. Row i says $\sum_{j\neq i} \pm v_j = 0$. Since $-v_j \equiv v_j$ modulo 2, this gives $\sum_{j\neq i} v_j \equiv 0$, that is, $N - v_i \equiv 0 \bmod 2$. So every v_i has the same parity as N, and all entries of $\mathbf{v}$ have the same parity.

Descent. Let K be the set of nonzero vectors $\mathbf{v} \in \ker T_A$ with integer entries, all entries ≥ 0, and at least one entry equal to 0. Suppose K is nonempty, and choose $\mathbf{v} \in K$ whose largest entry is as small as possible. Since $\mathbf{v}$ has a zero entry, all its entries are even by the parity step, so $\frac{1}{2}\mathbf{v}$ has integer entries. It lies in $\ker T_A$ (a subspace), is nonzero, has nonnegative entries and a zero entry, so $\frac{1}{2}\mathbf{v} \in K$. But its largest entry is half that of $\mathbf{v}$, which is positive, so it is smaller. This contradicts the choice of $\mathbf{v}$, so K is empty.

Conclusion. Let $c = \min_j w_j$ and $\mathbf{v} = \mathbf{w} - c\mathbf{1}$. Then $\mathbf{v} \in \ker T_A$, its entries are nonnegative integers, and at least one is 0. As K is empty, $\mathbf{v} = \mathbf{0}$, so $w_1 = \cdots = w_{13} = c$.

The same holds for rational masses (multiply by a common denominator) and in fact for real masses, but the real case needs more: one shows that the kernel of T_A over $\mathbb{R}$ is spanned by vectors with rational entries, which follows from Gauss–Jordan elimination never leaving the field of the entries (Section 3.4).

Section 3.2

Solution to Exercise 3.2.9

Uses. Proposition 3.2.7 (Row operations are left multiplications), Definition 3.2.2 (Elementary matrices)
Hint 1. Which rows of A changed, and how is each new row built from the old rows?
Hint 2. Row 3 of EA is $(5, 6) - 2(1, 2)$. Once you know the operation, perform it on I_3.
Sketch. EA is A with -2 times row 1 added to row 3, so $E = E_{1,-2,3}$. $E'A$ is A with rows 1 and 3 swapped, so $E' = E_{13}$.

Only row 3 changed in EA, and $(3, 2) = (5, 6) - 2(1, 2)$. So EA is A with -2 times row 1 added to row 3, and by Proposition 3.2.7 we can take $E = E_{1,-2,3}$. In $E'A$ rows 1 and 3 are swapped, so $E' = E_{13}$. Performing these operations on I_3,

$$E = E_{1,-2,3} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -2 & 0 & 1 \end{pmatrix}, \quad E' = E_{13} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

Solution to Exercise 3.2.13

Uses. Corollary 3.2.11 (Products of elementary matrices), Proposition 3.2.10 (Inverses of elementary matrices)
Hint 1. Invert each factor and reverse the order.
Hint 2. In $\mathbb{F}_5$, $3^{-1} = 2$ and $-4 = 1$.
Sketch. The inverse is $E_{2,-4,1}E_{1,3^{-1}}E_{12} = E_{2,1,1}E_{1,2}E_{12} = \left(\begin{smallmatrix} 1 & 2 \\ 1 & 0 \end{smallmatrix}\right)$.

By Corollary 3.2.11 and Proposition 3.2.10,

$$\left(E_{12}E_{1,3}E_{2,4,1}\right)^{-1} = E_{2,4,1}^{-1}E_{1,3}^{-1}E_{12}^{-1} = E_{2,-4,1}E_{1,3^{-1}}E_{12} = E_{2,1,1}E_{1,2}E_{12},$$

since $-4 = 1$ and $3 \cdot 2 = 6 = 1$ in $\mathbb{F}_5$. Performing the operations of the factors on I_2 from right to left: swapping the rows gives $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, scaling row 1 by 2 gives $\begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$, and adding row 2 to row 1 gives $\begin{pmatrix} 1 & 2 \\ 1 & 0 \end{pmatrix}$. As a check, $E_{12}E_{1,3}E_{2,4,1} = \begin{pmatrix} 0 & 1 \\ 3 & 2 \end{pmatrix}$, and

$$\begin{pmatrix} 0 & 1 \\ 3 & 2 \end{pmatrix}\begin{pmatrix} 1 & 2 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 5 & 6 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad \text{in } \mathbb{F}_5.$$

Solution to Exercise 3.2.20

Uses. Corollary 3.2.17 (Row operations preserve relations among columns), Proposition 3.2.7 (Row operations are left multiplications), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. Clear the first column below the top entry, then work on the second column.
Hint 2. In B, the third column is $\mathbf{e}_1 + 2\mathbf{e}_2$ and the first two columns are $\mathbf{e}_1, \mathbf{e}_2$.
Sketch. Add -2 times row 1 to row 2 and -1 times row 1 to row 3, add row 2 to row 3, scale row 2 by $-1/2$, and add -1 times row 2 to row 1. Since $\mathbf{b}_3 = \mathbf{b}_1 + 2\mathbf{b}_2$ and $\mathbf{b}_1, \mathbf{b}_2$ is independent, $\mathbf{a}_3 = \mathbf{a}_1 + 2\mathbf{a}_2$ and $\mathbf{a}_1, \mathbf{a}_2$ is independent.

Adding -2 times row 1 to row 2 and -1 times row 1 to row 3 gives rows $(1, 1, 3)$, $(0, -2, -4)$, $(0, 2, 4)$. Adding row 2 to row 3 makes row 3 zero. Scaling row 2 by $-1/2$ gives $(0, 1, 2)$, and adding -1 times this row to row 1 gives $(1, 0, 1)$. The result is B. So $B = GA$, where G is the product of the five elementary matrices, which is invertible by Corollary 3.2.11.

The columns of B are $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathbf{e}_1 + 2\mathbf{e}_2$. By Corollary 3.2.17(b), the third column of A is 1 times the first plus 2 times the second; and by Corollary 3.2.17(a), the first two columns of A are linearly independent, since $\mathbf{e}_1, \mathbf{e}_2$ is. Directly: $(1, 2, 1) + 2(1, 0, 3) = (3, 2, 7)$, and if $s(1, 2, 1) + t(1, 0, 3) = \mathbf{0}$, then the second entry gives $s = 0$ and then the first gives $t = 0$.

Solution to Exercise 3.2.26

Uses. Definition 3.2.21 (Row equivalence), Corollary 3.2.23 (Row equivalent matrices have the same kernel), Proposition 3.2.22 (Row equivalence is an equivalence relation)
Hint 1. Try to reach each matrix from A by row operations. When that seems impossible, compare kernels.
Hint 2. $\ker T_A = \operatorname{span}((2, -1))$. What is the kernel of (ii)?
Sketch. (i) Add -2 times row 1 to row 2. (iii) From (i), swap the rows and scale row 2 by 3. (ii) is not: its kernel is $\operatorname{span}((1, -2))$, while $\ker T_A = \operatorname{span}((2, -1))$.

(i) Yes: adding -2 times row 1 to row 2 of A gives $\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$.

(iii) Yes: from $\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$, swapping the rows gives $\begin{pmatrix} 0 & 0 \\ 1 & 2 \end{pmatrix}$, and scaling row 2 by 3 gives $\begin{pmatrix} 0 & 0 \\ 3 & 6 \end{pmatrix}$. By transitivity (Proposition 3.2.22), (iii) is row equivalent to A.

(ii) No. $A(x_1, x_2) = (x_1 + 2x_2, 2(x_1 + 2x_2))$, so $\ker T_A = \{\mathbf{x} \mid x_1 + 2x_2 = 0\} = \operatorname{span}((2, -1))$. For the matrix in (ii), $\mathbf{x} \mapsto (2x_1 + x_2, 2(2x_1 + x_2))$, so its kernel is $\operatorname{span}((1, -2))$. These are different, since $(2, -1)$ is not a multiple of $(1, -2)$, so the matrices are not row equivalent by Corollary 3.2.23.

Solution to Exercise 3.2.32

Uses. Proposition 3.2.28 (Column operations are right multiplications), Proposition 3.2.7 (Row operations are left multiplications)
Hint 1. Which column changed, and by a multiple of which other column?
Hint 2. Adding c times column j to column i is right multiplication by E_{icj}.
Sketch. Column 2 became $(2, 5) - 2(1, 4)$, so $E = E_{2,-2,1} = \begin{pmatrix} 1 & -2 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$. On the left, $E_{2,-2,1}B$ is B with -2 times row 2 added to row 1.

Only column 2 changed, and $(0, -3) = (2, 5) - 2(1, 4)$. So AE is A with -2 times column 1 added to column 2, which by Proposition 3.2.28(c) (with $i = 2$, $j = 1$) is $AE_{2,-2,1}$, where

$$E_{2,-2,1} = \begin{pmatrix} 1 & -2 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

By Proposition 3.2.7, $E_{2,-2,1}B$ is B with -2 times row 2 added to row 1: the indices play the opposite roles.

Solution to Exercise 3.2.36

Uses. Definition 3.2.2 (Elementary matrices), Proposition 3.2.10 (Inverses of elementary matrices)
Hint 1. Compare each matrix with the identity. In how many entries can an elementary matrix differ from I_m, and what do those entries look like?
Hint 2. A scaling differs from I_m in one diagonal entry, which is nonzero; a replacement in one off-diagonal entry; a swap in exactly four entries, which form the pattern $\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$ in rows and columns i, j.
Sketch. Elementary: (a) I_2; (b) $E_{1,-3,2}$, inverse $E_{1,3,2}$; (c) E_{12}, its own inverse; (f) $E_{3,4,1}$, inverse $E_{3,-4,1}$; (h) $E_{1,2}$, its own inverse since $2 \cdot 2 = 1$ in $\mathbb{F}_3$; (i) E_{23}, its own inverse. Not elementary: (d), (e), (g).

From Definition 3.2.2: E_{ic} differs from I_m only in entry (i,i), where it has $c \neq 0$; E_{icj} differs only in entry (j,i), where it has c; and E_{ij} differs in exactly the entries $(i,i),(j,j),(i,j),(j,i)$, which are $0,0,1,1$. So a matrix is elementary exactly when it equals I_m, or differs from I_m in a single entry that is either off the diagonal or a nonzero diagonal entry, or differs from I_m in exactly four entries forming a swap pattern. Inverses come from Proposition 3.2.10.

(a) Elementary: $I_2 = E_{1,1}$ (scaling row 1 by 1, or adding 0 times row 1 to row 2). Its inverse is I_2.

(b) Elementary: the single extra entry -3 is in position $(2,1)$, so this is $E_{1,-3,2}$, which adds -3 times row 1 to row 2. Its inverse is $E_{1,3,2} = \left(\begin{smallmatrix}1&0\\3&1\end{smallmatrix}\right)$.

(c) Elementary: E_{12} swaps the two rows, and it is its own inverse.

(d) Not elementary. It differs from I_2 in all four entries, but it has the entry 2, which a swap does not. (It is $E_{1,2}E_{12}$; see Non-example 3.2.5.)

(e) Not elementary. It differs from I_3 only in the diagonal entry $(3,3)$, which is 0, and scaling by 0 is not allowed. (This matrix is not invertible: it sends $\mathbf{e}_3$ to $\mathbf{0}$.)

(f) Elementary: the extra entry 4 is in position $(1,3)$, that is, row $j = 1$ and column $i = 3$. So this is $E_{3,4,1}$, which adds 4 times row 3 to row 1. Its inverse is $E_{3,-4,1}$.

(g) Not elementary: it differs from I_2 in exactly two entries.

(h) Elementary: $E_{1,2}$ scales row 1 by 2. In $\mathbb{F}_3$, $2 \cdot 2 = 4 = 1$, so $2^{-1} = 2$ and $E_{1,2}$ is its own inverse.

(i) Elementary: E_{23} swaps rows 2 and 3, and it is its own inverse.

Solution to Exercise 3.2.37

Uses. Proposition 3.2.7 (Row operations are left multiplications), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. Make the $(1,1)$ entry 1, clear the entry below it, make the $(2,2)$ entry 1, and clear the entry above it.
Hint 2. In $\mathbb{F}_5$, $2^{-1} = 3$ and $4^{-1} = 4$. To compute G, perform the same operations on I_2.
Sketch. (a) Scale row 1 by 3, add -1 times row 1 to row 2, scale row 2 by 4, add -2 times row 2 to row 1; $G = \left(\begin{smallmatrix}2&2\\3&4\end{smallmatrix}\right)$. (b) Add $-i$ times row 1 to row 2, scale row 2 by $1/3$, add $-i$ times row 2 to row 1; $G = \frac{1}{3}\left(\begin{smallmatrix}2&-i\\-i&1\end{smallmatrix}\right)$.

(a) In $\mathbb{F}_5$: scaling row 1 by $2^{-1} = 3$ gives $\left(\begin{smallmatrix}1&12\\1&1\end{smallmatrix}\right) = \left(\begin{smallmatrix}1&2\\1&1\end{smallmatrix}\right)$. Adding -1 times row 1 to row 2 gives $\left(\begin{smallmatrix}1&2\\0&-1\end{smallmatrix}\right) = \left(\begin{smallmatrix}1&2\\0&4\end{smallmatrix}\right)$. Scaling row 2 by $4^{-1} = 4$ gives $\left(\begin{smallmatrix}1&2\\0&1\end{smallmatrix}\right)$, and adding -2 times row 2 to row 1 gives I_2. So

$$G = E_{2,-2,1}E_{2,4}E_{1,-1,2}E_{1,3}.$$

Performing the same four operations on I_2: $\left(\begin{smallmatrix}3&0\\0&1\end{smallmatrix}\right)$, then $\left(\begin{smallmatrix}3&0\\-3&1\end{smallmatrix}\right) = \left(\begin{smallmatrix}3&0\\2&1\end{smallmatrix}\right)$, then $\left(\begin{smallmatrix}3&0\\8&4\end{smallmatrix}\right) = \left(\begin{smallmatrix}3&0\\3&4\end{smallmatrix}\right)$, then $\left(\begin{smallmatrix}3-6&-8\\3&4\end{smallmatrix}\right) = \left(\begin{smallmatrix}2&2\\3&4\end{smallmatrix}\right)$. So $G = \left(\begin{smallmatrix}2&2\\3&4\end{smallmatrix}\right)$. Check:

$$AG = \begin{pmatrix}2&4\\1&1\end{pmatrix}\begin{pmatrix}2&2\\3&4\end{pmatrix} = \begin{pmatrix}16&20\\5&6\end{pmatrix} = \begin{pmatrix}1&0\\0&1\end{pmatrix} \quad \text{in } \mathbb{F}_5.$$

(b) Adding $-i$ times row 1 to row 2 gives $\begin{pmatrix}1 & i\\ 0 & 2-i^2\end{pmatrix} = \begin{pmatrix}1 & i\\ 0 & 3\end{pmatrix}$. Scaling row 2 by $1/3$ gives $\begin{pmatrix}1 & i\\ 0 & 1\end{pmatrix}$, and adding $-i$ times row 2 to row 1 gives I_2. So $G = E_{2,-i,1}E_{2,1/3}E_{1,-i,2}$. Performing these operations on I_2: $\begin{pmatrix}1 & 0\\ -i & 1\end{pmatrix}$, then $\begin{pmatrix}1 & 0\\ -i/3 & 1/3\end{pmatrix}$, then

$$G = \begin{pmatrix}1-i(-i/3) & -i/3\\ -i/3 & 1/3\end{pmatrix} = \frac{1}{3}\begin{pmatrix}2 & -i\\ -i & 1\end{pmatrix},$$

using $1 + i^2/3 = 2/3$. Check:

$$AG = \frac{1}{3}\begin{pmatrix}1 & i\\ i & 2\end{pmatrix}\begin{pmatrix}2 & -i\\ -i & 1\end{pmatrix} = \frac{1}{3}\begin{pmatrix}2-i^2 & -i+i\\ 2i-2i & -i^2+2\end{pmatrix} = \frac{1}{3}\begin{pmatrix}3 & 0\\ 0 & 3\end{pmatrix} = I_2.$$

In both cases $GA = I_2 = AG$, so $G = A^{-1}$. Computing inverses this way is the subject of Algorithm 3.3.24.

Solution to Exercise 3.2.38

Uses. Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.28 (Column operations are right multiplications)
Hint 1. On the left, $E_{1,2,3}$ adds 2 times row 1 to row 3. On the right, it adds 2 times column 3 to column 1.
Hint 2. For the last part, read the subscript right to left: adding c times column j to column i is right multiplication by E_{icj}.
Sketch. $E_{1,2,3}A = \begin{pmatrix}1 & 2 & 3\\ 4 & 5 & 6\\ 9 & 12 & 15\end{pmatrix}$ and $AE_{1,2,3} = \begin{pmatrix}7 & 2 & 3\\ 16 & 5 & 6\\ 25 & 8 & 9\end{pmatrix}$. The last part needs $E = E_{3,2,1}$.

By Proposition 3.2.7, $E_{1,2,3}A$ is A with 2 times row 1 added to row 3:

$$E_{1,2,3}A = \begin{pmatrix}1 & 2 & 3\\ 4 & 5 & 6\\ 7+2 & 8+4 & 9+6\end{pmatrix} = \begin{pmatrix}1 & 2 & 3\\ 4 & 5 & 6\\ 9 & 12 & 15\end{pmatrix}.$$

By Proposition 3.2.28(c) with $i = 1$, $j = 3$, $AE_{1,2,3}$ is A with 2 times column 3 added to column 1:

$$AE_{1,2,3} = \begin{pmatrix}1+6 & 2 & 3\\ 4+12 & 5 & 6\\ 7+18 & 8 & 9\end{pmatrix} = \begin{pmatrix}7 & 2 & 3\\ 16 & 5 & 6\\ 25 & 8 & 9\end{pmatrix}.$$

Adding 2 times column 1 to column 3 is Proposition 3.2.28(c) with $i = 3$, $j = 1$, so $E = E_{3,2,1}$. Indeed $AE_{3,2,1} = \begin{pmatrix}1 & 2 & 5\\ 4 & 5 & 14\\ 7 & 8 & 23\end{pmatrix}$.

Solution to Exercise 3.2.39

Uses. Proposition 3.2.7 (Row operations are left multiplications), Definition 3.2.2 (Elementary matrices), induction on k
Hint 1. By Proposition 3.2.7, $E_{icj}E_{idj}$ is E_{idj} with c times row i added to row j. What are rows i and j of E_{idj}?
Hint 2. For (b), induct on k. In $\mathbb{F}_p$, $pc = 0$.
Sketch. Row i of E_{idj} is row i of I_m, and row j has d in column i; adding c times row i to row j turns d into $c + d$. Row i of E_{id} is d times row i of I_m, and scaling it by c gives cd. Then induction gives $E_{icj}^k = E_{i(kc)j}$, and $E_{i(pc)j} = E_{i,0,j} = I_m$ in $\mathbb{F}_p$.

(a) By Proposition 3.2.7, $E_{icj}E_{idj}$ is E_{idj} with c times row i added to row j. As $i \neq j$, row i of E_{idj} is row i of I_m, with a 1 in column i, and row j has 1 in column j and d in column i. After the operation, row j has 1 in column j and $d + c$ in column i, and the other rows are unchanged. That is the matrix $E_{i(c+d)j}$.

Similarly, $E_{ic}E_{id}$ is E_{id} with row i scaled by c. Row i of E_{id} has d in column i and zeros elsewhere, so the result has cd there, and it is $E_{i(cd)}$ (note $cd \neq 0$).

(b) For $k = 1$ the claim is clear. If $E_{icj}^k = E_{i(kc)j}$, then by (a),

$$E_{icj}^{k+1} = E_{icj}E_{icj}^k = E_{icj}E_{i(kc)j} = E_{i(c+kc)j} = E_{i((k+1)c)j}.$$

In $\mathbb{F}_p$ we have $pc = 0$, so $E_{icj}^p = E_{i,0,j} = I_m$. For example, over $\mathbb{F}_2$ every type 3 elementary matrix is its own inverse.

Solution to Exercise 3.2.40

Uses. Proposition 3.2.7 (Row operations are left multiplications), Definition 3.2.2 (Elementary matrices)
Hint 1. Compute each product by performing the operations on I_3, the right factor first.
Hint 2. In $E_{2d3}E_{1c2}$, row 2 is changed first, and the changed row 2 is then added to row 3.
Hint 3. For (c), track what each product does to the rows $\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3$ of an arbitrary A. Does either operation change a row that the other one adds?
Sketch. $E_{2d3}E_{1c2} = \begin{pmatrix} 1 & 0 & 0 \\ c & 1 & 0 \\ cd & d & 1 \end{pmatrix}$ and $E_{1c2}E_{2d3} = \begin{pmatrix} 1 & 0 & 0 \\ c & 1 & 0 \\ 0 & d & 1 \end{pmatrix}$: adding d times the new row 2 also adds cd times row 1 to row 3. For (b) and (c), compare the effects on rows $\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3$ of any A.

Write $\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3$ for the rows of a $3 \times n$ matrix A. By Proposition 3.2.7, a product $E'EA$ performs the operation of E first and then that of E'.

(a) $E_{2d3}E_{1c2}A$: first row 2 becomes $\mathbf{r}_2 + c\mathbf{r}_1$, then d times this new row 2 is added to row 3. The rows become

$$\mathbf{r}_1, \quad \mathbf{r}_2 + c\mathbf{r}_1, \quad \mathbf{r}_3 + d\mathbf{r}_2 + cd\mathbf{r}_1.$$

$E_{1c2}E_{2d3}A$: first row 3 becomes $\mathbf{r}_3 + d\mathbf{r}_2$, then row 2 becomes $\mathbf{r}_2 + c\mathbf{r}_1$. The rows become $\mathbf{r}_1$, $\mathbf{r}_2 + c\mathbf{r}_1$, $\mathbf{r}_3 + d\mathbf{r}_2$. Taking $A = I_3$,

$$E_{2d3}E_{1c2} = \begin{pmatrix} 1 & 0 & 0 \\ c & 1 & 0 \\ cd & d & 1 \end{pmatrix}, \quad E_{1c2}E_{2d3} = \begin{pmatrix} 1 & 0 & 0 \\ c & 1 & 0 \\ 0 & d & 1 \end{pmatrix}.$$

The products differ when $cd \neq 0$. The difference is the extra $cd\mathbf{r}_1$ in row 3: in the first order, the row that is added to row 3 has already absorbed $c\mathbf{r}_1$.

(b) $E_{1(cd)3}E_{1c2}E_{2d3}A$ performs, in order: $\mathbf{r}_3 \to \mathbf{r}_3 + d\mathbf{r}_2$; $\mathbf{r}_2 \to \mathbf{r}_2 + c\mathbf{r}_1$; then adds $cd\mathbf{r}_1$ to row 3. The rows become $\mathbf{r}_1$, $\mathbf{r}_2 + c\mathbf{r}_1$, $\mathbf{r}_3 + d\mathbf{r}_2 + cd\mathbf{r}_1$, the same as in the first computation of (a). Taking $A = I_3$ gives the identity.

(c) E_{1c2} and E_{1d3} both read only row 1, which neither changes, and they change different rows. In either order the rows of A become $\mathbf{r}_1$, $\mathbf{r}_2 + c\mathbf{r}_1$, $\mathbf{r}_3 + d\mathbf{r}_1$. Likewise E_{1c2} and E_{3d2} both change only row 2 and read rows 1 and 3, which neither changes; in either order row 2 becomes $\mathbf{r}_2 + c\mathbf{r}_1 + d\mathbf{r}_3$. Taking $A = I_3$, the matrices commute.

Solution to Exercise 3.2.41

Uses. Proposition 3.2.7 (Row operations are left multiplications), Definition 3.2.2 (Elementary matrices)
Hint 1. Follow only rows i and j; call them $\mathbf{u}$ and $\mathbf{v}$. The rightmost factor acts first.
Hint 2. The sequence is $(\mathbf{u}, \mathbf{v}) \to (\mathbf{u}, \mathbf{u}+\mathbf{v}) \to (-\mathbf{v}, \mathbf{u}+\mathbf{v}) \to \cdots$. In $\mathbb{F}_2$, what is $E_{i,-1}$?
Sketch. Rows i, j go $(\mathbf{u}, \mathbf{v}) \to (\mathbf{u}, \mathbf{u}+\mathbf{v}) \to (-\mathbf{v}, \mathbf{u}+\mathbf{v}) \to (-\mathbf{v}, \mathbf{u}) \to (\mathbf{v}, \mathbf{u})$. Over $\mathbb{F}_2$, $-1 = 1$, so $E_{i,-1} = I_m$ and $E_{ij} = E_{i,1,j}E_{j,1,i}E_{i,1,j}$. For (c), replace every swap by the product in (a).

(a) Let A be any matrix with m rows, and let $\mathbf{u}$ and $\mathbf{v}$ be its rows i and j. By Proposition 3.2.7, the product on the right performs four operations on A, starting with the rightmost factor. Only rows i and j change, as follows:

$$(\mathbf{u}, \mathbf{v}) \overset{E_{i,1,j}}{\to} (\mathbf{u}, \mathbf{u}+\mathbf{v}) \overset{E_{j,-1,i}}{\to} (\mathbf{u} - (\mathbf{u}+\mathbf{v}), \mathbf{u}+\mathbf{v}) = (-\mathbf{v}, \mathbf{u}+\mathbf{v})$$
$$\overset{E_{i,1,j}}{\to} (-\mathbf{v}, -\mathbf{v}+\mathbf{u}+\mathbf{v}) = (-\mathbf{v}, \mathbf{u}) \overset{E_{i,-1}}{\to} (\mathbf{v}, \mathbf{u}).$$

So the product performs the swap of rows i and j on every A; taking $A = I_m$ shows that it equals E_{ij}.

(b) In $\mathbb{F}_2$, $-1 = 1$, so $E_{i,-1} = E_{i,1} = I_m$ and $E_{j,-1,i} = E_{j,1,i}$. By (a), $E_{ij} = E_{i,1,j}E_{j,1,i}E_{i,1,j}$.

(c) In a product of elementary matrices, replace each factor E_{ij} by the product in (a). The result is the same matrix, written with factors of types 2 and 3 only.

Solution to Exercise 3.2.42

Uses. Proposition 3.2.7 (Row operations are left multiplications), Exercise 3.2.41
Hint 1. For (a), write out EA for each type and expand D.
Hint 2. For (b), compute D of a product $E_k \cdots E_1$ of type 3 matrices by writing it as $E_k \cdots E_1 I_2$.
Sketch. Adding t times row 1 to row 2 gives $a(d+tb) - b(c+ta) = ad - bc$, and similarly for row 2 into row 1; swapping gives $cb - da$; scaling a row by s multiplies D by s. So a product P of type 3 matrices has $D(P) = D(I_2) = 1$, while $D(E_{12}) = -1 \neq 1$ when $1 + 1 \neq 0$, and $D\big(E_{1,2}\big) = 2$.

(a) By Proposition 3.2.7, the type 3 matrices act as follows. Adding t times row 1 to row 2 gives $\begin{pmatrix} a & b \\ c+ta & d+tb \end{pmatrix}$, and

$$a(d+tb) - b(c+ta) = ad - bc.$$

Adding t times row 2 to row 1 gives $\begin{pmatrix} a+tc & b+td \\ c & d \end{pmatrix}$, and $(a+tc)d - (b+td)c = ad - bc$. Swapping the rows gives $\begin{pmatrix} c & d \\ a & b \end{pmatrix}$, with $D = cb - da = -D(A)$. Scaling row 1 by s gives $D\left(\begin{pmatrix} sa & sb \\ c & d \end{pmatrix}\right) = sad - sbc = sD(A)$, and scaling row 2 by s gives $a(sd) - b(sc) = sD(A)$.

(b) Let $P = E_k \cdots E_1$ with each E_l of type 3. Then $P = E_k \cdots E_1 I_2$, and applying (a) k times, $D(P) = D(I_2) = 1$. But $D(E_{12}) = 0 \cdot 0 - 1 \cdot 1 = -1$, and $-1 \neq 1$ because $1 + 1 \neq 0$. So E_{12} is not such a product. Over $\mathbb{F}_2$, $-1 = 1$ and the invariant D gives no obstruction, in line with Exercise 3.2.41(b), where E_{12} was written as a product of three type 3 matrices.

(c) No: $D\big(E_{1,2}\big) = 2 \neq 1$.

The number $D(A)$ is the determinant of A (Theorem 5.1.13), and (a) is the 2×2 case of the rules computed in Section 5.4.

Solution to Exercise 3.2.43

Uses. Proposition 3.2.14 (Invertible matrices preserve solution sets), Non-example 3.2.19 (Row operations move the column space)
Hint 1. Reread Proposition 3.2.14. Which right-hand side goes with GA?
Hint 2. Try $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and a single row operation.
Sketch. The proposition pairs $A\mathbf{x} = \mathbf{y}$ with $(GA)\mathbf{x} = G\mathbf{y}$, not with $(GA)\mathbf{x} = \mathbf{y}$. What it shows is $\mathbf{y} \in \operatorname{im} T_A \Leftrightarrow G\mathbf{y} \in \operatorname{im} T_{GA}$. Counterexample: $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$, $G = E_{1,-1,2}$, $GA = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$.

Proposition 3.2.14 compares $A\mathbf{x} = \mathbf{y}$ with $(GA)\mathbf{x} = G\mathbf{y}$: the right-hand side is multiplied by G too. The argument silently replaces $G\mathbf{y}$ by $\mathbf{y}$. What the proposition does give is $\mathbf{y} \in \operatorname{im} T_A \Leftrightarrow G\mathbf{y} \in \operatorname{im} T_{GA}$, so $\operatorname{im} T_{GA} = \{G\mathbf{y} \mid \mathbf{y} \in \operatorname{im} T_A\}$, which is usually a different subspace.

Counterexample: let $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \in \mathbb{R}^{2\times 1}$ and $G = E_{1,-1,2}$, so $GA = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$. Then $\operatorname{im} T_A = \operatorname{span}((1,1))$ and $\operatorname{im} T_{GA} = \operatorname{span}((1,0))$, and $(1,1)$ is not a multiple of $(1,0)$.

Solution to Exercise 3.2.44

Uses. Definition 3.2.21 (Row equivalence), Corollary 3.2.23 (Row equivalent matrices have the same kernel), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. Write $B = GA$ with G a product of elementary matrices. Which statements follow from associativity alone?
Hint 2. To disprove, use kernels (Corollary 3.2.23). For (a) and (c), try $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ or $A = I_2$ with B obtained by a swap.
Sketch. (b) and (e) are true: $BC = G(AC)$, and $B = GA$ is a product of invertible matrices. (a), (c), (d) are false: $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \sim \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ but the transposes have kernels $\operatorname{span}(\mathbf{e}_2) \neq \operatorname{span}(\mathbf{e}_1)$; with $C = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, CI_2 and CE_{12} have different kernels; $I_2 + I_2$ and $E_{12} + I_2$ have different kernels.

Throughout, $B = GA$ where $G = E_k \cdots E_1$ is a product of elementary matrices.

(a) False. Let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = E_{12}A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$, so $A \sim B$. Then $A^{\mathsf{T}} = A$ has kernel $\operatorname{span}(\mathbf{e}_2)$, while $B^{\mathsf{T}} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ sends $(x_1, x_2) \mapsto (x_2, 0)$ and has kernel $\operatorname{span}(\mathbf{e}_1)$. By Corollary 3.2.23, A^{T} and B^{T} are not row equivalent.

(b) True. $BC = (GA)C = G(AC) = E_k \cdots E_1(AC)$, so $AC \sim BC$.

(c) False. Let $A = I_2$, $B = E_{12}$ (so $A \sim B$), and $C = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. Then $CA = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $CB = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, whose kernels are $\operatorname{span}(\mathbf{e}_2)$ and $\operatorname{span}(\mathbf{e}_1)$, so CA and CB are not row equivalent.

(d) False. Let $A = C = D = I_2$ and $B = E_{12}$. Then $A + C = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$ and $B + D = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$. The kernel of $B + D$ is $\operatorname{span}((1, -1))$. The kernel of $A + C$ is $\{\mathbf{0}\}$ if $1 + 1 \neq 0$ and all of F^2 if $1 + 1 = 0$; either way it is not $\operatorname{span}((1, -1))$. So $A + C$ and $B + D$ are not row equivalent.

(e) True. G is invertible by Corollary 3.2.11, so $B = GA$ is a product of invertible matrices, which is invertible with inverse $A^{-1}G^{-1}$.

Solution to Exercise 3.2.45

Uses. Proposition 3.2.14 (Invertible matrices preserve solution sets), Definition 2.5.1 (Left inverse), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Theorem 2.7.2 (First Fundamental Theorem)
Hint 1. Rerun the proof of Proposition 3.2.14. Where exactly was G^{-1} used?
Hint 2. For (b), let the third row of G produce the sum of the two equations.
Hint 3. For (c), suppose $G\mathbf{z} = \mathbf{0}$. Choose $A = 0$ and $\mathbf{y} = \mathbf{z}$ and compare the two solution sets.
Sketch. (a) $\Rightarrow$ is multiplication by G; $\Leftarrow$ multiplies by H: $A\mathbf{x} = HGA\mathbf{x} = HG\mathbf{y} = \mathbf{y}$. (b) $G = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{pmatrix}$ appends the sum of the two equations; $H = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$. (c) If $G\mathbf{z} = \mathbf{0}$, then with $A = 0$, $\mathbf{y} = \mathbf{z}$, every x solves the second system, hence the first, so $\mathbf{z} = \mathbf{0}$.

(a) If $A\mathbf{x} = \mathbf{y}$, then $(GA)\mathbf{x} = G(A\mathbf{x}) = G\mathbf{y}$. Conversely, if $(GA)\mathbf{x} = G\mathbf{y}$, multiplying on the left by H gives

$$A\mathbf{x} = (HG)A\mathbf{x} = H((GA)\mathbf{x}) = H(G\mathbf{y}) = (HG)\mathbf{y} = \mathbf{y}.$$

Only the left inverse was used.

(b) Let $G = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{pmatrix}$ and $H = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$. Then $HG = I_2$. For a system of two equations with augmented matrix $(A \mid \mathbf{y})$, the matrix $G(A \mid \mathbf{y}) = (GA \mid G\mathbf{y})$ consists of the two original equations followed by their sum. By (a), appending this redundant equation does not change the solution set. (G is not square, so it is not invertible.)

(c) By Theorem 2.6.11 it suffices to show $\ker T_G = \{\mathbf{0}\}$. Let $\mathbf{z} \in F^m$ with $G\mathbf{z} = \mathbf{0}$. Take $A = 0 \in F^{m \times 1}$ and $\mathbf{y} = \mathbf{z}$. For every $x \in F = F^1$, $(GA)x = \mathbf{0} = G\mathbf{z} = G\mathbf{y}$, so every x solves the second system. By hypothesis every x then solves the first system, so $\mathbf{0} = Ax = \mathbf{y} = \mathbf{z}$. Hence $\ker T_G = \{\mathbf{0}\}$, and T_G is injective.

By Theorem 2.7.2, an injective T_G has a left inverse. So (a) and (c) together say: multiplying systems by G always preserves solution sets exactly when G has a left inverse.

Solution to Exercise 3.2.46

Uses. Proposition 3.2.30 (Column operations preserve the image), Proposition 2.4.23 (Transpose of a product), Corollary 3.2.11 (Products of elementary matrices), Definition 2.5.12 (Invertible)
Techniques. Transpose to trade rows for columns (Technique 3.2.27), Double containment (Technique 1.3.14)
Hint 1. If $B = GA$, then $B^{\mathsf{T}} = A^{\mathsf{T}}G^{\mathsf{T}}$. Which result about right multiplication applies?
Hint 2. You need G^{T} to be invertible. Transpose the equations $GG^{-1} = G^{-1}G = I_m$.
Sketch. $B^{\mathsf{T}} = A^{\mathsf{T}}G^{\mathsf{T}}$, and G^{T} is invertible with inverse $\left(G^{-1}\right)^{\mathsf{T}}$. By Proposition 3.2.30, $\operatorname{im} T_{B^{\mathsf{T}}} = \operatorname{im} T_{A^{\mathsf{T}}}$.

Let $A \sim B$, so $B = GA$ with G a product of elementary matrices, invertible by Corollary 3.2.11. By Proposition 2.4.23, $B^{\mathsf{T}} = A^{\mathsf{T}}G^{\mathsf{T}}$. Transposing $GG^{-1} = I_m$ and $G^{-1}G = I_m$ gives $\left(G^{-1}\right)^{\mathsf{T}}G^{\mathsf{T}} = I_m$ and $G^{\mathsf{T}}\left(G^{-1}\right)^{\mathsf{T}} = I_m$ (as $I_m^{\mathsf{T}} = I_m$), so G^{T} is invertible. By Proposition 3.2.30, $\operatorname{im} T_{B^{\mathsf{T}}} = \operatorname{im} T_{A^{\mathsf{T}}G^{\mathsf{T}}} = \operatorname{im} T_{A^{\mathsf{T}}}$.

Solution to Exercise 3.2.46

Uses. Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.22 (Row equivalence is an equivalence relation), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Techniques. Transpose to trade rows for columns (Technique 3.2.27), Double containment (Technique 1.3.14)
Hint 1. It suffices to treat a single row operation, then use symmetry.
Hint 2. Each row of EA is a combination of rows of A, so it lies in the row space of A.
Sketch. Every row of EA is a row of A or a combination of two rows of A, so the row space of EA is contained in that of A. Since A is obtained back from EA by an elementary operation, the reverse containment holds as well; then induct on the number of operations.

Write $R(A)$ for the row space. First let E be elementary. By Proposition 3.2.7, every row of EA is a row of A, a nonzero multiple of a row of A, or a row of A plus a multiple of another row of A. So every row of EA lies in $R(A)$, and since $R(A)$ is a subspace, $R(EA) \subseteq R(A)$ (Proposition 1.4.14). Also $A = E^{-1}(EA)$ with E^{-1} elementary, so the same argument gives $R(A) \subseteq R(EA)$. Hence $R(EA) = R(A)$. If $B = E_k \cdots E_1 A$, applying this k times gives $R(B) = R(A)$.

Solution to Exercise 3.2.47

Uses. Definition 3.2.21 (Row equivalence), Definition 3.2.1 (Elementary row operations), Definition 2.4.1 (Matrix product), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. With only one row, which elementary row operations are available?
Hint 2. For (b), if $B = GA$, then the columns of B are G times the columns of A. What do you learn about the two columns of B?
Sketch. (a) A matrix with one row admits only scalings, and a sequence of them multiplies by a nonzero scalar. (b) $B = G\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ has both columns equal to $G\mathbf{e}_1 \neq \mathbf{0}$, so $B = \begin{pmatrix} a & a \\ b & b \end{pmatrix}$ with $(a, b) \neq (0, 0)$; conversely each such B is reached by a scaling and a replacement, or a swap and a scaling.

(a) Swaps and replacements need two different rows, so the only elementary row operations on a $1 \times n$ matrix are scalings by nonzero scalars. A sequence of them multiplies the matrix by the product of the scalars, which is nonzero. So $A \sim B$ implies $B = sA$ with $s \neq 0$; conversely, if $B = sA$ with $s \neq 0$, scaling the row by s turns A into B.

(b) Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$. We claim that $B \sim A$ if and only if $B = \begin{pmatrix} a & a \\ b & b \end{pmatrix}$ with $(a, b) \neq (0, 0)$.

Suppose $B \sim A$, and write $B = GA$ with G a product of elementary matrices. By Definition 2.4.1, both columns of B equal $G\mathbf{e}_1$. This vector is nonzero, because G is invertible (Corollary 3.2.11) and so $G\mathbf{e}_1 = \mathbf{0}$ would give $\mathbf{e}_1 = G^{-1}\mathbf{0} = \mathbf{0}$. So $B = \begin{pmatrix} a & a \\ b & b \end{pmatrix}$ with $(a, b) = G\mathbf{e}_1 \neq (0, 0)$.

Conversely, let $(a, b) \neq (0, 0)$. If $a \neq 0$, scale row 1 of A by a to get $\begin{pmatrix} a & a \\ 0 & 0 \end{pmatrix}$, then add b/a times row 1 to row 2 to get $\begin{pmatrix} a & a \\ b & b \end{pmatrix}$. If $a = 0$, then $b \neq 0$; swap the rows of A to get $\begin{pmatrix} 0 & 0 \\ 1 & 1 \end{pmatrix}$, then scale row 2 by b.

Solution to Exercise 3.2.48

Uses. Definition 3.2.2 (Elementary matrices)
Hint 1. Count each type, but watch for coincidences. Which choices of c give I_m? Can a matrix of one type equal a matrix of another type?
Hint 2. Compare the diagonal entries: a swap has two diagonal entries 0, a scaling other than I_m is diagonal, and a replacement other than I_m has a nonzero off-diagonal entry and all diagonal entries 1.
Sketch. Apart from I_m, the types are disjoint. There are $\binom{m}{2}$ swaps (as $E_{ij} = E_{ji}$), $m(p-2)$ scalings with $c \notin \{0, 1\}$, and $m(m-1)(p-1)$ replacements with $c \neq 0$. Total $1 + \binom{m}{2} + m(p-2) + m(m-1)(p-1)$; for $p = m = 2$ this is 4: I_2, E_{12}, $E_{1,1,2}$, $E_{2,1,1}$.

The identity is elementary ($I_m = E_{1,1}$). We count the elementary matrices other than I_m.

Swaps. E_{ij} has diagonal entries 0 in positions i and j. Since $E_{ij} = E_{ji}$ and different pairs $\{i, j\}$ give different matrices, there are $\binom{m}{2} = m(m-1)/2$ of them.

Scalings other than I_m. E_{ic} with $c \notin \{0, 1\}$ is diagonal and differs from I_m exactly in position (i, i), where it has c. Different pairs (i, c) give different matrices, so there are $m(p-2)$ of them.

Replacements other than I_m. E_{icj} with $c \neq 0$ has all diagonal entries 1 and a single nonzero off-diagonal entry c in position (j,i). Different triples (i,c,j) give different matrices, so there are $m(m-1)(p-1)$ of them.

No matrix lies in two of these groups: swaps have zero diagonal entries, scalings other than I_m are diagonal with a diagonal entry different from 1, and replacements other than I_m are not diagonal but have all diagonal entries 1. So the number of elementary matrices in $\mathbb{F}_p^{m\times m}$ is

$$1 + m\frac{m-1}{2} + m(p-2) + m(m-1)(p-1).$$

For $p=2$, $m=2$ this is $1+1+0+2=4$:

$$I_2, \quad E_{12} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad E_{1,1,2} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \quad E_{2,1,1} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$

Solution to Exercise 3.2.49

Uses. Example 3.2.34 (A rotation built from shears)
Hint 1. Multiply out with $t = \tan(\theta/2)$ and $s = \sin\theta$, and simplify ts with the double-angle formulas.
Hint 2. $ts = 2\sin^2(\theta/2) = 1 - \cos\theta$. For (b), use $R_\pi = R_{\pi/2}^2$ and Example 3.2.34.
Sketch. With $t = \tan(\theta/2)$, $s = \sin\theta$, the product is $\begin{pmatrix} 1-ts & -t(2-ts) \\ s & 1-ts \end{pmatrix}$. Since $ts = 1-\cos\theta$, the diagonal entries are $\cos\theta$ and the top right entry is $-t(1+\cos\theta) = -\sin\theta$. For (b), $(S(-1)L(1)S(-1))^2 = S(-1)L(1)S(-2)L(1)S(-1)$.

(a) Let $t = \tan(\theta/2)$, which is defined because $\theta/2$ is not an odd multiple of $\pi/2$, and $s = \sin\theta$. Then

$$S(-t)L(s) = \begin{pmatrix} 1 & -t \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ s & 1 \end{pmatrix} = \begin{pmatrix} 1-ts & -t \\ s & 1 \end{pmatrix}, \quad S(-t)L(s)S(-t) = \begin{pmatrix} 1-ts & -t(1-ts)-t \\ s & 1-ts \end{pmatrix}.$$

By the double-angle formulas, $ts = (\sin(\theta/2)/\cos(\theta/2)) \cdot 2\sin(\theta/2)\cos(\theta/2) = 2\sin^2(\theta/2) = 1-\cos\theta$. So $1-ts = \cos\theta$, and the top right entry is

$$-t(\cos\theta + 1) = -\frac{\sin(\theta/2)}{\cos(\theta/2)} \cdot 2\cos^2(\theta/2) = -2\sin(\theta/2)\cos(\theta/2) = -\sin\theta.$$

Hence the product is R_θ, as desired. For $\theta = \pi/2$ this is the factorization $R = SLS$ of Example 3.2.34.

(b) $R_\pi = R_{\pi/2}R_{\pi/2}$, and by Example 3.2.34 $R_{\pi/2} = S(-1)L(1)S(-1)$. So

$$-I_2 = S(-1)L(1)S(-1)S(-1)L(1)S(-1) = S(-1)L(1)S(-2)L(1)S(-1),$$

using $S(-1)S(-1) = S(-2)$ (Exercise 3.2.39). (The formula in (a) is how images are rotated in software that can only shift pixels along rows and columns: each shear moves every row, or every column, by a fixed amount.)

Solution to Exercise 3.2.50

Uses. Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.10 (Inverses of elementary matrices), Corollary 3.2.11 (Products of elementary matrices)
Hint 1. If $a \neq 0$: scale row 1 by a^{-1}, clear the $(2,1)$ entry, and check that the new $(2,2)$ entry is $(ad-bc)/a$. If $a = 0$, swap first.
Hint 2. From $E_k\cdots E_1 A = I_2$, multiply on the left by $E_1^{-1}\cdots E_k^{-1}$.
Sketch. If $a \neq 0$: $E_{1a^{-1}}$, then $E_{1(-c)2}$, giving $\begin{pmatrix} 1 & b/a \\ 0 & (ad-bc)/a \end{pmatrix}$; then scale row 2 by $a/(ad-bc)$ and add $-b/a$ times row 2 to row 1. If $a = 0$ then $c \neq 0$; swap first. Then $A = E_1^{-1}\cdots E_k^{-1}$. For $A = \begin{pmatrix} 0 & 1 \\ -2 & 3 \end{pmatrix}$: $A = E_{12}E_{1,-2}E_{2,-3/2,1}$.

(a) *Case $a \neq 0$.* Scaling row 1 by a^{-1} gives $\begin{pmatrix} 1 & b/a \\ c & d \end{pmatrix}$. Adding $-c$ times row 1 to row 2 gives

$$\begin{pmatrix} 1 & b/a \\ 0 & d - cb/a \end{pmatrix} = \begin{pmatrix} 1 & b/a \\ 0 & (ad-bc)/a \end{pmatrix}.$$

The $(2,2)$ entry $\delta = (ad-bc)/a$ is nonzero. Scaling row 2 by δ^{-1} gives $\begin{pmatrix} 1 & b/a \\ 0 & 1 \end{pmatrix}$, and adding $-b/a$ times row 2 to row 1 gives I_2. With

$$E_1 = E_{1a^{-1}}, \quad E_2 = E_{1(-c)2}, \quad E_3 = E_{2\delta^{-1}}, \quad E_4 = E_{2(-b/a)1},$$

Proposition 3.2.7 gives $E_4E_3E_2E_1A = I_2$.

Case $a = 0$. Then $-bc = ad - bc \neq 0$, so $c \neq 0$. Swapping the rows gives $\begin{pmatrix} c & d \\ 0 & b \end{pmatrix}$, whose $(1,1)$ entry is nonzero and whose value of "$ad - bc$" is $cb - d \cdot 0 = cb \neq 0$. Apply the first case to it.

In either case $E_k \cdots E_1 A = I_2$. Multiplying on the left by $E_1^{-1} \cdots E_k^{-1}$, which is the inverse of $E_k \cdots E_1$ (Corollary 3.2.11), gives $A = E_1^{-1} \cdots E_k^{-1}$, and each E_l^{-1} is elementary by Proposition 3.2.10.

(b) Here $a = 0$. Swapping the rows gives $\begin{pmatrix} -2 & 3 \\ 0 & 1 \end{pmatrix}$. Scaling row 1 by $-1/2$ gives $\begin{pmatrix} 1 & -3/2 \\ 0 & 1 \end{pmatrix}$, and adding $3/2$ times row 2 to row 1 gives I_2. So $E_{2,3/2,1}E_{1,-1/2}E_{12}A = I_2$, and

$$A = E_{12}E_{1,-2}E_{2,-3/2,1} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} -2 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & -3/2 \\ 0 & 1 \end{pmatrix}.$$

Indeed, $\begin{pmatrix} -2 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & -3/2 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} -2 & 3 \\ 0 & 1 \end{pmatrix}$, and swapping its rows gives A. So T_A is: a horizontal shear by $-3/2$, then a horizontal stretch by 2 combined with the reflection across the x_2-axis, then the reflection across the line $x_1 = x_2$.

Solution to Exercise 3.2.51

Uses. Proposition 3.2.28 (Column operations are right multiplications), Corollary 3.2.11 (Products of elementary matrices), Theorem 2.4.2 (The matrix of a composite), Remark 3.2.29 (One matrix, two operations)
Hint 1. Use column 1 to clear the rest of row 1, then fix row 2. Compute H by performing the same column operations on I_3.
Hint 2. For (b), write $\mathbf{x} = H\mathbf{z}$. Then $A\mathbf{x} = (AH)\mathbf{z} = (z_1, z_2)$.
Sketch. Add -2 times column 1 to column 2 and -3 times column 1 to column 3, swap columns 2 and 3, add -2 times column 2 to column 1. On I_3 this gives $H = \begin{pmatrix} 7 & -3 & -2 \\ 0 & 0 & 1 \\ -2 & 1 & 0 \end{pmatrix}$. Since H is invertible, every $\mathbf{x}$ is $H\mathbf{z}$, and $A\mathbf{x} = (z_1, z_2)$ vanishes exactly when $\mathbf{z} = t\mathbf{e}_3$, that is, $\mathbf{x} = t\mathbf{h}_3 = t(-2, 1, 0)$.

(a) Adding -2 times column 1 to column 2 gives $\begin{pmatrix} 1 & 0 & 3 \\ 2 & 0 & 7 \end{pmatrix}$; adding -3 times column 1 to column 3 gives $\begin{pmatrix} 1 & 0 & 0 \\ 2 & 0 & 1 \end{pmatrix}$; swapping columns 2 and 3 gives $\begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \end{pmatrix}$; and adding -2 times column 2 to column 1 gives $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$. By Proposition 3.2.28, and since the first column operation is the leftmost factor (Remark 3.2.29),

$$H = E_{2,-2,1}E_{3,-3,1}E_{23}E_{1,-2,2}.$$

Performing the four column operations on I_3 (because $I_3H = H$):

$$I_3 \to \begin{pmatrix} 1 & -2 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \to \begin{pmatrix} 1 & -2 & -3 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \to \begin{pmatrix} 1 & -3 & -2 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \to \begin{pmatrix} 7 & -3 & -2 \\ 0 & 0 & 1 \\ -2 & 1 & 0 \end{pmatrix} = H.$$

(b) H is invertible (Corollary 3.2.11), so every $\mathbf{x} \in \mathbb{R}^3$ can be written as $\mathbf{x} = H\mathbf{z}$ with $\mathbf{z} = H^{-1}\mathbf{x}$. Then

$$A\mathbf{x} = (AH)\mathbf{z} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}\begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix} = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}.$$

So $\mathbf{x} \in \ker T_A$ if and only if $z_1 = z_2 = 0$, that is, $\mathbf{z} = t\mathbf{e}_3$ for some $t \in \mathbb{R}$, that is, $\mathbf{x} = tH\mathbf{e}_3 = t\mathbf{h}_3$. Hence $\ker T_A = \operatorname{span}(\mathbf{h}_3) = \operatorname{span}((-2, 1, 0))$. Check: $A(-2, 1, 0) = (-2 + 2, -4 + 4) = \mathbf{0}$.

Solution to Exercise 3.2.52

Uses. Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.28 (Column operations are right multiplications)
Hint 1. It suffices to use the matrices $E_{i,1,j}$. Describe $ME_{i,1,j}$ and $E_{i,1,j}M$ as column and row operations on M.

Hint 2. $ME_{i,1,j}$ is M with column j added to column i, and $E_{i,1,j}M$ is M with row i added to row j. Compare the entries in column i.
Sketch. $ME_{i,1,j}$ differs from M only in column i, by m_{kj} in row k; $E_{i,1,j}M$ differs from M only in row j, by m_{il} in column l. Comparing entry (k,i) for $k \neq j$ gives $m_{kj} = 0$; comparing entry (j,i) gives $m_{jj} = m_{ii}$. So M is diagonal with equal diagonal entries.

If $M = \lambda I_m$, then $ME = \lambda E = EM$ for every E.

Conversely, suppose M commutes with every type 3 elementary matrix, and let $i \neq j$. By Proposition 3.2.28, $ME_{i,1,j}$ is M with column j added to column i: it agrees with M outside column i, and its (k,i) entry is $m_{ki} + m_{kj}$. By Proposition 3.2.7, $E_{i,1,j}M$ is M with row i added to row j: it agrees with M outside row j, and its (j,l) entry is $m_{jl} + m_{il}$.

Compare the (k,i) entries for $k \neq j$: on the left $m_{ki} + m_{kj}$, on the right m_{ki} (row k is unchanged). So $m_{kj} = 0$ for all $k \neq j$. Compare the (j,i) entries: $m_{ji} + m_{jj} = m_{ji} + m_{ii}$, so $m_{jj} = m_{ii}$.

Since $m \geq 2$, every j has some $i \neq j$. So every off-diagonal entry of M is 0 and all diagonal entries are equal: $M = \lambda I_m$ with $\lambda = m_{11}$.

Solution to Exercise 3.2.53

Uses. Exercise 3.2.42, Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.10 (Inverses of elementary matrices)
Hint 1. It suffices to reduce A to I_2 with at most four row replacements, because inverses of type 3 matrices are of type 3. Type 3 operations do not change $ad - bc$ (Exercise 3.2.42).
Hint 2. First make sure the $(2,1)$ entry is nonzero. Then one replacement makes the $(1,1)$ entry equal to 1.
Hint 3. With $(1,1)$ entry 1, clear the $(2,1)$ entry. What does $ad - bc = 1$ say about the new $(2,2)$ entry?
Sketch. If $c = 0$, then $a \neq 0$; add row 1 to row 2 to make $c \neq 0$. Add $(1-a)/c$ times row 2 to row 1, making $a = 1$; add $-c$ times row 1 to row 2, making $c = 0$, and then $d = 1$ since $ad - bc$ is still 1; add $-b$ times row 2 to row 1. That is at most four replacements, and A is the product of their inverses in reverse order.

By Exercise 3.2.42(a), type 3 row operations do not change $D(A) = ad - bc$, so every matrix below has $D = 1$. We find type 3 matrices $E_1, \ldots, E_k$, with $k \leq 4$, such that $E_k \cdots E_1 A = I_2$. Then $A = E_1^{-1} \cdots E_k^{-1}$, and each E_l^{-1} is of type 3 by Proposition 3.2.10.

Step 1. If $c = 0$, then $ad = 1$, so $a \neq 0$. Adding row 1 to row 2 changes the $(2,1)$ entry to $a \neq 0$. So after at most one operation the $(2,1)$ entry, which we still call c, is nonzero.

Step 2. Add $(1-a)/c$ times row 2 to row 1. The new $(1,1)$ entry is $a + ((1-a)/c)c = 1$.

Step 3. Add $-c$ times row 1 to row 2. The new $(2,1)$ entry is $c - c \cdot 1 = 0$, so the matrix is $\begin{pmatrix} 1 & b' \\ 0 & d' \end{pmatrix}$ for some b', d'. Its value of D is d', and it is still 1, so $d' = 1$.

Step 4. Add $-b'$ times row 2 to row 1. This gives I_2.

We used three operations if $c \neq 0$ at the start and four if $c = 0$. So A is a product of at most four shears. For example, over $\mathbb{F}_2$ the swap E_{12} has $D = -1 = 1$, and Exercise 3.2.41(b) wrote it as three shears.

Solution to Exercise 3.2.54

Uses. Proposition 3.2.10 (Inverses of elementary matrices), Proposition 3.2.7 (Row operations are left multiplications), the division algorithm, strong induction on $|b|$
Hint 1. Operations by integer elementary matrices are invertible over $\mathbb{Z}$. What does that say about the common divisors of the two entries?
Hint 2. Imitate the Euclidean algorithm. If $b \neq 0$, write $a = qb + r$ with $0 \leq r < |b|$. Which operation turns (a,b) into (r,b)?
Hint 3. For (c), look at the first row of $G = E_k \cdots E_1$.
Sketch. The operations preserve the common divisors of the two entries, so they preserve the gcd. If $b = 0$, scale by ± 1. Otherwise add $-q$ times row 2 to row 1 and swap, which replaces (a,b) by (b,r) with $|r| < |b|$; induct on $|b|$. Then $G\begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} g \\ 0 \end{pmatrix}$ with G an integer matrix, whose first row (u,v) satisfies $ua + vb = g$. For $(42, 30)$: $G = \begin{pmatrix} -2 & 3 \\ 5 & -7 \end{pmatrix}$, and $-2 \cdot 42 + 3 \cdot 30 = 6$.

(a) The matrices E_{12}, $E_{i,-1}$, and E_{icj} with $c \in \mathbb{Z}$ have entries in $\{0, 1, -1, c\}$, so they are integer matrices. By Proposition 3.2.10 their inverses are E_{12}, $E_{i,-1}$, and $E_{i(-c)j}$, which are again integer elementary matrices.

(b) *Common divisors are preserved.* Let E be an integer elementary matrix and $\mathbf{w} \in \mathbb{Z}^2$. Each entry of $E\mathbf{w}$ is an integer combination of the entries of $\mathbf{w}$, so every common divisor of the entries of $\mathbf{w}$ divides both entries of $E\mathbf{w}$. Since $\mathbf{w} = E^{-1}(E\mathbf{w})$ and E^{-1} is also an integer elementary matrix by (a), the converse holds too. So $\mathbf{w}$ and $E\mathbf{w}$ have the same common divisors, and in particular the same gcd.

The algorithm. We prove the claim by strong induction on $|b|$. If $b = 0$, then $g = |a|$, and we are done after applying $E_{1,-1}$ if $a < 0$. If $b \neq 0$, divide with remainder: $a = qb + r$ with $q, r \in \mathbb{Z}$ and $0 \leq r < |b|$. Adding $-q$ times row 2 to row 1 (the matrix $E_{2,-q,1}$) turns $\begin{pmatrix} a \\ b \end{pmatrix}$ into $\begin{pmatrix} r \\ b \end{pmatrix}$, and swapping turns it into $\begin{pmatrix} b \\ r \end{pmatrix}$. These have the same gcd g, and $|r| < |b|$, so by induction some product of integer elementary matrices turns $\begin{pmatrix} b \\ r \end{pmatrix}$ into $\begin{pmatrix} g \\ 0 \end{pmatrix}$. Composing gives the claim.

(c) Let $G = E_k \cdots E_1$. It has integer entries, being a product of integer matrices. If its first row is (u, v), then the first entry of $G\begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} g \\ 0 \end{pmatrix}$ says $ua + vb = g$.

(d) Adding -1 times row 2 to row 1 gives $\begin{pmatrix} 12 \\ 30 \end{pmatrix}$; adding -2 times row 1 to row 2 gives $\begin{pmatrix} 12 \\ 6 \end{pmatrix}$; adding -2 times row 2 to row 1 gives $\begin{pmatrix} 0 \\ 6 \end{pmatrix}$; swapping gives $\begin{pmatrix} 6 \\ 0 \end{pmatrix}$. So $G = E_{12}E_{2,-2,1}E_{1,-2,2}E_{2,-1,1}$, with the first operation as the rightmost factor. Performing the four operations on I_2: $\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$, then $\begin{pmatrix} 1 & -1 \\ -2 & 3 \end{pmatrix}$, then $\begin{pmatrix} 5 & -7 \\ -2 & 3 \end{pmatrix}$, then

$$G = \begin{pmatrix} -2 & 3 \\ 5 & -7 \end{pmatrix}.$$

(This takes a shortcut through the algorithm of (b): instead of swapping after every division, it reduces whichever entry is larger.) So $u = -2$, $v = 3$: indeed $-2 \cdot 42 + 3 \cdot 30 = -84 + 90 = 6 = \gcd(42, 30)$. The second row says $5 \cdot 42 - 7 \cdot 30 = 0$.

Solution to Exercise 3.2.55

Uses. Exercise 3.2.42, Proposition 3.2.28 (Column operations are right multiplications)
Hint 1. For $ad - bc$, the row moves were handled in Exercise 3.2.42. Do the same computation for columns, or transpose.
Hint 2. For the gcd, every new entry is an integer combination of old entries, and every move can be undone by a move.
Hint 3. Compute both invariants for M and for each target. For a target that passes both tests, find the moves.
Sketch. Row moves keep $ad - bc$ by Exercise 3.2.42; a column move adding t times column 1 to column 2 gives $a(d + tc) - (b + ta)c = ad - bc$, and similarly for the other column move. Moves preserve the set of common divisors of the entries because they are integer combinations and reversible. M has $ad - bc = -8$ and gcd 2. The first target has gcd 1, the second has $ad - bc = 8$, and the third is reached by adding -3 times row 1 to row 2 and then -2 times column 1 to column 2.

(a) *The quantity $ad - bc$.* Row moves do not change it, by Exercise 3.2.42(a). Adding t times column 1 to column 2 gives $\begin{pmatrix} a & b+ta \\ c & d+tc \end{pmatrix}$, and $a(d + tc) - (b + ta)c = ad - bc$. Adding t times column 2 to column 1 gives $\begin{pmatrix} a+tb & b \\ c+td & d \end{pmatrix}$, and $(a + tb)d - b(c + td) = ad - bc$.

The gcd. After a move, each entry is an old entry plus an integer multiple of another old entry. So every integer dividing all four old entries divides all four new ones. The move is undone by the move with $-t$ in place of t, so conversely every common divisor of the new entries divides the old ones. The sets of common divisors agree, and so do the gcds.

(b) For M, $ad - bc = 16 - 24 = -8$ and the gcd of $2, 4, 6, 8$ is 2.

$\begin{pmatrix} 1 & 0 \\ 0 & -8 \end{pmatrix}$ has $ad - bc = -8$ but gcd 1, so it cannot be reached.

$\begin{pmatrix} 2 & 0 \\ 0 & 4 \end{pmatrix}$ has gcd 2 but $ad - bc = 8 \neq -8$, so it cannot be reached.

$\begin{pmatrix} 2 & 0 \\ 0 & -4 \end{pmatrix}$ can be reached. Adding -3 times row 1 to row 2 gives $\begin{pmatrix} 2 & 4 \\ 0 & -4 \end{pmatrix}$, and adding -2 times column 1 to column 2 gives $\begin{pmatrix} 2 & 0 \\ 0 & -4 \end{pmatrix}$.

In matrix terms, a move multiplies on the left or on the right by an integer elementary matrix E_{itj} (Proposition 3.2.7, Proposition 3.2.28). The two invariants here are the start of the theory of the Smith normal form, which classifies integer matrices up to such operations.

Solution to Exercise 3.2.56

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Exercise 3.2.41, Exercise 3.2.53, Proposition 3.2.7 (Row operations are left multiplications)
Hint 1. By Exercise 3.2.41(c), A is a product of matrices of types 2 and 3. Try to move all the scalings to the right end.
Hint 2. Compute $DE_{icj}D^{-1}$ for a diagonal D with nonzero diagonal entries, by tracking rows. It is again of type 3.
Hint 3. A diagonal matrix with entries t and t^{-1} in positions $k, k+1$ and 1 elsewhere is a product of type 3 matrices, by Exercise 3.2.53 applied in rows $k, k+1$. Use such matrices to push all of a diagonal matrix's entries into the last position.
Sketch. Write A as a product of type 2 and type 3 matrices. For diagonal invertible D, $DE_{icj}D^{-1} = E_{i(cd_j/d_i)j}$, so the scalings can be moved to the right: $A = P_1 D$ with P_1 a product of type 3 matrices and $D = \operatorname{diag}(d_1, \ldots, d_n)$. With $p_k = d_1 \cdots d_k$, $D = D_1 \cdots D_{n-1} E_{np_n}$, where D_k has p_k, p_k^{-1} in positions $k, k+1$; each D_k is a product of shears by the 2×2 result.

Write $\operatorname{diag}(d_1, \ldots, d_n)$ for the diagonal matrix with diagonal entries $d_1, \ldots, d_n$. A product of type 2 matrices is diagonal with nonzero diagonal entries, and conversely $\operatorname{diag}(d_1, \ldots, d_n) = E_{1d_1} \cdots E_{nd_n}$ when all $d_k \neq 0$ (each factor scales one row of I_n).

Step 1: only types 2 and 3. By Theorem 3.5.19, A is a product of elementary matrices, and by Exercise 3.2.41(c) we may assume that every factor has type 2 or 3.

Step 2: moving scalings to the right. Let $D = \operatorname{diag}(d_1, \ldots, d_n)$ with all $d_k \neq 0$, and let $i \neq j$. We claim

$$DE_{icj} = E_{ic'j}D, \quad c' = cd_j/d_i.$$

Indeed, apply $DE_{icj}D^{-1}$ to a matrix with rows $\mathbf{r}_1, \ldots, \mathbf{r}_n$, using Proposition 3.2.7 three times. $D^{-1} = \operatorname{diag}\left(d_1^{-1}, \ldots, d_n^{-1}\right)$ gives rows $\mathbf{r}_k/d_k$; then E_{icj} changes row j to $\mathbf{r}_j/d_j + c\mathbf{r}_i/d_i$; then D multiplies row k by d_k. The result has rows $\mathbf{r}_k$ for $k \neq j$ and $\mathbf{r}_j + c(d_j/d_i)\mathbf{r}_i$ in row j, which is what $E_{ic'j}$ does. So $DE_{icj}D^{-1} = E_{ic'j}$, which gives the claim. Using it repeatedly, and merging adjacent diagonal factors (a product of diagonal matrices is diagonal), we can move every type 2 factor in the product of Step 1 to the right end. So $A = P_1 D$ with P_1 a product of type 3 matrices and $D = \operatorname{diag}(d_1, \ldots, d_n)$, all $d_k \neq 0$.

Step 3: the diagonal part. For $1 \leq k < n$ and $t \neq 0$, let $D_k(t)$ be the diagonal matrix with t in position k, t^{-1} in position $k+1$, and 1 elsewhere. The 2×2 matrix $\operatorname{diag}\left(t, t^{-1}\right)$ has $ad - bc = 1$, so by Exercise 3.2.53 it is a product of 2×2 shears E_{1s2} and E_{2s1}. Replace each of these by the $n \times n$ matrix $E_{k,s,k+1}$, respectively $E_{k+1,s,k}$. By Proposition 3.2.7, these $n \times n$ matrices perform on rows $k, k+1$ of I_n exactly the operations that the 2×2 ones perform on rows $1, 2$ of I_2, and they leave the other rows alone. So their product is $D_k(t)$, which is therefore a product of type 3 matrices.

Now let $p_k = d_1 d_2 \cdots d_k$, and consider $D_1(p_1)D_2(p_2)\cdots D_{n-1}(p_{n-1})E_{np_n}$. All factors are diagonal. Its first diagonal entry is $p_1 = d_1$; for $2 \leq k \leq n-1$ its kth entry is $p_{k-1}^{-1}p_k = d_k$; and its nth entry is $p_{n-1}^{-1}p_n = d_n$. So it equals D.

Therefore $A = P_1 D_1(p_1)\cdots D_{n-1}(p_{n-1})E_{nd}$ with $d = p_n = d_1 \cdots d_n \neq 0$, and $P = P_1 D_1(p_1)\cdots D_{n-1}(p_{n-1})$ is a product of type 3 matrices.

Section 3.3

Solution to Exercise 3.3.4

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Proposition 3.2.7 (Row operations are left multiplications)
Hint 1. Pass 1 picks column 1. The $(1,1)$ entry is 0, so the first operation is a swap.

Hint 2. In pass 2 the pivot is in position $(2,2)$ and has to be scaled. Remember to clear above it as well as below it.
Sketch. The operations are E_{12}, $E_{1,-2,3}$, $E_{2,1/2}$, $E_{2,-1,1}$, $E_{2,-1,3}$, and $\operatorname{rref}(B)$ has rows $(1,0,-1)$, $(0,1,2)$, $(0,0,0)$. The pivot columns are 1 and 2.

Pass 1. Column 1 has nonzero entries, so $j=1$. The $(1,1)$ entry is 0 and row 2 is the topmost row with a nonzero entry in column 1, so we swap rows 1 and 2 (E_{12}). The new $(1,1)$ entry is 1, so no scaling is needed; $p_1=1$. Row 3 has entry 2 in column 1, so we add -2 times row 1 to row 3 ($E_{1,-2,3}$):

$$B \xrightarrow{E_{12}} \begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & 4 \\ 2 & 3 & 4 \end{pmatrix} \xrightarrow{E_{1,-2,3}} \begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & 4 \\ 0 & 1 & 2 \end{pmatrix}.$$

Pass 2. Column 2 has the nonzero entries $2, 1$ in the unpivoted rows $2, 3$, so $j=2$, and the $(2,2)$ entry is nonzero, so there is no swap. Scaling row 2 by $1/2$ ($E_{2,1/2}$) gives the row $(0,1,2)$, and $p_2=2$. Rows 1 and 3 have entry 1 in column 2, so we add -1 times row 2 to each ($E_{2,-1,1}$, $E_{2,-1,3}$):

$$\xrightarrow{E_{2,1/2}} \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 1 & 2 \end{pmatrix} \xrightarrow{E_{2,-1,1}} \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & 2 \\ 0 & 1 & 2 \end{pmatrix} \xrightarrow{E_{2,-1,3}} \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & 2 \\ 0 & 0 & 0 \end{pmatrix}.$$

End. The only unpivoted row is zero, so the next scan finds no column and the algorithm halts. The pivot columns are 1 and 2.

Solution to Exercise 3.3.15

Uses. Theorem 3.3.12 (Matrices in RREF)
Hint 1. Locate the leading entry of each row, then check (R1)–(R4) one at a time.
Hint 2. For (b), sort by the number of nonzero rows, and then by the position of the leading entries.
Sketch. (a) In RREF: the second and fourth. The first fails (R3), the third fails (R1), the fifth fails (R4). (b) 0, $\left(\begin{smallmatrix} 1 & a \\ 0 & 0 \end{smallmatrix}\right)$ for $a \in F$, $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, and I_2; over $\mathbb{F}_p$ there are $p+3$.

(a) By Theorem 3.3.12 we check (R1)–(R4).

- The first matrix fails (R3): the leading entry of row 3 (column 2) lies to the left of that of row 2 (column 3).
- The second is in RREF: the leading entries are 1s in columns 1 and 3, and those columns are $\mathbf{e}_1$ and $\mathbf{e}_2$.
- The third fails (R1): the zero row 2 lies above the nonzero row 3.
- The fourth is in RREF: leading 1s in columns 1 and 2, which are $\mathbf{e}_1$ and $\mathbf{e}_2$, and the zero row is last.
- The fifth fails (R4): column 3 contains the leading entry of row 2 and also a nonzero entry in row 3. (It also fails (R3).)

(b) Let $R \in F^{2\times 2}$ be in RREF. If R has no nonzero row, $R=0$. If it has one, it is row 1 by (R1). Its leading 1 is in column 1 or column 2: in the first case $R = \left(\begin{smallmatrix} 1 & a \\ 0 & 0 \end{smallmatrix}\right)$ with $a \in F$ arbitrary (column 2 contains no leading entry, so (R4) says nothing about it), and in the second case $R = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. If both rows are nonzero, their leading 1s are in columns 1 and 2 by (R3), and by (R4) $R = I_2$. All these matrices satisfy (R1)–(R4). Over $\mathbb{F}_p$ there are $1 + p + 1 + 1 = p + 3$ of them.

Solution to Exercise 3.3.21

Uses. Corollary 3.3.18 (RREF and row equivalence), Algorithm 3.3.1 (Gauss–Jordan elimination)
Hint 1. By Corollary 3.3.18(b), compare reduced row echelon forms.
Hint 2. C has a row that is a multiple of the other, so it has one pivot.
Sketch. $\operatorname{rref}(A) = \operatorname{rref}(B) = \left(\begin{smallmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$ and $\operatorname{rref}(C) = \left(\begin{smallmatrix} 1 & 2 & 3 \\ 0 & 0 & 0 \end{smallmatrix}\right)$, so $A \sim B$, and C is row equivalent to neither.

For A: adding -2 times row 1 to row 2 gives $\left(\begin{smallmatrix} 1 & 2 & 3 \\ 0 & 0 & 1 \end{smallmatrix}\right)$, and adding -3 times row 2 to row 1 gives $\left(\begin{smallmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$. For B: swapping the rows gives $\left(\begin{smallmatrix} 1 & 2 & 2 \\ 0 & 0 & 1 \end{smallmatrix}\right)$, and adding -2 times row 2 to row 1 gives $\left(\begin{smallmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$. For C: adding -3 times row 1 to row 2 gives $\left(\begin{smallmatrix} 1 & 2 & 3 \\ 0 & 0 & 0 \end{smallmatrix}\right)$. Each result satisfies (R1)–(R4), so by Corollary 3.3.18(c) these are the reduced row echelon forms. By Corollary 3.3.18(b), $A \sim B$, while C is row equivalent to neither.

Solution to Exercise 3.3.27

Uses. Algorithm 3.3.24 (Inverting a matrix by row reduction), Theorem 3.3.23 (Invertibility and RREF)
Hint 1. The two computations agree until some pivot has to be divided by. Which number is it?
Hint 2. Over $\mathbb{Q}$, pass 3 divides row 3 by 3. In $\mathbb{F}_3$, $3 = 0$.
Sketch. After two passes, valid over any field, the third row of $(A \mid I_3)$ is $(0, 0, 3 \mid -1, 2, 1)$. Over $\mathbb{Q}$, 3 is a pivot, and $3A^{-1}$ has rows $(1, -2, 2)$, $(1, 1, -1)$, $(-1, 2, 1)$. Over $\mathbb{F}_3$ the third row of the left block is zero, so A is not invertible.

Pass 1 adds -1 times row 1 to row 3; pass 2 adds -2 times row 2 to row 1 and 2 times row 2 to row 3. This is the same over any field:

$$\left(\begin{array}{ccc|ccc} 1 & 2 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccc|ccc} 1 & 2 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & -2 & 1 & -1 & 0 & 1 \end{array}\right)$$

$$\rightsquigarrow \left(\begin{array}{ccc|ccc} 1 & 0 & -2 & 1 & -2 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 3 & -1 & 2 & 1 \end{array}\right).$$

Over $\mathbb{Q}$. Pass 3 scales row 3 by $1/3$ and then adds 2 times row 3 to row 1 and -1 times row 3 to row 2:

$$\rightsquigarrow \left(\begin{array}{ccc|ccc} 1 & 0 & 0 & 1/3 & -2/3 & 2/3 \\ 0 & 1 & 0 & 1/3 & 1/3 & -1/3 \\ 0 & 0 & 1 & -1/3 & 2/3 & 1/3 \end{array}\right).$$

So A is invertible over $\mathbb{Q}$ and

$$A^{-1} = \frac{1}{3}\begin{pmatrix} 1 & -2 & 2 \\ 1 & 1 & -1 \\ -1 & 2 & 1 \end{pmatrix}.$$

Check: the first row of A times the columns of $3A^{-1}$ gives $(1 + 2, -2 + 2, 2 - 2) = (3, 0, 0)$, and similarly for the others.

Over $\mathbb{F}_3$. Here $3 = 0$, so the last row of the left block above is zero, and the algorithm stops: A is not invertible over $\mathbb{F}_3$. (Indeed, in the computation above, the last row of the right block gives -1 times row 1 of A plus 2 times row 2 plus row 3, which is $(-1 + 0 + 1, -2 + 2 + 0, 0 + 2 + 1) = (0, 0, 3)$, and $3 = 0$ in $\mathbb{F}_3$.)

Solution to Exercise 3.3.39

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Proposition 3.3.11 (Carrying extra columns along), Corollary 3.3.19 (Pivot columns, intrinsically)
Hint 1. No swaps are needed. Carry I_3 along to get G.
Hint 2. For (b), the entries of a non-pivot column of $\operatorname{rref}(A)$ are the coefficients (Corollary 3.3.19).
Sketch. $\operatorname{rref}(A)$ has rows $(1, 2, 0, 0, 5)$, $(0, 0, 1, 0, -4)$, $(0, 0, 0, 1, 2)$, so the pivot columns are $1, 3, 4$, and G has rows $(4, -2, 1)$, $(-3, 2, -1)$, $(1, -1, 1)$. Then $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_5 = 5\mathbf{a}_1 - 4\mathbf{a}_3 + 2\mathbf{a}_4$.

(a) We row reduce $(A \mid I_3)$, scanning only the first five columns (Proposition 3.3.11). Pass 1: the pivot is the $(1, 1)$ entry; add -2 times row 1 to row 2 and -1 times row 1 to row 3. Pass 2: column 2 now vanishes in rows 2 and 3, so the pivot is the $(2, 3)$ entry, which is 1; add -1 times row 2 to rows 1 and 3. Pass 3: the pivot is the $(3, 4)$ entry, which is 1; add row 3 to row 1 and -1 times row 3 to row 2. The stages after each pass are

$$\left(\begin{array}{ccccc|ccc} 1 & 2 & 1 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & -2 & -2 & 1 & 0 \\ 0 & 0 & 1 & 2 & 0 & -1 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccccc|ccc} 1 & 2 & 0 & -1 & 3 & 3 & -1 & 0 \\ 0 & 0 & 1 & 1 & -2 & -2 & 1 & 0 \\ 0 & 0 & 0 & 1 & 2 & 1 & -1 & 1 \end{array}\right)$$

$$\rightsquigarrow \left(\begin{array}{ccccc|ccc} 1 & 2 & 0 & 0 & 5 & 4 & -2 & 1 \\ 0 & 0 & 1 & 0 & -4 & -3 & 2 & -1 \\ 0 & 0 & 0 & 1 & 2 & 1 & -1 & 1 \end{array}\right).$$

So

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & 2 & 0 & 0 & 5 \\ 0 & 0 & 1 & 0 & -4 \\ 0 & 0 & 0 & 1 & 2 \end{pmatrix}, \quad G = \begin{pmatrix} 4 & -2 & 1 \\ -3 & 2 & -1 \\ 1 & -1 & 1 \end{pmatrix},$$

with pivot columns $1, 3, 4$. As a check, row 1 of GA is

$$4(1,2,1,0,1) - 2(2,4,3,1,0) + (1,2,2,2,1) = (1,2,0,0,5).$$

(b) By Corollary 3.3.19(b), $\mathbf{a}_2 = 2\mathbf{a}_1$ and $\mathbf{a}_5 = 5\mathbf{a}_1 - 4\mathbf{a}_3 + 2\mathbf{a}_4$. Indeed,

$$5(1,2,1) - 4(1,3,2) + 2(0,1,2) = (1,0,1) = \mathbf{a}_5.$$

Solution to Exercise 3.3.40

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Corollary 3.3.19 (Pivot columns, intrinsically)
Hint 1. The first two passes involve only the scalars 1 and -1, so they read the same over both fields (remember $-1 = 1$ in $\mathbb{F}_2$).
Hint 2. After two passes the third row is $(0,0,2,0)$. Can 2 be a pivot?
Sketch. After two passes both computations reach the rows $(1,0,-1,0)$, $(0,1,1,1)$, $(0,0,2,0)$. Over $\mathbb{Q}$, 2 is a pivot and $\operatorname{rref}(A)$ has rows $(1,0,0,0)$, $(0,1,0,1)$, $(0,0,1,0)$. Over $\mathbb{F}_2$, $2 = 0$ and $-1 = 1$, so $\operatorname{rref}(A)$ has rows $(1,0,1,0)$, $(0,1,1,1)$, $(0,0,0,0)$.

Pass 1 adds -1 times row 1 to row 3, which becomes $(0,-1,1,-1)$. Pass 2, with pivot $(2,2)$, adds -1 times row 2 to row 1 and row 2 to row 3:

$$\begin{pmatrix} 1 & 0 & -1 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 2 & 0 \end{pmatrix}.$$

So far every operation makes sense over any field.

Over $\mathbb{Q}$. The third row has the entry $2 \neq 0$ in column 3, which becomes the pivot of pass 3. Scaling row 3 by $1/2$ and adding row 3 to row 1 and -1 times row 3 to row 2 gives

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

Over $\mathbb{F}_2$. Here $2 = 0$ and $-1 = 1$, so after pass 2 the matrix is

$$\begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Its unpivoted row is zero, so the algorithm halts, and this is $\operatorname{rref}(A)$ over $\mathbb{F}_2$.

The computations part ways at the entry 2 in pass 3, which is a valid pivot over $\mathbb{Q}$ and is 0 over $\mathbb{F}_2$. In terms of Corollary 3.3.19: over $\mathbb{F}_2$ the third column of A is the sum of the first two, $(1,0,1) + (1,1,0) = (0,1,1)$, so column 3 is not a pivot column. Over $\mathbb{Q}$, a combination $x(1,0,1) + y(1,1,0)$ equal to $(0,1,1)$ would need $x = 1$ and $y = 1$ (from the third and second entries), but then the first entry is $2 \neq 0$; so the third column is a pivot column.

Solution to Exercise 3.3.41

Uses. Algorithm 3.3.24 (Inverting a matrix by row reduction), Theorem 3.3.23 (Invertibility and RREF)

Hint 1. In pass 1 for A, add $-i$ times row 1 to row 3, and remember $i^2 = -1$.
Hint 2. Pass 3 for A divides by $1 - i$, whose inverse is $(1 + i)/2$. For B, the left block gets a zero row in pass 2; read the relation off the right block.
Sketch. For A, the passes use $E_{1,-i,3}$, then $E_{2,-i,1}$ and $E_{2,-1,3}$, then a scaling by $(1 + i)/2$ and two replacements; the inverse has entries $(\pm 1 \pm i)/2$. For B, two passes leave the left row $(0, 0, 0)$ with right row $(-i, -1, 1)$, so B is not invertible, and $-i$ times row 1, minus row 2, plus row 3 is zero.

The matrix A. Pass 1 adds $-i$ times row 1 to row 3, which becomes $\big(0, -i^2, 1 \mid -i, 0, 1\big) = (0, 1, 1 \mid -i, 0, 1)$. Pass 2 (pivot $(2, 2)$) adds $-i$ times row 2 to row 1 and -1 times row 2 to row 3:

$$\left(\begin{array}{ccc|ccc} 1 & 0 & 1 & 1 & -i & 0 \\ 0 & 1 & i & 0 & 1 & 0 \\ 0 & 0 & 1-i & -i & -1 & 1 \end{array}\right).$$

Pass 3 scales row 3 by $(1 - i)^{-1} = (1 + i)/2$, which turns the right part of row 3 into $\frac{1}{2}(1 - i, -1 - i, 1 + i)$, and then adds -1 times row 3 to row 1 and $-i$ times row 3 to row 2. The result is

$$A^{-1} = \frac{1}{2}\begin{pmatrix} 1+i & 1-i & -1-i \\ -1-i & 1+i & 1-i \\ 1-i & -1-i & 1+i \end{pmatrix}.$$

Check: the first row of A times the first column of $2A^{-1}$ is $(1 + i) + i(-1 - i) = 1 + i - i + 1 = 2$, times the second column it is $(1 - i) + i(1 + i) = 0$, and times the third $(-1 - i) + i(1 - i) = 0$; the other rows are similar.

The matrix B. Pass 1 adds $-i$ times row 1 to row 3: the left part becomes $(i, 1, 0) - i(1, 0, i) = (0, 1, 1)$ and the right part $(-i, 0, 1)$. Pass 2 adds -1 times row 2 to row 3, which becomes $(0, 0, 0 \mid -i, -1, 1)$. The left block now has a zero row, so B is not invertible. The right part of the zero row says that $-i$ times row 1 of B, minus row 2, plus row 3, is zero:

$$-i(1, 0, i) - (0, 1, 1) + (i, 1, 0) = (0, 0, 1 - 1) = \mathbf{0}.$$

Solution to Exercise 3.3.42

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Theorem 3.3.23 (Invertibility and RREF)
Hint 1. Pass 1 works for every c. Write down the resulting rows 2 and 3.
Hint 2. They are $(0, c - 4, 0)$ and $(0, 0, c - 1)$. Split into cases according to which of $c - 4$ and $c - 1$ vanish. In $\mathbb{F}_3$, $4 = 1$.
Sketch. After pass 1 the rows are $(1, 2, 1)$, $(0, c - 4, 0)$, $(0, 0, c - 1)$. Over $\mathbb{R}$: $\operatorname{rref}(A_c) = I_3$ for $c \neq 1, 4$; $\operatorname{rref}(A_4)$ has rows $(1, 2, 0)$, $(0, 0, 1)$, $\mathbf{0}$; $\operatorname{rref}(A_1)$ has rows $(1, 0, 1)$, $(0, 1, 0)$, $\mathbf{0}$. Over $\mathbb{F}_3$, $c - 4 = c - 1$: $\operatorname{rref}(A_1)$ has rows $(1, 2, 1)$, $\mathbf{0}$, $\mathbf{0}$, and $\operatorname{rref}(A_c) = I_3$ for $c = 0, 2$.

Pass 1 adds -2 times row 1 to row 2 and -1 times row 1 to row 3, giving

$$\begin{pmatrix} 1 & 2 & 1 \\ 0 & c-4 & 0 \\ 0 & 0 & c-1 \end{pmatrix}.$$

(a) *If $c \neq 4$ and $c \neq 1$:* pass 2 scales row 2 by $(c - 4)^{-1}$, making it $(0, 1, 0)$, and adds -2 times it to row 1, which becomes $(1, 0, 1)$. Pass 3 scales row 3 to $(0, 0, 1)$ and subtracts it from row 1. So $\operatorname{rref}(A_c) = I_3$.

If $c = 4$: the rows are $(1, 2, 1)$, $(0, 0, 0)$, $(0, 0, 3)$. In pass 2, column 2 vanishes in rows 2 and 3, so the scan moves to column 3; the $(2, 3)$ entry is 0, so rows 2 and 3 are swapped. Scaling by $1/3$ and subtracting the new row 2 from row 1 gives

$$\operatorname{rref}(A_4) = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$

If $c = 1$: the rows are $(1, 2, 1)$, $(0, -3, 0)$, $(0, 0, 0)$. Pass 2 scales row 2 to $(0, 1, 0)$ and adds -2 times it to row 1, so

$$\operatorname{rref}(A_1) = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

By Theorem 3.3.23, A_c is invertible exactly when $c \neq 1$ and $c \neq 4$.

(b) In $\mathbb{F}_3$, $c - 4 = c - 1$, since $3 = 0$. If $c = 1$, rows 2 and 3 are both zero after pass 1, and

$$\operatorname{rref}(A_1) = \begin{pmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

If $c = 0$ or $c = 2$, then $c - 4 = c - 1 \neq 0$, and the computation of the first case of (a) applies verbatim: $\operatorname{rref}(A_c) = I_3$. So over $\mathbb{F}_3$, A_c is invertible exactly when $c \neq 1$.

Solution to Exercise 3.3.43

Uses. Corollary 3.3.18 (RREF and row equivalence), Theorem 3.3.12 (Matrices in RREF), Proposition 3.3.11 (Carrying extra columns along)
Hint 1. In each part, find a matrix in RREF that is row equivalent to the given one, and use Corollary 3.3.18(c).
Hint 2. For (b), $G(A \mid A) = (R \mid R)$. Check (R1)–(R4) for $(R \mid R)$: where are its leading entries?
Hint 3. For (c), first subtract each of the top rows from the corresponding bottom row.
Sketch. (a) Scaling every row by c turns A into cA, so $cA \sim A$. (b) $(A \mid A) \sim (R \mid R)$, whose nonzero rows have their leading entries in the left block, and whose pivot columns are those of R; so it satisfies (R1)–(R4). (c) Subtracting rows gives $\begin{pmatrix} A \\ 0 \end{pmatrix}$, and the run of the algorithm on A, performed on the top m rows, gives $\begin{pmatrix} R \\ 0 \end{pmatrix}$, which satisfies (R1)–(R4).

In each part we exhibit a matrix that satisfies (R1)–(R4) and is row equivalent to the given matrix; by Corollary 3.3.18(c) it is the reduced row echelon form.

(a) Scaling each of the m rows of A by c turns A into cA, so $cA \sim A \sim R$, and R is in RREF. So $\operatorname{rref}(cA) = R$.

(b) By Proposition 3.3.11(a), $G(A \mid A) = (GA \mid GA) = (R \mid R)$, so $(A \mid A) \sim (R \mid R)$. The nonzero rows of $(R \mid R)$ are the nonzero rows of R, in the same positions, and since the left block is R, their leading entries are the leading entries of R. So (R1), (R2), and (R3) hold for $(R \mid R)$ because they hold for R. The columns containing leading entries are the pivot columns of R, in the left block, and each of them is a standard basis vector; this is (R4). So $\operatorname{rref}((A \mid A)) = (R \mid R)$.

(c) For $i = 1, \ldots, m$, add -1 times row i to row $m + i$. This turns $\begin{pmatrix} A \\ A \end{pmatrix}$ into $\begin{pmatrix} A \\ 0 \end{pmatrix}$. Then perform the row operations of the run of Gauss–Jordan elimination on A, applied to rows $1, \ldots, m$ only; they turn $\begin{pmatrix} A \\ 0 \end{pmatrix}$ into $\begin{pmatrix} R \\ 0 \end{pmatrix}$. This matrix satisfies (R1)–(R4): its nonzero rows are those of R, at the top, and it is R with m zero rows appended. So $\operatorname{rref}\begin{pmatrix} A \\ A \end{pmatrix} = \begin{pmatrix} R \\ 0 \end{pmatrix}$.

Solution to Exercise 3.3.44

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.3.11 (Carrying extra columns along), Theorem 3.3.12 (Matrices in RREF), Corollary 3.3.18 (RREF and row equivalence)
Hint 1. Write $\operatorname{rref}((A \mid B)) = (S \mid T) = H(A \mid B)$ with H invertible. Then $S = HA$. It suffices to show that S is in RREF. Why?
Hint 2. Some nonzero rows of $(S \mid T)$ may have their leading entry in the right block. What do these rows look like in S, and where are they?
Hint 3. For (b), try $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$.
Sketch. $(S \mid T) = (HA \mid HB)$. The rows of $(S \mid T)$ whose leading entries lie in the left block come first, by (R3), and the remaining rows vanish in the left block; so S satisfies (R1)–(R4), with pivot columns the pivot columns of $(S \mid T)$ among $1, \ldots, n$. Then $S = \operatorname{rref}(HA) = \operatorname{rref}(A)$. For $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$, $B = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$: $\operatorname{rref}((A \mid B)) = I_2$, while $GB = (1, 1)$.

(a) By Theorem 3.3.10 and Proposition 3.3.11(a), $\operatorname{rref}((A \mid B)) = H(A \mid B) = (HA \mid HB)$ for some invertible H. Write $S = HA$ and $T = HB$. We show that S is in RREF; then $S = \operatorname{rref}(S) = \operatorname{rref}(HA) = \operatorname{rref}(A)$ by Corollary 3.3.18(a).

Let rows $1, \dots, r$ be the nonzero rows of $(S \mid T)$, with leading entries in columns $c_1 < \cdots < c_r$, and let t be the number of c_s that are at most n, so that $c_1, \dots, c_t \le n < c_{t+1}, \dots, c_r$. For $s \le t$, row s of S is nonzero, with the same leading entry as row s of $(S \mid T)$. For $s > t$, the leading entry of row s of $(S \mid T)$ is in the right block, so row s of S is zero; and rows $r+1, \dots, m$ of S are zero as well. So the nonzero rows of S are rows $1, \dots, t$, which is (R1), and (R2) and (R3) for S follow from (R2) and (R3) for $(S \mid T)$. Finally, for $s \le t$, column c_s of $(S \mid T)$ is $\mathbf{e}_s$ by (R2) and (R4), and it is a column of S. This is (R4) for S. By Theorem 3.3.12, S is in RREF.

(b) Let $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$. The run on A is the single operation $E_{1,-1,2}$, so $G = \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}$ and $GB = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$. But $(A \mid B) = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$ reduces to $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and then to I_2, whose last column is $\begin{pmatrix} 0 \\ 1 \end{pmatrix} \neq GB$. The full algorithm also pivots in the column of B, and then clears above that pivot.

Solution to Exercise 3.3.45

Uses. Corollary 3.3.18 (RREF and row equivalence), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Theorem 3.3.12 (Matrices in RREF)
Hint 1. Only one of the statements is true. Look for 2×2 counterexamples, or even 1×2 ones, with many zeros.
Hint 2. For (e), write $\operatorname{rref}(A) = GA$ with G invertible.
Sketch. (a) False for $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. (b) False for $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. (c) False for $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. (d) False for $\begin{pmatrix} 1 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 1 \end{pmatrix}$. (e) True: $\operatorname{rref}(A)B = G(AB)$, so Corollary 3.3.18(a) applies.

(a) False. Let $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. It satisfies (R1)–(R4), so $\operatorname{rref}(A) = A$ and $\operatorname{rref}(A)^{\mathsf{T}} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$, which violates (R1) and so is not even in RREF. In fact $\operatorname{rref}\left(A^{\mathsf{T}}\right) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.

(b) False. Let $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. Then $\operatorname{rref}(A) = A$, $\operatorname{rref}(B) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, and $\operatorname{rref}(A)\operatorname{rref}(B) = 0$. But $AB = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, which is its own reduced row echelon form.

(c) False. Let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} = E_{12}A$. Then $\operatorname{rref}(A) = \operatorname{rref}(B) = A$, but $\operatorname{im} T_A = \operatorname{span}(\mathbf{e}_1)$ and $\operatorname{im} T_B = \operatorname{span}(\mathbf{e}_2)$.

(d) False. Let $A = \begin{pmatrix} 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 1 \end{pmatrix}$ in $F^{1\times 2}$. Both images are all of F, but both matrices are in RREF and they are different.

(e) True. By Theorem 3.3.10, $\operatorname{rref}(A) = GA$ with G invertible, so $\operatorname{rref}(A)B = G(AB)$, and Corollary 3.3.18(a) gives $\operatorname{rref}(G(AB)) = \operatorname{rref}(AB)$.

Solution to Exercise 3.3.46

Uses. Theorem 3.3.17 (Uniqueness of the reduced row echelon form), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.4.33 (Block matrix), Definition 2.5.12 (Invertible)
Hint 1. Reread the statement proved by induction in the first proof of Theorem 3.3.17. For which s does it say anything about $\mathbf{g}_s$?
Hint 2. Try $R = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$.
Hint 3. For (b), show that $GR = R$ exactly when $G\mathbf{e}_s = \mathbf{e}_s$ for $s \le r$, and write G in block form.
Sketch. The induction gives $\mathbf{g}_s = \mathbf{e}_s$ only when $p_s \le n$, that is, for $s \le r$. Counterexample: $R = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, $G = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. In general $GR = R$ if and only if $G = \begin{pmatrix} I_r & X \\ 0 & Y \end{pmatrix}$, and such a G is invertible exactly when Y is.

(a) The induction in the first proof of Theorem 3.3.17 shows $p_s = q_s$ for all s, but $\mathbf{g}_s = \mathbf{e}_s$ only when $p_s \le n$, that is, for $s \le r$. It says nothing about the columns $\mathbf{g}_{r+1}, \dots, \mathbf{g}_m$, so the claim does not follow. It is false: for $R = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $G = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, G is invertible (with inverse $\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$) and $GR = R$, but $G \neq I_2$.

(b) Let $p_1 < \cdots < p_r$ be the pivot columns of R. If $GR = R$, then $G\mathbf{e}_s = G\mathbf{r}_{p_s} = \mathbf{r}_{p_s} = \mathbf{e}_s$ for $s \le r$ (Lemma 3.3.16(b)). Conversely, if $G\mathbf{e}_s = \mathbf{e}_s$ for $s \le r$, then by Lemma 3.3.16(a) (with $s = r$) every column of

R is a combination $\sum_{t\le r} c_t \mathbf{e}_t$, and G fixes it; so $GR = R$. Hence $GR = R$ if and only if the first r columns of G are $\mathbf{e}_1, \ldots, \mathbf{e}_r$, that is,

$$G = \begin{pmatrix} I_r & X \\ 0 & Y \end{pmatrix}$$

for some $X \in F^{r\times(m-r)}$ and $Y \in F^{(m-r)\times(m-r)}$.

Such a G is invertible if and only if Y is. If Y is invertible, block multiplication (Definition 2.4.33) shows that $\begin{pmatrix} I_r & -XY^{-1} \\ 0 & Y^{-1} \end{pmatrix}$ is a two-sided inverse of G. Conversely, let $H = \begin{pmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{pmatrix}$ be an inverse of G, in the same block sizes. The first block column of HG is $\begin{pmatrix} H_{11} \\ H_{21} \end{pmatrix}$, which must be $\begin{pmatrix} I_r \\ 0 \end{pmatrix}$, so $H_{21} = 0$. Then the lower right blocks of $HG = I_m$ and $GH = I_m$ say $H_{22}Y = I_{m-r}$ and $YH_{22} = I_{m-r}$. So Y is invertible.

So the invertible G with $GR = R$ are exactly the matrices $\begin{pmatrix} I_r & X \\ 0 & Y \end{pmatrix}$ with X arbitrary and Y invertible. Only when $r = m$ is $G = I_m$ forced.

Solution to Exercise 3.3.47

Uses. Lemma 3.3.7 (The loop invariant), Proposition 3.3.8 (Properties of the output)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Find the place in the proof of Lemma 3.3.7 where the choice of the *leftmost* column was used.
Hint 2. Run the modified algorithm on $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, choosing column 2 in the first pass.
Sketch. The proof used that rows $k+1, \ldots, m$ vanish to the left of the chosen column, which is what the leftmost choice guarantees; parts (b), (d), (e) of the invariant depend on it. Choosing column 2 first in $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ gives the output $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, which violates (R3).

The proof of Lemma 3.3.7 began with the observation that rows $k+1, \ldots, m$ vanish in the columns before the chosen column j. That is exactly what choosing the *leftmost* column guarantees, and parts (b), (d), and (e) were derived from it. With an arbitrary choice, none of them survives.

Counterexample: run the modified algorithm on $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, choosing column 2 in pass 1. The $(1,2)$ entry is already 1, so it becomes a pivot with $p_1 = 2$, and clearing column 2 adds -1 times row 1 to row 2, giving $\begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}$. In pass 2, the only unpivoted row is $(-1, 0)$, so $j = 1$; scaling by -1 gives $(1, 0)$, and clearing adds -1 times row 2 to row 1. The output is

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

which violates (R3), so it is not in RREF. (Here $p_1 = 2 > 1 = p_2$, so (b) of the invariant fails.)

What does survive is (a) and (c): the output is still row equivalent to A, and each pivot column is a standard basis vector, because a column $\mathbf{e}_s$ has zeros in all unpivoted rows whichever column is chosen next. Only the staircase is lost.

Solution to Exercise 3.3.48

Uses. Theorem 3.3.12 (Matrices in RREF), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Corollary 3.3.18 (RREF and row equivalence)
Hint 1. Sort the matrices in RREF by their set of pivot columns. Which entries are then forced, and which are free?
Hint 2. By Lemma 3.3.16(a), a non-pivot column has zeros below the rows of the pivots to its left, and is arbitrary in those rows.
Hint 3. For (b), how many matrices in RREF does a row equivalence class contain?
Sketch. No pivots: 1 matrix. One pivot in column 1, 2, 3: p^2, p, 1 matrices. Two pivots in columns $(1,2)$, $(1,3)$, $(2,3)$: p^2, p, 1. Total $1 + 2(p^2 + p + 1)$. By Corollary 3.3.18(b), each class contains exactly one matrix in RREF; for $p = 2$ there are 15 classes.

(a) By Theorem 3.3.12 we count the matrices satisfying (R1)–(R4), sorted by their pivot columns. The pivot columns are $\mathbf{e}_1, \mathbf{e}_2, \ldots$ in order, and by Lemma 3.3.16(a) a non-pivot column has zeros in every row below the rows of the pivots to its left, while its entries in those rows are arbitrary.

- No pivots: only the zero matrix. That is 1 matrix.
- One pivot, in column 1: $\begin{pmatrix} 1 & a & b \\ 0 & 0 & 0 \end{pmatrix}$, so p^2 matrices. In column 2: $\begin{pmatrix} 0 & 1 & a \\ 0 & 0 & 0 \end{pmatrix}$, so p. In column 3: $\begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$, so 1.
- Two pivots, in columns 1, 2: $\begin{pmatrix} 1 & 0 & a \\ 0 & 1 & b \end{pmatrix}$, so p^2. In columns 1, 3: $\begin{pmatrix} 1 & a & 0 \\ 0 & 0 & 1 \end{pmatrix}$, so p. In columns 2, 3: $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, so 1.

Each displayed matrix satisfies (R1)–(R4) for every choice of a, b. The total is $1 + 2\big(p^2 + p + 1\big) = 2p^2 + 2p + 3$.

(b) Every class contains a matrix in RREF, namely $\operatorname{rref}(A)$ for any A in it, and by Corollary 3.3.18(b) two matrices in RREF are row equivalent only if they are equal (as $\operatorname{rref}(R) = R$). So $R \mapsto$ (the class of R) is a bijection from the matrices in RREF to the classes, and there are $2p^2 + 2p + 3$ classes. For $p = 2$ this is 15.

Solution to Exercise 3.3.49

> *Uses.* Corollary 3.3.20 (The kernel is a complete invariant), Corollary 3.3.18 (RREF and row equivalence), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$)
> *Techniques.* Reduce to RREF (Technique 3.3.22)
> *Hint 1.* Find one matrix in RREF with this kernel.
> *Hint 2.* $R_0 = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix}$ works. By Corollary 3.3.20, A has the same kernel as R_0 exactly when $\operatorname{rref}(A) = R_0$. Which matrices have this reduced row echelon form?
> *Sketch.* The matrix R_0 is in RREF and has kernel $\operatorname{span}((1,1,1))$. By Corollary 3.3.20, $\ker T_A = \ker T_{R_0}$ if and only if $\operatorname{rref}(A) = R_0$, if and only if $A = HR_0$ with H invertible. So $A = \begin{pmatrix} a & b & -a-b \\ c & d & -c-d \end{pmatrix}$ with $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ invertible.

Let $R_0 = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix}$, which is in RREF. Its kernel consists of the $\mathbf{x}$ with $x_1 - x_3 = 0$ and $x_2 - x_3 = 0$, that is, $\mathbf{x} = x_3(1,1,1)$; so $\ker T_{R_0} = \operatorname{span}((1,1,1))$. By Corollary 3.3.20, $\ker T_A = \operatorname{span}((1,1,1))$ if and only if $\operatorname{rref}(A) = \operatorname{rref}(R_0) = R_0$.

If $\operatorname{rref}(A) = R_0$, then by Theorem 3.3.10, $GA = R_0$ with G invertible, so $A = G^{-1}R_0$. Conversely, if $A = HR_0$ with H invertible, then $\operatorname{rref}(A) = \operatorname{rref}(R_0) = R_0$ by Corollary 3.3.18(a). So the answer is the set of matrices

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix} = \begin{pmatrix} a & b & -a-b \\ c & d & -c-d \end{pmatrix}$$

with $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ invertible.

Solution to Exercise 3.3.50

> *Uses.* Definition 2.3.8 (Matrix–vector product), Corollary 3.3.20 (The kernel is a complete invariant), Exercise 3.2.46, Definition 1.3.10 (Span)
> *Techniques.* Reduce to RREF (Technique 3.3.22)
> *Hint 1.* The ith entry of $A\mathbf{x}$ is (row i of A) $\cdot\, \mathbf{x}$. How does $\mathbf{v} \cdot \mathbf{x}$ behave when $\mathbf{v}$ is a linear combination?
> *Hint 2.* For (b), one direction is Exercise 3.2.46. For the other, use (a) and Corollary 3.3.20.
> *Sketch.* (a) $A\mathbf{x} = \mathbf{0}$ says that every row is orthogonal to $\mathbf{x}$ in this sense, and $\mathbf{v} \mapsto \mathbf{v} \cdot \mathbf{x}$ respects linear combinations. (b) Row equivalent matrices have the same row space by Exercise 3.2.46. If the row spaces agree, (a) shows that the kernels agree, and Corollary 3.3.20 gives $A \sim B$.

(a) Let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be the rows of A. By Definition 2.3.8, the ith entry of $A\mathbf{x}$ is $a_{i1}x_1 + \cdots + a_{in}x_n = \mathbf{v}_i \cdot \mathbf{x}$, so $A\mathbf{x} = \mathbf{0}$ if and only if $\mathbf{v}_i \cdot \mathbf{x} = 0$ for all i. By distributivity, $(c\mathbf{u} + c'\mathbf{u}') \cdot \mathbf{x} = c(\mathbf{u} \cdot \mathbf{x}) + c'(\mathbf{u}' \cdot \mathbf{x})$, so if $\mathbf{v} = c_1\mathbf{v}_1 + \cdots + c_m\mathbf{v}_m$ and every $\mathbf{v}_i \cdot \mathbf{x} = 0$, then $\mathbf{v} \cdot \mathbf{x} = 0$. Conversely, each $\mathbf{v}_i$ lies in the row space. This proves (a).

(b) If $A \sim B$, they have the same row space by Exercise 3.2.46. Conversely, suppose A and B have the same row space. By (a), $\ker T_A$ and $\ker T_B$ are both the set of $\mathbf{x}$ with $\mathbf{v} \cdot \mathbf{x} = 0$ for all $\mathbf{v}$ in this common row space. So $\ker T_A = \ker T_B$, and $A \sim B$ by Corollary 3.3.20.

Solution to Exercise 3.3.51

Uses. Corollary 3.3.18 (RREF and row equivalence), Theorem 3.3.23 (Invertibility and RREF), Proposition 3.3.11 (Carrying extra columns along)
Hint 1. Work from the bottom up: for $i = n-1, n-2, \ldots, 1$, add $-a$ times row $i+1$ to row i. Any sequence of row operations that reaches $(I_n \mid C)$ will do, by Corollary 3.3.18(c).
Hint 2. Prove by downward induction on i what row i looks like after it has been processed.
Hint 3. For (b), U is the answer to (a) for $a = -1$.
Sketch. Processing rows from the bottom up, row i becomes $\left(\mathbf{e}_i^{\mathsf{T}} \mid \mathbf{c}_i\right)$ with $\mathbf{c}_i = \sum_{j \geq i} (-a)^{j-i} \mathbf{e}_j^{\mathsf{T}}$, because $\mathbf{e}_i^{\mathsf{T}} - a\mathbf{c}_{i+1} = \mathbf{c}_i$. So $H(B \mid I_n) = (I_n \mid C)$ for a product H of elementary matrices, and $B^{-1} = C$. For $a = -1$, (a) says that the matrix with 1 on the diagonal and -1 just above it has inverse U; so U^{-1} is that matrix.

(a) For $i = 1, \ldots, n$, let

$$\mathbf{c}_i = \sum_{j=i}^{n} (-a)^{j-i} \mathbf{e}_j^{\mathsf{T}},$$

the row vector we expect as row i of B^{-1}. For $i < n$, row i of $(B \mid I_n)$ has left part $\mathbf{e}_i^{\mathsf{T}} + a\mathbf{e}_{i+1}^{\mathsf{T}}$ and right part $\mathbf{e}_i^{\mathsf{T}}$. Row n has left part $\mathbf{e}_n^{\mathsf{T}}$ and right part $\mathbf{e}_n^{\mathsf{T}} = \mathbf{c}_n$.

For $i = n-1, n-2, \ldots, 1$ in this order, add $-a$ times row $i+1$ to row i. We claim that afterwards row i is $\left(\mathbf{e}_i^{\mathsf{T}} \mid \mathbf{c}_i\right)$. When row i is processed it has not been changed yet, and row $i+1$ is already $\left(\mathbf{e}_{i+1}^{\mathsf{T}} \mid \mathbf{c}_{i+1}\right)$ (for $i+1 = n$ this was noted above, and otherwise by induction). So row i becomes

$$\left(\mathbf{e}_i^{\mathsf{T}} + a\mathbf{e}_{i+1}^{\mathsf{T}} - a\mathbf{e}_{i+1}^{\mathsf{T}} \mid \mathbf{e}_i^{\mathsf{T}} - a\mathbf{c}_{i+1}\right) = \left(\mathbf{e}_i^{\mathsf{T}} \mid \mathbf{c}_i\right),$$

since

$$\mathbf{e}_i^{\mathsf{T}} - a \sum_{j \geq i+1} (-a)^{j-i-1} \mathbf{e}_j^{\mathsf{T}} = \mathbf{e}_i^{\mathsf{T}} + \sum_{j \geq i+1} (-a)^{j-i} \mathbf{e}_j^{\mathsf{T}} = \mathbf{c}_i.$$

At the end the matrix is $(I_n \mid C)$, where C has rows $\mathbf{c}_1, \ldots, \mathbf{c}_n$. Let H be the product of the elementary matrices used, so $H(B \mid I_n) = (HB \mid H) = (I_n \mid C)$. Since I_n is in RREF and $B \sim I_n$, Corollary 3.3.18(c) gives $\operatorname{rref}(B) = I_n$, and H is a product of elementary matrices with $HB = \operatorname{rref}(B)$. By Theorem 3.3.23, B is invertible and $B^{-1} = H = C$, whose (i,j) entry is $(-a)^{j-i}$ for $j \geq i$ and 0 otherwise.

(b) Take $a = -1$ in (a): the matrix B with 1 on the diagonal and -1 directly above it has inverse with entries $1^{j-i} = 1$ for $j \geq i$ and 0 below the diagonal, which is U. So $U = B^{-1}$ is invertible and $U^{-1} = B$: it has 1 on the diagonal, -1 in each position $(i, i+1)$, and 0 elsewhere.

Solution to Exercise 3.3.52

Uses. Definition 2.5.12 (Invertible), Definition 2.4.1 (Matrix product)
Hint 1. Row reduce for $n = 2$ and $n = 3$ over $\mathbb{Q}$ and look for a pattern.
Hint 2. Let J be the all-ones matrix, so $A = J - I_n$. Compute J^2, and look for an inverse of the form $\alpha J + \beta I_n$.
Hint 3. If $c = 0$, compute AJ.
Sketch. With J the all-ones matrix, $A = J - I_n$ and $J^2 = (n * 1)J$. If $c \neq 0$, then $c^{-1}J - I_n$ is a two-sided inverse of $J - I_n$, by direct multiplication. If $c = 0$, then $AJ = cJ = 0$ with $J \neq 0$, so A is not invertible. Over $\mathbb{F}_p$: invertible exactly when p does not divide $n-1$.

Let $J \in F^{n \times n}$ be the matrix all of whose entries are 1, so $A = J - I_n$. Each entry of J^2 is a sum of n products $1 \cdot 1$, so $J^2 = (n * 1)J = (c+1)J$.

Suppose $c \neq 0$, and let $C = c^{-1}J - I_n$. Then

$$AC = (J - I_n)\left(c^{-1}J - I_n\right) = c^{-1}J^2 - J - c^{-1}J + I_n = c^{-1}(c+1)J - J - c^{-1}J + I_n = I_n,$$

and the same computation, with the factors in the other order, gives $CA = I_n$ (all the matrices involved are combinations of J and I_n, which commute). So A is invertible and $A^{-1} = c^{-1}J - I_n$: its diagonal entries are $c^{-1} - 1$ and its other entries are c^{-1}. For instance, for $n = 3$ over $\mathbb{Q}$,

$$\begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{pmatrix}^{-1} = \frac{1}{2}\begin{pmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{pmatrix}.$$

Suppose $c = 0$. Then $AJ = J^2 - J = (c+1)J - J = cJ = 0$. If A were invertible, we would get $J = A^{-1}AJ = 0$, which is false. So A is not invertible. (This includes $n = 1$, where $A = (0)$.)

Over $\mathbb{F}_p$, $c = 0$ exactly when p divides $n - 1$. So A is invertible over $\mathbb{F}_p$ if and only if $n - 1$ is not a multiple of p; for example, over $\mathbb{F}_2$, if and only if n is even.

Solution to Exercise 3.3.53

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Theorem 3.3.23 (Invertibility and RREF), Definition 2.4.1 (Matrix product)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. For (a), show by induction on k that before pass k the current matrix is upper triangular, its first $k-1$ columns are $\mathbf{e}_1, \ldots, \mathbf{e}_{k-1}$, and rows $k, \ldots, n$ are still the rows of U.
Hint 2. In pass k the pivot is the (k,k) entry, and only rows above row k need clearing. Where is the off-diagonal entry of E_{kci} when $i < k$? Products of upper triangular matrices are upper triangular: check it entrywise.
Hint 3. For (b), take the first k with $u_{kk} = 0$, put $x_k = 1$ and $x_j = 0$ for $j > k$, and solve for $x_{k-1}, \ldots, x_1$ from the bottom up.
Sketch. (a) In pass k, rows $k, \ldots, n$ vanish in columns $1, \ldots, k-1$ and the (k,k) entry is $u_{kk} \neq 0$, so the pivot is (k,k) with no swap; the scaling is diagonal, and the replacements add multiples of row k to rows $i < k$, with elementary matrices E_{kci} whose extra entry (i,k) is above the diagonal. So $U^{-1} = G$ is a product of upper triangular matrices, and its diagonal is the product of their diagonals. (b) With k minimal and $u_{kk} = 0$, back substitution gives $\mathbf{x} \neq \mathbf{0}$ with $x_k = 1$ and $U\mathbf{x} = \mathbf{0}$.

(a) We show by induction on $k = 1, \ldots, n$ that before pass k, the current matrix M is upper triangular, its first $k-1$ columns are $\mathbf{e}_1, \ldots, \mathbf{e}_{k-1}$, and its rows $k, \ldots, n$ are those of U. For $k = 1$, $M = U$.

Assume this before pass k. Rows $k, \ldots, n$ of M vanish in columns $1, \ldots, k-1$ (as M is upper triangular), and the (k,k) entry is $u_{kk} \neq 0$. So step 1 of Algorithm 3.3.1 picks column k, and there is no swap. step 3 of Algorithm 3.3.1 multiplies by the diagonal matrix $E_{k,u_{kk}^{-1}}$. In column k, the rows $i > k$ have entry $u_{ik} = 0$, so step 4 of Algorithm 3.3.1 only changes rows $i < k$, using the matrices E_{kci} with $i < k$; the single off-diagonal entry of such a matrix is in position (i,k), above the diagonal. Adding a multiple of row k, which vanishes in columns $1, \ldots, k-1$, to a row $i < k$ changes it only in columns $k, \ldots, n$, all to the right of the diagonal entry (i,i). So after the pass, M is still upper triangular, column k is $\mathbf{e}_k$, columns $1, \ldots, k-1$ are unchanged, and rows $k+1, \ldots, n$ are untouched. This completes the induction.

After pass n the matrix is I_n, so $\operatorname{rref}(U) = I_n$, and by Theorem 3.3.23 U is invertible with $U^{-1} = G$, the product of the elementary matrices used. Each of them is upper triangular. If V and W are upper triangular, then $(VW)_{ij} = \sum_l v_{il} w_{lj}$ and a term can be nonzero only if $i \le l \le j$; so $(VW)_{ij} = 0$ for $i > j$, and $(VW)_{ii} = v_{ii} w_{ii}$. Hence G is upper triangular, and its diagonal is the entrywise product of the diagonals of its factors. The scaling in pass k has diagonal entry u_{kk}^{-1} in position k and 1 elsewhere, and the replacements have only 1s on the diagonal, so $G_{kk} = u_{kk}^{-1}$.

(b) Let k be the smallest index with $u_{kk} = 0$, so $u_{ii} \neq 0$ for $i < k$. Put $x_j = 0$ for $j > k$ and $x_k = 1$, and for $i = k-1, k-2, \ldots, 1$ in turn, put

$$x_i = -u_{ii}^{-1} \sum_{j=i+1}^{k} u_{ij} x_j.$$

Since U is upper triangular, entry i of $U\mathbf{x}$ is $\sum_{j \ge i} u_{ij} x_j$. For $i > k$ this involves only x_j with $j > k$, which are 0. For $i = k$ it is $u_{kk} \cdot 1 = 0$. For $i < k$ it is $u_{ii} x_i + \sum_{j=i+1}^{k} u_{ij} x_j = 0$ by the choice of x_i. So $U\mathbf{x} = \mathbf{0}$ with $\mathbf{x} \neq \mathbf{0}$. If U were invertible, then $\mathbf{x} = U^{-1}U\mathbf{x} = \mathbf{0}$. So U is not invertible.

Together, (a) and (b) show that an upper triangular matrix is invertible if and only if all its diagonal entries are nonzero.

Solution to Exercise 3.3.54

Uses. Definition 1.1.32 (Subfield), Algorithm 3.3.1 (Gauss–Jordan elimination), Theorem 3.3.23 (Invertibility and RREF), Corollary 3.3.18 (RREF and row equivalence)
Hint 1. Compare the two runs step by step. Which field operations does the algorithm use, and do they give the same results in F and in K?
Hint 2. For (b), run Algorithm 3.3.24 over F.
Hint 3. For (c), one direction is free. For the other, use (a) and Corollary 3.3.18(b) twice.
Sketch. The algorithm only tests entries for being 0, inverts nonzero entries, and adds and multiplies; a subfield is closed under these operations and computes them as K does. So by induction the runs over F and K perform the same operations. (b) Over K, $\operatorname{rref}(A) = I_n$; so the run over F gives $(I_n \mid G)$ with G over F, and $G = A^{-1}$. (c) $\operatorname{rref}_F(A) = \operatorname{rref}_K(A) = \operatorname{rref}_K(B) = \operatorname{rref}_F(B)$.

(a) By Definition 1.1.32, the sum and product of elements of F, computed in K, are their sum and product in F, and the inverse in K of a nonzero element of F lies in F and is its inverse there (inverses are unique). We show by induction on the number of operations performed that the runs of Algorithm 3.3.1 on A over F and over K perform the same operations, with the same current matrices, all of whose entries lie in F. At the start both current matrices are A. If the current matrices agree and have entries in F, then every decision of the next step (which column, whether an entry is 0, which row to swap) is the same, the scalars used (inverses and negatives of entries) are the same elements of F, and the operation produces the same matrix, with entries in F. So the outputs agree.

(b) Over K, A is invertible, so $\operatorname{rref}(A) = I_n$ by Theorem 3.3.23, and by (a) this also holds over F. Running Algorithm 3.3.24 over F produces $(I_n \mid G)$ with $G \in F^{n\times n}$ and $GA = I_n$, and by Theorem 3.3.23 G is the inverse of A, over F and hence over K (where inverses are unique).

(c) An elementary matrix over F is an elementary matrix over K, so row equivalence over F implies row equivalence over K. Conversely, if A and B are row equivalent over K, then by Corollary 3.3.18(b) over K and by (a),

$$\operatorname{rref}_F(A) = \operatorname{rref}_K(A) = \operatorname{rref}_K(B) = \operatorname{rref}_F(B),$$

where the subscript records the field used. By Corollary 3.3.18(b) over F, A and B are row equivalent over F.

Solution to Exercise 3.3.55

Uses. Proposition 3.3.11 (Carrying extra columns along), Corollary 3.3.18 (RREF and row equivalence), Theorem 3.3.23 (Invertibility and RREF)
Hint 1. Compute $\operatorname{rref}(A) = G_A A$ and $\operatorname{rref}(B) = G_B B$. When can $A \sim B$ hold, and how would you get from A to B?
Hint 2. If $G_A A = G_B B$, then $B = G_B^{-1} G_A A$. To compute $G_B^{-1} G_A$, you can row reduce $(G_B \mid G_A)$.
Sketch. Row reduce $(A \mid I_m)$ and $(B \mid I_m)$ to $(R_A \mid G_A)$ and $(R_B \mid G_B)$. If $R_A \neq R_B$, then A and B are not row equivalent. If $R_A = R_B$, then $G = G_B^{-1} G_A$ works. In (b), $G_A = \begin{pmatrix} 3 & -1 \\ -2 & 1 \end{pmatrix}$, $G_B = \begin{pmatrix} -2 & 1 \\ 1 & 0 \end{pmatrix}$, and $G = \begin{pmatrix} -2 & 1 \\ -1 & 1 \end{pmatrix}$.

(a) Row reduce $(A \mid I_m)$ and $(B \mid I_m)$, scanning only the first n columns. By Proposition 3.3.11 this gives $(R_A \mid G_A)$ and $(R_B \mid G_B)$ with $R_A = \operatorname{rref}(A) = G_A A$ and $R_B = \operatorname{rref}(B) = G_B B$, where G_A, G_B are invertible. If $R_A \neq R_B$, then A and B are not row equivalent, by Corollary 3.3.18(b). If $R_A = R_B$, then $G_A A = G_B B$, so $B = GA$ with $G = G_B^{-1} G_A$, which is invertible. To compute it, row reduce $(G_B \mid G_A)$, scanning only the first m columns: since G_B is invertible, $\operatorname{rref}(G_B) = I_m$, and the run's product is G_B^{-1} (Theorem 3.3.23), so the result is $\left(I_m \mid G_B^{-1} G_A\right)$ by Proposition 3.3.11.

(b) For A: adding -2 times row 1 to row 2 gives $\begin{pmatrix} 1 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix}$, and adding -1 times row 2 to row 1 gives $R_A = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \end{pmatrix}$. The same operations on I_2 give $G_A = \begin{pmatrix} 3 & -1 \\ -2 & 1 \end{pmatrix}$. For B: swapping the rows gives $\begin{pmatrix} 1 & 2 & 2 \\ 0 & 0 & 1 \end{pmatrix}$, and adding -2 times row 2 to row 1 gives $R_B = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \end{pmatrix} = R_A$. The same operations on I_2 give $G_B = \begin{pmatrix} -2 & 1 \\ 1 & 0 \end{pmatrix}$. So $A \sim B$. Since $G_B = E_{2,-2,1} E_{12}$, its inverse is $E_{12} E_{2,2,1} = \begin{pmatrix} 0 & 1 \\ 1 & 2 \end{pmatrix}$ (Corollary 3.2.11), and

$$G = G_B^{-1} G_A = \begin{pmatrix} 0 & 1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} 3 & -1 \\ -2 & 1 \end{pmatrix} = \begin{pmatrix} -2 & 1 \\ -1 & 1 \end{pmatrix}.$$

Check:

$$GA = \begin{pmatrix} -2+2 & -4+4 & -2+3 \\ -1+2 & -2+4 & -1+3 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 2 & 2 \end{pmatrix} = B.$$

Solution to Exercise 3.3.56

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Theorem 3.3.23 (Invertibility and RREF), Definition B.1.7 (Modulus)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Pass 1 is fine, since $a_{11} \neq 0$. Find an invariant that makes every later pass equally fine.
Hint 2. After pass 1, the entries in rows and columns $2, \dots, n$ are $a_{ij} - a_{i1}a_{1j}/a_{11}$. Show that this $(n-1) \times (n-1)$ block is again strictly diagonally dominant.
Hint 3. Bound $\sum_{j \geq 2, j \neq i} |a_{1j}|$ using row 1, and $\sum_{j \geq 2, j \neq i} |a_{ij}|$ using row i, and finish with $|x| - |y| \leq |x - y|$.
Sketch. Invariant before pass k: columns $1, \dots, k-1$ are $\mathbf{e}_1, \dots, \mathbf{e}_{k-1}$, rows $k, \dots, n$ vanish in those columns, and the block of rows and columns $k, \dots, n$ is strictly diagonally dominant. Then the (k,k) entry is a nonzero pivot, and the new block entries are $m_{ij} - m_{ik}m_{kj}/m_{kk}$. Bounding the off-diagonal entries of row i of the new block with the dominance of rows k and i and the triangle inequality shows that the new block is again strictly diagonally dominant. After n passes the matrix is I_n.

We show by induction on $k = 1, \dots, n$ that before pass k the current matrix M satisfies: (i) columns $1, \dots, k-1$ of M are $\mathbf{e}_1, \dots, \mathbf{e}_{k-1}$; (ii) rows $k, \dots, n$ of M vanish in columns $1, \dots, k-1$; (iii) the block $(m_{ij})_{k \leq i,j \leq n}$ is strictly diagonally dominant. For $k = 1$, $M = A$ and this is the hypothesis.

Assume (i)–(iii) before pass k. By (iii), $|m_{kk}| > \sum_{j>k, j \neq k} |m_{kj}| \geq 0$, so $m_{kk} \neq 0$. By (ii), the scan picks column k, and the (k,k) entry is nonzero, so there is no swap. The pass scales row k by m_{kk}^{-1} and then, for each $i \neq k$, adds $-m_{ik}$ times the new row k to row i. Row k vanishes in columns $1, \dots, k-1$ by (ii), so these columns do not change, and column k becomes $\mathbf{e}_k$. This gives (i) and (ii) for $k+1$. For $i, j > k$, the new entries are

$$m'_{ij} = m_{ij} - m_{ik}\frac{m_{kj}}{m_{kk}}.$$

To prove (iii) for $k+1$, fix $i > k$, and let $\sum'$ denote a sum over $j > k$ with $j \neq i$. The dominance of row k and of row i in the old block give

$$\sum{}' |m_{kj}| < |m_{kk}| - |m_{ki}|, \quad \sum{}' |m_{ij}| < |m_{ii}| - |m_{ik}|.$$

Using the triangle inequality and then these two bounds (the first multiplied by $|m_{ik}|/|m_{kk}| \geq 0$, so it may become an equality),

$$\begin{aligned} \sum{}' |m'_{ij}| &\leq \sum{}' |m_{ij}| + \frac{|m_{ik}|}{|m_{kk}|} \sum{}' |m_{kj}| \\ &< |m_{ii}| - |m_{ik}| + \frac{|m_{ik}|}{|m_{kk}|}(|m_{kk}| - |m_{ki}|) \\ &= |m_{ii}| - \left|\frac{m_{ik}m_{ki}}{m_{kk}}\right| \leq \left|m_{ii} - \frac{m_{ik}m_{ki}}{m_{kk}}\right| = |m'_{ii}|, \end{aligned}$$

where the last inequality is $|x| - |y| \leq |x - y|$. So the new block is strictly diagonally dominant, which completes the induction.

So every pass finds its pivot on the diagonal without a swap, and after pass n the matrix is I_n by (i). Hence $\operatorname{rref}(A) = I_n$, and A is invertible by Theorem 3.3.23.

Solution to Exercise 3.3.57

Uses. Definition 2.4.1 (Matrix product), Proposition 3.3.8 (Properties of the output), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.5.12 (Invertible)
Hint 1. The rows of G numbered $r+1, \dots, m$ are relations, since the corresponding rows of GA are zero.
Hint 2. Conversely, if $\mathbf{z}A = \mathbf{0}$, put $\mathbf{w} = \mathbf{z}G^{-1}$, so that $\mathbf{z} = \mathbf{w}G$ and $\mathbf{w} \operatorname{rref}(A) = \mathbf{0}$.

Hint 3. Look at the entries of $\mathbf{w}\,\mathrm{rref}(A)$ in the pivot columns.
Sketch. Row i of GA is (row i of G) A, so the last $m-r$ rows of G are relations, and so are their combinations. If $\mathbf{z}A=\mathbf{0}$, then $\mathbf{w}=\mathbf{z}G^{-1}$ satisfies $\mathbf{w}R=\mathbf{0}$ with $R=\mathrm{rref}(A)$; the entry of $\mathbf{w}R$ in column p_s is w_s, so $w_1=\cdots=w_r=0$, and $\mathbf{z}=\mathbf{w}G$ is a combination of rows $r+1,\ldots,m$ of G.

Let $R=\mathrm{rref}(A)=GA$ and let $\boldsymbol{\gamma}_1,\ldots,\boldsymbol{\gamma}_m$ be the rows of G. By Definition 2.4.1, row i of GA is $\boldsymbol{\gamma}_iA$, and $(c\mathbf{z}+c'\mathbf{z}')A=c\mathbf{z}A+c'\mathbf{z}'A$.

By Proposition 3.3.8(a), rows $r+1,\ldots,m$ of R are zero, so $\boldsymbol{\gamma}_iA=\mathbf{0}$ for $i>r$. Hence every linear combination of $\boldsymbol{\gamma}_{r+1},\ldots,\boldsymbol{\gamma}_m$ is a relation.

Conversely, let $\mathbf{z}A=\mathbf{0}$, and put $\mathbf{w}=\mathbf{z}G^{-1}$. Then $\mathbf{z}=\mathbf{w}G$, and

$$\mathbf{w}R=\mathbf{w}GA=\mathbf{z}A=\mathbf{0}.$$

Now $\mathbf{w}R$ is w_1 times row 1 of R, plus $\cdots$, plus w_m times row m of R. Let $p_1<\cdots<p_r$ be the pivot columns. Column p_s of R is $\mathbf{e}_s$ (Lemma 3.3.16(b)), so row i of R has entry 1 in column p_s if $i=s$ and 0 otherwise, and the entry of $\mathbf{w}R$ in column p_s is w_s. Hence $w_s=0$ for $s\le r$, and

$$\mathbf{z}=\mathbf{w}G=w_{r+1}\boldsymbol{\gamma}_{r+1}+\cdots+w_m\boldsymbol{\gamma}_m.$$

In the language of transposes, $\mathbf{z}A=\mathbf{0}$ says $A^{\mathsf{T}}\mathbf{z}^{\mathsf{T}}=\mathbf{0}$. So the transposes of the last $m-r$ rows of G span $\ker T_{A^{\mathsf{T}}}$, one of the four fundamental subspaces of Section 4.3.

Solution to Exercise 3.3.58

Uses. Theorem 3.3.12 (Matrices in RREF), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Corollary 3.3.18 (RREF and row equivalence)
Hint 1. Split according to whether the last column is a pivot column.
Hint 2. If column n is a pivot column, it must hold the last pivot. Delete the last row and the last column. If it is not, delete only the last column. In each case, what can the deleted column have been?
Hint 3. For (b), a class contains exactly one matrix in RREF, and a 2×4 matrix in RREF has 0, 1, or 2 nonzero rows, all at the top.
Sketch. If column n is a pivot column, it is the last one, so it is $\mathbf{e}_r$, row r is $(0,\ldots,0,1)$, and deleting row r and column n gives a bijection onto the $(r-1)\times(n-1)$ matrices in RREF without zero rows. Otherwise all r pivots lie in columns $1,\ldots,n-1$, those columns form an $r\times(n-1)$ matrix in RREF without zero rows, and column n is arbitrary: p^r choices. For $p=2$: $N(1,n)=2^n-1$, $N(2,3)=7$, $N(2,4)=4\cdot7+7=35$, and there are $1+15+35=51$ classes.

(a) Let R be an $r\times n$ matrix in RREF with no zero row. By Theorem 3.3.12, it has r pivots, one in each row, in columns $p_1<\cdots<p_r$.

Column n is a pivot column. Then $p_r=n$, column n is $\mathbf{e}_r$, and row r, whose leading entry is in column n, is $(0,\ldots,0,1)$. Deleting row r and column n leaves an $(r-1)\times(n-1)$ matrix R_0. Rows $1,\ldots,r-1$ of R have zero entries in column n, so they keep their leading entries, and R_0 satisfies (R1)–(R4) with no zero row. Conversely, for any such R_0, the matrix $\begin{pmatrix}R_0&0\\0&1\end{pmatrix}$ satisfies (R1)–(R4) with no zero row and has column n as a pivot column. So there are $N(r-1,n-1)$ matrices in this case.

Column n is not a pivot column. Then all r pivots lie in columns $1,\ldots,n-1$, and deleting column n leaves an $r\times(n-1)$ matrix in RREF without zero rows (the leading entries are unchanged). Conversely, given such a matrix, appending *any* column $\mathbf{c}\in\mathbb{F}_p^r$ gives a matrix satisfying (R1)–(R4): the leading entries are unchanged, and (R4) says nothing about a column without a leading entry. So there are $p^rN(r,n-1)$ matrices in this case. (When $r=n$ there are none, consistent with $N(n,n-1)=0$.)

Adding the two cases gives the recursion.

(b) With $p=2$: $N(1,1)=1$ and $N(1,n)=2N(1,n-1)+1$, so $N(1,2)=3$, $N(1,3)=7$, $N(1,4)=15$. Next $N(2,2)=4\cdot0+N(1,1)=1$, $N(2,3)=4\cdot1+3=7$, and

$$N(2,4)=4\cdot N(2,3)+N(1,3)=28+7=35.$$

A 2×4 matrix in RREF has $r \in \{0, 1, 2\}$ nonzero rows, which by (R1) are its top r rows, and they form an $r \times 4$ matrix in RREF without zero rows. So there are $N(0,4) + N(1,4) + N(2,4) = 1 + 15 + 35 = 51$ of them. As in Exercise 3.3.48, each row equivalence class contains exactly one matrix in RREF, so $\mathbb{F}_2^{2\times 4}$ has 51 classes.

The recursion is a p-analogue of Pascal's rule $\binom{n}{r} = \binom{n-1}{r} + \binom{n-1}{r-1}$. Using row spaces and dimension (Chapter 4), one can show that $N(r,n)$ is the number of r-dimensional subspaces of $\mathbb{F}_p^n$.

Solution to Exercise 3.3.59

Uses. Theorem 3.3.33 (PLU and LU factorizations), Theorem 3.3.37 (LDL^{T} factorization)
Hint 1. Run Gaussian elimination and record the multipliers; they are the entries of L below the diagonal.
Hint 2. For (b), the diagonal of U gives D. Here all its entries are equal.
Sketch. (a) The multipliers are $\ell_{21} = 3$, $\ell_{31} = -2$, $\ell_{32} = 3$, and U has rows $(1,2,0)$, $(0,1,2)$, $(0,0,-1)$. (b) The multipliers are $1/2$, $-1/2$, $1/2$, and U has diagonal $4,4,4$, so $D = 4I_3$ and $S = (2L)(2L)^{\mathsf{T}}$; the rows of $M = 2L$ are $(2,0,0)$, $(1,2,0)$, $(-1,1,2)$.

(a) Pass 1 uses the multipliers $\ell_{21} = 3$ and $\ell_{31} = -2$, leaving rows $(0,1,2)$ and $(0,3,5)$. Pass 2 uses $\ell_{32} = 3$, leaving $(0,0,-1)$. By Theorem 3.3.33(b),

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 3 & 1 & 0 \\ -2 & 3 & 1 \end{pmatrix} \begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & -1 \end{pmatrix}.$$

Check the last row:

$$-2(1,2,0) + 3(0,1,2) + (0,0,-1) = (-2,-1,5).$$

(b) Pass 1 uses $\ell_{21} = 2/4 = 1/2$ and $\ell_{31} = -2/4 = -1/2$, leaving rows $(0,4,2)$ and $(0,2,5)$. Pass 2 uses $\ell_{32} = 1/2$, leaving $(0,0,4)$. So

$$L = \begin{pmatrix} 1 & 0 & 0 \\ 1/2 & 1 & 0 \\ -1/2 & 1/2 & 1 \end{pmatrix}, \quad U = \begin{pmatrix} 4 & 2 & -2 \\ 0 & 4 & 2 \\ 0 & 0 & 4 \end{pmatrix},$$

and $D = 4I_3$. By Theorem 3.3.37, $S = L(4I_3)L^{\mathsf{T}}$; indeed $4L^{\mathsf{T}} = U$. So $S = (2L)(2L)^{\mathsf{T}} = MM^{\mathsf{T}}$ with

$$M = 2L = \begin{pmatrix} 2 & 0 & 0 \\ 1 & 2 & 0 \\ -1 & 1 & 2 \end{pmatrix}.$$

Check: the rows of M have pairwise products $4, 2, -2$ (row 1 with rows $1,2,3$), $1 + 4 = 5$, $-1 + 2 = 1$, and $1 + 1 + 4 = 6$, which are the entries of S.

Solution to Exercise 3.3.60

Uses. Lemma 3.3.32 (Products and inverses of triangular matrices), Exercise 3.3.53, Definition 2.5.12 (Invertible)
Hint 1. Suppose $L_1U_1 = L_2U_2$. Why are U_1 and U_2 invertible, and why is U_1^{-1} upper triangular?
Hint 2. Rearrange to $L_2^{-1}L_1 = U_2U_1^{-1}$, and look at both sides.
Sketch. $U_i = L_i^{-1}A$ is invertible, so by Exercise 3.3.53 it has nonzero diagonal entries and an upper triangular inverse. Then $L_2^{-1}L_1 = U_2U_1^{-1}$ is unit lower triangular and upper triangular, hence I_n.

Suppose $A = L_1U_1 = L_2U_2$ with L_1, L_2 unit lower triangular and U_1, U_2 upper triangular. By Lemma 3.3.32, L_i is invertible, so $U_i = L_i^{-1}A$ is invertible, as a product of invertible matrices. By Exercise 3.3.53(b), the diagonal entries of U_1 are nonzero, and then by Exercise 3.3.53(a), U_1^{-1} is upper triangular. Multiplying $L_1U_1 = L_2U_2$ on the left by L_2^{-1} and on the right by U_1^{-1} gives

$$L_2^{-1}L_1 = U_2U_1^{-1}.$$

By Lemma 3.3.32, the left side is unit lower triangular and the right side is upper triangular. A matrix that is both is diagonal, with the diagonal entries of the left side, which are 1. So $L_2^{-1}L_1 = I_n = U_2U_1^{-1}$, that is, $L_1 = L_2$ and $U_1 = U_2$.

Solution to Exercise 3.3.61

Uses. Exercise 3.2.54, Proposition 3.2.10 (Inverses of elementary matrices), Definition 2.4.33 (Block matrix), induction on n

Hint 1. (ii) ⇒ (i) is quick. For the converse, induct on n and imitate the first pass of Gauss–Jordan elimination, using only integer operations.

Hint 2. Let $B = A^{-1}$. The $(1,1)$ entry of $BA = I_n$ shows that the entries of the first column of A have greatest common divisor 1.

Hint 3. Use Exercise 3.2.54 on rows 1 and i, for $i = 2, \ldots, n$ in turn, to make the first column $\mathbf{e}_1$. Then show the lower right $(n-1)\times(n-1)$ block has an integer inverse.

Sketch. (ii) ⇒ (i): inverses of integer elementary matrices are integer elementary. (i) ⇒ (ii): the first column of A has gcd 1, because $\sum_k b_{1k}a_{k1} = 1$. Euclid's algorithm on pairs of rows, done with integer elementary matrices, gives $HA = \begin{pmatrix} 1 & \mathbf{w} \\ 0 & A' \end{pmatrix}$. This matrix has an integer inverse, and comparing blocks shows that A' has one too. By induction A' reduces to I_{n-1} by integer operations on rows $2, \ldots, n$, and integer replacements clear $\mathbf{w}$. So $PA = I_n$ for a product P of integer elementary matrices, and $A = P^{-1}$.

(ii) ⇒ (i). Integer elementary matrices have integer entries, and by Proposition 3.2.10 their inverses E_{ij}, $E_{i,-1}$, $E_{i(-c)j}$ are again integer elementary. If $A = E_1 \cdots E_k$ with all E_l integer elementary, then A is invertible with $A^{-1} = E_k^{-1} \cdots E_1^{-1}$, a product of integer matrices, so it has integer entries.

(i) ⇒ (ii). We show by induction on n that there is a product P of integer elementary matrices with $PA = I_n$; then $A = P^{-1}$ is a product of integer elementary matrices by the first part. For $n = 1$, $A = (a)$ with a and $1/a$ integers, so $a = \pm 1$, and $P = (1)$ or $P = E_{1,-1}$ works.

Let $n \geq 2$ and $B = A^{-1} \in \mathbb{Z}^{n\times n}$. The $(1,1)$ entry of $BA = I_n$ is $\sum_k b_{1k}a_{k1} = 1$, so every common divisor of $a_{11}, \ldots, a_{n1}$ divides 1. For $i = 2, \ldots, n$ in turn, if the current entries in positions $(1,1)$ and $(i,1)$ are not both 0, apply Exercise 3.2.54(b) to them: it gives 2×2 integer elementary matrices that turn this pair into (their gcd, 0), and acting on rows 1 and i only, they are $n \times n$ integer elementary matrices. Row operations of this kind do not change the set of common divisors of the entries of the first column (each new entry is an integer combination of old ones, and the operations can be undone by integer elementary matrices), so at the end the first column is $(g, 0, \ldots, 0)$, where $g \geq 1$ is a common divisor of the original entries; hence $g = 1$. So we have a product H_1 of integer elementary matrices with

$$H_1 A = \begin{pmatrix} 1 & \mathbf{w} \\ 0 & A' \end{pmatrix}, \quad \mathbf{w} \in \mathbb{Z}^{1\times(n-1)}, \quad A' \in \mathbb{Z}^{(n-1)\times(n-1)}.$$

This matrix is invertible with integer inverse $C = A^{-1}H_1^{-1}$. Write $C = \begin{pmatrix} c & \mathbf{x} \\ \mathbf{y} & C' \end{pmatrix}$ in the same block sizes. Comparing first block columns in $C(H_1A) = I_n$ gives $c = 1$ and $\mathbf{y} = \mathbf{0}$, and then the lower right blocks of $C(H_1A) = I_n$ and $(H_1A)C = I_n$ give $C'A' = I_{n-1}$ and $A'C' = I_{n-1}$. So A' is invertible with integer inverse C', and by the induction hypothesis there is a product P' of $(n-1)\times(n-1)$ integer elementary matrices with $P'A' = I_{n-1}$. Each factor F of P' gives the $n \times n$ integer elementary matrix $\begin{pmatrix} 1 & 0 \\ 0 & F \end{pmatrix}$ (with indices shifted by one), so $H_2 = \begin{pmatrix} 1 & 0 \\ 0 & P' \end{pmatrix}$ is a product of integer elementary matrices, and $H_2H_1A = \begin{pmatrix} 1 & \mathbf{w} \\ 0 & I_{n-1} \end{pmatrix}$. Finally, adding $-w_j$ times row $j+1$ to row 1, for $j = 1, \ldots, n-1$, clears $\mathbf{w}$ with integer replacements. This gives $PA = I_n$ with P a product of integer elementary matrices.

For the matrix of Example 3.3.25, which has an integer inverse, this explains why fractions could have been avoided there.

Section 3.4

Solution to Exercise 3.4.7

Uses. Proposition 3.4.1 (Solving with the reduced matrix), Corollary 3.4.4 (Consistency), Theorem 3.4.3 (Solving a system in reduced form)
Hint 1. Reduce $(A \mid \mathbf{y})$ with symbolic y_1, y_2, y_3. The first column is zero, so the first pivot is in column 2.
Hint 2. The first column is a free column. Its variable x_1 appears in no equation at all.
Sketch. A_r has rows $(0,1,2,0)$, $(0,0,0,1)$, $\mathbf{0}$, so x_2, x_4 are pivot variables and x_1, x_3 are free. The last entry of $G\mathbf{y}$ is $-3y_1 + y_2 + y_3$, so the system is consistent iff $y_2 + y_3 = 3y_1$. For $\mathbf{y} = (1,2,1)$: $x_2 = 1 - 2x_3$, $x_4 = 0$, with x_1, x_3 arbitrary.

We reduce $(A \mid \mathbf{y})$. Column 1 is zero, so pass 1 uses the pivot in position $(1,2)$: add -2 times row 1 to row 2 and -1 times row 1 to row 3. In pass 2, column 3 vanishes in rows 2 and 3, so the pivot is in position $(2,4)$; add -1 times row 2 to row 1 and row 2 to row 3:

$$\left(\begin{array}{cccc|c} 0 & 1 & 2 & 1 & y_1 \\ 0 & 2 & 4 & 3 & y_2 \\ 0 & 1 & 2 & 0 & y_3 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|c} 0 & 1 & 2 & 1 & y_1 \\ 0 & 0 & 0 & 1 & -2y_1 + y_2 \\ 0 & 0 & 0 & -1 & -y_1 + y_3 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|c} 0 & 1 & 2 & 0 & 3y_1 - y_2 \\ 0 & 0 & 0 & 1 & -2y_1 + y_2 \\ 0 & 0 & 0 & 0 & -3y_1 + y_2 + y_3 \end{array}\right).$$

So A_r has rows $(0,1,2,0)$, $(0,0,0,1)$, $(0,0,0,0)$, the pivot variables are x_2 and x_4, and the free variables are x_1 and x_3. By Corollary 3.4.4 the system is consistent if and only if $-3y_1 + y_2 + y_3 = 0$.

For $\mathbf{y} = (1,2,1)$ the condition holds $(-3 + 2 + 1 = 0)$, and the reduced system is $x_2 + 2x_3 = 1$, $x_4 = 0$. By Theorem 3.4.3(b), the solutions are the vectors $(x_1, 1 - 2x_3, x_3, 0)$ with $x_1, x_3 \in \mathbb{R}$ arbitrary. The unknown x_1 multiplies the zero column, so it occurs in no equation, and it is free for the most obvious reason. As a check, $A(0,1,0,0)$ is the second column $(1,2,1)$.

Solution to Exercise 3.4.18

Uses. Proposition 3.4.15 (A pivot in every column), Proposition 3.4.16 (A pivot in every row)
Hint 1. Locate the pivots. Is there a column without one? A row without one?
Hint 2. A column without a pivot is a free variable, which gives a nontrivial solution of $A\mathbf{x} = \mathbf{0}$. A row without a pivot is a zero row, which makes some $A\mathbf{x} = \mathbf{y}$ inconsistent.
Sketch. R_1: a pivot in every row but not in column 3, so always consistent, with nontrivial homogeneous solutions. R_2: a pivot in every column but not in row 3, so only the trivial solution, but not always consistent. R_3: neither. R_4: both.

By Proposition 3.4.15, $A\mathbf{x} = \mathbf{0}$ has only the trivial solution exactly when every column of A_r has a pivot, and by Proposition 3.4.16, $A\mathbf{x} = \mathbf{y}$ is consistent for every $\mathbf{y}$ exactly when every row has a pivot.

- R_1 has pivots in columns $1, 2$ and in both rows. Column 3 is free, so $A\mathbf{x} = \mathbf{0}$ has a nontrivial solution (for instance the basic solution $(-3, 1, 1)$), and $A\mathbf{x} = \mathbf{y}$ is consistent for every $\mathbf{y}$.
- R_2 has pivots in both columns but not in row 3. So $A\mathbf{x} = \mathbf{0}$ has only the trivial solution, but $A\mathbf{x} = \mathbf{y}$ is inconsistent for some $\mathbf{y}$.
- R_3 has pivots in columns $1, 3$ and rows $1, 2$. Column 2 and row 3 have none, so both properties fail.
- $R_4 = I_3$ has a pivot in every row and every column, so both properties hold.

Solution to Exercise 3.4.29

Uses. Definition 3.4.26 (Lagrange polynomials), Proposition 3.4.27 (Lagrange's formula), Theorem 3.4.24 (Polynomial interpolation)
Hint 1. Each L_i is the solution of a 3×3 system. Alternatively, guess L_i (for instance from the closed form previewed in Example 3.4.28) and check its values at the three nodes.
Hint 2. For (b), check whether the answer to (a) still makes sense with coefficients in $\mathbb{F}_5$, and quote uniqueness.
Sketch. $L_0 = 1 - \frac{4}{3}x + \frac{1}{3}x^2$, $L_1 = \frac{3}{2}x - \frac{1}{2}x^2$, $L_2 = -\frac{1}{6}x + \frac{1}{6}x^2$, and $p = 2L_0 - L_1 + 5L_2 = 2 - 5x + 2x^2$. Over $\mathbb{F}_5$, $2 - 5x + 2x^2 = 2 + 2x^2$ takes the values $2, 4 = -1, 20 = 0 = 5$, so it is the answer by uniqueness.

(a) Expanding the closed form of Example 3.4.28 suggests the candidates

$$L_0 = 1 - \frac{4}{3}x + \frac{1}{3}x^2, \quad L_1 = \frac{3}{2}x - \frac{1}{2}x^2, \quad L_2 = -\frac{1}{6}x + \frac{1}{6}x^2.$$

We check the values directly. $L_0(0) = 1, L_0(1) = 1 - \frac{4}{3} + \frac{1}{3} = 0, L_0(3) = 1 - 4 + 3 = 0$; $L_1(0) = 0, L_1(1) = \frac{3}{2} - \frac{1}{2} = 1$, $L_1(3) = \frac{9}{2} - \frac{9}{2} = 0$; $L_2(0) = 0$, $L_2(1) = 0$, $L_2(3) = -\frac{1}{2} + \frac{3}{2} = 1$. Each has degree at most 2, so by the uniqueness in Theorem 3.4.24 these are the Lagrange polynomials. By Proposition 3.4.27,

$$p = 2L_0 - L_1 + 5L_2 = 2 + \left(-\frac{8}{3} - \frac{3}{2} - \frac{5}{6}\right)x + \left(\frac{2}{3} + \frac{1}{2} + \frac{5}{6}\right)x^2 = 2 - 5x + 2x^2.$$

Check: $p(0) = 2$, $p(1) = 2 - 5 + 2 = -1$, $p(3) = 2 - 15 + 18 = 5$.

(b) In $\mathbb{F}_5$ the nodes $0, 1, 3$ are still distinct, so there is exactly one such p by Theorem 3.4.24. The polynomial $2 - 5x + 2x^2 = 2 + 2x^2$ has coefficients in $\mathbb{F}_5$, and its values are 2, $4 = -1$, and $2 + 18 = 20 = 0 = 5$ in $\mathbb{F}_5$. So $p = 2 + 2x^2$. (Reducing the answer over $\mathbb{Q}$ worked because the computation only divided by 2, 3, and 6, which are invertible in $\mathbb{F}_5$.)

Solution to Exercise 3.4.30

Uses. Algorithm 3.4.13 (Solving a linear system), Corollary 3.4.4 (Consistency), Theorem 3.4.9 (All solutions)
Hint 1. Row reduce $(A \mid \mathbf{y})$ with symbolic y_1, y_2, y_3. No swaps or scalings are needed.
Hint 2. The pivot columns are 1 and 3. The basic solutions come from columns 2, 4, 5 of A_r.
Sketch. The reduction gives rows $(1, 2, 0, 1, 3 \mid y_1)$, $(0, 0, 1, 2, 1 \mid -2y_1 + y_2)$, $(\mathbf{0} \mid 3y_1 - y_2 + y_3)$. (a) Consistent iff $y_2 = 3y_1 + y_3$. (b) $\mathbf{x}_0 = (1, 0, 1, 0, 0)$, $\mathbf{s}_1 = (-2, 1, 0, 0, 0)$, $\mathbf{s}_2 = (-1, 0, -2, 1, 0)$, $\mathbf{s}_3 = (-3, 0, -1, 0, 1)$.

(a) Add -2 times row 1 to row 2 and row 1 to row 3. Then column 2 vanishes below row 1, so the next pivot is in position $(2, 3)$; add -1 times row 2 to row 3. Row 1 already has a 0 in column 3. The result is

$$\left(\begin{array}{ccccc|c} 1 & 2 & 0 & 1 & 3 & y_1 \\ 0 & 0 & 1 & 2 & 1 & -2y_1 + y_2 \\ 0 & 0 & 0 & 0 & 0 & 3y_1 - y_2 + y_3 \end{array}\right).$$

So $k = 2$, and by Corollary 3.4.4 the system is consistent if and only if $3y_1 - y_2 + y_3 = 0$, that is, $y_2 = 3y_1 + y_3$.

(b) For $\mathbf{y} = (1, 3, 0)$ the last entry is $3 - 3 + 0 = 0$, and the last column becomes $(1, 1, 0)$. The pivot columns are $1, 3$ and the free columns $2, 4, 5$. Following Algorithm 3.4.13: $\mathbf{x}_0$ has $1, 1$ in positions $1, 3$, and the basic solutions come from columns 2, 4, 5 of A_r, which are $(2, 0, 0)$, $(1, 2, 0)$, $(3, 1, 0)$. So

$$\mathbf{x}_0 = \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \quad \mathbf{s}_1 = \begin{pmatrix} -2 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad \mathbf{s}_2 = \begin{pmatrix} -1 \\ 0 \\ -2 \\ 1 \\ 0 \end{pmatrix}, \quad \mathbf{s}_3 = \begin{pmatrix} -3 \\ 0 \\ -1 \\ 0 \\ 1 \end{pmatrix},$$

and the solution set is $\mathbf{x}_0 + \operatorname{span}(\mathbf{s}_1, \mathbf{s}_2, \mathbf{s}_3)$. As a check,

$$A\mathbf{x}_0 = \mathbf{a}_1 + \mathbf{a}_3 = (1, 2, -1) + (0, 1, 1) = (1, 3, 0),$$
$$A\mathbf{s}_3 = -3\mathbf{a}_1 - \mathbf{a}_3 + \mathbf{a}_5 = (-3, -6, 3) - (0, 1, 1) + (3, 7, -2) = \mathbf{0}.$$

Solution to Exercise 3.4.31

Uses. Algorithm 3.4.13 (Solving a linear system), Theorem 3.4.9 (All solutions), Corollary 3.4.14 (Counting solutions)
Hint 1. Reduce $(A \mid \mathbf{y})$; the first two passes are the same over both fields. Over $\mathbb{F}_2$, remember that $-1 = 1$ and $2 = 0$.
Hint 2. Over $\mathbb{Q}$ there are three pivots and one free variable; over $\mathbb{F}_2$ there are two of each.
Sketch. Over $\mathbb{Q}$, $(A \mid \mathbf{y})$ reduces to rows $(1, 0, 0, 0 \mid 1)$, $(0, 1, 0, 1 \mid 0)$, $(0, 0, 1, 0 \mid 0)$, so the solutions are $(1, 0, 0, 0) + t(0, -1, 0, 1)$. Over $\mathbb{F}_2$ it reduces to $(1, 0, 1, 0 \mid 1)$, $(0, 1, 1, 1 \mid 0)$, $(\mathbf{0} \mid 0)$, and there are $2^2 = 4$ solutions: $(1, 0, 0, 0)$, $(0, 1, 1, 0)$, $(1, 1, 0, 1)$, $(0, 0, 1, 1)$.

Pass 1 adds -1 times row 1 to row 3, and pass 2 adds -1 times row 2 to row 1 and row 2 to row 3:

$$\left(\begin{array}{cccc|c} 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 0 \\ 1 & 0 & 1 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|c} 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & -1 & 1 & -1 & 0 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|c} 1 & 0 & -1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 2 & 0 & 0 \end{array}\right).$$

Over $\mathbb{Q}$. Pass 3 scales row 3 by $1/2$, then adds row 3 to row 1 and -1 times row 3 to row 2, giving

$$\left(\begin{array}{cccc|c} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 \end{array}\right).$$

The pivot columns are $1, 2, 3$ and x_4 is free. So $\mathbf{x}_0 = (1, 0, 0, 0)$, $\mathbf{s}_1 = (0, -1, 0, 1)$, and the solutions are $(1, -t, 0, t)$ for $t \in \mathbb{Q}$: infinitely many.

Over $\mathbb{F}_2$. Here $-1 = 1$ and $2 = 0$, so the last matrix above is

$$\left(\begin{array}{cccc|c} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

which is in RREF. The last entry of the right side is 0, so the system is consistent. The pivot variables are x_1, x_2 and the free variables x_3, x_4, with $x_1 = 1 + x_3$ and $x_2 = x_3 + x_4$ (again since $-1 = 1$). The four choices of (x_3, x_4) give the solutions

$$(1, 0, 0, 0), \quad (0, 1, 1, 0), \quad (1, 1, 0, 1), \quad (0, 0, 1, 1).$$

That is 2^2 solutions, as Corollary 3.4.14(b) predicts with $q = 2$ and $\ell = 2$.

Solution to Exercise 3.4.32

Uses. Algorithm 3.4.13 (Solving a linear system), Corollary 3.4.4 (Consistency), Theorem 3.4.9 (All solutions)
Hint 1. Pass 1 adds $-i$ times row 1 to row 2. Remember $i^2 = -1$.
Hint 2. The coefficient matrix has pivot columns $1, 3$. For (c), when is $1 - it$ real for $t \in \mathbb{C}$ with t itself real?
Sketch. The reduction gives rows $(1, i, 0 \mid y_1)$, $(0, 0, 1 \mid -iy_1 + y_2)$, $(0, 0, 0 \mid iy_1 - y_2 + y_3)$. (a) $(1, 0, 2) + t(-i, 1, 0)$, $t \in \mathbb{C}$. (b) $iy_1 - y_2 + y_3 = 0$. (c) Only $(1, 0, 2)$.

Pass 1 adds $-i$ times row 1 to row 2: the new row 2 is

$$(i, -1, 1) - i(1, i, 0) = \left(0, -1 - i^2, 1\right) = (0, 0, 1),$$

with right side $y_2 - iy_1$. Then column 2 vanishes below row 1, so pass 2 uses the pivot in position $(2, 3)$ and adds -1 times row 2 to row 3:

$$\left(\begin{array}{ccc|c} 1 & i & 0 & y_1 \\ 0 & 0 & 1 & -iy_1 + y_2 \\ 0 & 0 & 0 & iy_1 - y_2 + y_3 \end{array}\right).$$

(a) For $\mathbf{y} = (1, 2 + i, 2)$ the right side is $(1, -i + 2 + i, i - 2 - i + 2) = (1, 2, 0)$. The pivot variables are x_1, x_3 and x_2 is free, with $x_1 = 1 - ix_2$ and $x_3 = 2$. So the solutions are

$$(1, 0, 2) + t(-i, 1, 0), \quad t \in \mathbb{C}.$$

Check: the left sides at $(-i, 1, 0)$ are $-i + i = 0$, $1 - 1 + 0 = 0$, and 0.

(b) By Corollary 3.4.4, exactly when $iy_1 - y_2 + y_3 = 0$.

(c) The solution with parameter t is $(1 - it, t, 2)$. If it is real, then $t = x_2$ is real, and then $1 - it$ is real only if $t = 0$. So $(1, 0, 2)$ is the only real solution. The complex solution set is a line in $\mathbb{C}^3$, and it meets $\mathbb{R}^3$ in a single point.

Solution to Exercise 3.4.33

Uses. Algorithm 3.4.13 (Solving a linear system), Corollary 3.4.4 (Consistency), Corollary 3.4.14 (Counting solutions)
Hint 1. Subtract row 1 from row 2 and a times row 1 from row 3. When can you use the $(2, 2)$ entry $a - 1$ as a pivot?
Hint 2. For $a \neq 1$, after clearing column 2 the last row is $(0, 0, (1 - a)(2 + a) \mid b - a)$. Treat $a = 1$ and $a = -2$ separately. In $\mathbb{F}_3$, $-2 = 1$.

Sketch. For $a \neq 1$ the reduction reaches rows $(1, 1, a \mid 1)$, $(0, 1, -1 \mid 0)$, $(0, 0, (1-a)(2+a) \mid b-a)$. Over $\mathbb{R}$: one solution if $a \neq 1, -2$; for $a = -2$, none if $b \neq -2$ and infinitely many if $b = -2$; for $a = 1$, none if $b \neq 1$ and infinitely many if $b = 1$. Over $\mathbb{F}_3$, $a = -2$ is $a = 1$: for $a = 1$ there are 9 solutions if $b = 1$ and none otherwise; for $a = 0, 2$ exactly one.

Adding -1 times row 1 to row 2 and $-a$ times row 1 to row 3 gives

$$\left(\begin{array}{ccc|c} 1 & 1 & a & 1 \\ 0 & a-1 & 1-a & 0 \\ 0 & 1-a & 1-a^2 & b-a \end{array}\right).$$

Case $a = 1$. Rows 2 and 3 become $(0, 0, 0 \mid 0)$ and $(0, 0, 0 \mid b-1)$, and the left block is in RREF with one pivot. If $b \neq 1$, the system is inconsistent. If $b = 1$, it is consistent with $\ell = 2$ free variables x_2, x_3.

Case $a \neq 1$. Scale row 2 by $(a-1)^{-1}$ to get $(0, 1, -1 \mid 0)$, and add $-(1-a)$ times it to row 3, which becomes

$$\big(0, 0, 1 - a^2 + (1-a) \mid b-a\big) = (0, 0, (1-a)(2+a) \mid b-a).$$

If $(1-a)(2+a) \neq 0$, this entry is a third pivot, and there are pivots in every column and every row; by Corollary 3.4.20 the system has exactly one solution. If $(1-a)(2+a) = 0$, then since $a \neq 1$ we have $2 + a = 0$, and the last row is $(0, 0, 0 \mid b-a)$: the system is inconsistent if $b \neq a$, and consistent with one free variable x_3 if $b = a$.

(a) Over $\mathbb{R}$, $2 + a = 0$ means $a = -2$. So the system has exactly one solution if $a \neq 1$ and $a \neq -2$; no solution if $a = 1, b \neq 1$ or $a = -2, b \neq -2$; and infinitely many (by Corollary 3.4.14(c)) if $(a, b) = (1, 1)$ or $(a, b) = (-2, -2)$.

(b) Over $\mathbb{F}_3$, $-2 = 1$, so the case $2 + a = 0$ with $a \neq 1$ never occurs. For $a = 1$: if $b = 1$ there are $3^2 = 9$ solutions by Corollary 3.4.14(b), and if $b \neq 1$ there are none. For $a = 0$ and $a = 2$, $(1-a)(2+a)$ equals 2 and $(-1)(4) = -1 = 2$, both nonzero, so there is exactly one solution for every b. The two exceptional values 1 and -2 of the real case collide in $\mathbb{F}_3$.

Solution to Exercise 3.4.34

Uses. Theorem 3.4.9 (All solutions), Remark 3.4.12 (Checking a description of the solutions), Proposition 3.1.19 (Solution sets are translates of the kernel)
Hint 1. Student 1 proved one containment. Which one? Compare the description with Example 3.4.10.
Hint 2. Every solution is $\mathbf{x}_0 + t_1\mathbf{s}_1 + t_2\mathbf{s}_2$. Is $\mathbf{x}_0 + \mathbf{s}_1$ in Student 1's set? For Student 2, express the new vectors through $\mathbf{x}_0, \mathbf{s}_1, \mathbf{s}_2$.
Sketch. (a) The check shows only that the line consists of solutions, not that it contains all of them; the solution set is a plane. The solution $(-3, 1, 2, 0) = \mathbf{x}_0 + \mathbf{s}_1$ is missing: its second and fourth coordinates would force $t = 1$ and $t = 0$. (b) Right: $(1, -1, 2, 0) = \mathbf{x}_0 - \mathbf{s}_1$ is a solution, $(0, 1, -2, 1) = \mathbf{s}_1 + \mathbf{s}_2$ and $(4, -1, -2, 1) = \mathbf{s}_2 - \mathbf{s}_1$ lie in $\ker T_A$, and $\mathbf{s}_1, \mathbf{s}_2$ are combinations of these two vectors.

By Example 3.4.10, the solution set is $\mathbf{x}_0 + \operatorname{span}(\mathbf{s}_1, \mathbf{s}_2)$ with $\mathbf{x}_0 = (-1, 0, 2, 0)$, $\mathbf{s}_1 = (-2, 1, 0, 0)$, and $\mathbf{s}_2 = (2, 0, -2, 1)$.

(a) Student 1 showed that every vector of the line $(-1, 0, 2, 0) + \operatorname{span}((0, 1, -2, 1))$ is a solution. That is one containment; the claim "the solution set is" needs the other one too, and it is false (Remark 3.4.12). For instance $\mathbf{x}_0 + \mathbf{s}_1 = (-3, 1, 2, 0)$ is a solution. If it were $(-1, 0, 2, 0) + t(0, 1, -2, 1)$, comparing second coordinates would give $t = 1$ and comparing fourth coordinates $t = 0$. So Student 1 has missed it. The solution set is a plane, with two free variables, and a line cannot be all of it.

(b) Student 2 is right. First, $(1, -1, 2, 0) = \mathbf{x}_0 - \mathbf{s}_1$ is a solution, and $(0, 1, -2, 1) = \mathbf{s}_1 + \mathbf{s}_2$ and $(4, -1, -2, 1) = \mathbf{s}_2 - \mathbf{s}_1$ lie in $\ker T_A$. Since $\ker T_A$ is a subspace, Student 2's set is contained in the solution set. Conversely, with $\mathbf{u}_1 = \mathbf{s}_1 + \mathbf{s}_2$ and $\mathbf{u}_2 = \mathbf{s}_2 - \mathbf{s}_1$, we have

$$\mathbf{s}_1 = \frac{1}{2}(\mathbf{u}_1 - \mathbf{u}_2), \quad \mathbf{s}_2 = \frac{1}{2}(\mathbf{u}_1 + \mathbf{u}_2),$$

so $\mathbf{s}_1, \mathbf{s}_2 \in \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$, and every solution

$$\mathbf{x}_0 + t_1\mathbf{s}_1 + t_2\mathbf{s}_2 = (\mathbf{x}_0 - \mathbf{s}_1) + (t_1 + 1)\mathbf{s}_1 + t_2\mathbf{s}_2$$

lies in $(1, -1, 2, 0) + \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$. (This uses $1 + 1 \neq 0$, which holds in $\mathbb{Q}$. In characteristic 2 we would have $\mathbf{u}_1 = \mathbf{u}_2$, and Student 2's set would only be a line.)

Solution to Exercise 3.4.35

Uses. Corollary 3.1.22 (Uniqueness depends only on A), Proposition 3.4.15 (A pivot in every column), Proposition 3.4.16 (A pivot in every row), Definition 2.3.8 (Matrix–vector product)
Hint 1. (a): uniqueness for one right-hand side is a statement about $\ker T_A$ (Corollary 3.1.22).
Hint 2. For (c), translate both statements into homogeneous systems with Proposition 3.4.15, and pad a solution for B with zeros. For (b) and (d), look at 1×2 and 2×1 matrices.
Sketch. (a) True: by Corollary 3.1.22, $\ker T_A = \{\mathbf{0}\}$, then Proposition 3.4.15. (b) False: the 2×1 matrix with column $(1, 0)$, and $\mathbf{y} = \mathbf{e}_2$. (c) True: a nontrivial solution of $B\mathbf{x} = \mathbf{0}$, padded with zeros in the deleted positions, is a nontrivial solution of $A\mathbf{x} = \mathbf{0}$. (d) False: $A = \begin{pmatrix} 0 & 1 \end{pmatrix}$, delete column 2.

(a) True. By Corollary 3.1.22(a), applied to the consistent system with exactly one solution, $\ker T_A = \{\mathbf{0}\}$; that is, $A\mathbf{x} = \mathbf{0}$ has only the trivial solution. By Proposition 3.4.15, A_r has a pivot in every column.

(b) False. Let $A \in F^{2\times 1}$ be the matrix with the single column $(1, 0)$. Then $Ax = (x, 0)$ is $\mathbf{0}$ only for $x = 0$, but $Ax = (0, 1)$ has no solution.

(c) True. By Proposition 3.4.15, we must show: if $B\mathbf{x} = \mathbf{0}$ has a nontrivial solution, so does $A\mathbf{x} = \mathbf{0}$. Let B consist of the columns $\mathbf{a}_{l_1}, \ldots, \mathbf{a}_{l_r}$ of A, and let $B\mathbf{u} = \mathbf{0}$ with $\mathbf{u} \neq \mathbf{0}$. Define $\mathbf{x} \in F^n$ by $x_{l_q} = u_q$ for $q = 1, \ldots, r$ and $x_l = 0$ for the deleted columns l. By Definition 2.3.8,

$$A\mathbf{x} = \sum_{q=1}^{r} u_q \mathbf{a}_{l_q} = B\mathbf{u} = \mathbf{0},$$

and $\mathbf{x} \neq \mathbf{0}$. (In terms of columns: a sublist of a linearly independent list is linearly independent.)

(d) False. Let $A = \begin{pmatrix} 0 & 1 \end{pmatrix} \in F^{1\times 2}$, which is in RREF with a pivot in its only row. Deleting the second column leaves $B = \begin{pmatrix} 0 \end{pmatrix}$, which has no pivot.

Solution to Exercise 3.4.36

Uses. Corollary 3.4.4 (Consistency), Corollary 3.4.14 (Counting solutions), Definition 2.5.12 (Invertible)
Hint 1. By Corollary 3.4.4, $\mathbf{y}$ works exactly when $G\mathbf{y}$ has zeros in positions $k + 1, \ldots, m$. How many vectors $\mathbf{z}$ have this property, and how are they related to the good $\mathbf{y}$?
Hint 2. For (b), count the pairs $(\mathbf{x}, \mathbf{y})$ with $A\mathbf{x} = \mathbf{y}$ in two ways.
Sketch. (a) $\mathbf{y} \mapsto G\mathbf{y}$ is a bijection of F^m (inverse $\mathbf{z} \mapsto G^{-1}\mathbf{z}$), and it maps the good $\mathbf{y}$ onto the $\mathbf{z}$ with $z_{k+1} = \cdots = z_m = 0$, of which there are q^k. (b) Each $\mathbf{x} \in F^n$ determines $\mathbf{y} = A\mathbf{x}$, so the q^n vectors $\mathbf{x}$ are split among the q^k consistent $\mathbf{y}$, each receiving q^{n-k} of them.

(a) Let G be invertible with $GA = A_r$, and let $Z = \{\mathbf{z} \in F^m \mid z_{k+1} = \cdots = z_m = 0\}$. By Corollary 3.4.4, $A\mathbf{x} = \mathbf{y}$ is consistent if and only if $G\mathbf{y} \in Z$. The map $\mathbf{y} \mapsto G\mathbf{y}$ is a bijection $F^m \to F^m$, with inverse $\mathbf{z} \mapsto G^{-1}\mathbf{z}$, so it restricts to a bijection from the set of good $\mathbf{y}$ onto Z. A vector of Z is determined by its first k entries, which are arbitrary, so $|Z| = q^k$.

(b) By Corollary 3.4.14(b), each consistent system has $q^\ell = q^{n-k}$ solutions. Now count the pairs $(\mathbf{x}, \mathbf{y}) \in F^n \times F^m$ with $A\mathbf{x} = \mathbf{y}$. Each $\mathbf{x}$ belongs to exactly one pair, namely $(\mathbf{x}, A\mathbf{x})$, so there are q^n pairs. On the other hand, grouping the pairs by $\mathbf{y}$, only the q^k consistent $\mathbf{y}$ occur, each in q^{n-k} pairs. So $q^n = q^k \cdot q^{n-k}$, and the identity just says that the solution sets of the consistent systems partition F^n.

Solution to Exercise 3.4.37

Uses. Definition 3.4.8 (Basic solutions), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Corollary 3.3.19 (Pivot columns, intrinsically), Definition 2.3.8 (Matrix–vector product)
Hint 1. If $j = f_t$ is free, try the basic solution $\mathbf{s}_t$. Which of its coordinates beyond position j could be nonzero?
Hint 2. A pivot coordinate $(\mathbf{s}_t)_{p_i} = -r_{if_t}$ with $p_i > f_t$ vanishes by Lemma 3.3.16(a). For the converse, rewrite $A\mathbf{x} = \mathbf{0}$ as an expression for $\mathbf{a}_j$.

Sketch. If $j = f_t$, then $\mathbf{s}_t$ has 1 in position j, 0 in the other free positions, and $-r_{ij}$ in position p_i; for $p_i > j$, $r_{ij} = 0$ by Lemma 3.3.16(a). Conversely, such an $\mathbf{x}$ gives $\mathbf{a}_j = -\sum_{l<j} x_l \mathbf{a}_l$, so column j is not a pivot column by Corollary 3.3.19(a).

Suppose x_j is free, say $j = f_t$, and consider the basic solution $\mathbf{s}_t$, which solves $A\mathbf{x} = \mathbf{0}$ (Theorem 3.4.9). It has a 1 in position j, and 0 in every other free position. In a pivot position $p_i > j$ it has the entry $-r_{ij}$ of A_r, where r_{ij} is the entry in row i of column $j < p_i$; this is 0 by Lemma 3.3.16(a), since column j lies to the left of the ith pivot. So $(\mathbf{s}_t)_l = 0$ for all $l > j$.

Conversely, suppose $A\mathbf{x} = \mathbf{0}$ with $x_j = 1$ and $x_l = 0$ for $l > j$. By Definition 2.3.8,

$$\mathbf{0} = A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_{j-1}\mathbf{a}_{j-1} + \mathbf{a}_j,$$

so $\mathbf{a}_j = -x_1\mathbf{a}_1 - \cdots - x_{j-1}\mathbf{a}_{j-1}$ is a linear combination of the earlier columns. By Corollary 3.3.19(a), column j is not a pivot column, so x_j is free.

So the basic solutions are the "staircase" solutions: $\mathbf{s}_t$ ends with a 1 in position f_t, followed only by zeros.

Solution to Exercise 3.4.38

Uses. Exercise 3.3.54, Corollary 3.4.4 (Consistency), Theorem 3.4.9 (All solutions), Proposition 3.4.15 (A pivot in every column)
Hint 1. By Exercise 3.3.54, Gauss–Jordan elimination on $(A \mid \mathbf{y})$ performs the same operations over F and over K. What does that say about the reduced augmented matrix?
Hint 2. The particular and basic solutions are built from the entries of $(A_r \mid G\mathbf{y})$.
Sketch. Row reducing $(A \mid \mathbf{y})$ uses only field operations on entries of F, so $(A_r \mid G\mathbf{y})$, the pivots, $\mathbf{x}_0$, and the $\mathbf{s}_j$ are the same over F and over K, and have entries in F. (a) Consistency over K is consistency over F, and then $\mathbf{x}_0 \in F^n$. (b) If the solution over K is unique, it is $\mathbf{x}_0$. (c) A free column exists, and $\mathbf{s}_1 \in F^n$ is nonzero.

Run Gauss–Jordan elimination on $(A \mid \mathbf{y})$, scanning only the first n columns. Every step uses only additions, multiplications, and inverses of nonzero entries, all of which stay in F, and whether an entry is 0 does not depend on whether we regard it in F or in K. So the run is the same over F and over K (this is the argument of Exercise 3.3.54), and it produces the same matrix $(A_r \mid \mathbf{z})$, with entries in F, and the same pivot and free columns. Hence the particular solution $\mathbf{x}_0$ (when the system is consistent) and the basic solutions $\mathbf{s}_j$ are the same over both fields, and lie in F^n.

(a) By Corollary 3.4.4, consistency over either field means $z_i = 0$ for $i > k$, the same condition. If the system has a solution in K^n, this condition holds, so $\mathbf{x}_0 \in F^n$ is a solution.

(b) If the solution in K^n is unique, it is $\mathbf{x}_0$ (which is a solution over K), and $\mathbf{x}_0 \in F^n$.

(c) If $A\mathbf{x} = \mathbf{0}$ has a nontrivial solution in K^n, then by Proposition 3.4.15 (over K) some column of A_r is free, so $\ell \geq 1$, and $\mathbf{s}_1 \in F^n$ is a nonzero solution.

Solution to Exercise 3.4.39

Uses. Lemma 3.4.23 (Too many roots), Theorem 3.4.24 (Polynomial interpolation), Proposition 3.4.15 (A pivot in every column), Proposition 3.4.16 (A pivot in every row), Corollary 3.4.19 (More unknowns than equations)
Hint 1. As in Theorem 3.4.24, $W\mathbf{a}$ lists the values of $a_0 + a_1x + \cdots + a_dx^d$ at $c_1, \ldots, c_m$.
Hint 2. For (a) with $m \geq d+1$, use Lemma 3.4.23 with $d+1$ of the nodes. For (b) with $m \leq d+1$, interpolate with a polynomial of degree at most $m-1$. The other directions are Corollary 3.4.19.
Sketch. $W\mathbf{a}$ lists the values of $p_\mathbf{a}$ at the nodes. (a) If $m \geq d+1$ and $W\mathbf{a} = \mathbf{0}$, then $p_\mathbf{a}$ vanishes at $d+1$ distinct points, so $\mathbf{a} = \mathbf{0}$. If $m < d+1$, there are more unknowns than equations. (b) If $m \leq d+1$, Theorem 3.4.24 gives p of degree at most $m-1 \leq d$ with any values. If $m > d+1$, there are more equations than unknowns. Interpretation: interpolating polynomials of degree at most d are unique when they exist iff $m \geq d+1$, and always exist iff $m \leq d+1$.

For $\mathbf{a} = (a_0, \ldots, a_d)$ let $p_\mathbf{a} = a_0 + a_1x + \cdots + a_dx^d$. As in the proof of Theorem 3.4.24, $W\mathbf{a} = (p_\mathbf{a}(c_1), \ldots, p_\mathbf{a}(c_m))$.

(a) Suppose $m \geq d+1$, and $W\mathbf{a} = \mathbf{0}$. Then $p_\mathbf{a}$ has degree at most d and vanishes at the $d+1$ distinct points $c_1, \ldots, c_{d+1}$, so $p_\mathbf{a} = \mathbf{0}$ by Lemma 3.4.23, and $\mathbf{a} = \mathbf{0}$. By Proposition 3.4.15, W_r has a pivot in every column. If $m < d+1$, then W has more columns than rows, and by Corollary 3.4.19(a) $W\mathbf{a} = \mathbf{0}$ has a nontrivial solution, so some column of W_r has no pivot.

(b) Suppose $m \leq d+1$, and let $\mathbf{v} \in F^m$. By Theorem 3.4.24 (with $n = m-1$ and the nodes $c_1, \ldots, c_m$) there is a polynomial p of degree at most $m-1 \leq d$ with $p(c_i) = v_i$ for all i. Its coefficients, padded with zeros up to a_d, form a solution of $W\mathbf{a} = \mathbf{v}$. So $W\mathbf{a} = \mathbf{v}$ is consistent for every $\mathbf{v}$, and by Proposition 3.4.16 W_r has a pivot in every row. If $m > d+1$, then W has more rows than columns, and by Corollary 3.4.19(b) some system $W\mathbf{a} = \mathbf{v}$ is inconsistent, so some row of W_r has no pivot.

In terms of polynomials: prescribing values at m distinct points, a polynomial of degree at most d with those values is unique (if it exists) exactly when $m \geq d+1$, and exists for all choices of values exactly when $m \leq d+1$. Both hold exactly when $m = d+1$, which is Theorem 3.4.24.

Solution to Exercise 3.4.40

Uses. Theorem 3.4.24 (Polynomial interpolation), Exercise 1.1.51, Definition 1.2.17 (Evaluation)
Hint 1. $\mathbb{F}_p$ has exactly p elements. Use them all as nodes.
Hint 2. For (b), Fermat's little theorem (Exercise 1.1.51) says $c^{p-1} = 1$ for $c \neq 0$.
Sketch. (a) The p elements $0, 1, \ldots, p-1$ of $\mathbb{F}_p$ are distinct nodes, so Theorem 3.4.24 with $n = p-1$ gives exactly one f of degree at most $p-1$ with $f(c) = g(c)$ for all c. Count: p^p functions and p^p polynomials (one for each list of p coefficients). (b) $f = 1 - x^{p-1}$, by Fermat.

(a) The elements $0, 1, \ldots, p-1$ of $\mathbb{F}_p$ are p distinct nodes. By Theorem 3.4.24 with $n = p-1$ and $d_c = g(c)$, there is exactly one $f \in \mathbb{F}_p[x]_{\leq p-1}$ with $f(c) = g(c)$ for all $c \in \mathbb{F}_p$, that is, whose polynomial function is g. Counting: there are p^p functions $\mathbb{F}_p \to \mathbb{F}_p$ (a value for each of p inputs), and p^p polynomials $a_0 + a_1 x + \cdots + a_{p-1}x^{p-1}$ (a coefficient for each of p positions). The map sending a polynomial to its function is therefore a bijection between two sets with p^p elements, consistent with what we proved.

(b) Let $f = 1 - x^{p-1}$, which has degree at most $p-1$. Then $f(0) = 1$, and for $c \neq 0$ Fermat's little theorem (Exercise 1.1.51) gives $c^{p-1} = 1$, so $f(c) = 0$. By the uniqueness in (a), f is the polynomial.

Polynomials of degree at least p are not needed to describe functions, and indeed $x^p - x$ has the zero function (Exercise 1.2.51); this does not contradict Lemma 3.4.23, since $x^p - x$ has degree p and only p roots are available.

Solution to Exercise 3.4.41

Uses. Theorem 3.4.24 (Polynomial interpolation), Definition 3.4.22 (Vandermonde matrix), Corollary 3.4.4 (Consistency)
Hint 1. The coefficient matrix is $V(1, 2, 3)$: the system asks for a polynomial of degree at most 2 with values $1, 2, 4$ at $1, 2, 3$. When are the nodes distinct in $\mathbb{F}_p$?
Hint 2. For $p = 2$ two nodes coincide. Compare the corresponding equations.
Sketch. For $p \geq 3$, the nodes $1, 2, 3$ are distinct in $\mathbb{F}_p$ ($3-1=2$, $3-2=1$, $2-1=1$ are nonzero), so there is exactly one solution by Theorem 3.4.24. For $p = 2$, the first and third equations read $a_0 + a_1 + a_2 = 1$ and $a_0 + a_1 + a_2 = 0$: no solution.

The coefficient matrix has rows $\left(1, c, c^2\right)$ for $c = 1, 2, 3$, so it is $V(1, 2, 3)$, and the system asks for $p = a_0 + a_1 x + a_2 x^2$ with $p(1) = 1$, $p(2) = 2$, $p(3) = 4$.

If $p \geq 3$, the differences $2-1 = 1$, $3-2 = 1$, and $3-1 = 2$ are nonzero in $\mathbb{F}_p$, so the nodes are distinct, and by Theorem 3.4.24 there is exactly one solution. (Over $\mathbb{Q}$ it is $(1, -1/2, 1/2)$, and the same computation works in $\mathbb{F}_p$ for $p \geq 3$, where 2 is invertible.)

If $p = 2$, then $3 = 1$ and $9 = 1$ in $\mathbb{F}_2$, so the third equation reads $a_0 + a_1 + a_2 = 4 = 0$, while the first reads $a_0 + a_1 + a_2 = 1$. Subtracting gives $0 = 1$, so there is no solution. (In the language of Corollary 3.4.4: the reduced augmented matrix has a row $(0, 0, 0 \mid 1)$.)

So the number of solutions is 1 for every odd prime, and 0 for $p = 2$.

Solution to Exercise 3.4.42

Uses. Corollary 3.4.20 (Square systems), Definition 1.2.17 (Evaluation), Proposition 1.2.18 (Degree and evaluation versus the operations)
Techniques. Uniqueness gives existence (Technique 3.4.21)

Hint 1. The four conditions are linear in a_0, a_1, a_2, a_3, so this is a square system. By Technique 3.4.21 it is enough to treat $u_0 = v_0 = u_1 = v_1 = 0$.
Hint 2. For (b), solve each system directly; then use that the conditions are linear in p.
Sketch. The conditions are $a_0 = u_0$, $a_1 = v_0$, $a_0 + a_1 + a_2 + a_3 = u_1$, $a_1 + 2a_2 + 3a_3 = v_1$. With zero data, $a_0 = a_1 = 0$, $a_2 + a_3 = 0$, $2a_2 + 3a_3 = 0$ force $\mathbf{a} = \mathbf{0}$, so Corollary 3.4.20 applies. $h_1 = 1 - 3x^2 + 2x^3$, $h_2 = x - 2x^2 + x^3$, $h_3 = 3x^2 - 2x^3$, $h_4 = -x^2 + x^3$, and $p = u_0 h_1 + v_0 h_2 + u_1 h_3 + v_1 h_4$.

(a) By Definition 1.2.17, the four conditions are

$$a_0 = u_0, \quad a_1 = v_0, \quad a_0 + a_1 + a_2 + a_3 = u_1, \quad a_1 + 2a_2 + 3a_3 = v_1,$$

a square linear system in a_0, a_1, a_2, a_3. By Corollary 3.4.20 it suffices to show that the homogeneous system has only the trivial solution. If all data are 0, then $a_0 = a_1 = 0$, so $a_2 + a_3 = 0$ and $2a_2 + 3a_3 = 0$; subtracting twice the first from the second gives $a_3 = 0$, and then $a_2 = 0$. So for all data there is exactly one solution.

(b) Solving the four systems:

- $u_0 = 1$: $a_0 = 1, a_1 = 0, a_2 + a_3 = -1, 2a_2 + 3a_3 = 0$, so $a_3 = 2$, $a_2 = -3$: $h_1 = 1 - 3x^2 + 2x^3$.
- $v_0 = 1$: $a_0 = 0, a_1 = 1, a_2 + a_3 = -1, 2a_2 + 3a_3 = -1$, so $a_3 = 1$, $a_2 = -2$: $h_2 = x - 2x^2 + x^3$.
- $u_1 = 1$: $a_0 = a_1 = 0, a_2 + a_3 = 1, 2a_2 + 3a_3 = 0$, so $a_3 = -2$, $a_2 = 3$: $h_3 = 3x^2 - 2x^3$.
- $v_1 = 1$: $a_0 = a_1 = 0, a_2 + a_3 = 0, 2a_2 + 3a_3 = 1$, so $a_3 = 1$, $a_2 = -1$: $h_4 = -x^2 + x^3$.

The four conditions depend linearly on p: values by Proposition 1.2.18(c), and p' because its coefficients are linear in those of p. So $u_0 h_1 + v_0 h_2 + u_1 h_3 + v_1 h_4$ satisfies the conditions with data u_0, v_0, u_1, v_1, and by uniqueness it is p. (These are the cubic Hermite polynomials, used in computer graphics to join curve segments smoothly.)

Solution to Exercise 3.4.43

Uses. Proposition 1.2.18 (Degree and evaluation versus the operations), Corollary 3.4.20 (Square systems), Definition 1.2.16 (Degree)
Techniques. Undetermined coefficients (Technique 3.1.9)
Hint 1. Both sides depend linearly on p. So it is enough to require the equation for $p = 1$, $p = x$, and $p = x^2$.
Hint 2. This gives a 3×3 system for w_0, w_1, w_2 whose coefficient matrix is the transpose of $V(-1, 0, 1)$.
Sketch. For $p = 1, x, x^2$ the conditions are $w_0 + w_1 + w_2 = 2$, $-w_0 + w_2 = 0$, $w_0 + w_2 = 2/3$, with the unique solution $(1/3, 4/3, 1/3)$. These three conditions suffice by linearity. For x^3 both sides are 0; for x^4 the integral is $2/5$ and the rule gives $2/3$.

(a) The integral and the right side both depend linearly on p: the right side by Proposition 1.2.18(c), and the integral because $\int (f + g) = \int f + \int g$ and $\int cf = c \int f$. So if the equation holds for $p = 1$, x, and x^2, it holds for every $a_0 + a_1 x + a_2 x^2$; conversely it must hold for these three. Since $\int_{-1}^{1} 1 = 2$, $\int_{-1}^{1} t \, dt = 0$, and $\int_{-1}^{1} t^2 \, dt = 2/3$, the conditions are

$$w_0 + w_1 + w_2 = 2, \quad -w_0 + w_2 = 0, \quad w_0 + w_2 = \frac{2}{3}.$$

The last two give $w_0 = w_2 = 1/3$, and the first gives $w_1 = 4/3$. So the only rule is

$$\int_{-1}^{1} p(t) \, dt = \frac{1}{3} p(-1) + \frac{4}{3} p(0) + \frac{1}{3} p(1),$$

Simpson's rule. (The coefficient matrix of the system is the transpose of $V(-1, 0, 1)$, which is invertible because $V(-1, 0, 1)$ is (Theorem 3.4.24, Proposition 2.4.23). This is why the weights exist and are unique for any three distinct nodes.)

(b) By linearity it is enough to check x^3: the integral is 0, and the rule gives $\frac{1}{3}(-1) + 0 + \frac{1}{3}(1) = 0$. For x^4 the integral is $2/5$, while the rule gives $\frac{1}{3} + \frac{1}{3} = 2/3$.

Solution to Exercise 3.4.44

Uses. Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 3.3.20 (The kernel is a complete invariant), Definition 3.2.21 (Row equivalence), Definition 2.5.12 (Invertible)
Hint 1. Two systems with the same nonempty solution set have the same homogeneous solution set. Why?
Hint 2. So $\ker T_A = \ker T_B$. What does Corollary 3.3.20 give? Then use a common solution $\mathbf{x}_0$ to compare $\mathbf{y}$ and $\mathbf{w}$.
Hint 3. For (b), two inconsistent systems have the same (empty) solution set.
Sketch. If S is the common solution set and $\mathbf{x}_0 \in S$, then $S = \mathbf{x}_0 + \ker T_A = \mathbf{x}_0 + \ker T_B$, so $\ker T_A = \ker T_B$, and Corollary 3.3.20 gives $B = HA$ with H a product of elementary matrices. Then $\mathbf{w} = B\mathbf{x}_0 = HA\mathbf{x}_0 = H\mathbf{y}$, so $(B \mid \mathbf{w}) = H(A \mid \mathbf{y})$. (b) The inconsistent systems $0x = 1, 0x = 0$ and $x = 0, x = 1$ have the same (empty) solution set, but their augmented matrices have different reduced forms.

(a) Let S be the common solution set and $\mathbf{x}_0 \in S$. By Proposition 3.1.19, $S = \mathbf{x}_0 + \ker T_A$ and $S = \mathbf{x}_0 + \ker T_B$. So $\mathbf{z} \in \ker T_A$ if and only if $\mathbf{x}_0 + \mathbf{z} \in S$ if and only if $\mathbf{z} \in \ker T_B$; that is, $\ker T_A = \ker T_B$. By Corollary 3.3.20, $A \sim B$, so $B = HA$ for a product H of elementary matrices (Definition 3.2.21). Then

$$\mathbf{w} = B\mathbf{x}_0 = HA\mathbf{x}_0 = H\mathbf{y},$$

and therefore $(B \mid \mathbf{w}) = (HA \mid H\mathbf{y}) = H(A \mid \mathbf{y})$, by the column-by-column description of HM (Proposition 3.2.14). Since H is a product of elementary matrices, this says $(A \mid \mathbf{y}) \sim (B \mid \mathbf{w})$.

(b) Take $m = 2$, $n = 1$, and the systems

$$0x = 1, \quad 0x = 0 \quad \text{and} \quad x = 0, \quad x = 1.$$

Both are inconsistent, so they have the same (empty) solution set. Their augmented matrices are $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$. The first is in RREF, and the second reduces to I_2, so their reduced row echelon forms differ and they are not row equivalent (Corollary 3.3.18(b)).

Solution to Exercise 3.4.45

Uses. Corollary 3.4.4 (Consistency), Proposition 3.1.8 (Systems and the map T_A), Proposition 3.1.19 (Solution sets are translates of the kernel), Proposition 3.3.11 (Carrying extra columns along), Definition 2.4.1 (Matrix product)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. Let U be the $n \times r$ matrix with columns $\mathbf{u}_1, \ldots, \mathbf{u}_r$, so that the span is $\operatorname{im} T_U$. By Corollary 3.4.4, $\operatorname{im} T_U$ is cut out by linear equations. Which ones?
Hint 2. If $GU = \operatorname{rref}(U)$ has k pivots, let B consist of the last $n - k$ rows of G. Then $\ker T_B = \operatorname{im} T_U$. Now choose the right-hand side so that $\mathbf{x}_0$ is a solution.
Sketch. Row reduce $(U \mid I_n)$ to $(\operatorname{rref}(U) \mid G)$, with k pivots, and let B be the last $n - k$ rows of G. By Corollary 3.4.4, $B\mathbf{y} = \mathbf{0}$ if and only if $\mathbf{y} \in \operatorname{im} T_U = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$. The system $B\mathbf{x} = B\mathbf{x}_0$ has the solution $\mathbf{x}_0$ and homogeneous solution set $\ker T_B$, so its solution set is $\mathbf{x}_0 + \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$. In (b), B has rows $(-1, 1, 0, 0)$ and $(0, 0, -1, 1)$, and the system is $-x_1 + x_2 = -1$, $-x_3 + x_4 = -2$.

(a) Let $U \in F^{n \times r}$ have columns $\mathbf{u}_1, \ldots, \mathbf{u}_r$, so that $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r) = \operatorname{im} T_U$ by Proposition 3.1.8(a). The procedure:

1. Row reduce $(U \mid I_n)$, scanning only the first r columns, to $(\operatorname{rref}(U) \mid G)$ (Proposition 3.3.11). Let k be the number of pivots.
2. If $k = n$, output the empty system (or $0x_1 = 0$): its solution set is F^n.
3. Otherwise, let $B \in F^{(n-k) \times n}$ consist of the last $n - k$ rows of G, and output the system $B\mathbf{x} = B\mathbf{x}_0$.

Correctness. The jth entry of $B\mathbf{y}$ is the $(k + j)$th entry of $G\mathbf{y}$ (Definition 2.4.1), so $B\mathbf{y} = \mathbf{0}$ if and only if $(G\mathbf{y})_i = 0$ for all $i > k$. By Corollary 3.4.4, applied to U, this holds if and only if $\mathbf{y} \in \operatorname{im} T_U$. So $\ker T_B = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$. (If $k = n$, the conditions are vacuous and $\operatorname{im} T_U = F^n$.) The system $B\mathbf{x} = B\mathbf{x}_0$ has the solution $\mathbf{x}_0$, so by Proposition 3.1.19 its solution set is $\mathbf{x}_0 + \ker T_B = \mathbf{x}_0 + \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r)$.

(b) Here U has rows $(1, 0)$, $(1, 0)$, $(0, 1)$, $(0, 1)$. Pass 1 adds -1 times row 1 to row 2, which becomes $(0, 0 \mid -1, 1, 0, 0)$. In pass 2, column 2 has a 0 in row 2, so rows 2 and 3 are swapped, and then -1 times the new row 2, which is $(0, 1 \mid 0, 0, 1, 0)$, is added to row 4:

$$\left(\begin{array}{cc|cccc} 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 1 \end{array}\right).$$

So $k = 2$, and B has rows $(-1, 1, 0, 0)$ and $(0, 0, -1, 1)$. Since $B\mathbf{x}_0 = (-1, -2)$, the system is

$$-x_1 + x_2 = -1, \quad -x_3 + x_4 = -2.$$

Check: $\mathbf{x}_0$ satisfies both equations, and $\mathbf{u}_1$ and $\mathbf{u}_2$ satisfy the homogeneous ones. Its solution set has two free variables, x_2 and x_4, matching the two parameters of $\mathbf{x}_0 + s\mathbf{u}_1 + t\mathbf{u}_2$. Part (a) of Exercise 3.1.41 found such a system by inspection; the procedure always works.

Solution to Exercise 3.4.46

Uses. Theorem 3.4.24 (Polynomial interpolation)
Hint 1. The nodes $1, \ldots, N$ are distinct in $\mathbb{F}_p$ because $N < p$, and none of them is 0.
Hint 2. For (a), $t + 1$ shares are the values of f at $t + 1$ distinct nodes, and f has degree at most t. For (b), add the condition $f(0) = s'$ to the t shares.
Sketch. (a) f is the unique polynomial of degree at most t with the given $t + 1$ values (Theorem 3.4.24), so the group can compute f and then $s = f(0)$. (b) The conditions $f(0) = s'$ and $f(i_q) = v_q$ prescribe values at the $t + 1$ distinct nodes $0, i_1, \ldots, i_t$, so exactly one f of degree at most t satisfies them, and its coefficients $a_1, \ldots, a_t$ are the unique choice. Every candidate secret is explained by exactly one choice of the random coefficients, so the observed shares are equally likely under every candidate secret, and they carry no information about s.

Since $N < p$, the elements $1, 2, \ldots, N$ of $\mathbb{F}_p$ are distinct and nonzero.

(a) Suppose people $i_0, \ldots, i_t$ pool their shares $f(i_0), \ldots, f(i_t)$. These are the values of f, a polynomial of degree at most t, at $t + 1$ distinct nodes. By Theorem 3.4.24 there is exactly one polynomial of degree at most t with these values, so the group can compute it (by solving the Vandermonde system, or with Proposition 3.4.27), and it is f. Then $s = f(0)$.

(b) Fix $s' \in \mathbb{F}_p$. A dealer with secret s' who chose $a_1, \ldots, a_t$ uses $f' = s' + a_1 x + \cdots + a_t x^t$, and produces the shares $v_1, \ldots, v_t$ exactly when $f'(i_q) = v_q$ for $q = 1, \ldots, t$. So the possible choices correspond to the polynomials f' of degree at most t with

$$f'(0) = s', \quad f'(i_1) = v_1, \quad \ldots, \quad f'(i_t) = v_t.$$

The $t + 1$ nodes $0, i_1, \ldots, i_t$ are distinct, so by Theorem 3.4.24 there is exactly one such f', and hence exactly one choice of $(a_1, \ldots, a_t)$.

If the dealer chooses $(a_1, \ldots, a_t)$ uniformly at random, each of the p^t choices has probability p^{-t}. By what we just proved, for each candidate secret s' exactly one of these choices produces the observed shares, so the observed shares are equally likely under every candidate secret. Seeing them gives no reason to prefer one value of s over another. (This is Shamir's secret sharing scheme.)

Solution to Exercise 3.4.47

Uses. Theorem 3.4.24 (Polynomial interpolation), Definition 1.2.17 (Evaluation), Definition 1.2.16 (Degree), induction on n
Hint 1. Compute p_0, p_1, p_2 and look for a pattern. Then consider the differences $p_n(x + 1) - p_n(x)$.
Hint 2. Show that there is a polynomial q of degree at most $n - 1$ with $q(t) = p_n(t + 1) - p_n(t)$ for all $t \in \mathbb{Q}$. What are its values at $0, 1, \ldots, n - 1$?
Hint 3. By uniqueness, $q = p_{n-1}$. Now induct.
Sketch. Induction on n; $p_0 = 1$ gives $p_0(1) = 1$. Expanding $(t + 1)^j$ by the binomial theorem, $p_n(t + 1) - p_n(t) = q(t)$ for a polynomial q of degree at most $n - 1$ (the t^n terms cancel). Then $q(k) = 2^{k+1} - 2^k = 2^k$ for $k = 0, \ldots, n - 1$, so $q = p_{n-1}$ by Theorem 3.4.24. Hence $p_n(n + 1) = 2^n + p_{n-1}(n)$, and induction gives $2^n + 2^n - 1$.

The polynomials p_n exist and are unique by Theorem 3.4.24, since $0, 1, \ldots, n$ are distinct in $\mathbb{Q}$. We induct on n. For $n = 0$, $p_0 = 1$ and $p_0(1) = 1 = 2^1 - 1$.

Let $n \geq 1$ and write $p_n = \sum_{j=0}^{n} a_j x^j$. For $t \in \mathbb{Q}$, the binomial theorem gives

$$p_n(t+1) - p_n(t) = \sum_{j=0}^{n} a_j\big((t+1)^j - t^j\big) = \sum_{j=1}^{n} a_j \sum_{i=0}^{j-1} \binom{j}{i} t^i = \sum_{i=0}^{n-1} b_i t^i,$$

where $b_i = \sum_{j=i+1}^{n} \binom{j}{i} a_j$. So with

$$q = b_0 + b_1 x + \cdots + b_{n-1} x^{n-1} \in \mathbb{Q}[x]_{\leq n-1}$$

we have $q(t) = p_n(t+1) - p_n(t)$ for every $t \in \mathbb{Q}$. In particular, for $k = 0, 1, \ldots, n-1$,

$$q(k) = p_n(k+1) - p_n(k) = 2^{k+1} - 2^k = 2^k.$$

By the uniqueness in Theorem 3.4.24 (with the n nodes $0, \ldots, n-1$), $q = p_{n-1}$. Therefore, using the induction hypothesis $p_{n-1}(n) = 2^n - 1$,

$$p_n(n+1) = p_n(n) + q(n) = 2^n + p_{n-1}(n) = 2^n + 2^n - 1 = 2^{n+1} - 1,$$

as desired. (For instance $p_2 = 1 + x/2 + x^2/2$ takes the values $1, 2, 4$ at $0, 1, 2$, and $p_2(3) = 1 + 3/2 + 9/2 = 7$.)

Section 3.5

Solution to Exercise 3.5.4

Uses. Definition 3.5.1 (Rank), Proposition 3.5.2 (First properties of rank), Theorem 3.4.24 (Polynomial interpolation), Theorem 3.3.23 (Invertibility and RREF)
Hint 1. For (a) and (c), use Proposition 3.5.2(d): count the columns that are not in the span of the earlier ones. Here every column is a multiple of the first.
Hint 2. For (b) over $\mathbb{Q}$, the nodes $1, 2, 3$ are distinct. What happens to them in $\mathbb{F}_2$?
Sketch. (a) Every column is a multiple of the first, which is nonzero: rank 1. (b) Over $\mathbb{Q}$, V is invertible by Theorem 3.4.24, so its reduced form is I_3 and the rank is 3. Over $\mathbb{F}_2$, rows 1 and 3 coincide and the rank is 2. (c) Rank 1.

(a) The first column $\mathbf{a}_1 = (1, -2, 3)$ is nonzero, and $\mathbf{a}_2 = -\mathbf{a}_1$, $\mathbf{a}_3 = 2\mathbf{a}_1$. By Proposition 3.5.2(d), only $j = 1$ counts, so the rank is 1.

(b) Over $\mathbb{Q}$ the nodes $1, 2, 3$ are distinct, so $V(1, 2, 3)$ is invertible by Theorem 3.4.24. By Theorem 3.3.23 its reduced form is I_3, which has 3 pivots. Over $\mathbb{F}_2$ we have $3 = 1$, $4 = 0$, and $9 = 1$, so the matrix is $\begin{pmatrix} 1 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 1 & 1 \end{pmatrix}$. Adding row 1 to rows 2 and 3 gives the rows $(1, 1, 1)$, $(0, 1, 1)$, $(0, 0, 0)$, and adding row 2 to row 1 gives

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix},$$

which is in RREF with 2 pivots. So the rank is 2 over $\mathbb{F}_2$: the nodes 1 and 3 coincide in $\mathbb{F}_2$, so two rows of V coincide.

(c) Every column equals the first, which is nonzero. By Proposition 3.5.2(d), the rank is 1.

Solution to Exercise 3.5.5

Uses. Proposition 3.5.2 (First properties of rank), Definition 1.3.10 (Span)
Hint 1. Write each column as a combination of two fixed vectors: $\mathbf{u} = (1, 2, \ldots, n)$ and the all-ones vector $\mathbf{1}$.
Hint 2. Column j is $\mathbf{u} + j\mathbf{1}$. Express column j through columns 1 and 2, and use Proposition 3.5.2(d).
Hint 3. To see that column 2 is not a multiple of column 1 in every field, look at the first two entries of both columns.
Sketch. Column j is $\mathbf{c}_j = \mathbf{u} + j\mathbf{1}$, and $\mathbf{c}_j = (2 - j)\mathbf{c}_1 + (j - 1)\mathbf{c}_2$. So only $j = 1, 2$ can count in Proposition 3.5.2(d). Both do: $\mathbf{c}_1 \neq \mathbf{0}$ because its first two entries $2, 3$ differ by 1, and $\mathbf{c}_2 = t\mathbf{c}_1$ would give $3 = 2t$ and $4 = 3t$, hence $1 = t$ and then $3 = 2$, which is false in every field.

Let $\mathbf{u} = (1, 2, \ldots, n)$ and $\mathbf{1} = (1, 1, \ldots, 1)$ in F^n. Column j of A is

$$\mathbf{c}_j = (1+j, 2+j, \ldots, n+j) = \mathbf{u} + j\mathbf{1}.$$

For every j, in the combination $(2-j)\mathbf{c}_1 + (j-1)\mathbf{c}_2 = (2-j)(\mathbf{u}+\mathbf{1}) + (j-1)(\mathbf{u}+2\mathbf{1})$ the coefficient of $\mathbf{u}$ is $(2-j)+(j-1) = 1$ and that of $\mathbf{1}$ is $(2-j)+2(j-1) = j$. So

$$(2-j)\mathbf{c}_1 + (j-1)\mathbf{c}_2 = \mathbf{u} + j\mathbf{1} = \mathbf{c}_j,$$

and for $j \geq 3$ the column $\mathbf{c}_j$ lies in $\operatorname{span}(\mathbf{c}_1, \mathbf{c}_2)$, hence in $\operatorname{span}\big(\mathbf{c}_1, \ldots, \mathbf{c}_{j-1}\big)$. By Proposition 3.5.2(d), $\operatorname{rank} A \leq 2$, and it remains to see that $j = 1$ and $j = 2$ both count.

The first two entries of $\mathbf{c}_1$ are 2 and 3, and $3 - 2 = 1 \neq 0$, so they are not both 0: $\mathbf{c}_1 \neq \mathbf{0}$. Suppose $\mathbf{c}_2 = t\mathbf{c}_1$ for some $t \in F$. Comparing the first two entries gives $3 = 2t$ and $4 = 3t$. Subtracting, $1 = t$, and then $3 = 2$, that is, $1 = 0$, which is false. So $\mathbf{c}_2 \notin \operatorname{span}(\mathbf{c}_1)$, and $\operatorname{rank} A = 2$.

Solution to Exercise 3.5.11

Uses. Proposition 3.5.8 (Right inverses from the pivots), Proposition 3.3.11 (Carrying extra columns along)
Hint 1. Reduce $(A \mid I_2)$. Only one row operation is needed.
Hint 2. The pivot columns are 1 and 2, so B has its 1s in positions $(1,1)$ and $(2,2)$: BG is G on top of two zero rows.
Sketch. Adding -1 times row 2 to row 1 gives $A_r = \left(\begin{smallmatrix} 1 & 0 & -1 & 1 \\ 0 & 1 & 1 & 1 \end{smallmatrix}\right)$ and $G = \left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix}\right)$. So $\operatorname{rank} A = 2$, $p_1 = 1$, $p_2 = 2$, and $BG = \left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{smallmatrix}\right)$.

Row 1 already has a leading 1 in column 1, and column 1 is clear below it. In pass 2, the entry in position $(2,2)$ is 1, and we add -1 times row 2 to row 1:

$$\left(\begin{array}{cccc|cc} 1 & 1 & 0 & 2 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{cccc|cc} 1 & 0 & -1 & 1 & 1 & -1 \\ 0 & 1 & 1 & 1 & 0 & 1 \end{array}\right).$$

So $\operatorname{rank} A = 2$, the pivot columns are 1 and 2, and $G = \left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix}\right)$. The matrix $B \in \mathbb{Q}^{4\times 2}$ has 1s in positions $(1,1)$ and $(2,2)$, so

$$BG = \begin{pmatrix} 1 & -1 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Check: $A(BG)$ is A times the columns $(1,0,0,0)$ and $(-1,1,0,0)$, that is, $\mathbf{a}_1 = (1,0)$ and $-\mathbf{a}_1 + \mathbf{a}_2 = (-1,0) + (1,1) = (0,1)$. So $A(BG) = I_2$.

Solution to Exercise 3.5.18

Uses. Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed), Theorem 3.5.14 (Third Fundamental Theorem, completed), Corollary 3.5.15 (Invertible matrices are square)
Hint 1. Each "moreover" clause is a constraint on the shape. Check it first.
Hint 2. For (d), compare with condition (VI) of Theorem 3.5.14.
Sketch. (a) None: injective needs $n \leq m$, but $5 > 3$. (b) $A = (I_3 \;\; 0)$, rank $3 = m$. (c) None: a right inverse needs $n \geq m$, but $3 < 5$. (d) None: rank $A = 4 = m = n$ makes T_A invertible.

(a) None. By Theorem 3.5.12, T_A injective forces $n \leq m$, and here $n = 5 > 3 = m$. (Concretely, $\operatorname{rank} A \leq 3 < 5$.)

(b) $A = \left(\begin{smallmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \end{smallmatrix}\right)$ is in RREF with 3 pivots, so $\operatorname{rank} A = 3 = m$ and T_A is surjective by Theorem 3.5.13.

(c) None. By Corollary 3.5.15(b), a matrix with a right inverse has $n \geq m$, and here $n = 3 < 5 = m$. The condition $\operatorname{rank} A = 3$ is possible, and it gives a left inverse instead.

(d) None. If $\operatorname{rank} A = 4$, then $\operatorname{rank} A = m = n$, so T_A is invertible by Theorem 3.5.14, and so is A (Remark 3.5.7).

Solution to Exercise 3.5.26

Uses. Corollary 3.5.15 (Invertible matrices are square), Theorem 3.5.23 (One-sided inverses of square matrices)
Hint 1. Cancelling A on the left from $AX = AY$ means multiplying on the left by a left inverse of A. Does A have one?
Hint 2. Try $A = \begin{pmatrix}1 & 0\end{pmatrix}$.
Sketch. Cancelling A on the left needs a left inverse of A, which a matrix with a right inverse has only when it is square. Counterexample: $A = \begin{pmatrix}1 & 0\end{pmatrix}$, $B = \begin{pmatrix}1\\0\end{pmatrix}$: $AB = I_1$, $BA = \begin{pmatrix}1 & 0\\0 & 0\end{pmatrix} \neq I_2$.

The step "cancelling A on the left" is the error. From $AX = AY$ we may conclude $X = Y$ if A has a left inverse C, by multiplying by C; in general we may not, since T_A need not be injective. Here A has a right inverse B, so $n \geq m$ by Corollary 3.5.15(b), and if $n > m$ then A has no left inverse at all, by Corollary 3.5.15(a).

The conclusion is false: for $A = \begin{pmatrix}1 & 0\end{pmatrix} \in F^{1\times 2}$ and $B = \begin{pmatrix}1\\0\end{pmatrix} \in F^{2\times 1}$, we have $AB = (1) = I_1$, but

$$BA = \begin{pmatrix}1 & 0\\0 & 0\end{pmatrix} \neq I_2.$$

When $m = n$, the conclusion is true, but its proof needs Theorem 3.5.23, not cancellation.

Solution to Exercise 3.5.30

Uses. Theorem 3.5.27 (Rank normal form), Proposition 3.2.7 (Row operations are left multiplications)
Hint 1. Compare row 2 with i times row 1.
Hint 2. One row operation reduces A. Then follow the first proof of Theorem 3.5.27: the only pivot column is column 1, so $P = I_3$.
Sketch. Row 2 is i times row 1, so $E_{1,-i,2}$ gives $A_r = \begin{pmatrix}1 & i & 1+i\\0 & 0 & 0\end{pmatrix}$ and $k = 1$, with $G = \begin{pmatrix}1 & 0\\-i & 1\end{pmatrix}$. Then $X = \begin{pmatrix}i & 1+i\end{pmatrix}$ and $H = U = \begin{pmatrix}1 & -i & -1-i\\0 & 1 & 0\\0 & 0 & 1\end{pmatrix}$.

Since $i(1, i, 1+i) = (i, -1, i-1)$, row 2 is i times row 1. Adding $-i$ times row 1 to row 2 gives

$$A_r = \begin{pmatrix}1 & i & 1+i\\0 & 0 & 0\end{pmatrix}, \quad G = E_{1,-i,2} = \begin{pmatrix}1 & 0\\-i & 1\end{pmatrix}.$$

So $k = \operatorname{rank} A = 1$, the pivot column is 1, and the free columns are $2, 3$. As in the first proof of Theorem 3.5.27, $P = I_3$, $X = \begin{pmatrix}i & 1+i\end{pmatrix}$, and

$$H = U = \begin{pmatrix}1 & -i & -1-i\\0 & 1 & 0\\0 & 0 & 1\end{pmatrix}.$$

Check: $A_r H$ has first column $(1, 0)$, second column $(-i+i, 0) = \mathbf{0}$, and third column $(-1-i+1+i, 0) = \mathbf{0}$. So $GAH = A_r H = \begin{pmatrix}1 & 0 & 0\\0 & 0 & 0\end{pmatrix} = N_1$.

Solution to Exercise 3.5.31

Uses. Proposition 3.5.2 (First properties of rank), Definition 3.5.1 (Rank), Algorithm 3.3.1 (Gauss–Jordan elimination), Proposition 1.1.17 (No zero divisors)
Hint 1. Row operations do not change the rank (Proposition 3.5.2(c)), so you may reorder the rows first. Put the row $(1, 1, t)$ on top.
Hint 2. After clearing the first column, add the new second row to the third. The last entry becomes $2 - t - t^2 = -(t-1)(t+2)$.
Hint 3. Treat the cases $t = 1$, $t = -2$, and the rest separately. In $\mathbb{F}_3$, which of these cases coincide?
Sketch. Swapping rows 1 and 3 and eliminating gives rows $(1, 1, t)$, $(0, t-1, 1-t)$, $(0, 0, -(t-1)(t+2))$. (a) Rank 1 for $t = 1$, rank 2 for $t = -2$, rank 3 otherwise. (b) In $\mathbb{F}_3$, $-2 = 1$, so the two exceptional values merge: rank 1 for $t = 1$ and rank 3 for $t = 0, 2$. Rank 2 never occurs.

By Proposition 3.5.2(c), row operations do not change the rank, so we may use any convenient sequence of them; at the end we reduce to RREF and count pivots. Swap rows 1 and 3, add -1 times the new row 1 to row 2, and add $-t$ times it to row 3:

$$A_t \rightsquigarrow \begin{pmatrix} 1 & 1 & t \\ 1 & t & 1 \\ t & 1 & 1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 1 & t \\ 0 & t-1 & 1-t \\ 0 & 1-t & 1-t^2 \end{pmatrix}.$$

Adding row 2 to row 3 makes the last entry $(1-t)+\left(1-t^2\right) = 2-t-t^2 = -(t-1)(t+2)$:

$$\rightsquigarrow \begin{pmatrix} 1 & 1 & t \\ 0 & t-1 & 1-t \\ 0 & 0 & -(t-1)(t+2) \end{pmatrix}.$$

These operations make sense over every field. Call this matrix M_t.

(a) $t = 1$. Rows 2 and 3 of M_1 are zero, and $M_1 = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$ is in RREF. So rank $A_1 = 1$.

$t \neq 1$. Scale row 2 by $1/(t-1)$, making it $(0, 1, -1)$, and add -1 times it to row 1, which becomes $(1, 0, t+1)$. If $t = -2$, row 3 is zero, and the result $\begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{pmatrix}$ is in RREF with 2 pivots, so rank $A_{-2} = 2$. If $t \neq 1, -2$, the entry $-(t-1)(t+2)$ is nonzero, so scaling row 3 and clearing column 3 gives I_3, and rank $A_t = 3$.

(b) In $\mathbb{F}_3$ we have $-2 = 1$, so $t+2 = t-1$, and the last entry of M_t is $-(t-1)^2$. For $t = 1$ the computation in (a) gives rank 1. For $t = 0$ and $t = 2$, the entry $t-1$ is nonzero and so is $-(t-1)^2$, by Proposition 1.1.17, so the computation in (a) gives rank 3. Rank 2 never occurs: over $\mathbb{R}$ it requires $t = -2$ with $t \neq 1$, but in $\mathbb{F}_3$ the values -2 and 1 are the same. (Over an arbitrary field, rank $A_t = 2$ exactly when $t = -2 \neq 1$, that is, when $t = -2$ and $3 \neq 0$ in F.)

Solution to Exercise 3.5.32

> *Uses.* Proposition 3.5.9 (Left inverses), Proposition 3.3.11 (Carrying extra columns along), Exercise 3.5.33
> *Hint 1.* Reduce $(A \mid I_3)$ over $\mathbb{F}_5$, scanning only the first two columns. You will need $3^{-1} = 2$.
> *Hint 2.* The first two rows of the right block form a left inverse. The third row $\mathbf{z}$ of the right block satisfies $\mathbf{z}A = \mathbf{0}$; add it to a row of the left inverse.
> *Sketch.* Reducing $(A \mid I_3)$ gives $A_r = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$ and G with rows $(3, 1, 0)$, $(4, 2, 0)$, $(1, 3, 1)$. So rank $A = 2$ and $C = \begin{pmatrix} 3 & 1 & 0 \\ 4 & 2 & 0 \end{pmatrix}$ is a left inverse. Adding the third row of G to the first row of C gives another, $\begin{pmatrix} 4 & 4 & 1 \\ 4 & 2 & 0 \end{pmatrix}$. There are $5^{2\cdot 1} = 25$ left inverses.

We reduce $(A \mid I_3)$ over $\mathbb{F}_5$, scanning the first two columns. Pass 1: the pivot is $(1, 1)$, and we add $-3 = 2$ times row 1 to row 2. Pass 2: the entry in position $(2, 2)$ is now $4 + 4 = 8 = 3$; we scale row 2 by $3^{-1} = 2$, then add $-2 = 3$ times row 2 to row 1 and $-1 = 4$ times row 2 to row 3:

$$\left(\begin{array}{cc|ccc} 1 & 2 & 1 & 0 & 0 \\ 3 & 4 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{cc|ccc} 1 & 2 & 1 & 0 & 0 \\ 0 & 3 & 2 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 \end{array}\right)$$

$$\rightsquigarrow \left(\begin{array}{cc|ccc} 1 & 2 & 1 & 0 & 0 \\ 0 & 1 & 4 & 2 & 0 \\ 0 & 1 & 0 & 0 & 1 \end{array}\right)$$

$$\rightsquigarrow \left(\begin{array}{cc|ccc} 1 & 0 & 3 & 1 & 0 \\ 0 & 1 & 4 & 2 & 0 \\ 0 & 0 & 1 & 3 & 1 \end{array}\right).$$

So $A_r = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$, rank $A = 2$, and by Proposition 3.3.11 the right block is G with $GA = A_r$. By the first approach to Proposition 3.5.9, the first two rows of G form a left inverse

$$C = \begin{pmatrix} 3 & 1 & 0 \\ 4 & 2 & 0 \end{pmatrix}.$$

Check: $3(1,2) + 1(3,4) = (6,10) = (1,0)$ and $4(1,2) + 2(3,4) = (10,16) = (0,1)$ in $\mathbb{F}_5$, so $CA = I_2$.

The third row $\mathbf{z} = (1,3,1)$ of G satisfies $\mathbf{z}A = \mathbf{0}$, since $\mathbf{z}A$ is row 3 of $GA = A_r$. So adding $\mathbf{z}$ to the first row of C gives another left inverse,

$$C' = \begin{pmatrix} 4 & 4 & 1 \\ 4 & 2 & 0 \end{pmatrix},$$

and indeed $4(1,2) + 4(3,4) + (0,1) = (16,25) = (1,0)$. By Exercise 3.5.33(c), with $q = 5$, $m = 3$, $n = 2$, there are $5^{2 \cdot 1} = 25$ left inverses: each row of C may be changed by any of the 5 multiples of $\mathbf{z}$.

Solution to Exercise 3.5.33

> *Uses.* Proposition 3.5.9 (Left inverses), Proposition 3.5.8 (Right inverses from the pivots), Corollary 3.4.14 (Counting solutions), Definition 2.4.1 (Matrix product), Corollary 3.5.15 (Invertible matrices are square), Theorem 3.5.23 (One-sided inverses of square matrices), Proposition 3.5.2 (First properties of rank)
> *Hint 1.* For (a) and (b), subtract: $AX = I_m = AX_0$ if and only if $A(X - X_0) = 0$, and similarly on the left.
> *Hint 2.* For (b), a row vector $\mathbf{z}$ satisfies $\mathbf{z}A = \mathbf{0}$ if and only if $\mathbf{w}A_r = \mathbf{0}$, where $\mathbf{w} = \mathbf{z}G^{-1}$. What is $\mathbf{w}A_r$ when $A_r = \begin{pmatrix} I_n \\ 0 \end{pmatrix}$?
> *Hint 3.* For (c), count the possible columns of K with Corollary 3.4.14(b), and the possible rows of $C - C_0$ using that the rows of G are linearly independent.
> *Sketch.* (a) $AX = I_m$ iff $A(X - X_0) = 0$. (b) $CA = I_n$ iff $ZA = 0$ for $Z = C - C_0$. A row $\mathbf{z}$ has $\mathbf{z}A = \mathbf{0}$ iff $\mathbf{w} = \mathbf{z}G^{-1}$ has $\mathbf{w}A_r = (w_1, \ldots, w_n) = \mathbf{0}$, iff $\mathbf{z} = \mathbf{w}G$ is a combination of rows $n+1, \ldots, m$ of G. (c) $\ker T_A$ has q^{n-m} elements, and there are m columns; the span of $m - n$ independent rows has q^{m-n} elements, and there are n rows. (d) If $n > m$, a nonzero kernel vector perturbs a right inverse; if $m > n$, row m of G perturbs a left inverse; if $m = n$, the inverse is unique.

(a) If $AX_0 = I_m$, then $AX = I_m$ if and only if $A(X - X_0) = AX - AX_0 = 0$. By Definition 2.4.1, column j of AK is $A\mathbf{k}_j$, so $AK = 0$ says exactly that each column $\mathbf{k}_j$ of K lies in $\ker T_A$.

(b) By the first approach to Proposition 3.5.9, $C_0 A = I_n$, and $A_r = \begin{pmatrix} I_n \\ 0 \end{pmatrix}$. So $CA = I_n$ if and only if $ZA = 0$, where $Z = C - C_0$, that is, if and only if every row $\mathbf{z}$ of Z satisfies $\mathbf{z}A = \mathbf{0}$. Let $\mathbf{z} \in F^{1 \times m}$ and $\mathbf{w} = \mathbf{z}G^{-1}$, so that $\mathbf{z} = \mathbf{w}G$. Since $A = G^{-1}A_r$,

$$\mathbf{z}A = \mathbf{z}G^{-1}A_r = \mathbf{w}A_r = \mathbf{w}\begin{pmatrix} I_n \\ 0 \end{pmatrix} = (w_1, \ldots, w_n).$$

So $\mathbf{z}A = \mathbf{0}$ if and only if $w_1 = \cdots = w_n = 0$, if and only if $\mathbf{z} = \mathbf{w}G = w_{n+1}\mathbf{g}_{n+1} + \cdots + w_m\mathbf{g}_m$, where $\mathbf{g}_i$ is row i of G (Definition 2.4.1). This is the claim.

(c) *Right inverses.* Fix a right inverse X_0 (one exists, Proposition 3.5.8). By (a), the right inverses correspond bijectively to the matrices K whose m columns lie in $\ker T_A$. The system $A\mathbf{x} = \mathbf{0}$ is consistent with $n - m$ free variables (Proposition 3.5.2(b)), so $\ker T_A$ has q^{n-m} elements by Corollary 3.4.14(b). Choosing the m columns independently gives $(q^{n-m})^m = q^{m(n-m)}$ matrices K.

Left inverses. The rows $\mathbf{g}_{n+1}, \ldots, \mathbf{g}_m$ of G are linearly independent: if $\mathbf{c}G = \mathbf{0}$ for a row vector $\mathbf{c}$, then $\mathbf{c} = \mathbf{c}GG^{-1} = \mathbf{0}$. So distinct coefficient lists $(w_{n+1}, \ldots, w_m)$ give distinct combinations, and their span has exactly q^{m-n} elements. By (b), a left inverse is determined by choosing each of the n rows of $C - C_0$ in this span, which gives $(q^{m-n})^n = q^{n(m-n)}$ left inverses.

(d) If A is square and has a one-sided inverse, it is invertible and every one-sided inverse equals A^{-1} (Theorem 3.5.23). Suppose A is not square. If A has a right inverse X_0, then $n > m$ (Corollary 3.5.15(b)), so $\operatorname{rank} A = m < n$ and A has a free column; the corresponding basic solution $\mathbf{s} \neq \mathbf{0}$ lies in $\ker T_A$, and by (a) the matrix $X_0 + \mathbf{s}\mathbf{e}_1^{\mathsf{T}}$, whose first column is changed by $\mathbf{s}$, is a second right inverse. If A has a left inverse, then $m > n$, so G has a row $\mathbf{g}_m$ beyond the first n, and $\mathbf{g}_m \neq \mathbf{0}$ as G is invertible. By (b), adding $\mathbf{g}_m$ to the first row of C_0 gives a second left inverse.

Solution to Exercise 3.5.34

Uses. Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.13 (Second Fundamental Theorem, completed), Theorem 2.4.2 (The matrix of a composite), Proposition 2.4.23 (Transpose of a product), Remark 3.5.7 (Inverses of T_A and inverses of A), Theorem 3.5.14 (Third Fundamental Theorem, completed)
Hint 1. Translate rank conditions into injectivity or surjectivity of T_A, T_B, and $T_{AB} = T_A \circ T_B$.
Hint 2. For (c), think of a matrix that kills its own image. For (d), transpose a left inverse. For (e), try $A = 0$.
Hint 3. For (f), which of T_A and T_B fails to be injective?
Sketch. (a) True: a composition of injective maps is injective. (b) True: a composition of surjective maps is surjective. (c) False: $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has rank 1 and $A^2 = 0$. (d) True: if $CA = I_n$, then $A^{\mathsf{T}}C^{\mathsf{T}} = I_n$, so $T_{A^{\mathsf{T}}}$ is surjective onto F^n. (e) False: for $A = 0 \in F^{2\times 2}$, every pair of invertible matrices works. (f) True: $T_B : F^m \to F^n$ is not injective, hence neither is $T_A \circ T_B$.

(a) True. By Theorem 3.5.12, T_A and T_B are injective. If $(T_A \circ T_B)(\mathbf{x}) = (T_A \circ T_B)(\mathbf{x}')$, then $T_B\mathbf{x} = T_B\mathbf{x}'$ by injectivity of T_A, and then $\mathbf{x} = \mathbf{x}'$. So $T_{AB} = T_A \circ T_B$ (Theorem 2.4.2(b)) is injective, and since $AB \in F^{m\times p}$, Theorem 3.5.12 gives $\operatorname{rank}(AB) = p$.

(b) True. By Theorem 3.5.13, $T_A : F^n \to F^m$ and $T_B : F^p \to F^n$ are surjective. Given $\mathbf{y} \in F^m$, choose $\mathbf{u} \in F^n$ with $A\mathbf{u} = \mathbf{y}$ and then $\mathbf{x} \in F^p$ with $B\mathbf{x} = \mathbf{u}$; then $AB\mathbf{x} = \mathbf{y}$. So T_{AB} is surjective, and $\operatorname{rank}(AB) = m$ by Theorem 3.5.13.

(c) False. For $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, which is in RREF with one pivot, $\operatorname{rank} A = 1$, but $A^2 = 0$ has rank 0.

(d) True. By Theorem 3.5.12 and Remark 3.5.7, A has a left inverse $C \in F^{n\times m}$, $CA = I_n$. By Proposition 2.4.23, $A^{\mathsf{T}}C^{\mathsf{T}} = (CA)^{\mathsf{T}} = I_n^{\mathsf{T}} = I_n$. So $A^{\mathsf{T}} \in F^{n\times m}$ has a right inverse, and by Theorem 3.5.13 (applied to A^{T}, which has n rows), $\operatorname{rank} A^{\mathsf{T}} = n$.

(e) False. Let $A = 0 \in F^{2\times 2}$, so $k = 0$ and $N_0 = 0$. Then $GAH = 0 = N_0$ for every pair of invertible G, H, for instance $G = H = I_2$ and $G = H = E_{12}$.

(f) True. Since $m > n$, the map $T_B : F^m \to F^n$ is not injective, by the "moreover" part of Theorem 3.5.12: there is $\mathbf{x} \neq \mathbf{0}$ with $B\mathbf{x} = \mathbf{0}$. Then $AB\mathbf{x} = \mathbf{0}$, so T_{AB} is not injective, and the $m \times m$ matrix AB is not invertible (Theorem 3.5.14).

Solution to Exercise 3.5.35

Uses. Corollary 3.5.15 (Invertible matrices are square), Theorem 3.5.23 (One-sided inverses of square matrices), Definition 2.5.12 (Invertible)
Hint 1. Which step assumes something that has not been shown?
Hint 2. For (b), take $n = 1$ and $m = 2$.
Hint 3. For (c), if $P = I_m$, then B is both a left and a right inverse of A. What does Corollary 3.5.15 say?
Sketch. (a) P^{-1} need not exist; the argument assumes the conclusion that P is invertible. (b) $A = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, $B = \begin{pmatrix} 1 & 0 \end{pmatrix}$: $BA = I_1$ but $AB = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. (c) $P^2 = P$ as computed. If $m = n$, then $AB = I_n$ by Theorem 3.5.23; if $AB = I_m$, then A is invertible, so $m = n$ by Corollary 3.5.15.

(a) The computation $P^2 = P$ is correct. The error is the last step: it multiplies by P^{-1}, but nothing shows that P is invertible. In fact, an invertible P with $P^2 = P$ is I_m, so assuming that P is invertible is assuming the conclusion.

(b) Let $A = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \in F^{2\times 1}$ and $B = \begin{pmatrix} 1 & 0 \end{pmatrix} \in F^{1\times 2}$. Then $BA = (1) = I_1$, but $AB = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \neq I_2$.

(c) $P^2 = P$ holds whenever $BA = I_n$, by the computation in the "proof". If $m = n$, then $BA = I_n$ gives $AB = I_n$ by Theorem 3.5.23. Conversely, if $P = AB = I_m$, then $AB = I_m$ and $BA = I_n$, so A is invertible (Definition 2.5.12) and $m = n$ by Corollary 3.5.15(c). So for $m > n$ (the only other possibility, by Corollary 3.5.15(a)), P is an idempotent different from I_m; in (b) it is the projection $(x_1, x_2) \mapsto (x_1, 0)$.

Solution to Exercise 3.5.36

Uses. Proposition 3.5.2 (First properties of rank), Definition 2.4.33 (Block matrix), Definition 1.3.10 (Span)
Hint 1. Use Proposition 3.5.2(d): the rank counts the columns that are not combinations of earlier columns.

Hint 2. A combination of earlier columns of $\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$ has top block a combination of columns of A and bottom block a combination of columns of B. Treat the first n columns and the last q columns separately.
Hint 3. For (b), only the bottom block of a column $(\mathbf{c}_l; \mathbf{b}_l)$ is needed to show it is new. For strictness, try 1×1 blocks.
Sketch. (a) For $j \le n$, $(\mathbf{a}_j; \mathbf{0})$ is a combination of earlier columns iff $\mathbf{a}_j$ is one of $\mathbf{a}_1, \ldots, \mathbf{a}_{j-1}$. For $(\mathbf{0}; \mathbf{b}_l)$, a combination $\sum c_i(\mathbf{a}_i; \mathbf{0}) + \sum_{i<l} d_i(\mathbf{0}; \mathbf{b}_i)$ equals it iff $\sum c_i \mathbf{a}_i = \mathbf{0}$ and $\sum d_i \mathbf{b}_i = \mathbf{b}_l$, which is possible iff $\mathbf{b}_l \in \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_{l-1})$. Count with Proposition 3.5.2(d). (b) The same count works for the first n columns, and a column $(\mathbf{c}_l; \mathbf{b}_l)$ with $\mathbf{b}_l$ new is new, by looking at bottom blocks. Strict: $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.

Write $\mathbf{a}_1, \ldots, \mathbf{a}_n$ for the columns of A, $\mathbf{b}_1, \ldots, \mathbf{b}_q$ for those of B, and $\mathbf{c}_1, \ldots, \mathbf{c}_q$ for those of C. For column vectors $\mathbf{u} \in F^m$ and $\mathbf{v} \in F^p$, write $(\mathbf{u}; \mathbf{v}) \in F^{m+p}$ for the column with $\mathbf{u}$ on top of $\mathbf{v}$. By Proposition 3.5.2(d), the rank of a matrix is the number of its *new* columns, those not in the span of the columns before them.

(a) The columns of $M = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$ are $(\mathbf{a}_1; \mathbf{0}), \ldots, (\mathbf{a}_n; \mathbf{0}), (\mathbf{0}; \mathbf{b}_1), \ldots, (\mathbf{0}; \mathbf{b}_q)$. For $j \le n$, the combinations of the earlier columns are the vectors $\left(\sum_{i<j} c_i \mathbf{a}_i; \mathbf{0}\right)$, so $(\mathbf{a}_j; \mathbf{0})$ is new in M if and only if $\mathbf{a}_j$ is new in A. For $1 \le l \le q$, the combinations of the columns before $(\mathbf{0}; \mathbf{b}_l)$ are the vectors

$$\left(\sum_{i=1}^{n} c_i \mathbf{a}_i; \sum_{i<l} d_i \mathbf{b}_i\right).$$

Such a vector equals $(\mathbf{0}; \mathbf{b}_l)$ for some choice of scalars if and only if $\mathbf{b}_l \in \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_{l-1})$: if $\mathbf{b}_l = \sum_{i<l} d_i \mathbf{b}_i$, take all $c_i = 0$, and conversely the bottom block gives such an expression. So $(\mathbf{0}; \mathbf{b}_l)$ is new in M if and only if $\mathbf{b}_l$ is new in B. Counting, $\operatorname{rank} M = \operatorname{rank} A + \operatorname{rank} B$.

(b) For $M' = \begin{pmatrix} A & C \\ 0 & B \end{pmatrix}$, the first n columns are as in (a), so exactly $\operatorname{rank} A$ of them are new. Let $1 \le l \le q$ with $\mathbf{b}_l$ new in B. Every combination of the columns of M' before $(\mathbf{c}_l; \mathbf{b}_l)$ has bottom block $\sum_{i<l} d_i \mathbf{b}_i$, which is not $\mathbf{b}_l$. So $(\mathbf{c}_l; \mathbf{b}_l)$ is new in M'. Hence M' has at least $\operatorname{rank} A + \operatorname{rank} B$ new columns. For strict inequality, take 1×1 blocks $A = B = (0)$ and $C = (1)$: then $M' = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has rank $1 > 0 + 0$.

Solution to Exercise 3.5.37

Uses. Corollary 3.4.4 (Consistency), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.3.8 (Properties of the output), Definition 2.4.1 (Matrix product)
Hint 1. If both held, compute $\mathbf{z}^{\mathsf{T}} A \mathbf{x}$ in two ways.
Hint 2. If (i) fails, Corollary 3.4.4 gives an $i > \operatorname{rank} A$ with $(G\mathbf{y})_i \neq 0$. Take $\mathbf{z}^{\mathsf{T}}$ to be row i of G.
Sketch. Both cannot hold: $0 = \left(\mathbf{z}^{\mathsf{T}} A\right)\mathbf{x} = \mathbf{z}^{\mathsf{T}}\mathbf{y} \neq 0$. If (i) fails, some $i > \operatorname{rank} A$ has $(G\mathbf{y})_i \neq 0$; with $\mathbf{z}^{\mathsf{T}}$ the ith row of G, $\mathbf{z}^{\mathsf{T}} A$ is row i of A_r, which is zero, and $\mathbf{z}^{\mathsf{T}}\mathbf{y} = (G\mathbf{y})_i$. For Example 3.4.6, $\mathbf{z} = (-1, -1/2, 1)$ and $\mathbf{z}^{\mathsf{T}}\mathbf{y} = 1$.

Not both. If $A\mathbf{x} = \mathbf{y}$ and $\mathbf{z}^{\mathsf{T}} A = \mathbf{0}$, then $\mathbf{z}^{\mathsf{T}}\mathbf{y} = \mathbf{z}^{\mathsf{T}}(A\mathbf{x}) = \left(\mathbf{z}^{\mathsf{T}} A\right)\mathbf{x} = 0$, so (ii) fails.

At least one. Suppose (i) fails. Let G be invertible with $GA = A_r$, and $k = \operatorname{rank} A$. By Corollary 3.4.4 there is an i with $k < i \le m$ and $(G\mathbf{y})_i \neq 0$. Let $\mathbf{z}^{\mathsf{T}}$ be row i of G. By Definition 2.4.1, $\mathbf{z}^{\mathsf{T}} A$ is row i of $GA = A_r$, which is zero since $i > k$ (Proposition 3.3.8(a)), and $\mathbf{z}^{\mathsf{T}}\mathbf{y}$ is the ith entry of $G\mathbf{y}$, which is nonzero. So (ii) holds.

The example. In Example 3.4.6, $k = 2$ and the last row of G is $(-1, -1/2, 1)$. So $\mathbf{z} = (-1, -1/2, 1)$, and indeed $\mathbf{z}^{\mathsf{T}} A = -(0, 0, 2, 4) - \frac{1}{2}(2, 4, 2, 0) + (1, 2, 3, 4) = \mathbf{0}$ while $\mathbf{z}^{\mathsf{T}}\mathbf{y} = -4 - 1 + 6 = 1$. In words: minus the first equation, minus half the second, plus the third, reads $0 = 1$. Such a $\mathbf{z}$ is a certificate of inconsistency that anyone can check without redoing the elimination.

Solution to Exercise 3.5.38

Uses. Theorem 3.5.23 (One-sided inverses of square matrices)
Hint 1. Group ABC as $A(BC)$, or as $(AB)C$, and apply Theorem 3.5.23.
Hint 2. For (c), take $C = (AB)^{-1}$ with A and B invertible and $AB \neq BA$.
Sketch. (a) $A(BC) = I_n$ gives $(BC)A = I_n$. (b) $(AB)C = I_n$ gives $C(AB) = I_n$. (c) False: with $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, $B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, and $C = (AB)^{-1} = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$, we get $BAC = \begin{pmatrix} 0 & 1 \\ -1 & 3 \end{pmatrix}$.

(a) True. $A(BC) = I_n$, so by Theorem 3.5.23, $(BC)A = I_n$.

(b) True. $(AB)C = I_n$, so by Theorem 3.5.23, $C(AB) = I_n$.

(c) False. Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$. Then $AB = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$, whose inverse is $C = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$ (check: $\begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$). So $ABC = I_2$. But $BA = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$, and

$$BAC = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 3 \end{pmatrix} \neq I_2.$$

This works over every field, since the $(1,1)$ entry is $0 \neq 1$. In general $BAC = BA(AB)^{-1}$, which is I_n only if $BA = AB$. Cyclic shifts of a product equal to I_n are again I_n, but other rearrangements need not be.

Solution to Exercise 3.5.39

Uses. Theorem 3.5.23 (One-sided inverses of square matrices), Proposition 2.4.14 (Algebra of matrices)
Techniques. Uniqueness gives existence (Technique 3.4.21)
Hint 1. Rewrite $AB - A - B = 0$ so that it becomes a product equal to I_n. Add I_n to both sides.
Hint 2. $(A - I_n)(B - I_n) = I_n$. Now use that a one-sided inverse of a square matrix is two-sided.
Sketch. $(A - I_n)(B - I_n) = AB - A - B + I_n = I_n$. By Theorem 3.5.23, $(B - I_n)(A - I_n) = I_n$ as well, that is, $BA - A - B + I_n = I_n$. So $BA = A + B = AB$.

Expanding with the distributive laws (Proposition 2.4.14),

$$\begin{aligned}(A - I_n)(B - I_n) &= AB - A - B + I_n \\ &= (A + B) - A - B + I_n = I_n.\end{aligned}$$

So $B - I_n$ is a right inverse of the square matrix $A - I_n$. By Theorem 3.5.23 it is also a left inverse:

$$I_n = (B - I_n)(A - I_n) = BA - B - A + I_n.$$

Hence $BA = A + B = AB$, as desired.

The proof computes nothing: the commutation comes entirely from Theorem 3.5.23, applied to the square matrix $A - I_n$.

Solution to Exercise 3.5.40

Uses. Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Proposition 1.5.14 (Appending a vector), Proposition 1.4.14 (The span is the smallest subspace containing a list), Definition 1.6.1 (Basis), Theorem 2.2.1 (Linear maps are determined by a basis)
Techniques. Check it on a basis (Technique 2.2.7), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. For (a), imitate the second approach to Proposition 3.5.9. First show that $T\mathbf{v}_1, \ldots, T\mathbf{v}_n$ is linearly independent.
Hint 2. Append to $T\mathbf{v}_1, \ldots, T\mathbf{v}_n$ each $\mathbf{w}_i$ that is not yet in the span. Then define S on the resulting basis of W.
Hint 3. For (b), choose a preimage of each $\mathbf{c}_i$ and define R on the basis $\mathbf{c}_1, \ldots, \mathbf{c}_m$.
Sketch. (a) $T\mathbf{v}_1, \ldots, T\mathbf{v}_n$ is independent since $\ker T = \{\mathbf{0}\}$. Appending each $\mathbf{w}_i$ not yet in the span keeps independence (Proposition 1.5.14) and ends with a list spanning W, hence a basis. Define $S(T\mathbf{v}_j) = \mathbf{v}_j$ and $S = \mathbf{0}$ on the appended vectors; $S \circ T$ fixes each $\mathbf{v}_j$, so it is id_V. (b) Pick $\mathbf{u}_i$ with $T\mathbf{u}_i = \mathbf{c}_i$ and let $R(\mathbf{c}_i) = \mathbf{u}_i$; $T \circ R$ fixes each $\mathbf{c}_i$, so it is id_W.

(a) *The images are independent.* If $c_1 T\mathbf{v}_1 + \cdots + c_n T\mathbf{v}_n = \mathbf{0}$, then $T(c_1\mathbf{v}_1 + \cdots + c_n\mathbf{v}_n) = \mathbf{0}$ by linearity, so $c_1\mathbf{v}_1 + \cdots + c_n\mathbf{v}_n = \mathbf{0}$, because $\ker T = \{\mathbf{0}\}$ (Theorem 2.6.11), and all $c_j = 0$ because $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is independent.

Extending to a basis of W. Let $\mathcal{L}_0 = T\mathbf{v}_1, \ldots, T\mathbf{v}_n$, and for $i = 1, \ldots, p$ let $\mathcal{L}_i = \mathcal{L}_{i-1}$ if $\mathbf{w}_i \in \operatorname{span}(\mathcal{L}_{i-1})$, and $\mathcal{L}_i = \mathcal{L}_{i-1}, \mathbf{w}_i$ otherwise. Each $\mathcal{L}_i$ is independent by Proposition 1.5.14, and every $\mathbf{w}_i$ lies in $\operatorname{span}(\mathcal{L}_p)$. So $\operatorname{span}(\mathcal{L}_p)$ is a subspace containing a spanning list of W, hence equals W (Proposition 1.4.14), and $\mathcal{L}_p = T\mathbf{v}_1, \ldots, T\mathbf{v}_n, \mathbf{w}_{i_1}, \ldots, \mathbf{w}_{i_t}$ is a basis of W (Definition 1.6.1).

Defining S. By Theorem 2.2.1 there is a linear $S : W \to V$ with $S(T\mathbf{v}_j) = \mathbf{v}_j$ for each j and $S(\mathbf{w}_{i_s}) = \mathbf{0}$ for each s. Then $(S \circ T)(\mathbf{v}_j) = \mathbf{v}_j$ for every j, so the linear maps $S \circ T$ and id_V agree on a basis of V and are equal by the uniqueness in Theorem 2.2.1.

(b) Since T is surjective, for each i there is $\mathbf{u}_i \in V$ with $T\mathbf{u}_i = \mathbf{c}_i$; fix one. By Theorem 2.2.1 there is a linear $R : W \to V$ with $R(\mathbf{c}_i) = \mathbf{u}_i$ for each i. Then $(T \circ R)(\mathbf{c}_i) = \mathbf{c}_i$ for every i, so $T \circ R = \mathrm{id}_W$, again by uniqueness in Theorem 2.2.1.

In (a), some finiteness assumption on W is what lets the extension stop; Section 4.1 develops this. In (b) the choice of the $\mathbf{u}_i$ is where right inverses get their freedom, as in Exercise 3.5.33(a).

Solution to Exercise 3.5.41

Uses. Theorem 3.5.27 (Rank normal form), Proposition 3.5.2 (First properties of rank), Theorem 2.4.34 (Block multiplication), Theorem 3.5.13 (Second Fundamental Theorem, completed), Theorem 2.4.2 (The matrix of a composite), Theorem 3.3.12 (Matrices in RREF)
Hint 1. For (a), $N_kQ = \begin{pmatrix} Q_1 \\ 0 \end{pmatrix}$, where Q_1 consists of the first k rows of Q. Zero rows do not affect relations among the columns, so $\operatorname{rank}(N_kQ) = \operatorname{rank} Q_1$ by Proposition 3.5.2(d).
Hint 2. $Q_1 = (I_k \;\; 0)Q$, and both $T_{(I_k \;\; 0)}$ and T_Q are surjective. Apply Theorem 3.5.13 to Q_1.
Hint 3. For (b), compare a given normal form with the one from Theorem 3.5.27: $N_j = \left(GG_0^{-1}\right)N_k\left(H_0^{-1}H\right)$. For (c), find a normal form of AH.
Sketch. (a) By block multiplication $N_kQ = \begin{pmatrix} Q_1 \\ 0 \end{pmatrix}$, and its columns satisfy the same relations as those of Q_1, so $\operatorname{rank}(N_kQ) = \operatorname{rank} Q_1$. As $T_{Q_1} = T_{(I_k \;\; 0)} \circ T_Q$ is surjective onto F^k, $\operatorname{rank} Q_1 = k$. (b) With $G_0AH_0 = N_k$, $k = \operatorname{rank} A$: $N_j = \left(GG_0^{-1}\right)N_k\left(H_0^{-1}H\right)$, so $j = \operatorname{rank} N_j = \operatorname{rank}\left(N_kH_0^{-1}H\right) = k$ by row invariance and (a). (c) $G_0(AH)\left(H^{-1}H_0\right) = N_k$, so $\operatorname{rank}(AH) = k$ by (b). (d) Use (c) and row invariance for $\Rightarrow$; both are equivalent to N_k for $\Leftarrow$.

(a) Partition Q into its first k rows $Q_1 \in F^{k\times n}$ and the remaining rows Q_2, and N_k into blocks with row sizes $k, m-k$ and column sizes $k, n-k$. By Theorem 2.4.34,

$$N_kQ = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = \begin{pmatrix} Q_1 \\ 0 \end{pmatrix}.$$

A list of scalars $x_1, \dots, x_n$ satisfies $\sum_l x_l\mathbf{q}'_l = \mathbf{0}$ for the columns $\mathbf{q}'_l$ of $\begin{pmatrix} Q_1 \\ 0 \end{pmatrix}$ if and only if it satisfies $\sum_l x_l\mathbf{q}_l = \mathbf{0}$ for the columns $\mathbf{q}_l$ of Q_1, since the extra entries are all 0. In particular, a column of $\begin{pmatrix} Q_1 \\ 0 \end{pmatrix}$ is a combination of the earlier ones exactly when the same holds in Q_1, so $\operatorname{rank}(N_kQ) = \operatorname{rank} Q_1$ by Proposition 3.5.2(d).

Now $Q_1 = (I_k \;\; 0)Q$, where $(I_k \;\; 0) \in F^{k\times n}$ (again by block multiplication). The map $T_{(I_k \;\; 0)}$ sends $(x_1, \dots, x_n)$ to $(x_1, \dots, x_k)$, so it is surjective onto F^k, and T_Q is surjective because Q is invertible. So $T_{Q_1} = T_{(I_k \;\; 0)} \circ T_Q$ (Theorem 2.4.2(b)) is surjective, and $\operatorname{rank} Q_1 = k$ by Theorem 3.5.13. Hence $\operatorname{rank}(N_kQ) = k$.

(b) By Theorem 3.5.27 there are invertible G_0, H_0 with $G_0AH_0 = N_k$, where $k = \operatorname{rank} A$. So $A = G_0^{-1}N_kH_0^{-1}$, and if $GAH = N_j$, then

$$N_j = \left(GG_0^{-1}\right)N_k\left(H_0^{-1}H\right).$$

The matrix N_j satisfies (R1)–(R4), so it is in RREF with j pivots (Theorem 3.3.12), and $\operatorname{rank} N_j = j$. On the other hand, GG_0^{-1} is invertible, so by Proposition 3.5.2(c) and (a) with $Q = H_0^{-1}H$,

$$\operatorname{rank} N_j = \operatorname{rank}\left(N_kH_0^{-1}H\right) = k.$$

So $j = k = \operatorname{rank} A$.

(c) With G_0, H_0, k as in (b), $G_0(AH)\left(H^{-1}H_0\right) = G_0AH_0 = N_k$, and $H^{-1}H_0$ is invertible. By (b), applied to the matrix AH, $\operatorname{rank}(AH) = k = \operatorname{rank} A$.

(d) If $B = GAH$, then $\operatorname{rank} B = \operatorname{rank}(G(AH)) = \operatorname{rank}(AH) = \operatorname{rank} A$ by Proposition 3.5.2(c) and (c). Conversely, if both have rank k, then $G_1AH_1 = N_k = G_2BH_2$ for invertible G_1, H_1, G_2, H_2, so

$$B = \left(G_2^{-1}G_1\right)A\left(H_1H_2^{-1}\right),$$

with both brackets invertible.

Solution to Exercise 3.5.42

Uses. Theorem 3.5.27 (Rank normal form), Theorem 2.4.34 (Block multiplication), Proposition 2.4.14 (Algebra of matrices)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. Start from $A = G^{-1}N_kH^{-1}$. Which square matrices are obviously idempotent?
Hint 2. $N_k^2 = N_k$. Conjugates of idempotents are idempotent: $\left(XN_kX^{-1}\right)^2 = XN_k^2X^{-1}$. Insert $H^{-1}H$ or GG^{-1} in the right place.
Sketch. $A = G^{-1}N_kH^{-1} = \left(G^{-1}H^{-1}\right)\left(HN_kH^{-1}\right)$, and $\left(HN_kH^{-1}\right)^2 = HN_k^2H^{-1} = HN_kH^{-1}$ since $N_k^2 = N_k$. Similarly $A = \left(G^{-1}N_kG\right)\left(G^{-1}H^{-1}\right)$.

By Theorem 3.5.27, $GAH = N_k$ for invertible G, H and $k = \operatorname{rank} A$, so $A = G^{-1}N_kH^{-1}$. Here $N_k \in F^{n\times n}$, and by block multiplication $N_k^2 = \begin{pmatrix} I_k^2 & 0 \\ 0 & 0 \end{pmatrix} = N_k$. Now

$$A = G^{-1}N_kH^{-1} = \left(G^{-1}H^{-1}\right)\left(HN_kH^{-1}\right).$$

The first factor $S = G^{-1}H^{-1}$ is invertible, with inverse HG. The second, $P = HN_kH^{-1}$, satisfies

$$P^2 = HN_k\left(H^{-1}H\right)N_kH^{-1} = HN_k^2H^{-1} = HN_kH^{-1} = P.$$

Similarly $A = \left(G^{-1}N_kG\right)\left(G^{-1}H^{-1}\right)$, and $P' = G^{-1}N_kG$ is idempotent by the same computation, while $S' = G^{-1}H^{-1}$ is invertible.

So up to an invertible factor, every square matrix is an idempotent. The idempotent $P = HN_kH^{-1}$ fixes the first k columns of H and kills the others; in the language of Corollary 3.5.29, it is the projection onto the span of $\mathbf{b}_1, \ldots, \mathbf{b}_k$ along the kernel of A.

Solution to Exercise 3.5.43

Uses. Theorem 3.5.27 (Rank normal form), Theorem 2.4.34 (Block multiplication), Definition 2.4.21 (Transpose)
Hint 1. Solve the problem for N_k first: which $n \times m$ matrix Y satisfies $N_kYN_k = N_k$ and $YN_kY = Y$?
Hint 2. $Y = N_k^{\mathsf{T}}$ works. Transport it with $A = G^{-1}N_kH^{-1}$: try $X = HN_k^{\mathsf{T}}G$.
Hint 3. For (c), write $\mathbf{y} = A\mathbf{x}_0$ and compute $AX\mathbf{y}$.
Sketch. (a) By block multiplication $N_kN_k^{\mathsf{T}}N_k = N_k$ and $N_k^{\mathsf{T}}N_kN_k^{\mathsf{T}} = N_k^{\mathsf{T}}$. With $A = G^{-1}N_kH^{-1}$ and $X = HN_k^{\mathsf{T}}G$, the factors $H^{-1}H$ and GG^{-1} cancel in AXA and XAX. (b) If $CA = I_n$, then $ACA = A$ and $CAC = C$; similarly for right inverses. (c) If $\mathbf{y} = A\mathbf{x}_0$, then $AX\mathbf{y} = AXA\mathbf{x}_0 = A\mathbf{x}_0 = \mathbf{y}$.

(a) First take $A = N_k$, and let $Y = N_k^{\mathsf{T}} \in F^{n\times m}$, which has 1 in positions $(1,1), \ldots, (k,k)$ and 0 elsewhere. By block multiplication, $N_kN_k^{\mathsf{T}} \in F^{m\times m}$ has the block form $\begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix}$, and then

$$N_kN_k^{\mathsf{T}}N_k = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix} = N_k,$$

where the second factor is $N_k \in F^{m\times n}$. In the same way $N_k^{\mathsf{T}}N_kN_k^{\mathsf{T}} = N_k^{\mathsf{T}}$.

For general A, take G, H invertible with $GAH = N_k$ (Theorem 3.5.27), so $A = G^{-1}N_kH^{-1}$, and let $X = HN_k^{\mathsf{T}}G$. Then

$$\begin{aligned} AXA &= G^{-1}N_k\left(H^{-1}H\right)N_k^{\mathsf{T}}\left(GG^{-1}\right)N_kH^{-1} \\ &= G^{-1}N_kN_k^{\mathsf{T}}N_kH^{-1} = G^{-1}N_kH^{-1} = A, \\ XAX &= HN_k^{\mathsf{T}}\left(GG^{-1}\right)N_k\left(H^{-1}H\right)N_k^{\mathsf{T}}G \\ &= HN_k^{\mathsf{T}}N_kN_k^{\mathsf{T}}G = HN_k^{\mathsf{T}}G = X. \end{aligned}$$

(b) If $CA = I_n$, then $ACA = A(CA) = A$ and $CAC = (CA)C = C$. If $AC = I_m$, then $ACA = (AC)A = A$ and $CAC = C(AC) = C$.

(c) If $A\mathbf{x} = \mathbf{y}$ is consistent, say $\mathbf{y} = A\mathbf{x}_0$, then $A(X\mathbf{y}) = AXA\mathbf{x}_0 = A\mathbf{x}_0 = \mathbf{y}$.

So a generalized inverse solves every consistent system $A\mathbf{x} = \mathbf{y}$ by a single matrix multiplication, even when A has neither kind of one-sided inverse. Generalized inverses are not unique: by (b) and Exercise 3.5.33(d), a non-square matrix with a one-sided inverse has more than one.

Solution to Exercise 3.5.44

Uses. Theorem 3.5.27 (Rank normal form), Corollary 3.5.25 (The invertible matrix theorem), Definition 2.4.1 (Matrix product)
Hint 1. One direction is quick: if A is invertible and $AB = 0$, multiply by A^{-1}.
Hint 2. For the other, solve the problem for N_k with $k < n$ first. Which nonzero matrix U has $N_kU = UN_k = 0$?
Hint 3. Take U with a single 1 in position (n, n), and transport it: $B = HUG$.
Sketch. If A is invertible and $AB = 0$, then $B = A^{-1}AB = 0$. If not, $k = \operatorname{rank} A < n$ and $GAH = N_k$. The matrix U with a single 1 in position (n, n) has $N_kU = 0$ and $UN_k = 0$, because column n and row n of N_k are zero. Then $B = HUG \neq 0$ satisfies $AB = G^{-1}N_kUG = 0$ and $BA = HUN_kH^{-1} = 0$.

If A is invertible and $AB = 0$, then $B = A^{-1}(AB) = 0$. So an invertible A has no such B.

Conversely, suppose A is not invertible, so $k = \operatorname{rank} A < n$ (Corollary 3.5.25). By Theorem 3.5.27, $GAH = N_k$ for invertible G, H, so $A = G^{-1}N_kH^{-1}$. Let $U \in F^{n\times n}$ have entry 1 in position (n, n) and 0 elsewhere. Since $k < n$, column n and row n of N_k are zero. By Definition 2.4.1, N_kU has as its only possibly nonzero column $N_k\mathbf{e}_n$, which is column n of N_k, so $N_kU = 0$; and UN_k has as its only possibly nonzero row $\mathbf{e}_n^{\mathsf{T}}N_k$, which is row n of N_k, so $UN_k = 0$. Let $B = HUG$. Then $B \neq 0$, since otherwise $U = H^{-1}BG^{-1} = 0$, and

$$AB = G^{-1}N_k\big(H^{-1}H\big)UG = G^{-1}(N_kU)G = 0,$$
$$BA = HU\big(GG^{-1}\big)N_kH^{-1} = H(UN_k)H^{-1} = 0,$$

as desired. (In fact $B = HUG$ has rank 1, the rank of U, by Exercise 3.5.41(c) and Proposition 3.5.2(c).)

Solution to Exercise 3.5.45

Uses. Theorem 3.5.27 (Rank normal form), Corollary 3.5.24 (Products of square matrices)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. If $GAH = N_k$ and $N_k = D_1 + D_2$ with D_1, D_2 invertible, what can you say about A?
Hint 2. Choose $c \in F$ with $c \neq 0, 1$. Split each diagonal entry of N_k, which is 1 or 0, as a sum of two nonzero scalars.
Sketch. (a) $A = G^{-1}N_kH^{-1}$, so it suffices to split N_k. With $c \neq 0, 1$, let D_1 be diagonal with entries c (k times) and then 1, and D_2 diagonal with entries $1 - c$ (k times) and then -1. Both are invertible and $D_1 + D_2 = N_k$; then $A = G^{-1}D_1H^{-1} + G^{-1}D_2H^{-1}$. (b) The only invertible 1×1 matrix over $\mathbb{F}_2$ is (1), and $(1) + (1) = (0)$.

(a) By Theorem 3.5.27, $A = G^{-1}N_kH^{-1}$ with G, H invertible. Suppose $N_k = D_1 + D_2$ with D_1, D_2 invertible. Then

$$A = G^{-1}D_1H^{-1} + G^{-1}D_2H^{-1},$$

and each term is a product of invertible matrices, hence invertible (Corollary 3.5.24). So it suffices to split N_k.

Since F has at least three elements, there is $c \in F$ with $c \neq 0$ and $c \neq 1$. Let D_1 be the diagonal matrix with diagonal entries $c, \ldots, c$ (k times) followed by $1, \ldots, 1$ ($n - k$ times), and D_2 the diagonal matrix with entries $1 - c, \ldots, 1 - c$ (k times) followed by $-1, \ldots, -1$. Their sum is diagonal with entries $c + (1 - c) = 1$ (k times) and $1 + (-1) = 0$, that is, N_k. A diagonal matrix whose diagonal entries d_i are all nonzero is invertible, with inverse the diagonal matrix with entries d_i^{-1}; and c, 1, $1 - c$, -1 are all nonzero. So D_1 and D_2 are invertible.

(b) Over $\mathbb{F}_2$, a 1×1 matrix (a) is invertible if and only if $a \neq 0$, that is, $a = 1$. The only sum of two invertible 1×1 matrices is $(1) + (1) = (0)$, so (1) is not such a sum.

Solution to Exercise 3.5.46

Uses. Exercise 3.5.45, Theorem 3.5.27 (Rank normal form), Theorem 2.4.34 (Block multiplication), Theorem 3.3.23 (Invertibility and RREF), Theorem 3.5.23 (One-sided inverses of square matrices), Corollary 3.5.24 (Products of square matrices)
Techniques. Block decomposition (Technique 2.4.35)

Hint 1. As in Exercise 3.5.45, it suffices to write each $N_k \in \mathbb{F}_2^{n\times n}$ as a sum of two invertible matrices. Diagonal splittings are impossible now, since the only nonzero scalar is 1.
Hint 2. Work with small diagonal blocks. Split $(0) = (1) + (1)$, $I_2 = \begin{pmatrix}1&1\\1&0\end{pmatrix} + \begin{pmatrix}0&1\\1&1\end{pmatrix}$, and $\begin{pmatrix}1&0\\0&0\end{pmatrix} = \begin{pmatrix}1&1\\1&0\end{pmatrix} + \begin{pmatrix}0&1\\1&0\end{pmatrix}$. A block diagonal matrix with invertible blocks is invertible.
Hint 3. The blocks above handle every N_k except $N_n = I_n$ for odd n. For that you need a 3×3 block: find an invertible X such that $I_3 + X$ is also invertible.
Sketch. Reduce to N_k as in Exercise 3.5.45. Write N_k as block diagonal with blocks I_2, $\begin{pmatrix}1&0\\0&0\end{pmatrix}$, (0), and I_3, each split into two invertible blocks: $(0) = (1) + (1)$, $I_2 = \begin{pmatrix}1&1\\1&0\end{pmatrix} + \begin{pmatrix}0&1\\1&1\end{pmatrix}$, $\begin{pmatrix}1&0\\0&0\end{pmatrix} = \begin{pmatrix}1&1\\1&0\end{pmatrix} + \begin{pmatrix}0&1\\1&0\end{pmatrix}$, $I_3 = X + (I_3 + X)$ with $X = \begin{pmatrix}0&0&1\\1&0&1\\0&1&0\end{pmatrix}$. For k even use $k/2$ blocks I_2; for k odd and $k < n$ use one $\begin{pmatrix}1&0\\0&0\end{pmatrix}$; for $k = n$ odd use one I_3. The remaining diagonal positions are (0) blocks.

As in the proof of Exercise 3.5.45(a), $A = G^{-1}N_kH^{-1}$, and it suffices to write $N_k = X + Y$ with X, Y invertible. We use block diagonal matrices (Theorem 2.4.34): if $X = \operatorname{diag}(X_1, \ldots, X_r)$ and $Y = \operatorname{diag}(Y_1, \ldots, Y_r)$ are block diagonal with the same block sizes, then $X + Y = \operatorname{diag}(X_1 + Y_1, \ldots, X_r + Y_r)$, and if each X_i is invertible, then X is invertible, with inverse $\operatorname{diag}\left(X_1^{-1}, \ldots, X_r^{-1}\right)$, by block multiplication.

Building blocks. Over $\mathbb{F}_2$:

- $(0) = (1) + (1)$.
- $I_2 = \begin{pmatrix}1&1\\1&0\end{pmatrix} + \begin{pmatrix}0&1\\1&1\end{pmatrix}$, and $\begin{pmatrix}1&0\\0&0\end{pmatrix} = \begin{pmatrix}1&1\\1&0\end{pmatrix} + \begin{pmatrix}0&1\\1&0\end{pmatrix}$. Here $\begin{pmatrix}1&1\\1&0\end{pmatrix}$ reduces to I_2 by adding row 1 to row 2 and then row 2 to row 1; $\begin{pmatrix}0&1\\1&1\end{pmatrix}$ reduces to I_2 by a swap and then adding row 2 to row 1; and $\begin{pmatrix}0&1\\1&0\end{pmatrix}$ is a swap. So all three are invertible (Theorem 3.3.23).
- $I_3 = X + (I_3 + X)$ with
$$X = \begin{pmatrix}0&0&1\\1&0&1\\0&1&0\end{pmatrix}, \quad I_3 + X = \begin{pmatrix}1&0&1\\1&1&1\\0&1&1\end{pmatrix}.$$
Both are invertible: one checks that $X\begin{pmatrix}1&1&0\\0&0&1\\1&0&0\end{pmatrix} = I_3$ and $(I_3 + X)\begin{pmatrix}0&1&1\\1&1&0\\1&1&1\end{pmatrix} = I_3$, and a one-sided inverse of a square matrix is an inverse (Theorem 3.5.23).

Assembling N_k. The diagonal of N_k is k ones followed by $n - k$ zeros. Partition it into consecutive diagonal blocks as follows, putting (0) blocks on all remaining zero positions.

- If k is even, use $k/2$ blocks I_2.
- If k is odd and $k < n$, use $(k-1)/2$ blocks I_2 and then one block $\begin{pmatrix}1&0\\0&0\end{pmatrix}$, which covers the last one and the first zero.
- If $k = n$ is odd, then $n \geq 3$; use one block I_3 and $(n-3)/2$ blocks I_2.

In each case N_k is block diagonal with blocks from the list above, so splitting each block as shown writes N_k as a sum of two block diagonal matrices with invertible blocks, which are invertible.

Finally $A = G^{-1}XH^{-1} + G^{-1}YH^{-1}$, a sum of two invertible matrices (Corollary 3.5.24). The case $k = n = 1$ is exactly the one excluded by $n \geq 2$.

Section 3.6

Solution to Exercise 3.6.6

Uses. Corollary 3.3.19 (Pivot columns, intrinsically), Corollary 3.2.17 (Row operations preserve relations among columns), Proposition 3.1.8 (Systems and the map T_A), Corollary 3.4.4 (Consistency), Non-example 3.2.19 (Row operations move the column space)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. Every column of A has third entry equal to the sum of the first two. Does $(1, 0, 0)$?

Hint 2. Row operations preserve the relations among the columns, so they preserve *which* columns are pivot columns. Do they preserve the columns themselves?
Hint 3. Use Corollary 3.3.19(b): every column of A is a combination of the pivot columns *of* A.
Sketch. (a) The columns $(1,2,3)$, $(2,4,6)$, $(0,1,1)$ all satisfy $y_3 = y_1 + y_2$, so every vector of $\operatorname{im} T_A$ does, and $(1,0,0)$ does not. The relations transfer, but the columns of $\operatorname{rref}(A) = GA$ are $G\mathbf{a}_j$, and they span $\operatorname{im} T_{GA}$, not $\operatorname{im} T_A$. (b) The pivot columns of A, $(1,2,3)$ and $(0,1,1)$, span $\operatorname{im} T_A$, which is the plane $y_3 = y_1 + y_2$.

(a) The columns of A are $\mathbf{a}_1 = (1,2,3)$, $\mathbf{a}_2 = (2,4,6)$, and $\mathbf{a}_3 = (0,1,1)$, and each satisfies $y_3 = y_1 + y_2$. This condition is preserved by sums and scalar multiples, so every linear combination of the columns satisfies it, and by Proposition 3.1.8(a) every vector of $\operatorname{im} T_A$ does. The vector $(1,0,0)$ has $0 \neq 1 + 0$, so it is not in $\operatorname{im} T_A$.

The first sentence of the argument is correct (Corollary 3.2.17), and it does show that columns 1 and 3 of A are independent and that column 2 is a combination of them. The error is the step from relations to the vectors themselves. Writing $\operatorname{rref}(A) = GA$ with G invertible, the columns of $\operatorname{rref}(A)$ are $G\mathbf{a}_1, G\mathbf{a}_2, G\mathbf{a}_3$, so they span $\operatorname{im} T_{GA}$, the image of T_A moved by G. Row operations move the image (Non-example 3.2.19).

(b) By Corollary 3.3.19(b), the non-pivot column $\mathbf{a}_2$ is a combination of the pivot column $\mathbf{a}_1$ (indeed $\mathbf{a}_2 = 2\mathbf{a}_1$, read off the entry 2 of $\operatorname{rref}(A)$). So $\operatorname{im} T_A = \operatorname{span}(\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3) = \operatorname{span}(\mathbf{a}_1, \mathbf{a}_3) = \operatorname{span}((1,2,3),(0,1,1))$. For an equation: we showed that every vector of $\operatorname{im} T_A$ satisfies $y_3 = y_1 + y_2$. Conversely, if $y_3 = y_1 + y_2$, then

$$y_1(1,2,3) + (y_2 - 2y_1)(0,1,1) = (y_1, y_2, y_1 + y_2) = \mathbf{y},$$

so $\mathbf{y} \in \operatorname{im} T_A$. Hence $\operatorname{im} T_A = \{\mathbf{y} \in \mathbb{R}^3 \mid y_3 = y_1 + y_2\}$. (The same equation comes out of Corollary 3.4.4: reducing A uses $E_{1,-2,2}$, $E_{1,-3,3}$, and $E_{2,-1,3}$, and the last row of G is $(-1,-1,1)$.)

Solution to Exercise 3.6.7

Uses. Corollary 3.3.19 (Pivot columns, intrinsically), Theorem 3.4.9 (All solutions), Definition 3.4.8 (Basic solutions), Proposition 3.1.8 (Systems and the map T_A)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. Columns 1 and 3 are the pivot columns. What does Corollary 3.3.19(b) say about columns 2 and 4?
Hint 2. The kernel depends only on $\operatorname{rref}(A)$: use the basic solutions. The image is spanned by the pivot columns of A.
Sketch. (a) $\mathbf{a}_2 = 2\mathbf{a}_1 = (2,2,4)$ and $\mathbf{a}_4 = -\mathbf{a}_1 + 3\mathbf{a}_3 = (-1,2,-5)$. (b) $\ker T_A = \operatorname{span}((-2,1,0,0),(1,0,-3,1))$, and $\operatorname{im} T_A = \operatorname{span}(\mathbf{a}_1, \mathbf{a}_3)$, which is the plane $y_3 = 3y_1 - y_2$.

(a) The pivot columns of $\operatorname{rref}(A)$ are 1 and 3, so these are the pivot columns of A, and columns 2 and 4 are free. By Corollary 3.3.19(b), each free column of A is the combination of the pivot columns to its left whose coefficients are the entries of the corresponding column of $\operatorname{rref}(A)$:

$$\mathbf{a}_2 = 2\mathbf{a}_1 = (2,2,4), \quad \mathbf{a}_4 = -\mathbf{a}_1 + 3\mathbf{a}_3 = (-1, -1+3, -2-3) = (-1,2,-5).$$

So

$$A = \begin{pmatrix} 1 & 2 & 0 & -1 \\ 1 & 2 & 1 & 2 \\ 2 & 4 & -1 & -5 \end{pmatrix}.$$

(b) By Theorem 3.4.9, $\ker T_A$ is spanned by the basic solutions (Definition 3.4.8), one for each free column, read off from $\operatorname{rref}(A)$: $\mathbf{s}_1 = (-2,1,0,0)$ and $\mathbf{s}_2 = (1,0,-3,1)$. As a check, $A\mathbf{s}_1 = -2\mathbf{a}_1 + \mathbf{a}_2 = \mathbf{0}$ and $A\mathbf{s}_2 = \mathbf{a}_1 - 3\mathbf{a}_3 + \mathbf{a}_4 = \mathbf{0}$.

By (a), every column of A is a combination of $\mathbf{a}_1$ and $\mathbf{a}_3$, so $\operatorname{im} T_A = \operatorname{span}(\mathbf{a}_1, \mathbf{a}_3)$ (Proposition 3.1.8(a)). A vector $\mathbf{y}$ lies in it if and only if $\mathbf{y} = s(1,1,2) + t(0,1,-1) = (s, s+t, 2s-t)$ for some s,t. Such s,t must be $s = y_1$ and $t = y_2 - y_1$, and then the third entry is $2y_1 - (y_2 - y_1) = 3y_1 - y_2$. So $\operatorname{im} T_A = \{\mathbf{y} \in \mathbb{R}^3 \mid y_3 = 3y_1 - y_2\}$.

Solution to Exercise 3.6.8

Uses. Proposition 3.2.30 (Column operations preserve the image), Non-example 3.2.31 (Column operations change the kernel), Corollary 3.2.23 (Row equivalent matrices have the same kernel), Proposition 2.4.23 (Transpose of a product), Exercise 3.5.41, Definition 2.5.1 (Left inverse)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. (a) and (b) are in Section 3.2.5. For (c), transpose: $\mathbf{z}A = \mathbf{0}$ says $A^\mathsf{T}\mathbf{z}^\mathsf{T} = \mathbf{0}$. What is $(AH)^\mathsf{T}$?
Hint 2. For (d), try $A = \begin{pmatrix}0 & 1\end{pmatrix}$ and a swap. For (f), if $CA = I_n$, find a left inverse of AH.
Sketch. (a) Same, Proposition 3.2.30. (b) Not always: $\begin{pmatrix}1 & 1\end{pmatrix}$ and $\begin{pmatrix}0 & 1\end{pmatrix}$. (c) Same: $(AH)^\mathsf{T} = H^\mathsf{T}A^\mathsf{T}$ is a row operation applied to A^T, which keeps the kernel; or directly, $\mathbf{z}AH = \mathbf{0} \Leftrightarrow \mathbf{z}A = \mathbf{0}$. (d) Not always: $\begin{pmatrix}0 & 1\end{pmatrix}$ and $\begin{pmatrix}1 & 0\end{pmatrix}$. (e) Same, by Exercise 3.5.41(c). (f) Same: $\left(H^{-1}C\right)(AH) = I_n$.

Since $A = (AH)H^{-1}$ and H^{-1} is invertible, a property that passes from A to AH for every invertible H also passes back from AH to A. So in each "same" case it suffices to show one direction.

(a) Always the same, by Proposition 3.2.30.

(b) Not always. For $A = \begin{pmatrix}1 & 1\end{pmatrix}$ and $H = E_{1,-1,2}$ (which adds -1 times column 2 to column 1), $AH = \begin{pmatrix}0 & 1\end{pmatrix}$, and the kernels are $\operatorname{span}((1,-1))$ and $\operatorname{span}((1,0))$ (Non-example 3.2.31).

(c) Always the same. Transposing, $\mathbf{z}A = \mathbf{0}$ says $A^\mathsf{T}\mathbf{z}^\mathsf{T} = \mathbf{0}$, that is, $\mathbf{z}^\mathsf{T} \in \ker T_{A^\mathsf{T}}$. By Proposition 2.4.23, $(AH)^\mathsf{T} = H^\mathsf{T}A^\mathsf{T}$, and H^T is invertible, with inverse $\left(H^{-1}\right)^\mathsf{T}$. So by Corollary 3.2.23, $\ker T_{(AH)^\mathsf{T}} = \ker T_{H^\mathsf{T}A^\mathsf{T}} = \ker T_{A^\mathsf{T}}$. (Directly: if $\mathbf{z}A = \mathbf{0}$ then $\mathbf{z}AH = \mathbf{0}$, and the converse follows by multiplying on the right by H^{-1}.) This is Corollary 3.2.23 seen in the mirror of Technique 3.2.27.

(d) Not always. $A = \begin{pmatrix}0 & 1\end{pmatrix}$ is in RREF, and with $H = E_{12}$, $AH = \begin{pmatrix}1 & 0\end{pmatrix}$ is also in RREF. They are different matrices, so their reduced forms differ (and so do their pivot columns).

(e) Always the same, by Exercise 3.5.41(c).

(f) Always the same. If $CA = I_n$, then $\left(H^{-1}C\right)(AH) = H^{-1}(CA)H = H^{-1}H = I_n$, so $H^{-1}C$ is a left inverse of AH.

Solution to Exercise 3.6.9

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Corollary 3.2.23 (Row equivalent matrices have the same kernel), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.3.8 (Matrix–vector product), Definition 2.4.1 (Matrix product)
Techniques. Reduce to RREF (Technique 3.3.22)
Hint 1. One direction is one line. For the other, first treat the case where $A = R$ is in RREF, then use $R = GA$.
Hint 2. If $A = R$ is in RREF with pivot columns $p_1, \ldots, p_r$, guess Y with $YR = B$ from the pivot columns: $R\mathbf{e}_{p_s} = \mathbf{e}_s$, so Y must send $\mathbf{e}_s$ to column p_s of B.
Hint 3. For a free column j, the relation $\mathbf{r}_j = \sum_s r_{sj}\mathbf{r}_{p_s}$ among the columns of R is a vector of $\ker T_R$. Transfer it to B.
Sketch. If $B = XA$ and $A\mathbf{x} = \mathbf{0}$, then $B\mathbf{x} = \mathbf{0}$. Conversely, let $R = GA = \operatorname{rref}(A)$, so $\ker T_R = \ker T_A \subseteq \ker T_B$. Let Y have column s equal to column p_s of B for $s \le r$ and $\mathbf{0}$ for $s > r$. Every column of R is $\mathbf{r}_j = \sum_{s\le r} r_{sj}\mathbf{e}_s$, and the relation $\mathbf{r}_j = \sum_s r_{sj}\mathbf{r}_{p_s}$ lies in $\ker T_R$, so it holds in B: $\mathbf{b}_j = \sum_s r_{sj}\mathbf{b}_{p_s} = Y\mathbf{r}_j$. Hence $YR = B$, and $X = YG$ works. (b) Row k of XA is the combination of the rows of A with coefficients from row k of X.

(a) Suppose $B = XA$. If $A\mathbf{x} = \mathbf{0}$, then $B\mathbf{x} = X(A\mathbf{x}) = \mathbf{0}$. So $\ker T_A \subseteq \ker T_B$.

Conversely, suppose $\ker T_A \subseteq \ker T_B$. By Theorem 3.3.10, $R = \operatorname{rref}(A) = GA$ for an invertible G, and $\ker T_R = \ker T_A$ (Corollary 3.2.23), so $\ker T_R \subseteq \ker T_B$. Let $p_1 < \cdots < p_r$ be the pivot columns, write $\mathbf{r}_j$ and $\mathbf{b}_j$ for the columns of R and B, and let $Y \in F^{p\times m}$ be the matrix whose column s is $\mathbf{b}_{p_s}$ for $s \le r$ and $\mathbf{0}$ for $s > r$. We show $YR = B$, column by column.

Fix j. By Lemma 3.3.16(a) (with $s = r$), $\mathbf{r}_j = \sum_{s=1}^{r} r_{sj}\mathbf{e}_s$, so by Definition 2.3.8,

$$Y\mathbf{r}_j = \sum_{s=1}^{r} r_{sj}Y\mathbf{e}_s = \sum_{s=1}^{r} r_{sj}\mathbf{b}_{p_s}.$$

On the other hand, $\mathbf{r}_{p_s} = \mathbf{e}_s$ (Lemma 3.3.16(b)), so $\mathbf{r}_j = \sum_{s=1}^{r} r_{sj}\mathbf{r}_{p_s}$. This says that the vector

$$\mathbf{x} = \mathbf{e}_j - \sum_{s=1}^{r} r_{sj}\mathbf{e}_{p_s}$$

satisfies $R\mathbf{x} = \mathbf{0}$. (If $j = p_t$ is itself a pivot column, then $r_{sj} = 0$ for $s \neq t$ and $r_{tj} = 1$, so $\mathbf{x} = \mathbf{0}$, and the argument still works.) Hence $\mathbf{x} \in \ker T_B$, that is, $\mathbf{b}_j = \sum_s r_{sj}\mathbf{b}_{p_s} = Y\mathbf{r}_j$. So the columns of YR are those of B, and $YR = B$ (Definition 2.4.1). With $X = YG$, we get $XA = Y(GA) = YR = B$, as desired.

(b) By the row description of a product (Definition 2.4.1, as in the second proof of Proposition 3.2.7), row k of XA is x_{k1} times row 1 of A, plus $\cdots$, plus x_{km} times row m of A. So "$B = XA$ for some X" says exactly that every row of B is a linear combination of the rows of A, and (b) is a restatement of (a).

If $\ker T_A = \ker T_B$, then (b) applies in both directions, so A and B have the same row space; this generalizes one half of Exercise 3.3.50(b) to matrices with different numbers of rows. The proof of (a) is the second proof of Theorem 3.3.17 once more: it used only relations among the columns.

Solution to Exercise 3.6.10

Uses. Exercise 3.2.42, Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Theorem 3.3.23 (Invertibility and RREF), Corollary 3.4.20 (Square systems), Proposition 3.3.8 (Properties of the output), Proposition 3.2.10 (Inverses of elementary matrices)
Techniques. Reduce to elementary matrices (Technique 5.4.6), Reduce to RREF (Technique 3.3.22)
Hint 1. By Exercise 3.2.42, $D(EY) = D(E)D(Y)$ for every elementary E and every Y: check that $D(E)$ is 1, -1, or s for the three types.
Hint 2. If $X = E_1 \cdots E_t$, apply the previous hint t times, once to XY and once to $X = XI_2$.
Hint 3. If X is not invertible, write $X = G^{-1}R$ with $R = \operatorname{rref}(X) \neq I_2$. What is the second row of R, and of RY?
Sketch. For elementary E, $D(EY) = D(E)D(Y)$: the factors $1, -1, s$ of Exercise 3.2.42 are $D(E)$. For $X = E_1 \cdots E_t$, induction gives $D(XY) = D(E_1)\cdots D(E_t)D(Y)$, and with $Y = I_2$, $D(X) = D(E_1)\cdots D(E_t)$. If X is not invertible, $X = PR$ with $P = G^{-1}$ a product of elementary matrices and $R = \operatorname{rref}(X)$ having zero second row; then $D(XY) = D(P)D(RY) = 0$ and $D(X) = D(P)D(R) = 0$.

Step 1: elementary matrices. By Exercise 3.2.42, for every $Y \in F^{2\times 2}$, $D(EY) = D(Y)$ if E has type 3, $D(E_{12}Y) = -D(Y)$, and $D(E_{is}Y) = sD(Y)$. Directly from the definition, $D(E) = 1$ for $E = \begin{pmatrix} 1 & 0 \\ t & 1 \end{pmatrix}$ or $\begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}$, $D(E_{12}) = 0 \cdot 0 - 1 \cdot 1 = -1$, and $D(E_{1s}) = D(E_{2s}) = s$. So in all cases

$$D(EY) = D(E)D(Y) \quad \text{for every elementary } E \text{ and every } Y. \tag{C.1.6}$$

Step 2: invertible X. By Theorem 3.5.19, $X = E_1E_2\cdots E_t$ with each E_i elementary. Applying (C.1.6) t times,

$$D(XY) = D(E_1(E_2\cdots E_tY)) = D(E_1)D(E_2\cdots E_tY) = \cdots = D(E_1)\cdots D(E_t)D(Y).$$

With $Y = I_2$, and $D(I_2) = 1$, this gives $D(X) = D(E_1)\cdots D(E_t)$. Hence $D(XY) = D(X)D(Y)$.

Step 3: X not invertible. Let $R = \operatorname{rref}(X) = GX$ with G a product of elementary matrices (Theorem 3.3.10). Since X is not invertible, $R \neq I_2$ (Theorem 3.3.23). A 2×2 matrix in RREF with two pivots is I_2 (Corollary 3.4.20, (i) $\Leftrightarrow$ (iii)), so R has at most one pivot and its second row is zero (Proposition 3.3.8(a)). Then the second row of RY is zero as well (row 2 of RY is row 2 of R times Y), so $D(R) = 0$ and $D(RY) = 0$, since a matrix with zero second row has $c = d = 0$. Now $P = G^{-1}$ is a product of elementary matrices (Proposition 3.2.10), and $X = PR$, so Step 2 applied to P gives

$$D(XY) = D(P(RY)) = D(P)D(RY) = 0, \quad D(X) = D(PR) = D(P)D(R) = 0.$$

So $D(XY) = 0 = D(X)D(Y)$.

Step 3 is the part that is easy to forget, since a matrix that is not invertible is not a product of elementary matrices at all. In Section 5.4 the same strategy (elementary matrices, then invertible matrices, then a separate argument for the rest) proves $\det(AB) = \det A \det B$ for every n (Theorem 5.4.10).

Solution to Exercise 3.6.11

Uses. Proposition 3.2.7 (Row operations are left multiplications), Proposition 3.2.28 (Column operations are right multiplications)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Look for a quantity that every move increases. What happens to the sum of all entries when a row with sum $s < 0$ is negated?
Hint 2. An increasing quantity proves termination only if it can take finitely many values. Which matrices can occur? Find an invariant relating each entry to the starting entry.
Sketch. Invariant: every entry is $\pm$ the corresponding starting entry, so at most 2^{mn} matrices can occur. Monovariant: negating a row or column with sum $s < 0$ changes the total sum S by $-2s > 0$. So S strictly increases, no matrix occurs twice, and there are fewer than 2^{mn} moves. When no move is possible, all row and column sums are ≥ 0. Each move is left multiplication by $E_{i,-1}$ or right multiplication by $E_{j,-1}$.

(a) Let A be the starting matrix and M the current one.

Invariant. Every entry of M is $\pm$ the corresponding entry of A. This holds at the start, and a move multiplies some entries by -1, which keeps it true. So M is one of at most 2^{mn} matrices (two choices of sign for each entry).

Monovariant. Let $S(M)$ be the sum of all entries of M. If a move negates a row or column whose entries sum to $s < 0$, the entries of that line now sum to $-s$, and no other entry changes, so S changes by $-s - s = -2s > 0$. So S strictly increases with every move.

In a sequence of moves $M_0 = A, M_1, M_2, \ldots$, the values $S(M_0) < S(M_1) < \cdots$ are distinct, so the matrices $M_0, M_1, \ldots$ are distinct. By the invariant they come from a set of at most 2^{mn} matrices, so the sequence has at most 2^{mn} terms, that is, fewer than 2^{mn} moves.

(b) Make moves as long as one is possible. By (a) this stops, and it stops exactly when no row and no column has a negative sum.

(c) Negating row i is left multiplication by $E_{i,-1}$ (Proposition 3.2.7), and negating column j is right multiplication by the $n \times n$ matrix $E_{j,-1}$ (Proposition 3.2.28). Since $(EX)E' = E(XE')$, the final matrix is $D_1 A D_2$, where D_1 is the product of the row negations (the last one leftmost) and D_2 the product of the column negations (the first one leftmost). Both are diagonal with entries ± 1, and they are products of type 2 elementary matrices.

The proof follows the two halves of Technique 3.3.5. The monovariant alone would not do: an increasing real number can increase forever. The invariant supplies the finiteness.

Solution to Exercise 3.6.12

Uses. Definition 1.2.17 (Evaluation), Lemma 3.4.23 (Too many roots), Proposition 3.1.19 (Solution sets are translates of the kernel)
Techniques. Undetermined coefficients (Technique 3.1.9), Particular plus homogeneous (Technique 3.1.18)
Hint 1. Write $p = a_0 + a_1 x + \cdots + a_4 x^4$ and expand $(t+1)^k - t^k$ for $k = 1, \ldots, 4$. The difference $p(t+1) - p(t)$ is then a polynomial expression of degree at most 3 in t.
Hint 2. A polynomial of degree at most 3 that vanishes at every $t \in \mathbb{Q}$ is the zero polynomial (Lemma 3.4.23). So you may compare coefficients: four linear equations in $a_1, \ldots, a_4$.
Hint 3. The system is triangular. What does a_0 do? For (b), sum $p(k+1) - p(k)$ over $k = 0, \ldots, N-1$.
Sketch. The difference is $(a_1 + a_2 + a_3 + a_4) + (2a_2 + 3a_3 + 4a_4)t + (3a_3 + 6a_4)t^2 + 4a_4 t^3$. Comparing with t^3: $a_4 = 1/4$, $a_3 = -1/2$, $a_2 = 1/4$, $a_1 = 0$, and a_0 is free. So $p = (x(x-1)/2)^2 + a_0$: a particular solution plus the constants, which are the homogeneous solutions. Telescoping gives (b).

(a) Write $p = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4$. By the binomial theorem,

$$(t+1) - t = 1, \quad (t+1)^2 - t^2 = 2t + 1,$$
$$(t+1)^3 - t^3 = 3t^2 + 3t + 1, \quad (t+1)^4 - t^4 = 4t^3 + 6t^2 + 4t + 1,$$

so for every $t \in \mathbb{Q}$ (Definition 1.2.17),

$$p(t+1)-p(t)=c_0+c_1t+c_2t^2+c_3t^3,$$

where

$$c_0=a_1+a_2+a_3+a_4,\quad c_1=2a_2+3a_3+4a_4,\quad c_2=3a_3+6a_4,\quad c_3=4a_4.$$

The condition is that $q=(c_0-0)+c_1x+c_2x^2+(c_3-1)x^3\in\mathbb{Q}[x]_{\le 3}$ satisfies $q(t)=0$ for every $t\in\mathbb{Q}$. If q vanishes at all of $\mathbb{Q}$, it vanishes at the four distinct points $0,1,2,3$, so $q=\mathbf{0}$ by Lemma 3.4.23; conversely, $q=\mathbf{0}$ certainly vanishes everywhere. So the condition is the linear system

$$a_1+a_2+a_3+a_4=0,\quad 2a_2+3a_3+4a_4=0,\quad 3a_3+6a_4=0,\quad 4a_4=1$$

in the unknowns $a_0,\dots,a_4$, in which a_0 does not occur. Solving from the bottom: $a_4=1/4$, $a_3=-2a_4=-1/2$, $2a_2=-3a_3-4a_4=3/2-1=1/2$, so $a_2=1/4$, and $a_1=-(a_2+a_3+a_4)=0$. So the solutions are

$$p=a_0+\frac{1}{4}x^2-\frac{1}{2}x^3+\frac{1}{4}x^4\quad(a_0\in\mathbb{Q}),$$

and $\frac{1}{4}x^2-\frac{1}{2}x^3+\frac{1}{4}x^4$ is the polynomial whose value at t is $(t(t-1)/2)^2$, since $t^2(t-1)^2=t^4-2t^3+t^2$. In the language of Proposition 3.1.19, applied to the linear map $p\mapsto(p(t+1)-p(t))_t$, this is a particular solution plus the homogeneous solutions, which are the constants: the same triangular system with right-hand side 0 forces $a_1=\cdots=a_4=0$.

(b) Let p be the solution with $a_0=0$, so $p(t)=(t(t-1)/2)^2$. Summing $p(k+1)-p(k)=k^3$ over $k=0,\dots,N-1$, the left side telescopes:

$$0^3+1^3+\cdots+(N-1)^3=p(N)-p(0)=(N(N-1)/2)^2.$$

The method needs a field in which comparing coefficients is allowed, which used four distinct points $0,1,2,3$, and in which 2, 3, 4 are nonzero, for the triangular solve. Over $\mathbb{F}_p$ with $p\ge 5$ both hold. Over $\mathbb{F}_2$ and $\mathbb{F}_3$ both fail: for instance x^3-x vanishes at every point of $\mathbb{F}_3$, so a polynomial identity on the field no longer determines the coefficients.

Solution to Exercise 3.6.13

> *Uses.* Corollary 3.4.20 (Square systems), Exercise 3.5.37, Proposition 2.4.23 (Transpose of a product)
> *Techniques.* Uniqueness gives existence (Technique 3.4.21), Extremal choice and minimal counterexamples (Technique 1.5.9)
> *Hint 1.* The system in (a) is square. By Corollary 3.4.20 it suffices to show that $4x_i=x_{i-1}+x_{i+1}$ for all i forces $\mathbf{x}=\mathbf{0}$.
> *Hint 2.* Choose k with $|x_k|$ as large as possible, and compare $4|x_k|$ with $|x_{k-1}|+|x_{k+1}|$.
> *Hint 3.* In (b), the vector $(1,\dots,1)$ is a homogeneous solution. Show it spans the homogeneous solutions (look at a largest entry again), note that the matrix is symmetric, and apply Exercise 3.5.37.
> *Sketch.* (a) For a homogeneous solution, take k with $|x_k|$ maximal: $4|x_k|\le|x_{k-1}|+|x_{k+1}|\le 2|x_k|$, so $x_k=0$ and $\mathbf{x}=\mathbf{0}$; the system is square, so Corollary 3.4.20 gives existence and uniqueness. (b) Summing the equations gives $0=\sum y_i$, which is necessary. The homogeneous solutions are the constant vectors (at a largest entry x_k, both neighbors equal x_k; go around the cycle). The matrix L is symmetric, so $\mathbf{z}^{\mathsf{T}}L=\mathbf{0}$ iff $L\mathbf{z}=\mathbf{0}$ iff $\mathbf{z}$ is constant, and Exercise 3.5.37 says $L\mathbf{x}=\mathbf{y}$ is solvable iff $\mathbf{z}^{\mathsf{T}}\mathbf{y}=0$ for those $\mathbf{z}$, that is, iff $\sum y_i=0$.

(a) This is a system of n equations in n unknowns, so by Corollary 3.4.20 ((iv) ⇒ (vi)) it suffices to show that the homogeneous system has only the trivial solution. Let $\mathbf{x}$ satisfy $4x_i=x_{i-1}+x_{i+1}$ for all i, and choose k with $|x_k|\ge|x_i|$ for all i (an extremal choice). Then

$$4|x_k|=|x_{k-1}+x_{k+1}|\le|x_{k-1}|+|x_{k+1}|\le 2|x_k|,$$

so $2|x_k|\le 0$ and $x_k=0$. As $|x_k|$ is the largest of the $|x_i|$, every $x_i=0$.

(b) Let $L\in\mathbb{R}^{n\times n}$ be the coefficient matrix: 2 on the diagonal, -1 in the positions $(i,i-1)$ and $(i,i+1)$ (modulo n), and 0 elsewhere. It is symmetric, $L^{\mathsf{T}}=L$, because $j=i+1$ exactly when $i=j-1$. Let $\mathbf{1}=(1,\dots,1)$.

Necessity. Each x_j occurs in three equations, with total coefficient $2-1-1=0$ (in equation j with 2, and in equations $j-1$ and $j+1$ with -1; these are three different equations since $n \geq 3$). So summing all equations gives $0 = y_1 + \cdots + y_n$, and a solution can exist only if $\sum y_i = 0$.

The homogeneous solutions are the constant vectors. Constant vectors are solutions, since $2c - c - c = 0$. Conversely, let $L\mathbf{x} = \mathbf{0}$, and let x_k be a largest entry. Then $2x_k = x_{k-1} + x_{k+1}$ with $x_{k-1} \leq x_k$ and $x_{k+1} \leq x_k$, which forces $x_{k-1} = x_{k+1} = x_k$. So the neighbors of a largest entry are largest entries too, and going around the cycle, all entries equal x_k. Thus $L\mathbf{x} = \mathbf{0}$ if and only if $\mathbf{x} \in \operatorname{span}(\mathbf{1})$.

Sufficiency. Suppose $\sum y_i = 0$ but $L\mathbf{x} = \mathbf{y}$ has no solution. By Exercise 3.5.37 there is $\mathbf{z}$ with $\mathbf{z}^{\mathsf{T}}L = \mathbf{0}$ and $\mathbf{z}^{\mathsf{T}}\mathbf{y} \neq 0$. Transposing (Proposition 2.4.23), $L^{\mathsf{T}}\mathbf{z} = L\mathbf{z} = \mathbf{0}$, so $\mathbf{z} = c\mathbf{1}$ for some c, and then $\mathbf{z}^{\mathsf{T}}\mathbf{y} = c(y_1 + \cdots + y_n) = 0$, a contradiction.

So with 4 the homogeneous system has only the trivial solution and every $\mathbf{y}$ is reached; with 2 there is a homogeneous solution $\mathbf{1}$, and in exchange one condition on $\mathbf{y}$. For a square system the two failures come together, as Corollary 3.4.20 says they must.

Solution to Exercise 3.6.14

> *Uses.* Corollary 3.4.20 (Square systems), Proposition 3.1.19 (Solution sets are translates of the kernel)
> *Techniques.* Uniqueness gives existence (Technique 3.4.21)
> *Hint 1.* Squareness only sets the technique up; its content is the homogeneous uniqueness. Check it: is there a nonzero p with $p(0) = p(1) = p'(1/2) = 0$?
> *Hint 2.* Compare $p'(1/2)$ with $p(1) - p(0)$ for a general p.
> *Sketch.* The argument never proves that the homogeneous system has only the trivial solution, and it does not: $x^2 - x$ is a nonzero solution. Since $p'(1/2) = b + c = p(1) - p(0)$ for every p, a solution exists only if $w = v - u$, and then the solutions are $u + (v-u)x + t\big(x^2 - x\big)$, infinitely many. So the claim fails for every (u, v, w).

The argument checks that the problem is linear and square, which is what makes Technique 3.4.21 *applicable*, and then skips the technique itself: the homogeneous problem must be shown to have only the trivial solution, and here it does not. For $p = a + bx + cx^2$, the homogeneous conditions are $a = 0$, $a + b + c = 0$, and $b + c = 0$, and $p = x^2 - x$ (that is, $a = 0$, $b = -1$, $c = 1$) satisfies all three.

In fact, for every p,

$$p(1) - p(0) = b + c = p'(1/2).$$

So a solution can exist only if $w = v - u$. If $w = v - u$, then $u + (v-u)x$ is a solution, and by Proposition 3.1.19 the solutions are $u + (v-u)x + t\big(x^2 - x\big)$ for $t \in \mathbb{R}$, since the homogeneous solutions are the multiples of $x^2 - x$ (the first two homogeneous equations give $a = 0$ and $c = -b$, and the third is then automatic). So the conclusion "exactly one" holds for no (u, v, w): there are no solutions when $w \neq v - u$ and infinitely many when $w = v - u$. By Corollary 3.4.20 this had to be so once uniqueness failed.

Problems for Chapter 3

Solution to Problem 3.1

> *Uses.* Definition 2.1.1 (Linear map), Corollary 3.1.22 (Uniqueness depends only on A), Proposition 3.1.8 (Systems and the map T_A), Definition 2.6.5 (Kernel), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
> *Techniques.* Particular plus homogeneous (Technique 3.1.18), Double containment (Technique 1.3.14)
> *Hint 1.* For (a), the statement is Proposition 3.1.19. Prove the two containments, and check that $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$ is injective.
> *Hint 2.* For (b), split into the cases $\ker T_A = \{\mathbf{0}\}$ and $\ker T_A \neq \{\mathbf{0}\}$. In the second case, how large is the solution set of a consistent system?
> *Sketch.* (a) If $T(\mathbf{x}_0) = \mathbf{y}$, then $S = \mathbf{x}_0 + \ker T$: $T(\mathbf{x}_0 + \mathbf{z}) = \mathbf{y} + \mathbf{0}$, and $T(\mathbf{x} - \mathbf{x}_0) = \mathbf{0}$ for $\mathbf{x} \in S$; translation by $\mathbf{x}_0$ is injective. (b) If $\ker T_A = \{\mathbf{0}\}$, every consistent system has exactly one solution, so the set is $\operatorname{im} T_A$. Otherwise each consistent system has a solution set in bijection with $\ker T_A$, which has at least two elements, and inconsistent ones have none, so the set is empty.

(a) *Statement* (Proposition 3.1.19). Let $T : V \to W$ be linear, $\mathbf{y} \in W$, and $S = \{\mathbf{x} \in V \mid T(\mathbf{x}) = \mathbf{y}\}$. If $\mathbf{x}_0 \in S$, then $S = \mathbf{x}_0 + \ker T$, and $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$ is a bijection from $\ker T$ onto S.

Proof. We prove both containments. If $\mathbf{z} \in \ker T$, then $T(\mathbf{x}_0 + \mathbf{z}) = T(\mathbf{x}_0) + T(\mathbf{z}) = \mathbf{y} + \mathbf{0} = \mathbf{y}$, so $\mathbf{x}_0 + \mathbf{z} \in S$. Conversely, if $\mathbf{x} \in S$, put $\mathbf{z} = \mathbf{x} - \mathbf{x}_0$; then $T(\mathbf{z}) = T(\mathbf{x}) - T(\mathbf{x}_0) = \mathbf{y} - \mathbf{y} = \mathbf{0}$, so $\mathbf{z} \in \ker T$ and $\mathbf{x} = \mathbf{x}_0 + \mathbf{z} \in \mathbf{x}_0 + \ker T$. Hence $S = \mathbf{x}_0 + \ker T$, so the map $\mathbf{z} \mapsto \mathbf{x}_0 + \mathbf{z}$ sends $\ker T$ onto S. It is injective, since $\mathbf{x}_0 + \mathbf{z} = \mathbf{x}_0 + \mathbf{z}'$ gives $\mathbf{z} = \mathbf{z}'$ after adding $-\mathbf{x}_0$. So it is a bijection.

(b) Let U be the set of $\mathbf{y}$ for which $A\mathbf{x} = \mathbf{y}$ has exactly one solution. Every $\mathbf{y} \in U$ makes the system consistent, so $U \subseteq \operatorname{im} T_A$ (Proposition 3.1.8(a)).

Case $\ker T_A = \{\mathbf{0}\}$. Let $\mathbf{y} \in \operatorname{im} T_A$. The system $A\mathbf{x} = \mathbf{y}$ is consistent, so by Corollary 3.1.22(a) it has exactly one solution, and $\mathbf{y} \in U$. Hence $U = \operatorname{im} T_A$.

Case $\ker T_A \neq \{\mathbf{0}\}$. Then $\ker T_A$ contains $\mathbf{0}$ (Proposition 2.1.4) and some $\mathbf{z} \neq \mathbf{0}$, so it has at least two elements. If $A\mathbf{x} = \mathbf{y}$ is consistent, its solution set is in bijection with $\ker T_A$ by (a), applied to $T = T_A$, so it has at least two elements. If it is inconsistent, it has none. Either way $\mathbf{y} \notin U$, so $U = \varnothing$.

So the set is $\operatorname{im} T_A$ when $\ker T_A = \{\mathbf{0}\}$, and empty otherwise. Uniqueness is all or nothing: it holds for every consistent right-hand side or for none.

Solution to Problem 3.2

> *Uses.* Corollary 3.2.17 (Row operations preserve relations among columns), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Definition 2.4.1 (Matrix product), Theorem 3.3.12 (Matrices in RREF), Proposition 3.3.8 (Properties of the output)
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8), Transpose to trade rows for columns (Technique 3.2.27)
> *Hint 1.* For (a), R and $R' = GR$ have the same relations among their columns (Corollary 3.2.17). Which column is a pivot column, and what a free column is, are statements about such relations (Lemma 3.3.16).
> *Hint 2.* For (b), the smallest example has one row and two columns.
> *Hint 3.* For (c), count nonzero rows. The nonzero rows of a matrix in RREF are linearly independent: look at the pivot columns. Right multiplication by an invertible H keeps rows independent.
> *Sketch.* (a) Column j is a combination of earlier columns, with given coefficients, in R exactly when it is in R'; so the pivot columns agree, the pivot columns of both are $\mathbf{e}_1, \ldots, \mathbf{e}_r$, and each free column has the same expression through the pivot columns in both. (b) $R = \begin{pmatrix} 0 & 1 \end{pmatrix}$, $H = E_{12}$, $R' = \begin{pmatrix} 1 & 0 \end{pmatrix}$. (c) If R has r nonzero rows, they are independent (entry p_t isolates the coefficient of row t). Row s of RH is (row s of R)H, so the zero rows stay zero and the others stay independent, hence nonzero. So RH has r nonzero rows, which are its pivot rows.

(a) *Statement* (Theorem 3.3.17). If $R, R' \in F^{m \times n}$ are in RREF and $R' = GR$ for an invertible $G \in F^{m \times m}$, then $R = R'$.

Proof. Write $\mathbf{r}_j$ and $\mathbf{r}'_j = G\mathbf{r}_j$ for the columns. By Corollary 3.2.17, for all scalars $x_1, \ldots, x_n$,

$$x_1\mathbf{r}_1 + \cdots + x_n\mathbf{r}_n = \mathbf{0} \quad \Leftrightarrow \quad x_1\mathbf{r}'_1 + \cdots + x_n\mathbf{r}'_n = \mathbf{0}.$$

An equation $\mathbf{r}_j = c_1\mathbf{r}_1 + \cdots + c_{j-1}\mathbf{r}_{j-1}$ is such a relation (with $x_j = -1$, $x_l = c_l$ for $l < j$, and $x_l = 0$ for $l > j$), so it holds in R if and only if the same equation holds in R'. Hence $\mathbf{r}_j$ is a combination of the earlier columns of R exactly when $\mathbf{r}'_j$ is a combination of the earlier columns of R', and by Lemma 3.3.16(c) the two matrices have the same pivot columns $p_1 < \cdots < p_r$. By Lemma 3.3.16(b), $\mathbf{r}_{p_s} = \mathbf{e}_s = \mathbf{r}'_{p_s}$. If j is a free column with pivot columns $p_1, \ldots, p_t$ to its left, Lemma 3.3.16(d) gives the relation $\mathbf{r}_j = \sum_{s \le t} r_{sj}\mathbf{r}_{p_s}$, which therefore also holds in R':

$$\mathbf{r}'_j = \sum_{s \le t} r_{sj}\mathbf{r}'_{p_s} = \sum_{s \le t} r_{sj}\mathbf{e}_s = \mathbf{r}_j.$$

So every column of R' equals the corresponding column of R.

(b) $R = \begin{pmatrix} 0 & 1 \end{pmatrix}$ and $R' = \begin{pmatrix} 1 & 0 \end{pmatrix}$ both satisfy (R1)–(R4), so they are in RREF (Theorem 3.3.12), and $R' = RE_{12}$ with E_{12} the 2×2 swap, which is invertible. The proof of (a) breaks because right multiplication does not preserve the relations among the columns: here $\mathbf{r}_1 = \mathbf{0}$ but $\mathbf{r}'_1 \neq \mathbf{0}$.

(c) Let R have pivot columns $p_1 < \cdots < p_r$. By Theorem 3.3.12 and Proposition 3.3.8, rows $1, \ldots, r$ of R are nonzero and the others are zero; write $\mathbf{u}_1, \ldots, \mathbf{u}_r \in F^{1\times n}$ for the nonzero rows. They are linearly independent: if $c_1\mathbf{u}_1 + \cdots + c_r\mathbf{u}_r = \mathbf{0}$, look at entry p_t. Column p_t of R is $\mathbf{e}_t$ (Lemma 3.3.16(b)), so $\mathbf{u}_s$ has entry 1 there if $s = t$ and 0 otherwise, and the entry p_t of the combination is c_t. So every $c_t = 0$.

By Definition 2.4.1, row s of RH is $\mathbf{u}_sH$ for $s \le r$, and $\mathbf{0}H = \mathbf{0}$ for $s > r$. The rows $\mathbf{u}_1H, \ldots, \mathbf{u}_rH$ are again independent: if $\sum_s c_s\mathbf{u}_sH = \mathbf{0}$, then $\big(\sum_s c_s\mathbf{u}_s\big)H = \mathbf{0}$, multiplying on the right by H^{-1} gives $\sum_s c_s\mathbf{u}_s = \mathbf{0}$, and so every $c_s = 0$. In particular each $\mathbf{u}_sH$ is nonzero (a list containing $\mathbf{0}$ is dependent). So RH has exactly r nonzero rows. Since RH is in RREF, its pivots are the leading entries of its nonzero rows (Theorem 3.3.12), so it has r pivots, as R does.

Part (c) is the transpose of a row statement in disguise (Technique 3.2.27): the rows of RH are the columns of $H^{\mathsf{T}}R^{\mathsf{T}}$, and left multiplication by an invertible matrix preserves independence of columns (Corollary 3.2.17).

Solution to Problem 3.3

> *Uses.* Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Proposition 3.3.11 (Carrying extra columns along), Proposition 3.3.8 (Properties of the output), Corollary 3.2.11 (Products of elementary matrices), Proposition 3.2.7 (Row operations are left multiplications), Definition 2.4.1 (Matrix product)
> *Techniques.* Reduce to RREF (Technique 3.3.22)
> *Hint 1.* For (a), if $GA = I_n$ with G invertible, then $A = G^{-1}$. If $\operatorname{rref}(A) \neq I_n$, its last row is zero, and a matrix with a zero row has no right inverse.
> *Hint 2.* For (b), at every stage the current matrix is $G'(A \mid I_n) = (G'A \mid G')$ for a product G' of elementary matrices. What is row i of $G'A$ in terms of row i of G'?
> *Hint 3.* If A were invertible, compute $\mathbf{z} = \mathbf{z}AA^{-1}$.
> *Sketch.* (a) A is invertible iff $\operatorname{rref}(A) = I_n$, and then $A^{-1} = G$; the algorithm computes $(\operatorname{rref}(A) \mid G)$ by Proposition 3.3.11. (b) The current matrix is $(G'A \mid G')$ with G' invertible, so $\mathbf{z} =$ row i of G' is nonzero and $\mathbf{z}A =$ row i of $G'A = \mathbf{0}$; if A were invertible, $\mathbf{z} = \mathbf{z}AA^{-1} = \mathbf{0}$. (c) Over $\mathbb{F}_5$, two passes give the left row $(0,0,0)$ with right row $(4,4,1)$, and indeed $-\mathbf{r}_1 - \mathbf{r}_2 + \mathbf{r}_3 = (0,0,5) = \mathbf{0}$ there. Over $\mathbb{Q}$ the same row is $(0,0,5)$, a third pivot, so A is invertible over $\mathbb{Q}$.

(a) *Statement* (Theorem 3.3.23). Let $A \in F^{n\times n}$, and let G be a product of elementary matrices with $GA = \operatorname{rref}(A)$. Then A is invertible if and only if $\operatorname{rref}(A) = I_n$, and in that case $A^{-1} = G$.

Proof. If $\operatorname{rref}(A) = I_n$, then $GA = I_n$, and G is invertible (Corollary 3.2.11), so $A = G^{-1}$ and $AG = G^{-1}G = I_n$; thus $A^{-1} = G$. Conversely, suppose $R = \operatorname{rref}(A) \neq I_n$. If R had n pivots, they would lie in columns $p_1 < \cdots < p_n$ among $1, \ldots, n$, forcing $p_s = s$, and then $R = I_n$ by Proposition 3.3.8(c). So R has fewer than n pivots, and its last row is zero (Proposition 3.3.8(a)). Then the last row of RX is zero for every X, so $RX \neq I_n$ and R is not invertible. If A were invertible, $R = GA$ would be invertible with inverse $A^{-1}G^{-1}$. So A is not invertible.

The algorithm. By Proposition 3.3.11, Gauss–Jordan elimination on $(A \mid I_n)$, scanning only the left block, ends at $(\operatorname{rref}(A) \mid G)$, where G is the product of the elementary matrices of the run on A. By the theorem, if the left block is I_n then $A^{-1} = G$, and otherwise A is not invertible.

(b) Each row operation is left multiplication by an elementary matrix (Proposition 3.2.7), so at every stage the current matrix is $G'(A \mid I_n) = (G'A \mid G')$ for some product G' of elementary matrices, which is invertible (Corollary 3.2.11). Let $\mathbf{z}$ be row i of G', the row i of the right block. By Definition 2.4.1, row i of $G'A$ is $\mathbf{z}A$, and this is the zero row by assumption. And $\mathbf{z} \neq \mathbf{0}$: otherwise row i of $G'X$ would be zero for every X, and G' would have no right inverse.

If A were invertible, then $\mathbf{z} = \mathbf{z}\big(AA^{-1}\big) = (\mathbf{z}A)A^{-1} = \mathbf{0}A^{-1} = \mathbf{0}$, a contradiction. So A is not invertible. The vector $\mathbf{z}$ is a *certificate*: anyone can check $\mathbf{z}A = \mathbf{0}$ by one multiplication, without redoing the elimination.

(c) Over $\mathbb{F}_5$ the entry 9 is 4. Pass 1 adds -2 times row 1 to row 2 and -3 times row 1 to row 3:

$$\left(\begin{array}{ccc|ccc} 1 & 2 & 3 & 1 & 0 & 0 \\ 2 & 0 & 1 & 0 & 1 & 0 \\ 3 & 2 & 4 & 0 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccc|ccc} 1 & 2 & 3 & 1 & 0 & 0 \\ 0 & 1 & 0 & 3 & 1 & 0 \\ 0 & 1 & 0 & 2 & 0 & 1 \end{array}\right),$$

using $-4 = 1$, $-5 = 0$, $-2 = 3$, and $-3 = 2$ in $\mathbb{F}_5$. Pass 2 has its pivot at $(2,2)$; adding -1 times row 2 to row 3 makes row 3 of the left block zero, with right block row $(2-3, 0-1, 1) = (-1,-1,1) = (4,4,1)$. So $\mathbf{z} = (4,4,1)$, and indeed

$$\mathbf{z}A = -(1,2,3) - (2,0,1) + (3,2,9) = (0,0,5) = (0,0,0) \quad \text{in } \mathbb{F}_5.$$

So A is not invertible over $\mathbb{F}_5$: there, its third row is the sum of the first two.

Over $\mathbb{Q}$ the same computation gives $\mathbf{z}A = (0,0,5) \neq \mathbf{0}$, so the certificate is lost. Indeed, over $\mathbb{Q}$ pass 1 leaves the rows $(0,-4,-5)$ and $(0,-4,0)$ below the first, pass 2 scales the first of them to $(0,1,5/4)$ and adds 4 times it to the last, which becomes $(0,0,5)$. So a third pivot appears, $\operatorname{rref}(A) = I_3$, and A is invertible over $\mathbb{Q}$. Whether a matrix with integer entries is invertible can depend on the field in which the entries are read (compare Example 3.5.3).

Solution to Problem 3.4

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Lemma 3.3.16 (Reading the columns of a matrix in RREF), Theorem 2.4.34 (Block multiplication), Theorem 3.5.14 (Third Fundamental Theorem, completed), Lemma 2.4.24 (Matrix units), Theorem 3.3.12 (Matrices in RREF), Proposition 3.5.2 (First properties of rank), Exercise 3.5.41
Techniques. Reduce to RREF (Technique 3.3.22), Block decomposition (Technique 2.4.35)
Hint 1. For (a), start from $GA = A_r$. Permute the columns of A_r so that the pivot columns come first, and then clear the block next to I_k with one block column operation.
Hint 2. For (b), $N_k = \sum_{i=1}^{k} \mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$. Rank is unchanged by invertible factors on either side.
Hint 3. For (c), factor N_k as a product of an $m \times k$ and a $k \times n$ matrix.
Sketch. (a) $GA = A_r$; with P the permutation putting the pivot columns first, $A_rP = \begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix}$, and $U = \begin{pmatrix} I_k & -X \\ 0 & I \end{pmatrix}$ clears X: $GA(PU) = N_k$. (b) $A = G^{-1}N_kH^{-1} = \sum_{i \le k} G^{-1}\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}H^{-1}$, and each term has the rank of $\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$, which is 1. (c) $N_k = \begin{pmatrix} I_k \\ 0 \end{pmatrix}\begin{pmatrix} I_k & 0 \end{pmatrix}$, so $A = CS$ with C the first k columns of G^{-1} and S the first k rows of H^{-1}.

(a) *Statement* (Theorem 3.5.27). Let $A \in F^{m\times n}$ have rank k, and let $N_k \in F^{m\times n}$ have 1 in positions $(1,1), \dots, (k,k)$ and 0 elsewhere. Then $GAH = N_k$ for some invertible $G \in F^{m\times m}$ and $H \in F^{n\times n}$.

Proof. Let G be invertible with $GA = A_r$ (Theorem 3.3.10), with pivot columns $p_1 < \cdots < p_k$ and free columns $f_1 < \cdots < f_\ell$, $\ell = n - k$. Let P have columns $\mathbf{e}_{p_1}, \dots, \mathbf{e}_{p_k}, \mathbf{e}_{f_1}, \dots, \mathbf{e}_{f_\ell}$; these are the standard basis vectors in another order, so they form a basis of F^n, and P is invertible (Theorem 3.5.14, Remark 3.5.7). Column j of A_rP is column p_j of A_r, which is $\mathbf{e}_j$, for $j \le k$ (Lemma 3.3.16(b)), and column f_i of A_r for $j = k + i$. All rows of A_r below row k are zero, so in block form $A_rP = \begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix}$ for some $X \in F^{k\times\ell}$. Let $U = \begin{pmatrix} I_k & -X \\ 0 & I_\ell \end{pmatrix}$. By block multiplication (Theorem 2.4.34), $U\begin{pmatrix} I_k & X \\ 0 & I_\ell \end{pmatrix} = I_n = \begin{pmatrix} I_k & X \\ 0 & I_\ell \end{pmatrix}U$, so U is invertible, and

$$A_rPU = \begin{pmatrix} I_k & X \\ 0 & 0 \end{pmatrix}\begin{pmatrix} I_k & -X \\ 0 & I_\ell \end{pmatrix} = \begin{pmatrix} I_k & -X + X \\ 0 & 0 \end{pmatrix} = N_k.$$

With $H = PU$, we get $GAH = A_rPU = N_k$. (If $k = 0$ or $\ell = 0$, the absent blocks are simply omitted.)

(b) By (a), $A = G^{-1}N_kH^{-1}$. By Lemma 2.4.24, $N_k = \sum_{i=1}^{k} \mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$, where $\mathbf{e}_i \in F^m$ on the left and $\mathbf{e}_i \in F^n$ on the right. So

$$A = \sum_{i=1}^{k} B_i, \quad B_i = G^{-1}\left(\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}\right)H^{-1}.$$

The matrix $\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ has a single nonzero entry, a 1 in position (i,i). Swapping row i to the top gives a matrix whose only nonzero row is $\mathbf{e}_i^{\mathsf{T}}$, which satisfies (R1)–(R4) and so is in RREF with one pivot (Theorem 3.3.12); so it has rank 1. Multiplying by invertible matrices on the left (Proposition 3.5.2(c)) and on the right (Exercise 3.5.41(c)) does not change the rank, so $\operatorname{rank} B_i = 1$.

(c) By block multiplication,

$$\begin{pmatrix} I_k \\ 0 \end{pmatrix}\begin{pmatrix} I_k & 0 \end{pmatrix} = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix} = N_k,$$

where the left factor is $m \times k$ and the right one is $k \times n$. So

$$A = G^{-1}N_kH^{-1} = \left(G^{-1}\begin{pmatrix} I_k \\ 0 \end{pmatrix}\right)\left(\begin{pmatrix} I_k & 0 \end{pmatrix}H^{-1}\right) = CS,$$

where C consists of the first k columns of G^{-1} and S of the first k rows of H^{-1}.

Problem 3.17 finds a factorization of this shape in which S is the nonzero part of $\operatorname{rref}(A)$, and shows that it is unique. Section 4.3 studies such factorizations in general.

Solution to Problem 3.5

Uses. Algorithm 3.3.1 (Gauss–Jordan elimination), Proposition 3.3.11 (Carrying extra columns along), Exercise 3.3.57, Corollary 3.3.19 (Pivot columns, intrinsically), Definition 3.4.8 (Basic solutions), Theorem 3.4.9 (All solutions), Corollary 3.4.4 (Consistency), Corollary 3.4.14 (Counting solutions), Proposition 3.5.8 (Right inverses from the pivots), Theorem 3.5.13 (Second Fundamental Theorem, completed)
Techniques. Reduce to RREF (Technique 3.3.22), Particular plus homogeneous (Technique 3.1.18)
Hint 1. Carry I_3 along. The two computations agree until a pivot must be divided by 5.
Hint 2. Over $\mathbb{F}_5$, read the relations off the free columns of $\operatorname{rref}(A)$, and the consistency condition off the last row of G.
Hint 3. For (d), use Proposition 3.5.8: place the rows of G in the pivot rows of a 5×3 matrix.
Sketch. After two passes, valid over any field, the rows are $(1,2,0,1,3)$, $(0,0,1,2,-5)$, $(0,0,0,0,5)$. Over $\mathbb{Q}$, $\operatorname{rank} A = 3$ with pivot columns $1,3,5$. Over $\mathbb{F}_5$, $5 = 0$: $\operatorname{rank} A = 2$, and $\mathbf{r}_1 - \mathbf{r}_2 + \mathbf{r}_3 = (0,0,0,0,5) = \mathbf{0}$. Over $\mathbb{F}_5$: $\mathbf{a}_2 = 2\mathbf{a}_1$, $\mathbf{a}_4 = \mathbf{a}_1 + 2\mathbf{a}_3$, $\mathbf{a}_5 = 3\mathbf{a}_1$; the condition is $y_1 - y_2 + y_3 = 0$ (25 vectors); the solutions of $A\mathbf{x} = (1,1,0)$ are $(1,0,4,0,0) + \operatorname{span}((3,1,0,0,0),(4,0,3,1,0),(2,0,0,0,1))$, 125 of them. (d) Over $\mathbb{Q}$ a right inverse has rows $(2/5, 3/5, -3/5)$, $\mathbf{0}$, $(-1,0,1)$, $\mathbf{0}$, $(1/5, -1/5, 1/5)$; over $\mathbb{F}_5$ there is none, since $\operatorname{rank} A = 2 < 3$.

(a) We reduce $(A \mid I_3)$. Pass 1 adds -2 times row 1 to row 2 and -1 times row 1 to row 3. In pass 2, column 2 vanishes in rows 2 and 3, so the pivot is at $(2,3)$, and we add -1 times row 2 to row 3. These steps are the same over any field:

$$\left(\begin{array}{ccccc|ccc} 1 & 2 & 0 & 1 & 3 & 1 & 0 & 0 \\ 2 & 4 & 1 & 4 & 1 & 0 & 1 & 0 \\ 1 & 2 & 1 & 3 & 3 & 0 & 0 & 1 \end{array}\right) \rightsquigarrow \left(\begin{array}{ccccc|ccc} 1 & 2 & 0 & 1 & 3 & 1 & 0 & 0 \\ 0 & 0 & 1 & 2 & -5 & -2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 5 & 1 & -1 & 1 \end{array}\right).$$

Over $\mathbb{Q}$. Pass 3 scales row 3 by $1/5$ and clears column 5, adding -3 times row 3 to row 1 and 5 times row 3 to row 2:

$$\rightsquigarrow \left(\begin{array}{ccccc|ccc} 1 & 2 & 0 & 1 & 0 & 2/5 & 3/5 & -3/5 \\ 0 & 0 & 1 & 2 & 0 & -1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1/5 & -1/5 & 1/5 \end{array}\right).$$

So $\operatorname{rank} A = 3$, with pivot columns $1,3,5$.

Over $\mathbb{F}_5$. Here $5 = 0$ and $-5 = 0$, so after pass 2 the third row of the left block is zero and the algorithm halts:

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & 2 & 0 & 1 & 3 \\ 0 & 0 & 1 & 2 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad G = \begin{pmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 1 & -1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 3 & 1 & 0 \\ 1 & 4 & 1 \end{pmatrix}.$$

So $\operatorname{rank} A = 2$, with pivot columns $1,3$. The last row of G is a relation among the rows $\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3$ of A (Exercise 3.3.57):

$$\mathbf{r}_1 - \mathbf{r}_2 + \mathbf{r}_3 = (1-2+1, 2-4+2, 0-1+1, 1-4+3, 3-1+3) = (0,0,0,0,5).$$

This is $\mathbf{0}$ in $\mathbb{F}_5$ but not in $\mathbb{Q}$, and it is exactly why the third pivot disappears.

(b) Over $\mathbb{F}_5$ the free columns are $2,4,5$. By Corollary 3.3.19(b), with the entries of $\operatorname{rref}(A)$ as coefficients,

$$\mathbf{a}_2 = 2\mathbf{a}_1, \quad \mathbf{a}_4 = \mathbf{a}_1 + 2\mathbf{a}_3, \quad \mathbf{a}_5 = 3\mathbf{a}_1.$$

(Check: $\mathbf{a}_1 + 2\mathbf{a}_3 = (1,2,1) + (0,2,2) = (1,4,3) = \mathbf{a}_4$, and $3\mathbf{a}_1 = (3,6,3) = (3,1,3) = \mathbf{a}_5$.) The basic solutions (Definition 3.4.8) are

$$\mathbf{s}_1 = (-2,1,0,0,0) = (3,1,0,0,0), \quad \mathbf{s}_2 = (-1,0,-2,1,0) = (4,0,3,1,0), \quad \mathbf{s}_3 = (-3,0,0,0,1) = (2,0,0,0,1),$$

and $\ker T_A = \operatorname{span}(\mathbf{s}_1, \mathbf{s}_2, \mathbf{s}_3)$ by Theorem 3.4.9(b).

(c) By Corollary 3.4.4, $A\mathbf{x} = \mathbf{y}$ is consistent if and only if the third entry of $G\mathbf{y}$ vanishes, that is, $y_1 - y_2 + y_3 = 0$. The vectors satisfying it are determined by $y_1, y_2 \in \mathbb{F}_5$ (then $y_3 = y_2 - y_1$), so there are 25 of them. For $\mathbf{y} = (1,1,0)$, $G\mathbf{y} = (1, -2+1, 1-1+0) = (1,4,0)$, so the system is consistent, with particular solution $\mathbf{x}_0 = (1,0,4,0,0)$ (pivot variables $x_1 = 1, x_3 = 4$, free variables 0). Check: $A\mathbf{x}_0 = \mathbf{a}_1 + 4\mathbf{a}_3 = (1, 2+4, 1+4) = (1,1,0)$. By Theorem 3.4.9 the solutions are

$$\mathbf{x}_0 + t_1\mathbf{s}_1 + t_2\mathbf{s}_2 + t_3\mathbf{s}_3 \quad (t_1, t_2, t_3 \in \mathbb{F}_5),$$

and there are $5^3 = 125$ of them (Corollary 3.4.14(b)).

(d) Over $\mathbb{Q}$, $\operatorname{rank} A = 3$ is the number of rows, so by Proposition 3.5.8 the matrix $X = BG$, which has row i of G in row p_i and zeros in the free rows, is a right inverse:

$$X = \begin{pmatrix} 2/5 & 3/5 & -3/5 \\ 0 & 0 & 0 \\ -1 & 0 & 1 \\ 0 & 0 & 0 \\ 1/5 & -1/5 & 1/5 \end{pmatrix}.$$

Check: the first row of A times the columns of X gives $(2/5 + 3/5, 3/5 - 3/5, -3/5 + 3/5) = (1,0,0)$, and the other rows work the same way. Over $\mathbb{F}_5$, $\operatorname{rank} A = 2 < 3$, so T_A is not surjective and A has no right inverse (Theorem 3.5.13).

Solution to Problem 3.6

Uses. Theorem 3.3.23 (Invertibility and RREF), Theorem 3.4.9 (All solutions), Definition 1.1.29 (Complex numbers)
Techniques. Reduce to RREF (Technique 3.3.22), Try small cases and small fields (Technique 1.2.38)
Hint 1. Row reduce $A - \lambda I_2 = \begin{pmatrix} -\lambda & -1 \\ 1 & -\lambda \end{pmatrix}$ with λ as a symbol. Swap the rows first, so that you never divide by λ.
Hint 2. You should reach $\begin{pmatrix} 1 & -\lambda \\ 0 & -(1+\lambda^2) \end{pmatrix}$. So everything depends on whether $\lambda^2 = -1$ in the field.
Sketch. Swapping and adding λ times row 1 to row 2 gives $\begin{pmatrix} 1 & -\lambda \\ 0 & -(1+\lambda^2) \end{pmatrix}$, so $A - \lambda I_2$ is invertible iff $\lambda^2 \neq -1$, and otherwise its kernel is $\operatorname{span}((\lambda, 1))$. Solutions of $\lambda^2 = -1$: none in $\mathbb{R}$ and $\mathbb{F}_3$; $\pm i$ in $\mathbb{C}$; 1 in $\mathbb{F}_2$; 2, 3 in $\mathbb{F}_5$.

The equation $A\mathbf{x} = \lambda\mathbf{x}$ says $(A - \lambda I_2)\mathbf{x} = \mathbf{0}$. We row reduce $A - \lambda I_2 = \begin{pmatrix} -\lambda & -1 \\ 1 & -\lambda \end{pmatrix}$ over any field. Swapping the rows and then adding λ times row 1 to row 2 gives

$$\begin{pmatrix} 1 & -\lambda \\ -\lambda & -1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & -\lambda \\ 0 & -1 - \lambda^2 \end{pmatrix}.$$

If $1 + \lambda^2 \neq 0$, the second row has a pivot, and clearing gives I_2; so $A - \lambda I_2$ is invertible (Theorem 3.3.23) and only $\mathbf{x} = \mathbf{0}$ satisfies $A\mathbf{x} = \lambda\mathbf{x}$. If $1 + \lambda^2 = 0$, the reduced form is $\begin{pmatrix} 1 & -\lambda \\ 0 & 0 \end{pmatrix}$, so $A - \lambda I_2$ is not invertible, and by Theorem 3.4.9 the solutions are the multiples of the basic solution $(\lambda, 1)$. (Check: $A(\lambda,1) = (-1, \lambda) = (\lambda^2, \lambda) = \lambda(\lambda,1)$, using $\lambda^2 = -1$.)

So we need the solutions of $\lambda^2 = -1$ in each field.

- $\mathbb{R}$: none, since $\lambda^2 \geq 0 > -1$. So $A - \lambda I_2$ is invertible for every real λ.
- $\mathbb{C}$: $\lambda = \pm i$, with $\mathbf{x} \in \operatorname{span}((i,1))$, respectively $\operatorname{span}((-i,1))$.
- $\mathbb{F}_2$: $-1 = 1$, and $\lambda = 1$ works ($0^2 = 0$ does not). The solutions are the multiples of $(1,1)$, that is, $(0,0)$ and $(1,1)$.

- $\mathbb{F}_3$: the squares are $0, 1, 1$, and $-1 = 2$ is not among them. No λ.
- $\mathbb{F}_5$: $-1 = 4 = 2^2 = 3^2$, so $\lambda = 2$ or 3, with $\mathbf{x} \in \operatorname{span}((2,1))$, respectively $\operatorname{span}((3,1))$.

Over $\mathbb{R}$, T_A rotates the plane by $90°$, so no nonzero vector is sent to a multiple of itself, and the computation agrees. Whether such vectors exist depends on the field, through the single equation $\lambda^2 = -1$; Section 7.2 takes this up.

Solution to Problem 3.7

Uses. Proposition 3.5.2 (First properties of rank), Proposition 3.3.8 (Properties of the output), Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Corollary 3.2.11 (Products of elementary matrices)
Techniques. Reduce to elementary matrices (Technique 5.4.6), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. (a) Does a pass of the algorithm ever start on a row of zeros? Try the zero matrix.
Hint 2. (b) Which matrices are products of elementary matrices? Try $A = 0$.
Sketch. (a) A pass creates a pivot only in a column with a nonzero entry in an unpivoted row; zero rows never get pivots. $\operatorname{rank} A \le \min(m,n)$ bounds the rank from above only. Counterexample: $A = (0) \in F^{1\times 1}$, or $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$. (b) Only invertible matrices are products of elementary matrices. Counterexample: $A = 0$, $B = I_m$.

(a) The step "every row receives a pivot" is wrong. A pass of Gauss–Jordan elimination creates a pivot only in a column that has a nonzero entry in an unpivoted row, and the algorithm halts as soon as the unpivoted rows are zero (step 1 of Algorithm 3.3.1). The count of rows and columns gives $\operatorname{rank} A \le \min(m,n)$ (Proposition 3.5.2(a)), an upper bound, not equality. For example, $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ has $m = n = 2$ and $\operatorname{rref}(A) = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, so $\operatorname{rank} A = 1 < 2$. It has no right inverse: if $AX = I_2$, then the two rows of AX would be equal (both rows of A are equal), but the rows of I_2 are not. The smallest counterexample is $A = (0) \in F^{1\times 1}$.

(b) The first step is wrong: Theorem 3.5.19 applies only to invertible matrices, and only those are products of elementary matrices (Corollary 3.2.11). For $A = 0$ and $B = I_m$, $\operatorname{rank}(AB) = \operatorname{rank} 0 = 0$, while $\operatorname{rank} B = m \ge 1$. The argument does prove the claim when A is invertible, which is Proposition 3.5.2(c). (In general only $\operatorname{rank}(AB) \le \operatorname{rank} B$ holds; see Section 4.3.)

Solution to Problem 3.8

Uses. Corollary 3.1.22 (Uniqueness depends only on A), Theorem 3.5.12 (First Fundamental Theorem, completed), Exercise 3.4.37, Proposition 3.5.2 (First properties of rank), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Theorem 3.3.12 (Matrices in RREF)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Reduce to RREF (Technique 3.3.22)
Hint 1. (a) A unique solution for one $\mathbf{y}$ says something about $\ker T_A$. (b) Take $\mathbf{y} = A\mathbf{x}$ for an arbitrary $\mathbf{x}$.
Hint 2. (c) Exercise 3.4.37 describes the free columns using only the kernel. (d) Column operations move pivots: try a 1×2 example.
Hint 3. (e) Column j of GA is $G\mathbf{a}_j$. (f) Add two matrix units.
Sketch. (a) True: $\ker T_A = \{\mathbf{0}\}$ by Corollary 3.1.22, so $\operatorname{rank} A = n \le m$. (b) True: $\mathbf{x}$ solves $A\mathbf{x} = A\mathbf{x}$, hence $B\mathbf{x} = A\mathbf{x}$ for every $\mathbf{x}$. (c) True: by Exercise 3.4.37 the free columns are determined by the kernel, and rank = n − (number of free columns). (d) False: $(0\ \ 1)$ and $(0\ \ 1)E_{12} = (1\ \ 0)$. (e) True: $G\mathbf{a}_j = \mathbf{0}$ with G invertible. (f) False: $\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}} + \mathbf{e}_2\mathbf{e}_2^{\mathsf{T}} = I_2$ has rank 2.

(a) True. If $A\mathbf{x} = \mathbf{y}$ has exactly one solution, then $\ker T_A = \{\mathbf{0}\}$ by Corollary 3.1.22(a). By Theorem 3.5.12, $\operatorname{rank} A = n$, and $n = \operatorname{rank} A \le m$.

(b) True. Let $\mathbf{x} \in F^n$ and $\mathbf{y} = A\mathbf{x}$. Then $\mathbf{x}$ solves $A\mathbf{x} = \mathbf{y}$, so by hypothesis it solves $B\mathbf{x} = \mathbf{y}$, that is, $B\mathbf{x} = A\mathbf{x}$. With $\mathbf{x} = \mathbf{e}_j$, column j of B equals column j of A, for every j.

(c) True. By Exercise 3.4.37, x_j is a free variable of A if and only if some $\mathbf{x} \in \ker T_A$ has $x_j = 1$ and $x_l = 0$ for all $l > j$. This condition involves only $\ker T_A$, so A and B have the same free columns, and by Proposition 3.5.2(b), $\operatorname{rank} A = n -$ (number of free columns) $= \operatorname{rank} B$. The number of rows plays no role.

(d) False. Let $A = (0\ \ 1)$ and $H = E_{12}$. Both A and $AH = (1\ \ 0)$ are in RREF (Theorem 3.3.12), with pivot columns 2 and 1 respectively.

(e) True. Write $\operatorname{rref}(A) = GA$ with G invertible (Theorem 3.3.10). Column j of GA is $G\mathbf{a}_j$, so if it is zero, then $\mathbf{a}_j = G^{-1}G\mathbf{a}_j = \mathbf{0}$.

(f) False. The matrix units $\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $\mathbf{e}_2\mathbf{e}_2^{\mathsf{T}} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ each have exactly one nonzero column, so by Proposition 3.5.2(d) each has rank 1. Their sum I_2 has rank 2. So the set is not closed under addition.

Solution to Problem 3.9

> *Uses.* Exercise 3.4.39, Proposition 3.4.16 (A pivot in every row), Proposition 3.5.2 (First properties of rank), Corollary 3.4.14 (Counting solutions), Proposition 3.4.15 (A pivot in every column), Corollary 3.1.22 (Uniqueness depends only on A), Definition 1.2.17 (Evaluation)
> *Techniques.* Undetermined coefficients (Technique 3.1.9), Particular plus homogeneous (Technique 3.1.18)
> *Hint 1.* Write $p = a_0 + a_1x + \cdots + a_nx^n$. The conditions are a linear system $W\mathbf{a} = \mathbf{d}$ whose coefficient matrix has rows $(1, c_i, \ldots, c_i^n)$.
> *Hint 2.* Exercise 3.4.39 says where W has its pivots. Count free columns.
> *Sketch.* The conditions are $W\mathbf{a} = \mathbf{d}$ with $W \in F^{k\times(n+1)}$, rows $(1, c_i, \ldots, c_i^n)$. (a) If $k \le n+1$, W has a pivot in every row, so $\operatorname{rank} W = k$: the system is consistent and has $n+1-k$ free variables, hence q^{n+1-k} solutions. (b) If $k > n+1$, W has a pivot in every column (at most one solution) but not in every row (some $\mathbf{d}$ inconsistent). (c) $7^2 = 49$ and $7^1 = 7$.

Write $p = a_0 + a_1x + \cdots + a_nx^n$, so that p corresponds to $\mathbf{a} = (a_0, \ldots, a_n) \in F^{n+1}$. By Definition 1.2.17, $p(c_i) = d_i$ reads $a_0 + a_1c_i + \cdots + a_nc_i^n = d_i$. So the conditions form the linear system $W\mathbf{a} = \mathbf{d}$, where $\mathbf{d} = (d_1, \ldots, d_k)$ and $W \in F^{k\times(n+1)}$ has rows $\left(1, c_i, c_i^2, \ldots, c_i^n\right)$, the matrix of Exercise 3.4.39 with $m = k$ and $d = n$.

(a) Since $k \le n+1$, Exercise 3.4.39(b) shows that W_r has a pivot in every row, so $\operatorname{rank} W = k$ and the system is consistent for every $\mathbf{d}$ (Proposition 3.4.16). It has $(n+1) - k$ free columns (Proposition 3.5.2(b)), so by Corollary 3.4.14(b) it has exactly q^{n+1-k} solutions. Each solution $\mathbf{a}$ is one polynomial.

(b) Since $k > n+1$, Exercise 3.4.39(a) shows that W_r has a pivot in every column, so $W\mathbf{a} = \mathbf{0}$ has only the trivial solution (Proposition 3.4.15), and every system $W\mathbf{a} = \mathbf{d}$ has at most one solution (Corollary 3.1.22). By Exercise 3.4.39(b), W_r does not have a pivot in every row, so some $W\mathbf{a} = \mathbf{d}$ is inconsistent (Proposition 3.4.16).

(c) Here $q = 7$, $n = 4$, and the nodes $1, 2, 4$ are distinct, so $k = 3 \le 5$ and there are $7^{5-3} = 49$ such polynomials. Adding the condition $p(0) = 0$ gives $k = 4$ distinct nodes $0, 1, 2, 4$, and $7^{5-4} = 7$ polynomials.

In words: each condition at a new node cuts the number of polynomials by a factor of q, until there are $n+1$ conditions and exactly one polynomial is left (Theorem 3.4.24).

Solution to Problem 3.10

> *Uses.* Corollary 3.3.19 (Pivot columns, intrinsically), Lemma 1.5.10 (Linear dependence lemma), Proposition 1.4.14 (The span is the smallest subspace containing a list), Definition 1.6.1 (Basis), Theorem 3.5.13 (Second Fundamental Theorem, completed)
> *Techniques.* Reduce to RREF (Technique 3.3.22)
> *Hint 1.* By Corollary 3.3.19(a), a column is a pivot column exactly when it is not a combination of the columns before it. Apply this to the columns of $(A \mid I_m)$.
> *Hint 2.* The pivot columns are independent: none is a combination of the earlier ones. They span: every column of $(A \mid I_m)$, in particular every $\mathbf{e}_i$, is a combination of them.
> *Hint 3.* For (c), compare the span of the list built so far with the span of all columns of $(A \mid I_m)$ before column $n+i$.
> *Sketch.* (a) For $j \le n$, $\mathbf{a}_j \notin \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_{j-1})$ by independence, so columns $1, \ldots, n$ are pivot columns. No pivot column is a combination of earlier pivot columns, so the pivot columns are independent (Lemma 1.5.10), and every column is a combination of them (Corollary 3.3.19(b)), so their span contains $\mathbf{e}_1, \ldots, \mathbf{e}_m$. The columns of $(A \mid I_m)$ span F^m, so its rank is m. (b) Pivot columns $1, 2, 3, 6$: the basis $\mathbf{a}_1, \mathbf{a}_2, \mathbf{e}_1, \mathbf{e}_4$, with $\mathbf{e}_2 = \mathbf{a}_1 - 2\mathbf{e}_1$, $\mathbf{e}_3 = -\mathbf{a}_1 + \mathbf{a}_2 + \mathbf{e}_1$. (c) By induction, the list built before step i spans the same subspace as $\mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_1, \ldots, \mathbf{e}_{i-1}$.

(a) The columns of $M = (A \mid I_m)$ are $\mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_1, \ldots, \mathbf{e}_m$. By Corollary 3.3.19(a), applied to M, column j is a pivot column if and only if it is not a linear combination of columns $1, \ldots, j-1$. For $j \le n$ these are $\mathbf{a}_1, \ldots, \mathbf{a}_{j-1}$, and $\mathbf{a}_j$ is not a combination of them because the list $\mathbf{a}_1, \ldots, \mathbf{a}_n$ is independent (a combination would give a nontrivial relation with coefficient -1 on $\mathbf{a}_j$). So columns $1, \ldots, n$ are pivot columns; let the others be $n + i_1 < \cdots < n + i_t$. Let $\mathcal{P} = \mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_t}$ be the list of pivot columns, in order.

$\mathcal{P}$ *is independent.* No pivot column is a combination of the columns before it, so in particular none is a combination of the pivot columns before it. If $\mathcal{P}$ were dependent, the linear dependence lemma (Lemma 1.5.10) would give an entry in the span of the earlier entries. So $\mathcal{P}$ is independent.

$\mathcal{P}$ *spans* F^m. By Corollary 3.3.19(b), every non-pivot column of M is a combination of the pivot columns to its left, so every column of M lies in $\operatorname{span}(\mathcal{P})$. In particular $\mathbf{e}_1, \ldots, \mathbf{e}_m \in \operatorname{span}(\mathcal{P})$, and since $\operatorname{span}(\mathcal{P})$ is a subspace (Proposition 1.4.14), it contains every combination of them, which is all of F^m.

So $\mathcal{P}$ is a basis of F^m (Definition 1.6.1). Finally, the columns of M span F^m, so $\operatorname{rank} M = m$ by Theorem 3.5.13 ((III) ⇔ (VI)), and $\operatorname{rank} M$ is the number of pivot columns, $n + t$.

(b) We apply the criterion of (a) to the columns $\mathbf{a}_1, \mathbf{a}_2, \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4$ one at a time, without reducing.

- $\mathbf{a}_1 \neq \mathbf{0}$ and $\mathbf{a}_2$ is not a multiple of $\mathbf{a}_1$ (third entries), as (a) predicts.
- $\mathbf{e}_1$: a combination $x\mathbf{a}_1 + y\mathbf{a}_2 = (2x + y, x + y, y, 0)$ equal to $\mathbf{e}_1$ needs $y = 0$, then $x = 0$, and then $2x + y = 0 \neq 1$. So column 3 is a pivot column.
- $\mathbf{e}_2 = \mathbf{a}_1 - 2\mathbf{e}_1$, so column 4 is not.
- $\mathbf{e}_3 = -\mathbf{a}_1 + \mathbf{a}_2 + \mathbf{e}_1$, since $(-2 + 1 + 1, -1 + 1, 1, 0) = (0, 0, 1, 0)$; so column 5 is not.
- $\mathbf{e}_4$: every earlier column has fourth entry 0, and so does every combination of them. So column 6 is a pivot column.

The pivot columns are $1, 2, 3, 6$, and $\mathbf{a}_1, \mathbf{a}_2, \mathbf{e}_1, \mathbf{e}_4$ is a basis of $\mathbb{Q}^4$. (Row reducing $(A \mid I_4)$ confirms this: the result has pivots in columns $1, 2, 3, 6$, and its columns 4 and 5 are $(1, 0, -2, 0)$ and $(-1, 1, 1, 0)$, the coefficients found above.)

(c) Let $\mathcal{L}_{i-1}$ be the list built before step i, and $V_{i-1} = \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n, \mathbf{e}_1, \ldots, \mathbf{e}_{i-1})$, the span of the columns of M before column $n + i$. We show by induction on i that $\operatorname{span}(\mathcal{L}_{i-1}) = V_{i-1}$. For $i = 1$ both are $\operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n)$. Suppose it holds for i. If $\mathbf{e}_i \in V_{i-1} = \operatorname{span}(\mathcal{L}_{i-1})$, then $\mathcal{L}_i = \mathcal{L}_{i-1}$ and $V_i = V_{i-1}$, because adding a vector of a span to the spanning list does not change the span. Otherwise $\mathbf{e}_i$ is appended to both lists, and the spans stay equal. This completes the induction.

So the procedure appends $\mathbf{e}_i$ exactly when $\mathbf{e}_i \notin V_{i-1}$, that is, by Corollary 3.3.19(a), exactly when column $n + i$ of M is a pivot column. The greedy extension and the pivot columns of $(A \mid I_m)$ are the same construction; the second one can be carried out by a single row reduction.

Solution to Problem 3.11

> *Uses.* Exercise 3.6.9, Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Definition 2.3.8 (Matrix–vector product), Definition 2.4.1 (Matrix product), Theorem 3.5.13 (Second Fundamental Theorem, completed), Proposition 3.3.8 (Properties of the output), Theorem 3.4.9 (All solutions), Exercise 3.3.57
> *Techniques.* Undetermined coefficients (Technique 3.1.9), Reduce to RREF (Technique 3.3.22)
> *Hint 1.* Let U and W be the matrices with columns $\mathbf{u}_j$ and $\mathbf{w}_j$, and write $T = T_X$. Then the conditions say $XU = W$, and the relations among the $\mathbf{u}_j$ are the vectors of $\ker T_U$.
> *Hint 2.* Now (a) is Exercise 3.6.9. For (b), two solutions differ by a Z with $ZU = 0$. If the $\mathbf{u}_j$ do not span, the last row of an invertible G with $GU = \operatorname{rref}(U)$ gives such a Z.
> *Hint 3.* For (c), every relation among the $\mathbf{u}_j$ is a multiple of one basic solution. Build X from G as in the proof of Exercise 3.6.9.
> *Sketch.* With $T = T_X$, the conditions are $XU = W$, and "relations transfer" is $\ker T_U \subseteq \ker T_W$; (a) is Exercise 3.6.9. (b) If the $\mathbf{u}_j$ span, $ZU = 0$ forces $Z = 0$. If not, $\operatorname{rank} U < n$, row n of $\operatorname{rref}(U) = GU$ is zero, and $\mathbf{z} =$ row n of G is nonzero with $\mathbf{z}U = \mathbf{0}$; adding $\mathbf{z}$ to the first row of X gives another solution. (c) The relations are the multiples of $(2, 1, -1)$, and $2\mathbf{w}_1 + \mathbf{w}_2 - \mathbf{w}_3 = \mathbf{0}$; the solutions are $X = \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \end{pmatrix} + \begin{pmatrix} \alpha \\ \beta \end{pmatrix}(-1 \;\; 1 \;\; 1)$. With $\mathbf{w}_3 = (2, 5)$ there is none.

Let $U \in F^{n \times k}$ and $W \in F^{m \times k}$ have columns $\mathbf{u}_1, \ldots, \mathbf{u}_k$ and $\mathbf{w}_1, \ldots, \mathbf{w}_k$. Every linear map $T : F^n \to F^m$ is T_X for exactly one $X \in F^{m \times n}$ (Proposition 2.3.17), and column j of XU is $X\mathbf{u}_j$ (Definition 2.4.1). So $T_X(\mathbf{u}_j) = \mathbf{w}_j$ for all j if and only if $XU = W$. By Definition 2.3.8, a relation $\sum_j c_j \mathbf{u}_j = \mathbf{0}$ is a vector $\mathbf{c} \in \ker T_U$, and it holds among the $\mathbf{w}_j$ exactly when $\mathbf{c} \in \ker T_W$.

(a) So the condition on relations says $\ker T_U \subseteq \ker T_W$, and the existence of T says $W = XU$ for some X. These are equivalent by Exercise 3.6.9(a), applied with $A = U$ and $B = W$.

(b) Let $XU = W$. Another matrix X' satisfies $X'U = W$ if and only if $Z = X' - X$ satisfies $ZU = 0$. So T is unique if and only if $ZU = 0$ forces $Z = 0$.

Suppose the $\mathbf{u}_j$ span F^n, and $ZU = 0$. Then $Z\mathbf{u}_j = \mathbf{0}$ for every j, so $Z\mathbf{v} = \mathbf{0}$ for every combination $\mathbf{v}$ of the $\mathbf{u}_j$, which is every $\mathbf{v} \in F^n$. In particular every column $Z\mathbf{e}_i$ of Z is zero, and $Z = 0$.

Suppose the $\mathbf{u}_j$ do not span F^n. By Theorem 3.5.13 ((III) $\Leftrightarrow$ (VI)), $\operatorname{rank} U < n$, so row n of $\operatorname{rref}(U)$ is zero (Proposition 3.3.8(a)). Let G be invertible with $GU = \operatorname{rref}(U)$, and let $\mathbf{z}$ be row n of G. Then $\mathbf{z}U$ is row n of GU, which is zero, and $\mathbf{z} \neq \mathbf{0}$ since G is invertible. Let $Z \in F^{m\times n}$ have first row $\mathbf{z}$ and all other rows zero. Then $Z \neq 0$ and $ZU = 0$ (its first row is $\mathbf{z}U = \mathbf{0}$), so $X + Z$ is a second solution.

(c) Row reducing U (adding -1 times row 1 to row 3, then -1 times row 2 to row 1 and row 2 to row 3) gives

$$U = \begin{pmatrix} 1 & 1 & 3 \\ 0 & 1 & 1 \\ 1 & 0 & 2 \end{pmatrix}, \quad \operatorname{rref}(U) = \begin{pmatrix} 1 & 0 & 2 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad G = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & 0 \\ -1 & 1 & 1 \end{pmatrix}.$$

The basic solution is $(-2, -1, 1)$, so by Theorem 3.4.9 the relations among the $\mathbf{u}_j$ are exactly the multiples of $-2\mathbf{u}_1 - \mathbf{u}_2 + \mathbf{u}_3 = \mathbf{0}$. And $-2\mathbf{w}_1 - \mathbf{w}_2 + \mathbf{w}_3 = (-2, -2) - (0, 2) + (2, 4) = \mathbf{0}$, so by (a) a map exists. Following the proof of Exercise 3.6.9, let Y have columns $\mathbf{w}_1, \mathbf{w}_2$ (the $\mathbf{w}$'s at the pivot columns $1, 2$) and $\mathbf{0}$; then

$$X = YG = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 2 & 0 \end{pmatrix}\begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & 0 \\ -1 & 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \end{pmatrix}.$$

Check: $X\mathbf{u}_1 = (1, 1)$, $X\mathbf{u}_2 = (1 - 1, 1 + 1) = (0, 2)$, $X\mathbf{u}_3 = (3 - 1, 3 + 1) = (2, 4)$. Since $\operatorname{rank} U = 2 < 3$, T is not unique. By (b) and its proof, the other solutions differ from X by matrices Z with $ZU = 0$, that is, whose rows $\mathbf{z}$ satisfy $\mathbf{z}U = \mathbf{0}$. By Exercise 3.3.57 these rows are the multiples of the last row $(-1, 1, 1)$ of G. So the maps are exactly

$$T(\mathbf{x}) = \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \end{pmatrix}\mathbf{x} + \begin{pmatrix} \alpha \\ \beta \end{pmatrix}(-x_1 + x_2 + x_3) \quad (\alpha, \beta \in \mathbb{Q}).$$

If $\mathbf{w}_3 = (2, 5)$, then $-2\mathbf{w}_1 - \mathbf{w}_2 + \mathbf{w}_3 = (0, 1) \neq \mathbf{0}$: the relation among the $\mathbf{u}_j$ fails for the $\mathbf{w}_j$, so by (a) there is no such map.

Solution to Problem 3.12

Uses. Lemma 2.4.24 (Matrix units), Definition 2.3.1 (Matrix of a linear map), Proposition 2.4.14 (Algebra of matrices), Proposition 3.5.2 (First properties of rank), Definition 1.3.10 (Span)
Techniques. Translate between maps and matrices (Technique 2.3.27), Reduce to RREF (Technique 3.3.22)
Hint 1. Column j of M is the coordinate vector of C_A applied to the jth matrix unit. Compute $A\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}} - \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}A$ entry by entry, or compute $C_A(X)$ for a general X and read off the coefficients.
Hint 2. For (b), use Proposition 3.5.2(d): count the columns of M that are not combinations of the earlier ones. Split into the cases $c \neq 0$; $c = 0, b \neq 0$; $b = c = 0$.
Sketch. $C_A(X)$ has entries $bx_{21} - cx_{12}$, $-bx_{11} + (a - d)x_{12} + bx_{22}$, $cx_{11} + (d - a)x_{21} - cx_{22}$, $cx_{12} - bx_{21}$, so M has columns $\mathbf{m}_1 = (0, -b, c, 0)$, $\mathbf{m}_2 = (-c, a - d, 0, c)$, $\mathbf{m}_3 = (b, 0, d - a, -b)$, $\mathbf{m}_4 = -\mathbf{m}_1$. Column 4 never counts. If $c \neq 0$: $\mathbf{m}_1, \mathbf{m}_2$ count, $\mathbf{m}_3 = ((d - a)/c)\mathbf{m}_1 - (b/c)\mathbf{m}_2$ does not. If $c = 0 \neq b$: $\mathbf{m}_1$ and $\mathbf{m}_3$ count. If $b = c = 0$: rank 2 when $a \neq d$, and $M = 0$ when $a = d$. (c) $C_A(X) = \left(\begin{smallmatrix} x_{21} & x_{22} - x_{11} \\ 0 & -x_{21} \end{smallmatrix}\right)$: kernel $\operatorname{span}(I_2, A)$, image the Y with $y_{21} = 0$ and $y_{11} + y_{22} = 0$.

(a) By the distributive laws for matrix multiplication (Proposition 2.4.14), $C_A(X + X') = AX + AX' - XA - X'A = C_A(X) + C_A(X')$ and $C_A(tX) = tC_A(X)$, so C_A is linear. For $X = \left(\begin{smallmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{smallmatrix}\right)$,

$$AX - XA = \begin{pmatrix} ax_{11} + bx_{21} & ax_{12} + bx_{22} \\ cx_{11} + dx_{21} & cx_{12} + dx_{22} \end{pmatrix} - \begin{pmatrix} ax_{11} + cx_{12} & bx_{11} + dx_{12} \\ ax_{21} + cx_{22} & bx_{21} + dx_{22} \end{pmatrix},$$

so

$$C_A(X) = \begin{pmatrix} bx_{21} - cx_{12} & -bx_{11} + (a-d)x_{12} + bx_{22} \\ cx_{11} + (d-a)x_{21} - cx_{22} & cx_{12} - bx_{21} \end{pmatrix}.$$

The coordinates of X in the basis of matrix units are $(x_{11}, x_{12}, x_{21}, x_{22})$ (Lemma 2.4.24(a)), so by Definition 2.3.1, M is the matrix taking these coordinates to those of $C_A(X)$:

$$M = \begin{pmatrix} 0 & -c & b & 0 \\ -b & a-d & 0 & b \\ c & 0 & d-a & -c \\ 0 & c & -b & 0 \end{pmatrix}.$$

Its columns are $\mathbf{m}_1 = (0, -b, c, 0)$, $\mathbf{m}_2 = (-c, a-d, 0, c)$, $\mathbf{m}_3 = (b, 0, d-a, -b)$, and $\mathbf{m}_4 = (0, b, -c, 0) = -\mathbf{m}_1$.

(b) By Proposition 3.5.2(d), $\operatorname{rank} M$ is the number of j with $\mathbf{m}_j \notin \operatorname{span}(\mathbf{m}_1, \ldots, \mathbf{m}_{j-1})$. Since $\mathbf{m}_4 = -\mathbf{m}_1$, $j = 4$ never counts.

Case $c \neq 0$. Then $\mathbf{m}_1 \neq \mathbf{0}$, so $j = 1$ counts; and $\mathbf{m}_2 \notin \operatorname{span}(\mathbf{m}_1)$, since its first entry is $-c \neq 0$ while that of $\mathbf{m}_1$ is 0. But $\mathbf{m}_3$ is a combination of $\mathbf{m}_1$ and $\mathbf{m}_2$:

$$\frac{d-a}{c}\mathbf{m}_1 - \frac{b}{c}\mathbf{m}_2 = (b, -(d-a)b/c - (a-d)b/c, d-a, -b) = (b, 0, d-a, -b) = \mathbf{m}_3.$$

So $\operatorname{rank} M = 2$.

Case $c = 0$, $b \neq 0$. Then $\mathbf{m}_1 = (0, -b, 0, 0) \neq \mathbf{0}$ counts, $\mathbf{m}_2 = (0, a-d, 0, 0)$ is a multiple of $\mathbf{m}_1$, and $\mathbf{m}_3 = (b, 0, d-a, -b)$ is not in $\operatorname{span}(\mathbf{m}_1, \mathbf{m}_2)$, whose vectors have first entry 0. So $\operatorname{rank} M = 2$.

Case $b = c = 0$. Then $\mathbf{m}_1 = \mathbf{0}$, $\mathbf{m}_2 = (0, a-d, 0, 0)$, $\mathbf{m}_3 = (0, 0, d-a, 0)$. If $a \neq d$, then $j = 2$ and $j = 3$ count, and $\operatorname{rank} M = 2$. If $a = d$, then $M = 0$ and $\operatorname{rank} M = 0$.

The case $b = c = 0$, $a = d$ is exactly $A = aI_2$. So $\operatorname{rank} M = 0$ for scalar A and $\operatorname{rank} M = 2$ otherwise.

(c) Here $a = b = d = 1$ and $c = 0$, so by (a)

$$C_A(X) = \begin{pmatrix} x_{21} & x_{22} - x_{11} \\ 0 & -x_{21} \end{pmatrix}.$$

So $AX = XA$ if and only if $x_{21} = 0$ and $x_{11} = x_{22}$, that is, $X = \begin{pmatrix} s & t \\ 0 & s \end{pmatrix} = (s-t)I_2 + tA$ for some s, t. The matrices commuting with A are exactly those in $\operatorname{span}(I_2, A)$. The image consists of matrices Y with $y_{21} = 0$ and $y_{22} = -y_{11}$, and every such Y is an image: take $x_{21} = y_{11}$, $x_{22} = y_{12}$, $x_{11} = x_{12} = 0$. So the image is $\{Y \mid y_{21} = 0, y_{11} + y_{22} = 0\}$. Both descriptions use two parameters, matching $\operatorname{rank} M = 2$ and the $4 - 2$ free columns.

Solution to Problem 3.13

Uses. Corollary 3.4.20 (Square systems), Definition 1.2.17 (Evaluation)
Techniques. Uniqueness gives existence (Technique 3.4.21), Undetermined coefficients (Technique 3.1.9)
Hint 1. Count: eight coefficients, and the conditions $p(0) = d_1 = q(0)$ count as two equations.
Hint 2. For (b), it suffices to solve the homogeneous system. The conditions at 0 say that p and q have the same coefficients of 1, x, and x^2.
Hint 3. For (c), if (p, q) is the spline for symmetric data, then so is the pair $(\tilde{q}, \tilde{p})$, where $\tilde{q}(t) = q(-t)$ and $\tilde{p}(t) = p(-t)$. Uniqueness then says that $p(t) = q(-t)$.
Sketch. (a) Eight linear equations ($p(-1)$, $p(0)$, $q(0)$, $q(1)$, two matching conditions, two end conditions) in eight coefficients. (b) Homogeneous: $a_0 = b_0 = 0$, $a_1 = b_1 = u$, $a_2 = b_2 = w$; the end conditions give $a_3 = w/3$, $b_3 = -w/3$; then $p(-1) = 0$ gives $u = 2w/3$ and $q(1) = 0$ gives $u = -2w/3$, so $u = w = 0$. By Corollary 3.4.20 every system has exactly one solution. (c) By symmetry and uniqueness $p(t) = q(-t)$, so $b_1 = 0$, and $q(1) = 0$, $q''(1) = 0$ give $q = 1 - \frac{3}{2}x^2 + \frac{1}{2}x^3$, $p = 1 - \frac{3}{2}x^2 - \frac{1}{2}x^3$.

Write $p = a_0 + a_1x + a_2x^2 + a_3x^3$ and $q = b_0 + b_1x + b_2x^2 + b_3x^3$.

(a) By Definition 1.2.17 and the formulas for p' and p'', the conditions read

$$a_0 - a_1 + a_2 - a_3 = d_0, \quad a_0 = d_1, \quad b_0 = d_1, \quad b_0 + b_1 + b_2 + b_3 = d_2,$$
$$a_1 = b_1, \quad 2a_2 = 2b_2, \quad 2a_2 - 6a_3 = 0, \quad 2b_2 + 6b_3 = 0.$$

These are eight linear equations in the eight unknowns $a_0, \dots, a_3, b_0, \dots, b_3$.

(b) By Corollary 3.4.20 ((iv) ⇒ (vi)) it suffices to show that the homogeneous system, with $d_0 = d_1 = d_2 = 0$, has only the trivial solution. Its equations give $a_0 = b_0 = 0$, $a_1 = b_1 =: u$, $a_2 = b_2 =: w$, $a_3 = w/3$, and $b_3 = -w/3$. The two remaining equations become

$$-u + w - \frac{w}{3} = 0 \quad \text{and} \quad u + w - \frac{w}{3} = 0,$$

that is, $u = 2w/3$ and $u = -2w/3$. So $4w/3 = 0$, hence $w = 0$ and $u = 0$, and all eight coefficients vanish. Therefore every system of this form, for every d_0, d_1, d_2, has exactly one solution.

(c) Let (p, q) be the spline for $(0, 1, 0)$. Define $\tilde{p} = \sum_k (-1)^k a_k x^k$ and $\tilde{q} = \sum_k (-1)^k b_k x^k$, so that $\tilde{p}(t) = p(-t)$ and $\tilde{q}(t) = q(-t)$ for all t. From the formulas, $\tilde{q}'(t) = -q'(-t)$ and $\tilde{q}''(t) = q''(-t)$, and likewise for $\tilde{p}$. We check that $(\tilde{q}, \tilde{p})$ is also a natural cubic spline for $(0, 1, 0)$:

- $\tilde{q}(-1) = q(1) = 0$, $\tilde{q}(0) = q(0) = 1 = p(0) = \tilde{p}(0)$, and $\tilde{p}(1) = p(-1) = 0$;
- $\tilde{q}'(0) = -q'(0) = -p'(0) = \tilde{p}'(0)$ and $\tilde{q}''(0) = q''(0) = p''(0) = \tilde{p}''(0)$;
- $\tilde{q}''(-1) = q''(1) = 0$ and $\tilde{p}''(1) = p''(-1) = 0$.

By the uniqueness in (b), $(\tilde{q}, \tilde{p}) = (p, q)$, so $a_k = (-1)^k b_k$ for every k.

So it remains to find q. From $a_1 = -b_1$ and $a_1 = b_1$ we get $b_1 = 0$; and $b_0 = 1$. The conditions $q(1) = 0$ and $q''(1) = 0$ give $1 + b_2 + b_3 = 0$ and $2b_2 + 6b_3 = 0$, so $b_2 = -3b_3$ and $1 - 2b_3 = 0$: $b_3 = 1/2$, $b_2 = -3/2$. Hence

$$q = 1 - \frac{3}{2}x^2 + \frac{1}{2}x^3, \quad p = 1 - \frac{3}{2}x^2 - \frac{1}{2}x^3.$$

Check the conditions not used: $p(-1) = 1 - 3/2 + 1/2 = 0$ and $p''(-1) = -3 - 3 \cdot (-1) = 0$. The spline is the function $t \mapsto 1 - \frac{3}{2}t^2 + \frac{1}{2}|t|^3$ on $[-1, 1]$.

The same holds for any nodes $t_0 < t_1 < \cdots < t_N$, with one cubic on each interval. Counting conditions again gives a square system, and uniqueness follows from an integration by parts: for a homogeneous spline s, $\int (s'')^2 = 0$, so s'' vanishes, s is linear on each interval and zero at the nodes. Solving the system by hand would be hopeless, but uniqueness is enough.

Solution to Problem 3.14

Uses. Theorem 2.4.34 (Block multiplication), Definition 2.5.12 (Invertible), Proposition 3.5.2 (First properties of rank), Exercise 3.5.41, Exercise 3.5.36, Corollary 3.5.25 (The invertible matrix theorem), Theorem 3.5.14 (Third Fundamental Theorem, completed)
Techniques. Block decomposition (Technique 2.4.35), Reduce to RREF (Technique 3.3.22)
Hint 1. Imitate one pass of elimination with blocks: subtract CA^{-1} times the first block row from the second. Then clear B with a block column operation.
Hint 2. $P = \begin{pmatrix} I_k & 0 \\ -CA^{-1} & I_\ell \end{pmatrix}$ and $Q = \begin{pmatrix} I_k & -A^{-1}B \\ 0 & I_\ell \end{pmatrix}$. Their inverses change the sign of the off-diagonal block.
Hint 3. Rank is unchanged by invertible factors on both sides, and Exercise 3.5.36 computes the rank of a block diagonal matrix.
Sketch. $PM = \begin{pmatrix} A & B \\ 0 & S \end{pmatrix}$ and $(PM)Q = \begin{pmatrix} A & 0 \\ 0 & S \end{pmatrix}$, with P, Q invertible (flip the sign of the off-diagonal block). So $\operatorname{rank} M = \operatorname{rank}\begin{pmatrix} A & 0 \\ 0 & S \end{pmatrix} = \operatorname{rank} A + \operatorname{rank} S = k + \operatorname{rank} S$. M is invertible iff $\operatorname{rank} M = k + \ell$ iff $\operatorname{rank} S = \ell$. (c) $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$, $B = C = I_2$, $S = D - A^{-1} = \begin{pmatrix} t+2 & 0 \\ -1/2 & t+1/2 \end{pmatrix}$, which has rank 2 unless $t = -2$ or $t = -1/2$.

(a) Let

$$P = \begin{pmatrix} I_k & 0 \\ -CA^{-1} & I_\ell \end{pmatrix}, \quad Q = \begin{pmatrix} I_k & -A^{-1}B \\ 0 & I_\ell \end{pmatrix}.$$

By block multiplication (Theorem 2.4.34),

$$PM = \begin{pmatrix} A & B \\ -CA^{-1}A + C & -CA^{-1}B + D \end{pmatrix} = \begin{pmatrix} A & B \\ 0 & S \end{pmatrix}, \quad (PM)Q = \begin{pmatrix} A & -AA^{-1}B + B \\ 0 & S \end{pmatrix} = \begin{pmatrix} A & 0 \\ 0 & S \end{pmatrix}.$$

P is invertible: $\begin{pmatrix} I_k & 0 \\ CA^{-1} & I_\ell \end{pmatrix}$ is a two-sided inverse, since both products have off-diagonal block $CA^{-1} - CA^{-1} = 0$ and identity diagonal blocks. Likewise $\begin{pmatrix} I_k & A^{-1}B \\ 0 & I_\ell \end{pmatrix}$ is a two-sided inverse of Q (Definition 2.5.12).

(b) Left multiplication by an invertible matrix does not change the rank (Proposition 3.5.2(c)), and neither does right multiplication (Exercise 3.5.41(c)). So by (a) and Exercise 3.5.36(a),

$$\operatorname{rank} M = \operatorname{rank}\begin{pmatrix} A & 0 \\ 0 & S \end{pmatrix} = \operatorname{rank} A + \operatorname{rank} S = k + \operatorname{rank} S,$$

where $\operatorname{rank} A = k$ because A is invertible (Theorem 3.5.14). M is square of size $k + \ell$, so it is invertible if and only if $\operatorname{rank} M = k + \ell$ (Corollary 3.5.25), if and only if $\operatorname{rank} S = \ell$, if and only if S is invertible.

(c) Here $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$, $B = C = I_2$, and $D = \begin{pmatrix} t & 1 \\ 1 & t \end{pmatrix}$. Row reducing $(A \mid I_2)$ gives $A^{-1} = \begin{pmatrix} -2 & 1 \\ 3/2 & -1/2 \end{pmatrix}$ (check: $\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}\begin{pmatrix} -2 & 1 \\ 3/2 & -1/2 \end{pmatrix} = \begin{pmatrix} -2+3 & 1-1 \\ -6+6 & 3-2 \end{pmatrix} = I_2$). So

$$S = D - A^{-1} = \begin{pmatrix} t+2 & 0 \\ -1/2 & t+1/2 \end{pmatrix}.$$

If $t \neq -2$ and $t \neq -1/2$, the first column of S is nonzero, and the second column $(0, t+1/2)$ is not a multiple of it (a multiple $c(t+2, -1/2)$ with first entry 0 needs $c = 0$), so $\operatorname{rank} S = 2$ (Proposition 3.5.2(d)). If $t = -2$, then $S = \begin{pmatrix} 0 & 0 \\ -1/2 & -3/2 \end{pmatrix}$, and if $t = -1/2$, then $S = \begin{pmatrix} 3/2 & 0 \\ -1/2 & 0 \end{pmatrix}$; in both cases the two columns are proportional and $\operatorname{rank} S = 1$. By (b), $\operatorname{rank} M_t = 4$ for $t \notin \{-2, -1/2\}$, and $\operatorname{rank} M_t = 3$ for those two values.

Solution to Problem 3.15

Uses. Corollary 3.4.20 (Square systems)
Techniques. Uniqueness gives existence (Technique 3.4.21), A sum of nonnegative terms (Technique 6.1.9)
Hint 1. The system is square. By Corollary 3.4.20 it suffices to show that with all $s_i = 0$ the only solution is $\mathbf{v} = \mathbf{0}$.
Hint 2. For a homogeneous solution, multiply equation i by v_i and add over $i = 1, \dots, n$. You may add the term for $i = 0$ for free, since $v_0 = 0$. Pair the term (i, j) with the term (j, i).
Hint 3. You should get $\sum_{i,j} c_{ij}(v_i - v_j)^2 = 0$. A sum of nonnegative terms vanishes only if every term does. Then use connectedness.
Sketch. (a) n equations, n unknowns. For $\mathbf{s} = \mathbf{0}$: $0 = \sum_{i=0}^{n} v_i \sum_j c_{ij}(v_i - v_j)$, and symmetrizing in i, j gives $\frac{1}{2}\sum_{i,j} c_{ij}(v_i - v_j)^2 = 0$. So $v_i = v_j$ whenever $c_{ij} > 0$, hence all potentials equal $v_0 = 0$ by connectedness, and Corollary 3.4.20 gives existence and uniqueness. (b) The double sum $\sum_{i,j} c_{ij}(v_i - v_j)$ over all nodes is 0 by antisymmetry. (c) $4v_1 - v_2 - v_3 = 0$, $-v_1 + 2v_2 - v_3 = 1$, $-v_1 - v_2 + 3v_3 = 0$ give $\mathbf{v} = (4, 11, 5)/13$; the diagonal carries $1/13$ A from 3 to 1; the effective resistance is $11/13\ \Omega$.

Throughout, sums over i or j run over all nodes $0, \dots, n$ unless stated otherwise, and $v_0 = 0$.

(a) The equations are linear in $v_1, \dots, v_n$ (the terms with $j = 0$ contribute $c_{i0}v_i$), and there are n of them, so the system is square. By Corollary 3.4.20 ((iv) $\Rightarrow$ (vi)) it suffices to show that the homogeneous system, with every $s_i = 0$, has only the trivial solution.

Let $\mathbf{v}$ solve the homogeneous system. Multiply equation i by v_i and add over $i = 1, \dots, n$. We may also add the term with $i = 0$, which is $v_0 \sum_j c_{0j}(v_0 - v_j) = 0$ because $v_0 = 0$, whatever the inner sum is. So

$$E := \sum_i \sum_j c_{ij} v_i (v_i - v_j) = 0.$$

Renaming i and j and using $c_{ji} = c_{ij}$, the same sum is $E = \sum_i \sum_j c_{ij} v_j (v_j - v_i)$. Adding the two expressions,

$$0 = 2E = \sum_i \sum_j c_{ij}\bigl(v_i(v_i - v_j) - v_j(v_i - v_j)\bigr) = \sum_i \sum_j c_{ij}(v_i - v_j)^2.$$

Every term is a nonnegative real number, so every term is 0: whenever i and j are joined, $c_{ij} > 0$ forces $v_i = v_j$. Since the network is connected, every node i is joined to node 0 by a path of resistors, along which the potential does not change; so $v_i = v_0 = 0$. Thus the homogeneous system has only the trivial solution, and for every $\mathbf{s}$ there is exactly one solution.

(b) The current flowing out of node 0 through the resistors is $\sum_j c_{0j}(v_0 - v_j)$. Now

$$\sum_i \sum_j c_{ij}(v_i - v_j) = 0,$$

because the terms (i,j) and (j,i) cancel: $c_{ij}(v_i - v_j) + c_{ji}(v_j - v_i) = 0$. Splitting off $i = 0$ and using the equations at the other nodes,

$$\sum_j c_{0j}(v_0 - v_j) = -\sum_{i=1}^{n} s_i.$$

So a current $s_1 + \cdots + s_n$ flows into the ground node, as conservation of charge requires; the equation at node 0 is a consequence of the others, just as one balance equation was redundant in Exercise 3.1.38.

(c) The conductances are $c_{01} = 2$ and $c_{12} = c_{23} = c_{30} = c_{13} = 1$, and $\mathbf{s} = (0,1,0)$. The equations at nodes 1, 2, 3 are

$$\begin{aligned} 2v_1 + (v_1 - v_2) + (v_1 - v_3) = 0, &\quad \text{that is,} \quad 4v_1 - v_2 - v_3 = 0,\\ (v_2 - v_1) + (v_2 - v_3) = 1, &\quad \text{that is,} \quad -v_1 + 2v_2 - v_3 = 1,\\ (v_3 - v_2) + v_3 + (v_3 - v_1) = 0, &\quad \text{that is,} \quad -v_1 - v_2 + 3v_3 = 0. \end{aligned}$$

The first gives $v_2 = 4v_1 - v_3$; then the third gives $-5v_1 + 4v_3 = 0$, so $v_3 = 5v_1/4$ and $v_2 = 11v_1/4$. The second becomes $(-4 + 22 - 5)v_1/4 = 1$, so $v_1 = 4/13$. Hence

$$v_1 = \frac{4}{13}, \quad v_2 = \frac{11}{13}, \quad v_3 = \frac{5}{13}.$$

Check: $-4 + 22 - 5 = 13$ in the second equation, and $-4 - 11 + 15 = 0$ in the third. The current through the diagonal is $c_{31}(v_3 - v_1) = 1/13$ A, from node 3 to node 1. The effective resistance between nodes 2 and 0 is $v_2/1 = 11/13\ \Omega$.

The argument in (a) follows the same strategy as the uniqueness of the plate temperatures in Exercise 3.1.47, with an energy in place of a maximum. In physical terms, $\frac{1}{2}\sum_{i,j} c_{ij}(v_i - v_j)^2$ is the power dissipated in the resistors, and a network with no sources dissipates no power only if no current flows.

Solution to Problem 3.16

Uses. Corollary 3.4.20 (Square systems), Exercise 3.5.37, Proposition 2.4.23 (Transpose of a product)
Techniques. Uniqueness gives existence (Technique 3.4.21), Particular plus homogeneous (Technique 3.1.18)
Hint 1. P_n is square, so it is invertible if and only if $P_n\mathbf{x} = \mathbf{0}$ forces $\mathbf{x} = \mathbf{0}$. Treat x_1 as a parameter: the first $n-1$ equations then determine $x_2, \ldots, x_n$ one at a time.
Hint 2. The forced values are x_1 times the sequence $u_1 = 1$, $u_2 = -1$, $u_{i+1} = -u_i - u_{i-1}$, which is $1, -1, 0, 1, -1, 0, \ldots$. The last equation then says $-x_1 u_{n+1} = 0$, where u_{n+1} continues the sequence.
Hint 3. For (b), P_n is symmetric, so $\mathbf{z}^{\mathsf{T}} P_n = \mathbf{0}$ means $P_n\mathbf{z} = \mathbf{0}$. Over $\mathbb{F}_2$ the only nonzero such $\mathbf{z}$ is $(1,1,0,1,1,0,\ldots,1,1)$.
Sketch. (a) For $n \geq 2$, the first $n-1$ equations of $P_n\mathbf{x} = \mathbf{0}$ hold exactly for $\mathbf{x} = x_1\mathbf{u}$ with $\mathbf{u} = (u_1, \ldots, u_n)$, $u_i = 1, -1, 0$ according as $i \equiv 1, 2, 0 \bmod 3$. The last equation is $x_1(u_{n-1} + u_n) = -x_1 u_{n+1} = 0$. If $n \not\equiv 2$, $u_{n+1} = \pm 1$ forces $x_1 = 0$, so P_n is invertible (Corollary 3.4.20); if $n \equiv 2$, $\mathbf{u}$ is a nonzero kernel vector. (b) $P_n\mathbf{x} = \mathbf{y}$ is unsolvable iff some $\mathbf{z}$ has $P_n\mathbf{z} = \mathbf{0}$

and $\mathbf{z}^{\mathsf{T}}\mathbf{y} \neq 0$; the only candidate is $\mathbf{z} = \mathbf{u} = (1, 1, 0, \ldots, 1, 1)$, and $\mathbf{u}^{\mathsf{T}}\mathbf{y}$ counts the lit lamps in positions not divisible by 3, modulo 2.

(a) For $n = 1$, $P_1 = (1)$ is invertible, and $1 \not\equiv 2 \bmod 3$. Let $n \geq 2$. Since P_n is square, it is invertible if and only if $P_n\mathbf{x} = \mathbf{0}$ has only the trivial solution (Corollary 3.4.20). The equations of $P_n\mathbf{x} = \mathbf{0}$ are

$$x_1 + x_2 = 0, \quad x_{i-1} + x_i + x_{i+1} = 0 \quad (2 \leq i \leq n-1), \quad x_{n-1} + x_n = 0.$$

Define $u_1 = 1$, $u_2 = -1$, and $u_{i+1} = -u_i - u_{i-1}$ for $i \geq 2$. Then $u_3 = 1 - 1 = 0$, $u_4 = 0 + 1 = 1$, $u_5 = -1 - 0 = -1$, and by induction the sequence repeats with period 3:

$$u_i = 1, -1, 0 \quad \text{according as} \quad i \equiv 1, 2, 0 \bmod 3.$$

(Indeed, if u_{i-1}, u_i, u_{i+1} is $1, -1, 0$ or $-1, 0, 1$ or $0, 1, -1$, then $u_{i+2} = -u_{i+1} - u_i$ continues the pattern.)

The first $n-1$ equations. We claim that they hold exactly for the vectors $\mathbf{x} = t\mathbf{u}$, $t \in F$, where $\mathbf{u} = (u_1, \ldots, u_n)$. If they hold, put $t = x_1$. The first equation gives $x_2 = -t = tu_2$, and equation i gives $x_{i+1} = -x_i - x_{i-1}$, so by induction $x_i = tu_i$ for all $i \leq n$. Conversely, $t\mathbf{u}$ satisfies them by the definition of the sequence.

The last equation. For $\mathbf{x} = t\mathbf{u}$ it reads $t(u_{n-1} + u_n) = 0$, that is, $-tu_{n+1} = 0$. If $n \not\equiv 2 \bmod 3$, then $n + 1 \not\equiv 0$, so $u_{n+1} = \pm 1$ and $t = 0$: only the trivial solution, and P_n is invertible. If $n \equiv 2 \bmod 3$, then $u_{n+1} = 0$, so $\mathbf{u} \neq \mathbf{0}$ solves $P_n\mathbf{x} = \mathbf{0}$, and P_n is not invertible. Nothing in the argument depends on the field.

(b) As in Exercise 3.1.40, a set of presses $\mathbf{x} \in \mathbb{F}_2^n$ switches off the pattern $\mathbf{y}$ exactly when $P_n\mathbf{x} = \mathbf{y}$: lamp i is toggled by presses at $i-1, i, i+1$. Let $n \equiv 2 \bmod 3$. By (a), $\ker T_{P_n} = \{t\mathbf{u} \mid t \in \mathbb{F}_2\} = \{\mathbf{0}, \mathbf{u}\}$, where, since $-1 = 1$ in $\mathbb{F}_2$,

$$\mathbf{u} = (1, 1, 0, 1, 1, 0, \ldots, 1, 1),$$

with $u_i = 0$ exactly when 3 divides i.

By Exercise 3.5.37, $P_n\mathbf{x} = \mathbf{y}$ has no solution if and only if there is $\mathbf{z}$ with $\mathbf{z}^{\mathsf{T}}P_n = \mathbf{0}$ and $\mathbf{z}^{\mathsf{T}}\mathbf{y} \neq 0$. The matrix P_n is symmetric, so transposing (Proposition 2.4.23), $\mathbf{z}^{\mathsf{T}}P_n = \mathbf{0}$ says $P_n\mathbf{z} = \mathbf{0}$, that is, $\mathbf{z} \in \{\mathbf{0}, \mathbf{u}\}$. And $\mathbf{0}^{\mathsf{T}}\mathbf{y} = 0$. So the pattern cannot be switched off if and only if $\mathbf{u}^{\mathsf{T}}\mathbf{y} \neq 0$. Finally, $\mathbf{u}^{\mathsf{T}}\mathbf{y} = \sum_{3\nmid i} y_i$ in $\mathbb{F}_2$, which is 0 exactly when the number of lit lamps in positions not divisible by 3 is even.

Solution to Problem 3.17

Uses. Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Theorem 2.4.34 (Block multiplication), Theorem 3.5.14 (Third Fundamental Theorem, completed), Corollary 1.5.17 (Sublists), Corollary 3.5.16 (Lists of vectors in F^m), Theorem 3.3.12 (Matrices in RREF), Proposition 3.5.8 (Right inverses from the pivots), Proposition 3.5.9 (Left inverses), Corollary 3.3.18 (RREF and row equivalence), Corollary 3.5.21 (Invertibility and row equivalence), Exercise 1.5.43, Theorem 3.5.13 (Second Fundamental Theorem, completed)

Techniques. Reduce to RREF (Technique 3.3.22), Uniqueness via two candidates (Technique 1.1.8)

Hint 1. For existence in (a), write $GA = \begin{pmatrix} S \\ 0 \end{pmatrix}$ and split G^{-1} into its first r columns and the rest. For uniqueness, S has a right inverse.

Hint 2. For the converse, a matrix C with r columns and $\operatorname{rank} C = r$ can be reduced to $\begin{pmatrix} I_r \\ 0 \end{pmatrix}$ by row operations (as in the first proof of Proposition 3.5.9). Apply the same operations to CS.

Hint 3. For (b), (a) sets up a bijection $(C, S) \mapsto CS$. For (c), count $r \times n$ matrices of rank r twice: with (b) for $m = r$, and as lists of r independent rows.

Sketch. (a) $GA = \begin{pmatrix} S \\ 0 \end{pmatrix}$, so $A = G^{-1}\begin{pmatrix} S \\ 0 \end{pmatrix} = CS$ with C the first r columns of G^{-1}; they are independent, so $\operatorname{rank} C = r$. If $CS = C'S$, multiply by a right inverse of S (rank r = number of rows). Conversely, $KC = \begin{pmatrix} I_r \\ 0 \end{pmatrix}$ for an invertible K, so $K(CS) = \begin{pmatrix} S \\ 0 \end{pmatrix}$, which is in RREF; hence $\operatorname{rref}(CS) = \begin{pmatrix} S \\ 0 \end{pmatrix}$. (b) $(C, S) \mapsto CS$ is a bijection onto the rank r matrices, and the C's are the independent lists of r vectors in F^m, counted by Exercise 1.5.43. (c) With $m = r$: $N(r, n) \cdot |\text{rank-}\, r \text{ matrices in } F^{r\times r}| = |\text{independent lists of } r \text{ rows in } F^n|$. For $r = 2$, $n = 3$ the quotient is $q^2 + q + 1$.

(a) *Existence.* Let G be invertible with $GA = \operatorname{rref}(A)$ (Theorem 3.3.10). Since $\operatorname{rank} A = r$, the nonzero rows of $\operatorname{rref}(A)$ are its first r rows, so $GA = \begin{pmatrix} S \\ 0 \end{pmatrix}$. Split $G^{-1} = \begin{pmatrix} C & C' \end{pmatrix}$ with $C \in F^{m\times r}$ its first r columns. By block multiplication (Theorem 2.4.34),

$$A = G^{-1}\begin{pmatrix} S \\ 0 \end{pmatrix} = \begin{pmatrix} C & C' \end{pmatrix}\begin{pmatrix} S \\ 0 \end{pmatrix} = CS.$$

The columns of G^{-1} form a basis of F^m (Theorem 3.5.14, as G^{-1} is invertible), so the columns of C are independent (Corollary 1.5.17), and $\operatorname{rank} C = r$ by Corollary 3.5.16(a).

Uniqueness of C. S satisfies (R1)–(R4), so it is in RREF and its pivots are the leading entries of its r nonzero rows (Theorem 3.3.12); so $\operatorname{rank} S = r$, the number of its rows. By Proposition 3.5.8, $SZ = I_r$ for some Z. If $CS = C'S$, then $C = CSZ = C'SZ = C'$.

Converse. Let $C \in F^{m\times r}$ have rank r and S be in RREF with no zero row. Since $\operatorname{rank} C$ is the number of columns of C, the first proof of Proposition 3.5.9 shows that $KC = \begin{pmatrix} I_r \\ 0 \end{pmatrix}$ for an invertible K (one with $KC = \operatorname{rref}(C)$). Then

$$K(CS) = \begin{pmatrix} I_r \\ 0 \end{pmatrix} S = \begin{pmatrix} S \\ 0 \end{pmatrix}.$$

This matrix satisfies (R1)–(R4): S does, and the zero rows come last. By Corollary 3.5.21(b), $CS \sim \begin{pmatrix} S \\ 0 \end{pmatrix}$, so $\operatorname{rref}(CS) = \begin{pmatrix} S \\ 0 \end{pmatrix}$ by Corollary 3.3.18(c). It has r pivots, so $\operatorname{rank}(CS) = r$.

(b) Let $\mathcal{C}$ be the set of $C \in F^{m\times r}$ of rank r, $\mathcal{S}$ the set of $r \times n$ matrices in RREF with no zero row, and $\mathcal{A}$ the set of $A \in F^{m\times n}$ of rank r. By the converse in (a), $(C, S) \mapsto CS$ maps $\mathcal{C} \times \mathcal{S}$ into $\mathcal{A}$. It is onto, by the existence part. It is injective: if $CS = C'S' = A$, then by the converse $\begin{pmatrix} S \\ 0 \end{pmatrix} = \operatorname{rref}(A) = \begin{pmatrix} S' \\ 0 \end{pmatrix}$, so $S = S'$, and then $C = C'$ by uniqueness. Hence $|\mathcal{A}| = |\mathcal{C}| \cdot |\mathcal{S}| = |\mathcal{C}| N(r, n)$. A matrix in $F^{m\times r}$ has rank r if and only if its r columns are independent (Corollary 3.5.16(a)), so by Exercise 1.5.43(b), $|\mathcal{C}| = (q^m - 1)(q^m - q)\cdots(q^m - q^{r-1})$.

(c) Take $m = r$ in (b): the number of $r \times n$ matrices of rank r is $N(r, n)(q^r - 1)\cdots(q^r - q^{r-1})$. We count them a second way. An $r \times n$ matrix A has rank r if and only if its rows are linearly independent:

- if $\operatorname{rank} A = r$, then A has a right inverse X (Theorem 3.5.13), and a relation $\mathbf{z}A = \mathbf{0}$ among the rows gives $\mathbf{z} = \mathbf{z}AX = \mathbf{0}$;
- if $\operatorname{rank} A < r$, the last row of $\operatorname{rref}(A) = GA$ is zero, so the last row $\mathbf{g}$ of G is nonzero (as G is invertible) and satisfies $\mathbf{g}A = \mathbf{0}$, a nontrivial relation among the rows.

So by Exercise 1.5.43(b), applied to rows in F^n, there are $(q^n - 1)(q^n - q)\cdots(q^n - q^{r-1})$ such matrices. Equating the two counts and dividing by the nonzero integer $(q^r - 1)\cdots(q^r - q^{r-1})$ gives the formula.

For $r = 2$, $n = 3$:

$$N(2, 3) = \frac{(q^3 - 1)(q^3 - q)}{(q^2 - 1)(q^2 - q)} = \frac{(q^3 - 1)\cdot q(q^2 - 1)}{(q^2 - 1)\cdot q(q - 1)} = \frac{q^3 - 1}{q - 1} = q^2 + q + 1,$$

which is the number of 2×3 matrices in RREF with two pivots found in Exercise 3.3.48 over $\mathbb{F}_p$ (p^2, p, and 1 for the pivot columns $(1, 2)$, $(1, 3)$, $(2, 3)$), with $q = p$. The same count works over any finite field.

With $m = n = r$, part (b) counts the invertible $n \times n$ matrices, since $N(n, n) = 1$ (only I_n): there are $(q^n - 1)(q^n - q)\cdots(q^n - q^{n-1})$ of them. The numbers $N(r, n)$ are the *Gaussian binomial coefficients*; by Exercise 3.3.50 they also count the subspaces of F^n spanned by r independent vectors.

Solution to Problem 3.18

Uses. Corollary 3.4.20 (Square systems), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Exercise 3.3.54, Exercise 3.3.52
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)

Hint 1. Suppose A is not invertible over $\mathbb{Q}$. Then $A\mathbf{x} = \mathbf{0}$ for some nonzero rational $\mathbf{x}$. Clear denominators, and divide by the largest power of 2 dividing all entries.
Hint 2. Now $\mathbf{x}$ has integer entries, not all even. Reduce the equations $A\mathbf{x} = \mathbf{0}$ modulo 2.
Hint 3. For (c), $\overline{A}$ has zeros on the diagonal and ones elsewhere: see Exercise 3.3.52. For (d), try $2I_n$.
Sketch. (a) If $A\mathbf{x} = \mathbf{0}$ with $\mathbf{x} \in \mathbb{Q}^n$ nonzero, scale $\mathbf{x}$ to an integer vector with an odd entry. Reducing modulo 2 gives $\overline{A}\,\overline{\mathbf{x}} = \mathbf{0}$ with $\overline{\mathbf{x}} \neq \mathbf{0}$, so $\overline{A}$ is not invertible. Invertibility over $\mathbb{Q}$ gives invertibility over $\mathbb{R}$ since the reduced form does not depend on the field. (b) $\overline{A} = I_n$. (c) $\overline{A} = J - I_n$, invertible over $\mathbb{F}_2$ iff $n-1$ is odd; $\begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 2 \end{pmatrix}$ has third row the sum of the first two. (d) $2I_n$.

(a) We prove the contrapositive. Suppose A is not invertible over $\mathbb{Q}$. By Corollary 3.4.20 there is a nonzero $\mathbf{x} \in \mathbb{Q}^n$ with $A\mathbf{x} = \mathbf{0}$. Multiplying by a common denominator of its entries, we may assume $\mathbf{x} \in \mathbb{Z}^n$, still nonzero. Let 2^e be the largest power of 2 dividing every entry of $\mathbf{x}$ (it exists, since some entry is a nonzero integer), and replace $\mathbf{x}$ by $2^{-e}\mathbf{x}$. Now $\mathbf{x}$ has integer entries, $A\mathbf{x} = \mathbf{0}$, and some entry of $\mathbf{x}$ is odd.

Each equation $\sum_j a_{ij}x_j = 0$ is an identity between integers, so it remains true after reducing modulo 2, because reduction modulo 2 respects sums and products (Lemma 1.1.21). That is, $\overline{A}\,\overline{\mathbf{x}} = \mathbf{0}$ in $\mathbb{F}_2^n$, where $\overline{\mathbf{x}}$ is the vector of remainders of $\mathbf{x}$. Since some entry of $\mathbf{x}$ is odd, $\overline{\mathbf{x}} \neq \mathbf{0}$. So $\overline{A}$ is not invertible over $\mathbb{F}_2$ (Corollary 3.4.20).

So if $\overline{A}$ is invertible, then A is invertible over $\mathbb{Q}$, that is, $\operatorname{rref}(A) = I_n$ computed over $\mathbb{Q}$. By Exercise 3.3.54, the reduced form is the same over $\mathbb{R}$, so A is invertible over $\mathbb{R}$ too.

(b) For such A, $\overline{A} = I_n$, which is invertible.

(c) Now $\overline{A}$ has 0 on the diagonal and 1 elsewhere. By Exercise 3.3.52, this matrix is invertible over $\mathbb{F}_2$ if and only if $(n-1) * 1 \neq 0$ in $\mathbb{F}_2$, that is, if and only if n is even. Then A is invertible by (a). For $n = 3$, the matrix

$$\begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 2 \end{pmatrix}$$

has even diagonal entries and odd off-diagonal entries, but its third column is the sum of the first two, so $A(1, 1, -1) = \mathbf{0}$ and A is not invertible.

(d) $A = 2I_n$ is invertible over $\mathbb{Q}$, with inverse $\frac{1}{2}I_n$, but $\overline{A} = 0$.

The point of (a) is that a single computation over a small field certifies invertibility over an infinite one. Choosing $\mathbf{x}$ with an odd entry is an extremal choice, as in Technique 1.5.9: without it, reducing modulo 2 could turn $\mathbf{x}$ into $\mathbf{0}$ and prove nothing. Section 5.3 revisits this with determinants (Technique 5.3.21).

Solution to Problem 3.19

Uses. Corollary 3.4.20 (Square systems), Lemma 3.4.23 (Too many roots), Definition 1.2.17 (Evaluation), Proposition 1.1.17 (No zero divisors)
Techniques. Uniqueness gives existence (Technique 3.4.21)
Hint 1. It is enough to show that $C\mathbf{x} = \mathbf{0}$ forces $\mathbf{x} = \mathbf{0}$. Row i of $C\mathbf{x} = \mathbf{0}$ says that the function $t \mapsto \sum_j x_j/(t + b_j)$ vanishes at $t = a_i$.
Hint 2. Clear denominators: multiply by $\prod_k (t + b_k)$. The result $P(t) = \sum_j x_j \prod_{k \neq j}(t + b_k)$ is the value at t of a polynomial of degree at most $n - 1$.
Hint 3. P vanishes at the n distinct points $a_1, \ldots, a_n$. Then evaluate P at $t = -b_j$.
Sketch. If $C\mathbf{x} = \mathbf{0}$, let $P(t) = \sum_j x_j \prod_{k \neq j}(t + b_k)$, the value of a polynomial of degree at most $n - 1$. Then $P(a_i) = \prod_k (a_i + b_k) \cdot (C\mathbf{x})_i = 0$ for all i, so this polynomial is zero (Lemma 3.4.23) and P vanishes everywhere. But $P(-b_j) = x_j \prod_{k \neq j}(b_k - b_j)$, so $x_j = 0$. Square system, trivial kernel: invertible. (b) $a_i = i$, $b_j = j - 1$.

(a) C is square, so by Corollary 3.4.20 it suffices to show that $C\mathbf{x} = \mathbf{0}$ implies $\mathbf{x} = \mathbf{0}$. Let $C\mathbf{x} = \mathbf{0}$.

A polynomial. For a list of scalars $\beta_1, \ldots, \beta_s$, the function $t \mapsto \prod_{k=1}^{s}(t + \beta_k)$ is the polynomial function of a polynomial of degree at most s: this is clear for $s = 0$ (the constant 1), and if $t \mapsto f(t) = \sum_{i \leq d} e_i t^i$, then

$$(t+\beta)f(t) = \sum_{i\le d} e_i t^{i+1} + \sum_{i\le d} \beta e_i t^i,$$

which is again a polynomial expression in t, of degree at most $d+1$. So for each j there is $q_j \in F[x]_{\le n-1}$ with $q_j(t) = \prod_{k\neq j}(t+b_k)$ for all $t \in F$, and $p = \sum_j x_j q_j \in F[x]_{\le n-1}$ satisfies

$$p(t) = \sum_{j=1}^{n} x_j \prod_{k\neq j}(t+b_k) \quad \text{for all } t \in F,$$

since evaluation is linear (Definition 1.2.17).

It vanishes at the a_i. Fix i. Every factor $a_i + b_k$ is nonzero, and $\prod_{k\neq j}(a_i+b_k) = \prod_k (a_i+b_k)/(a_i+b_j)$. So

$$p(a_i) = \prod_{k=1}^{n}(a_i+b_k) \cdot \sum_{j=1}^{n} \frac{x_j}{a_i+b_j} = \prod_{k=1}^{n}(a_i+b_k) \cdot (C\mathbf{x})_i = 0.$$

Thus p has degree at most $n-1$ and vanishes at the n distinct points $a_1, \ldots, a_n$, so $p = \mathbf{0}$ by Lemma 3.4.23 (with $n-1$ in place of n). Hence $p(t) = 0$ for every $t \in F$.

Evaluating at $-b_j$. For $l \neq j$, the product $\prod_{k\neq l}(-b_j + b_k)$ contains the factor $k = j$, which is 0. So only the term $l = j$ survives:

$$0 = p(-b_j) = x_j \prod_{k\neq j}(b_k - b_j).$$

The b_k are distinct, so the product is nonzero (Proposition 1.1.17), and $x_j = 0$. As j was arbitrary, $\mathbf{x} = \mathbf{0}$. So C is invertible.

(b) Take $F = \mathbb{Q}$, $a_i = i$, and $b_j = j - 1$ for $i, j = 1, \ldots, n$. The a_i are distinct, the b_j are distinct, and $a_i + b_j = i + j - 1 \ge 1$, so it is nonzero. The Cauchy matrix is then H_n, which is therefore invertible.

The proof never computes C^{-1}; it shows that the only combination of the functions $t \mapsto 1/(t+b_j)$ vanishing at n points is the trivial one, and lets Corollary 3.4.20 produce the inverse. This is Technique 3.4.21 in its pure form: interpolation by the functions $1/(t+b_j)$ in place of the monomials t^j. (A formula for C^{-1} exists, but is much harder to find this way.)

Section 4.1

Solution to Exercise 4.1.9

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero), Definition 4.1.5 (Dimension)
Hint 1. Split $(a, b, a+b, a-b)$ into a part with a and a part with b.
Hint 2. Check that the two vectors you get are independent by looking at their first two coordinates.
Sketch. $(a, b, a+b, a-b) = a(1,0,1,1) + b(0,1,1,-1)$, so these two vectors span U. A relation $a(1,0,1,1) + b(0,1,1,-1) = \mathbf{0}$ has first two coordinates a and b, so it is trivial. Hence $\dim U = 2$.

For all $a, b \in F$,

$$(a, b, a+b, a-b) = a(1,0,1,1) + b(0,1,1,-1),$$

so $(1,0,1,1), (0,1,1,-1)$ lies in U and spans it. If $a(1,0,1,1) + b(0,1,1,-1) = \mathbf{0}$, then the first two coordinates give $a = 0$ and $b = 0$, so the list is independent (Theorem 1.5.5). It is a basis of U by Proposition 1.6.2, and $\dim U = 2$. This holds over every field, $\mathbb{F}_2$ included, where $a - b = a + b$.

Solution to Exercise 4.1.15

Uses. Theorem 4.1.10 (Independent lists are short), Example 4.1.7 (Dimensions of the standard spaces), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. The list has $4 = \dim F[x]_{\le 3}$ entries, so it suffices to check independence.

Hint 2. The degrees are $1, 2, 3, 3$, so Proposition 1.5.24 does not apply directly. Write out a relation and compare coefficients, starting from the constant and x coefficients.
Sketch. Length $4 = \dim F[x]_{\leq 3}$, so independence suffices. In $a(1+x) + b\big(1+2x+x^2\big) + c\big(x^2+x^3\big) + dx^3 = 0$, the constant term gives $a + b = 0$, the x term $a + 2b = 0$, so $b = 0 = a$; then x^2 gives $c = 0$ and x^3 gives $d = 0$.

Since $\dim F[x]_{\leq 3} = 4$ (Example 4.1.7), by Theorem 4.1.10(b) it suffices to show that the four polynomials are independent. Suppose

$$a(1+x) + b\big(1+2x+x^2\big) + c\big(x^2+x^3\big) + dx^3 = 0.$$

Comparing coefficients of 1, x, x^2, and x^3 gives

$$a + b = 0, \quad a + 2b = 0, \quad b + c = 0, \quad c + d = 0.$$

Subtracting the first equation from the second gives $b = 0$, and then $a = 0$, $c = 0$, and $d = 0$. So the only relation is trivial (Theorem 1.5.5), and the list is a basis. Every step was valid over every field.

Solution to Exercise 4.1.20

Uses. Theorem 4.1.16 (Extending to a basis), Proposition 1.5.14 (Appending a vector), Proposition 1.5.15 (Short lists, zeros, and repeats)
Hint 1. Sift the list $(1, 2, 1), \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$: keep each entry that is not in the span of the entries kept before it.
Hint 2. $\mathbf{e}_1$ is never a multiple of $(1, 2, 1)$. For the third vector, describe $\operatorname{span}((1, 2, 1), \mathbf{e}_1)$ and test $\mathbf{e}_2$.
Sketch. In both cases $\mathbf{e}_1$ is kept. $\operatorname{span}((1, 2, 1), \mathbf{e}_1) = \{(a + b, 2a, a)\}$, whose vectors have second coordinate 2 times the third; $\mathbf{e}_2$ fails this, so it is kept, and $(1, 2, 1), \mathbf{e}_1, \mathbf{e}_2$ is a basis in both cases, by length.

We follow the proof of Theorem 4.1.16 with $\mathcal{S} = \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$. The vector $\mathbf{e}_1$ is not a multiple of $(1, 2, 1)$, since a multiple $t(1, 2, 1)$ with third coordinate 0 has $t = 0$. So $(1, 2, 1), \mathbf{e}_1$ is independent (Proposition 1.5.15(d)). Its span consists of the vectors $a(1, 2, 1) + b\mathbf{e}_1 = (a + b, 2a, a)$, whose second coordinate is 2 times the third. The vector $\mathbf{e}_2 = (0, 1, 0)$ fails this test, since $1 \neq 2 \cdot 0$ in every field. So $(1, 2, 1), \mathbf{e}_1, \mathbf{e}_2$ is independent (Proposition 1.5.14), and as it has length $3 = \dim F^3$, it is a basis. The same vectors are appended in (a) and (b): the computation used only that $1 \neq 0$.

Solution to Exercise 4.1.24

Uses. Proposition 1.5.24 (Distinct degrees), Theorem 4.1.10 (Independent lists are short), Proposition 4.1.21 (Dimensions of subspaces)
Hint 1. Find three independent polynomials in U; powers of $x - 2$ are natural.
Hint 2. Find one polynomial of degree at most 3 that is not in U, and use Proposition 4.1.21(b).
Sketch. $x - 2$, $(x - 2)^2$, $(x - 2)^3$ lie in U and have distinct degrees, so $\dim U \geq 3$. The constant 1 is not in U, so $\dim U < 4$. Hence $\dim U = 3$, and the three polynomials form a basis.

The polynomials $x - 2$, $(x - 2)^2$, $(x - 2)^3$ vanish at 2, so they lie in U, and they are independent by Proposition 1.5.24. So $\dim U \geq 3$ by Theorem 4.1.10(a), applied in U. The constant polynomial 1 does not vanish at 2, so $U \neq \mathbb{R}[x]_{\leq 3}$, and $\dim U < 4$ by Proposition 4.1.21(b). Hence $\dim U = 3$, and the three polynomials, an independent list of length $\dim U$ in U, form a basis of U by Theorem 4.1.10(b).

Solution to Exercise 4.1.29

Uses. Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps)
Hint 1. If $n \leq 4$, what does Corollary 4.1.27 say about A^n, and hence about A^4?
Hint 2. For $n \geq 5$, generalize the shift: send $\mathbf{e}_5 \mapsto \mathbf{e}_4 \mapsto \cdots \mapsto \mathbf{e}_1 \mapsto \mathbf{0}$ and kill the remaining standard basis vectors.
Sketch. If $n \leq 4$, then $A^5 = 0$ gives $A^n = 0$, so $A^4 = A^{4-n}A^n = 0$. For $n \geq 5$, take $A = U_{12} + U_{23} + U_{34} + U_{45}$, with $A\mathbf{e}_{j+1} = \mathbf{e}_j$ for $j \leq 4$ and $A\mathbf{e}_j = \mathbf{0}$ otherwise; then $A^4\mathbf{e}_5 = \mathbf{e}_1$ and $A^5 = 0$.

Suppose $n \leq 4$ and $A^5 = 0$. By Corollary 4.1.27, $A^n = 0$, so $A^4 = A^{4-n}A^n = 0$. So no such A exists for $n \leq 4$.

For $n \geq 5$, let $A \in F^{n\times n}$ have 1 in positions $(1, 2), (2, 3), (3, 4), (4, 5)$ and 0 elsewhere. Then $A\mathbf{e}_1 = \mathbf{0}$, $A\mathbf{e}_j = \mathbf{e}_{j-1}$ for $2 \leq j \leq 5$, and $A\mathbf{e}_j = \mathbf{0}$ for $j \geq 6$. Hence $A^4\mathbf{e}_5 = \mathbf{e}_1 \neq \mathbf{0}$, so $A^4 \neq 0$. And $A^5\mathbf{e}_j = \mathbf{0}$ for every j: for $j \leq 5$ the vector $\mathbf{e}_j$ reaches $\mathbf{0}$ after $j \leq 5$ steps, and for $j \geq 6$ after one. Since A^5 kills a basis, $A^5 = 0$. So the answer is: exactly for $n \geq 5$.

Solution to Exercise 4.1.33

Uses. Proposition 4.1.31 (Every square matrix satisfies a polynomial)
Techniques. Too many vectors force a dependence (Technique 4.1.30)
Hint 1. Compute A^2 and compare it with A and I_2.
Hint 2. From $A^2 = 2A - I_2$, show by induction that $A^k = kA - (k-1)I_2$.
Sketch. $A^2 = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = 2A - I_2$, so $A^2 - 2A + I_2 = 0$. Induction gives $A^k = kA - (k-1)I_2 = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix}$, so $A^{10} = \begin{pmatrix} 1 & 10 \\ 0 & 1 \end{pmatrix}$.

We have $A^2 = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = 2A - I_2$, so $A^2 - 2A + I_2 = 0$ is a nontrivial relation. We show $A^k = kA - (k-1)I_2$ for $k \geq 1$ by induction. For $k = 1$ it reads $A = A$. If it holds for k, then

$$A^{k+1} = A(kA - (k-1)I_2) = kA^2 - (k-1)A = k(2A - I_2) - (k-1)A = (k+1)A - kI_2.$$

Hence $A^{10} = 10A - 9I_2 = \begin{pmatrix} 1 & 10 \\ 0 & 1 \end{pmatrix}$.

Solution to Exercise 4.1.39

Uses. Proposition 4.1.34 (Size of a vector space over a finite field), Corollary 4.1.35 (Counting independent lists and bases)
Hint 1. By Proposition 4.1.34, a finite vector space over $\mathbb{F}_5$ has 5^n elements for some n.
Hint 2. For (c), use $N_3(2,2) = (3^2 - 1)(3^2 - 3)$.
Sketch. (a) No: 100 is not a power of 5. (b) $5^3 = 125$. (c) $(9-1)(9-3) = 48$.

(a) No. A vector space over $\mathbb{F}_5$ with finitely many elements is finite-dimensional, so it has $5^{\dim V}$ elements by Proposition 4.1.34, and $100 = 2^2 \cdot 5^2$ is not a power of 5.

(b) A 3-dimensional subspace is a 3-dimensional vector space over $\mathbb{F}_5$, so it has $5^3 = 125$ elements.

(c) By Corollary 4.1.35, $\mathbb{F}_3^2$ has $N_3(2,2) = (9-1)(9-3) = 48$ bases.

Solution to Exercise 4.1.40

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.5.24 (Distinct degrees), Corollary 1.5.17 (Sublists), Proposition 1.6.7 (Standard bases)
Hint 1. In each case solve the defining conditions for some of the coordinates and write a general element as a combination of fixed vectors with the remaining coordinates as coefficients.
Hint 2. In (a), $x_4 = -x_1 - x_2 - x_3$. In (b), $p(0)$ is the constant term and $p(1)$ is the sum of the coefficients. In (c), use matrix units.
Sketch. (a) $\mathbf{x} = x_1(\mathbf{e}_1 - \mathbf{e}_4) + x_2(\mathbf{e}_2 - \mathbf{e}_4) + x_3(\mathbf{e}_3 - \mathbf{e}_4)$; dimension 3. (b) $p = a_2(x^2 - x) + a_3(x^3 - x)$; dimension 2. (c) The six U_{ij} with $i \leq j$; dimension 6.

(a) For $\mathbf{x} \in U_1$ we have $x_4 = -x_1 - x_2 - x_3$, so

$$\mathbf{x} = x_1(\mathbf{e}_1 - \mathbf{e}_4) + x_2(\mathbf{e}_2 - \mathbf{e}_4) + x_3(\mathbf{e}_3 - \mathbf{e}_4).$$

The three vectors $\mathbf{e}_i - \mathbf{e}_4$ lie in U_1, so they span U_1. A combination $\sum_{i=1}^{3} c_i(\mathbf{e}_i - \mathbf{e}_4)$ has first three coordinates c_1, c_2, c_3, so it is $\mathbf{0}$ only if all $c_i = 0$. So they form a basis (Proposition 1.6.2), and $\dim U_1 = 3$.

(b) Let $p = a_0 + a_1 x + a_2 x^2 + a_3 x^3$. Then $p(0) = a_0$ and $p(1) = a_0 + a_1 + a_2 + a_3$, so $p \in U_2$ if and only if $a_0 = 0$ and $a_1 = -a_2 - a_3$, that is,

$$p = a_2(x^2 - x) + a_3(x^3 - x).$$

So $x^2 - x, x^3 - x$ spans U_2, and it is independent because its entries are nonzero with distinct degrees (Proposition 1.5.24). Hence $\dim U_2 = 2$.

(c) An upper triangular A is $\sum_{i \leq j} a_{ij} U_{ij}$, so the six matrix units $U_{11}, U_{12}, U_{13}, U_{22}, U_{23}, U_{33}$ span U_3. They are a sublist of the standard basis of $F^{3\times 3}$ (Proposition 1.6.7), hence independent (Corollary 1.5.17). So $\dim U_3 = 6$.

Solution to Exercise 4.1.41

Uses. Corollary 4.1.11 (Spanning lists are long), Proposition 4.1.21 (Dimensions of subspaces), Proposition 1.5.15 (Short lists, zeros, and repeats), Definition 1.4.1 (Subspace)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)

Hint 1. Length alone can force a property only in one direction: a list longer than $\dim V$ cannot be independent, and a list shorter than $\dim V$ cannot span. It never forces a list to span or to be independent.
Hint 2. For (d), think of two different lines in a plane. For (e), apply Proposition 4.1.21(b) inside W. For (f), what are the elements of $\mathbb{R}^2$?
Sketch. (a) False: five copies of $\mathbf{0}$. (b) False: three copies of $\mathbf{0}$. (c) True by Corollary 4.1.11(b). (d) False: two different 1-dimensional subspaces. (e) True: U is a subspace of the vector space W of full dimension. (f) False: $\mathbb{R}^2$ is not a subset of $\mathbb{R}^3$, though $\{(x, y, 0)\}$ is a 2-dimensional subspace.

(a) False. The list $\mathbf{0}, \mathbf{0}, \mathbf{0}, \mathbf{0}, \mathbf{0}$ spans $\{\mathbf{0}\} \neq V$.

(b) False. The list $\mathbf{0}, \mathbf{0}, \mathbf{0}$ is dependent (Proposition 1.5.15(c)).

(c) True. A spanning list of length $4 = \dim V$ is a basis by Corollary 4.1.11(b), so it is independent.

(d) False. Let $\mathbf{v}_1, ..., \mathbf{v}_4$ be a basis of V. Then $\operatorname{span}(\mathbf{v}_1)$ and $\operatorname{span}(\mathbf{v}_2)$ are both 1-dimensional, and they differ, since $\mathbf{v}_2 \notin \operatorname{span}(\mathbf{v}_1)$ by independence.

(e) True. W is a vector space with the operations of V, and U is a subspace of W: it is a subset closed under the same operations (Definition 1.4.1). Since $\dim U = \dim W$, Proposition 4.1.21(b), applied in W, gives $U = W$.

(f) False. The elements of $\mathbb{R}^2$ are pairs and those of $\mathbb{R}^3$ are triples, so $\mathbb{R}^2$ is not a subset of $\mathbb{R}^3$. The subset $\{(x, y, 0) \mid x, y \in \mathbb{R}\}$ is a 2-dimensional subspace of $\mathbb{R}^3$, with basis $\mathbf{e}_1, \mathbf{e}_2$, and it is a copy of $\mathbb{R}^2$ in a sense made precise in Section 4.5.

Solution to Exercise 4.1.42

Uses. Theorem 4.1.16 (Extending to a basis), Proposition 1.5.14 (Appending a vector), Theorem 4.1.10 (Independent lists are short)
Hint 1. The span of $\mathbf{v}_1, \mathbf{v}_2$ consists of the vectors $(b, 0, a + 2b, 2a + b)$. Is $\mathbf{e}_1$ of this form?
Hint 2. For $\mathbf{e}_1$ you need $b = 1$, $a = -2$, and $2a + b = 0$, that is, $-3 = 0$. Which field allows this? Stop sifting as soon as you have 4 vectors.
Sketch. $\mathbf{e}_1 \in \operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$ exactly when $3 = 0$; indeed $\mathbf{v}_1 + \mathbf{v}_2 = (1, 0, 3, 3)$, which is $\mathbf{e}_1$ in $\mathbb{F}_3^4$. Over $\mathbb{Q}$ sifting keeps $\mathbf{e}_1$ and $\mathbf{e}_2$ (all of $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_1)$ has second coordinate 0). Over $\mathbb{F}_3$ it deletes $\mathbf{e}_1$ and keeps $\mathbf{e}_2$ and $\mathbf{e}_3$.

The vectors $\mathbf{v}_1, \mathbf{v}_2$ are independent over every field, since $a\mathbf{v}_1 + b\mathbf{v}_2 = (b, 0, a + 2b, 2a + b)$ is $\mathbf{0}$ only if $b = 0$ and then $a = 0$. Their span consists of the vectors $(b, 0, a + 2b, 2a + b)$.

Is $\mathbf{e}_1$ in the span? We need $b = 1$, $a + 2 = 0$, and $2a + 1 = 0$. The second gives $a = -2$, and then the third reads $-3 = 0$. Over $\mathbb{Q}$ this is false, so $\mathbf{e}_1$ is kept. Over $\mathbb{F}_3$ it is true, and indeed $\mathbf{v}_1 + \mathbf{v}_2 = (1, 0, 3, 3) = \mathbf{e}_1$ there, so $\mathbf{e}_1$ is deleted.

Over $\mathbb{Q}$. The vectors of $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_1)$ have second coordinate 0, so $\mathbf{e}_2$ is not among them and is kept. Now $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_1, \mathbf{e}_2$ is independent (Proposition 1.5.14) of length $4 = \dim \mathbb{Q}^4$, so it is a basis (Theorem 4.1.10(b)), and $\mathbf{e}_3, \mathbf{e}_4$ are deleted.

Over $\mathbb{F}_3$. Again $\mathbf{e}_2$ is kept, because every vector of $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$ has second coordinate 0. The span of $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_2$ consists of the vectors $(b, d, a + 2b, 2a + b)$. For $\mathbf{e}_3 = (0, 0, 1, 0)$ we would need $b = 0$, $a = 1$, and $2a = 0$, which is false in $\mathbb{F}_3$. So $\mathbf{e}_3$ is kept, and $\mathbf{v}_1, \mathbf{v}_2, \mathbf{e}_2, \mathbf{e}_3$ is a basis of $\mathbb{F}_3^4$.

The answers differ because whether a vector lies in a span is a question about solving linear equations, and here the equations are solvable exactly when $3 = 0$ in F.

Solution to Exercise 4.1.43

Uses. Example 1.4.11 (Matrices), Theorem 4.1.10 (Independent lists are short), Proposition 4.1.21 (Dimensions of subspaces), Proposition 1.6.7 (Standard bases)
Hint 1. Generalize Example 4.1.22. Which matrix units lie in U, and which combinations of diagonal ones do?
Hint 2. Use U_{ij} for $i \neq j$ and $U_{ii} - U_{nn}$ for $i < n$ to get a lower bound, and $U_{11} \notin U$ for an upper bound.
Sketch. The $n^2 - n$ matrices U_{ij} $(i \neq j)$ and the $n - 1$ matrices $U_{ii} - U_{nn}$ $(i < n)$ lie in U and are independent, since a combination of them has these coefficients as its off-diagonal and first $n - 1$ diagonal entries. So $\dim U \geq n^2 - 1$. Since $\operatorname{tr} U_{11} = 1$, $U \neq F^{n \times n}$, so $\dim U < n^2$. Hence $\dim U = n^2 - 1$ and the list is a basis.

U is a subspace by Example 1.4.11. The $n^2 - n$ matrices U_{ij} with $i \neq j$ have trace 0, and so do the $n-1$ matrices $U_{ii} - U_{nn}$ with $1 \leq i < n$. Consider a combination

$$A = \sum_{i \neq j} a_{ij} U_{ij} + \sum_{i=1}^{n-1} c_i (U_{ii} - U_{nn}).$$

Its (i,j) entry is a_{ij} for $i \neq j$, its (i,i) entry is c_i for $i < n$, and its (n,n) entry is $-(c_1 + \cdots + c_{n-1})$. If $A = 0$, all a_{ij} and c_i are 0. So these $n^2 - 1$ matrices form an independent list in U, and $\dim U \geq n^2 - 1$ by Theorem 4.1.10(a), applied in U. On the other hand, $\operatorname{tr} U_{11} = 1 \neq 0$, so $U \neq F^{n \times n}$ and $\dim U < n^2$ by Proposition 4.1.21(b). Hence $\dim U = n^2 - 1$, and the independent list above, of length $\dim U$, is a basis of U (Theorem 4.1.10(b)). For $n = 1$ the list is empty and $U = \{0\}$.

Solution to Exercise 4.1.44

Uses. Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps), Proposition 2.4.14 (Algebra of matrices), Definition 2.5.12 (Invertible)
Hint 1. First replace m by n using Corollary 4.1.27.
Hint 2. Multiply out $(I_n - A)\big(I_n + A + \cdots + A^{n-1}\big)$; the sum telescopes.
Sketch. By Corollary 4.1.27, $A^n = 0$. Then $(I_n - A)\big(I_n + A + \cdots + A^{n-1}\big) = I_n - A^n = I_n$, and the product in the other order telescopes in the same way.

By Corollary 4.1.27, $A^n = 0$. Let $B = I_n + A + \cdots + A^{n-1}$. By distributivity (Proposition 2.4.14),

$$(I_n - A)B = \big(I_n + A + \cdots + A^{n-1}\big) - \big(A + A^2 + \cdots + A^n\big) = I_n - A^n = I_n,$$

and in the same way $B(I_n - A) = I_n - A^n = I_n$, since A commutes with its powers. So B is a two-sided inverse of $I_n - A$ (Definition 2.5.12). Exercise 2.5.39 gave the inverse $I_n + A + \cdots + A^{m-1}$; the point here is that the terms from A^n on are all 0, so at most n terms are needed.

Solution to Exercise 4.1.45

Uses. Definition 1.2.9 (Function spaces), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.6.2 (Bases are independent spanning lists), Corollary 4.1.13 (Detecting infinite dimension)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. To show that $\delta_{x_1}, \ldots, \delta_{x_k}$ is independent for distinct points, evaluate a relation at x_j. Which terms survive?
Hint 2. For spanning in (a), compare f with $\sum_i f(x_i)\delta_{x_i}$ at each point. For (b), use Corollary 4.1.13.
Sketch. For distinct $x_1, \ldots, x_k$, evaluating $\sum a_i \delta_{x_i} = 0$ at x_j kills every term but the j-th and gives $a_j = 0$. In (a), $f = \sum_i f(x_i)\delta_{x_i}$ because both sides agree at every x_j. In (b), X has k distinct points for every k, so F^X has independent lists of every length.

Let $x_1, \ldots, x_k \in X$ be distinct, and suppose $\sum_{i=1}^k a_i \delta_{x_i} = 0$, the zero function. Evaluating at x_j, and using that $\delta_{x_i}(x_j)$ is 1 for $i = j$ and 0 for $i \neq j$, gives $a_j = 0$. So $\delta_{x_1}, \ldots, \delta_{x_k}$ is independent (Theorem 1.5.5). Evaluation at x_j is a linear map $F^X \to F$ that kills every δ_{x_i} except δ_{x_j}, which is the move of Technique 4.1.25.

(a) For $f \in F^X$, the function $g = \sum_{i=1}^n f(x_i)\delta_{x_i}$ satisfies $g(x_j) = f(x_j)$ for every j, so $g = f$. So $\delta_{x_1}, \ldots, \delta_{x_n}$ spans F^X, and with the independence above it is a basis (Proposition 1.6.2). Hence $\dim F^X = n$. For $X = \{1, \ldots, n\}$, these functions are the standard basis vectors of F^n (Remark 1.2.11).

(b) If X is infinite, then for every k it contains k distinct points, and the corresponding δ's form an independent list of length k. By Corollary 4.1.13, F^X is infinite-dimensional.

Solution to Exercise 4.1.46

Uses. Proposition 1.6.2 (Bases are independent spanning lists), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.1.17 (No zero divisors)
Hint 1. A symmetric matrix is determined by its entries on and above the diagonal. Find one matrix in S for each such position.
Hint 2. For K, look at the diagonal: $a_{ii} = -a_{ii}$ means $(1+1)a_{ii} = 0$. When $1 + 1 = 0$, compare the conditions defining S and K.

Sketch. (a) Basis U_{ii} $(1 \le i \le n)$ and $U_{ij} + U_{ji}$ $(i < j)$: $n + n(n-1)/2$ matrices. (b) If $1 + 1 \neq 0$, the diagonal of a skew-symmetric matrix is 0, and $U_{ij} - U_{ji}$ $(i < j)$ is a basis. If $1 + 1 = 0$, then $-a = a$ for all a, so $K = S$.

(a) If $A \in S$, then

$$A = \sum_{i=1}^{n} a_{ii} U_{ii} + \sum_{i<j} a_{ij}\big(U_{ij} + U_{ji}\big),$$

since both sides have (i, j) entry a_{ij} for $i \le j$, and (j, i) entry $a_{ij} = a_{ji}$ for $i < j$. The matrices U_{ii} and $U_{ij} + U_{ji}$ $(i < j)$ are symmetric, so they span S. A combination $\sum_i c_{ii} U_{ii} + \sum_{i<j} c_{ij}\big(U_{ij} + U_{ji}\big)$ has (i, j) entry c_{ij} for $i \le j$, so it is 0 only if all coefficients are 0. So these matrices form a basis of S, and

$$\dim S = n + n\frac{n-1}{2} = n\frac{n+1}{2}.$$

(b) Suppose $1 + 1 \neq 0$. For $A \in K$, $a_{ii} = -a_{ii}$ gives $(1 + 1)a_{ii} = 0$, so $a_{ii} = 0$ (Proposition 1.1.17). Then $A = \sum_{i<j} a_{ij}\big(U_{ij} - U_{ji}\big)$, as both sides have (i, j) entry a_{ij} and (j, i) entry $-a_{ij} = a_{ji}$ for $i < j$, and zero diagonal. The matrices $U_{ij} - U_{ji}$ lie in K and are independent, since a combination of them has (i, j) entry equal to the coefficient of $U_{ij} - U_{ji}$ for $i < j$. So $\dim K = n(n-1)/2$.

Suppose $1 + 1 = 0$. Then $-1 = 1$, so $-a_{ji} = a_{ji}$ and the conditions defining K and S coincide. Hence $K = S$ and $\dim K = n(n+1)/2$ by (a).

Solution to Exercise 4.1.47

Uses. Definition B.1.1 (Complex conjugate), Theorem 1.4.3 (Subspace criterion), Proposition 1.6.2 (Bases are independent spanning lists), Example 4.1.7 (Dimensions of the standard spaces)
Hint 1. Conjugation satisfies $\overline{z + w} = \overline{z} + \overline{w}$ and $\overline{tz} = t\overline{z}$ for real t, but $\overline{iz} = -i\overline{z}$. What does $a_{ii} = \overline{a_{ii}}$ say about diagonal entries?
Hint 2. For (b), a Hermitian matrix is determined by n real diagonal entries and the complex entries above the diagonal, each of which carries two real parameters. Find a matrix in H for each real parameter.
Sketch. (a) The conditions are preserved by sums and real multiples because conjugation is additive and fixes reals; $I_n \in H$ but $iI_n \notin H$. (b) Basis over $\mathbb{R}$: U_{kk}, and for $k < l$ both $U_{kl} + U_{lk}$ and $i(U_{kl} - U_{lk})$: $n + 2 \cdot n(n-1)/2 = n^2$ matrices. And $\dim_{\mathbb{R}} \mathbb{C}^{n\times n} = 2 \dim_{\mathbb{C}} \mathbb{C}^{n\times n} = 2n^2$.

(a) The zero matrix is Hermitian. If $A, B \in H$ and $t \in \mathbb{R}$, then for all i, j,

$$(A + tB)_{ji} = a_{ji} + tb_{ji} = \overline{a_{ij}} + t\overline{b_{ij}} = \overline{a_{ij} + tb_{ij}},$$

since conjugation is additive and $\bar{t} = t$ for real t. So H is a subspace over $\mathbb{R}$ (Theorem 1.4.3). It is not a subspace over $\mathbb{C}$: $I_n \in H$, but iI_n has diagonal entry i, while a Hermitian matrix has $a_{11} = \overline{a_{11}}$, so a_{11} is real.

(b) For $k < l$, let $X_{kl} = U_{kl} + U_{lk}$ and $Y_{kl} = i(U_{kl} - U_{lk})$. These are Hermitian: the (k, l) and (l, k) entries are $1, 1$ and $i, -i$, which are conjugate pairs, and the other entries are 0. So are the U_{kk}. Let $A \in H$. Its diagonal entries are real, and for $k < l$ write $a_{kl} = x_{kl} + iy_{kl}$ with $x_{kl}, y_{kl} \in \mathbb{R}$, so that $a_{lk} = x_{kl} - iy_{kl}$. Then

$$A = \sum_{k=1}^{n} a_{kk} U_{kk} + \sum_{k<l} (x_{kl} X_{kl} + y_{kl} Y_{kl}),$$

since both sides have the same (k, k), (k, l), and (l, k) entries. So these matrices span H over $\mathbb{R}$. If a real combination $\sum_k r_k U_{kk} + \sum_{k<l} (s_{kl} X_{kl} + t_{kl} Y_{kl})$ is 0, its (k, k) entries give $r_k = 0$, and its (k, l) entry $s_{kl} + it_{kl} = 0$ gives $s_{kl} = t_{kl} = 0$, because s_{kl}, t_{kl} are real. So they form a basis of H over $\mathbb{R}$, and

$$\dim_{\mathbb{R}} H = n + 2 \cdot \frac{n(n-1)}{2} = n^2.$$

Since $\dim_{\mathbb{C}} \mathbb{C}^{n\times n} = n^2$, Example 4.1.7(c) gives $\dim_{\mathbb{R}} \mathbb{C}^{n\times n} = 2n^2$. So the Hermitian matrices are a real subspace of exactly half the real dimension.

Solution to Exercise 4.1.48

Uses. Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.16 (Extending to a basis)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. If a sum lies in a subspace, must its terms?
Hint 2. Try $V = \mathbb{R}^2$ with the standard basis and $U = \operatorname{span}((1,1))$.
Sketch. The step "each term $a_i\mathbf{v}_i$ lies in U" is wrong: a sum can lie in a subspace without its terms doing so. The claim is false: in $\mathbb{R}^2$, no standard basis vector lies in $U = \operatorname{span}((1,1))$, so $\mathcal{B}' = ()$, which does not span U. What is true is the reverse: a basis of U extends to a basis of V (Theorem 4.1.16).

The error is the sentence "each term $a_i\mathbf{v}_i$ lies in U". A subspace is closed under sums, but a sum lying in U says nothing about its terms. For instance $(1,0) + (0,1) \in \operatorname{span}((1,1))$, while neither term is.

The claim is false. Take $V = \mathbb{R}^2$, $\mathcal{B} = \mathbf{e}_1, \mathbf{e}_2$, and $U = \operatorname{span}((1,1))$. Neither $\mathbf{e}_1$ nor $\mathbf{e}_2$ is a multiple of $(1,1)$, so $\mathcal{B}' = ()$, whose span $\{\mathbf{0}\}$ is not U. A basis of V need not have any vectors in a given subspace, which is why the proof of Proposition 4.1.21 had to build a basis of U from scratch. The correct relation goes the other way: a basis of U can be extended to a basis of V (Theorem 4.1.16), so *some* basis of V contains a basis of U.

Solution to Exercise 4.1.49

Uses. Theorem 1.5.5 (Independence is decided at zero), Theorem 4.1.10 (Independent lists are short), Lemma 1.3.9 (Arithmetic of linear combinations)
Hint 1. Rewrite $\sum_i a_i(\mathbf{v}_i - \mathbf{w}) = \mathbf{0}$ as $\sum_i a_i\mathbf{v}_i = \left(\sum_i a_i\right)\mathbf{w}$. Split into the cases $\sum_i a_i = 0$ and $\sum_i a_i \neq 0$.
Hint 2. For (b), the differences $(\mathbf{v}_i - \mathbf{w}) - (\mathbf{v}_m - \mathbf{w})$ lie in the span. Are they independent?
Sketch. (a) A relation $\sum a_i(\mathbf{v}_i - \mathbf{w}) = \mathbf{0}$ says $\sum a_i\mathbf{v}_i = s\mathbf{w}$ with $s = \sum a_i$. If $s = 0$ the relation is trivial by independence of the $\mathbf{v}_i$; so a nontrivial one has $s \neq 0$ and gives $\mathbf{w} = \sum(a_i/s)\mathbf{v}_i$. Conversely, coefficients t_i with sum 1 give the nontrivial relation $\sum t_i(\mathbf{v}_i - \mathbf{w}) = \mathbf{w} - \mathbf{w} = \mathbf{0}$. (b) The $m-1$ vectors $\mathbf{v}_i - \mathbf{v}_m$ $(i < m)$ lie in the span and are independent.

(a) For scalars $a_1, \ldots, a_m$ with $s = a_1 + \cdots + a_m$, Lemma 1.3.9 gives

$$\sum_{i=1}^{m} a_i(\mathbf{v}_i - \mathbf{w}) = \sum_{i=1}^{m} a_i\mathbf{v}_i - s\mathbf{w}.$$

($\Rightarrow$) Suppose the a_i form a nontrivial relation of the list, so $\sum_i a_i\mathbf{v}_i = s\mathbf{w}$. If $s = 0$, then $\sum_i a_i\mathbf{v}_i = \mathbf{0}$, and independence forces every $a_i = 0$, which is false. So $s \neq 0$, and $\mathbf{w} = \sum_i(a_i/s)\mathbf{v}_i$, where the coefficients $t_i = a_i/s$ satisfy $\sum_i t_i = s/s = 1$.

($\Leftarrow$) If $\mathbf{w} = \sum_i t_i\mathbf{v}_i$ with $\sum_i t_i = 1$, then $\sum_i t_i(\mathbf{v}_i - \mathbf{w}) = \mathbf{w} - 1\mathbf{w} = \mathbf{0}$, and not all t_i are 0 since they sum to 1. So the list is dependent.

(b) Let $W = \operatorname{span}(\mathbf{v}_1 - \mathbf{w}, \ldots, \mathbf{v}_m - \mathbf{w})$, which is finite-dimensional. If $m = 1$ there is nothing to prove. For $m \geq 2$ and $i < m$, the vector $\mathbf{v}_i - \mathbf{v}_m = (\mathbf{v}_i - \mathbf{w}) - (\mathbf{v}_m - \mathbf{w})$ lies in W. These $m-1$ vectors are independent: if $\sum_{i<m} c_i(\mathbf{v}_i - \mathbf{v}_m) = \mathbf{0}$, then $\sum_{i<m} c_i\mathbf{v}_i - \left(\sum_{i<m} c_i\right)\mathbf{v}_m = \mathbf{0}$, and independence of $\mathbf{v}_1, \ldots, \mathbf{v}_m$ gives $c_i = 0$ for all $i < m$. By Theorem 4.1.10(a), applied in W, $\dim W \geq m - 1$.

Geometrically, (a) says the translated list is dependent exactly when $\mathbf{w}$ lies on the affine hull of the $\mathbf{v}_i$, the "flat" through them (Section 4.7).

Solution to Exercise 4.1.50

Uses. Proposition 4.1.21 (Dimensions of subspaces), Corollary 1.5.13 (Independence, one entry at a time), Definition 1.4.1 (Subspace)
Hint 1. Each U_{i-1} is a subspace of U_i and differs from it. What does Proposition 4.1.21(b), applied in U_i, say about their dimensions?
Hint 2. The dimensions form a strictly increasing sequence of integers between 0 and n. For existence, use the spans of the first i vectors of a basis.
Sketch. U_{i-1} is a proper subspace of U_i, so $\dim U_{i-1} < \dim U_i$. Hence $\dim U_i \geq \dim U_0 + i \geq i$, and $k \leq \dim U_k \leq n$. For a basis $\mathbf{b}_1, \ldots, \mathbf{b}_n$, the spans $U_i = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_i)$ increase strictly. If $k = n$, then $n \geq \dim U_n \geq \dim U_0 + n$ forces $\dim U_0 = 0$ and equality throughout.

(a) For $1 \leq i \leq k$, U_{i-1} is a subset of U_i closed under the operations, so it is a subspace of U_i (Definition 1.4.1), and $U_{i-1} \neq U_i$. By Proposition 4.1.21, applied in the finite-dimensional space U_i, $\dim U_{i-1} < \dim U_i$. So the

integers $\dim U_0 < \dim U_1 < \cdots < \dim U_k$ increase strictly, which gives $\dim U_i \geq \dim U_0 + i \geq i$. In particular $k \leq \dim U_k \leq n$, again by Proposition 4.1.21.

(b) Let $\mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V and $U_i = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_i)$ for $0 \leq i \leq n$. Then $U_{i-1} \subseteq U_i$, and $U_{i-1} \neq U_i$ because $\mathbf{b}_i \notin U_{i-1}$ (Corollary 1.5.13). So this is a chain with $k = n$.

Now let $U_0 \subsetneq \cdots \subsetneq U_n$ be any chain with $k = n$. By (a), $n \geq \dim U_n \geq \dim U_0 + n$, so $\dim U_0 = 0$, and then $i \leq \dim U_i \leq \dim U_n - (n - i) \leq i$ for every i, using the strict increase once more. So $\dim U_i = i$. In particular $U_0 = \{\mathbf{0}\}$, and $U_n = V$ by Proposition 4.1.21(b).

Solution to Exercise 4.1.51

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Example 2.1.9 (Maps of polynomials), Proposition 1.1.17 (No zero divisors), Proposition 1.5.15 (Short lists, zeros, and repeats)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Show that $D^j\left(x^k\right) = k(k-1)\cdots(k-j+1)x^{k-j}$ for $j \leq k$, and $D^j\left(x^k\right) = 0$ for $j > k$. What are $D^n p$ and $D^{n+1} p$?
Hint 2. $D^n p$ is the constant $n! a_n$, where $a_n \neq 0$ is the leading coefficient. Apply Proposition 4.1.26 with $T = D$ and $k = n$, then count.
Sketch. By induction on j, $D^j x^k = k(k-1)\cdots(k-j+1)x^{k-j}$ for $j \leq k$, so $D^n p = n! a_n \neq 0$ and $D^{n+1} p = 0$. By Proposition 4.1.26 the $n+1$ polynomials $p, \ldots, D^n p$ are independent. They lie in $F[x]_{\leq n}$, which has dimension $n+1$, so they form a basis. Over $\mathbb{F}_2$, $D\left(x^2\right) = 2x = 0$, and the list $x^2, 0, 0$ contains $\mathbf{0}$.

(a) By Example 2.1.9, $D\left(x^k\right) = kx^{k-1}$ for $k \geq 1$ and $D(1) = 0$. By induction on j, $D^j\left(x^k\right) = k(k-1)\cdots(k-j+1)x^{k-j}$ for $0 \leq j \leq k$; in particular $D^k\left(x^k\right) = k!$ is a constant, and hence $D^j\left(x^k\right) = 0$ for $j > k$.

Write $p = a_0 + a_1 x + \cdots + a_n x^n$ with $a_n \neq 0$. By linearity, $D^n p = \sum_k a_k D^n\left(x^k\right) = n! a_n$, since the terms with $k < n$ vanish. This is nonzero, since $n! \neq 0$ and $a_n \neq 0$ (Proposition 1.1.17). And $D^{n+1} p = D(n! a_n) = 0$. By Proposition 4.1.26, applied to $T = D \in \mathrm{L}(F[x])$, $\mathbf{v} = p$, and $k = n$, the list $p, Dp, \ldots, D^n p$ is independent. Each $D^j p$ has degree at most n, so the list lies in $F[x]_{\leq n}$. It has $n + 1 = \dim F[x]_{\leq n}$ entries, so it is a basis by Theorem 4.1.10(b).

(b) Over $\mathbb{F}_2$, $D\left(x^2\right) = 2x = 0$, so the list is $x^2, 0, 0$. It contains $\mathbf{0}$, so it is dependent (Proposition 1.5.15(c)). Here $2! = 2 = 0$, so the hypothesis fails, and the chain from x^2 reaches $\mathbf{0}$ after one step instead of two.

Solution to Exercise 4.1.52

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Definition 2.3.1 (Matrix of a linear map), (1.6.1)
Hint 1. Since $T^{n-1} \neq 0$, some $\mathbf{v}$ has $T^{n-1}\mathbf{v} \neq \mathbf{0}$. What is $T^n \mathbf{v}$?
Hint 2. For (b), write $\mathbf{b}_i = T^{n-i}\mathbf{v}$ and compute $T\mathbf{b}_i$ in terms of the $\mathbf{b}$'s. The i-th column of the matrix is $[T\mathbf{b}_i]_{\mathcal{B}}$.
Sketch. (a) Choose $\mathbf{v}$ with $T^{n-1}\mathbf{v} \neq \mathbf{0}$; since $T^n \mathbf{v} = \mathbf{0}$, the chain $\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is independent (Proposition 4.1.26) of length n, hence a basis. (b) With $\mathbf{b}_i = T^{n-i}\mathbf{v}$: $T\mathbf{b}_1 = \mathbf{0}$ and $T\mathbf{b}_i = \mathbf{b}_{i-1}$ for $i \geq 2$. So the matrix has 1's just above the diagonal and 0's elsewhere.

(a) Since $T^{n-1} \neq 0$, there is $\mathbf{v} \in V$ with $T^{n-1}\mathbf{v} \neq \mathbf{0}$, and $T^n \mathbf{v} = \mathbf{0}$. By Proposition 4.1.26 with $k = n - 1$, the list $\mathbf{v}, T\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is independent. It has $n = \dim V$ entries, so it is a basis (Theorem 4.1.10(b)).

(b) The list $\mathcal{B}$ is a reordering of the basis in (a), so it is a basis. Write $\mathbf{b}_i = T^{n-i}\mathbf{v}$ for $1 \leq i \leq n$. Then $T\mathbf{b}_1 = T^n \mathbf{v} = \mathbf{0}$, and $T\mathbf{b}_i = T^{n-i+1}\mathbf{v} = \mathbf{b}_{i-1}$ for $2 \leq i \leq n$. So $[T\mathbf{b}_1]_{\mathcal{B}} = \mathbf{0}$ and, by (1.6.1), $[T\mathbf{b}_i]_{\mathcal{B}} = \mathbf{e}_{i-1}$ for $i \geq 2$. These are the columns of $[T]_{\mathcal{B}\mathcal{B}}$ (Definition 2.3.1), so

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & & & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix},$$

the matrix with 1 in positions $(i, i+1)$ and 0 elsewhere. It is the matrix of the shift N from the start of Section 4.1.7, so every such T looks like the shift in a suitable basis. This is the simplest case of the Jordan form (Section 10.3).

Solution to Exercise 4.1.53

Uses. Corollary 4.1.35 (Counting independent lists and bases), Theorem 3.5.14 (Third Fundamental Theorem, completed), Proposition 4.1.34 (Size of a vector space over a finite field)
Hint 1. A matrix is invertible exactly when its columns form a basis (Theorem 3.5.14), so there are $N_2(n,n)$ invertible matrices out of 2^{n^2}.
Hint 2. Write the fraction as $\prod_{j=1}^{n}(1-2^{-j})$. Keep the factor $1/2$ and bound the rest with $\prod(1-a_j) \geq 1-\sum a_j$ for $0 \leq a_j \leq 1$.
Sketch. (a) $168/512 = 21/64$. (b) The fraction is $\prod_{i=0}^{n-1}(2^n-2^i)/2^n = \prod_{j=1}^{n}(1-2^{-j})$. By induction, $\prod(1-a_j) \geq 1-\sum a_j$ when all $a_j \in [0,1]$, so $\prod_{j=2}^{n}(1-2^{-j}) \geq 1-(1/2-2^{-n}) > 1/2$, and the fraction exceeds $1/4$.

By Theorem 3.5.14, $A \in F^{n\times n}$ is invertible if and only if its columns form a basis of F^n, and A is determined by its list of columns. So by Corollary 4.1.35 there are $N_2(n,n) = \prod_{i=0}^{n-1}(2^n-2^i)$ invertible matrices in $\mathbb{F}_2^{n\times n}$, out of 2^{n^2} in all (Proposition 4.1.34).

(a) For $n=3$: $(8-1)(8-2)(8-4) = 168$, out of $2^9 = 512$, so the fraction is $168/512 = 21/64 \approx 0.33$.

(b) Dividing each of the n factors by 2^n,

$$N_2\frac{n,n}{2^{n^2}} = \prod_{i=0}^{n-1}(1-2^{i-n}) = \prod_{j=1}^{n}(1-2^{-j}).$$

First, if $a_2,\dots,a_n \in [0,1]$, then $\prod_{j=2}^{n}(1-a_j) \geq 1-\sum_{j=2}^{n} a_j$. This is clear for an empty product, and if P is the product of the first factors and S their sum, with $P \geq 1-S$, then, since $1-a \geq 0$,

$$P(1-a) \geq (1-S)(1-a) = 1-(S+a)+Sa \geq 1-(S+a).$$

With $a_j = 2^{-j}$ we get $\sum_{j=2}^{n} 2^{-j} = 1/2 - 2^{-n} < 1/2$, so

$$\prod_{j=1}^{n}(1-2^{-j}) = \frac{1}{2}\prod_{j=2}^{n}(1-2^{-j}) \geq \frac{1}{2}\left(\frac{1}{2}+2^{-n}\right) > \frac{1}{4}.$$

(As $n \to \infty$ the fraction decreases to about 0.289.)

Solution to Exercise 4.1.54

Uses. Proposition 4.1.37 (Counting subspaces), Corollary 4.1.35 (Counting independent lists and bases)
Techniques. Double counting (Technique 4.1.36)
Hint 1. Use Proposition 4.1.37 with $q=2$, $n=4$.
Hint 2. For (b), factor q^i out of each factor q^n-q^i in $N_q(n,k)$, and write the count as a ratio of products of factors q^j-1.
Sketch. (a) $1, 15, 35, 15, 1$, so 67 subspaces in all. (b) $N_q(n,k) = q^{k(k-1)/2}\prod_{j=n-k+1}^{n}(q^j-1)$, so the count is $[n]!/([k]![n-k]!)$ with $[m]! = \prod_{j=1}^{m}(q^j-1)$, which is symmetric in k and $n-k$.

(a) With $q=2$ and $n=4$, Proposition 4.1.37 gives

$$k=1: \frac{15}{1} = 15, \quad k=2: \frac{15\cdot 14}{3\cdot 2} = 35, \quad k=3: \frac{15\cdot 14\cdot 12}{7\cdot 6\cdot 4} = 15,$$

and of course one subspace each of dimensions 0 and 4. So $\mathbb{F}_2^4$ has $1+15+35+15+1 = 67$ subspaces.

(b) Factoring q^i out of q^n-q^i,

$$N_q(n,k) = \prod_{i=0}^{k-1} q^i(q^{n-i}-1) = q^{k(k-1)/2}\prod_{j=n-k+1}^{n}(q^j-1).$$

For $n=k$ this reads $N_q(k,k) = q^{k(k-1)/2}\prod_{j=1}^{k}(q^j-1)$. Writing $[m]! = \prod_{j=1}^{m}(q^j-1)$, with $[0]!=1$, the number of k-dimensional subspaces is therefore

$$N_q\frac{n,k}{N_q}(k,k) = \frac{\prod_{j=n-k+1}^{n}(q^j-1)}{[k]!} = \frac{[n]!}{[k]!\,[n-k]!},$$

since $\prod_{j=n-k+1}^{n}(q^j-1) = [n]!/[n-k]!$. The last expression does not change when k is replaced by $n-k$. (Duality explains the symmetry: sending U to the functionals that vanish on U matches the k-dimensional subspaces of V with the $(n-k)$-dimensional subspaces of the dual space, which has the same dimension as V (Section 13.1).)

Solution to Exercise 4.1.55

Uses. Exercise 4.1.52, Corollary 2.2.6 (Agreeing on a spanning list), Proposition 2.1.24 (Algebra of composition)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. By Exercise 4.1.52 there is $\mathbf{v}$ with $\mathbf{v}, N\mathbf{v}, \dots, N^{n-1}\mathbf{v}$ a basis. Expand $S\mathbf{v}$ in this basis.
Hint 2. If $S\mathbf{v} = \sum c_i N^i\mathbf{v}$, let $P = \sum c_i N^i$. Compare S and P on each basis vector $N^j\mathbf{v}$, using that both commute with N^j.
Sketch. Polynomials in N commute with N. Conversely, take $\mathbf{v}$ with $\mathbf{v}, \dots, N^{n-1}\mathbf{v}$ a basis, write $S\mathbf{v} = \sum_i c_i N^i\mathbf{v}$, and let $P = \sum_i c_i N^i$. Since S and P commute with N^j, $SN^j\mathbf{v} = N^jS\mathbf{v} = N^jP\mathbf{v} = PN^j\mathbf{v}$. So S and P agree on a basis, and $S = P$.

($\Leftarrow$) N commutes with each power N^i, since $NN^i = N^{i+1} = N^iN$. By the distributive laws of Proposition 2.1.24, N commutes with every combination $\sum_i c_i N^i$.

($\Rightarrow$) Suppose $SN = NS$. By induction on j, $SN^j = N^jS$ for all $j \geq 0$: if $SN^j = N^jS$, then $SN^{j+1} = (SN)N^j = NSN^j = NN^jS = N^{j+1}S$. By Exercise 4.1.52 there is $\mathbf{v} \in V$ such that $\mathbf{v}, N\mathbf{v}, \dots, N^{n-1}\mathbf{v}$ is a basis of V. Expand $S\mathbf{v}$ in it:

$$S\mathbf{v} = c_0\mathbf{v} + c_1N\mathbf{v} + \cdots + c_{n-1}N^{n-1}\mathbf{v},$$

and let $P = c_0\mathrm{id}_V + c_1N + \cdots + c_{n-1}N^{n-1}$, so that $S\mathbf{v} = P\mathbf{v}$. For each j, using that S and P both commute with N^j,

$$S\big(N^j\mathbf{v}\big) = N^j(S\mathbf{v}) = N^j(P\mathbf{v}) = P\big(N^j\mathbf{v}\big).$$

So S and P agree on every vector of a basis of V, and therefore $S = P$ (Corollary 2.2.6).

Without the hypothesis $N^{n-1} \neq 0$ the statement fails: for $n \geq 2$ and $N = 0$, every S commutes with N, but the combinations of powers of 0 are only the multiples of id_V.

Solution to Exercise 4.1.56

Uses. Proposition 4.1.31 (Every square matrix satisfies a polynomial), Proposition 2.1.24 (Algebra of composition), Definition 2.6.1 (Injective), Definition 2.5.12 (Invertible)
Techniques. Too many vectors force a dependence (Technique 4.1.30), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. By Proposition 4.1.31 there is a nontrivial relation $\sum_{j=0}^{N} c_jT^j = 0$. Let r be the smallest index with $c_r \neq 0$ and factor out T^r.
Hint 2. T^r is injective, so $T^rR = 0$ forces $R = 0$. Now $R = c_r\mathrm{id}_V + TQ$ for a combination Q of powers of T. Solve for id_V.
Sketch. Take $\sum_{j=r}^{N} c_jT^j = 0$ with $c_r \neq 0$. Then $T^rR = 0$ with $R = \sum_{j\geq r} c_jT^{j-r}$, and T^r is injective, so $R = 0$. Writing $R = c_r\mathrm{id}_V + TQ$ gives $T\big(-c_r^{-1}Q\big) = \mathrm{id}_V$, and Q commutes with T, so $-c_r^{-1}Q$ is a two-sided inverse. For M: $1 \notin \operatorname{im} M$; the step that fails is the existence of a relation among $\mathrm{id}, M, M^2, \dots$, since these are independent ($M^j(1) = x^j$).

(a) If $V = \{\mathbf{0}\}$, then $T = \mathrm{id}_V$ and $T^{-1} = \mathrm{id}_V$. Otherwise $n = \dim V \geq 1$, and by Proposition 4.1.31 there are $c_0, \dots, c_N$ ($N = n^2$), not all 0, with $\sum_{j=0}^{N} c_jT^j = 0$. Let r be the smallest index with $c_r \neq 0$, and let

$$R = c_r\mathrm{id}_V + c_{r+1}T + \cdots + c_NT^{N-r},$$

so that $\sum_{j=r}^{N} c_jT^j = T^rR$ by Proposition 2.1.24. Thus $T^rR = 0$. The map T^r is injective, as a composite of injective maps. For every $\mathbf{u} \in V$, $T^r(R\mathbf{u}) = \mathbf{0} = T^r(\mathbf{0})$, so $R\mathbf{u} = \mathbf{0}$. Hence $R = 0$. Let $Q = c_{r+1}\mathrm{id}_V + c_{r+2}T + \cdots + c_NT^{N-r-1}$ (an empty sum is 0), so that $R = c_r\mathrm{id}_V + TQ$, and let $S = -c_r^{-1}Q$. Then $R = 0$ gives

$$TS = -c_r^{-1}TQ = -c_r^{-1}(R - c_r\mathrm{id}_V) = \mathrm{id}_V.$$

Since S is a combination of powers of T, it commutes with T, so $ST = TS = \mathrm{id}_V$ as well. So T is invertible (Definition 2.5.12), and $T^{-1} = S$ is a combination of $\mathrm{id}_V, T, \dots, T^{N-r-1}$.

(b) If $xp = 0$, then every coefficient of p, which is a coefficient of xp shifted by one place, is 0; so M is injective. Every xp has constant coefficient 0, so $1 \notin \operatorname{im} M$, and M is not surjective. The argument of (a) fails at its first step: there is no nontrivial relation $\sum_j c_j M^j = 0$, because applying it to 1 gives $\sum_j c_j x^j = 0$, which forces all $c_j = 0$. The space $\mathrm{L}(F[x])$ is infinite-dimensional, and the powers of M never become too many.

In particular, an injective operator on a finite-dimensional space is surjective. Section 4.2 proves this again with dimension counting (Corollary 4.2.18).

Solution to Exercise 4.1.57

> *Uses.* Theorem 4.1.10 (Independent lists are short), Theorem 1.5.5 (Independence is decided at zero), Example 4.1.7 (Dimensions of the standard spaces)
> *Techniques.* Too many vectors force a dependence (Technique 4.1.30)
> *Hint 1.* Encode A_i as the vector $\mathbf{x}_i \in \mathbb{R}^n$ whose t-th entry is 1 if $t \in A_i$ and 0 otherwise. There are $n+1$ of these.
> *Hint 2.* Take a nontrivial relation and move the terms with negative coefficients to the other side. When is the t-th entry of a combination of the $\mathbf{x}_i$ with positive coefficients positive?
> *Sketch.* The $n+1$ indicator vectors in $\mathbb{R}^n$ are dependent. Split a nontrivial relation as $\sum_{i\in I} c_i\mathbf{x}_i = \sum_{j\in J} d_j\mathbf{x}_j$ with all $c_i, d_j > 0$, where I and J are the indices with positive and negative coefficients. Both are nonempty, since a positive combination of nonzero vectors with entries ≥ 0 is nonzero. The t-th entry of the left side is positive exactly when $t \in \bigcup_I A_i$, and likewise on the right.

For each i, let $\mathbf{x}_i \in \mathbb{R}^n$ have t-th entry 1 if $t \in A_i$ and 0 otherwise; $\mathbf{x}_i \neq \mathbf{0}$ since $A_i \neq \emptyset$. These are $n+1$ vectors in $\mathbb{R}^n$, and $\dim \mathbb{R}^n = n$, so they are dependent (Theorem 4.1.10(a)): there are real $a_1, \ldots, a_{n+1}$, not all 0, with $\sum_i a_i\mathbf{x}_i = \mathbf{0}$. Let $I = \{i \mid a_i > 0\}$ and $J = \{j \mid a_j < 0\}$, which are disjoint. Moving the negative terms across,

$$\mathbf{y} = \sum_{i\in I} a_i\mathbf{x}_i = \sum_{j\in J} (-a_j)\mathbf{x}_j,$$

where all coefficients now are positive.

Consider the t-th entry of $\mathbf{y}$. On the left it is $\sum_{i\in I, t\in A_i} a_i$, a sum of positive numbers, which is positive if $t \in \bigcup_{i\in I} A_i$ and 0 otherwise. On the right, in the same way, it is positive exactly when $t \in \bigcup_{j\in J} A_j$. So the two unions are both equal to the set of t with $y_t > 0$, and hence equal to each other.

It remains to see that I and J are nonempty. Not all a_i are 0, so $I \cup J \neq \emptyset$; say $I \neq \emptyset$. Pick $i_0 \in I$ and $t \in A_{i_0}$. Then $y_t \geq a_{i_0} > 0$, so $\mathbf{y} \neq \mathbf{0}$, and the right side, an empty sum if $J = \emptyset$, would be $\mathbf{0}$. So $J \neq \emptyset$. The case $J \neq \emptyset$ is symmetric.

Solution to Exercise 4.1.58

> *Uses.* Theorem 1.6.10 (Every spanning list contains a basis), Lemma 2.4.24 (Matrix units), Definition 3.2.2 (Elementary matrices), Proposition 3.2.10 (Inverses of elementary matrices), Proposition 2.5.17 (Algebra of inverses), Theorem 4.1.10 (Independent lists are short)
> *Hint 1.* It is enough to show that the invertible matrices span $F^{n\times n}$, since a spanning list contains a basis. Write each matrix unit as a difference of two invertible matrices.
> *Hint 2.* For $i \neq j$, $U_{ij} = \big(I + U_{ij}\big) - I$. For U_{ii}, pick $j \neq i$ and let $P = E_{ij}$ be the swap. Show $P + U_{ii} = P\big(I + U_{ji}\big)$.
> *Sketch.* For $n = 1$ take (1). For $n \geq 2$: if $i \neq j$ then $\big(I + U_{ij}\big)\big(I - U_{ij}\big) = I$ because $U_{ij}^2 = 0$, so $U_{ij} = \big(I + U_{ij}\big) - I$ is a difference of invertibles. For U_{ii}, take $j \neq i$ and the swap $P = E_{ij}$; then $PU_{ii} = U_{ji}$, so $P + U_{ii} = P\big(I + U_{ji}\big)$ is invertible and $U_{ii} = (P + U_{ii}) - P$. So finitely many invertible matrices span, and a basis can be extracted from them. Over $\mathbb{F}_2$: I_2, $I_2 + U_{12}$, $I_2 + U_{21}$, $\left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$.

For $n = 1$, the matrix (1) is an invertible basis of $F^{1\times 1}$. Let $n \geq 2$, and write $I = I_n$. By Lemma 2.4.24, $U_{ij}U_{kl} = U_{il}$ if $j = k$ and 0 otherwise.

Off-diagonal units. For $i \neq j$, $U_{ij}^2 = 0$, so $\big(I + U_{ij}\big)\big(I - U_{ij}\big) = I - U_{ij}^2 = I$ and likewise $\big(I - U_{ij}\big)\big(I + U_{ij}\big) = I$. So $I + U_{ij}$ is invertible, and $U_{ij} = \big(I + U_{ij}\big) - I$.

Diagonal units. Fix i and choose $j \neq i$. Let $P = E_{ij}$ be the elementary matrix that swaps rows i and j (Definition 3.2.2); it is invertible with $P^{-1} = P$ (Proposition 3.2.10). Its i-th column is $\mathbf{e}_j$, so $PU_{ii} = P\mathbf{e}_i\mathbf{e}_i^{\mathsf{T}} = \mathbf{e}_j\mathbf{e}_i^{\mathsf{T}} = U_{ji}$. Hence

$$P\big(I + U_{ji}\big) = P + PU_{ji} = P + P(PU_{ii}) = P + U_{ii}.$$

By the previous paragraph $I + U_{ji}$ is invertible, so $P + U_{ii}$ is a product of invertible matrices and is invertible (Proposition 2.5.17). And $U_{ii} = (P + U_{ii}) - P$.

So every matrix unit is a combination of finitely many invertible matrices, and these invertible matrices span $F^{n\times n}$, since the matrix units do. By Theorem 1.6.10, some sublist of them is a basis.

For $\mathbb{F}_2^{2\times 2}$, take

$$I_2 = \begin{pmatrix}1&0\\0&1\end{pmatrix},\quad \begin{pmatrix}1&1\\0&1\end{pmatrix},\quad \begin{pmatrix}1&0\\1&1\end{pmatrix},\quad \begin{pmatrix}1&1\\1&0\end{pmatrix}.$$

Each is invertible: the first three are I_2 and $I_2 + U_{12}$, $I_2 + U_{21}$, and the last is $E_{12} + U_{11}$. A combination $aI_2 + b(I_2 + U_{12}) + c(I_2 + U_{21}) + d(E_{12} + U_{11})$ has $(1,1)$ entry $a + b + c + d$ and $(2,2)$ entry $a + b + c$, so if it is 0 then $d = 0$; its $(1,2)$ and $(2,1)$ entries are then b and c, so $b = c = 0$, and finally $a = 0$. Four independent vectors in the 4-dimensional space $\mathbb{F}_2^{2\times 2}$ form a basis (Theorem 4.1.10(b)).

Solution to Exercise 4.1.59

Uses. Exercise 1.5.33, Proposition 1.6.19 (Coordinates respect linear combinations), Definition 1.6.14 (Coordinates)
Hint 1. By Exercise 1.5.33, replacing $\mathbf{b}_i$ by $\mathbf{w}$ gives a basis exactly when the i-th $\mathcal{B}$-coordinate of $\mathbf{w}$ is nonzero. Express both conditions (a) and (b) by coordinates.
Hint 2. Let β_j be the j-th $\mathcal{C}$-coordinate of $\mathbf{b}_i$ and γ_j the i-th $\mathcal{B}$-coordinate of $\mathbf{c}_j$. Take the i-th $\mathcal{B}$-coordinate of both sides of $\mathbf{b}_i = \sum_j \beta_j\mathbf{c}_j$.
Sketch. By Exercise 1.5.33, (a) holds iff $\gamma_j \neq 0$ and (b) holds iff $\beta_j \neq 0$, where $\mathbf{b}_i = \sum_j \beta_j\mathbf{c}_j$ and γ_j is the i-th $\mathcal{B}$-coordinate of $\mathbf{c}_j$. Taking i-th $\mathcal{B}$-coordinates of $\mathbf{b}_i = \sum_j \beta_j\mathbf{c}_j$ gives $1 = \sum_j \beta_j\gamma_j$, so some $\beta_j\gamma_j \neq 0$.

For $\mathbf{w} \in V$, Exercise 1.5.33 says that replacing $\mathbf{b}_i$ by $\mathbf{w}$ in the independent list $\mathcal{B}$ gives an independent list if and only if the coefficient of $\mathbf{b}_i$ in $\mathbf{w}$, that is, the i-th coordinate of $[\mathbf{w}]_{\mathcal{B}}$, is nonzero, and that the span is then still V. So the new list is a basis exactly in that case. Let γ_j be the i-th coordinate of $\big[\mathbf{c}_j\big]_{\mathcal{B}}$. Then (a) holds for j if and only if $\gamma_j \neq 0$.

In the same way, with the roles of the bases exchanged, write $[\mathbf{b}_i]_{\mathcal{C}} = (\beta_1, \ldots, \beta_n)$, that is, $\mathbf{b}_i = \sum_j \beta_j\mathbf{c}_j$. Then (b) holds for j if and only if $\beta_j \neq 0$.

Take the i-th $\mathcal{B}$-coordinate of both sides of $\mathbf{b}_i = \sum_j \beta_j\mathbf{c}_j$. On the left it is 1, since $[\mathbf{b}_i]_{\mathcal{B}} = \mathbf{e}_i$. On the right, by Proposition 1.6.19(c), it is $\sum_j \beta_j\gamma_j$. So $\sum_{j=1}^{n} \beta_j\gamma_j = 1 \neq 0$, and some term $\beta_j\gamma_j$ is nonzero. For that j, both $\beta_j \neq 0$ and $\gamma_j \neq 0$, so (a) and (b) both hold.

Solution to Exercise 4.1.60

Uses. Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps), Theorem 4.1.10 (Independent lists are short), Theorem 1.5.5 (Independence is decided at zero), Proposition 2.1.17 (Compositions of linear maps are linear), Proposition 1.2.35 (Zero products), Definition 1.1.28 (Characteristic)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Too many vectors force a dependence (Technique 4.1.30)
Hint 1. Let $\varphi : F^{n\times n} \to F^{n\times n}$, $\varphi(X) = XB - BX$. Show that φ is linear and that $\varphi\big(A^k\big) = kA^k$ for all $k \geq 1$.
Hint 2. Suppose $A^1, \ldots, A^N$ are all nonzero, with $N = n^2 + 1$. Show they are independent: to isolate the coefficient of A^m in a relation, apply the composite of the maps $\varphi - j\,\mathrm{id}$ for $j \neq m$.
Hint 3. So some A^k with $k \leq n^2 + 1$ is 0. Finish with Corollary 4.1.27.
Sketch. $\varphi(X) = XB - BX$ is linear, and $\varphi\big(A^{k+1}\big) = A\varphi\big(A^k\big) + \varphi(A)A^k$ gives $\varphi\big(A^k\big) = kA^k$. If $A, \ldots, A^N$ ($N = n^2 + 1$) were all nonzero, applying $\prod_{j\neq m}(\varphi - j\,\mathrm{id})$ to a relation $\sum c_kA^k = 0$ would leave $c_m \prod_{j\neq m}(m - j)A^m = 0$, and $\prod_{j\neq m}(m - j)$ is a nonzero integer, nonzero in F. So $c_m = 0$ for all m, and $N > n^2$ independent matrices is impossible. Hence A is nilpotent, and $A^n = 0$.

Let $\varphi : F^{n\times n} \to F^{n\times n}$ be $\varphi(X) = XB - BX$. It is linear, since $(X + cY)B - B(X + cY) = (XB - BX) + c(YB - BY)$. We show $\varphi\big(A^k\big) = kA^k$ for $k \geq 1$ by induction. For $k = 1$ this is the hypothesis. If it holds for k, then

$$\varphi\big(A^{k+1}\big) = AA^kB - BAA^k = A\big(A^kB - BA^k\big) + (AB - BA)A^k = A\big(kA^k\big) + AA^k = (k + 1)A^{k+1}.$$

For an integer j, let $L_j = \varphi - j\,\mathrm{id}$, a linear map on $F^{n\times n}$; here j stands for $j \cdot 1 \in F$. Then $L_j\big(A^k\big) = (k - j)A^k$, and therefore $L_j\big(cA^k\big) = c(k - j)A^k$ for every scalar c.

Let $N = n^2 + 1$, and suppose, to the contrary, that $A^k \neq 0$ for $k = 1, \ldots, N$. We show that $A, A^2, \ldots, A^N$ is independent. Let $\sum_{k=1}^{N} c_kA^k = 0$, and fix $m \in \{1, \ldots, N\}$. Apply the composite $L = L_1 \cdots L_{m-1}L_{m+1} \cdots L_N$, which is linear (Proposition 2.1.17). Applying the factors one at a time,

$$L\big(A^k\big) = \left(\prod_{j\neq m}(k - j)\right)A^k,$$

which is 0 for $k \neq m$, because the product contains the factor $k - k = 0$. So applying L to the relation leaves

$$c_m\left(\prod_{j\neq m}(m - j)\right)A^m = 0.$$

The product is a product of nonzero integers, hence a nonzero integer, and in a field of characteristic 0 a nonzero integer is a nonzero element. Since $A^m \neq 0$, Proposition 1.2.35 gives $c_m = 0$. As m was arbitrary, the relation is trivial, and $A, \ldots, A^N$ is an independent list of $n^2 + 1$ vectors in $F^{n\times n}$, contradicting Theorem 4.1.10(a).

So $A^k = 0$ for some k with $1 \leq k \leq n^2 + 1$, and Corollary 4.1.27 gives $A^n = 0$.

The hypothesis on F is needed. Over $\mathbb{F}_3$, the matrices

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix}$$

satisfy $AB - BA = A$ (check it), while $A^3 = I_3$. In the proof, the integers $1, 2, 3, \ldots$ are no longer distinct in $\mathbb{F}_3$, so φ cannot tell the powers of A apart.

Section 4.2

Solution to Exercise 4.2.4

> *Uses.* Proposition 4.2.3 (Properties of restriction), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Example 2.1.9 (Maps of polynomials)
> *Hint 1.* $\ker D$ is the constants. Intersect it with each subspace.
> *Hint 2.* The image of a restriction to $\mathrm{span}(\mathcal{L})$ is spanned by the values on $\mathcal{L}$ (Proposition 2.1.16(a)).
> *Sketch.* $\ker D = \mathrm{span}(1)$. (a) $U \cap \ker D = \{\mathbf{0}\}$, so the kernel is $\{\mathbf{0}\}$ and the image is $\mathrm{span}\big(2x, 3x^2\big) = \mathrm{span}\big(x, x^2\big)$. (b) $U' \cap \ker D = \mathrm{span}(1)$, and the image is $\mathrm{span}(0, 1) = \mathrm{span}(1)$. (c) $U'' = \mathrm{span}\big(x, x^2, x^3\big)$.

Over $\mathbb{R}$, $D\big(a_0 + a_1x + a_2x^2 + a_3x^3\big) = a_1 + 2a_2x + 3a_3x^2$ is $\mathbf{0}$ exactly when $a_1 = a_2 = a_3 = 0$, so $\ker D = \mathrm{span}(1)$.

(a) A polynomial $ax^2 + bx^3$ is constant only if $a = b = 0$, so $U \cap \ker D = \{\mathbf{0}\}$, and $\ker(D|_U) = \{\mathbf{0}\}$ by Proposition 4.2.3(c). By Proposition 2.1.16(a), $\mathrm{im}(D|_U) = \mathrm{span}\big(D\big(x^2\big), D\big(x^3\big)\big) = \mathrm{span}\big(2x, 3x^2\big) = \mathrm{span}\big(x, x^2\big)$.

(b) Here $U' \cap \ker D = \mathrm{span}(1)$, which is $\ker(D|_{U'})$, and $\mathrm{im}(D|_{U'}) = \mathrm{span}(D(1), D(x)) = \mathrm{span}(\mathbf{0}, 1) = \mathrm{span}(1)$.

(c) Let $U'' = \mathrm{span}\big(x, x^2, x^3\big)$. Its only constant is $\mathbf{0}$, so $D|_{U''}$ is injective, and $\mathrm{im}(D|_{U''}) = \mathrm{span}\big(1, 2x, 3x^2\big) = \mathbb{R}[x]_{\leq 2} = \mathrm{im}\, D$. (So does $\mathrm{span}\big(x + 1, x^2, x^3\big)$; such a subspace is not unique.)

Solution to Exercise 4.2.10

Uses. Theorem 4.2.7 (The image of T_A), Remark 3.4.11 (A basis of the kernel), Definition 3.4.8 (Basic solutions)
Hint 1. Row reduce. Subtract twice row 1 from row 2 first.
Hint 2. For (b), use the basis from (a) and compare entries, starting with the third.
Sketch. $A_r = \begin{pmatrix} 1 & -1 & 0 & -2 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}$, with pivot columns 1, 3. So $(1,2,0), (2,5,1)$ is a basis of $\operatorname{im} T_A$, and the basic solutions $(1,1,0,0), (2,0,-1,1)$ are a basis of $\ker T_A$. (b) No: $a(1,2,0) + b(2,5,1)$ has third entry b, so $b = 0$, and then the second entry is $2a = 2 \neq 0$.

(a) Adding -2 times row 1 to row 2 gives rows $(1,-1,2,0)$, $(0,0,1,1)$, $(0,0,1,1)$. Adding -1 times row 2 to row 3 and -2 times row 2 to row 1 gives

$$A_r = \begin{pmatrix} 1 & -1 & 0 & -2 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

The pivot columns are 1 and 3, so by Theorem 4.2.7 the columns $(1,2,0)$ and $(2,5,1)$ of A form a basis of $\operatorname{im} T_A$. The free columns are 2 and 4, and the basic solutions are $\mathbf{s}_1 = (1,1,0,0)$ and $\mathbf{s}_2 = (2,0,-1,1)$, a basis of $\ker T_A$ (Remark 3.4.11). Check: $\mathbf{a}_1 + \mathbf{a}_2 = \mathbf{0}$ and $2\mathbf{a}_1 - \mathbf{a}_3 + \mathbf{a}_4 = (2-2+0, 4-5+1, 0-1+1) = \mathbf{0}$.

(b) No. If $a(1,2,0) + b(2,5,1) = (1,0,0)$, the third entry gives $b = 0$, the first then gives $a = 1$, and the second entry is $2 \neq 0$. So $(1,0,0) \notin \operatorname{im} T_A$, although it is a pivot column of A_r.

Solution to Exercise 4.2.13

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Proposition 1.6.2 (Bases are independent spanning lists)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. For (a), set each entry of $T(\mathbf{x})$ to 0.
Hint 2. For (b), show one containment directly, and compare dimensions using rank–nullity.
Sketch. (a) $T(\mathbf{x}) = \mathbf{0}$ iff $x_1 = x_2 = x_3$, so $\ker T = \operatorname{span}((1,1,1))$. (b) The entries of $T(\mathbf{x})$ sum to 0, so $\operatorname{im} T \subseteq P = \{y_1 + y_2 + y_3 = 0\}$. By rank–nullity $\dim \operatorname{im} T = 3 - 1 = 2$, and P has the basis $(1,-1,0), (0,1,-1)$, so $\dim P = 2$ and $\operatorname{im} T = P$.

(a) $T(\mathbf{x}) = \mathbf{0}$ means $x_1 = x_2$, $x_2 = x_3$, and $x_3 = x_1$, that is, $x_1 = x_2 = x_3$. So $\ker T = \operatorname{span}((1,1,1))$, which has dimension 1.

(b) Let $P = \{\mathbf{y} \in F^3 \mid y_1 + y_2 + y_3 = 0\}$. The entries of $T(\mathbf{x})$ add up to $(x_1 - x_2) + (x_2 - x_3) + (x_3 - x_1) = 0$, so $\operatorname{im} T \subseteq P$. By Theorem 4.2.11 and (a), $\dim \operatorname{im} T = 3 - 1 = 2$. On the other hand, every $\mathbf{y} \in P$ satisfies

$$\mathbf{y} = y_1(1,-1,0) + (y_1 + y_2)(0,1,-1),$$

since the third entry of the right side is $-y_1 - y_2 = y_3$. The two vectors lie in P and are independent (look at the first entries, then the second), so they form a basis of P and $\dim P = 2$. By Proposition 4.1.21(b), applied in P, $\operatorname{im} T = P$. Every step is valid over every field.

Solution to Exercise 4.2.17

Uses. Proposition 4.2.15 (Rank through any matrix), Definition 2.3.1 (Matrix of a linear map), Theorem 4.2.11 (Rank–nullity)
Hint 1. The columns of the matrix are $T(1)$, $T(x)$, $T(x^2)$.
Hint 2. Over $\mathbb{F}_2$, the entry 2 is 0 and so is 4.
Sketch. The matrix is $A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 2 & 4 \end{pmatrix}$. Over $\mathbb{Q}$ it reduces to I_3, so $\operatorname{rank} T = 3$ and $\operatorname{nullity} T = 0$. Over $\mathbb{F}_2$, $A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 0 & 0 \end{pmatrix}$ has rank 2, so $\operatorname{nullity} T = 1$, and $\ker T_A = \operatorname{span}((0,1,1))$ gives $p = x + x^2$.

The columns of $A = [T]$ are $T(1) = (1,1,1)$, $T(x) = (0,1,2)$, and $T(x^2) = (0,1,4)$:

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 2 & 4 \end{pmatrix}.$$

Over $\mathbb{Q}$, subtracting row 1 from rows 2 and 3 gives rows $(0,1,1)$ and $(0,2,4)$, and subtracting twice the new row 2 from row 3 leaves $(0,0,2)$. There are three pivots, so $\operatorname{rank} A = 3$. By Proposition 4.2.15, $\operatorname{rank} T = 3$, and $\operatorname{nullity} T = 3 - 3 = 0$ by Theorem 4.2.11.

Over $\mathbb{F}_2$, $2 = 4 = 0$, so $A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 0 & 0 \end{pmatrix}$. Rows 1 and 3 agree, and subtracting row 1 from rows 2 and 3 gives $A_r = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix}$. So $\operatorname{rank} T = 2$ and $\operatorname{nullity} T = 1$. The basic solution is $(0,1,1)$, which is $\left[x + x^2\right]$; indeed $x + x^2$ takes the values 0, $1 + 1 = 0$, and 0 at 0, 1, and $2 = 0$. Over $\mathbb{F}_2$, a nonzero polynomial can vanish at every point of the field.

Solution to Exercise 4.2.22

Uses. Corollary 4.2.21 (Dimension obstructions), Example 4.1.7 (Dimensions of the standard spaces)
Hint 1. Compute the dimensions involved first: $\dim F^{2\times 3} = 6$, $\dim F[x]_{\le 4} = 5$, $\dim F[x]_{\le 3} = 4 = \dim F^{2\times 2}$.
Hint 2. In (c), how small can $\dim \ker T$ be?
Sketch. (a) None: $6 > 5$. (b) $a_0 + a_1 x + a_2 x^2 + a_3 x^3 \mapsto \begin{pmatrix} a_0 & a_1 \\ a_2 & a_3 \end{pmatrix}$. (c) None: $\dim \ker T \ge 5 - 2 = 3$. (d) $T(x_1, x_2, x_3, x_4) = (x_2, x_3, x_4)$.

(a) None. By Example 4.1.7, $\dim F^{2\times 3} = 6 > 5 = \dim F[x]_{\le 4}$, so no linear map between them is injective (Corollary 4.2.21(b)).

(b) $T\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3\right) = \begin{pmatrix} a_0 & a_1 \\ a_2 & a_3 \end{pmatrix}$ is linear (coefficients are added and scaled entrywise) and surjective, indeed bijective.

(c) None. By Corollary 4.2.21(a), every linear map $\mathbb{R}^5 \to \mathbb{R}^2$ has $\dim \ker T \ge 5 - 2 = 3$, while $\dim \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) = 2$.

(d) $T(x_1, x_2, x_3, x_4) = (x_2, x_3, x_4)$ is linear, and $T(\mathbf{x}) = \mathbf{0}$ if and only if $x_2 = x_3 = x_4 = 0$, so $\ker T = \operatorname{span}(\mathbf{e}_1)$. (Rank–nullity allows it: $1 + 3 = 4$.)

Solution to Exercise 4.2.35

Uses. Theorem 4.2.7 (The image of T_A), Remark 3.4.11 (A basis of the kernel), Theorem 4.2.11 (Rank–nullity)
Hint 1. Clear the first column with $-i$ times row 1.
Hint 2. The third row becomes a multiple of the second.
Sketch. $A_r = \begin{pmatrix} 1 & i & 0 & 1 \\ 0 & 0 & 1 & i \\ 0 & 0 & 0 & 0 \end{pmatrix}$, pivot columns $1, 3$. So $(1, i, 0), (0, 1, 1 + i)$ is a basis of $\operatorname{im} T_A$, and the basic solutions $(-i, 1, 0, 0), (-1, 0, -i, 1)$ form a basis of $\ker T_A$; $2 + 2 = 4$.

Adding $-i$ times row 1 to row 2 gives $\left(i - i, -1 - i^2, 1 - 0, 2i - i\right) = (0, 0, 1, i)$. Adding $-(1 + i)$ times this row to row 3 gives $(0, 0, 0, -1 + i - (1 + i)i) = (0, 0, 0, -1 + i - i + 1) = \mathbf{0}$. So

$$A_r = \begin{pmatrix} 1 & i & 0 & 1 \\ 0 & 0 & 1 & i \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

with pivot columns $1, 3$ and free columns $2, 4$. By Theorem 4.2.7, columns 1 and 3 of A, $(1, i, 0)$ and $(0, 1, 1 + i)$, form a basis of $\operatorname{im} T_A$. The basic solutions are $(-i, 1, 0, 0)$ and $(-1, 0, -i, 1)$, a basis of $\ker T_A$ (Remark 3.4.11). Check: $-i\mathbf{a}_1 + \mathbf{a}_2 = (-i + i, 1 - 1, 0) = \mathbf{0}$, and $-\mathbf{a}_1 - i\mathbf{a}_3 + \mathbf{a}_4 = \mathbf{0}$: the first entries give $-1 + 0 + 1 = 0$, the second $-i - i + 2i = 0$, and the third $0 - i(1 + i) + (-1 + i) = 0$. Rank–nullity: $2 + 2 = 4$.

Solution to Exercise 4.2.36

Uses. Theorem 4.2.11 (Rank–nullity), Remark 3.4.11 (A basis of the kernel), Corollary 3.3.19 (Pivot columns, intrinsically)
Hint 1. Over $\mathbb{Q}$, swap rows 1 and 2 to get a pivot in position $(1, 1)$.
Hint 2. Over $\mathbb{F}_3$, reduce the entries first: $-1 = 2$ and $-2 = 1$. Compare the first two columns.

Sketch. Over $\mathbb{Q}$, $M_r = \begin{pmatrix} 1 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{pmatrix}$: rank 3, kernel spanned by $(-2, 0, -1, 1)$. Over $\mathbb{F}_3$, $M_r = \begin{pmatrix} 1 & 2 & 0 & 2 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}$: rank 2, kernel basis $(1, 1, 0, 0), (1, 0, 2, 1)$. An integer relation among the columns stays a relation modulo 3; but $\mathbf{m}_2 - 2\mathbf{m}_1 = (0, 0, 6)$ is zero only modulo 3.

Over $\mathbb{Q}$. Swap rows 1 and 2 and scale the new row 1 by -1, giving $(1, 2, -2, 0)$. Adding 2 times it to row 3 gives $(0, 6, -1, -1)$. Swap this into row 2 and scale by $1/6$; clearing column 2 and then column 3 (with the pivot row $(0, 0, 1, 1)$) gives

$$M_r = \begin{pmatrix} 1 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{pmatrix}.$$

So $\operatorname{rank} M = 3$, $\dim \ker T_M = 4 - 3 = 1$ by Theorem 4.2.11, and the basic solution $(-2, 0, -1, 1)$ is a basis of $\ker T_M$.

Over $\mathbb{F}_3$. Reducing the entries, $M = \begin{pmatrix} 0 & 0 & 1 & 1 \\ 2 & 1 & 2 & 0 \\ 1 & 2 & 0 & 2 \end{pmatrix}$. Swap rows 1 and 3; adding -2 times the new row 1 to row 2 gives $(0, -3, 2, -4) = (0, 0, 2, 2)$. Scaling by $2^{-1} = 2$ gives $(0, 0, 1, 1)$, and subtracting it from row 3 leaves $\mathbf{0}$:

$$M_r = \begin{pmatrix} 1 & 2 & 0 & 2 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

So $\operatorname{rank} M = 2$ and $\dim \ker T_M = 2$, with basic solutions $(-2, 1, 0, 0) = (1, 1, 0, 0)$ and $(-2, 0, -1, 1) = (1, 0, 2, 1)$.

If $\mathbf{x}$ has integer entries and $M\mathbf{x} = \mathbf{0}$ over $\mathbb{Q}$, then every entry of $M\mathbf{x}$ is the integer 0, so it is 0 modulo 3 as well. That is why $(-2, 0, -1, 1)$, read in $\mathbb{F}_3$, is the second basic solution. The converse fails because a combination of the columns can be a nonzero integer vector divisible by 3: $\mathbf{m}_2 - 2\mathbf{m}_1 = (0, 0, 6)$, so $(-2, 1, 0, 0)$ is in the kernel over $\mathbb{F}_3$ but not over $\mathbb{Q}$. (By Corollary 3.3.19, column 2 is free over $\mathbb{F}_3$ precisely because $\mathbf{m}_2 = 2\mathbf{m}_1$ there.)

Solution to Exercise 4.2.37

Uses. Example 4.1.7 (Dimensions of the standard spaces), Theorem 4.2.11 (Rank–nullity), Theorem 4.2.7 (The image of T_A)
Hint 1. The sets $\ker T_A$ and $\operatorname{im} T_A$ do not depend on which scalars we use. They are complex subspaces.
Hint 2. Example 4.1.7(c): a complex space of complex dimension d has real dimension $2d$.
Sketch. $\operatorname{im} T_A$ is a complex subspace of complex dimension $r = \operatorname{rank} A$, so its real dimension is $2r$. Over $\mathbb{R}$, $\mathbb{C}^n$ has dimension $2n$, so rank–nullity gives $\dim_{\mathbb{R}} \ker T_A = 2n - 2r = 2(n - r) = 2 \dim_{\mathbb{C}} \ker T_A$.

The set $\operatorname{im} T_A = \{A\mathbf{x} \mid \mathbf{x} \in \mathbb{C}^n\}$ is the same whether we regard T_A over $\mathbb{C}$ or over $\mathbb{R}$, and it is a subspace over $\mathbb{C}$ of dimension $r = \operatorname{rank} A$ (Theorem 4.2.7). By Example 4.1.7(c), its dimension over $\mathbb{R}$ is $2r$. So the rank of T_A over $\mathbb{R}$ is $2r$. The domain $\mathbb{C}^n$ has real dimension $2n$, so by Theorem 4.2.11 over $\mathbb{R}$, $\dim_{\mathbb{R}} \ker T_A = 2n - 2r$. Over $\mathbb{C}$, $\dim_{\mathbb{C}} \ker T_A = n - r$. Hence $\dim_{\mathbb{R}} \ker T_A = 2 \dim_{\mathbb{C}} \ker T_A$, which also follows from Example 4.1.7(c) applied to the complex subspace $\ker T_A$.

Solution to Exercise 4.2.38

Uses. Corollary 4.2.21 (Dimension obstructions), Theorem 4.2.11 (Rank–nullity), Example 4.1.7 (Dimensions of the standard spaces)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Items (a), (b), (c), and (e) are about dimensions only. Use rank–nullity.
Hint 2. For (d), look for two maps $\mathbb{R}^2 \to \mathbb{R}^2$ that kill the same line but send the other directions to different lines.
Sketch. (a) True: $\dim \ker T \geq 7 - 4$. (b) True: $\dim W = \operatorname{rank} T \leq 5$. (c) False: $6 > 5$. (d) False: $(x, y) \mapsto (x, 0)$ and $(x, y) \mapsto (0, x)$. (e) True: $\dim V = 2 \dim \ker T$.

(a) True, by Corollary 4.2.21(a): $\dim \ker T \geq 7 - 4 = 3$.

(b) True. $W = \operatorname{im} T$, so $\dim W = \operatorname{rank} T = 5 - \dim \ker T \leq 5$ by Theorem 4.2.11.

(c) False. $\dim F^{2\times 3} = 6 > 5 = \dim F[x]_{\leq 4}$ (Example 4.1.7), so no linear map between them is injective (Corollary 4.2.21(b)).

(d) False. Let $S(x, y) = (x, 0)$ and $T(x, y) = (0, x)$ on $\mathbb{R}^2$. Both have kernel $\operatorname{span}(\mathbf{e}_2)$, but $\operatorname{im} S = \operatorname{span}(\mathbf{e}_1)$ and $\operatorname{im} T = \operatorname{span}(\mathbf{e}_2)$. (They do have images of the same dimension, by rank–nullity.)

(e) True. By Theorem 4.2.11, $\dim V = \dim \ker T + \dim \operatorname{im} T = 2 \dim \ker T$.

Solution to Exercise 4.2.39

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 1.5.24 (Distinct degrees), Theorem 4.1.10 (Independent lists are short), Example 2.1.9 (Maps of polynomials)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Find polynomials with $T(p) = (1, 0)$ and $T(p) = (0, 1)$.
Hint 2. Rank–nullity gives $\dim \ker T$. Two independent vectors in a 2-dimensional space are a basis.
Sketch. $T(1) = (1, 0)$ and $T(x - 1) = (0, 1)$, so T is surjective and $\dim \ker T = 4 - 2 = 2$. Expanding, $(x - 1)^2$ and $(x - 1)^3$ vanish at 1 together with their derivatives, and they have distinct degrees, so they are an independent list of length 2 in $\ker T$.

T is linear, as evaluation and the formal derivative are (Example 2.1.9). Since $T(1) = (1, 0)$ and $T(x - 1) = (0, 1)$, the image contains a basis of F^2, so T is surjective, and $\dim \ker T = 4 - 2 = 2$ by Theorem 4.2.11.

Now $(x - 1)^2 = x^2 - 2x + 1$ has derivative $2x - 2$, and $(x - 1)^3 = x^3 - 3x^2 + 3x - 1$ has derivative $3x^2 - 6x + 3$. Both polynomials and both derivatives vanish at 1, so both polynomials lie in $\ker T$. They are nonzero with degrees 2 and 3, so they are independent (Proposition 1.5.24). An independent list of length $2 = \dim \ker T$ in $\ker T$ is a basis of it (Theorem 4.1.10(b)). Every step is valid over every field.

Solution to Exercise 4.2.40

Uses. Example 2.1.9 (Maps of polynomials), Proposition 1.1.17 (No zero divisors), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Proposition 1.6.7 (Standard bases)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. $D\left(\sum_j a_j x^j\right) = \sum_{j\geq 1} j a_j x^{j-1}$. When is $j a_j = 0$ in $\mathbb{F}_p$?
Hint 2. Which monomials can be values of D? Count them and compare with rank D.
Sketch. $j a_j = 0$ iff $p \mid j$ or $a_j = 0$, so $\ker D = \operatorname{span}\left(x^j \mid p \mid j\right)$, of dimension $\lfloor n/p \rfloor + 1$, and $\operatorname{rank} D = n - \lfloor n/p \rfloor$. Every value of D is a combination of the x^{j-1} with $1 \leq j \leq n$ and $p \nmid j$; there are $n - \lfloor n/p \rfloor$ of these, so they span $\operatorname{im} D$. For $p = 3$, $n = 7$: $\ker D = \operatorname{span}\left(1, x^3, x^6\right)$, $\operatorname{im} D = \operatorname{span}\left(1, x, x^3, x^4, x^6\right)$.

For $f = \sum_{j=0}^{n} a_j x^j$, $D(f) = \sum_{j=1}^{n} j a_j x^{j-1}$, where $j a_j$ means $(j \cdot 1) a_j$ in $\mathbb{F}_p$. So $D(f) = \mathbf{0}$ if and only if $j a_j = 0$ for $1 \leq j \leq n$. If $p \mid j$, then $j \cdot 1 = 0$ and this holds for every a_j; if $p \nmid j$, then $j \cdot 1 \neq 0$ and it forces $a_j = 0$ (Proposition 1.1.17). Hence

$$\ker D = \operatorname{span}\left(x^j \mid 0 \leq j \leq n,\ p \mid j\right) = \operatorname{span}\left(1, x^p, x^{2p}, \ldots, x^{\lfloor n/p \rfloor p}\right),$$

and these monomials are independent, being part of the standard basis (Proposition 1.6.7). So $\operatorname{nullity} D = \lfloor n/p \rfloor + 1$, and by Theorem 4.2.11, $\operatorname{rank} D = (n + 1) - (\lfloor n/p \rfloor + 1) = n - \lfloor n/p \rfloor$.

Let $J = \{j \mid 1 \leq j \leq n,\ p \nmid j\}$, which has $n - \lfloor n/p \rfloor$ elements, and $S = \operatorname{span}\left(x^{j-1} \mid j \in J\right)$, of dimension $|J|$. Every value $D(p) = \sum_{j\in J} j a_j x^{j-1}$ lies in S, so $\operatorname{im} D \subseteq S$, and both have dimension $n - \lfloor n/p \rfloor$. By Proposition 4.1.21(b), $\operatorname{im} D = S$: the image is spanned by the monomials x^i with $0 \leq i \leq n - 1$ and $i + 1$ not divisible by p.

For $p = 3$ and $n = 7$: $\ker D = \operatorname{span}\left(1, x^3, x^6\right)$, $\operatorname{nullity} D = 3$, $\operatorname{rank} D = 5$, and $J = \{1, 2, 4, 5, 7\}$, so $\operatorname{im} D = \operatorname{span}\left(1, x, x^3, x^4, x^6\right)$. The monomials x^2 and x^5 are not derivatives, because the only candidates x^3 and x^6 have derivative 0.

Solution to Exercise 4.2.41

Uses. Definition 2.4.21 (Transpose), Exercise 4.1.46, Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces)

Techniques. Study a linear map on a space of matrices (Technique 4.2.29)
Hint 1. T is linear because transposition is. The dimensions of the symmetric and skew-symmetric matrices are in Exercise 4.1.46.
Hint 2. Show $\operatorname{im} T \subseteq$ (the claimed space) directly, then compare dimensions.
Hint 3. For (c), what is the (i,i) entry of $X - X^{\mathsf{T}}$?
Sketch. (a) $T(X) = 0$ iff $X = X^{\mathsf{T}}$; symmetric matrices have dimension $n(n+1)/2$, so $\operatorname{rank} T = n^2 - n(n+1)/2 = n(n-1)/2$. (b) $\left(X - X^{\mathsf{T}}\right)^{\mathsf{T}} = -\left(X - X^{\mathsf{T}}\right)$, so $\operatorname{im} T$ lies in the skew-symmetric matrices, which have dimension $n(n-1)/2$ when $1+1 \neq 0$. (c) Values of T are symmetric (as $-1 = 1$) with zero diagonal; that space has basis $U_{ij} + U_{ji}$, $i < j$, so dimension $n(n-1)/2$.

Since $(aX+Y)^{\mathsf{T}} = aX^{\mathsf{T}} + Y^{\mathsf{T}}$ entry by entry (Definition 2.4.21), T is linear.

(a) $T(X) = 0$ if and only if $X = X^{\mathsf{T}}$, so $\ker T$ is the space S of symmetric matrices, and $\dim S = n(n+1)/2$ by Exercise 4.1.46(a). By Theorem 4.2.11, $\operatorname{rank} T = n^2 - n(n+1)/2 = n(n-1)/2$.

(b) Since $\left(X^{\mathsf{T}}\right)^{\mathsf{T}} = X$, we have $\left(X - X^{\mathsf{T}}\right)^{\mathsf{T}} = X^{\mathsf{T}} - X = -\left(X - X^{\mathsf{T}}\right)$, so every value of T is skew-symmetric: $\operatorname{im} T \subseteq K$. If $1+1 \neq 0$, then $\dim K = n(n-1)/2 = \operatorname{rank} T$ (Exercise 4.1.46(b)), so $\operatorname{im} T = K$ by Proposition 4.1.21(b).

(c) Suppose $1+1 = 0$, so $-1 = 1$. By the computation in (b), every value of T satisfies $Y^{\mathsf{T}} = -Y = Y$, so it is symmetric, and its (i,i) entry is $x_{ii} - x_{ii} = 0$. So $\operatorname{im} T \subseteq Z$, the symmetric matrices with zero diagonal. A matrix in Z equals $\sum_{i<j} y_{ij}\left(U_{ij} + U_{ji}\right)$, and these $n(n-1)/2$ matrices are independent (the (i,j) entry of a combination, for $i < j$, is the coefficient of $U_{ij} + U_{ji}$). So $\dim Z = n(n-1)/2 = \operatorname{rank} T$, and $\operatorname{im} T = Z$. Since U_{11} is symmetric but not in Z, the image is a proper subspace of the symmetric matrices.

Solution to Exercise 4.2.42

Uses. Theorem 4.2.11 (Rank–nullity), Example 4.2.25 (Kernels of linear functionals), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.1.10 (Independent lists are short), Lemma 2.4.24 (Matrix units)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Every value $(\mathbf{r}, \mathbf{c})$ of Φ satisfies $\sum_i r_i = \sum_j c_j$. Why? These vectors form the kernel of a nonzero linear functional on F^{2n}.
Hint 2. To see that every such $(\mathbf{r}, \mathbf{c})$ is a value, try $X = \sum_i r_i U_{i1} + \sum_j c_j U_{1j} - sU_{11}$ with $s = \sum_i r_i$.
Hint 3. For (b), there are $(n-1)^2$ matrices; check that they lie in Z_n and are independent.
Sketch. (a) $Z_n = \ker \Phi$. Values of Φ lie in $H = \left\{(\mathbf{r}, \mathbf{c}) \mid \sum r_i = \sum c_j\right\}$, of dimension $2n-1$, and the matrix in the hint shows every element of H is a value. So $\operatorname{rank} \Phi = 2n-1$ and $\dim Z_n = n^2 - 2n + 1$. (b) Each listed matrix has row and column sums 0, and the (i,j) entry of a combination, for $i, j < n$, is the coefficient of the (i,j)th matrix; an independent list of length $\dim Z_n$ is a basis.

(a) Φ is linear, since row and column sums are, and $Z_n = \ker \Phi$. Let $H = \left\{(\mathbf{r}, \mathbf{c}) \in F^{2n} \;\middle|\; r_1 + \cdots + r_n = c_1 + \cdots + c_n\right\}$. Every value of Φ lies in H, since both sums equal the sum of all entries of X. H is the kernel of the linear functional $(\mathbf{r}, \mathbf{c}) \mapsto \sum_i r_i - \sum_j c_j$, which is not zero (it sends $\mathbf{e}_1$ to 1), so $\dim H = 2n-1$ (Example 4.2.25).

Conversely, let $(\mathbf{r}, \mathbf{c}) \in H$ with $s = \sum_i r_i = \sum_j c_j$, and let

$$X = \sum_{i=1}^{n} r_i U_{i1} + \sum_{j=1}^{n} c_j U_{1j} - sU_{11}.$$

For $i \geq 2$, the only entry of row i of X that can be nonzero is r_i; row 1 has sum $r_1 + \sum_j c_j - s = r_1$. For $j \geq 2$, the only entry of column j that can be nonzero is c_j; column 1 has sum $\sum_i r_i + c_1 - s = c_1$. So $\Phi(X) = (\mathbf{r}, \mathbf{c})$, and $\operatorname{im} \Phi = H$. By Theorem 4.2.11,

$$\dim Z_n = n^2 - (2n-1) = (n-1)^2.$$

(b) Let $V_{ij} = U_{ij} - U_{in} - U_{nj} + U_{nn}$ for $i, j \leq n-1$. Row i and row n of V_{ij} contain one 1 and one -1, and so do columns j and n; all other rows and columns are zero. So $V_{ij} \in Z_n$. In a combination $\sum_{i,j<n} c_{ij} V_{ij}$, the only term with a nonzero (i,j) entry for $i, j < n$ is $c_{ij} V_{ij}$, so the combination is 0 only if all $c_{ij} = 0$. These $(n-1)^2$ independent matrices form a basis of Z_n by (a) and Theorem 4.1.10(b).

Solution to Exercise 4.2.43

Uses. Definition 2.4.1 (Matrix product), Theorem 4.2.11 (Rank–nullity), Proposition 2.4.14 (Algebra of matrices), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.6.2 (Bases are independent spanning lists)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29)
Hint 1. Column j of AX is A times column j of X. So when is $AX = 0$?
Hint 2. If $\mathbf{k}_1, \dots, \mathbf{k}_d$ is a basis of $\ker T_A$, let K_{ij} be the $n \times p$ matrix whose column j is $\mathbf{k}_i$ and whose other columns are $\mathbf{0}$. Show these dp matrices form a basis of $\ker L_A$.
Sketch. $AX = 0$ iff every column of X lies in $\ker T_A$. With a basis $\mathbf{k}_1, \dots, \mathbf{k}_d$ of $\ker T_A$, $d = n - \operatorname{rank} A$, the matrices K_{ij} (column j equal to $\mathbf{k}_i$, others zero) form a basis of $\ker L_A$: expand each column, and compare columns for independence. So $\dim \ker L_A = p(n - \operatorname{rank} A)$, and rank–nullity gives $\operatorname{rank} L_A = np - p(n - \operatorname{rank} A) = p \operatorname{rank} A$.

L_A is linear by Proposition 2.4.14. By Definition 2.4.1, column j of AX is $A\mathbf{x}_j$, where $\mathbf{x}_j$ is column j of X. So $AX = 0$ if and only if $\mathbf{x}_j \in \ker T_A$ for every j.

Let $d = \dim \ker T_A = n - \operatorname{rank} A$ (Theorem 4.2.11) and let $\mathbf{k}_1, \dots, \mathbf{k}_d$ be a basis of $\ker T_A$. For $1 \le i \le d$ and $1 \le j \le p$, let $K_{ij} \in F^{n \times p}$ have column j equal to $\mathbf{k}_i$ and all other columns zero. Each K_{ij} lies in $\ker L_A$. If $X \in \ker L_A$, write $\mathbf{x}_j = \sum_i c_{ij}\mathbf{k}_i$; then X and $\sum_{i,j} c_{ij}K_{ij}$ have the same column j for every j, so they are equal, and the K_{ij} span $\ker L_A$. If $\sum_{i,j} c_{ij}K_{ij} = 0$, then column j gives $\sum_i c_{ij}\mathbf{k}_i = \mathbf{0}$, so $c_{ij} = 0$ for all i (Theorem 1.5.5). So the K_{ij} form a basis of $\ker L_A$, and $\dim \ker L_A = dp$. By Theorem 4.2.11,

$$\operatorname{rank} L_A = np - p(n - \operatorname{rank} A) = p \cdot \operatorname{rank} A.$$

Solution to Exercise 4.2.44

Uses. Proposition 4.2.3 (Properties of restriction), Theorem 4.2.11 (Rank–nullity), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. (a) is rank–nullity for $T{\restriction_U}$.
Hint 2. (b) Take a basis $\mathbf{w}_1, \dots, \mathbf{w}_r$ of $\operatorname{im} T$, pick $\mathbf{v}_i$ with $T(\mathbf{v}_i) = \mathbf{w}_i$, and let $U = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_r)$.
Sketch. (a) $\ker(T{\restriction_U}) = U \cap \ker T$; apply rank–nullity to $T{\restriction_U}$. (b) With U as in the hint, $\operatorname{im}(T{\restriction_U}) = \operatorname{span}(\mathbf{w}_i) = \operatorname{im} T$, and $\sum c_i\mathbf{v}_i \in \ker T$ gives $\sum c_i\mathbf{w}_i = \mathbf{0}$, so all $c_i = 0$. For any such U, (a) gives $\dim U = \operatorname{rank} T$. (c) $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ and $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$.

(a) By Proposition 4.2.3(c), $T{\restriction_U} \in \mathrm{L}(U, W)$ has kernel $U \cap \ker T$. By Theorem 4.2.11 applied to it, $\dim U = \dim(U \cap \ker T) + \dim \operatorname{im}(T{\restriction_U})$.

(b) By Theorem 4.2.11, $\operatorname{im} T$ is finite-dimensional; let $\mathbf{w}_1, \dots, \mathbf{w}_r$ be a basis, $r = \operatorname{rank} T$, and choose $\mathbf{v}_i \in V$ with $T(\mathbf{v}_i) = \mathbf{w}_i$. Let $U = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_r)$. By Proposition 2.1.16(a), $\operatorname{im}(T{\restriction_U}) = \operatorname{span}(\mathbf{w}_1, \dots, \mathbf{w}_r) = \operatorname{im} T$. If $\mathbf{u} = \sum_i c_i\mathbf{v}_i \in \ker T$, then $\mathbf{0} = T(\mathbf{u}) = \sum_i c_i\mathbf{w}_i$, so all $c_i = 0$ (Theorem 1.5.5) and $\mathbf{u} = \mathbf{0}$. So $U \cap \ker T = \{\mathbf{0}\}$.

If U is any subspace with these two properties, it is finite-dimensional because V is, and (a) gives $\dim U = \dim \operatorname{im} T + 0 = \operatorname{rank} T$.

(c) $T(x, y, z) = \mathbf{0}$ means $x = -y$ and $z = -y$, so $\ker T = \operatorname{span}((1, -1, 1))$, and $\operatorname{rank} T = 2$, so $\operatorname{im} T = \mathbb{R}^2$. For $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$: $T(\mathbf{e}_1) = (1, 0)$ and $T(\mathbf{e}_3) = (0, 1)$ span $\mathbb{R}^2$, and a vector $(a, 0, c)$ is a multiple $t(1, -1, 1)$ only if $t = 0$. For $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$: $T(\mathbf{e}_1) = (1, 0)$ and $T(\mathbf{e}_2) = (1, 1)$ span $\mathbb{R}^2$, and $(a, b, 0) = t(1, -1, 1)$ forces $t = 0$. So U is not determined by T; only its dimension is.

Solution to Exercise 4.2.45

Uses. Theorem 4.2.11 (Rank–nullity), Theorem 4.1.10 (Independent lists are short), Corollary 1.5.17 (Sublists), Corollary 4.1.11 (Spanning lists are long)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Theorem 4.1.10(b) applies to independent lists *in* $\ker T$. Is each $\mathbf{v}_i$ with $i \le k$ in $\ker T$?
Hint 2. Try $T(x, y) = x$ on $\mathbb{R}^2$ with the basis $(1, 1), (1, 0)$.
Hint 3. To repair, subtract from each $\mathbf{v}_i$ ($i \le k$) a combination of $\mathbf{v}_{k+1}, \dots, \mathbf{v}_n$ with the same image under T.
Sketch. The proof never checks that $\mathbf{v}_1, \dots, \mathbf{v}_k$ lie in $\ker T$. Counterexample: $T(x, y) = x$, $\mathbf{v}_1 = (1, 1)$, $\mathbf{v}_2 = (1, 0)$; $T(\mathbf{v}_2) = 1$ is a basis of $\operatorname{im} T = \mathbb{R}$, but $\mathbf{v}_1 \notin \ker T$. Repair: write $T(\mathbf{v}_i) = \sum_{j>k} c_{ij}T(\mathbf{v}_j)$ and set $\mathbf{v}_{i'} = \mathbf{v}_i - \sum_{j>k} c_{ij}\mathbf{v}_j$; then $\mathbf{v}_{1'}, \dots, \mathbf{v}_{k'}$ is a basis of $\ker T$.

The error. Theorem 4.1.10(b), applied in the vector space $\ker T$, needs an independent list of vectors *of* $\ker T$. The proof never shows that $\mathbf{v}_1, \dots, \mathbf{v}_k$ lie in $\ker T$, and they need not.

Counterexample. Let $T : \mathbb{R}^2 \to \mathbb{R}$, $T(x, y) = x$, with the basis $\mathbf{v}_1 = (1, 1)$, $\mathbf{v}_2 = (1, 0)$ of $\mathbb{R}^2$ and $k = 1$. Then $T(\mathbf{v}_2) = 1$ is a basis of $\operatorname{im} T = \mathbb{R}$, but $T(\mathbf{v}_1) = 1 \neq 0$, so $\mathbf{v}_1$ is not in $\ker T = \operatorname{span}(\mathbf{e}_2)$.

Repair. The claim holds if we also assume $\mathbf{v}_1, \dots, \mathbf{v}_k \in \ker T$; then the proof above is correct. Without that assumption we can modify the $\mathbf{v}_i$. For $i \leq k$, $T(\mathbf{v}_i) \in \operatorname{im} T$, so $T(\mathbf{v}_i) = \sum_{j>k} c_{ij} T(\mathbf{v}_j)$ for some scalars c_{ij}. Let $\mathbf{v}_{i'} = \mathbf{v}_i - \sum_{j>k} c_{ij} \mathbf{v}_j$. Then $T(\mathbf{v}_{i'}) = \mathbf{0}$, and the list $\mathbf{v}_{1'}, \dots, \mathbf{v}_{k'}, \mathbf{v}_{k+1}, \dots, \mathbf{v}_n$ spans V (each $\mathbf{v}_i$ is recovered by adding back a combination of the later vectors) and has length n, so it is a basis (Corollary 4.1.11(b)). Its sublist $\mathbf{v}_{1'}, \dots, \mathbf{v}_{k'}$ is independent (Corollary 1.5.17), lies in $\ker T$, and has length $k = \dim \ker T$, so it is a basis of $\ker T$. In the counterexample, $\mathbf{v}_{1'} = (1, 1) - (1, 0) = (0, 1)$.

Solution to Exercise 4.2.46

> *Uses.* Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations)
> *Techniques.* Dimension counting (Technique 4.2.24)
> *Hint 1.* $T^2 = 0$ says that T kills every value of T. Compare $\operatorname{im} T$ and $\ker T$.
> *Hint 2.* For the construction, send $\mathbf{e}_{k+i} \mapsto \mathbf{e}_i$ for $1 \leq i \leq k$ and every other standard basis vector to $\mathbf{0}$.
> *Sketch.* $T^2 = 0$ iff $\operatorname{im} T \subseteq \ker T$, which forces $k \leq n - k$. Conversely, if $2k \leq n$, the map with $T(\mathbf{e}_{k+i}) = \mathbf{e}_i$ $(i \leq k)$ and $T(\mathbf{e}_j) = \mathbf{0}$ otherwise has image $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_k)$, which it kills.

Only if. If $T^2 = 0$, then $T(T(\mathbf{v})) = \mathbf{0}$ for all $\mathbf{v}$, so $\operatorname{im} T \subseteq \ker T$. By Proposition 4.1.21(a) and Theorem 4.2.11, $k = \dim \operatorname{im} T \leq \dim \ker T = n - k$, so $2k \leq n$.

If. Suppose $2k \leq n$. By Theorem 2.2.1 there is $T \in \mathrm{L}(F^n)$ with $T(\mathbf{e}_{k+i}) = \mathbf{e}_i$ for $1 \leq i \leq k$ (these indices are at most $2k \leq n$) and $T(\mathbf{e}_j) = \mathbf{0}$ for every other j. By Proposition 2.1.16(a), $\operatorname{im} T = \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_k)$, so $\operatorname{rank} T = k$. For $i \leq k$, the index i is not of the form $k + i'$ with $i' \geq 1$, so $T(\mathbf{e}_i) = \mathbf{0}$. Hence $T^2(\mathbf{e}_j) = T(T(\mathbf{e}_j)) = \mathbf{0}$ for every j, since $T(\mathbf{e}_j)$ is $\mathbf{0}$ or some $\mathbf{e}_i$ with $i \leq k$. A linear map that kills a basis is 0, so $T^2 = 0$.

Solution to Exercise 4.2.47

> *Uses.* Corollary 4.2.18 (Injective if and only if surjective), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Example 2.1.9 (Maps of polynomials)
> *Techniques.* Uniqueness gives existence (Technique 3.4.21), Dimension counting (Technique 4.2.24)
> *Hint 1.* Both spaces have dimension 4, so it suffices to show $\ker T = \{\mathbf{0}\}$.
> *Hint 2.* Write $p = a_0 + a_1 x + a_2 x^2 + a_3 x^3$ and compute the four entries of $T(p)$.
> *Sketch.* $T(p) = (a_0, a_1, a_0 + a_1 + a_2 + a_3, a_1 + 2a_2 + 3a_3)$. If this is $\mathbf{0}$, then $a_0 = a_1 = 0$, $a_2 + a_3 = 0$, and $2a_2 + 3a_3 = 0$; subtracting twice the third equation from the fourth gives $a_3 = 0$, then $a_2 = 0$. So T is injective, hence bijective. (b) Solving $a_2 + a_3 = 1$, $2a_2 + 3a_3 = 0$ gives $p = 3x^2 - 2x^3$.

(a) T is linear since evaluation and the formal derivative are (Example 2.1.9). For $p = a_0 + a_1 x + a_2 x^2 + a_3 x^3$, $p' = a_1 + 2a_2 x + 3a_3 x^2$, so

$$T(p) = (a_0, a_1, a_0 + a_1 + a_2 + a_3, a_1 + 2a_2 + 3a_3).$$

If $T(p) = \mathbf{0}$, then $a_0 = a_1 = 0$, $a_2 + a_3 = 0$, and $2a_2 + 3a_3 = 0$. Subtracting twice the third equation from the fourth gives $a_3 = 0$, and then $a_2 = 0$. So $\ker T = \{\mathbf{0}\}$, and T is injective (Theorem 2.6.11). Both spaces have dimension 4, so T is bijective by Corollary 4.2.18. No step divided by anything, so this holds over every field.

(b) We need $a_0 = a_1 = 0$, $a_2 + a_3 = 1$, and $2a_2 + 3a_3 = 0$. Subtracting twice the first of the last two from the second gives $a_3 = -2$, so $a_2 = 3$, and $p = 3x^2 - 2x^3$. Check: $p(1) = 1$, $p' = 6x - 6x^2$ vanishes at 0 and 1.

Solution to Exercise 4.2.48

> *Uses.* Example 4.2.28 (Sums of powers)
> *Hint 1.* By Example 4.2.28 such a p exists. Try $p = ax^4 + bx^3 + cx^2 + dx$, and compute $\Delta(x^4) = 4x^3 + 6x^2 + 4x + 1$.
> *Hint 2.* Telescoping gives $\sum_{t=0}^{N-1} t^3 = p(N) - p(0)$. Then replace N by $N + 1$.
> *Sketch.* $\Delta p = 4ax^3 + (6a + 3b)x^2 + (4a + 3b + 2c)x + (a + b + c + d)$, so $a = 1/4$, $b = -1/2$, $c = 1/4$, $d = 0$, and $p = (x(x-1)/2)^2$. Then $\sum_{t=0}^{N-1} t^3 = (N(N-1)/2)^2$; replace N by $N + 1$.

Using $\Delta(x^4) = 4x^3 + 6x^2 + 4x + 1$, $\Delta(x^3) = 3x^2 + 3x + 1$, $\Delta(x^2) = 2x + 1$, and $\Delta(x) = 1$, for $p = ax^4 + bx^3 + cx^2 + dx$ (a constant term may be dropped, since constants lie in $\ker \Delta$) we get

$$\Delta p = 4ax^3 + (6a + 3b)x^2 + (4a + 3b + 2c)x + (a + b + c + d).$$

Setting this equal to x^3: $a = 1/4$; $6a + 3b = 0$ gives $b = -1/2$; $4a + 3b + 2c = 0$ gives $c = 1/4$; and $a + b + c + d = 0$ gives $d = 0$. So

$$p = \frac{1}{4}x^4 - \frac{1}{2}x^3 + \frac{1}{4}x^2 = \frac{1}{4}x^2(x-1)^2 = \left(\frac{x(x-1)}{2}\right)^2.$$

By the telescoping identity of Example 4.2.28, $0^3 + 1^3 + \cdots + (N-1)^3 = p(N) - p(0) = (N(N-1)/2)^2$ for every $N \geq 1$. Applying this with $N + 1$ in place of N gives $1^3 + \cdots + N^3 = (N(N+1)/2)^2$.

Solution to Exercise 4.2.49

Uses. Proposition 4.2.26 (Subspaces that must meet), Proposition 1.4.16 (Intersections of subspaces), Example 4.2.25 (Kernels of linear functionals)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Induct on k, using Proposition 4.2.26 for the intersection of $U_1 \cap \cdots \cap U_k$ with U_{k+1}.
Hint 2. For (c), in F^n, use the coordinate hyperplanes $x_i = 0$.
Sketch. (a) For $k = 1$ it is trivial; if $X = U_1 \cap \cdots \cap U_k$ satisfies the bound, then $\dim(X \cap U_{k+1}) \geq \dim X + \dim U_{k+1} - n$, which is the bound for $k + 1$. (b) The bound is $(n-1)^2 - (n-2)n = 1$. (c) $U_i = \{\mathbf{x} \in F^n \mid x_i = 0\}$ has dimension $n - 1$, and their intersection is $\{\mathbf{0}\}$.

(a) By induction on k. For $k = 1$ the claim is $\dim U_1 \geq \dim U_1$. Suppose it holds for k, and let $X = U_1 \cap \cdots \cap U_k$, a subspace (Proposition 1.4.16). By Proposition 4.2.26 and the inductive hypothesis,

$$\dim(X \cap U_{k+1}) \geq \dim X + \dim U_{k+1} - n \geq \sum_{i=1}^{k+1} \dim U_i - (k-1)n - n,$$

which is the claim for $k + 1$.

(b) With $k = n - 1$ subspaces of dimension $n - 1$, the bound is $(n-1)(n-1) - (n-2)n = n^2 - 2n + 1 - n^2 + 2n = 1$. So the intersection has dimension at least 1 and contains a nonzero vector.

(c) Choose a basis and identify V with F^n by coordinates. The subspace $U_i = \{\mathbf{x} \in F^n \mid x_i = 0\}$ is the kernel of the nonzero functional $\mathbf{x} \mapsto x_i$, so it has dimension $n - 1$ (Example 4.2.25). A vector in all n of them has every coordinate 0, so $U_1 \cap \cdots \cap U_n = \{\mathbf{0}\}$.

Solution to Exercise 4.2.50

Uses. Exercise 2.6.39, Proposition 2.6.15 (Kernels and images of composites), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24), Proving TFAE (Technique 2.7.1)
Hint 1. Exercise 2.6.39(c) already gives (i) ⇔ (ii) and (iv) ⇔ (v), with no dimension needed.
Hint 2. $\ker T \subseteq \ker T^2$ and $\operatorname{im} T^2 \subseteq \operatorname{im} T$ always. Containment plus equal dimension gives equality.
Hint 3. For the example, try differentiation on $\mathbb{R}[x]$.
Sketch. (i) ⇔ (ii) and (iv) ⇔ (v) are Exercise 2.6.39(c). Since $\ker T \subseteq \ker T^2$, (ii) holds iff the dimensions agree, iff $\operatorname{rank} T^2 = \operatorname{rank} T$ by rank–nullity for T and T^2. Since $\operatorname{im} T^2 \subseteq \operatorname{im} T$, (iv) holds iff the ranks agree. On $\mathbb{R}[x]$, D is surjective, so $\operatorname{im} D^2 = \operatorname{im} D$, but $\ker D \cap \operatorname{im} D$ is the constants.

By Exercise 2.6.39(c), (i) ⇔ (ii) and (iv) ⇔ (v). It remains to connect (ii), (iii), and (iv).

(ii) ⇔ (iii). By Proposition 2.6.15(a), $\ker T \subseteq \ker T^2$. By Proposition 4.1.21(b), applied in $\ker T^2$, they are equal if and only if $\dim \ker T = \dim \ker T^2$. By Theorem 4.2.11 for T and for T^2, $\dim \ker T = \dim V - \operatorname{rank} T$ and $\dim \ker T^2 = \dim V - \operatorname{rank} T^2$. So (ii) holds if and only if $\operatorname{rank} T = \operatorname{rank} T^2$.

(iii) ⇔ (iv). By Proposition 2.6.15(b), $\operatorname{im} T^2 \subseteq \operatorname{im} T$, so by Proposition 4.1.21(b) they are equal if and only if $\operatorname{rank} T^2 = \operatorname{rank} T$.

Infinite dimensions. Let D be differentiation on $\mathbb{R}[x]$. Every polynomial is a derivative, so $\operatorname{im} D = \mathbb{R}[x]$ and $\operatorname{im} D^2 = D(\operatorname{im} D) = \operatorname{im} D$, which is (iv). But $\ker D$ is the constants, which lie in $\operatorname{im} D$, so $\ker D \cap \operatorname{im} D \neq \{\mathbf{0}\}$ and (i) fails. The dimension count in (ii) ⇔ (iii) ⇔ (iv) has nothing to count here.

Solution to Exercise 4.2.51

Uses. Proposition 2.6.15 (Kernels and images of composites), Proposition 4.1.21 (Dimensions of subspaces), Exercise 2.6.39, Theorem 4.2.11 (Rank–nullity), Theorem 2.4.2 (The matrix of a composite)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Dimension counting (Technique 4.2.24)
Hint 1. $\ker T^0 \subseteq \ker T^1 \subseteq \cdots$. If every inclusion up to $\ker T^{n+1}$ were strict, how large would $\dim \ker T^{n+1}$ be?
Hint 2. For (b), if $T^{m+2}\mathbf{v} = \mathbf{0}$, then $T\mathbf{v} \in \ker T^{m+1}$. Induct on m.
Hint 3. For (c), apply Exercise 2.6.39(c) to $S = T^n$.
Sketch. (a) A strict inclusion of subspaces raises the dimension by at least 1, so if all inclusions $\ker T^k \subseteq \ker T^{k+1}$ for $k = 0, \ldots, n$ were strict, $\dim \ker T^{n+1} \geq n+1$. (b) If $\ker T^{m+1} = \ker T^m$ and $T^{m+2}\mathbf{v} = \mathbf{0}$, then $T\mathbf{v} \in \ker T^{m+1} = \ker T^m$, so $\mathbf{v} \in \ker T^{m+1}$; induct. Since $k \leq n \leq 2n$, $\ker T^n = \ker T^k = \ker T^{2n}$. (c) With $S = T^n$, $\ker S^2 = \ker S$, so $\ker S \cap \operatorname{im} S = \{\mathbf{0}\}$; rank–nullity gives the dimensions.

For all $j \geq 0$, $\ker T^j \subseteq \ker T^{j+1}$, since $T^{j+1} = T \circ T^j$ (Proposition 2.6.15(a)).

(a) Suppose, to the contrary, that $\ker T^k \neq \ker T^{k+1}$ for every $k = 0, 1, \ldots, n$. A proper subspace has strictly smaller dimension (Proposition 4.1.21(b)), so $\dim \ker T^{k+1} \geq \dim \ker T^k + 1$ for each such k, and since $\dim \ker T^0 = \dim \ker \mathrm{id}_V = 0$, induction gives $\dim \ker T^{n+1} \geq n+1$. This contradicts $\dim \ker T^{n+1} \leq n$ (Proposition 4.1.21(a)).

(b) We show by induction on $m \geq k$ that $\ker T^{m+1} = \ker T^m$; the case $m = k$ is the hypothesis. Suppose $\ker T^{m+1} = \ker T^m$, and let $\mathbf{v} \in \ker T^{m+2}$. Then $T^{m+1}(T\mathbf{v}) = \mathbf{0}$, so $T\mathbf{v} \in \ker T^{m+1} = \ker T^m$, that is, $T^{m+1}\mathbf{v} = \mathbf{0}$. So $\ker T^{m+2} \subseteq \ker T^{m+1}$, and the other containment always holds. Chaining the equalities, $\ker T^m = \ker T^k$ for all $m \geq k$. With $k \leq n$ from (a), $\ker T^n = \ker T^k = \ker T^{2n}$.

(c) Let $S = T^n$. By (b), $\ker S^2 = \ker T^{2n} = \ker T^n = \ker S$, so $\ker S \cap \operatorname{im} S = \{\mathbf{0}\}$ by Exercise 2.6.39(c). By Theorem 4.2.11, $\dim \ker S + \dim \operatorname{im} S = n$. For $A \in F^{n\times n}$, apply this to $T = T_A$, using $(T_A)^n = T_{A^n}$ (Theorem 2.4.2).

With the direct sums of Section 4.4, (c) says $V = \ker T^n \oplus \operatorname{im} T^n$. This is Fitting's decomposition, the starting point of Section 10.1.

Solution to Exercise 4.2.52

Uses. Proposition 4.2.3 (Properties of restriction), Theorem 4.2.11 (Rank–nullity), Proposition 2.6.15 (Kernels and images of composites), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Restrict to a subspace (Technique 4.2.5), Dimension counting (Technique 4.2.24)
Hint 1. Let $S = T^{k-1}|_{\ker T^k}$. Its kernel is $\ker T^{k-1}$. Show that its image is $\operatorname{im} T^{k-1} \cap \ker T$.
Hint 2. For (b), $\operatorname{im} T^k \subseteq \operatorname{im} T^{k-1}$.
Hint 3. For (c), $n = \dim \ker T^m = d_1 + \cdots + d_m$.
Sketch. (a) $S = T^{k-1}|_{\ker T^k}$ has kernel $\ker T^k \cap \ker T^{k-1} = \ker T^{k-1}$ and image $\operatorname{im} T^{k-1} \cap \ker T$ (a vector $T^{k-1}\mathbf{v}$ lies in $\ker T$ iff $\mathbf{v} \in \ker T^k$). Rank–nullity for S is the claim. (b) The subspaces $\operatorname{im} T^{k-1} \cap \ker T$ shrink as k grows. (c) $n = d_1 + \cdots + d_m \leq m d_1 = m \dim \ker T$.

(a) Let $S = T^{k-1}|_{\ker T^k} : \ker T^k \to V$, which is linear (Proposition 4.2.3(c)). Its kernel is $\ker T^k \cap \ker T^{k-1} = \ker T^{k-1}$, since $\ker T^{k-1} \subseteq \ker T^k$. Its image is $\operatorname{im} T^{k-1} \cap \ker T$: if $\mathbf{v} \in \ker T^k$, then $T^{k-1}\mathbf{v} \in \operatorname{im} T^{k-1}$ and $T\big(T^{k-1}\mathbf{v}\big) = T^k\mathbf{v} = \mathbf{0}$; conversely, if $\mathbf{w} = T^{k-1}\mathbf{v}$ lies in $\ker T$, then $T^k\mathbf{v} = T\mathbf{w} = \mathbf{0}$, so $\mathbf{v} \in \ker T^k$ and $\mathbf{w} = S(\mathbf{v})$. By Theorem 4.2.11 for S,

$$\dim \ker T^k = \dim \ker T^{k-1} + \dim\big(\operatorname{im} T^{k-1} \cap \ker T\big).$$

(b) Since $T^k = T^{k-1} \circ T$, $\operatorname{im} T^k \subseteq \operatorname{im} T^{k-1}$ (Proposition 2.6.15(b)). So $\operatorname{im} T^k \cap \ker T \subseteq \operatorname{im} T^{k-1} \cap \ker T$, and $d_{k+1} \leq d_k$ by (a) and Proposition 4.1.21(a).

(c) If $T^m = 0$, then $\ker T^m = V$, and $\ker T^0 = \{\mathbf{0}\}$, so the sum telescopes:

$$n = \dim \ker T^m - \dim \ker T^0 = d_1 + d_2 + \cdots + d_m \leq m d_1 = m \dim \ker T,$$

using (b). Hence $\dim \ker T \geq n/m$, and $\operatorname{rank} T = n - \dim \ker T \leq n - n/m = (m-1)n/m$.

For $m = 2$ this is the bound $\operatorname{rank} T \leq n/2$ of Exercise 4.2.46. For the shift N on F^4 of Section 4.1.7, $d_1 = d_2 = d_3 = d_4 = 1$; how the d_k can decrease is what Section 10.3 classifies.

Solution to Exercise 4.2.53

Uses. Proposition 4.2.3 (Properties of restriction), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 4.1.21 (Dimensions of subspaces), Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 3.5.14 (Third Fundamental Theorem, completed), Remark 3.5.7 (Inverses of T_A and inverses of A), Proposition 2.4.14 (Algebra of matrices)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. If $(I_m - AB)\mathbf{x} = \mathbf{0}$, then $\mathbf{x} = AB\mathbf{x}$. Compute $(I_n - BA)(B\mathbf{x})$.
Hint 2. If also $B\mathbf{x} = \mathbf{0}$, what is $\mathbf{x}$?
Hint 3. For (b), swap the roles of A and B.
Sketch. If $\mathbf{x} = AB\mathbf{x}$, then $(I_n - BA)B\mathbf{x} = B\mathbf{x} - B(AB\mathbf{x}) = \mathbf{0}$, and $B\mathbf{x} = \mathbf{0}$ forces $\mathbf{x} = A(B\mathbf{x}) = \mathbf{0}$. So $T_B\restriction_{\ker(I_m - AB)}$ is injective into $\ker(I_n - BA)$, giving $\leq$; by symmetry, equality. A square matrix is invertible iff its kernel is $\{\mathbf{0}\}$.

(a) Let $\mathbf{x} \in \ker T_{I_m - AB}$, so $\mathbf{x} = AB\mathbf{x}$. Then

$$(I_n - BA)(B\mathbf{x}) = B\mathbf{x} - B(AB\mathbf{x}) = B\mathbf{x} - B\mathbf{x} = \mathbf{0},$$

so $B\mathbf{x} \in \ker T_{I_n - BA}$. If $B\mathbf{x} = \mathbf{0}$, then $\mathbf{x} = A(B\mathbf{x}) = \mathbf{0}$. So the restriction of T_B to $\ker T_{I_m - AB}$ is linear with kernel $\{\mathbf{0}\}$ (Proposition 4.2.3(c)), hence injective, with image inside $\ker T_{I_n - BA}$.

(b) By (a) and Proposition 4.2.6(b), $\dim\ker(I_m - AB) = \dim\operatorname{im}\left(T_B\restriction_{\ker(I_m - AB)}\right) \leq \dim\ker(I_n - BA)$, using Proposition 4.1.21(a). Applying (a) with the roles of A and B exchanged (and m, n exchanged) gives the reverse inequality.

(c) For a square matrix $C \in F^{k\times k}$, $\ker T_C = \{\mathbf{0}\}$ if and only if $\operatorname{rank} C = k$ (Theorem 3.5.12), if and only if T_C is invertible (Theorem 3.5.14), if and only if C is invertible (Remark 3.5.7). By (b), $\ker(I_m - AB) = \{\mathbf{0}\}$ if and only if $\ker(I_n - BA) = \{\mathbf{0}\}$.

Replacing A by $\lambda^{-1}A$ for a scalar $\lambda \neq 0$ shows $\dim\ker(\lambda I_m - AB) = \dim\ker(\lambda I_n - BA)$: in the language of Section 7.2, AB and BA have the same nonzero eigenvalues, with eigenspaces of the same dimensions, even when $m \neq n$.

Solution to Exercise 4.2.54

Uses. Corollary 4.2.21 (Dimension obstructions), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Definition 2.5.12 (Invertible)
Hint 1. Find an injective linear map from S into F^n. What does a nonzero invertible matrix do to $\mathbf{e}_1$?
Hint 2. For (b), multiply $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ by $\begin{pmatrix} a & b \\ -b & a \end{pmatrix}$.
Hint 3. For (c), you need a matrix M such that M and $I_2 + M$ are both invertible. Recall Exercise 1.1.56.
Sketch. (a) $X \mapsto X\mathbf{e}_1$ is linear $S \to F^n$, and injective: if $X\mathbf{e}_1 = \mathbf{0}$ with $X \neq 0$, then X is invertible and $\mathbf{e}_1 = X^{-1}\mathbf{0} = \mathbf{0}$. So $\dim S \leq n$. (b) $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}\begin{pmatrix} a & b \\ -b & a \end{pmatrix} = (a^2 + b^2)I_2$. (c) $\operatorname{span}(I_2, M)$ with $M = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$: $M(M + I_2) = I_2$.

(a) The map $\varphi : S \to F^n$, $\varphi(X) = X\mathbf{e}_1$, is linear. If $\varphi(X) = \mathbf{0}$ and $X \neq 0$, then X is invertible, so $\mathbf{e}_1 = X^{-1}(X\mathbf{e}_1) = \mathbf{0}$, which is false. So $\ker\varphi = \{0\}$, φ is injective (Theorem 2.6.11), and $\dim S \leq n$ by Corollary 4.2.21(b).

(b) $S = \operatorname{span}(I_2, J)$ with $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, and I_2, J are independent, so $\dim S = 2$. For $(a, b) \neq (0, 0)$,

$$\begin{pmatrix} a & -b \\ b & a \end{pmatrix}\begin{pmatrix} a & b \\ -b & a \end{pmatrix} = \begin{pmatrix} a^2 + b^2 & 0 \\ 0 & a^2 + b^2 \end{pmatrix},$$

and the product in the other order is the same, so $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ has inverse $\left(a^2 + b^2\right)^{-1}\begin{pmatrix} a & b \\ -b & a \end{pmatrix}$, since $a^2 + b^2 > 0$. (This is $\mathbb{C}$ in disguise.)

(c) Let $M = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} \in \mathbb{F}_2^{2\times 2}$ and $S = \operatorname{span}(I_2, M) = \{0, I_2, M, I_2 + M\}$. Over $\mathbb{F}_2$, $M^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} = I_2 + M$, so $M(M + I_2) = M^2 + M = I_2 + M + M = I_2$, and likewise $(M + I_2)M = I_2$. So M and $I_2 + M$ are invertible, as is I_2, and I_2, M are independent, so $\dim S = 2$. (The four matrices multiply like the field $\mathbb{F}_4$ of Exercise 1.1.56, with M as α.)

Solution to Exercise 4.2.55

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.1.19 (Extending linear maps and separating vectors), Theorem 1.5.5 (Independence is decided at zero), Proposition 4.1.34 (Size of a vector space over a finite field)
Hint 1. For (a), with a basis $\mathbf{b}_1, \ldots, \mathbf{b}_k$ of C, consider $\varphi : \mathbb{F}_2^n \to \mathbb{F}_2^k$, $\mathbf{y} \mapsto (\mathbf{b}_1 \cdot \mathbf{y}, \ldots, \mathbf{b}_k \cdot \mathbf{y})$. Its kernel is $C^\perp$. Why is it surjective?
Hint 2. If φ were not surjective, a nonzero linear functional on $\mathbb{F}_2^k$ would vanish on $\operatorname{im}\varphi$ (Proposition 4.1.19(b)). Turn that into a linear relation among the $\mathbf{b}_i$.
Hint 3. For (b), let C be the span of the indicator vectors of the clubs. Show $C \subseteq C^\perp$ and count.
Sketch. (a) $\ker\varphi = C^\perp$ by bilinearity. If $\operatorname{im}\varphi \neq \mathbb{F}_2^k$, some nonzero $f(\mathbf{z}) = \sum a_i z_i$ vanishes on $\operatorname{im}\varphi$, so $(\sum a_i \mathbf{b}_i) \cdot \mathbf{y} = 0$ for all $\mathbf{y}$; taking $\mathbf{y} = \mathbf{e}_j$ gives $\sum a_i \mathbf{b}_i = \mathbf{0}$, contradicting independence. So $\dim C^\perp = n - k$. (b) Indicator vectors satisfy $\mathbf{v}_A \cdot \mathbf{v}_B = |A \cap B| = 0$ in $\mathbb{F}_2$, so their span C satisfies $C \subseteq C^\perp$, whence $\dim C \leq n - \dim C$ and $|C| \leq 2^{\lfloor n/2 \rfloor}$. Unions of the pairs $\{1,2\}, \{3,4\}, \ldots$ attain the bound.

The product is linear in each argument: $(a\mathbf{x} + \mathbf{x}') \cdot \mathbf{y} = a(\mathbf{x} \cdot \mathbf{y}) + \mathbf{x}' \cdot \mathbf{y}$, and symmetrically, directly from the formula.

(a) Let $\mathbf{b}_1, \ldots, \mathbf{b}_k$ be a basis of C and define $\varphi : \mathbb{F}_2^n \to \mathbb{F}_2^k$ by $\varphi(\mathbf{y}) = (\mathbf{b}_1 \cdot \mathbf{y}, \ldots, \mathbf{b}_k \cdot \mathbf{y})$, which is linear. If $\mathbf{y} \in C^\perp$, then $\varphi(\mathbf{y}) = \mathbf{0}$. Conversely, if $\varphi(\mathbf{y}) = \mathbf{0}$ and $\mathbf{c} = \sum_i a_i \mathbf{b}_i \in C$, then $\mathbf{c} \cdot \mathbf{y} = \sum_i a_i (\mathbf{b}_i \cdot \mathbf{y}) = 0$. So $C^\perp = \ker\varphi$, a subspace.

We show that φ is surjective. If not, $\operatorname{im}\varphi$ is a subspace of $\mathbb{F}_2^k$ missing some vector $\mathbf{z}_0$, and by Proposition 4.1.19(b) there is a linear $f : \mathbb{F}_2^k \to \mathbb{F}_2$ with $f(\mathbf{z}_0) = 1$ and $f = 0$ on $\operatorname{im}\varphi$. Writing $a_i = f(\mathbf{e}_i)$, we have $f(\mathbf{z}) = \sum_i a_i z_i$, and not all a_i are 0 since $f \neq 0$. For every $\mathbf{y}$,

$$0 = f(\varphi(\mathbf{y})) = \sum_{i=1}^{k} a_i (\mathbf{b}_i \cdot \mathbf{y}) = \left(\sum_{i=1}^{k} a_i \mathbf{b}_i \right) \cdot \mathbf{y}.$$

Taking $\mathbf{y} = \mathbf{e}_j$ shows that the jth entry of $\sum_i a_i \mathbf{b}_i$ is 0, for every j. So $\sum_i a_i \mathbf{b}_i = \mathbf{0}$ with not all $a_i = 0$, contradicting the independence of the $\mathbf{b}_i$ (Theorem 1.5.5). Hence $\operatorname{rank}\varphi = k$, and by Theorem 4.2.11, $\dim C^\perp = n - k$.

(b) Number the residents $1, \ldots, n$, and for a club $A \subseteq \{1, \ldots, n\}$ let $\mathbf{v}_A \in \mathbb{F}_2^n$ have 1 in the positions of the members and 0 elsewhere. Then $\mathbf{v}_A \cdot \mathbf{v}_B$ counts the common members modulo 2, so it is 0 for any two clubs A, B, including $A = B$ (each club has an even number of members). Let C be the span of all the $\mathbf{v}_A$. By linearity in each argument, $\mathbf{c} \cdot \mathbf{c}' = 0$ for all $\mathbf{c}, \mathbf{c}' \in C$, so $C \subseteq C^\perp$. With $k = \dim C$, (a) gives $k \leq n - k$, so $k \leq n/2$, and as k is an integer, $k \leq \lfloor n/2 \rfloor$. Different clubs have different vectors $\mathbf{v}_A$, all in C, so the number of clubs is at most $|C| = 2^k \leq 2^{\lfloor n/2 \rfloor}$ (Proposition 4.1.34).

For the construction, let $m = \lfloor n/2 \rfloor$ and take as clubs all unions of some of the pairs $\{1,2\}, \{3,4\}, \ldots, \{2m-1, 2m\}$, including the empty union. There are 2^m of them, each a union of pairs, so of even size, and the intersection of two of them is the union of their common pairs, also of even size.

Solution to Exercise 4.2.56

Uses. Theorem 4.2.11 (Rank–nullity), Corollary 2.6.24 (The columns decide), Theorem 4.2.7 (The image of T_A), Proposition 4.2.33 (Distinct columns give distance three), Theorem 4.2.34 (Syndrome decoding)
Hint 1. (a) The columns include $\mathbf{e}_1, \ldots, \mathbf{e}_r$.
Hint 2. (b) Proposition 4.2.33 gives at least 3. For a codeword of weight 3, use three columns adding up to $\mathbf{0}$, such as $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$.
Hint 3. (c) If $H_r\mathbf{x} \neq \mathbf{0}$, the syndrome is one of the columns.
Sketch. (a) T_{H_r} is surjective, so $\operatorname{rank} H_r = r$ and $\dim C_r = n - r$. (b) Distinct nonzero columns give weight ≥ 3; the positions of $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2$ give a codeword of weight 3. (c) If $H_r\mathbf{x} = \mathbf{h}_j$, then $\mathbf{x} + \mathbf{e}_j \in C_r$; if $H_r\mathbf{x} = \mathbf{0}$, $\mathbf{x} \in C_r$. Two codewords within distance 1 of $\mathbf{x}$ are within distance 2 of each other, hence equal.

(a) The vectors $\mathbf{e}_1, \ldots, \mathbf{e}_r$ are among the columns, so the columns span $\mathbb{F}_2^r$, T_{H_r} is surjective (Corollary 2.6.24), and $\operatorname{rank} H_r = \dim \operatorname{im} T_{H_r} = r$ (Theorem 4.2.7). By Theorem 4.2.11, $\dim C_r = n - r$.

(b) The columns are nonzero and pairwise distinct, so every nonzero codeword has weight at least 3 (Proposition 4.2.33). Since $r \geq 2$, the vectors $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathbf{e}_1 + \mathbf{e}_2$ are three different columns, in positions i, j, l say, and their sum is $\mathbf{0}$. So the vector with 1s in positions i, j, l is a codeword of weight 3.

(c) *Existence.* If $H_r\mathbf{x} = \mathbf{0}$, then $\mathbf{x}$ is a codeword. Otherwise $H_r\mathbf{x}$ is a nonzero vector of $\mathbb{F}_2^r$, hence equal to some column $\mathbf{h}_j$, and $H_r(\mathbf{x} + \mathbf{e}_j) = \mathbf{h}_j + \mathbf{h}_j = \mathbf{0}$. So $\mathbf{x} + \mathbf{e}_j$ is a codeword at distance 1 from $\mathbf{x}$.

Uniqueness. If $\mathbf{c}, \mathbf{c}' \in C_r$ are both within distance 1 of $\mathbf{x}$, then $d(\mathbf{c}, \mathbf{c}') \leq 2$ by the triangle inequality, so $\mathbf{c} - \mathbf{c}'$ is a codeword of weight at most 2, and it is $\mathbf{0}$ by (b).

So C_r is perfect: 2^{n-r} codewords, each with $n + 1 = 2^r$ words within distance 1, account for all 2^n words.

Solution to Exercise 4.2.57

Uses. Example 4.2.32 (The Hamming code), Theorem 4.2.34 (Syndrome decoding)
Hint 1. Put the message in positions $3, 5, 6, 7$ and compute $x_1 = x_3 + x_5 + x_7$, $x_2 = x_3 + x_6 + x_7$, $x_4 = x_5 + x_6 + x_7$.
Hint 2. The syndrome is the sum of the columns $\mathbf{h}_j$ at the 1s of the received word; read it as a binary number.
Sketch. (a) 1100110. (b) 1000110 has syndrome $(0, 1, 0) = 2$, so it decodes to 1100110 and the message 0110; 1101011 has syndrome $(1, 1, 0) = 6$, so it decodes to 1101001 and the message 0001. (c) Syndrome $\mathbf{h}_1 + \mathbf{h}_2 = (0, 1, 1) = 3$, so the decoder flips bit 3 and returns 1110000, the wrong codeword.

(a) With $(x_3, x_5, x_6, x_7) = (0, 1, 1, 0)$: $x_1 = 0 + 1 + 0 = 1$, $x_2 = 0 + 1 + 0 = 1$, $x_4 = 1 + 1 + 0 = 0$. The codeword is 1100110.

(b) The word 1000110 has 1s in positions $1, 5, 6$, so its syndrome is $\mathbf{h}_1 + \mathbf{h}_5 + \mathbf{h}_6 = (0, 0, 1) + (1, 0, 1) + (1, 1, 0) = (0, 1, 0)$, binary for 2. By Theorem 4.2.34, flipping bit 2 gives the codeword 1100110, and the message is 0110. The word 1101011 has 1s in positions $1, 2, 4, 6, 7$, with syndrome $(0, 0, 1) + (0, 1, 0) + (1, 0, 0) + (1, 1, 0) + (1, 1, 1) = (1, 1, 0)$, binary for 6. Flipping bit 6 gives 1101001, and the message (positions $3, 5, 6, 7$) is 0001.

(c) The received word 1100000 has syndrome $\mathbf{h}_1 + \mathbf{h}_2 = (0, 1, 1)$, binary for 3, so the decoder flips bit 3 and returns 1110000. That is a codeword (Section 4.2.7), but not the one sent. The code corrects one error; two errors can be mistaken for one error at a third position, since the minimum distance is only 3.

Section 4.3

Solution to Exercise 4.3.2

Uses. Proposition 4.3.1 (Invertible factors preserve rank), Proposition 2.6.18 (The column space is spanned by the columns)
Hint 1. G adds -2 times row 1 to row 2, and H adds -2 times column 1 to column 2.
Hint 2. All three matrices have rank 1, so each kernel and each image is a line. Find a spanning vector for each.
Sketch. $GA = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$ and $AH = \begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}$. The kernels are $\operatorname{span}((-2, 1))$, $\operatorname{span}((-2, 1))$, $\operatorname{span}(\mathbf{e}_2)$, and the images are $\operatorname{span}((1, 2))$, $\operatorname{span}(\mathbf{e}_1)$, $\operatorname{span}((1, 2))$, for A, GA, AH respectively. So GA keeps the kernel of A and moves the image, and AH keeps the image and moves the kernel.

Multiplying out,

$$GA = \begin{pmatrix} 1 & 2 \\ 2-4 & 4-8 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix},$$

$$AH = \begin{pmatrix} 1 & -2+2 \\ 2 & -4+4 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}.$$

The columns of A are $(1, 2)$ and $2(1, 2)$, so $\operatorname{im} A = \operatorname{span}((1, 2))$ (Proposition 2.6.18), and $A\mathbf{x} = \mathbf{0}$ means $x_1 + 2x_2 = 0$, so $\ker A = \operatorname{span}((-2, 1))$. For GA, the columns are $\mathbf{e}_1$ and $2\mathbf{e}_1$, so $\operatorname{im}(GA) = \operatorname{span}(\mathbf{e}_1)$, and $GA\mathbf{x} = \mathbf{0}$ again means $x_1 + 2x_2 = 0$, so $\ker(GA) = \operatorname{span}((-2, 1))$. For AH, the columns are $(1, 2)$ and $\mathbf{0}$, so $\operatorname{im}(AH) = \operatorname{span}((1, 2))$, and $AH\mathbf{x} = x_1(1, 2)$ vanishes exactly when $x_1 = 0$, so $\ker(AH) = \operatorname{span}(\mathbf{e}_2)$.

So $\ker(GA) = \ker A$ but $\operatorname{im}(GA) \neq \operatorname{im} A$, and $\operatorname{im}(AH) = \operatorname{im} A$ but $\ker(AH) \neq \ker A$, as Proposition 4.3.1 and Intuition (Outputs and inputs) predict. All three matrices have rank 1. Note that $\ker(AH) = H^{-1}(\ker A)$: indeed $H^{-1} = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$ and $H^{-1}(-2, 1) = (0, 1)$.

Solution to Exercise 4.3.7

Uses. Theorem 4.3.3 (Rank of a product), Proposition 3.5.2 (First properties of rank), Corollary 3.5.25 (The invertible matrix theorem), Theorem 2.4.34 (Block multiplication)
Hint 1. $\operatorname{rank}(BA) \le \operatorname{rank} A$, and A has only m rows.
Hint 2. For (b), try block matrices built from I_m and zeros.
Hint 3. For (c), sandwich $I_m = (AB)(AB) = A(BA)B$.
Sketch. (a) $\operatorname{rank}(BA) \le \operatorname{rank} A \le m < n$, so BA is not invertible. (b) $A = \begin{pmatrix} I_m & 0 \end{pmatrix}$, $B = \begin{pmatrix} I_m \\ 0 \end{pmatrix}$. (c) $m = \operatorname{rank}(I_m) = \operatorname{rank}(A(BA)B) \le \operatorname{rank}(BA) \le m$.

(a) By Theorem 4.3.3 and Proposition 3.5.2(a), $\operatorname{rank}(BA) \le \operatorname{rank} A \le m < n$. An invertible $n \times n$ matrix has rank n (Corollary 3.5.25), so BA is not invertible.

(b) Let $A = \begin{pmatrix} I_m & 0 \end{pmatrix} \in F^{m \times n}$ and $B = \begin{pmatrix} I_m \\ 0 \end{pmatrix} \in F^{n \times m}$, where the zero blocks have $n - m$ columns and $n - m$ rows. By Theorem 2.4.34, $AB = I_m I_m + 0 \cdot 0 = I_m$. (Here $BA = \begin{pmatrix} I_m & 0 \\ 0 & 0 \end{pmatrix}$, of rank m.)

(c) If $AB = I_m$, then $I_m = (AB)(AB) = A(BA)B$. By Theorem 4.3.3, applied twice,

$$m = \operatorname{rank}(I_m) = \operatorname{rank}(A(BA)B) \le \operatorname{rank}(BA) \le m,$$

so $\operatorname{rank}(BA) = m$.

Solution to Exercise 4.3.11

Uses. Theorem 4.3.8 (Row rank equals column rank), Proposition 4.3.1 (Invertible factors preserve rank), Corollary 4.1.11 (Spanning lists are long)
Hint 1. Subtract twice row 1 from row 2, then scale by $2^{-1} = 3$.
Hint 2. For (b), the row space has dimension rank A. Are rows 1 and 2 multiples of each other?
Sketch. $\operatorname{rref}(A) = \begin{pmatrix} 1 & 0 & 4 & 4 \\ 0 & 1 & 3 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}$, so $\operatorname{rank} A = 2$ and $(1, 0, 4, 4), (0, 1, 3, 2)$ is a basis of the row space. Rows 1 and 2 are not proportional, so they are independent, and two independent vectors in a 2-dimensional space form a basis. Row 3 is row 1 plus twice row 2.

(a) Adding -2 times row 1 to row 2 gives $(0, 1 - 4, 1, -6) = (0, 2, 1, 4)$ in $\mathbb{F}_5$, and scaling by $2^{-1} = 3$ gives $(0, 6, 3, 12) = (0, 1, 3, 2)$. Adding -4 times this row to row 3 gives $(0, 0, 2 - 12, 3 - 8) = (0, 0, 0, 0)$, and adding -2 times it to row 1 gives $(1, 0, -6, -1) = (1, 0, 4, 4)$. So

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & 0 & 4 & 4 \\ 0 & 1 & 3 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$\operatorname{rank} A = 2$, and by the second proof of Theorem 4.3.8 the nonzero rows $(1, 0, 4, 4)$ and $(0, 1, 3, 2)$ form a basis of the row space of A.

(b) The row space has dimension 2. Rows 1 and 2 of A are not proportional (a multiple $c(1, 2, 0, 3)$ with third entry 1 does not exist), so they are linearly independent, and two independent vectors in a 2-dimensional space form a basis. Row 3 must be a combination of them, say row 3 $= a$ (row 1) $+ b$ (row 2). The first entries give $0 = a + 2b$ and the second entries $4 = 2a + b$; so $a = -2b = 3b$ and $4 = 7b = 2b$ in $\mathbb{F}_5$, giving $b = 2$ and $a = 1$. Indeed $(1, 2, 0, 3) + 2(2, 1, 1, 0) = (5, 4, 2, 3) = (0, 4, 2, 3)$ in $\mathbb{F}_5$.

Solution to Exercise 4.3.19

Uses. Proposition 4.3.16 (Rank-one matrices), Example 4.3.18 (Powers of a rank-one matrix)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. Every row is a multiple of $(3, 1, 1)$.
Hint 2. $A^k = (\operatorname{tr} A)^{k-1} A$. Over $\mathbb{F}_2$, reduce the trace modulo 2.
Sketch. (a) $A = (1, 2, -1)(3, 1, 1)^{\mathsf{T}}$, so $\operatorname{rank} A = 1$, $\operatorname{tr} A = 3 + 2 - 1 = 4$, and $A^{10} = 4^9 A = 262144A$. (b) Over $\mathbb{F}_2$, $\operatorname{tr} A = 0$, so $A^2 = 0$.

(a) The rows are 1, 2, and -1 times $(3, 1, 1)$, so $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u} = (1, 2, -1)$ and $\mathbf{v} = (3, 1, 1)$, both nonzero, and $\operatorname{rank} A = 1$ by Proposition 4.3.16. Its trace is $3 + 2 - 1 = 4$, so by Example 4.3.18, $A^{10} = 4^9 A = 262144A$.

(b) Over $\mathbb{F}_2$, $A = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 1 & 1 & 1 \end{pmatrix} = (1,0,1)(1,1,1)^{\mathsf{T}}$, of rank one, with $\operatorname{tr} A = 1+0+1 = 0$. So $A^2 = (\operatorname{tr} A)A = 0$. Directly: $(1,1,1)\cdot(1,0,1) = 2 = 0$ in $\mathbb{F}_2$.

Solution to Exercise 4.3.25

Uses. Theorem 4.3.21 (Column–row factorization), Corollary 4.3.24 (Rank as a number of rank-one pieces)
Hint 1. Clear the first column with row 1. Row 3 is the sum of rows 1 and 2.
Hint 2. The pivot columns are 1 and 3.
Sketch. $\operatorname{rref}(A) = \begin{pmatrix} 1 & i & 0 & 2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$, with pivot columns $1, 3$. So $C = \begin{pmatrix} 1 & 0 \\ i & 1 \\ 1+i & 1 \end{pmatrix}$, $R = \begin{pmatrix} 1 & i & 0 & 2 \\ 0 & 0 & 1 & 0 \end{pmatrix}$, and $A = (1, i, 1+i)(1\ \ i\ \ 0\ \ 2) + (0,1,1)(0\ \ 0\ \ 1\ \ 0)$.

Adding $-i$ times row 1 to row 2 gives $\left(i - i, -1 - i^2, 1, 2i - 2i\right) = (0,0,1,0)$. Row 3 is the sum of rows 1 and 2 of A, so adding -1 times each of them to it gives $\mathbf{0}$. Hence

$$\operatorname{rref}(A) = \begin{pmatrix} 1 & i & 0 & 2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

with pivot columns 1 and 3, and $\operatorname{rank} A = 2$. By Theorem 4.3.21,

$$A = CR, \quad C = \begin{pmatrix} 1 & 0 \\ i & 1 \\ 1+i & 1 \end{pmatrix}, \quad R = \begin{pmatrix} 1 & i & 0 & 2 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

Check: column 2 of CR is $i(1, i, 1+i) = (i, -1, -1+i)$ and column 4 is $2(1, i, 1+i) = (2, 2i, 2+2i)$, the columns of A. By Corollary 4.3.24 and its proof,

$$A = \begin{pmatrix} 1 \\ i \\ 1+i \end{pmatrix}(1\ \ i\ \ 0\ \ 2) + \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}(0\ \ 0\ \ 1\ \ 0).$$

Solution to Exercise 4.3.26

Uses. Proposition 4.3.5 (Rank of a product, exactly), Theorem 4.2.11 (Rank–nullity)
Hint 1. Row 3 of A is the sum of rows 1 and 2, so $\operatorname{rank} A = 2$ and $\ker A$ is a line.
Hint 2. For (b), how small can $\operatorname{rank}(AB)$ be when $\operatorname{rank} B = 2$ and $\dim \ker A = 1$?
Sketch. $\ker A = \operatorname{span}((1,1,-1))$. $\operatorname{im} B_1$ contains $(1,1,-1)$, so $\operatorname{im} B_1 \cap \ker A = \ker A$ and $\operatorname{rank}(AB_1) = 2 - 1 = 1$; $\operatorname{im} B_2 = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ misses it, so $\operatorname{rank}(AB_2) = 2$. (b) No: $\operatorname{rank}(AB) = 2 - \dim(\operatorname{im} B \cap \ker A) \geq 2 - 1 = 1$.

(a) $A\mathbf{x} = \mathbf{0}$ means $x_1 + x_3 = 0$, $x_2 + x_3 = 0$, and $x_1 + x_2 + 2x_3 = 0$, the third being the sum of the first two. So $\ker A = \operatorname{span}((1,1,-1))$ and $\operatorname{rank} A = 2$.

The first column of B_1 is $(1,1,-1)$, so $\ker A \subseteq \operatorname{im} B_1$ and $\operatorname{im} B_1 \cap \ker A = \ker A$, of dimension 1. The columns of B_1 are independent, so $\operatorname{rank} B_1 = 2$, and (4.3.1) gives $\operatorname{rank}(AB_1) = 2 - 1 = 1$. Indeed

$$AB_1 = \begin{pmatrix} 1-1 & 0 \\ 1-1 & 1 \\ 1+1-2 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \\ 0 & 1 \end{pmatrix},$$

which has rank 1.

$\operatorname{im} B_2 = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ consists of the vectors with third entry 0, and the only such multiple of $(1,1,-1)$ is $\mathbf{0}$. So $\operatorname{im} B_2 \cap \ker A = \{\mathbf{0}\}$ and $\operatorname{rank}(AB_2) = 2$. Indeed $AB_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{pmatrix}$, the first two columns of A, which are independent.

(b) No. If $\operatorname{rank} B = 2$, then by (4.3.1), $\operatorname{rank}(AB) = 2 - \dim(\operatorname{im} B \cap \ker A) \geq 2 - \dim \ker A = 1$, so $AB \neq 0$.

Solution to Exercise 4.3.27

Uses. Proposition 4.3.13 (Dimensions of the four subspaces), Definition 4.3.12 (The four fundamental subspaces)
Hint 1. Over either field, row 3 is the sum of rows 1 and 2, and the first two rows are already in RREF.
Hint 2. Over $\mathbb{F}_2$, compare the basic solutions with the rows. Over $\mathbb{Q}$, apply A to a general vector $a(1,1,0,0)+b(0,0,1,1)$ of the row space.
Sketch. Over both fields $\operatorname{rref}(A)=\begin{pmatrix}1&1&0&0\\0&0&1&1\\0&0&0&0\end{pmatrix}$, $r=2$, pivot columns $1,3$. Over $\mathbb{F}_2$: $\operatorname{im}A=\operatorname{span}((1,0,1),(0,1,1))$, $\ker A=\operatorname{span}((1,1,0,0),(0,0,1,1))=\operatorname{im}A^{\mathsf{T}}$, $\ker A^{\mathsf{T}}=\operatorname{span}((1,1,1))$. Over $\mathbb{Q}$: $\ker A=\operatorname{span}((-1,1,0,0),(0,0,-1,1))$, $\ker A^{\mathsf{T}}=\operatorname{span}((1,1,-1))$, and $A(a,a,b,b)=(2a,2b,2a+2b)$ vanishes only for $a=b=0$.

Over any field, row 3 of A is the sum of rows 1 and 2, so subtracting rows 1 and 2 from row 3 gives

$$\operatorname{rref}(A)=\begin{pmatrix}1&1&0&0\\0&0&1&1\\0&0&0&0\end{pmatrix},$$

with $r=2$, pivot columns $1,3$, and free columns $2,4$. Here $m=3$ and $n=4$, so Proposition 4.3.13 predicts dimensions 2, 2, 2, 1.

(a) Over $\mathbb{F}_2$:

- $\operatorname{im}A$ has the basis $(1,0,1),(0,1,1)$, columns 1 and 3 of A.
- The basic solutions are $(-1,1,0,0)=(1,1,0,0)$ and $(0,0,-1,1)=(0,0,1,1)$, a basis of $\ker A$.
- $\operatorname{im}A^{\mathsf{T}}$ has the basis $(1,1,0,0),(0,0,1,1)$, the nonzero rows of $\operatorname{rref}(A)$.
- Row 1 plus row 2 plus row 3 is $(2,2,2,2)=\mathbf{0}$, so $(1,1,1)\in\ker A^{\mathsf{T}}$, which has dimension $3-2=1$; so $\ker A^{\mathsf{T}}=\operatorname{span}((1,1,1))$.

The bases of $\ker A$ and $\operatorname{im}A^{\mathsf{T}}$ are the same list, so $\operatorname{im}A^{\mathsf{T}}=\ker A$. Each row is "orthogonal" to itself: $(1,1,0,0)\cdot(1,1,0,0)=2=0$ in $\mathbb{F}_2$.

(b) Over $\mathbb{Q}$, $\operatorname{im}A=\operatorname{span}((1,0,1),(0,1,1))$ and $\operatorname{im}A^{\mathsf{T}}=\operatorname{span}((1,1,0,0),(0,0,1,1))$ as before. The basic solutions are now $(-1,1,0,0)$ and $(0,0,-1,1)$, and row 1 plus row 2 minus row 3 is $\mathbf{0}$, so $\ker A^{\mathsf{T}}=\operatorname{span}((1,1,-1))$. A vector of the row space is $\mathbf{w}=(a,a,b,b)$, and $A\mathbf{w}=(2a,2b,2a+2b)$. This is $\mathbf{0}$ only if $a=b=0$, since $2\neq 0$ in $\mathbb{Q}$. So $\operatorname{im}A^{\mathsf{T}}\cap\ker A=\{\mathbf{0}\}$. The two computations differ only in whether $1+1=0$.

Solution to Exercise 4.3.28

Uses. Proposition 4.3.16 (Rank-one matrices), Proposition 4.3.13 (Dimensions of the four subspaces), Theorem 4.2.11 (Rank–nullity), Exercise 3.3.50
Hint 1. In (a), A has rank 1, so $A=\mathbf{u}\mathbf{v}^{\mathsf{T}}$. What must $\mathbf{u}$ be, and which condition on $\mathbf{v}$ makes $\ker A$ correct?
Hint 2. In (b) and (e), count dimensions. In (c), every row has dot product 0 with every vector of the null space (Exercise 3.3.50(a)).
Sketch. (a) $A=(1,0,1)(1,-1,1)^{\mathsf{T}}$. (b) None: $\dim\ker A\geq 4-2=2$. (c) None: $(1,1,0)\cdot(1,0,0)=1\neq 0$. (d) $A=\begin{pmatrix}0&1\\0&0\end{pmatrix}$. (e) None: $r=3-r$ is impossible.

(a) Such an A has rank 1, so $A=\mathbf{u}\mathbf{v}^{\mathsf{T}}$, and we may take $\mathbf{u}=(1,0,1)$ (Proposition 4.3.16). Then $A\mathbf{x}=\left(\mathbf{v}^{\mathsf{T}}\mathbf{x}\right)\mathbf{u}$, so $\ker A=\left\{\mathbf{x}\;\middle|\;\mathbf{v}^{\mathsf{T}}\mathbf{x}=0\right\}$. We need $\mathbf{v}^{\mathsf{T}}(1,1,0)=0$ and $\mathbf{v}^{\mathsf{T}}(0,1,1)=0$, that is, $v_1+v_2=0=v_2+v_3$; take $\mathbf{v}=(1,-1,1)$. Then

$$A=\begin{pmatrix}1\\0\\1\end{pmatrix}\begin{pmatrix}1&-1&1\end{pmatrix}=\begin{pmatrix}1&-1&1\\0&0&0\\1&-1&1\end{pmatrix}.$$

Its kernel contains $(1,1,0)$ and $(0,1,1)$, which are independent, and has dimension $3-1=2$ (Theorem 4.2.11), so it is their span; and $\operatorname{im}A=\operatorname{span}((1,0,1))$.

(b) None. By Theorem 4.2.11, $\dim\ker A=4-\operatorname{rank}A\geq 4-2=2$, while $\dim\operatorname{span}(\mathbf{e}_1)=1$.

(c) None, over every field. By Exercise 3.3.50(a), every vector of the row space has dot product 0 with every vector of the null space, but $(1,1,0)\cdot(1,0,0)=1\neq 0$.

(d) $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$: its image is spanned by its nonzero column $\mathbf{e}_1$, and $A(x_1, x_2) = (x_2, 0)$ vanishes exactly when $x_2 = 0$, so $\ker A = \operatorname{span}(\mathbf{e}_1)$ too.

(e) None. If $\operatorname{im} A = \ker A$, then $\operatorname{rank} A = \dim \ker A = 3 - \operatorname{rank} A$ by Theorem 4.2.11, so $2 \operatorname{rank} A = 3$, which no integer satisfies. In general, a square matrix with $\operatorname{im} A = \ker A$ must have even size.

Solution to Exercise 4.3.29

Uses. Exercise 3.3.50, Proposition 2.4.22 (Transpose is a linear involution), Definition 4.3.12 (The four fundamental subspaces)
Techniques. Transpose to trade rows for columns (Technique 3.2.27), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), think of invertible matrices.
Hint 2. For (b), Exercise 3.3.50(a) describes $\ker A$ in terms of the row space alone. Then transpose for (c).
Hint 3. For (d), find two 2×2 matrices of rank 1 with the same kernel.
Sketch. (a) False: I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ are both invertible. (b) True: $\ker A$ is the set of $\mathbf{x}$ with $\mathbf{w} \cdot \mathbf{x} = 0$ for all $\mathbf{w}$ in the row space. (c) True: apply (b) to A^{T} and B^{T}, whose row spaces are $\operatorname{im} A$ and $\operatorname{im} B$. (d) False: $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.

(a) False. I_2 and $B = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ are both invertible, so both have column space and row space F^2 and null space and left null space $\{\mathbf{0}\}$; but $I_2 \neq B$.

(b) True. By Exercise 3.3.50(a), $\ker A$ is the set of $\mathbf{x} \in F^n$ with $\mathbf{w} \cdot \mathbf{x} = 0$ for every $\mathbf{w}$ in the row space of A. This description involves only the row space, so equal row spaces give equal null spaces.

(c) True. The row space of A^{T} is $\operatorname{im}\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = \operatorname{im} A$ (Proposition 2.4.22), and likewise for B. So if $\operatorname{im} A = \operatorname{im} B$, then A^{T} and B^{T} have the same row space, and (b) gives $\ker A^{\mathsf{T}} = \ker B^{\mathsf{T}}$.

(d) False. Let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. Both send (x_1, x_2) to a vector that is zero exactly when $x_1 = 0$, so $\ker A = \ker B = \operatorname{span}(\mathbf{e}_2)$, but $\operatorname{im} A = \operatorname{span}(\mathbf{e}_1)$ and $\operatorname{im} B = \operatorname{span}(\mathbf{e}_2)$. Parts (b)–(d) show that the row space determines the null space and the column space determines the left null space, but that the null space does not determine the column space.

Solution to Exercise 4.3.30

Uses. Proposition 4.3.5 (Rank of a product, exactly), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. By (4.3.1), $\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A)$. Bound the subtracted term.
Hint 2. For (c), induct on k, applying (a) to $A_1 \cdots A_{k-1}$ and A_k.
Hint 3. For the example in (d), take the shift N with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$.
Sketch. (a) $\dim(\operatorname{im} B \cap \ker A) \leq \dim \ker A = n - \operatorname{rank} A$. (b) Put $\operatorname{rank}(AB) = 0$. (c) Induction: $\operatorname{rank}(PA_k) \geq \operatorname{rank} P + \operatorname{rank} A_k - n$ with $P = A_1 \cdots A_{k-1}$. (d) With all $A_i = A$, $k(n-1) - (k-1)n = n - k$; the shift has rank $N^k = n - k$.

(a) By (4.3.1), $\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A)$. Since $\operatorname{im} B \cap \ker A \subseteq \ker A$, its dimension is at most $\dim \ker A = n - \operatorname{rank} A$ (Proposition 4.1.21(a), Theorem 4.2.11(a)). Hence

$$\begin{aligned} \operatorname{rank}(AB) &\geq \operatorname{rank} B - (n - \operatorname{rank} A) \\ &= \operatorname{rank} A + \operatorname{rank} B - n. \end{aligned}$$

(b) If $AB = 0$, then $0 = \operatorname{rank}(AB) \geq \operatorname{rank} A + \operatorname{rank} B - n$.

(c) By induction on k. For $k = 1$ there is nothing to prove. For $k \geq 2$, let $P = A_1 \cdots A_{k-1}$. By (a), $\operatorname{rank}(PA_k) \geq \operatorname{rank} P + \operatorname{rank} A_k - n$, and by the induction hypothesis,

$$\operatorname{rank} P \geq \operatorname{rank} A_1 + \cdots + \operatorname{rank} A_{k-1} - (k-2)n.$$

Substituting the second inequality into the first gives the claim for k.

(d) With $A_1 = \cdots = A_k = A$, (c) gives $\operatorname{rank}\left(A^k\right) \geq k(n-1) - (k-1)n = n - k$. For the shift $N \in F^{n\times n}$ with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$ for $j \geq 2$, the power N^k sends $\mathbf{e}_j$ to $\mathbf{e}_{j-k}$ for $j > k$ and to $\mathbf{0}$ for $j \leq k$, so $\operatorname{im} N^k = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{n-k})$ and $\operatorname{rank} N^k = n - k$ for $k \leq n$. In particular $\operatorname{rank} N = n - 1$.

Sylvester's inequality is the lower bound that the exact formula hides: the product loses at most $\dim\ker A$ dimensions, because the lost directions lie in $\ker A$.

Solution to Exercise 4.3.31

Uses. Proposition 4.3.5 (Rank of a product, exactly), Proposition 2.6.15 (Kernels and images of composites), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Rewrite the inequality as $\operatorname{rank}(BC) - \operatorname{rank}(A(BC)) \leq \operatorname{rank} B - \operatorname{rank}(AB)$: what A destroys of $\operatorname{im}(BC)$ is at most what it destroys of $\operatorname{im} B$.
Hint 2. Express both sides with (4.3.1). How are $\operatorname{im}(BC)$ and $\operatorname{im} B$ related?
Hint 3. For (b), take $B = I_n$. For (c), take the three matrices A, A^k, A.
Sketch. By (4.3.1), $\operatorname{rank} B - \operatorname{rank}(AB) = \dim(\operatorname{im} B \cap \ker A)$ and $\operatorname{rank}(BC) - \operatorname{rank}(ABC) = \dim(\operatorname{im}(BC) \cap \ker A)$. Since $\operatorname{im}(BC) \subseteq \operatorname{im} B$, the second is at most the first. (b) $B = I_n$. (c) With A, A^k, A: $2\operatorname{rank}\left(A^{k+1}\right) \leq \operatorname{rank}\left(A^k\right) + \operatorname{rank}\left(A^{k+2}\right)$, which rearranges to $d_{k+1} \leq d_k$.

(a) By (4.3.1), applied to A and B and to A and BC,

$$\operatorname{rank} B - \operatorname{rank}(AB) = \dim(\operatorname{im} B \cap \ker A),$$
$$\operatorname{rank}(BC) - \operatorname{rank}(ABC) = \dim(\operatorname{im}(BC) \cap \ker A).$$

By Proposition 2.6.15(b), $\operatorname{im}(BC) \subseteq \operatorname{im} B$, so $\operatorname{im}(BC) \cap \ker A \subseteq \operatorname{im} B \cap \ker A$, and Proposition 4.1.21(a) gives

$$\operatorname{rank}(BC) - \operatorname{rank}(ABC) \leq \operatorname{rank} B - \operatorname{rank}(AB).$$

Rearranging gives (a). In words: of the directions in $\operatorname{im}(BC)$, which is part of $\operatorname{im} B$, the matrix A can destroy no more than it destroys of all of $\operatorname{im} B$.

(b) Let $A \in F^{m\times n}$ and $C \in F^{n\times q}$, and take $B = I_n$ in (a): $\operatorname{rank} A + \operatorname{rank} C \leq \operatorname{rank} I_n + \operatorname{rank}(AC) = n + \operatorname{rank}(AC)$.

(c) Apply (a) to the three $n \times n$ matrices A, A^k, A:

$$\operatorname{rank}\left(A^{k+1}\right) + \operatorname{rank}\left(A^{k+1}\right) \leq \operatorname{rank}\left(A^k\right) + \operatorname{rank}\left(A^{k+2}\right).$$

Rearranged, $\operatorname{rank}\left(A^{k+1}\right) - \operatorname{rank}\left(A^{k+2}\right) \leq \operatorname{rank}\left(A^k\right) - \operatorname{rank}\left(A^{k+1}\right)$, that is, $d_{k+1} \leq d_k$. (For $k = 0$, $A^0 = I_n$.) By rank–nullity, $d_k = \dim\ker A^{k+1} - \dim\ker A^k$, so this is Exercise 4.2.52(b) once more.

Solution to Exercise 4.3.32

Uses. Theorem 4.3.3 (Rank of a product), Exercise 4.3.30, Lemma 2.4.24 (Matrix units), Proposition 2.6.18 (The column space is spanned by the columns), Corollary 1.5.17 (Sublists), Theorem 4.2.7 (The image of T_A)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. The bounds are Theorem 4.3.3 and Sylvester's inequality. For the converse, use matrices made of 0s and a few 1s.
Hint 2. Let A have 1 in positions $(1,1), \ldots, (a,a)$ and 0 elsewhere. Let B have, in its columns $1, \ldots, b$, distinct standard basis vectors $\mathbf{e}_{t_1}, \ldots, \mathbf{e}_{t_b}$. What is AB?
Hint 3. AB keeps exactly the columns $\mathbf{e}_{t_k}$ with $t_k \leq a$. How many of the t_k can you place in $\{1, \ldots, a\}$?
Sketch. Necessity: Theorem 4.3.3 and Exercise 4.3.30(a). Sufficiency: $A = \sum_{i\leq a} \mathbf{e}_i\mathbf{e}_i^{\mathsf{T}}$ and $B = \sum_{k\leq b} \mathbf{e}_{t_k}\mathbf{e}_k^{\mathsf{T}}$ with distinct t_k; then $AB = \sum_{k:t_k\leq a} \mathbf{e}_{t_k}\mathbf{e}_k^{\mathsf{T}}$ has rank $|\{k \mid t_k \leq a\}|$. Take $t_k = k$ for $k \leq r$ and $t_k = a + k - r$ for $r < k \leq b$; this needs $r \leq a$ and $a + b - r \leq n$. For $(5; 3, 4)$, $r \in \{2, 3\}$.

Necessity. By Theorem 4.3.3, $\operatorname{rank}(AB) \leq \min(a, b)$, and by Exercise 4.3.30(a), $\operatorname{rank}(AB) \geq a + b - n$; ranks are nonnegative.

Sufficiency. Let r satisfy the bounds. A matrix whose nonzero columns are distinct standard basis vectors has rank equal to the number of those columns, since its image is spanned by them (Proposition 2.6.18),

they are independent as part of the standard basis (Corollary 1.5.17), and rank is the dimension of the image (Theorem 4.2.7). Let

$$A = \sum_{i=1}^{a} \mathbf{e}_i \mathbf{e}_i^{\mathsf{T}} \in F^{m\times n},$$

whose columns are $\mathbf{e}_1, \dots, \mathbf{e}_a \in F^m$ followed by zeros, so $\operatorname{rank} A = a$. Choose distinct indices $t_1, \dots, t_b \in \{1, \dots, n\}$, specified below, and let

$$B = \sum_{k=1}^{b} \mathbf{e}_{t_k} \mathbf{e}_k^{\mathsf{T}} \in F^{n\times p},$$

whose columns are $\mathbf{e}_{t_1}, \dots, \mathbf{e}_{t_b} \in F^n$ followed by zeros, so $\operatorname{rank} B = b$. By Lemma 2.4.24(c), $\mathbf{e}_i \mathbf{e}_i^{\mathsf{T}} \mathbf{e}_{t_k} \mathbf{e}_k^{\mathsf{T}}$ is $\mathbf{e}_i \mathbf{e}_k^{\mathsf{T}}$ if $t_k = i$ and 0 otherwise, so

$$AB = \sum_{k:t_k \le a} \mathbf{e}_{t_k} \mathbf{e}_k^{\mathsf{T}},$$

whose nonzero columns are the distinct vectors $\mathbf{e}_{t_k}$ with $t_k \le a$. So $\operatorname{rank}(AB)$ is the number of k with $t_k \le a$.

Now take $t_k = k$ for $1 \le k \le r$ and $t_k = a + (k - r)$ for $r < k \le b$. These are distinct, since $r \le a$. They lie in $\{1, \dots, n\}$, since the largest is $a + b - r \le n$ when $r \ge a + b - n$. Exactly $t_1, \dots, t_r$ are at most a, as $r \le b$ and $t_k > a$ for $k > r$. So $\operatorname{rank}(AB) = r$.

The example. With $n = 5$, $a = 3$, $b = 4$: $\max(0, 3 + 4 - 5) = 2$ and $\min(3, 4) = 3$, so $r \in \{2, 3\}$. Take $A = \begin{pmatrix} I_3 & 0 \\ 0 & 0 \end{pmatrix} \in F^{5\times 5}$. For $r = 3$, take $t = (1, 2, 3, 4)$, that is, $B = \begin{pmatrix} I_4 & 0 \\ 0 & 0 \end{pmatrix}$; then $AB = A$ has rank 3. For $r = 2$, take $t = (1, 2, 4, 5)$, that is, B has columns $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_4, \mathbf{e}_5, \mathbf{0}$; then AB has columns $\mathbf{e}_1, \mathbf{e}_2, \mathbf{0}, \mathbf{0}, \mathbf{0}$, of rank 2.

Solution to Exercise 4.3.33

Uses. Proposition 4.3.5 (Rank of a product, exactly), Theorem 4.3.3 (Rank of a product), Proposition 2.4.23 (Transpose of a product), Proposition 2.4.22 (Transpose is a linear involution)
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. (a) is (4.3.1) for the product $A^{\mathsf{T}}A$.
Hint 2. For (b), if $\mathbf{y} = A\mathbf{x}$ and $A^{\mathsf{T}}\mathbf{y} = \mathbf{0}$, compute $\mathbf{y}^{\mathsf{T}}\mathbf{y}$ in two ways.
Hint 3. For (c), $\operatorname{rank} A = \operatorname{rank}\left(A^{\mathsf{T}}A\right) \le \operatorname{rank} A^{\mathsf{T}}$. Now apply the same to A^{T}.
Sketch. (a) is (4.3.1). (b) If $\mathbf{y} = A\mathbf{x} \in \ker A^{\mathsf{T}}$, then $\sum_i y_i^2 = \mathbf{y}^{\mathsf{T}}\mathbf{y} = \mathbf{x}^{\mathsf{T}}A^{\mathsf{T}}\mathbf{y} = 0$, so $\mathbf{y} = \mathbf{0}$. (c) $\operatorname{rank} A = \operatorname{rank}\left(A^{\mathsf{T}}A\right) \le \operatorname{rank} A^{\mathsf{T}}$ by Theorem 4.3.3, and the same for A^{T} gives the reverse; then $\operatorname{rank}\left(AA^{\mathsf{T}}\right) = \operatorname{rank}\left(\left(A^{\mathsf{T}}\right)^{\mathsf{T}}A^{\mathsf{T}}\right) = \operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$.

(a) This is (4.3.1) with A^{T} in the role of A and A in the role of B.

(b) Let $\mathbf{y} \in \operatorname{im} A \cap \ker A^{\mathsf{T}}$, say $\mathbf{y} = A\mathbf{x}$ with $A^{\mathsf{T}}\mathbf{y} = \mathbf{0}$. By Proposition 2.4.23, $\mathbf{y}^{\mathsf{T}} = \mathbf{x}^{\mathsf{T}}A^{\mathsf{T}}$, so

$$y_1^2 + \cdots + y_m^2 = \mathbf{y}^{\mathsf{T}}\mathbf{y} = \mathbf{x}^{\mathsf{T}}\left(A^{\mathsf{T}}\mathbf{y}\right) = \mathbf{x}^{\mathsf{T}}\mathbf{0} = 0.$$

A sum of squares of real numbers is 0 only if every term is 0 (Technique 6.1.9), so $\mathbf{y} = \mathbf{0}$. By (a), $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$.

(c) By (b) and Theorem 4.3.3, $\operatorname{rank} A = \operatorname{rank}\left(A^{\mathsf{T}}A\right) \le \operatorname{rank} A^{\mathsf{T}}$. Applying this to the real matrix A^{T}, whose transpose is A (Proposition 2.4.22), gives $\operatorname{rank} A^{\mathsf{T}} \le \operatorname{rank} A$. So $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$. Finally, (b) for A^{T} gives $\operatorname{rank}\left(AA^{\mathsf{T}}\right) = \operatorname{rank}\left(\left(A^{\mathsf{T}}\right)^{\mathsf{T}}A^{\mathsf{T}}\right) = \operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$.

Over $\mathbb{C}$ the same argument works with the conjugate transpose A^* in place of A^{T}, since $\overline{y_1}y_1 + \cdots + \overline{y_m}y_m = |y_1|^2 + \cdots + |y_m|^2$; this is Proposition 6.5.9. Exercise 4.3.34 shows what goes wrong with A^{T}.

Solution to Exercise 4.3.34

Uses. Exercise 4.3.33, Exercise 3.3.54, Corollary 3.5.25 (The invertible matrix theorem)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)

Hint 1. Look for a nonzero vector $\mathbf{y}$ with $y_1^2 + \cdots + y_m^2 = 0$, and use it as a one-column matrix.
Hint 2. For (c), a rational matrix is a real matrix, and its rank does not depend on which of the two fields we compute in.
Sketch. (a) False: $A = (1,1)^{\mathsf{T}}$ gives $A^{\mathsf{T}}A = 1 + 1 = 0$. (b) False: $A = (1,i)^{\mathsf{T}}$ gives $1 + i^2 = 0$. (c) True, by Exercise 4.3.33 and Exercise 3.3.54. (d) False: $A = \begin{pmatrix} 1 & 0 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$ gives $A^{\mathsf{T}}A = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$. The failing step is "a sum of squares is 0 only if each term is 0".

(a) False. Let $A = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \in \mathbb{F}_2^{2\times 1}$, of rank 1. Then $A^{\mathsf{T}}A = (1 \cdot 1 + 1 \cdot 1) = (0)$, of rank 0.

(b) False. Let $A = \begin{pmatrix} 1 \\ i \end{pmatrix} \in \mathbb{C}^{2\times 1}$, of rank 1. Then $A^{\mathsf{T}}A = \left(1 + i^2\right) = (0)$.

(c) True. A matrix with rational entries is also a real matrix, and by Exercise 3.3.54(a) its reduced row echelon form, hence its rank, is the same over $\mathbb{Q}$ and over $\mathbb{R}$. The same holds for $A^{\mathsf{T}}A$, which also has rational entries. So $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$ over $\mathbb{Q}$ follows from Exercise 4.3.33(b) over $\mathbb{R}$.

(d) False. Over $\mathbb{F}_2$, let $A = \begin{pmatrix} 1 & 0 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$, whose two columns are independent. Then

$$A^{\mathsf{T}}A = \begin{pmatrix} 1+1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix},$$

which has rank 1 and is not invertible (Corollary 3.5.25).

In each false case, the vector $\mathbf{y} = A\mathbf{e}_1$, that is, $(1,1)$, $(1,i)$, or $(1,1,0)$, is nonzero, satisfies $\mathbf{y}^{\mathsf{T}}\mathbf{y} = 0$, and lies in $\operatorname{im} A \cap \ker A^{\mathsf{T}}$, which is exactly what Exercise 4.3.33(a) says must happen when the rank drops. The proof of Exercise 4.3.33(b) used that a sum of squares vanishes only when every term does, which is a property of $\mathbb{R}$ (and of its subfields), not of fields in general.

Solution to Exercise 4.3.35

Uses. Non-example 4.2.8 (The columns of A_r are the wrong vectors), Proposition 4.3.1 (Invertible factors preserve rank), Theorem 4.2.7 (The image of T_A)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Which operations preserve the column space: row operations or column operations?
Hint 2. Try $A = \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$.
Hint 3. The conclusion $\operatorname{rank} A = r$ is still right. Why do $\operatorname{im} A$ and $\operatorname{im} A_r$ have the same dimension even though they are different?
Sketch. The false step is $\operatorname{im} A = \operatorname{im} A_r$: row operations preserve the row space and the relations among the columns, not the column space. For $A = \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$, $\operatorname{im} A = \operatorname{span}((1,2))$ but $\operatorname{im} A_r = \operatorname{span}(\mathbf{e}_1)$. The claim is true. Repair: $A = G^{-1}A_r$, so $\operatorname{rank} A = \operatorname{rank} A_r = r$ by Proposition 4.3.1(a) (or directly by Theorem 4.2.7); the rest of the argument is the second proof of Theorem 4.3.8.

The error. The step "row operations do not change the column space" is false. Row operations preserve the row space and the linear relations among the columns, but they move the columns themselves. For $A = \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$ we have $A_r = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$, so $\operatorname{im} A = \operatorname{span}((1,2))$ while $\operatorname{im} A_r = \operatorname{span}(\mathbf{e}_1)$ (Non-example 4.2.8). In particular the intermediate conclusion $\operatorname{im} A = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_r)$ is false for this A.

The conclusion. The claim is true; it is Theorem 4.3.8. Only the first half of the argument needs repair. With G invertible and $GA = A_r$, Proposition 4.3.1(a) gives $\operatorname{rank} A = \operatorname{rank}(GA) = \operatorname{rank} A_r = r$, although $\operatorname{im} A \neq \operatorname{im} A_r$ in general. (This is also the definition of rank A as the number of pivots, together with Theorem 4.2.7.) The second half is correct as stated: A and A_r have the same row space, and the nonzero rows of A_r are independent. It is the second proof of Theorem 4.3.8.

The two halves are not symmetric: row operations keep the row space as a set, but keep the column space only up to an invertible map, so only its dimension survives.

Solution to Exercise 4.3.36

Uses. Proposition 4.3.5 (Rank of a product, exactly), Theorem 4.2.11 (Rank–nullity), Proposition 2.6.15 (Kernels and images of composites), Example 4.3.4 (A product of rank zero)

Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), see Example 4.3.4.
Hint 2. For (b), what are $\ker A$ and $\operatorname{im} B$ when both ranks are n?
Hint 3. For (c), the columns may avoid each other while the rows do not. Try 2×2 matrices with a single nonzero entry each, in the same column.
Hint 4. For (d), use (4.3.1) with A^k and A: the loss is $\dim\left(\operatorname{im} A^k \cap \ker A\right)$.
Sketch. (a) False: $M = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ give $MN = N$, $NM = 0$. (b) True: $\ker A = \{\mathbf{0}\}$, so $\operatorname{rank}(AB) = \operatorname{rank} B = n$. (c) False: $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ has rank 1. (d) True: $\operatorname{im} A \cap \ker A = \{\mathbf{0}\}$, and $\operatorname{im} A^k \subseteq \operatorname{im} A$, so $\operatorname{rank}\left(A^{k+1}\right) = \operatorname{rank}\left(A^k\right) - \dim\left(\operatorname{im} A^k \cap \ker A\right) = \operatorname{rank}\left(A^k\right)$.

(a) False. With $M = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, we have $MN = N$, of rank 1, and $NM = 0$ (Example 4.3.4).

(b) True. A has n columns and rank n, so $\dim \ker A = 0$ (Theorem 4.2.11). By (4.3.1), $\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A) = n - 0 = n$.

(c) False. Let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. Then $\operatorname{im} A = \operatorname{span}(\mathbf{e}_1)$ and $\operatorname{im} B = \operatorname{span}(\mathbf{e}_2)$ meet only in $\mathbf{0}$, but $A + B = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ has rank $1 < 2$. Here the row spaces coincide. (If both $\operatorname{im} A \cap \operatorname{im} B = \{\mathbf{0}\}$ and $\operatorname{im} A^{\mathsf{T}} \cap \operatorname{im} B^{\mathsf{T}} = \{\mathbf{0}\}$, then the equality does hold, but that needs more work.)

(d) True. By (4.3.1) with $B = A$, the hypothesis says $\operatorname{im} A \cap \ker A = \{\mathbf{0}\}$. For $k \geq 1$, (4.3.1) applied to A and A^k gives

$$\operatorname{rank}\left(A^{k+1}\right) = \operatorname{rank}\left(A^k\right) - \dim\left(\operatorname{im} A^k \cap \ker A\right).$$

Since $A^k = A \circ A^{k-1}$ as maps, $\operatorname{im} A^k \subseteq \operatorname{im} A$ (Proposition 2.6.15(b)), so $\operatorname{im} A^k \cap \ker A \subseteq \operatorname{im} A \cap \ker A = \{\mathbf{0}\}$, and $\operatorname{rank}\left(A^{k+1}\right) = \operatorname{rank}\left(A^k\right)$. By induction, $\operatorname{rank}\left(A^k\right) = \operatorname{rank} A$ for all $k \geq 1$.

Solution to Exercise 4.3.37

Uses. Theorem 3.5.23 (One-sided inverses of square matrices), Proposition 4.3.20 (Rank is subadditive), Proposition 4.3.16 (Rank-one matrices), Corollary 3.5.25 (The invertible matrix theorem)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17), Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Multiply out, using $\mathbf{u}\mathbf{v}^{\mathsf{T}}\mathbf{u}\mathbf{v}^{\mathsf{T}} = s\mathbf{u}\mathbf{v}^{\mathsf{T}}$.
Hint 2. For (b), apply $I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ to $\mathbf{u}$. For the rank, compare I_n with $\left(I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) - \mathbf{u}\mathbf{v}^{\mathsf{T}}$.
Hint 3. $J = \mathbf{1}\mathbf{1}^{\mathsf{T}}$, where $\mathbf{1}$ is the vector of ones.
Sketch. (a) $\left(I + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right)\left(I - (1+s)^{-1}\mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = I + \mathbf{u}\mathbf{v}^{\mathsf{T}} - (1+s)^{-1}(1+s)\mathbf{u}\mathbf{v}^{\mathsf{T}} = I$. (b) $\left(I + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right)\mathbf{u} = (1+s)\mathbf{u} = \mathbf{0}$ with $\mathbf{u} \neq \mathbf{0}$; and $n = \operatorname{rank} I \leq \operatorname{rank}\left(I + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) + 1$. (c) $cJ = (c\mathbf{1})\mathbf{1}^{\mathsf{T}}$, $s = cn$: invertible iff $1 + cn \neq 0$, inverse $I - c(1+cn)^{-1}J$. $I_4 + J$: invertible over $\mathbb{Q}$ (inverse $I - J/5$), not over $\mathbb{F}_5$.

(a) Let $N = \mathbf{u}\mathbf{v}^{\mathsf{T}}$. Then $N^2 = \mathbf{u}\left(\mathbf{v}^{\mathsf{T}}\mathbf{u}\right)\mathbf{v}^{\mathsf{T}} = sN$ (Technique 4.3.17), so

$$\begin{aligned}(I_n + N)\left(I_n - (1+s)^{-1}N\right) &= I_n + N - (1+s)^{-1}(N + sN) \\ &= I_n + N - N = I_n.\end{aligned}$$

A one-sided inverse of a square matrix is two-sided (Theorem 3.5.23), so $I_n + N$ is invertible with the stated inverse.

(b) Suppose $1 + s = 0$. Then $\mathbf{u} \neq \mathbf{0}$, since otherwise $s = 0$. Now $(I_n + N)\mathbf{u} = \mathbf{u} + \mathbf{u}\left(\mathbf{v}^{\mathsf{T}}\mathbf{u}\right) = (1+s)\mathbf{u} = \mathbf{0}$, so $I_n + N$ has a nonzero vector in its kernel and is not invertible (Corollary 3.5.25). Its rank is at most $n - 1$. Also $\mathbf{v} \neq \mathbf{0}$, since $\mathbf{v}^{\mathsf{T}}\mathbf{u} = -1$, so N has rank one (Proposition 4.3.16), and by Proposition 4.3.20,

$$\begin{aligned}n = \operatorname{rank} I_n &= \operatorname{rank}((I_n + N) + (-N)) \\ &\leq \operatorname{rank}(I_n + N) + 1.\end{aligned}$$

So $\operatorname{rank}(I_n + N) = n - 1$.

(c) $J = \mathbf{1}\mathbf{1}^{\mathsf{T}}$, so $cJ = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u} = c\mathbf{1}$ and $\mathbf{v} = \mathbf{1}$, and $s = \mathbf{1}^{\mathsf{T}}(c\mathbf{1}) = cn$, where n means $n \cdot 1 \in F$. By (a) and (b), $I_n + cJ$ is invertible if and only if $1 + cn \neq 0$, and then

$$(I_n + cJ)^{-1} = I_n - \frac{c}{1+cn}J.$$

For $I_4 + J$, $c = 1$ and $1 + cn = 5$. Over $\mathbb{Q}$, $5 \neq 0$, so $(I_4 + J)^{-1} = I_4 - J/5$. Over $\mathbb{F}_5$, $5 = 0$, so $I_4 + J$ is not invertible, and indeed $(I_4 + J)\mathbf{1} = \mathbf{1} + 4\mathbf{1} = 5\mathbf{1} = \mathbf{0}$.

Solution to Exercise 4.3.38

Uses. Proposition 4.3.16 (Rank-one matrices), Example 4.3.18 (Powers of a rank-one matrix), Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17), Cyclicity of trace (Technique 2.4.29)
Hint 1. A rank-one matrix X satisfies $X^2 = (\operatorname{tr} X)X$.
Hint 2. What is the trace of a commutator?
Sketch. $X = AB - BA$ has rank one, so $X^2 = (\operatorname{tr} X)X$ by Example 4.3.18, and $\operatorname{tr} X = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$. Example: $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $AB - BA = B$.

Let $X = AB - BA$. Since $\operatorname{rank} X = 1$, Example 4.3.18 gives $X^2 = (\operatorname{tr} X)X$. By linearity and cyclicity of the trace (Proposition 2.4.27, Proposition 2.4.28), $\operatorname{tr} X = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$. Hence $X^2 = 0$.

For an example, let $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. Then $AB = B$ and $BA = 0$, so $AB - BA = B$, which has rank 1, and indeed $B^2 = 0$.

The hypothesis cannot be weakened to $\operatorname{rank}(AB - BA) \leq 2$: with $A = \mathbf{e}_1\mathbf{e}_2^{\mathsf{T}}$ and $B = \mathbf{e}_2\mathbf{e}_1^{\mathsf{T}}$ in $F^{2\times 2}$, $AB - BA = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$, which has rank 2 and square I_2 over every field.

Solution to Exercise 4.3.39

Uses. Proposition 4.3.20 (Rank is subadditive), Proposition 4.3.16 (Rank-one matrices), Lemma 2.4.24 (Matrix units), Proposition 4.3.1 (Invertible factors preserve rank)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. Write $A = (A + B) + (-B)$ and apply subadditivity.
Hint 2. Changing entry (i, j) by c adds $c\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$.
Hint 3. $M_t = (1 - t)I_5 + tJ$, where J is the all-ones matrix, of rank one.
Sketch. (a) $\operatorname{rank} A \leq \operatorname{rank}(A + B) + \operatorname{rank}(-B)$ and symmetrically. (b) The change adds $c\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$, of rank at most 1; apply (a). (c) $M_t = (1 - t)I_5 + tJ$; for $t \neq 1$, $(1 - t)I_5$ has rank 5 and tJ rank at most 1, so $\operatorname{rank} M_t \geq 4$.

(a) $-B$ has the same image as B, so $\operatorname{rank}(-B) = \operatorname{rank} B$. By Proposition 4.3.20, $\operatorname{rank} A = \operatorname{rank}((A + B) + (-B)) \leq \operatorname{rank}(A + B) + \operatorname{rank} B$, so $\operatorname{rank}(A + B) \geq \operatorname{rank} A - \operatorname{rank} B$. Exchanging A and B gives $\operatorname{rank}(A + B) \geq \operatorname{rank} B - \operatorname{rank} A$.

(b) Changing entry (i, j) of A from a_{ij} to $a_{ij} + c$ replaces A by $A' = A + c\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ (Lemma 2.4.24). The matrix $c\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ has rank 0 (if $c = 0$) or 1 (Proposition 4.3.16). By (a) and Proposition 4.3.20, $\operatorname{rank} A - 1 \leq \operatorname{rank} A' \leq \operatorname{rank} A + 1$.

(c) Let J be the all-ones matrix, $J = \mathbf{1}\mathbf{1}^{\mathsf{T}}$, of rank 1. Then $M_t = (1 - t)I_5 + tJ$. For $t \neq 1$, $(1 - t)I_5$ is invertible, of rank 5, and $\operatorname{rank}(tJ) \leq 1$, so by (a), $\operatorname{rank} M_t \geq 5 - 1 = 4$. (For $t = 1$, $M_1 = J$ has rank 1. By Exercise 4.3.37(c), applied to $I_5 + (t/(1 - t))J$, the rank is exactly 4 only for $t = -1/4$.)

Solution to Exercise 4.3.40

Uses. Proposition 4.3.20 (Rank is subadditive), Proposition 4.3.16 (Rank-one matrices), Proposition 4.3.1 (Invertible factors preserve rank), Theorem 4.3.8 (Row rank equals column rank), Theorem 3.5.13 (Second Fundamental Theorem, completed), Proposition 2.6.15 (Kernels and images of composites), Theorem 3.4.24 (Polynomial interpolation), Corollary 3.5.16 (Lists of vectors in F^m), Theorem 2.4.34 (Block multiplication)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. $(i - j)^2 = i^2 - 2ij + j^2$. Let $\mathbf{1}$, $\mathbf{w}$, $\mathbf{q}$ be the vectors with entries 1, i, i^2.
Hint 2. Write $A = XMX^{\mathsf{T}}$ with $X = (\mathbf{1}\ \mathbf{w}\ \mathbf{q}) \in F^{n\times 3}$ and a 3×3 matrix M. When is M invertible, and when are the columns of X independent?

Hint 3. Over $\mathbb{F}_2$, $-2 = 0$ and $i^2 = i$.
Sketch. (a) $A = \mathbf{q}\mathbf{1}^\mathsf{T} - 2\mathbf{w}\mathbf{w}^\mathsf{T} + \mathbf{1}\mathbf{q}^\mathsf{T}$. (b) $A = XMX^\mathsf{T}$ with $M = \begin{pmatrix} 0 & 0 & 1 \\ 0 & -2 & 0 \\ 1 & 0 & 0 \end{pmatrix}$, invertible when $2 \neq 0$. Rows $1, 2, 3$ of X form the Vandermonde matrix for the distinct nodes $1, 2, 3$, so rank $X = 3$, and T_{X^T} is onto F^3. Hence $\operatorname{im} A = \operatorname{im}(XM) = \operatorname{im} X$, of dimension 3. (c) Over $\mathbb{F}_2$, $a_{ij} = i + j$, so $A = \mathbf{w}\mathbf{1}^\mathsf{T} + \mathbf{1}\mathbf{w}^\mathsf{T}$ has rank 2.

Let $\mathbf{1}, \mathbf{w}, \mathbf{q} \in F^n$ have entries 1, i, and i^2 in position i.

(a) Since $(i-j)^2 = i^2 \cdot 1 - 2ij + 1 \cdot j^2$, entry by entry

$$A = \mathbf{q}\mathbf{1}^\mathsf{T} - 2\mathbf{w}\mathbf{w}^\mathsf{T} + \mathbf{1}\mathbf{q}^\mathsf{T}.$$

Each term has rank at most one (Proposition 4.3.16), so rank $A \leq 3$ by Proposition 4.3.20.

(b) Let $X = (\mathbf{1} \;\; \mathbf{w} \;\; \mathbf{q}) \in F^{n\times 3}$ and $M = \begin{pmatrix} 0 & 0 & 1 \\ 0 & -2 & 0 \\ 1 & 0 & 0 \end{pmatrix}$. By block multiplication (Theorem 2.4.34), $XMX^\mathsf{T} = \mathbf{q}\mathbf{1}^\mathsf{T} - 2\mathbf{w}\mathbf{w}^\mathsf{T} + \mathbf{1}\mathbf{q}^\mathsf{T} = A$. Suppose $2 \neq 0$ in F.

M is invertible. $M^2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, which is invertible since $4 \neq 0$; so M has the inverse $M\left(M^2\right)^{-1}$.

rank $X = 3$. The nodes $1, 2, 3$ of F are distinct, since their differences are 1 and 2, both nonzero. The first three rows of X form the matrix $\begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 4 \\ 1 & 3 & 9 \end{pmatrix}$, which is invertible by Theorem 3.4.24, so its columns are independent. A relation among the columns of X restricts to a relation among the columns of this 3×3 matrix, so the columns of X are independent, and rank $X = 3$ (Corollary 3.5.16(a)).

Conclusion. By Theorem 4.3.8, rank $X^\mathsf{T} = 3$, so $T_{X^\mathsf{T}} : F^n \to F^3$ is surjective. Hence $\operatorname{im} A = \operatorname{im}\left(XMX^\mathsf{T}\right) = \operatorname{im}(XM)$ (Proposition 2.6.15(b)), and $\operatorname{rank}(XM) = \operatorname{rank} X = 3$ (Proposition 4.3.1). So rank $A = 3$.

(c) Over $\mathbb{F}_2$, $-2 = 0$, and i^2 has the same parity as i, so $\mathbf{q} = \mathbf{w}$ and $a_{ij} = i + j$. So $A = \mathbf{w}\mathbf{1}^\mathsf{T} + \mathbf{1}\mathbf{w}^\mathsf{T}$ has rank at most 2. Rows 1 and 2 are $(0, 1, 0, 1, \ldots)$ and $(1, 0, 1, 0, \ldots)$, which are independent, so rank $A \geq 2$ by Theorem 4.3.8. Hence rank $A = 2$ over $\mathbb{F}_2$.

Solution to Exercise 4.3.41

Uses. Proposition 4.3.16 (Rank-one matrices)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^\mathsf{T}$ (Technique 4.3.17)
Hint 1. For "only if", write $A = \mathbf{u}\mathbf{v}^\mathsf{T}$, so $a_{ij} = u_i v_j$.
Hint 2. For "if", assume $A \neq 0$ and fix an entry $a_{kl} \neq 0$. Solve the condition for a_{ij}.
Sketch. If $A = \mathbf{u}\mathbf{v}^\mathsf{T}$, both sides are $u_i u_k v_j v_l$. Conversely, if $a_{kl} \neq 0$, the condition gives $a_{ij} = a_{il}\left(a_{kj}/a_{kl}\right)$, so $A = \mathbf{u}\mathbf{v}^\mathsf{T}$ with $\mathbf{u}$ column l and $v_j = a_{kj}/a_{kl}$. (b) $4 - t^2 = 0$ and $2t^2 - 8 = 0$, and the remaining condition holds for all t: $t = \pm 2$.

(a) *Only if.* If $A = 0$, both sides are 0. If rank $A = 1$, then $A = \mathbf{u}\mathbf{v}^\mathsf{T}$ (Proposition 4.3.16), so $a_{ij} = u_i v_j$, and both sides equal $u_i u_k v_j v_l$.

If. Suppose the condition holds. If $A = 0$, then rank $A = 0$. Otherwise fix k, l with $a_{kl} \neq 0$. For all i, j, the condition gives

$$a_{ij} = a_{il} \cdot \frac{a_{kj}}{a_{kl}}.$$

Let $\mathbf{u} = (a_{1l}, \ldots, a_{ml})$, column l of A, and $\mathbf{v} = (a_{k1}, \ldots, a_{kn})/a_{kl}$. Then $a_{ij} = u_i v_j$ for all i, j, so $A = \mathbf{u}\mathbf{v}^\mathsf{T}$, and rank $A \leq 1$ by Proposition 4.3.16 (in fact $= 1$, since $u_k = a_{kl} \neq 0$ and $v_l = 1$).

(b) The matrix is nonzero, so it has rank 1 exactly when all the conditions in (a) hold. With rows $1, 2$ and columns $(1, 2)$, $(1, 3)$, $(2, 3)$ they read $1 \cdot 4 = t \cdot t$, $1 \cdot 2t = 2 \cdot t$, and $t \cdot 2t = 2 \cdot 4$ (the other choices of indices repeat these or are trivial). The second always holds, and the first and third both say $t^2 = 4$. So $t = 2$ or $t = -2$, giving $\begin{pmatrix} 1 & 2 & 2 \\ 2 & 4 & 4 \end{pmatrix}$ and $\begin{pmatrix} 1 & -2 & 2 \\ -2 & 4 & -4 \end{pmatrix}$.

Solution to Exercise 4.3.42

Uses. Proposition 4.3.20 (Rank is subadditive), Exercise 4.3.30, Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. One inequality always holds: $I_n = A + (I_n - A)$.
Hint 2. If $A^2 = A$, then $A(I_n - A) = 0$. Which inequality bounds $\operatorname{rank} A + \operatorname{rank}(I_n - A)$ from above?
Hint 3. Conversely, show $\ker A \subseteq \operatorname{im}(I_n - A)$, compare dimensions, and conclude $A(I_n - A) = 0$.
Sketch. Always $n = \operatorname{rank} I_n \le \operatorname{rank} A + \operatorname{rank}(I_n - A)$. If $A^2 = A$, then $A(I_n - A) = 0$, and Sylvester gives $\operatorname{rank} A + \operatorname{rank}(I_n - A) \le n$. Conversely, $A\mathbf{x} = \mathbf{0}$ implies $\mathbf{x} = (I_n - A)\mathbf{x}$, so $\ker A \subseteq \operatorname{im}(I_n - A)$; the hypothesis says $\dim \ker A = n - \operatorname{rank} A = \operatorname{rank}(I_n - A)$, so $\ker A = \operatorname{im}(I_n - A)$, that is, $A(I_n - A) = 0$.

By Proposition 4.3.20, $n = \operatorname{rank} I_n = \operatorname{rank}(A + (I_n - A)) \le \operatorname{rank} A + \operatorname{rank}(I_n - A)$ for every A.

If. Suppose $A^2 = A$. Then $A(I_n - A) = A - A^2 = 0$, so by Exercise 4.3.30(b), $\operatorname{rank} A + \operatorname{rank}(I_n - A) \le n$. With the inequality above, equality holds.

Only if. Suppose $\operatorname{rank} A + \operatorname{rank}(I_n - A) = n$. If $A\mathbf{x} = \mathbf{0}$, then $\mathbf{x} = \mathbf{x} - A\mathbf{x} = (I_n - A)\mathbf{x}$, so $\ker A \subseteq \operatorname{im}(I_n - A)$. By Theorem 4.2.11 and the hypothesis, $\dim \ker A = n - \operatorname{rank} A = \operatorname{rank}(I_n - A) = \dim \operatorname{im}(I_n - A)$. By Proposition 4.1.21(b), $\ker A = \operatorname{im}(I_n - A)$. So $A(I_n - A)\mathbf{x} = \mathbf{0}$ for every $\mathbf{x}$, that is, $A - A^2 = 0$.

So a matrix is idempotent exactly when the ranks of A and $I_n - A$ are as small as subadditivity allows. Geometrically, F^n then splits into $\operatorname{im} A$, on which A acts as the identity, and $\ker A = \operatorname{im}(I_n - A)$; this is the decomposition of Section 4.4.

Solution to Exercise 4.3.43

Uses. Theorem 4.3.21 (Column–row factorization), Proposition 3.5.9 (Left inverses), Proposition 3.5.8 (Right inverses from the pivots), Proposition 2.4.28 (Cyclicity of the trace), Proposition 4.3.23 (Factorizations through F^k)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. C has independent columns and R has independent rows. What one-sided inverses do they have?
Hint 2. Multiply $CRCR = CR$ on the left by a left inverse of C and on the right by a right inverse of R.
Hint 3. $\operatorname{tr}(CR) = \operatorname{tr}(RC)$.
Sketch. $\operatorname{rank} C = r$ = number of columns, so $LC = I_r$ for some L; $\operatorname{rank} R = r$ = number of rows, so $RZ = I_r$ for some Z. Multiplying $C(RC)R = CR$ by L on the left and Z on the right gives $RC = I_r$. Then $\operatorname{tr} A = \operatorname{tr}(CR) = \operatorname{tr}(RC) = \operatorname{tr} I_r = r \cdot 1$. Over $\mathbb{F}_2$, I_2 and 0 both have trace 0.

(a) By Theorem 4.3.21, $\operatorname{rank} C = r$, the number of columns of C, and $\operatorname{rank} R = r$, the number of rows of R. By Proposition 3.5.9 and Proposition 3.5.8, there are $L \in F^{r \times n}$ with $LC = I_r$ and $Z \in F^{n \times r}$ with $RZ = I_r$. Since $A^2 = A$, $C(RC)R = CR$. Multiplying on the left by L and on the right by Z,

$$\begin{aligned} RC &= (LC)(RC)(RZ) = L(CRCR)Z \\ &= L(CR)Z = (LC)(RZ) = I_r. \end{aligned}$$

(The same argument works for any factorization $A = XY$ with inner size r, by Proposition 4.3.23.)

(b) By Proposition 2.4.28, $\operatorname{tr} A = \operatorname{tr}(CR) = \operatorname{tr}(RC) = \operatorname{tr} I_r = r \cdot 1$.

(c) In $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$, $r \cdot 1$ is the integer r, so $\operatorname{tr} A = \operatorname{rank} A$ by (b); the idempotent $A = 0$ has trace and rank 0. Over $\mathbb{F}_2$, the idempotents I_2 and 0 have trace $1 + 1 = 0$ and 0, but ranks 2 and 0. In general, (b) determines $\operatorname{rank} A$ only modulo the characteristic of F. For example, the rank of the idempotent $A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ is $1 = \operatorname{tr} A$, which (b) predicts over any field.

Solution to Exercise 4.3.44

Uses. Proposition 4.3.23 (Factorizations through F^k), Proposition 2.4.8 (Four views of the product), Proposition 3.5.9 (Left inverses), Proposition 3.5.8 (Right inverses from the pivots), Corollary 3.5.21 (Invertibility and row equivalence), Corollary 3.3.18 (RREF and row equivalence)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. By Proposition 4.3.23(b), the columns of C and of C' are both bases of $\operatorname{im} A$. Express one basis in terms of the other.
Hint 2. C has a left inverse, so $CX = CY$ implies $X = Y$.

Hint 3. For (b), $R' = P^{-1}R$ says that R' and R are row equivalent.
Sketch. The columns of C form a basis of $\operatorname{im} A$ and the columns of C' lie in it, so $C' = CP$ for a unique P; likewise $C = C'Q$, and $CPQ = C$ gives $PQ = I_r$ by cancelling C, so P is invertible. Then $CR = CPR'$ gives $R = PR'$. (b) If R' is in RREF, then $R' = P^{-1}R$ is row equivalent to the RREF matrix R, so $R' = R$, and then $P = I_r$ and $C' = C$.

By Proposition 4.3.23(b), the columns of C form a basis of $\operatorname{im} A$, and so do the columns of C'. Since $\operatorname{rank} C = r$ is the number of columns of C, C has a left inverse L (Proposition 3.5.9), so $CX = CY$ implies $X = LCX = LCY = Y$. That is, C can be cancelled on the left.

(a) Each column of C' lies in $\operatorname{im} A$, so it is a combination of the columns of C; collecting the coefficients into the columns of $P \in F^{r\times r}$ gives $C' = CP$ (Proposition 2.4.8(b)). Symmetrically, $C = C'Q$ for some Q. Then $C(PQ) = C'Q = C = CI_r$, so $PQ = I_r$ by cancellation. Likewise $C'(QP) = C'$ and C' can be cancelled, so $QP = I_r$. So P is invertible. It is unique: if also $C' = CP'$, then $CP = CP'$ gives $P = P'$. Finally, $CR = A = C'R' = CPR'$, so $R = PR'$ by cancellation, and $R' = P^{-1}R$.

(b) Let R be the first r rows of $\operatorname{rref}(A)$ and suppose R' is in RREF. By (a), $R' = P^{-1}R$ with P^{-1} invertible, so $R' \sim R$ (Corollary 3.5.21); both are in RREF, so $R' = R$ by Corollary 3.3.18(c). Then $R = PR$, and since R has a right inverse Z (Proposition 3.5.8), $I_r = RZ = PRZ = P$. So $C' = C$. (Problem 3.17 proved the uniqueness of C for this R by the same cancellation.)

Solution to Exercise 4.3.45

Uses. Proposition 4.3.23 (Factorizations through F^k), Proposition 3.5.9 (Left inverses), Proposition 3.5.8 (Right inverses from the pivots), Theorem 4.3.3 (Rank of a product), Proposition 4.3.1 (Invertible factors preserve rank), Corollary 3.5.25 (The invertible matrix theorem)
Hint 1. $A^2 = C(RC)R$. Use one-sided inverses of C and R to show $\operatorname{rank}(RC) = \operatorname{rank}(A^2)$.
Hint 2. For (b), compute AX and XA first; both equal $C(RC)^{-1}R$.
Hint 3. For (c), $A = AXA = A^2X$.
Sketch. (a) With $LC = I_r$ and $RZ = I_r$, $RC = L(CRCR)Z = LA^2Z$, so $\operatorname{rank}(RC) \geq \operatorname{rank}(A^2) = r$ and RC is invertible. (b) $AX = CRC(RC)^{-2}R = C(RC)^{-1}R$ and $XA = C(RC)^{-2}RCR = C(RC)^{-1}R$; then $AXA = C(RC)^{-1}RCR = CR$ and $XAX = C(RC)^{-1}RC(RC)^{-2}R = X$. (c) $\operatorname{rank} A = \operatorname{rank}(A^2X) \leq \operatorname{rank}(A^2) \leq \operatorname{rank} A$.

By Proposition 4.3.23(b), C has r independent columns and R has r independent rows, so $\operatorname{rank} C = \operatorname{rank} R = r$, and there are L and Z with $LC = I_r$ and $RZ = I_r$ (Proposition 3.5.9, Proposition 3.5.8).

(a) $A^2 = CRCR$, so $LA^2Z = (LC)(RC)(RZ) = RC$. By Theorem 4.3.3, $\operatorname{rank}(RC) = \operatorname{rank}(LA^2Z) \leq \operatorname{rank}(A^2)$, and also $\operatorname{rank}(A^2) = \operatorname{rank}(C(RC)R) \leq \operatorname{rank}(RC)$. So $\operatorname{rank}(RC) = \operatorname{rank}(A^2) = r$, and the $r \times r$ matrix RC is invertible (Corollary 3.5.25).

(b) Let $K = RC$, invertible by (a), and $X = CK^{-2}R$. Then

$$AX = CRCK^{-2}R = CKK^{-2}R = CK^{-1}R,$$
$$XA = CK^{-2}RCR = CK^{-2}KR = CK^{-1}R,$$

so $AX = XA$. Next, $AXA = CK^{-1}RCR = CK^{-1}KR = CR = A$, and

$$XAX = CK^{-1}RCK^{-2}R = CK^{-1}KK^{-2}R = CK^{-2}R = X.$$

(c) If $AXA = A$ and $AX = XA$, then $A = A(XA) = A(AX) = A^2X$. By Theorem 4.3.3, $\operatorname{rank} A = \operatorname{rank}(A^2X) \leq \operatorname{rank}(A^2) \leq \operatorname{rank} A$. So $\operatorname{rank}(A^2) = \operatorname{rank} A$.

The matrix X is called the *group inverse* of A. If A is invertible, then $r = n$, C and R are invertible, and $X = C(RC)^{-2}R = CC^{-1}R^{-1}C^{-1}R^{-1}R = A^{-1}$. For the projection $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = \mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$, $RC = (1)$ and $X = A$. For $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $\operatorname{rank}(N^2) = 0 < 1$, and no such X exists.

Section 4.4

Solution to Exercise 4.4.11

Uses. Theorem 4.4.7 (Criteria for direct sums), Proposition 1.1.17 (No zero divisors)

Techniques. Compare components (Technique 4.4.8)
Hint 1. For (a), compare coordinates: each of the three vectors has a coordinate equal to 1 where another has 0.
Hint 2. For (b), use (IV) of Theorem 4.4.7: it remains to decide when $U_3 \cap (U_1 + U_2) = \{\mathbf{0}\}$. Solve $c(0,1,1) = a(1,1,0) + b(1,0,1)$.
Sketch. (a) If $a(1,1,0) = b(1,0,1)$, the second coordinates give $a = 0$ and the third give $b = 0$; the other pairs are similar. (b) $c(0,1,1) = (a+b, a, b)$ forces $a = b = c$ and $2c = 0$. If $1+1 \neq 0$, then $c = 0$, so (IV) holds. Over $\mathbb{F}_2$, $(1,1,0) + (1,0,1) + (0,1,1) = \mathbf{0}$ violates (II).

(a) If $a(1,1,0) = b(1,0,1)$, then comparing second coordinates gives $a = 0$, and comparing third coordinates gives $b = 0$, so the common vector is $\mathbf{0}$. In the same way, comparing coordinates shows $U_1 \cap U_3 = \{\mathbf{0}\}$ (from $a(1,1,0) = c(0,1,1)$, the first coordinates give $a = 0$ and the third give $c = 0$) and $U_2 \cap U_3 = \{\mathbf{0}\}$ (from $b(1,0,1) = c(0,1,1)$, the first coordinates give $b = 0$ and the second give $c = 0$).

(b) We check (IV) of Theorem 4.4.7. By (a), $U_2 \cap U_1 = \{\mathbf{0}\}$. Suppose $c(0,1,1) \in U_1 + U_2$, say

$$(0, c, c) = a(1,1,0) + b(1,0,1) = (a+b, a, b).$$

Then $a = c$, $b = c$, and $a + b = 0$, so $(1+1)c = 0$. If $1+1 \neq 0$, then $c = 0$ (Proposition 1.1.17), so $U_3 \cap (U_1 + U_2) = \{\mathbf{0}\}$ and the sum is direct. Over $\mathbb{F}_2$, taking $c = 1$ gives

$$(1,1,0) + (1,0,1) + (0,1,1) = (0,0,0),$$

a decomposition of $\mathbf{0}$ with nonzero components, so (II) fails and the sum is not direct.

So the pairwise intersections are trivial over every field, but directness depends on the field. Over $\mathbb{F}_2$, the three lines lie in the plane $x_1 + x_2 + x_3 = 0$, like the three lines of Non-example 4.4.6(b).

Solution to Exercise 4.4.23

Uses. Example 4.2.25 (Kernels of linear functionals), Proposition 4.4.16 (Complements exist), Proposition 4.4.21 (Two out of three), Proposition 1.2.35 (Zero products)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. U is the kernel of a nonzero linear functional. What is $\dim U$, and what must the dimension of a complement be?
Hint 2. For a nonzero $\mathbf{v}$, when is $U \cap \operatorname{span}(\mathbf{v}) = \{\mathbf{0}\}$? Then apply Proposition 4.4.21.
Sketch. $\dim U = 3$ (Example 4.2.25), so every complement is a line $\operatorname{span}(\mathbf{v})$, $\mathbf{v} \neq \mathbf{0}$ (Proposition 4.4.16(b)). If $\mathbf{v} \in U$, then $\operatorname{span}(\mathbf{v}) \subseteq U$; if $\mathbf{v} \notin U$, then $a\mathbf{v} \in U$ forces $a = 0$. So $\operatorname{span}(\mathbf{v})$ is a complement iff $\mathbf{v} \notin U$, by (i) and (iii) of Proposition 4.4.21. (b) $(1,1,1,1) \in U$ iff $1+1+1+1 = 0$: no over $\mathbb{Q}$ and $\mathbb{F}_3$, yes over $\mathbb{F}_2$.

(a) U is the kernel of the nonzero linear functional $\mathbf{x} \mapsto x_1 + x_2 + x_3 + x_4$, so $\dim U = 3$ (Example 4.2.25). By Proposition 4.4.16(b), every complement of U has dimension $4 - 3 = 1$, so it is $\operatorname{span}(\mathbf{v})$ for some $\mathbf{v} \neq \mathbf{0}$. Conversely, let $\mathbf{v} \neq \mathbf{0}$. If $\mathbf{v} \in U$, then $\operatorname{span}(\mathbf{v}) \subseteq U$ meets U in a nonzero vector and is not a complement. If $\mathbf{v} \notin U$ and $a\mathbf{v} \in U$ with $a \neq 0$, then $\mathbf{v} = a^{-1}(a\mathbf{v}) \in U$, a contradiction; so $U \cap \operatorname{span}(\mathbf{v}) = \{\mathbf{0}\}$. Since also $\dim U + \dim \operatorname{span}(\mathbf{v}) = 3 + 1 = 4$, Proposition 4.4.21 gives $F^4 = U \oplus \operatorname{span}(\mathbf{v})$. So the complements of U are exactly the lines $\operatorname{span}(\mathbf{v})$ with $\mathbf{v} \notin U$ (and then automatically $\mathbf{v} \neq \mathbf{0}$).

(b) By (a), $\operatorname{span}((1,1,1,1))$ is a complement exactly when $(1,1,1,1) \notin U$, that is, when $1+1+1+1 \neq 0$ in F. In $\mathbb{Q}$, $1+1+1+1 = 4 \neq 0$, so yes. In $\mathbb{F}_2$, $1+1+1+1 = 0$, so no: there $(1,1,1,1) \in U$. In $\mathbb{F}_3$, $1+1+1+1 = 1 \neq 0$, so yes.

Solution to Exercise 4.4.30

Uses. Definition 4.4.24 (Projection along a complement), Theorem 4.4.7 (Criteria for direct sums), Example 4.2.25 (Kernels of linear functionals)
Techniques. Split the space with an idempotent (Technique 4.4.28)
Hint 1. Subtract from $\mathbf{x}$ the multiple of $(1,1,1)$ that makes the coordinates sum to 0.
Hint 2. Over $\mathbb{F}_3$, is $(1,1,1)$ in U?
Sketch. With $m = (x_1 + x_2 + x_3)/3$, $\mathbf{x} = (\mathbf{x} - m(1,1,1)) + m(1,1,1)$ is a decomposition, and $t(1,1,1) \in U$ forces $3t = 0$. So $\operatorname{Pr}_{W,U}$ has all entries $1/3$ and $\operatorname{Pr}_{U,W} = I_3 - \operatorname{Pr}_{W,U}$. Over $\mathbb{F}_3$, $1+1+1 = 0$ puts W inside U; the division by 3 is impossible.

(a) For $\mathbf{x} \in \mathbb{Q}^3$, let $m = (x_1 + x_2 + x_3)/3$. The coordinates of $\mathbf{x} - m(1,1,1)$ sum to $(x_1 + x_2 + x_3) - 3m = 0$, so

$$\mathbf{x} = (\mathbf{x} - m(1,1,1)) + m(1,1,1)$$

is a decomposition of $\mathbf{x}$ along U and W. If $t(1,1,1) \in U$, then $3t = 0$ and $t = 0$, so $U \cap W = \{\mathbf{0}\}$. By Theorem 4.4.7, $\mathbb{Q}^3 = U \oplus W$, with $\mathrm{Pr}_{W,U}(\mathbf{x}) = m(1,1,1)$ and $\mathrm{Pr}_{U,W}(\mathbf{x}) = \mathbf{x} - m(1,1,1)$. Their matrices are

$$\mathrm{Pr}_{W,U} : \frac{1}{3}\begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}, \quad \mathrm{Pr}_{U,W} : \frac{1}{3}\begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix}.$$

(b) In $\mathbb{F}_3$, $1 + 1 + 1 = 0$, so $(1,1,1) \in U$ and $W \subseteq U$. Then $U + W = U$, which has dimension 2 (Example 4.2.25), so $U + W \neq \mathbb{F}_3^3$. The step that fails is the division by 3 in the definition of m, since $3 = 0$ in $\mathbb{F}_3$. Correspondingly, the uniqueness argument fails too: $3t = 0$ holds for every $t \in \mathbb{F}_3$.

Solution to Exercise 4.4.33

Uses. Theorem 4.4.19 (Dimension of a sum), Theorem 4.2.11 (Rank–nullity), Theorem 4.2.7 (The image of T_A), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. Write a general vector of U as $(a, a+b, b+c, c)$ and substitute it into the two equations that define W.
Hint 2. Over $\mathbb{Q}$ the first equation becomes $2(a+b+c) = 0$. What does it become over $\mathbb{F}_2$?
Sketch. Over every field, the spanning vectors of U are independent, so $\dim U = 3$, and W is cut out by two independent equations, so $\dim W = 2$. A vector $(a, a+b, b+c, c)$ of U lies in W iff $2(a+b+c) = 0$ and $a = b + c$. Over $\mathbb{Q}$ this forces $a = 0$ and $c = -b$: $U \cap W = \mathrm{span}((0,1,0,-1))$, and $\dim(U + W) = 4$. Over $\mathbb{F}_2$ the first condition is empty, $\dim(U \cap W) = 2$, so $W \subseteq U$ and $\dim(U + W) = 3$.

(a) If $a(1,1,0,0) + b(0,1,1,0) + c(0,0,1,1) = (a, a+b, b+c, c) = \mathbf{0}$, then $a = c = 0$ from the first and last coordinates, and then $b = 0$. So the spanning list of U is independent and $\dim U = 3$; this works over every field. The subspace W is the kernel of the linear map $F^4 \to F^2$ with matrix

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 0 & -1 & 0 \end{pmatrix}.$$

Its first two columns $(1,1)$ and $(1,0)$ are independent, so it has rank 2 (Theorem 4.2.7), and $\dim W = 4 - 2 = 2$ by Theorem 4.2.11.

A general vector of U is $(a, a+b, b+c, c)$. It lies in W if and only if

$$2a + 2b + 2c = 0 \quad \text{and} \quad a = b + c.$$

Over $\mathbb{Q}$, the first condition says $a + b + c = 0$, and together with $a = b + c$ it gives $2a = 0$, so $a = 0$ and $c = -b$. Hence $U \cap W = \{(0, b, 0, -b) \mid b \in \mathbb{Q}\} = \mathrm{span}((0,1,0,-1))$, of dimension 1. By Theorem 4.4.19, $\dim(U + W) = 3 + 2 - 1 = 4$, so $U + W = \mathbb{Q}^4$.

(b) Over $\mathbb{F}_2$ the same arguments give $\dim U = 3$ and $\dim W = 2$ (the matrix is now $\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix}$, with the same first two columns). But $2 = 0$ in $\mathbb{F}_2$, so the first condition holds for every vector of U, and $U \cap W$ consists of the vectors with $a = b + c$:

$$(b + c, c, b + c, c) = b(1,0,1,0) + c(1,1,1,1), \quad b, c \in \mathbb{F}_2.$$

So $\dim(U \cap W) = 2 = \dim W$, which means $W \subseteq U$, and $\dim(U + W) = 3 + 2 - 2 = 3$, so $U + W = U$. This is visible directly: over $\mathbb{F}_2$, each spanning vector of U has an even number of entries 1, so U is the 3-dimensional subspace $x_1 + x_2 + x_3 + x_4 = 0$, and W lies in it by definition. (Over $\mathbb{Q}$, U is the subspace $x_1 - x_2 + x_3 - x_4 = 0$.)

Solution to Exercise 4.4.34

Uses. Non-example 4.4.6 (Sums that are not direct), Proposition 4.4.9 (Grouping summands), Example 4.4.17 (Complements are not unique), Proposition 4.4.16 (Complements exist), Proposition 4.4.21 (Two out of three)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Dimension counting (Technique 4.2.24)
Hint 1. Three of the statements are false, and lines through $\mathbf{0}$ in $\mathbb{R}^2$ give counterexamples to all three.
Hint 2. For the true ones, use Proposition 4.4.9, Proposition 4.4.16(b), and Proposition 4.4.21.

Sketch. (a) False: three lines in $\mathbb{R}^2$. (b) True: a selection of independent subspaces is independent. (c) False: the y-axis and the line $y = x$ are both complements of the x-axis. (d) True: both dimensions are $\dim V - \dim U$. (e) False: U, W the axes of $\mathbb{R}^2$ and X the line $y = x$. (f) True: two out of three.

(a) False. In $\mathbb{R}^2$, the lines $\operatorname{span}(\mathbf{e}_1)$, $\operatorname{span}(\mathbf{e}_2)$, $\operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$ meet pairwise in $\{\mathbf{0}\}$, but their sum is not direct (Non-example 4.4.6(b)).

(b) True, by the last part of Proposition 4.4.9: a selection of independent subspaces is independent.

(c) False. In $\mathbb{R}^2$, with $U = \operatorname{span}(\mathbf{e}_1)$, both $W = \operatorname{span}(\mathbf{e}_2)$ and $X = \operatorname{span}((1,1))$ are complements of U (Example 4.4.17), and $W \neq X$.

(d) True. By Proposition 4.4.16(b), $\dim W = \dim V - \dim U = \dim X$.

(e) False. In $\mathbb{R}^2$, let $U = \operatorname{span}(\mathbf{e}_1)$, $W = \operatorname{span}(\mathbf{e}_2)$, and $X = \operatorname{span}((1,1))$. Then $\mathbb{R}^2 = U \oplus W$, but $X \cap U = X \cap W = \{\mathbf{0}\}$, so $(X \cap U) \oplus (X \cap W) = \{\mathbf{0}\} \neq X$. The components of a vector of X lie in U and W, but not in X.

(f) True. Conditions (ii) and (iii) of Proposition 4.4.21 hold, so $V = U \oplus W$.

Solution to Exercise 4.4.35

Uses. Definition 4.2.1 (Restriction), Theorem 4.4.7 (Criteria for direct sums), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Test injectivity at $\mathbf{0}$ (Technique 2.6.12)
Hint 1. For (a), $T(\mathbf{u}_1 + \cdots + \mathbf{u}_k) = T(\mathbf{u}_1) + \cdots + T(\mathbf{u}_k)$.
Hint 2. For (b), use criterion (II): pull a decomposition of $\mathbf{0}$ back through T.
Sketch. (a) Both sides consist of the vectors $T(\mathbf{u}_1) + \cdots + T(\mathbf{u}_k)$ with $\mathbf{u}_i \in U_i$. (b) If $T(\mathbf{u}_1) + \cdots + T(\mathbf{u}_k) = \mathbf{0}$, then $T\left(\sum_i \mathbf{u}_i\right) = \mathbf{0}$, so $\sum_i \mathbf{u}_i = \mathbf{0}$, so every $\mathbf{u}_i = \mathbf{0}$ and every $T(\mathbf{u}_i) = \mathbf{0}$. (c) $T(x, y) = x + y$ maps both axes of F^2 onto F.

(a) An element of the left side is $T(\mathbf{u}_1 + \cdots + \mathbf{u}_k)$ with $\mathbf{u}_i \in U_i$, and by linearity this equals $T(\mathbf{u}_1) + \cdots + T(\mathbf{u}_k)$, a typical element of the right side. Reading the same equation backwards gives the other containment.

(b) We check (II) of Theorem 4.4.7. Let $T(\mathbf{u}_1) + \cdots + T(\mathbf{u}_k) = \mathbf{0}$ with $\mathbf{u}_i \in U_i$. Then $T(\mathbf{u}_1 + \cdots + \mathbf{u}_k) = \mathbf{0}$, so $\mathbf{u}_1 + \cdots + \mathbf{u}_k = \mathbf{0}$ since T is injective (Theorem 2.6.11). As $U_1, \ldots, U_k$ are independent, every $\mathbf{u}_i = \mathbf{0}$, so every $T(\mathbf{u}_i) = \mathbf{0}$.

(c) Let $T : F^2 \to F$, $T(x, y) = x + y$, and $U_1 = \operatorname{span}(\mathbf{e}_1)$, $U_2 = \operatorname{span}(\mathbf{e}_2)$, which are independent. Both images are all of F, and $F + F$ is not direct, since $F \cap F = F \neq \{\mathbf{0}\}$.

Solution to Exercise 4.4.36

Uses. Example 4.4.5 (Direct sums), Definition 4.4.24 (Projection along a complement), Theorem 4.1.10 (Independent lists are short)
Techniques. Compare components (Technique 4.4.8)
Hint 1. Solve $(x, y) = a(1, i) + b(1, -i)$ for a and b.
Hint 2. Compute $R(1, i)$ and $R(1, -i)$.
Sketch. The vectors $(1, i)$ and $(1, -i)$ are not proportional, so they form a basis and $\mathbb{C}^2 = U \oplus W$. Solving gives $a = (x - iy)/2$, so $\operatorname{Pr}_{U,W}(x, y) = ((x - iy)/2, (ix + y)/2)$ and $P = \frac{1}{2}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}$. (b) $R(1, i) = (-i, 1) = -i(1, i)$ and $R(1, -i) = (i, 1) = i(1, -i)$, so $\lambda = -i$ and $\mu = i$.

(a) If $(1, -i) = c(1, i)$, then $c = 1$ and $-i = i$, which is false; so $(1, i), (1, -i)$ is independent, hence a basis of $\mathbb{C}^2$ (Theorem 4.1.10(b)), and $\mathbb{C}^2 = U \oplus W$ by Example 4.4.5(a). To decompose (x, y), solve $a(1, i) + b(1, -i) = (x, y)$, that is, $a + b = x$ and $i(a - b) = y$. Then $a - b = -iy$, so

$$a = \frac{x - iy}{2}, \quad b = \frac{x + iy}{2}.$$

Hence $\operatorname{Pr}_{U,W}(x, y) = a(1, i) = ((x - iy)/2, (ix + y)/2)$, and

$$P = \frac{1}{2}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}, \quad P^2 = \frac{1}{4}\begin{pmatrix} 1 + (-i)i & -i - i \\ i + i & i(-i) + 1 \end{pmatrix} = \frac{1}{4}\begin{pmatrix} 2 & -2i \\ 2i & 2 \end{pmatrix} = P.$$

(b) $R(1, i) = (-i, 1) = -i(1, i)$, since $(-i)i = 1$; and $R(1, -i) = (i, 1) = i(1, -i)$, since $i(-i) = 1$. By linearity, $R(\mathbf{u}) = -i\mathbf{u}$ for $\mathbf{u} \in U$ and $R(\mathbf{w}) = i\mathbf{w}$ for $\mathbf{w} \in W$, so $\lambda = -i$ and $\mu = i$.

Over $\mathbb{R}$, the quarter turn maps no line through $\mathbf{0}$ into itself. Over $\mathbb{C}$, it splits $\mathbb{C}^2$ into two lines on which it acts as multiplication by a scalar. This is diagonalization (Section 7.4) in its simplest form.

Solution to Exercise 4.4.37

> *Uses.* Non-example 4.4.6 (Sums that are not direct), Theorem 4.4.7 (Criteria for direct sums), Theorem 4.4.13 (Bases and dimension of a sum)
> *Techniques.* Induction on the number of summands (Technique 4.4.10)
> *Hint 1.* Test the claim on three lines in $\mathbb{R}^2$ before looking for the error.
> *Hint 2.* Where does a combination of entries of $\mathcal{B}_1$ and $\mathcal{B}_2$ lie?
> *Sketch.* The claim is false: three lines in $\mathbb{R}^2$ that meet pairwise in $\mathbf{0}$ have dimensions adding up to $3 > 2$. The error is "it lies in U_1 or in U_2": a combination of entries of $\mathcal{B}_1$ and $\mathcal{B}_2$ lies in $U_1 + U_2$, which is usually much larger than $U_1 \cup U_2$. The argument is correct under criterion (IV), $U_3 \cap (U_1 + U_2) = \{\mathbf{0}\}$.

The claim is false. The lines $\operatorname{span}(\mathbf{e}_1)$, $\operatorname{span}(\mathbf{e}_2)$, and $\operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$ in $\mathbb{R}^2$ meet pairwise in $\{\mathbf{0}\}$, their dimensions add up to 3, and their sum is $\mathbb{R}^2$, of dimension 2.

The error is the sentence "it lies in U_1 or in U_2". A combination of entries of $\mathcal{B}_1$ and $\mathcal{B}_2$ is a vector of U_1 plus a vector of U_2, so it lies in $U_1 + U_2$, not in $U_1 \cup U_2$. To conclude that both sides vanish, the argument needs $U_3 \cap (U_1 + U_2) = \{\mathbf{0}\}$. In the example, $\mathbf{e}_1 + \mathbf{e}_2$ lies in U_3 and also in $U_1 + U_2$, and the argument breaks exactly there.

With the hypotheses $U_2 \cap U_1 = \{\mathbf{0}\}$ and $U_3 \cap (U_1 + U_2) = \{\mathbf{0}\}$ instead, the argument is valid. (For an entry of $\mathcal{B}_2$, the right side is a combination of entries of $\mathcal{B}_1$ and lies in U_1, so the pairwise hypothesis is enough there.) These are condition (IV) of Theorem 4.4.7, and the corrected argument is a proof of (IV) $\Rightarrow$ (I) combined with Theorem 4.4.13(c).

Solution to Exercise 4.4.38

> *Uses.* Theorem 4.4.19 (Dimension of a sum)
> *Techniques.* Extend a basis of a subspace (Technique 4.1.18)
> *Hint 1.* Do a basis of U and a basis of W have to share any vectors at all?
> *Hint 2.* Try $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ with basis $\mathbf{e}_1, \mathbf{e}_2$, and $W = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3, \mathbf{e}_3)$ with basis $\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3, \mathbf{e}_3$, in $\mathbb{R}^3$.
> *Sketch.* The claim that the shared vectors form a basis of $U \cap W$ is unjustified and usually false. With $\mathcal{B} = \mathbf{e}_1, \mathbf{e}_2$ and $\mathcal{C} = \mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3, \mathbf{e}_3$, no vector is shared and no entry of either basis lies in $U \cap W = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$. The repair is to choose the bases: extend one basis of $U \cap W$ to both, as in the first proof of Theorem 4.4.19.

The error is the claim that the vectors occurring in both $\mathcal{B}$ and $\mathcal{C}$ form a basis of $U \cap W$. Arbitrary bases need not share any vector, and the entries of $\mathcal{B}$ that happen to lie in $U \cap W$ need not span it.

For example, in $\mathbb{R}^3$ let $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ with $\mathcal{B} = \mathbf{e}_1, \mathbf{e}_2$, and $W = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3, \mathbf{e}_3)$ with $\mathcal{C} = \mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3, \mathbf{e}_3$. The bases share no vector, so the procedure deletes nothing and returns four vectors in $\mathbb{R}^3$, which cannot be a basis. Here $U \cap W = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$, since a vector $a(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) + b\mathbf{e}_3 = (a, a, a + b)$ of W lies in U exactly when $b = -a$; and none of $\mathbf{e}_1$, $\mathbf{e}_2$, $\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3$, $\mathbf{e}_3$ lies in this line.

The argument becomes correct if the bases are chosen with care: start from a basis of $U \cap W$ and extend it to a basis of U and to a basis of W. Then the shared vectors are exactly the chosen basis of $U \cap W$, and what remains to be shown is that the merged list is independent. That is the first proof of Theorem 4.4.19.

Solution to Exercise 4.4.39

> *Uses.* Remark 4.4.22 (No formula for three subspaces), Proposition 1.4.16 (Intersections of subspaces), Proposition 4.4.2 (Sums are the smallest containing subspaces), Theorem 4.4.19 (Dimension of a sum)
> *Hint 1.* For (a), see Remark 4.4.22.
> *Hint 2.* For (c), apply the dimension formula three times: to $U + W$ and X, to U and W, and to $U \cap X$ and $W \cap X$.
> *Sketch.* (a) Three distinct lines: $\dim(U + W + X) = 2$ but $e = 3$. (b) $U \cap X$ and $W \cap X$ lie in the subspace $(U + W) \cap X$. (c) $\dim(U + W + X) = \dim(U + W) + \dim X - \dim((U \cap X) + (W \cap X))$; expand $\dim(U + W)$ and $\dim((U \cap X) + (W \cap X))$ by the formula, using $(U \cap X) \cap (W \cap X) = U \cap W \cap X$.

(a) Let $U = \operatorname{span}(\mathbf{e}_1)$, $W = \operatorname{span}(\mathbf{e}_2)$, and $X = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$. All pairwise intersections and the triple intersection are $\{\mathbf{0}\}$, so $e(U, W, X) = 3$, but $\dim(U + W + X) = \dim \mathbb{R}^2 = 2$ (Remark 4.4.22). Here $(U + W) \cap X = X$, while $(U \cap X) + (W \cap X) = \{\mathbf{0}\}$.

(b) $U \cap X \subseteq U \subseteq U + W$ and $U \cap X \subseteq X$, so $U \cap X \subseteq (U + W) \cap X$; likewise $W \cap X \subseteq (U + W) \cap X$. Since $(U + W) \cap X$ is a subspace (Proposition 1.4.16), it contains $(U \cap X) + (W \cap X)$ by Proposition 4.4.2(b).

(c) All the subspaces involved are finite-dimensional, being contained in $U + W + X$ (Theorem 4.4.13(a)). By Proposition 4.4.2(a), $U + W + X = (U + W) + X$, so Theorem 4.4.19 and the hypothesis give

$$\dim(U + W + X) = \dim(U + W) + \dim X - \dim((U \cap X) + (W \cap X)).$$

By Theorem 4.4.19 again, $\dim(U + W) = \dim U + \dim W - \dim(U \cap W)$, and since $(U \cap X) \cap (W \cap X) = U \cap W \cap X$,

$$\dim((U \cap X) + (W \cap X)) = \dim(U \cap X) + \dim(W \cap X) - \dim(U \cap W \cap X).$$

Substituting both gives $\dim(U + W + X) = e(U, W, X)$.

For instance, the hypothesis holds when $X \subseteq U$, since then both sides equal X.

Solution to Exercise 4.4.40

Uses. Theorem 4.4.19 (Dimension of a sum), Proposition 4.1.21 (Dimensions of subspaces), Example 4.2.25 (Kernels of linear functionals)
Techniques. Induction on the number of summands (Technique 4.4.10), Dimension counting (Technique 4.2.24)
Hint 1. Induct on k. In the inductive step, apply the dimension formula to $X = U_1 \cap \cdots \cap U_{k-1}$ and U_k.
Hint 2. $\dim(X + U_k) \le n$.
Sketch. (a) For $k = 1$ it is an equality. With $X = U_1 \cap \cdots \cap U_{k-1}$, $\dim(X \cap U_k) = \dim X + \dim U_k - \dim(X + U_k) \ge \dim X + \dim U_k - n$, and the inductive hypothesis bounds $\dim X$. (b) The intersection is $\operatorname{span}(\mathbf{e}_{k+1}, \ldots, \mathbf{e}_n)$, of dimension $n - k = k(n-1) - (k-1)n$. (c) For $n - 1$ subspaces of dimension $n - 1$, the bound is $(n-1)^2 - (n-2)n = 1$.

(a) We induct on k. For $k = 1$ both sides equal $\dim U_1$. Let $k \ge 2$, and put $X = U_1 \cap \cdots \cap U_{k-1}$; by the inductive hypothesis, $\dim X \ge \dim U_1 + \cdots + \dim U_{k-1} - (k-2)n$. By Theorem 4.4.19 and $\dim(X + U_k) \le n$ (Proposition 4.1.21(a)),

$$\begin{aligned} \dim(X \cap U_k) &= \dim X + \dim U_k - \dim(X + U_k) \\ &\ge \dim U_1 + \cdots + \dim U_{k-1} - (k-2)n + \dim U_k - n \\ &= \dim U_1 + \cdots + \dim U_k - (k-1)n. \end{aligned}$$

Since $X \cap U_k = U_1 \cap \cdots \cap U_k$, this is the claim.

(b) Each U_i is the kernel of the nonzero functional $\mathbf{x} \mapsto x_i$, so $\dim U_i = n - 1$ (Example 4.2.25), and the bound in (a) is $k(n-1) - (k-1)n = n - k$. The intersection consists of the vectors with $x_1 = \cdots = x_k = 0$, which is $\operatorname{span}(\mathbf{e}_{k+1}, \ldots, \mathbf{e}_n)$, of dimension $n - k$.

(c) For $k = n - 1$ subspaces of dimension $n - 1$, (a) gives

$$\dim(U_1 \cap \cdots \cap U_{n-1}) \ge (n-1)^2 - (n-2)n = 1.$$

Solution to Exercise 4.4.41

Uses. Proposition 2.6.18 (The column space is spanned by the columns), Proposition 4.4.2 (Sums are the smallest containing subspaces), Theorem 4.4.19 (Dimension of a sum), Theorem 4.2.7 (The image of T_A), Proposition 4.1.21 (Dimensions of subspaces)
Hint 1. The column space of $\begin{pmatrix} A & B \end{pmatrix}$ is spanned by the columns of A together with those of B.
Hint 2. $(A + B)\mathbf{x} = A\mathbf{x} + B\mathbf{x}$.
Sketch. (a) $\operatorname{im}\begin{pmatrix} A & B \end{pmatrix} = \operatorname{im} A + \operatorname{im} B$ by Proposition 2.6.18 and Proposition 4.4.2(c), so (a) is the dimension formula. (b) $\operatorname{im}(A + B) \subseteq \operatorname{im} A + \operatorname{im} B$. (c) $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ have images $\operatorname{span}(\mathbf{e}_1)$ and $\operatorname{span}(\mathbf{e}_2)$, but $A + B = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ has rank 1.

(a) By Proposition 2.6.18, $\operatorname{im} A$, $\operatorname{im} B$, and $\operatorname{im}(A \;\; B)$ are the spans of the columns of A, of B, and of both together. So $\operatorname{im}(A \;\; B) = \operatorname{im} A + \operatorname{im} B$ by Proposition 4.4.2(c), and since rank is the dimension of the image (Theorem 4.2.7), Theorem 4.4.19 gives

$$\operatorname{rank}(A \;\; B) = \dim(\operatorname{im} A + \operatorname{im} B) = \operatorname{rank} A + \operatorname{rank} B - \dim(\operatorname{im} A \cap \operatorname{im} B).$$

(b) For every $\mathbf{x} \in F^n$, $(A+B)\mathbf{x} = A\mathbf{x} + B\mathbf{x} \in \operatorname{im} A + \operatorname{im} B$. So $\operatorname{im}(A+B) \subseteq \operatorname{im} A + \operatorname{im} B$, and by Proposition 4.1.21(a) and (a),

$$\operatorname{rank}(A+B) \le \dim(\operatorname{im} A + \operatorname{im} B) = \operatorname{rank} A + \operatorname{rank} B - \dim(\operatorname{im} A \cap \operatorname{im} B).$$

(c) Let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. Then $\operatorname{im} A = \operatorname{span}(\mathbf{e}_1)$ and $\operatorname{im} B = \operatorname{span}(\mathbf{e}_2)$ meet only in $\mathbf{0}$, and $\operatorname{rank} A + \operatorname{rank} B = 2$. But $A + B = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ has rank 1. The loss comes from the other side: A and B both kill $\mathbf{e}_2$, so $A + B$ does too.

Solution to Exercise 4.4.42

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.4.16 (Complements exist), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Theorem 4.4.27 (Idempotents are projections), Proposition 4.4.26 (Properties of projections)
Techniques. Extend a basis of a subspace (Technique 4.1.18), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. One direction of (a) is rank–nullity. For the other, a complement X of U has the same dimension as W.
Hint 2. Define T to kill a basis of U and to send a basis of X to a basis of W. For (b), use Theorem 4.4.27.
Sketch. (a) ($\Rightarrow$) is rank–nullity. ($\le$) Let X be a complement of U, so $\dim X = \dim V - \dim U = \dim W$. Glue bases $\mathbf{u}_i$ of U and $\mathbf{x}_j$ of X into a basis of V, and let $T(\mathbf{u}_i) = \mathbf{0}$ and $T(\mathbf{x}_j) = \mathbf{w}_j$, a basis of W. Then $\operatorname{im} T = W$ and $\ker T = U$. (b) An idempotent has $V = \operatorname{im} T \oplus \ker T = W \oplus U$; conversely, $\mathrm{Pr}_{W,U}$ works. (c) $T(x,y) = (y,0)$. An idempotent fixes its image and kills its kernel, so these meet only in $\mathbf{0}$.

(a) If $\ker T = U$ and $\operatorname{im} T = W$, then $\dim U + \dim W = \dim V$ by Theorem 4.2.11. Conversely, suppose $\dim U + \dim W = \dim V$. Let X be a complement of U (Proposition 4.4.16), so $\dim X = \dim V - \dim U = \dim W$; call this number r. Let $\mathbf{u}_1, \dots, \mathbf{u}_k$, $\mathbf{x}_1, \dots, \mathbf{x}_r$, and $\mathbf{w}_1, \dots, \mathbf{w}_r$ be bases of U, X, and W. Since $V = U \oplus X$, the list $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{x}_1, \dots, \mathbf{x}_r$ is a basis of V (Theorem 4.4.13(b)), so there is $T \in \mathrm{L}(V)$ with $T(\mathbf{u}_i) = \mathbf{0}$ and $T(\mathbf{x}_j) = \mathbf{w}_j$ for all i, j (Theorem 2.2.1). Its image is $\operatorname{span}(\mathbf{w}_1, \dots, \mathbf{w}_r) = W$ (Proposition 2.1.16). For $\mathbf{v} = \sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{x}_j$, we get $T(\mathbf{v}) = \sum_j b_j \mathbf{w}_j$, which is $\mathbf{0}$ if and only if all $b_j = 0$, that is, if and only if $\mathbf{v} \in U$. So $\ker T = U$.

(b) If $T^2 = T$, then $V = \operatorname{im} T \oplus \ker T = W \oplus U$ by Theorem 4.4.27. Conversely, if $V = U \oplus W$, then $T = \mathrm{Pr}_{W,U}$ satisfies $T^2 = T$, $\operatorname{im} T = W$, and $\ker T = U$ by Proposition 4.4.26.

(c) Here $\dim U + \dim W = 2$, and $T(x,y) = (y,0)$ has $\ker T = \operatorname{span}(\mathbf{e}_1) = \operatorname{im} T$. Suppose some T with $T^2 = T$ had $\ker T = \operatorname{im} T = \operatorname{span}(\mathbf{e}_1)$. Then $\mathbf{e}_1 = T(\mathbf{x})$ for some $\mathbf{x}$, so $T(\mathbf{e}_1) = T^2(\mathbf{x}) = T(\mathbf{x}) = \mathbf{e}_1$; but $\mathbf{e}_1 \in \ker T$, so $T(\mathbf{e}_1) = \mathbf{0}$, a contradiction.

Solution to Exercise 4.4.43

Uses. Proposition 2.6.8 (Kernels and images are subspaces), Theorem 4.4.7 (Criteria for direct sums), Proposition 1.2.35 (Zero products), Theorem 4.4.27 (Idempotents are projections), Definition 2.4.21 (Transpose), Lemma 2.4.24 (Matrix units), Theorem 4.4.13 (Bases and dimension of a sum)
Techniques. Split the space with an idempotent (Technique 4.4.28)
Hint 1. Write $2 = 1 + 1$, which is invertible in F. Split $\mathbf{v} = 2^{-1}(\mathbf{v} + T(\mathbf{v})) + 2^{-1}(\mathbf{v} - T(\mathbf{v}))$ and check where each piece lies.
Hint 2. Equivalently, $P = 2^{-1}(\mathrm{id}_V + T)$ is idempotent. For (b), apply (a) to $A \mapsto A^{\mathrm{T}}$.
Sketch. (a) $T(\mathbf{v} + T\mathbf{v}) = \mathbf{v} + T\mathbf{v}$ and $T(\mathbf{v} - T\mathbf{v}) = -(\mathbf{v} - T\mathbf{v})$, so the split shows $V = V_+ + V_-$; if $T\mathbf{v} = \mathbf{v} = -\mathbf{v}$, then $2\mathbf{v} = \mathbf{0}$ and $\mathbf{v} = \mathbf{0}$. (b) Transposition is linear with square the identity, and V_+, V_- are the symmetric and skew-symmetric matrices. The symmetric ones have basis U_{ii} and $U_{ij} + U_{ji}$ ($i < j$), so dimension $n(n+1)/2$, and the skew-symmetric ones have dimension $n^2 - n(n+1)/2 = n(n-1)/2$. (c) $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$: $V_+ = V_- = \operatorname{span}(\mathbf{e}_1)$.

(a) $V_+ = \ker(T - \mathrm{id}_V)$ and $V_- = \ker(T + \mathrm{id}_V)$ are subspaces (Proposition 2.6.8). Write $2 = 1 + 1$, which is nonzero by hypothesis. For $\mathbf{v} \in V$, put $\mathbf{v}_+ = 2^{-1}(\mathbf{v} + T(\mathbf{v}))$ and $\mathbf{v}_- = 2^{-1}(\mathbf{v} - T(\mathbf{v}))$. Then $\mathbf{v}_+ + \mathbf{v}_- = 2^{-1}(2\mathbf{v}) = \mathbf{v}$, and since $T^2 = \mathrm{id}_V$,

$$T(\mathbf{v}_+) = 2^{-1}(T(\mathbf{v}) + \mathbf{v}) = \mathbf{v}_+, \quad T(\mathbf{v}_-) = 2^{-1}(T(\mathbf{v}) - \mathbf{v}) = -\mathbf{v}_-.$$

So $\mathbf{v}_+ \in V_+$ and $\mathbf{v}_- \in V_-$, and $V = V_+ + V_-$. If $\mathbf{v} \in V_+ \cap V_-$, then $\mathbf{v} = T(\mathbf{v}) = -\mathbf{v}$, so $2\mathbf{v} = \mathbf{0}$ and $\mathbf{v} = \mathbf{0}$ (Proposition 1.2.35). By Theorem 4.4.7, $V = V_+ \oplus V_-$.

In the language of Theorem 4.4.27, $P = 2^{-1}(\mathrm{id}_V + T)$ satisfies $P^2 = 4^{-1}\big(\mathrm{id}_V + 2T + T^2\big) = 2^{-1}(\mathrm{id}_V + T) = P$, with $\operatorname{im} P = V_+$ and $\ker P = V_-$.

(b) The map $A \mapsto A^{\mathsf{T}}$ on $F^{n\times n}$ is linear, and $\big(A^{\mathsf{T}}\big)^{\mathsf{T}} = A$ (Definition 2.4.21). Its V_+ consists of the symmetric matrices and its V_- of the skew-symmetric ones, so (a) gives the direct sum, with $A = 2^{-1}\big(A + A^{\mathsf{T}}\big) + 2^{-1}\big(A - A^{\mathsf{T}}\big)$. Write $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$. A matrix $A = \sum_{i,j} a_{ij}U_{ij}$ is symmetric if and only if $a_{ij} = a_{ji}$ for all i, j, that is, if and only if

$$A = \sum_{i=1}^{n} a_{ii}U_{ii} + \sum_{i<j} a_{ij}\big(U_{ij} + U_{ji}\big).$$

So the $n + n(n-1)/2$ matrices U_{ii} and $U_{ij} + U_{ji}$ $(i < j)$ span the symmetric matrices, and they are independent, since a combination of them has entry a_{ij} in position (i, j) for $i \le j$, and the matrix units are independent (Lemma 2.4.24). Hence the symmetric matrices have dimension $n(n+1)/2$, and by Theorem 4.4.13(c) the skew-symmetric matrices have dimension $n^2 - n(n+1)/2 = n(n-1)/2$.

(c) Over $\mathbb{F}_2$, let T have matrix $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$. Then T^2 has matrix $\left(\begin{smallmatrix}1 & 2\\ 0 & 1\end{smallmatrix}\right) = I_2$. $T(x, y) = (x + y, y)$ equals (x, y) if and only if $y = 0$, so $V_+ = \operatorname{span}(\mathbf{e}_1)$, and since $-1 = 1$ in $\mathbb{F}_2$, $V_- = V_+$. So $V_+ + V_- = \operatorname{span}(\mathbf{e}_1) \neq \mathbb{F}_2^2$. (Likewise, over $\mathbb{F}_2$ the skew-symmetric matrices are exactly the symmetric ones.)

Solution to Exercise 4.4.44

Uses. Theorem 4.4.7 (Criteria for direct sums), Theorem 4.4.13 (Bases and dimension of a sum), Definition 4.2.14 (Rank and nullity of a linear map), Proposition 4.4.2 (Sums are the smallest containing subspaces)
Techniques. Compare components (Technique 4.4.8)
Hint 1. If $T(\mathbf{u} + \mathbf{w}) = \mathbf{0}$, then $T(\mathbf{u}) + T(\mathbf{w}) = \mathbf{0}$ with $T(\mathbf{u}) \in U$ and $T(\mathbf{w}) \in W$. Compare components.
Hint 2. Subspaces of independent subspaces are independent: $(U \cap \ker T) \cap (W \cap \ker T) \subseteq U \cap W$.
Sketch. (a) If $\mathbf{u} + \mathbf{w} \in \ker T$, then $T\mathbf{u} + T\mathbf{w} = \mathbf{0}$ is a decomposition of $\mathbf{0}$ along $U \oplus W$, so $T\mathbf{u} = T\mathbf{w} = \mathbf{0}$. The image: $T(\mathbf{u} + \mathbf{w}) = T\mathbf{u} + T\mathbf{w}$. Both sums are direct because their summands lie in U and W. (b) Dimensions add in a direct sum. (c) $T(x, y) = (x + y, 0)$ has kernel $\operatorname{span}((1, -1))$, which meets both axes trivially.

(a) Let $\mathbf{v} = \mathbf{u} + \mathbf{w} \in \ker T$ with $\mathbf{u} \in U$ and $\mathbf{w} \in W$. Then $\mathbf{0} = T(\mathbf{u}) + T(\mathbf{w})$ with $T(\mathbf{u}) \in U$ and $T(\mathbf{w}) \in W$, a decomposition of $\mathbf{0}$ along $U \oplus W$, so $T(\mathbf{u}) = T(\mathbf{w}) = \mathbf{0}$ by (II) of Theorem 4.4.7. Hence $\mathbf{u} \in U \cap \ker T$ and $\mathbf{w} \in W \cap \ker T$, so $\ker T \subseteq (U \cap \ker T) + (W \cap \ker T)$. The reverse containment holds because $\ker T$ is a subspace containing both summands (Proposition 4.4.2(b)). The sum is direct, since $(U \cap \ker T) \cap (W \cap \ker T) \subseteq U \cap W = \{\mathbf{0}\}$.

For the image, every $T(\mathbf{u} + \mathbf{w}) = T(\mathbf{u}) + T(\mathbf{w})$ lies in $\operatorname{im}(T{\restriction_U}) + \operatorname{im}(T{\restriction_W})$, and conversely $T(\mathbf{u}) + T(\mathbf{w}) = T(\mathbf{u} + \mathbf{w}) \in \operatorname{im} T$. By hypothesis $\operatorname{im}(T{\restriction_U}) \subseteq U$ and $\operatorname{im}(T{\restriction_W}) \subseteq W$, so their intersection lies in $U \cap W = \{\mathbf{0}\}$, and the sum is direct.

(b) By (a) and Theorem 4.4.13(c), $\dim \operatorname{im} T = \dim \operatorname{im}(T{\restriction_U}) + \dim \operatorname{im}(T{\restriction_W})$, which is the claim (Definition 4.2.14).

(c) Let $T(x, y) = (x + y, 0)$. Then $\ker T = \operatorname{span}((1, -1))$, and a vector $(t, -t)$ lies on an axis only if $t = 0$. So $(U \cap \ker T) + (W \cap \ker T) = \{\mathbf{0}\} \neq \ker T$. Here $T(\mathbf{e}_2) = \mathbf{e}_1 \notin W$, so the hypothesis fails.

Solution to Exercise 4.4.45

Uses. Theorem 4.2.11 (Rank–nullity), Theorem 4.3.8 (Row rank equals column rank), Theorem 4.2.7 (The image of T_A), Proposition 4.4.21 (Two out of three), Proposition 2.4.23 (Transpose of a product)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Over every field the dimensions add up to n, so by Proposition 4.4.21 only the intersection matters.
Hint 2. If $\mathbf{x} = A^{\mathsf{T}}\mathbf{y}$ and $A\mathbf{x} = \mathbf{0}$, compute $\mathbf{x}^{\mathsf{T}}\mathbf{x}$.

Sketch. $\dim\ker A + \dim\operatorname{im} A^{\mathsf{T}} = (n - \operatorname{rank} A) + \operatorname{rank} A = n$. Over $\mathbb{R}$, if $\mathbf{x} = A^{\mathsf{T}}\mathbf{y} \in \ker A$, then $\mathbf{x}^{\mathsf{T}}\mathbf{x} = \mathbf{y}^{\mathsf{T}}A\mathbf{x} = 0$, and $x_1^2 + \cdots + x_n^2 = 0$ forces $\mathbf{x} = \mathbf{0}$. Over $\mathbb{C}$, $A = \begin{pmatrix}1 & i\end{pmatrix}$ has $\ker A = \operatorname{span}((-i, 1)) = \operatorname{im} A^{\mathsf{T}}$. Over $\mathbb{F}_2$, $A = \begin{pmatrix}1 & 1\end{pmatrix}$ has $\ker A = \operatorname{span}((1,1)) = \operatorname{im} A^{\mathsf{T}}$.

Over every field, $\dim\ker A = n - \operatorname{rank} A$ by Theorem 4.2.11, and $\dim\operatorname{im} A^{\mathsf{T}} = \operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$ by Theorem 4.2.7 and Theorem 4.3.8. So condition (iii) of Proposition 4.4.21 always holds, and $F^n = \ker A \oplus \operatorname{im} A^{\mathsf{T}}$ if and only if $\ker A \cap \operatorname{im} A^{\mathsf{T}} = \{\mathbf{0}\}$.

Over $\mathbb{R}$. Let $\mathbf{x} \in \ker A \cap \operatorname{im} A^{\mathsf{T}}$, say $\mathbf{x} = A^{\mathsf{T}}\mathbf{y}$. By Proposition 2.4.23, $\mathbf{x}^{\mathsf{T}} = \mathbf{y}^{\mathsf{T}}A$, so

$$x_1^2 + \cdots + x_n^2 = \mathbf{x}^{\mathsf{T}}\mathbf{x} = \mathbf{y}^{\mathsf{T}}(A\mathbf{x}) = \mathbf{y}^{\mathsf{T}}\mathbf{0} = 0.$$

A sum of squares of real numbers vanishes only if each term does, so $\mathbf{x} = \mathbf{0}$.

Over $\mathbb{C}$. Let $A = \begin{pmatrix}1 & i\end{pmatrix} \in \mathbb{C}^{1\times 2}$. Then $A\mathbf{x} = x_1 + ix_2 = 0$ if and only if $x_1 = -ix_2$, so $\ker A = \operatorname{span}((-i, 1))$. Also $\operatorname{im} A^{\mathsf{T}} = \operatorname{span}((1, i))$, and $(-i, 1) = -i(1, i)$. So $\ker A = \operatorname{im} A^{\mathsf{T}}$ is a line, and the sum is not direct. The real argument breaks because $(1,i)^{\mathsf{T}}(1,i) = 1 + i^2 = 0$. Over $\mathbb{C}$ the correct statement uses the conjugate transpose (Section 6.6).

Over $\mathbb{F}_2$. Let $A = \begin{pmatrix}1 & 1\end{pmatrix} \in \mathbb{F}_2^{1\times 2}$. Then $\ker A = \{\mathbf{x} \mid x_1 + x_2 = 0\} = \operatorname{span}((1,1)) = \operatorname{im} A^{\mathsf{T}}$, and again the sum is not direct; here $(1,1)^{\mathsf{T}}(1,1) = 1 + 1 = 0$.

Solution to Exercise 4.4.46

Uses. Proposition 4.4.16 (Complements exist), Proposition 4.4.21 (Two out of three), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. If $U = \{\mathbf{0}\}$ or $U = V$, what must a complement be?
Hint 2. Otherwise, take a complement W with basis $\mathbf{w}_1, \ldots, \mathbf{w}_r$ and a nonzero $\mathbf{u} \in U$. Tilt $\mathbf{w}_1$ towards $\mathbf{u}$: try $\operatorname{span}(\mathbf{w}_1 + \mathbf{u}, \mathbf{w}_2, \ldots, \mathbf{w}_r)$.
Sketch. A complement W of $\{\mathbf{0}\}$ satisfies $W = \{\mathbf{0}\} + W = V$, and a complement of V satisfies $W = V \cap W = \{\mathbf{0}\}$. If $\{\mathbf{0}\} \neq U \neq V$, take a complement W with basis $\mathbf{w}_1, \ldots, \mathbf{w}_r$ ($r \geq 1$) and $\mathbf{u} \in U$ nonzero. If $a(\mathbf{w}_1 + \mathbf{u}) + \sum_{j\geq 2} a_j\mathbf{w}_j \in U$, then $a\mathbf{w}_1 + \sum_{j\geq 2} a_j\mathbf{w}_j \in U \cap W$, so all coefficients vanish. So $W' = \operatorname{span}(\mathbf{w}_1 + \mathbf{u}, \mathbf{w}_2, \ldots, \mathbf{w}_r)$ has dimension r and meets U trivially, hence is a complement, and $\mathbf{w}_1 + \mathbf{u} \notin W$.

If $U = \{\mathbf{0}\}$, then $V = \{\mathbf{0}\} \oplus V$, and any complement W satisfies $W = \{\mathbf{0}\} + W = V$. If $U = V$, then $V = V \oplus \{\mathbf{0}\}$, and any complement W satisfies $W = V \cap W = \{\mathbf{0}\}$. In both cases the complement is unique.

Now suppose $\{\mathbf{0}\} \neq U \neq V$. By Proposition 4.4.16, U has a complement W, of dimension $r = \dim V - \dim U \geq 1$; let $\mathbf{w}_1, \ldots, \mathbf{w}_r$ be a basis of W, and let $\mathbf{u} \in U$ be nonzero. Let $W' = \operatorname{span}(\mathbf{w}_1 + \mathbf{u}, \mathbf{w}_2, \ldots, \mathbf{w}_r)$. Suppose

$$\mathbf{y} = a(\mathbf{w}_1 + \mathbf{u}) + a_2\mathbf{w}_2 + \cdots + a_r\mathbf{w}_r \in U.$$

Then $a\mathbf{w}_1 + a_2\mathbf{w}_2 + \cdots + a_r\mathbf{w}_r = \mathbf{y} - a\mathbf{u}$ lies in W and in U, hence is $\mathbf{0}$, and since $\mathbf{w}_1, \ldots, \mathbf{w}_r$ is independent, $a = a_2 = \cdots = a_r = 0$ (Theorem 1.5.5), so $\mathbf{y} = \mathbf{0}$. This shows $U \cap W' = \{\mathbf{0}\}$, and, taking $\mathbf{y} = \mathbf{0}$, that the spanning list of W' is independent, so $\dim W' = r$. By Proposition 4.4.21, $V = U \oplus W'$. Finally $W' \neq W$: if $\mathbf{w}_1 + \mathbf{u} \in W$, then $\mathbf{u} = (\mathbf{w}_1 + \mathbf{u}) - \mathbf{w}_1 \in U \cap W = \{\mathbf{0}\}$, a contradiction. So U has at least two complements.

Solution to Exercise 4.4.47

Uses. Example 2.1.9 (Maps of polynomials), Lemma 3.4.23 (Too many roots), Theorem 3.4.24 (Polynomial interpolation), Theorem 4.4.7 (Criteria for direct sums), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 4.2.11 (Rank–nullity)
Hint 1. A polynomial of degree at most k that vanishes at $k + 1$ distinct points is $\mathbf{0}$.
Hint 2. Given p, interpolate its values at $c_0, \ldots, c_k$ by a polynomial q of degree at most k. Then $p - q \in Z$.
Hint 3. For the second count, Z is the kernel of $p \mapsto (p(c_0), \ldots, p(c_k))$.
Sketch. $Z \cap F[x]_{\leq k} = \{\mathbf{0}\}$ by Lemma 3.4.23. For p, let $q \in F[x]_{\leq k}$ interpolate the values $p(c_i)$ (Theorem 3.4.24); then $p = (p - q) + q$ with $p - q \in Z$. So $\dim Z = (n + 1) - (k + 1) = n - k$ by Theorem 4.4.13(c). Alternatively, evaluation $F[x]_{\leq n} \to F^{k+1}$ is onto by interpolation and has kernel Z; rank–nullity gives the same answer.

The map $\mathrm{ev} : F[x]_{\leq n} \to F^{k+1}$, $p \mapsto (p(c_0), \ldots, p(c_k))$, is linear (Example 2.1.9), and $Z = \ker \mathrm{ev}$ is a subspace.

If $p \in Z \cap F[x]_{\le k}$, then p has degree at most k and vanishes at the $k+1$ distinct points $c_0, \dots, c_k$, so $p = \mathbf{0}$ by Lemma 3.4.23. Next, let $p \in F[x]_{\le n}$. By Theorem 3.4.24 there is $q \in F[x]_{\le k}$ with $q(c_i) = p(c_i)$ for $i = 0, \dots, k$. Since $k \le n$, $p - q \in F[x]_{\le n}$, and it vanishes at every c_i, so $p - q \in Z$ and $p = (p-q) + q \in Z + F[x]_{\le k}$. By Theorem 4.4.7, $F[x]_{\le n} = Z \oplus F[x]_{\le k}$.

First count. By Theorem 4.4.13(c), $n + 1 = \dim Z + (k+1)$, so $\dim Z = n - k$.

Second count. The map ev is surjective: for $(d_0, \dots, d_k) \in F^{k+1}$, the interpolating polynomial of Theorem 3.4.24 lies in $F[x]_{\le k} \subseteq F[x]_{\le n}$ and has these values. By Theorem 4.2.11, $\dim Z = \dim \ker \mathrm{ev} = (n+1) - (k+1) = n - k$.

The decomposition $p = (p-q) + q$ says that the projection onto $F[x]_{\le k}$ along Z sends p to its interpolating polynomial at $c_0, \dots, c_k$. Note that the hypothesis requires F to have at least $k+1$ elements.

Solution to Exercise 4.4.48

Uses. Theorem 4.4.13 (Bases and dimension of a sum), Theorem 4.2.11 (Rank–nullity), Theorem 4.2.7 (The image of T_A), Proposition 4.1.21 (Dimensions of subspaces), Proposition 4.4.21 (Two out of three)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Since $A + B$ is invertible, every $\mathbf{x}$ equals $(A+B)\mathbf{y} = A\mathbf{y} + B\mathbf{y}$ for some $\mathbf{y}$. What does that say about $\operatorname{im} A + \operatorname{im} B$?
Hint 2. $AB = 0$ means $\operatorname{im} B \subseteq \ker A$. Combine this with rank–nullity for A.
Sketch. (a) Every $\mathbf{x} = (A+B)\mathbf{y}$ lies in $\operatorname{im} A + \operatorname{im} B$, so $\operatorname{im} A + \operatorname{im} B = F^n$ and $\operatorname{rank} A + \operatorname{rank} B \ge n$. Also $\operatorname{im} B \subseteq \ker A$, so $\operatorname{rank} B \le n - \operatorname{rank} A$. Hence $\operatorname{rank} A + \operatorname{rank} B = n$, and two out of three gives the direct sum. (b) $\operatorname{im} B \subseteq \ker A$, with equal dimensions. (c) Symmetrically $\operatorname{im} A = \ker B$. Without $BA = 0$: $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 0 \\ 1 & 1 \end{pmatrix}$.

(a) For $\mathbf{x} \in F^n$, invertibility of $A + B$ gives $\mathbf{y}$ with $\mathbf{x} = (A+B)\mathbf{y} = A\mathbf{y} + B\mathbf{y}$, so $\operatorname{im} A + \operatorname{im} B = F^n$. By Theorem 4.4.13(a) and Theorem 4.2.7, $n \le \operatorname{rank} A + \operatorname{rank} B$. On the other hand, $A(B\mathbf{y}) = \mathbf{0}$ for every $\mathbf{y}$, so $\operatorname{im} B \subseteq \ker A$, and by Proposition 4.1.21(a) and Theorem 4.2.11, $\operatorname{rank} B \le \dim \ker A = n - \operatorname{rank} A$. Hence $\operatorname{rank} A + \operatorname{rank} B = n$. Conditions (ii) and (iii) of Proposition 4.4.21 hold for $\operatorname{im} A$ and $\operatorname{im} B$, so $F^n = \operatorname{im} A \oplus \operatorname{im} B$.

(b) $\operatorname{im} B \subseteq \ker A$, and $\dim \operatorname{im} B = \operatorname{rank} B = n - \operatorname{rank} A = \dim \ker A$, so $\operatorname{im} B = \ker A$ by Proposition 4.1.21(b).

(c) If $BA = 0$, the hypotheses are symmetric in A and B (note $B + A = A + B$), so (b) with the roles exchanged gives $\operatorname{im} A = \ker B$.

Without $BA = 0$, let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 1 \end{pmatrix}$. Then $AB = 0$ and $A + B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$ is invertible, with inverse $\begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}$, but $BA = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \ne 0$, and $\operatorname{im} A = \operatorname{span}(\mathbf{e}_1)$ while $\ker B = \operatorname{span}((1,-1))$.

The kernels are complementary in any case: $\ker A \cap \ker B \subseteq \ker(A+B) = \{\mathbf{0}\}$, and by (a), $\dim \ker A + \dim \ker B = (n - \operatorname{rank} A) + (n - \operatorname{rank} B) = n$, so $F^n = \ker A \oplus \ker B$ by Proposition 4.4.21, whether or not $BA = 0$. In the example, $\ker A = \operatorname{span}(\mathbf{e}_2)$ and $\ker B = \operatorname{span}((1,-1))$.

Solution to Exercise 4.4.49

Uses. Proposition 4.2.6 (Injective maps preserve dimension), Proposition 4.4.21 (Two out of three), Proposition 4.4.16 (Complements exist), Definition 4.4.24 (Projection along a complement), Proposition 4.4.26 (Properties of projections), Proposition 4.1.21 (Dimensions of subspaces), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 4.1.34 (Size of a vector space over a finite field)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. (a) Γ_S is the image of the linear map $\mathbf{w} \mapsto \mathbf{w} + S(\mathbf{w})$. Show that this map is injective and that $\Gamma_S \cap U = \{\mathbf{0}\}$, and count dimensions.
Hint 2. (b) Given a complement W, decompose each $\mathbf{w} \in W_0$ along $V = U \oplus W$. Its W-component should be $\mathbf{w} + S(\mathbf{w})$.
Hint 3. (c) A linear map $W_0 \to U$ is determined by the images of a basis of W_0, which can be any vectors of U.
Sketch. (a) If $\mathbf{w} + S\mathbf{w} = \mathbf{0}$ or $\mathbf{w} + S\mathbf{w} \in U$, then $\mathbf{w} \in U \cap W_0 = \{\mathbf{0}\}$; so $\dim \Gamma_S = \dim W_0 = n - k$ and two out of three applies. (b) For a complement W, let $S = -\operatorname{Pr}_{U,W}|_{W_0}$, with values in U. Then $\mathbf{w} + S(\mathbf{w}) = \operatorname{Pr}_{W,U}(\mathbf{w}) \in W$, so $\Gamma_S \subseteq W$, with equal dimensions. If $\Gamma_S = \Gamma_{S'}$, compare components in $W_0 \oplus U$. (c) $|\mathrm{L}(W_0, U)| = \left(q^k\right)^{n-k}$. (d) The four planes $x_1 = 0$, $x_2 = 0$, $x_1 + x_3 = 0$, $x_2 + x_3 = 0$.

Let $n = \dim V$ and $k = \dim U$, so $\dim W_0 = n - k$ (Proposition 4.4.16(b)).

(a) The map $g : W_0 \to V$, $g(\mathbf{w}) = \mathbf{w} + S(\mathbf{w})$, is linear with image Γ_S, so Γ_S is a subspace. If $g(\mathbf{w}) \in U$, then $\mathbf{w} = g(\mathbf{w}) - S(\mathbf{w}) \in U$, as $S(\mathbf{w}) \in U$; so $\mathbf{w} \in U \cap W_0 = \{\mathbf{0}\}$. Taking $g(\mathbf{w}) = \mathbf{0}$ shows that g is injective, so $\dim \Gamma_S = n - k$ (Proposition 4.2.6(a)); and in general it shows $U \cap \Gamma_S = \{\mathbf{0}\}$. By Proposition 4.4.21, $V = U \oplus \Gamma_S$.

(b) *Existence.* Let W be a complement of U. Define $S : W_0 \to U$ by $S(\mathbf{w}) = -\mathrm{Pr}_{U,W}(\mathbf{w})$; it is linear with values in U (Proposition 4.4.26). For $\mathbf{w} \in W_0$,

$$\mathbf{w} + S(\mathbf{w}) = \mathbf{w} - \mathrm{Pr}_{U,W}(\mathbf{w}) = \mathrm{Pr}_{W,U}(\mathbf{w}) \in W,$$

by Proposition 4.4.26(d). So $\Gamma_S \subseteq W$. Both have dimension $n - k$, by (a) and Proposition 4.4.16(b), so $\Gamma_S = W$ (Proposition 4.1.21(b)).

Uniqueness. Suppose $\Gamma_S = \Gamma_{S'}$, and let $\mathbf{w} \in W_0$. Then $\mathbf{w} + S(\mathbf{w}) \in \Gamma_{S'}$, so $\mathbf{w} + S(\mathbf{w}) = \mathbf{w}' + S'(\mathbf{w}')$ for some $\mathbf{w}' \in W_0$. Both sides are decompositions along $V = W_0 \oplus U$, so comparing components gives $\mathbf{w} = \mathbf{w}'$ and $S(\mathbf{w}) = S'(\mathbf{w}') = S'(\mathbf{w})$. Hence $S = S'$.

(c) By (a) and (b), $S \mapsto \Gamma_S$ is a bijection from $\mathrm{L}(W_0, U)$ onto the set of complements of U. Fix a basis $\mathbf{w}_1, \ldots, \mathbf{w}_{n-k}$ of W_0. By Theorem 2.2.1, $S \mapsto (S(\mathbf{w}_1), \ldots, S(\mathbf{w}_{n-k}))$ is a bijection from $\mathrm{L}(W_0, U)$ onto the set of $(n-k)$-tuples of vectors of U. Since $|U| = q^k$ (Proposition 4.1.34), there are $\left(q^k\right)^{n-k} = q^{k(n-k)}$ complements.

(d) Here $n = 3$ and $k = 1$, so there are $2^2 = 4$ complements. Take $W_0 = \mathrm{span}(\mathbf{e}_2, \mathbf{e}_3) = \{\mathbf{x} \mid x_1 = 0\}$. Since $(1,1,0) \notin W_0$, $U \cap W_0 = \{\mathbf{0}\}$, and $1 + 2 = 3$, so W_0 is a complement of U (Proposition 4.4.21). A map $S : W_0 \to U$ is given by $S(\mathbf{e}_2) = a(1,1,0)$ and $S(\mathbf{e}_3) = b(1,1,0)$ with $a, b \in \mathbb{F}_2$, and $\Gamma_S = \mathrm{span}(\mathbf{e}_2 + a(1,1,0), \mathbf{e}_3 + b(1,1,0))$. The four choices give

$$\begin{aligned}
(a,b) = (0,0) &: \mathrm{span}((0,1,0),(0,0,1)) = \{x_1 = 0\},\\
(a,b) = (1,0) &: \mathrm{span}((1,0,0),(0,0,1)) = \{x_2 = 0\},\\
(a,b) = (0,1) &: \mathrm{span}((0,1,0),(1,1,1)) = \{x_1 + x_3 = 0\},\\
(a,b) = (1,1) &: \mathrm{span}((1,0,0),(1,1,1)) = \{x_2 + x_3 = 0\}.
\end{aligned}$$

These are exactly the planes of $\mathbb{F}_2^3$ that do not contain $(1,1,0)$.

Solution to Exercise 4.4.50

Uses. Exercise 1.4.21, Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 4.4.21 (Two out of three), Proposition 4.4.16 (Complements exist)
Techniques. Dimension counting (Technique 4.2.24), Extend a basis of a subspace (Technique 4.1.18)
Hint 1. Induct on $c = \dim V - \dim U$. If $c \geq 1$, find a vector $\mathbf{v}$ that lies in neither U nor W.
Hint 2. Two proper subspaces never cover V (Exercise 1.4.21). Enlarge U and W by $\mathbf{v}$, apply the inductive hypothesis, and add $\mathbf{v}$ back to the common complement.
Hint 3. For (b), a complement of a line in $\mathbb{F}_2^2$ is another line. How many lines are there?
Sketch. (a) Induct on c. If $c = 0$, take $X = \{\mathbf{0}\}$. Otherwise U, W are proper, so some $\mathbf{v}$ lies in neither. $U' = U + \mathrm{span}(\mathbf{v})$ and $W' = W + \mathrm{span}(\mathbf{v})$ have dimension $\dim U + 1$; take a common complement X' and set $X = X' + \mathrm{span}(\mathbf{v})$. Then $\dim X = c$, and if $\mathbf{x}' + a\mathbf{v} \in U$ with $\mathbf{x}' \in X'$, then $\mathbf{x}' \in U' \cap X' = \{\mathbf{0}\}$ and $a\mathbf{v} \in U$ forces $a = 0$. Two out of three. (b) There are only three lines, and a common complement would be a fourth.

(a) Let $n = \dim V$ and $d = \dim U = \dim W$. We prove the claim by induction on $c = n - d$, for all pairs of subspaces of V of equal dimension. If $c = 0$, then $U = W = V$ (Proposition 4.1.21(b)) and $X = \{\mathbf{0}\}$ works.

Let $c \geq 1$. Then U and W are proper subspaces, so $U \cup W \neq V$ by Exercise 1.4.21; choose $\mathbf{v} \in V$ with $\mathbf{v} \notin U$ and $\mathbf{v} \notin W$. If $a\mathbf{v} \in U$ with $a \neq 0$, then $\mathbf{v} = a^{-1}(a\mathbf{v}) \in U$; so $U \cap \mathrm{span}(\mathbf{v}) = \{\mathbf{0}\}$, and $U' = U + \mathrm{span}(\mathbf{v})$ has dimension $d + 1$ by Theorem 4.4.13(c). Likewise $W' = W + \mathrm{span}(\mathbf{v})$ has dimension $d + 1$. By the inductive hypothesis there is X' with $V = U' \oplus X' = W' \oplus X'$, and $\dim X' = n - d - 1$. Let $X = X' + \mathrm{span}(\mathbf{v})$. Since $\mathbf{v} \in U'$, we have $X' \cap \mathrm{span}(\mathbf{v}) \subseteq X' \cap U' = \{\mathbf{0}\}$, so $\dim X = n - d$.

We show $U \cap X = \{\mathbf{0}\}$. Let $\mathbf{y} = \mathbf{x}' + a\mathbf{v} \in U$ with $\mathbf{x}' \in X'$ and $a \in F$. Then $\mathbf{x}' = \mathbf{y} - a\mathbf{v}$ lies in U', since $\mathbf{y} \in U \subseteq U'$ and $\mathbf{v} \in U'$. So $\mathbf{x}' \in U' \cap X' = \{\mathbf{0}\}$, and $a\mathbf{v} = \mathbf{y} \in U$, which forces $a = 0$ since $\mathbf{v} \notin U$. Hence $\mathbf{y} = \mathbf{0}$.

As $\dim U + \dim X = n$, Proposition 4.4.21 gives $V = U \oplus X$. The same argument with W and W' in place of U and U' gives $V = W \oplus X$.

(b) Each line through $\mathbf{0}$ in $\mathbb{F}_2^2$ contains exactly one nonzero vector, so there are exactly three lines: $\operatorname{span}(\mathbf{e}_1)$, $\operatorname{span}(\mathbf{e}_2)$, $\operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$. A complement of a line has dimension 1 (Proposition 4.4.16(b)) and is a line different from it. A common complement of all three would be a fourth line, which does not exist.

So (a) does not extend to three subspaces over every field. Over an infinite field it does extend to any finite number of subspaces of equal dimension, by the same induction together with Exercise 1.4.43.

Solution to Exercise 4.4.51

Uses. Exercise 4.3.43, Proposition 2.4.27 (The trace is linear), Theorem 4.2.7 (The image of T_A), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 4.4.29 (Projections of a direct sum)
Techniques. Compare components (Technique 4.4.8), Split the space with an idempotent (Technique 4.4.28)
Hint 1. Every $\mathbf{x}$ equals $\sum_i P_i\mathbf{x}$, so the images add up to F^n. Directness is then a dimension count. How is $\operatorname{rank} P_i$ related to $\operatorname{tr} P_i$ over these fields?
Hint 2. For (b), decompose $P_j\mathbf{x}$ in two ways: as itself, a vector of $\operatorname{im} P_j$, and as $\sum_i P_i(P_j\mathbf{x})$.
Sketch. (a) $\mathbf{x} = \sum_i P_i\mathbf{x}$, so $\sum_i \operatorname{im} P_i = F^n$. By Exercise 4.3.43, $\operatorname{rank} P_i = \operatorname{tr} P_i$, so $\sum_i \dim \operatorname{im} P_i = \operatorname{tr}\left(\sum_i P_i\right) = \operatorname{tr} I_n = n$, and Theorem 4.4.13(c) makes the sum direct. (b) $P_j\mathbf{x} = \sum_i P_iP_j\mathbf{x}$ has components $P_iP_j\mathbf{x} \in \operatorname{im} P_i$, while $P_j\mathbf{x} \in \operatorname{im} P_j$ also has the decomposition with $P_j\mathbf{x}$ in slot j and $\mathbf{0}$ elsewhere; compare components. (c) Over $\mathbb{F}_2$, take $P_1 = P_2 = P_3 = I_1$.

(a) For $\mathbf{x} \in F^n$, $\mathbf{x} = I_n\mathbf{x} = P_1\mathbf{x} + \cdots + P_k\mathbf{x}$, so $\operatorname{im} P_1 + \cdots + \operatorname{im} P_k = F^n$. Over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$, an idempotent matrix has rank equal to its trace (Exercise 4.3.43(c)). So, using Theorem 4.2.7 and Proposition 2.4.27,

$$\dim \operatorname{im} P_1 + \cdots + \dim \operatorname{im} P_k = \operatorname{tr} P_1 + \cdots + \operatorname{tr} P_k = \operatorname{tr}(P_1 + \cdots + P_k) = \operatorname{tr} I_n = n.$$

This is the dimension of the sum, so the sum is direct by Theorem 4.4.13(c).

(b) Fix j and $\mathbf{x} \in F^n$, and let $\mathbf{y} = P_j\mathbf{x} \in \operatorname{im} P_j$. Since $\sum_i P_i = I_n$,

$$\mathbf{y} = P_1\mathbf{y} + \cdots + P_k\mathbf{y},$$

a decomposition of $\mathbf{y}$ along $\operatorname{im} P_1, \ldots, \operatorname{im} P_k$. Another decomposition of $\mathbf{y}$ has component $\mathbf{y}$ in $\operatorname{im} P_j$ and $\mathbf{0}$ in every other $\operatorname{im} P_i$. By (a) the two agree, so $P_i\mathbf{y} = P_iP_j\mathbf{x} = \mathbf{0}$ for $i \neq j$. As $\mathbf{x}$ was arbitrary, $P_iP_j = 0$.

By (b) and Proposition 4.4.29(b), the P_i are the projections of the decomposition in (a).

(c) Over $\mathbb{F}_2$, let $n = 1$, $k = 3$, and $P_1 = P_2 = P_3 = I_1 = (1)$. Each is idempotent, and $P_1 + P_2 + P_3 = (1{+}1{+}1) = I_1$, but $P_1P_2 = I_1 \neq 0$. What fails is (a): the ranks add up to $3 > 1$, while the trace only records them modulo 2.

Solution to Exercise 4.4.52

Uses. Proposition 4.1.34 (Size of a vector space over a finite field), Theorem 4.4.7 (Criteria for direct sums), Proposition 4.4.21 (Two out of three), Proposition 4.2.6 (Injective maps preserve dimension)
Techniques. Double counting (Technique 4.1.36)
Hint 1. Two members of a spread share only $\mathbf{0}$. Count nonzero vectors.
Hint 2. The subspace Γ_M of vectors $(\mathbf{x}, M\mathbf{x})$ meets $\Gamma_{M'}$ only in $\mathbf{0}$ when $M - M'$ is invertible. Add the subspace of vectors $(\mathbf{0}, \mathbf{y})$.
Hint 3. Over $\mathbb{F}_2$, $C = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$ satisfies $C^2 = C + I_2$ and $C^3 = I_2$. Try $M \in \{0, I_2, C, C^2\}$.
Sketch. (a) Each member has $q^2 - 1$ nonzero vectors, no nonzero vector lies in two members, and F^4 has $q^4 - 1$ nonzero vectors; so $m(q^2 - 1) \leq q^4 - 1$, i.e. $m \leq q^2 + 1$. (b) Take Γ_M for $M \in \{0, I_2, C, C^2\}$ and $\Gamma_\infty = \{(\mathbf{0}, \mathbf{y})\}$. Every difference of two of the four matrices is I_2, C, or C^2, all invertible, so $\Gamma_M \cap \Gamma_{M'} = \{\mathbf{0}\}$; and $\Gamma_M \cap \Gamma_\infty = \{\mathbf{0}\}$. Two-dimensional subspaces of $\mathbb{F}_2^4$ meeting trivially are complements.

Write vectors of F^4 as $(\mathbf{x}, \mathbf{y})$ with $\mathbf{x}, \mathbf{y} \in F^2$.

(a) Let $U_1, \ldots, U_m$ be a spread. For $i \neq j$, $U_i \cap U_j = \{\mathbf{0}\}$, so the sets $U_i \setminus \{\mathbf{0}\}$ are pairwise disjoint subsets of $F^4 \setminus \{\mathbf{0}\}$. Each U_i has q^2 elements (Proposition 4.1.34), so

$$m(q^2 - 1) \leq q^4 - 1 = (q^2 - 1)(q^2 + 1),$$

and $m \leq q^2 + 1$.

(b) For $M \in \mathbb{F}_2^{2\times 2}$ let $\Gamma_M = \{(\mathbf{x}, M\mathbf{x}) \mid \mathbf{x} \in \mathbb{F}_2^2\}$, the image of the injective linear map $\mathbf{x} \mapsto (\mathbf{x}, M\mathbf{x})$, so $\dim \Gamma_M = 2$ (Proposition 4.2.6(a)). Let $\Gamma_\infty = \{(\mathbf{0}, \mathbf{y}) \mid \mathbf{y} \in \mathbb{F}_2^2\}$, also of dimension 2. Let

$$C = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} = C + I_2, \quad C^3 = CC^2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = I_2.$$

So C and C^2 are invertible, with $C^{-1} = C^2$. We claim that $\Gamma_0, \Gamma_{I_2}, \Gamma_C, \Gamma_{C^2}, \Gamma_\infty$ is a spread.

Since $-1 = 1$ in $\mathbb{F}_2$, the differences of two distinct matrices among $0, I_2, C, C^2$ are

$$I_2 - 0 = I_2, \quad C - 0 = C, \quad C^2 - 0 = C^2, \quad C - I_2 = C^2, \quad C^2 - I_2 = C, \quad C^2 - C = I_2,$$

all invertible. If $(\mathbf{x}, M\mathbf{x}) = (\mathbf{x}', M'\mathbf{x}')$ with $M \neq M'$ among them, then $\mathbf{x} = \mathbf{x}'$ and $(M - M')\mathbf{x} = \mathbf{0}$, so $\mathbf{x} = (M - M')^{-1}\mathbf{0} = \mathbf{0}$. Hence $\Gamma_M \cap \Gamma_{M'} = \{\mathbf{0}\}$. Also, $(\mathbf{x}, M\mathbf{x}) = (\mathbf{0}, \mathbf{y})$ forces $\mathbf{x} = \mathbf{0}$ and then $\mathbf{y} = \mathbf{0}$, so $\Gamma_M \cap \Gamma_\infty = \{\mathbf{0}\}$. Any two of the five subspaces have dimensions adding up to 4 and meet only in $\mathbf{0}$, so they are complements of each other by Proposition 4.4.21. This spread has $2^2 + 1$ members, so the bound in (a) is attained.

The four matrices $0, I_2, C, C^2$, with matrix addition and multiplication, form the field with four elements (Section 14.3). The same construction, with $\mathbb{F}_{q^2}$ realized as q^2 matrices in $F^{2\times 2}$, gives a spread of size $q^2 + 1$ for every q.

Section 4.5

Solution to Exercise 4.5.9

Uses. Theorem 4.5.6 (Classification by dimension), Theorem 4.5.8 (Dimension of $\mathrm{L}(V, W)$), Example 4.1.7 (Dimensions of the standard spaces), Definition 2.4.26 (Trace)
Hint 1. By Theorem 4.5.6, it is enough to compute dimensions.
Hint 2. For (d), (e), and (g), write down a basis: which matrix units or monomials are allowed?
Sketch. The dimensions are $6, 6, 6, 6, 6, 3, 3$. So (a)–(e) form one class and (f), (g) another.

By Theorem 4.5.6, two finite-dimensional spaces are isomorphic exactly when their dimensions agree. We compute the dimensions.

(a) $2 \cdot 3 = 6$ (Example 4.1.7). **(b)** 6, with basis $1, x, \ldots, x^5$. **(c)** $3 \cdot 2 = 6$ by Theorem 4.5.8. **(d)** An upper triangular matrix is $\sum_{i \le j} a_{ij} U_{ij}$ with unique coefficients, so the six matrix units U_{ij} with $i \le j$ form a basis: dimension 6. **(e)** $p(0) = 0$ means that the constant coefficient vanishes, so $x, x^2, \ldots, x^6$ is a basis: dimension 6. **(f)** $1 \cdot 3 = 3$ by Theorem 4.5.8. **(g)** $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ has trace 0 when $d = -a$, and then it equals $a(U_{11} - U_{22}) + bU_{12} + cU_{21}$, with unique coefficients. So $U_{11} - U_{22}, U_{12}, U_{21}$ is a basis: dimension 3.

So the classes are $\{(a), (b), (c), (d), (e)\}$ and $\{(f), (g)\}$.

Solution to Exercise 4.5.13

Uses. Proposition 4.5.12 (Calculus of change of coordinates), Definition 4.5.10 (Change-of-coordinates matrix), Proposition 2.5.28 (Inverse of a 2×2 matrix), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
Hint 1. $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = M^{-1}N$, where N and M have the vectors of $\mathcal{B}$ and $\mathring{\mathcal{B}}$ as columns. For a 2×2 matrix with $ad - bc \neq 0$, the inverse is $(ad - bc)^{-1}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$ (Proposition 2.5.28).
Hint 2. In $\mathbb{F}_5$, $3^{-1} = 2$. Alternatively, find the columns $[\mathbf{b}_j]_{\mathring{\mathcal{B}}}$ by solving $x(1,1) + y(1,4) = \mathbf{b}_j$ directly.
Sketch. $M = \begin{pmatrix} 1 & 1 \\ 1 & 4 \end{pmatrix}$ has $ad - bc = 3$, so $M^{-1} = 2\begin{pmatrix} 4 & -1 \\ -1 & 1 \end{pmatrix} = \begin{pmatrix} 3 & 3 \\ 3 & 2 \end{pmatrix}$, and $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = M^{-1}N = \begin{pmatrix} 4 & 1 \\ 2 & 2 \end{pmatrix}$. Then $\mathbf{v} = (4, 6) = (4, 1)$ and $[\mathbf{v}]_{\mathring{\mathcal{B}}} = (5, 4) = (0, 4)$; indeed $4(1, 4) = (4, 16) = (4, 1)$.

(a) Let $N = \begin{pmatrix} 1 & 3 \\ 2 & 4 \end{pmatrix}$ and $M = \begin{pmatrix} 1 & 1 \\ 1 & 4 \end{pmatrix}$. Then $1 \cdot 4 - 3 \cdot 2 = -2 = 3$ and $1 \cdot 4 - 1 \cdot 1 = 3$ are nonzero in $\mathbb{F}_5$, so both matrices are invertible (Proposition 2.5.28), their columns are independent (Corollary 3.5.25), and two independent vectors in $\mathbb{F}_5^2$ form a basis (Theorem 4.1.10(b)). Since $3 \cdot 2 = 6 = 1$, we have $3^{-1} = 2$ and

$$M^{-1} = 2\begin{pmatrix} 4 & -1 \\ -1 & 1 \end{pmatrix} = \begin{pmatrix} 8 & -2 \\ -2 & 2 \end{pmatrix} = \begin{pmatrix} 3 & 3 \\ 3 & 2 \end{pmatrix}.$$

So

$$[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = M^{-1}N = \begin{pmatrix} 3 & 3 \\ 3 & 2 \end{pmatrix}\begin{pmatrix} 1 & 3 \\ 2 & 4 \end{pmatrix} = \begin{pmatrix} 9 & 21 \\ 7 & 17 \end{pmatrix} = \begin{pmatrix} 4 & 1 \\ 2 & 2 \end{pmatrix}.$$

Check: $4(1,1) + 2(1,4) = (6,12) = (1,2)$ and $1(1,1) + 2(1,4) = (3,9) = (3,4)$.

(b) $\mathbf{v} = (1,2) + (3,4) = (4,6) = (4,1)$, and

$$[\mathbf{v}]_{\mathring{\mathcal{B}}} = \begin{pmatrix} 4 & 1 \\ 2 & 2 \end{pmatrix}\begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 5 \\ 4 \end{pmatrix} = \begin{pmatrix} 0 \\ 4 \end{pmatrix}.$$

Check: $0(1,1) + 4(1,4) = (4,16) = (4,1) = \mathbf{v}$.

Solution to Exercise 4.5.20

Uses. Theorem 4.5.17 (Change of basis), Proposition 2.3.16 (The matrix of T_A), Definition 2.3.1 (Matrix of a linear map)
Hint 1. With $P = [\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}} = \begin{pmatrix} 1 & 2 \\ 1 & 1 \end{pmatrix}$, the formula is $[T_A]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = P^{-1}AP$.
Hint 2. $P^{-1} = \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix}$. For the check, write $A(1,1)$ and $A(2,1)$ as combinations of $(1,1)$ and $(2,1)$.
Sketch. $AP = \begin{pmatrix} 2 & 6 \\ 2 & 3 \end{pmatrix}$ and $P^{-1}AP = \begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}$. Indeed $A(1,1) = (2,2) = 2(1,1)$ and $A(2,1) = (6,3) = 3(2,1)$.

By Proposition 2.3.16, $[T_A]_{\mathcal{E}\mathcal{E}} = A$, and $P = [\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}} = \begin{pmatrix} 1 & 2 \\ 1 & 1 \end{pmatrix}$ has the vectors of $\mathring{\mathcal{B}}$ as columns. It is invertible over every field, with $P^{-1} = \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix}$ (multiply to check). By Theorem 4.5.17,

$$[T_A]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = P^{-1}AP = \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} 2 & 6 \\ 2 & 3 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}.$$

Directly: $A(1,1) = (2,2) = 2(1,1) + 0(2,1)$ and $A(2,1) = (6,3) = 0(1,1) + 3(2,1)$, so the columns of $[T_A]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$ are $(2,0)$ and $(0,3)$. In the basis $\mathring{\mathcal{B}}$, T_A just scales each basis vector. Finding such bases is the subject of Section 7.4.

Solution to Exercise 4.5.32

Uses. Proposition 4.5.27 (Similarity invariants), Theorem 4.5.25 (Similar matrices are one operator in two bases), Definition 4.5.23 (Similar matrices)
Techniques. Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. Compare traces first, and remember that only I_2 is similar to I_2.
Hint 2. For (b), $N = M - I_2$ satisfies $N^2 = 0$ and $N \neq 0$. Find $\mathbf{w}$ with $N\mathbf{w} \neq \mathbf{0}$; what is the matrix of T_M in the basis $N\mathbf{w}, \mathbf{w}$?
Sketch. (a) No: $S^{-1}I_2S = I_2 \neq J$. (c) No: $\mathrm{tr} = 3 \neq 2$. (b) Yes: with $\mathbf{w} = \mathbf{e}_1$, $N\mathbf{w} = (1,-1)$; in the basis $(1,-1), (1,0)$, T_M fixes the first vector and sends the second to itself plus the first, so $S = \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}$ works. Check $MS = SJ$.

(a) Not similar: $S^{-1}I_2S = I_2 \neq J$ for every invertible S.

(c) Not similar: $\mathrm{tr}\, M = 3 \neq 2 = \mathrm{tr}\, J$ (Proposition 4.5.27(b)).

(b) Similar. Both matrices have trace 2 and rank 2, which only says that similarity is possible. Let $N = M - I_2 = \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}$. Then $N^2 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$, while $N\mathbf{e}_1 = (1,-1) \neq \mathbf{0}$. Let $\mathring{\mathcal{B}} = (1,-1), (1,0)$, a basis since the vectors are not parallel. Then $M(1,-1) = (1,-1) + N(1,-1) = (1,-1)$, because $N(1,-1) = N^2\mathbf{e}_1 = \mathbf{0}$, and $M(1,0) = (1,0) + N\mathbf{e}_1 = (1,0) + (1,-1)$. So the columns of $[T_M]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}$ are $(1,0)$ and $(1,1)$, that is, $[T_M]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = J$. By Theorem 4.5.25 and Theorem 4.5.17, $S = \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}$, whose columns are the vectors of $\mathring{\mathcal{B}}$, satisfies $S^{-1}MS = J$. Check:

$$MS = \begin{pmatrix} 2 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ -1 & -1 \end{pmatrix}, \quad SJ = \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ -1 & -1 \end{pmatrix}.$$

Solution to Exercise 4.5.38

Uses. Proposition 4.5.12 (Calculus of change of coordinates), Corollary 3.5.25 (The invertible matrix theorem), Theorem 4.1.10 (Independent lists are short), Theorem 3.3.10 ($GA = \mathrm{rref}(A)$)

Hint 1. $[\mathrm{id}]_{\mathcal{BE}}$ is the inverse of the matrix M whose columns are the vectors of $\mathcal{B}$. Row reduce $(M \mid I_3)$ over $\mathbb{F}_3$, where $2^{-1} = 2$.
Hint 2. For (c), $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = \left([\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}}\right)^{-1}[\mathrm{id}]_{\mathcal{EB}}$. For (d), add the three vectors.
Sketch. $M^{-1} = \begin{pmatrix} 2 & 2 & 1 \\ 1 & 2 & 2 \\ 2 & 1 & 2 \end{pmatrix}$ over $\mathbb{F}_3$ (over $\mathbb{Q}$ it is $\frac{1}{2}\begin{pmatrix} 1 & 1 & -1 \\ -1 & 1 & 1 \\ 1 & -1 & 1 \end{pmatrix}$, and $1/2 = 2$ in $\mathbb{F}_3$). Then $[(1,2,0)]_{\mathcal{B}} = (0,2,1)$, and $[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = \begin{pmatrix} 0 & 2 & 1 \\ 1 & 0 & 2 \\ 0 & 1 & 1 \end{pmatrix}$. Over $\mathbb{F}_2$ the three vectors add to $\mathbf{0}$.

(a) Let $M = [\mathrm{id}]_{\mathcal{EB}} = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}$. Row reducing $(M \mid I_3)$ over $\mathbb{F}_3$ (or inverting over $\mathbb{Q}$ and reading $1/2$ as 2, since $2 \cdot 2 = 4 = 1$) gives

$$M^{-1} = \begin{pmatrix} 2 & 2 & 1 \\ 1 & 2 & 2 \\ 2 & 1 & 2 \end{pmatrix},$$

and one checks $MM^{-1} = I_3$ over $\mathbb{F}_3$; for instance, the first row of the product is $(1\cdot 2 + 1\cdot 2, 1\cdot 2 + 1\cdot 1, 1\cdot 1 + 1\cdot 2) = (4,3,3) = (1,0,0)$. So M is invertible, its columns form a basis of $\mathbb{F}_3^3$ (Corollary 3.5.25, Theorem 4.1.10(b)), and $[\mathrm{id}]_{\mathcal{BE}} = M^{-1}$ by Proposition 4.5.12(b).

(b) $[(1,2,0)]_{\mathcal{B}} = M^{-1}(1,2,0) = (2+4, 1+4, 2+2) = (6,5,4) = (0,2,1)$. Check: $2(0,1,1) + (1,0,1) = (1,2,3) = (1,2,0)$.

(c) $[\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}} = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}$ has inverse $\begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}$, so

$$[\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{B}} = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 & 1 \\ 1 & 0 & -1 \\ 0 & 1 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 2 & 1 \\ 1 & 0 & 2 \\ 0 & 1 & 1 \end{pmatrix}.$$

Check the first column: $0(1,0,0) + 1(1,1,0) + 0(1,1,1) = (1,1,0)$, the first vector of $\mathcal{B}$.

(d) No: over $\mathbb{F}_2$, $(1,1,0) + (0,1,1) + (1,0,1) = (2,2,2) = \mathbf{0}$, a nontrivial dependence.

Solution to Exercise 4.5.39

Uses. Proposition 4.5.12 (Calculus of change of coordinates), Example 4.5.26 (A similarity and a non-similarity), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Remark 4.5.28 (What the invariants cannot do), Theorem 4.5.8 (Dimension of $\mathrm{L}(V,W)$), Theorem 4.5.6 (Classification by dimension)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Two of the six are false, and the counterexamples are in this section.
Hint 2. For (c), compute $\dim \operatorname{im} T$. For (f), compute $S^{-1}(cI_n)S$.
Sketch. (a) True: the inverse of $[\mathrm{id}]_{\mathcal{B}'\mathcal{B}}$ is $[\mathrm{id}]_{\mathcal{B}\mathcal{B}'}$. (b) False: $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \sim \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$ over $\mathbb{Q}$. (c) True by rank–nullity. (d) False: I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. (e) True: $2\dim W = 6$. (f) True: $S^{-1}(cI_n)S = cI_n$.

(a) True, by Proposition 4.5.12(b).

(b) False. Over $\mathbb{Q}$, $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \sim \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$ (Example 4.5.26), and the diagonals $(1,1)$ and $(2,0)$ differ.

(c) True. $\ker T = \{\mathbf{0}\}$, so by Theorem 4.2.11, $\dim \operatorname{im} T = \dim V = \dim W$. Then $\operatorname{im} T = W$ by Proposition 4.1.21(b), so T is bijective, hence an isomorphism.

(d) False. I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ both have rank 2 and trace 2, and they are not similar (Remark 4.5.28).

(e) True. W is finite-dimensional: if $\mathbf{v}_1, \mathbf{v}_2$ is a basis of V, then $T \mapsto T(\mathbf{v}_1)$ is a surjective linear map $\mathrm{L}(V,W) \to W$ (every $\mathbf{w}$ is $T(\mathbf{v}_1)$ for the T with $\mathbf{v}_1 \mapsto \mathbf{w}$ and $\mathbf{v}_2 \mapsto \mathbf{0}$), so $\dim W \le 6$ by Theorem 4.2.11. Then Theorem 4.5.8 gives $2\dim W = 6$, so $\dim W = 3$ and $W \cong F^3$ (Theorem 4.5.6).

(f) True. $S^{-1}(cI_n)S = cS^{-1}S = cI_n$ for every invertible S.

Solution to Exercise 4.5.40

Uses. Corollary 4.1.11 (Spanning lists are long), Definition 4.5.10 (Change-of-coordinates matrix), Proposition 4.5.12 (Calculus of change of coordinates)
Hint 1. Write $x = (x-a)+a$ and expand x^j by the binomial theorem, which holds in $F[x]$ because multiplication of polynomials is commutative.
Hint 2. For (b), expand $(x-a)^j$ in powers of x. For (c), the two matrices of (a) and (b) are inverse to each other; compute the (i,j) entry of their product.
Sketch. $x^j = \sum_i \binom{j}{i} a^{j-i}(x-a)^i$ shows that $\mathcal{B}_a$ spans, hence is a basis, and gives the columns of $[\mathrm{id}]_{\mathcal{B}_a\mathcal{B}}$. Likewise $(x-a)^j = \sum_i \binom{j}{i}(-a)^{j-i}x^i$. The product $[\mathrm{id}]_{\mathcal{B}\mathcal{B}_a}[\mathrm{id}]_{\mathcal{B}_a\mathcal{B}} = I$ has (i,j) entry $a^{j-i}\sum_k (-1)^{k-i}\binom{k}{i}\binom{j}{k}$.

Here an integer such as $\binom{j}{i}$ stands for the corresponding sum of 1's in F.

(a) By the binomial theorem in $F[x]$,

$$x^j = ((x-a)+a)^j = \sum_{i=0}^{j} \binom{j}{i} a^{j-i}(x-a)^i.$$

So $1, x, \ldots, x^n$ lie in $\mathrm{span}(\mathcal{B}_a)$, which is therefore all of $F[x]_{\le n}$. A spanning list of length $n+1 = \dim F[x]_{\le n}$ is a basis (Corollary 4.1.11(b)). The display gives $[x^j]_{\mathcal{B}_a}$, the j-th column of $[\mathrm{id}]_{\mathcal{B}_a\mathcal{B}}$: its i-th entry is $\binom{j}{i}a^{j-i}$ for $i \le j$ and 0 for $i > j$.

(b) Similarly $(x-a)^j = \sum_{i=0}^{j}\binom{j}{i}(-a)^{j-i}x^i$, so the (i,j) entry of $[\mathrm{id}]_{\mathcal{B}\mathcal{B}_a}$ is $\binom{j}{i}(-a)^{j-i}$ for $i \le j$ and 0 otherwise.

(c) By Proposition 4.5.12(b), the two matrices are inverse to each other. The (i,j) entry of $[\mathrm{id}]_{\mathcal{B}\mathcal{B}_a}[\mathrm{id}]_{\mathcal{B}_a\mathcal{B}}$ is, for $i \le j$,

$$\sum_{k=i}^{j} \binom{k}{i}(-a)^{k-i}\binom{j}{k}a^{j-k} = a^{j-i}\sum_{k=i}^{j}(-1)^{k-i}\binom{j}{k}\binom{k}{i},$$

since only $i \le k \le j$ contribute. With $F = \mathbb{Q}$ and $a = 1$, this entry of I_{n+1} is 1 if $i = j$ and 0 if $i < j$, which is the identity. (The case $j > n$ is covered by taking n larger.)

Solution to Exercise 4.5.41

Uses. Theorem 4.1.16 (Extending to a basis), Theorem 4.5.8 (Dimension of $\mathrm{L}(V,W)$), Proposition 4.5.5 (Isomorphisms preserve linear structure), Proposition 1.6.7 (Standard bases)
Techniques. Choose a convenient basis (Technique 4.5.33), Transport along an isomorphism (Technique 4.5.7), Dimension counting (Technique 4.2.24)
Hint 1. Extend $\mathbf{v}_0$ to a basis $\mathcal{B}$ of V with $\mathbf{v}_0$ first. What does $T(\mathbf{v}_0) = \mathbf{0}$ say about $[T]_{\mathcal{C}\mathcal{B}}$?
Hint 2. The condition is that the first column is zero. Transport K to matrices with Theorem 4.5.8.
Sketch. With $\mathbf{v}_0$ the first vector of $\mathcal{B}$, $T \in K$ iff the first column of $[T]_{\mathcal{C}\mathcal{B}}$ is $\mathbf{0}$. The isomorphism $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ carries K onto the matrices with zero first column, a subspace with basis U_{ij}, $j \ge 2$, of dimension $(n-1)m$.

If $m = 0$, then $\mathrm{L}(V,W) = \{0\} = K$, of dimension 0. Let $m \ge 1$. Extend $\mathbf{v}_0$ to a basis $\mathcal{B} = \mathbf{v}_0, \mathbf{v}_2, \ldots, \mathbf{v}_n$ of V (Theorem 4.1.16), and choose a basis $\mathcal{C}$ of W. The first column of $[T]_{\mathcal{C}\mathcal{B}}$ is $[T(\mathbf{v}_0)]_{\mathcal{C}}$, which is $\mathbf{0}$ exactly when $T(\mathbf{v}_0) = \mathbf{0}$. So the isomorphism $\Phi : T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ of Theorem 4.5.8 carries K onto

$$Z = \{A \in F^{m\times n} \mid \text{the first column of } A \text{ is } \mathbf{0}\}.$$

Z consists of the combinations of the matrix units U_{ij} with $j \ge 2$, which are independent (Proposition 1.6.7(b)); so Z is a subspace with $\dim Z = m(n-1)$. Then $K = \mathrm{im}(\Phi^{-1}|_Z)$ is a subspace of $\mathrm{L}(V,W)$ with $\dim K = \dim Z$, by Proposition 4.5.5(b) and (c) applied to the isomorphism Φ^{-1}.

Solution to Exercise 4.5.41

Uses. Definition 2.1.21 (Pointwise operations), Theorem 4.1.16 (Extending to a basis), Theorem 2.2.1 (Linear maps are determined by a basis), Theorem 4.2.11 (Rank–nullity), Theorem 4.5.8 (Dimension of $\mathrm{L}(V,W)$), Proposition 2.6.8 (Kernels and images are subspaces)
Techniques. Dimension counting (Technique 4.2.24), Choose a convenient basis (Technique 4.5.33)
Hint 1. K is the kernel of a linear map $\mathrm{L}(V,W) \to W$. Which one?

Hint 2. Evaluation $\varepsilon(T) = T(\mathbf{v}_0)$ is linear and surjective. Apply rank–nullity in $\mathrm{L}(V, W)$, whose dimension you know.
Sketch. $\varepsilon : T \mapsto T(\mathbf{v}_0)$ is linear with kernel K, and surjective because a map can send $\mathbf{v}_0$ anywhere. So $\dim K = nm - m$.

Let $\varepsilon : \mathrm{L}(V, W) \to W$, $\varepsilon(T) = T(\mathbf{v}_0)$. It is linear because the operations on $\mathrm{L}(V, W)$ are pointwise: $(S + cT)(\mathbf{v}_0) = S(\mathbf{v}_0) + cT(\mathbf{v}_0)$. Its kernel is K, which is therefore a subspace (Proposition 2.6.8). It is surjective: given $\mathbf{w} \in W$, extend $\mathbf{v}_0$ to a basis $\mathbf{v}_0, \mathbf{v}_2, \ldots, \mathbf{v}_n$ of V, and let T be the linear map with $T(\mathbf{v}_0) = \mathbf{w}$ and $T(\mathbf{v}_j) = \mathbf{0}$ for $j \geq 2$ (Theorem 2.2.1). By Theorem 4.2.11(b) and Theorem 4.5.8,

$$\dim K = \dim \mathrm{L}(V, W) - \dim W = nm - m = (n-1)m.$$

Solution to Exercise 4.5.42

Uses. Theorem 4.1.16 (Extending to a basis), Theorem 4.5.8 (Dimension of $\mathrm{L}(V, W)$), Proposition 4.5.5 (Isomorphisms preserve linear structure), Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Proposition 1.6.7 (Standard bases), Proposition 2.6.22 (Testing injectivity and surjectivity on a basis)
Techniques. Choose a convenient basis (Technique 4.5.33), Choose a basis adapted to a preserved subspace (Technique 4.5.36), Transport along an isomorphism (Technique 4.5.7)
Hint 1. Choose a basis of V that starts with a basis of U, and a basis of W that starts with a basis of U'.
Hint 2. In these bases, the condition says that certain entries of $[T]_{\mathcal{C}\mathcal{B}}$ vanish. Which ones, and how many?
Hint 3. Compare the proof of Proposition 4.5.35. Then transport along $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$.
Sketch. With adapted bases, $\mathrm{im}(T\restriction_U) \subseteq U'$ iff $T(\mathbf{u}_j) \in U'$ for $j \leq k$, iff the first k columns of $[T]_{\mathcal{C}\mathcal{B}}$ vanish in rows $k'+1, \ldots, m$. Those $k(m-k')$ entries are forced to be 0 and the other $mn - k(m-k')$ are free, so the set corresponds to the span of the remaining matrix units.

Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be a basis of U, extended to a basis $\mathcal{B}$ of V, and $\mathbf{u}'_1, \ldots, \mathbf{u}'_{k'}$ a basis of U', extended to a basis $\mathcal{C}$ of W (Theorem 4.1.16). A vector of W lies in U' if and only if its $\mathcal{C}$-coordinates vanish after position k', as in the proof of Proposition 4.5.35. Since $T(\mathbf{u}_1), \ldots, T(\mathbf{u}_k)$ spans $\mathrm{im}(T\restriction_U)$ (Proposition 2.6.22(d)) and U' is a subspace, $\mathrm{im}(T\restriction_U) \subseteq U'$ holds if and only if $T(\mathbf{u}_j) \in U'$ for $j = 1, \ldots, k$, that is, if and only if the entries of $[T]_{\mathcal{C}\mathcal{B}}$ in rows $k'+1, \ldots, m$ and columns $1, \ldots, k$ are all 0.

So the isomorphism $T \mapsto [T]_{\mathcal{C}\mathcal{B}}$ (Theorem 4.5.8) carries our set onto the set Z of matrices whose entries in those $k(m-k')$ positions vanish. Z is the span of the matrix units U_{ij} in the other $mn - k(m-k')$ positions, which are independent (Proposition 1.6.7(b)); so Z is a subspace of that dimension. By Proposition 4.5.5(b), (c), applied to the inverse isomorphism, our set is a subspace of $\mathrm{L}(V, W)$ of the same dimension. For $V = W$ and $U = U'$, take $m = n$ and $k' = k$.

Solution to Exercise 4.5.43

Uses. Exercise 2.5.46, Theorem 4.1.10 (Independent lists are short), Theorem 4.5.25 (Similar matrices are one operator in two bases), Proposition 4.5.24 (Similarity is an equivalence relation), Proposition 1.5.14 (Appending a vector)
Techniques. Choose a convenient basis (Technique 4.5.33)
Hint 1. (a) Apply the hypothesis to $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathbf{e}_1 + \mathbf{e}_2$.
Hint 2. (b) By (a) there is $\mathbf{v}$ with $A\mathbf{v} \notin \mathrm{span}(\mathbf{v})$. For the matrix, you need $A(A\mathbf{v})$ in terms of $\mathbf{v}$ and $A\mathbf{v}$: use $A^2 - (\mathrm{tr}\, A)A + \delta(A)I_2 = 0$ (Exercise 2.5.46(a)).
Hint 3. (c) Both matrices are similar to the same C. (d) What are the trace and δ of A^{T}, and when is A^{T} scalar?
Sketch. (a) $A\mathbf{e}_1 = \lambda\mathbf{e}_1$, $A\mathbf{e}_2 = \mu\mathbf{e}_2$, and $A(\mathbf{e}_1 + \mathbf{e}_2) = \nu(\mathbf{e}_1 + \mathbf{e}_2)$ force $\lambda = \nu = \mu$. (b) Pick $\mathbf{v}$ with $A\mathbf{v} \notin \mathrm{span}(\mathbf{v})$; then $\mathbf{v}, A\mathbf{v}$ is independent, and $A^2\mathbf{v} = (\mathrm{tr}\, A)A\mathbf{v} - \delta(A)\mathbf{v}$ gives the second column. (c) Both are similar to the same C_A. (d) A^{T} has the same trace and δ, and is scalar iff A is. (e) Both matrices have trace -1 and $\delta = 1$ and are not scalar.

(a) By hypothesis $A\mathbf{e}_1 = \lambda\mathbf{e}_1$, $A\mathbf{e}_2 = \mu\mathbf{e}_2$, and $A(\mathbf{e}_1 + \mathbf{e}_2) = \nu(\mathbf{e}_1 + \mathbf{e}_2)$ for some scalars. The last equation reads $\lambda\mathbf{e}_1 + \mu\mathbf{e}_2 = \nu\mathbf{e}_1 + \nu\mathbf{e}_2$, so $\lambda = \nu = \mu$. The columns of A are then $\lambda\mathbf{e}_1$ and $\lambda\mathbf{e}_2$, that is, $A = \lambda I_2$.

(b) By (a) there is $\mathbf{v}$ with $A\mathbf{v} \notin \mathrm{span}(\mathbf{v})$. Then $\mathbf{v} \neq \mathbf{0}$ (as $A\mathbf{0} = \mathbf{0}$ lies in every span), so the list $\mathbf{v}$ is independent, and $\mathbf{v}, A\mathbf{v}$ is independent by Proposition 1.5.14. Two independent vectors in F^2 form a basis (Theorem 4.1.10(b)). In this basis, T_A sends the first vector $\mathbf{v}$ to the second vector $A\mathbf{v}$, with coordinates $(0, 1)$. By Exercise 2.5.46(a), $A^2 = (\mathrm{tr}\, A)A - \delta(A)I_2$, so

$$A(A\mathbf{v}) = -\delta(A)\mathbf{v} + (\mathrm{tr}\, A)A\mathbf{v},$$

with coordinates $(-\delta(A), \mathrm{tr}\, A)$. So the matrix is C_A.

(c) Let A and B be non-scalar with $\operatorname{tr} A = \operatorname{tr} B$ and $\delta(A) = \delta(B)$. Then $C_A = C_B$. By (b) and Theorem 4.5.25, $A \sim C_A$ and $B \sim C_B = C_A$, so $A \sim B$ (Proposition 4.5.24).

(d) If $A = cI_2$, then $A^{\mathsf{T}} = A$. Otherwise A^{T} is not scalar either, since $(cI_2)^{\mathsf{T}} = cI_2$ and $\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A$. The diagonal of A^{T} is that of A, and $\delta\left(A^{\mathsf{T}}\right) = ad - cb = \delta(A)$. So $A \sim A^{\mathsf{T}}$ by (c).

(e) R is not scalar, $\operatorname{tr} R = -1$, and $\delta(R) = 0 \cdot (-1) - (-1) \cdot 1 = 1$. The rotation matrix is not scalar, its trace is $2\cos(2\pi/3) = -1$, and its δ is $\cos^2 + \sin^2 = 1$. By (c), the two are similar over $\mathbb{R}$.

Solution to Exercise 4.5.44

Uses. Exercise 4.5.43, Proposition 4.5.27 (Similarity invariants), Definition 4.5.23 (Similar matrices)
Techniques. Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. (a) is a direct expansion; then $\delta\left(S^{-1}\right)\delta(S) = \delta(I_2) = 1$.
Hint 2. (b) Existence is Exercise 4.5.43(b). For uniqueness, which invariants separate the matrices in the list? What are the trace and δ of $\left(\begin{smallmatrix} 0 & -d \\ 1 & t \end{smallmatrix}\right)$?
Sketch. (a) Expanding, $\delta(XY) = (ad - bc)(eh - fg)$ for $X = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, $Y = \left(\begin{smallmatrix} e & f \\ g & h \end{smallmatrix}\right)$; so $\delta\left(S^{-1}AS\right) = \delta\left(S^{-1}\right)\delta(A)\delta(S) = \delta(A)$. (b) A scalar matrix is similar only to itself; a non-scalar A is similar to $\left(\begin{smallmatrix} 0 & -\delta(A) \\ 1 & \operatorname{tr} A \end{smallmatrix}\right)$, which is not scalar; and $\left(\begin{smallmatrix} 0 & -d \\ 1 & t \end{smallmatrix}\right)$ has trace t and $\delta = d$, so different (t, d) give non-similar matrices. (c) q scalars plus q^2 pairs (t, d).

(a) For $X = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ and $Y = \left(\begin{smallmatrix} e & f \\ g & h \end{smallmatrix}\right)$, $XY = \left(\begin{smallmatrix} ae+bg & af+bh \\ ce+dg & cf+dh \end{smallmatrix}\right)$, and expanding,

$$\begin{aligned} \delta(XY) &= (ae + bg)(cf + dh) - (af + bh)(ce + dg) \\ &= adeh + bcfg - adfg - bceh = (ad - bc)(eh - fg), \end{aligned}$$

since the terms $acef$ and $bdgh$ cancel. If $B = S^{-1}AS$, then $\delta\left(S^{-1}\right)\delta(S) = \delta\left(S^{-1}S\right) = \delta(I_2) = 1$, and since scalars commute,

$$\delta(B) = \delta\left(S^{-1}\right)\delta(A)\delta(S) = \delta(A).$$

(b) *Existence.* If A is scalar, it is in the list. Otherwise $A \sim \left(\begin{smallmatrix} 0 & -\delta(A) \\ 1 & \operatorname{tr} A \end{smallmatrix}\right)$ by Exercise 4.5.43(b) and Theorem 4.5.25.

Uniqueness. A scalar matrix cI_2 is similar only to itself (Exercise 4.5.39(f)), so it is not similar to any other matrix of the list; the matrices $\left(\begin{smallmatrix} 0 & -d \\ 1 & t \end{smallmatrix}\right)$ are not scalar, because of the entry 1. Finally, $\left(\begin{smallmatrix} 0 & -d \\ 1 & t \end{smallmatrix}\right)$ has trace t and $\delta = 0 \cdot t - (-d) \cdot 1 = d$. By (a) and Proposition 4.5.27(b), two matrices of this form with different pairs (t, d) are not similar.

(c) Over $\mathbb{F}_q$ the list has q scalar matrices and q^2 matrices $\left(\begin{smallmatrix} 0 & -d \\ 1 & t \end{smallmatrix}\right)$, and by (b) each similarity class contains exactly one of them. So there are $q^2 + q$ classes.

Solution to Exercise 4.5.45

Uses. Definition 4.5.23 (Similar matrices), Corollary 4.5.21 (Matrices of one linear map), Proposition 4.5.27 (Similarity invariants)
Techniques. Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. Compare the last sentence with Definition 4.5.23. Which relation between the left and right factors does similarity require?
Hint 2. For a counterexample, look for two 2×2 matrices of rank 1 that differ in an invariant.
Sketch. Similarity needs $B = S^{-1}AS$, with the left factor the inverse of the right one; nothing makes $G'^{-1}G = S^{-1}$. The argument proves only $B = GAH$, which is Corollary 4.5.21. Counterexample: $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ have rank 1 but traces 0 and 1.

The error is in the last sentence. Similarity requires $B = S^{-1}AS$: the left factor must be the inverse of the right factor. The argument produces $B = G''AS$ with $G'' = G'^{-1}G$ and $S = HH'^{-1}$ both invertible, but nothing forces $G'' = S^{-1}$. What it proves is that A and B are matrices of one linear map with possibly different bases on the domain and the target (Corollary 4.5.21).

The claim is false: $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ both have rank 1, but their traces are 0 and 1, so they are not similar (Proposition 4.5.27(b)).

Solution to Exercise 4.5.46

Uses. Definition 4.5.23 (Similar matrices), Proposition 4.5.27 (Similarity invariants), Lemma 2.4.24 (Matrix units)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. Only one statement is true. For counterexamples, use matrix units, and remember that only 0 is similar to 0 and only I_n to I_n.
Hint 2. $U_{11} \sim U_{22}$ (swap the basis vectors). Try $C = U_{11}$ in (a) and (b).
Sketch. (a) False: $U_{11} \sim U_{22}$ and $U_{11} \sim U_{11}$, but $2U_{11}$ (rank 1 or 0) is not similar to $U_{11} + U_{22}$ (rank 2). (b) False: $U_{11}U_{11} = U_{11}$ but $U_{22}U_{11} = 0$. (c) True by Proposition 4.5.27(d). (d) False: $U_{12}^2 = 0 = 0^2$.

We write U_{ij} for the matrix units (here in $F^{n\times n}$). Swapping $\mathbf{e}_1$ and $\mathbf{e}_2$ in the standard basis shows $U_{11} \sim U_{22}$: with S the matrix of the swap, $S^{-1}U_{11}S = U_{22}$.

(a) False. Take $A = C = D = U_{11}$ and $B = U_{22}$. Then $A + C = 2U_{11}$, while $B + D = U_{11} + U_{22}$ has rank 2. If $2 \neq 0$ in F, then $2U_{11}$ has rank 1; if $2 = 0$, it is the zero matrix, of rank 0. Either way the ranks differ, so the sums are not similar.

(b) False. With $A = U_{11}$, $B = U_{22}$, and $C = U_{11}$, we get $AC = U_{11}$ and $BC = U_{22}U_{11} = 0$ (Lemma 2.4.24(c)). Only 0 is similar to 0.

(c) True: apply Proposition 4.5.27(d) with $-c$ in place of c.

(d) False. $A = U_{12}$ and $B = 0$ satisfy $A^2 = 0 = B^2$, but $A \neq 0$ is not similar to 0.

Solution to Exercise 4.5.47

Uses. Lemma 2.4.24 (Matrix units), Proposition 2.4.27 (The trace is linear), Definition 2.4.26 (Trace), Proposition 1.6.7 (Standard bases)
Techniques. Cyclicity of trace (Technique 2.4.29), Check it on a basis (Technique 2.2.7)
Hint 1. Apply the hypothesis to $A = SX$: it says $f(XS) = f(SX)$ for every X and every invertible S.
Hint 2. For $k \neq l$, the matrix $I_n + U_{kl}$ is invertible, with inverse $I_n - U_{kl}$. Deduce $f(XU_{kl}) = f(U_{kl}X)$.
Hint 3. Take $X = U_{ik}$. Then $XU_{kl} = U_{il}$ and $U_{kl}X = \delta_{li}U_{kk}$. What does this say about $f(U_{il})$ for $i \neq l$, and about $f(U_{ll})$?
Sketch. Invariance with $A = SX$ gives $f(XS) = f(SX)$. With $S = I + U_{kl}$ $(k \neq l)$ and linearity, $f(XU_{kl}) = f(U_{kl}X)$. For $X = U_{ik}$ this reads $f(U_{il}) = \delta_{li}f(U_{kk})$. So $f(U_{il}) = 0$ for $i \neq l$ and $f(U_{ll}) = f(U_{kk})$ for all $k \neq l$. With c the common value, $f(A) = \sum a_{ij}f(U_{ij}) = c\,\mathrm{tr}\,A$.

If $n = 1$, then $f(a) = af(1) = f(1)\,\mathrm{tr}(a)$ by linearity. Let $n \geq 2$.

Step 1. For $X \in F^{n\times n}$ and invertible S, the hypothesis with $A = SX$ gives $f\big(S^{-1}SXS\big) = f(SX)$, that is,

$$f(XS) = f(SX).$$

Step 2. Let $k \neq l$. By Lemma 2.4.24(c), $U_{kl}U_{kl} = \delta_{lk}U_{kl} = 0$, so $(I_n + U_{kl})(I_n - U_{kl}) = I_n - U_{kl}^2 = I_n$, and likewise in the other order. So $S = I_n + U_{kl}$ is invertible, and Step 1 gives $f(X + XU_{kl}) = f(X + U_{kl}X)$. By linearity,

$$f(XU_{kl}) = f(U_{kl}X) \quad \text{for all } X \text{ and all } k \neq l.$$

Step 3. Take $X = U_{ik}$. By Lemma 2.4.24(c), $XU_{kl} = U_{il}$ and $U_{kl}X = \delta_{li}U_{kk}$, so

$$f(U_{il}) = \delta_{li}f(U_{kk}) \quad \text{for all } i \text{ and all } k \neq l.$$

If $i \neq l$, choose any $k \neq l$ (possible since $n \geq 2$); then $f(U_{il}) = 0$. If $i = l$, we get $f(U_{ll}) = f(U_{kk})$ for every $k \neq l$. So all $f(U_{kk})$ are equal to a single $c \in F$.

Conclusion. For $A = \sum_{i,j} a_{ij}U_{ij}$ (Proposition 1.6.7(b)), linearity gives

$$f(A) = \sum_{i,j} a_{ij}f\big(U_{ij}\big) = c\sum_i a_{ii} = c\,\mathrm{tr}\,A.$$

Conversely, every $c\,\mathrm{tr}$ is linear and similarity-invariant (Proposition 2.4.27, Proposition 4.5.27(b)).

Solution to Exercise 4.5.48

Uses. Definition 4.5.30 (Trace of an operator), Lemma 2.4.24 (Matrix units), Proposition 1.6.7 (Standard bases), Proposition 2.4.12 (Matrices of sums and scalar multiples), Proposition 2.4.27 (The trace is linear)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29)
Hint 1. Use the basis of matrix units. The diagonal entry of $[T]$ belonging to U_{ij} is the U_{ij}-coordinate of $T(U_{ij})$, which is the (i,j) entry of $AU_{ij}B$.
Hint 2. Write $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$, so the (i,j) entry of $AU_{ij}B$ is $\left(\mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_i\right)\left(\mathbf{e}_j^{\mathsf{T}}B\mathbf{e}_j\right)$.
Sketch. The (i,j) entry of $AU_{ij}B$ is $a_{ii}b_{jj}$, so $\operatorname{tr} T = \sum_{i,j} a_{ii}b_{jj} = (\operatorname{tr} A)(\operatorname{tr} B)$. With $B = I_n$ or $A = I_n$ the traces are $n \operatorname{tr} A$ and $n \operatorname{tr} B$, and $X \mapsto AX - XA$ has trace $n \operatorname{tr} A - n \operatorname{tr} A = 0$.

In the basis of matrix units $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ (Proposition 1.6.7(b), Lemma 2.4.24), the U_{ij}-coordinate of a matrix is its (i,j) entry. So the diagonal entry of $[T]$ in the position of U_{ij} is the (i,j) entry of $T(U_{ij}) = A\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}B$, which by Lemma 2.4.24(b) is

$$\mathbf{e}_i^{\mathsf{T}}A\mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}B\mathbf{e}_j = a_{ii}b_{jj}.$$

Summing over all i and j (Definition 4.5.30),

$$\operatorname{tr} T = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ii}b_{jj} = (\operatorname{tr} A)(\operatorname{tr} B).$$

With $B = I_n$, the operator $X \mapsto AX$ has trace $(\operatorname{tr} A)(\operatorname{tr} I_n) = n \operatorname{tr} A$; with $A = I_n$, $X \mapsto XB$ has trace $n \operatorname{tr} B$. The trace of an operator is linear in the operator, by Proposition 2.4.12 and Proposition 2.4.27, so $X \mapsto AX - XA$ has trace $n \operatorname{tr} A - n \operatorname{tr} A = 0$.

Solution to Exercise 4.5.49

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 1.5.14 (Appending a vector), Theorem 4.1.10 (Independent lists are short), Definition 4.5.30 (Trace of an operator), Theorem 4.5.25 (Similar matrices are one operator in two bases), Proposition 4.5.27 (Similarity invariants), Proposition 4.5.24 (Similarity is an equivalence relation)
Techniques. Choose a convenient basis (Technique 4.5.33)
Hint 1. If $\mathbf{v} = P\mathbf{w}$, compute $P\mathbf{v}$.
Hint 2. For independence of the combined list, split a relation into a part in $\operatorname{im} P$ and a part in $\ker P$. Count with rank–nullity.
Hint 3. For (c), both matrices are similar to the same N_r.
Sketch. If $\mathbf{v} = P\mathbf{w}$ then $P\mathbf{v} = P^2\mathbf{w} = \mathbf{v}$, so a vector in $\ker P \cap \operatorname{im} P$ equals $P\mathbf{v} = \mathbf{0}$. A relation among the combined list gives a vector in both subspaces, hence zero, so the list is independent; it has $r + (n-r) = n$ vectors. P fixes the first r and kills the rest, so its matrix is N_r and $\operatorname{tr} P = r$. In (c), $A \sim N_r \sim B$.

(a) If $\mathbf{v} = P\mathbf{w} \in \operatorname{im} P$, then $P\mathbf{v} = P^2\mathbf{w} = P\mathbf{w} = \mathbf{v}$. If also $\mathbf{v} \in \ker P$, then $\mathbf{v} = P\mathbf{v} = \mathbf{0}$. Let $\mathbf{p}_1, \dots, \mathbf{p}_r$ be a basis of $\operatorname{im} P$ and $\mathbf{k}_1, \dots, \mathbf{k}_s$ a basis of $\ker P$, where $s = n - r$ by Theorem 4.2.11. Suppose $\sum_i a_i\mathbf{p}_i + \sum_j b_j\mathbf{k}_j = \mathbf{0}$. The vector $\mathbf{x} = \sum_i a_i\mathbf{p}_i = -\sum_j b_j\mathbf{k}_j$ lies in $\operatorname{im} P \cap \ker P = \{\mathbf{0}\}$, so all a_i and all b_j are 0 by independence of the two bases. So the combined list of n vectors is independent, hence a basis of V (Theorem 4.1.10(b)).

(b) $P\mathbf{p}_i = \mathbf{p}_i$ and $P\mathbf{k}_j = \mathbf{0}$, so the matrix of P in this basis has columns $\mathbf{e}_1, \dots, \mathbf{e}_r, \mathbf{0}, \dots, \mathbf{0}$; it is N_r. Hence $\operatorname{tr} P = \operatorname{tr} N_r = r \cdot 1$ (Definition 4.5.30). Over a field of characteristic p, this determines r only modulo p.

(c) If $A \sim B$, then $\operatorname{rank} A = \operatorname{rank} B$ (Proposition 4.5.27(a)). Conversely, if both have rank r, apply (b) to T_A and T_B on F^n: each has matrix N_r in a suitable basis, so $A \sim N_r$ and $B \sim N_r$ by Theorem 4.5.25, and $A \sim B$ by Proposition 4.5.24.

Solution to Exercise 4.5.50

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Theorem 4.5.25 (Similar matrices are one operator in two bases), Proposition 4.5.24 (Similarity is an equivalence relation), Proposition 2.4.23 (Transpose of a product)
Techniques. Choose a convenient basis (Technique 4.5.33), Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Choose $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$, and look at $\mathbf{v}, N\mathbf{v}, \dots, N^{n-1}\mathbf{v}$.
Hint 2. These vectors are independent by Proposition 4.1.26. Where does N send each of them?
Hint 3. For (c), check that J_n^{T} satisfies the hypotheses of (b). The transpose of a power is the power of the transpose.

Sketch. Pick $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$; since $N^n\mathbf{v} = \mathbf{0}$, Proposition 4.1.26 makes $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ independent, hence a basis. N sends each vector to the next and the last to $\mathbf{0}$, which is J_n. (b) T_A and T_B both have matrix J_n. (c) $\left(J_n^{\mathsf{T}}\right)^k = \left(J_n^k\right)^{\mathsf{T}}$.

(a) Since $N^{n-1} \neq 0$, there is $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$, and $N^n\mathbf{v} = \mathbf{0}$. By Proposition 4.1.26 with $k = n-1$, the list $\mathcal{B} = \mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ is independent, and it has n vectors, so it is a basis (Theorem 4.1.10(b)). N sends the j-th vector $N^{j-1}\mathbf{v}$ to $N^j\mathbf{v}$, the $(j+1)$-th vector, for $j < n$, and the last vector to $N^n\mathbf{v} = \mathbf{0}$. So the columns of $[N]_{\mathcal{B}\mathcal{B}}$ are $\mathbf{e}_2, \ldots, \mathbf{e}_n, \mathbf{0}$, and $[N]_{\mathcal{B}\mathcal{B}} = J_n$.

(b) T_A and T_B satisfy the hypotheses of (a) on F^n (since $(T_A)^k = T_{A^k}$). So $A \sim J_n$ and $B \sim J_n$ by Theorem 4.5.25, and $A \sim B$ (Proposition 4.5.24).

(c) $J_n\mathbf{e}_j = \mathbf{e}_{j+1}$ for $j < n$ and $J_n\mathbf{e}_n = \mathbf{0}$, so $J_n^{n-1}\mathbf{e}_1 = \mathbf{e}_n \neq \mathbf{0}$ and $J_n^n = 0$. By Proposition 2.4.23, $\left(J_n^{\mathsf{T}}\right)^k = \left(J_n^k\right)^{\mathsf{T}}$, so J_n^{T} satisfies the same two conditions, and $J_n \sim J_n^{\mathsf{T}}$ by (b). Concretely, reversing the order of the basis $\mathcal{B}$ turns J_n into J_n^{T}.

Solution to Exercise 4.5.51

Uses. Proposition 4.3.16 (Rank-one matrices), Proposition 2.4.28 (Cyclicity of the trace), Theorem 4.2.11 (Rank–nullity), Theorem 4.1.16 (Extending to a basis), Proposition 1.5.14 (Appending a vector), Theorem 4.1.10 (Independent lists are short), Theorem 4.5.25 (Similar matrices are one operator in two bases), Proposition 4.5.27 (Similarity invariants)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17), Choose a convenient basis (Technique 4.5.33)
Hint 1. Write $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u}, \mathbf{v} \neq \mathbf{0}$. Then $A\mathbf{x} = \left(\mathbf{v}^{\mathsf{T}}\mathbf{x}\right)\mathbf{u}$, so $\ker A = \left\{\mathbf{x} \;\middle|\; \mathbf{v}^{\mathsf{T}}\mathbf{x} = 0\right\}$, and $t = \mathbf{v}^{\mathsf{T}}\mathbf{u}$.
Hint 2. If $t \neq 0$, then $\mathbf{u} \notin \ker A$; use $\mathbf{u}$ followed by a basis of $\ker A$. If $t = 0$, then $\mathbf{u} \in \ker A$; pick $\mathbf{w}$ with $A\mathbf{w} = \mathbf{u}$ and use $\mathbf{w}, \mathbf{u}$, followed by more vectors of $\ker A$.
Sketch. $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$, $t = \mathbf{v}^{\mathsf{T}}\mathbf{u}$, $\ker A = \left\{\mathbf{x} \;\middle|\; \mathbf{v}^{\mathsf{T}}\mathbf{x} = 0\right\}$ has dimension $n-1$. If $t \neq 0$: in the basis $\mathbf{u}$, then a basis of $\ker A$, A has matrix tU_{11}. If $t = 0$: choose $\mathbf{w}$ with $\mathbf{v}^{\mathsf{T}}\mathbf{w} = 1$, so $A\mathbf{w} = \mathbf{u}$; extend $\mathbf{u}$ to a basis of $\ker A$; in the basis $\mathbf{w}, \mathbf{u}, \ldots$, the matrix is U_{21}.

By Proposition 4.3.16, $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u}, \mathbf{v} \neq \mathbf{0}$. Then $A\mathbf{x} = \mathbf{u}\left(\mathbf{v}^{\mathsf{T}}\mathbf{x}\right) = \left(\mathbf{v}^{\mathsf{T}}\mathbf{x}\right)\mathbf{u}$, so $\ker A = \left\{\mathbf{x} \;\middle|\; \mathbf{v}^{\mathsf{T}}\mathbf{x} = 0\right\}$, which has dimension $n-1$ by Theorem 4.2.11. By Proposition 2.4.28, $t = \operatorname{tr}\left(\mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \operatorname{tr}\left(\mathbf{v}^{\mathsf{T}}\mathbf{u}\right) = \mathbf{v}^{\mathsf{T}}\mathbf{u}$.

Case $t \neq 0$**.** Then $A\mathbf{u} = t\mathbf{u} \neq \mathbf{0}$, so $\mathbf{u} \notin \ker A$. Let $\mathbf{k}_2, \ldots, \mathbf{k}_n$ be a basis of $\ker A$; by Proposition 1.5.14, $\mathbf{k}_2, \ldots, \mathbf{k}_n, \mathbf{u}$ is independent, so (reordering) $\mathbf{u}, \mathbf{k}_2, \ldots, \mathbf{k}_n$ is a basis of F^n (Theorem 4.1.10(b)). T_A sends $\mathbf{u}$ to $t\mathbf{u}$ and each $\mathbf{k}_j$ to $\mathbf{0}$, so its matrix in this basis is tU_{11}.

Case $t = 0$**.** Then $\mathbf{u} \in \ker A$. Some entry v_i of $\mathbf{v}$ is nonzero; let $\mathbf{w} = v_i^{-1}\mathbf{e}_i$, so $\mathbf{v}^{\mathsf{T}}\mathbf{w} = 1$ and $A\mathbf{w} = \mathbf{u}$. Extend $\mathbf{u}$ to a basis $\mathbf{u}, \mathbf{k}_3, \ldots, \mathbf{k}_n$ of $\ker A$ (Theorem 4.1.16). Since $A\mathbf{w} \neq \mathbf{0}$, $\mathbf{w} \notin \ker A$, so as before $\mathbf{w}, \mathbf{u}, \mathbf{k}_3, \ldots, \mathbf{k}_n$ is a basis of F^n. T_A sends $\mathbf{w}$ to $\mathbf{u}$, the second basis vector, and the other basis vectors to $\mathbf{0}$. So its matrix is U_{21}.

In both cases Theorem 4.5.25 gives the similarity. Two matrices of rank 1 with the same trace t are similar to the same matrix, hence to each other; conversely, similar matrices have the same trace (Proposition 4.5.27(b)).

Solution to Exercise 4.5.52

Uses. Theorem 3.5.27 (Rank normal form), Proposition 2.5.17 (Algebra of inverses), Example 2.5.14 (Invertible maps and matrices)
Techniques. Choose a convenient basis (Technique 4.5.33)
Hint 1. The property "is a sum of two invertible matrices" survives $A \mapsto GAH$ with G, H invertible. So assume $A = N_r$.
Hint 2. Write $N_r = \operatorname{diag}(1, \ldots, 1, 0, \ldots, 0)$ as the sum of two diagonal matrices with nonzero diagonal entries. You need a scalar c with $c \neq 0$ and $1 - c \neq 0$.
Sketch. If $A = GN_rH$ and $N_r = X + Y$, then $A = GXH + GYH$. Choose $c \in F$ with $c \neq 0, 1$, and split $N_r = \operatorname{diag}(c, \ldots, c, 1, \ldots, 1) + \operatorname{diag}(1-c, \ldots, 1-c, -1, \ldots, -1)$. Over $\mathbb{F}_2$, the only invertible 1×1 matrix is (1), and $(1) + (1) = (0)$.

By Theorem 3.5.27, $G'AH' = N_r$ for some invertible G', H', where $r = \operatorname{rank} A$; so $A = GN_rH$ with $G = G'^{-1}$ and $H = H'^{-1}$ invertible. If $N_r = X + Y$ with X and Y invertible, then $A = GXH + GYH$, and GXH and GYH are invertible (Proposition 2.5.17(b)). So it suffices to treat N_r.

Choose $c \in F$ with $c \neq 0$ and $c \neq 1$, which is possible because F has at least three elements. Let

$$X = \operatorname{diag}(c, \ldots, c, 1, \ldots, 1), \quad Y = \operatorname{diag}(1-c, \ldots, 1-c, -1, \ldots, -1),$$

with r entries c (respectively $1-c$) followed by $n-r$ entries 1 (respectively -1). Then $X+Y=N_r$, and X and Y are invertible because their diagonal entries are nonzero (Example 2.5.14(d)).

Over $\mathbb{F}_2$, the only invertible 1×1 matrix is (1), and $(1)+(1)=(0)\neq(1)$. So (1) is not a sum of two invertible matrices.

Solution to Exercise 4.5.53

Uses. Exercise 4.5.52, Theorem 3.5.27 (Rank normal form), Theorem 2.4.34 (Block multiplication), Proposition 2.5.17 (Algebra of inverses)
Techniques. Choose a convenient basis (Technique 4.5.33), Block decomposition (Technique 2.4.35)
Hint 1. As in Exercise 4.5.52, it suffices to treat N_r. Over $\mathbb{F}_2$ a diagonal matrix with a 0 on the diagonal is not invertible, so the splitting must use non-diagonal blocks.
Hint 2. Block diagonal matrices with invertible blocks are invertible. Split N_r into diagonal blocks and decompose each block separately. Which small blocks can you decompose? Try (0), I_2, $\mathrm{diag}(1,0)$, and I_3.
Hint 3. $(0)=(1)+(1)$, $I_2=\begin{pmatrix}1&1\\1&0\end{pmatrix}+\begin{pmatrix}0&1\\1&1\end{pmatrix}$, $\mathrm{diag}(1,0)=\begin{pmatrix}1&1\\1&0\end{pmatrix}+\begin{pmatrix}0&1\\1&0\end{pmatrix}$. For I_3, try X with $X\mathbf{e}_1=\mathbf{e}_3$, $X\mathbf{e}_2=\mathbf{e}_1+\mathbf{e}_3$, $X\mathbf{e}_3=\mathbf{e}_2$, and $Y=I_3+X$.
Sketch. Reduce to N_r. Decompose the blocks $(0)=(1)+(1)$, I_2, $\mathrm{diag}(1,0)$, and I_3 explicitly over $\mathbb{F}_2$. Then cut N_r into diagonal blocks of these types: if $r=0$, use (0)'s; if $r=1$, use $\mathrm{diag}(1,0)$ and (0)'s (here $n\geq 2$ is needed); if $r\geq 2$, write I_r with I_2's and at most one I_3, and the rest with (0)'s. Block diagonal sums of invertible blocks finish the proof.

As in the solution of Exercise 4.5.52, $A=GN_rH$ with G, H invertible, and it suffices to write $N_r=X+Y$ with X, Y invertible. All arithmetic is in $\mathbb{F}_2$, where $1+1=0$.

Block diagonal matrices. If $D=\mathrm{diag}(D_1,\dots,D_s)$ is block diagonal and $D_i=X_i+Y_i$ with X_i, Y_i invertible, then $D=\mathrm{diag}(X_1,\dots,X_s)+\mathrm{diag}(Y_1,\dots,Y_s)$, and $\mathrm{diag}(X_1,\dots,X_s)$ is invertible with inverse $\mathrm{diag}\left(X_1^{-1},\dots,X_s^{-1}\right)$ by Theorem 2.4.34; likewise for the Y_i.

Small blocks. Over $\mathbb{F}_2$:

- $(0)=(1)+(1)$.
- $I_2=\begin{pmatrix}1&1\\1&0\end{pmatrix}+\begin{pmatrix}0&1\\1&1\end{pmatrix}$, and both summands are invertible: $\begin{pmatrix}1&1\\1&0\end{pmatrix}$ has inverse $\begin{pmatrix}0&1\\1&1\end{pmatrix}$ (multiply to check), and vice versa.
- $\mathrm{diag}(1,0)=\begin{pmatrix}1&1\\1&0\end{pmatrix}+\begin{pmatrix}0&1\\1&0\end{pmatrix}$, and $\begin{pmatrix}0&1\\1&0\end{pmatrix}$ is its own inverse.
- $I_3=X_3+Y_3$ with

$$X_3=\begin{pmatrix}0&1&0\\0&0&1\\1&1&0\end{pmatrix},\quad Y_3=I_3+X_3=\begin{pmatrix}1&1&0\\0&1&1\\1&1&1\end{pmatrix}.$$

  X_3 is invertible: its columns $\mathbf{e}_3$, $\mathbf{e}_1+\mathbf{e}_3$, $\mathbf{e}_2$ span $\mathbb{F}_2^3$, since $\mathbf{e}_1=(\mathbf{e}_1+\mathbf{e}_3)+\mathbf{e}_3$. Y_3 is invertible: if $Y_3(x,y,z)=(x+y,y+z,x+y+z)=\mathbf{0}$, then $x=y=z$ (from the first two entries) and the third entry is $3x=x=0$.

Cutting N_r into blocks. If $r=0$, then N_r is a block diagonal matrix of n blocks (0). If $r=1$, then since $n\geq 2$, $N_1=\mathrm{diag}(\mathrm{diag}(1,0),(0),\dots,(0))$. If $r\geq 2$, write $r=2a$ or $r=2a+3$ with $a\geq 0$; then I_r is block diagonal with a blocks I_2 and, if r is odd, one block I_3, and $N_r=\mathrm{diag}(I_r,(0),\dots,(0))$. In every case each block has a decomposition from the list above, and the block diagonal step gives $N_r=X+Y$ with X and Y invertible.

Solution to Exercise 4.5.54

Uses. Definition 1.2.13 (Polynomials), Proposition 2.7.7 (Bijective linear maps are invertible), Proposition 4.5.5 (Isomorphisms preserve linear structure), Proposition 4.1.21 (Dimensions of subspaces), Example 2.1.9 (Maps of polynomials)
Hint 1. (a) In terms of coefficient sequences, S shifts every coefficient up by one place.
Hint 2. (b) Compare dimensions. (c) Every polynomial has an antiderivative; which polynomials have derivative 0? (d) Contrapositive of Proposition 4.5.5(c).
Sketch. (a) $S\left(a_0+a_1x+\cdots+a_dx^d\right)=a_0x+\cdots+a_dx^{d+1}$ is linear, injective, and onto $xF[x]$; $1\notin xF[x]$. (b) A subspace isomorphic to V has dimension $\dim V$, so it is V. (c) $D\left(\sum a_kx^{k+1}/(k+1)\right)=\sum a_kx^k$, and $D(1)=0$. (d) If W were finite-dimensional, so would V be.

(a) For $p = a_0 + a_1x + \cdots + a_dx^d$, $S(p) = a_0x + a_1x^2 + \cdots + a_dx^{d+1}$, whose coefficient sequence is that of p shifted by one place. So S is linear, and $S(p) = \mathbf{0}$ forces all $a_k = 0$, so S is injective. Every $q = b_1x + \cdots + b_ex^e \in xF[x]$ is $S\big(b_1 + b_2x + \cdots + b_ex^{e-1}\big)$. So S is a linear bijection onto $xF[x]$, an isomorphism (Proposition 2.7.7). The subspace $xF[x]$ is proper, since $1 \notin xF[x]$; so S is not surjective as a map $F[x] \to F[x]$.

(b) If U is a subspace of a finite-dimensional V and $U \cong V$, then $\dim U = \dim V$ (Proposition 4.5.5(c)), so $U = V$ by Proposition 4.1.21(b).

(c) $D\big(a_0 + a_1x + \cdots + a_dx^d\big) = a_1 + 2a_2x + \cdots + da_dx^{d-1}$ (Example 2.1.9). Given $q = \sum_{k=0}^{e} b_kx^k \in \mathbb{R}[x]$, the polynomial $p = \sum_{k=0}^{e} \frac{b_k}{k+1}x^{k+1}$ satisfies $D(p) = q$, so D is surjective. But $D(1) = 0$ with $1 \neq 0$, so D is not injective. Rank–nullity forbids both phenomena for operators on finite-dimensional spaces (Corollary 4.2.18).

(d) If W were finite-dimensional, then V, being isomorphic to W, would be finite-dimensional by Proposition 4.5.5(c), applied to an isomorphism $W \to V$.

Solution to Exercise 4.5.55

Uses. Theorem 4.5.25 (Similar matrices are one operator in two bases), Definition 4.5.23 (Similar matrices), Proposition 2.5.28 (Inverse of a 2×2 matrix)
Techniques. Choose a convenient basis (Technique 4.5.33)
Hint 1. (a) Look for $\mathbf{v} \in \mathbb{C}^2$ with $R\mathbf{v} = i\mathbf{v}$ and $\mathbf{w}$ with $R\mathbf{w} = -i\mathbf{w}$. Then use them as the columns of S.
Hint 2. (b) If $S^{-1}RS = \operatorname{diag}(p, q)$ with S real, then the first column $\mathbf{s}$ of S satisfies $R\mathbf{s} = p\mathbf{s}$. Write this out.
Hint 3. (c) Try $S = \operatorname{diag}(1, -1)$, a reflection.
Sketch. (a) $R(1, -i) = (i, 1) = i(1, -i)$ and $R(1, i) = -i(1, i)$, so $S = \begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}$ works. (b) $R(x, y) = p(x, y)$ means $-y = px$ and $x = py$, so $\big(1 + p^2\big)x = 0$, giving $x = y = 0$; but columns of an invertible S are nonzero. (c) $\operatorname{diag}(1, -1)R \operatorname{diag}(1, -1) = -R$: conjugating a rotation by a reflection reverses its direction.

(a) $R(x, y) = (-y, x)$. So $R(1, -i) = (i, 1) = i(1, -i)$ and $R(1, i) = (-i, 1) = -i(1, i)$. Let $S = \begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}$; it is invertible, since $1 \cdot i - 1 \cdot (-i) = 2i \neq 0$ (Proposition 2.5.28). In the basis of its columns, T_R has matrix $\operatorname{diag}(i, -i)$, so $S^{-1}RS = \operatorname{diag}(i, -i)$ (Theorem 4.5.25). Equivalently, $RS = \begin{pmatrix} i & -i \\ 1 & 1 \end{pmatrix} = S \operatorname{diag}(i, -i)$.

(b) Suppose $S^{-1}RS = \operatorname{diag}(p, q)$ with $S \in \mathbb{R}^{2\times 2}$ invertible and $p, q \in \mathbb{R}$. Then $RS = S \operatorname{diag}(p, q)$, and comparing first columns, $R\mathbf{s} = p\mathbf{s}$ for the first column $\mathbf{s} = (x, y)$ of S. That is, $-y = px$ and $x = py$, so $x = py = -p^2x$ and $\big(1 + p^2\big)x = 0$. Since $1 + p^2 > 0$, $x = 0$, and then $y = -px = 0$. But $\mathbf{s} \neq \mathbf{0}$, because S is invertible. So no such S exists, and R is not similar over $\mathbb{R}$ to a real diagonal matrix.

(c) With $S = \operatorname{diag}(1, -1) = S^{-1}$,

$$S^{-1}RS = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = -R.$$

Geometrically, $-R$ is the rotation by $-\pi/2$, and the similarity is a change of basis from $\mathbf{e}_1, \mathbf{e}_2$ to $\mathbf{e}_1, -\mathbf{e}_2$, which reverses the orientation of the plane. A counterclockwise quarter turn, viewed in a mirror, is a clockwise one. So over $\mathbb{R}$, a rotation and its inverse are similar, although they are different operators.

Solution to Exercise 4.5.56

Uses. Theorem 4.5.17 (Change of basis), Definition 4.5.30 (Trace of an operator), Proposition 2.5.28 (Inverse of a 2×2 matrix)
Hint 1. In the basis $\mathcal{U} = (1, 2), (1, 1)$, the matrix of T is diagonal. Which diagonal matrix?
Hint 2. $[T]_{\mathcal{E}\mathcal{E}} = Q[T]_{\mathcal{U}\mathcal{U}}Q^{-1}$ with $Q = [\mathrm{id}]_{\mathcal{E}\mathcal{U}} = \begin{pmatrix} 1 & 1 \\ 2 & 1 \end{pmatrix}$.
Sketch. $[T]_{\mathcal{U}\mathcal{U}} = \operatorname{diag}(3, -1)$, $Q^{-1} = \begin{pmatrix} -1 & 1 \\ 2 & -1 \end{pmatrix}$, and $[T]_{\mathcal{E}\mathcal{E}} = \begin{pmatrix} -5 & 4 \\ -8 & 7 \end{pmatrix}$. The trace is 2 either way.

$T(1, 2) = 3(1, 2)$ and $T(1, 1) = -(1, 1)$, so in the basis $\mathcal{U} = (1, 2), (1, 1)$ (a basis over every field, since $1 \cdot 1 - 1 \cdot 2 = -1 \neq 0$), $[T]_{\mathcal{U}\mathcal{U}} = \operatorname{diag}(3, -1)$. With $Q = [\mathrm{id}]_{\mathcal{E}\mathcal{U}} = \begin{pmatrix} 1 & 1 \\ 2 & 1 \end{pmatrix}$ and $Q^{-1} = [\mathrm{id}]_{\mathcal{U}\mathcal{E}} = \begin{pmatrix} -1 & 1 \\ 2 & -1 \end{pmatrix}$ (Proposition 2.5.28), Theorem 4.5.17 gives

$$[T]_{\mathcal{E}\mathcal{E}} = Q\begin{pmatrix}3 & 0\\ 0 & -1\end{pmatrix}Q^{-1} = \begin{pmatrix}3 & -1\\ 6 & -1\end{pmatrix}\begin{pmatrix}-1 & 1\\ 2 & -1\end{pmatrix} = \begin{pmatrix}-5 & 4\\ -8 & 7\end{pmatrix}.$$

Check: $\begin{pmatrix}-5 & 4\\ -8 & 7\end{pmatrix}\begin{pmatrix}1\\ 2\end{pmatrix} = \begin{pmatrix}3\\ 6\end{pmatrix}$ and $\begin{pmatrix}-5 & 4\\ -8 & 7\end{pmatrix}\begin{pmatrix}1\\ 1\end{pmatrix} = \begin{pmatrix}-1\\ -1\end{pmatrix}$. The trace is $-5+7=2$ from the standard matrix and $3+(-1)=2$ from the diagonal one, as Definition 4.5.30 requires.

Section 4.6

Solution to Exercise 4.6.6

Uses. Theorem 1.4.3 (Subspace criterion), Definition 4.6.1 (Product space)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), check the subspace criterion one component at a time.
Hint 2. For (b), try the smallest interesting case, $V = W = F$. Is there a line in $F \times F = F^2$ that is not a product?
Sketch. (a) Componentwise. (b) False: the diagonal $\{(t,t) \mid t \in F\}$ is a subspace of $F \times F$. A product $V' \times W'$ containing $(1,1)$ has $1 \in V'$ and $0 \in W'$, so it contains $(1,0)$, which is not on the diagonal.

(a) $(\mathbf{0},\mathbf{0}) \in V' \times W'$. If $(\mathbf{v},\mathbf{w}), (\mathbf{v}',\mathbf{w}') \in V' \times W'$ and $a \in F$, then $a(\mathbf{v},\mathbf{w}) + (\mathbf{v}',\mathbf{w}') = (a\mathbf{v}+\mathbf{v}', a\mathbf{w}+\mathbf{w}')$, whose components lie in V' and W' because these are subspaces. By Theorem 1.4.3, $V' \times W'$ is a subspace.

(b) The claim is false. Take $V = W = F$ and the diagonal $D = \{(t,t) \mid t \in F\}$, which is a subspace of $F \times F$ (it is $\operatorname{span}((1,1))$). Suppose $D = V' \times W'$. Since $(1,1) \in D$, we get $1 \in V'$ and $0 \in W'$ (as W' is a subspace), so $(1,0) \in V' \times W' = D$. But $(1,0)$ is not of the form (t,t).

Solution to Exercise 4.6.17

Uses. Lemma 4.6.14 (Equal cosets), Definition 1.3.10 (Span)
Hint 1. A general element of U is $a(1,0,1) + b(0,1,1)$. Write it out.
Hint 2. By Lemma 4.6.14, $\mathbf{v} + U = \mathbf{w} + U$ exactly when $\mathbf{v} - \mathbf{w} \in U$, that is, when $\mathbf{v}$ and $\mathbf{w}$ have the same value of $z - x - y$.
Sketch. (a) $a(1,0,1) + b(0,1,1) = (a, b, a+b)$. (b) The values of $z-x-y$ are $0, 1, 1, -1$, so only $(0,0,1) + U = (2,-1,2) + U$; also $(1,2,3) + U = U$.

(a) $a(1,0,1) + b(0,1,1) = (a, b, a+b)$, and every (x,y,z) with $z = x + y$ has this form with $a = x$, $b = y$. So $U = \{(x,y,z) \mid z - x - y = 0\}$. By Lemma 4.6.14, $(x,y,z) \in \mathbf{v} + U$ if and only if $(x,y,z) - \mathbf{v} \in U$, that is, $(z - v_3) - (x - v_1) - (y - v_2) = 0$, which is $z - x - y = v_3 - v_1 - v_2$.

(b) Let $f(x,y,z) = z - x - y$. By (a) and Lemma 4.6.14, two cosets $\mathbf{v} + U$ and $\mathbf{w} + U$ are equal if and only if $f(\mathbf{v}) = f(\mathbf{w})$. The values are

$$f(1,2,3) = 0, \quad f(0,0,1) = 1, \quad f(2,-1,2) = 1, \quad f(1,1,1) = -1.$$

So $(0,0,1) + U = (2,-1,2) + U$, and the other two cosets are different from each other and from it. (The first one is U itself, since $(1,2,3) \in U$.)

Solution to Exercise 4.6.24

Uses. Lemma 4.6.14 (Equal cosets), Definition 4.6.20 (Quotient space)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18)
Hint 1. By Lemma 4.6.14, two representatives of one coset differ by $t(1,1)$. For each formula, compare its values at $\mathbf{v}$ and at $\mathbf{v} + t(1,1)$.
Hint 2. To show that a formula is not well defined, one pair of representatives of the same coset suffices, for example $(0,0)$ and $(1,1)$.
Sketch. (a) No: $(0,0)$ and $(1,1)$ give 0 and 2. (b) Yes, linear. (c) Yes (a function of (b)), not linear. (d) Yes, linear; it equals $-\mathrm{id}$, since $(v_2, v_1) + (v_1, v_2) \in U$. (e) No: $(0,0) + U$ and $(1,1) + U$ go to U and $(1,0) + U \neq U$.

Two representatives of the same coset differ by $t(1,1)$ for some $t \in \mathbb{R}$ (Lemma 4.6.14). Write $\mathbf{v}' = \mathbf{v} + t(1,1)$.

(a) Not well defined: $(0,0) + U = (1,1) + U$, but the formula gives 0 and 2.

(b) Well defined, since $v_1' - v_2' = (v_1 + t) - (v_2 + t) = v_1 - v_2$. It is linear: $f(a(\mathbf{v} + U) + (\mathbf{w} + U)) = f((a\mathbf{v} + \mathbf{w}) + U) = a(v_1 - v_2) + (w_1 - w_2)$.

(c) Well defined, since it is the square of the function in (b). Not linear: $f((1,0)+U)=1$ but $f(2((1,0)+U))=f((2,0)+U)=4\neq 2$.

(d) Well defined: swapping the coordinates of $\mathbf{v}'$ gives $(v_2,v_1)+t(1,1)$, which lies in the same coset as (v_2,v_1). It is linear, by the same computation as in (b). In fact $(v_2,v_1)+(v_1,v_2)=(v_1+v_2)(1,1)\in U$, so $(v_2,v_1)+U=-(\mathbf{v}+U)$, and $S=-\mathrm{id}$.

(e) Not well defined: $(0,0)+U=(1,1)+U$, but the formula gives $(0,0)+U=U$ and $(1,0)+U$, which differ because $(1,0)\notin U$.

Solution to Exercise 4.6.37

Uses. Theorem 4.6.34 (First isomorphism theorem), Lemma 4.6.14 (Equal cosets), Proposition 1.2.18 (Degree and evaluation versus the operations)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. U is the kernel of $E:F[x]\to F^2$, $E(p)=(p(1),p(2))$. Is E surjective? Try polynomials of degree at most 1.
Hint 2. An isomorphism carries bases to bases, so compute $E(1)$ and $E(x)$. For x^2+U, solve $E(x^2)=aE(1)+bE(x)$.
Sketch. E is linear with kernel U, and surjective: $a+(b-a)(x-1)\mapsto(a,b)$. The first isomorphism theorem gives $F[x]/U\cong F^2$, and $p+U=q+U$ iff $p-q\in U$ iff $E(p)=E(q)$. $\tilde{E}$ sends $1+U, x+U$ to $(1,1),(1,2)$, a basis. From $(1,4)=-2(1,1)+3(1,2)$, $x^2+U=-2(1+U)+3(x+U)$. Over $\mathbb{F}_2$ this reads $x^2+U=x+U$.

(a) Let $E:F[x]\to F^2$, $E(p)=(p(1),p(2))$. It is linear by Proposition 1.2.18, and $\ker E=U$. It is surjective: for $(a,b)\in F^2$, the polynomial $p=a+(b-a)(x-1)$ has $p(1)=a$ and $p(2)=a+(b-a)=b$. By Theorem 4.6.34, $\tilde{E}:F[x]/U\to F^2$, $p+U\mapsto(p(1),p(2))$, is an isomorphism. Moreover $p+U=q+U$ if and only if $p-q\in U$ (Lemma 4.6.14), that is, $p(1)-q(1)=0$ and $p(2)-q(2)=0$.

(b) $\tilde{E}(1+U)=(1,1)$ and $\tilde{E}(x+U)=(1,2)$. These are independent, since $(1,2)-(1,1)=(0,1)$, so together with $(1,1)$ they span F^2; hence they form a basis of F^2, and their preimages $1+U, x+U$ form a basis of $F[x]/U$ ($\tilde{E}^{-1}$ is an isomorphism). Next, $\tilde{E}(x^2+U)=(1,4)$, and $a(1,1)+b(1,2)=(1,4)$ gives $a+b=1$, $a+2b=4$, so $b=3$ and $a=-2$. Hence

$$x^2+U=-2(1+U)+3(x+U)=(3x-2)+U.$$

Check: $x^2-(3x-2)=x^2-3x+2$ vanishes at 1 and at 2. Over $\mathbb{F}_2$ we have $3=1$ and $2=0$, so the answer reads $x^2+U=x+U$: there $2=0$, so U is the set of polynomials vanishing at 0 and 1, and x^2-x is one of them.

Solution to Exercise 4.6.38

Uses. Theorem 4.6.5 (Dimension of a product), Proposition 4.6.7 (Maps into and out of a product), Theorem 4.2.11 (Rank–nullity), Theorem 4.1.10 (Independent lists are short)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. For (a), use Theorem 4.6.5 with the basis $1, x, x^2$ of each factor.
Hint 2. For (b), D is the kernel of $(p,q)\mapsto p(0)-q(1)$, a linear map $V\times V\to F$. Find its rank, then guess five independent elements of D.
Sketch. (a) $(1,\mathbf{0}),(x,\mathbf{0}),(x^2,\mathbf{0}),(\mathbf{0},1),(\mathbf{0},x),(\mathbf{0},x^2)$; dimension 6. (b) $D=\ker\varphi$ for the surjective $\varphi(p,q)=p(0)-q(1)$, so $\dim D=5$. A basis: $(x,\mathbf{0}),(x^2,\mathbf{0}),(\mathbf{0},x-1),(\mathbf{0},x^2-1),(1,1)$.

(a) By Theorem 4.6.5, applied to the basis $1, x, x^2$ of V in each factor,

$$(1,\mathbf{0}),\quad (x,\mathbf{0}),\quad (x^2,\mathbf{0}),\quad (\mathbf{0},1),\quad (\mathbf{0},x),\quad (\mathbf{0},x^2)$$

is a basis of $V\times V$, which therefore has dimension 6.

(b) Let $\varphi:V\times V\to F, \varphi(p,q)=p(0)-q(1)$. By Proposition 4.6.7(b), with $S_1=\mathrm{ev}_0$ and $S_2=-\mathrm{ev}_1$, it is linear, and $D=\ker\varphi$ is a subspace. Since $\varphi(1,\mathbf{0})=1$, the image is a nonzero subspace of F, hence all of F. By rank–nullity, $\dim D=6-1=5$. The five pairs

$$(x,\mathbf{0}),\quad (x^2,\mathbf{0}),\quad (\mathbf{0},x-1),\quad (\mathbf{0},x^2-1),\quad (1,1)$$

lie in D (for each, $p(0) = q(1)$). They are independent: if $a(x, \mathbf{0}) + b\big(x^2, \mathbf{0}\big) + c(\mathbf{0}, x - 1) + d\big(\mathbf{0}, x^2 - 1\big) + e(1, 1) = \mathbf{0}$, the first component $e + ax + bx^2$ is the zero polynomial, so $a = b = e = 0$, and then the second component $c(x - 1) + d\big(x^2 - 1\big) = -(c + d) + cx + dx^2$ vanishes, so $c = d = 0$. Five independent vectors in the five-dimensional space D form a basis (Theorem 4.1.10(b)).

Solution to Exercise 4.6.39

Uses. Proposition 4.6.7 (Maps into and out of a product), Proposition 2.6.8 (Kernels and images are subspaces), Theorem 4.4.7 (Criteria for direct sums), Proposition 4.6.29 (Complements and the quotient), Proposition 2.7.7 (Bijective linear maps are invertible)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), the map $\mathbf{v} \mapsto (\mathbf{v}, T(\mathbf{v}))$ is linear by Proposition 4.6.7(a). Its first component makes it injective.
Hint 2. For (b), split $(\mathbf{v}, \mathbf{w})$ as $(\mathbf{v}, T(\mathbf{v})) + (\mathbf{0}, \mathbf{w} - T(\mathbf{v}))$. Then use Proposition 4.6.29.
Hint 3. For (c), the two conditions say that each $\mathbf{v}$ is the first component of exactly one element $(\mathbf{v}, \mathbf{w})$ of G. Define $S(\mathbf{v}) = \mathbf{w}$ and prove it is linear by uniqueness.
Sketch. (a) $\varphi(\mathbf{v}) = (\mathbf{v}, T(\mathbf{v}))$ is linear and injective with image G_T. (b) $(\mathbf{v}, \mathbf{w}) = (\mathbf{v}, T\mathbf{v}) + (\mathbf{0}, \mathbf{w} - T\mathbf{v})$, and $(\mathbf{v}, T\mathbf{v}) = (\mathbf{0}, \mathbf{w})$ forces $\mathbf{v} = \mathbf{0}$, then $\mathbf{w} = \mathbf{0}$. Then $(V \times W)/G_T \cong \{\mathbf{0}\} \times W \cong W$. (c) The conditions give existence and uniqueness of $\mathbf{w}$ with $(\mathbf{v}, \mathbf{w}) \in G$; call it $S(\mathbf{v})$. Since G is a subspace, $(a\mathbf{v} + \mathbf{v}', aS\mathbf{v} + S\mathbf{v}') \in G$, so S is linear, and $G = G_S$.

(a) Let $\varphi : V \to V \times W$, $\varphi(\mathbf{v}) = (\mathbf{v}, T(\mathbf{v}))$. It is linear by Proposition 4.6.7(a) (with the maps id_V and T), its image is G_T, which is therefore a subspace (Proposition 2.6.8), and it is injective because the first component of $\varphi(\mathbf{v})$ is $\mathbf{v}$. So $\varphi : V \to G_T$ is a bijective linear map, hence an isomorphism.

(b) Every $(\mathbf{v}, \mathbf{w}) \in V \times W$ equals $(\mathbf{v}, T(\mathbf{v})) + (\mathbf{0}, \mathbf{w} - T(\mathbf{v}))$, a vector of G_T plus a vector of $\{\mathbf{0}\} \times W$. If $(\mathbf{v}, T(\mathbf{v})) = (\mathbf{0}, \mathbf{w})$ lies in both subspaces, then $\mathbf{v} = \mathbf{0}$, so $\mathbf{w} = T(\mathbf{0}) = \mathbf{0}$. So the sum is direct (Theorem 4.4.7) and $V \times W = G_T \oplus (\{\mathbf{0}\} \times W)$. By Proposition 4.6.29, $(V \times W)/G_T \cong \{\mathbf{0}\} \times W$, and $(\mathbf{0}, \mathbf{w}) \mapsto \mathbf{w}$ is an isomorphism $\{\mathbf{0}\} \times W \to W$.

(c) If $G = G_S$, then $(\mathbf{0}, \mathbf{w}) \in G_S$ forces $\mathbf{w} = S(\mathbf{0}) = \mathbf{0}$, and $\mathbf{v}$ is the first component of $(\mathbf{v}, S(\mathbf{v})) \in G_S$.

Conversely, assume the two conditions. For each $\mathbf{v} \in V$ there is some $\mathbf{w}$ with $(\mathbf{v}, \mathbf{w}) \in G$, and only one: if $(\mathbf{v}, \mathbf{w}), (\mathbf{v}, \mathbf{w}') \in G$, then their difference $(\mathbf{0}, \mathbf{w} - \mathbf{w}')$ lies in $G \cap (\{\mathbf{0}\} \times W) = \{\mathbf{0}\}$, so $\mathbf{w} = \mathbf{w}'$. Define $S(\mathbf{v})$ to be this $\mathbf{w}$. For $\mathbf{v}, \mathbf{v}' \in V$ and $a \in F$, the vector $a(\mathbf{v}, S(\mathbf{v})) + (\mathbf{v}', S(\mathbf{v}')) = (a\mathbf{v} + \mathbf{v}', aS(\mathbf{v}) + S(\mathbf{v}'))$ lies in G, so by uniqueness $S(a\mathbf{v} + \mathbf{v}') = aS(\mathbf{v}) + S(\mathbf{v}')$. Thus S is linear. By construction $G_S \subseteq G$, and every $(\mathbf{v}, \mathbf{w}) \in G$ has $\mathbf{w} = S(\mathbf{v})$, so $G = G_S$.

Solution to Exercise 4.6.40

Uses. Definition 4.6.12 (Coset), Definition 4.6.20 (Quotient space)
Techniques. Double containment (Technique 1.3.14)
Hint 1. Prove each equality of sets by double containment. For $\supseteq$ in (a), write $(\mathbf{v} + \mathbf{w}) + \mathbf{u} = (\mathbf{v} + \mathbf{u}) + (\mathbf{w} + \mathbf{0})$.
Hint 2. For (b), $a\mathbf{v} + \mathbf{u} = a\big(\mathbf{v} + a^{-1}\mathbf{u}\big)$. For (c), how many elements does a coset of U have?
Sketch. (a) $(\mathbf{v} + \mathbf{u}) + (\mathbf{w} + \mathbf{u}') = (\mathbf{v} + \mathbf{w}) + (\mathbf{u} + \mathbf{u}')$, and conversely $(\mathbf{v} + \mathbf{w}) + \mathbf{u} = (\mathbf{v} + \mathbf{u}) + (\mathbf{w} + \mathbf{0})$. (b) Similar, with a^{-1}. (c) $0(\mathbf{v} + U) = \{\mathbf{0}\}$, which is not a coset when $U \neq \{\mathbf{0}\}$, because every coset is in bijection with U.

(a) An element of the left side is $(\mathbf{v} + \mathbf{u}) + (\mathbf{w} + \mathbf{u}') = (\mathbf{v} + \mathbf{w}) + (\mathbf{u} + \mathbf{u}')$ with $\mathbf{u}, \mathbf{u}' \in U$, and $\mathbf{u} + \mathbf{u}' \in U$. Conversely, $(\mathbf{v} + \mathbf{w}) + \mathbf{u} = (\mathbf{v} + \mathbf{u}) + (\mathbf{w} + \mathbf{0})$ is in the left side.

(b) An element of the left side is $a(\mathbf{v} + \mathbf{u}) = a\mathbf{v} + a\mathbf{u}$ with $a\mathbf{u} \in U$. Conversely, $a\mathbf{v} + \mathbf{u} = a\big(\mathbf{v} + a^{-1}\mathbf{u}\big)$ with $a^{-1}\mathbf{u} \in U$.

(c) $0(\mathbf{v} + U) = \{0\mathbf{x} \mid \mathbf{x} \in \mathbf{v} + U\} = \{\mathbf{0}\}$. A coset $\mathbf{x} + U$ is in bijection with U via $\mathbf{u} \mapsto \mathbf{x} + \mathbf{u}$, so when $U \neq \{\mathbf{0}\}$ it has at least two elements, and $\{\mathbf{0}\}$ is not a coset. So scalar multiplication by 0 leads out of the set of cosets, and the set operations do not even define a scalar multiplication on it. By (a) and (b), the set operations agree with those of Definition 4.6.20 in all other cases. The quotient definition sets $0(\mathbf{v} + U) = 0\mathbf{v} + U = U$ instead.

In particular, the sum in V/U is the sum of the cosets as sets, which gives a second reason why addition is well defined.

Solution to Exercise 4.6.41

Uses. Proposition 4.6.26 (The quotient map), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Lemma 4.6.14 (Equal cosets), Theorem 4.4.7 (Criteria for direct sums), Definition 1.6.1 (Basis)
Hint 1. A relation $\sum_j c_j(\mathbf{v}_j + U) = \mathbf{0} + U$ says exactly that $\sum_j c_j \mathbf{v}_j \in U$.
Hint 2. For (b), the span of the cosets is $\pi(X)$. When is $\pi(X)$ all of V/U?
Sketch. (a) $\sum_j c_j(\mathbf{v}_j + U) = U$ iff $\sum_j c_j \mathbf{v}_j \in X \cap U$. If $X \cap U = \{\mathbf{0}\}$ and the $\mathbf{v}_j$ are independent, then all $c_j = 0$; conversely, a relation among the $\mathbf{v}_j$, or a nonzero vector of $X \cap U$, gives a nontrivial relation among the cosets. (b) The span of the cosets is $\pi(X)$, and $\pi(X) = V/U$ iff every $\mathbf{v}$ is in $X + U$. (c) Combine: $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is a basis of X and $V = U \oplus X$.

Throughout, $\pi : V \to V/U$ is the quotient map. For scalars c_j, $\sum_j c_j(\mathbf{v}_j + U) = \left(\sum_j c_j \mathbf{v}_j\right) + U$, which is the zero coset if and only if $\sum_j c_j \mathbf{v}_j \in U$ (Corollary 4.6.15(c)).

(a) Suppose the cosets are independent. If $\sum_j c_j \mathbf{v}_j = \mathbf{0}$, then $\sum_j c_j(\mathbf{v}_j + U) = U$, so all $c_j = 0$; thus $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is independent. If $\mathbf{x} = \sum_j c_j \mathbf{v}_j \in X \cap U$, then $\sum_j c_j(\mathbf{v}_j + U) = U$, so all $c_j = 0$ and $\mathbf{x} = \mathbf{0}$. Conversely, assume both conditions and let $\sum_j c_j(\mathbf{v}_j + U) = U$. Then $\sum_j c_j \mathbf{v}_j \in X \cap U = \{\mathbf{0}\}$, so $\sum_j c_j \mathbf{v}_j = \mathbf{0}$ and all $c_j = 0$ by independence.

(b) The span of $\pi(\mathbf{v}_1), \ldots, \pi(\mathbf{v}_k)$ is $\operatorname{im}(\pi\restriction_X) = \{\mathbf{x} + U \mid \mathbf{x} \in X\}$ (Proposition 2.1.16(a)). This is all of V/U if and only if for every $\mathbf{v} \in V$ there is $\mathbf{x} \in X$ with $\mathbf{v} - \mathbf{x} \in U$ (Lemma 4.6.14), that is, $\mathbf{v} \in X + U$. So the cosets span V/U if and only if $X + U = V$.

(c) By (a) and (b), the cosets form a basis of V/U if and only if $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is independent (hence a basis of X), $X \cap U = \{\mathbf{0}\}$, and $X + U = V$. The last two conditions say that X is a complement of U (Theorem 4.4.7). This matches Proposition 4.6.29: $\pi\restriction_X$ is an isomorphism exactly when X is a complement, and isomorphisms carry bases to bases.

Solution to Exercise 4.6.42

Uses. Theorem 4.6.34 (First isomorphism theorem), Proposition 4.6.29 (Complements and the quotient), Theorem 4.4.19 (Dimension of a sum), Lemma 2.4.24 (Matrix units)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. The function $\psi(A) = a_{12} - a_{21}$ is linear on V. What is its kernel?
Hint 2. For (b), compute $S \cap K$ and the dimensions of S and K. For (c), what is $-A$ over $\mathbb{F}_2$?
Sketch. (a) $\psi(A) = a_{12} - a_{21}$ is linear and surjective with kernel S; apply Theorem 4.6.34. (b) $A \in S \cap K$ gives $A = -A$, so $(1+1)A = 0$ and $A = 0$; $\dim S = 3$, $\dim K = 1$. (c) Over $\mathbb{F}_2$, $-A = A$, so $K = S$. $\operatorname{span}(U_{12})$ is a complement, since $\psi(U_{12}) = 1$.

(a) Let $\psi : V \to F$, $\psi(A) = a_{12} - a_{21}$. It is linear, and surjective since $\psi(U_{12}) = 1$ (Lemma 2.4.24). A 2×2 matrix is symmetric exactly when $a_{12} = a_{21}$, so $\ker \psi = S$. By Theorem 4.6.34, $\tilde{\psi} : V/S \to F$, $A + S \mapsto a_{12} - a_{21}$, is well defined and an isomorphism.

(b) If $A \in S \cap K$, then $A = A^{\mathsf{T}} = -A$, so $(1+1)A = 0$, and $A = 0$ after multiplying by $(1+1)^{-1}$. The space S has basis $U_{11}, U_{22}, U_{12} + U_{21}$, so $\dim S = 3$. For $A \in K$, the diagonal entries satisfy $a_{ii} = -a_{ii}$, so they vanish, and $a_{21} = -a_{12}$; hence $K = \operatorname{span}(U_{12} - U_{21})$ has dimension 1. By Theorem 4.4.19, $\dim(S + K) = 3 + 1 - 0 = 4$, so $S + K = V$ and $V = S \oplus K$.

(c) Over $\mathbb{F}_2$, $-A = A$ for every A, so $K = S$ and $S \cap K = S \neq \{0\}$. Let $L = \operatorname{span}(U_{12})$. A nonzero multiple cU_{12} is not symmetric, so $L \cap S = \{0\}$, and $\dim S + \dim L = 4$, so $V = S \oplus L$. Equivalently, by Proposition 4.6.29: $\psi(U_{12}) = 1 \neq 0$, so $\pi\restriction_L$ is an isomorphism onto the one-dimensional space V/S.

The quotient $V/S \cong F$ is described by the same formula over every field; only the familiar complement of skew-symmetric matrices breaks down in characteristic 2.

Solution to Exercise 4.6.43

Uses. Theorem 4.6.30 (Universal property of the quotient), Theorem 4.6.34 (First isomorphism theorem)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18)
Hint 1. Compare the student's implication with the one in Technique 4.6.18. Which way does each go?
Hint 2. Take $T = \mathrm{id}$, so that $\ker T = \{\mathbf{0}\}$ is inside every U.

Sketch. The student proved "equal outputs imply equal inputs", which is injectivity. Well-definedness needs "equal inputs imply equal outputs". With $T = \mathrm{id}_{\mathbb{R}^2}$ and $U = \mathrm{span}(\mathbf{e}_1)$: $\mathbf{e}_1 + U = \mathbf{0} + U$ but $T(\mathbf{e}_1) \neq T(\mathbf{0})$. The right hypothesis is $U \subseteq \ker T$.

The argument proves the wrong implication. It shows that if two cosets have the same value, then they are equal, which is injectivity of S, assuming S exists. Well-definedness is the converse: if $\mathbf{v} + U = \mathbf{v}' + U$, then $T(\mathbf{v}) = T(\mathbf{v}')$. That is, $\mathbf{v} - \mathbf{v}' \in U$ must imply $\mathbf{v} - \mathbf{v}' \in \ker T$, which needs $U \subseteq \ker T$, the opposite of the given containment.

Example: $T = \mathrm{id}_{\mathbb{R}^2}$, so $\ker T = \{\mathbf{0}\} \subseteq U$ for $U = \mathrm{span}(\mathbf{e}_1)$. Then $\mathbf{e}_1 + U = \mathbf{0} + U$, but the formula assigns $T(\mathbf{e}_1) = \mathbf{e}_1$ to the first name and $T(\mathbf{0}) = \mathbf{0}$ to the second.

By Theorem 4.6.30, the formula defines a (linear) map exactly when $U \subseteq \ker T$. Together with the student's hypothesis $\ker T \subseteq U$, that means $U = \ker T$, and then the student's argument is a correct proof that $S = \tilde{T}$ is injective, which is half of Theorem 4.6.34.

Solution to Exercise 4.6.44

Uses. Theorem 4.6.34 (First isomorphism theorem), Theorem 4.6.30 (Universal property of the quotient), Proposition 4.6.26 (The quotient map), Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 1.6.16 (The coordinate map is a bijection)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. A nonzero linear map $f : V \to F$ is surjective, since its image is a nonzero subspace of F. Apply Theorem 4.6.34.
Hint 2. Conversely, if $\dim(V/U) = 1$, compose π with a coordinate map $V/U \to F$.
Hint 3. For (b), both f and g induce isomorphisms $V/U \to F$ with $U = \ker f = \ker g$. What are the linear maps $F \to F$?
Sketch. (a) If $f \neq 0$, then $\mathrm{im}\, f = F$ and $V/\ker f \cong F$. If $\mathbf{v}_0 + U$ is a basis of V/U, let φ be its coordinate map and $f = \varphi \circ \pi$; then $\ker f = \ker \pi = U$ and $f(\mathbf{v}_0) = 1$. (b) $\tilde{g} \circ \tilde{f}^{-1} : F \to F$ is multiplication by some $c \neq 0$, so $\tilde{g} = c\tilde{f}$ and $g = cf$.

(a) Suppose $U = \ker f$ with $f \neq 0$. Pick $\mathbf{v}$ with $f(\mathbf{v}) = a \neq 0$; then $f((t/a)\mathbf{v}) = t$ for every $t \in F$, so f is surjective. By Theorem 4.6.34, $V/U \cong F$, which has dimension 1.

Conversely, suppose $\dim(V/U) = 1$, and let $\mathbf{v}_0 + U$ be a basis of V/U. Its coordinate map $\varphi : V/U \to F$, $c(\mathbf{v}_0 + U) \mapsto c$, is a linear bijection (Proposition 1.6.19, Proposition 1.6.16). Let $f = \varphi \circ \pi : V \to F$. It is linear, and since φ is injective, $\ker f = \ker \pi = U$ (Proposition 4.6.26). It is nonzero because $f(\mathbf{v}_0) = \varphi(\mathbf{v}_0 + U) = 1$.

(b) If $g = cf$ with $c \neq 0$, then $g(\mathbf{v}) = 0$ if and only if $f(\mathbf{v}) = 0$. Conversely, let $U = \ker f = \ker g$. As in (a), f and g are surjective, so Theorem 4.6.34 gives isomorphisms $\tilde{f}, \tilde{g} : V/U \to F$ with $f = \tilde{f} \circ \pi$ and $g = \tilde{g} \circ \pi$. The map $h = \tilde{g} \circ \tilde{f}^{-1} : F \to F$ is linear, so $h(t) = th(1)$ for all t; let $c = h(1)$, which is nonzero because h is bijective. Then $\tilde{g} = h \circ \tilde{f} = c\tilde{f}$, and $g = \tilde{g} \circ \pi = c\tilde{f} \circ \pi = cf$.

Solution to Exercise 4.6.45

Uses. Theorem 4.6.30 (Universal property of the quotient), Theorem 4.6.34 (First isomorphism theorem), Proposition 4.1.19 (Extending linear maps and separating vectors), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. One direction is one line. For the other, T_B kills $\ker T_A$, so it factors through $F^n/\ker T_A$, and that quotient is isomorphic to $\mathrm{im}\, T_A$.
Hint 2. You get a linear map $R_0 : \mathrm{im}\, T_A \to F^p$ with $R_0(A\mathbf{x}) = B\mathbf{x}$. It is only defined on $\mathrm{im}\, T_A$. Extend it to F^m with Proposition 4.1.19(a).
Sketch. If $B = CA$ and $A\mathbf{x} = \mathbf{0}$, then $B\mathbf{x} = \mathbf{0}$. Conversely, Theorem 4.6.30 gives S with $T_B = S \circ \pi$, and $R_0 = S \circ \widetilde{T_A}^{-1} : \mathrm{im}\, T_A \to F^p$ satisfies $R_0(A\mathbf{x}) = B\mathbf{x}$. Extend R_0 to $R \in \mathrm{L}(F^m, F^p)$ and let C be its matrix.

If $B = CA$ and $A\mathbf{x} = \mathbf{0}$, then $B\mathbf{x} = C(A\mathbf{x}) = \mathbf{0}$, so $\ker T_A \subseteq \ker T_B$.

Conversely, suppose $\ker T_A \subseteq \ker T_B$, and let $\pi : F^n \to F^n/\ker T_A$ be the quotient map. By Theorem 4.6.30(a), there is a linear $S : F^n/\ker T_A \to F^p$ with $S(\mathbf{x} + \ker T_A) = B\mathbf{x}$. By Theorem 4.6.34, $\widetilde{T_A} : F^n/\ker T_A \to \mathrm{im}\, T_A$, $\mathbf{x} + \ker T_A \mapsto A\mathbf{x}$, is an isomorphism. Let $R_0 = S \circ \widetilde{T_A}^{-1} : \mathrm{im}\, T_A \to F^p$; it is linear, and

$$R_0(A\mathbf{x}) = S(\mathbf{x} + \ker T_A) = B\mathbf{x} \quad \text{for all } \mathbf{x} \in F^n.$$

By Proposition 4.1.19(a), R_0 extends to a linear map $R : F^m \to F^p$. By Proposition 2.3.17, $R = T_C$ for some $C \in F^{p\times m}$. Then $CA\mathbf{x} = R(A\mathbf{x}) = B\mathbf{x}$ for all $\mathbf{x}$; taking $\mathbf{x} = \mathbf{e}_j$ shows that CA and B have the same columns, so $CA = B$.

The extension step is where choices enter: for $p \geq 1$, C is unique exactly when $\operatorname{im} T_A = F^m$, that is, $\operatorname{rank} A = m$.

Solution to Exercise 4.6.46

Uses. Proposition 4.6.7 (Maps into and out of a product), Proposition 4.6.26 (The quotient map), Theorem 4.6.34 (First isomorphism theorem)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. For (b) "⇐": given $(\mathbf{w}_1, \mathbf{w}_2)$, choose preimages $\mathbf{x}_1$ under T_1 and $\mathbf{x}_2$ under T_2. You need one vector that works for both. Split $\mathbf{x}_1 - \mathbf{x}_2$ along $\ker T_1 + \ker T_2$.
Hint 2. For (b) "⇒": to write $\mathbf{v} \in V$ as a sum, find $\mathbf{x}$ with $T(\mathbf{x}) = (T_1(\mathbf{v}), \mathbf{0})$.
Hint 3. For (c), apply (a) and (b) to the two quotient maps.
Sketch. (a) Both components vanish. (b) If $\mathbf{x}_1 - \mathbf{x}_2 = \mathbf{k}_1 + \mathbf{k}_2$ with $\mathbf{k}_i \in \ker T_i$, then $\mathbf{v} = \mathbf{x}_1 - \mathbf{k}_1 = \mathbf{x}_2 + \mathbf{k}_2$ maps to $(\mathbf{w}_1, \mathbf{w}_2)$. Conversely, if $T(\mathbf{x}) = (T_1\mathbf{v}, \mathbf{0})$, then $\mathbf{v} = (\mathbf{v} - \mathbf{x}) + \mathbf{x} \in \ker T_1 + \ker T_2$. (c) The quotient maps are surjective with kernels U and W; then use Theorem 4.6.34.

T is linear by Proposition 4.6.7(a).

(a) $T(\mathbf{v}) = (\mathbf{0}, \mathbf{0})$ if and only if $T_1(\mathbf{v}) = \mathbf{0}$ and $T_2(\mathbf{v}) = \mathbf{0}$.

(b) Suppose $\ker T_1 + \ker T_2 = V$, and let $(\mathbf{w}_1, \mathbf{w}_2) \in W_1 \times W_2$. Since T_1, T_2 are surjective, there are $\mathbf{x}_1, \mathbf{x}_2 \in V$ with $T_1(\mathbf{x}_1) = \mathbf{w}_1$ and $T_2(\mathbf{x}_2) = \mathbf{w}_2$. Write $\mathbf{x}_1 - \mathbf{x}_2 = \mathbf{k}_1 + \mathbf{k}_2$ with $\mathbf{k}_i \in \ker T_i$, and let

$$\mathbf{v} = \mathbf{x}_1 - \mathbf{k}_1 = \mathbf{x}_2 + \mathbf{k}_2.$$

Then $T_1(\mathbf{v}) = T_1(\mathbf{x}_1) = \mathbf{w}_1$ and $T_2(\mathbf{v}) = T_2(\mathbf{x}_2) = \mathbf{w}_2$, so $T(\mathbf{v}) = (\mathbf{w}_1, \mathbf{w}_2)$.

Conversely, suppose T is surjective, and let $\mathbf{v} \in V$. Choose $\mathbf{x}$ with $T(\mathbf{x}) = (T_1(\mathbf{v}), \mathbf{0})$. Then $T_2(\mathbf{x}) = \mathbf{0}$ and $T_1(\mathbf{v} - \mathbf{x}) = \mathbf{0}$, so $\mathbf{v} = (\mathbf{v} - \mathbf{x}) + \mathbf{x} \in \ker T_1 + \ker T_2$.

(c) The quotient maps $\pi_U : V \to V/U$ and $\pi_W : V \to V/W$ are surjective with kernels U and W (Proposition 4.6.26). The map in question is (π_U, π_W), so by (a) its kernel is $U \cap W$, and by (b) it is surjective if and only if $U + W = V$. In that case Theorem 4.6.34 gives $V/(U \cap W) \cong V/U \times V/W$.

Part (c) is a linear-algebra version of the Chinese remainder theorem: when $U + W = V$, a pair of conditions "$\mathbf{v} \equiv \mathbf{a} (\mathrm{mod}\, U)$" and "$\mathbf{v} \equiv \mathbf{b} (\mathrm{mod}\, W)$" always has a solution, unique modulo $U \cap W$.

Solution to Exercise 4.6.47

Uses. Proposition 4.6.7 (Maps into and out of a product), Theorem 4.6.34 (First isomorphism theorem), Theorem 4.6.5 (Dimension of a product), Proposition 4.1.21 (Dimensions of subspaces), Proposition 4.2.6 (Injective maps preserve dimension), Theorem 4.6.27 (Dimension of a quotient)
Techniques. Pass to a quotient (Technique 4.6.31), Dimension counting (Technique 4.2.24)
Hint 1. Find a linear map out of V whose kernel is $U_1 \cap \cdots \cap U_m$ and whose target is finite-dimensional.
Hint 2. Use $T : V \to V/U_1 \times \cdots \times V/U_m$, $\mathbf{v} \mapsto (\mathbf{v} + U_1, \ldots, \mathbf{v} + U_m)$, and Theorem 4.6.34. The image need not be the whole product.
Sketch. T has kernel $\cap_i U_i$, so $V/\cap_i U_i \cong \operatorname{im} T$, a subspace of a product of dimension $\sum_i \dim(V/U_i)$. (b) Substitute $\dim(V/X) = \dim V - \dim X$. (c) $4 + 4 + 3 - 2 \cdot 5 = 1$.

(a) Let $T : V \to V/U_1 \times \cdots \times V/U_m$, $T(\mathbf{v}) = (\mathbf{v} + U_1, \ldots, \mathbf{v} + U_m)$. It is linear by Proposition 4.6.7(a), and $T(\mathbf{v}) = \mathbf{0}$ if and only if $\mathbf{v} \in U_i$ for every i, so $\ker T = U_1 \cap \cdots \cap U_m =: X$. The product is finite-dimensional of dimension $\sum_i \dim(V/U_i)$ (Theorem 4.6.5), so its subspace $\operatorname{im} T$ is finite-dimensional with $\dim \operatorname{im} T \leq \sum_i \dim(V/U_i)$ (Proposition 4.1.21). By Theorem 4.6.34, $\tilde{T} : V/X \to \operatorname{im} T$ is an isomorphism; its inverse is injective with finite-dimensional domain $\operatorname{im} T$, so by Proposition 4.2.6(a), V/X is finite-dimensional with $\dim(V/X) = \dim \operatorname{im} T \leq \sum_i \dim(V/U_i)$.

(b) By Theorem 4.6.27, (a) reads $\dim V - \dim X \leq \sum_{i=1}^m (\dim V - \dim U_i) = m \dim V - \sum_i \dim U_i$. Rearranging, $\dim X \geq \sum_i \dim U_i - (m-1) \dim V$.

(c) By (b), the intersection has dimension at least $4 + 4 + 3 - 2 \cdot 5 = 1$, so it contains a nonzero vector.

Solution to Exercise 4.6.48

Uses. Proposition 4.6.7 (Maps into and out of a product), Theorem 4.6.5 (Dimension of a product), Theorem 4.2.11 (Rank–nullity), Proposition 2.4.14 (Algebra of matrices)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. $A\mathbf{1}$ is the vector of row sums and $A^{\mathsf{T}}\mathbf{1}$ the vector of column sums, so $Z = \ker\Phi$. The image of Φ is not all of $F^n \times F^n$: both vectors have the same sum of entries.
Hint 2. Let $D = \{(\mathbf{r}, \mathbf{c}) \mid r_1 + \cdots + r_n = c_1 + \cdots + c_n\}$, of dimension $2n - 1$. To show $\operatorname{im}\Phi = D$, look for a preimage supported on the first row and first column.
Sketch. $Z = \ker\Phi$. $\operatorname{im}\Phi \subseteq D$, since both sums equal the sum of all entries. For $(\mathbf{r}, \mathbf{c}) \in D$ with common sum s, $A = \mathbf{r}\mathbf{e}_1^{\mathsf{T}} + \mathbf{e}_1\mathbf{c}^{\mathsf{T}} - s\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}$ has $\Phi(A) = (\mathbf{r}, \mathbf{c})$. So $\operatorname{rank}\Phi = 2n - 1$ and $\dim Z = n^2 - 2n + 1$.

Φ is linear (Proposition 4.6.7(a)), and $A\mathbf{1}$ and $A^{\mathsf{T}}\mathbf{1}$ are the vectors of row sums and column sums of A. So $Z = \ker\Phi$, a subspace. Let $\sigma(\mathbf{x}) = x_1 + \cdots + x_n$ and

$$D = \{(\mathbf{r}, \mathbf{c}) \in F^n \times F^n \mid \sigma(\mathbf{r}) = \sigma(\mathbf{c})\}.$$

D is the kernel of $(\mathbf{r}, \mathbf{c}) \mapsto \sigma(\mathbf{r}) - \sigma(\mathbf{c})$, a linear map onto F (it sends $(\mathbf{e}_1, \mathbf{0})$ to 1), so $\dim D = 2n - 1$ by Theorem 4.6.5 and rank–nullity.

Both $\sigma(A\mathbf{1})$ and $\sigma\left(A^{\mathsf{T}}\mathbf{1}\right)$ equal the sum of all entries of A, so $\operatorname{im}\Phi \subseteq D$. Conversely, let $(\mathbf{r}, \mathbf{c}) \in D$ with $s = \sigma(\mathbf{r}) = \sigma(\mathbf{c})$, and let

$$A = \mathbf{r}\mathbf{e}_1^{\mathsf{T}} + \mathbf{e}_1\mathbf{c}^{\mathsf{T}} - s\mathbf{e}_1\mathbf{e}_1^{\mathsf{T}}.$$

Using $\mathbf{e}_1^{\mathsf{T}}\mathbf{1} = 1$, $\mathbf{c}^{\mathsf{T}}\mathbf{1} = s$, and $\mathbf{r}^{\mathsf{T}}\mathbf{1} = s$,

$$A\mathbf{1} = \mathbf{r} + s\mathbf{e}_1 - s\mathbf{e}_1 = \mathbf{r}, \quad A^{\mathsf{T}}\mathbf{1} = \mathbf{e}_1\left(\mathbf{r}^{\mathsf{T}}\mathbf{1}\right) + \mathbf{c} - s\mathbf{e}_1 = \mathbf{c}.$$

So $\operatorname{im}\Phi = D$, and by rank–nullity $\dim Z = n^2 - (2n - 1) = (n - 1)^2$.

Solution to Exercise 4.6.49

Uses. Proposition 4.6.26 (The quotient map), Proposition 4.2.3 (Properties of restriction), Theorem 4.6.34 (First isomorphism theorem), Theorem 4.6.27 (Dimension of a quotient)
Techniques. Pass to a quotient (Technique 4.6.31)
Hint 1. The map is the quotient map $U + W \to (U + W)/U$ restricted to W. Why does every coset have a representative in W?
Hint 2. For (b), take dimensions on both sides of (a).
Sketch. $(\mathbf{u} + \mathbf{w}) + U = \mathbf{w} + U$, so the map is onto, and $\mathbf{w} + U = U$ iff $\mathbf{w} \in U$. By the first isomorphism theorem, $W/(U \cap W) \cong (U + W)/U$. Then $\dim W - \dim(U \cap W) = \dim(U + W) - \dim U$.

(a) Let $\pi : U + W \to (U + W)/U$ be the quotient map of the space $U + W$ by its subspace U, and $\varphi = \pi\restriction_W$, which is linear. Every element of $(U + W)/U$ is $(\mathbf{u} + \mathbf{w}) + U = \mathbf{w} + U = \varphi(\mathbf{w})$ for some $\mathbf{u} \in U$, $\mathbf{w} \in W$, so φ is surjective. Its kernel is $W \cap \ker\pi = W \cap U$ (Proposition 4.2.3(c)). By Theorem 4.6.34, $W/(U \cap W) \cong \operatorname{im}\varphi = (U + W)/U$.

(b) Let U and W be finite-dimensional. Then $U + W$ is finite-dimensional (it is spanned by bases of U and W), and isomorphic finite-dimensional spaces have equal dimensions. By (a) and Theorem 4.6.27, applied in W and in $U + W$,

$$\dim W - \dim(U \cap W) = \dim(U + W) - \dim U,$$

which rearranges to $\dim(U + W) = \dim U + \dim W - \dim(U \cap W)$.

Solution to Exercise 4.6.50

Uses. Proposition 4.6.26 (The quotient map), Proposition 2.6.8 (Kernels and images are subspaces), Theorem 4.6.30 (Universal property of the quotient), Theorem 4.6.34 (First isomorphism theorem), Lemma 4.6.14 (Equal cosets), Theorem 4.2.11 (Rank–nullity)
Techniques. Pass to a quotient (Technique 4.6.31)

Hint 1. (a) $X/U = \operatorname{im}(\pi\restriction_X)$. For $\pi^{-1}(X/U) \subseteq X$: if $\mathbf{v}+U = \mathbf{x}+U$ with $\mathbf{x} \in X$, then $\mathbf{v}-\mathbf{x} \in U \subseteq X$.
Hint 2. (b) Given Y, take $X = \pi^{-1}(Y)$. Check that it is a subspace containing U and that $\pi(X) = Y$. Uniqueness comes from (a).
Hint 3. (c) Induce a map $V/U \to V/X$ from the quotient map $V \to V/X$ with Theorem 4.6.30, and compute its kernel.
Sketch. (a) $X/U = \pi(X)$ is a subspace, and $\mathbf{v}+U \in X/U$ forces $\mathbf{v} \in X+U = X$. (b) $X = \pi^{-1}(Y)$ is a subspace containing $\ker\pi = U$, with $\pi(X) = Y$ since π is onto; if also $Y = X'/U$, then $X' = \pi^{-1}(Y) = X$ by (a). (c) π_X kills U, so it induces $\rho : V/U \to V/X$, $\mathbf{v}+U \mapsto \mathbf{v}+X$, onto, with kernel X/U. (d) $\pi\restriction_X$ has kernel U and image X/U.

(a) $X/U = \operatorname{im}(\pi\restriction_X)$, the image of a linear map, so it is a subspace (Proposition 2.6.8). Clearly $X \subseteq \pi^{-1}(X/U)$. Conversely, if $\pi(\mathbf{v}) \in X/U$, then $\mathbf{v}+U = \mathbf{x}+U$ for some $\mathbf{x} \in X$, so $\mathbf{v}-\mathbf{x} \in U \subseteq X$ (Lemma 4.6.14), and $\mathbf{v} = \mathbf{x}+(\mathbf{v}-\mathbf{x}) \in X$.

(b) Let Y be a subspace of V/U and $X = \pi^{-1}(Y)$. It is a subspace of V: it contains $\mathbf{0}$, and if $\mathbf{v}, \mathbf{v}' \in X$ and $a \in F$, then $\pi(a\mathbf{v}+\mathbf{v}') = a\pi(\mathbf{v})+\pi(\mathbf{v}') \in Y$. It contains U, because $\pi(U) = \{\mathbf{0}\} \subseteq Y$. And $X/U = \pi(X) = Y$: the containment $\subseteq$ is the definition of X, and every $\mathbf{y} \in Y$ is $\pi(\mathbf{v})$ for some $\mathbf{v}$ (as π is surjective), which then lies in X. For uniqueness, if $Y = X'/U$ with $U \subseteq X'$, then $X' = \pi^{-1}(X'/U) = \pi^{-1}(Y) = X$ by (a).

(c) Let $\pi_X : V \to V/X$ be the quotient map. Its kernel X contains U, so by Theorem 4.6.30(a) it induces a linear $\rho : V/U \to V/X$, $\rho(\mathbf{v}+U) = \mathbf{v}+X$, with image $\operatorname{im}\pi_X = V/X$ and kernel $\{\mathbf{v}+U \mid \mathbf{v} \in X\} = X/U$. By Theorem 4.6.34, $(V/U)/(X/U) \cong V/X$.

(d) $\pi\restriction_X : X \to V/U$ is linear with kernel $X \cap U = U$ and image X/U, so rank–nullity gives $\dim X = \dim U + \dim(X/U)$.

So the subspaces of V/U correspond to the subspaces of V that contain U, with dimensions shifted down by $\dim U$. The set X/U is also literally the quotient of the space X by its subspace U, which explains the notation.

Solution to Exercise 4.6.51

Uses. Theorem 4.6.27 (Dimension of a quotient), Theorem 4.5.6 (Classification by dimension), Example 4.6.36 (The first isomorphism theorem at work), Example 4.6.23 (Quotient spaces), Theorem 4.6.34 (First isomorphism theorem), Example 2.1.9 (Maps of polynomials)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. In finite dimensions, everything is decided by dimensions (Theorem 4.5.6 and Theorem 4.6.27).
Hint 2. In general, look in $F[x]$. The backward shift of Example 4.6.36(d) gives $F[x]/\operatorname{span}(1) \cong F[x]$, and multiplication by x maps $F[x]$ isomorphically onto the polynomials with constant term 0.
Sketch. Finite dimensions: all three are true, by comparing $\dim V - \dim U$ and $\dim V - \dim W$. In general all three are false in $V = F[x]$: (a) $U = \operatorname{span}(1)$; (b) $U = \operatorname{span}(1)$, $W = \{\mathbf{0}\}$; (c) $U = F[x]$, $W = \operatorname{im} M = \{p \mid p(0) = 0\}$, where $V/U = \{\mathbf{0}\}$ but $V/W \cong F$.

Finite-dimensional V. All three statements are true. By Theorem 4.6.27, $\dim(V/U) = \dim V - \dim U$ and $\dim(V/W) = \dim V - \dim W$, and finite-dimensional spaces are isomorphic exactly when their dimensions agree (Theorem 4.5.6).

(a) $\dim(V/U) = \dim V - \dim U < \dim V$ when $U \neq \{\mathbf{0}\}$.

(b) $\dim V - \dim U = \dim V - \dim W$ gives $\dim U = \dim W$.

(c) $\dim U = \dim W$ gives $\dim(V/U) = \dim(V/W)$.

General V. All three fail for $V = F[x]$.

(a) By Example 4.6.36(d), $F[x]/\operatorname{span}(1) \cong F[x]$, although $\operatorname{span}(1) \neq \{\mathbf{0}\}$.

(b) Take $U = \operatorname{span}(1)$ and $W = \{\mathbf{0}\}$. Then $V/U \cong V \cong V/W$ (Example 4.6.23(c)), but U is one-dimensional and W is zero, so $U \not\cong W$.

(c) Take $U = F[x]$ and $W = \{p \mid p(0) = 0\}$. Multiplication by x, $M(p) = xp$, is linear and injective (Example 2.1.9), and its image is W (a polynomial with constant term 0 is x times the polynomial with its

coefficients shifted down). So $U = F[x] \cong W$. But $V/U = \{\mathbf{0}\}$, while $V/W \cong F$ by Theorem 4.6.34 applied to ev_0, which is surjective with kernel W.

The finite-dimensional arguments all rest on subtracting dimensions, which is exactly what is unavailable in infinite dimensions.

Solution to Exercise 4.6.52

> *Uses.* Proposition 4.6.32 (Operators on a quotient), Proposition 4.2.3 (Properties of restriction), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces)
> *Techniques.* Restrict to a subspace (Technique 4.2.5), Pass to a quotient (Technique 4.6.31)
> *Hint 1.* Apply rank–nullity to $\pi|_{\operatorname{im} T}$, where $\pi : V \to V/U$.
> *Hint 2.* Its kernel is $\operatorname{im} T \cap U$, which contains $T(U) = \operatorname{im} T_U$. Its image is $\pi(\operatorname{im} T)$. Compare it with $\operatorname{im}(T/U)$.
> *Sketch.* $\pi|_{\operatorname{im} T}$ has kernel $\operatorname{im} T \cap U \supseteq T(U)$ and image $\{T\mathbf{v} + U\} = \operatorname{im}(T/U)$. So $\operatorname{rank} T = \dim(\operatorname{im} T \cap U) + \operatorname{rank}(T/U) \geq \operatorname{rank} T_U + \operatorname{rank}(T/U)$, with equality iff $\operatorname{im} T \cap U = T(U)$. Example: the 2×2 shift with $U = \operatorname{span}(\mathbf{e}_1)$.

(a) Let $X = \operatorname{im} T$ and $\pi : V \to V/U$. The restriction $\pi|_X$ is linear with kernel $X \cap U$ (Proposition 4.2.3(c)) and image $\{T(\mathbf{v}) + U \mid \mathbf{v} \in V\} = \{(T/U)(\mathbf{v} + U)\} = \operatorname{im}(T/U)$. By rank–nullity,

$$\operatorname{rank} T = \dim X = \dim(X \cap U) + \operatorname{rank}(T/U).$$

Since $T(U) \subseteq U$ and $T(U) \subseteq X$, we have $\operatorname{im} T_U = T(U) \subseteq X \cap U$, so $\dim(X \cap U) \geq \operatorname{rank} T_U$ (Proposition 4.1.21), and (a) follows.

(b) By the computation in (a), equality holds if and only if $\dim(X \cap U) = \dim T(U)$, which, as $T(U) \subseteq X \cap U$, holds if and only if $T(U) = X \cap U$ (Proposition 4.1.21(b)).

(c) Let $N \in \mathrm{L}(F^2)$ with $N(\mathbf{e}_1) = \mathbf{0}$, $N(\mathbf{e}_2) = \mathbf{e}_1$, and $U = \operatorname{span}(\mathbf{e}_1)$. Then $N_U = 0$, and $(N/U)(\mathbf{e}_2 + U) = \mathbf{e}_1 + U = \mathbf{0} + U$, so $N/U = 0$. Both ranks are 0, but $\operatorname{rank} N = 1$. Here $\operatorname{im} N \cap U = U$, while $N(U) = \{\mathbf{0}\}$.

In matrix terms (Proposition 4.6.32(b)): if $M = \begin{pmatrix} A & B \\ 0 & C \end{pmatrix}$ with square diagonal blocks, then $\operatorname{rank} M \geq \operatorname{rank} A + \operatorname{rank} C$, and the example $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ shows that the off-diagonal block can add rank.

Solution to Exercise 4.6.53

> *Uses.* Theorem 4.6.30 (Universal property of the quotient), Theorem 4.6.27 (Dimension of a quotient), Theorem 4.2.7 (The image of T_A), Theorem 4.2.11 (Rank–nullity)
> *Techniques.* Pass to a quotient (Technique 4.6.31)
> *Hint 1.* Check the containments $\operatorname{im} T_{BC} \subseteq \operatorname{im} T_B$ and $\operatorname{im} T_{ABC} \subseteq \operatorname{im} T_{AB}$, and that T_A maps $\operatorname{im} T_B$ into $\operatorname{im} T_{AB}$.
> *Hint 2.* Define $\varphi : \operatorname{im} T_B \to \operatorname{im} T_{AB}/\operatorname{im} T_{ABC}$ by $\varphi(\mathbf{x}) = A\mathbf{x} + \operatorname{im} T_{ABC}$. Why does it vanish on $\operatorname{im} T_{BC}$? Why is the induced map surjective?
> *Hint 3.* A surjective linear map cannot increase dimension. Translate both quotient dimensions with Theorem 4.6.27.
> *Sketch.* Let $X = \operatorname{im} T_B \supseteq Y = \operatorname{im} T_{BC}$ and $X' = \operatorname{im} T_{AB} \supseteq Y' = \operatorname{im} T_{ABC}$. The map $\mathbf{x} \mapsto A\mathbf{x} + Y'$ on X kills Y (as $ABC\mathbf{z} \in Y'$), so it induces $X/Y \to X'/Y'$, which is onto since $AB\mathbf{z} + Y'$ is the image of $B\mathbf{z} + Y$. Hence $\operatorname{rank}(AB) - \operatorname{rank}(ABC) \leq \operatorname{rank} B - \operatorname{rank}(BC)$.

Let $X = \operatorname{im} T_B$, $Y = \operatorname{im} T_{BC}$, $X' = \operatorname{im} T_{AB}$, and $Y' = \operatorname{im} T_{ABC}$. Since $BC\mathbf{z} = B(C\mathbf{z})$ and $ABC\mathbf{z} = AB(C\mathbf{z})$, we have $Y \subseteq X$ and $Y' \subseteq X'$, and $AX \subseteq X'$ since $A(B\mathbf{z}) = (AB)\mathbf{z}$.

Define $\varphi : X \to X'/Y'$ by $\varphi(\mathbf{x}) = A\mathbf{x} + Y'$. It is linear, being the composite of $T_A|_X : X \to X'$ with the quotient map $X' \to X'/Y'$. For $\mathbf{x} = BC\mathbf{z} \in Y$, $A\mathbf{x} = ABC\mathbf{z} \in Y'$, so $\varphi(\mathbf{x}) = \mathbf{0}$. By Theorem 4.6.30, φ induces a linear map $\tilde{\varphi} : X/Y \to X'/Y'$ with $\tilde{\varphi}(\mathbf{x} + Y) = A\mathbf{x} + Y'$. It is surjective: every element of X'/Y' is $AB\mathbf{z} + Y' = \tilde{\varphi}(B\mathbf{z} + Y)$.

By rank–nullity, $\dim(X'/Y') = \dim \operatorname{im} \tilde{\varphi} \leq \dim(X/Y)$. By Theorem 4.6.27 and Theorem 4.2.7,

$$\operatorname{rank}(AB) - \operatorname{rank}(ABC) \leq \operatorname{rank} B - \operatorname{rank}(BC),$$

which rearranges to the inequality.

The quotient proof makes the meaning visible: T_A maps "what B reaches beyond BC" onto "what AB reaches beyond ABC", and a linear map cannot make a space bigger.

Solution to Exercise 4.6.54

Uses. Theorem 4.4.7 (Criteria for direct sums), Proposition 4.4.16 (Complements exist), Proposition 4.6.29 (Complements and the quotient), Theorem 4.5.8 (Dimension of $\mathrm{L}(V,W)$), Proposition 4.1.34 (Size of a vector space over a finite field), Proposition 4.2.6 (Injective maps preserve dimension)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Dimension counting (Technique 4.2.24)
Hint 1. A complement is a choice of one vector in each coset of U, made linearly (Proposition 4.6.29). Starting from W_0, each $\mathbf{w} \in W_0$ can be moved within its coset by a vector of U, namely $S(\mathbf{w})$.
Hint 2. For (b), given a complement W, decompose each $\mathbf{w} \in W_0$ along $V = U \oplus W$ as $\mathbf{w} = \mathbf{u} + \mathbf{x}$, and set $S(\mathbf{w}) = -\mathbf{u}$.
Hint 3. For (c), $\mathrm{L}(W_0, U)$ has dimension $(n-k)k$ (Theorem 4.5.8); count its elements.
Sketch. (a) W_S is the image of $\mathbf{w} \mapsto \mathbf{w} + S\mathbf{w}$. If $\mathbf{w} + S\mathbf{w} \in U$, then $\mathbf{w} \in U \cap W_0 = \{\mathbf{0}\}$; and $U + W_S \supseteq U + W_0 = V$. (b) If $V = U \oplus W$, let $-S(\mathbf{w})$ be the U-component of $\mathbf{w} \in W_0$; S is linear by uniqueness of components, $W_S \subseteq W$, and dimensions agree. If $W_S = W_{S'}$, comparing $\mathbf{w} + S\mathbf{w} = \mathbf{w}' + S'\mathbf{w}'$ in $W_0 \oplus U$ gives $S = S'$. (c) $|\mathrm{L}(W_0, U)| = q^{k(n-k)}$. In $\mathbb{F}_3^2$: 3.

By Proposition 4.4.16(b), $\dim W_0 = n - k$.

(a) W_S is the image of the linear map $\mathbf{w} \mapsto \mathbf{w} + S(\mathbf{w})$, $W_0 \to V$, so it is a subspace. If $\mathbf{w} + S(\mathbf{w}) \in U$, then $\mathbf{w} \in U$ (as $S(\mathbf{w}) \in U$), so $\mathbf{w} \in U \cap W_0 = \{\mathbf{0}\}$ and the vector is $\mathbf{0}$. So $U \cap W_S = \{\mathbf{0}\}$. Every $\mathbf{w} \in W_0$ equals $(\mathbf{w} + S(\mathbf{w})) - S(\mathbf{w}) \in W_S + U$, so $U + W_S \supseteq U + W_0 = V$. Hence $V = U \oplus W_S$ (Theorem 4.4.7).

(b) Let W be a complement of U. Each $\mathbf{w} \in W_0$ has a unique decomposition $\mathbf{w} = \mathbf{u} + \mathbf{x}$ with $\mathbf{u} \in U$, $\mathbf{x} \in W$; set $S(\mathbf{w}) = -\mathbf{u}$. If $\mathbf{w} = \mathbf{u} + \mathbf{x}$ and $\mathbf{w}' = \mathbf{u}' + \mathbf{x}'$, then $a\mathbf{w} + \mathbf{w}' = (a\mathbf{u} + \mathbf{u}') + (a\mathbf{x} + \mathbf{x}')$ is the decomposition of $a\mathbf{w} + \mathbf{w}'$, so S is linear, with values in U. Now $\mathbf{w} + S(\mathbf{w}) = \mathbf{x} \in W$, so $W_S \subseteq W$. Both have dimension $n - k$: W by Proposition 4.4.16(b), and W_S because $\mathbf{w} \mapsto \mathbf{w} + S(\mathbf{w})$ is injective (if $\mathbf{w} + S(\mathbf{w}) = \mathbf{0}$, then $\mathbf{w} = -S(\mathbf{w}) \in U \cap W_0 = \{\mathbf{0}\}$) and Proposition 4.2.6(a). So $W_S = W$.

For uniqueness, suppose $W_S = W_{S'}$. For $\mathbf{w} \in W_0$, the vector $\mathbf{w} + S(\mathbf{w})$ lies in $W_{S'}$, so $\mathbf{w} + S(\mathbf{w}) = \mathbf{w}' + S'(\mathbf{w}')$ for some $\mathbf{w}' \in W_0$. Then $\mathbf{w} - \mathbf{w}' = S'(\mathbf{w}') - S(\mathbf{w}) \in W_0 \cap U = \{\mathbf{0}\}$, so $\mathbf{w}' = \mathbf{w}$ and $S(\mathbf{w}) = S'(\mathbf{w})$. Hence $S = S'$.

(c) By (a) and (b), $S \mapsto W_S$ is a bijection from $\mathrm{L}(W_0, U)$ onto the set of complements of U. The space $\mathrm{L}(W_0, U)$ has dimension $(n-k)k$ (Theorem 4.5.8), so it has $q^{k(n-k)}$ elements (Proposition 4.1.34). For a line U in $\mathbb{F}_3^2$, $n = 2$ and $k = 1$, so there are $3^1 = 3$ complements. Indeed, $\mathbb{F}_3^2$ has $(9-1)/2 = 4$ lines, and every line other than U meets U only in $\mathbf{0}$.

Solution to Exercise 4.6.55

Uses. Proposition 4.6.29 (Complements and the quotient), Proposition 4.6.32 (Operators on a quotient), Example 2.1.9 (Maps of polynomials), Proposition 1.2.18 (Degree and evaluation versus the operations), Definition 2.3.1 (Matrix of a linear map)
Techniques. Pass to a quotient (Technique 4.6.31), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Scale a nonzero element of degree d to make it monic. By minimality of d, which polynomials of degree less than d lie in U?
Hint 2. To show $F[x]_{\le d-1} + U = F[x]$, induct on the degree of q: subtract a multiple of $x^{e-d}p \in U$ to kill the leading term of q.
Hint 3. For (b), apply Proposition 4.6.32 to $M(q) = xq$. The last basis vector goes to $x^d + U$; rewrite x^d modulo p.
Sketch. (a) A nonzero element of degree d divided by its leading coefficient is p. Nonzero elements of U have degree $\ge d$, so $U \cap F[x]_{\le d-1} = \{\mathbf{0}\}$. If $\deg q = e \ge d$ with leading coefficient b, then $x^{e-d}p \in U$ and $\deg\left(q - bx^{e-d}p\right) < e$, so by induction $q \in F[x]_{\le d-1} + U$. By Proposition 4.6.29, $F[x]/U \cong F[x]_{\le d-1}$. (b) $M(U) \subseteq U$ gives $X = M/U$, and $X\left(x^j + U\right) = x^{j+1} + U$ for $j < d-1$, $X\left(x^{d-1} + U\right) = x^d + U = -\left(c_0 + \cdots + c_{d-1}x^{d-1}\right) + U$: the companion matrix of p.

(a) Let $p_0 \in U$ be nonzero of degree d with leading coefficient $a \neq 0$. Then $p = a^{-1}p_0 \in U$ has degree d and leading coefficient 1, so it has the stated form. By the hypothesis applied j times, $x^j p \in U$ for every $j \ge 0$, and $x^j p$ has degree $d + j$ and leading coefficient 1.

Intersection. A nonzero element of U has degree at least d, by the choice of d, so $U \cap F[x]_{\le d-1} = \{\mathbf{0}\}$.

Sum. We show by strong induction on e that every q of degree e lies in $F[x]_{\le d-1} + U$; the zero polynomial lies there trivially. If $e \le d-1$, then $q \in F[x]_{\le d-1}$. If $e \ge d$, let b be the leading coefficient of q. Then $q - bx^{e-d}p$

is zero or has degree less than e, because the coefficients of x^e cancel (Proposition 1.2.18). By induction it lies in $F[x]_{\le d-1} + U$, and since $bx^{e-d}p \in U$, so does q.

Hence $F[x] = F[x]_{\le d-1} \oplus U$, and by Proposition 4.6.29, $q \mapsto q + U$ restricts to an isomorphism $F[x]_{\le d-1} \to F[x]/U$. So $\dim(F[x]/U) = d$, and $1+U, x+U, \dots, x^{d-1}+U$ is a basis of $F[x]/U$ (the image of the basis $1, x, \dots, x^{d-1}$). If $d = 0$, then $p = 1$ and $U = F[x]$.

(b) Multiplication by x, $M(q) = xq$, is linear (Example 2.1.9), and $M(U) \subseteq U$ by hypothesis. By Proposition 4.6.32(a), $X = M/U$ is an operator on $F[x]/U$ with $X(q+U) = xq + U$. On the basis,

$$X\big(x^j + U\big) = x^{j+1} + U \quad (0 \le j \le d-2),$$

and, since $p \in U$,

$$X\big(x^{d-1} + U\big) = x^d + U = \big(x^d - p\big) + U = -c_0(1+U) - c_1(x+U) - \cdots - c_{d-1}\big(x^{d-1}+U\big).$$

So the matrix of X has 1s just below the diagonal, last column $(-c_0, -c_1, \dots, -c_{d-1})$, and zeros elsewhere:

$$\begin{pmatrix} 0 & 0 & \cdots & 0 & -c_0 \\ 1 & 0 & \cdots & 0 & -c_1 \\ 0 & 1 & \cdots & 0 & -c_2 \\ \vdots & & \ddots & & \vdots \\ 0 & 0 & \cdots & 1 & -c_{d-1} \end{pmatrix}.$$

This is the companion matrix of p, which reappears in Section 7.3.

One can show that U is exactly the set of polynomial multiples of p (polynomial multiplication and division come in Section 7.1). So the quotients of $F[x]$ by such subspaces are finite-dimensional, and multiplication by x on them is the basic example of an operator with a cyclic vector.

Section 4.7

Solution to Exercise 4.7.24

Uses. Proposition 4.7.20 (Affine independence through differences)
Hint 1. Subtract the first point from the others and test the differences for linear independence.
Hint 2. In (b), the relation $a(-1,1,0) + b(-1,0,1) + c(0,1,1) = \mathbf{0}$ leads to $-2a = 0$. What happens to this step over $\mathbb{F}_2$?
Sketch. (a) The differences $(1,1,1)$ and $(3,3,3)$ are dependent; $2\mathbf{v}_0 - 3\mathbf{v}_1 + \mathbf{v}_2 = \mathbf{0}$. (b) The differences are independent over $\mathbb{R}$, so the points are the vertices of a tetrahedron. (c) Over $\mathbb{F}_2$, the four points add up to $\mathbf{0}$, and $1+1+1+1 = 0$.

(a) The differences from $(1,2,3)$ are $(1,1,1)$ and $(3,3,3) = 3(1,1,1)$, which are linearly dependent, so the list is affinely dependent (Proposition 4.7.20). Translating $3(1,1,1) - (3,3,3) = \mathbf{0}$ back as in the proof of the proposition gives the affine dependence

$$2(1,2,3) - 3(2,3,4) + (4,5,6) = (2-6+4, 4-9+5, 6-12+6) = \mathbf{0}, \quad 2 - 3 + 1 = 0.$$

(b) The differences from $(1,0,0)$ are $(-1,1,0)$, $(-1,0,1)$, $(0,1,1)$. If $a(-1,1,0) + b(-1,0,1) + c(0,1,1) = \mathbf{0}$, then $-a - b = 0$, $a + c = 0$, and $b + c = 0$. So $b = -a$ and $c = -a$, and the last equation gives $-2a = 0$, so $a = 0$ over $\mathbb{R}$, and then $b = c = 0$. The differences are independent, and the four points are affinely independent.

(c) Over $\mathbb{F}_2$ the step $-2a = 0 \Rightarrow a = 0$ fails, and $a = b = c = 1$ is a relation: $(1,1,0) + (1,0,1) + (0,1,1) = (2,2,2) = \mathbf{0}$. Correspondingly,

$$(1,0,0) + (0,1,0) + (0,0,1) + (1,1,1) = (2,2,2) = \mathbf{0} \quad \text{and} \quad 1+1+1+1 = 0$$

in $\mathbb{F}_2$, an affine dependence. The four points lie in the plane $x_1 + x_2 + x_3 = 1$ of $\mathbb{F}_2^3$.

Solution to Exercise 4.7.43

Uses. Theorem 2.4.34 (Block multiplication), Theorem 2.5.10 (Left and right inverses agree)
Hint 1. Multiply the two block matrices in both orders.

Hint 2. For the 3×3 matrix, A is the rotation $\begin{pmatrix}0&-1\\1&0\end{pmatrix}$, whose inverse is $\begin{pmatrix}0&1\\-1&0\end{pmatrix}$.
Sketch. Both products are $\begin{pmatrix}I_n&\mathbf{0}\\0&1\end{pmatrix}=I_{n+1}$. The translation by $\mathbf{a}$ inverts to the translation by $-\mathbf{a}$. For the 3×3 matrix, $-A^{-1}(3,1)=-(1,-3)=(-1,3)$, giving $\begin{pmatrix}0&1&-1\\-1&0&3\\0&0&1\end{pmatrix}$.

By Theorem 2.4.34,

$$\begin{pmatrix}A&\mathbf{b}\\0&1\end{pmatrix}\begin{pmatrix}A^{-1}&-A^{-1}\mathbf{b}\\0&1\end{pmatrix}=\begin{pmatrix}AA^{-1}&-AA^{-1}\mathbf{b}+\mathbf{b}\\0&1\end{pmatrix}=\begin{pmatrix}I_n&\mathbf{0}\\0&1\end{pmatrix}=I_{n+1},$$

and

$$\begin{pmatrix}A^{-1}&-A^{-1}\mathbf{b}\\0&1\end{pmatrix}\begin{pmatrix}A&\mathbf{b}\\0&1\end{pmatrix}=\begin{pmatrix}A^{-1}A&A^{-1}\mathbf{b}-A^{-1}\mathbf{b}\\0&1\end{pmatrix}=I_{n+1}.$$

For the translation, $A=I_n$ and $\mathbf{b}=\mathbf{a}$, so the inverse is $\begin{pmatrix}I_n&-\mathbf{a}\\0&1\end{pmatrix}$, the matrix of the translation by $-\mathbf{a}$.

For the 3×3 matrix, $A=\begin{pmatrix}0&-1\\1&0\end{pmatrix}$ and $\mathbf{b}=(3,1)$. Since $A\begin{pmatrix}0&1\\-1&0\end{pmatrix}=I_2$, $A^{-1}=\begin{pmatrix}0&1\\-1&0\end{pmatrix}$, and $-A^{-1}\mathbf{b}=-(1,-3)=(-1,3)$. So the inverse is $\begin{pmatrix}0&1&-1\\-1&0&3\\0&0&1\end{pmatrix}$. Check: the product of the first row of the inverse with the third column of the original is $0\cdot 3+1\cdot 1+(-1)\cdot 1=0$, as it should be.

Solution to Exercise 4.7.46

Uses. Theorem 4.7.8 (Affine subspaces of F^n are solution sets), Theorem 4.7.14 (Affine subspaces are the sets closed under affine combinations), Proposition 4.7.3 (Direction and base points), Corollary 2.6.31 (Fibers are translates of the kernel)
Hint 1. (a) and (b) are solution sets of linear equations, in $\mathbb{R}^3$ and in $\mathbb{R}[x]$. Find one solution and the homogeneous solutions.
Hint 2. For (c) and (d), look for an affine combination of three points of the set, such as $\mathbf{u}+\mathbf{v}-\mathbf{w}$, that leaves the set.
Sketch. (a) $(2,-1,0)+\operatorname{span}((1,-2,1))$, a line. (b) The fiber of $p\mapsto(p(0),p(1))$ over $(1,3)$: $1+2x+\{p\mid p(0)=p(1)=0\}$, an affine subspace with infinite-dimensional direction. (c) No: $(1,0)+(0,1)-(0,0)=(1,1)$. (d) No: the set is $\{(0,0),(1,1),(2,1)\}$, and $(1,1)+(2,1)-(0,0)=(0,2)$ is missing.

(a) Yes. The homogeneous equations $x_1+x_2+x_3=0$, $x_1=x_3$ give $x_2=-2x_3$, so their solutions are $\operatorname{span}((1,-2,1))$. One solution of the system is $(2,-1,0)$: $2-1+0=1$ and $2-0=2$. By Theorem 4.7.8(a), the set is $(2,-1,0)+\operatorname{span}((1,-2,1))$, a line, with direction $\operatorname{span}((1,-2,1))$ and dimension 1.

(b) Yes. The map $T:\mathbb{R}[x]\to\mathbb{R}^2$, $T(p)=(p(0),p(1))$, is linear, and the set is the fiber $T^{-1}((1,3))$, which contains $1+2x$. By Corollary 2.6.31 it is $1+2x+\ker T$, an affine subspace with direction $\ker T=\{p\mid p(0)=p(1)=0\}$. This direction contains $x^j(x-1)$ for every $j\geq 1$, and these polynomials have distinct degrees, so $\ker T$ is infinite-dimensional and the dimension is not defined.

(c) No. The points $(1,0)$, $(0,1)$, $(0,0)$ lie in the set, and the affine combination $(1,0)+(0,1)-(0,0)=(1,1)$ does not, since $1\cdot 1\neq 0$. By Theorem 4.7.14 the set is not affine.

(d) No. In $\mathbb{F}_3$, $0^2=0$, $1^2=1$, and $2^2=4=1$, so the set is $\{(0,0),(1,1),(2,1)\}$. The affine combination $(1,1)+(2,1)-(0,0)=(3,2)=(0,2)$ is not in it, so it is not affine by Theorem 4.7.14.

Solution to Exercise 4.7.47

Uses. Remark 4.7.26 (Frames exist, and coordinates are coordinates), Proposition 4.7.32 (Barycentric coordinates on a simplex)
Hint 1. Since $\mathbf{v}_0=\mathbf{0}$, (t_1,t_2) are the coordinates of the point in the basis $(4,0),(1,3)$, and $t_0=1-t_1-t_2$.
Hint 2. Solve $4t_1+t_2=x$ and $3t_2=y$. A negative t_i puts the point beyond the edge opposite $\mathbf{v}_i$.
Sketch. $t_2=y/3$ and $t_1=(x-y/3)/4$. This gives $\mathbf{p}:\left(\frac{1}{4},\frac{5}{12},\frac{1}{3}\right)$, inside; $\mathbf{q}:\left(-\frac{1}{4},\frac{7}{12},\frac{2}{3}\right)$, beyond the edge $\mathbf{v}_1\mathbf{v}_2$; $\mathbf{r}:\left(1,-\frac{1}{3},\frac{1}{3}\right)$, beyond the edge $\mathbf{v}_0\mathbf{v}_2$.

The differences $(4,0)$ and $(1,3)$ are independent, so the points form an affine frame of $\mathbb{R}^2$. By Remark 4.7.26, since $\mathbf{v}_0 = \mathbf{0}$, a point (x,y) has $(x,y) = t_1(4,0) + t_2(1,3)$, that is, $4t_1 + t_2 = x$ and $3t_2 = y$, and $t_0 = 1 - t_1 - t_2$. So $t_2 = y/3$ and $t_1 = (x - y/3)/4$.

For $\mathbf{p} = (2,1)$: $t_2 = \frac{1}{3}$, $t_1 = \left(2 - \frac{1}{3}\right)/4 = \frac{5}{12}$, $t_0 = 1 - \frac{5}{12} - \frac{4}{12} = \frac{1}{4}$. All are positive, so $\mathbf{p}$ lies in the triangle (Proposition 4.7.32). Check: $\frac{5}{12}(4,0) + \frac{1}{3}(1,3) = \left(\frac{5}{3} + \frac{1}{3}, 1\right) = (2,1)$.

For $\mathbf{q} = (3,2)$: $t_2 = \frac{2}{3}$, $t_1 = \left(3 - \frac{2}{3}\right)/4 = \frac{7}{12}$, $t_0 = 1 - \frac{7}{12} - \frac{8}{12} = -\frac{1}{4}$. So $\mathbf{q}$ is outside, beyond the edge $\mathbf{v}_1\mathbf{v}_2$ opposite $\mathbf{v}_0$. Check: $\frac{7}{12}(4,0) + \frac{2}{3}(1,3) = \left(\frac{7}{3} + \frac{2}{3}, 2\right) = (3,2)$.

For $\mathbf{r} = (-1,1)$: $t_2 = \frac{1}{3}$, $t_1 = \left(-1 - \frac{1}{3}\right)/4 = -\frac{1}{3}$, $t_0 = 1 + \frac{1}{3} - \frac{1}{3} = 1$. So $\mathbf{r}$ is outside, beyond the edge $\mathbf{v}_0\mathbf{v}_2$ opposite $\mathbf{v}_1$. Check: $-\frac{1}{3}(4,0) + \frac{1}{3}(1,3) = (-1,1)$.

Solution to Exercise 4.7.48

Uses. Theorem 4.7.42 (Affine maps as matrices), Example 4.7.36 (Affine maps), Definition 4.7.41 (Homogeneous coordinates)
Hint 1. Each matrix is $\begin{pmatrix} A & \mathbf{b} \\ 0 & 1 \end{pmatrix}$ with A the linear part and $\mathbf{b}$ the image of $\mathbf{0}$. The scaling about $(1,1)$ is $\mathbf{v} \mapsto 3\mathbf{v} - 2(1,1)$.
Hint 2. By Theorem 4.7.42(c), $M_T M_R$ is the matrix of $T \circ R$, which rotates first.
Sketch. $M_T = \begin{pmatrix} 1 & 0 & 2 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}$, $M_R = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, $M_S = \begin{pmatrix} 3 & 0 & -2 \\ 0 & 3 & -2 \\ 0 & 0 & 1 \end{pmatrix}$. $M_T M_R = \begin{pmatrix} 0 & -1 & 2 \\ 1 & 0 & -1 \\ 0 & 0 & 1 \end{pmatrix}$ is $\mathbf{v} \mapsto R\mathbf{v} + (2,-1)$, and $M_R M_T = \begin{pmatrix} 0 & -1 & 1 \\ 1 & 0 & 2 \\ 0 & 0 & 1 \end{pmatrix}$ is $\mathbf{v} \mapsto R\mathbf{v} + (1,2)$. (c) $(2,-1)$, and $(4,-2,2)$.

(a) By Theorem 4.7.42, the matrix of $\mathbf{v} \mapsto A\mathbf{v} + \mathbf{b}$ is $\begin{pmatrix} A & \mathbf{b} \\ 0 & 1 \end{pmatrix}$. The scaling about $(1,1)$ is $\mathbf{v} \mapsto (1,1) + 3(\mathbf{v} - (1,1)) = 3\mathbf{v} - (2,2)$ (Example 4.7.36). So

$$M_T = \begin{pmatrix} 1 & 0 & 2 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}, \quad M_R = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad M_S = \begin{pmatrix} 3 & 0 & -2 \\ 0 & 3 & -2 \\ 0 & 0 & 1 \end{pmatrix}.$$

(b) Multiplying,

$$M_T M_R = \begin{pmatrix} 0 & -1 & 2 \\ 1 & 0 & -1 \\ 0 & 0 & 1 \end{pmatrix}, \quad M_R M_T = \begin{pmatrix} 0 & -1 & 1 \\ 1 & 0 & 2 \\ 0 & 0 & 1 \end{pmatrix}.$$

By Theorem 4.7.42(c), the first is the matrix of $T \circ R$, which rotates and then translates: $\mathbf{v} \mapsto R\mathbf{v} + (2,-1)$. The second is $R \circ T$, which translates and then rotates: $\mathbf{v} \mapsto R(\mathbf{v} + (2,-1)) = R\mathbf{v} + (1,2)$, since $R(2,-1) = (1,2)$. The two maps have the same linear part but differ by a translation, so the order matters.

(c) By Definition 4.7.41, $(6,-3,3)$ represents $3^{-1}(6,-3) = (2,-1)$. Multiplying $\widehat{(2,-1)} = (2,-1,1)$ by 2 gives $(4,-2,2)$.

Solution to Exercise 4.7.49

Uses. Proposition 4.7.45 (Perspective projection in homogeneous coordinates), Theorem 4.7.42 (Affine maps as matrices), Definition 4.7.41 (Homogeneous coordinates)
Hint 1. Parametrize the line as $\mathbf{c} + s(\mathbf{v} - \mathbf{c})$ and solve for the s that makes the third coordinate 0.
Hint 2. For (b), compute $\tau_{\mathbf{a}}(\pi(\tau_{-\mathbf{a}}(\mathbf{v})))$ with the formula for π; note that $\tau_{-\mathbf{a}}$ does not change z.
Hint 3. In (c), the translation matrices are $\begin{pmatrix} I_3 & \pm\mathbf{a} \\ 0 & 1 \end{pmatrix}$. Multiply $PM_{\tau_{-\mathbf{a}}}$ first.
Sketch. (a) $s = d/(d-z)$, and the first coordinate is $c_1 + s(x - c_1) = (dx - c_1 z)/(d - z)$. (b) $\pi(x - c_1, y - c_2, z) + \mathbf{a}$ has first coordinate $d(x - c_1)/(d - z) + c_1$, the same. (c) The product is $\begin{pmatrix} 1 & 0 & -c_1/d & 0 \\ 0 & 1 & -c_2/d & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1/d & 1 \end{pmatrix}$, which sends $\hat{\mathbf{v}}$ to $(x - c_1 z/d, y - c_2 z/d, 0, 1 - z/d)$.

(a) The line through $\mathbf{c}$ and $\mathbf{v}$ consists of the points $\mathbf{c} + s(\mathbf{v} - \mathbf{c})$, whose third coordinate is $d + s(z - d)$. It vanishes exactly for $s = d/(d - z)$, which exists since $z \neq d$. The first coordinate is then

$$c_1 + \frac{d}{d-z}(x - c_1) = \frac{c_1(d-z) + dx - dc_1}{d-z} = \frac{dx - c_1 z}{d-z},$$

and the second is $(dy - c_2 z)/(d-z)$ in the same way.

(b) $\tau_{-\mathbf{a}}(\mathbf{v}) = (x - c_1, y - c_2, z)$ has third coordinate $z \neq d$, so by the formula for π (the case $c_1 = c_2 = 0$ of (a)),

$$\pi(\tau_{-\mathbf{a}}(\mathbf{v})) = \left(\frac{d(x-c_1)}{d-z}, \frac{d(y-c_2)}{d-z}, 0\right).$$

Adding $\mathbf{a}$, the first coordinate becomes $(dx - dc_1 + c_1(d-z))/(d-z) = (dx - c_1 z)/(d-z)$, and likewise the second. By (a), this is $\pi_{\mathbf{c}}(\mathbf{v})$.

(c) With $M_{\tau_{\pm\mathbf{a}}} = \begin{pmatrix} I_3 & \pm\mathbf{a} \\ 0 & 1 \end{pmatrix}$,

$$PM_{\tau_{-\mathbf{a}}} = \begin{pmatrix} 1 & 0 & 0 & -c_1 \\ 0 & 1 & 0 & -c_2 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1/d & 1 \end{pmatrix}, \quad M_{\tau_{\mathbf{a}}} PM_{\tau_{-\mathbf{a}}} = \begin{pmatrix} 1 & 0 & -c_1/d & 0 \\ 0 & 1 & -c_2/d & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1/d & 1 \end{pmatrix}.$$

(In the second product, row 1 is row 1 plus c_1 times row 4 of $PM_{\tau_{-\mathbf{a}}}$, and similarly for row 2.) This matrix sends $\hat{\mathbf{v}} = (x, y, z, 1)$ to $(x - c_1 z/d, y - c_2 z/d, 0, 1 - z/d)$. The last entry is nonzero, and dividing by it gives first coordinate $(x - c_1 z/d)/(1 - z/d) = (dx - c_1 z)/(d-z)$, and similarly for the second, which is $\pi_{\mathbf{c}}(\mathbf{v})$ by (a).

Solution to Exercise 4.7.50

Uses. Proposition 4.7.45 (Perspective projection in homogeneous coordinates), Definition 4.7.41 (Homogeneous coordinates), Proposition 4.7.17 (The affine hull)

Hint 1. P is linear and $\widehat{\mathbf{v} + s\mathbf{w}} = \hat{\mathbf{v}} + s\begin{pmatrix}\mathbf{w}\\0\end{pmatrix}$, so $P\widehat{\mathbf{v} + s\mathbf{w}} = \mathbf{h}_1 + s\mathbf{h}_2$ with $\mathbf{h}_1 = P\hat{\mathbf{v}}$ and $\mathbf{h}_2 = P\begin{pmatrix}\mathbf{w}\\0\end{pmatrix}$.

Hint 2. Let α and β be the last entries of $\mathbf{h}_1$ and $\mathbf{h}_2$. Dividing $\mathbf{h}_1 + s\mathbf{h}_2$ by $\alpha + s\beta$ writes the image point as an affine combination of $\pi(\mathbf{v})$ and $\mathbf{q}_{\mathbf{w}}$ with coefficients $\alpha/(\alpha + s\beta)$ and $s\beta/(\alpha + s\beta)$.

Sketch. $\mathbf{h}_2 = (w_1, w_2, 0, -w_3/d)$ represents $\mathbf{q}_{\mathbf{w}}$. With $\alpha = 1 - v_3/d$ and $\beta = -w_3/d$, the point $\pi(\mathbf{v} + s\mathbf{w})$ is the first three entries of $\mathbf{h}_1 + s\mathbf{h}_2$ divided by $\alpha + s\beta$, which equals $\alpha/(\alpha + s\beta) \cdot \pi(\mathbf{v}) + s\beta/(\alpha + s\beta) \cdot \mathbf{q}_{\mathbf{w}}$, an affine combination. In (b), z is constant along the line, so $\pi(\mathbf{v} + s\mathbf{w}) = \pi(\mathbf{v}) + (s/\alpha)(w_1, w_2, 0)$.

(a) $P\begin{pmatrix}\mathbf{w}\\0\end{pmatrix} = (w_1, w_2, 0, -w_3/d) = \mathbf{h}_2$, whose last entry $\beta = -w_3/d$ is nonzero, so it represents $\beta^{-1}(w_1, w_2, 0) = \mathbf{q}_{\mathbf{w}}$. Let $\mathbf{h}_1 = P\hat{\mathbf{v}} = (v_1, v_2, 0, \alpha)$ with $\alpha = 1 - v_3/d \neq 0$; it represents $\pi(\mathbf{v})$ by Proposition 4.7.45. Since $\widehat{\mathbf{v} + s\mathbf{w}} = \hat{\mathbf{v}} + s\begin{pmatrix}\mathbf{w}\\0\end{pmatrix}$ and P is linear, $P\widehat{\mathbf{v} + s\mathbf{w}} = \mathbf{h}_1 + s\mathbf{h}_2$. If $v_3 + sw_3 \neq d$, its last entry $\alpha + s\beta = 1 - (v_3 + sw_3)/d$ is nonzero, and by Proposition 4.7.45,

$$\pi(\mathbf{v} + s\mathbf{w}) = \frac{1}{\alpha + s\beta}((v_1, v_2, 0) + s(w_1, w_2, 0)) = \frac{\alpha}{\alpha + s\beta}\pi(\mathbf{v}) + \frac{s\beta}{\alpha + s\beta}\mathbf{q}_{\mathbf{w}},$$

using $(v_1, v_2, 0) = \alpha\pi(\mathbf{v})$ and $(w_1, w_2, 0) = \beta\mathbf{q}_{\mathbf{w}}$. The coefficients add up to 1, so the point lies in $\operatorname{aff}(\pi(\mathbf{v}), \mathbf{q}_{\mathbf{w}})$ (Proposition 4.7.17), which is the line through $\pi(\mathbf{v})$ and $\mathbf{q}_{\mathbf{w}}$ if these differ, and the single point $\mathbf{q}_{\mathbf{w}}$ otherwise. The point $\mathbf{q}_{\mathbf{w}}$ depends only on $\mathbf{w}$, so this holds for every line $\mathbf{v} + \operatorname{span}(\mathbf{w})$ with $v_3 \neq d$. (A line in this direction with $v_3 = d$ contains a point $\mathbf{v} + s\mathbf{w}$ with $v_3 + sw_3 \neq d$, and we may start from that point instead.)

(b) If $w_3 = 0$, then $(w_1, w_2) \neq (0, 0)$, and every point of the line has third coordinate $v_3 \neq d$. So

$$\pi(\mathbf{v} + s\mathbf{w}) = \frac{1}{\alpha}(v_1 + sw_1, v_2 + sw_2, 0) = \pi(\mathbf{v}) + \frac{s}{\alpha}(w_1, w_2, 0).$$

As s runs over $\mathbb{R}$, so does s/α, and the image is the line $\pi(\mathbf{v}) + \operatorname{span}((w_1, w_2, 0))$.

Solution to Exercise 4.7.51

Uses. Theorem 4.7.14 (Affine subspaces are the sets closed under affine combinations), Proposition 4.7.17 (The affine hull)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Try the smallest field first.
Hint 2. If F has an element $t \notin \{0,1\}$, take $\mathbf{a} \in E_1 \setminus E_2$ and $\mathbf{b} \in E_2 \setminus E_1$, and ask where $(1-t)\mathbf{a} + t\mathbf{b}$ lies.
Hint 3. If $\mathbf{c} = (1-t)\mathbf{a} + t\mathbf{b} \in E_1$, then $\mathbf{b}$ is an affine combination of $\mathbf{a}$ and $\mathbf{c}$.
Sketch. Over $\mathbb{F}_2$ it is false: in $V = \mathbb{F}_2$, $\{0\} \cup \{1\} = \mathbb{F}_2$. If $|F| \geq 3$ it is true: with $\mathbf{a}, \mathbf{b}$ as in the hint and $t \notin \{0,1\}$, $\mathbf{c} = (1-t)\mathbf{a} + t\mathbf{b} \in E_1 \cup E_2$. If $\mathbf{c} \in E_1$, then $\mathbf{b} = (1-1/t)\mathbf{a} + (1/t)\mathbf{c} \in E_1$; if $\mathbf{c} \in E_2$, then $\mathbf{a} = (1/(1-t))\mathbf{c} - (t/(1-t))\mathbf{b} \in E_2$. Both are contradictions.

The answer depends on F. Over $\mathbb{F}_2$ the statement is false: in $V = \mathbb{F}_2$, the points $\{0\}$ and $\{1\}$ are affine subspaces, neither contains the other, and their union $\mathbb{F}_2$ is a subspace.

Now suppose F has more than two elements, and choose $t \in F$ with $t \neq 0$ and $t \neq 1$. Suppose $E_1 \cup E_2$ is affine but neither of E_1, E_2 contains the other. Pick $\mathbf{a} \in E_1$ with $\mathbf{a} \notin E_2$, and $\mathbf{b} \in E_2$ with $\mathbf{b} \notin E_1$. The point $\mathbf{c} = (1-t)\mathbf{a} + t\mathbf{b}$ is an affine combination of elements of $E_1 \cup E_2$, so it lies in $E_1 \cup E_2$ by Theorem 4.7.14.

If $\mathbf{c} \in E_1$, then

$$\left(1 - \frac{1}{t}\right)\mathbf{a} + \frac{1}{t}\mathbf{c} = \left(1 - \frac{1}{t} + \frac{1-t}{t}\right)\mathbf{a} + \mathbf{b} = \mathbf{b},$$

an affine combination of $\mathbf{a}, \mathbf{c} \in E_1$, so $\mathbf{b} \in E_1$, a contradiction. If $\mathbf{c} \in E_2$, then

$$\frac{1}{1-t}\mathbf{c} - \frac{t}{1-t}\mathbf{b} = \mathbf{a} + \frac{t}{1-t}\mathbf{b} - \frac{t}{1-t}\mathbf{b} = \mathbf{a},$$

an affine combination of $\mathbf{c}, \mathbf{b} \in E_2$ (the coefficients add up to $(1-t)/(1-t) = 1$), so $\mathbf{a} \in E_2$, a contradiction. Hence, when $|F| \geq 3$, the statement is true. The argument breaks down over $\mathbb{F}_2$ exactly because the line through $\mathbf{a}$ and $\mathbf{b}$ has no third point.

Solution to Exercise 4.7.52

Uses. Proposition 4.7.10 (Intersections of affine subspaces), Theorem 4.4.19 (Dimension of a sum), Proposition 4.1.21 (Dimensions of subspaces), Corollary 4.7.6 (Parallel affine subspaces are equal or disjoint)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Let $U = \operatorname{dir} H$ and $U' = \operatorname{dir} H'$. If $U \neq U'$, what is $U + U'$?
Hint 2. To find a common point, write $\mathbf{h}' - \mathbf{h} = \mathbf{u} + \mathbf{u}'$ with $\mathbf{h} \in H$, $\mathbf{h}' \in H'$, $\mathbf{u} \in U$, $\mathbf{u}' \in U'$.
Sketch. If $U \neq U'$, then $U' \not\subseteq U$ (equal dimensions), so $U + U'$ strictly contains U and equals V. Writing $\mathbf{h}' - \mathbf{h} = \mathbf{u} + \mathbf{u}'$ gives the common point $\mathbf{h} + \mathbf{u} = \mathbf{h}' - \mathbf{u}'$. By Proposition 4.7.10 the intersection has direction $U \cap U'$, of dimension $2(n-1) - n = n - 2$.

Let $U = \operatorname{dir} H$ and $U' = \operatorname{dir} H'$, both of dimension $n-1$, and suppose H and H' are not parallel, so $U \neq U'$. If $U' \subseteq U$, then $U' = U$ by Proposition 4.1.21(b), which is not the case. So some vector of U' lies outside U, and $U \subsetneq U + U'$. Then $n - 1 < \dim(U + U') \leq n$, so $U + U' = V$ by Proposition 4.1.21(b).

Pick $\mathbf{h} \in H$ and $\mathbf{h}' \in H'$, and write $\mathbf{h}' - \mathbf{h} = \mathbf{u} + \mathbf{u}'$ with $\mathbf{u} \in U$ and $\mathbf{u}' \in U'$. Then $\mathbf{h} + \mathbf{u} = \mathbf{h}' - \mathbf{u}'$ lies in H and in H'. By Proposition 4.7.10, $H \cap H'$ is an affine subspace with direction $U \cap U'$, and by Theorem 4.4.19,

$$\dim(U \cap U') = \dim U + \dim U' - \dim(U + U') = 2(n-1) - n = n - 2.$$

For $n = 2$, the hyperplanes are lines. Two lines in a plane are either parallel, or they meet in an affine subspace of dimension 0, a single point.

Solution to Exercise 4.7.53

Uses. Proposition 1.5.14 (Appending a vector), Theorem 4.1.10 (Independent lists are short), Definition 4.7.5 (Direction, dimension, parallel)
Hint 1. The lines meet if and only if $\mathbf{p} + a\mathbf{u} = \mathbf{q} + b\mathbf{w}$ for some scalars. Rewrite this as a statement about $\mathbf{q} - \mathbf{p}$.
Hint 2. The lines are parallel if and only if $\operatorname{span}(\mathbf{u}) = \operatorname{span}(\mathbf{w})$, that is, if and only if $\mathbf{u}, \mathbf{w}$ is dependent. Then use Proposition 1.5.14.

Sketch. $\ell_1 \cap \ell_2 \neq \emptyset$ if and only if $\mathbf{q}-\mathbf{p} \in \operatorname{span}(\mathbf{u},\mathbf{w})$, and the lines are parallel if and only if $\mathbf{u},\mathbf{w}$ is dependent. So "disjoint and not parallel" means "$\mathbf{u},\mathbf{w}$ independent and $\mathbf{q}-\mathbf{p} \notin \operatorname{span}(\mathbf{u},\mathbf{w})$", which is the independence of $\mathbf{u},\mathbf{w},\mathbf{q}-\mathbf{p}$ by Proposition 1.5.14. In dimension 2, three vectors are dependent.

The lines meet if and only if $\mathbf{p}+a\mathbf{u} = \mathbf{q}+b\mathbf{w}$ for some $a,b \in F$, that is, if and only if $\mathbf{q}-\mathbf{p} = a\mathbf{u}-b\mathbf{w}$ for some a,b, that is, if and only if $\mathbf{q}-\mathbf{p} \in \operatorname{span}(\mathbf{u},\mathbf{w})$.

The lines are parallel if and only if $\operatorname{span}(\mathbf{u}) = \operatorname{span}(\mathbf{w})$. Since $\mathbf{u},\mathbf{w} \neq \mathbf{0}$, this holds if and only if $\mathbf{w} = c\mathbf{u}$ for some c (necessarily nonzero), that is, if and only if $\mathbf{u},\mathbf{w}$ is linearly dependent: a nontrivial relation $a\mathbf{u}+b\mathbf{w}=\mathbf{0}$ must have $a,b \neq 0$, as both vectors are nonzero.

So ℓ_1,ℓ_2 are disjoint and not parallel if and only if $\mathbf{u},\mathbf{w}$ is independent and $\mathbf{q}-\mathbf{p} \notin \operatorname{span}(\mathbf{u},\mathbf{w})$. By Proposition 1.5.14, this is equivalent to the independence of $\mathbf{u},\mathbf{w},\mathbf{q}-\mathbf{p}$. (If $\mathbf{u},\mathbf{w}$ is dependent, so is the longer list, and both sides fail.)

If $\dim V = 2$, no list of three vectors is independent (Theorem 4.1.10), so two lines are never disjoint and non-parallel.

Solution to Exercise 4.7.54

Uses. Proposition 4.7.17 (The affine hull), Theorem 4.7.8 (Affine subspaces of F^n are solution sets), Proposition 4.1.21 (Dimensions of subspaces)
Hint 1. The direction is spanned by $(1,1,-1,0)$ and $(-1,1,1,1)$. Find the dimension, then the number of equations from Theorem 4.7.8(b).
Hint 2. An equation $a_1x_1+\cdots+a_4x_4=c$ works for the direction if $(a_1,\ldots,a_4)$ kills both direction vectors. Find two independent such rows, then compute the right-hand sides at $(1,0,2,1)$.
Sketch. The two differences are independent, so the hull is a plane and needs $4-2=2$ equations. The rows $(1,0,1,0)$ and $(1,-1,0,2)$ kill both differences, and the system $x_1+x_3=3$, $x_1-x_2+2x_4=3$ works.

By Proposition 4.7.17(b), the hull is $(1,0,2,1)+\operatorname{span}(\mathbf{d}_1,\mathbf{d}_2)$ with $\mathbf{d}_1=(1,1,-1,0)$ and $\mathbf{d}_2=(-1,1,1,1)$. These are independent (the last entries force the coefficient of $\mathbf{d}_2$ to be 0, and then that of $\mathbf{d}_1$), so the hull is a plane, and by Theorem 4.7.8(b) it takes $4-2=2$ equations, and no fewer.

A row $\mathbf{a}=(a_1,a_2,a_3,a_4)$ with $A\mathbf{d}_1 = A\mathbf{d}_2 = 0$ satisfies $a_1+a_2-a_3=0$ and $-a_1+a_2+a_3+a_4=0$. Taking $(a_3,a_4)=(1,0)$ gives $(1,0,1,0)$, and $(a_3,a_4)=(0,2)$ gives $(1,-1,0,2)$. With $A=\begin{pmatrix}1&0&1&0\\1&-1&0&2\end{pmatrix}$, of rank 2, and $A(1,0,2,1)=(3,3)$, the system is

$$x_1+x_3=3, \quad x_1-x_2+2x_4=3.$$

Its solution set is an affine subspace containing $(1,0,2,1)$ with direction $\ker T_A$ of dimension $4-2=2$, which contains $\mathbf{d}_1,\mathbf{d}_2$; so the direction is $\operatorname{span}(\mathbf{d}_1,\mathbf{d}_2)$ by Proposition 4.1.21(b), and the solution set is the hull. Check the other points: $2+1=3$, $2-1+2=3$, and $0+3=3$, $0-1+4=3$.

Solution to Exercise 4.7.55

Uses. Theorem 2.1.3 (Checking linearity), Definition 4.7.35 (Affine map)
Hint 1. Replace f by $g=f-f(\mathbf{0})$. It satisfies the same identity and $g(\mathbf{0})=\mathbf{0}$.
Hint 2. Take $\mathbf{v}=\mathbf{0}$ to get $g\left(\frac{1}{2}\mathbf{u}\right)=\frac{1}{2}g(\mathbf{u})$. Then $g(\mathbf{u}+\mathbf{v})=2g\left(\frac{1}{2}(\mathbf{u}+\mathbf{v})\right)$.
Hint 3. Additivity gives $g(k\mathbf{u})=kg(\mathbf{u})$ for integers k. For $r=k/m$, compute $mg(r\mathbf{u})$.
Sketch. $g=f-f(\mathbf{0})$ satisfies the midpoint identity and $g(\mathbf{0})=\mathbf{0}$, so $g(\mathbf{u}/2)=g(\mathbf{u})/2$ and $g(\mathbf{u}+\mathbf{v})=2g((\mathbf{u}+\mathbf{v})/2)=g(\mathbf{u})+g(\mathbf{v})$. By induction $g(k\mathbf{u})=kg(\mathbf{u})$ for $k\geq 0$, also for $k<0$ since $g(-\mathbf{u})=-g(\mathbf{u})$, and $mg((k/m)\mathbf{u})=g(k\mathbf{u})=kg(\mathbf{u})$. So g is linear over $\mathbb{Q}$ and $f=g+f(\mathbf{0})$.

Let $g(\mathbf{x})=f(\mathbf{x})-f(\mathbf{0})$. Then $g(\mathbf{0})=\mathbf{0}$, and subtracting $f(\mathbf{0})=\frac{1}{2}f(\mathbf{0})+\frac{1}{2}f(\mathbf{0})$ from the hypothesis gives

$$g\left(\frac{1}{2}\mathbf{u}+\frac{1}{2}\mathbf{v}\right)=\frac{1}{2}g(\mathbf{u})+\frac{1}{2}g(\mathbf{v}) \quad \text{for all } \mathbf{u},\mathbf{v}.$$

With $\mathbf{v}=\mathbf{0}$ this says $g\left(\frac{1}{2}\mathbf{u}\right)=\frac{1}{2}g(\mathbf{u})$. Applying that to $\mathbf{u}+\mathbf{v}$,

$$g(\mathbf{u}+\mathbf{v})=2g\left(\frac{1}{2}(\mathbf{u}+\mathbf{v})\right)=2\left(\frac{1}{2}g(\mathbf{u})+\frac{1}{2}g(\mathbf{v})\right)=g(\mathbf{u})+g(\mathbf{v}).$$

So g is additive. By induction on k, $g(k\mathbf{u}) = kg(\mathbf{u})$ for integers $k \geq 0$ (the case $k = 0$ is $g(\mathbf{0}) = \mathbf{0}$, and $g((k+1)\mathbf{u}) = g(k\mathbf{u}) + g(\mathbf{u})$). Since $g(\mathbf{u}) + g(-\mathbf{u}) = g(\mathbf{0}) = \mathbf{0}$, the same holds for negative k. For $r = k/m$ with $k, m \in \mathbb{Z}$ and $m > 0$,

$$mg(r\mathbf{u}) = g(mr\mathbf{u}) = g(k\mathbf{u}) = kg(\mathbf{u}),$$

so $g(r\mathbf{u}) = rg(\mathbf{u})$. Hence g is additive and homogeneous over $\mathbb{Q}$, so it is linear by Theorem 2.1.3, and $f = g + f(\mathbf{0})$ is affine.

Solution to Exercise 4.7.56

Uses. Definition 4.7.18 (Affine independence), Example 4.7.19 (Affine independence)
Hint 1. Changing a coefficient changes the vector that the combination represents. Is the new combination still $\mathbf{0}$?
Hint 2. Test the claim on a list containing $\mathbf{0}$.
Sketch. Replacing c_0 by $c_0 - s$ changes the combination to $-s\mathbf{v}_0$, which need not be $\mathbf{0}$, so the new coefficients need not form an affine dependence. The forward half is true. The converse is false: $\mathbf{0}, \mathbf{e}_1$ is affinely independent but linearly dependent.

The first half is correct: an affine dependence is a nontrivial linear relation, so a linearly independent list has none.

The error is in the converse. After c_0 is replaced by $c_0 - s$, the combination represents

$$(c_0 - s)\mathbf{v}_0 + c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k = \mathbf{0} - s\mathbf{v}_0 = -s\mathbf{v}_0,$$

which is not $\mathbf{0}$ unless $s = 0$ or $\mathbf{v}_0 = \mathbf{0}$. So the new coefficients are not an affine dependence, and affine independence says nothing about them. (The last sentence of the argument is also confused, but the claim fails before it.)

The converse is false. The list $\mathbf{0}, \mathbf{e}_1$ in $\mathbb{R}^2$ consists of two distinct points, so it is affinely independent (Example 4.7.19(a)), but it contains $\mathbf{0}$, so it is linearly dependent. Likewise $(0,0), (1,0), (0,1)$ is affinely independent and linearly dependent (Example 4.7.19(b)).

Solution to Exercise 4.7.57

Uses. Theorem 4.7.22 (Characterizations of affine independence), Proposition 4.7.17 (The affine hull), Corollary 4.7.6 (Parallel affine subspaces are equal or disjoint), Proposition 4.7.3 (Direction and base points), Proposition 4.1.34 (Size of a vector space over a finite field)
Hint 1. For (a), write $\mathbf{g}$ as an affine combination of $\mathbf{v}_i$ and $\mathbf{m}_i$. To see that two medians differ, show that if the median from $\mathbf{v}_0$ contained $\mathbf{v}_1$, then $\mathbf{v}_2$ would lie in $\operatorname{aff}(\mathbf{v}_0, \mathbf{v}_1)$.
Hint 2. For (b), in $\mathbb{F}_3$ we have $1/2 = 2 = -1$, so $\mathbf{m}_i = -(\mathbf{v}_j + \mathbf{v}_k)$. Compute $\mathbf{m}_i - \mathbf{v}_i$.
Hint 3. Let $\mathbf{s} = \mathbf{v}_0 + \mathbf{v}_1 + \mathbf{v}_2$. Show $\mathbf{s} \neq \mathbf{0}$, and that $\mathbf{v}_1 - \mathbf{v}_0 \in \operatorname{span}(\mathbf{s})$ would give an affine dependence, using $3 = 0$.
Sketch. (a) $\mathbf{g} = \frac{1}{3}\mathbf{v}_i + \frac{2}{3}\mathbf{m}_i$ lies on every median. If two medians were equal, the median from $\mathbf{v}_0$ would contain $\mathbf{v}_1$, so $\mathbf{m}_0 \in \operatorname{aff}(\mathbf{v}_0, \mathbf{v}_1)$ and $\mathbf{v}_2 = 2\mathbf{m}_0 - \mathbf{v}_1$ would be in it too. Distinct lines share at most one point. (b) $\mathbf{m}_i - \mathbf{v}_i = -\mathbf{s}$ for every i, and $\mathbf{s} \neq \mathbf{0}$, so each median is $\mathbf{v}_i + \operatorname{span}(\mathbf{s})$. If $\mathbf{v}_j - \mathbf{v}_i = c\mathbf{s}$, the coefficients of the resulting relation add up to $-3c = 0$, giving an affine dependence. So the medians are three distinct parallel lines, disjoint by Corollary 4.7.6, with 3 points each, covering all 9 points.

(a) Write $\mathbf{m}_0 = \frac{1}{2}(\mathbf{v}_1 + \mathbf{v}_2)$, and similarly $\mathbf{m}_1, \mathbf{m}_2$. Then

$$\frac{1}{3}\mathbf{v}_0 + \frac{2}{3}\mathbf{m}_0 = \frac{1}{3}(\mathbf{v}_0 + \mathbf{v}_1 + \mathbf{v}_2) = \mathbf{g},$$

an affine combination of $\mathbf{v}_0$ and $\mathbf{m}_0$, so $\mathbf{g}$ lies on the median from $\mathbf{v}_0$ (Proposition 4.7.17), and likewise on the other two. The median from $\mathbf{v}_0$ is a line, since $\mathbf{m}_0 \neq \mathbf{v}_0$: otherwise $\mathbf{v}_0$ would be an affine combination of $\mathbf{v}_1, \mathbf{v}_2$, contradicting Theorem 4.7.22(V).

Suppose two medians coincide, say those from $\mathbf{v}_0$ and $\mathbf{v}_1$ (the other cases are the same up to renaming). Then $\mathbf{v}_1$ lies on the median from $\mathbf{v}_0$, so this median is $\operatorname{aff}(\mathbf{v}_0, \mathbf{v}_1)$, and it contains $\mathbf{m}_0$. Then $\mathbf{v}_2 = 2\mathbf{m}_0 - \mathbf{v}_1$ is an affine combination of points of $\operatorname{aff}(\mathbf{v}_0, \mathbf{v}_1)$, so it lies there, contradicting Theorem 4.7.22(V). So the medians are three distinct lines. Two distinct lines meet in at most one point: their intersection is empty or

an affine subspace of dimension at most 1 (Proposition 4.7.10), and if it had dimension 1 it would equal both lines (Proposition 4.1.21(b) applied to the directions, and Proposition 4.7.3). So $\mathbf{g}$ is the only common point.

(b) In $\mathbb{F}_3$, $2 \cdot 2 = 4 = 1$, so $1/2 = 2 = -1$, and $\mathbf{m}_i = -(\mathbf{v}_j + \mathbf{v}_k)$, where $\{i,j,k\} = \{0,1,2\}$. Let $\mathbf{s} = \mathbf{v}_0 + \mathbf{v}_1 + \mathbf{v}_2$. Then $\mathbf{m}_i - \mathbf{v}_i = -\mathbf{s}$ for every i. If $\mathbf{s} = \mathbf{0}$, then $\mathbf{v}_2 = -\mathbf{v}_0 - \mathbf{v}_1 = 2\mathbf{v}_0 + 2\mathbf{v}_1$ with $2 + 2 = 4 = 1$, an affine combination of $\mathbf{v}_0, \mathbf{v}_1$, contradicting affine independence. So $\mathbf{s} \neq \mathbf{0}$, and the median from $\mathbf{v}_i$ is $\mathbf{v}_i + \operatorname{span}(\mathbf{s})$. All three medians have direction $\operatorname{span}(\mathbf{s})$, so they are parallel.

Suppose two of them coincide, say $\mathbf{v}_1 - \mathbf{v}_0 = c\mathbf{s}$ for some $c \in \mathbb{F}_3$ (by Proposition 4.7.3(c)). Then

$$(-1-c)\mathbf{v}_0 + (1-c)\mathbf{v}_1 - c\mathbf{v}_2 = \mathbf{0},$$

with coefficient sum $-3c = 0$, and the coefficients are not all 0 (that would need $c = -1$, $c = 1$, and $c = 0$). This is an affine dependence, a contradiction. So the three medians are distinct parallel lines, hence pairwise disjoint (Corollary 4.7.6). Each has $|\operatorname{span}(\mathbf{s})| = 3$ points, so together they have $9 = \left|\mathbb{F}_3^2\right|$ points (Proposition 4.1.34), and they cover $\mathbb{F}_3^2$.

Solution to Exercise 4.7.58

Uses. Theorem 4.7.39 (Affine maps are determined by a frame), Theorem 4.7.42 (Affine maps as matrices), Proposition 4.7.20 (Affine independence through differences), Corollary 3.5.25 (The invertible matrix theorem), Proposition 2.4.8 (Four views of the product)
Techniques. Homogenize: add a coordinate 1 (Technique 4.7.21)
Hint 1. In (a), $f(\mathbf{0})$ is the translation part, and $f(\mathbf{e}_j) - f(\mathbf{0})$ is column j of the linear part.
Hint 2. In (b), compose: if h sends $\mathbf{0}, \mathbf{e}_1, \mathbf{e}_2$ to $(1,1), (3,1), (1,2)$, then $g = f \circ h^{-1}$.
Hint 3. In (c), $M\hat{\mathbf{a}}_i = \hat{\mathbf{b}}_i$ for all i says $M\hat{A} = \hat{B}$. The columns of $\hat{A}$ are independent by the second approach to Proposition 4.7.20.
Sketch. (a) $f(\mathbf{x}) = \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix}\mathbf{x} + (2,1)$. (b) $h(\mathbf{x}) = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}\mathbf{x} + (1,1)$, and $g = f \circ h^{-1}$ is $g(\mathbf{y}) = \begin{pmatrix} 1 & -1 \\ \frac{1}{2} & 2 \end{pmatrix}\mathbf{y} + \left(2, -\frac{3}{2}\right)$. (c) $M_g\hat{A} = \hat{B}$ column by column, and $\hat{A}$ has independent columns, so it is invertible.

(a) By Theorem 4.7.39 there is exactly one such map. Its translation part is $f(\mathbf{0}) = (2,1)$, and its linear part L has $L(\mathbf{e}_1) = (4,2) - (2,1) = (2,1)$ and $L(\mathbf{e}_2) = (1,3) - (2,1) = (-1,2)$. So

$$f(\mathbf{x}) = \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix}\mathbf{x} + \begin{pmatrix} 2 \\ 1 \end{pmatrix}, \quad M_f = \begin{pmatrix} 2 & -1 & 2 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

(b) The affine map $h(\mathbf{x}) = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}\mathbf{x} + (1,1)$ sends $\mathbf{0}, \mathbf{e}_1, \mathbf{e}_2$ to $(1,1), (3,1), (1,2)$, and it is bijective with $h^{-1}(\mathbf{y}) = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{pmatrix}(\mathbf{y} - (1,1))$. The map $g = f \circ h^{-1}$ is affine and sends $(1,1), (3,1), (1,2)$ to $(2,1), (4,2), (1,3)$, so it is the unique such map (Theorem 4.7.39). Explicitly,

$$g(\mathbf{y}) = \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix}\left(\begin{pmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{pmatrix}\left(\mathbf{y} - \begin{pmatrix} 1 \\ 1 \end{pmatrix}\right) + \begin{pmatrix} 2 \\ 1 \end{pmatrix}\right) = \begin{pmatrix} 1 & -1 \\ \frac{1}{2} & 2 \end{pmatrix}\mathbf{y} + \begin{pmatrix} 2 \\ -\frac{3}{2} \end{pmatrix}.$$

Check: $g(1,1) = \left(0, \frac{5}{2}\right) + \left(2, -\frac{3}{2}\right) = (2,1)$, $g(3,1) = \left(2, \frac{7}{2}\right) + \left(2, -\frac{3}{2}\right) = (4,2)$, $g(1,2) = \left(-1, \frac{9}{2}\right) + \left(2, -\frac{3}{2}\right) = (1,3)$.

(c) The columns of $\hat{A}$ are the lifts $\hat{\mathbf{a}}_i$, which are linearly independent by the second approach to Proposition 4.7.20. So $\hat{A}$ is invertible (Corollary 3.5.25). Let g be the affine map with $g(\mathbf{a}_i) = \mathbf{b}_i$ (Theorem 4.7.39). By Theorem 4.7.42(a), $M_g\hat{\mathbf{a}}_i = \hat{\mathbf{b}}_i$ for each i, which says that $M_g\hat{A} = \hat{B}$ column by column (Proposition 2.4.8). Hence $M_g = \hat{B}\hat{A}^{-1}$. For (b),

$$\hat{A} = \begin{pmatrix} 1 & 3 & 1 \\ 1 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix}, \quad \hat{A}^{-1} = \begin{pmatrix} -\frac{1}{2} & -1 & \frac{5}{2} \\ \frac{1}{2} & 0 & -\frac{1}{2} \\ 0 & 1 & -1 \end{pmatrix}, \quad \hat{B}\hat{A}^{-1} = \begin{pmatrix} 2 & 4 & 1 \\ 1 & 2 & 3 \\ 1 & 1 & 1 \end{pmatrix}\hat{A}^{-1} = \begin{pmatrix} 1 & -1 & 2 \\ \frac{1}{2} & 2 & -\frac{3}{2} \\ 0 & 0 & 1 \end{pmatrix},$$

in agreement with (b).

Solution to Exercise 4.7.59

Uses. Corollary 4.7.23 (Affinely independent lists are short), Definition 4.7.28 (Convex combination, convex set, convex hull)
Techniques. Slide along a dependence (Technique 4.7.33)
Hint 1. The $n+2$ points are affinely dependent. Take an affine dependence $\sum_i d_i \mathbf{v}_i = \mathbf{0}$, $\sum_i d_i = 0$.
Hint 2. Split the indices by the sign of d_i, and move the negative terms to the other side.
Sketch. Let $\sum_i d_i \mathbf{v}_i = \mathbf{0}$, $\sum_i d_i = 0$, not all $d_i = 0$. Put $I = \{i \mid d_i > 0\}$ and J the rest; both are nonempty, and $s = \sum_{i\in I} d_i = -\sum_{j\in J} d_j > 0$. Then $\sum_{i\in I}(d_i/s)\mathbf{v}_i = \sum_{j\in J}(-d_j/s)\mathbf{v}_j$ is a common point. In the examples, $(1,1)$ is the midpoint of $(2,0)$ and $(0,2)$, and lies inside the triangle $(0,0),(4,0),(0,4)$.

By Corollary 4.7.23, the $n+2$ points are affinely dependent: there are $d_1, \dots, d_{n+2}$, not all 0, with $\sum_i d_i \mathbf{v}_i = \mathbf{0}$ and $\sum_i d_i = 0$. Let $I = \{i \mid d_i > 0\}$ and $J = \{j \mid d_j \le 0\}$. Since the d_i add up to 0 and are not all 0, some d_i is positive and some is negative, so I and J are nonempty. Let $s = \sum_{i\in I} d_i > 0$; then $\sum_{j\in J} d_j = -s$. Moving the terms with $j \in J$ to the other side of the dependence and dividing by s,

$$\mathbf{p} = \sum_{i\in I} \frac{d_i}{s}\mathbf{v}_i = \sum_{j\in J} \frac{-d_j}{s}\mathbf{v}_j.$$

On the left, the coefficients are positive and add up to 1; on the right, they are nonnegative and add up to $(-(-s))/s = 1$. So $\mathbf{p}$ lies in both convex hulls.

For $(0,0),(2,0),(0,2),(1,1)$: the dependence $(2,0)+(0,2)-2(1,1) = \mathbf{0}$ (coefficients $0,1,1,-2$, sum 0) gives $I = \{2,3\}$ and $J = \{1,4\}$, with common point $(1,1) = \frac{1}{2}(2,0) + \frac{1}{2}(0,2)$, which is also the endpoint $(1,1)$ of the segment $\operatorname{conv}\{(0,0),(1,1)\}$. For $(0,0),(4,0),(0,4),(1,1)$: $2(0,0)+(4,0)+(0,4)-4(1,1) = \mathbf{0}$, with coefficients $2,1,1,-4$ adding up to 0, gives $I = \{1,2,3\}$ and $J = \{4\}$: the point $(1,1) = \frac{1}{2}(0,0) + \frac{1}{4}(4,0) + \frac{1}{4}(0,4)$ lies in the triangle.

Solution to Exercise 4.7.60

Uses. Theorem 4.7.37 (Affine maps preserve affine combinations)
Hint 1. The point $\left(\frac{1}{2},\frac{1}{2}\right)$ is the midpoint of $(0,0)$ and $(1,1)$, and also of $(1,0)$ and $(0,1)$.
Hint 2. For (b), try $h'(\mathbf{y}) = c - y_1 - y_2 + 2y_3$ and choose c.
Sketch. (a) Affine maps preserve midpoints, so $h\left(\frac{1}{2},\frac{1}{2}\right)$ is the average of two positive numbers and also of two negative numbers. (b) $h'(\mathbf{y}) = \frac{1}{2} - y_1 - y_2 + 2y_3$ gives $\frac{1}{2}, \frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}$.

(a) Suppose such an affine h exists. The point $\mathbf{m} = \left(\frac{1}{2},\frac{1}{2}\right)$ is the affine combination $\frac{1}{2}(0,0) + \frac{1}{2}(1,1)$, and also $\frac{1}{2}(1,0) + \frac{1}{2}(0,1)$. By Theorem 4.7.37(II),

$$h(\mathbf{m}) = \frac{1}{2}h(0,0) + \frac{1}{2}h(1,1) > 0 \quad \text{and} \quad h(\mathbf{m}) = \frac{1}{2}h(1,0) + \frac{1}{2}h(0,1) < 0,$$

a contradiction. In words, the segment between the two positive points crosses the segment between the two negative points, and at the crossing point an affine function would have to be both positive and negative.

(b) The four points become $\varphi(0,0) = (0,0,0)$, $\varphi(1,1) = (1,1,1)$, $\varphi(1,0) = (1,0,0)$, and $\varphi(0,1) = (0,1,0)$. Let $h'(\mathbf{y}) = \frac{1}{2} - y_1 - y_2 + 2y_3$. Then h' takes the values $\frac{1}{2}, \frac{1}{2} - 2 + 2 = \frac{1}{2}, -\frac{1}{2}$, and $-\frac{1}{2}$ at these points, as required. The midpoint argument of (a) no longer applies, because φ is not affine: the midpoint of $\varphi(0,0)$ and $\varphi(1,1)$ is $\left(\frac{1}{2},\frac{1}{2},\frac{1}{2}\right)$, while that of $\varphi(1,0)$ and $\varphi(0,1)$ is $\left(\frac{1}{2},\frac{1}{2},0\right)$.

Solution to Exercise 4.7.61

Uses. Theorem 4.7.14 (Affine subspaces are the sets closed under affine combinations)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Over $\mathbb{F}_2$, an affine combination of $\mathbf{s}_1, \dots, \mathbf{s}_k$ is the sum of the $\mathbf{s}_i$ whose coefficient is 1, and there is an odd number of them.

Hint 2. Show by induction that the sum of any odd number of elements of S lies in S: replace the first three summands by their sum.
Sketch. ($\Rightarrow$) $\mathbf{u}+\mathbf{v}+\mathbf{w}$ is an affine combination, as $1+1+1=1$ in $\mathbb{F}_2$. ($\Leftarrow$) An affine combination over $\mathbb{F}_2$ is a sum of an odd number $2j+1$ of elements of S; replacing three of them by their sum, which is in S, lowers j, so by induction the sum lies in S. Then Theorem 4.7.14 applies. The first set is the subspace $x_1+x_2+x_3=0$; the second is the plane $x_1+x_2+x_3=1$, and both pass the test.

($\Rightarrow$) If S is affine, then $\mathbf{u}+\mathbf{v}+\mathbf{w}=1\mathbf{u}+1\mathbf{v}+1\mathbf{w}$ is an affine combination, since $1+1+1=1$ in $\mathbb{F}_2$, so it lies in S by Theorem 4.7.14.

($\Leftarrow$) Every coefficient in $\mathbb{F}_2$ is 0 or 1, so an affine combination $\sum_i c_i\mathbf{s}_i$ of elements of S is the sum of those $\mathbf{s}_i$ with $c_i=1$, and their number is odd, because the coefficients add up to 1 in $\mathbb{F}_2$. We show by induction on $j\geq 0$ that a sum of $2j+1$ elements of S (repetitions allowed) lies in S. For $j=0$ it is a single element of S. For $j\geq 1$, the sum $\mathbf{s}_1+\mathbf{s}_2+\mathbf{s}_3+\mathbf{s}_4+\cdots+\mathbf{s}_{2j+1}$ equals $\mathbf{s}'+\mathbf{s}_4+\cdots+\mathbf{s}_{2j+1}$ with $\mathbf{s}'=\mathbf{s}_1+\mathbf{s}_2+\mathbf{s}_3\in S$ by hypothesis, a sum of $2(j-1)+1$ elements of S, which lies in S by induction. So S is closed under affine combinations, and it is affine by Theorem 4.7.14.

The first set consists of the vectors with $x_1+x_2+x_3=0$, and each of its triples sums to a vector with the same property, so it passes the test; it is in fact a subspace. The second consists of the vectors with $x_1+x_2+x_3=1$, and the sum of three such vectors has coordinate sum $1+1+1=1$, so it passes too: it is the affine plane $(1,0,0)+\{\mathbf{x}\mid x_1+x_2+x_3=0\}$. (It is the plane of Exercise 4.7.24(c).)

Solution to Exercise 4.7.62

Uses. Theorem 4.7.42 (Affine maps as matrices), Example 4.7.36 (Affine maps), Proposition 2.5.28 (Inverse of a 2×2 matrix), Proposition 3.1.19 (Solution sets are translates of the kernel)
Hint 1. The rotation about $\mathbf{a}$ has matrix $\begin{pmatrix} R & \mathbf{a}-R\mathbf{a} \\ 0 & 1\end{pmatrix}$. Multiply in the right order.
Hint 2. A fixed point solves $(I_2-R_\theta)\mathbf{c}=\mathbf{b}$. Compute $ad-bc$ for I_2-R_θ.
Hint 3. If $\mathbf{c}=R_\theta\mathbf{c}+\mathbf{b}$, then $\mathbf{b}=\mathbf{c}-R_\theta\mathbf{c}$; substitute into f.
Sketch. (a) $\begin{pmatrix}0&-1&1\\1&0&-1\\0&0&1\end{pmatrix}\begin{pmatrix}0&-1&0\\1&0&0\\0&0&1\end{pmatrix}=\begin{pmatrix}-1&0&1\\0&-1&-1\\0&0&1\end{pmatrix}$, the map $\mathbf{v}\mapsto-\mathbf{v}+(1,-1)$, with fixed point $\left(\frac{1}{2},-\frac{1}{2}\right)$; it is $\mathbf{v}\mapsto\mathbf{c}-(\mathbf{v}-\mathbf{c})$.
(b) I_2-R_θ has $ad-bc=(1-\cos\theta)^2+\sin^2\theta=2-2\cos\theta\neq 0$, so the fixed point exists and is unique, and $f(\mathbf{v})=R_\theta\mathbf{v}+\mathbf{c}-R_\theta\mathbf{c}=\mathbf{c}+R_\theta(\mathbf{v}-\mathbf{c})$.

(a) Let $R=\begin{pmatrix}0&-1\\1&0\end{pmatrix}$. The rotation about $(0,0)$ has matrix $M_1=\begin{pmatrix}R&\mathbf{0}\\0&1\end{pmatrix}$. The rotation about $\mathbf{a}=(1,0)$ is $\mathbf{v}\mapsto R\mathbf{v}+(\mathbf{a}-R\mathbf{a})$ (Example 4.7.36), with $\mathbf{a}-R\mathbf{a}=(1,0)-(0,1)=(1,-1)$. The composite applies M_1 first, so by Theorem 4.7.42(c) its matrix is

$$\begin{pmatrix}0&-1&1\\1&0&-1\\0&0&1\end{pmatrix}\begin{pmatrix}0&-1&0\\1&0&0\\0&0&1\end{pmatrix}=\begin{pmatrix}-1&0&1\\0&-1&-1\\0&0&1\end{pmatrix},$$

the map $g(\mathbf{v})=-\mathbf{v}+(1,-1)$. Its fixed points solve $2\mathbf{v}=(1,-1)$, so $\mathbf{c}=\left(\frac{1}{2},-\frac{1}{2}\right)$, and $g(\mathbf{v})=-\mathbf{v}+2\mathbf{c}=\mathbf{c}-(\mathbf{v}-\mathbf{c})$. This is the rotation by 180° about $\mathbf{c}$, since $R_\pi=-I_2$.

(b) A fixed point is a solution of $R_\theta\mathbf{c}+\mathbf{b}=\mathbf{c}$, that is, of $(I_2-R_\theta)\mathbf{c}=\mathbf{b}$, where

$$I_2-R_\theta=\begin{pmatrix}1-\cos\theta&\sin\theta\\-\sin\theta&1-\cos\theta\end{pmatrix}.$$

Here $ad-bc=(1-\cos\theta)^2+\sin^2\theta=2-2\cos\theta$, which is nonzero because $\cos\theta\neq 1$. By Proposition 2.5.28, I_2-R_θ is invertible, so the fixed point $\mathbf{c}=(I_2-R_\theta)^{-1}\mathbf{b}$ exists and is unique. Then $\mathbf{b}=\mathbf{c}-R_\theta\mathbf{c}$, and

$$f(\mathbf{v})=R_\theta\mathbf{v}+\mathbf{c}-R_\theta\mathbf{c}=\mathbf{c}+R_\theta(\mathbf{v}-\mathbf{c}),$$

the rotation by θ about $\mathbf{c}$. Part (a) is the case $\theta=\pi$, $\mathbf{b}=(1,-1)$.

Solution to Exercise 4.7.63

Uses. Proposition 4.7.3 (Direction and base points), Corollary 4.7.6 (Parallel affine subspaces are equal or disjoint), Proposition 4.1.34 (Size of a vector space over a finite field), Proposition 4.1.37 (Counting subspaces)
Techniques. Double counting (Technique 4.1.36)
Hint 1. Group the affine subspaces by their direction. How many translates does a k-dimensional subspace U have?
Hint 2. The translates of U are disjoint and cover F^n, and each has $|U| = q^k$ elements.
Sketch. Each k-dimensional affine subspace has exactly one direction, a k-dimensional subspace U. The distinct translates of U partition F^n (Corollary 4.7.6), and each has q^k elements, so there are $q^n/q^k = q^{n-k}$ of them. (b) $\mathbb{F}_3^2$ has 4 one-dimensional subspaces, so $4 \cdot 3 = 12$ lines; $\mathbb{F}_2^3$ has 7 two-dimensional subspaces, so $7 \cdot 2 = 14$ planes.

(a) By Proposition 4.7.3(a), each affine subspace has exactly one direction, so the k-dimensional affine subspaces are grouped by their directions, which are the k-dimensional subspaces U of F^n. Fix such a U. By Corollary 4.7.6, the distinct translates of U are pairwise disjoint and every vector lies in one of them. Each translate $\mathbf{v} + U$ is in bijection with U via $\mathbf{u} \mapsto \mathbf{v} + \mathbf{u}$, so it has $|U| = q^k$ elements (Proposition 4.1.34). Since $|F^n| = q^n$, there are exactly $q^n/q^k = q^{n-k}$ translates of U. Summing over U gives the claim.

(b) By Proposition 4.1.37, $\mathbb{F}_3^2$ has $(9-1)/(3-1) = 4$ one-dimensional subspaces, so it has $4 \cdot 3^{2-1} = 12$ lines. And $\mathbb{F}_2^3$ has $((8-1)(8-2))/((4-1)(4-2)) = 42/6 = 7$ two-dimensional subspaces, so it has $7 \cdot 2^{3-2} = 14$ planes.

Solution to Exercise 4.7.64

Uses. Exercise 2.1.39, Definition 4.7.35 (Affine map)
Hint 1. First extend the identity to all $t \in \mathbb{R}$. For $t > 1$, the point $\mathbf{v}$ lies on the segment from $\mathbf{u}$ to $\mathbf{w} = (1-t)\mathbf{u} + t\mathbf{v}$.
Hint 2. For $t < 0$, swap the roles of $\mathbf{u}$ and $\mathbf{v}$.
Hint 3. Now $g = f - f(\mathbf{0})$ respects all affine combinations of two points and fixes $\mathbf{0}$. Use Exercise 2.1.39(a).
Sketch. For $t > 1$, $\mathbf{v} = (1-1/t)\mathbf{u} + (1/t)\mathbf{w}$ with $1/t \in (0,1)$, so $f(\mathbf{v}) = (1-1/t)f(\mathbf{u}) + (1/t)f(\mathbf{w})$, which solves to $f(\mathbf{w}) = (1-t)f(\mathbf{u}) + tf(\mathbf{v})$. For $t < 0$, write the point as $(1-t')\mathbf{v} + t'\mathbf{u}$ with $t' = 1 - t > 1$. So $g = f - f(\mathbf{0})$ satisfies $g(a\mathbf{u} + b\mathbf{v}) = ag(\mathbf{u}) + bg(\mathbf{v})$ whenever $a + b = 1$, and $g(\mathbf{0}) = \mathbf{0}$; since $1 + 1 \neq 0$ in $\mathbb{R}$, g is linear.

We first show that the identity holds for all $t \in \mathbb{R}$. Let $t > 1$ and $\mathbf{w} = (1-t)\mathbf{u} + t\mathbf{v}$. Then

$$\left(1 - \frac{1}{t}\right)\mathbf{u} + \frac{1}{t}\mathbf{w} = \left(1 - \frac{1}{t} + \frac{1-t}{t}\right)\mathbf{u} + \mathbf{v} = \mathbf{v},$$

and $1/t \in (0,1)$, so the hypothesis gives $f(\mathbf{v}) = \left(1 - \frac{1}{t}\right)f(\mathbf{u}) + \frac{1}{t}f(\mathbf{w})$. Multiplying by t and solving,

$$f(\mathbf{w}) = tf(\mathbf{v}) - (t-1)f(\mathbf{u}) = (1-t)f(\mathbf{u}) + tf(\mathbf{v}).$$

If $t < 0$, then $(1-t)\mathbf{u} + t\mathbf{v} = (1-t')\mathbf{v} + t'\mathbf{u}$ with $t' = 1 - t > 1$, and the case just proved, with $\mathbf{u}$ and $\mathbf{v}$ exchanged, gives $f((1-t')\mathbf{v} + t'\mathbf{u}) = (1-t')f(\mathbf{v}) + t'f(\mathbf{u}) = (1-t)f(\mathbf{u}) + tf(\mathbf{v})$.

Now let $g(\mathbf{x}) = f(\mathbf{x}) - f(\mathbf{0})$. Then $g(\mathbf{0}) = \mathbf{0}$, and for $a + b = 1$,

$$g(a\mathbf{u} + b\mathbf{v}) = af(\mathbf{u}) + bf(\mathbf{v}) - (a+b)f(\mathbf{0}) = ag(\mathbf{u}) + bg(\mathbf{v}).$$

Since $1 + 1 \neq 0$ in $\mathbb{R}$, Exercise 2.1.39(a) shows that g is linear. Hence $f = g + f(\mathbf{0})$ is affine.

Solution to Exercise 4.7.65

Uses. Proposition 4.7.32 (Barycentric coordinates on a simplex), Theorem 4.7.22 (Characterizations of affine independence)
Hint 1. Work in barycentric coordinates (Proposition 4.7.32). A vertex $\mathbf{v}_0$ has coordinates $(1, 0, \ldots, 0)$.
Hint 2. If $\mathbf{v}_0 = (1-t)\mathbf{a} + t\mathbf{b}$, compare coordinates $i \geq 1$: a sum of two nonnegative numbers is 0.
Hint 3. If $\mathbf{p}$ is not a vertex, two of its coordinates are positive, say $t_0, t_1 > 0$. Move $\mathbf{p}$ a little in the direction $\pm(\mathbf{v}_0 - \mathbf{v}_1)$.
Sketch. If $\mathbf{v}_0 = (1-t)\mathbf{a} + t\mathbf{b}$, the barycentric coordinates satisfy $0 = (1-t)\alpha_i + t\beta_i$ for $i \geq 1$ with both terms nonnegative, so $\alpha_i = \beta_i = 0$ and $\mathbf{a} = \mathbf{b} = \mathbf{v}_0$. If $\mathbf{p}$ has $t_0, t_1 > 0$, then with $\delta = \min(t_0, t_1)$, the points $\mathbf{p} \pm \delta(\mathbf{v}_0 - \mathbf{v}_1)$ lie in the simplex, differ, and have midpoint $\mathbf{p}$.

Let σ have vertices $\mathbf{v}_0, \ldots, \mathbf{v}_k$, and write points of σ in barycentric coordinates (Proposition 4.7.32). The vertex $\mathbf{v}_j$ has coordinates $\mathbf{e}_j$, with 1 in place j and 0 elsewhere.

Vertices are extreme. Suppose $\mathbf{v}_j = (1-t)\mathbf{a} + t\mathbf{b}$ with $\mathbf{a}, \mathbf{b} \in \sigma$ and $t \in (0,1)$, and let $\mathbf{a}, \mathbf{b}$ have barycentric coordinates (α_i) and (β_i). Then $\sum_i ((1-t)\alpha_i + t\beta_i)\mathbf{v}_i$ is an affine combination representing $\mathbf{v}_j$, so by unique-

ness (Theorem 4.7.22(IV)), $(1-t)\alpha_i + t\beta_i = 0$ for $i \neq j$. Both terms are nonnegative and $1-t, t > 0$, so $\alpha_i = \beta_i = 0$ for $i \neq j$, and then $\alpha_j = \beta_j = 1$. Hence $\mathbf{a} = \mathbf{b} = \mathbf{v}_j$.

Other points are not extreme. Let $\mathbf{p} \in \sigma$ have coordinates (t_i) and not be a vertex. The t_i are nonnegative and add up to 1, and they are not a standard basis vector, so at least two of them are positive, say $t_r, t_s > 0$ with $r \neq s$. Let $\delta = \min(t_r, t_s) > 0$, and $\mathbf{a} = \mathbf{p} + \delta(\mathbf{v}_r - \mathbf{v}_s)$, $\mathbf{b} = \mathbf{p} - \delta(\mathbf{v}_r - \mathbf{v}_s)$. Their coordinates are those of $\mathbf{p}$ with t_r, t_s replaced by $t_r + \delta, t_s - \delta$ and by $t_r - \delta, t_s + \delta$; these are nonnegative and add up to 1, so $\mathbf{a}, \mathbf{b} \in \sigma$. They differ, since $\mathbf{v}_r \neq \mathbf{v}_s$, and $\mathbf{p} = \frac{1}{2}\mathbf{a} + \frac{1}{2}\mathbf{b}$. So $\mathbf{p}$ is not extreme.

The extreme points are defined in terms of the set σ alone, so σ determines its vertex set. In particular, a k-simplex is not a k'-simplex for $k' \neq k$.

Section 4.8

Solution to Exercise 4.8.4

Uses. Proposition 2.4.36 (Products of upper triangular matrices), Lemma 2.4.24 (Matrix units), Theorem 4.1.10 (Independent lists are short), Theorem 4.3.3 (Rank of a product), Proposition 4.2.26 (Subspaces that must meet), Exercise 4.3.30, Proposition 4.5.27 (Similarity invariants), Proposition 2.4.27 (The trace is linear)
Techniques. Too many vectors force a dependence (Technique 4.1.30), Dimension counting (Technique 4.2.24), Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. (a) In which subspace of $F^{2\times 2}$ do the powers of A lie, and what is its dimension? (b) Compare ranks. (c) Use Proposition 4.2.26.
Hint 2. (d) Iterate Sylvester's inequality. (e) Traces differ by 2. What happens when $2 = 0$?
Sketch. (a) True: I_2, A, A^2, A^3 lie in the 3-dimensional space of upper triangular matrices (Technique 4.1.30). (b) False: $\operatorname{rank}(BA) \leq \operatorname{rank} A \leq 2$. (c) True: $\dim(U \cap W) \geq 4 + 4 - 7 = 1$. (d) True: $0 = \operatorname{rank} T^3 \geq 3 \operatorname{rank} T - 10$; the bound is attained by a shift of size 3 next to one of size 2. (e) True exactly when $1 + 1 \neq 0$ in F: then $\operatorname{tr}(A + I_2) = \operatorname{tr} A + 2 \neq \operatorname{tr} A$. When $1 + 1 = 0$, $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ are similar.

(a) True. The upper triangular matrices form a subspace of $F^{2\times 2}$ of dimension 3, with basis the matrix units U_{11}, U_{12}, U_{22} (Lemma 2.4.24), and products of upper triangular matrices are upper triangular (Proposition 2.4.36). So I_2, A, A^2, A^3 are four vectors in a 3-dimensional space, and they are dependent (Theorem 4.1.10(a)). The move is Technique 4.1.30 in the smallest space available; in all of $F^{2\times 2}$ it would only give a relation among $I_2, A, \ldots, A^4$.

(b) False. By Theorem 4.3.3, $\operatorname{rank}(BA) \leq \operatorname{rank} A \leq 2$, while $\operatorname{rank} I_3 = 3$.

(c) True. By Proposition 4.2.26, $\dim(U \cap W) \geq 4 + 4 - 7 = 1$.

(d) True. Let A be the standard matrix of T, so $A^3 = 0$. By Exercise 4.3.30(c) with $A_1 = A_2 = A_3 = A$,

$$0 = \operatorname{rank} A^3 \geq 3 \operatorname{rank} A - 2 \cdot 5,$$

so $\operatorname{rank} A \leq 10/3$, and $\operatorname{rank} A \leq 3$. The bound is attained: the operator that sends $\mathbf{e}_3 \mapsto \mathbf{e}_2 \mapsto \mathbf{e}_1 \mapsto \mathbf{0}$ and $\mathbf{e}_5 \mapsto \mathbf{e}_4 \mapsto \mathbf{0}$ has rank 3 and cube 0.

(e) True exactly when $1 + 1 \neq 0$ in F, as over $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{F}_p$ for odd p. Similar matrices have the same trace (Proposition 4.5.27(b)), and $\operatorname{tr}(A + I_2) = \operatorname{tr} A + 2$ (Proposition 2.4.27). If $2 \neq 0$, the traces differ, so $A \not\sim A + I_2$. If $2 = 0$, as over $\mathbb{F}_2$, the traces agree, and for $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ we get $A + I_2 = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, which is $S^{-1}AS$ for the swap $S = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) = S^{-1}$. The move, comparing an invariant, can only prove that two matrices are not similar; to prove similarity, a matrix S has to be found (Technique 4.5.29).

Solution to Exercise 4.8.5

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Proposition 1.5.15 (Short lists, zeros, and repeats), Theorem 4.1.10 (Independent lists are short)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Why should $T^{k+1}\mathbf{v}$ be $\mathbf{0}$?

Hint 2. Try $T = \mathrm{id}_V$.
Sketch. The step "$T^{k+j}\mathbf{v} = \mathbf{0}$ for $j \geq 1$" needs $T^{k+1}\mathbf{v} = \mathbf{0}$, which is not assumed. For $T = \mathrm{id}_V$, $\mathbf{v} \neq \mathbf{0}$, and $k = 1$, the list $\mathbf{v}, \mathbf{v}$ is dependent. With the missing hypothesis the argument is the proof of Proposition 4.1.26.

The error. The argument uses $T^{k+j}\mathbf{v} = \mathbf{0}$ for $j \geq 1$, which follows from $T^{k+1}\mathbf{v} = \mathbf{0}$ but not from anything in the hypotheses. Only $T^k\mathbf{v} \neq \mathbf{0}$ is assumed, and that says nothing about later powers.

The claim is false. Let $T = \mathrm{id}_V$ and $\mathbf{v} \neq \mathbf{0}$, and $k = 1$. Then $T\mathbf{v} = \mathbf{v} \neq \mathbf{0}$, but the list $\mathbf{v}, T\mathbf{v} = \mathbf{v}, \mathbf{v}$ has a repeated vector and is dependent (Proposition 1.5.15). A less trivial example is the rotation $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ on $\mathbb{R}^2$, with $\mathbf{v} = \mathbf{e}_1$ and $k = 2$: $R^2\mathbf{e}_1 = -\mathbf{e}_1 \neq \mathbf{0}$, and $\mathbf{e}_1, \mathbf{e}_2, -\mathbf{e}_1$ is dependent. In fact, whenever $k \geq \dim V$, the list has more than $\dim V$ entries and is dependent (Theorem 4.1.10(a)), whatever T is.

With the hypothesis $T^{k+1}\mathbf{v} = \mathbf{0}$ added, every step of the argument is correct, and it is the proof of Proposition 4.1.26.

Solution to Exercise 4.8.6

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Example 2.6.4 (Injective, surjective, both, neither), Exercise 4.5.54, Corollary 4.2.18 (Injective if and only if surjective)
Techniques. Dimension counting (Technique 4.2.24), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Which results does the argument use, and what are their hypotheses?
Hint 2. Look at multiplication by x on $F[x]$.
Sketch. Rank–nullity and Proposition 4.1.21(b) assume V finite-dimensional; for infinite-dimensional V the equation $\dim \operatorname{im} T = \dim V - 0$ has no meaning as a computation with numbers. Multiplication by x on $F[x]$ is injective, and 1 is not in its image. For finite-dimensional V the argument is correct (Corollary 4.2.18).

The error. Both steps need V to be finite-dimensional. Rank–nullity (Theorem 4.2.11(b)) is stated for finite-dimensional domains, and "a subspace of the same dimension is everything" (Proposition 4.1.21(b)) is stated for finite-dimensional V. If V is infinite-dimensional, "$\dim V$" is not a number, and subtracting $\dim \ker T = 0$ from it carries no information. Even the conclusion that $\operatorname{im} T$ and V are isomorphic, which is true for an injective T, does not make them equal: $F[x]$ is isomorphic to its proper subspace $xF[x]$ (Exercise 4.5.54).

The claim is false. Let $M \in \mathrm{L}(F[x])$ be multiplication by x. If $xp = \mathbf{0}$, then $p = \mathbf{0}$, so M is injective. Every value xp has constant coefficient 0, so the constant polynomial 1 is not a value, and M is not surjective (Example 2.6.4).

For finite-dimensional V the argument is correct, and it is the proof of Corollary 4.2.18.

Solution to Exercise 4.8.7

Uses. Exercise 4.2.44, Proposition 4.2.26 (Subspaces that must meet), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.2.11 (Rank–nullity), Proposition 4.2.3 (Properties of restriction), Proposition 2.6.18 (The column space is spanned by the columns), Proposition 4.4.2 (Sums are the smallest containing subspaces), Theorem 4.3.8 (Row rank equals column rank), Proposition 1.5.14 (Appending a vector)
Techniques. Restrict to a subspace (Technique 4.2.5), Dimension counting (Technique 4.2.24)
Hint 1. (a) $\operatorname{rank}(T\restriction_H) = \dim H - \dim(H \cap \ker T)$. How small can $H \cap \ker T$ be inside $\ker T$?
Hint 2. (b) $A'\mathbf{x}' = A\mathbf{x}$, where $\mathbf{x}$ is $\mathbf{x}'$ with a 0 inserted in position j. So A' is T_A restricted to the hyperplane $x_j = 0$. Directly: $\operatorname{im} A = \operatorname{im} A' + \operatorname{span}(\mathbf{a}_j)$.
Sketch. (a) $\operatorname{rank}(T\restriction_H) = (n-1) - \dim(H \cap \ker T)$, and $\dim \ker T - 1 \leq \dim(H \cap \ker T) \leq \dim \ker T$ by Proposition 4.2.26; the upper value is attained exactly when $\ker T \subseteq H$. (b) $\operatorname{im} A' = \operatorname{im}\left(T_A\restriction_{H_j}\right)$ with $H_j = \{\mathbf{x} \mid x_j = 0\}$, and $\ker A \subseteq H_j$ means no solution of $A\mathbf{x} = \mathbf{0}$ has $x_j \neq 0$, which means that $\mathbf{a}_j$ is not a combination of the others. Directly, $\operatorname{im} A = \operatorname{im} A' + \operatorname{span}(\mathbf{a}_j)$. (c) One column at a time, and rows by transposing.

(a) By Exercise 4.2.44(a), $\operatorname{rank}(T\restriction_H) = (n-1) - \dim(H \cap \ker T)$. Since $H \cap \ker T \subseteq \ker T$, its dimension is at most $\dim \ker T$, with equality if and only if $H \cap \ker T = \ker T$, that is, $\ker T \subseteq H$ (Proposition 4.1.21). By Proposition 4.2.26, $\dim(H \cap \ker T) \geq (n-1) + \dim \ker T - n = \dim \ker T - 1$. So $\dim(H \cap \ker T)$ is $\dim \ker T$ or $\dim \ker T - 1$, and with $\operatorname{rank} T = n - \dim \ker T$ (Theorem 4.2.11(b)),

$$\operatorname{rank}(T{\restriction_H}) = \begin{cases} \operatorname{rank} T - 1 & \text{if } \ker T \subseteq H \\ \operatorname{rank} T & \text{otherwise.} \end{cases}$$

(b) *From (a).* Let $H_j = \{\mathbf{x} \in F^n \mid x_j = 0\}$, a subspace of dimension $n-1$. For $\mathbf{x}' \in F^{n-1}$, let $\mathbf{x} \in H_j$ be $\mathbf{x}'$ with a 0 inserted in position j; this is a bijection $F^{n-1} \to H_j$, and $A'\mathbf{x}' = A\mathbf{x}$. So $\operatorname{im} A' = \operatorname{im}\left(T_A{\restriction_{H_j}}\right)$, and by (a) the rank drops if and only if $\ker A \subseteq H_j$, that is, if and only if every solution of $A\mathbf{x} = \mathbf{0}$ has $x_j = 0$. If $\mathbf{a}_j = \sum_{i \neq j} c_i \mathbf{a}_i$, then $\mathbf{x} = \mathbf{e}_j - \sum_{i \neq j} c_i \mathbf{e}_i$ solves $A\mathbf{x} = \mathbf{0}$ with $x_j = 1$. Conversely, if $A\mathbf{x} = \mathbf{0}$ with $x_j \neq 0$, then $\mathbf{a}_j = -x_j^{-1} \sum_{i \neq j} x_i \mathbf{a}_i$. So $\ker A \subseteq H_j$ exactly when $\mathbf{a}_j$ is not a combination of the other columns.

Directly. By Proposition 2.6.18, $\operatorname{im} A'$ is spanned by the columns other than $\mathbf{a}_j$, and $\operatorname{im} A = \operatorname{im} A' + \operatorname{span}(\mathbf{a}_j)$ (Proposition 4.4.2). If $\mathbf{a}_j \in \operatorname{im} A'$, the two images are equal. Otherwise a basis of $\operatorname{im} A'$ followed by $\mathbf{a}_j$ is independent (Proposition 1.5.14) and spans $\operatorname{im} A$, so $\operatorname{rank} A = \operatorname{rank} A' + 1$. The direct proof is shorter here, because deleting a column has an obvious effect on the column space; the restriction proof is the one that also applies to an arbitrary hyperplane, where there are no columns to delete.

(c) By (b), deleting one column lowers the rank by at most 1. Deleting a row of A deletes a column of A^{T}, and $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$ (Theorem 4.3.8), so it also lowers the rank by at most 1. Deleting k rows and l columns one at a time, each time from a matrix with at least two rows or two columns respectively, lowers the rank by at most $k + l$.

Solution to Exercise 4.8.8

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Proposition 1.5.15 (Short lists, zeros, and repeats), Proposition 1.2.35 (Zero products), Proposition 4.1.34 (Size of a vector space over a finite field)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Dimension counting (Technique 4.2.24)
Hint 1. Compute $T^k\mathbf{w}$ and $T^{k+1}\mathbf{w}$. Only one term of $\mathbf{w}$ survives T^k.
Hint 2. If $a_0 \neq 0$, the chain of $\mathbf{w}$ is independent by Proposition 4.1.26, and it has the right length. If $a_0 = 0$, what is $T^k\mathbf{w}$?
Sketch. (a) $T^j\mathbf{w} \in W$, $T^k\mathbf{w} = a_0 T^k\mathbf{v}$, and $T^{k+1}\mathbf{w} = \mathbf{0}$. If $a_0 \neq 0$, the chain of $\mathbf{w}$ is independent of length $k+1 = \dim W$, so it is a basis. If $a_0 = 0$, its last vector is $\mathbf{0}$. (b) The coordinates $(a_0, \ldots, a_k)$ of $\mathbf{w}$ are unique, with $a_0 \neq 0$: $(q-1)q^k$ vectors.

(a) By Proposition 4.1.26, $\mathbf{v}, \ldots, T^k\mathbf{v}$ is a basis of W, so $\dim W = k+1$. For $j \geq 0$,

$$T^j\mathbf{w} = \sum_{i=0}^{k} a_i T^{i+j}\mathbf{v} \in W,$$

and since $T^l\mathbf{v} = \mathbf{0}$ for $l \geq k+1$, only the terms with $i + j \leq k$ survive. In particular $T^k\mathbf{w} = a_0 T^k\mathbf{v}$ and $T^{k+1}\mathbf{w} = \mathbf{0}$.

If $a_0 \neq 0$, then $T^k\mathbf{w} \neq \mathbf{0}$ (Proposition 1.2.35), so $\mathbf{w}, T\mathbf{w}, \ldots, T^k\mathbf{w}$ is independent by Proposition 4.1.26. It is a list of $k+1 = \dim W$ vectors in W, so it is a basis of W (Theorem 4.1.10(b)). If $a_0 = 0$, then $T^k\mathbf{w} = \mathbf{0}$ is an entry of the list, which is therefore dependent (Proposition 1.5.15) and not a basis.

(b) If $\operatorname{span}\left(\mathbf{w}, \ldots, T^k\mathbf{w}\right) = W$, then this spanning list of length $\dim W$ is a basis (Corollary 4.1.11(b)), so by (a) the condition is again $a_0 \neq 0$. The vectors of W correspond bijectively to their coordinate vectors $(a_0, \ldots, a_k) \in F^{k+1}$, and those with $a_0 \neq 0$ number $(q-1)q^k$. So exactly $(q-1)q^k$ of the q^{k+1} vectors of W (Proposition 4.1.34) generate it, that is, all except those in the hyperplane $\operatorname{span}\left(T\mathbf{v}, \ldots, T^k\mathbf{v}\right) = \operatorname{im}(T{\restriction_W})$.

Solution to Exercise 4.8.9

Uses. Theorem 4.1.10 (Independent lists are short), Proposition 2.4.14 (Algebra of matrices), Corollary 4.2.18 (Injective if and only if surjective), Theorem 3.5.23 (One-sided inverses of square matrices), Proposition 2.4.36 (Products of upper triangular matrices), Exercise 4.1.56
Techniques. Too many vectors force a dependence (Technique 4.1.30), Dimension counting (Technique 4.2.24)
Hint 1. (a) The $d+1$ matrices $I_n, A, \ldots, A^d$ lie in S. In a relation among them, look at the smallest index with a nonzero coefficient, and multiply by a power of A^{-1}.
Hint 2. (b) $X \mapsto AX$ maps S into S and is injective. Which $X \in S$ does surjectivity produce?

Sketch. (a) $\sum_{i\geq j} c_i A^i = 0$ with $c_j \neq 0$; multiplying by A^{-j} gives $c_j I_n = -A\big(c_{j+1}I_n + \cdots + c_d A^{d-j-1}\big)$, so A^{-1} is a polynomial in A, hence in S. (b) $L(X) = AX$ is injective on S, hence surjective, so $AX = I_n$ for some $X \in S$, and $X = A^{-1}$. (c) Upper triangular matrices form such an S.

By induction, $A^i \in S$ for every $i \geq 0$: $A^0 = I_n \in S$, and $A^{i+1} = A^i A$ is a product of two elements of S.

(a) The $d+1$ matrices $I_n, A, \ldots, A^d$ lie in the d-dimensional space S, so they satisfy a relation $\sum_{i=0}^{d} c_i A^i = 0$ with not all $c_i = 0$ (Theorem 4.1.10(a)). Let j be the smallest index with $c_j \neq 0$. Multiplying $\sum_{i=j}^{d} c_i A^i = 0$ by $\big(A^{-1}\big)^j$ gives

$$c_j I_n + c_{j+1} A + \cdots + c_d A^{d-j} = 0.$$

If $j = d$ this says $c_d I_n = 0$, which is impossible since $n \geq 1$. So $j < d$, and

$$A\big(c_{j+1}I_n + c_{j+2}A + \cdots + c_d A^{d-j-1}\big) = -c_j I_n.$$

The matrix $B = -c_j^{-1}\big(c_{j+1}I_n + \cdots + c_d A^{d-j-1}\big)$ lies in S and satisfies $AB = I_n$, so $B = A^{-1}$ (multiply by A^{-1} on the left). This is the argument of Exercise 4.1.56, run inside S.

(b) Let $L : S \to S$, $L(X) = AX$. It maps S into S by hypothesis, and it is linear by Proposition 2.4.14. It is injective: if $AX = 0$, then $X = A^{-1}AX = 0$. Since S is finite-dimensional, L is surjective (Corollary 4.2.18), so $AX = I_n$ for some $X \in S$, and then $X = A^{-1}$ (Theorem 3.5.23).

The second proof is shorter and gives no formula; the first expresses A^{-1} as a polynomial in A of degree less than $\dim S$, and so shows that A^{-1} lies in every such S that contains A.

(c) The upper triangular matrices form a subspace of $F^{n\times n}$ that contains I_n and is closed under products (Proposition 2.4.36). By (a) or (b), it contains the inverse of each of its invertible elements.

Solution to Exercise 4.8.10

Uses. Proposition 4.3.5 (Rank of a product, exactly), Theorem 4.2.11 (Rank–nullity), Proposition 4.1.21 (Dimensions of subspaces), Proposition 2.6.15 (Kernels and images of composites)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. Write both sides with (4.3.1): $\operatorname{rank}(AB) = \operatorname{rank} B - \dim(\operatorname{im} B \cap \ker A)$ and $\operatorname{rank} A + \operatorname{rank} B - n = \operatorname{rank} B - \dim \ker A$.
Hint 2. When does a subspace of $\ker A$ have the dimension of $\ker A$?
Sketch. (a) The difference of the two sides is $\dim \ker A - \dim(\operatorname{im} B \cap \ker A)$, which is 0 exactly when $\operatorname{im} B \cap \ker A = \ker A$. (b) $AB = 0$ means $\operatorname{im} B \subseteq \ker A$, so $\operatorname{rank} B \leq n - \operatorname{rank} A$, with equality exactly when the containment is an equality. (c) (a) with $A = B = N$; for the shift with $n \geq 2$, $\ker N = \operatorname{span}(\mathbf{e}_1) \subseteq \operatorname{im} N$ and $\operatorname{rank} N^2 = n - 2$.

(a) By (4.3.1) and Theorem 4.2.11(a),

$$\operatorname{rank}(AB) - (\operatorname{rank} A + \operatorname{rank} B - n) = \dim \ker A - \dim(\operatorname{im} B \cap \ker A).$$

Since $\operatorname{im} B \cap \ker A \subseteq \ker A$, this is 0 if and only if $\operatorname{im} B \cap \ker A = \ker A$ (Proposition 4.1.21(b)), that is, if and only if $\ker A \subseteq \operatorname{im} B$.

(b) $AB = 0$ means $A(B\mathbf{x}) = \mathbf{0}$ for all $\mathbf{x}$, that is, $\operatorname{im} B \subseteq \ker A$. So $\operatorname{rank} B \leq \dim \ker A = n - \operatorname{rank} A$, with equality if and only if $\operatorname{im} B = \ker A$ (Proposition 4.1.21(b)). (This also follows from (a), since $\operatorname{rank}(AB) = 0$.)

(c) Take $A = B = N$ in (a). For the shift, $\ker N = \operatorname{span}(\mathbf{e}_1)$ and $\operatorname{im} N = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{n-1})$, so $\ker N \subseteq \operatorname{im} N$ when $n \geq 2$. Indeed N^2 sends $\mathbf{e}_j$ to $\mathbf{e}_{j-2}$ for $j \geq 3$ and kills $\mathbf{e}_1, \mathbf{e}_2$, so $\operatorname{rank} N^2 = n - 2 = 2(n-1) - n$. For $n = 1$ the shift is 0, and $\ker N = F^1$ is not contained in $\operatorname{im} N = \{\mathbf{0}\}$; indeed $\operatorname{rank} N^2 = 0 \neq 2 \cdot 0 - 1$.

Solution to Exercise 4.8.11

Uses. Theorem 4.4.19 (Dimension of a sum), Theorem 4.2.11 (Rank–nullity), Proposition 4.2.3 (Properties of restriction), Example 4.8.3 (Sylvester's inequality, three ways)
Techniques. Restrict to a subspace (Technique 4.2.5), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Does $A(B\mathbf{x}) = \mathbf{0}$ say anything about $A\mathbf{x}$?
Hint 2. Try $A = B = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. For the repair, restrict T_B to $\ker(AB)$.

Sketch. "A kills $B\mathbf{x}$" is not "A kills $\mathbf{x}$", and $\ker(AB) \subseteq \ker A + \ker B$ is false: for $A = B = N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $\ker N^2 = F^2$ but $\ker N + \ker N = \operatorname{span}(\mathbf{e}_1)$. The claim is true (Sylvester): T_B maps $\ker(AB)$ into $\ker A$ with kernel $\ker B$, so $\dim \ker(AB) \leq \dim \ker B + \dim \ker A$.

The error. From $A(B\mathbf{x}) = \mathbf{0}$ we learn that $B\mathbf{x} \in \ker A$, which says nothing about $A\mathbf{x}$. The step treats $AB\mathbf{x} = \mathbf{0}$ like a product of numbers that vanishes only if a factor does. The resulting containment $\ker(AB) \subseteq \ker A + \ker B$ is false. For $A = B = N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, we have $N^2 = 0$, so $\ker(AB) = F^2$, while $\ker N + \ker N = \operatorname{span}(\mathbf{e}_1)$.

The claim is true. It is Sylvester's inequality for square matrices. A repair is the kernel proof of Example 4.8.3. The vector $B\mathbf{x}$ lies in $\ker A$ for every $\mathbf{x} \in \ker(AB)$, so T_B restricts to a linear map $R : \ker(AB) \to \ker A$ (Proposition 4.2.3), and $\ker R = \ker(AB) \cap \ker B = \ker B$. Rank–nullity for R gives

$$\dim \ker(AB) = \dim \ker B + \dim \operatorname{im} R \leq \dim \ker B + \dim \ker A.$$

The repaired argument uses B to move $\ker(AB)$ into $\ker A$, where the false argument tried to place $\ker(AB)$ inside $\ker A + \ker B$ directly. In the example, R is N restricted to F^2, which maps F^2 onto $\ker N$ with kernel $\ker N$, and the inequality $2 \leq 1 + 1$ is an equality.

Solution to Exercise 4.8.12

Uses. Theorem 3.5.27 (Rank normal form), Theorem 2.4.34 (Block multiplication), Corollary 2.6.31 (Fibers are translates of the kernel), Proposition 4.5.5 (Isomorphisms preserve linear structure), Proposition 4.1.34 (Size of a vector space over a finite field)
Techniques. Choose a convenient basis (Technique 4.5.33), Transport along an isomorphism (Technique 4.5.7)
Hint 1. The condition $AXA = A$ survives $A \mapsto GAH$: if $A = G'NH'$ with G', H' invertible, substitute and set $Y = H'XG'$.
Hint 2. For $N = \left(\begin{smallmatrix} I_r & 0 \\ 0 & 0 \end{smallmatrix}\right) \in F^{m\times n}$ and $Y \in F^{n\times m}$ in blocks, $NYN = \left(\begin{smallmatrix} Y_{11} & 0 \\ 0 & 0 \end{smallmatrix}\right)$.
Sketch. By Theorem 3.5.27, $A = G'NH'$ with $G' = G^{-1}$ and $H' = H^{-1}$ invertible. Then $AXA = G'(NYN)H'$ with $Y = H'XG'$, and $X \mapsto H'XG'$ is an isomorphism of $F^{n\times m}$. $NYN = \left(\begin{smallmatrix} Y_{11} & 0 \\ 0 & 0 \end{smallmatrix}\right)$, so K corresponds to $Y_{11} = 0$, of dimension $nm - r^2$, and $X_0 = H'^{-1}N^{\mathsf{T}}G'^{-1}$ solves $AXA = A$. Over $\mathbb{F}_q$: q^{mn-r^2}. (c) $AXA = sA$ with s the sum of the entries of X, so Σ_A is the set of X whose entries add up to 1.

(a) By Theorem 3.5.27 there are invertible G and H with $GAH = N$, where $N = \left(\begin{smallmatrix} I_r & 0 \\ 0 & 0 \end{smallmatrix}\right) \in F^{m\times n}$. Let $G' = G^{-1}$ and $H' = H^{-1}$, so $A = G'NH'$. For $X \in F^{n\times m}$, put $Y = H'XG' \in F^{n\times m}$. Then

$$AXA = G'NH'XG'NH' = G'(NYN)H'.$$

Since G' and H' are invertible, $AXA = 0$ if and only if $NYN = 0$, and $AXA = A$ if and only if $NYN = N$. Write $Y = \left(\begin{smallmatrix} Y_{11} & Y_{12} \\ Y_{21} & Y_{22} \end{smallmatrix}\right)$ with $Y_{11} \in F^{r\times r}$. By Theorem 2.4.34,

$$NYN = \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} Y_{11} & Y_{12} \\ Y_{21} & Y_{22} \end{pmatrix}\begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} Y_{11} & 0 \\ 0 & 0 \end{pmatrix}.$$

So $NYN = 0$ exactly when $Y_{11} = 0$, and $NYN = N$ exactly when $Y_{11} = I_r$. The map $\Phi(X) = H'XG'$ is linear and invertible on $F^{n\times m}$, with inverse $Y \mapsto HYG$. It carries K onto $K_0 = \{Y \mid Y_{11} = 0\}$, the matrices whose top left $r \times r$ block is zero, a subspace of dimension $nm - r^2$. By Proposition 4.5.5, K is a subspace and $\dim K = mn - r^2$.

The matrix $Y_0 = N^{\mathsf{T}} \in F^{n\times m}$ has $Y_{11} = I_r$, so $X_0 = \Phi^{-1}(Y_0) = HN^{\mathsf{T}}G$ lies in Σ_A. Finally, Σ_A is the set of solutions of $\Psi(X) = A$ for the linear map $\Psi(X) = AXA$, so it is $X_0 + \ker \Psi = X_0 + K$ for any solution X_0 (Corollary 2.6.31).

(b) $X \mapsto X - X_0$ is a bijection from Σ_A onto K, which has q^{mn-r^2} elements (Proposition 4.1.34). So there are q^{mn-r^2} solutions. For an invertible $A \in F^{n\times n}$, this is $q^0 = 1$: the only solution is A^{-1}.

(c) Here $A = \mathbf{1}\mathbf{1}^{\mathsf{T}}$ with $\mathbf{1} = (1, 1)$, so $AXA = \mathbf{1}\big(\mathbf{1}^{\mathsf{T}}X\mathbf{1}\big)\mathbf{1}^{\mathsf{T}} = sA$, where $s = \mathbf{1}^{\mathsf{T}}X\mathbf{1}$ is the sum of the four entries of X. So $AXA = A$ if and only if the entries of X add up to 1. This is a translate of the 3-dimensional subspace of matrices whose entries add up to 0, in agreement with $mn - r^2 = 4 - 1$.

Solution to Exercise 4.8.13

Uses. Theorem 2.4.34 (Block multiplication), Proposition 4.3.1 (Invertible factors preserve rank), Lemma 4.8.2 (Ranks of block triangular matrices), Example 4.8.3 (Sylvester's inequality, three ways), Exercise 4.3.31
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. The left factor subtracts A times the second block row from the first, and the right factor subtracts the first block column times C from the second.
Hint 2. The result is $\left(\begin{smallmatrix} 0 & -ABC \\ B & 0 \end{smallmatrix}\right)$. Compare its rank with that of M, using Lemma 4.8.2.
Sketch. (a) $\left(\begin{smallmatrix} 0 & -ABC \\ B & 0 \end{smallmatrix}\right)$. (b) The outer factors are invertible, so $\operatorname{rank} M = \operatorname{rank} B + \operatorname{rank}(ABC)$ (swap the block columns and use the block diagonal case of the lemma), while $\operatorname{rank} M \geq \operatorname{rank}(AB) + \operatorname{rank}(BC)$ by the lower triangular case. (c) $B = I_n$.

(a) By Theorem 2.4.34,

$$\begin{pmatrix} I_m & -A \\ 0 & I_n \end{pmatrix}\begin{pmatrix} AB & 0 \\ B & BC \end{pmatrix} = \begin{pmatrix} AB - AB & -ABC \\ B & BC \end{pmatrix} = \begin{pmatrix} 0 & -ABC \\ B & BC \end{pmatrix},$$

and

$$\begin{pmatrix} 0 & -ABC \\ B & BC \end{pmatrix}\begin{pmatrix} I_p & -C \\ 0 & I_q \end{pmatrix} = \begin{pmatrix} 0 & -ABC \\ B & -BC + BC \end{pmatrix} = \begin{pmatrix} 0 & -ABC \\ B & 0 \end{pmatrix}.$$

(b) The matrices $\left(\begin{smallmatrix} I_m & -A \\ 0 & I_n \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} I_p & -C \\ 0 & I_q \end{smallmatrix}\right)$ are invertible, with inverses $\left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} I_p & C \\ 0 & I_q \end{smallmatrix}\right)$, as block multiplication checks. So $\operatorname{rank} M = \operatorname{rank}\left(\begin{smallmatrix} 0 & -ABC \\ B & 0 \end{smallmatrix}\right)$ by Proposition 4.3.1. Exchanging the two block columns of the last matrix (multiplication on the right by an invertible permutation matrix) gives $\left(\begin{smallmatrix} -ABC & 0 \\ 0 & B \end{smallmatrix}\right)$, whose rank is $\operatorname{rank}(ABC) + \operatorname{rank} B$ by Lemma 4.8.2(b). On the other hand, M is block lower triangular with diagonal blocks AB and BC, so $\operatorname{rank} M \geq \operatorname{rank}(AB) + \operatorname{rank}(BC)$ by Lemma 4.8.2(a). Together,

$$\operatorname{rank}(AB) + \operatorname{rank}(BC) \leq \operatorname{rank} M = \operatorname{rank} B + \operatorname{rank}(ABC).$$

(c) Take $n = p$ and $B = I_n$, with $A \in F^{m\times n}$ and $C \in F^{n\times q}$. Then (b) reads $\operatorname{rank} A + \operatorname{rank} C \leq n + \operatorname{rank}(AC)$, which is Sylvester's inequality for the product AC, and the computation in (a) becomes the one in Example 4.8.3 (up to the order of the blocks). Exercise 4.3.31 proves the same inequality by restriction.

Solution to Exercise 4.8.14

Uses. Proposition 4.6.32 (Operators on a quotient), Proposition 4.1.26 (Nilpotent chains are independent), Corollary 4.6.15 (Cosets partition V), Theorem 4.6.27 (Dimension of a quotient), Theorem 4.1.10 (Independent lists are short), Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps)
Techniques. Pass to a quotient (Technique 4.6.31), Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Apply Proposition 4.1.26 to the induced operator T/U on V/U and the vector $\mathbf{v} + U$.
Hint 2. For (b), let k be the largest index with $T^k\mathbf{v} \notin U$, and count in V/U.
Sketch. (a) $(T/U)^j(\mathbf{v} + U) = T^j\mathbf{v} + U$, which is nonzero for $j = k$ and zero for $j = k + 1$; Proposition 4.1.26 in V/U gives independence. A combination of the $T^i\mathbf{v}$ that lies in U gives a relation among the cosets, so all coefficients vanish. (b) For $\mathbf{v}$ with $T^k\mathbf{v} \notin U$, $T^{k+1}\mathbf{v} \in U$, (a) gives $k + 1 \leq \dim V/U = d$; if $\mathbf{v} \in U$ already, every $T^j\mathbf{v} \in U$. The case $U = \{\mathbf{0}\}$ is Corollary 4.1.27.

(a) By Proposition 4.6.32(a), there is an operator T/U on V/U with $(T/U)(\mathbf{x} + U) = T\mathbf{x} + U$, and by induction on j, $(T/U)^j(\mathbf{v} + U) = T^j\mathbf{v} + U$. By Corollary 4.6.15(c), $T^k\mathbf{v} + U$ is not the zero coset, since $T^k\mathbf{v} \notin U$, and $T^{k+1}\mathbf{v} + U$ is the zero coset. By Proposition 4.1.26, applied to T/U and $\mathbf{v} + U$, the cosets $\mathbf{v} + U, \ldots, T^k\mathbf{v} + U$ are independent.

Now suppose $\mathbf{y} = \sum_{i=0}^{k} a_i T^i\mathbf{v} \in U$. Then $\sum_i a_i\left(T^i\mathbf{v} + U\right) = \mathbf{y} + U = U$, the zero of V/U, so every $a_i = 0$ and $\mathbf{y} = \mathbf{0}$. Taking $\mathbf{y} = \mathbf{0}$ shows that the list is independent, and in general this shows that its span meets U only in $\mathbf{0}$.

(b) Let $\mathbf{v} \in V$. If $\mathbf{v} \in U$, then $T^j\mathbf{v} \in U$ for every j, because T maps U into itself. Otherwise let k be the largest index with $T^k\mathbf{v} \notin U$; it exists and $k < m$, since $T^m\mathbf{v} \in U$ and, once a vector $T^j\mathbf{v}$ lies in U, so do all later ones.

By (a), V/U contains $k+1$ independent cosets, and $\dim V/U = \dim V - \dim U = d$ (Theorem 4.6.27), so $k+1 \le d$ (Theorem 4.1.10(a)). Hence $T^d\mathbf{v} = T^{d-k-1}\big(T^{k+1}\mathbf{v}\big) \in U$. So $T^d(V) \subseteq U$.

For $U = \{\mathbf{0}\}$, the hypothesis says that T is nilpotent, and the conclusion is $T^{\dim V} = 0$, which is Corollary 4.1.27. In general T is only nilpotent "modulo U", and the bound is the dimension of what is left, V/U.

Problems for Chapter 4

Solution to Problem 4.1

> *Uses.* Theorem 4.2.11 (Rank–nullity), Theorem 4.1.16 (Extending to a basis), Proposition 4.1.21 (Dimensions of subspaces), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Theorem 1.5.5 (Independence is decided at zero), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
> *Techniques.* Extend a basis of a subspace (Technique 4.1.18), Dimension counting (Technique 4.2.24)
> *Hint 1.* (b) Extend a basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of $\ker T$ to $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{w}_1, \dots, \mathbf{w}_r$, and show that $T(\mathbf{w}_1), \dots, T(\mathbf{w}_r)$ is a basis of $\operatorname{im} T$.
> *Hint 2.* (c) For spanning, write $T(\mathbf{v}) = \sum c_j T(\mathbf{v}_j)$; then $\mathbf{v} - \sum c_j \mathbf{v}_j \in \ker T$. For independence, apply T to a relation. Notice which step of (b) needed $\dim V < \infty$ and which step of (c) does not.
> *Sketch.* (b) The values $T(\mathbf{w}_j)$ span $\operatorname{im} T$ because the $\mathbf{u}_i$ are killed, and a relation $\sum b_j T(\mathbf{w}_j) = \mathbf{0}$ puts $\sum b_j \mathbf{w}_j$ in $\ker T$, so it is a combination of the $\mathbf{u}_i$, and independence of the basis forces $b = \mathbf{0}$. Count: $n = k + r$. (c) $\mathbf{v} - \sum c_j \mathbf{v}_j \in \ker T$ gives spanning; applying T to a relation kills the kernel part and leaves a relation among the basis $T(\mathbf{v}_j)$. So V has a finite basis of length $\dim \ker T + \dim \operatorname{im} T$.

(a) Let V be finite-dimensional and $T \in \mathrm{L}(V, W)$. Then $\operatorname{im} T$ is finite-dimensional, and $\dim \ker T + \dim \operatorname{im} T = \dim V$.

(b) Since $\ker T$ is a subspace of the finite-dimensional space V, it is finite-dimensional (Proposition 4.1.21(a)). Let $\mathbf{u}_1, \dots, \mathbf{u}_k$ be a basis of $\ker T$ and extend it to a basis $\mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{w}_1, \dots, \mathbf{w}_r$ of V (Theorem 4.1.16), so $\dim V = k + r$. We show that $T(\mathbf{w}_1), \dots, T(\mathbf{w}_r)$ is a basis of $\operatorname{im} T$; then $\operatorname{im} T$ is finite-dimensional with $\dim \operatorname{im} T = r = \dim V - \dim \ker T$.

Spanning. By Proposition 2.1.16, $\operatorname{im} T$ is spanned by the values of T on the basis, $\mathbf{0}, \dots, \mathbf{0}, T(\mathbf{w}_1), \dots, T(\mathbf{w}_r)$, and the zeros can be dropped.

Independence. If $\sum_j b_j T(\mathbf{w}_j) = \mathbf{0}$, then $T\big(\sum_j b_j \mathbf{w}_j\big) = \mathbf{0}$, so $\sum_j b_j \mathbf{w}_j \in \ker T$ and $\sum_j b_j \mathbf{w}_j = \sum_i a_i \mathbf{u}_i$ for some scalars a_i. The relation $\sum_i a_i \mathbf{u}_i - \sum_j b_j \mathbf{w}_j = \mathbf{0}$ among the vectors of a basis forces every $b_j = 0$ (Theorem 1.5.5).

(c) Let $\mathbf{u}_1, \dots, \mathbf{u}_k$ be a basis of $\ker T$ and $\mathbf{v}_1, \dots, \mathbf{v}_r$ as described; here V is any vector space, and we only assume that $\ker T$ and $\operatorname{im} T$ are finite-dimensional. Let $\mathcal{L} = \mathbf{u}_1, \dots, \mathbf{u}_k, \mathbf{v}_1, \dots, \mathbf{v}_r$.

$\mathcal{L}$ spans V. Let $\mathbf{v} \in V$. Then $T(\mathbf{v}) \in \operatorname{im} T$, so $T(\mathbf{v}) = \sum_j c_j T(\mathbf{v}_j)$ for some scalars c_j, and $T\big(\mathbf{v} - \sum_j c_j \mathbf{v}_j\big) = \mathbf{0}$. So $\mathbf{v} - \sum_j c_j \mathbf{v}_j \in \ker T$ is a combination of the $\mathbf{u}_i$, and $\mathbf{v}$ is a combination of $\mathcal{L}$.

$\mathcal{L}$ is independent. If $\sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{v}_j = \mathbf{0}$, apply T: the first sum is killed, and $\sum_j b_j T(\mathbf{v}_j) = \mathbf{0}$ (Proposition 2.1.4). The $T(\mathbf{v}_j)$ are independent, so every $b_j = 0$, and then $\sum_i a_i \mathbf{u}_i = \mathbf{0}$ forces every $a_i = 0$.

So $\mathcal{L}$ is a basis of V, V is finite-dimensional, and $\dim V = k + r = \dim \ker T + \dim \operatorname{im} T$, which is rank–nullity again. The proof in (b) needs $\dim V < \infty$ before it starts, to extend a basis of the kernel to a basis of V. The proof in (c) only needs finite spanning lists for the kernel and the image, and it produces one for V. Contrapositively, if V is infinite-dimensional, then $\ker T$ or $\operatorname{im} T$ is. For instance multiplication by x on $F[x]$ has kernel $\{\mathbf{0}\}$, so its image $xF[x]$ is infinite-dimensional, and differentiation over $\mathbb{Q}$ has a 1-dimensional kernel and the infinite-dimensional image $\mathbb{Q}[x]$.

Solution to Problem 4.2

> *Uses.* Theorem 4.3.8 (Row rank equals column rank), Theorem 4.3.21 (Column–row factorization), Proposition 4.3.23 (Factorizations through F^k), Proposition 2.4.23 (Transpose of a product), Theorem 4.3.3 (Rank of a product), Theorem 4.1.10 (Independent lists are short), Proposition 2.6.18 (The column space is spanned by the columns), Proposition 2.4.8 (Four views of the product), Theorem 3.5.14 (Third Fundamental Theorem, completed)
> *Techniques.* Transpose to trade rows for columns (Technique 3.2.27), Restrict to a subspace (Technique 4.2.5)

Hint 1. (b) A factorization $A = CR$ with inner size $r = \operatorname{rank} A$ transposes to $A^{\mathsf{T}} = R^{\mathsf{T}}C^{\mathsf{T}}$.
Hint 2. (c) The columns in J form a basis of $\operatorname{im} A$, so $A = CX$ where C consists of these columns. Restrict to the rows in I: $A_{I\cdot} = C_{I\cdot}X$, and $C_{I\cdot} = A_{IJ}$.
Sketch. (b) $A = CR$ with $C \in F^{m\times r}$, $R \in F^{r\times n}$ (Theorem 4.3.21), so $A^{\mathsf{T}} = R^{\mathsf{T}}C^{\mathsf{T}}$ has rank at most r; applied to A^{T}, $\operatorname{rank} A \le \operatorname{rank} A^{\mathsf{T}}$. (c) Let $C =$ the columns in J, a basis of $\operatorname{im} A$, so $A = CX$; taking the rows in I, $A_{I\cdot} = A_{IJ}X$ has rank r, so $\operatorname{rank} A_{IJ} \ge r$ and the $r \times r$ matrix A_{IJ} is invertible. Conversely an invertible $k \times k$ submatrix A_{IJ} makes the columns J of A independent, so $k \le \operatorname{rank} A$.

(a) For every $A \in F^{m\times n}$, $\operatorname{rank} A^{\mathsf{T}} = \operatorname{rank} A$: the rows of A span a subspace of F^n of the same dimension as the subspace of F^m spanned by its columns.

(b) Let $r = \operatorname{rank} A$. If $r = 0$, then $A = 0$ and $A^{\mathsf{T}} = 0$. Otherwise, by Theorem 4.3.21, $A = CR$ with $C \in F^{m\times r}$ and $R \in F^{r\times n}$. By Proposition 2.4.23, $A^{\mathsf{T}} = R^{\mathsf{T}}C^{\mathsf{T}}$ with inner size r, so $\operatorname{rank} A^{\mathsf{T}} \le r = \operatorname{rank} A$ by Proposition 4.3.23(a). Applying this to A^{T}, whose transpose is A, gives $\operatorname{rank} A \le \operatorname{rank} A^{\mathsf{T}}$.

(c) Let $C \in F^{m\times r}$ consist of the columns of A with indices in J. They are r independent vectors in the r-dimensional space $\operatorname{im} A$ (Proposition 2.6.18), so they form a basis of $\operatorname{im} A$ (Theorem 4.1.10(b)). Every column of A is therefore a combination of the columns of C, so $A = CX$ for some $X \in F^{r\times n}$ (Proposition 2.4.8). Taking the rows with indices in I on both sides, $A_{I\cdot} = C_{I\cdot}X$, where $A_{I\cdot} \in F^{r\times n}$ consists of the rows of A in I and $C_{I\cdot} = A_{IJ}$. The r rows of $A_{I\cdot}$ are independent, so $\operatorname{rank} A_{I\cdot} = r$ by (a). By Theorem 4.3.3,

$$r = \operatorname{rank}\bigl(A_{IJ}X\bigr) \le \operatorname{rank} A_{IJ} \le r,$$

so the $r \times r$ matrix A_{IJ} has rank r and is invertible (Theorem 3.5.14).

The largest invertible submatrix. By (a) there are r independent rows and r independent columns, so by what we just proved, A has an invertible $r \times r$ submatrix. Conversely, let A_{IJ} be an invertible $k \times k$ submatrix. A relation among the columns of A with indices in J gives, in the rows with indices in I, the same relation among the columns of A_{IJ}, which are independent. So the k columns of A in J are independent, and $k \le \operatorname{rank} A$.

The point of (c) is that the rows and the columns can be chosen separately: any r independent rows meet any r independent columns in an invertible submatrix. In Section 5.5 the same characterization of the rank is phrased with determinants.

Solution to Problem 4.3

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps), Theorem 1.5.5 (Independence is decided at zero), Proposition 1.2.35 (Zero products), Theorem 4.1.10 (Independent lists are short)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. (b) Apply T^k to a relation $\sum_i a_i T^i\mathbf{v} = \mathbf{0}$: only $a_0T^k\mathbf{v}$ survives. Continue with T^{k-1}, and so on. For the corollary, let k be the last index with $T^k\mathbf{v} \ne \mathbf{0}$.
Hint 2. (c) Apply T^j to $\mathbf{w} = \sum_i a_iT^i\mathbf{v}$. Which terms survive, and why are the surviving vectors independent?
Sketch. (b) After $a_0, \dots, a_{i-1}$ are known to vanish, T^{k-i} applied to the relation leaves $a_iT^k\mathbf{v} = \mathbf{0}$. For the corollary, the chain of a nonzero $\mathbf{v}$ has at most n entries, so $T^n\mathbf{v} = \mathbf{0}$. (c) $T^j\mathbf{w} = \sum_{i\le k-j} a_iT^{i+j}\mathbf{v}$, and $T^j\mathbf{v}, \dots, T^k\mathbf{v}$ are part of the independent chain, so $T^j\mathbf{w} = \mathbf{0}$ forces $a_0 = \cdots = a_{k-j} = 0$.

(a) Proposition 4.1.26: let $T \in \mathrm{L}(V)$, $\mathbf{v} \in V$, and $k \ge 0$ with $T^k\mathbf{v} \ne \mathbf{0}$ and $T^{k+1}\mathbf{v} = \mathbf{0}$. Then $\mathbf{v}, T\mathbf{v}, \dots, T^k\mathbf{v}$ is linearly independent. Corollary 4.1.27: if $\dim V = n$ and $T^m = 0$ for some $m \ge 1$, then $T^n = 0$.

(b) *The proposition.* For $l \ge k+1$, $T^l\mathbf{v} = T^{l-k-1}\bigl(T^{k+1}\mathbf{v}\bigr) = \mathbf{0}$. Let $\sum_{i=0}^{k} a_iT^i\mathbf{v} = \mathbf{0}$. We show $a_i = 0$ by induction on i. Suppose $a_0 = \cdots = a_{i-1} = 0$ (no assumption for $i = 0$). Applying T^{k-i} to $\sum_{l=i}^{k} a_lT^l\mathbf{v} = \mathbf{0}$ gives

$$a_iT^k\mathbf{v} + \sum_{l=i+1}^{k} a_lT^{k+l-i}\mathbf{v} = \mathbf{0},$$

and every exponent in the sum is at least $k+1$, so $a_iT^k\mathbf{v} = \mathbf{0}$. Since $T^k\mathbf{v} \ne \mathbf{0}$, $a_i = 0$ (Proposition 1.2.35). So the list is independent (Theorem 1.5.5).

The corollary. Let $\mathbf{v} \neq \mathbf{0}$. Since $T^m\mathbf{v} = \mathbf{0}$, there is a largest k with $T^k\mathbf{v} \neq \mathbf{0}$, and $T^{k+1}\mathbf{v} = \mathbf{0}$. By the proposition, $\mathbf{v}, \ldots, T^k\mathbf{v}$ is an independent list of length $k+1$ in V, so $k+1 \leq n$ (Theorem 4.1.10(a)), and $T^n\mathbf{v} = T^{n-k-1}\left(T^{k+1}\mathbf{v}\right) = \mathbf{0}$. Also $T^n\mathbf{0} = \mathbf{0}$. So $T^n = 0$.

(c) Fix j with $1 \leq j \leq k+1$. For $i \geq k-j+1$, $T^j\left(T^i\mathbf{v}\right) = T^{i+j}\mathbf{v} = \mathbf{0}$, since $i+j \geq k+1$. So the right side is contained in $\ker T^j \cap W$. Conversely, let $\mathbf{w} = \sum_{i=0}^{k} a_i T^i\mathbf{v} \in W$ with $T^j\mathbf{w} = \mathbf{0}$. The terms with $i+j \geq k+1$ vanish, so

$$\mathbf{0} = T^j\mathbf{w} = \sum_{i=0}^{k-j} a_i T^{i+j}\mathbf{v}.$$

The vectors $T^j\mathbf{v}, \ldots, T^k\mathbf{v}$ are entries of the independent chain, so $a_0 = \cdots = a_{k-j} = 0$, and $\mathbf{w} \in \operatorname{span}\left(T^{k-j+1}\mathbf{v}, \ldots, T^k\mathbf{v}\right)$. These j vectors are independent, being entries of the chain, so $\dim\left(\ker T^j \cap W\right) = j$.

So on W the kernels of the powers grow by exactly one dimension at each step, until $\ker T^{k+1} \cap W = W$. In particular $\ker T \cap W$ is the line spanned by the last vector $T^k\mathbf{v}$, the vector that becomes an eigenvector when the chain is shifted in Proposition 7.2.37.

Solution to Problem 4.4

Uses. Theorem 4.4.27 (Idempotents are projections), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Theorem 4.5.17 (Change of basis), Theorem 2.4.34 (Block multiplication), Theorem 4.2.11 (Rank–nullity), Proposition 4.5.5 (Isomorphisms preserve linear structure), Proposition 4.4.21 (Two out of three)
Techniques. Choose a basis adapted to a preserved subspace (Technique 4.5.36), Study a linear map on a space of matrices (Technique 4.2.29), Split the space with an idempotent (Technique 4.4.28)
Hint 1. A basis of $\operatorname{im} P$ followed by a basis of $\ker P$ gives an invertible S with $S^{-1}PS = D = \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$. The map $X \mapsto S^{-1}XS$ is an isomorphism of $F^{n\times n}$ that turns δ into $Y \mapsto DY - YD$.
Hint 2. Compute $DY - YD$ for $Y = \begin{pmatrix} Y_{11} & Y_{12} \\ Y_{21} & Y_{22} \end{pmatrix}$.
Sketch. With $D = S^{-1}PS$ and $Y = S^{-1}XS$, $\delta(X) = S(DY - YD)S^{-1}$ and $DY - YD = \begin{pmatrix} 0 & Y_{12} \\ -Y_{21} & 0 \end{pmatrix}$. So $\ker\delta$ corresponds to block diagonal Y (dimension $r^2 + (n-r)^2$) and $\operatorname{im}\delta$ to block off-diagonal Y (dimension $2r(n-r)$). DZD and $(I-D)Z(I-D)$ pick out the diagonal blocks, so they vanish exactly on the off-diagonal matrices, and the conditions transport. Block diagonal plus block off-diagonal is a direct sum, and the diagonal part of Y is $DYD + (I-D)Y(I-D)$.

If $r = 0$ or $r = n$, then $P = 0$ or $P = I_n$ (an idempotent of full rank is invertible, and $P^2 = P$ then gives $P = I_n$), so $\delta = 0$, and all three statements hold with $\ker\delta = F^{n\times n}$ and $\operatorname{im}\delta = \{0\}$. So let $1 \leq r \leq n-1$. By Theorem 4.4.27, $F^n = \operatorname{im} P \oplus \ker P$, and P fixes $\operatorname{im} P$ pointwise and kills $\ker P$. Let $S \in F^{n\times n}$ have as columns a basis of $\operatorname{im} P$ followed by a basis of $\ker P$; together they form a basis of F^n (Theorem 4.4.13), so S is invertible. In this basis T_P has the matrix $D = \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$, so $S^{-1}PS = D$ (Theorem 4.5.17). For $X \in F^{n\times n}$ write $Y = S^{-1}XS$. Then

$$S^{-1}\delta(X)S = S^{-1}PS\,S^{-1}XS - S^{-1}XS\,S^{-1}PS = DY - YD.$$

The map $X \mapsto S^{-1}XS$ is linear and invertible, with inverse $Y \mapsto SYS^{-1}$, so it carries $\ker\delta$ onto $\ker\delta_D$ and $\operatorname{im}\delta$ onto $\operatorname{im}\delta_D$, where $\delta_D(Y) = DY - YD$ (Proposition 4.5.5). In blocks, with $Y_{11} \in F^{r\times r}$, Theorem 2.4.34 gives

$$DY - YD = \begin{pmatrix} Y_{11} & Y_{12} \\ 0 & 0 \end{pmatrix} - \begin{pmatrix} Y_{11} & 0 \\ Y_{21} & 0 \end{pmatrix} = \begin{pmatrix} 0 & Y_{12} \\ -Y_{21} & 0 \end{pmatrix}.$$

(a) $\delta_D(Y) = 0$ if and only if $Y_{12} = 0$ and $Y_{21} = 0$. So $\ker\delta_D$ is the space of block diagonal matrices, of dimension $r^2 + (n-r)^2$, and $\ker\delta$ has the same dimension.

(b) By rank–nullity, $\operatorname{rank}\delta = n^2 - r^2 - (n-r)^2 = 2r(n-r)$. The image of δ_D consists of the block off-diagonal matrices $\begin{pmatrix} 0 & Z_{12} \\ Z_{21} & 0 \end{pmatrix}$, since Y_{12} and $-Y_{21}$ can be anything. For $Z' = \begin{pmatrix} Z_{11} & Z_{12} \\ Z_{21} & Z_{22} \end{pmatrix}$,

$$DZ'D = \begin{pmatrix} Z_{11} & 0 \\ 0 & 0 \end{pmatrix}, \quad (I_n - D)Z'(I_n - D) = \begin{pmatrix} 0 & 0 \\ 0 & Z_{22} \end{pmatrix},$$

so $Z' \in \operatorname{im}\delta_D$ if and only if $DZ'D = 0$ and $(I_n - D)Z'(I_n - D) = 0$. For $Z = SZ'S^{-1}$, we have $PZP = S(DZ'D)S^{-1}$ and $(I_n - P)Z(I_n - P) = S((I_n - D)Z'(I_n - D))S^{-1}$, using $I_n - P = S(I_n - D)S^{-1}$. So $Z \in \operatorname{im}\delta$ if and only if $PZP = 0$ and $(I_n - P)Z(I_n - P) = 0$.

(c) By (a) and (b), $\dim\ker\delta + \dim\operatorname{im}\delta = n^2$. A matrix in both is, after conjugation by S, both block diagonal and block off-diagonal, hence 0. So $F^{n\times n} = \ker\delta \oplus \operatorname{im}\delta$ by Proposition 4.4.21. Let $X_0 = PXP + (I_n - P)X(I_n - P)$. It commutes with P: since $P^2 = P$ and $P(I_n - P) = 0 = (I_n - P)P$, both PX_0 and X_0P equal PXP. And $X - X_0 = PX(I_n - P) + (I_n - P)XP$ satisfies the two conditions of (b), because $P(X - X_0)P = 0$ and $(I_n - P)(X - X_0)(I_n - P) = 0$ by the same two identities. So $X = X_0 + (X - X_0)$ is the decomposition.

Choosing the basis made the computation a matter of reading blocks. The formula in (c) needs no basis at all, and could have been guessed from the blocks: PXP and $(I_n - P)X(I_n - P)$ are the two diagonal blocks of X seen through the decomposition $F^n = \operatorname{im}P \oplus \ker P$.

Solution to Problem 4.5

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Corollary 4.1.11 (Spanning lists are long), Proposition 1.2.18 (Degree and evaluation versus the operations), Proposition 2.1.24 (Algebra of composition), Exercise 2.1.32
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Dimension counting (Technique 4.2.24)
Hint 1. Δ lowers the degree by exactly one when the leading coefficient is multiplied by a nonzero number. Compute the degree and leading coefficient of $\Delta^k p$, and apply Proposition 4.1.26 to Δ and p.
Hint 2. $\Delta^k = (S - \mathrm{id})^k$ is a combination of $\mathrm{id}, S, \ldots, S^k$. For (c), $(x+1)^p = x^p + 1$ over $\mathbb{F}_p$.
Sketch. (a) For $\deg q = d \geq 1$ with leading coefficient c and $dc \neq 0$, Δq has degree $d-1$ and leading coefficient dc; so $\Delta^k p$ has degree $n-k$ and leading coefficient $n(n-1)\cdots(n-k+1)c \neq 0$ for $k \leq n$, and $\Delta^{n+1}p = \mathbf{0}$. By Proposition 4.1.26, $p, \Delta p, \ldots, \Delta^n p$ is a basis of $F[x]_{\leq n}$. Each $\Delta^k p = \sum_j \binom{k}{j}(-1)^{k-j}p(x+j)$ lies in the span of the translates, so they span, and $n+1$ spanning vectors form a basis. (b) $\Delta^2 x^2 = 2$, so $1 = \frac{1}{2}\left((x+2)^2 - 2(x+1)^2 + x^2\right)$. (c) $(x+j)^p = x^p + j$.

(a) All the maps involved send $F[x]_{\leq n}$ into itself, since $p(x+j)$ has the same degree as p. By the binomial theorem, for $j \geq 1$ the polynomial $\Delta(x^j) = (x+1)^j - x^j$ has degree at most $j-1$, and its coefficient of x^{j-1} is $j * 1$; and $\Delta(1) = \mathbf{0}$. Let $q = q_0 + q_1 x + \cdots + q_d x^d$ with $d \geq 1$ and $c = q_d \neq 0$. By linearity, $\Delta q = \sum_{j=0}^{d} q_j \Delta(x^j)$, and only the term $j = d$ can contribute to the coefficient of x^{d-1}, which is therefore dc. If $dc \neq 0$, then Δq has degree exactly $d-1$ and leading coefficient dc; and Δ kills constants. Let p have degree n and leading coefficient c. By induction on k, for $k \leq n$, $\Delta^k p$ has degree $n-k$ and leading coefficient $n(n-1)\cdots(n-k+1)c$. This coefficient is nonzero: its integer factors $n, n-1, \ldots, n-k+1$ are factors of $n!$, which is nonzero in F, so none of them is 0 in F, and a product of nonzero elements of a field is nonzero. In particular $\Delta^n p = n!c$ is a nonzero constant, and $\Delta^{n+1}p = \mathbf{0}$.

By Proposition 4.1.26, applied to Δ on $F[x]_{\leq n}$, the list $p, \Delta p, \ldots, \Delta^n p$ is independent. It has $n+1 = \dim F[x]_{\leq n}$ entries, so it is a basis (Theorem 4.1.10(b)). Since S commutes with id, the binomial theorem for commuting operators (which has the same proof as for numbers, using Proposition 2.1.24) gives

$$\Delta^k p = (S - \mathrm{id})^k p = \sum_{j=0}^{k} \binom{k}{j} (-1)^{k-j} S^j p = \sum_{j=0}^{k} \binom{k}{j} (-1)^{k-j} p(x+j).$$

So every $\Delta^k p$ with $k \leq n$ lies in the span of $p(x), p(x+1), \ldots, p(x+n)$, and this span is all of $F[x]_{\leq n}$. A spanning list of length $n+1 = \dim F[x]_{\leq n}$ is a basis (Corollary 4.1.11(b)).

(b) For $p = x^2$, $\Delta p = 2x+1$ and $\Delta^2 p = 2$. By the formula above, $2 = \Delta^2 p = (x+2)^2 - 2(x+1)^2 + x^2$, so

$$1 = \frac{1}{2}(x+2)^2 - (x+1)^2 + \frac{1}{2}x^2.$$

Check: $\frac{1}{2}(x^2 + 4x + 4) - (x^2 + 2x + 1) + \frac{1}{2}x^2 = 2 - 1 = 1$.

(c) Over $\mathbb{F}_p$, the binomial coefficients $\binom{p}{i}$ with $0 < i < p$ are 0, so $S(x^p) = (x+1)^p = x^p + 1$, and $S(1) = 1$. By induction on j, $S^j(x^p) = x^p + j * 1$. So the translates of x^p are the polynomials $x^p + c$ with $c \in \mathbb{F}_p$; they lie in $\operatorname{span}(x^p, 1)$ and include x^p and $x^p + 1$, so they span exactly this 2-dimensional space. For $n = p$ the factor p of $n!$ is 0 in $\mathbb{F}_p$, the chain $x^p, \Delta x^p = 1, \Delta^2 x^p = \mathbf{0}$ stops after two steps, and the argument of (a) breaks exactly there.

Solution to Problem 4.6

Uses. Proposition 4.3.13 (Dimensions of the four subspaces), Theorem 3.3.12 (Matrices in RREF), Theorem 4.2.11 (Rank–nullity), Theorem 4.1.10 (Independent lists are short), Proposition 4.4.2 (Sums are the smallest containing subspaces), Theorem 4.4.19 (Dimension of a sum)
Techniques. Dimension counting (Technique 4.2.24), Reduce to RREF (Technique 3.3.22)
Hint 1. (a) A combination of the rows is $\left(\sum a_i \mathbf{u}_i + \sum b_j \mathbf{w}_j, \sum a_i \mathbf{u}_i\right)$. For the kernel, $\mathbf{u} + \mathbf{w} = \mathbf{0}$ means $\mathbf{u} = -\mathbf{w} \in U \cap W$.
Hint 2. (b) Row reduction keeps the row space. In R, the rows with a pivot in the left half come first. Count: if s rows have a nonzero left half and d others are nonzero, the kernel in (a) has dimension $(s + d) - s$.
Sketch. (a) Combinations of the rows give exactly the pairs $(\mathbf{u} + \mathbf{w}, \mathbf{u})$; projecting to the left half gives $U + W$, and $\mathbf{u} + \mathbf{w} = \mathbf{0}$ forces $\mathbf{u} \in U \cap W$. (b) The nonzero rows of R are a basis of Z. The s rows with a pivot in the left half have independent left halves (pivot columns), which span the image $U + W$. The other d nonzero rows are $(\mathbf{0}, \mathbf{c})$, independent, in the kernel, whose dimension is $(s + d) - s = d$; so the $\mathbf{c}$'s are a basis of $U \cap W$. (c) Over $\mathbb{F}_2$: $U + W$ has basis $(1,0,0,1), (0,1,0,1), (0,0,1,1)$ and $U \cap W = \operatorname{span}((1,0,1,0))$. Over $\mathbb{Q}$, $U + W = \mathbb{Q}^4$ and $U \cap W = \{\mathbf{0}\}$.

(a) A combination of the rows of M with coefficients a_i and b_j is

$$\left(\sum_i a_i \mathbf{u}_i + \sum_j b_j \mathbf{w}_j, \sum_i a_i \mathbf{u}_i\right) = (\mathbf{u} + \mathbf{w}, \mathbf{u}),$$

with $\mathbf{u} = \sum_i a_i \mathbf{u}_i \in U$ and $\mathbf{w} = \sum_j b_j \mathbf{w}_j \in W$, and every such pair arises. So the row space is Z. The map $\pi(\mathbf{a}, \mathbf{b}) = \mathbf{a}$ is linear, and $\pi(Z) = \{\mathbf{u} + \mathbf{w}\} = U + W$. A pair $(\mathbf{u} + \mathbf{w}, \mathbf{u})$ lies in $\ker \pi$ exactly when $\mathbf{u} = -\mathbf{w}$, that is, $\mathbf{u} \in U \cap W$; and for $\mathbf{u} \in U \cap W$, $(\mathbf{0}, \mathbf{u}) = (\mathbf{u} + (-\mathbf{u}), \mathbf{u}) \in Z$. So $\ker(\pi\restriction_Z) = \{(\mathbf{0}, \mathbf{u}) \mid \mathbf{u} \in U \cap W\}$, which is isomorphic to $U \cap W$ by $(\mathbf{0}, \mathbf{u}) \mapsto \mathbf{u}$.

(b) Row operations do not change the row space, and the nonzero rows of R form a basis of it (Proposition 4.3.13(b)), so they form a basis of Z. In R the pivots move to the right from one row to the next (Theorem 3.3.12), so the nonzero rows split into s rows $\mathbf{r}_1, \ldots, \mathbf{r}_s$ with their pivot in the left half, followed by d rows of the form $(\mathbf{0}, \mathbf{c}_1), \ldots, (\mathbf{0}, \mathbf{c}_d)$.

The left halves of the $\mathbf{r}_i$ form a basis of $U + W$. They span $\pi(Z) = U + W$, since π of the other basis vectors of Z is $\mathbf{0}$. They are independent: in a relation $\sum_i c_i \pi(\mathbf{r}_i) = \mathbf{0}$, look at the pivot column of $\mathbf{r}_i$, which lies in the left half and in which every other row of R has a 0; it gives $c_i = 0$.

The $\mathbf{c}_j$ form a basis of $U \cap W$. The vectors $(\mathbf{0}, \mathbf{c}_j)$ are independent, being nonzero rows of R, and they lie in $\ker(\pi\restriction_Z)$. By rank–nullity for $\pi\restriction_Z$, this kernel has dimension $\dim Z - \dim(U + W) = (s + d) - s = d$. So they form a basis of it (Theorem 4.1.10(b)), and by (a) the $\mathbf{c}_j$ form a basis of $U \cap W$. In passing, $\dim(U + W) + \dim(U \cap W) = s + d = \dim Z = \dim U + \dim W$ when the $\mathbf{u}_i$ and the $\mathbf{w}_j$ are bases, which is Theorem 4.4.19 once more.

(c) The matrix is

$$M = \begin{pmatrix} 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Over $\mathbb{F}_2$, where $-1 = 1$, Gauss–Jordan elimination gives

$$R = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \end{pmatrix}.$$

So $U + W$ has basis $(1,0,0,1), (0,1,0,1), (0,0,1,1)$, the hyperplane $x_1 + x_2 + x_3 + x_4 = 0$, and $U \cap W = \operatorname{span}((1,0,1,0))$. Indeed $(1,0,1,0) = \mathbf{u}_1 + \mathbf{u}_2 = \mathbf{w}_1 + \mathbf{w}_2$ over $\mathbb{F}_2$.

Over $\mathbb{Q}$, the same elimination ends with a pivot in each of the first four columns, since

$$R = \begin{pmatrix} 1 & 0 & 0 & 0 & \frac{1}{2} & 0 & -\frac{1}{2} & 0 \\ 0 & 1 & 0 & 0 & \frac{1}{2} & 1 & \frac{1}{2} & 0 \\ 0 & 0 & 1 & 0 & -\frac{1}{2} & 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 1 & \frac{1}{2} & 0 & -\frac{1}{2} & 0 \end{pmatrix},$$

so $U + W = \mathbb{Q}^4$ and $U \cap W = \{\mathbf{0}\}$. Directly: $U = \{(a, a+b, b, 0)\}$ and $W = \{(d, 0, c, c-d)\}$, and a common vector has $a = b = c = d$ and $2a = 0$. Over $\mathbb{Q}$ this forces $a = 0$, and over $\mathbb{F}_2$ it does not.

The column method of Example 4.4.20 finds the intersection as a relation among the given vectors; this method finds bases of both spaces in one reduction, with no relation to interpret.

Solution to Problem 4.7

Uses. Definition 4.5.23 (Similar matrices), Proposition 4.5.27 (Similarity invariants), Proposition 4.3.1 (Invertible factors preserve rank), Proposition 2.4.14 (Algebra of matrices), Theorem 4.4.19 (Dimension of a sum), Proposition 4.4.2 (Sums are the smallest containing subspaces), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Compare components (Technique 4.4.8)
Hint 1. Compute $A(I_n - A - B)$ and $(I_n - A - B)B$.
Hint 2. (c) Show $\operatorname{im}(A+B) = \operatorname{im} A + \operatorname{im} B$ and $\operatorname{im} A \cap \operatorname{im} B = \{\mathbf{0}\}$. For the first, $(A+B)A = A$.
Sketch. (a) $AG = -AB = GB$ for $G = I_n - A - B$, so $B = G^{-1}AG$. (b) $A = I_n$, $B = 0$. (c) $(A+B)^2 = A + AB + BA + B = A + B$. $(A+B)A\mathbf{x} = A\mathbf{x}$ gives $\operatorname{im} A \subseteq \operatorname{im}(A+B)$, likewise for B, so $\operatorname{im}(A+B) = \operatorname{im} A + \operatorname{im} B$; and $\mathbf{y} = A\mathbf{x} = B\mathbf{z}$ gives $\mathbf{y} = A\mathbf{y} = AB\mathbf{z} = \mathbf{0}$.

(a) Let $G = I_n - A - B$. Using $A^2 = A$ and $B^2 = B$,

$$AG = A - A^2 - AB = -AB, \quad GB = B - AB - B^2 = -AB.$$

So $AG = GB$, and since G is invertible, $B = G^{-1}AG$. So $A \sim B$, and $\operatorname{rank} A = \operatorname{rank} B$ (Proposition 4.5.27(a)). The rank statement alone also follows from Proposition 4.3.1: $\operatorname{rank} A = \operatorname{rank}(AG) = \operatorname{rank}(GB) = \operatorname{rank} B$.

(b) $A = I_n$ and $B = 0$ are idempotent of ranks n and 0, and $I_n - A - B = 0$ is not invertible.

(c) $(A+B)^2 = A^2 + AB + BA + B^2 = A + B$ (Proposition 2.4.14). For every $\mathbf{x}$, $(A+B)A\mathbf{x} = A^2\mathbf{x} + BA\mathbf{x} = A\mathbf{x}$, so $\operatorname{im} A \subseteq \operatorname{im}(A+B)$; similarly $(A+B)B\mathbf{x} = B\mathbf{x}$ gives $\operatorname{im} B \subseteq \operatorname{im}(A+B)$. Hence $\operatorname{im} A + \operatorname{im} B \subseteq \operatorname{im}(A+B)$ (Proposition 4.4.2), and the converse containment holds because $(A+B)\mathbf{x} = A\mathbf{x} + B\mathbf{x}$. So $\operatorname{im}(A+B) = \operatorname{im} A + \operatorname{im} B$. If $\mathbf{y} \in \operatorname{im} A \cap \operatorname{im} B$, say $\mathbf{y} = A\mathbf{x} = B\mathbf{z}$, then $\mathbf{y} = A^2\mathbf{x} = A\mathbf{y} = AB\mathbf{z} = \mathbf{0}$. By Theorem 4.4.19,

$$\operatorname{rank}(A+B) = \dim(\operatorname{im} A + \operatorname{im} B) = \operatorname{rank} A + \operatorname{rank} B.$$

Over $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, (c) also follows from tr = rank for idempotents (Exercise 4.3.43), since the trace is additive. The argument above works over every field, where the trace of an idempotent only determines its rank modulo the characteristic.

Solution to Problem 4.8

Uses. Exercise 4.3.30, Exercise 4.2.52, Proposition 4.2.15 (Rank through any matrix), Theorem 4.2.11 (Rank–nullity), Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps), Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Exercise 4.5.50
Techniques. Dimension counting (Technique 4.2.24), Apply an operator to a relation to kill terms (Technique 4.1.25)

Hint 1. (a) Sylvester with k factors: $0 = \operatorname{rank} N^k \geq k \operatorname{rank} N - (k-1)n$.
Hint 2. (b) The k jumps $d_1, \ldots, d_k$ add up to $\dim\ker N^k = n$, and none exceeds $d_1 = n/k$. (c) Let m be the least exponent with $N^m = 0$, and compare $n = d_1 + \cdots + d_m$ with md_1.
Sketch. (a) $\operatorname{rank} N \leq (k-1)n/k$. (b) $d_1 + \cdots + d_k = n$ with every $d_j \leq n/k$ forces $d_j = n/k$, so $\dim\ker N^j = jn/k$, and $\dim\ker N^{k-1} < n$. Example: n/k shifts of size k. (c) With $N^m = 0$ minimal, $n = d_1 + \cdots + d_m \leq m$, so $m = n$ and $N^{n-1} \neq 0$; a vector with $N^{n-1}\mathbf{v} \neq \mathbf{0}$ has a chain of length n, which is a basis.

(a) Let A be the matrix of N in some basis, so $A^k = 0$ and $\operatorname{rank} A = \operatorname{rank} N$ (Proposition 4.2.15). By Exercise 4.3.30(c) with all k factors equal to A,

$$0 = \operatorname{rank} A^k \geq k \operatorname{rank} A - (k-1)n,$$

so $\operatorname{rank} N \leq (k-1)n/k$ and $\dim\ker N = n - \operatorname{rank} N \geq n/k$. The kernel proof of Exercise 4.2.52 and this one bound the same quantity; the kernel proof is the kernel proof of Sylvester's inequality (Example 4.8.3), applied k times.

(b) Since $N^k = 0$, $\sum_{j=1}^{k} d_j = \dim\ker N^k - \dim\ker N^0 = n$. By Exercise 4.2.52(b), $d_j \leq d_1 = n/k$ for every j. A sum of k numbers, each at most n/k, equals n only if every term equals n/k. So $\dim\ker N^j = d_1 + \cdots + d_j = jn/k$ for $0 \leq j \leq k$. In particular $\dim\ker N^{k-1} = n - n/k < n$, so $N^{k-1} \neq 0$: a nilpotent operator whose kernel is as small as the bound allows takes the full k steps to die.

For an example, let $m = n/k$ and choose a basis $\mathbf{b}_{i,l}$ of V, indexed by $1 \leq i \leq m$ and $1 \leq l \leq k$. Define N by $N\mathbf{b}_{i,1} = \mathbf{0}$ and $N\mathbf{b}_{i,l} = \mathbf{b}_{i,l-1}$ for $l \geq 2$. Then N^k kills every basis vector, so $N^k = 0$, and N sends the basis vectors $\mathbf{b}_{i,l}$ with $l \geq 2$ to distinct basis vectors and the others to $\mathbf{0}$. So $\operatorname{im} N$ is spanned by the $m(k-1)$ independent vectors $\mathbf{b}_{i,l}$ with $l \leq k-1$, $\operatorname{rank} N = m(k-1)$, and $\dim\ker N = n - m(k-1) = m$.

(c) For $n = 1$ there is nothing to prove, since $N^0 = \mathrm{id} \neq 0$. Let $n \geq 2$, and let m be the least exponent with $N^m = 0$; it exists by Corollary 4.1.27, with $m \leq n$. With the jumps as above, $n = d_1 + \cdots + d_m \leq md_1 = m$, so $m = n$ and $N^{n-1} \neq 0$. (Part (a) with $k = n-1$ gives the same: $N^{n-1} = 0$ would force $1 \geq n/(n-1)$.) So there is $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$ and $N^n\mathbf{v} = \mathbf{0}$. By Proposition 4.1.26, $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ is independent, and it has n entries, so it is a basis (Theorem 4.1.10(b)). In this basis N is the shift (Exercise 4.5.50).

Solution to Problem 4.9

Uses. Theorem 4.2.11 (Rank–nullity), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.1.16 (Linear maps preserve spans and linear relations), Corollary 4.2.18 (Injective if and only if surjective)
Techniques. Dimension counting (Technique 4.2.24), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. Let $\rho_i = \operatorname{rank} T_i$, and $\rho_0 = \rho_k = 0$. Show $\dim V_i = \rho_{i-1} + \rho_i$ with rank–nullity. Then the alternating sum telescopes.
Hint 2. (c) In an exact sequence, $\rho_i = n_i - \rho_{i-1}$, so $\rho_i = r_i$. Conversely, build $T_i : F^{n_i} \to F^{n_{i+1}}$ that kills the first r_{i-1} standard basis vectors and sends the next r_i to $\mathbf{e}_1, \ldots, \mathbf{e}_{r_i}$.
Sketch. (a) $\dim V_i = \dim\ker T_i + \operatorname{rank} T_i = \rho_{i-1} + \rho_i$ (with $\ker T_1 = \{\mathbf{0}\}$ and, at V_k, $\dim V_k = \rho_{k-1}$ by surjectivity), so $\sum (-1)^i(\rho_{i-1} + \rho_i) = -\rho_0 + (-1)^k\rho_k = 0$. (b) $k = 2$: an isomorphism, $n_1 = n_2$. $k = 3$: $\dim V_2 = \dim V_1 + \dim V_3$, rank–nullity for T_2. (c) Necessity: $\rho_i = r_i$ by induction, and ranks are nonnegative, $\rho_k = 0$. Sufficiency: the maps above have $\operatorname{im} T_i = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{r_i}) = \ker T_{i+1}$.

Write $\rho_i = \operatorname{rank} T_i$ for $1 \leq i \leq k-1$, and $\rho_0 = \rho_k = 0$.

(a) We claim $\dim V_i = \rho_{i-1} + \rho_i$ for every i. For $i = 1$: T_1 is injective, so rank–nullity gives $\dim V_1 = 0 + \rho_1$. For $2 \leq i \leq k-1$: $\dim\ker T_i = \dim\operatorname{im} T_{i-1} = \rho_{i-1}$ by exactness, and rank–nullity for T_i gives $\dim V_i = \rho_{i-1} + \rho_i$. For $i = k$: T_{k-1} is surjective, so $\dim V_k = \rho_{k-1} = \rho_{k-1} + \rho_k$. Hence

$$\sum_{i=1}^{k} (-1)^i \dim V_i = \sum_{i=1}^{k} (-1)^i \rho_{i-1} + \sum_{i=1}^{k} (-1)^i \rho_i = \sum_{i=0}^{k-1} (-1)^{i+1} \rho_i + \sum_{i=1}^{k} (-1)^i \rho_i,$$

and the terms with $1 \leq i \leq k-1$ cancel in pairs, leaving $-\rho_0 + (-1)^k\rho_k = 0$.

(b) For $k = 2$, T_1 is injective and surjective, an isomorphism, and (a) says $\dim V_1 = \dim V_2$. For $k = 3$, T_1 is injective, T_2 is surjective, and $\operatorname{im} T_1 = \ker T_2$; (a) says $\dim V_2 = \dim V_1 + \dim V_3 = \dim\ker T_2 + \dim\operatorname{im} T_2$,

which is rank–nullity for T_2. For example, $\ker T \xrightarrow{\iota} V \xrightarrow{T} \operatorname{im} T$, with ι the inclusion and T viewed as a map onto its image, is exact. So (a) is rank–nullity applied along a chain of maps.

(c) *Necessity.* By the claim in (a), $\rho_i = n_i - \rho_{i-1}$ with $\rho_0 = 0$, so by induction $\rho_i = r_i$ for $1 \le i \le k-1$. Ranks are nonnegative, so $r_i \ge 0$ for these i, and $r_k = n_k - \rho_{k-1} = 0$ by the claim at $i = k$.

Sufficiency. Suppose all $r_i \ge 0$ and $r_k = 0$. Let $V_i = F^{n_i}$. Then $r_{i-1} + r_i = n_i$, so we may define T_i, for $1 \le i \le k-1$, on the standard basis of F^{n_i} by

$$T_i(\mathbf{e}_j) = \mathbf{0} \quad (j \le r_{i-1}), \quad T_i\left(\mathbf{e}_{r_{i-1}+j}\right) = \mathbf{e}_j \quad (1 \le j \le r_i)$$

(Theorem 2.2.1). This makes sense because $r_i \le r_i + r_{i+1} = n_{i+1}$. The values on the basis are $\mathbf{0}$ and the independent vectors $\mathbf{e}_1, \dots, \mathbf{e}_{r_i}$, so $\operatorname{im} T_i = \operatorname{span}\left(\mathbf{e}_1, \dots, \mathbf{e}_{r_i}\right)$ (Proposition 2.1.16) and $\operatorname{rank} T_i = r_i$. A vector $\sum_j x_j \mathbf{e}_j$ is killed by T_i exactly when $x_j = 0$ for $j > r_{i-1}$, so $\ker T_i = \operatorname{span}\left(\mathbf{e}_1, \dots, \mathbf{e}_{r_{i-1}}\right)$. Hence $\operatorname{im} T_{i-1} = \ker T_i$ for $2 \le i \le k-1$; $\ker T_1 = \{\mathbf{0}\}$ since $r_0 = 0$; and $\operatorname{im} T_{k-1} = \operatorname{span}\left(\mathbf{e}_1, \dots, \mathbf{e}_{r_{k-1}}\right) = F^{n_k}$ since $r_{k-1} = n_k - r_k = n_k$. The sequence is exact.

The condition $r_k = 0$ alone is the vanishing of the alternating sum in (a), since $r_k = \sum_{i=1}^{k} (-1)^{k-i} n_i$. It is not sufficient: $(n_1, n_2, n_3, n_4) = (1, 0, 0, 1)$ has alternating sum 0, but $r_2 = -1$, and indeed $F \to \{\mathbf{0}\}$ cannot be injective.

Solution to Problem 4.10

Uses. Proposition 4.4.16 (Complements exist), Proposition 4.4.31 (Defining maps summand by summand), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 4.5.5 (Isomorphisms preserve linear structure), Corollary 4.1.35 (Counting independent lists and bases), Theorem 4.4.27 (Idempotents are projections), Proposition 4.4.26 (Properties of projections), Proposition 4.1.37 (Counting subspaces), Exercise 4.4.49, Exercise 4.1.54, Theorem 4.2.11 (Rank–nullity)
Techniques. Double counting (Technique 4.1.36), Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. (a) Fix a complement X of U. A map with kernel U and image W is determined by its restriction to X, which must be an isomorphism $X \to W$. Count isomorphisms by the image of a fixed basis of X.
Hint 2. (b) An idempotent is the projection onto its image along its kernel. Count pairs (image, complement). (c) Count triples (kernel, image, isomorphism).
Sketch. (a) $T \mapsto T{\restriction_X}$ is a bijection onto the isomorphisms $X \to W$ (inverse: $\varphi \mapsto \varphi \circ \Pr_{X,U}$), and isomorphisms correspond to bases of W: $N_q(r,r)$. (b) $P \mapsto (\operatorname{im} P, \ker P)$ is a bijection onto pairs of complementary subspaces; there are $N_q(n,r)/N_q(r,r)$ choices of image and $q^{r(n-r)}$ complements of each. For $n = 2$: $1 + (q+1)q + 1 = q^2 + q + 2$. (c) Choose the kernel ($N_q(n,n-r)/N_q(n-r,n-r)$ ways, equal to the number of r-dimensional subspaces), the image, and then (a). For $n = q = 2$: $1 + 9 + 6 = 16$.

(a) By Proposition 4.4.16, U has a complement X, with $\dim X = n - \dim U = r$. Let T have kernel U and image W. Then $T{\restriction_X}$ is injective, since $X \cap \ker T = X \cap U = \{\mathbf{0}\}$, and its image is $T(U + X) = T(V) = W$. So $T{\restriction_X}$ is an isomorphism $X \to W$, and T is determined by it, since T is 0 on U (Proposition 4.4.31). Conversely, for an isomorphism $\varphi : X \to W$, the map T that is 0 on U and φ on X (Proposition 4.4.31) has image $\varphi(X) = W$, and $T(\mathbf{u} + \mathbf{x}) = \varphi(\mathbf{x}) = \mathbf{0}$ exactly when $\mathbf{x} = \mathbf{0}$, so its kernel is U. So the operators in question correspond bijectively to the isomorphisms $X \to W$. Fix a basis $\mathbf{x}_1, \dots, \mathbf{x}_r$ of X. A linear map $X \to W$ is determined by the list of values $\varphi(\mathbf{x}_1), \dots, \varphi(\mathbf{x}_r)$, which can be any list (Theorem 2.2.1), and it is an isomorphism exactly when this list is a basis of W (Proposition 4.5.5). There are $N_q(r,r)$ bases of W.

(b) By Theorem 4.4.27, an idempotent P satisfies $V = \operatorname{im} P \oplus \ker P$ and $P = \Pr_{\operatorname{im} P, \ker P}$. Conversely, for every pair (Y, Z) with $V = Y \oplus Z$, the projection $\Pr_{Y,Z}$ is idempotent with image Y and kernel Z (Proposition 4.4.26). So idempotents of rank r correspond bijectively to pairs (Y, Z) of complementary subspaces with $\dim Y = r$. There are $N_q(n,r)/N_q(r,r)$ subspaces Y of dimension r (Proposition 4.1.37), and each has $q^{r(n-r)}$ complements (Exercise 4.4.49(c)). Multiplying gives the formula.

For $n = 2$: $r = 0$ and $r = 2$ give 1 each (0 and I_2). For $r = 1$, $N_q(2,1)/N_q(1,1) = \left(q^2 - 1\right)/(q-1) = q + 1$, times $q^{1 \cdot 1} = q$. The total is $q^2 + q + 2$, as in Problem 2.8(b) for $q = p$ prime.

(c) An operator of rank r has a kernel of dimension $n-r$ and an image of dimension r (Theorem 4.2.11), and by (a) each such pair is realized by $N_q(r,r)$ operators. The number of $(n-r)$-dimensional subspaces equals the number of r-dimensional ones (Exercise 4.1.54(b)), namely $N_q(n,r)/N_q(r,r)$. So the count is

$$\left(N_q \frac{n,r}{N_q}(r,r)\right)^2 \cdot N_q(r,r) = N_q \frac{(n,r)^2}{N_q}(r,r).$$

For $n=q=2$: $r=0$ gives 1; $r=1$ gives $N_2(2,1)^2/N_2(1,1) = 3^2/1 = 9$; $r=2$ gives $N_2(2,2) = 3\cdot 2 = 6$. The total $16 = 2^4$ is the number of 2×2 matrices over $\mathbb{F}_2$.

Solution to Problem 4.11

Uses. Theorem 4.3.3 (Rank of a product), Exercise 4.3.30, Theorem 2.4.34 (Block multiplication), Proposition 2.4.14 (Algebra of matrices)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. $(AB)^2 = A(BA)B$. Bound $\operatorname{rank}\big((AB)^2\big)$ from above by $\operatorname{rank}(BA)$ and from below by Sylvester's inequality.
Hint 2. For (c), take $n=2m$ and block matrices built from I_m and 0, with $AB\neq 0$ and $BA=0$.
Sketch. (a) $\operatorname{rank}(BA) \geq \operatorname{rank}(A(BA)B) = \operatorname{rank}\big((AB)^2\big) \geq 2\operatorname{rank}(AB) - n$. (b) With $a = \operatorname{rank}(AB)$, $a - \operatorname{rank}(BA) \leq \min(a, n-a) \leq n/2$, and symmetrically. (c) $A = \left(\begin{smallmatrix} 0 & I_m \\ 0 & 0 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 0 & 0 \\ 0 & I_m \end{smallmatrix}\right)$ give $AB = A$ of rank m and $BA = 0$; for odd n add a zero row and column.

(a) By associativity, $(AB)^2 = A(BA)B$, so $\operatorname{rank}\big((AB)^2\big) \leq \operatorname{rank}(BA)$ by Theorem 4.3.3 (applied twice). By Sylvester's inequality (Exercise 4.3.30(a)) for the product of AB with itself, $\operatorname{rank}\big((AB)^2\big) \geq 2\operatorname{rank}(AB) - n$. Together, $\operatorname{rank}(BA) \geq 2\operatorname{rank}(AB) - n$.

(b) Let $a = \operatorname{rank}(AB)$. By (a), $a - \operatorname{rank}(BA) \leq n - a$, and trivially $a - \operatorname{rank}(BA) \leq a$. So $a - \operatorname{rank}(BA) \leq \min(a, n-a) \leq n/2$, and since the left side is an integer, it is at most $\lfloor n/2 \rfloor$. Exchanging the roles of A and B gives $\operatorname{rank}(BA) - \operatorname{rank}(AB) \leq \lfloor n/2 \rfloor$.

(c) Let $m = \lfloor n/2 \rfloor$; for $m = 0$ there is nothing to show. If $n = 2m$, let

$$A = \begin{pmatrix} 0 & I_m \\ 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 \\ 0 & I_m \end{pmatrix}.$$

By Theorem 2.4.34, $AB = \left(\begin{smallmatrix} 0 & I_m \\ 0 & 0 \end{smallmatrix}\right) = A$, of rank m, and $BA = \left(\begin{smallmatrix} 0 & 0 \\ 0 & I_m \end{smallmatrix}\right)\left(\begin{smallmatrix} 0 & I_m \\ 0 & 0 \end{smallmatrix}\right) = 0$. If $n = 2m+1$, use $\left(\begin{smallmatrix} A & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} B & 0 \\ 0 & 0 \end{smallmatrix}\right)$, whose products are $\left(\begin{smallmatrix} AB & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} BA & 0 \\ 0 & 0 \end{smallmatrix}\right)$. In both cases $\operatorname{rank}(AB) - \operatorname{rank}(BA) = m$.

For $n=2$ this is Example 4.3.4. The proof of (a) is the move of Problem 2.9: products in the other order are sandwiched inside powers, $(AB)^{k+1} = A(BA)^k B$, and a rank inequality controls the powers.

Solution to Problem 4.12

Uses. Theorem 4.3.3 (Rank of a product), Exercise 4.2.50, Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 4.5.17 (Change of basis), Theorem 2.4.34 (Block multiplication), Theorem 3.5.23 (One-sided inverses of square matrices), Proposition 4.3.1 (Invertible factors preserve rank), Lemma 4.8.2 (Ranks of block triangular matrices)
Techniques. Choose a basis adapted to a preserved subspace (Technique 4.5.36), Block decomposition (Technique 2.4.35)
Hint 1. (a) $\operatorname{rank} A = \operatorname{rank}\big(A^2 B\big) \leq \operatorname{rank} A^2 \leq \operatorname{rank} A$. Then use Exercise 4.2.50.
Hint 2. (b) In a basis of $\operatorname{im} A$ followed by a basis of $\ker A$, A becomes $\left(\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ with A_1 invertible. Write B in the same basis in blocks and translate $A^2 B = A$.
Sketch. (a) The ranks are squeezed, and Exercise 4.2.50 turns $\operatorname{rank} A^2 = \operatorname{rank} A$ into $\operatorname{im} A \cap \ker A = \{\mathbf{0}\}$ and $\operatorname{im} A + \ker A = F^n$. (b) Conjugating by the adapted basis matrix S: $A' = \left(\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, A_1 invertible, $B' = \left(\begin{smallmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{smallmatrix}\right)$. $A'^2 B' = A'$ gives $A_1 B_{11} = I_r$ and $B_{12} = 0$, so $A'B' - B'A' = \left(\begin{smallmatrix} 0 & 0 \\ -B_{21}A_1 & 0 \end{smallmatrix}\right)$, whose square is 0. (c) Its rank is $\operatorname{rank} B_{21} \leq \min(r, n-r)$; take $A = \left(\begin{smallmatrix} I_k & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} I_k & 0 \\ C & 0 \end{smallmatrix}\right)$ with C of rank k.

(a) By Theorem 4.3.3, $\operatorname{rank} A = \operatorname{rank}\big(A^2 B\big) \leq \operatorname{rank} A^2 \leq \operatorname{rank} A$, so $\operatorname{rank} A^2 = \operatorname{rank} A$. By Exercise 4.2.50, this implies $\ker A \cap \operatorname{im} A = \{\mathbf{0}\}$ and $\ker A + \operatorname{im} A = F^n$, that is, $F^n = \operatorname{im} A \oplus \ker A$.

(b) If $r = 0$, then $A = 0$ and $AB - BA = 0$. If $r = n$, then A is invertible, $A^2B = A$ gives $AB = I_n$, so $B = A^{-1}$ and $AB - BA = 0$. So let $1 \le r \le n-1$, and let S have as columns a basis of $\operatorname{im} A$ followed by a basis of $\ker A$; by (a) and Theorem 4.4.13 these form a basis of F^n, so S is invertible. T_A maps $\operatorname{im} A$ into itself and kills $\ker A$, so by Proposition 4.5.35 and Theorem 4.5.17,

$$A' = S^{-1}AS = \begin{pmatrix} A_1 & 0 \\ 0 & 0 \end{pmatrix},$$

with $A_1 \in F^{r\times r}$ the matrix of T_A restricted to $\operatorname{im} A$. This restriction is injective, since its kernel is $\operatorname{im} A \cap \ker A = \{\mathbf{0}\}$, so A_1 is invertible. Write $B' = S^{-1}BS = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}$. Conjugating $A^2B = A$ by S gives $A'^2B' = A'$, and by Theorem 2.4.34,

$$A'^2B' = \begin{pmatrix} A_1^2B_{11} & A_1^2B_{12} \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} A_1 & 0 \\ 0 & 0 \end{pmatrix}.$$

Since A_1 is invertible, $A_1B_{11} = I_r$ and $B_{12} = 0$. Then also $B_{11}A_1 = I_r$ (Theorem 3.5.23), and

$$A'B' = \begin{pmatrix} A_1B_{11} & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}, \quad B'A' = \begin{pmatrix} B_{11}A_1 & 0 \\ B_{21}A_1 & 0 \end{pmatrix} = \begin{pmatrix} I_r & 0 \\ B_{21}A_1 & 0 \end{pmatrix}.$$

So $C' = A'B' - B'A' = \begin{pmatrix} 0 & 0 \\ -B_{21}A_1 & 0 \end{pmatrix}$, and $C'^2 = 0$ by block multiplication. Since $AB - BA = SC'S^{-1}$, we get $(AB - BA)^2 = SC'^2S^{-1} = 0$.

(c) For $r = 0$ and $r = n$, $AB - BA = 0$ by (b). Otherwise, by Proposition 4.3.1, $\operatorname{rank}(AB - BA) = \operatorname{rank} C'$. Exchanging the two block rows of C' (an invertible row operation) gives $\begin{pmatrix} -B_{21}A_1 & 0 \\ 0 & 0 \end{pmatrix}$, so $\operatorname{rank} C' = \operatorname{rank}(B_{21}A_1)$ by Lemma 4.8.2(b), and $\operatorname{rank}(B_{21}A_1) = \operatorname{rank} B_{21}$ because A_1 is invertible. Since $B_{21} \in F^{(n-r)\times r}$, its rank is at most $\min(r, n-r)$.

For the examples, let $2k \le n$, let $A = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix}$, and let $B = \begin{pmatrix} I_k & 0 \\ C & 0 \end{pmatrix}$, where $C \in F^{(n-k)\times k}$ has I_k in its top k rows and zeros below, so that $\operatorname{rank} C = k$; this needs $n - k \ge k$. Then $A^2B = AB = \begin{pmatrix} I_k & 0 \\ 0 & 0 \end{pmatrix} = A$, and $BA = \begin{pmatrix} I_k & 0 \\ C & 0 \end{pmatrix}$, so $AB - BA = \begin{pmatrix} 0 & 0 \\ -C & 0 \end{pmatrix}$ has rank k.

Everything followed from choosing the basis adapted to $F^n = \operatorname{im} A \oplus \ker A$. In it, A is invertible on one summand and 0 on the other, and the hypothesis $A^2B = A$ pins down two of the four blocks of B.

Solution to Problem 4.13

Uses. Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps), Theorem 4.1.16 (Extending to a basis), Theorem 4.5.17 (Change of basis), Proposition 4.5.27 (Similarity invariants), Lemma 2.4.24 (Matrix units), Proposition 2.4.27 (The trace is linear), Exercise 4.1.43, Proposition 1.4.14 (The span is the smallest subspace containing a list)
Techniques. Extend a basis of a subspace (Technique 4.1.18), Choose a basis adapted to a preserved subspace (Technique 4.5.36), Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. (a) N maps $\ker N^j$ into $\ker N^{j-1}$. Build a basis by taking a basis of $\ker N$, extending it to one of $\ker N^2$, and so on up to $\ker N^n = F^n$.
Hint 2. (b) U_{ij} for $i \ne j$ is nilpotent. Check that $U_{ii} - U_{jj} + U_{ij} - U_{ji}$ has square 0. (c) U_{ii} and $U_{ii} + U_{ij}$.
Sketch. (a) In a basis adapted to $\ker N \subseteq \ker N^2 \subseteq \cdots \subseteq \ker N^n = F^n$, each basis vector from level j is sent into $\ker N^{j-1}$, which is spanned by earlier basis vectors; so the matrix is strictly upper triangular, and $\operatorname{tr} N$ equals its trace, 0. (b) Nilpotents lie in the trace-zero space by (a). Conversely U_{ij} $(i \ne j)$ and $U_{ii} - U_{jj} = E - U_{ij} + U_{ji}$, with E of square 0, are combinations of nilpotents, and these matrices span the trace-zero space. (c) U_{ii} and $U_{ii} + U_{ij}$ are idempotent, so their span contains every matrix unit.

(a) Let $K_j = \ker N^j$, so $K_0 = \{\mathbf{0}\} \subseteq K_1 \subseteq \cdots \subseteq K_n$, and $K_n = F^n$ by Corollary 4.1.27. If $N^j\mathbf{x} = \mathbf{0}$, then $N^{j-1}(N\mathbf{x}) = \mathbf{0}$, so N maps K_j into K_{j-1}. Choose a basis of K_1, extend it to a basis of K_2 (Theorem 4.1.16, applied in K_2), extend that to a basis of K_3, and so on. The result is a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of F^n such that, for each j, the first $\dim K_j$ vectors form a basis of K_j. If $\mathbf{b}_l$ was added at level j, that is, $\mathbf{b}_l \in K_j$ and $l > \dim K_{j-1}$, then $N\mathbf{b}_l \in K_{j-1}$ is a combination of $\mathbf{b}_1, \ldots, \mathbf{b}_{\dim K_{j-1}}$, all of which come before $\mathbf{b}_l$. So column l of

$[T_N]_{\mathcal{B}\mathcal{B}}$ has nonzero entries only in rows $< l$: the matrix is strictly upper triangular, and by Theorem 4.5.17 it equals $S^{-1}NS$ for the invertible S with columns $\mathcal{B}$. Its diagonal is zero, so $\operatorname{tr} N = \operatorname{tr}\left(S^{-1}NS\right) = 0$ (Proposition 4.5.27(b)).

(b) Let W be the trace-zero subspace. By (a) and Proposition 2.4.27, every nilpotent matrix lies in W, and so does their span. Conversely, for $i \neq j$, the matrix unit U_{ij} satisfies $U_{ij}^2 = 0$ (Lemma 2.4.24(c)), so it is nilpotent. Let $E = U_{ii} - U_{jj} + U_{ij} - U_{ji}$. By Lemma 2.4.24(c), E maps $\mathbf{e}_i$ to $\mathbf{e}_i - \mathbf{e}_j$ and $\mathbf{e}_j$ to $\mathbf{e}_i - \mathbf{e}_j$, and kills the other standard basis vectors. So $E\left(\mathbf{e}_i - \mathbf{e}_j\right) = \mathbf{0}$, $E^2\mathbf{e}_i = E^2\mathbf{e}_j = \mathbf{0}$, and $E^2 = 0$. (In rows and columns i, j, E is $\left(\begin{smallmatrix} 1 & 1 \\ -1 & -1 \end{smallmatrix}\right)$.) Hence

$$U_{ii} - U_{jj} = E - U_{ij} + U_{ji}$$

is a combination of nilpotent matrices. The matrices U_{ij} with $i \neq j$ and $U_{ii} - U_{nn}$ with $i < n$ lie in W, number $n^2 - 1 = \dim W$ (Exercise 4.1.43), and are independent, since their entries sit in different positions except for the last diagonal entry. So they form a basis of W, and W is contained in the span of the nilpotent matrices.

(c) $U_{ii}^2 = U_{ii}$, and for $i \neq j$, $\left(U_{ii} + U_{ij}\right)^2 = U_{ii} + U_{ij} + U_{ij}U_{ii} + U_{ij}^2 = U_{ii} + U_{ij}$, because $U_{ij}U_{ii} = 0$ and $U_{ij}U_{ij} = 0$ when $i \neq j$. So every matrix unit $U_{ij} = \left(U_{ii} + U_{ij}\right) - U_{ii}$ is a combination of idempotents, and the matrix units span $F^{n\times n}$.

Nilpotent matrices are trapped in a hyperplane because their trace is 0; idempotents are not, since $\operatorname{tr} P = \operatorname{rank} P \cdot 1$ can be anything. Neither set is a subspace: a sum of two nilpotent matrices can be invertible (Problem 2.10(b)).

Solution to Problem 4.14

> *Uses.* Proposition 4.4.12 (Concatenating independent lists), Proposition 4.1.34 (Size of a vector space over a finite field), Corollary 4.1.35 (Counting independent lists and bases), Proposition 4.1.37 (Counting subspaces), Exercise 4.4.49, Proposition 1.5.14 (Appending a vector)
> *Techniques.* Double counting (Technique 4.1.36)
> *Hint 1.* Count pairs (W, basis of W). A list $\mathbf{w}_1, \ldots, \mathbf{w}_j$ is a basis of such a W exactly when a basis of U followed by the $\mathbf{w}$'s is independent.
> *Hint 2.* Choose $\mathbf{w}_i$ outside $\operatorname{span}(U, \mathbf{w}_1, \ldots, \mathbf{w}_{i-1})$, which has q^{k+i-1} elements.
> *Sketch.* The lists $\mathbf{w}_1, \ldots, \mathbf{w}_j$ for which U's basis followed by them is independent number $\prod_{i=0}^{j-1}\left(q^n - q^{k+i}\right) = q^{jk}N_q(n-k, j)$. Each such list spans a W with $W \cap U = \{\mathbf{0}\}$, every basis of such a W is such a list, and each W has $N_q(j, j)$ bases. Divide. $j = n - k$: $q^{k(n-k)}$ complements. $j = 1$: $q^k\left(q^{n-k} - 1\right)/(q-1)$, all lines not in U. In $\mathbb{F}_2^3$ with $k = 1$: 6 lines and 4 planes.

Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be a basis of U. For a list $\mathcal{W} = \mathbf{w}_1, \ldots, \mathbf{w}_j$, the concatenation $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathcal{W}$ is independent if and only if $\mathcal{W}$ is independent and $\operatorname{span}(\mathcal{W}) \cap U = \{\mathbf{0}\}$ (Proposition 4.4.12). So the lists $\mathcal{W}$ with this property are exactly the bases of the j-dimensional subspaces W with $W \cap U = \{\mathbf{0}\}$, and each such W has $N_q(j, j)$ bases (Corollary 4.1.35). Let L be the number of such lists; then the number of subspaces is $L/N_q(j, j)$.

To count the lists, choose $\mathbf{w}_1, \mathbf{w}_2, \ldots$ in turn. Given $\mathbf{w}_1, \ldots, \mathbf{w}_{i-1}$ with $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{w}_1, \ldots, \mathbf{w}_{i-1}$ independent, the list stays independent after appending $\mathbf{w}_i$ exactly when $\mathbf{w}_i$ is not in the span of the list so far (Proposition 1.5.14), a subspace of dimension $k + i - 1$ with q^{k+i-1} elements (Proposition 4.1.34). So

$$L = \prod_{i=1}^{j}\left(q^n - q^{k+i-1}\right) = \prod_{i=0}^{j-1} q^k\left(q^{n-k} - q^i\right) = q^{jk}N_q(n-k, j),$$

and the number of subspaces is $q^{jk}N_q(n-k, j)/N_q(j, j)$.

Checks. For $j = n - k$, the factor $N_q(n-k, n-k)/N_q(n-k, n-k)$ is 1, and the count $q^{k(n-k)}$ is the number of complements of U (Exercise 4.4.49(c)). For $j = 1$ the count is $q^k\left(q^{n-k} - 1\right)/(q-1) = \left(q^n - q^k\right)/(q-1)$: the $q^n - q^k$ vectors outside U, grouped into lines of $q - 1$ nonzero vectors each, which is every line not

contained in U. In $\mathbb{F}_2^3$ with $k=1$: $j=1$ gives $2\cdot 3/1=6$ lines, which are the 7 lines minus U itself; $j=2$ gives $2^2\cdot 1=4$ planes, which are the 7 planes minus the 3 planes that contain U.

Solution to Problem 4.15

Uses. Corollary 4.7.23 (Affinely independent lists are short), Exercise 4.7.59, Proposition 4.7.30 (Convex sets and convex hulls), Proposition 4.7.32 (Barycentric coordinates on a simplex), Definition 4.7.28 (Convex combination, convex set, convex hull)
Techniques. Too many vectors force a dependence (Technique 4.1.30)
Hint 1. Induct on m. For $m\ge n+2$, the induction hypothesis gives, for each i, a point $\mathbf{p}_i$ in every C_j with $j\neq i$.
Hint 2. The $m\ge n+2$ points $\mathbf{p}_i$ are affinely dependent. Split an affine dependence by the signs of its coefficients, as in Radon's theorem, and show that the resulting point lies in every C_l.
Sketch. (a) Induction on m, the case $m=n+1$ being the hypothesis. For $m\ge n+2$, pick $\mathbf{p}_i\in\bigcap_{j\neq i}C_j$. An affine dependence $\sum d_i\mathbf{p}_i=\mathbf{0}$, $\sum d_i=0$, gives $\mathbf{q}=\sum_{i\in I}(d_i/s)\mathbf{p}_i=\sum_{j\in J}(-d_j/s)\mathbf{p}_j$ with $I=\{d_i>0\}$. For each l, l misses I or J, and the points indexed by the other set all lie in C_l, so $\mathbf{q}\in C_l$. (b) The $n+1$ facets of an n-simplex: any n share a vertex, all $n+1$ share nothing.

(a) We induct on m. For $m=n+1$ the hypothesis says exactly that all the sets have a common point. Let $m\ge n+2$, and assume the statement for $m-1$ sets. For each i, the $m-1\ge n+1$ sets C_j with $j\neq i$ satisfy the hypothesis, so by induction there is a point $\mathbf{p}_i$ in every C_j with $j\neq i$.

The $m\ge n+2$ points $\mathbf{p}_1,\dots,\mathbf{p}_m$ are affinely dependent (Corollary 4.7.23): there are $d_1,\dots,d_m$, not all 0, with $\sum_i d_i\mathbf{p}_i=\mathbf{0}$ and $\sum_i d_i=0$. As in the solution of Exercise 4.7.59, let $I=\{i\mid d_i>0\}$ and $J=\{j\mid d_j\le 0\}$; both are nonempty, $s=\sum_{i\in I}d_i>0$, and

$$\mathbf{q}=\sum_{i\in I}\frac{d_i}{s}\mathbf{p}_i=\sum_{j\in J}\frac{-d_j}{s}\mathbf{p}_j,$$

where both sides are convex combinations. Now fix l. If $l\notin I$, then every $\mathbf{p}_i$ with $i\in I$ lies in C_l (because $i\neq l$), so the left side is a convex combination of points of the convex set C_l, and $\mathbf{q}\in C_l$ (Proposition 4.7.30(a)). If $l\in I$, then $l\notin J$, and the right side shows $\mathbf{q}\in C_l$ in the same way. So $\mathbf{q}$ lies in all m sets.

(b) Let $\mathbf{v}_0,\dots,\mathbf{v}_n$ be affinely independent (an affine frame of V) and $C_i=\operatorname{conv}\{\mathbf{v}_j\mid j\neq i\}$ for $i=0,\dots,n$, the $n+1$ facets of the simplex. Any n of them, say all except C_l, contain $\mathbf{v}_l$. But a point in all $n+1$ would lie in the simplex with every barycentric coordinate 0 (Proposition 4.7.32: a point of C_i has ith coordinate 0), while the coordinates add up to 1.

The proof is "too many vectors" in affine form: as soon as there are more points than an affine frame can hold, they satisfy an affine dependence, and the dependence, split by signs, produces the common point.

Solution to Problem 4.16

Uses. Theorem 4.3.3 (Rank of a product), Theorem 3.5.14 (Third Fundamental Theorem, completed), Theorem 4.3.21 (Column–row factorization), Proposition 2.4.14 (Algebra of matrices)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Compute M^2 and rank M.
Hint 2. $(BA)^3=B(AB)^2A$. Show that BA is invertible by comparing ranks, then cancel.
Sketch. (a) $M^2=9M$ and rank $M=2$. Then $\operatorname{rank}(BA)\ge\operatorname{rank}(A(BA)B)=\operatorname{rank}(M^2)=2$, so $BA\in\mathbb{R}^{2\times 2}$ is invertible, and $(BA)^3=BM^2A=9(BA)^2$ gives $BA=9I_2$. (b) The column–row factorization $A=\begin{pmatrix}8&2\\2&5\\-2&4\end{pmatrix}$, $B=\begin{pmatrix}1&0&-1/2\\0&1&1\end{pmatrix}$.

(a) A direct computation gives

$$M^2=\begin{pmatrix}72&18&-18\\18&45&36\\-18&36&45\end{pmatrix}=9M.$$

The first two columns of M are not proportional, and the third is $(-2,4,5)=-\frac{1}{2}(8,2,-2)+(2,5,4)$, so $\operatorname{rank}M=2$. By associativity, $M^2=A(BA)B$, so by Theorem 4.3.3,

$$2 = \operatorname{rank}(9M) = \operatorname{rank}\left(M^2\right) \leq \operatorname{rank}(BA) \leq 2.$$

So $BA \in \mathbb{R}^{2\times 2}$ has rank 2 and is invertible (Theorem 3.5.14). Now

$$(BA)^3 = B(AB)(AB)A = BM^2A = 9BMA = 9BABA = 9(BA)^2,$$

and multiplying by $\left((BA)^{-1}\right)^2$ gives $BA = 9I_2$.

(b) By Theorem 4.3.21, $M = CR$ with C the pivot columns of M and R the nonzero rows of $\operatorname{rref}(M)$:

$$A = \begin{pmatrix} 8 & 2 \\ 2 & 5 \\ -2 & 4 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 & -\frac{1}{2} \\ 0 & 1 & 1 \end{pmatrix}.$$

Indeed AB has columns $(8,2,-2)$, $(2,5,4)$, and $-\frac{1}{2}(8,2,-2) + (2,5,4) = (-2,4,5)$, and

$$BA = \begin{pmatrix} 8+1 & 2-2 \\ 2-2 & 5+4 \end{pmatrix} = 9I_2.$$

The identity $M^2 = 9M$ says that $M/9$ is idempotent of rank 2, and $BA/9$ is the corresponding identity on the 2-dimensional space through which M factors. This is Problem B6 of the 1969 Putnam Competition.

Solution to Problem 4.17

> *Uses.* Theorem 4.2.11 (Rank–nullity), Theorem 3.5.14 (Third Fundamental Theorem, completed), Theorem 4.1.10 (Independent lists are short), Proposition 2.6.18 (The column space is spanned by the columns), Notation 1.1.25 ($\mathbb{F}_p$)
> *Techniques.* Try small cases and small fields (Technique 1.2.38), Dimension counting (Technique 4.2.24)
> *Hint 1.* Show that every row of M_n has n entries 1 and n entries -1, so that $M_n\mathbf{1} = \mathbf{0}$ for $\mathbf{1} = (1,\ldots,1)$.
> *Hint 2.* For the lower bound, reduce the top left $2n \times 2n$ block modulo 2: it becomes $J - I$, where J is the all-ones matrix. Compute $(J-I)^2$ over $\mathbb{F}_2$. Then show that integer columns that are independent modulo 2 are independent over $\mathbb{Q}$.
> *Sketch.* a_{ij} depends only on $(i-j) \bmod (2n+1)$: it is 1 for residues $1,\ldots,n$ and -1 for $n+1,\ldots,2n$. So each row has n entries of each sign, $M_n\mathbf{1} = \mathbf{0}$, and $\operatorname{rank} M_n \leq 2n$. The top left $2n \times 2n$ block M' reduces modulo 2 to $J - I$, and $(J-I)^2 = (2n-2)J + I = I$ over $\mathbb{F}_2$. A rational relation among the columns of M' can be scaled to an integer relation with some odd coefficient, which reduces to a nontrivial relation over $\mathbb{F}_2$; impossible. So M' is invertible over $\mathbb{Q}$, the first $2n$ columns of M_n are independent, and $\operatorname{rank} M_n = 2n$.

Index rows and columns by $1,\ldots,2n+1$. For $i > j$, the entry a_{ij} lies on the $(i-j)$th diagonal below the main one, so $a_{ij} = 1$ if $i - j \leq n$ and $a_{ij} = -1$ if $i - j \geq n+1$. For $i < j$, $a_{ij} = -a_{ji}$ is -1 if $j - i \leq n$ and 1 if $j - i \geq n+1$. In both cases, with ρ the remainder of $i - j$ modulo $2n+1$ (so $\rho \in \{1,\ldots,2n\}$ for $i \neq j$; for $i < j$, $\rho = 2n+1-(j-i)$),

$$a_{ij} = 1 \text{ if } 1 \leq \rho \leq n, \quad a_{ij} = -1 \text{ if } n+1 \leq \rho \leq 2n.$$

Upper bound. In row i, as j runs over the $2n$ indices different from i, the remainder ρ runs over $1,\ldots,2n$, each once. So row i has n entries equal to 1 and n equal to -1, and $M_n\mathbf{1} = \mathbf{0}$ for $\mathbf{1} = (1,\ldots,1)$. Hence $\dim\ker M_n \geq 1$ and $\operatorname{rank} M_n \leq 2n$ (Theorem 4.2.11).

Lower bound. Let M' be the top left $2n \times 2n$ block of M_n. Its entries are integers, 0 on the diagonal and ± 1 elsewhere, so its reduction modulo 2 is $J - I$ over $\mathbb{F}_2$, where J is the all-ones matrix of size $2n$. Since $J^2 = (2n)J$, over $\mathbb{F}_2$

$$(J-I)^2 = J^2 - 2J + I = (2n-2)J + I = I,$$

so $J - I$ is invertible over $\mathbb{F}_2$ and its columns are independent there (Theorem 3.5.14). Now suppose the columns $\mathbf{c}_1,\ldots,\mathbf{c}_{2n}$ of M' satisfy $\sum_j t_j\mathbf{c}_j = \mathbf{0}$ with $t_j \in \mathbb{Q}$, not all 0. Multiplying by a common denominator, we may take the t_j to be integers, and dividing by the largest power of 2 that divides all of them, we may assume that some t_j is odd. Reducing the integer equation $\sum_j t_j\mathbf{c}_j = \mathbf{0}$ modulo 2 gives a relation among the columns of $J - I$ over $\mathbb{F}_2$ with a coefficient 1, which is impossible. So the columns of M' are independent

over $\mathbb{Q}$. A relation among the first $2n$ columns of M_n is, in its first $2n$ rows, a relation among the columns of M', so the first $2n$ columns of M_n are independent, and $\operatorname{rank} M_n \geq 2n$ (Proposition 2.6.18, Theorem 4.1.10).

So $\operatorname{rank} M_n = 2n$, over $\mathbb{Q}$ and therefore also over $\mathbb{R}$ (Gauss–Jordan elimination never leaves $\mathbb{Q}$). The same argument shows that M_n has rank $2n$ over $\mathbb{F}_2$ as well. Reducing modulo a prime can only lower the rank of an integer matrix, so a lower bound modulo p is a lower bound over $\mathbb{Q}$; this is the reason to look at the matrix modulo 2, where it becomes the very simple $J - I$. This is Problem B5 of the 1988 Putnam Competition.

Solution to Problem 4.18

Uses. Theorem 4.2.11 (Rank–nullity), Theorem 4.6.27 (Dimension of a quotient), Theorem 4.6.34 (First isomorphism theorem), Exercise 4.6.49, Exercise 4.6.50, Proposition 4.6.28 (Lifting a basis of a quotient), Proposition 4.2.3 (Properties of restriction), Example 2.6.27 (Differentiation on $F[x]$), Example 4.8.3 (Sylvester's inequality, three ways)
Techniques. Pass to a quotient (Technique 4.6.31), Restrict to a subspace (Technique 4.2.5)
Hint 1. (a) $\dim(W/\operatorname{im} T) = \dim W - \operatorname{rank} T$. For (c), compute $\dim\ker(ST)$ by restricting T to $\ker(ST)$: it maps onto $\ker S \cap \operatorname{im} T$ with kernel $\ker T$.
Hint 2. For the cokernel, use $\operatorname{im}(ST) \subseteq \operatorname{im} S \subseteq W$ and show $\operatorname{im} S/\operatorname{im}(ST) \cong V/(\operatorname{im} T + \ker S)$. For nested $A \subseteq B \subseteq X$, $\dim(X/A) = \dim(X/B) + \dim(B/A)$ by the third isomorphism theorem.
Sketch. (a) Rank–nullity and $\dim(W/\operatorname{im} T) = \dim W - \operatorname{rank} T$. (b) $\ker M = \{\mathbf{0}\}$, $\mathbb{Q}[x]/x\mathbb{Q}[x] \cong \mathbb{Q}$ by ev_0: $\operatorname{ind} M = -1$. $\ker D$ = constants and D is onto: $\operatorname{ind} D = 1$. (c) With $k = \dim(\ker S \cap \operatorname{im} T)$: $\dim\ker(ST) = \dim\ker T + k$. And $\dim(W/\operatorname{im} ST) = \dim(W/\operatorname{im} S) + \dim(V/\operatorname{im} T) - \dim\ker S + k$, using $\operatorname{im} S/\operatorname{im}(ST) \cong V/(\operatorname{im} T + \ker S)$ and $(\operatorname{im} T + \ker S)/\operatorname{im} T \cong \ker S/(\ker S \cap \operatorname{im} T)$. Subtract. $DM = \mathrm{id} + MD$ is bijective (index 0), and MD has kernel and cokernel of dimension 1.

We use one fact about nested subspaces $A \subseteq B \subseteq X$: if X/B and B/A are finite-dimensional, so is X/A, and

$$\dim(X/A) = \dim(X/B) + \dim(B/A). \tag{C.1.7}$$

Indeed B/A is a subspace of X/A with quotient $(X/A)/(B/A) \cong X/B$ (Exercise 4.6.50(c)), so Proposition 4.6.28 applies. Also, a subspace or a quotient of a finite-dimensional space is finite-dimensional.

(a) $\ker T$ is finite-dimensional, and $\dim(W/\operatorname{im} T) = \dim W - \operatorname{rank} T$ (Theorem 4.6.27). By rank–nullity, $\operatorname{ind} T = \dim\ker T - \dim W + \operatorname{rank} T = \dim V - \dim W$.

(b) M is injective, so $\ker M = \{\mathbf{0}\}$. Its image is $x\mathbb{Q}[x]$, the polynomials with constant coefficient 0, which is the kernel of the surjective map $\mathrm{ev}_0 : \mathbb{Q}[x] \to \mathbb{Q}$, $p \mapsto p(0)$. By the first isomorphism theorem (Theorem 4.6.34), $\mathbb{Q}[x]/x\mathbb{Q}[x] \cong \mathbb{Q}$. So M is Fredholm with $\operatorname{ind} M = 0 - 1 = -1$. Over $\mathbb{Q}$, $\ker D$ is the space of constants (Example 2.6.27), and D is surjective, since $x^k = D\big(x^{k+1}/(k+1)\big)$. So $\operatorname{ind} D = 1 - 0 = 1$.

(c) Let $k = \dim(\ker S \cap \operatorname{im} T)$, which is finite since $\ker S$ is finite-dimensional.

The kernel. $\ker(ST) = \{\mathbf{u} \mid T\mathbf{u} \in \ker S\}$. So T restricts to a linear map $R : \ker(ST) \to \ker S \cap \operatorname{im} T$, which is onto: if $\mathbf{y} = T\mathbf{u} \in \ker S$, then $\mathbf{u} \in \ker(ST)$. Its kernel is $\ker T$, which is contained in $\ker(ST)$. By the first isomorphism theorem, $\ker(ST)/\ker T \cong \ker S \cap \operatorname{im} T$, and by Proposition 4.6.28, $\ker(ST)$ is finite-dimensional with

$$\dim\ker(ST) = \dim\ker T + k.$$

The cokernel. We have $\operatorname{im}(ST) \subseteq \operatorname{im} S \subseteq W$. The map $\sigma : V \to \operatorname{im} S/\operatorname{im}(ST)$, $\mathbf{v} \mapsto S\mathbf{v} + \operatorname{im}(ST)$, is linear and surjective. Its kernel is the set of $\mathbf{v}$ with $S\mathbf{v} = ST\mathbf{u}$ for some $\mathbf{u}$, that is, with $\mathbf{v} - T\mathbf{u} \in \ker S$; so $\ker\sigma = \operatorname{im} T + \ker S$, and $\operatorname{im} S/\operatorname{im}(ST) \cong V/(\operatorname{im} T + \ker S)$. Apply (C.1.7) to $\operatorname{im} T \subseteq \operatorname{im} T + \ker S \subseteq V$. The space $V/\operatorname{im} T$ is finite-dimensional, hence so are its subspace $(\operatorname{im} T + \ker S)/\operatorname{im} T$ and its quotient $V/(\operatorname{im} T + \ker S)$, and

$$\dim(V/(\operatorname{im} T + \ker S)) = \dim(V/\operatorname{im} T) - \dim((\operatorname{im} T + \ker S)/\operatorname{im} T).$$

By the second isomorphism theorem (Exercise 4.6.49(a)), $(\operatorname{im} T + \ker S)/\operatorname{im} T \cong \ker S/(\ker S \cap \operatorname{im} T)$, of dimension $\dim\ker S - k$ (Theorem 4.6.27). So

$$\dim(\operatorname{im} S/\operatorname{im}(ST)) = \dim(V/\operatorname{im} T) - \dim\ker S + k.$$

Applying (C.1.7) to $\operatorname{im}(ST) \subseteq \operatorname{im} S \subseteq W$ shows that $W/\operatorname{im}(ST)$ is finite-dimensional, with

$$\dim(W/\operatorname{im}(ST)) = \dim(W/\operatorname{im} S) + \dim(V/\operatorname{im} T) - \dim\ker S + k.$$

The index. Subtracting,

$$\operatorname{ind}(ST) = \dim\ker T + k - \dim(W/\operatorname{im} S) - \dim(V/\operatorname{im} T) + \dim\ker S - k = \operatorname{ind} T + \operatorname{ind} S.$$

The check. $DM(p) = D(xp) = p + xD(p)$, so $DM\left(x^j\right) = (j+1)x^j$. Over $\mathbb{Q}$ this is a bijection on the basis of monomials up to nonzero factors, so DM is invertible and $\operatorname{ind}(DM) = 0 = \operatorname{ind} D + \operatorname{ind} M$. For MD, the kernel is $\ker D$ (constants, dimension 1), and the image is $M(D(\mathbb{Q}[x])) = M(\mathbb{Q}[x]) = x\mathbb{Q}[x]$, with 1-dimensional quotient. So $\operatorname{ind}(MD) = 1 - 1 = 0$, as the formula predicts.

For operators on a finite-dimensional space the index is 0 by (a), and that is the content of "injective if and only if surjective". On $\mathbb{Q}[x]$ the index of M is -1, which measures exactly how far M is from that statement: it is injective but misses a 1-dimensional space. The kernel computation in (c) is the kernel proof of Sylvester's inequality (Example 4.8.3), done with equality.

Section 5.1

Solution to Exercise 5.1.5

Uses. Definition 5.1.1 (Determinant function), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Hint 1. The columns of cA are $c\mathbf{a}_1, \ldots, c\mathbf{a}_n$. Pull the scalars out one column at a time.
Hint 2. For the zero column, a linear map sends $\mathbf{0}$ to 0. Alternatively, $\mathbf{0} = 0 \cdot \mathbf{0}$.
Sketch. Linearity in column j pulls out one factor c, for each of the n columns. A zero column $\mathbf{0} = 0 \cdot \mathbf{0}$ pulls out a factor 0.

The columns of cA are $c\mathbf{a}_1, \ldots, c\mathbf{a}_n$. By linearity in the first column, then the second, and so on,

$$D(c\mathbf{a}_1, c\mathbf{a}_2, \ldots, c\mathbf{a}_n) = cD(\mathbf{a}_1, c\mathbf{a}_2, \ldots, c\mathbf{a}_n) = \cdots = c^n D(\mathbf{a}_1, \ldots, \mathbf{a}_n).$$

Taking $c = -1$ gives $D(-A) = (-1)^n D(A)$. If the j-th column of A is $\mathbf{0}$, then $\mathbf{0} = 0 \cdot \mathbf{0}$, and linearity in column j gives $D(A) = 0 \cdot D(A) = 0$. (Equivalently, the linear map $\mathbf{x} \mapsto D(\ldots, \mathbf{x}, \ldots)$ sends $\mathbf{0}$ to 0 by Proposition 2.1.4.)

Solution to Exercise 5.1.16

Uses. Definition 5.1.14 (The 2×2 determinant), Definition 1.1.19 (Integers modulo n), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$)
Hint 1. Over $\mathbb{Q}$, $\det A = 3 \cdot 2 - 5 \cdot 4$.
Hint 2. Reducing the entries modulo p and then computing gives the same result as computing over $\mathbb{Z}$ and then reducing, by Lemma 1.1.21.
Sketch. Over $\mathbb{Q}$, $\det A = -14$. Over $\mathbb{F}_p$ it is $-14 \bmod p$, which is 0 exactly when $p \mid 14$, that is, $p = 2$ or $p = 7$.

Over $\mathbb{Q}$, $\det A = 3 \cdot 2 - 5 \cdot 4 = -14$. By Lemma 1.1.21, computing $ad - bc$ in $\mathbb{F}_p$ from the remainders of the entries gives the remainder of -14 modulo p. In $\mathbb{F}_7$ this is 0, since $7 \mid 14$. In $\mathbb{F}_2$ the matrix is $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, with determinant $1 \cdot 0 - 1 \cdot 0 = 0$, as it should be since $2 \mid 14$. In general $\det A = 0$ over $\mathbb{F}_p$ exactly when $p \mid 14$, that is, for $p = 2$ and $p = 7$.

Solution to Exercise 5.1.19

Uses. Definition 5.1.1 (Determinant function), Theorem 5.1.13 (The 2×2 determinant), Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives)
Hint 1. Normalization and alternation are a single evaluation and a substitution $b = a$, $d = c$. For multilinearity, fix one column and ask whether the value is a linear function of the entries of the other column.
Hint 2. A nonzero constant term, or a product of two entries from the same column, prevents linearity in that column.
Hint 3. Over $\mathbb{F}_2$, $-1 = 1$. Which of the four functions is affected?
Sketch. Over $\mathbb{Q}$: (a) fails all three axioms; (b) is multilinear only; (c) is $-\det$, which is multilinear and alternating but not normalized; (d) is normalized and alternating, but contains the product ac of two entries of the first column, so it is not multilinear. Over $\mathbb{F}_2$ only (c) changes: there $-\det = \det$ is a determinant function.

(a) $D(I_2) = 2 \neq 1$ and $D\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} = 1 \neq 0$, so D is neither normalized nor alternating. For the fixed second column $(0, 1)$, the map $(a, c) \mapsto a + 1$ sends $\mathbf{0}$ to 1, so it is not linear (Proposition 2.1.4), and D is not multilinear.

(b) For a fixed second column (b, d), $(a, c) \mapsto ba - dc$ is linear, and for a fixed first column (a, c), $(b, d) \mapsto ab - cd$ is linear, so D is multilinear. But $D(I_2) = 1 \cdot 0 - 0 \cdot 1 = 0$ and $D\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} = 1$, so D is neither normalized nor alternating.

(c) $D = -\det$. By Theorem 5.1.13, det is multilinear and alternating, and negating both sides of each defining identity shows that $-\det$ is too. But $D(I_2) = -1 \neq 1$.

(d) $D(I_2) = (1 - 0)(1 - 0) = 1$, and if the columns are equal, then $a = b$ and $D(A) = 0$. So D is normalized and alternating. For the fixed second column $(0, 0)$, $D(A) = a(-c) = -ac$. The map $(a, c) \mapsto -ac$ is not linear: it sends $(1, 1)$ to -1 and $(2, 2) = 2(1, 1)$ to $-4 \neq 2 \cdot (-1)$. So D is not multilinear.

Over $\mathbb{F}_2$. In (a), $D(I_2) = 1 + 1 = 0$, and the other two failures are unchanged. In (b) nothing changes. In (d), the map $(a, c) \mapsto -ac = ac$ sends $(1, 0)$ and $(0, 1)$ to 0 but their sum $(1, 1)$ to 1, so it is still not linear. In (c), $-1 = 1$, so $D = -\det = \det$ is a determinant function. So only the answer to (c) changes.

Solution to Exercise 5.1.20

Uses. Definition 5.1.1 (Determinant function), Proposition 5.1.10 (Alternating implies antisymmetric), Lemma 5.1.8 (Column replacement)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. In (a) and (b), every column is a multiple of a standard basis vector. Pull out the scalars, then sort the columns into the order $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ by interchanges.
Hint 2. In (c), use Lemma 5.1.8 to clear the entries above the diagonal, working from the left.
Sketch. (a) $D = 5 \cdot 3 \cdot 2 \cdot D(\mathbf{e}_3, \mathbf{e}_2, \mathbf{e}_1) = -30$, one interchange. (b) $D(\mathbf{e}_3, \mathbf{e}_1, \mathbf{e}_2) = 1$, two interchanges. (c) Column replacements turn A into I_3, so $D(A) = 1$.

(a) The columns are $5\mathbf{e}_3$, $3\mathbf{e}_2$, and $2\mathbf{e}_1$. By linearity in each column and then Proposition 5.1.10 (interchanging columns 1 and 3),

$$D(A) = 30D(\mathbf{e}_3, \mathbf{e}_2, \mathbf{e}_1) = -30D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3) = -30.$$

(b) The columns are $\mathbf{e}_3, \mathbf{e}_1, \mathbf{e}_2$. Interchanging columns 1 and 2, then columns 2 and 3,

$$D(A) = D(\mathbf{e}_3, \mathbf{e}_1, \mathbf{e}_2) = -D(\mathbf{e}_1, \mathbf{e}_3, \mathbf{e}_2) = D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3) = 1.$$

(c) The columns are $\mathbf{e}_1$, $2\mathbf{e}_1 + \mathbf{e}_2$, and $3\mathbf{e}_1 + 4\mathbf{e}_2 + \mathbf{e}_3$. By Lemma 5.1.8, subtracting 2 times column 1 from column 2, then 3 times column 1 from column 3, does not change D, and leaves the columns $\mathbf{e}_1$, $\mathbf{e}_2$, $4\mathbf{e}_2 + \mathbf{e}_3$. Subtracting 4 times the new column 2 from column 3 leaves $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$. So $D(A) = D(I_3) = 1$.

Solution to Exercise 5.1.21

Uses. Definition 5.1.1 (Determinant function), Exercise 5.1.5, Remark 5.1.4
Hint 1. Linearity in column j splits column j while the other columns stay fixed. Carry out the splitting honestly for $n = 2$.
Hint 2. Test the claim with $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$.
Sketch. For $n \geq 2$, splitting each column separately produces 2^n terms, not 2; the proof keeps only two of them. For $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$, $\det(A + B) = 1$ but $\det A + \det B = 0$.

The middle equality is wrong. Linearity in column j applies when the other columns are held fixed, so it splits one column at a time. For $n = 2$, splitting column 1 and then column 2 gives four terms:

$$D(A + B) = D(\mathbf{a}_1, \mathbf{a}_2) + D(\mathbf{a}_1, \mathbf{b}_2) + D(\mathbf{b}_1, \mathbf{a}_2) + D(\mathbf{b}_1, \mathbf{b}_2),$$

and in general there are 2^n terms. The argument silently drops all of them except $D(A)$ and $D(B)$. The claim is false for every $n \geq 2$. For $n = 2$, take $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$: then $A + B = I_2$, so $D(A + B) = 1$, while $D(A) = D(B) = 0$ because each has a zero column (Exercise 5.1.5). (For $n = 1$ the claim is true, since $D(a) = a$ by Example 5.1.2.)

Solution to Exercise 5.1.22

Uses. Proposition 5.1.17 (Dependent columns), Theorem 5.1.13 (The 2×2 determinant)

Hint 1. Compare the logical form of the proposition with the way it is used.
Hint 2. Is there a multilinear alternating D that vanishes at a matrix with independent columns?
Sketch. The argument uses the converse of Proposition 5.1.17. The claim is false for $D = 0$ and $A = I_n$.

Proposition 5.1.17 says "dependent columns $\Rightarrow D(A) = 0$". The argument uses the converse, "$D(A) = 0 \Rightarrow$ dependent columns", which does not follow. In fact the claim is false: $D = 0$ is multilinear and alternating, and $D(I_n) = 0$ although the columns of I_n are independent.

For a determinant function, the conclusion is true, but the proof must use normalization: for $n = 2$ see Exercise 5.1.25, and for general n see Theorem 5.4.7.

Solution to Exercise 5.1.23

Uses. Definition 5.1.14 (The 2×2 determinant), Example 5.1.15 (det is signed area)
Hint 1. The pieces are: two right triangles with legs a and c, two with legs b and d, and two rectangles with sides b and c.
Hint 2. For (b), compare the slopes c/a and d/b of the two edges.
Sketch. The area of P is $(a+b)(c+d) - ac - bd - 2bc = ad - bc$. The inequality $ad > bc$ says $c/a < d/b$, so (b, d) is steeper than (a, c) and lies counterclockwise from it.

(a) Because $ad > bc$, the vector (a, c) has smaller slope than (b, d) (see (b)), so P sits in the rectangle as in Figure 5.1.2, and P together with the six pieces below tiles the rectangle without overlaps. (If $ad \leq bc$, the pieces would overlap and the computation below would not apply.) The rectangle has area $(a+b)(c+d)$. Outside P it contains two right triangles with legs a and c (below the edge from $\mathbf{0}$ to (a, c) and above the opposite edge), two right triangles with legs b and d (left of the edge from $\mathbf{0}$ to (b, d) and right of the opposite edge), and two rectangles with sides b and c (in the lower right and upper left corners). So

$$\operatorname{area}(P) = (a+b)(c+d) - 2 \cdot \frac{ac}{2} - 2 \cdot \frac{bd}{2} - 2bc = ac + ad + bc + bd - ac - bd - 2bc = ad - bc.$$

(b) Since $a, b > 0$, dividing $ad > bc$ by ab gives $d/b > c/a$. Both vectors lie in the open first quadrant, and (b, d) has the larger slope, so its polar angle is larger: turning from (a, c) to (b, d) is a counterclockwise turn through an angle in $(0, \pi/2)$. So the signed area of Example 5.1.15 is $+\operatorname{area}(P) = ad - bc = \det\begin{pmatrix} a & b \\ c & d \end{pmatrix}$, consistent with (a).

Solution to Exercise 5.1.24

Uses. Definition 5.1.1 (Determinant function), Definition 1.1.28 (Characteristic)
Hint 1. For (b), only alternation is in doubt. Compute per at a matrix with two equal columns (a, c).
Hint 2. You get $ac + ca = (1+1)ac$. When does this vanish for all a, c?
Sketch. (a) is a direct check. (b) With equal columns, per $A = (1+1)ac$, which vanishes for all a, c exactly when $1 + 1 = 0$. So per is a determinant function exactly when $\operatorname{char} F = 2$, and then per $=$ det.

(a) $\operatorname{per}(I_2) = 1 \cdot 1 + 0 \cdot 0 = 1$. For a fixed second column (b, d), the map $(a, c) \mapsto da + bc$ is linear, and for a fixed first column (a, c), the map $(b, d) \mapsto cb + ad$ is linear, so per is multilinear. Interchanging the columns gives $\begin{pmatrix} b & a \\ d & c \end{pmatrix}$, whose permanent is $bc + ad = \operatorname{per} A$.

(b) By (a), per is a determinant function if and only if it is alternating. A matrix with equal columns is $\begin{pmatrix} a & a \\ c & c \end{pmatrix}$, with permanent $ac + ac = (1+1)ac$. If $1 + 1 = 0$, this is 0 for all a, c. If $1 + 1 \neq 0$, then $a = c = 1$ gives $1 + 1 \neq 0$. So per is a determinant function on $F^{2\times 2}$ if and only if $1 + 1 = 0$, that is, $\operatorname{char} F = 2$ (Definition 1.1.28). In that case $-bc = bc$, so per $=$ det, as Theorem 5.1.13 requires.

Solution to Exercise 5.1.25

Uses. Proposition 5.1.17 (Dependent columns), Definition 1.5.1 (Linear independence), Corollary 3.5.25 (The invertible matrix theorem), Theorem 3.5.12 (First Fundamental Theorem, completed), Definition 2.4.1 (Matrix product), Definition 2.5.12 (Invertible)
Hint 1. One direction is Proposition 5.1.17. For the other, you need an explicit dependence relation built from a, b, c, d.
Hint 2. Compute $d(a, c) - c(b, d)$ and $-b(a, c) + a(b, d)$.
Hint 3. Both are multiples of $\det A$. When are their coefficients not both zero?

Sketch. $d\mathbf{a}_1 - c\mathbf{a}_2 = (\det A, 0)$ and $-b\mathbf{a}_1 + a\mathbf{a}_2 = (0, \det A)$. If $\det A = 0$, one of these is a nontrivial dependence unless $A = 0$. For (b), combine with the Fundamental Theorems, and multiply out to check the inverse.

Write $\mathbf{a}_1 = (a, c)$ and $\mathbf{a}_2 = (b, d)$.

(a) If the columns are dependent, then $\det A = 0$ by Proposition 5.1.17, since det is multilinear and alternating (Theorem 5.1.13). Conversely, suppose $\det A = 0$. We compute

$$d\mathbf{a}_1 - c\mathbf{a}_2 = (da - cb, dc - cd) = (\det A, 0) = \mathbf{0}, \quad -b\mathbf{a}_1 + a\mathbf{a}_2 = (-ba + ab, -bc + ad) = (0, \det A) = \mathbf{0}.$$

If $(c, d) \neq (0, 0)$, the first relation has coefficients $d, -c$ not both zero, so the columns are dependent. If $c = d = 0$ but $(a, b) \neq (0, 0)$, the second relation has coefficients $-b, a$ not both zero. If $a = b = c = d = 0$, then $\mathbf{a}_1 = \mathbf{0}$, and $1 \cdot \mathbf{a}_1 + 0 \cdot \mathbf{a}_2 = \mathbf{0}$ is a dependence. In every case the columns are dependent.

(b) By Corollary 3.5.25 and Theorem 3.5.12 (as in the proof of Corollary 5.1.18), a square matrix is invertible if and only if its columns are linearly independent. By (a), this happens if and only if $\det A \neq 0$. Now let $C = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$. Multiplying out,

$$AC = \begin{pmatrix} ad - bc & -ab + ba \\ cd - dc & -cb + da \end{pmatrix} = (\det A) I_2, \quad CA = \begin{pmatrix} da - bc & db - bd \\ -ca + ac & -cb + ad \end{pmatrix} = (\det A) I_2.$$

If $\det A \neq 0$, it follows that $(\det A)^{-1} C$ is a two-sided inverse of A.

Solution to Exercise 5.1.26

Uses. Definition 5.1.14 (The 2×2 determinant), Exercise 5.1.25, Exercise 1.1.44
Hint 1. Use $i^2 = -1$.
Hint 2. By Exercise 5.1.25, the columns are dependent exactly when the determinant is 0. Compute it as a polynomial in z.
Sketch. (a) $(1 + i)(1 - i) - 2i = 2 - 2i$. (b) The determinant is $z^2 - i^2 = z^2 + 1$, which vanishes exactly for $z = \pm i$. For $z = i$ the columns are equal; for $z = -i$ they are negatives of each other.

(a) $(1 + i)(1 - i) - 2 \cdot i = 1 - i^2 - 2i = 2 - 2i$.

(b) The determinant is $z \cdot z - i \cdot i = z^2 + 1$. By Exercise 5.1.25, the columns are dependent exactly when $z^2 + 1 = 0$, that is (Exercise 1.1.44), when $z = i$ or $z = -i$. For $z = i$ both columns are (i, i), so $\mathbf{a}_1 - \mathbf{a}_2 = \mathbf{0}$. For $z = -i$ the columns are $(-i, i)$ and $(i, -i)$, so $\mathbf{a}_1 + \mathbf{a}_2 = \mathbf{0}$.

Solution to Exercise 5.1.27

Uses. Theorem 5.1.13 (The 2×2 determinant), Definition 2.4.1 (Matrix product), Definition 2.3.15 (The linear map of a matrix), Proposition 2.1.17 (Compositions of linear maps are linear)
Hint 1. Fix A and regard $D(B) = \det(AB)$ as a function of the columns of B.
Hint 2. The columns of AB are $A\mathbf{b}_1$ and $A\mathbf{b}_2$. Show that D is multilinear and alternating, and apply part (a) of Theorem 5.1.13.
Sketch. $D(\mathbf{b}_1, \mathbf{b}_2) = \det(A\mathbf{b}_1, A\mathbf{b}_2)$ is multilinear, because $\mathbf{x} \mapsto A\mathbf{x}$ is linear, and alternating, because equal columns of B give equal columns of AB. So $D(B) = \det(B) D(I_2) = \det B \det A$.

Fix A, and define $D : F^{2\times 2} \to F$ by $D(B) = \det(AB)$. The columns of AB are $A\mathbf{b}_1$ and $A\mathbf{b}_2$ (Definition 2.4.1), so $D(\mathbf{b}_1, \mathbf{b}_2) = \det(A\mathbf{b}_1, A\mathbf{b}_2)$.

Multilinear. For fixed $\mathbf{b}_2$, the map $\mathbf{x} \mapsto \det(A\mathbf{x}, A\mathbf{b}_2)$ is the composite of the linear map T_A with the linear map $\mathbf{y} \mapsto \det(\mathbf{y}, A\mathbf{b}_2)$, so it is linear (Proposition 2.1.17). The same holds in the second column.

Alternating. If $\mathbf{b}_1 = \mathbf{b}_2$, then $A\mathbf{b}_1 = A\mathbf{b}_2$, so $D(B) = 0$.

By part (a) of Theorem 5.1.13, $D(B) = \det(B) D(I_2) = \det(B) \det(A)$, as desired.

Solution to Exercise 5.1.27

Uses. Definition 5.1.14 (The 2×2 determinant), Definition 2.4.1 (Matrix product)
Hint 1. Write $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ and $B = \begin{pmatrix} p & q \\ r & s \end{pmatrix}$ and compute AB.
Hint 2. Expand $\det(AB)$; four of the eight products cancel in pairs.

Sketch. $AB = \begin{pmatrix} ap+br & aq+bs \\ cp+dr & cq+ds \end{pmatrix}$. Expanding the determinant, the terms $acpq$ and $bdrs$ cancel, and the rest factor as $(ad-bc)(ps-qr)$.

With $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ and $B = \begin{pmatrix} p & q \\ r & s \end{pmatrix}$, we have $AB = \begin{pmatrix} ap+br & aq+bs \\ cp+dr & cq+ds \end{pmatrix}$, so

$$\begin{aligned} \det(AB) &= (ap+br)(cq+ds) - (aq+bs)(cp+dr) \\ &= acpq + adps + bcqr + bdrs - acpq - adqr - bcps - bdrs \\ &= ad(ps-qr) - bc(ps-qr) = (ad-bc)(ps-qr) = \det A \det B. \end{aligned}$$

The first approach is the one that generalizes: Theorem 5.4.10 proves $\det(AB) = \det A \det B$ for all n, and the direct computation would be hopeless for large n.

Solution to Exercise 5.1.28

Uses. Exercise 5.1.27, Lemma 5.1.8 (Column replacement), Example 5.1.15 (det is signed area)
Hint 1. Use Exercise 5.1.27 and compute $\det R_\theta$ and $\det S_t$.
Hint 2. For the interpretation: the columns of $R_\theta A$ are the columns of A rotated by θ, and the columns of AS_t are $\mathbf{a}_1$ and $\mathbf{a}_2 + t\mathbf{a}_1$.
Sketch. $\det R_\theta = \cos^2\theta + \sin^2\theta = 1$ and $\det S_t = 1$, so both equalities follow from multiplicativity. Rotating a parallelogram, or sliding one edge parallel to the other, preserves its signed area.

By Exercise 5.1.27, $\det(R_\theta A) = \det(R_\theta)\det A$ and $\det(AS_t) = \det A \det S_t$. Since $\det R_\theta = \cos^2\theta + \sin^2\theta = 1$ and $\det S_t = 1 \cdot 1 - t \cdot 0 = 1$, both equalities hold. (The second also follows from Lemma 5.1.8, since AS_t has columns $\mathbf{a}_1$ and $\mathbf{a}_2 + t\mathbf{a}_1$.)

The columns of $R_\theta A$ are $R_\theta \mathbf{a}_1$ and $R_\theta \mathbf{a}_2$, so $P(R_\theta \mathbf{a}_1, R_\theta \mathbf{a}_2)$ is $P(\mathbf{a}_1, \mathbf{a}_2)$ rotated by θ, and the first equality says that rotation preserves signed area (area and orientation). The second says that sliding the edge $\mathbf{a}_2$ parallel to the edge $\mathbf{a}_1$ preserves signed area. These are the two facts used informally in Intuition (Signed area is linear in each column); with Example 5.1.15 they are now theorems.

Solution to Exercise 5.1.29

Uses. Theorem 5.1.13 (The 2×2 determinant), Definition 5.1.14 (The 2×2 determinant)
Hint 1. By Theorem 5.1.13, every multilinear alternating D is $c\det$ for $c = D(I_2)$. Conversely, which multiples of det are multilinear and alternating?
Hint 2. So the condition is $c\det\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} = 6$, that is, $-2c = 6$. Solve it in each field.
Sketch. The candidates are exactly $D = c\det$ with $c \in F$, and the condition is $-2c = 6$. Over $\mathbb{Q}$, $c = -3$. Over $\mathbb{F}_2$, it reads $0 = 0$, so $D = 0$ and $D = \det$ both work. Over $\mathbb{F}_3$, it reads $c = 0$, so only $D = 0$.

By part (a) of Theorem 5.1.13, every multilinear alternating D equals $c\det$ with $c = D(I_2)$. Conversely, for every $c \in F$ the function $c\det$ is multilinear and alternating, since multiplying the identities defining these properties by c preserves them. So the functions in question are the $c\det$ with $c\det\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} = 6$. Since $\det\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} = 4 - 6 = -2$, the condition is $-2c = 6$.

(a) Over $\mathbb{Q}$, $c = -3$, so $D = -3\det$ is the only one.

(b) Over $\mathbb{F}_2$, $-2 = 0$ and $6 = 0$, so the condition holds for both $c = 0$ and $c = 1$: the answers are $D = 0$ and $D = \det$.

(c) Over $\mathbb{F}_3$, $-2 = 1$ and $6 = 0$, so $c = 0$, and $D = 0$ is the only one.

Solution to Exercise 5.1.30

Uses. Definition 5.1.1 (Determinant function), Theorem 5.1.13 (The 2×2 determinant), Exercise 1.1.18
Hint 1. Normalization and alternation hold over every field. Test multilinearity on $(c\mathbf{e}_1, \mathbf{e}_2)$.
Hint 2. Multilinearity would force $c^2 = c$ for every $c \in F$. Which fields satisfy this? (See Exercise 1.1.18.)
Sketch. $(\det I_2)^2 = 1$, and equal columns give $0^2 = 0$. Linearity in the first column forces $c^2 = (\det(c\mathbf{e}_1, \mathbf{e}_2))^2 = c$ for all c, so $F = \{0, 1\}$, which is $\mathbb{F}_2$. Over $\mathbb{F}_2$, $x^2 = x$ for every x, so $(\det A)^2 = \det A$.

Let $E(A) = (\det A)^2$. Then $E(I_2) = 1$, and if the columns of A are equal, then $\det A = 0$ and $E(A) = 0$. So E is a determinant function if and only if it is multilinear.

Suppose E is multilinear. For every $c \in F$, linearity in the first column gives $E(c\mathbf{e}_1, \mathbf{e}_2) = cE(\mathbf{e}_1, \mathbf{e}_2) = c$, while directly $E(c\mathbf{e}_1, \mathbf{e}_2) = \left(\det\begin{pmatrix} c & 0 \\ 0 & 1 \end{pmatrix}\right)^2 = c^2$. So $c^2 = c$ for every $c \in F$, and by Exercise 1.1.18 every element of F is 0 or 1. Thus $F = \{0, 1\}$. In such a field $1 + 1 \neq 1$ (else $1 = 0$), so $1 + 1 = 0$ and F has the tables of $\mathbb{F}_2$.

Conversely, in $\mathbb{F}_2$ we have $0^2 = 0$ and $1^2 = 1$, so $E(A) = \det A$ for every A, and E is a determinant function by Theorem 5.1.13. So the answer is: exactly when $F = \mathbb{F}_2$.

Solution to Exercise 5.1.31

Uses. Theorem 5.1.13 (The 2×2 determinant), Exercise 5.1.25, Proposition 5.1.10 (Alternating implies antisymmetric), Non-example 5.1.3 (One axiom at a time)
Hint 1. (a) Use part (a) of Theorem 5.1.13 and Exercise 5.1.25.
Hint 2. (b) The hypothesis $D(cA) = c^2 D(A)$ is weaker than multilinearity. Look back at Non-example 5.1.3.
Hint 3. (c) Count the interchanges needed to sort $\mathbf{a}_2, \mathbf{a}_3, \mathbf{a}_1$.
Sketch. (a) True: $0 = D(A) = \det(A)D(I_2)$ with $\det A \neq 0$, so $D(I_2) = 0$ and $D = 0$. (b) False: $D = |\det|$. (c) True: two interchanges.

(a) True. By part (a) of Theorem 5.1.13, $D = D(I_2)\det$. Since A is invertible, $\det A \neq 0$ by Exercise 5.1.25, so $0 = D(A) = D(I_2)\det A$ forces $D(I_2) = 0$, and then $D = 0$.

(b) False. Let $D(A) = |\det A|$. It is alternating (Non-example 5.1.3), and $D(cA) = \left|c^2 \det A\right| = c^2 D(A)$. If $D = \lambda \det$ for some $\lambda \in \mathbb{R}$, then evaluating at I_2 gives $\lambda = 1$, and evaluating at $\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$ gives $1 = -\lambda$. These are incompatible.

(c) True. Interchanging columns 1 and 3 and then columns 2 and 3, Proposition 5.1.10 gives

$$D(\mathbf{a}_2, \mathbf{a}_3, \mathbf{a}_1) = -D(\mathbf{a}_1, \mathbf{a}_3, \mathbf{a}_2) = D(\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3).$$

Solution to Exercise 5.1.32

Uses. Definition 5.1.1 (Determinant function), Theorem 5.1.13 (The 2×2 determinant)
Hint 1. Each coordinate of $\mathbf{x} \times \mathbf{y}$ is a 2×2 determinant built from two coordinates of $\mathbf{x}$ and of $\mathbf{y}$. Use this for multilinearity.
Hint 2. For alternation there are three cases: $\mathbf{x} = \mathbf{y}$, $\mathbf{y} = \mathbf{z}$, and $\mathbf{x} = \mathbf{z}$. In the last two, expand and watch the six terms cancel in pairs.
Sketch. Each $(\mathbf{x} \times \mathbf{y})_k$ is bilinear in $\mathbf{x}, \mathbf{y}$, so each term $(\mathbf{x} \times \mathbf{y})_k z_k$ is linear in each of $\mathbf{x}, \mathbf{y}, \mathbf{z}$. $\mathbf{x} \times \mathbf{x} = \mathbf{0}$, and $(\mathbf{x} \times \mathbf{y}) \cdot \mathbf{y}$ and $(\mathbf{x} \times \mathbf{y}) \cdot \mathbf{x}$ expand to six terms cancelling in pairs. $\mathbf{e}_1 \times \mathbf{e}_2 = \mathbf{e}_3$.

Multilinear. The coordinate $(\mathbf{x} \times \mathbf{y})_3 = x_1 y_2 - x_2 y_1$ is the determinant of $\begin{pmatrix} x_1 & y_1 \\ x_2 & y_2 \end{pmatrix}$, and similarly for the other two coordinates, so by Theorem 5.1.13 each coordinate of $\mathbf{x} \times \mathbf{y}$ is linear in $\mathbf{x}$ for fixed $\mathbf{y}$, and linear in $\mathbf{y}$ for fixed $\mathbf{x}$. Hence each term $(\mathbf{x} \times \mathbf{y})_k z_k$ is linear in each of $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$ when the other two are fixed, and so is their sum D.

Alternating. If $\mathbf{x} = \mathbf{y}$, every coordinate of $\mathbf{x} \times \mathbf{x}$ has the form $x_i x_j - x_j x_i = 0$, so $D = 0$. If $\mathbf{y} = \mathbf{z}$,

$$D = (x_2 y_3 - x_3 y_2) y_1 + (x_3 y_1 - x_1 y_3) y_2 + (x_1 y_2 - x_2 y_1) y_3,$$

and the six terms cancel in pairs: $x_2 y_1 y_3$ with $-x_2 y_1 y_3$, $-x_3 y_1 y_2$ with $x_3 y_1 y_2$, and $-x_1 y_2 y_3$ with $x_1 y_2 y_3$. If $\mathbf{x} = \mathbf{z}$,

$$D = (x_2 y_3 - x_3 y_2) x_1 + (x_3 y_1 - x_1 y_3) x_2 + (x_1 y_2 - x_2 y_1) x_3,$$

and again $x_1 x_2 y_3$, $x_1 x_3 y_2$, and $x_2 x_3 y_1$ each appear once with each sign.

Normalized. $\mathbf{e}_1 \times \mathbf{e}_2 = (0 \cdot 0 - 0 \cdot 1, 0 \cdot 0 - 1 \cdot 0, 1 \cdot 1 - 0 \cdot 0) = \mathbf{e}_3$, so $D(I_3) = D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3) = 1$.

Solution to Exercise 5.1.33

Uses. Proposition 5.1.10 (Alternating implies antisymmetric), Proposition 5.1.17 (Dependent columns), Corollary 5.1.18 (Non-invertible matrices), Exercise 5.1.32
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. The columns are $\mathbf{e}_1 + 3\mathbf{e}_2$, $\mathbf{e}_2 + 4\mathbf{e}_3$, and $2\mathbf{e}_1 + \mathbf{e}_3$. Expanding gives eight terms. Discard those with a repeated basis vector.

Hint 2. Exactly two terms survive. One of them needs $D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1)$; compute it with interchanges.
Hint 3. For (b), solve $A\mathbf{x} = \mathbf{0}$ over $\mathbb{F}_5$, starting from the first row.
Sketch. The surviving terms are $D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$ and $3 \cdot 4 \cdot 2 \cdot D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1) = 24D(I_3)$, so $D(A) = 25D(I_3)$. Over $\mathbb{F}_5$, $3\mathbf{a}_1 + \mathbf{a}_2 + \mathbf{a}_3 = (5, 10, 5) = \mathbf{0}$, and $25 = 0$. Over $\mathbb{Q}$, a determinant function gives $D(A) = 25 \neq 0$.

(a) The columns are $\mathbf{a}_1 = \mathbf{e}_1 + 3\mathbf{e}_2$, $\mathbf{a}_2 = \mathbf{e}_2 + 4\mathbf{e}_3$, and $\mathbf{a}_3 = 2\mathbf{e}_1 + \mathbf{e}_3$. Expanding each column by multilinearity writes $D(A)$ as a sum of eight terms, one for each choice of a basis vector from each column. A term in which some $\mathbf{e}_k$ is chosen twice is 0 because D is alternating. If $\mathbf{e}_1$ is chosen from $\mathbf{a}_1$, then $\mathbf{a}_3$ must contribute $\mathbf{e}_3$, so $\mathbf{a}_2$ must contribute $\mathbf{e}_2$. If $\mathbf{e}_2$ is chosen from $\mathbf{a}_1$, then $\mathbf{a}_2$ must contribute $\mathbf{e}_3$, so $\mathbf{a}_3$ must contribute $\mathbf{e}_1$. So only two terms survive:

$$D(A) = 1 \cdot 1 \cdot 1 \cdot D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3) + 3 \cdot 4 \cdot 2 \cdot D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1).$$

By two interchanges (Proposition 5.1.10), $D(\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1) = -D(\mathbf{e}_1, \mathbf{e}_3, \mathbf{e}_2) = D(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$. Hence $D(A) = (1 + 24)D(I_3) = 25D(I_3)$.

(b) Over $\mathbb{F}_5$, solve $A\mathbf{x} = \mathbf{0}$: the first row gives $x_1 = -2x_3 = 3x_3$, the second gives $x_2 = -3x_1 = -9x_3 = x_3$, and the third, $4x_2 + x_3 = 5x_3 = 0$, then holds automatically. Taking $x_3 = 1$,

$$3\mathbf{a}_1 + \mathbf{a}_2 + \mathbf{a}_3 = (3 + 0 + 2, 9 + 1 + 0, 0 + 4 + 1) = (5, 10, 5) = \mathbf{0} \quad \text{in } \mathbb{F}_5^3.$$

So the columns are dependent over $\mathbb{F}_5$, and Proposition 5.1.17 gives $D(A) = 0$. This agrees with (a), because $25 = 0$ in $\mathbb{F}_5$.

(c) Let D be a determinant function on $\mathbb{Q}^{3\times 3}$. By (a), $D(A) = 25 \neq 0$, so A is invertible by Corollary 5.1.18.

Solution to Exercise 5.1.34

Uses. Lemma 2.1.22 (Functions into a vector space), Definition 1.4.1 (Subspace), Theorem 1.4.3 (Subspace criterion), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space), Theorem 5.1.13 (The 2×2 determinant), Definition 4.1.5 (Dimension)
Hint 1. For (a), check that $0 \in \mathrm{Alt}_n$ and that $D + sD'$ is multilinear and alternating whenever D and D' are.
Hint 2. For (b), part (a) of Theorem 5.1.13 says every element of Alt_2 is a multiple of det.
Sketch. Sums and scalar multiples of linear maps are linear, and $0 + 0 = 0$, so Alt_n is closed under linear combinations. By Theorem 5.1.13, Alt_2 consists exactly of the multiples of det $\neq 0$, so det alone is a basis.

(a) The zero function is multilinear and alternating. Let $D, D' \in \mathrm{Alt}_n$ and $s \in F$, and let $E = D + sD'$. Fix a column index j and the other columns. The map $\mathbf{x} \mapsto E(\ldots, \mathbf{x}, \ldots)$ is $\mathbf{x} \mapsto D(\ldots, \mathbf{x}, \ldots) + sD'(\ldots, \mathbf{x}, \ldots)$, a linear combination of two linear maps $F^n \to F$, hence linear (Proposition 2.1.23). If A has two equal columns, then $E(A) = D(A) + sD'(A) = 0 + s \cdot 0 = 0$. So $E \in \mathrm{Alt}_n$, and Alt_n is a subspace by Theorem 1.4.3.

(b) By part (b) of Theorem 5.1.13, $\det \in \mathrm{Alt}_2$, so $\mathrm{span}(\det) \subseteq \mathrm{Alt}_2$ by (a). By part (a) of Theorem 5.1.13, every $D \in \mathrm{Alt}_2$ equals $D(I_2) \det \in \mathrm{span}(\det)$. Hence $\mathrm{Alt}_2 = \mathrm{span}(\det)$. Since $\det(I_2) = 1$, det is not the zero function, so the one-element list det is linearly independent and is a basis of Alt_2. Thus $\dim \mathrm{Alt}_2 = 1$.

The expansion in Intuition (What the proof did, and where it leads) suggests that $\dim \mathrm{Alt}_n = 1$ for every n; this follows from Section 5.3.

Solution to Exercise 5.1.35

Uses. Proposition 5.1.10 (Alternating implies antisymmetric), Definition 5.1.1 (Determinant function)
Hint 1. First show that interchanging two adjacent columns negates D. Which hypothesis did the first proof of Proposition 5.1.10 actually use?
Hint 2. If $\mathbf{a}_i = \mathbf{a}_j$ with $j > i + 1$, move column j to position $i + 1$ by interchanging adjacent columns.
Sketch. The expansion proof of Proposition 5.1.10, with $j = i + 1$, uses alternation only for columns i and $i + 1$, so adjacent interchanges negate D. If $\mathbf{a}_i = \mathbf{a}_j$ with $i < j$, then $j - i - 1$ adjacent interchanges bring column j next to column i, giving a matrix A' with $D(A') = 0$ and $D(A) = \pm D(A')$.

Step 1. Fix i and the columns other than i and $i + 1$, and let $f(\mathbf{x}, \mathbf{y})$ be the value of D with $\mathbf{x}$ in column i and $\mathbf{y}$ in column $i + 1$. By hypothesis $f(\mathbf{x}, \mathbf{x}) = 0$ for every $\mathbf{x}$. The first proof of Proposition 5.1.10 used nothing else besides multilinearity, so it gives $f(\mathbf{y}, \mathbf{x}) = -f(\mathbf{x}, \mathbf{y})$. That is, interchanging two adjacent columns negates D.

Step 2. Let A have $\mathbf{a}_i = \mathbf{a}_j$ with $i < j$. If $j = i + 1$, then $D(A) = 0$ by hypothesis. Otherwise, interchange columns $j - 1$ and j, then columns $j - 2$ and $j - 1$, and so on, ending with columns $i + 1$ and $i + 2$. These $j - i - 1$ adjacent interchanges move the vector $\mathbf{a}_j$ from position j to position $i + 1$, and never touch column i. The resulting matrix A' has $\mathbf{a}_i$ in column i and $\mathbf{a}_j = \mathbf{a}_i$ in column $i + 1$, so $D(A') = 0$. By Step 1, $D(A) = (-1)^{j-i-1} D(A') = 0$. Hence D is alternating.

Solution to Exercise 5.1.36

Uses. Proposition 5.1.17 (Dependent columns), Theorem 4.1.10 (Independent lists are short), Remark 5.1.6
Hint 1. What can you say about any k vectors in F^n when $k > n$?
Hint 2. They are dependent. Now repeat the first proof of Proposition 5.1.17 for f.
Sketch. Any $k > n = \dim F^n$ vectors are dependent, so one of them is a combination of the others. Expanding f in that slot gives terms with a repeated argument.

Let $\mathbf{v}_1, \ldots, \mathbf{v}_k \in F^n$. Since $\dim F^n = n < k$, the list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is linearly dependent (Theorem 4.1.10). As in the first proof of Proposition 5.1.17, some $\mathbf{v}_m$ equals $\sum_{j \neq m} b_j \mathbf{v}_j$, and linearity in slot m gives

$$f(\mathbf{v}_1, \ldots, \mathbf{v}_k) = \sum_{j \neq m} b_j f\big(\mathbf{v}_1, \ldots, \mathbf{v}_j, \ldots, \mathbf{v}_k\big),$$

where in the j-th term $\mathbf{v}_j$ occupies both slot j and slot m. Each term is 0 because f is alternating. So $f(\mathbf{v}_1, \ldots, \mathbf{v}_k) = 0$ for all inputs, that is, $f = 0$.

For $k = 3$ and $n = 2$, f would measure a signed volume of the parallelepiped spanned by three vectors in the plane. Such a parallelepiped is flat, so its volume is 0, and the result says that no alternating multilinear function can do better.

Solution to Exercise 5.1.37

Uses. Theorem 5.1.13 (The 2×2 determinant), Proposition 5.1.10 (Alternating implies antisymmetric), Remark 5.1.6, Definition 1.5.1 (Linear independence)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. $f_{ij}(\mathbf{x}, \mathbf{y})$ is the 2×2 determinant of rows i and j of the 3×2 matrix with columns $\mathbf{x}, \mathbf{y}$.
Hint 2. For (b), evaluate a vanishing combination at $(\mathbf{e}_1, \mathbf{e}_2)$, $(\mathbf{e}_1, \mathbf{e}_3)$, and $(\mathbf{e}_2, \mathbf{e}_3)$.
Hint 3. For (c), write $\mathbf{x} = \sum_i x_i \mathbf{e}_i$ and $\mathbf{y} = \sum_j y_j \mathbf{e}_j$ and expand. Group the terms (i, j) and (j, i).
Sketch. (a) Each f_{ij} is a 2×2 determinant of coordinates. (b) $f_{ij}(\mathbf{e}_k, \mathbf{e}_l)$ is 1 if $(k, l) = (i, j)$ and 0 for the other pairs $k < l$. (c) Expanding gives $f(\mathbf{x}, \mathbf{y}) = \sum_{i,j} x_i y_j f(\mathbf{e}_i, \mathbf{e}_j)$; diagonal terms vanish, and antisymmetry pairs (i, j) with (j, i) into $(x_i y_j - x_j y_i) f(\mathbf{e}_i, \mathbf{e}_j)$.

(a) $f_{ij}(\mathbf{x}, \mathbf{y}) = \det\begin{pmatrix} x_i & y_i \\ x_j & y_j \end{pmatrix}$, and the coordinates x_i, x_j depend linearly on $\mathbf{x}$. By Theorem 5.1.13, f_{ij} is linear in $\mathbf{x}$ for fixed $\mathbf{y}$ and in $\mathbf{y}$ for fixed $\mathbf{x}$, and $f_{ij}(\mathbf{x}, \mathbf{x}) = x_i x_j - x_j x_i = 0$.

(b) For $k < l$, $f_{ij}(\mathbf{e}_k, \mathbf{e}_l) = 1$ if $(k, l) = (i, j)$, and 0 otherwise. If $c_{12} f_{12} + c_{13} f_{13} + c_{23} f_{23} = 0$, evaluating at $(\mathbf{e}_1, \mathbf{e}_2)$, $(\mathbf{e}_1, \mathbf{e}_3)$, and $(\mathbf{e}_2, \mathbf{e}_3)$ gives $c_{12} = c_{13} = c_{23} = 0$.

(c) Expanding $\mathbf{x} = \sum_i x_i \mathbf{e}_i$ and $\mathbf{y} = \sum_j y_j \mathbf{e}_j$,

$$f(\mathbf{x}, \mathbf{y}) = \sum_{i=1}^{3} \sum_{j=1}^{3} x_i y_j f\big(\mathbf{e}_i, \mathbf{e}_j\big).$$

The terms with $i = j$ vanish since f is alternating. For $i < j$, $f\big(\mathbf{e}_j, \mathbf{e}_i\big) = -f\big(\mathbf{e}_i, \mathbf{e}_j\big)$ by Proposition 5.1.10 (which holds for f by Remark 5.1.6), so the terms (i, j) and (j, i) combine to $\big(x_i y_j - x_j y_i\big) f\big(\mathbf{e}_i, \mathbf{e}_j\big)$. Hence

$$f(\mathbf{x}, \mathbf{y}) = \sum_{i<j} f\big(\mathbf{e}_i, \mathbf{e}_j\big) f_{ij}(\mathbf{x}, \mathbf{y}),$$

as desired. With (a) and (b), the f_{ij} form a basis of the space of multilinear alternating functions of two vectors in F^3, which therefore has dimension 3, compared with dimension 1 for two vectors in F^2 (Exercise 5.1.34).

Solution to Exercise 5.1.38

Uses. Theorem 5.1.13 (The 2×2 determinant), Definition 2.4.26 (Trace), Exercise 5.1.25, Exercise 1.1.44
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. The columns of $A + tI_2$ are $\mathbf{a}_1 + t\mathbf{e}_1$ and $\mathbf{a}_2 + t\mathbf{e}_2$. Expand into four terms.
Hint 2. The mixed terms are $t\det(\mathbf{a}_1, \mathbf{e}_2)$ and $t\det(\mathbf{e}_1, \mathbf{a}_2)$. Compute them from the formula.
Hint 3. For (b), $A + tI_2$ is invertible exactly when its determinant is nonzero (Exercise 5.1.25).
Sketch. Expanding, $\det(A + tI_2) = \det A + t\det(\mathbf{a}_1, \mathbf{e}_2) + t\det(\mathbf{e}_1, \mathbf{a}_2) + t^2$, and the middle terms are ta and td. For the rotation, $\det(A + tI_2) = t^2 + 1$, which vanishes for $t = \pm i$ and for no real t.

(a) Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. The columns of $A + tI_2$ are $\mathbf{a}_1 + t\mathbf{e}_1$ and $\mathbf{a}_2 + t\mathbf{e}_2$. Expanding by multilinearity,

$$\det(A + tI_2) = \det(\mathbf{a}_1, \mathbf{a}_2) + t\det(\mathbf{a}_1, \mathbf{e}_2) + t\det(\mathbf{e}_1, \mathbf{a}_2) + t^2\det(\mathbf{e}_1, \mathbf{e}_2).$$

Here $\det(\mathbf{a}_1, \mathbf{e}_2) = \det\begin{pmatrix} a & 0 \\ c & 1 \end{pmatrix} = a$, $\det(\mathbf{e}_1, \mathbf{a}_2) = \det\begin{pmatrix} 1 & b \\ 0 & d \end{pmatrix} = d$, and $\det(\mathbf{e}_1, \mathbf{e}_2) = 1$. So $\det(A + tI_2) = \det A + (a + d)t + t^2$, and $a + d = \operatorname{tr} A$.

(b) Here $\operatorname{tr} A = 0$ and $\det A = 0 \cdot 0 - (-1) \cdot 1 = 1$, so $\det(A + tI_2) = t^2 + 1$. By Exercise 5.1.25, $A + tI_2$ fails to be invertible exactly when $t^2 + 1 = 0$. Over $\mathbb{C}$ this means $t = i$ or $t = -i$ (Exercise 1.1.44). Over $\mathbb{R}$ there is no such t, since $t^2 + 1 \geq 1$.

So $A\mathbf{x} = -t\mathbf{x}$ has a nonzero solution $\mathbf{x}$ for $t = \pm i$ over $\mathbb{C}$ but for no real t: the rotation by $\pi/2$ moves every nonzero real vector off its own line. This is the first appearance of eigenvalues, which Section 7.3 finds through exactly this kind of determinant.

Solution to Exercise 5.1.39

Uses. Exercise 5.1.25, Definition 1.5.1 (Linear independence), Proposition 5.1.10 (Alternating implies antisymmetric), Proposition 1.2.35 (Zero products)
Hint 1. By Exercise 5.1.25, count the pairs of columns that are linearly independent. Choose the first column, then the second.
Hint 2. Two vectors are independent exactly when the first is nonzero and the second is not a multiple of the first. How many multiples does a nonzero vector of $\mathbb{F}_p^2$ have?
Hint 3. For (b), interchanging the columns is a bijection on $\mathbb{F}_3^{2\times 2}$. What does it do to the determinant?
Sketch. (a) $(p^2 - 1)(p^2 - p)$: a nonzero first column, then a second column outside its p multiples. (b) For $p = 3$ that is 48; interchanging the columns negates det and so swaps det $= 1$ with det $= 2 = -1$. (c) $(4 - 1)(4 - 2) = 6$, all with det $= 1$.

(a) By Exercise 5.1.25, $\det A \neq 0$ exactly when the columns $\mathbf{a}_1, \mathbf{a}_2$ are linearly independent, which happens exactly when $\mathbf{a}_1 \neq \mathbf{0}$ and $\mathbf{a}_2$ is not a multiple of $\mathbf{a}_1$. (If $\mathbf{a}_1 = \mathbf{0}$, then $1 \cdot \mathbf{a}_1 = \mathbf{0}$; if $\mathbf{a}_2 = c\mathbf{a}_1$, then $c\mathbf{a}_1 - \mathbf{a}_2 = \mathbf{0}$. Conversely, if $x\mathbf{a}_1 + y\mathbf{a}_2 = \mathbf{0}$ with $y \neq 0$, then $\mathbf{a}_2 = -y^{-1}x\mathbf{a}_1$, and if $y = 0$ then $x\mathbf{a}_1 = \mathbf{0}$ with $x \neq 0$, so $\mathbf{a}_1 = \mathbf{0}$.) There are $p^2 - 1$ nonzero vectors in $\mathbb{F}_p^2$. For $\mathbf{a}_1 \neq \mathbf{0}$, the multiples $c\mathbf{a}_1$ with $c \in \mathbb{F}_p$ are pairwise distinct, because $c\mathbf{a}_1 = c'\mathbf{a}_1$ gives $(c - c')\mathbf{a}_1 = \mathbf{0}$ and hence $c = c'$ (Proposition 1.2.35). So there are $p^2 - p$ choices for $\mathbf{a}_2$, and $(p^2 - 1)(p^2 - p)$ matrices in all.

(b) For $p = 3$ the count is $8 \cdot 6 = 48$. The nonzero elements of $\mathbb{F}_3$ are 1 and $2 = -1$. Interchanging the two columns is a bijection from $\mathbb{F}_3^{2\times 2}$ to itself (it is its own inverse), and it negates the determinant (Proposition 5.1.10). So it maps the matrices with $\det A = 1$ bijectively onto those with $\det A = -1 = 2$. These two sets have the same size and together contain all 48 matrices, so each has 24 elements.

(c) For $p = 2$ the count is $(4 - 1)(4 - 2) = 6$, and the only nonzero element of $\mathbb{F}_2$ is 1, so all six have $\det A = 1$.

Solution to Exercise 5.1.40

Uses. Proposition 5.1.10 (Alternating implies antisymmetric), Proposition 5.1.17 (Dependent columns)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Expand every column. A term corresponds to choosing $\mathbf{a}_k$ or $\mathbf{a}_{k+1}$ in each column k, so there are 2^n terms.
Hint 2. Show that if the choices are not all "first" or all "second", then some vector is chosen twice. Look for a column k where the second option is chosen, followed by a column $k + 1$ where the first is.
Hint 3. The all-second term is $D(\mathbf{a}_2, \ldots, \mathbf{a}_n, \mathbf{a}_1)$. Move $\mathbf{a}_1$ back to the front by adjacent interchanges.

Sketch. Only the two constant choices survive: a switch from "second" in column k to "first" in column $k+1$ puts $\mathbf{a}_{k+1}$ in both columns. So the value is $D(\mathbf{a}_1, ..., \mathbf{a}_n) + D(\mathbf{a}_2, ..., \mathbf{a}_n, \mathbf{a}_1)$, and $n-1$ adjacent interchanges give the second term as $(-1)^{n-1} D(\mathbf{a}_1, ..., \mathbf{a}_n)$. For even n, the alternating sum of the columns telescopes to $\mathbf{0}$.

We prove (b); (a) is the case $n = 3$, where $1 + (-1)^2 = 2$. Indices are read modulo n, so column n is $\mathbf{a}_n + \mathbf{a}_1$.

(b) Expanding each column k into its two terms writes the left side as a sum of 2^n terms, one for each $\varepsilon = (\varepsilon_1, ..., \varepsilon_n) \in \{0, 1\}^n$:

$$T_\varepsilon = D\big(\mathbf{a}_{1+\varepsilon_1}, \mathbf{a}_{2+\varepsilon_2}, ..., \mathbf{a}_{n+\varepsilon_n}\big).$$

Suppose ε is not constant. Choose k with $\varepsilon_k = 1$, and walk forward cyclically from k. Since some entry of ε is 0, there is a first index l after k (cyclically) with $\varepsilon_l = 0$, and then $\varepsilon_{l-1} = 1$. So column $l-1$ of T_ε holds $\mathbf{a}_l$, and column l also holds $\mathbf{a}_l$. These are different columns because $n \geq 2$, so $T_\varepsilon = 0$ since D is alternating. Only the two constant choices remain:

$$D(\mathbf{a}_1 + \mathbf{a}_2, ..., \mathbf{a}_n + \mathbf{a}_1) = D(\mathbf{a}_1, \mathbf{a}_2, ..., \mathbf{a}_n) + D(\mathbf{a}_2, ..., \mathbf{a}_n, \mathbf{a}_1).$$

In the second term, interchange columns $n-1$ and n, then columns $n-2$ and $n-1$, and so on, ending with columns 1 and 2. These $n-1$ interchanges move $\mathbf{a}_1$ from the last position to the first and keep the others in order, and each negates D (Proposition 5.1.10). So the second term is $(-1)^{n-1} D(\mathbf{a}_1, ..., \mathbf{a}_n)$, which proves (b).

(c) Let n be even and $\mathbf{c}_k = \mathbf{a}_k + \mathbf{a}_{k+1}$. Then the sum telescopes:

$$\mathbf{c}_1 - \mathbf{c}_2 + \mathbf{c}_3 - \cdots - \mathbf{c}_n = \mathbf{a}_1 + (\mathbf{a}_2 - \mathbf{a}_2) + \cdots + (\mathbf{a}_n - \mathbf{a}_n) - \mathbf{a}_{n+1} = \mathbf{a}_1 - \mathbf{a}_1 = \mathbf{0}.$$

The coefficients are $\pm 1 \neq 0$, so the columns are dependent, and the left side of (b) is 0 by Proposition 5.1.17, matching $1 + (-1)^{n-1} = 0$.

Solution to Exercise 5.1.41

Uses. Theorem 4.1.16 (Extending to a basis), Definition 4.1.5 (Dimension), Proposition 1.6.19 (Coordinates respect linear combinations), Definition 1.5.1 (Linear independence)
Hint 1. Alternation: if two columns are equal, use (ii) to turn one of them into $\mathbf{0}$, then use (i) with $c = 0$.
Hint 2. Additivity in column k: fix the other $n-1$ columns. If they are dependent, show D vanishes for every choice of column k.
Hint 3. If they are independent, extend them to a basis of F^n by one vector $\mathbf{w}$. Write $\mathbf{x} = s\mathbf{w} + (...)$ and use (ii) to strip off the other part.
Sketch. Subtracting one of two equal columns from the other makes a zero column, and (i) with $c = 0$ gives $D = 0$. Fix all columns but the k-th. If they are dependent, (ii) produces a zero column among them, so $D(..., \mathbf{x}, ...) = 0$ for all $\mathbf{x}$. Otherwise extend them by one vector $\mathbf{w}$ to a basis; writing $\mathbf{x} = s(\mathbf{x})\mathbf{w} + \sum_{j \neq k} c_j \mathbf{a}_j$, (ii) and (i) give $D(..., \mathbf{x}, ...) = s(\mathbf{x}) D(..., \mathbf{w}, ...)$, where s is a coordinate function and hence linear.

A zero column. If column k of A is $\mathbf{0}$, then by (i) with $c = 0$, $D(A) = D(..., 0 \cdot \mathbf{0}, ...) = 0 \cdot D(A) = 0$.

Alternating. Suppose $\mathbf{a}_i = \mathbf{a}_j$ with $i \neq j$. Adding -1 times column j to column i does not change D, by (ii), and produces a matrix whose column i is $\mathbf{0}$. So $D(A) = 0$.

Multilinear. Fix k and the columns $\mathbf{a}_j$ for $j \neq k$, and let $g(\mathbf{x})$ be the value of D with $\mathbf{x}$ in column k. We show that g is linear.

Suppose first that the list $(\mathbf{a}_j)_{j \neq k}$ is linearly dependent (so $n \geq 2$). Then some $\mathbf{a}_m$ with $m \neq k$ is a linear combination $\sum b_j \mathbf{a}_j$ of the others, the sum running over $j \notin \{k, m\}$. For any $\mathbf{x}$, adding $-b_j$ times column j to column m for each such j does not change D, by (ii), and turns column m into $\mathbf{0}$. So $g(\mathbf{x}) = 0$ for every $\mathbf{x}$, and g is linear.

Suppose instead that $(\mathbf{a}_j)_{j \neq k}$ is linearly independent. It has $n-1$ vectors, so by Theorem 4.1.16 it extends to a basis of F^n, and since every basis of F^n has n vectors (Definition 4.1.5), exactly one vector $\mathbf{w}$ is added. Let $s(\mathbf{x})$ be the coefficient of $\mathbf{w}$ when $\mathbf{x}$ is written in this basis, so $\mathbf{x} = s(\mathbf{x})\mathbf{w} + \sum_{j \neq k} c_j \mathbf{a}_j$ for some scalars c_j.

The function s is a coordinate of the coordinate map, so it is linear (Proposition 1.6.19). Adding $-c_j$ times column j to column k for each $j \neq k$ does not change D, by (ii), so by (i)

$$g(\mathbf{x}) = g(s(\mathbf{x})\mathbf{w}) = s(\mathbf{x})g(\mathbf{w}).$$

So g is the linear function s times the constant $g(\mathbf{w})$, hence linear. In both cases D is linear in column k, and k was arbitrary.

Solution to Exercise 5.1.42

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Definition 3.2.2 (Elementary matrices), Exercise 5.1.27, Exercise 5.1.25

Hint 1. First show $D(I_2) = 1$, that $D(G) \neq 0$ for invertible G, and that $D\big(GXG^{-1}\big) = D(X)$.

Hint 2. For the shear $S_t = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}$, check that $\begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix} S_1 \begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix}^{-1} = S_t$ and that $S_1^2 = S_2$. Deduce $D(S_1) = 1$.

Hint 3. Conjugating by the swap $P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ handles lower shears and $\begin{pmatrix} 1 & 0 \\ 0 & t \end{pmatrix}$. For P itself, check that $S_1 \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} S_1 \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} = P$.

Hint 4. Now $D(E) = \det E$ for every elementary matrix. Use Theorem 3.5.19 for invertible A. If A is not invertible, write a zero column with a shear and use $D\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = 0$.

Sketch. D is invariant under conjugation by invertible matrices. Conjugating S_1 by $\begin{pmatrix} t & 0 \\ 0 & 1 \end{pmatrix}$ gives S_t, so $D(S_1) = D(S_2) = D(S_1)^2$, and $D(S_1) = 1$. Conjugating by P gives the lower shears and the second scaling, and P is three shears times $\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$, so $D(P) = -1$. So $D = \det$ on elementary matrices, hence on invertible matrices. A non-invertible A satisfies $AS = AS\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ or $A = A\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ for a shear S, so $D(A) = 0$.

Write $\operatorname{diag}(s,t) = \begin{pmatrix} s & 0 \\ 0 & t \end{pmatrix}$, $S_t = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}$, $L_t = \begin{pmatrix} 1 & 0 \\ t & 1 \end{pmatrix}$, and $P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

Step 0. $D(I_2) = D(\operatorname{diag}(1,1)) = 1$. If G is invertible, then $D(G)D\big(G^{-1}\big) = D(I_2) = 1$, so $D(G) \neq 0$ and $D\big(G^{-1}\big) = D(G)^{-1}$. Hence $D\big(GXG^{-1}\big) = D(G)D(X)D(G)^{-1} = D(X)$ for every X.

Step 1: shears. For $t \neq 0$, a direct multiplication gives $\operatorname{diag}(t,1)S_1 \operatorname{diag}\big(t^{-1},1\big) = S_t$, so $D(S_t) = D(S_1)$ by Step 0. Also $S_1S_1 = S_2$, so $D(S_1)^2 = D(S_2) = D(S_1)$. Since S_1 is invertible, $D(S_1) \neq 0$, and therefore $D(S_1) = 1$. So $D(S_t) = 1$ for all t (for $t = 0$, $S_0 = I_2$). Next, $P = P^{-1}$ and $PS_tP = L_t$, so $D(L_t) = 1$ as well.

Step 2: scalings and the swap. $P \operatorname{diag}(t,1)P = \operatorname{diag}(1,t)$, so $D(\operatorname{diag}(1,t)) = t$. Multiplying out,

$$S_1L_{-1}S_1 = \begin{pmatrix} 0 & 1 \\ -1 & 1 \end{pmatrix} S_1 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \operatorname{diag}(-1,1) = P,$$

so $D(P) = 1 \cdot 1 \cdot 1 \cdot (-1) = -1$.

Step 3: invertible matrices. The elementary matrices in $\mathbb{R}^{2\times 2}$ are P, the scalings $\operatorname{diag}(t,1)$ and $\operatorname{diag}(1,t)$ with $t \neq 0$, and the shears S_t and L_t. By Steps 1 and 2, $D(E) = \det E$ for each of them ($\det P = -1$, $\det \operatorname{diag}(t,1) = \det \operatorname{diag}(1,t) = t$, and $\det S_t = \det L_t = 1$). If A is invertible, then $A = E_1 \cdots E_k$ for some elementary matrices E_i (Theorem 3.5.19), and by multiplicativity of D and of det (Exercise 5.1.27),

$$D(A) = D(E_1) \cdots D(E_k) = \det(E_1) \cdots \det(E_k) = \det A.$$

Step 4: non-invertible matrices. Let A be non-invertible, so $\det A = 0$ and its columns are dependent (Exercise 5.1.25). Note $D(\operatorname{diag}(0,1)) = 0$, and $D(\operatorname{diag}(1,0)) = D(P \operatorname{diag}(0,1)P) = 0$ by Step 0. If $\mathbf{a}_1 = \mathbf{0}$, then $A = A \operatorname{diag}(0,1)$, so $D(A) = D(A) \cdot 0 = 0$. If $\mathbf{a}_1 \neq \mathbf{0}$, a dependence $x\mathbf{a}_1 + y\mathbf{a}_2 = \mathbf{0}$ must have $y \neq 0$, so $\mathbf{a}_2 = c\mathbf{a}_1$ with $c = -y^{-1}x$. Then AS_{-c} has columns $\mathbf{a}_1$ and $\mathbf{0}$, so $AS_{-c} = AS_{-c} \operatorname{diag}(1,0)$, and

$$D(A) = D(A)D(S_{-c}) = D(AS_{-c}) = D(AS_{-c})D(\operatorname{diag}(1,0)) = 0.$$

In both cases $D(A) = 0 = \det A$. Hence $D = \det$.

Section 5.2

Solution to Exercise 5.2.9

Uses. Proposition 5.2.5 (Composition and inverses)
Hint 1. $\sigma^2(i) = \sigma(\sigma(i))$. Apply σ to each entry of the bottom row of σ.
Hint 2. Compare σ^3 with σ^{-1}: what is σ^4?
Sketch. $\sigma^2 = \begin{pmatrix}1&2&3&4\\4&3&2&1\end{pmatrix}$, $\sigma^3 = \begin{pmatrix}1&2&3&4\\3&1&4&2\end{pmatrix} = \sigma^{-1}$, and $\sigma^4 = \mathrm{id}$. Since σ, σ^2, σ^3 are not the identity, $m = 4$.

Applying σ to each entry $2, 4, 1, 3$ of the bottom row of σ gives $\sigma(2), \sigma(4), \sigma(1), \sigma(3) = 4, 3, 2, 1$, so $\sigma^2 = \begin{pmatrix}1&2&3&4\\4&3&2&1\end{pmatrix}$. Applying σ to $4, 3, 2, 1$ gives $3, 1, 4, 2$, so $\sigma^3 = \begin{pmatrix}1&2&3&4\\3&1&4&2\end{pmatrix}$, and applying it once more gives $1, 2, 3, 4$, so $\sigma^4 = \mathrm{id}$. Reading σ from the bottom up, σ^{-1} sends $2, 4, 1, 3$ to $1, 2, 3, 4$, so $\sigma^{-1} = \begin{pmatrix}1&2&3&4\\3&1&4&2\end{pmatrix} = \sigma^3$, as it must be since $\sigma^3\sigma = \sigma^4 = \mathrm{id}$. None of σ, σ^2, σ^3 is the identity, so the least m is 4.

Solution to Exercise 5.2.28

Uses. Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.2.26 (Sign of a cycle)
Hint 1. Apply sgn and use Proposition 5.2.25. Values of sgn are numbers, so they commute.
Hint 2. For (b), compute the signs of the two given permutations.
Sketch. $\mathrm{sgn}(\sigma^2) = \mathrm{sgn}(\sigma)^2 = 1$, and $\mathrm{sgn}(\sigma\rho\sigma^{-1}\rho^{-1}) = \mathrm{sgn}(\sigma)^2\mathrm{sgn}(\rho)^2 = 1$. A transposition is odd, and $(1\ 2)(3\ 4\ 5)$ has sign $(-1)(+1) = -1$, so neither is a square.

(a) By Proposition 5.2.25, $\mathrm{sgn}(\sigma^2) = \mathrm{sgn}(\sigma)^2 = 1$, and

$$\mathrm{sgn}(\sigma\rho\sigma^{-1}\rho^{-1}) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\rho)\,\mathrm{sgn}(\sigma^{-1})\,\mathrm{sgn}(\rho^{-1}) = \mathrm{sgn}(\sigma)^2\mathrm{sgn}(\rho)^2 = 1,$$

where we used $\mathrm{sgn}(\sigma^{-1}) = \mathrm{sgn}(\sigma)$ and that the integers $\mathrm{sgn}(\sigma), \mathrm{sgn}(\rho)$ commute.

(b) $\mathrm{sgn}((1\ 2)) = -1$, and by Proposition 5.2.26 and Proposition 5.2.25, $\mathrm{sgn}((1\ 2)(3\ 4\ 5)) = (-1)^1(-1)^2 = -1$. By (a) every square has sign 1, so neither permutation is a square.

Solution to Exercise 5.2.33

Uses. Proposition 5.2.16 (Cycle decomposition), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.25 (Multiplicativity of the sign)
Hint 1. Write τ in two-line notation first. For $\sigma\tau$, apply τ first.
Hint 2. For the signs, use the cycle notation and Proposition 5.2.26, and check the answers against Proposition 5.2.25.
Sketch. $\sigma = (1\ 2\ 5\ 3\ 6\ 4)$ and $\tau = \begin{pmatrix}1&2&3&4&5&6\\4&6&3&1&5&2\end{pmatrix}$. Then $\sigma\tau = \begin{pmatrix}1&2&3&4&5&6\\1&4&6&2&3&5\end{pmatrix} = (2\ 4)(3\ 6\ 5)$, $\tau\sigma = \begin{pmatrix}1&2&3&4&5&6\\6&5&2&4&3&1\end{pmatrix} = (1\ 6)(2\ 5\ 3)$, and $\sigma^{-1} = \begin{pmatrix}1&2&3&4&5&6\\4&1&5&6&2&3\end{pmatrix} = (1\ 4\ 6\ 3\ 5\ 2)$. The signs are $-1, 1, -1, -1, -1$.

Following $1 \mapsto 2 \mapsto 5 \mapsto 3 \mapsto 6 \mapsto 4 \mapsto 1$, we get $\sigma = (1\ 2\ 5\ 3\ 6\ 4)$, a 6-cycle. The permutation τ interchanges $1, 4$ and $2, 6$, so $\tau = \begin{pmatrix}1&2&3&4&5&6\\4&6&3&1&5&2\end{pmatrix}$.

$\sigma\tau$. Applying σ to the bottom row $4, 6, 3, 1, 5, 2$ of τ gives $\sigma(4), \sigma(6), \sigma(3), \sigma(1), \sigma(5), \sigma(2) = 1, 4, 6, 2, 3, 5$. So $\sigma\tau = \begin{pmatrix}1&2&3&4&5&6\\1&4&6&2&3&5\end{pmatrix} = (2\ 4)(3\ 6\ 5)$.

$\tau\sigma$. Applying τ to the bottom row $2, 5, 6, 1, 3, 4$ of σ gives $6, 5, 2, 4, 3, 1$. So $\tau\sigma = \begin{pmatrix}1&2&3&4&5&6\\6&5&2&4&3&1\end{pmatrix} = (1\ 6)(2\ 5\ 3)$.

σ^{-1}. Running the cycle of σ backwards, $\sigma^{-1} = (4\ 6\ 3\ 5\ 2\ 1) = (1\ 4\ 6\ 3\ 5\ 2)$, which in two-line notation is $\begin{pmatrix}1&2&3&4&5&6\\4&1&5&6&2&3\end{pmatrix}$.

Signs. By Proposition 5.2.26, a 6-cycle has sign $(-1)^5 = -1$, so $\mathrm{sgn}(\sigma) = \mathrm{sgn}(\sigma^{-1}) = -1$. Also $\mathrm{sgn}(\tau) = (-1)(-1) = 1$, $\mathrm{sgn}(\sigma\tau) = (-1)\cdot 1 = -1$ (a transposition times a 3-cycle), and $\mathrm{sgn}(\tau\sigma) = -1$ in the same way. These agree with Proposition 5.2.25: $\mathrm{sgn}(\sigma\tau) = \mathrm{sgn}(\tau\sigma) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau) = -1$.

Solution to Exercise 5.2.34

Uses. Definition 5.2.21 (Inversion), Corollary 5.2.24 (Formulas for the sign), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.25 (Multiplicativity of the sign)
Hint 1. In (a), the bottom row of $(k\ l)$ is $1, \ldots, k-1, l, k+1, \ldots, l-1, k, l+1, \ldots, n$. Only pairs involving position k or position l can be inverted.
Hint 2. In (b), the bottom row is $2, 3, \ldots, n, 1$. In (c), every pair is inverted, and ω is a product of the disjoint transpositions $(i\ n+1-i)$ for $i < (n+1)/2$.

Sketch. (a) Position k (entry l) is inverted with each of the $l-k$ later positions up to l, and position l (entry k) with each of the $l-k-1$ positions strictly between. (b) The inversions are (i,n) for $i<n$, so $\mathrm{inv}=n-1$ and the sign is $(-1)^{n-1}$. (c) $\mathrm{inv}(\omega)=n(n-1)/2$, while ω is a product of $\lfloor n/2\rfloor$ disjoint transpositions. So ω is even exactly when $n\equiv 0$ or 1 modulo 4.

(a) The bottom row of $(k\ l)$ has l in position k, k in position l, and i in position i otherwise. A pair of positions avoiding k and l has entries $i<j$ in order. Let $m\notin\{k,l\}$. If $m<k$, its entry m is smaller than both l and k, so neither pair (m,k) nor (m,l) is inverted. If $m>l$, its entry m is larger than both, so again neither is inverted. If $k<m<l$, then (k,m) is inverted since $l>m$, and (m,l) is inverted since $m>k$. Finally, (k,l) is inverted since $l>k$. So the inversions are (k,m) and (m,l) for the $l-k-1$ values of m strictly between k and l, together with (k,l): in total $2(l-k-1)+1=2(l-k)-1$.

(b) The bottom row of $(1\ 2\ \ldots\ n)$ is $2,3,\ldots,n,1$. The entries $2,\ldots,n$ are in increasing order, and each is larger than the final entry 1. So the inversions are (i,n) for $1\le i\le n-1$, and $\mathrm{inv}=n-1$. By Corollary 5.2.24 the sign is $(-1)^{n-1}$, which is the sign of an n-cycle in Proposition 5.2.26.

(c) The bottom row of ω is $n,n-1,\ldots,1$, so every pair $i<j$ is an inversion and $\mathrm{inv}(\omega)=n(n-1)/2$. Hence $\mathrm{sgn}(\omega)=(-1)^{n(n-1)/2}$ by Corollary 5.2.24. On the other hand, ω interchanges i and $n+1-i$, so it is the product of the disjoint transpositions $(i\ n+1-i)$ for $1\le i<(n+1)/2$; there are $\lfloor n/2\rfloor$ of them (the middle point is fixed when n is odd). So $\mathrm{sgn}(\omega)=(-1)^{\lfloor n/2\rfloor}$ by Proposition 5.2.25, and the two expressions agree. Now $\lfloor n/2\rfloor$ is even exactly when $n\equiv 0$ or 1 modulo 4, so ω is even exactly for these n. For example ω is odd in S_2 and S_3, even in S_4 and S_5, and odd in S_6 and S_7.

Solution to Exercise 5.2.35

Uses. Lemma 5.2.22 (A transposition changes inv by an odd number), Exercise 5.2.34
Hint 1. Test the claim with $\sigma=\mathrm{id}$ and $\tau=(1\ 3)$.
Hint 2. Look at an entry that sits between the two interchanged positions. Is it still on the same side of each interchanged entry?
Sketch. The claim fails for $\sigma=\mathrm{id},\tau=(1\ 3)$: $\mathrm{inv}((1\ 3))=3$. The error is "nothing else": every entry between the two interchanged positions also changes its order relative to both interchanged entries. The correct statement is Lemma 5.2.22: the change is odd, and it is ±1 for adjacent transpositions.

The claim is false: $\mathrm{inv}(\mathrm{id})=0$, while the bottom row of $(1\ 3)$ is $3,2,1$, which has 3 inversions. The error is the sentence "changes their relative order and nothing else". Think of an inversion as a pair of *entries* that appear in the wrong order, and interchange the entries a_k and a_l in positions $k<l$. An entry a_m with $m<k$ or $m>l$ stays on the same side of both a_k and a_l, so its pairs with them keep their status. But an entry a_m with $k<m<l$ used to stand to the right of a_k and to the left of a_l, and afterwards stands to the left of a_k and to the right of a_l. So the relative order of a_m with *both* interchanged entries changes, and the pairs $\{a_m,a_k\}$ and $\{a_m,a_l\}$ both change status. In the example, the entry 2 in the middle forms an inversion with 3 and with 1 afterwards, and with neither before. Each such m changes the count by -2, 0, or 2, which is why the total change is always odd (Lemma 5.2.22). When $l=k+1$ there is no entry in between, and then the claim is true.

Solution to Exercise 5.2.36

Uses. Definition 5.2.29 (Permutation matrix), Definition 2.4.1 (Matrix product), Proposition 5.2.30 (Algebra of permutation matrices)
Hint 1. Compute the $(\sigma(i),k)$ entry of $E_\sigma A$ from the definition of the product: $\sum_j (E_\sigma)_{\sigma(i)j}a_{jk}$. Which j gives a nonzero term?
Hint 2. For (b), $E_\sigma^{\mathsf T}=E_{\sigma^{-1}}$, so by Proposition 5.2.30 the columns of $AE_\sigma^{\mathsf T}$ are the columns of A rearranged. Combine this with (a).
Sketch. $(E_\sigma)_{\sigma(i)j}=1$ exactly when $j=i$, so $(E_\sigma A)_{\sigma(i)k}=a_{ik}$. Dually, column $\sigma(j)$ of $AE_{\sigma^{-1}}$ is column j of A. Together, $\left(E_\sigma AE_\sigma^{\mathsf T}\right)_{\sigma(i)\sigma(j)}=a_{ij}$: renaming vertex i as $\sigma(i)$ replaces the adjacency matrix A by $E_\sigma AE_\sigma^{\mathsf T}$.

(a) For every k, the $(\sigma(i),k)$ entry of $E_\sigma A$ is $\sum_{j=1}^{n}(E_\sigma)_{\sigma(i)j}a_{jk}$. By Definition 5.2.29, $(E_\sigma)_{\sigma(i)j}=1$ if $\sigma(i)=\sigma(j)$, that is, if $j=i$, and 0 otherwise. So the sum is a_{ik}, and row $\sigma(i)$ of $E_\sigma A$ is row i of A.

(b) Let $B = AE_\sigma^{\mathsf{T}} = AE_{\sigma^{-1}}$ (Proposition 5.2.30). By part (a) of that proposition, column p of B is column $\sigma^{-1}(p)$ of A; with $p = \sigma(j)$, column $\sigma(j)$ of B is column j of A, so $b_{i\sigma(j)} = a_{ij}$. By (a) applied to B, row $\sigma(i)$ of $E_\sigma B$ is row i of B. Hence the $(\sigma(i), \sigma(j))$ entry of $E_\sigma A E_\sigma^{\mathsf{T}} = E_\sigma B$ is $b_{i\sigma(j)} = a_{ij}$.

(c) Rename each vertex i as $\sigma(i)$. In the renamed graph, $\sigma(i)$ and $\sigma(j)$ are joined exactly when i and j were joined in the original, so its adjacency matrix A' satisfies $a'_{\sigma(i)\sigma(j)} = a_{ij}$ for all i, j. Since σ is a bijection, every entry of A' is of this form, so by (b), $A' = E_\sigma A E_\sigma^{\mathsf{T}} = E_\sigma A E_\sigma^{-1}$. Renaming the vertices replaces the adjacency matrix by a similar matrix, conjugated by a permutation matrix.

Solution to Exercise 5.2.37

> *Uses.* Proposition 5.2.25 (Multiplicativity of the sign), Definition 5.2.21 (Inversion)
> *Hint 1.* (a) and (d): try $\sigma = \tau = (1\ 2)$. (b): try two disjoint transpositions.
> *Hint 2.* (c): an inversion of σ is a pair $i < j$ with $\sigma(i) > \sigma(j)$. Rename $p = \sigma(j)$ and $q = \sigma(i)$, and see what σ^{-1} does to $p < q$.
> *Hint 3.* (e): use Proposition 5.2.25.
> *Sketch.* (a) False: $(1\ 2)^2 = \mathrm{id}$ is even. (b) False for $n \geq 4$: $(1\ 2)(3\ 4)$. (c) True: $(i, j) \mapsto (\sigma(j), \sigma(i))$ is a bijection from the inversions of σ to those of σ^{-1}. (d) False: $\mathrm{inv}\big((1\ 2)^2\big) = 0 \neq 2$. (e) True, by multiplicativity.

(a) False. $(1\ 2)$ is odd, but $(1\ 2)(1\ 2) = \mathrm{id}$ is even. In fact the product of two odd permutations is always even, by Proposition 5.2.25.

(b) False when $n \geq 4$. For $\sigma = (1\ 2)(3\ 4)$, the two disjoint transpositions commute, so $\sigma^2 = (1\ 2)^2(3\ 4)^2 = \mathrm{id}$, but σ moves four points, so it is neither the identity nor a transposition. (For $n \leq 3$ the statement is true, as Table 5.2.1 shows for $n = 3$.)

(c) True. Let (i, j) be an inversion of σ, so $i < j$ and $\sigma(i) > \sigma(j)$. Put $p = \sigma(j)$ and $q = \sigma(i)$. Then $p < q$ and $\sigma^{-1}(p) = j > i = \sigma^{-1}(q)$, so (p, q) is an inversion of σ^{-1}. The same argument applied to σ^{-1}, whose inverse is σ, sends an inversion (p, q) of σ^{-1} to the inversion $\big(\sigma^{-1}(q), \sigma^{-1}(p)\big)$ of σ, and the two maps are inverse to each other. So they are bijections, and $\mathrm{inv}\big(\sigma^{-1}\big) = \mathrm{inv}(\sigma)$.

(d) False. With $\sigma = \tau = (1\ 2)$, $\mathrm{inv}(\sigma\tau) = \mathrm{inv}(\mathrm{id}) = 0$ but $\mathrm{inv}(\sigma) + \mathrm{inv}(\tau) = 2$. Only the parities add (Corollary 5.2.24 and Proposition 5.2.25).

(e) True. By Proposition 5.2.25, $\mathrm{sgn}\big(\sigma\tau\sigma^{-1}\big) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau)\,\mathrm{sgn}\big(\sigma^{-1}\big) = \mathrm{sgn}(\sigma)^2\,\mathrm{sgn}(\tau) = \mathrm{sgn}(\tau)$.

Solution to Exercise 5.2.38

> *Uses.* Theorem 5.3.4 (Existence and uniqueness of the determinant), Remark 5.2.32 (Two comments on the theorem), Theorem 5.2.31 (Alternating functions and permutations)
> *Hint 1.* How is the existence of a determinant function on $F^{n\times n}$ proved in Section 5.3, and what does that proof use?
> *Hint 2.* Suppose $F = \mathbb{F}_2$. What does $\det E_\sigma = (-1)^r$ tell you about r?
> *Sketch.* The argument is circular: the existence half of Theorem 5.3.4 is proved with a formula involving sgn, which is defined using Theorem 5.2.18. It also takes F arbitrary, but if $1 + 1 = 0$ then $(-1)^r = 1$ for every r and nothing about r follows. Over $\mathbb{Q}$, with a determinant function constructed without permutations, the argument would be valid.

There are two errors.

Circularity. The proof assumes that a determinant function exists on $F^{n\times n}$. For $n \geq 3$ the existence of a determinant function is the existence half of Theorem 5.3.4, which Section 5.3 proves by checking that a formula built from sgn satisfies the axioms. That formula only makes sense once sgn is well defined, that is, once Theorem 5.2.18 is known. So the argument assumes what it is trying to prove.

The field. Even granting a determinant function, the conclusion "$(-1)^r$ is determined, so the parity of r is determined" needs $1 \neq -1$ in F. Over $\mathbb{F}_2$, $(-1)^r = 1$ for every r, so the equation $\det E_\sigma = (-1)^r$ says nothing about r.

The core of the argument is sound, as Remark 5.2.32 explains: if one had a multilinear alternating D on $\mathbb{Q}^{n\times n}$ with $D(I_n) \neq 0$, constructed without permutations, then the induction in the proof of Theorem 5.2.31 gives $(-1)^r D(I_n) = D(E_\sigma) = (-1)^s D(I_n)$ for two factorizations, and $r \equiv s$ modulo 2 follows.

Solution to Exercise 5.2.39

Uses. Definition 5.2.15 (Cycle), Proposition 5.2.5 (Composition and inverses), Proposition 5.2.16 (Cycle decomposition)
Hint 1. Evaluate the left side at $\sigma(a_i)$, and at a point y not of this form.
Hint 2. For (b), find ρ with $\rho(1) = k$ and $\rho(2) = l$, and apply (a).
Hint 3. For (c), write the conjugate of a product as a product of conjugates: $\sigma\gamma\delta\sigma^{-1} = \big(\sigma\gamma\sigma^{-1}\big)\big(\sigma\delta\sigma^{-1}\big)$.
Sketch. Let $\gamma = (a_1 \ \dots \ a_k)$. At $\sigma(a_i)$, $\sigma\gamma\sigma^{-1}$ gives $\sigma(\gamma(a_i)) = \sigma(a_{i+1})$ (indices mod k), and at any other y, $\sigma^{-1}(y)$ is not an a_i, so y is fixed. For (b), take ρ with $\rho(1) = k$, $\rho(2) = l$. For (c), rename each entry by σ: (5 1 4)(3 2).

(a) Let $\gamma = (a_1 \ \dots \ a_k)$, and read indices modulo k, so $\gamma(a_i) = a_{i+1}$ and $a_{k+1} = a_1$. For each i,

$$\sigma\gamma\sigma^{-1}(\sigma(a_i)) = \sigma(\gamma(a_i)) = \sigma(a_{i+1}).$$

If $y \in [n]$ is not one of $\sigma(a_1), \dots, \sigma(a_k)$, then $\sigma^{-1}(y)$ is not one of $a_1, \dots, a_k$, so γ fixes it and $\sigma\gamma\sigma^{-1}(y) = \sigma\big(\sigma^{-1}(y)\big) = y$. Since $\sigma(a_1), \dots, \sigma(a_k)$ are distinct (as σ is injective), this is exactly the cycle $(\sigma(a_1) \ \dots \ \sigma(a_k))$.

(b) The sets $[n] \setminus \{1, 2\}$ and $[n] \setminus \{k, l\}$ both have $n - 2$ elements, so there is a bijection β between them. Define $\rho(1) = k$, $\rho(2) = l$, and $\rho(i) = \beta(i)$ for $i \geq 3$. Then ρ is a bijection of $[n]$, and by (a), $\rho(1\ 2)\rho^{-1} = (\rho(1)\ \rho(2)) = (k\ l)$.

(c) Since $\sigma^{-1}\sigma = \mathrm{id}$, we have $\sigma\gamma\delta\sigma^{-1} = \big(\sigma\gamma\sigma^{-1}\big)\big(\sigma\delta\sigma^{-1}\big)$. Here σ sends $1 \mapsto 5$, $2 \mapsto 1$, $3 \mapsto 4$, $4 \mapsto 3$, $5 \mapsto 2$, so by (a),

$$\sigma(1\ 2\ 3)(4\ 5)\sigma^{-1} = (5\ 1\ 4)(3\ 2) = (1\ 4\ 5)(2\ 3).$$

Solution to Exercise 5.2.40

Uses. Definition 5.2.23 (Sign of a permutation), Lemma 5.2.17 (Cycles as products of transpositions), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.25 (Multiplicativity of the sign)
Hint 1. An even permutation is a product of an even number of transpositions. Group them in pairs.
Hint 2. Show that a product of two transpositions is a product of at most two 3-cycles. Distinguish whether the two transpositions are equal, share one point, or are disjoint.
Hint 3. If they share one point, name them $(a\ b)$ and $(b\ c)$; by Lemma 5.2.17 their product is $(a\ b\ c)$. If they are disjoint, insert $(b\ c)(b\ c) = \mathrm{id}$.
Sketch. Pair up the transpositions of an even factorization. Equal transpositions multiply to id; $(a\ b)(b\ c) = (a\ b\ c)$; and for disjoint ones, $(a\ b)(c\ d) = (a\ b)(b\ c)(b\ c)(c\ d) = (a\ b\ c)(b\ c\ d)$. Conversely, 3-cycles are even.

Let σ be even, so $\sigma = \tau_1\tau_2\cdots\tau_{2q}$ for some transpositions τ_i, and $\sigma = (\tau_1\tau_2)(\tau_3\tau_4)\cdots\big(\tau_{2q-1}\tau_{2q}\big)$. It suffices to show that a product π of two transpositions is a product of 3-cycles (with the empty product allowed). There are three cases.

The transpositions are equal. Then $\pi = \mathrm{id}$, the empty product.

They share exactly one point. Since $(x\ y) = (y\ x)$, we can write them as $(a\ b)$ and $(b\ c)$ with a, b, c distinct, in the order they occur in π. By Lemma 5.2.17, $\pi = (a\ b)(b\ c) = (a\ b\ c)$.

They are disjoint, say $(a\ b)$ and $(c\ d)$ with a, b, c, d distinct. Inserting $(b\ c)^2 = \mathrm{id}$ and using the previous case twice,

$$\pi = (a\ b)(b\ c)(b\ c)(c\ d) = (a\ b\ c)(b\ c\ d).$$

Conversely, a 3-cycle is even by Proposition 5.2.26, so a product of 3-cycles is even by Proposition 5.2.25. Hence a permutation is even if and only if it is a product of 3-cycles. (We need $n \geq 3$ for 3-cycles to exist; for $n \leq 2$ the only even permutation is id, the empty product.)

Solution to Exercise 5.2.41

Uses. Proposition 5.2.16 (Cycle decomposition), Proposition 5.2.30 (Algebra of permutation matrices), Definition 5.2.15 (Cycle)
Hint 1. For a k-cycle $\gamma = (a_1 \ \dots \ a_k)$, compute $\gamma^m(a_i)$.
Hint 2. Disjoint cycles commute, so $\sigma^m = \gamma_1^m \cdots \gamma_t^m$, and γ_s^m moves only points of its own cycle. When is the product the identity?
Hint 3. For (b), $E_\sigma^m = E_{\sigma^m}$, and $E_\pi = I_n$ only when $\pi = \mathrm{id}$.

Sketch. $\gamma^m(a_i) = a_{i+m}$ (indices mod k), so $\gamma^m = \mathrm{id}$ iff $k \mid m$. Since the γ_s commute and move disjoint sets, $\sigma^m = \mathrm{id}$ iff each $\gamma_s^m = \mathrm{id}$ iff each $k_s \mid m$. In (b), $E_\sigma^m = E_{\sigma^m}$, so the answer is the order of σ, $\mathrm{lcm}(3,4) = 12$.

(a) Let $\gamma = (a_1 \ \ldots \ a_k)$ and read indices modulo k. By induction on m, $\gamma^m(a_i) = a_{i+m}$, and γ^m fixes every point outside $\{a_1, \ldots, a_k\}$. So $\gamma^m = \mathrm{id}$ if and only if $a_{i+m} = a_i$ for all i, that is, if and only if k divides m. The least such $m \geq 1$ is k.

Now let $\sigma = \gamma_1 \cdots \gamma_t$ with disjoint cycles γ_s of lengths k_s. Disjoint cycles commute, so $\sigma^m = \gamma_1^m \cdots \gamma_t^m$. Each γ_s^m maps the entries of γ_s among themselves and fixes all other points. So for x an entry of γ_s, $\sigma^m(x) = \gamma_s^m(x)$, and σ^m fixes the points that no γ_s moves. Hence $\sigma^m = \mathrm{id}$ if and only if $\gamma_s^m = \mathrm{id}$ for every s, that is, if and only if every k_s divides m. The least such $m \geq 1$ is $\mathrm{lcm}(k_1, \ldots, k_t)$.

(b) By Proposition 5.2.30, $E_\sigma^m = E_{\sigma^m}$. A permutation matrix E_π equals I_7 only if $\mathbf{e}_{\pi(j)} = \mathbf{e}_j$ for all j, that is, $\pi = \mathrm{id}$. So $E_\sigma^m = I_7$ if and only if $\sigma^m = \mathrm{id}$, and by (a) the least such m is $\mathrm{lcm}(3,4) = 12$.

Solution to Exercise 5.2.42

Uses. Exercise 5.2.28, Exercise 5.2.41, Proposition 5.2.26 (Sign of a cycle)
Hint 1. Square a 5-cycle $(b_1\ b_2\ b_3\ b_4\ b_5)$: where does b_1 go?
Hint 2. For (b), the square of a 4-cycle $(b_1\ b_2\ b_3\ b_4)$ is $(b_1\ b_3)(b_2\ b_4)$.
Hint 3. For (c), compute a sign (Exercise 5.2.28).
Sketch. (a) $(b_1 \ \ldots \ b_5)^2 = (b_1\ b_3\ b_5\ b_2\ b_4)$, so $\sigma = (1\ 4\ 2\ 5\ 3)$. (b) $\sigma = (1\ 3\ 2\ 4)$. (c) $(1\ 2)(3\ 4\ 5)$ is odd, and squares are even.

(a) For a 5-cycle $\gamma = (b_1\ b_2\ b_3\ b_4\ b_5)$, γ^2 sends $b_i \mapsto b_{i+2}$ (indices mod 5), so $\gamma^2 = (b_1\ b_3\ b_5\ b_2\ b_4)$. We want this to be $(1\ 2\ 3\ 4\ 5)$, so we take $b_1 = 1, b_3 = 2, b_5 = 3, b_2 = 4, b_4 = 5$, that is, $\sigma = (1\ 4\ 2\ 5\ 3)$. Check: σ sends $1 \mapsto 4 \mapsto 2 \mapsto 5 \mapsto 3 \mapsto 1$, so σ^2 sends $1 \mapsto 2$, $2 \mapsto 3$, $3 \mapsto 4$, $4 \mapsto 5$, $5 \mapsto 1$.

(b) For $\gamma = (b_1\ b_2\ b_3\ b_4)$, γ^2 sends $b_1 \mapsto b_3 \mapsto b_1$ and $b_2 \mapsto b_4 \mapsto b_2$, so $\gamma^2 = (b_1\ b_3)(b_2\ b_4)$. Taking $b_1 = 1, b_3 = 2, b_2 = 3, b_4 = 4$ gives $\sigma = (1\ 3\ 2\ 4)$ with $\sigma^2 = (1\ 2)(3\ 4)$.

(c) By Proposition 5.2.26, $\mathrm{sgn}((1\ 2)(3\ 4\ 5)) = (-1)(+1) = -1$. By Exercise 5.2.28, every square σ^2 is even. So $(1\ 2)(3\ 4\ 5)$ is not a square.

Solution to Exercise 5.2.43

Uses. Lemma 5.2.22 (A transposition changes inv by an odd number), Definition 5.2.21 (Inversion)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. For the lower bound, start from id and multiply on the right by adjacent transpositions one at a time. By how much can inv change at each step?
Hint 2. For the upper bound, induct on $\mathrm{inv}(\sigma)$. If $\sigma \neq \mathrm{id}$, find k with $\sigma(k) > \sigma(k+1)$, and show that $\mathrm{inv}(\sigma(k\ k+1)) = \mathrm{inv}(\sigma) - 1$.
Sketch. Each adjacent transposition changes inv by exactly 1 (Lemma 5.2.22), so a product of r of them has inv $\leq r$. Conversely, if $\mathrm{inv}(\sigma) > 0$, the bottom row has a descent $\sigma(k) > \sigma(k+1)$; interchanging those two entries removes exactly one inversion. Repeating (bubble sort) reaches id after $\mathrm{inv}(\sigma)$ steps, and reversing the steps writes σ as a product of $\mathrm{inv}(\sigma)$ adjacent transpositions.

Lower bound. Suppose $\sigma = s_1 \cdots s_r$ with adjacent transpositions s_i. By Lemma 5.2.22, $\mathrm{inv}(s_1 \cdots s_j) \leq \mathrm{inv}(s_1 \cdots s_{j-1}) + 1$ for each j, and $\mathrm{inv}(\mathrm{id}) = 0$, so by induction $\mathrm{inv}(s_1 \cdots s_j) \leq j$. In particular $\mathrm{inv}(\sigma) \leq r$.

Upper bound. We show by induction on $N = \mathrm{inv}(\sigma)$ that σ is a product of N adjacent transpositions. If $N = 0$, the bottom row of σ has no pair out of order, so it is increasing, and an increasing arrangement of $1, \ldots, n$ is $1, \ldots, n$. So $\sigma = \mathrm{id}$, the empty product. If $N > 0$, the bottom row is not increasing, so $\sigma(k) > \sigma(k+1)$ for some k. Let $s = (k\ k+1)$. By Remark 5.2.11, the bottom row of σs is that of σ with the entries in positions k and $k+1$ interchanged. The proof of Lemma 5.2.22 shows that, for an adjacent transposition, the pairs other than $(k, k+1)$ contribute the same number of inversions before and after, so $\mathrm{inv}(\sigma s) - \mathrm{inv}(\sigma)$ is the change in the status of $(k, k+1)$ alone. Here that pair changes from inverted to not inverted, so $\mathrm{inv}(\sigma s) = N - 1$, and by the induction hypothesis $\sigma s = s_1 \cdots s_{N-1}$ with adjacent transpositions s_i. Then $\sigma = \sigma s s = s_1 \cdots s_{N-1} s$, a product of N adjacent transpositions.

The upper bound is the analysis of *bubble sort*, which repeatedly interchanges an adjacent pair that is out of order. Each interchange lowers inv by exactly 1, so the algorithm stops after exactly $\operatorname{inv}(\sigma)$ interchanges, whichever out-of-order pairs it picks.

Solution to Exercise 5.2.44

Uses. Theorem 5.2.31 (Alternating functions and permutations), Definition 5.1.1 (Determinant function), Proposition 5.2.26 (Sign of a cycle)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. In (a), let $\sigma(j)$ be the row of the nonzero entry in column j. Why is σ a permutation?
Hint 2. Pull the scalars c_j out of the columns by multilinearity, and apply Theorem 5.2.31 to what is left.
Hint 3. In (b), read off σ column by column and find its cycle notation.
Sketch. (a) The rows $\sigma(j)$ of the nonzero entries are distinct because each row has one nonzero entry, so $\sigma \in S_n$. Multilinearity gives $D(A) = c_1 \cdots c_n D(E_\sigma) = c_1 \cdots c_n \operatorname{sgn}(\sigma) D(I_n)$. (b) $\sigma = (1\ 3\ 4\ 2)$, odd, and $c_1c_2c_3c_4 = i \cdot 2 \cdot (1-i)(-1) = -2-2i$, so $D(A) = (2+2i)D(I_4)$. (c) $\sigma = (1\ 3\ 2)$, even, so $D(B) = 8D(I_3) = 2D(I_3)$ in $\mathbb{F}_3$.

(a) For each column j, let $\sigma(j)$ be the row of its nonzero entry and c_j that entry, so column j is $c_j \mathbf{e}_{\sigma(j)}$. If $\sigma(j) = \sigma(j')$ with $j \neq j'$, row $\sigma(j)$ would have two nonzero entries; so σ is injective, hence a permutation. Pulling c_j out of column j for each j (multilinearity, Definition 5.1.1) and applying Theorem 5.2.31,

$$D(A) = c_1 \cdots c_n D\big(\mathbf{e}_{\sigma(1)}, \ldots, \mathbf{e}_{\sigma(n)}\big) = c_1 \cdots c_n D(E_\sigma) = \operatorname{sgn}(\sigma) c_1 \cdots c_n D(I_n).$$

(b) The columns of A are $i\mathbf{e}_3$, $2\mathbf{e}_1$, $(1-i)\mathbf{e}_4$, and $-\mathbf{e}_2$. So $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 2 \end{pmatrix}$, that is, $1 \mapsto 3 \mapsto 4 \mapsto 2 \mapsto 1$, the 4-cycle $(1\ 3\ 4\ 2)$, which is odd by Proposition 5.2.26. The product of the scalars is

$$i \cdot 2 \cdot (1-i) \cdot (-1) = -2i(1-i) = -2i + 2i^2 = -2 - 2i.$$

So $D(A) = -(-2-2i)D(I_4) = (2+2i)D(I_4)$.

(c) The columns of B are $2\mathbf{e}_3$, $2\mathbf{e}_1$, $2\mathbf{e}_2$, so $\sigma = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix} = (1\ 3\ 2)$, a 3-cycle, which is even. Hence $D(B) = 2^3 D(I_3) = 8D(I_3) = 2D(I_3)$, since $8 = 2$ in $\mathbb{F}_3$.

Solution to Exercise 5.2.45

Uses. Definition 5.2.15 (Cycle), Proposition 5.2.16 (Cycle decomposition), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.27 (Half of all permutations are even)
Hint 1. Count lists $a_1, \ldots, a_k$ of distinct elements, then ask how many lists name the same cycle.
Hint 2. Two lists name the same k-cycle exactly when one is a rotation of the other. Why?
Hint 3. For (b), a product of two disjoint transpositions is determined by how it splits $[4]$ into two pairs.
Sketch. There are $n!/(n-k)!$ lists of k distinct elements, and each k-cycle has exactly k names (its rotations), giving $n!/((n-k)!k)$. In S_4: $1 + 6 + 8 + 6 + 3 = 24$. The even ones are id, the 3-cycles, and the double transpositions: $1 + 8 + 3 = 12 = 4!/2$.

(a) By the argument of Proposition 5.2.4, there are $n(n-1)\cdots(n-k+1) = n!/(n-k)!$ lists $a_1, \ldots, a_k$ of distinct elements of $[n]$, and each names the k-cycle $(a_1\ \ldots\ a_k)$. The k rotations $a_p, a_{p+1}, \ldots, a_k, a_1, \ldots, a_{p-1}$ name the same cycle. Conversely, if $(b_1\ \ldots\ b_k) = \gamma = (a_1\ \ldots\ a_k)$, then b_1 is moved by γ, so $b_1 = a_p$ for some p, and then $b_2 = \gamma(b_1) = a_{p+1}$, $b_3 = \gamma(b_2) = a_{p+2}$, and so on (indices mod k); so the list b is a rotation of the list a. The k rotations of a list of distinct elements are distinct lists, since their first entries differ. So each k-cycle has exactly k names, and there are $n!/((n-k)!\,k)$ of them.

(b) By Proposition 5.2.16, each $\sigma \in S_4$ is a product of disjoint cycles whose lengths add up to at most 4, so its cycle notation is one of: id; a transposition; a 3-cycle; a 4-cycle; two disjoint transpositions. By (a) there are $4!/(2! \cdot 2) = 6$ transpositions, $4!/(1! \cdot 3) = 8$ three-cycles, and $4!/(0! \cdot 4) = 6$ four-cycles. A product of two disjoint transpositions $(a\ b)(c\ d)$ is determined by the partition $\{\{a,b\},\{c,d\}\}$ of $[4]$, and there are 3 such partitions (the partner of 1 determines it). The total is $1 + 6 + 8 + 6 + 3 = 24 = 4!$, as it must be.

By Proposition 5.2.26, transpositions and 4-cycles are odd, while id, 3-cycles, and products of two disjoint transpositions are even. So there are $1 + 8 + 3 = 12$ even permutations and $6 + 6 = 12$ odd ones, as Proposition 5.2.27 predicts.

Solution to Exercise 5.2.46

Uses. Exercise 5.2.39, Proposition 5.2.13 (Products of transpositions), Proposition 1.1.17 (No zero divisors), Definition 5.2.23 (Sign of a permutation)
Hint 1. First find $f(\mathrm{id})$. Then show that f takes the same value c on every transposition, using Exercise 5.2.39.
Hint 2. Compute c^2 from $(1\ 2)^2 = \mathrm{id}$, and conclude that $c = \pm 1$.
Hint 3. Every σ is a product of transpositions, so $f(\sigma)$ is a power of c.
Sketch. $f(\mathrm{id})^2 = f(\mathrm{id}) \neq 0$ gives $f(\mathrm{id}) = 1$. Each transposition is $\rho(1\ 2)\rho^{-1}$, so f of it is $f(\rho)cf(\rho)^{-1} = c$ where $c = f((1\ 2))$. Then $c^2 = f(\mathrm{id}) = 1$, so $c = \pm 1$, and $f(\tau_1 \cdots \tau_r) = c^r$ is 1 or $(-1)^r = \mathrm{sgn}(\sigma)$.

$f(\mathrm{id}) = 1$. From $f(\mathrm{id}) = f(\mathrm{id}\ \mathrm{id}) = f(\mathrm{id})^2$ and $f(\mathrm{id}) \neq 0$, cancelling one factor $f(\mathrm{id})$ gives $f(\mathrm{id}) = 1$. Consequently $f(\rho)f\left(\rho^{-1}\right) = f(\mathrm{id}) = 1$, so $f\left(\rho^{-1}\right) = f(\rho)^{-1}$.

f is constant on transpositions. Let $c = f((1\ 2))$. By Exercise 5.2.39, every transposition has the form $\rho(1\ 2)\rho^{-1}$, and since F is commutative,

$$f\left(\rho(1\ 2)\rho^{-1}\right) = f(\rho)cf(\rho)^{-1} = c.$$

$c = \pm 1$. Since $(1\ 2)^2 = \mathrm{id}$, $c^2 = f(\mathrm{id}) = 1$, so $(c-1)(c+1) = 0$, and by Proposition 1.1.17, $c = 1$ or $c = -1$.

Conclusion. Let $\sigma \in S_n$, and write $\sigma = \tau_1 \cdots \tau_r$ with transpositions τ_i (Proposition 5.2.13). Then $f(\sigma) = f(\tau_1) \cdots f(\tau_r) = c^r$. If $c = 1$, then $f(\sigma) = 1$ for all σ. If $c = -1$, then $f(\sigma) = (-1)^r = \mathrm{sgn}(\sigma)$ by Definition 5.2.23. (If $1 + 1 = 0$ in F, the two cases coincide.)

Solution to Exercise 5.2.47

Uses. Proposition 5.2.25 (Multiplicativity of the sign), Remark 5.2.11 (Composing with a transposition)
Techniques. Parity via an invariant (Technique 5.2.19)
Hint 1. Number the cells $1, \ldots, 16$ row by row and call the empty space tile 16. A position is then a permutation $\pi \in S_{16}$, with $\pi(p)$ the tile in cell p. What does a move do to π?
Hint 2. A move interchanges the contents of two adjacent cells, so it multiplies π by a transposition, flipping $\mathrm{sgn}(\pi)$. What else flips with every move?
Hint 3. Color the cells like a checkerboard. Every move changes the color of the cell holding the empty space. Consider the product of $\mathrm{sgn}(\pi)$ and ± 1 for that color.
Sketch. Encode a position as $\pi \in S_{16}$ ($\pi(p)$ = tile in cell p, the empty space being 16). A move with the empty space in cell p and a tile in an adjacent cell q replaces π by $\pi(p\ q)$, which flips $\mathrm{sgn}(\pi)$, and also moves the empty space to a cell of the other checkerboard color. So $\mathrm{sgn}(\pi)$ times the color sign of the empty cell is invariant. It is $+1$ for the solved position and -1 for the target, which has $\pi = (14\ 15)$ and the empty space in the same cell.

Number the cells $1, \ldots, 16$ row by row from the top left, and call the empty space tile 16. A position is then described by the permutation $\pi \in S_{16}$ with $\pi(p)$ the tile in cell p. The solved position is $\pi = \mathrm{id}$, and the target position is $\pi = (14\ 15)$.

Suppose the empty space is in cell p, so $\pi(p) = 16$, and the tile in an adjacent cell q slides into it. Afterwards cell p holds $\pi(q)$, cell q holds 16, and all other cells are unchanged. By Remark 5.2.11 this is the position $\pi(p\ q)$, so by Proposition 5.2.25 every move multiplies $\mathrm{sgn}(\pi)$ by -1.

Give the cell in row r and column c the color $\varepsilon = (-1)^{r+c}$, and let $\varepsilon(\pi)$ be the color of the cell containing the empty space. Two cells that share an edge differ by 1 in exactly one of r, c, so they have opposite colors. Hence every move also multiplies $\varepsilon(\pi)$ by -1, and the product $Q(\pi) = \mathrm{sgn}(\pi)\varepsilon(\pi)$ is unchanged by every move.

In the solved position, $Q = \mathrm{sgn}(\mathrm{id}) \cdot (-1)^{4+4} = 1$. In the target position, the empty space is again in row 4, column 4, and $\mathrm{sgn}((14\ 15)) = -1$, so $Q = -1$. Since moves never change Q, the target cannot be reached from the solved position.

The same argument shows that every position reachable from the solved one with the empty space back in the bottom right corner is an even permutation. Neither $\mathrm{sgn}(\pi)$ nor $\varepsilon(\pi)$ is invariant on its own; the invariant is their product.

Solution to Exercise 5.2.48

Uses. Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.25 (Multiplicativity of the sign), Definition 5.2.23 (Sign of a permutation)
Techniques. Parity via an invariant (Technique 5.2.19)
Hint 1. Regard the row as the bottom row of a permutation σ. Which permutation γ satisfies "the row after the move is the bottom row of $\sigma\gamma$"?
Hint 2. γ is a 3-cycle, so moves preserve the sign. That rules out odd σ.
Hint 3. For even σ: a move at positions $p-2, p-1, p$ carries the entry at position p two places to the left. Use this to bring 1 to the front, then 2 to position 2, and so on. What happens with the last two entries?
Sketch. A move at positions $i, i+1, i+2$ replaces σ by $\sigma\gamma$ with $\gamma = (i\ i+2\ i+1)$, a 3-cycle, so sgn is invariant and odd orders cannot be sorted. For even orders, move 1 left two places at a time; if it gets stuck in position 2, two moves at positions $1, 2, 3$ bring it to the front. Then sort positions $2, \ldots, n$ the same way without touching position 1, and so on, until only positions $n-1, n$ remain. The result is id or $(n-1\ n)$, and since the sign is still 1, it is id. Answer: exactly the even orders.

Write the row as the bottom row of $\sigma \in S_n$, so that the entry in position i is $\sigma(i)$. A move at positions $i, i+1, i+2$ produces the row whose entries in these positions are $\sigma(i+2), \sigma(i), \sigma(i+1)$. This is the bottom row of $\sigma\gamma$, where $\gamma(i) = i+2$, $\gamma(i+1) = i$, $\gamma(i+2) = i+1$, and γ fixes everything else; that is, $\gamma = (i\ i+2\ i+1)$. By Proposition 5.2.26 and Proposition 5.2.25, $\operatorname{sgn}(\sigma\gamma) = \operatorname{sgn}(\sigma)$. So moves never change the sign, and since the sorted row is id, with sign 1, an odd starting order can never be sorted.

Now let σ be even. We sort the row in stages, placing the value v in position v at stage v, for $v = 1, \ldots, n-2$, using only moves within positions $v, \ldots, n$ at stage v. Suppose the values $1, \ldots, v-1$ are already in positions $1, \ldots, v-1$, and v is in position $p \geq v$. While $p \geq v+2$, a move at positions $p-2, p-1, p$ carries the entry v from position p to position $p-2$ and does not touch positions before $p-2 \geq v$. When this stops, $p = v$ or $p = v+1$. If $p = v+1$, then $v+2 \leq n$ (as $v \leq n-2$), and two moves at positions $v, v+1, v+2$ change x, v, z there into z, x, v and then into v, z, x. Either way v ends in position v, and positions $1, \ldots, v-1$ were not touched.

After stage $n-2$, the values $1, \ldots, n-2$ are in place, and positions $n-1$ and n hold $n-1$ and n in some order. So the current permutation is id or $(n-1\ n)$. Since moves preserve the sign and σ is even, it is even, so it is id: the row is sorted.

Answer: the row can be sorted exactly when the starting order is an even permutation.

Solution to Exercise 5.2.49

Uses. Definition 5.2.21 (Inversion), Exercise 5.2.34, Proposition 5.2.13 (Products of transpositions)
Hint 1. In (a), write $(\sigma\rho(i) - \sigma\rho(j))/(i-j)$ as a product of two fractions. Which two?
Hint 2. For (b), the reversal conditions are 0/1 quantities u, v, and "exactly one" is $u + v - 2uv$. Sum over all pairs, and note that $\{i, j\} \mapsto \{\rho(i), \rho(j)\}$ is a bijection on two-element sets.
Hint 3. For (c), by (b), $(-1)^{\operatorname{inv}(\sigma\rho)} = (-1)^{\operatorname{inv}(\sigma)}(-1)^{\operatorname{inv}(\rho)}$, and inv of a transposition is odd.
Sketch. (a) $(\sigma\rho(i) - \sigma\rho(j))/(i-j) = [(\sigma(\rho(i)) - \sigma(\rho(j)))/(\rho(i) - \rho(j))] \cdot [(\rho(i) - \rho(j))/(i-j)]$, and a product of two nonzero rationals is negative exactly when one factor is. (b) Summing $u + v - 2uv$ over pairs gives $\operatorname{inv}(\sigma\rho) = \operatorname{inv}(\rho) + \operatorname{inv}(\sigma) - 2M$, since the pairs $\{\rho(i), \rho(j)\}$ run over all pairs. (c) So $(-1)^{\operatorname{inv}}$ is multiplicative and is -1 on transpositions; hence $(-1)^r = (-1)^{\operatorname{inv}(\sigma)} = (-1)^s$ for factorizations of lengths r and s.

(a) Let $i \neq j$. Since ρ and σ are injective, $\rho(i) \neq \rho(j)$ and $\sigma(\rho(i)) \neq \sigma(\rho(j))$, so in $\mathbb{Q}$,

$$\frac{\sigma\rho(i) - \sigma\rho(j)}{i-j} = \frac{\sigma(\rho(i)) - \sigma(\rho(j))}{\rho(i) - \rho(j)} \cdot \frac{\rho(i) - \rho(j)}{i-j},$$

a product of two nonzero rationals. The left side is negative exactly when $\sigma\rho$ reverses $\{i, j\}$, the second factor is negative exactly when ρ reverses $\{i, j\}$, and the first factor is negative exactly when σ reverses $\{\rho(i), \rho(j)\}$. A product of two nonzero rationals is negative exactly when exactly one factor is negative.

(b) Let P be the set of two-element subsets of $[n]$. For $p = \{i, j\} \in P$, let $u_p = 1$ if ρ reverses p and $u_p = 0$ otherwise, and let $v_p = 1$ if σ reverses $\rho(p) = \{\rho(i), \rho(j)\}$ and $v_p = 0$ otherwise. By (a), $\sigma\rho$ reverses p exactly when $u_p + v_p = 1$, and the integer $u_p + v_p - 2u_pv_p$ is 1 in that case and 0 otherwise. So

$$\operatorname{inv}(\sigma\rho) = \sum_{p\in P}\left(u_p + v_p - 2u_pv_p\right) = \sum_{p\in P} u_p + \sum_{p\in P} v_p - 2\sum_{p\in P} u_pv_p.$$

The first sum is $\operatorname{inv}(\rho)$. Since ρ is a bijection, $p \mapsto \rho(p)$ is a bijection of P (with inverse $p \mapsto \rho^{-1}(p)$), so as p runs over P, $\rho(p)$ runs over P once, and the second sum is the number of elements of P reversed by σ, which is $\operatorname{inv}(\sigma)$. Hence $\operatorname{inv}(\sigma\rho) - \operatorname{inv}(\sigma) - \operatorname{inv}(\rho)$ is even.

(c) By (b), $(-1)^{\operatorname{inv}(\sigma\rho)} = (-1)^{\operatorname{inv}(\sigma)}(-1)^{\operatorname{inv}(\rho)}$ for all σ, ρ. By Exercise 5.2.34, $\operatorname{inv}((k\ l)) = 2(l-k)-1$ is odd, so $(-1)^{\operatorname{inv}(\tau)} = -1$ for every transposition τ. If $\sigma = \tau_1\cdots\tau_r$, then by induction on r, $(-1)^{\operatorname{inv}(\sigma)} = (-1)^{\operatorname{inv}(\tau_1)}\cdots(-1)^{\operatorname{inv}(\tau_r)} = (-1)^r$. So two factorizations of σ of lengths r and s give $(-1)^r = (-1)^{\operatorname{inv}(\sigma)} = (-1)^s$, and r and s have the same parity.

Compared with Approach 2 in the text, this proof establishes multiplicativity first and gets the parity theorem from it, while the text proves the parity theorem first and gets multiplicativity for free from the definition.

Solution to Exercise 5.2.50

> *Uses.* Proposition 5.2.16 (Cycle decomposition), Lemma 5.2.17 (Cycles as products of transpositions), Definition 5.2.23 (Sign of a permutation)
> *Hint 1.* $\sigma\tau$ agrees with σ except at a and b: $(\sigma\tau)(a) = \sigma(b)$ and $(\sigma\tau)(b) = \sigma(a)$. So only the orbits containing a or b can change.
> *Hint 2.* If a and b are in one orbit, list it as $a, x_1, \ldots, x_p, b, y_1, \ldots, y_q$ in the order σ visits it, and follow $\sigma\tau$ from a and from b. If they are in different orbits, follow $\sigma\tau$ from a.
> *Hint 3.* For (c), (a) shows that each transposition changes c by 1, and $c(\mathrm{id}) = n$.
> *Sketch.* (a) Same orbit $a, x_1, \ldots, x_p, b, y_1, \ldots, y_q$: under $\sigma\tau$, $a \mapsto y_1 \mapsto \cdots \mapsto y_q \mapsto a$ and $b \mapsto x_1 \mapsto \cdots \mapsto x_p \mapsto b$, so the orbit splits in two. Different orbits $a, x_1, \ldots, x_p$ and $b, y_1, \ldots, y_q$: $a \mapsto y_1 \mapsto \cdots \mapsto y_q \mapsto b \mapsto x_1 \mapsto \cdots \mapsto x_p \mapsto a$, so they merge. (b) Start from $c(\mathrm{id}) = n$; each factor changes c by ± 1. (c) r factors give $c(\sigma) \geq n - r$, and Lemma 5.2.17 gives $n - c(\sigma)$ factors.

(a) Since τ fixes every point other than a and b, $(\sigma\tau)(x) = \sigma(x)$ for $x \notin \{a, b\}$, while $(\sigma\tau)(a) = \sigma(b)$ and $(\sigma\tau)(b) = \sigma(a)$. An orbit of σ containing neither a nor b is mapped into itself by σ, hence by $\sigma\tau$, on which they agree; so it is also an orbit of $\sigma\tau$. It remains to see what happens to the orbits containing a or b.

Same orbit. By Proposition 5.2.16, the orbit of a is $a, \sigma(a), \sigma^2(a), \ldots$ until it returns to a, and b occurs in it. Write it as $a, x_1, \ldots, x_p, b, y_1, \ldots, y_q$ in this order, with $p, q \geq 0$, so σ sends $a \mapsto x_1 \mapsto \cdots \mapsto x_p \mapsto b \mapsto y_1 \mapsto \cdots \mapsto y_q \mapsto a$ (where $a \mapsto x_1$ is read as $a \mapsto b$ if $p = 0$, and so on). Then $\sigma\tau$ sends $a \mapsto \sigma(b) = y_1 \mapsto \cdots \mapsto y_q \mapsto \sigma\left(y_q\right) = a$ and $b \mapsto \sigma(a) = x_1 \mapsto \cdots \mapsto x_p \mapsto \sigma\left(x_p\right) = b$. (If $q = 0$, then $\sigma(b) = a$ and a is fixed by $\sigma\tau$; similarly if $p = 0$.) So the orbit splits into the two orbits $\left\{a, y_1, \ldots, y_q\right\}$ and $\left\{b, x_1, \ldots, x_p\right\}$ of $\sigma\tau$, and $c(\sigma\tau) = c(\sigma) + 1$.

Different orbits. Write them as $a, x_1, \ldots, x_p$ and $b, y_1, \ldots, y_q$ in the order σ visits them. Then $\sigma\tau$ sends $a \mapsto \sigma(b) = y_1 \mapsto \cdots \mapsto y_q \mapsto \sigma\left(y_q\right) = b \mapsto \sigma(a) = x_1 \mapsto \cdots \mapsto x_p \mapsto \sigma\left(x_p\right) = a$, with the same conventions when p or q is 0. So the two orbits merge into one orbit of $\sigma\tau$, and $c(\sigma\tau) = c(\sigma) - 1$.

(b) We show by induction on r that $c(\tau_1\cdots\tau_r) - (n - r)$ is even. For $r = 0$, $c(\mathrm{id}) = n$. For the step, (a) gives $c(\tau_1\cdots\tau_r) = c(\tau_1\cdots\tau_{r-1}) \pm 1$, which changes $c - (n - r)$ by $\pm 1 + 1$, an even number. So if $\sigma = \tau_1\cdots\tau_r = \tau'_1\cdots\tau'_s$, then r and s both have the parity of $n - c(\sigma)$, which proves Theorem 5.2.18, and $\operatorname{sgn}(\sigma) = (-1)^r = (-1)^{n-c(\sigma)}$.

(c) If $\sigma = \tau_1\cdots\tau_r$, then by (a) and induction, $c\left(\tau_1\cdots\tau_j\right) \geq n - j$ for each j, so $c(\sigma) \geq n - r$, that is, $r \geq n - c(\sigma)$. On the other hand, Proposition 5.2.16 and Lemma 5.2.17 write σ as a product of exactly $n - c(\sigma)$ transpositions. So the least number is $n - c(\sigma)$.

Solution to Exercise 5.2.51

> *Uses.* Corollary 5.2.24 (Formulas for the sign), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Proposition 1.1.17 (No zero divisors), Proposition 5.2.26 (Sign of a cycle)
> *Hint 1.* For (a), multiply all the nonzero elements together, before and after applying μ_a.
> *Hint 2.* For (b), use Corollary 5.2.24 (b) over the field $\mathbb{F}_p$, with $\mathbf{x} = (1, 2, \ldots, p-1) \in \mathbb{F}_p^{p-1}$. What is $\mathbf{x}^{\mu_a}$?
> *Hint 3.* Each factor of $\Delta(\mathbf{x}^{\mu_a})$ is $aj - ai = a(j - i)$, and there are $(p-1)(p-2)/2$ factors. Then use (a) and that $p - 2$ is odd.

Sketch. (a) μ_a permutes the factors of $P = 1 \cdot 2 \cdots (p-1) \neq 0$, so $a^{p-1}P = P$. (b) With $\mathbf{x} = (1, \ldots, p-1)$, $\mathbf{x}^{\mu_a} = (a, 2a, \ldots, (p-1)a)$, so $\Delta(\mathbf{x}^{\mu_a}) = a^N \Delta(\mathbf{x})$ with $N = (p-1)(p-2)/2$, and $\Delta(\mathbf{x}) \neq 0$. By Corollary 5.2.24, $\operatorname{sgn}(\mu_a) = a^N$ in $\mathbb{F}_p$. With $h = (p-1)/2$, $a^h = \pm 1$ by (a), and $a^N = \left(a^h\right)^{p-2} = a^h$ since $p-2$ is odd. (c) $\mu_2 = (1\ 2\ 4)(3\ 6\ 5)$ is even and $2^3 = 1$; $\mu_3 = (1\ 3\ 2\ 6\ 4\ 5)$ is odd and $3^3 = -1$.

Since p is prime, $\mathbb{F}_p$ is a field (Proposition 1.1.24). If $ak = ak'$ then $k = k'$ (multiply by a^{-1}), and $ak \neq 0$ for $k \neq 0$, so μ_a is indeed a permutation of the $p-1$ nonzero elements.

(a) Let $P = 1 \cdot 2 \cdots (p-1) \in \mathbb{F}_p$, which is nonzero by Proposition 1.1.17. Since μ_a is a bijection of the nonzero elements, the products of $1, \ldots, p-1$ and of $a \cdot 1, a \cdot 2, \ldots, a(p-1)$ have the same factors in a different order, so they are equal: $a^{p-1}P = P$. Cancelling P gives $a^{p-1} = 1$.

(b) Let $\mathbf{x} = (1, 2, \ldots, p-1) \in \mathbb{F}_p^{p-1}$, so $x_k = k$. Its entries are distinct, so $\Delta(\mathbf{x}) \neq 0$. The k-th entry of $\mathbf{x}^{\mu_a}$ is $x_{\mu_a(k)} = ak$. So each factor of $\Delta(\mathbf{x}^{\mu_a})$ is $aj - ai = a(j-i)$, and since there are $N = \binom{p-1}{2} = (p-1)(p-2)/2$ factors,

$$\Delta(\mathbf{x}^{\mu_a}) = a^N \Delta(\mathbf{x}).$$

By Corollary 5.2.24 (b) over $F = \mathbb{F}_p$, the left side is $\operatorname{sgn}(\mu_a)\Delta(\mathbf{x})$. Cancelling $\Delta(\mathbf{x}) \neq 0$, $\operatorname{sgn}(\mu_a) = a^N$ in $\mathbb{F}_p$. Let $h = (p-1)/2$. By (a), $\left(a^h\right)^2 = 1$, so $a^h = \pm 1$ by Proposition 1.1.17. Since $N = h(p-2)$ and $p-2$ is odd, $a^N = \left(a^h\right)^{p-2} = a^h$. So $\operatorname{sgn}(\mu_a) = a^h$ in $\mathbb{F}_p$. Because p is odd, $1 \neq -1$ in $\mathbb{F}_p$, so this equation in $\mathbb{F}_p$ determines the integer $\operatorname{sgn}(\mu_a)$.

(c) For $p = 7$, μ_2 sends $1 \mapsto 2 \mapsto 4 \mapsto 1$ and $3 \mapsto 6 \mapsto 5 \mapsto 3$, so $\mu_2 = (1\ 2\ 4)(3\ 6\ 5)$, which is even by Proposition 5.2.26; and $2^3 = 8 = 1$ in $\mathbb{F}_7$. Also μ_3 sends $1 \mapsto 3 \mapsto 2 \mapsto 6 \mapsto 4 \mapsto 5 \mapsto 1$, a 6-cycle, which is odd; and $3^3 = 27 = -1$ in $\mathbb{F}_7$.

Section 5.3

Solution to Exercise 5.3.7

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Exercise 5.1.34, Definition 1.5.1 (Linear independence), Definition 4.1.5 (Dimension), Proposition 1.1.15 (Multiplying by zero)
Hint 1. The last sentence of Theorem 5.3.4 writes every $D \in \operatorname{Alt}_n$ as a scalar multiple of det.
Hint 2. For the dimension, the list consisting of det alone is independent because $\det \neq 0$. For the last claim, write $D = c \det$ and evaluate at A.
Sketch. Every $D \in \operatorname{Alt}_n$ equals $D(I_n) \det$, and $\det \in \operatorname{Alt}_n$, so $\operatorname{Alt}_n = \operatorname{span}(\det)$. Since $\det(I_n) = 1$, det is not the zero function, so it alone is a basis. If $D(A) \neq 0$, then $D = c \det$ with $c \det A \neq 0$, which forces $c \neq 0$ and $\det A \neq 0$.

By Theorem 5.3.4, every $D \in \operatorname{Alt}_n$ satisfies $D = D(I_n) \det \in \operatorname{span}(\det)$. Conversely, $\det \in \operatorname{Alt}_n$ and Alt_n is a subspace (Exercise 5.1.34), so $\operatorname{span}(\det) \subseteq \operatorname{Alt}_n$. Hence $\operatorname{Alt}_n = \operatorname{span}(\det)$. Since $\det(I_n) = 1$, det is not the zero function, so the one-element list det is linearly independent and is a basis of Alt_n. Thus $\dim \operatorname{Alt}_n = 1$.

Now let $D \in \operatorname{Alt}_n$ with $D(A) \neq 0$, and let $c = D(I_n)$, so $D = c \det$. If $c = 0$ or $\det A = 0$, then $D(A) = c \det A = 0$ by Proposition 1.1.15, which is false. So $c \neq 0$ and $\det A \neq 0$.

Solution to Exercise 5.3.8

Uses. Definition 5.3.6 (Determinant), Proposition 5.2.8 (Reindexing sums over S_n), Proposition 5.2.25 (Multiplicativity of the sign)
Hint 1. Fix σ and reorder the product $a_{\sigma(1)1} \cdots a_{\sigma(n)n}$ by its row index. If $i = \sigma(j)$, what is j in terms of i?
Hint 2. You should get $\prod_j a_{\sigma(j)j} = \prod_i a_{i\sigma^{-1}(i)}$. Then use $\operatorname{sgn}(\sigma^{-1}) = \operatorname{sgn}(\sigma)$ and substitute σ^{-1} for σ in the sum.
Sketch. As j runs over $[n]$, $i = \sigma(j)$ runs over $[n]$ once each, with $j = \sigma^{-1}(i)$, so $\prod_j a_{\sigma(j)j} = \prod_i a_{i\sigma^{-1}(i)}$. With $\operatorname{sgn}(\sigma) = \operatorname{sgn}(\sigma^{-1})$, $\det A = \sum_\sigma g(\sigma^{-1})$ for $g(\rho) = \operatorname{sgn}(\rho) \prod_i a_{i\rho(i)}$, and reindexing by $\sigma \mapsto \sigma^{-1}$ gives $\sum_\sigma g(\sigma)$.

Fix $\sigma \in S_n$. As j runs over $[n]$, the row index $i = \sigma(j)$ runs over $[n]$, taking each value once, and $j = \sigma^{-1}(i)$. Since multiplication in F is commutative, we may reorder the factors by their row index:

$$a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n} = a_{1\sigma^{-1}(1)} a_{2\sigma^{-1}(2)} \cdots a_{n\sigma^{-1}(n)}.$$

Let $g(\rho) = \operatorname{sgn}(\rho) a_{1\rho(1)} \cdots a_{n\rho(n)}$ for $\rho \in S_n$. Since $\operatorname{sgn}(\sigma) = \operatorname{sgn}\left(\sigma^{-1}\right)$ by Proposition 5.2.25, the term of σ in the Leibniz formula is $g\left(\sigma^{-1}\right)$. By Proposition 5.2.8,

$$\det A = \sum_{\sigma \in S_n} g\left(\sigma^{-1}\right) = \sum_{\sigma \in S_n} g(\sigma),$$

which is the claim. The right side is the Leibniz formula for the transpose A^{T}, whose (j,i) entry is a_{ij}. So this exercise shows $\det A^{\mathsf{T}} = \det A$; Theorem 5.4.14 records this and draws the consequences.

Solution to Exercise 5.3.16

Uses. Proposition 5.3.15 (Triangular matrices)
Hint 1. Both matrices in (a) are triangular. Multiply the diagonal entries.
Hint 2. In (b), N and $cI_n + N$ are upper triangular. What are their diagonal entries?
Sketch. (a) $2 \cdot (-1) \cdot 3 \cdot 1/2 = -3$ and $i(1+i)(1-i) = 2i$. (b) N is upper triangular with zero diagonal, and $cI_n + N$ is upper triangular with every diagonal entry c.

(a) The first matrix is upper triangular, so by Proposition 5.3.15 its determinant is $2 \cdot (-1) \cdot 3 \cdot 1/2 = -3$. The second is lower triangular, so its determinant is $i(1+i)(1-i) = i\left(1 - i^2\right) = 2i$.

(b) A strictly upper triangular N is upper triangular with all diagonal entries 0, so $\det N = 0 \cdot \cdots \cdot 0 = 0$ by Proposition 5.3.15 (here $n \geq 1$). The matrix $cI_n + N$ has (i,j) entry equal to that of N, which is 0, for $i > j$, and $c + 0 = c$ on the diagonal, so it is upper triangular with all diagonal entries c, and $\det(cI_n + N) = c^n$.

Solution to Exercise 5.3.23

Uses. Corollary 5.3.9 (Rule of Sarrus), Proposition 5.3.20 (Reduction modulo p), Proposition 5.1.17 (Dependent columns)
Techniques. Reduce modulo p (Technique 5.3.21)
Hint 1. The down-right diagonals give $1 \cdot 1 \cdot 1$, $0 \cdot 1 \cdot 1$, and $3 \cdot 3 \cdot 4$.
Hint 2. For (b), reduce the answer to (a) instead of recomputing (Proposition 5.3.20).
Hint 3. For (c), solve the system row by row over $\mathbb{F}_5$, starting with $x_1 + 3x_3 = 0$.
Sketch. (a) $(1 + 0 + 36) - (3 + 4 + 0) = 30$. (b) $30 = 2 \cdot 3 \cdot 5$, so $\det \overline{A}$ is 0 modulo 2, 3, 5, and 2 modulo 7. (c) $\mathbf{x} = (2, 3, 1)$; a dependence among the columns forces $\det \overline{A} = 0$, matching $5 \mid 30$.

(a) The diagonals running down to the right have products $1 \cdot 1 \cdot 1 = 1$, $0 \cdot 1 \cdot 1 = 0$, and $3 \cdot 3 \cdot 4 = 36$; the diagonals running up to the right have products $1 \cdot 1 \cdot 3 = 3$, $4 \cdot 1 \cdot 1 = 4$, and $1 \cdot 3 \cdot 0 = 0$. By Corollary 5.3.9, $\det A = 37 - 7 = 30$.

(b) By Proposition 5.3.20, $\det \overline{A} = 30 \bmod p$. Since $30 = 2 \cdot 3 \cdot 5$, we get $\det \overline{A} = 0$ for $p = 2, 3, 5$, and $\det \overline{A} = 30 \bmod 7 = 2$ for $p = 7$.

(c) Over $\mathbb{F}_5$, the rows of $\overline{A}\mathbf{x} = \mathbf{0}$ read $x_1 + 3x_3 = 0$, $3x_1 + x_2 + x_3 = 0$, and $x_1 + 4x_2 + x_3 = 0$. The first gives $x_1 = -3x_3 = 2x_3$, and then the second gives $x_2 = -7x_3 = 3x_3$. With $x_3 = 1$, $\mathbf{x} = (2, 3, 1)$, and the third row checks: $2 + 12 + 1 = 15 = 0$. So $2\mathbf{a}_1 + 3\mathbf{a}_2 + \mathbf{a}_3 = \mathbf{0}$ is a nontrivial dependence among the columns of $\overline{A}$, which forces $\det \overline{A} = 0$ by Proposition 5.1.17. This agrees with (b), since $5 \mid 30$.

Solution to Exercise 5.3.24

Uses. Definition 5.3.6 (Determinant), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.25 (Multiplicativity of the sign)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. The term of σ is nonzero exactly when $\sigma(j)$ is one of the two rows where column j is nonzero, for every j.
Hint 2. Columns 1 and 3 are nonzero only in rows 2 and 4, and columns 2 and 4 only in rows 1 and 3. So σ must send $\{1,3\}$ onto $\{2,4\}$ and $\{2,4\}$ onto $\{1,3\}$.
Sketch. The surviving σ, written as bottom rows, are 2, 1, 4, 3 (even, product 120), 2, 3, 4, 1 (a 4-cycle, product 15), 4, 1, 2, 3 (a 4-cycle, product 8), and 4, 3, 2, 1 (even, product 1). So $\det B = 120 - 15 - 8 + 1 = 98$.

The term of σ is nonzero exactly when $b_{\sigma(j)j} \neq 0$ for every j. Column 1 is nonzero in rows 2 and 4, column 2 in rows 1 and 3, column 3 in rows 2 and 4, and column 4 in rows 1 and 3. Since σ is injective, $\sigma(1)$ and $\sigma(3)$ are the two rows 2 and 4 in some order, and $\sigma(2)$ and $\sigma(4)$ are 1 and 3 in some order. So exactly $2 \cdot 2 = 4$ permutations survive. Writing σ by its bottom row $\sigma(1), \sigma(2), \sigma(3), \sigma(4)$:

- 2, 1, 4, 3, that is, (1 2)(3 4), which is even, with product $b_{21}b_{12}b_{43}b_{34} = 3 \cdot 2 \cdot 5 \cdot 4 = 120$;

- $2, 3, 4, 1$, that is, $(1\ 2\ 3\ 4)$, which is odd by Proposition 5.2.26, with product $b_{21}b_{32}b_{43}b_{14} = 3 \cdot 1 \cdot 5 \cdot 1 = 15$;
- $4, 1, 2, 3$, that is, $(1\ 4\ 3\ 2)$, which is odd, with product $b_{41}b_{12}b_{23}b_{34} = 1 \cdot 2 \cdot 1 \cdot 4 = 8$;
- $4, 3, 2, 1$, that is, $(1\ 4)(2\ 3)$, which is even, with product $b_{41}b_{32}b_{23}b_{14} = 1$.

(The products of two disjoint transpositions are even by Proposition 5.2.25.) Hence $\det B = 120 - 15 - 8 + 1 = 98$.

Solution to Exercise 5.3.25

Uses. Definition 5.3.6 (Determinant), Proposition 5.2.26 (Sign of a cycle), Theorem 5.2.31 (Alternating functions and permutations), Remark 5.3.11 (Sarrus does not generalize)
Hint 1. How many terms does the Leibniz formula have for $n = 4$? How many products does the claim produce?
Hint 2. The diagonal from a_{12} is $a_{12}a_{23}a_{34}a_{41}$. Which permutation is this the term of, and what is its sign?
Hint 3. Try a permutation matrix whose nonzero entries are not all on one diagonal, such as I_4 with its first two columns interchanged.
Sketch. The argument shows that each diagonal is a term, not that each term is a diagonal: 8 diagonals cover only 8 of the 24 terms. And the signs are not those of the permutations: the downward diagonals from a_{12} and a_{14} are terms of 4-cycles, which are odd, and the upward diagonals from a_{41} and a_{43} are terms of even products of two transpositions. For I_4 with columns 1 and 2 interchanged, every diagonal contains a 0, so the claim gives 0, but $\det = -1$.

There are two errors. First, the argument shows that each diagonal is a term of the Leibniz formula, but not that each term is a diagonal. There are $4! = 24$ terms and only 8 diagonals, so 16 terms are missing. For example, the term $a_{21}a_{12}a_{33}a_{44}$ of $(1\ 2)$ lies on no diagonal. Second, the signs are wrong. The diagonal from a_{12} is $a_{12}a_{23}a_{34}a_{41}$, the term of the permutation σ with $\sigma(2) = 1$, $\sigma(3) = 2$, $\sigma(4) = 3$, $\sigma(1) = 4$, which is the 4-cycle $(1\ 4\ 3\ 2)$. By Proposition 5.2.26 it is odd, so this product enters $\det A$ with sign -1, while the claim adds it. The same happens for the downward diagonal from a_{14}, the term of the 4-cycle $(1\ 2\ 3\ 4)$, and in the other direction for the upward diagonals from a_{41} and a_{43}, the terms of the even permutations $(1\ 4)(2\ 3)$ and $(1\ 2)(3\ 4)$, which the claim subtracts. Only the four diagonals from a_{11}, a_{13}, a_{42}, and a_{44} get the right sign. For $n = 3$ the downward diagonals are id and two 3-cycles, which are even, and the upward ones are transpositions; that is why the rule of Sarrus works (Remark 5.3.11).

Each error gives a counterexample. Let A be I_4 with columns 1 and 2 interchanged, so its nonzero entries are $a_{21} = a_{12} = a_{33} = a_{44} = 1$. Then $\det A = -\det I_4 = -1$ by Theorem 5.2.31. But every diagonal contains a zero entry: the downward diagonals start at $a_{11} = 0$, a_{12} (followed by $a_{23} = 0$), $a_{13} = 0$, and $a_{14} = 0$, and the upward ones start at $a_{41} = a_{42} = a_{43} = 0$ and at a_{44} (followed by $a_{31} = 0$). So the claim gives 0. If $1 + 1 \neq 0$ in F, the sign error gives a second counterexample: let A be the permutation matrix whose nonzero entries are exactly $a_{12}, a_{23}, a_{34}, a_{41}$. Then $\det A = \operatorname{sgn}((1\ 4\ 3\ 2)) = -1$, while every diagonal except the one from a_{12} contains a 0, so the claim gives $+1 \neq -1$.

Solution to Exercise 5.3.26

Uses. Definition 5.3.6 (Determinant), Lemma 5.3.2 (Expanding every column), Proposition 5.3.15 (Triangular matrices)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Is $(x_1 + y_1)(x_2 + y_2) = x_1x_2 + y_1y_2$? Test the claim with two diagonal matrices that add up to I_n.
Hint 2. For (b), expand the product $\prod_j \left(a_{\sigma(j)j} + b_{\sigma(j)j}\right)$ by choosing one of the two summands in each factor, and record the set S of j where you chose a.
Sketch. The second equality replaces a product of sums by the sum of two products; a product of n sums expands into 2^n terms. With $A = \operatorname{diag}(1, 0, 1, \ldots, 1)$ and $B = \operatorname{diag}(0, 1, 0, \ldots, 0)$, $\det A = \det B = 0$ but $\det(A + B) = \det I_n = 1$. For (b), $\prod_j \left(a_{\sigma(j)j} + b_{\sigma(j)j}\right) = \sum_S \prod_{j \in S} a_{\sigma(j)j} \prod_{j \notin S} b_{\sigma(j)j}$, and exchanging the sums over σ and S gives $\sum_S \det C_S$.

(a) The second equality is false. A product of n sums is not the sum of the two "pure" products: by distributivity, $\prod_{j=1}^{n} \left(x_j + y_j\right)$ is a sum of 2^n terms, one for each way of choosing x_j or y_j in each factor, and the argument keeps only the two terms that choose x every time or y every time. For every $n \geq 2$ and every field the claim is false: let $A = \operatorname{diag}(1, 0, 1, \ldots, 1)$ and $B = \operatorname{diag}(0, 1, 0, \ldots, 0)$. Each has a zero diagonal entry, so $\det A = \det B = 0$ by Proposition 5.3.15, while $A + B = I_n$ has determinant 1. (For $n = 1$ the claim is true, since then each product has a single factor.)

(b) For each σ, distributivity gives

$$\prod_{j=1}^{n}\bigl(a_{\sigma(j)j}+b_{\sigma(j)j}\bigr)=\sum_{S\subseteq[n]}\prod_{j\in S}a_{\sigma(j)j}\prod_{j\notin S}b_{\sigma(j)j},$$

where S records the factors in which $a_{\sigma(j)j}$ was chosen. The (i,j) entry of C_S is a_{ij} if $j\in S$ and b_{ij} if $j\notin S$, so the term for S is $\prod_j (C_S)_{\sigma(j)j}$. Multiplying by $\operatorname{sgn}(\sigma)$, summing over σ, and exchanging the two finite sums,

$$\det(A+B)=\sum_{S\subseteq[n]}\sum_{\sigma\in S_n}\operatorname{sgn}(\sigma)\prod_{j=1}^{n}(C_S)_{\sigma(j)j}=\sum_{S\subseteq[n]}\det C_S.$$

The same identity follows from multilinearity alone, by expanding each column $\mathbf{a}_j+\mathbf{b}_j$ as in Lemma 5.3.2. So it holds for every multilinear D in place of det; the terms $S=[n]$ and $S=\emptyset$ are $\det A$ and $\det B$, and the other 2^n-2 terms are what the argument in (a) dropped.

Solution to Exercise 5.3.27

Uses. Definition 5.3.6 (Determinant), Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.2.27 (Half of all permutations are even), Definition 5.1.1 (Determinant function), Theorem 5.3.4 (Existence and uniqueness of the determinant)
Techniques. Cancel terms in pairs (Technique 5.3.5)
Hint 1. (a) In the term of σ, which entry comes from row r? Imitate the multilinearity part of the proof of Theorem 5.3.4.
Hint 2. (b) If rows r and s are equal, compare the terms of σ and $\tau\sigma$, where $\tau=(r\ s)$; note that the transposition now acts on the left.
Hint 3. (c) Row i of ΛA is d_i times row i of A, and column j of $A\Lambda$ is $d_j\mathbf{a}_j$.
Sketch. (a) The term of σ contains exactly one entry of row r, namely $a_{r\sigma^{-1}(r)}$, so det is a fixed linear combination of the entries of row r. (b) If rows r,s are equal and $\tau=(r\ s)$, then $a_{\tau(\sigma(j))j}=a_{\sigma(j)j}$ for all j and $\operatorname{sgn}(\tau\sigma)=-\operatorname{sgn}(\sigma)$; pair each even σ with $\tau\sigma$. (c) Pull d_i out of each row by (a), and out of each column by multilinearity.

(a) Fix $r\in[n]$ and all rows except row r, and let $\mathbf{x}=(x_1,\dots,x_n)$ be row r, so $a_{rj}=x_j$. In the term of σ, the entry from row r is $a_{\sigma(j)j}$ for the unique j with $\sigma(j)=r$, that is, $j=\sigma^{-1}(r)$. So

$$\det A=\sum_{\sigma\in S_n}b_\sigma x_{\sigma^{-1}(r)},\quad\text{where } b_\sigma=\operatorname{sgn}(\sigma)\prod_{j\neq\sigma^{-1}(r)}a_{\sigma(j)j}$$

does not depend on $\mathbf{x}$. As in the proof of Theorem 5.3.4, a function of this form is linear in $\mathbf{x}$.

(b) Suppose rows $r\neq s$ are equal, so $a_{rj}=a_{sj}$ for every j, and let $\tau=(r\ s)$. For every j, $\tau(\sigma(j))$ equals $\sigma(j)$ unless $\sigma(j)\in\{r,s\}$, in which case it is the other element of $\{r,s\}$; since rows r and s are equal, $a_{\tau(\sigma(j))j}=a_{\sigma(j)j}$ in all cases. Also $\operatorname{sgn}(\tau\sigma)=-\operatorname{sgn}(\sigma)$ by Proposition 5.2.25. So the term of $\tau\sigma$ is the negative of the term of σ. The map $\sigma\mapsto\tau\sigma$ maps even permutations to odd ones and odd ones to even ones, and it is its own inverse, so it maps the set S_n^+ of even permutations bijectively onto the set of odd ones (as in the proof of Proposition 5.2.27). Hence

$$\det A=\sum_{\sigma\in S_n^+}\bigl(t_\sigma(A)+t_{\tau\sigma}(A)\bigr)=0,$$

where $t_\sigma(A)$ denotes the term of σ.

(c) Row i of ΛA is d_i times row i of A. Pulling the factor d_i out of row i for each i, by (a), gives $\det(\Lambda A)=d_1\cdots d_n\det A$. Column j of $A\Lambda$ is $d_j\mathbf{a}_j$, and pulling the factors out of the columns by multilinearity gives $\det(A\Lambda)=d_1\cdots d_n\det A$.

Here is what (a) and (b) mean. Let $D(A)=\det A^{\mathsf T}$. The columns of A are the rows of $A^{\mathsf T}$, so by (a) and (b), D is multilinear and alternating, and $D(I_n)=1$. By Theorem 5.3.4, $D=\det$, that is, $\det A^{\mathsf T}=\det A$; Theorem 5.4.14 records this.

Solution to Exercise 5.3.28

Uses. Definition 5.3.6 (Determinant), Definition 1.1.29 (Complex numbers), Exercise 5.1.5
Techniques. det is a polynomial in the entries (Technique 5.3.18)

Hint 1. Check that $\overline{z+w} = \overline{z} + \overline{w}$ and $\overline{zw} = \overline{z} \cdot \overline{w}$, and apply this to the Leibniz formula.
Hint 2. For (b), compute $\det \overline{A}$ in two ways: by (a), and as $\det(-A)$.
Sketch. Conjugation respects sums and products, and fixes ± 1, so conjugating the Leibniz formula for A term by term gives the formula for $\overline{A}$. A real A has $\overline{A} = A$, so $\det A = \overline{\det A}$ is real. In (b), $\overline{\det A} = \det(-A) = (-1)^n \det A$.

(a) For $z = x + yi$ and $w = u + vi$, we have $\overline{z+w} = (x+u) - (y+v)i = \overline{z} + \overline{w}$, and

$$\overline{z} \cdot \overline{w} = (x - yi)(u - vi) = (xu - yv) - (xv + yu)i = \overline{zw},$$

since $zw = (xu - yv) + (xv + yu)i$. By induction, conjugation respects finite sums and products, and it fixes the real numbers ± 1. Conjugating the Leibniz formula term by term,

$$\overline{\det A} = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) \overline{a_{\sigma(1)1}} \cdots \overline{a_{\sigma(n)n}} = \det \overline{A}.$$

If every entry of A is real, then $\overline{A} = A$, so $\overline{\det A} = \det A$, which says that $\det A$ is real.

(b) By (a) and Exercise 5.1.5, $\overline{\det A} = \det \overline{A} = \det(-A) = (-1)^n \det A$. If n is even, $\overline{\det A} = \det A$, so $\det A$ is real. If n is odd, $\overline{\det A} = -\det A$, so the real part of $\det A$ is 0: $\det A$ is purely imaginary.

Solution to Exercise 5.3.29

Uses. Definition 5.3.6 (Determinant), Theorem 5.2.31 (Alternating functions and permutations), Definition 5.2.29 (Permutation matrix)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. Fix σ. The rows $\sigma(j)$ for $j \in C$ are $|C|$ different rows. Can they all avoid R?
Hint 2. For (b), if $a_{kk} = 0$, take $R = \{k, \ldots, n\}$ and $C = \{1, \ldots, k\}$.
Hint 3. For (c), look for a permutation matrix whose first $s = n - r$ columns have their 1s below row r.
Sketch. (a) The $|C|$ distinct rows $\sigma(j)$, $j \in C$, cannot all lie in $[n] \setminus R$, which has fewer than $|C|$ elements; so some $a_{\sigma(j)j}$ with $j \in C$ lies in the zero block, and every term vanishes. (b) A zero at (k,k) in an upper triangular matrix gives a zero block on rows $k, \ldots, n$ and columns $1, \ldots, k$, of total size $n+1$. (c) The permutation matrix with columns $\mathbf{e}_{r+1}, \ldots, \mathbf{e}_n, \mathbf{e}_1, \ldots, \mathbf{e}_r$ has a zero $r \times (n-r)$ block in its upper left corner and determinant ± 1.

(a) Let $\sigma \in S_n$. The rows $\sigma(j)$ for $j \in C$ are $|C|$ distinct elements of $[n]$. The set $[n] \setminus R$ has $n - |R| < |C|$ elements, so not all of these rows lie in it: there is $j \in C$ with $\sigma(j) \in R$. Then $a_{\sigma(j)j} = 0$, and the term of σ vanishes. Since every term vanishes, $\det A = 0$.

(b) Let A be upper triangular with $a_{kk} = 0$, and let $R = \{k, k+1, \ldots, n\}$ and $C = \{1, 2, \ldots, k\}$. For $i \in R$ and $j \in C$ we have $i \geq k \geq j$, so either $i > j$, and $a_{ij} = 0$ because A is upper triangular, or $i = j = k$, and $a_{ij} = a_{kk} = 0$. Since $|R| + |C| = (n - k + 1) + k = n + 1 > n$, part (a) gives $\det A = 0$, in agreement with Proposition 5.3.15.

(c) Let $1 \leq r \leq n-1$ and $s = n - r$. Let A be the matrix with columns $\mathbf{e}_{r+1}, \ldots, \mathbf{e}_n, \mathbf{e}_1, \ldots, \mathbf{e}_r$, that is, the permutation matrix E_σ with $\sigma(j) = r + j$ for $j \leq s$ and $\sigma(j) = j - s$ for $j > s$ (Definition 5.2.29). For $i \in R = \{1, \ldots, r\}$ and $j \in C = \{1, \ldots, s\}$, the column $\mathbf{e}_{r+j}$ has a 0 in row $i \leq r$, so $a_{ij} = 0$, and $|R| + |C| = n$. But $\det A = \operatorname{sgn}(\sigma) = \pm 1 \neq 0$ by Theorem 5.2.31.

Solution to Exercise 5.3.30

Uses. Definition 5.3.6 (Determinant), Proposition 5.3.15 (Triangular matrices), Proposition 5.3.17 (Block-diagonal matrices), Proposition 5.1.17 (Dependent columns), Definition 2.4.21 (Transpose)
Hint 1. (a) Try a matrix with two equal columns.
Hint 2. (b) If $\det A \neq 0$, some term $t_\sigma(A)$ is nonzero. Where are its n nonzero entries?
Hint 3. (c) What kind of matrix is A^{T}, and what are its diagonal entries? (d) Try $n = 2$ and $A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.
Sketch. (a) False: the all-ones matrix with $n \geq 2$. (b) True: a nonzero term uses n nonzero entries, one in each row and each column, and these must be all of them. (c) True: A^{T} is lower triangular with the same diagonal. (d) False for $n \geq 2$: $\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has determinant -1, but $\det \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} = 0$.

(a) False for every $n \geq 2$. The matrix with every entry 1 has two equal columns, so its determinant is 0. (For $n = 1$ the statement is true.)

(b) True. Since $\det A \neq 0$, some term of the Leibniz formula is nonzero, so the n entries $a_{\sigma(1)1}, \ldots, a_{\sigma(n)n}$ are nonzero for some σ. They lie in n different positions, and A has only n nonzero entries, so these are all of them. They lie one in each column, and, since σ is a bijection, one in each row.

(c) True. The (i,j) entry of A^{T} is a_{ji}, which is 0 when $j > i$, that is, when $i < j$. So A^{T} is lower triangular, with the same diagonal entries a_{jj} as A. By Proposition 5.3.15, both determinants equal $a_{11}\cdots a_{nn}$.

(d) False for every $n \geq 2$. For $n = 2$, take $A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ and $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. Then $\det A = 0$ (a zero column), while $\det(A+N) = \det\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = -1$. For $n > 2$, take $A' = \begin{pmatrix} A & 0 \\ 0 & I_{n-2} \end{pmatrix}$ and $N' = \begin{pmatrix} N & 0 \\ 0 & 0 \end{pmatrix}$, which is still strictly upper triangular. By Proposition 5.3.17, $\det A' = \det A = 0$ and $\det(A'+N') = \det(A+N) = -1$. (For $n = 1$, $N = 0$ and the statement is true.)

Solution to Exercise 5.3.31

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Proposition 5.2.8 (Reindexing sums over S_n), Proposition 5.2.30 (Algebra of permutation matrices), Definition 1.1.28 (Characteristic), Proposition 5.3.20 (Reduction modulo p)

Hint 1. For (a), the proof of Theorem 5.3.4 for normalization and multilinearity did not use the signs. For the last claim, the columns of AE_π are $\mathbf{a}_{\pi(1)}, \ldots, \mathbf{a}_{\pi(n)}$; reindex the sum.

Hint 2. For (b), if $1 + 1 = 0$, compare per with det term by term. If $1 + 1 \neq 0$, evaluate per at the matrix with columns $\mathbf{e}_1 + \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2, \mathbf{e}_3, \ldots, \mathbf{e}_n$.

Hint 3. For (c), reduce both $\det A$ and $\operatorname{per} A$ modulo 2.

Sketch. (a) Part 2 of the proof of Theorem 5.3.4 works without signs. The term of σ in $\operatorname{per}(AE_\pi)$ is the term of $\sigma\pi^{-1}$ in $\operatorname{per} A$, and $\sigma \mapsto \sigma\pi^{-1}$ is a bijection. (b) If $1 + 1 = 0$, then $\operatorname{sgn}(\sigma) = 1$ in F, so per = det. Otherwise the matrix with two equal columns $\mathbf{e}_1 + \mathbf{e}_2$ has permanent $1 + 1 \neq 0$. (c) Each term is 0 or 1; modulo 2 the signs disappear, so $\det A \equiv \operatorname{per} A$.

(a) per is L with every sign replaced by 1, and the proof that L is normalized and multilinear (Part 2 of the proof of Theorem 5.3.4) never used the signs. So per is normalized and multilinear. By Proposition 5.2.30, the (i,j) entry of AE_π is $a_{i\pi(j)}$, so

$$\operatorname{per}(AE_\pi) = \sum_{\sigma \in S_n} \prod_{j=1}^{n} a_{\sigma(j)\pi(j)} = \sum_{\sigma \in S_n} \prod_{j=1}^{n} a_{\sigma(\pi^{-1}(j))j},$$

after reordering the product by $j' = \pi(j)$. The last sum is $\sum_\sigma g\left(\sigma\pi^{-1}\right)$ with $g(\rho) = \prod_j a_{\rho(j)j}$, which equals $\sum_\sigma g(\sigma) = \operatorname{per} A$ by Proposition 5.2.8.

(b) If $1 + 1 = 0$, then $-1 = 1$ in F, so $\operatorname{sgn}(\sigma) = 1$ in F for every σ, and $\operatorname{per} A = \det A$ for every A. In particular per is a determinant function. Conversely, suppose $1 + 1 \neq 0$, and let A have columns $\mathbf{e}_1 + \mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_2, \mathbf{e}_3, \ldots, \mathbf{e}_n$. A term of $\operatorname{per} A$ is nonzero exactly when $\sigma(1), \sigma(2) \in \{1, 2\}$ and $\sigma(j) = j$ for $j \geq 3$, which leaves $\sigma = \mathrm{id}$ and $\sigma = (1\ 2)$, each with product 1. So $\operatorname{per} A = 1 + 1 \neq 0$, although A has two equal columns, and per is not alternating. (By (a) and Theorem 5.3.4, when $1 + 1 = 0$ the determinant function per must equal det, as we saw directly.)

(c) Each product $a_{\sigma(1)1}\cdots a_{\sigma(n)n}$ is 1 if all its factors are 1 and 0 otherwise, so $\operatorname{per} A$ counts the permutations with $a_{\sigma(j)j} = 1$ for every j. For $n = 1$, $\det A = \operatorname{per} A = a_{11}$. For $n \geq 2$, reducing modulo 2 with Proposition 5.3.20 gives $(\det A) \bmod 2 = \det \overline{A}$, and $\det \overline{A} = \operatorname{per} \overline{A}$ by (b), since $1 + 1 = 0$ in $\mathbb{F}_2$. Reducing the sum per A term by term in the same way gives $\operatorname{per} \overline{A} = (\operatorname{per} A) \bmod 2$. So $\det A$ and $\operatorname{per} A$ have the same remainder modulo 2.

Solution to Exercise 5.3.32

Uses. Lemma 5.1.8 (Column replacement), Definition 5.1.1 (Determinant function), Proposition 5.3.20 (Reduction modulo p)

Hint 1. What are the possible entries of $\mathbf{a}_j - \mathbf{a}_1$?

Hint 2. Subtract column 1 from every other column. This does not change $\det A$, and afterwards columns $2, \ldots, n$ have even entries.

Hint 3. Pull a factor 2 out of each of the columns $2, \ldots, n$. What is left is an integer matrix.

Sketch. For $j \geq 2$, $a_{ij} - a_{i1} \in \{-2, 0, 2\}$. Subtracting column 1 from each other column leaves $\det A$ unchanged (Lemma 5.1.8) and makes columns $2, \ldots, n$ equal to 2 times integer vectors. Pulling out the $n-1$ factors of 2 leaves the determinant of an integer matrix, which is an integer.

For $j \geq 2$, add -1 times column 1 to column j. By Lemma 5.1.8 none of these steps changes the determinant, and since column 1 is never changed, the result is the matrix A' with columns $\mathbf{a}_1, \mathbf{a}_2 - \mathbf{a}_1, \ldots, \mathbf{a}_n - \mathbf{a}_1$. Each entry $a_{ij} - a_{i1}$ with $j \geq 2$ is a difference of two elements of $\{1, -1\}$, so it lies in $\{-2, 0, 2\}$. Hence $\mathbf{a}_j - \mathbf{a}_1 = 2\mathbf{c}_j$ for a vector $\mathbf{c}_j$ with integer entries. Pulling the factor 2 out of each of the columns $2, \ldots, n$ by multilinearity,

$$\det A = \det A' = 2^{n-1} \det(\mathbf{a}_1, \mathbf{c}_2, \ldots, \mathbf{c}_n).$$

The last matrix has integer entries, so its determinant is an integer (Proposition 5.3.20). Hence 2^{n-1} divides $\det A$.

Solution to Exercise 5.3.33

Uses. Definition 5.3.6 (Determinant), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t), Proposition 5.2.26 (Sign of a cycle), Proposition 1.1.17 (No zero divisors)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. $A + tI_3 = \begin{pmatrix} t & 0 & 1 \\ 1 & t & 0 \\ 0 & 1 & t \end{pmatrix}$. Which permutations avoid the zero entries?
Hint 2. Only id and (1 2 3) survive. For (b), factor $t^3 + 1 = (t+1)\left(t^2 - t + 1\right)$.
Sketch. The surviving terms are t^3 (identity) and $a_{21}a_{32}a_{13} = 1$ for the even permutation (1 2 3), so $\det(A + tI_3) = t^3 + 1$, with $c_2 = 0 = \operatorname{tr} A$ and $c_0 = 1 = \det A$. Roots: $-1, \left(1 \pm i\sqrt{3}\right)/2$ over $\mathbb{C}$; only -1 over $\mathbb{R}$; $t = 1$ over $\mathbb{F}_2$.

(a) $A + tI_3 = \begin{pmatrix} t & 0 & 1 \\ 1 & t & 0 \\ 0 & 1 & t \end{pmatrix}$, whose zero entries are in positions $(1,2)$, $(2,3)$, and $(3,1)$. A term is nonzero only if $\sigma(2) \neq 1$, $\sigma(3) \neq 2$, and $\sigma(1) \neq 3$. Checking the six permutations, only id (with product $t \cdot t \cdot t$) and (1 2 3) (with $\sigma(1) = 2$, $\sigma(2) = 3$, $\sigma(3) = 1$ and product $a_{21}a_{32}a_{13} = 1$) survive; for instance the term of (1 3 2) contains $a_{31} = 0$. The 3-cycle is even (Proposition 5.2.26), so

$$\det(A + tI_3) = t^3 + 1.$$

This matches Proposition 5.3.19: $c_2 = 0 = \operatorname{tr} A$, and $c_0 = 1 = \det A$, since $A = E_{(1\,2\,3)}$ has determinant $\operatorname{sgn}((1\ 2\ 3)) = 1$.

(b) $t^3 + 1 = (t+1)\left(t^2 - t + 1\right)$, as multiplying out confirms. Over $\mathbb{C}$, let $z_\pm = \left(1 \pm i\sqrt{3}\right)/2$. Then $z_+ + z_- = 1$ and $z_+ z_- = (1+3)/4 = 1$, so $t^2 - t + 1 = (t - z_+)(t - z_-)$, and $t^3 + 1 = (t+1)(t - z_+)(t - z_-)$. A product in a field is 0 only if a factor is 0 (Proposition 1.1.17), so the roots are $t = -1$ and $t = z_\pm$. Over $\mathbb{R}$, $t^2 - t + 1 = (t - 1/2)^2 + 3/4 > 0$, so $t = -1$ is the only root. Over $\mathbb{F}_2$, $0^3 + 1 = 1$ and $1^3 + 1 = 0$, so $t = 1$ is the only root (consistent with the real root -1, since $-1 = 1$ in $\mathbb{F}_2$).

Solution to Exercise 5.3.34

Uses. Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t), Definition 5.2.10 (Transposition), Definition 5.1.14 (The 2×2 determinant)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. In the proof of Proposition 5.3.19, the term of σ involves powers of t only up to the number of fixed points of σ. Which σ fix at least $n-2$ points?
Hint 2. A permutation that moves exactly two points is a transposition. So only id and the transpositions contribute to t^{n-2}.
Sketch. Only σ with at least $n-2$ fixed points contribute to t^{n-2}: the identity and the transpositions. From $\prod_k (a_{kk} + t)$ the coefficient is $\sum_{i<j} a_{ii}a_{jj}$. The term of $(i\ j)$ is $-a_{ji}a_{ij} \prod_{k \neq i,j} (a_{kk} + t)$, contributing $-a_{ij}a_{ji}$.

We use the notation of the proof of Proposition 5.3.19. The term $T_\sigma(t)$ involves only the powers t^p with $p \leq f_\sigma$, the number of fixed points of σ. So only permutations with at least $n-2$ fixed points contribute to c_{n-2}. Such a σ is either id or moves exactly two points i, j; in the second case $\sigma(i)$ is a moved point different from i, so $\sigma(i) = j$, and likewise $\sigma(j) = i$, so $\sigma = (i\ j)$.

For $\sigma = \mathrm{id}$, $T_{\mathrm{id}}(t) = \prod_{k=1}^{n}(a_{kk}+t)$. A product of t^{n-2} arises by choosing a_{kk} in exactly two factors, $k=i$ and $k=j$, so the coefficient of t^{n-2} is $\sum_{i<j} a_{ii}a_{jj}$.

For $\sigma = (i\ j)$ with $i<j$, which is odd,

$$T_\sigma(t) = -a_{ji}a_{ij}\prod_{k\notin\{i,j\}}(a_{kk}+t),$$

and the coefficient of t^{n-2} is $-a_{ij}a_{ji}$, from choosing t in all $n-2$ factors. Adding up,

$$c_{n-2} = \sum_{i<j} a_{ii}a_{jj} - \sum_{i<j} a_{ij}a_{ji} = \sum_{i<j}\bigl(a_{ii}a_{jj} - a_{ij}a_{ji}\bigr),$$

and $a_{ii}a_{jj} - a_{ij}a_{ji} = \det\begin{pmatrix} a_{ii} & a_{ij} \\ a_{ji} & a_{jj}\end{pmatrix}$. For $n=2$ this gives $c_0 = \det A$, as it should.

Solution to Exercise 5.3.35

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Definition 1.6.14 (Coordinates), Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 2.1.17 (Compositions of linear maps are linear), Remark 5.1.6
Hint 1. For existence, the coordinate map $\mathbf{w} \mapsto [\mathbf{w}]_{\mathcal{B}}$ is linear and $\left[\mathbf{v}_j\right]_{\mathcal{B}} = \mathbf{e}_j$.
Hint 2. For uniqueness, given g, define $D(\mathbf{x}_1,\dots,\mathbf{x}_n) = g(\Phi(\mathbf{x}_1),\dots,\Phi(\mathbf{x}_n))$ for $\mathbf{x}_j \in F^n$, where $\Phi(\mathbf{x}) = x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n$. Show $D = \det$.
Sketch. The given f is det composed with the linear coordinate map in each slot, so it is multilinear; equal vectors have equal coordinates, so it is alternating; and $f(\mathbf{v}_1,\dots,\mathbf{v}_n) = \det I_n = 1$. If g is another, then $D = g\circ(\Phi,\dots,\Phi)$ is a determinant function on $F^{n\times n}$, so $D = \det$, and $g(\mathbf{w}_1,\dots) = D\bigl([\mathbf{w}_1]_{\mathcal{B}},\dots\bigr) = f(\mathbf{w}_1,\dots)$.

Existence. Fix j and the vectors $\mathbf{w}_i$ for $i\neq j$. The map $\mathbf{w}\mapsto f(\mathbf{w}_1,\dots,\mathbf{w},\dots,\mathbf{w}_n)$ is the composite of the coordinate map $\mathbf{w}\mapsto[\mathbf{w}]_{\mathcal{B}}$, which is linear (Proposition 1.6.19), with the map $\mathbf{x}\mapsto\det(\dots,\mathbf{x},\dots)$, which is linear because det is multilinear. So it is linear (Proposition 2.1.17), and f is multilinear. If $\mathbf{w}_i = \mathbf{w}_j$ with $i\neq j$, then $[\mathbf{w}_i]_{\mathcal{B}} = \left[\mathbf{w}_j\right]_{\mathcal{B}}$, so $f(\mathbf{w}_1,\dots,\mathbf{w}_n) = 0$ because det is alternating. Finally, $\left[\mathbf{v}_j\right]_{\mathcal{B}} = \mathbf{e}_j$, so $f(\mathbf{v}_1,\dots,\mathbf{v}_n) = \det I_n = 1$.

Uniqueness. Let g be multilinear and alternating with $g(\mathbf{v}_1,\dots,\mathbf{v}_n) = 1$. Let $\Phi: F^n\to V$, $\Phi(\mathbf{x}) = x_1\mathbf{v}_1+\cdots+x_n\mathbf{v}_n$, which is linear, and define $D: F^{n\times n}\to F$ by $D(\mathbf{x}_1,\dots,\mathbf{x}_n) = g(\Phi(\mathbf{x}_1),\dots,\Phi(\mathbf{x}_n))$. As in the existence part, D is multilinear and alternating, and $D(I_n) = g(\Phi(\mathbf{e}_1),\dots,\Phi(\mathbf{e}_n)) = g(\mathbf{v}_1,\dots,\mathbf{v}_n) = 1$. So D is a determinant function, and $D=\det$ by Theorem 5.3.4. Now let $\mathbf{w}_1,\dots,\mathbf{w}_n\in V$. By the definition of coordinates (Definition 1.6.14), $\Phi\bigl(\left[\mathbf{w}_j\right]_{\mathcal{B}}\bigr) = \mathbf{w}_j$, so

$$\begin{aligned} g(\mathbf{w}_1,\dots,\mathbf{w}_n) &= D\bigl([\mathbf{w}_1]_{\mathcal{B}},\dots,[\mathbf{w}_n]_{\mathcal{B}}\bigr) \\ &= \det\bigl([\mathbf{w}_1]_{\mathcal{B}},\dots,[\mathbf{w}_n]_{\mathcal{B}}\bigr) = f(\mathbf{w}_1,\dots,\mathbf{w}_n).\end{aligned}$$

Hence $g=f$. Section 13.4 uses this to define the determinant of an operator without choosing a basis.

Solution to Exercise 5.3.36

Uses. Proposition 5.3.20 (Reduction modulo p), Theorem 5.2.31 (Alternating functions and permutations), Proposition 5.3.15 (Triangular matrices), Corollary 5.1.18 (Non-invertible matrices)
Techniques. Reduce modulo p (Technique 5.3.21)
Hint 1. Reduce A modulo 2. What kind of matrix do you get?
Hint 2. Modulo 2, A becomes a permutation matrix, whose determinant is $\pm1 = 1$ in $\mathbb{F}_2$.
Hint 3. Modulo 2, B has a zero row. Modulo 3, it is upper triangular.
Sketch. (a) Modulo 2, A is the permutation matrix with columns $\mathbf{e}_2,\mathbf{e}_1,\mathbf{e}_4,\mathbf{e}_3$, of determinant 1 in $\mathbb{F}_2$, so $\det A$ is odd. (b) Modulo 2, B has a zero row, so $\det\overline{B} = 0$, which only says $\det B$ is even. Modulo 3, B is upper triangular with diagonal $1,2,1$, so $\det B\equiv 2 \bmod 3$ and $\det B\neq 0$.

(a) Modulo 2, the entries of A become

$$\overline{A} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix},$$

the permutation matrix with columns $\mathbf{e}_2, \mathbf{e}_1, \mathbf{e}_4, \mathbf{e}_3$, that is, E_σ for $\sigma = (1\ 2)(3\ 4)$. By Theorem 5.2.31, $\det \overline{A} = \operatorname{sgn}(\sigma) = 1$ in $\mathbb{F}_2$. By Proposition 5.3.20, $\det A$ is odd, so $\det A \neq 0$, and A is invertible by Corollary 5.1.18. (In fact $\det A = 39$.)

(b) Modulo 2, the second row of B becomes $(0, 0, 0)$. Every term of the Leibniz formula contains an entry of the second row, so $\det \overline{B} = 0$ in $\mathbb{F}_2$. By Proposition 5.3.20 this only says that $\det B$ is even, which is compatible with $\det B = 0$ and with $\det B \neq 0$. Modulo 3,

$$\overline{B} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

which is upper triangular, so $\det \overline{B} = 1 \cdot 2 \cdot 1 = 2 \neq 0$ in $\mathbb{F}_3$ by Proposition 5.3.15. By Proposition 5.3.20, $\det B$ is not divisible by 3, so $\det B \neq 0$ and B is invertible by Corollary 5.1.18. (In fact $\det B = -64$.)

Solution to Exercise 5.3.37

Uses. Proposition 5.2.30 (Algebra of permutation matrices), Theorem 5.2.31 (Alternating functions and permutations), Proposition 5.3.17 (Block-diagonal matrices), Corollary 5.2.24 (Formulas for the sign), Definition 5.2.21 (Inversion)
Hint 1. Rearrange the columns: moving the last k columns to the front turns the matrix into $\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$.
Hint 2. This rearrangement is $M \mapsto ME_\pi$ for a permutation π. Count the inversions of π.
Sketch. Let M be the given matrix, $n = k + m$, and $\pi(j) = m + j$ for $j \leq k$, $\pi(k + i) = i$ for $i \leq m$. Then $ME_\pi = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$. The inversions of π are exactly the km pairs $(j, k + i)$, so $\operatorname{sgn}(\pi) = (-1)^{km}$, and $\det M = \operatorname{sgn}(\pi) \det(ME_\pi) = (-1)^{km} \det A \det B$.

Let M be the given matrix and $n = k + m$. Its first m columns are $(\mathbf{0}, \mathbf{b}_i)$ for $i \leq m$, and its last k columns are $(\mathbf{a}_j, \mathbf{0})$ for $j \leq k$. Define $\pi \in S_n$ by $\pi(j) = m + j$ for $j \leq k$ and $\pi(k + i) = i$ for $i \leq m$. By Proposition 5.2.30, the matrix ME_π has columns $\mathbf{c}_{\pi(1)}, \ldots, \mathbf{c}_{\pi(n)}$, where $\mathbf{c}_p$ denotes column p of M; that is, $(\mathbf{a}_1, \mathbf{0}), \ldots, (\mathbf{a}_k, \mathbf{0}), (\mathbf{0}, \mathbf{b}_1), \ldots, (\mathbf{0}, \mathbf{b}_m)$. So $ME_\pi = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$, and $\det(ME_\pi) = \operatorname{sgn}(\pi) \det M$ by Theorem 5.2.31.

The bottom row of π is $m + 1, \ldots, m + k, 1, \ldots, m$. Two positions that both lie among the first k, or both among the last m, carry increasing entries, so they are not inversions. A position $j \leq k$ and a position $k + i$ form an inversion, since $\pi(j) = m + j > i = \pi(k + i)$. So π has exactly km inversions, and $\operatorname{sgn}(\pi) = (-1)^{km}$ by Corollary 5.2.24. Using Proposition 5.3.17 and $\operatorname{sgn}(\pi)^2 = 1$,

$$\det M = \operatorname{sgn}(\pi) \det(ME_\pi) = (-1)^{km} \det A \det B.$$

Solution to Exercise 5.3.38

Uses. Definition 5.3.6 (Determinant), Figure 5.3.1, Proposition 5.1.17 (Dependent columns)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. Write $\det A = P - N$, where P is the sum of the three products for even permutations and N the sum for odd ones. Each product is 0 or 1.
Hint 2. So $\det A \leq 3$, with equality only if all three even products are 1. Look at the top row of Figure 5.3.1: which positions do the three even permutations use together?
Sketch. (a) $\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix}$ has determinant $1 + 1 - 0 = 2$. (b) Each of the six products in (5.3.2) is 0 or 1, so $\det A \leq 3$, and $\det A = 3$ forces all three even products to be 1. The three even permutations together use each of the nine positions exactly once, so then every entry is 1, and $\det A = 0$, a contradiction.

(a) Let $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix}$. In (5.3.2), the even terms are $a_{11}a_{22}a_{33} = 1$, $a_{21}a_{32}a_{13} = 0$, and $a_{31}a_{12}a_{23} = 1$, and the odd terms are $a_{21}a_{12}a_{33} = 0$, $a_{11}a_{32}a_{23} = 0$, and $a_{31}a_{22}a_{13} = 0$. So $\det A = 2$.

(b) Let A have entries in $\{0,1\}$. In (5.3.2), $\det A = P - N$, where P is the sum of the three products for the even permutations and N is the sum of the three for the odd ones. Each product is 0 or 1, so $P \leq 3$ and $N \geq 0$, and $\det A \leq 3$. Suppose $\det A = 3$. Then $P = 3$, so all three even products equal 1, and all the entries they use equal 1. The three even permutations id, (1 2 3), (1 3 2) use the positions (j,j), $(j+1,j)$, and $(j+2,j)$ in column j, with row indices read modulo 3; in each column these are the three different rows. So together they use all nine positions (the top row of Figure 5.3.1), and every entry of A is 1. But then A has equal columns and $\det A = 0 \neq 3$, a contradiction. Since $\det A$ is an integer, $\det A \leq 2$.

Solution to Exercise 5.3.39

Uses. Definition 5.1.1 (Determinant function), Exercise 5.1.35, Theorem 5.3.4 (Existence and uniqueness of the determinant), Remark 5.2.32 (Two comments on the theorem), Proposition 2.1.17 (Compositions of linear maps are linear)
Techniques. Cancel terms in pairs (Technique 5.3.5)
Hint 1. (a) For column 1, the minors $A^{(i)}$ do not involve column 1. For column $k \geq 2$, the entries a_{i1} are fixed, and column $k-1$ of $A^{(i)}$ is column k of A with its i-th entry deleted.
Hint 2. (b) If columns $k, k+1$ are equal with $k \geq 2$, every minor $A^{(i)}$ has two equal adjacent columns. The case $k = 1$ is the real work: expand each $D_{n-1}\big(A^{(i)}\big)$ once more along its first column.
Hint 3. For $k = 1$ with $x_i = a_{i1} = a_{i2}$, you get a double sum over $i \neq l$ of $\pm x_i x_l D_{n-2}\big(A^{\{i,l\}}\big)$, where $A^{\{i,l\}}$ deletes rows i, l and columns $1, 2$. Compare the signs of the (i,l) and (l,i) terms. Then use Exercise 5.1.35.
Sketch. (a) $D_{n(I_n)} = D_{n-1}(I_{n-1}) = 1$; in column 1, D_n is $\sum (-1)^{i+1} a_{i1} \cdot (\text{const})$; in column $k \geq 2$ each summand is a constant times D_{n-1} of a matrix depending linearly on column k. (b) Equal columns $k, k+1$ with $k \geq 2$ make every minor vanish. For $k = 1$, expanding twice gives $\sum_{i \neq l} \varepsilon_{il} x_i x_l D_{n-2}\big(A^{\{i,l\}}\big)$, with $\varepsilon_{il} = (-1)^{i+l}$ for $l < i$ and $-(-1)^{i+l}$ for $l > i$; the terms (i,l) and (l,i) cancel. With Exercise 5.1.35, D_n is alternating. (c) D_n is a nonzero multilinear alternating function on $\mathbb{Q}^{n \times n}$ built without sgn.

We write $\mathbf{a}_k^{(i)}$ for column k of A with its i-th entry deleted, so $A^{(i)}$ has columns $\mathbf{a}_2^{(i)}, \ldots, \mathbf{a}_n^{(i)}$.

(a) We show by induction on n that D_n is normalized and multilinear. For $n = 1$, $D_1(1) = 1$ and D_1 is linear. Let $n \geq 2$ and assume the claim for $n-1$.

Normalized. The first column of I_n is $\mathbf{e}_1$, so only $i = 1$ contributes, and $I_n^{(1)} = I_{n-1}$. Hence $D_n(I_n) = D_{n-1}(I_{n-1}) = 1$.

Linear in column 1. The minors $A^{(i)}$ do not involve column 1, so for fixed columns $2, \ldots, n$, $D_n(A) = \sum_i (-1)^{i+1} a_{i1} \gamma_i$ with constants γ_i. This is linear in $(a_{11}, \ldots, a_{n1})$.

Linear in column $k \geq 2$. Fix all columns except column k. Each a_{i1} is then constant, and $A^{(i)}$ has column $k-1$ equal to $\mathbf{a}_k^{(i)}$, which depends linearly on $\mathbf{a}_k$ (deleting an entry is a linear map $F^n \to F^{n-1}$), while its other columns are fixed. By the induction hypothesis D_{n-1} is linear in column $k-1$, so $\mathbf{a}_k \mapsto D_{n-1}\big(A^{(i)}\big)$ is a composite of linear maps, hence linear (Proposition 2.1.17). A linear combination of linear maps is linear, so D_n is linear in column k.

(b) We show by induction on $n \geq 2$ that $D_n(A) = 0$ whenever two adjacent columns of A are equal. For $n = 2$, $D_2(A) = a_{11}a_{22} - a_{21}a_{12}$, which vanishes when the two columns are equal. Let $n \geq 3$, assume the claim for $n-1$, and suppose $\mathbf{a}_k = \mathbf{a}_{k+1}$.

Case $k \geq 2$. Each $A^{(i)}$ has equal adjacent columns $\mathbf{a}_k^{(i)} = \mathbf{a}_{k+1}^{(i)}$, in positions $k-1$ and k. By the induction hypothesis, $D_{n-1}\big(A^{(i)}\big) = 0$ for every i, so $D_n(A) = 0$.

Case $k = 1$. Write $x_i = a_{i1} = a_{i2}$. For $i \neq l$, let $A^{\{i,l\}}$ be A with rows i, l and columns $1, 2$ deleted; it depends only on the set $\{i,l\}$. The first column of $A^{(i)}$ is $\mathbf{a}_2^{(i)}$, whose entries are x_l for $l \neq i$, with x_l in position l if $l < i$ and in position $l-1$ if $l > i$. Deleting that position and the first column of $A^{(i)}$ leaves $A^{\{i,l\}}$. So the definition of D_{n-1} gives

$$D_{n-1}\big(A^{(i)}\big) = \sum_{l<i} (-1)^{l+1} x_l D_{n-2}\big(A^{\{i,l\}}\big)$$

$$+\sum_{l>i}(-1)^l x_l D_{n-2}\left(A^{\{i,l\}}\right).$$

Substituting into the definition of D_n,

$$D_n(A)=\sum_{i\neq l}\varepsilon_{il}x_i x_l D_{n-2}\left(A^{\{i,l\}}\right),$$

where the sum runs over ordered pairs (i,l) of distinct indices and

$$\varepsilon_{il}=\begin{cases}(-1)^{i+1}(-1)^{l+1}=(-1)^{i+l} & \text{if } l<i\\ (-1)^{i+1}(-1)^{l}=-(-1)^{i+l} & \text{if } l>i.\end{cases}$$

For $i<l$, the ordered pairs (i,l) and (l,i) give the same product $x_i x_l D_{n-2}\left(A^{\{i,l\}}\right)$ with the signs $\varepsilon_{il}=-(-1)^{i+l}$ and $\varepsilon_{li}=(-1)^{i+l}$, so they cancel. Grouping the terms in these pairs (Technique 5.3.5), $D_n(A)=0$.

By (a) and the above, D_n is multilinear and vanishes whenever two adjacent columns are equal, so it is alternating by Exercise 5.1.35 (for $n=1$ there is nothing to check). Together with $D_n(I_n)=1$, D_n is a determinant function, and $D_n=\det$ by Theorem 5.3.4.

(c) The construction of D_n and parts (a) and (b) never mention permutations or signs. Over $F=\mathbb{Q}$, D_n is a multilinear alternating function with $D_n(I_n)=1\neq 0$. By part (2) of Remark 5.2.32, if σ were a product of r transpositions and also of s transpositions, then $(-1)^r=D_n(E_\sigma)=(-1)^s$, so r and s would have the same parity. This proves Theorem 5.2.18 without Approach 1: a product of differences or Approach 2: counting inversions. Expanding along the first column is the subject of Section 5.5.

Solution to Exercise 5.3.40

Uses. Proposition 5.3.20 (Reduction modulo p), Exercise 5.3.31, Proposition 5.2.16 (Cycle decomposition), Corollary 5.1.18 (Non-invertible matrices), Proposition 5.1.17 (Dependent columns)
Techniques. Reduce modulo p (Technique 5.3.21), Cancel terms in pairs (Technique 5.3.5)
Hint 1. Work modulo 2. What is $\overline{A}$, and what does the Leibniz formula over $\mathbb{F}_2$ count?
Hint 2. Over $\mathbb{F}_2$, $\det\overline{A}$ is the number of permutations with no fixed points (derangements), modulo 2. To find its parity, pair each derangement σ with σ^{-1}.
Hint 3. The unpaired derangements satisfy $\sigma^2=\mathrm{id}$, so they are products of $n/2$ disjoint transpositions. Count them: how many choices are there for the partner of 1?
Sketch. Modulo 2, $\overline{A}$ has 0 on the diagonal and 1 elsewhere, and $\det\overline{A}$ is the number of derangements of $[n]$ modulo 2. The involution $\sigma\mapsto\sigma^{-1}$ on derangements shows that this number has the parity of the number of fixed-point-free involutions, which is $(n-1)(n-3)\cdots 3\cdot 1$, an odd number. So $\det A$ is odd. For $n=3$, the matrix $\begin{pmatrix}0&1&-1\\-1&0&1\\1&-1&0\end{pmatrix}$ has determinant 0.

Reduce modulo 2: $\overline{A}$ has 0 on the diagonal and 1 off the diagonal, since $-1=1$ in $\mathbb{F}_2$. In $\mathbb{F}_2$, $\operatorname{sgn}(\sigma)=1$ for every σ, and the term of σ is 1 if $\sigma(j)\neq j$ for every j and 0 otherwise. So $\det\overline{A}$ is the number d of *derangements* of $[n]$, the permutations without fixed points, reduced modulo 2 (compare part (c) of Exercise 5.3.31).

Pairing. If σ is a derangement, so is σ^{-1}, and $\left(\sigma^{-1}\right)^{-1}=\sigma$. So $\sigma\mapsto\sigma^{-1}$ is an involution of the set of derangements, and the derangements with $\sigma^{-1}\neq\sigma$ fall into pairs $\{\sigma,\sigma^{-1}\}$. Hence d has the same parity as the number m_n of derangements with $\sigma^{-1}=\sigma$, that is, with $\sigma^2=\mathrm{id}$ (Technique 5.3.5).

Counting involutions. Let σ be a derangement with $\sigma^2=\mathrm{id}$. Every orbit of σ has size 2: for each i, $\sigma(i)\neq i$ but $\sigma^2(i)=i$. By Proposition 5.2.16, σ is a product of $n/2$ disjoint transpositions, so it pairs up the elements of $[n]$. Conversely, every way of splitting $[n]$ into $n/2$ pairs gives such a σ. We count these by induction on the even number n: there are $n-1$ choices for the partner p of 1, and then the remaining $n-2$ elements must be split into pairs, in m_{n-2} ways. With $m_2=1$, we get $m_n=(n-1)(n-3)\cdots 3\cdot 1$, a product of odd numbers, which is odd.

So d is odd, $\det \overline{A} = 1$ in $\mathbb{F}_2$, and $\det A$ is odd by Proposition 5.3.20. In particular $\det A \neq 0$, and A is invertible by Corollary 5.1.18.

For odd n the conclusion can fail. With $n = 3$ and $A = \begin{pmatrix} 0 & 1 & -1 \\ -1 & 0 & 1 \\ 1 & -1 & 0 \end{pmatrix}$, every row sums to 0, so $\mathbf{a}_1 + \mathbf{a}_2 + \mathbf{a}_3 = \mathbf{0}$ and $\det A = 0$ by Proposition 5.1.17. Here the argument breaks down because $m_3 = 0$: a permutation of an odd number of points cannot pair them all up.

Section 5.4

Solution to Exercise 5.4.5

Uses. Proposition 5.4.1 (Determinants of elementary matrices), Corollary 5.4.4 (Products of elementary matrices), Proposition 3.2.28 (Column operations are right multiplications), Remark 3.2.29 (One matrix, two operations)
Hint 1. Read off the type of each factor from its subscripts: two subscripts without a comma is a swap, two with a comma a scaling, three a replacement.
Hint 2. $AG = \big((AE_{13})E_{2,4}\big)E_{3,-7,1}$, so the leftmost factor acts first. As a right factor, E_{icj} adds c times column j to column i.
Sketch. $\det G = (-1) \cdot 4 \cdot 1 = -4$ and $\det(AG) = 5 \cdot (-4) = -20$. The operations are: swap columns 1 and 3, then scale column 2 by 4, then add -7 times column 1 to column 3.

E_{13} swaps, $E_{2,4}$ scales by 4, and $E_{3,-7,1}$ is a replacement, so by Corollary 5.4.4 and Proposition 5.4.1,

$$\begin{aligned} \det G &= \det E_{13} \det E_{2,4} \det E_{3,-7,1} \\ &= (-1) \cdot 4 \cdot 1 = -4, \end{aligned}$$

and $\det(AG) = \det A \det G = -20$. Since $AG = \big((AE_{13})E_{2,4}\big)E_{3,-7,1}$, the column operations are performed from the leftmost factor to the rightmost (Remark 3.2.29). By Proposition 3.2.28 they are: swap columns 1 and 3; scale column 2 by 4; add -7 times column 1 to column 3. Their effects on the determinant, -1, 4, and 1, multiply to $\det G$, as they should.

Solution to Exercise 5.4.9

Uses. Corollary 5.3.9 (Rule of Sarrus), Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Compute $\det A(t)$ with the rule of Sarrus. It does not depend on the field.
Hint 2. You should get $1 - 2t^2$. In each field, decide when $2t^2 = 1$ has a solution.
Sketch. $\det A(t) = 1 - 2t^2$. Over $\mathbb{R}$: invertible unless $t = \pm 1/\sqrt{2}$. Over $\mathbb{Q}$: always, since $\sqrt{2}$ is irrational. Over $\mathbb{F}_3$: $1 - 2t^2 = 1 + t^2 \in \{1, 2\}$, so always. Over $\mathbb{F}_7$: $2t^2 = 1$ means $t^2 = 4$, so invertible unless $t \in \{2, 5\}$.

The diagonals running down to the right have products 1, $t \cdot t \cdot 0 = 0$, and 0, and those running up to the right have products 0, $t \cdot t \cdot 1 = t^2$, and $1 \cdot t \cdot t = t^2$. So $\det A(t) = 1 - 2t^2$ by Corollary 5.3.9, and by Theorem 5.4.7, $A(t)$ is invertible exactly when $2t^2 \neq 1$.

Over $\mathbb{R}$, $2t^2 = 1$ exactly for $t = \pm 1/\sqrt{2}$, so $A(t)$ is invertible for all other t. Over $\mathbb{Q}$ there is no solution, since $2t^2 = 1$ would give $(2t)^2 = 2$ with $2t$ rational; so $A(t)$ is always invertible. Over $\mathbb{F}_3$, $-2 = 1$, so $\det A(t) = 1 + t^2$, and $t^2 \in \{0, 1\}$ for $t \in \{0, 1, 2\}$. So $\det A(t) \in \{1, 2\}$ is never 0, and $A(t)$ is always invertible. Over $\mathbb{F}_7$, $2^{-1} = 4$, so $2t^2 = 1$ means $t^2 = 4$, that is, $t = 2$ or $t = -2 = 5$. So $A(t)$ is invertible exactly when $t \notin \{2, 5\}$.

Solution to Exercise 5.4.12

Uses. Theorem 5.4.10 (Multiplicativity), induction on k
Hint 1. Determinants are elements of F, so they commute even when the matrices do not.
Hint 2. For the inverse, take determinants of $AA^{-1} = I_n$.
Sketch. $\det(AB) = \det A \det B = \det B \det A = \det(BA)$. Induction gives $\det\big(A^{k+1}\big) = \det\big(A^k\big) \det A = (\det A)^{k+1}$. From $AA^{-1} = I_n$, $\det A \det A^{-1} = 1$. For $k > 0$, $\det\big(A^{-k}\big) = \det\Big(\big(A^{-1}\big)^k\Big) = \big(\det A^{-1}\big)^k = (\det A)^{-k}$.

By Theorem 5.4.10 and commutativity of multiplication in F, $\det(AB) = \det A \det B = \det B \det A = \det(BA)$.

For powers, $\det\big(A^0\big) = \det I_n = 1 = (\det A)^0$, and if $\det\big(A^k\big) = (\det A)^k$, then $\det\big(A^{k+1}\big) = \det\big(A^k A\big) = \det\big(A^k\big) \det A = (\det A)^{k+1}$. By induction, $\det\big(A^k\big) = (\det A)^k$ for all $k \geq 0$.

If A is invertible, then $\det A \det\left(A^{-1}\right) = \det\left(AA^{-1}\right) = \det I_n = 1$, so $\det\left(A^{-1}\right) = (\det A)^{-1}$. For $k > 0$, the case already proved, applied to A^{-1}, gives $\det\left(A^{-k}\right) = \det\left(\left(A^{-1}\right)^k\right) = \left(\det A^{-1}\right)^k = (\det A)^{-k}$.

Solution to Exercise 5.4.16

Uses. Corollary 5.4.15 (Rows), Theorem 5.4.14 (The transpose), Exercise 5.1.5
Hint 1. Describe each matrix as the result of row operations on the original matrix, or on its transpose.
Hint 2. In (b), the new second row is 2 times the old one plus -3 times the first row. In (c), take the transpose first.
Sketch. (a) One swap: -7. (b) Scale row 2 by 2, then add -3 times row 1: 14. (c) The transpose is the original matrix with 5 times row 1 added to row 3: 7. (d) $3^3 \cdot 7 = 189$.

Call the given matrix M.

(a) This is M with rows 1 and 2 swapped, so its determinant is -7 by Corollary 5.4.15(b).

(b) Scaling row 2 of M by 2 gives determinant 14, and adding -3 times row 1 to the new row 2 does not change it. The result is the given matrix, so its determinant is 14.

(c) The transpose of this matrix is M with 5 times row 1 added to row 3. By Theorem 5.4.14 and Corollary 5.4.15(b), its determinant is $\det M = 7$.

(d) This is $3M$, so by Exercise 5.1.5 its determinant is $3^3 \det M = 189$.

Solution to Exercise 5.4.30

Uses. Algorithm 5.4.22 (Determinant by elimination), Proposition 5.3.20 (Reduction modulo p), Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Stage 1 clears column 1 using row 1. Check the $(2,2)$ entry afterwards.
Hint 2. For (b), reduce your answer to (a) modulo p (Proposition 5.3.20).
Sketch. After stage 1 the rows below row 1 are $(0,0,2,1)$, $(0,1,-1,3)$, $(0,-2,4,10)$. Swap rows 2 and 3, add 2 times row 2 to row 4, then subtract row 3 from row 4. The diagonal is $1,1,2,15$ with one swap, so $\det A = -30$. The reduction is invertible exactly for $p \notin \{2,3,5\}$.

(a) Stage 1 adds 2, -3, and -1 times row 1 to rows 2, 3, and 4. Stage 2 finds a 0 in position $(2,2)$, swaps rows 2 and 3, and adds 2 times the new row 2 to row 4. Stage 3 adds -1 times row 3 to row 4:

$$A \xrightarrow{\text{stage 1}} \begin{pmatrix} 1 & 3 & 0 & 2 \\ 0 & 0 & 2 & 1 \\ 0 & 1 & -1 & 3 \\ 0 & -2 & 4 & 10 \end{pmatrix},$$

$$\xrightarrow{\text{stage 2}} \begin{pmatrix} 1 & 3 & 0 & 2 \\ 0 & 1 & -1 & 3 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 2 & 16 \end{pmatrix} \xrightarrow{\text{stage 3}} \begin{pmatrix} 1 & 3 & 0 & 2 \\ 0 & 1 & -1 & 3 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 15 \end{pmatrix}.$$

There was one swap, so $\det A = (-1) \cdot 1 \cdot 1 \cdot 2 \cdot 15 = -30$.

(b) By Proposition 5.3.20, the determinant of the reduction is $-30 \bmod p$, which is 0 exactly when p divides $30 = 2 \cdot 3 \cdot 5$. By Theorem 5.4.7 over $\mathbb{F}_p$, the reduction is invertible exactly when $p \notin \{2,3,5\}$.

Solution to Exercise 5.4.31

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Exercise 5.1.5, Exercise 5.4.12, Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Both matrices are invertible by Theorem 5.4.7, so the inverses make sense.
Hint 2. Use $\det(cA) = c^3 \det A$ for 3×3 matrices, and $\det\left(A^{-1}\right) = (\det A)^{-1}$.
Sketch. -6, $9/2$, 16, 2, 4, -8.

Since $\det A$ and $\det B$ are nonzero, A and B are invertible (Theorem 5.4.7). By Theorem 5.4.10, Theorem 5.4.14, Exercise 5.4.12, and Exercise 5.1.5 (with $n = 3$):

- $\det(AB) = 2 \cdot (-3) = -6$;
- $\det\left(A^{-1}B^2\right) = (1/2) \cdot 9 = 9/2$;

- $\det\left(2A^{\mathsf{T}}\right) = 2^3 \det A = 16$;
- $\det\left(BAB^{-1}\right) = \det B \det A (\det B)^{-1} = 2$;
- $\det\left(A^{\mathsf{T}}A\right) = (\det A)^2 = 4$;
- $\det\left(-A^3\right) = (-1)^3 (\det A)^3 = -8$.

Solution to Exercise 5.4.32

Uses. Theorem 5.4.10 (Multiplicativity), Exercise 5.1.5, Theorem 2.4.34 (Block multiplication)
Hint 1. Take determinants: what does $A^2 = -I_n$ say about $(\det A)^2$?
Hint 2. For odd n you need -1 to be a square in F. For even n, find a 2×2 example and place copies of it along the diagonal.
Sketch. $(\det A)^2 = \det(-I_n) = (-1)^n$. If n is odd this needs a square root of -1 in F, which $\mathbb{R}$ and $\mathbb{F}_3$ lack. For even n, the block diagonal matrix with blocks $J = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ works over every field, as $J^2 = -I_2$. Over $\mathbb{C}$ and $\mathbb{F}_5$, iI_n and $2I_n$ work for every n. So: (a), (c) exactly the even n; (b), (d) every n.

If $A^2 = -I_n$, then by Theorem 5.4.10 and Exercise 5.1.5,

$$(\det A)^2 = \det\left(A^2\right) = \det(-I_n) = (-1)^n.$$

So if n is odd, $\det A$ is a square root of -1 in F.

Conversely, let $J = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. Then $J^2 = \left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = -I_2$ over every field. If $n = 2l$ is even, let A be block diagonal with l diagonal blocks equal to J. Block diagonal matrices multiply block by block (Theorem 2.4.34), so A^2 is block diagonal with blocks $J^2 = -I_2$, that is, $A^2 = -I_n$.

(a) Squares of real numbers are nonnegative, so $(\det A)^2 = -1$ is impossible: there is no such A for odd n. For even n there is. Answer: exactly the even n.

(b) $A = iI_n$ has $A^2 = i^2 I_n = -I_n$, for every n.

(c) In $\mathbb{F}_3$, $0^2 = 0$, $1^2 = 1$, and $2^2 = 4 = 1$, so $-1 = 2$ is not a square. As in (a), the answer is exactly the even n.

(d) In $\mathbb{F}_5$, $2^2 = 4 = -1$, so $A = 2I_n$ has $A^2 = -I_n$ for every n.

Solution to Exercise 5.4.33

Uses. Theorem 5.4.14 (The transpose), Exercise 5.1.5, Proposition 1.1.17 (No zero divisors), Definition 2.4.21 (Transpose), Corollary 5.4.8 (Vanishing determinants)
Hint 1. Compute $\det A^{\mathsf{T}}$ in two ways: by Theorem 5.4.14 and from $A^{\mathsf{T}} = -A$.
Hint 2. For (b), read off what $a_{ji} = -a_{ij}$ says on the diagonal and off it. For the kernel vector, try a vector built from a, b, c.
Hint 3. Over $\mathbb{F}_2$, $-1 = 1$. What does skew-symmetric mean there?
Sketch. (a) $\det A = \det A^{\mathsf{T}} = \det(-A) = (-1)^n \det A = -\det A$, so $(1+1)\det A = 0$. (b) $a_{ii} = -a_{ii}$ forces $a_{ii} = 0$, and the entries below the diagonal are the negatives of those above; $\mathbf{x} = (c, -b, a)$. (c) Over $\mathbb{F}_2$ skew-symmetric means symmetric, and I_3 is symmetric with determinant 1.

(a) By Theorem 5.4.14 and Exercise 5.1.5,

$$\begin{aligned} \det A &= \det A^{\mathsf{T}} = \det(-A) \\ &= (-1)^n \det A = -\det A, \end{aligned}$$

since n is odd. So $(1+1)\det A = 0$, and as $1 + 1 \neq 0$, $\det A = 0$ (Proposition 1.1.17).

(b) $A^{\mathsf{T}} = -A$ says $a_{ji} = -a_{ij}$ for all i, j (Definition 2.4.21). For $i = j$ this is $(1+1)a_{ii} = 0$, so $a_{ii} = 0$. For $i \neq j$ it says that the entries below the diagonal are the negatives of those above it. With $a = a_{12}$, $b = a_{13}$, and $c = a_{23}$, A has the stated form, and conversely every matrix of that form satisfies $A^{\mathsf{T}} = -A$. Let $\mathbf{x} = (c, -b, a)$. Then

$$A\mathbf{x} = (-ab + ba, -ac + ca, -bc + cb) = \mathbf{0},$$

and $\mathbf{x} \neq \mathbf{0}$ because $A \neq 0$ means that a, b, c are not all 0. So the columns of A are dependent, and $\det A = 0$ by Corollary 5.4.8, as (a) predicts.

(c) In $\mathbb{F}_2$, $-1 = 1$, so $A^{\mathsf{T}} = -A$ means $A^{\mathsf{T}} = A$. The identity matrix I_3 is symmetric, hence skew-symmetric over $\mathbb{F}_2$, and $\det I_3 = 1 \neq 0$. So the hypothesis $1 + 1 \neq 0$ in (a) cannot be dropped.

Solution to Exercise 5.4.34

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Exercise 5.4.12, Proposition 1.1.17 (No zero divisors), Proposition 5.4.1 (Determinants of elementary matrices)
Hint 1. Apply det to the defining equation. You get a polynomial equation for $d = \det A$.
Hint 2. Factor: $d^2 - d = d(d-1)$ and $d^2 - 1 = (d-1)(d+1)$. For the examples, try 0, I_n, and a scaling matrix.
Sketch. (a) $d^2 = d$, so $d \in \{0, 1\}$: the zero matrix and I_n. (b) $d^k = 0$, so $d = 0$: the zero matrix. (c) $d^2 = 1$, so $d = \pm 1$: I_n and $E_{1,-1}$. (d) $d^2 = 1$: again I_n and $E_{1,-1}$.

Write $d = \det A$, and use Exercise 5.4.12 for $\det\left(A^k\right) = d^k$. The zero matrix has determinant 0 (it has a zero column), and I_n has determinant 1.

(a) $d^2 = d$, so $d(d-1) = 0$ and $d \in \{0, 1\}$ (Proposition 1.1.17). Both occur: $0^2 = 0$ and $I_n^2 = I_n$.

(b) $d^k = \det 0 = 0$, and a product of nonzero scalars is nonzero, so $d = 0$. It occurs for the zero matrix.

(c) $d^2 = \det I_n = 1$, so $(d-1)(d+1) = 0$ and $d = \pm 1$. Both occur: $I_n^2 = I_n$, and the scaling $E_{1,-1}$ satisfies $E_{1,-1}^2 = E_{1,1} = I_n$ and has determinant -1 (Proposition 5.4.1). (If $1 + 1 = 0$, the two values coincide.)

(d) $d^2 = \det A^{\mathsf{T}} \det A = \det\left(A^{\mathsf{T}} A\right) = 1$ by Theorem 5.4.14, so $d = \pm 1$. Both occur: I_n, and $E_{1,-1}$, which is diagonal, so $E_{1,-1}^{\mathsf{T}} E_{1,-1} = E_{1,-1}^2 = I_n$.

Solution to Exercise 5.4.35

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Corollary 3.2.11 (Products of elementary matrices), Theorem 3.5.23 (One-sided inverses of square matrices), Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Reduce to elementary matrices (Technique 5.4.6)
Hint 1. What is the hypothesis of Theorem 3.5.19? Is the zero matrix a product of elementary matrices?
Hint 2. To repair the proof, show that if A or B is not invertible, then neither is AB.
Sketch. The factorization exists only for invertible matrices; a product of elementary matrices is always invertible, so for example 0 is not one. The argument proves the claim when A and B are both invertible. If A or B is not invertible, then AB is not invertible (an inverse C of AB would give A the right inverse BC and B the left inverse CA), so both sides are 0.

The claim is true, but the proof covers only invertible A and B. Theorem 3.5.19 applies to invertible matrices, and it cannot apply to any other matrix, since a product of elementary matrices is invertible (Corollary 3.2.11). For instance, the zero matrix is not a product of elementary matrices.

To repair the argument, it remains to treat the case where A or B is not invertible; then $\det A \det B = 0$ by Theorem 5.4.7. Suppose AB were invertible, with inverse C. Then $A(BC) = I_n$ and $(CA)B = I_n$, so A has a right inverse and B has a left inverse, and both are invertible by Theorem 3.5.23. So if A or B is not invertible, then AB is not invertible, and $\det(AB) = 0 = \det A \det B$. (The first proof of Theorem 5.4.10 avoids factoring A at all.)

Solution to Exercise 5.4.36

Uses. Theorem 5.1.13 (The 2×2 determinant), Theorem 5.2.31 (Alternating functions and permutations), Theorem 5.4.26 (Block-triangular matrices), Definition 5.2.29 (Permutation matrix)
Hint 1. What kind of object is Theorem 5.1.13 about? Are the blocks elements of F?
Hint 2. For (b), look for blocks that each have a zero column, while M is a permutation matrix.
Sketch. (a) Theorem 5.1.13 is about 2×2 matrices with entries in the field F. Blocks are not elements of F, and M is a $2m \times 2m$ matrix, whose determinant is defined through its $2m$ columns; that blocks multiply like entries says nothing about determinants. (b) $A = D = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $B = C = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ make M the permutation matrix of $(2\ 4)$, with determinant -1, while every block has determinant 0. (c) This is Theorem 5.4.26, since $\det 0 = 0$.

(a) Theorem 5.1.13 is about functions on $F^{2\times 2}$, matrices whose four entries are elements of the field F. The blocks are matrices, not elements of F (their products do not even commute), and M is a $2m \times 2m$ matrix whose determinant is defined through its $2m$ columns. Theorem 2.4.34 says only how products of block matrices are computed. It says nothing about determinants, so the formula of Theorem 5.1.13 cannot simply be transplanted.

(b) Let $A = D = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = C = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$. Then

$$M = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix},$$

whose columns are $\mathbf{e}_1, \mathbf{e}_4, \mathbf{e}_3, \mathbf{e}_2$. So $M = E_\sigma$ for the transposition $\sigma = (2\ 4)$ (Definition 5.2.29), and $\det M = \operatorname{sgn}(\sigma) = -1$ by Theorem 5.2.31. Each of A, B, C, D has a zero column, hence determinant 0, so the claimed formula gives 0. Since $-1 \neq 0$ in every field, the claim is false.

(c) If $C = 0$, then $\det C = 0$ (as $m \geq 1$, C has a zero column), so the claim reads $\det M = \det A \det D$, which is Theorem 5.4.26.

Solution to Exercise 5.4.37

Uses. Corollary 5.4.15 (Rows), Proposition 5.3.15 (Triangular matrices), Theorem 5.2.31 (Alternating functions and permutations), Definition 5.2.29 (Permutation matrix), Proposition 5.2.26 (Sign of a cycle)
Hint 1. Subtract each row from the row below it, starting at the bottom, so that every subtraction uses an original row.
Hint 2. For P_n you get an upper triangular matrix. For Q_n you get rows of the form $(1, \ldots, 1, 0, \ldots, 0)$; subtract again, starting at the bottom.
Sketch. For $i = n, \ldots, 2$, replace row i by row i minus row $i-1$. In P_n, row i becomes $(0, \ldots, 0, 1, \ldots, 1)$ with its first 1 in column i: upper triangular with 1s on the diagonal. In Q_n, row i becomes $(1, \ldots, 1, 0, \ldots, 0)$ with $i-1$ ones; repeating the subtraction turns row i into $\mathbf{e}_{i-1}^{\mathsf{T}}$, and clearing row 1 with these leaves $n\mathbf{e}_n^{\mathsf{T}}$. The rows $n\mathbf{e}_n^{\mathsf{T}}, \mathbf{e}_1^{\mathsf{T}}, \ldots, \mathbf{e}_{n-1}^{\mathsf{T}}$ give n times a cyclic permutation matrix of sign $(-1)^{n-1}$.

Row replacements do not change the determinant (Corollary 5.4.15). In both cases, first replace row i by row i minus row $i-1$ for $i = n, n-1, \ldots, 2$, in this order, so that row $i-1$ is still the original row when it is used.

P_n. The new row i (for $i \geq 2$) has entries $\min(i, j) - \min(i-1, j)$, which is 0 for $j \leq i-1$ and 1 for $j \geq i$. Row 1 is $(1, \ldots, 1)$. The result is upper triangular with every diagonal entry 1, so $\det P_n = 1$ by Proposition 5.3.15.

Q_n. The new row i (for $i \geq 2$) has entries $\max(i, j) - \max(i-1, j)$, which is 1 for $j \leq i-1$ and 0 for $j \geq i$. Row 1 is $(1, 2, \ldots, n)$. Repeat the procedure on rows $2, \ldots, n$: for $i = n, \ldots, 3$, subtract the current row $i-1$ from row i. Since row i has $i-1$ leading ones and row $i-1$ has $i-2$, row i becomes $\mathbf{e}_{i-1}^{\mathsf{T}}$, and row 2 is $\mathbf{e}_1^{\mathsf{T}}$ already. Finally subtract j times row $j+1$ (which is $\mathbf{e}_j^{\mathsf{T}}$) from row 1, for $j = 1, \ldots, n-1$; this leaves row 1 equal to $n\mathbf{e}_n^{\mathsf{T}}$. None of these steps changes the determinant. Pulling the factor n out of row 1 (Corollary 5.4.15), $\det Q_n = n \det R$, where R has rows $\mathbf{e}_n^{\mathsf{T}}, \mathbf{e}_1^{\mathsf{T}}, \ldots, \mathbf{e}_{n-1}^{\mathsf{T}}$. The columns of R are $\mathbf{e}_2, \mathbf{e}_3, \ldots, \mathbf{e}_n, \mathbf{e}_1$, so $R = E_\sigma$ for the n-cycle σ with $\sigma(j) = j+1$ for $j < n$ and $\sigma(n) = 1$ (Definition 5.2.29). By Theorem 5.2.31 and Proposition 5.2.26, $\det R = \operatorname{sgn}(\sigma) = (-1)^{n-1}$. Hence $\det Q_n = (-1)^{n-1} n$. (For $n = 1$ there is nothing to do: $Q_1 = (1)$.)

Solution to Exercise 5.4.38

Uses. Theorem 2.4.34 (Block multiplication), Theorem 5.4.10 (Multiplicativity), Exercise 5.1.5
Hint 1. A and B are not square, so Theorem 5.4.10 does not apply directly. Make them square without changing AB.
Hint 2. Add $n-m$ zero columns to A and $n-m$ zero rows to B.
Sketch. With $A' = (A\ \ 0) \in F^{n\times n}$ and $B' = \begin{pmatrix} B \\ 0 \end{pmatrix} \in F^{n\times n}$, block multiplication gives $A'B' = AB + 0 = AB$. Since A' has a zero column, $\det(AB) = \det A' \det B' = 0$. For $m \geq n$ the conclusion fails: $A = (I_n\ \ 0) \in F^{n\times m}$ and $B = A^{\mathsf{T}}$ give $AB = I_n$.

Let $A' = (A\ \ 0) \in F^{n\times n}$ be A followed by $n-m$ zero columns, and let $B' = \begin{pmatrix} B \\ 0 \end{pmatrix} \in F^{n\times n}$ be B followed by $n-m$ zero rows. By Theorem 2.4.34, $A'B' = AB + 0\cdot 0 = AB$. Since $m < n$, A' has a zero column, so $\det A' = 0$ (Exercise 5.1.5), and by Theorem 5.4.10,

$$\det(AB) = \det(A'B') = \det A' \det B' = 0.$$

For $m \geq n$ the conclusion fails. If $m = n$, take $A = B = I_n$. If $m > n$, let $A \in F^{n\times m}$ be I_n followed by $m-n$ zero columns, and $B = A^{\mathsf{T}} \in F^{m\times n}$. Then $AB = I_n$ by Theorem 2.4.34, so $\det(AB) = 1$.

Solution to Exercise 5.4.39

Uses. Definition 5.4.18 (Determinant of an operator), Definition 2.3.1 (Matrix of a linear map), Definition 2.4.1 (Matrix product), Corollary 5.4.27 (Several diagonal blocks), Theorem 5.4.14 (The transpose)
Hint 1. Let U_{ij} be the matrix with 1 in position (i,j) and 0 elsewhere. These n^2 matrices form a basis of $F^{n\times n}$; the order in which you list them matters.
Hint 2. AU_{ij} has column j equal to column i of A, and zeros elsewhere. List the U_{ij} column by column, that is, $U_{11}, U_{21}, \ldots, U_{n1}, U_{12}, \ldots$.
Hint 3. For R_A, list them row by row instead. You should get a block diagonal matrix with blocks A^{T}.
Sketch. With the basis $U_{11}, \ldots, U_{n1}, U_{12}, \ldots, U_{nn}$, the coordinates of X are its columns stacked, and L_A multiplies each column by A: its matrix is block diagonal with n blocks A. With the basis listed row by row, R_A replaces each row $\mathbf{r}^{\mathsf{T}}$ by $\mathbf{r}^{\mathsf{T}}A = \left(A^{\mathsf{T}}\mathbf{r}\right)^{\mathsf{T}}$, so its matrix is block diagonal with n blocks A^{T}. Then use Corollary 5.4.27 and $\det A^{\mathsf{T}} = \det A$.

For $i, j \in [n]$, let U_{ij} have 1 in position (i,j) and 0 elsewhere. Every $X \in F^{n\times n}$ is $\sum_{i,j} x_{ij}U_{ij}$, and the coefficients are the entries of X, so they are unique. Hence the U_{ij}, in any order, form a basis of $F^{n\times n}$, and the coordinates of X are its entries in the corresponding order.

L_A. List the basis column by column: $\mathcal{B} = U_{11}, U_{21}, \ldots, U_{n1}, U_{12}, \ldots, U_{nn}$, so that U_{kj} is the basis vector number $(j-1)n + k$. By Definition 2.4.1, column l of AU_{ij} is A times column l of U_{ij}, which is $A\mathbf{e}_i = \mathbf{a}_i$ for $l = j$ and $\mathbf{0}$ otherwise. So

$$L_A(U_{ij}) = AU_{ij} = \sum_{k=1}^{n} a_{ki}U_{kj}.$$

Hence the column of $[L_A]_{\mathcal{B}\mathcal{B}}$ belonging to U_{ij} has the entries $a_{1i}, \ldots, a_{ni}$ in the positions $(j-1)n+1, \ldots, jn$, and zeros elsewhere (Definition 2.3.1). That is, $[L_A]_{\mathcal{B}\mathcal{B}}$ is block diagonal with n diagonal blocks, each equal to A. By Corollary 5.4.27, $\det L_A = (\det A)^n$.

R_A. List the basis row by row: $\mathcal{B}' = U_{11}, U_{12}, \ldots, U_{1n}, U_{21}, \ldots, U_{nn}$, so that U_{ik} is number $(i-1)n + k$. The (r,k) entry of $U_{ij}A$ is $\sum_l (U_{ij})_{rl}a_{lk}$, which is a_{jk} if $r = i$ and 0 otherwise. So

$$R_A(U_{ij}) = U_{ij}A = \sum_{k=1}^{n} a_{jk}U_{ik},$$

and the column of $[R_A]_{\mathcal{B}'\mathcal{B}'}$ belonging to U_{ij} has the entries $a_{j1}, \ldots, a_{jn}$ in the positions $(i-1)n+1, \ldots, in$, and zeros elsewhere. So $[R_A]_{\mathcal{B}'\mathcal{B}'}$ is block diagonal with n diagonal blocks, each the matrix whose column j is $(a_{j1}, \ldots, a_{jn})$, that is, A^{T}. By Corollary 5.4.27 and Theorem 5.4.14, $\det R_A = \left(\det A^{\mathsf{T}}\right)^n = (\det A)^n$.

Solution to Exercise 5.4.40

Uses. Definition 5.4.18 (Determinant of an operator), Definition 5.2.29 (Permutation matrix), Theorem 5.2.31 (Alternating functions and permutations), Definition 5.2.23 (Sign of a permutation), Example 5.4.19 (Two operators on matrices and polynomials)
Hint 1. Use the basis of matrices U_{ij} with a single 1, as in Example 5.4.19. What does T do to it?
Hint 2. T permutes the basis, so its matrix is a permutation matrix. Count the transpositions in that permutation.
Sketch. $T(U_{ij}) = U_{ji}$, so T permutes the basis by the permutation π of $[n^2]$ exchanging the positions of U_{ij} and U_{ji} for $i < j$. Its matrix is E_π, and π is a product of $n(n-1)/2$ disjoint transpositions, so $\det T = \operatorname{sgn}(\pi) = (-1)^{n(n-1)/2}$. This is 1 exactly when $n \equiv 0$ or 1 modulo 4.

Let U_{ij} be the matrix with 1 in position (i,j) and 0 elsewhere, and list these n^2 matrices in some order $\mathbf{b}_1, \ldots, \mathbf{b}_{n^2}$; they form a basis of $F^{n\times n}$, as in Exercise 5.4.39. Since $U_{ij}^{\mathsf{T}} = U_{ji}$, there is a permutation π of $[n^2]$ with $T(\mathbf{b}_l) = \mathbf{b}_{\pi(l)}$ for every l: π exchanges the positions of U_{ij} and U_{ji} for $i \neq j$ and fixes the positions of the U_{ii}. So column l of the matrix of T is $\mathbf{e}_{\pi(l)}$, that is, the matrix is the permutation matrix E_π (Definition 5.2.29), and $\det T = \operatorname{sgn}(\pi)$ by Theorem 5.2.31.

The permutation π is the product of the transpositions exchanging the positions of U_{ij} and U_{ji}, one for each pair $i < j$. There are $n(n-1)/2$ such pairs, so $\operatorname{sgn}(\pi) = (-1)^{n(n-1)/2}$ by Definition 5.2.23. Hence $\det T = (-1)^{n(n-1)/2}$, in agreement with Example 5.4.19 for $n = 2$.

If $1 + 1 \neq 0$, then $-1 \neq 1$, and $\det T = 1$ exactly when $n(n-1)/2$ is even, that is, when $n(n-1)$ is divisible by 4. One of n and $n-1$ is odd, so this happens exactly when n or $n-1$ is divisible by 4: $n \equiv 0$ or 1 modulo 4. For instance, $\det T = -1$ for $n = 2, 3$ and $\det T = 1$ for $n = 4, 5$.

Solution to Exercise 5.4.41

Uses. Theorem 5.4.10 (Multiplicativity), Exercise 5.4.12, Exercise 5.1.5, Theorem 5.4.7 (Invertibility and the determinant), Definition 4.5.23 (Similar matrices), Definition 2.4.26 (Trace)
Hint 1. (a) I_2 is similar only to itself. (d) Try matrices with a zero column.
Hint 2. (c) Take determinants of $AB = -BA$, and remember that n is odd.
Sketch. (a) False: $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ and I_2. (b) True: $\det A \det B (\det A)^{-1}(\det B)^{-1} = 1$. (c) True: $\det A \det B = (-1)^n \det B \det A = -\det A \det B$, so $\det A \det B = 0$. (d) False: $A = 0$, $B = \left(\begin{smallmatrix}1 & 0\\ 0 & 0\end{smallmatrix}\right)$, $C = \left(\begin{smallmatrix}0 & 0\\ 0 & 1\end{smallmatrix}\right)$.

(a) False. $A = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ and $B = I_2$ have determinant 1 and trace 2. But $S^{-1} I_2 S = I_2 \neq A$ for every invertible S, so A is not similar to I_2.

(b) True. By Theorem 5.4.10 and Exercise 5.4.12,

$$\begin{aligned}&\det\left(ABA^{-1}B^{-1}\right)\\ &= \det A \det B (\det A)^{-1}(\det B)^{-1} = 1,\end{aligned}$$

because scalars commute.

(c) True. Taking determinants, with Exercise 5.1.5 for the factor -1,

$$\begin{aligned}\det A \det B = \det(AB) &= \det(-BA)\\ &= (-1)^n \det B \det A = -\det A \det B.\end{aligned}$$

So $2 \det A \det B = 0$, hence $\det A = 0$ or $\det B = 0$, and the corresponding matrix is not invertible (Theorem 5.4.7). (For even n the statement fails: $A = \left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix}0 & 1\\ 1 & 0\end{smallmatrix}\right)$ are invertible, and $AB = \left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right) = -BA$.)

(d) False. Let $n = 2$, $A = 0$, $B = \left(\begin{smallmatrix}1 & 0\\ 0 & 0\end{smallmatrix}\right)$, and $C = \left(\begin{smallmatrix}0 & 0\\ 0 & 1\end{smallmatrix}\right)$. Then $\det A = \det B = 0$, but $\det(A + C) = \det C = 0$ while $\det(B + C) = \det I_2 = 1$.

Solution to Exercise 5.4.42

Uses. Proposition 5.3.20 (Reduction modulo p), Theorem 5.4.10 (Multiplicativity)
Hint 1. The determinant of a matrix with integer entries is an integer.
Hint 2. Which integers have an integer reciprocal?
Sketch. $\det A$ and $\det A^{-1}$ are integers whose product is $\det I_n = 1$, so both are ± 1.

By Proposition 5.3.20, the determinant of a matrix with integer entries is an integer, so $\det A$ and $\det\left(A^{-1}\right)$ are integers. By Theorem 5.4.10, their product is $\det\left(AA^{-1}\right) = \det I_n = 1$. The only integers u with $uv = 1$ for some integer v are ± 1, since $|u| \geq 2$ would give $|uv| \geq 2$ for $v \neq 0$. Hence $\det A = \pm 1$.

Solution to Exercise 5.4.43

Uses. Theorem 2.4.34 (Block multiplication), Theorem 5.4.26 (Block-triangular matrices), Theorem 5.4.10 (Multiplicativity)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Imitate what you would do for a 2×2 matrix $\left(\begin{smallmatrix} a & b \\ b & a \end{smallmatrix}\right)$: add the second column to the first, then subtract the first row from the second.
Hint 2. With blocks, these operations are multiplications by $Q = \left(\begin{smallmatrix} I & 0 \\ I & I \end{smallmatrix}\right)$ on the right and $P = \left(\begin{smallmatrix} I & 0 \\ -I & I \end{smallmatrix}\right)$ on the left.
Sketch. With $P = \left(\begin{smallmatrix} I & 0 \\ -I & I \end{smallmatrix}\right)$ and $Q = \left(\begin{smallmatrix} I & 0 \\ I & I \end{smallmatrix}\right)$, block multiplication gives $PMQ = \left(\begin{smallmatrix} A+B & B \\ 0 & A-B \end{smallmatrix}\right)$. Both P and Q have determinant 1, so $\det M = \det(A+B)\det(A-B)$ by Theorem 5.4.26.

Let $M = \left(\begin{smallmatrix} A & B \\ B & A \end{smallmatrix}\right)$, $P = \left(\begin{smallmatrix} I_m & 0 \\ -I_m & I_m \end{smallmatrix}\right)$, and $Q = \left(\begin{smallmatrix} I_m & 0 \\ I_m & I_m \end{smallmatrix}\right)$. By Theorem 2.4.34,

$$MQ = \begin{pmatrix} A+B & B \\ B+A & A \end{pmatrix},$$

$$\begin{aligned} PMQ &= \begin{pmatrix} A+B & B \\ -(A+B)+(B+A) & -B+A \end{pmatrix} \\ &= \begin{pmatrix} A+B & B \\ 0 & A-B \end{pmatrix}. \end{aligned}$$

P and Q are block lower triangular with diagonal blocks I_m, so $\det P = \det Q = 1$ by Theorem 5.4.26. By Theorem 5.4.10 and Theorem 5.4.26,

$$\begin{aligned} \det M &= \det P \det M \det Q = \det(PMQ) \\ &= \det(A+B)\det(A-B). \end{aligned}$$

Solution to Exercise 5.4.44

Uses. Corollary 5.4.15 (Rows), Lemma 5.1.8 (Column replacement), Theorem 5.4.26 (Block-triangular matrices), Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Every row sums to $s = 1+z+z^2$. Add the second and third columns to the first, and pull out s.
Hint 2. Then subtract row 1 from rows 2 and 3, and look for the factor $1-z$ in the new rows. Recall $(1-z)s = 1-z^3$.
Sketch. Adding columns 2 and 3 to column 1 and pulling out $s = 1+z+z^2$ leaves first column $(1,1,1)$. Subtracting row 1 from rows 2, 3 gives rows $(1-z)(0,1,z)$ and $(1-z)(0,-z,1+z)$. So $\det C(z) = s(1-z)^2\left(1+z+z^2\right) = \left(1-z^3\right)^2$. Non-invertible exactly when $z^3 = 1$: $z = 1, \omega, \omega^2$ in $\mathbb{C}$; $z = 1$ in $\mathbb{R}$; $z \in \{1,2,4\}$ in $\mathbb{F}_7$.

(a) Let $s = 1+z+z^2$. Adding columns 2 and 3 to column 1 does not change the determinant (Lemma 5.1.8), and makes every entry of column 1 equal to s. Pulling out s, and then subtracting row 1 from rows 2 and 3 (Corollary 5.4.15),

$$\begin{aligned} \det C(z) &= s\det\begin{pmatrix} 1 & z & z^2 \\ 1 & 1 & z \\ 1 & z^2 & 1 \end{pmatrix} \\ &= s\det\begin{pmatrix} 1 & z & z^2 \\ 0 & 1-z & z-z^2 \\ 0 & z^2-z & 1-z^2 \end{pmatrix}. \end{aligned}$$

Row 2 of the last matrix is $(1-z)(0,1,z)$, and row 3 is $(1-z)(0,-z,1+z)$. Pulling out both factors $1-z$ and using Theorem 5.4.26 with a 1×1 upper left block,

$$\begin{aligned} \det C(z) &= s(1-z)^2\det\begin{pmatrix} 1 & z \\ -z & 1+z \end{pmatrix} \\ &= s(1-z)^2\left(1+z+z^2\right) = ((1-z)s)^2 = \left(1-z^3\right)^2, \end{aligned}$$

since $(1-z)\left(1+z+z^2\right) = 1-z^3$. Every step is valid over any field.

(b) By Theorem 5.4.7, $C(z)$ fails to be invertible exactly when $\left(1-z^3\right)^2 = 0$, that is, when $z^3 = 1$. Over $\mathbb{C}$ the solutions are the cube roots of unity 1, $\omega = \left(-1+i\sqrt{3}\right)/2$, and $\omega^2 = \overline{\omega}$. Over $\mathbb{R}$, only $z = 1$. Over $\mathbb{F}_7$, cubing the nonzero elements gives $1^3 = 1$, $2^3 = 8 = 1$, $3^3 = 27 = 6$, $4^3 = 64 = 1$, $5^3 = 125 = 6$, and $6^3 = 216 = 6$, so $z \in \{1, 2, 4\}$.

Solution to Exercise 5.4.45

Uses. Theorem 2.4.34 (Block multiplication), Proposition 5.4.17 (Similar matrices have equal determinants), Theorem 5.4.26 (Block-triangular matrices), Exercise 5.3.28, Definition 5.3.6 (Determinant)
Hint 1. Regard $M = \left(\begin{smallmatrix} B & -C \\ C & B \end{smallmatrix}\right)$ as a complex matrix. Its determinant is the same whether computed over $\mathbb{R}$ or over $\mathbb{C}$.
Hint 2. Conjugate by $P = \left(\begin{smallmatrix} I & 0 \\ iI & I \end{smallmatrix}\right)$, whose inverse is $\left(\begin{smallmatrix} I & 0 \\ -iI & I \end{smallmatrix}\right)$, and simplify $P^{-1}MP$ with block multiplication.
Hint 3. $B - iC$ is the entrywise complex conjugate of A. Use Exercise 5.3.28.
Sketch. Over $\mathbb{C}$, $P^{-1}MP = \left(\begin{smallmatrix} B-iC & -C \\ 0 & B+iC \end{smallmatrix}\right)$ with $P = \left(\begin{smallmatrix} I & 0 \\ iI & I \end{smallmatrix}\right)$. So $\det M = \det(B-iC)\det(B+iC) = \overline{\det A}\det A = |\det A|^2$.

Let $M = \left(\begin{smallmatrix} B & -C \\ C & B \end{smallmatrix}\right)$. Its determinant is given by the Leibniz formula (Definition 5.3.6), which involves only sums and products of the (real) entries, so it is the same whether we regard M as a real or a complex matrix. We work over $\mathbb{C}$. Let $P = \left(\begin{smallmatrix} I_n & 0 \\ iI_n & I_n \end{smallmatrix}\right)$ and $P' = \left(\begin{smallmatrix} I_n & 0 \\ -iI_n & I_n \end{smallmatrix}\right)$. By Theorem 2.4.34, $PP' = P'P = I_{2n}$, so $P' = P^{-1}$, and

$$MP = \begin{pmatrix} B - iC & -C \\ C + iB & B \end{pmatrix},$$

$$\begin{aligned} P^{-1}MP &= \begin{pmatrix} B - iC & -C \\ -i(B - iC) + C + iB & iC + B \end{pmatrix} \\ &= \begin{pmatrix} B - iC & -C \\ 0 & B + iC \end{pmatrix}, \end{aligned}$$

using $-i(-iC) = i^2C = -C$. By Proposition 5.4.17 and Theorem 5.4.26,

$$\begin{aligned} \det M &= \det\left(P^{-1}MP\right) \\ &= \det(B - iC)\det(B + iC). \end{aligned}$$

Since B and C are real, $B - iC = \overline{A}$, the entrywise complex conjugate of A, and $\det\overline{A} = \overline{\det A}$ by Exercise 5.3.28. Hence $\det M = \overline{\det A}\det A = |\det A|^2 \geq 0$.

Solution to Exercise 5.4.46

Uses. Theorem 5.4.10 (Multiplicativity), Exercise 5.3.28
Hint 1. Over $\mathbb{C}$, the scalar $a^2 + b^2$ factors as $(a + ib)(a - ib)$. Does the same factorization work for commuting matrices?
Hint 2. $\det(A - iB)$ is the complex conjugate of $\det(A + iB)$, by Exercise 5.3.28.
Hint 3. For the example, take $n = 2$ and look for A and B with small entries such that $A^2 + B^2$ has determinant -1.
Sketch. $(A + iB)(A - iB) = A^2 - iAB + iBA + B^2 = A^2 + B^2$ when $AB = BA$. So $\det\left(A^2 + B^2\right) = z\overline{z} = |z|^2 \geq 0$ with $z = \det(A + iB)$. Without commuting: $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 1 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ give $A^2 + B^2 = \left(\begin{smallmatrix} 2 & 3 \\ 1 & 1 \end{smallmatrix}\right)$, with determinant -1.

Regard A and B as complex matrices; this does not change $\det\left(A^2 + B^2\right)$, which is computed from the entries by the Leibniz formula. Since $AB = BA$,

$$\begin{aligned} (A + iB)(A - iB) &= A^2 - iAB + iBA - i^2B^2 \\ &= A^2 + B^2. \end{aligned}$$

Let $z = \det(A + iB)$. Since A and B are real, $A - iB$ is the entrywise conjugate of $A + iB$, so $\det(A - iB) = \overline{z}$ by Exercise 5.3.28. By Theorem 5.4.10,

$$\det\left(A^2 + B^2\right) = z\overline{z} = |z|^2 \geq 0.$$

Without the hypothesis, let $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 1 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. Then $A^2 = \left(\begin{smallmatrix} 2 & 2 \\ 2 & 2 \end{smallmatrix}\right)$ and $B^2 = \left(\begin{smallmatrix} 0 & 1 \\ -1 & -1 \end{smallmatrix}\right)$, so $A^2 + B^2 = \left(\begin{smallmatrix} 2 & 3 \\ 1 & 1 \end{smallmatrix}\right)$, whose determinant is $2 - 3 = -1 < 0$. Indeed $AB = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $BA = \left(\begin{smallmatrix} 2 & 2 \\ -1 & -1 \end{smallmatrix}\right)$ are different.

Solution to Exercise 5.4.47

Uses. Lemma 5.4.2 (Multiplying by an elementary matrix), Proposition 5.4.1 (Determinants of elementary matrices), Theorem 5.4.7 (Invertibility and the determinant), Corollary 5.4.8 (Vanishing determinants), Proposition 1.2.35 (Zero products)
Hint 1. (a) Compute $\det(XE_{1c})$, and write down the inverse map. Which values can the determinant of an invertible matrix take?
Hint 2. (b) A 2×2 matrix is invertible exactly when its columns are independent. Count the choices of the first column, then of the second.
Sketch. (a) $\det(XE_{1c}) = c\det X$, and $Y \mapsto YE_{1,c^{-1}}$ is the inverse map. G is the disjoint union of the $p-1$ sets $\{\det = c\}$, $c \neq 0$, each in bijection with H. (b) The first column is any of the p^2-1 nonzero vectors, and the second any of the p^2-p vectors that are not multiples of the first. (c) For $p=2$, $H=G$ has the 6 matrices I_2, E_{12}, and the four with exactly three entries 1.

(a) For $X \in H$, $\det(XE_{1c}) = \det X \det E_{1c} = c$ by Lemma 5.4.2 and Proposition 5.4.1, and XE_{1c} is invertible. So the map sends H into $H_c = \{A \in G \mid \det A = c\}$. Similarly $Y \mapsto YE_{1,c^{-1}}$ sends H_c into H, and the two maps are inverse to each other, since $E_{1c}E_{1,c^{-1}} = E_{1,c^{-1}}E_{1c} = I_n$. So $|H_c| = |H|$. By Theorem 5.4.7, every $A \in G$ has $\det A \neq 0$, so G is the disjoint union of the $p-1$ sets H_c with $c \neq 0$. Hence $|G| = (p-1)|H|$.

(b) By Corollary 5.4.8, $A \in \mathbb{F}_p^{2\times 2}$ is invertible exactly when its columns $\mathbf{a}_1, \mathbf{a}_2$ are linearly independent. This holds exactly when $\mathbf{a}_1 \neq \mathbf{0}$ and $\mathbf{a}_2$ is not a multiple of $\mathbf{a}_1$. Indeed, if $x\mathbf{a}_1 + y\mathbf{a}_2 = \mathbf{0}$ with $(x,y) \neq (0,0)$, then either $y \neq 0$ and $\mathbf{a}_2 = -y^{-1}x\mathbf{a}_1$, or $y = 0$, $x \neq 0$, and $\mathbf{a}_1 = \mathbf{0}$; conversely, $\mathbf{a}_1 = \mathbf{0}$ or $\mathbf{a}_2 = t\mathbf{a}_1$ gives a nontrivial relation. There are p^2-1 nonzero vectors in $\mathbb{F}_p^2$. For each of them, the multiples $t\mathbf{a}_1$ with $t \in \mathbb{F}_p$ are p distinct vectors, since $t\mathbf{a}_1 = t'\mathbf{a}_1$ forces $t = t'$ (Proposition 1.2.35), so there are p^2-p choices of $\mathbf{a}_2$. Hence $|G| = (p^2-1)(p^2-p)$, and by (a),

$$|H| = \frac{(p^2-1)(p^2-p)}{p-1} = p(p^2-1).$$

(c) For $p=2$ the formula gives $2\cdot 3 = 6$. Over $\mathbb{F}_2$ the only nonzero scalar is 1, so $H=G$. The invertible 2×2 matrices over $\mathbb{F}_2$ are those with $ad-bc = ad+bc = 1$, that is, with exactly one of the products ad and bc equal to 1:

$$\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad \begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \begin{pmatrix}1&1\\0&1\end{pmatrix},$$
$$\begin{pmatrix}1&0\\1&1\end{pmatrix},\quad \begin{pmatrix}0&1\\1&1\end{pmatrix},\quad \begin{pmatrix}1&1\\1&0\end{pmatrix}.$$

Solution to Exercise 5.4.48

Uses. Exercise 3.2.53, Proposition 3.2.7 (Row operations are left multiplications), Proposition 5.4.1 (Determinants of elementary matrices), Theorem 5.4.10 (Multiplicativity), Proposition 5.1.17 (Dependent columns), Proposition 5.3.15 (Triangular matrices), Proposition 3.2.10 (Inverses of elementary matrices)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. Imitate Exercise 3.2.53, column by column: for $k = 1, \ldots, n-1$, use replacements to make column k equal to $\mathbf{e}_k$ without disturbing columns $1, \ldots, k-1$.
Hint 2. To make the (k,k) entry equal to 1, you need a nonzero entry in column k below row k. If there is none, first add row k to row $k+1$. Why is the (k,k) entry then nonzero?
Hint 3. Replacements do not change the determinant. After column $n-1$, read off the last diagonal entry, and clear the last column above it.
Sketch. Keep the invariant that columns $1, \ldots, k-1$ are $\mathbf{e}_1, \ldots, \mathbf{e}_{k-1}$; then rows $k, \ldots, n$ vanish in those columns, so adding them to other rows does not break the invariant. Column k has a nonzero entry in rows $k, \ldots, n$ (else the columns are dependent); arrange one in a row $j > k$, add $(1-m_{kk})/m_{jk}$ times row j to row k to get a 1, and clear the rest of column k. At the end the matrix is upper triangular with diagonal $1, \ldots, 1, d$, where $d = \det A$ because replacements preserve det; clearing column n above d gives $\operatorname{diag}(1, \ldots, 1, d)$. Then $A = E_1^{-1}\cdots E_t^{-1}E_{n,d}$.

(a) Every matrix below is obtained from A by replacements, so it is invertible with determinant $\det A$ (Proposition 3.2.7, Proposition 5.4.1, Theorem 5.4.10). We process $k = 1, \ldots, n-1$ in turn, keeping the

following invariant: before step k, columns $1, \dots, k-1$ of the current matrix M are $\mathbf{e}_1, \dots, \mathbf{e}_{k-1}$. Then for $l < k$, every row other than row l has entry 0 in column l. In particular rows $k, \dots, n$ vanish in columns $1, \dots, k-1$, so adding a multiple of one of these rows to another row does not change columns $1, \dots, k-1$. All replacements in step k add multiples of rows numbered at least k.

Step k. Column k of M has a nonzero entry in one of the rows $k, \dots, n$: otherwise column k would be a combination of $\mathbf{e}_1, \dots, \mathbf{e}_{k-1}$, that is, of columns $1, \dots, k-1$, and $\det M = 0$ by Proposition 5.1.17. If $m_{jk} = 0$ for every $j > k$, then $m_{kk} \neq 0$, and we add row k to row $k+1$ (possible as $k+1 \leq n$); now $m_{k+1,k} = m_{kk} \neq 0$. So we may choose $j > k$ with $c = m_{jk} \neq 0$. Adding $(1 - m_{kk})c^{-1}$ times row j to row k changes the (k,k) entry to $m_{kk} + (1 - m_{kk}) = 1$. Finally, for each $i \neq k$, add $-m_{ik}$ times row k to row i; this makes column k equal to $\mathbf{e}_k$. The invariant now holds before step $k+1$.

After step $n-1$, columns $1, \dots, n-1$ are $\mathbf{e}_1, \dots, \mathbf{e}_{n-1}$, so the matrix is upper triangular with diagonal entries $1, \dots, 1, m_{nn}$, and $m_{nn} = \det A$ by Proposition 5.3.15. In particular $m_{nn} \neq 0$. Row n is $(0, \dots, 0, m_{nn})$, so adding $-m_{in}m_{nn}^{-1}$ times row n to row i, for each $i < n$, clears column n above the diagonal and changes nothing else. The result is $\operatorname{diag}(1, \dots, 1, \det A)$, reached by replacements $E_1, \dots, E_t$.

(b) By (a), $A = E_1^{-1} \cdots E_t^{-1} \operatorname{diag}(1, \dots, 1, \det A)$, and each E_l^{-1} is a replacement by Proposition 3.2.10. If $\det A = 1$, the last factor is I_n, and A is a product of replacements. In general the last factor is the scaling $E_{n,\det A}$.

Solution to Exercise 5.4.49

Uses. Exercise 5.4.48, Proposition 5.2.30 (Algebra of permutation matrices), Theorem 3.3.10 ($GA = \operatorname{rref}(A)$), Theorem 3.3.23 (Invertibility and RREF), Proposition 3.3.8 (Properties of the output), Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Reduce to elementary matrices (Technique 5.4.6)
Hint 1. First show $f(I_n) = 1$, that $f(G) \neq 0$ for invertible G, and that $f\left(GXG^{-1}\right) = f(X)$.
Hint 2. Show that all replacements are conjugate to $E_{1,1,2}$, using a scaling and a permutation matrix. Then compare $E_{1,1,2}^2$ with $E_{1,2,2}$; treat $1 + 1 = 0$ separately.
Hint 3. For invertible A, use Exercise 5.4.48. For A not invertible, write $A = G^{-1} \operatorname{rref}(A)$, and note that $\operatorname{rref}(A)$ is unchanged by left multiplication with $\operatorname{diag}(1, \dots, 1, 0)$.
Sketch. f is invariant under conjugation by invertible matrices. Conjugating $E_{i,1,j}$ by E_{jc} gives E_{icj}, and conjugating by a permutation matrix moves it to $E_{1,1,2}$; so all replacements have the same value $s \neq 0$. From $E_{1,1,2}^2 = E_{1,2,2}$ we get $s^2 = s$ (or $s^2 = 1$ if $1 + 1 = 0$), so $s = 1$. Conjugating $\operatorname{diag}(t, 1, \dots, 1)$ by E_{1n} gives $f(\operatorname{diag}(1, \dots, 1, t)) = t$, so $f(A) = \det A$ for invertible A by Exercise 5.4.48. If A is not invertible, $\operatorname{rref}(A) = Z \operatorname{rref}(A)$ with $Z = \operatorname{diag}(1, \dots, 1, 0)$ and $f(Z) = 0$.

Throughout, let U_{ji} be the matrix with 1 in position (j,i) and 0 elsewhere, so that $E_{icj} = I_n + cU_{ji}$ for $i \neq j$.

Step 0. $f(I_n) = f(\operatorname{diag}(1, \dots, 1)) = 1$. If G is invertible, then $f(G)f\left(G^{-1}\right) = f(I_n) = 1$, so $f(G) \neq 0$ and $f\left(G^{-1}\right) = f(G)^{-1}$. Hence $f\left(GXG^{-1}\right) = f(G)f(X)f(G)^{-1} = f(X)$ for every X, because values of f commute.

Step 1: replacements. Let $i \neq j$ and $c \neq 0$, and let $D = E_{jc}$, so $D^{-1} = E_{j,c^{-1}}$. Multiplying U_{ji} on the left by D scales its row j by c. Multiplying on the right by D^{-1} scales its column j by c^{-1}, and that column is zero since $i \neq j$. So $DU_{ji}D^{-1} = cU_{ji}$, hence $DE_{i,1,j}D^{-1} = E_{icj}$, and $f\left(E_{icj}\right) = f\left(E_{i,1,j}\right)$ by Step 0. Next choose $\sigma \in S_n$ with $\sigma(i) = 1$ and $\sigma(j) = 2$, possible as $i \neq j$ and $n \geq 2$. By Proposition 5.2.30, $E_\sigma^{-1} = E_{\sigma^{-1}}$, and $XE_{\sigma^{-1}}$ has column l equal to column $\sigma^{-1}(l)$ of X. So $U_{ji}E_{\sigma^{-1}}$ has its only nonzero column in position $\sigma(i)$, equal to $\mathbf{e}_j$; multiplying by E_σ on the left turns this column into $E_\sigma \mathbf{e}_j = \mathbf{e}_{\sigma(j)}$. Hence $E_\sigma U_{ji} E_\sigma^{-1} = U_{\sigma(j)\sigma(i)} = U_{21}$, and $E_\sigma E_{i,1,j} E_\sigma^{-1} = I_n + U_{21} = E_{1,1,2}$. So every replacement E_{icj} with $c \neq 0$ has the value $s = f\left(E_{1,1,2}\right)$, and $s \neq 0$ by Step 0. (A replacement with $c = 0$ is I_n, with $f(I_n) = 1$.)

Since $U_{21}^2 = 0$, we have $E_{1,1,2}^2 = I_n + 2U_{21}$, where $2 = 1 + 1$. If $1 + 1 \neq 0$, this is the replacement $E_{1,2,2}$, so $s^2 = s$, and $s = 1$ because $s \neq 0$. If $1 + 1 = 0$, then $E_{1,1,2}^2 = I_n$, so $s^2 = 1$, and $(s-1)^2 = s^2 - (1+1)s + 1 = s^2 + 1 = 1 + 1 = 0$, so again $s = 1$. Thus $f(E) = 1 = \det E$ for every replacement E.

Step 2: invertible matrices. E_{1n} is its own inverse, and $E_{1n} \operatorname{diag}(t, 1, \dots, 1) E_{1n} = \operatorname{diag}(1, \dots, 1, t) = E_{n,t}$, as conjugating by E_{1n} swaps rows 1 and n and then columns 1 and n. So $f(\operatorname{diag}(1, \dots, 1, t)) = t$ for every $t \in F$, by

Step 0; for $t \neq 0$ this matrix is the scaling E_{nt}. If A is invertible, then by Exercise 5.4.48(b), $A = R_1 \cdots R_q E_{n,\det A}$ with replacements R_l, and

$$f(A) = f(R_1)\cdots f\big(R_q\big) f\big(E_{n,\det A}\big) = \det A.$$

Step 3: matrices that are not invertible. Let A be not invertible, so $\det A = 0$ (Theorem 5.4.7). By Theorem 3.3.10, $A = G^{-1}R$ with G invertible and $R = \operatorname{rref}(A)$, and $R \neq I_n$ by Theorem 3.3.23. So R has fewer than n pivots, and its last row is zero by Proposition 3.3.8. Let $Z = \operatorname{diag}(1, \ldots, 1, 0)$. Multiplying by Z on the left replaces the last row by zeros, so $ZR = R$. By the computation in Step 2 with $t = 0$, $f(Z) = 0$. Hence $f(R) = f(Z)f(R) = 0$, and $f(A) = f\big(G^{-1}\big)f(R) = 0 = \det A$.

So $f(A) = \det A$ for every A.

Solution to Exercise 5.4.50

Uses. Proposition 5.4.29 (Schur complement), Theorem 5.4.10 (Multiplicativity)
Techniques. Block elimination (Technique 5.4.28)
Hint 1. Start from Proposition 5.4.29, and combine the two determinants on the right into one.
Hint 2. $ACA^{-1} = C$ when A and C commute. For the example, a zero row in M is an easy way to make $\det M = 0$.
Sketch. $\det M = \det A \det\big(D - CA^{-1}B\big) = \det\big(AD - ACA^{-1}B\big) = \det(AD - CB)$. Example: $A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $B = C = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, $D = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$; then M has a zero row, while $AD - CB = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$.

By Proposition 5.4.29 and Theorem 5.4.10,

$$\begin{aligned} \det\begin{pmatrix} A & B \\ C & D \end{pmatrix} &= \det A \det\big(D - CA^{-1}B\big) \\ &= \det\big(A\big(D - CA^{-1}B\big)\big) \\ &= \det\big(AD - ACA^{-1}B\big). \end{aligned}$$

Since $AC = CA$, we have $ACA^{-1} = CAA^{-1} = C$, so the right side is $\det(AD - CB)$.

For the example, let $A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $B = C = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and $D = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$. Then A is invertible, and $AC = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right) \neq \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right) = CA$. The third row of $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ is the first row of C followed by the first row of D, which is zero, so $\det\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) = 0$. But $AD = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $CB = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, so $\det(AD - CB) = \det\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = -1$.

Section 5.5

Solution to Exercise 5.5.5

Uses. Theorem 5.5.3 (Cofactor expansion), Lemma 5.5.2 (A row or column with one nonzero entry)
Hint 1. Look for a row or a column with a single nonzero entry.
Hint 2. Row 3 is $(0, 0, 1, 0)$. After deleting row 3 and column 3, look at the first row of what is left.
Sketch. Expanding along row 3 leaves $M_{\widehat{33}} = \left(\begin{smallmatrix} i & 0 & 0 \\ 1 & 3 & 1 \\ 2 & 1 & 1 \end{smallmatrix}\right)$ with sign $+$. Expanding that along its first row gives $i(3-1) = 2i$.
So $\det M = 2i$.

Row 3 of M is $(0, 0, 1, 0)$, so by Lemma 5.5.2,

$$\det M = (-1)^{3+3} \cdot 1 \cdot \det M_{\widehat{33}} = \det\begin{pmatrix} i & 0 & 0 \\ 1 & 3 & 1 \\ 2 & 1 & 1 \end{pmatrix}.$$

The first row of this matrix is $(i, 0, 0)$, so expanding along it,

$$\det M = (-1)^{1+1} i \det\begin{pmatrix} 3 & 1 \\ 1 & 1 \end{pmatrix} = i(3-1) = 2i.$$

Rows with a single nonzero entry are the best choice, since each expansion then has a single term.

Solution to Exercise 5.5.13

Uses. Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Theorem 5.5.9 (The adjugate and the inverse), Proposition 5.3.20 (Reduction modulo p)
Hint 1. Compute the cofactors over $\mathbb{Z}$ and reduce modulo 7 at the end. Remember to transpose.
Hint 2. $\det A = -19$ over $\mathbb{Z}$, which is 2 in $\mathbb{F}_7$, and $2^{-1} = 4$ in $\mathbb{F}_7$.
Sketch. Over $\mathbb{Z}$, $\operatorname{adj} A = \begin{pmatrix} -1 & -6 & 2 \\ -9 & 3 & -1 \\ 12 & -4 & -5 \end{pmatrix}$ and $\det A = -19$. In $\mathbb{F}_7$, $\det A = 2$ and $\operatorname{adj} A = \begin{pmatrix} 6 & 1 & 2 \\ 5 & 3 & 6 \\ 5 & 3 & 2 \end{pmatrix}$, so $A^{-1} = 4 \operatorname{adj} A = \begin{pmatrix} 3 & 4 & 1 \\ 6 & 5 & 3 \\ 6 & 5 & 1 \end{pmatrix}$.

We compute over $\mathbb{Z}$ and reduce at the end (Proposition 5.3.20). The cofactors are

$$\begin{aligned} c_{11} &= 1 \cdot 3 - 1 \cdot 4 = -1, & c_{12} &= -(3 \cdot 3 - 1 \cdot 0) = -9, & c_{13} &= 3 \cdot 4 - 1 \cdot 0 = 12, \\ c_{21} &= -(2 \cdot 3 - 0 \cdot 4) = -6, & c_{22} &= 1 \cdot 3 - 0 \cdot 0 = 3, & c_{23} &= -(1 \cdot 4 - 2 \cdot 0) = -4, \\ c_{31} &= 2 \cdot 1 - 0 \cdot 1 = 2, & c_{32} &= -(1 \cdot 1 - 0 \cdot 3) = -1, & c_{33} &= 1 \cdot 1 - 2 \cdot 3 = -5. \end{aligned}$$

Expanding along row 1, $\det A = 1 \cdot (-1) + 2 \cdot (-9) + 0 \cdot 12 = -19$, which is 2 in $\mathbb{F}_7$. Transposing C_A and reducing modulo 7,

$$\operatorname{adj} A = \begin{pmatrix} -1 & -6 & 2 \\ -9 & 3 & -1 \\ 12 & -4 & -5 \end{pmatrix} = \begin{pmatrix} 6 & 1 & 2 \\ 5 & 3 & 6 \\ 5 & 3 & 2 \end{pmatrix} \quad \text{in } \mathbb{F}_7^{3\times 3}.$$

Since $2 \cdot 4 = 8 = 1$ in $\mathbb{F}_7$, $(\det A)^{-1} = 4$, and by Theorem 5.5.9

$$A^{-1} = 4 \operatorname{adj} A = \begin{pmatrix} 24 & 4 & 8 \\ 20 & 12 & 24 \\ 20 & 12 & 8 \end{pmatrix} = \begin{pmatrix} 3 & 4 & 1 \\ 6 & 5 & 3 \\ 6 & 5 & 1 \end{pmatrix}.$$

Check: the first row of AA^{-1} is $(3 + 12, 4 + 10, 1 + 6) = (15, 14, 7) = (1, 0, 0)$, the second is $(9 + 6 + 6, 12 + 5 + 5, 3 + 3 + 1) = (21, 22, 7) = (0, 1, 0)$, and the third is $(24 + 18, 20 + 15, 12 + 3) = (42, 35, 15) = (0, 0, 1)$, all modulo 7.

Solution to Exercise 5.5.16

Uses. Theorem 5.5.14 (Cramer's rule), Lemma 5.5.2 (A row or column with one nonzero entry), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate)
Hint 1. Column j of B^{-1} is the solution of $B\mathbf{x} = \mathbf{e}_j$.
Hint 2. In $B_i(\mathbf{e}_j)$, column i has a single nonzero entry. Where is it?
Sketch. Column j of B^{-1} is $B^{-1}\mathbf{e}_j$, the solution of $B\mathbf{x} = \mathbf{e}_j$. Its i-th entry is $\det B_i(\mathbf{e}_j)/\det B$. Column i of $B_i(\mathbf{e}_j)$ has a single 1 in row j, and deleting row j and column i leaves $B_{\hat{j}\hat{i}}$. So $\det B_i(\mathbf{e}_j) = (-1)^{i+j} \det B_{\hat{j}\hat{i}} = c_{ji}$.

The (i, j) entry of B^{-1} is the i-th entry of its j-th column $B^{-1}\mathbf{e}_j$, which is the solution of $B\mathbf{x} = \mathbf{e}_j$. By Theorem 5.5.14 it equals $\det B_i(\mathbf{e}_j)/\det B$. Column i of $B_i(\mathbf{e}_j)$ is $\mathbf{e}_j$, whose only nonzero entry is the 1 in row j. Deleting row j and column i from $B_i(\mathbf{e}_j)$ removes the replaced column, so it leaves $B_{\hat{j}\hat{i}}$. By Lemma 5.5.2,

$$\det B_i(\mathbf{e}_j) = (-1)^{j+i} \det B_{\hat{j}\hat{i}} = c_{ji}.$$

Hence the (i, j) entry of B^{-1} is $c_{ji}/\det B$, the (i, j) entry of $(\det B)^{-1} C_B^{\mathsf{T}}$.

Solution to Exercise 5.5.26

Uses. Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.7 (Invertibility and the determinant), Theorem 3.4.24 (Polynomial interpolation)
Hint 1. Group the factors $j - i$ of the product by their larger index j.
Hint 2. For (b), the nodes $0, 1, 2, 3, 4$ are all the elements of $\mathbb{F}_5$. Reduce the integer from (a) modulo 5, or compute directly. Then think of g as a list of 5 values.
Sketch. (a) For fixed j, the factors $j - i$ with $1 \le i < j$ are $j - 1, j - 2, \ldots, 1$, with product $(j - 1)!$. So the determinant is $\prod_{j=2}^{n} (j - 1)! = 1! \cdots (n - 1)!$, which is 12 for $n = 4$. (b) The same grouping gives $1!2!3!4! = 288 = 3$ in $\mathbb{F}_5$, which is nonzero. So V is invertible, and for any values $g(0), \ldots, g(4)$ there is exactly one P of degree at most 4 taking them.

(a) With $c_k = k+1$, Theorem 5.5.21 gives $\det V(1,\dots,n) = \prod_{1\le i<j\le n}(j-i)$. For a fixed j, the factors with $i = 1,\dots,j-1$ are $j-1, j-2,\dots,1$, whose product is $(j-1)!$. So

$$\det V(1,\dots,n) = \prod_{j=2}^{n}(j-1)! = 1!\cdot 2!\cdots(n-1)!.$$

For $n=4$ this is $1\cdot 2\cdot 6 = 12$.

(b) By Theorem 5.5.21, $\det V(0,1,2,3,4) = \prod_{0\le i<j\le 4}(j-i)$, computed in $\mathbb{F}_5$. Grouping by j as in (a), this is $1!\cdot 2!\cdot 3!\cdot 4! = 1\cdot 2\cdot 6\cdot 24 = 288$, and $288 = 57\cdot 5 + 3$, so the determinant is $3 \neq 0$ in $\mathbb{F}_5$. (Each factor $j-i$ lies in $\{1,2,3,4\}$, so the product is nonzero by Proposition 1.1.17, without computing it.) So $V = V(0,1,2,3,4)$ is invertible by Theorem 5.4.7.

Given $g : \mathbb{F}_5 \to \mathbb{F}_5$, a polynomial $P = \sum_{k=0}^{4} a_k x^k$ satisfies $P(t) = g(t)$ for all $t \in \mathbb{F}_5$ if and only if $V\mathbf{a} = (g(0), g(1), g(2), g(3), g(4))$, where $\mathbf{a} = (a_0,\dots,a_4)$. Since V is invertible, this system has exactly one solution. (This is Theorem 3.4.24 with all five elements of $\mathbb{F}_5$ as nodes.)

Solution to Exercise 5.5.33

Uses. Lemma 5.5.2 (A row or column with one nonzero entry), Theorem 5.5.3 (Cofactor expansion), Proposition 5.3.20 (Reduction modulo p), Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Row 2 has a single nonzero entry. After deleting its row and column, look for another row or column with a single nonzero entry.
Hint 2. For (b), reduce the answer to (a) modulo p.
Sketch. Row 2 gives $\det A = 2\det\begin{pmatrix}3&0&2\\1&5&1\\2&0&1\end{pmatrix}$, and column 2 of that minor gives $5\det\begin{pmatrix}3&2\\2&1\end{pmatrix} = -5$. So $\det A = -10$, and the reduction is invertible exactly for $p \notin \{2,5\}$.

(a) Row 2 is $(0,2,0,0)$, so by Lemma 5.5.2,

$$\det A = (-1)^{2+2}\cdot 2\det A_{\widehat{22}} = 2\det\begin{pmatrix}3&0&2\\1&5&1\\2&0&1\end{pmatrix}.$$

Column 2 of this minor is $(0,5,0)$, so, again by Lemma 5.5.2,

$$\det\begin{pmatrix}3&0&2\\1&5&1\\2&0&1\end{pmatrix} = (-1)^{2+2}\cdot 5\det\begin{pmatrix}3&2\\2&1\end{pmatrix} = 5(3-4) = -5.$$

Hence $\det A = -10$.

(b) By Proposition 5.3.20, the determinant of the reduction is $-10 \bmod p$, which is 0 exactly when p divides 10. By Theorem 5.4.7 over $\mathbb{F}_p$, the reduction is invertible exactly when $p \neq 2$ and $p \neq 5$.

Solution to Exercise 5.5.34

Uses. Lemma 5.5.2 (A row or column with one nonzero entry), Definition 3.3.31 (Triangular matrices), Theorem 5.4.14 (The transpose), induction on n
Techniques. Induction on matrix size (Technique 5.5.17)
Hint 1. For an upper triangular matrix, look at the first column.
Hint 2. Deleting row 1 and column 1 of an upper triangular matrix leaves an upper triangular matrix. Which diagonal entries does it have?
Sketch. If A is upper triangular, its first column is $(a_{11}, 0, \dots, 0)$, so $\det A = a_{11}\det A_{\widehat{11}}$, and $A_{\widehat{11}}$ is upper triangular with diagonal $a_{22},\dots,a_{nn}$. Induction finishes. A lower triangular matrix is the transpose of an upper triangular one.

We induct on n; for $n=1$ there is nothing to prove. Let $n \ge 2$ and let A be upper triangular, so $a_{ij} = 0$ whenever $i > j$. The first column of A is $(a_{11}, 0, \dots, 0)$, so by Lemma 5.5.2,

$$\det A = (-1)^{1+1}a_{11}\det A_{\widehat{11}}.$$

The (p,q) entry of $A_{\widehat{1}\widehat{1}}$ is $a_{p+1,q+1}$, which is 0 when $p > q$. So $A_{\widehat{1}\widehat{1}}$ is upper triangular with diagonal entries $a_{22}, \ldots, a_{nn}$, and by the induction hypothesis $\det A_{\widehat{1}\widehat{1}} = a_{22}\cdots a_{nn}$. Hence $\det A = a_{11}a_{22}\cdots a_{nn}$.

If A is lower triangular, then A^{T} is upper triangular with the same diagonal, and $\det A = \det A^{\mathsf{T}}$ by Theorem 5.4.14. (Alternatively, expand along the first row.)

Solution to Exercise 5.5.35

Uses. Theorem 5.5.3 (Cofactor expansion), Theorem 5.5.14 (Cramer's rule), Theorem 5.4.7 (Invertibility and the determinant), (5.5.3)
Hint 1. Expand $\det B(t)$ along the first row and factor. Check your factorization at $t = 1$.
Hint 2. For (b), $\det B_2(\mathbf{y}) = \det\begin{pmatrix} 1 & 1 & t \\ 1 & 2 & 1 \\ t & 3 & 1 \end{pmatrix}$; it factors as $-2(t-1)^2$.
Hint 3. For $t = 1$, every column of $B(1)$ is $(1,1,1)$. For $t = -2$, add the three equations.
Sketch. (a) Expanding along row 1, $\det B(t) = (t-1) - (1-t) + t\big(1-t^2\big) = -t^3 + 3t - 2 = -(t-1)^2(t+2)$, so the solution is unique exactly for $t \notin \{1, -2\}$. (b) $\det B_2(\mathbf{y}) = -2(t-1)^2$, so $x_2 = 2/(t+2)$. (c) At $t = 1$, each $B_i(\mathbf{y})$ keeps two columns $(1,1,1)$, so all three determinants vanish, but the equations say $x_1 + x_2 + x_3 = 1, 2, 3$ at once. At $t = -2$, $\det B_2(\mathbf{y}) = -18 \neq 0$, so there is no solution by (5.5.3).

(a) Expanding along the first row,

$$\begin{aligned} \det B(t) &= 1\cdot(t-1) - 1\cdot(1-t) + t\big(1-t^2\big) \\ &= -t^3 + 3t - 2 = -(t-1)^2(t+2), \end{aligned}$$

since $(t-1)^2(t+2) = \big(t^2 - 2t + 1\big)(t+2) = t^3 - 3t + 2$. By Theorem 5.4.7 and Theorem 5.5.14, the system has exactly one solution when $\det B(t) \neq 0$, that is, when $t \neq 1$ and $t \neq -2$. (If $\det B(t) = 0$, then $B(t)$ is not invertible, so the system has either no solution or more than one.)

(b) Replacing column 2 by $\mathbf{y}$ and expanding along the first row,

$$\begin{aligned} \det B_2(\mathbf{y}) = \det\begin{pmatrix} 1 & 1 & t \\ 1 & 2 & 1 \\ t & 3 & 1 \end{pmatrix} &= (2-3) - (1-t) + t(3-2t) \\ &= -2t^2 + 4t - 2 = -2(t-1)^2. \end{aligned}$$

By Theorem 5.5.14, for $t \notin \{1, -2\}$,

$$x_2 = \frac{-2(t-1)^2}{-(t-1)^2(t+2)} = \frac{2}{t+2}.$$

(c) For $t = 1$, every column of $B(1)$ is $(1,1,1)$. Replacing one column by $\mathbf{y}$ leaves two columns equal to $(1,1,1)$, so $\det B_i(\mathbf{y}) = 0$ for $i = 1, 2, 3$. But the three equations read $x_1 + x_2 + x_3 = 1$, $x_1 + x_2 + x_3 = 2$, and $x_1 + x_2 + x_3 = 3$, which contradict each other. So the vanishing of all the determinants in (5.5.3) does not imply that a solution exists.

For $t = -2$, part (b) gives $\det B_2(\mathbf{y}) = -2 \cdot 9 = -18 \neq 0$, while $\det B(-2) = 0$. By (5.5.3), a solution would satisfy $x_2 \cdot 0 = -18$, so there is none. Directly: the rows of $B(-2)$ add up to $\mathbf{0}^{\mathsf{T}}$, so adding the three equations gives $0 = 1 + 2 + 3$.

Solution to Exercise 5.5.36

Uses. Corollary 5.5.12 (Integer inverses), Theorem 5.5.9 (The adjugate and the inverse), Corollary 5.4.15 (Rows), Proposition 5.3.15 (Triangular matrices)
Hint 1. By Corollary 5.5.12 it is enough to have $\det A = \pm 1$.
Hint 2. Start from an upper triangular matrix with 1s on the diagonal, and add rows to other rows until no entry is 0.

Sketch. From $\begin{pmatrix}1&2&1\\0&1&1\\0&0&1\end{pmatrix}$, add row 1 to row 2 and then the new row 2 to row 3: $A = \begin{pmatrix}1&2&1\\1&3&2\\1&3&3\end{pmatrix}$, with $\det A = 1$. Its adjugate is $\begin{pmatrix}3&-3&1\\-1&2&-1\\0&-1&1\end{pmatrix}$, which is A^{-1}.

Start with $U = \begin{pmatrix}1&2&1\\0&1&1\\0&0&1\end{pmatrix}$, which has $\det U = 1$ by Proposition 5.3.15. Adding row 1 to row 2, and then the new row 2 to row 3, gives

$$A = \begin{pmatrix}1&2&1\\1&3&2\\1&3&3\end{pmatrix},$$

and these replacements do not change the determinant (Corollary 5.4.15), so $\det A = 1$. No entry of A is 0. The cofactors are

$$\begin{aligned} c_{11} &= 9-6 = 3, & c_{12} &= -(3-2) = -1, & c_{13} &= 3-3 = 0,\\ c_{21} &= -(6-3) = -3, & c_{22} &= 3-1 = 2, & c_{23} &= -(3-2) = -1,\\ c_{31} &= 4-3 = 1, & c_{32} &= -(2-1) = -1, & c_{33} &= 3-2 = 1. \end{aligned}$$

(As a check, $1\cdot 3 + 2\cdot(-1) + 1\cdot 0 = 1 = \det A$.) By Theorem 5.5.9,

$$A^{-1} = \operatorname{adj} A = C_A^{\mathsf{T}} = \begin{pmatrix}3&-3&1\\-1&2&-1\\0&-1&1\end{pmatrix}.$$

Indeed, the first row of AA^{-1} is $(3-2+0, -3+4-1, 1-2+1) = (1,0,0)$, and the other rows check the same way.

Solution to Exercise 5.5.37

Uses. Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Proposition 5.3.15 (Triangular matrices), Theorem 5.5.9 (The adjugate and the inverse), Definition 3.3.31 (Triangular matrices)
Hint 1. The (i,j) entry of $\operatorname{adj} B$ is $c_{ji} = (-1)^{i+j}\det B_{\hat{j}\hat{i}}$. For $i > j$, show that $B_{\hat{j}\hat{i}}$ is upper triangular with a zero on its diagonal.
Hint 2. Row p of $B_{\hat{j}\hat{i}}$ is row p or $p+1$ of B, and column q is column q or $q+1$. Look at the diagonal position $p = j$.
Sketch. For $j < i$, row p of $B_{\hat{j}\hat{i}}$ is row r_p of B and column q is column s_q, with $r_p = p$ for $p < j$, $r_p = p+1$ otherwise, $s_q = q$ for $q < i$, $s_q = q+1$ otherwise. For $p > q$ one checks $r_p > s_q$, so the minor matrix is upper triangular, and its (j,j) entry is $b_{j+1,j} = 0$. So $c_{ji} = 0$. The diagonal entry $c_{ii} = \det B_{\hat{i}\hat{i}}$ is the product of the other diagonal entries. Then $B^{-1} = (\det B)^{-1}\operatorname{adj} B$.

(a) The (i,j) entry of $\operatorname{adj} B$ is $c_{ji} = (-1)^{i+j}\det B_{\hat{j}\hat{i}}$. Let $i > j$, and let $N = B_{\hat{j}\hat{i}}$. For $p, q \in [n-1]$, the (p,q) entry of N is $b_{r_p s_q}$, where

$$r_p = \begin{cases} p & \text{if } p < j \\ p+1 & \text{if } p \geq j \end{cases}, \quad s_q = \begin{cases} q & \text{if } q < i \\ q+1 & \text{if } q \geq i \end{cases}.$$

Let $p > q$. Then $r_p \geq p \geq q+1 \geq s_q$. If $r_p = s_q$, all these are equalities, so $r_p = p$ and $s_q = q+1$, which means $p < j$ and $q \geq i$; but then $p = q+1 > i > j > p$, which is impossible. So $r_p > s_q$ and $b_{r_p s_q} = 0$, since B is upper triangular. Hence N is upper triangular. Its diagonal entry in position (j,j), which exists since $j < i \leq n$, is $b_{r_j s_j} = b_{j+1,j} = 0$ (as $j \geq j$ and $j < i$). By Proposition 5.3.15, $\det N = 0$, so the (i,j) entry of $\operatorname{adj} B$ is 0. Thus $\operatorname{adj} B$ is upper triangular.

The (i,i) entry of $\operatorname{adj} B$ is $c_{ii} = \det B_{\hat{i}\hat{i}}$. Deleting row i and column i of an upper triangular matrix leaves an upper triangular matrix whose diagonal entries are the b_{kk} with $k \neq i$ (the same index computation with $i = j$ gives $r_p = s_p$). So $c_{ii} = \prod_{k\neq i} b_{kk}$ by Proposition 5.3.15.

(b) If B is invertible, then $\det B = b_{11}\cdots b_{nn} \neq 0$, and $B^{-1} = (\det B)^{-1} \operatorname{adj} B$ by Theorem 5.5.9. This is upper triangular by (a), and its (i,i) entry is $\prod_{k\neq i} b_{kk} / \prod_k b_{kk} = b_{ii}^{-1}$.

Solution to Exercise 5.5.38

Uses. Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Theorem 5.4.14 (The transpose), Exercise 5.1.5, Example 5.5.7 (The 2×2 case)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a) and (b), compare the minors of A^{T} and of cA with those of A.
Hint 2. For $n = 2$, Example 5.5.7 gives adj explicitly; is it linear? For $n \geq 3$, compare $\operatorname{adj}(I_n + U_{11})$ with $\operatorname{adj} I_n + \operatorname{adj} U_{11}$ in (c), where U_{11} has a single entry 1, and use U_{11} again in (d).
Sketch. (a) True: $\left(A^{\mathsf{T}}\right)_{\hat{i}\hat{j}} = \left(A_{\hat{j}\hat{i}}\right)^{\mathsf{T}}$, so the cofactor matrix of A^{T} is C_A^{T}. (b) True: $(cA)_{\hat{i}\hat{j}} = cA_{\hat{i}\hat{j}}$ has determinant $c^{n-1}\det A_{\hat{i}\hat{j}}$. (c) True for $n = 2$, where $\operatorname{adj}\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) = \left(\begin{smallmatrix} s & -q \\ -r & p \end{smallmatrix}\right)$ is linear; false for $n \geq 3$: the $(2,2)$ entry of $\operatorname{adj}(I_n + U_{11})$ is 2, but that of $\operatorname{adj} I_n + \operatorname{adj} U_{11} = I_n + 0$ is 1. (d) True for $n = 2$ (applying adj twice gives the identity); false for $n \geq 3$, since $\operatorname{adj} U_{11} = 0 = \operatorname{adj} 0$.

(a) True. Deleting row i and column j of A^{T} gives $\left(A_{\hat{j}\hat{i}}\right)^{\mathsf{T}}$, so by Theorem 5.4.14 the (i,j) cofactor of A^{T} is $(-1)^{i+j}\det A_{\hat{j}\hat{i}} = c_{ji}$, where c_{ji} is a cofactor of A. So $C_{A^{\mathsf{T}}} = C_A^{\mathsf{T}}$, and $\operatorname{adj}\left(A^{\mathsf{T}}\right) = C_{A^{\mathsf{T}}}^{\mathsf{T}} = C_A = (\operatorname{adj} A)^{\mathsf{T}}$.

(b) True. Deleting a row and a column of cA gives $cA_{\hat{i}\hat{j}}$, an $(n-1)\times(n-1)$ matrix, so its determinant is $c^{n-1}\det A_{\hat{i}\hat{j}}$ (Exercise 5.1.5). So every cofactor, and hence adj, is multiplied by c^{n-1}.

(c) True for $n = 2$ and false for $n \geq 3$. For $n = 2$, Example 5.5.7 shows $\operatorname{adj}\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) = \left(\begin{smallmatrix} s & -q \\ -r & p \end{smallmatrix}\right)$, whose entries are linear in p, q, r, s, so $\operatorname{adj}(A+B) = \operatorname{adj} A + \operatorname{adj} B$. For $n \geq 3$, first note that for a diagonal matrix D with diagonal entries $d_1, \ldots, d_n$ and $i \neq j$, the matrix $D_{\hat{i}\hat{j}}$ has a zero row, namely what is left of row j of D after its only nonzero entry, in column j, is deleted. So $\operatorname{adj} D$ is diagonal, with (i,i) entry $\det D_{\hat{i}\hat{i}} = \prod_{k\neq i} d_k$. Now take $A = I_n$ and $B = U_{11}$, the matrix with a single entry 1 in position $(1,1)$. Then $A + B$ is diagonal with entries $2, 1, \ldots, 1$, so the $(2,2)$ entry of $\operatorname{adj}(A+B)$ is $2\cdot 1\cdots 1 = 2$. On the other hand, $\operatorname{adj} I_n = I_n$ and $\operatorname{adj} U_{11} = 0$ (see (d)), so the $(2,2)$ entry of $\operatorname{adj} A + \operatorname{adj} B$ is 1. Since $2 \neq 1$ in every field, $\operatorname{adj}(A+B) \neq \operatorname{adj} A + \operatorname{adj} B$.

(d) True for $n = 2$ and false for $n \geq 3$. For $n = 2$, applying the formula of Example 5.5.7 twice returns $\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right)$, so adj has a left inverse (itself) and is injective. For $n \geq 3$, let U_{11} have a single entry 1 in position $(1,1)$. Every $(n-1)\times(n-1)$ submatrix $U_{11\hat{i}\hat{j}}$ has at most one nonzero entry, so it has a zero row (as $n - 1 \geq 2$) and determinant 0. So $\operatorname{adj} U_{11} = 0 = \operatorname{adj} 0$, with $U_{11} \neq 0$.

Solution to Exercise 5.5.39

Uses. Theorem 5.5.9 (The adjugate and the inverse), Theorem 5.4.10 (Multiplicativity), Exercise 5.1.5, Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Take determinants of $A \operatorname{adj} A = (\det A) I_n$. This settles the invertible case.
Hint 2. If $\det A = 0$, suppose $\operatorname{adj} A$ were invertible and multiply $A \operatorname{adj} A = 0$ on the right by $(\operatorname{adj} A)^{-1}$. What is the adjugate of the zero matrix?
Sketch. From $A \operatorname{adj} A = (\det A) I_n$, $\det A \det(\operatorname{adj} A) = (\det A)^n$, so we can divide when $\det A \neq 0$. If $\det A = 0$ and $\operatorname{adj} A$ were invertible, then $A = A \operatorname{adj} A (\operatorname{adj} A)^{-1} = 0$, so $\operatorname{adj} A = \operatorname{adj} 0 = 0$ (as $n \geq 2$), which is not invertible. So $\det(\operatorname{adj} A) = 0 = (\det A)^{n-1}$.

By Theorem 5.5.9, Theorem 5.4.10, and Exercise 5.1.5,

$$\det A \det(\operatorname{adj} A) = \det(A \operatorname{adj} A) = \det((\det A) I_n) = (\det A)^n.$$

If $\det A \neq 0$, dividing by $\det A$ gives $\det(\operatorname{adj} A) = (\det A)^{n-1}$.

Suppose $\det A = 0$; we show $\det(\operatorname{adj} A) = 0$, which equals $(\det A)^{n-1}$ since $n - 1 \geq 1$. Suppose instead that $\operatorname{adj} A$ is invertible (Theorem 5.4.7). Since $A \operatorname{adj} A = 0 \cdot I_n = 0$,

$$A = A(\operatorname{adj} A)(\operatorname{adj} A)^{-1} = 0(\operatorname{adj} A)^{-1} = 0.$$

But every minor of the zero matrix is the determinant of a zero matrix of size $n-1 \geq 1$, hence 0, so $\operatorname{adj} A = \operatorname{adj} 0 = 0$, which is not invertible. This contradiction shows $\det(\operatorname{adj} A) = 0$.

Solution to Exercise 5.5.40

Uses. Theorem 5.5.9 (The adjugate and the inverse), Exercise 5.5.39, Proposition 5.3.19 ($\det(A+tI_n)$ as a function of t), Lemma 3.4.23 (Too many roots), Technique 5.3.18 (det is a polynomial in the entries)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. For invertible A, $\operatorname{adj} A = (\det A)A^{-1}$, and $\operatorname{adj} A$ is invertible too. Apply the same formula to $\operatorname{adj} A$, using Exercise 5.5.39.
Hint 2. For general A, replace A by $A+tI_n$. Each entry of both sides is a polynomial in t, and the two sides agree whenever $\det(A+tI_n) \neq 0$.
Hint 3. How many t can make $\det(A+tI_n) = 0$? If two polynomials of degree at most d agree at more than d points, they are equal. Then put $t = 0$.
Sketch. If A is invertible, $\operatorname{adj} A = (\det A)A^{-1}$ is invertible with determinant $(\det A)^{n-1}$, so $\operatorname{adj}(\operatorname{adj} A) = (\det A)^{n-1}\big((\det A)A^{-1}\big)^{-1} = (\det A)^{n-2}A$. In general, every entry of $\operatorname{adj}(\operatorname{adj}(A+tI_n))$ and of $\det(A+tI_n)^{n-2}(A+tI_n)$ is a polynomial in t of bounded degree, and they agree for all t outside the at most n roots of $\det(A+tI_n)$. Over an infinite field that is more points than the degree, so they agree as polynomials, in particular at $t = 0$.

Invertible A. By Theorem 5.5.9, $\operatorname{adj} A = (\det A)A^{-1}$, which is invertible, and $\det(\operatorname{adj} A) = (\det A)^{n-1}$ by Exercise 5.5.39. Applying Theorem 5.5.9 to $\operatorname{adj} A$,

$$\begin{aligned}\operatorname{adj}(\operatorname{adj} A) &= \det(\operatorname{adj} A)(\operatorname{adj} A)^{-1} = (\det A)^{n-1}\big((\det A)A^{-1}\big)^{-1} \\ &= (\det A)^{n-1}(\det A)^{-1}A = (\det A)^{n-2}A.\end{aligned}$$

All A, F infinite. For $t \in F$, let $A_t = A + tI_n$. Every entry of A_t is a polynomial in t of degree at most 1. A determinant of size m whose entries are polynomials in t of degree at most d is a polynomial in t of degree at most md, by the Leibniz formula (Technique 5.3.18). So each entry of $\operatorname{adj} A_t$ is a polynomial in t of degree at most $n-1$, and each entry of $\operatorname{adj}(\operatorname{adj} A_t)$ is one of degree at most $(n-1)^2$. Also $\det A_t$ is a polynomial of degree at most n, and a product of polynomials in t of degrees at most d_1 and d_2 is a polynomial of degree at most $d_1 + d_2$ (expand by distributivity, as in the proof of Lemma 5.5.23). So each entry of $\det(A_t)^{n-2}A_t$ is a polynomial of degree at most $n(n-2)+1 = (n-1)^2$. Let $d = (n-1)^2$, which bounds both degrees.

Fix a position (i,j), and let P and Q be the polynomials of degree at most d that give the (i,j) entries of the two sides. By Proposition 5.3.19, $\det A_t$ is the value at t of a polynomial of degree n with leading coefficient 1, which is nonzero, so it has at most n roots (Lemma 3.4.23). For every other t, A_t is invertible, and the first part gives $P(t) = Q(t)$. Since F is infinite, there are more than $d+1$ such t, so $P - Q$ is a polynomial of degree at most d with more than $d+1$ roots, and $P = Q$ by Lemma 3.4.23. In particular $P(0) = Q(0)$. As this holds for every (i,j), $\operatorname{adj}(\operatorname{adj} A) = (\det A)^{n-2}A$.

Solution to Exercise 5.5.40 BEYOND 21-242

Uses. Exercise 5.5.51, Theorem 5.5.30 (Rank via minors), Example 5.5.7 (The 2×2 case)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. For $n = 2$, compute $\operatorname{adj}(\operatorname{adj} A)$ from Example 5.5.7.
Hint 2. For $n \geq 3$ and $\det A = 0$, the right side is 0. What is the rank of $\operatorname{adj} A$ (Exercise 5.5.51), and what does that say about its minors of order $n-1$?
Sketch. For $n = 2$, adj swaps the diagonal entries and negates the others, so applying it twice gives $A = (\det A)^0 A$. For $n \geq 3$ and A not invertible, $\operatorname{rank}(\operatorname{adj} A) \leq 1 \leq n-2$, so all minors of order $n-1$ of $\operatorname{adj} A$ vanish (Theorem 5.5.30), and $\operatorname{adj}(\operatorname{adj} A) = 0 = (\det A)^{n-2}A$. Invertible A was handled in the first approach.

For $n = 2$, Example 5.5.7 gives $\operatorname{adj}\begin{pmatrix} p & q \\ r & s \end{pmatrix} = \begin{pmatrix} s & -q \\ -r & p \end{pmatrix}$, and applying it again gives $\begin{pmatrix} p & q \\ r & s \end{pmatrix}$. So $\operatorname{adj}(\operatorname{adj} A) = A = (\det A)^0 A$. Let $n \geq 3$. Invertible A was handled in the first approach. If A is not invertible, then $(\det A)^{n-2}A = 0$, and by Exercise 5.5.51, $\operatorname{rank}(\operatorname{adj} A) \leq 1 \leq n-2$. By Theorem 5.5.30, every minor of order $n-1$ of $\operatorname{adj} A$ is 0 (and if $\operatorname{adj} A = 0$, trivially so). These minors are, up to sign, the entries of $\operatorname{adj}(\operatorname{adj} A)$, so $\operatorname{adj}(\operatorname{adj} A) = 0$.

Solution to Exercise 5.5.41

Uses. Theorem 5.5.9 (The adjugate and the inverse), Theorem 5.4.10 (Multiplicativity), Proposition 5.3.19 ($\det(A+tI_n)$ as a function of t), Lemma 3.4.23 (Too many roots), Technique 5.3.18 (det is a polynomial in the entries)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. Prove it first for invertible A and B, using $\operatorname{adj} X = (\det X)X^{-1}$.
Hint 2. Then replace A and B by $A+tI_n$ and $B+tI_n$. For how many t can either fail to be invertible? Compare the entries of both sides as polynomials in t.
Sketch. For invertible A, B: $\operatorname{adj}(AB) = \det(AB)(AB)^{-1} = \big(\det BB^{-1}\big)\big(\det AA^{-1}\big) = (\operatorname{adj} B)(\operatorname{adj} A)$. In general, the entries of $\operatorname{adj}((A+tI)(B+tI))$ and of $\operatorname{adj}(B+tI)\operatorname{adj}(A+tI)$ are polynomials in t of degree at most $2(n-1)$, and they agree except at the at most $2n$ values of t where $A+tI$ or $B+tI$ is singular. An infinite field has more points than that, so the polynomials are equal; set $t=0$.

For $n=1$ both sides are (1), so let $n \geq 2$.

Invertible A and B. By Theorem 5.5.9 and Theorem 5.4.10, AB is invertible and

$$\operatorname{adj}(AB) = \det(AB)(AB)^{-1} = \det A \det B\, B^{-1}A^{-1} = \big(\det B\, B^{-1}\big)\big(\det A\, A^{-1}\big) = (\operatorname{adj} B)(\operatorname{adj} A).$$

General A and B. For $t \in F$, let $A_t = A+tI_n$ and $B_t = B+tI_n$. The entries of $A_tB_t = AB + t(A+B) + t^2I_n$ are polynomials in t of degree at most 2, so by the Leibniz formula (Technique 5.3.18) the entries of $\operatorname{adj}(A_tB_t)$, which are $\pm$ determinants of size $n-1$, are polynomials in t of degree at most $2(n-1)$. The entries of $\operatorname{adj} A_t$ and $\operatorname{adj} B_t$ have degree at most $n-1$, so the entries of $(\operatorname{adj} B_t)(\operatorname{adj} A_t)$, which are sums of products of two such, have degree at most $2(n-1)$ (a product of polynomials in t of degrees at most d_1 and d_2 is one of degree at most d_1+d_2, by distributivity).

Fix a position, and let $P, Q \in F[x]_{\leq 2(n-1)}$ give the corresponding entries of the two sides. By Proposition 5.3.19, $\det A_t$ and $\det B_t$ are values of polynomials of degree n with leading coefficient 1, so each vanishes for at most n values of t (Lemma 3.4.23). For all other t, A_t and B_t are invertible, and $P(t) = Q(t)$ by the first part. Since F is infinite, this happens for more than $2(n-1)+1$ values of t, so $P = Q$ by Lemma 3.4.23. Setting $t=0$ at every position gives $\operatorname{adj}(AB) = (\operatorname{adj} B)(\operatorname{adj} A)$.

Solution to Exercise 5.5.42

Uses. Lemma 5.5.23 (A polynomial with prescribed roots), Theorem 5.5.3 (Cofactor expansion), Corollary 5.4.15 (Rows), Lemma 5.5.2 (A row or column with one nonzero entry)
Techniques. Expose a factor with row and column operations (Technique 5.5.22), Polynomial identity arguments (Technique 5.5.24)
Hint 1. What is the coefficient of c^3 in $D(a,b,c)$? Compare with the right side. Then test $a=0, b=1, c=2$.
Hint 2. For (b), subtract row 1 from rows 2 and 3, and use $b^3-a^3 = (b-a)\big(b^2+ab+a^2\big)$.
Sketch. (a) Two polynomials with the same roots need not be equal: D has degree 3 in c with leading coefficient $b-a$, two known roots do not determine it, and the right side has degree 2. At $(0,1,2)$, $D=6$ but the right side is 2. (b) Row operations give $D = (b-a)(c-a)\det\begin{pmatrix} 1 & b^2+ab+a^2 \\ 1 & c^2+ca+a^2 \end{pmatrix} = (b-a)(c-a)(c-b)(a+b+c)$.

(a) The step "two polynomials with the same roots are equal" is false: x and $2x$ have the same roots. Lemma 5.5.23 says that a polynomial of degree at most n is determined by n distinct roots *together with* its coefficient of x^n. Here $n=3$, but only two roots are known, and the coefficients are not compared. In fact, expanding along the last row, the coefficient of c^3 in $D(a,b,c)$ is the cofactor $(-1)^{3+3}\det\begin{pmatrix} 1 & a \\ 1 & b \end{pmatrix} = b-a$, which is nonzero, while the right side has degree 2 in c. (The claim "the right side vanishes exactly at $c=a$ and $c=b$" does not repair this, since D may have a third root.) Concretely, for $a=0, b=1, c=2$,

$$D(0,1,2) = \det\begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 2 & 8 \end{pmatrix} = 8-2 = 6,$$

while $(1-0)(2-0)(2-1) = 2$, in $\mathbb{Q}$. (Over some fields the claim happens to hold, for instance over $\mathbb{F}_2$, where three distinct elements do not exist; by (b), it fails exactly when there are distinct a,b,c with $a+b+c \neq 1$.)

(b) We show $D(a,b,c) = (a+b+c)(b-a)(c-a)(c-b)$ for all $a,b,c \in F$. Subtract row 1 from rows 2 and 3; this does not change the determinant (Corollary 5.4.15). Since $b^3 - a^3 = (b-a)\big(b^2+ab+a^2\big)$, the new rows 2 and 3 are

$$(b-a)\big(0,\,1,\,b^2+ab+a^2\big) \quad \text{and} \quad (c-a)\big(0,\,1,\,c^2+ca+a^2\big).$$

Pulling out the factors $b-a$ and $c-a$ (Corollary 5.4.15) and expanding along the first column, whose only nonzero entry is the 1 in row 1 (Lemma 5.5.2),

$$\begin{aligned} D(a,b,c) &= (b-a)(c-a)\det\begin{pmatrix} 1 & b^2+ab+a^2 \\ 1 & c^2+ca+a^2 \end{pmatrix} \\ &= (b-a)(c-a)\big(c^2-b^2+a(c-b)\big) = (b-a)(c-a)(c-b)(a+b+c). \end{aligned}$$

No division was used, so this holds in every field, including when a,b,c are not distinct. At $(0,1,2)$ it gives $3\cdot 2 = 6$, as computed in (a).

Solution to Exercise 5.5.43

Uses. Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.14 (The transpose), Corollary 5.4.8 (Vanishing determinants), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. A linear relation among infinite sequences gives in particular a relation among their first k entries. Which matrix has columns $\big(1,\lambda_i,\dots,\lambda_i^{k-1}\big)$?
Hint 2. For (b), differentiate a relation $\sum_i a_i e^{\lambda_i t} = 0$ repeatedly and set $t=0$.
Sketch. (a) If $\sum_i a_i \mathbf{s}_{\lambda_i} = \mathbf{0}$, the entries in positions $0,\dots,k-1$ give $V^{\mathsf T}\mathbf{a} = \mathbf{0}$ with $V = V(\lambda_1,\dots,\lambda_k)$. Since $\det V^{\mathsf T} = \det V = \prod_{i<j}(\lambda_j-\lambda_i) \neq 0$, $\mathbf{a} = \mathbf{0}$. (b) Differentiating m times and setting $t=0$ gives $\sum_i a_i \lambda_i^m = 0$ for $m = 0,\dots,k-1$, the same system.

Let $V = V(\lambda_1,\dots,\lambda_k) \in F^{k\times k}$, whose row i is $\big(1,\lambda_i,\dots,\lambda_i^{k-1}\big)$. The $(m+1)$-th row of $V^{\mathsf T}$ is $\big(\lambda_1^m,\dots,\lambda_k^m\big)$, so for $\mathbf{a} = (a_1,\dots,a_k)$, the system $V^{\mathsf T}\mathbf{a} = \mathbf{0}$ says that $\sum_i a_i\lambda_i^m = 0$ for $m = 0,\dots,k-1$. By Theorem 5.5.21 and Theorem 5.4.14, $\det V^{\mathsf T} = \prod_{i<j}(\lambda_j-\lambda_i) \neq 0$, so $V^{\mathsf T}$ is invertible and the only solution is $\mathbf{a} = \mathbf{0}$ (Corollary 5.4.8).

(a) If $\sum_i a_i \mathbf{s}_{\lambda_i} = \mathbf{0}$, then the entries in positions $m = 0,\dots,k-1$ give $\sum_i a_i\lambda_i^m = 0$. So $\mathbf{a} = \mathbf{0}$, and the sequences are independent by Theorem 1.5.5.

(b) If $\sum_i a_i e^{\lambda_i t} = 0$ for all $t \in \mathbb{R}$, then differentiating m times gives $\sum_i a_i\lambda_i^m e^{\lambda_i t} = 0$ for all t, and setting $t=0$ gives $\sum_i a_i\lambda_i^m = 0$, for $m = 0,\dots,k-1$. So $\mathbf{a} = \mathbf{0}$.

Solution to Exercise 5.5.44

Uses. Theorem 5.5.14 (Cramer's rule), Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.5.3 (Cofactor expansion), Definition 3.4.22 (Vandermonde matrix), Theorem 3.4.24 (Polynomial interpolation)
Hint 1. The coefficient vector $\mathbf{a}$ of p solves $V\mathbf{a} = \mathbf{d}$, and the coefficient of x^n is its last entry. Replace the last column of V by $\mathbf{d}$ and expand along that column.
Hint 2. Deleting row $i+1$ and the last column of V leaves $V(c_0,\dots,c_{i-1},c_{i+1},\dots,c_n)$. Divide its Vandermonde product into that of V: which factors are left over?
Hint 3. For (b), which polynomial of degree at most n takes the values c_i^m?
Sketch. By Cramer, $a_n = \det V_{n+1}(\mathbf{d})/\det V$. Expanding along the last column, $\det V_{n+1}(\mathbf{d}) = \sum_i (-1)^{i+n} d_i \det V_i$, where V_i omits c_i. The quotient $\det V/\det V_i$ is the product of the factors of $\det V$ involving c_i, namely $\prod_{j<i}(c_i-c_j)\prod_{k>i}(c_k-c_i) = (-1)^{n-i}\prod_{j\neq i}(c_i-c_j)$. The signs cancel. For (b), the interpolating polynomial of the values c_i^m is x^m.

(a) Write $p = a_0 + a_1x + \cdots + a_nx^n$. As in Section 3.4, $\mathbf{a} = (a_0,\dots,a_n)$ solves $V\mathbf{a} = \mathbf{d}$, where $V = V(c_0,\dots,c_n)$ and $\mathbf{d} = (d_0,\dots,d_n)$, and $\det V \neq 0$ by Theorem 5.5.21. The coefficient a_n is the entry of $\mathbf{a}$ in position $n+1$, so by Theorem 5.5.14, $a_n = \det V_{n+1}(\mathbf{d})/\det V$, where $V_{n+1}(\mathbf{d})$ is V with its last column replaced by $\mathbf{d}$.

Expanding along the last column, whose entry in row $i+1$ is d_i,

$$\det V_{n+1}(\mathbf{d}) = \sum_{i=0}^{n} (-1)^{(i+1)+(n+1)} d_i \det W_i,$$

where W_i is V with row $i+1$ and the last column deleted. Its rows are $\left(1, c_k, \ldots, c_k^{n-1}\right)$ for $k \neq i$, so $W_i = V(c_0, \ldots, c_{i-1}, c_{i+1}, \ldots, c_n)$, and by Theorem 5.5.21 $\det W_i$ is the product of $c_l - c_k$ over all $k < l$ with $k, l \neq i$. The product for $\det V$ has, in addition, exactly the factors that involve i:

$$\det V = \det W_i \cdot \prod_{j<i}(c_i - c_j) \cdot \prod_{k>i}(c_k - c_i) = (-1)^{n-i} \det W_i \prod_{j \neq i}(c_i - c_j),$$

since there are $n - i$ indices $k > i$, and $c_k - c_i = -(c_i - c_k)$. Hence

$$a_n = \sum_{i=0}^{n} (-1)^{i+n} d_i \frac{\det W_i}{\det V} = \sum_{i=0}^{n} (-1)^{i+n}(-1)^{n-i} \frac{d_i}{\prod_{j \neq i}(c_i - c_j)} = \sum_{i=0}^{n} \frac{d_i}{\prod_{j \neq i}(c_i - c_j)},$$

since $(-1)^{i+n}(-1)^{n-i} = (-1)^{2n} = 1$.

(b) Let $0 \leq m \leq n$ and $d_i = c_i^m$. The polynomial x^m has degree at most n and takes the values c_i^m at the nodes, so by the uniqueness in Theorem 3.4.24 it is p. Its coefficient of x^n is 0 if $m < n$ and 1 if $m = n$, and by (a) this coefficient is $\sum_i c_i^m / \prod_{j \neq i}(c_i - c_j)$.

Solution to Exercise 5.5.45

Uses. Proposition 5.5.18 (Tridiagonal determinants), Lemma 5.5.23 (A polynomial with prescribed roots), Theorem 5.4.7 (Invertibility and the determinant), $\sin(a+b) + \sin(a-b) = 2\sin a \cos b$
Techniques. Induction on matrix size (Technique 5.5.17), Polynomial identity arguments (Technique 5.5.24)
Hint 1. (a) is Proposition 5.5.18 with $a_k = x$ and $b_k c_k = 1$. For the polynomial, induct with the recurrence.
Hint 2. (b) Induct on n. The identity $\sin((n+2)\theta) + \sin(n\theta) = 2\sin((n+1)\theta)\cos\theta$ is the recurrence in disguise.
Hint 3. (c) The numbers $2\cos(k\pi/(n+1))$, $k = 1, \ldots, n$, are distinct roots of P_n. How many roots can a polynomial of degree n with leading coefficient 1 have, given Lemma 5.5.23?
Sketch. (a) By Proposition 5.5.18, $d_n = x d_{n-1} - d_{n-2}$, and by induction $P_n = xP_{n-1} - P_{n-2}$ has degree n and leading coefficient 1. (b) $d_0 = 1$ and $d_1 = 2\cos\theta = \sin 2\theta / \sin\theta$; the sine identity turns the recurrence into the claim for $n+1$. (c) $\sin((n+1)\theta) = 0$ for $\theta = k\pi/(n+1)$, giving n distinct roots $2\cos(k\pi/(n+1))$ in $(-2, 2)$. By Lemma 5.5.23, $P_n(x) = \prod_k (x - 2\cos(k\pi/(n+1)))$ for all x, which vanishes only at these points.

(a) By Proposition 5.5.18 with $a_k = x$ and $b_k = c_k = 1$, $d_n(x) = x d_{n-1}(x) - d_{n-2}(x)$ for $n \geq 2$, with $d_0(x) = 1$ and $d_1(x) = x$. Define $P_0 = 1$, $P_1 = x$, and $P_n = xP_{n-1} - P_{n-2}$, where multiplying by x shifts the coefficients up by one place. By induction, $P_n \in \mathbb{R}[x]_{\leq n}$ has coefficient 1 of x^n (it comes from xP_{n-1} alone, as P_{n-2} has degree at most $n-2$), and $P_n(x) = d_n(x)$ for every x, since both sides satisfy the same recurrence with the same initial values.

(b) Let $x = 2\cos\theta$ with $0 < \theta < \pi$, so $\sin\theta \neq 0$, and let $e_n = \sin((n+1)\theta)/\sin\theta$. Then $e_0 = 1 = d_0$ and $e_1 = \sin 2\theta / \sin\theta = 2\cos\theta = d_1$. With $a = (n+1)\theta$ and $b = \theta$, the identity $\sin(a+b) + \sin(a-b) = 2\sin a \cos b$ gives

$$e_{n+1} + e_{n-1} = 2\cos\theta\, e_n = x e_n,$$

so (e_n) satisfies the same recurrence as $(d_n(x))$. By induction, $d_n(x) = e_n$ for all n.

(c) For $k = 1, \ldots, n$, let $\theta_k = k\pi/(n+1) \in (0, \pi)$ and $x_k = 2\cos\theta_k$. Since cos is strictly decreasing on $(0, \pi)$, the x_k are distinct. By (b), $d_n(x_k) = \sin(k\pi)/\sin\theta_k = 0$. So P_n is a polynomial of degree at most n with coefficient 1 of x^n and the n distinct roots $x_1, \ldots, x_n$, and Lemma 5.5.23 gives

$$d_n(x) = P_n(x) = (x - x_1)(x - x_2)\cdots(x - x_n) \quad \text{for every } x \in \mathbb{R}.$$

A product of real numbers is 0 only if a factor is, so $d_n(x) = 0$ exactly when x is one of the x_k, and by Theorem 5.4.7 these are exactly the x for which $M_n(x)$ is singular.

Solution to Exercise 5.5.46

Uses. Proposition 5.5.20 (Companion matrices), Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Use Proposition 5.5.20 with $a_0 = 2$, $a_1 = 1$, $a_2 = a_3 = 0$, and reduce $-a_k$ modulo 3.
Hint 2. Evaluate $t^4 + t + 2$ at $t = 0, 1, 2$.

Sketch. The matrix A of Proposition 5.5.20 has last column $-(2,1,0,0) = (1,2,0,0)$ in $\mathbb{F}_3$ and 1s just below the diagonal. The values $p(0) = 2$, $p(1) = 1$, $p(2) = 2$ are nonzero.

Let $p = 2 + x + x^4 \in \mathbb{F}_3[x]$, so $a_0 = 2$, $a_1 = 1$, $a_2 = a_3 = 0$. In $\mathbb{F}_3$, $-2 = 1$ and $-1 = 2$, so the matrix of Proposition 5.5.20 is

$$A = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix},$$

and $\det(tI_4 - A) = p(t)$ for every $t \in \mathbb{F}_3$. Now $p(0) = 2$, $p(1) = 1 + 1 + 2 = 4 = 1$, and $p(2) = 16 + 2 + 2 = 20 = 2$ in $\mathbb{F}_3$. None of these is 0, so $tI_4 - A$ is invertible for every $t \in \mathbb{F}_3$ by Theorem 5.4.7. (In Section 7.2 this says that A has no eigenvalue in $\mathbb{F}_3$.)

Solution to Exercise 5.5.47

Uses. Theorem 2.4.34 (Block multiplication), Theorem 5.4.26 (Block-triangular matrices), Theorem 5.4.10 (Multiplicativity)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Multiply M on the left by $\left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$, and on the right by the same matrix.
Hint 2. For (b), apply (a) to $\mathbf{u} \in F^{n\times 1}$ and $\mathbf{v}^{\mathsf{T}} \in F^{1\times n}$, so that one of the two products is 1×1.
Sketch. With $P = \left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$, block multiplication gives $PM = \left(\begin{smallmatrix} I_m+AB & 0 \\ B & I_n \end{smallmatrix}\right)$ and $MP = \left(\begin{smallmatrix} I_m & 0 \\ B & I_n+BA \end{smallmatrix}\right)$. Since $\det P = 1$, both $\det(I_m + AB)$ and $\det(I_n + BA)$ equal $\det M$. For (b), $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $n \times n$ and $\mathbf{v}^{\mathsf{T}}\mathbf{u}$ is 1×1; with $\mathbf{u} = \mathbf{v} = (1, \ldots, 1)$, $\det(I_n + J) = 1 + n$.

(a) Let $P = \left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$. By Theorem 2.4.34,

$$PM = \begin{pmatrix} I_m + AB & -A + A \\ B & I_n \end{pmatrix} = \begin{pmatrix} I_m + AB & 0 \\ B & I_n \end{pmatrix}, \quad MP = \begin{pmatrix} I_m & A - A \\ B & BA + I_n \end{pmatrix} = \begin{pmatrix} I_m & 0 \\ B & I_n + BA \end{pmatrix}.$$

By Theorem 5.4.26, $\det P = \det I_m \det I_n = 1$, $\det(PM) = \det(I_m + AB)$, and $\det(MP) = \det(I_n + BA)$. By Theorem 5.4.10, both equal $\det P \det M = \det M$.

(b) Apply (a) with $A = \mathbf{u} \in F^{n\times 1}$ and $B = \mathbf{v}^{\mathsf{T}} \in F^{1\times n}$, so that $AB = \mathbf{u}\mathbf{v}^{\mathsf{T}} \in F^{n\times n}$ and $BA = \mathbf{v}^{\mathsf{T}}\mathbf{u} \in F^{1\times 1}$:

$$\det\left(I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det\left(1 + \mathbf{v}^{\mathsf{T}}\mathbf{u}\right) = 1 + \mathbf{v}^{\mathsf{T}}\mathbf{u}.$$

With $\mathbf{u} = \mathbf{v} = (1, \ldots, 1)$, we have $\mathbf{u}\mathbf{v}^{\mathsf{T}} = J$ and $\mathbf{v}^{\mathsf{T}}\mathbf{u} = n$, so $\det(I_n + J) = 1 + n$.

Solution to Exercise 5.5.48

Uses. Definition 5.1.1 (Determinant function), Lemma 5.5.8 (Replacing a row or a column), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Definition 2.4.26 (Trace), Definition 2.4.1 (Matrix product), Definition 5.3.6 (Determinant), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Column j of $A + tB$ is $\mathbf{a}_j + t\mathbf{b}_j$. Expand by multilinearity in every column, and group the terms by the number of columns in which $t\mathbf{b}_j$ was chosen.
Hint 2. The terms with exactly one such column j are $t \det A_j(\mathbf{b}_j)$. Evaluate $\det A_j(\mathbf{b}_j)$ with Lemma 5.5.8 and compare with the diagonal entries of $\operatorname{adj}(A)B$.
Sketch. Expanding, $\det(A + tB) = \sum_{S\subseteq[n]} t^{|S|} \det A_S$, where A_S takes $\mathbf{b}_j$ in the columns $j \in S$ and $\mathbf{a}_j$ elsewhere. So $e_k = \sum_{|S|=k} \det A_S$, with $e_0 = \det A$ and $e_n = \det B$. For $|S| = 1$, $\det A_j(\mathbf{b}_j) = \sum_i b_{ij}c_{ij}$, which is the (j,j) entry of $\operatorname{adj}(A)B$. For (b), take $B = I_n$: $\operatorname{tr}(\operatorname{adj} A) = \sum_i c_{ii}$. Expanding each $\det A_S$ by the Leibniz formula shows that these e_k are the coefficients of Proposition 5.3.19.

(a) Column j of $A + tB$ is $\mathbf{a}_j + t\mathbf{b}_j$. For $S \subseteq [n]$, let A_S be the matrix whose column j is $\mathbf{b}_j$ if $j \in S$ and $\mathbf{a}_j$ if $j \notin S$. Expanding by linearity in each column, one column at a time,

$$\det(A + tB) = \sum_{S\subseteq[n]} t^{|S|} \det A_S.$$

Grouping by $k = |S|$ gives the claim with $e_k = \sum_{|S|=k} \det A_S$, which does not depend on t. In particular $e_0 = \det A_\emptyset = \det A$ and $e_n = \det A_{[n]} = \det B$. The sets with one element give

$$e_1 = \sum_{j=1}^{n} \det A_j(\mathbf{b}_j) = \sum_{j=1}^{n}\sum_{i=1}^{n} b_{ij}c_{ij}$$

by part (b) of Lemma 5.5.8, where c_{ij} are the cofactors of A. The (j,j) entry of $\operatorname{adj}(A)B$ is $\sum_i (\operatorname{adj} A)_{ji} b_{ij} = \sum_i c_{ij}b_{ij}$, so $e_1 = \sum_j (\operatorname{adj}(A)B)_{jj} = \operatorname{tr}(\operatorname{adj}(A)B)$.

(b) With $B = I_n$, $e_1 = \operatorname{tr}(\operatorname{adj} A) = \sum_i c_{ii} = \sum_i \det A_{\hat{i}\hat{i}}$. It remains to see that these e_k are the coefficients c_k built in the proof of Proposition 5.3.19. (Comparing values of $t \mapsto \det(A + tI_n)$ is not enough, since over a small field a function does not determine its coefficients.) Now A_S has column $\mathbf{e}_j$ for $j \in S$, so in the Leibniz formula for $\det A_S$ the term of σ vanishes unless $\sigma(j) = j$ for all $j \in S$, that is, unless $S \subseteq \operatorname{Fix}(\sigma)$; in that case it is $\operatorname{sgn}(\sigma)\prod_{j\notin S} a_{\sigma(j)j}$. Writing $S' = \operatorname{Fix}(\sigma) \setminus S$,

$$\prod_{j\notin S} a_{\sigma(j)j} = \prod_{j\notin \operatorname{Fix}(\sigma)} a_{\sigma(j)j} \prod_{j\in S'} a_{jj}.$$

Summing over the S with $|S| = k$, that is, over the $S' \subseteq \operatorname{Fix}(\sigma)$ with $|S'| = |\operatorname{Fix}(\sigma)| - k$, gives exactly the coefficient $e_{\sigma,k}$ of that proof, and summing over σ gives $e_k = c_k$. (For $n = 2$, $\det A_{\hat{1}\hat{1}} + \det A_{\hat{2}\hat{2}} = a_{22} + a_{11} = \operatorname{tr} A$, in agreement with the coefficient of t^{n-1} found there.)

Solution to Exercise 5.5.49

Uses. (5.5.3), Theorem 5.5.14 (Cramer's rule), Corollary 5.5.12 (Integer inverses)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Recall (5.5.3): every solution satisfies $x_i \det B = \det B_i(\mathbf{y})$, whether or not B is invertible.
Hint 2. For (b), try a matrix all of whose columns are equal. For (c), try $n = 2$ and $B = 2I_2$.
Sketch. (a) True, by (5.5.3). (b) False: $B = J$ (all entries 1) with $n = 3$ and $\mathbf{y} = \mathbf{e}_1$; each $B_i(\mathbf{y})$ has two equal columns, but the equations contradict each other. (c) False: $2I_2\mathbf{x} = \mathbf{e}_1$ gives $x_1 = 1/2$. (d) True: Cramer gives $\mathbf{x} = \mathbf{0}$, so $\mathbf{y} = B\mathbf{0} = \mathbf{0}$.

(a) True. If $\mathbf{x}$ were a solution, then by (5.5.3), $\det B_i(\mathbf{y}) = x_i \det B = 0$, a contradiction.

(b) False. Let $n = 3$, let $B = J$ be the matrix with all entries 1, and let $\mathbf{y} = \mathbf{e}_1$. Replacing one column of J by $\mathbf{e}_1$ leaves two columns equal to $(1,1,1)$, so $\det B_i(\mathbf{y}) = 0$ for every i, and $\det J = 0$. But the equations $x_1 + x_2 + x_3 = 1$ and $x_1 + x_2 + x_3 = 0$ (rows 1 and 2) contradict each other, so there is no solution. (Exercise 5.5.35 gives another example.) For general $n \geq 2$, the same J and $\mathbf{y} = \mathbf{e}_1$ work when $n \geq 3$; for $n = 2$, take $B = 0$ and $\mathbf{y} = \mathbf{e}_1$.

(c) False. With $B = 2I_2$ and $\mathbf{y} = \mathbf{e}_1$, the solution is $\mathbf{x} = (1/2, 0)$. Integrality does hold when $\det B = \pm 1$, by Corollary 5.5.12.

(d) True. By Theorem 5.5.14, the unique solution has $x_i = \det B_i(\mathbf{y})/\det B = 0$ for every i, so $\mathbf{x} = \mathbf{0}$ and $\mathbf{y} = B\mathbf{0} = \mathbf{0}$.

Solution to Exercise 5.5.50

Uses. Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.10 (Multiplicativity), Exercise 5.1.5, Theorem 5.2.31 (Alternating functions and permutations), Definition 5.2.29 (Permutation matrix)
Hint 1. (a) List the six factors $c_j - c_i$ for $i < j$ with $c_0 = 1$, $c_1 = i$, $c_2 = -1$, $c_3 = -i$, and multiply them in pairs.
Hint 2. (b) The $(j+1, l+1)$ entry of V^2 is $\sum_{k=0}^{3} \omega^{k(j+l)}$. When is $\omega^{j+l} = 1$? If $z^4 = 1$ and $z \neq 1$, then $1 + z + z^2 + z^3 = 0$.
Sketch. (a) The factors are $i-1$, -2, $-i-1$, $-1-i$, $-2i$, $1-i$, with product $-16i$. (b) $\left(V^2\right)_{j+1,l+1} = \sum_k \omega^{k(j+l)}$ is 4 when $j + l \equiv 0 \bmod 4$ and 0 otherwise, so $V^2 = 4P$ with P the matrix of $j \mapsto -j \bmod 4$, a single transposition $(2\ 4)$ on the indices; $\det(V)^2 = 4^4(-1) = -256 = (-16i)^2$. (c) $(2-1)(4-1)(3-1)(4-2)(3-2)(3-4) = -12 = 3$.

(a) With $c_0 = 1$, $c_1 = i$, $c_2 = -1$, $c_3 = -i$, Theorem 5.5.21 gives the product of

$$c_1 - c_0 = i - 1, \quad c_2 - c_0 = -2, \quad c_3 - c_0 = -1 - i, \quad c_2 - c_1 = -1 - i, \quad c_3 - c_1 = -2i, \quad c_3 - c_2 = 1 - i.$$

Now $(i-1)(1-i) = -(1-i)^2 = -(-2i) = 2i$ and $(-1-i)^2 = (1+i)^2 = 2i$, so the product is

$$2i \cdot 2i \cdot (-2) \cdot (-2i) = (-4)(4i) = -16i.$$

(b) The $(j+1, l+1)$ entry of V^2 is $\sum_{k=0}^{3} \omega^{jk}\omega^{kl} = \sum_{k=0}^{3} z^k$ with $z = \omega^{j+l}$. If $j+l$ is divisible by 4, then $z = 1$ and the sum is 4. Otherwise $z \neq 1$ and $z^4 = \left(\omega^4\right)^{j+l} = 1$, so $(z-1)\left(1+z+z^2+z^3\right) = z^4 - 1 = 0$ gives $1 + z + z^2 + z^3 = 0$. So $V^2 = 4P$, where P has a 1 in position $(j+1, l+1)$ exactly when $l \equiv -j \bmod 4$. This is the permutation matrix E_π of the permutation π of $\{1,2,3,4\}$ that fixes 1 and 3 and swaps 2 and 4 (the indices $j+1$ for $j = 1, 3$), so $\det P = \operatorname{sgn}(\pi) = -1$ (Theorem 5.2.31). By Theorem 5.4.10 and Exercise 5.1.5,

$$(\det V)^2 = \det\left(V^2\right) = 4^4 \det P = -256.$$

Indeed $(-16i)^2 = 256i^2 = -256$. This determines $\det V$ up to sign, as $\pm 16i$.

(c) With $c_0, \ldots, c_3 = 1, 2, 4, 3$, the factors are $2-1=1$, $4-1=3$, $3-1=2$, $4-2=2$, $3-2=1$, and $3-4=-1$. Their product is $1 \cdot 3 \cdot 2 \cdot 2 \cdot 1 \cdot (-1) = -12 = 3$ in $\mathbb{F}_5$. (The argument of (b) works verbatim in $\mathbb{F}_5$ with $\omega = 2$ and gives $(\det V)^2 = 4^4 \cdot (-1) = -256 = 4$, and indeed $3^2 = 9 = 4$.)

Solution to Exercise 5.5.51

Uses. Theorem 5.5.9 (The adjugate and the inverse), Theorem 5.5.30 (Rank via minors), Theorem 4.2.11 (Rank–nullity), Theorem 4.2.7 (The image of T_A), Proposition 4.1.21 (Dimensions of subspaces)
Hint 1. The entries of $\operatorname{adj} A$ are, up to sign, the minors of order $n-1$. Use Theorem 5.5.30 for the last two cases.
Hint 2. If $\operatorname{rank} A = n-1$, then $A \operatorname{adj} A = 0$. Where do the columns of $\operatorname{adj} A$ lie, and what is the dimension of that subspace?
Sketch. If $\operatorname{rank} A = n$, $\operatorname{adj} A = (\det A)A^{-1}$ is invertible. If $\operatorname{rank} A \leq n-2$, all minors of order $n-1$ vanish (Theorem 5.5.30), so $\operatorname{adj} A = 0$. If $\operatorname{rank} A = n-1$, then $\det A = 0$, so $A \operatorname{adj} A = 0$ and $\operatorname{im} T_{\operatorname{adj} A} \subseteq \ker T_A$, which has dimension 1 by rank–nullity; and some minor of order $n-1$ is nonzero, so $\operatorname{adj} A \neq 0$.

If $\operatorname{rank} A = n$, then A is invertible and $\operatorname{adj} A = (\det A)A^{-1}$ is invertible (Theorem 5.5.9), so $\operatorname{rank}(\operatorname{adj} A) = n$.

The entries of $\operatorname{adj} A$ are $\pm \det A_{\hat{i}\hat{j}}$, the minors of order $n-1$ of A. If $\operatorname{rank} A \leq n-2$, these all vanish by Theorem 5.5.30 (if $A = 0$, trivially), so $\operatorname{adj} A = 0$ and $\operatorname{rank}(\operatorname{adj} A) = 0$.

Let $\operatorname{rank} A = n-1$. Then A is not invertible, so $\det A = 0$ and $A \operatorname{adj} A = 0$ by Theorem 5.5.9. So for every $\mathbf{x}$, $A(\operatorname{adj} A)\mathbf{x} = \mathbf{0}$, that is, $\operatorname{im} T_{\operatorname{adj} A} \subseteq \ker T_A$. By rank–nullity (Theorem 4.2.11), $\dim \ker T_A = n - (n-1) = 1$, so $\operatorname{rank}(\operatorname{adj} A) = \dim \operatorname{im} T_{\operatorname{adj} A} \leq 1$ (Theorem 4.2.7, Proposition 4.1.21). On the other hand, by Theorem 5.5.30, A has a nonzero minor of order $n-1$, so $\operatorname{adj} A \neq 0$ and $\operatorname{rank}(\operatorname{adj} A) \geq 1$. Hence $\operatorname{rank}(\operatorname{adj} A) = 1$.

Solution to Exercise 5.5.52

Uses. Definition 2.4.1 (Matrix product), Definition 5.1.1 (Determinant function), Theorem 5.2.31 (Alternating functions and permutations), Definition 5.3.6 (Determinant), Definition 5.5.29 (Minors of order k)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Column j of AB is $\sum_k b_{kj}\mathbf{a}_k$, where $\mathbf{a}_1, \ldots, \mathbf{a}_n \in F^m$ are the columns of A. Expand $\det(AB)$ by multilinearity in all m columns, as in Lemma 5.3.2.
Hint 2. The terms are indexed by functions $f : [m] \to [n]$. Which vanish? An injective f is determined by its image S and a permutation $\sigma \in S_m$.
Hint 3. For fixed $S = \{s_1 < \cdots < s_m\}$, collect the terms with image S and recognize the Leibniz formula for $B_{S[m]}$.
Sketch. Expanding, $\det(AB) = \sum_f \left(\prod_j b_{f(j)j}\right) \det\left(\mathbf{a}_{f(1)}, \ldots, \mathbf{a}_{f(m)}\right)$ over all $f : [m] \to [n]$. Non-injective f repeat a column. An injective f with image $S = \{s_1 < \cdots < s_m\}$ is $f(j) = s_{\sigma(j)}$ for a unique $\sigma \in S_m$, and $\det\left(\mathbf{a}_{s_{\sigma(1)}}, \ldots\right) = \operatorname{sgn}(\sigma) \det A_{[m]S}$. Summing over σ gives $\det A_{[m]S} \sum_\sigma \operatorname{sgn}(\sigma) \prod_j b_{s_{\sigma(j)}j} = \det A_{[m]S} \det B_{S[m]}$.

Let $\mathbf{a}_1, \ldots, \mathbf{a}_n \in F^m$ be the columns of A. By Definition 2.4.1, column j of AB is $A\mathbf{b}_j = \sum_{k=1}^{n} b_{kj}\mathbf{a}_k$. Expanding $\det(AB)$ by linearity in each of its m columns (exactly as in the proof of Lemma 5.3.2, with $\mathbf{a}_k$ in place of $\mathbf{e}_k$),

$$\det(AB) = \sum_{f:[m]\to[n]} \left(\prod_{j=1}^{m} b_{f(j)j}\right) \det\left(\mathbf{a}_{f(1)}, \ldots, \mathbf{a}_{f(m)}\right),$$

the sum running over all functions $f : [m] \to [n]$. If f is not injective, the matrix $\left(\mathbf{a}_{f(1)}, \ldots, \mathbf{a}_{f(m)}\right)$ has two equal columns, so its determinant is 0.

An injective f has an image $S = f([m])$ with m elements; write $S = \{s_1 < s_2 < \cdots < s_m\}$. Then there is exactly one $\sigma \in S_m$ with $f(j) = s_{\sigma(j)}$ for all j, and conversely every pair (S, σ) gives an injective f in this way. The matrix with columns $\mathbf{a}_{s_1}, \ldots, \mathbf{a}_{s_m}$ is $A_{[m]S}$ (Definition 5.5.29), so by Theorem 5.2.31,

$$\det\left(\mathbf{a}_{s_{\sigma(1)}}, \ldots, \mathbf{a}_{s_{\sigma(m)}}\right) = \operatorname{sgn}(\sigma) \det A_{[m]S}.$$

Hence

$$\det(AB) = \sum_{|S|=m} \det A_{[m]S} \sum_{\sigma \in S_m} \operatorname{sgn}(\sigma) \prod_{j=1}^{m} b_{s_{\sigma(j)} j}.$$

The (p, j) entry of $B_{S[m]}$ is $b_{s_p j}$, so the inner sum is the Leibniz formula (Definition 5.3.6) for $\det B_{S[m]}$. This proves the formula. If $m > n$, there are no injective f and no sets S, and both sides are 0.

Solution to Exercise 5.5.53

Uses. Corollary 5.4.15 (Rows), Lemma 5.1.8 (Column replacement), Theorem 5.4.26 (Block-triangular matrices), Theorem 5.4.7 (Invertibility and the determinant), induction on n

Techniques. Expose a factor with row and column operations (Technique 5.5.22), Induction on matrix size (Technique 5.5.17)

Hint 1. Subtract the last row from each other row. The difference $1/(x_i + y_j) - 1/(x_n + y_j)$ has numerator $x_n - x_i$, which does not depend on j.

Hint 2. Pull $x_n - x_i$ out of row i and $1/(x_n + y_j)$ out of column j; the last row becomes all 1s. Then subtract the last column from the others and do the same with the y's.

Hint 3. After both rounds, the matrix is block triangular with C_{n-1} in the corner and 1 in position (n, n).

Sketch. Subtracting row n from row $i < n$ gives entries $(x_n - x_i)/\big((x_i + y_j)(x_n + y_j)\big)$. Pulling out $x_n - x_i$ from rows $i < n$ and $1/(x_n + y_j)$ from every column makes row n all 1s and leaves $1/(x_i + y_j)$ elsewhere. Subtracting column n from columns $j < n$ and pulling out $y_n - y_j$ and $1/(x_i + y_n)$ leaves $\left(\begin{smallmatrix} C_{n-1} & 1 \\ 0 & 1 \end{smallmatrix}\right)$. So $\det C_n$ is $\det C_{n-1}$ times the factors involving index n, and induction finishes. For H_n, take $x_i = i$, $y_j = j - 1$; $\det H_3 = 1/2160$.

(a) We induct on n. For $n = 1$, both sides are $1/(x_1 + y_1)$. Let $n \geq 2$.

Rows. For each $i < n$, subtract row n from row i; the determinant does not change (Corollary 5.4.15). The new (i, j) entry, for $i < n$, is

$$\frac{1}{x_i + y_j} - \frac{1}{x_n + y_j} = \frac{x_n - x_i}{(x_i + y_j)(x_n + y_j)}.$$

Pull the factor $x_n - x_i$ out of row i, for each $i < n$, and then the factor $1/(x_n + y_j)$ out of column j, for each j (Corollary 5.4.15 and linearity in columns). The result is the matrix C' with entries $1/(x_i + y_j)$ for $i < n$ and with last row $(1, \ldots, 1)$, and

$$\det C_n = \frac{\prod_{i<n}(x_n - x_i)}{\prod_{j=1}^{n}(x_n + y_j)} \det C'.$$

Columns. For each $j < n$, subtract column n from column j of C' (Lemma 5.1.8). The last row becomes $(0, \ldots, 0, 1)$, and for $i < n$ the new (i, j) entry is

$$\frac{1}{x_i + y_j} - \frac{1}{x_i + y_n} = \frac{y_n - y_j}{(x_i + y_j)(x_i + y_n)}.$$

Pull $y_n - y_j$ out of column j, for each $j < n$, and $1/(x_i + y_n)$ out of row i, for each $i < n$. Row $i < n$ becomes $(1/(x_i + y_1), \ldots, 1/(x_i + y_{n-1}), 1)$, since its last entry $1/(x_i + y_n)$ is divided by $1/(x_i + y_n)$, and the last row stays $(0, \ldots, 0, 1)$. So the result is $\left(\begin{smallmatrix} C_{n-1} & \mathbf{1} \\ 0 & 1 \end{smallmatrix}\right)$, where C_{n-1} is built from $x_1, \ldots, x_{n-1}$ and $y_1, \ldots, y_{n-1}$, and its determinant is $\det C_{n-1}$ by Theorem 5.4.26. Altogether

$$\det C_n = \frac{\prod_{i<n}(x_n - x_i)\prod_{j<n}(y_n - y_j)}{\prod_{j=1}^{n}(x_n + y_j)\prod_{i<n}(x_i + y_n)} \det C_{n-1}.$$

The new numerator factors are those of the claimed numerator with larger index n, and the new denominator factors are the $x_i + y_j$ with $i = n$ or $j = n$. So the induction hypothesis for C_{n-1} gives the formula.

(b) With $x_i = i$ and $y_j = j - 1$, we have $x_i + y_j = i + j - 1 \geq 1$, so $C_n = H_n$. The x_i are distinct and the y_j are distinct, so every factor in the numerator of (a) is nonzero, and $\det H_n \neq 0$; H_n is invertible by Theorem 5.4.7. For $n = 3$, the numerator is $((2-1)(3-1)(3-2))^2 = 4$, and the denominator is the product of $i + j - 1$ over $i, j \in \{1, 2, 3\}$:

$$(1 \cdot 2 \cdot 3)(2 \cdot 3 \cdot 4)(3 \cdot 4 \cdot 5) = 6 \cdot 24 \cdot 60 = 8640.$$

So $\det H_3 = 4/8640 = 1/2160$.

Section 5.6

Solution to Exercise 5.6.6

Uses. Theorem 5.4.26 (Block-triangular matrices), Corollary 5.4.15 (Rows), Proposition 5.3.15 (Triangular matrices), Theorem 5.3.3 (The Leibniz formula), Theorem 5.2.31 (Alternating functions and permutations)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12), Expose a factor with row and column operations (Technique 5.5.22)
Hint 1. In (a), look at the upper right 2×3 corner. In (b), every row differs from row 1 in one entry. In (c), most columns have a single nonzero entry.
Hint 2. (a) is block lower triangular. In (b), subtract row 1 from the other rows. In (c), list the permutations that avoid the zeros, column by column.
Sketch. (a) Block lower triangular with diagonal blocks of determinants 3 and 25: $\det A = 75$. (b) Subtracting row 1 from rows 2, 3, 4 leaves an upper triangular matrix with diagonal $1, x-1, x-1, x-1$: $\det B(x) = (x-1)^3$. (c) Only $\sigma = (1\ 4)(2\ 3)$ survives, and it is even: $\det C = 1 \cdot 5 \cdot 2 \cdot 3 = 30$.

(a) The entries in rows 1, 2 and columns 3, 4, 5 are all 0, so $A = \begin{pmatrix} A_1 & 0 \\ X & A_2 \end{pmatrix}$ is block lower triangular, with

$$A_1 = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 3 \\ 4 & 0 & 1 \end{pmatrix}.$$

By Theorem 5.4.26, $\det A = \det A_1 \det A_2$. Here $\det A_1 = 4 - 1 = 3$, and expanding A_2 along its first row, $\det A_2 = 1(1 - 0) - 2(0 - 12) + 0 = 25$. So $\det A = 75$. The block X never enters; elimination would have computed with it anyway.

(b) Subtract row 1 from each of rows 2, 3, 4. These replacements do not change the determinant (Corollary 5.4.15), and row i becomes $(x-1)\mathbf{e}_i^{\mathsf{T}}$. The result is upper triangular with diagonal entries $1, x-1, x-1, x-1$, so $\det B(x) = (x-1)^3$ by Proposition 5.3.15. The factor $x - 1$ was exposed by the replacements before anything was multiplied out.

(c) We find the permutations σ with $c_{\sigma(j)j} \neq 0$ for every j. Columns 1, 2, 3 have their only nonzero entries in rows 4, 3, 2, so $\sigma(1) = 4$, $\sigma(2) = 3$, $\sigma(3) = 2$. Column 4 has nonzero entries in rows 1 and 4, and row 4 is taken, so $\sigma(4) = 1$. Thus $\sigma = (1\ 4)(2\ 3)$, a product of two transpositions, which is even (Proposition 5.2.25). By Theorem 5.3.3,

$$\det C = c_{41}c_{32}c_{23}c_{14} = 1 \cdot 5 \cdot 2 \cdot 3 = 30.$$

The entry 7 belongs to no surviving term. Elimination would need swaps, and would carry the 7 along until it ended up above the diagonal.

Solution to Exercise 5.6.7

Uses. Corollary 5.4.15 (Rows), Lemma 5.1.8 (Column replacement), Proposition 5.3.17 (Block-diagonal matrices), Corollary 5.5.12 (Integer inverses), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate)
Techniques. Expose a factor with row and column operations (Technique 5.5.22), Induction on matrix size (Technique 5.5.17), Factor the matrix (Technique 5.6.1)
Hint 1. Subtract each row from the row below it, starting from the bottom. What does Pascal's rule do to the entries?
Hint 2. After the row operations, the first column is $\mathbf{e}_1$. Now subtract each column from the column to its right, starting from the right, and identify the lower right block.
Sketch. Replacing row i by row i minus row $i-1$ (for $i = n, \ldots, 2$) turns the entries into $\binom{i+j-3}{i-1}$, so column 1 becomes $\mathbf{e}_1$. Replacing column j by column j minus column $j-1$ (for $j = n, \ldots, 2$) turns row 1 into $\mathbf{e}_1^{\mathsf{T}}$ and the rest into $\binom{i+j-4}{i-2}$, which is P_{n-1}. So $\det P_n = \det P_{n-1} = \cdots = 1$, and $P_n^{-1} = \operatorname{adj} P_n$ is integral.

(a) We show $\det P_n = \det P_{n-1}$ for $n \geq 2$; since $P_1 = (1)$, induction on n then gives $\det P_n = 1$.

Rows. For $i = n, n-1, \ldots, 2$ in turn, subtract row $i-1$ from row i. Since we work from the bottom up, row $i-1$ is still the original row when it is used. For $i \geq 2$, Pascal's rule with $m = i+j-2 \geq 1$ and $k = i-1 \geq 1$ gives the new entry

$$\binom{i+j-2}{i-1} - \binom{i+j-3}{i-2} = \binom{i+j-3}{i-1}.$$

For $j = 1$ this is $\binom{i-2}{i-1} = 0$. So column 1 is now $\mathbf{e}_1$, and row 1 is still $(1, 1, \ldots, 1)$.

Columns. For $j = n, n-1, \ldots, 2$ in turn, subtract column $j-1$ from column j. In row 1 the new entries are $1 - 1 = 0$. In a row $i \geq 2$, Pascal's rule with $m = i+j-3 \geq 1$ and $k = i-1 \geq 1$ gives

$$\begin{aligned}\binom{i+j-3}{i-1} - \binom{i+j-4}{i-1} &= \binom{i+j-4}{i-2} \\ &= \binom{(i-1)+(j-1)-2}{(i-1)-1},\end{aligned}$$

the $(i-1, j-1)$ entry of P_{n-1}. Column 1 is unchanged.

The matrix is now $\begin{pmatrix} 1 & 0 \\ 0 & P_{n-1} \end{pmatrix}$, and all the operations were replacements, which do not change the determinant (Corollary 5.4.15, Lemma 5.1.8). By Proposition 5.3.17, $\det P_n = \det P_{n-1}$.

(b) Since $\det P_n = 1$ and P_n has integer entries, $P_n^{-1} = \operatorname{adj} P_n$ has integer entries (Corollary 5.5.12). For $P_3 = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & 6 \end{pmatrix}$ the cofactors are

$$\begin{aligned} c_{11} &= 3, \quad c_{12} = -3, c_{13} = 1, \\ c_{21} &= -3, c_{22} = 5, \quad c_{23} = -2, \\ c_{31} &= 1, \quad c_{32} = -2, c_{33} = 1, \end{aligned}$$

so

$$P_3^{-1} = \begin{pmatrix} 3 & -3 & 1 \\ -3 & 5 & -2 \\ 1 & -2 & 1 \end{pmatrix}.$$

Multiplying out confirms $P_3 P_3^{-1} = I_3$.

Solution to Exercise 5.6.7

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Proposition 5.3.15 (Triangular matrices)
Techniques. Expose a factor with row and column operations (Technique 5.5.22), Induction on matrix size (Technique 5.5.17), Factor the matrix (Technique 5.6.1)
Hint 1. Look for a lower triangular L with $P_n = LL^{\mathsf{T}}$. Try L with entries $\binom{i-1}{k-1}$, the rows of Pascal's triangle.
Hint 2. The (i, j) entry of LL^{T} is $\sum_k \binom{i-1}{k-1}\binom{j-1}{k-1}$. Count the ways to choose $j-1$ objects from $i-1$ red and $j-1$ blue ones.

Sketch. With $l_{ik} = \binom{i-1}{k-1}$, L is lower triangular with 1s on the diagonal, and Vandermonde's identity gives $\left(LL^{\mathsf{T}}\right)_{ij} = \sum_k \binom{i-1}{k-1}\binom{j-1}{j-k} = \binom{i+j-2}{j-1} = p_{ij}$. So $\det P_n = (\det L)^2 = 1$.

Let $L \in \mathbb{Q}^{n\times n}$ have entries $l_{ik} = \binom{i-1}{k-1}$. Then $l_{ik} = 0$ for $k > i$ and $l_{ii} = 1$, so L is lower triangular with 1s on the diagonal, and $\det L = 1$ by Proposition 5.3.15. The terms with $k > \min(i,j)$ vanish, and for $k \le j$ we have $\binom{j-1}{k-1} = \binom{j-1}{j-k}$, so

$$\left(LL^{\mathsf{T}}\right)_{ij} = \sum_{k=1}^{\min(i,j)} \binom{i-1}{k-1}\binom{j-1}{j-k}.$$

The k-th term counts the ways to choose $j-1$ objects from a set of $i-1$ red and $j-1$ blue objects using exactly $k-1$ red and $j-k$ blue ones. Every choice has between 0 and $\min(i,j)-1$ red objects, so the sum is $\binom{i+j-2}{j-1} = \binom{i+j-2}{i-1} = p_{ij}$. Hence $P_n = LL^{\mathsf{T}}$, and $\det P_n = \det L \det L^{\mathsf{T}} = 1$ by Theorem 5.4.10 and Theorem 5.4.14.

The row operations of the first approach compute this factorization step by step. The second approach finds it at once, but only after guessing L.

Solution to Exercise 5.6.8

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Proposition 5.1.10 (Alternating implies antisymmetric), Definition 5.1.1 (Determinant function), Definition 2.4.26 (Trace)
Techniques. Recognize the determinant by its axioms (Technique 5.4.11), Expand by multilinearity (Technique 5.1.7)
Hint 1. Do not compute. Show that D is multilinear and alternating, and evaluate it at I_n.
Hint 2. For alternation, suppose columns k and l of X are equal. Only the summands $j = k$ and $j = l$ survive. How are their matrices related?
Hint 3. $D(I_n) = \sum_j \det(\mathbf{e}_1, \ldots, A\mathbf{e}_j, \ldots, \mathbf{e}_n)$. Expand $A\mathbf{e}_j = \sum_i a_{ij}\mathbf{e}_i$ in column j.
Sketch. Each summand is multilinear (in column j it is det composed with $\mathbf{x} \mapsto A\mathbf{x}$), so D is. If $\mathbf{x}_k = \mathbf{x}_l$ with $k \ne l$, the summands with $j \notin \{k,l\}$ have two equal columns, and the summands $j = k$ and $j = l$ differ by interchanging columns k and l, so they cancel. Hence $D = D(I_n)\det$, and $D(I_n) = \sum_j a_{jj} = \operatorname{tr} A$.

(a) Write $D = D_1 + \cdots + D_n$, where $D_j(X)$ is the j-th summand. We check the hypotheses of Theorem 5.3.4.

Multilinear. In column j, D_j is the composite of the linear map $\mathbf{x} \mapsto A\mathbf{x}$ with det as a function of column j, so it is linear in column j. In every other column D_j is linear because det is. So each D_j is multilinear, and so is their sum, since a sum of functions that are linear in a column is linear in that column.

Alternating. Suppose $\mathbf{x}_k = \mathbf{x}_l = \mathbf{x}$ for some $k < l$. If $j \notin \{k,l\}$, the matrix in $D_j(X)$ still has $\mathbf{x}$ in columns k and l, so $D_j(X) = 0$. The matrix in $D_k(X)$ has $A\mathbf{x}$ in column k and $\mathbf{x}$ in column l; the matrix in $D_l(X)$ has $\mathbf{x}$ in column k and $A\mathbf{x}$ in column l, and agrees with the first elsewhere. So it is the first matrix with columns k and l interchanged, and $D_l(X) = -D_k(X)$ by Proposition 5.1.10. Hence $D(X) = 0$.

By Theorem 5.3.4, $D(X) = D(I_n)\det X$. To find $D(I_n)$, note that $A\mathbf{e}_j = \sum_i a_{ij}\mathbf{e}_i$ and expand $D_j(I_n)$ in column j:

$$D_j(I_n) = \sum_{i=1}^{n} a_{ij} \det(\mathbf{e}_1, \ldots, \mathbf{e}_{j-1}, \mathbf{e}_i, \mathbf{e}_{j+1}, \ldots, \mathbf{e}_n).$$

For $i \ne j$ the vector $\mathbf{e}_i$ appears twice, so only $i = j$ survives, with value $a_{jj}\det I_n = a_{jj}$. So $D(I_n) = \sum_j a_{jj} = \operatorname{tr} A$, as desired.

(b) By Theorem 5.3.4, $E = E(I_n)\det$. Applying this to each summand and using (a),

$$\begin{aligned}\sum_j E(\mathbf{x}_1, \ldots, A\mathbf{x}_j, \ldots, \mathbf{x}_n) &= E(I_n)D(X) \\ &= E(I_n)(\operatorname{tr} A)\det X = (\operatorname{tr} A)E(X).\end{aligned}$$

The left side of (b) makes sense for any alternating form on a vector space, without a basis, so it can serve as a definition of the trace of an operator; compare Section 13.4. Over $\mathbb{R}$, $D(X)$ is the coefficient of t in

$\det(X + tAX) = \det(I_n + tA)\det X$, so (a) says that the trace is the rate at which $\det(I_n + tA)$ changes at $t = 0$ (Remark 5.5.28).

Solution to Exercise 5.6.9

Uses. Proposition 5.4.17 (Similar matrices have equal determinants), Theorem 5.4.10 (Multiplicativity), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t), Lemma 3.4.23 (Too many roots), Exercise 5.5.47, Exercise 5.1.5
Techniques. Polynomial identity arguments (Technique 5.5.24), det is a polynomial in the entries (Technique 5.3.18)
Hint 1. For (a), $BA = A^{-1}(AB)A$.
Hint 2. For (b), the entries of $tI_n - (A + sI_n)B$ have the form $\alpha + \beta s$. What does the Leibniz formula then say about its determinant? For which s does (a) apply to $A + sI_n$?
Hint 3. For (c), write $tI_n - AB = t\big(I_n - t^{-1}AB\big)$ and pull out t^n. The case $t = 0$ is multiplicativity.
Sketch. (a) $tI_n - BA = A^{-1}(tI_n - AB)A$ is similar to $tI_n - AB$. (b) Both determinants are sums of products of n affine functions of s, hence polynomial of degree at most n in s. By (a), $g(s) = 0$ whenever $A + sI_n$ is invertible, which fails for at most n values of s. An infinite field supplies $n + 1$ other values, so all $e_k = 0$ and $g(0) = 0$. (c) For $t \neq 0$, $\det(tI_n - AB) = t^n \det\big(I_n + \big(-t^{-1}A\big)B\big) = t^n \det\big(I_n + B\big(-t^{-1}A\big)\big) = \det(tI_n - BA)$. For $t = 0$, $\det(-AB) = (-1)^n \det A \det B = \det(-BA)$.

(a) Since A is invertible, $BA = A^{-1}(AB)A$, so

$$\begin{aligned} tI_n - BA &= A^{-1}(tI_n)A - A^{-1}(AB)A \\ &= A^{-1}(tI_n - AB)A. \end{aligned}$$

Similar matrices have equal determinants (Proposition 5.4.17), so $\det(tI_n - BA) = \det(tI_n - AB)$.

(b) Every entry of $tI_n - (A + sI_n)B = (tI_n - AB) - sB$ has the form $\alpha + \beta s$ with $\alpha, \beta \in F$ independent of s. Each term of the Leibniz formula is $\pm$ a product of n such entries, and multiplying out a product of n affine functions of s gives $c_0 + c_1 s + \cdots + c_n s^n$ for scalars c_k independent of s (as in the proof of Proposition 5.3.19). Summing over S_n, the first determinant has this form, and likewise the second, whose matrix $(tI_n - BA) - sB$ also has affine entries. Their difference g is therefore $e_0 + e_1 s + \cdots + e_n s^n$ for some $e_k \in F$.

By Proposition 5.3.19, $\det(A + sI_n)$ is the value at s of a polynomial of degree n with leading coefficient 1. That polynomial is not zero, so by Lemma 3.4.23 it has at most n roots, and $A + sI_n$ is invertible for all but at most n values of s. For each such s, (a) applied to $A + sI_n$ gives $g(s) = 0$.

Since F is infinite, there are $n + 1$ distinct values of s at which $A + sI_n$ is invertible. The polynomial $e_0 + e_1 x + \cdots + e_n x^n \in F[x]_{\leq n}$ vanishes at all of them, so it is zero by Lemma 3.4.23, and $g(s) = 0$ for every s. At $s = 0$ this is the identity for A.

(c) If $t \neq 0$, then $tI_n - AB = t\big(I_n + \big(-t^{-1}A\big)B\big)$, so by Exercise 5.1.5 and Exercise 5.5.47 (with $m = n$, and $-t^{-1}A$ in place of A),

$$\begin{aligned} \det(tI_n - AB) &= t^n \det\big(I_n + \big(-t^{-1}A\big)B\big) \\ &= t^n \det\big(I_n + B\big(-t^{-1}A\big)\big) = \det(tI_n - BA). \end{aligned}$$

If $t = 0$, then by Exercise 5.1.5 and Theorem 5.4.10, $\det(-AB) = (-1)^n \det A \det B = (-1)^n \det B \det A = \det(-BA)$.

The two proofs pay in different ways. The polynomial argument has to avoid the at most n values where $A + sI_n$ is singular and still find $n + 1$ others, so it needs more than $2n$ scalars, which an infinite field guarantees. Sylvester's identity holds over every field, but the reduction to it divides by t, so $t = 0$ is a separate case. In Section 7.3 the identity says that AB and BA have the same characteristic polynomial.

Solution to Exercise 5.6.10

Uses. Lemma 3.4.23 (Too many roots), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate)
Techniques. Polynomial identity arguments (Technique 5.5.24), Try small cases and small fields (Technique 1.2.38)
Hint 1. Over a finite field, how many values of t can be left after excluding up to n of them?

Hint 2. Polynomials of degree at most d that agree at $d+1$ distinct points are equal. What are the degrees here? For the example, try a diagonal matrix with diagonal entries 0 and 1.
Sketch. The last step needs more agreement points than the degree of the polynomials, which is up to $(n-1)^2$. Over a finite field, "all but at most n values" can be very few values, or none: for $A = \operatorname{diag}(0,1) \in \mathbb{F}_2^{2\times 2}$, both A and $A + I_2 = \operatorname{diag}(1,0)$ are singular. The argument is valid once $|F| \geq n^2 - n + 2$, in particular over every infinite field.

The error is the last step. Two polynomial functions of degree at most d are equal if they agree at $d+1$ distinct points (Lemma 3.4.23), and "all but finitely many points" supplies that many points only if the field has enough elements. Over a finite field it can supply none.

The example. Let $A = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \in \mathbb{F}_2^{2\times 2}$. Then $A + 0 \cdot I_2 = A$ and $A + 1 \cdot I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ are both singular, so there is no $t \in \mathbb{F}_2$ at which the two sides are known to agree, and the argument proves nothing about A.

When the argument works. The entries of $A + tI_n$ have degree at most 1 in t, so the cofactors of $A + tI_n$, which are determinants of size $n-1$, have degree at most $n-1$, and the entries of $\operatorname{adj}(\operatorname{adj}(A + tI_n))$ have degree at most $(n-1)^2$. On the other side, $\det(A + tI_n)^{n-2}$ has degree at most $n(n-2)$, so the entries of $\det(A + tI_n)^{n-2}(A + tI_n)$ have degree at most $n(n-2) + 1 = (n-1)^2$. The difference has degree at most $(n-1)^2$, and it vanishes at every t for which $A + tI_n$ is invertible, of which there are at least $|F| - n$ (Proposition 5.3.19). So the argument is correct when $|F| - n \geq (n-1)^2 + 1$, that is, $|F| \geq n^2 - n + 2$, and in particular over every infinite field.

Solution to Exercise 5.6.11

Uses. Proposition 5.4.1 (Determinants of elementary matrices), Corollary 5.4.4 (Products of elementary matrices), Exercise 5.4.48, Proposition 5.1.10 (Alternating implies antisymmetric)
Techniques. Reduce to elementary matrices (Technique 5.4.6)
Hint 1. One direction is multiplicativity. For the other, Exercise 5.4.48 writes every invertible matrix as replacements times one scaling.
Hint 2. For (b), the second proof of Proposition 5.1.10 performs a swap with three column replacements and one sign change.
Sketch. (a) Replacements have determinant 1 and E_{ic} has determinant $c > 0$, so such a product has positive determinant. Conversely, $A = E_1 \cdots E_t E_{n,\det A}$ with replacements E_k, and $E_{n,\det A}$ is a positive scaling when $\det A > 0$. (b) $E_{12} = E_{1,1,2}E_{2,-1,1}E_{1,1,2}E_{2,-1}$; a product of replacements and positive scalings has positive determinant, while $\det E_{12} = -1$.

(a) ($\Leftarrow$) By Proposition 5.4.1, a replacement has determinant 1 and E_{ic} has determinant c. So by Corollary 5.4.4, a product of replacements and scalings E_{ic} with $c > 0$ has determinant equal to the product of the scaling factors, which is positive.

($\Rightarrow$) By Exercise 5.4.48 (b), $A = E_1 \cdots E_t E_{n,\det A}$, where $E_1, \ldots, E_t$ are replacements. If $\det A > 0$, the last factor is a scaling by a positive number. (If $n = 1$, then $A = (\det A) = E_{1,\det A}$ directly.)

(b) In the second proof of Proposition 5.1.10, the columns $(\mathbf{x}, \mathbf{y})$ become $(\mathbf{x}+\mathbf{y}, \mathbf{y})$, then $(\mathbf{x}+\mathbf{y}, -\mathbf{x})$, then $(\mathbf{y}, -\mathbf{x})$, and finally $(\mathbf{y}, \mathbf{x})$ after scaling the second column by -1. Starting from I_2 and recording each column operation as a multiplication on the right (Proposition 3.2.28), this reads

$$\begin{aligned} E_{12} &= E_{1,1,2}E_{2,-1,1}E_{1,1,2}E_{2,-1} \\ &= \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \end{aligned}$$

and multiplying out gives $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. A negative scaling is unavoidable: by (a), a product of replacements and positive scalings has positive determinant, while $\det E_{12} = -1$. Over $\mathbb{R}$, the sign of the determinant splits the invertible matrices into two classes, and the factors allowed in (a) never leave the class with positive determinant; Section 8.4 returns to this for rotations and reflections.

Solution to Exercise 5.6.12

Uses. Theorem 5.5.21 (The Vandermonde determinant), Exercise 5.5.26, Corollary 5.4.15 (Rows), Theorem 5.4.7 (Invertibility and the determinant), Corollary 5.4.8 (Vanishing determinants), Proposition 2.4.23 (Transpose of a product), Proposition 5.3.19 ($\det(A+tI_n)$ as a function of t), Lemma 3.4.23 (Too many roots)
Techniques. Reduce modulo p (Technique 5.3.21), det is a polynomial in the entries (Technique 5.3.18)
Hint 1. (a) Factor i out of row i. (b) Compute $\det M(x)$ as a polynomial in x and look at its parity. (c) Do not compute a determinant: look at the kernel. (d) How many roots can $\det(A+tI_n)$ have?
Hint 2. (b) The polynomial is x^3+x^2-2x-1, and $x^3+x^2=x^2(x+1)$ is even for integers. For real x, compare the values at 1 and 2. (c) If $\left(I_n+A^{\mathsf{T}}A\right)\mathbf{v}=\mathbf{0}$, multiply on the left by $\mathbf{v}^{\mathsf{T}}$.
Sketch. (a) Row i is $i\left(1,i,i^2,i^3\right)$, so $\det A = 4!\det V(1,2,3,4) = 24\cdot 12 = 288$. (b) $\det M(x)=x^3+x^2-2x-1$ is odd at every integer, but changes sign between 1 and 2. (c) $\mathbf{v}^{\mathsf{T}}\left(I_n+A^{\mathsf{T}}A\right)\mathbf{v}=\mathbf{v}^{\mathsf{T}}\mathbf{v}+(A\mathbf{v})^{\mathsf{T}}(A\mathbf{v})$ is a sum of squares, zero only for $\mathbf{v}=\mathbf{0}$. (d) $\det(A+tI_n)$ is a nonzero polynomial of degree n, so it cannot vanish at all of $0,1,\ldots,n$.

(a) Row i of A is $\left(i,i^2,i^3,i^4\right)=i\left(1,i,i^2,i^3\right)$, which is i times row i of the Vandermonde matrix $V(1,2,3,4)$. Pulling the factor i out of each row (Corollary 5.4.15) and using Exercise 5.5.26 (a),

$$\begin{aligned}\det A &= 1\cdot 2\cdot 3\cdot 4\cdot \det V(1,2,3,4)\\ &= 24\cdot(1!\cdot 2!\cdot 3!) = 288\neq 0.\end{aligned}$$

So A is invertible by Theorem 5.4.7. Recognizing the form made the computation unnecessary; even $\det V\neq 0$ follows at once from Theorem 5.5.21, since the nodes are distinct.

(b) Expanding along the first row,

$$\begin{aligned}\det M(x) &= x(x(x+1)-1)-1\cdot((x+1)-0)\\ &= x^3+x^2-2x-1.\end{aligned}$$

If x is an integer, $x^3+x^2=x^2(x+1)$ is a product with an even factor, and $2x$ is even, so $\det M(x)$ is odd, in particular nonzero, and $M(x)$ is invertible. (This is Technique 5.3.21 applied to a family: modulo 2 the determinant is 1 for every integer x.) On the other hand $\det M(1)=-1<0<7=\det M(2)$, and a polynomial function is continuous, so by the intermediate value theorem $\det M(x_0)=0$ for some real $x_0\in(1,2)$, and $M(x_0)$ is not invertible.

(c) Let $C=I_n+A^{\mathsf{T}}A$, and suppose $C\mathbf{v}=\mathbf{0}$. By Proposition 2.4.23, $\mathbf{v}^{\mathsf{T}}A^{\mathsf{T}}A\mathbf{v}=(A\mathbf{v})^{\mathsf{T}}(A\mathbf{v})$, so

$$\begin{aligned}0=\mathbf{v}^{\mathsf{T}}C\mathbf{v} &= \mathbf{v}^{\mathsf{T}}\mathbf{v}+(A\mathbf{v})^{\mathsf{T}}(A\mathbf{v})\\ &= \sum_{i=1}^{n}v_i^2+\sum_{k=1}^{m}(A\mathbf{v})_k^2.\end{aligned}$$

A sum of squares of real numbers is 0 only if every term is 0, so $\mathbf{v}=\mathbf{0}$. By Corollary 5.4.8, C is invertible. A determinant would be hopeless here: $\det C$ is a polynomial of degree up to $2n$ in the entries of A, with no evident sign.

(d) By Proposition 5.3.19, $\det(A+tI_n)=p(t)$ for the polynomial $p=x^n+c_{n-1}x^{n-1}+\cdots+c_0\in\mathbb{Q}[x]$. Since its coefficient of x^n is 1, p is not zero, so by Lemma 3.4.23 it does not vanish at all $n+1$ points $0,1,\ldots,n$. For a point t where it does not vanish, $A+tI_n$ is invertible by Theorem 5.4.7.

Solution to Exercise 5.6.13

Uses. Theorem 5.3.3 (The Leibniz formula), Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.2.16 (Cycle decomposition), Proposition 5.2.8 (Reindexing sums over S_n)
Techniques. Cancel terms in pairs (Technique 5.3.5), Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. In $t_{\sigma^{-1}}(A)$, reindex the product by $j=\sigma(i)$, and then use $a_{i\sigma(i)}=-a_{\sigma(i)i}$.
Hint 2. If $\sigma^2=\mathrm{id}$, every orbit of σ has one or two elements. Since n is odd, they cannot all have two.
Hint 3. Pair σ with σ^{-1}. The permutations equal to their own inverse are left over, and (b) disposes of them.
Sketch. (a) $\prod_j a_{\sigma^{-1}(j)j}=\prod_i a_{i\sigma(i)}=(-1)^n\prod_i a_{\sigma(i)i}$ and $\operatorname{sgn}\left(\sigma^{-1}\right)=\operatorname{sgn}(\sigma)$. (b) Orbits of an involution have size 1 or 2 and partition a set of odd size, so some j is fixed, and $a_{jj}=0$ is a factor. (c) $\sigma\mapsto\sigma^{-1}$ is an involution of S_n whose fixed points are the σ with $\sigma^2=\mathrm{id}$; pairs cancel by (a), and fixed points contribute 0 by (b). (d) $\det A=-\det A$ only gives $(1+1)\det A=0$; pairing never divides.

(a) By definition, $t_{\sigma^{-1}}(A) = \operatorname{sgn}(\sigma^{-1}) \prod_{j=1}^{n} a_{\sigma^{-1}(j)j}$. As i runs over $[n]$, so does $j = \sigma(i)$, so the product can be indexed by i instead:

$$\begin{aligned}\prod_{j=1}^{n} a_{\sigma^{-1}(j)j} &= \prod_{i=1}^{n} a_{i\sigma(i)} \\ &= \prod_{i=1}^{n} \bigl(-a_{\sigma(i)i}\bigr) = (-1)^n \prod_{i=1}^{n} a_{\sigma(i)i}.\end{aligned}$$

Since $\operatorname{sgn}(\sigma^{-1}) = \operatorname{sgn}(\sigma)$ (Proposition 5.2.25) and n is odd, $t_{\sigma^{-1}}(A) = -t_\sigma(A)$.

(b) Suppose $\sigma^2 = \mathrm{id}$, and let $i \in [n]$. The least $k \geq 1$ with $\sigma^k(i) = i$ is 1 or 2, so by Proposition 5.2.16 the orbit of i has one or two elements, and the orbits partition $[n]$. If every orbit had two elements, n would be even. So some orbit is $\{j\}$, that is, $\sigma(j) = j$, and $t_\sigma(A)$ contains the factor $a_{\sigma(j)j} = a_{jj} = 0$.

(c) The map $\varphi(\sigma) = \sigma^{-1}$ is a bijection of S_n with $\varphi(\varphi(\sigma)) = \sigma$, and its fixed points are the σ with $\sigma = \sigma^{-1}$, that is, $\sigma^2 = \mathrm{id}$. Let Q be the set of fixed points, and let P contain exactly one element of each pair $\{\sigma, \sigma^{-1}\}$ with $\sigma \neq \sigma^{-1}$. Every permutation lies in exactly one of Q, P, and $\varphi(P)$, so by Theorem 5.3.3, (a), and (b),

$$\begin{aligned}\det A &= \sum_{\sigma \in P} \bigl(t_\sigma(A) + t_{\sigma^{-1}}(A)\bigr) + \sum_{\sigma \in Q} t_\sigma(A) \\ &= 0 + 0 = 0.\end{aligned}$$

This is Technique 5.3.5 in its version with fixed points.

(d) The earlier argument shows $\det A = \det A^{\mathsf{T}} = \det(-A) = (-1)^n \det A = -\det A$, that is, $(1+1)\det A = 0$, and concludes by dividing by $1+1$. Over $\mathbb{F}_2$ this equation reads $0 = 0$. The pairing argument never divides: over $\mathbb{F}_2$, (a) says that $t_{\sigma^{-1}}(A) = t_\sigma(A)$, and the two terms of each pair cancel because $x + x = 0$ there. The hypothesis $a_{ii} = 0$ enters only in (b). When $1 + 1 \neq 0$ it follows from $a_{ii} = -a_{ii}$, but over $\mathbb{F}_2$ it is a genuine assumption: I_3 satisfies $a_{ji} = -a_{ij}$ over $\mathbb{F}_2$ and has determinant 1 (Exercise 5.4.33 (c)).

Solution to Exercise 5.6.14

Uses. Definition 5.2.21 (Inversion), Corollary 5.2.24 (Formulas for the sign), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.30 (Algebra of permutation matrices), Exercise 5.2.36, Corollary 5.4.27 (Several diagonal blocks), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Theorem 5.2.31 (Alternating functions and permutations)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Sort the pairs of positions $p < q$ by the parities of p and q. Only one kind of pair can be inverted.
Hint 2. For (c), rearrange the rows *and* the columns of M by π: consider $E_\pi^{\mathsf{T}} M E_\pi$, whose (p,q) entry is $m_{\pi(p)\pi(q)}$.
Sketch. (a) The odd positions carry $1, \ldots, n$ in order and the even positions $n+1, \ldots, 2n$ in order. A pair (position $2i$, position $2j-1$) with $j > i$ is inverted, since $n + i > j$, and no other pair is; there are $\sum_i (n-i) = n(n-1)/2$ of them. (b) $n = 3$: (2 4 5 3), sign -1; $n = 4$: (2 5 3)(4 6 7), sign 1. (c) $E_\pi^{\mathsf{T}} M E_\pi$ is block diagonal with blocks $\left(\begin{smallmatrix} a_i & b_i \\ c_i & d_i \end{smallmatrix}\right)$, and $\det\bigl(E_\pi^{\mathsf{T}} M E_\pi\bigr) = \operatorname{sgn}(\pi)^2 \det M = \det M$.

(a) The entry in position $2i-1$ is i, and the entry in position $2i$ is $n+i$. Consider positions $p < q$. If both are odd, or both even, their entries are in increasing order. If $p = 2i-1$ and $q = 2j$, then $i \leq j < n + j$, so the pair is in order. If $p = 2i$ and $q = 2j-1$, then $q > p$ means $j > i$, and the entries satisfy $n + i > n \geq j$, so the pair is an inversion. For fixed i there are $n - i$ such j, so

$$\operatorname{inv}(\pi) = \sum_{i=1}^{n} (n-i) = n\frac{n-1}{2},$$

and $\operatorname{sgn}(\pi) = (-1)^{n(n-1)/2}$ by Corollary 5.2.24.

(b) For $n = 3$ the bottom row is $1, 4, 2, 5, 3, 6$. Following $2 \mapsto 4 \mapsto 5 \mapsto 3 \mapsto 2$, and noting that 1 and 6 are fixed, $\pi = (2\ 4\ 5\ 3)$, a 4-cycle, with sign $-1 = (-1)^3$. For $n = 4$ the bottom row is $1, 5, 2, 6, 3, 7, 4, 8$, so $\pi = (2\ 5\ 3)(4\ 6\ 7)$, with sign $1 = (-1)^6$. Both agree with (a) by Proposition 5.2.26. The cycle type changes

irregularly with n, while the inversion count has a closed form, so inversions are the right tool for this permutation.

(c) Let $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ and $N = E_\pi^{\mathsf{T}} M E_\pi$. By Proposition 5.2.30 (a), column q of ME_π is column $\pi(q)$ of M. By Proposition 5.2.30 (c), $E_\pi^{\mathsf{T}} = E_{\pi^{-1}}$, and by Exercise 5.2.36 (a), row p of $E_{\pi^{-1}} X$ is row $\pi(p)$ of X. So $n_{pq} = m_{\pi(p)\pi(q)}$.

For $p, q \in \{2i-1, 2i\}$ the indices $\pi(p), \pi(q)$ lie in $\{i, n+i\}$, and these four entries of N form the block $\begin{pmatrix} m_{ii} & m_{i,n+i} \\ m_{n+i,i} & m_{n+i,n+i} \end{pmatrix} = \begin{pmatrix} a_i & b_i \\ c_i & d_i \end{pmatrix}$. If instead $p \in \{2i-1, 2i\}$ and $q \in \{2j-1, 2j\}$ with $i \neq j$, then $m_{\pi(p)\pi(q)}$ is an off-diagonal entry of one of the diagonal matrices A, B, C, D, so it is 0. Hence N is block diagonal with the 2×2 blocks $\begin{pmatrix} a_i & b_i \\ c_i & d_i \end{pmatrix}$, and by Corollary 5.4.27,

$$\det N = \prod_{i=1}^{n} (a_i d_i - b_i c_i).$$

Finally, $\det N = \det E_\pi^{\mathsf{T}} \det M \det E_\pi = \operatorname{sgn}(\pi)^2 \det M = \det M$ by Theorem 5.4.10, Theorem 5.4.14, and Theorem 5.2.31. So the sign does not enter: rearranging the rows and the columns in the same way costs $\operatorname{sgn}(\pi)^2 = 1$. Only rearranging the columns alone, as in $\det(ME_\pi) = \operatorname{sgn}(\pi) \det M$, costs a sign.

Solution to Exercise 5.6.15

Uses. Lemma 5.5.2 (A row or column with one nonzero entry), Theorem 5.2.31 (Alternating functions and permutations), Theorem 5.4.26 (Block-triangular matrices)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. Carry out the interchange of rows 1 and 3 for the given B, and compare the lower right 2×2 block with $B_{\widehat{31}}$.
Hint 2. After interchanging rows 1 and i, in which position is the old row 1? Deleting row i from B keeps the other rows in their original order.
Sketch. The lower right block is not $B_{\widehat{ij}}$: after interchanging rows 1 and i, the old row 1 sits in position i, behind rows $2, \ldots, i-1$. For the given B, the claim predicts $\det B = -1 \cdot \det I_2 = -1$, but B is the permutation matrix of the 3-cycle $(1\ 3\ 2)$, so $\det B = 1$, as $(-1)^{3+1}$ predicts. Moving row i to the top by $i-1$ adjacent interchanges keeps the other rows in order and gives the correct sign $(-1)^{i+j}$.

The error. The last step identifies the lower right block with $B_{\widehat{ij}}$. Interchanging rows 1 and i moves the old row 1 into position i, so after the first row is removed, the remaining rows appear in the order $2, 3, \ldots, i-1, 1, i+1, \ldots, n$. The minor $B_{\widehat{ij}}$ has them in the order $1, 2, \ldots, i-1, i+1, \ldots, n$. The two agree only when $i \leq 2$, and the same problem occurs with the columns when $j \geq 3$.

The counterexample. For the given B, row 3 is $(1, 0, 0)$, so $b_{31} = 1$ is the only nonzero entry, and $B_{\widehat{31}}$, obtained by deleting row 3 and column 1, is I_2. The claim, with $\varepsilon = -1$, predicts $\det B = -1$. But the columns of B are $\mathbf{e}_3, \mathbf{e}_1, \mathbf{e}_2$, so $B = E_\sigma$ for the 3-cycle $\sigma = (1\ 3\ 2)$, which is even, and $\det B = 1$ (Theorem 5.2.31). In the argument, interchanging rows 1 and 3 gives $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$, whose lower right block $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ is $B_{\widehat{31}}$ with its rows interchanged.

The repair. Move row i to the top by $i-1$ interchanges of adjacent rows, which keeps the other rows in order, and likewise for column j. This gives the sign $(-1)^{(i-1)+(j-1)} = (-1)^{i+j}$ of Lemma 5.5.2, which for this B is $(-1)^4 = 1$.

Problems for Chapter 5

Solution to Problem 5.1

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Theorem 5.3.3 (The Leibniz formula), Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.1.11 (Antisymmetric implies alternating when $1 + 1 \neq 0$), Definition 5.1.1 (Determinant function)
Techniques. Cancel terms in pairs (Technique 5.3.5)

Hint 1. For (b), suppose columns $k \neq l$ are equal and let $\tau = (k\ l)$. Compare the terms of σ and $\sigma\tau$, and do not reindex the whole sum.
Hint 2. For (c), the product $a_{11}\cdots a_{1n}$ takes one entry from each column, and permuting the columns only permutes its factors. To break alternation, use a matrix whose columns are all equal but whose first row is not zero.
Sketch. (a) There is exactly one determinant function on $F^{n\times n}$, the Leibniz formula L, and every multilinear alternating D equals $D(I_n)L$. (b) If columns $k \neq l$ agree and $\tau = (k\ l)$, then $\sigma\tau$ uses the same entries as σ with the opposite sign, so $t_{\sigma\tau} = -t_\sigma$; grouping each even σ with $\sigma\tau$ writes $L(A)$ as a sum of zeros. (c) det is antisymmetric, and the product of the first-row entries is multilinear, invariant under column permutations, and 0 at I_n; over $\mathbb{F}_2$, invariance is antisymmetry. On the matrix with first row all 1s and other rows 0, $D = 0 + 1$. When $1 + 1 \neq 0$, antisymmetry implies alternation, and uniqueness leaves only det.

(a) *Statement* (Theorem 5.3.4). Let $n \geq 1$. The function

$$L(A) = \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n}$$

is a determinant function on $F^{n\times n}$, and it is the only one. Moreover, every multilinear alternating $D : F^{n\times n} \to F$ satisfies $D = D(I_n)L$.

(b) Let A have equal columns k and l, where $k \neq l$, and let $\tau = (k\ l)$. Write $t_\sigma(A) = \operatorname{sgn}(\sigma)\prod_j a_{\sigma(j)j}$. The permutation $\sigma\tau$ agrees with σ except that $(\sigma\tau)(k) = \sigma(l)$ and $(\sigma\tau)(l) = \sigma(k)$. So

$$\prod_j a_{(\sigma\tau)(j)j} = \left(\prod_{j\notin\{k,l\}} a_{\sigma(j)j}\right) a_{\sigma(l)k} a_{\sigma(k)l},$$

and since columns k and l are equal, $a_{\sigma(l)k} = a_{\sigma(l)l}$ and $a_{\sigma(k)l} = a_{\sigma(k)k}$. So the products of entries in $t_{\sigma\tau}(A)$ and $t_\sigma(A)$ agree, while $\operatorname{sgn}(\sigma\tau) = -\operatorname{sgn}(\sigma)$ by Proposition 5.2.25. Hence $t_{\sigma\tau}(A) = -t_\sigma(A)$.

The map $\sigma \mapsto \sigma\tau$ is its own inverse and changes the sign, so it maps the even permutations bijectively onto the odd ones. Therefore

$$L(A) = \sum_{\sigma \text{ even}} (t_\sigma(A) + t_{\sigma\tau}(A)) = \sum_{\sigma \text{ even}} 0 = 0.$$

No step divides by $1 + 1$: over $\mathbb{F}_2$ the two terms of a pair are equal and cancel because $x + x = 0$.

(c) Write $g(A) = a_{11}a_{12}\cdots a_{1n}$, so $D = \det + g$.

Normalized. $\det I_n = 1$, and $g(I_n)$ contains the factor $a_{12} = 0$ (as $n \geq 2$). So $D(I_n) = 1$.

Multilinear. g contains exactly one entry of each column, namely a_{1k} from column k. With the other columns fixed, g is a constant times a_{1k}, a linear function of column k. So g is multilinear, and so is $D = \det + g$.

Antisymmetric. Interchanging two columns negates det (Proposition 5.1.10) and permutes the factors of g, so it leaves g unchanged. In $\mathbb{F}_2$, $-1 = 1$, so both det and g are unchanged, and $D(A') = D(A) = -D(A)$ for the interchanged matrix A'.

Not alternating. Let A have first row $(1, \ldots, 1)$ and all other rows 0. All columns of A are equal to $\mathbf{e}_1$, so $\det A = 0$, but $g(A) = 1$, and $D(A) = 1 \neq 0$.

If $1 + 1 \neq 0$, an antisymmetric function is alternating (Proposition 5.1.11). So a normalized, multilinear, antisymmetric D would be a determinant function, hence equal to det by uniqueness, and det is alternating. So over such a field the three conditions determine det, while over $\mathbb{F}_2$ they allow at least two functions, for every $n \geq 2$. This is why the definition asks for alternation (compare Example 5.1.12, the case $n = 2$).

Solution to Problem 5.2

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Definition 5.1.1 (Determinant function), Theorem 5.4.10 (Multiplicativity), Exercise 5.1.5, Corollary 5.4.27 (Several diagonal blocks), Theorem 2.4.34 (Block multiplication)
Techniques. Recognize the determinant by its axioms (Technique 5.4.11)
Hint 1. For (b), fix A and regard $D(B) = \det(AB)$ as a function of the columns of B. Column j of AB is $A\mathbf{b}_j$.
Hint 2. For (c), take determinants: $(\det A)^2 = 2^n$. When is 2^n the square of a rational number? For even n, look for a 2×2 example and use blocks.
Sketch. (b) $D(B) = \det(A\mathbf{b}_1, \ldots, A\mathbf{b}_n)$ is linear in each column (a linear map followed by det) and vanishes when two columns of B agree, so $D(B) = D(I_n) \det B = \det A \det B$. Then $\det A \det A^{-1} = \det I_n = 1$. (c) $(\det A)^2 = 2^n$ with $\det A \in \mathbb{Q}$; for odd $n = 2k+1$ this makes $\det A/2^k$ a rational square root of 2. For even n, use $n/2$ diagonal blocks $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$. Over $\mathbb{R}$, $\sqrt{2}I_n$ works for every n.

(a) Theorem 5.4.7: $A \in F^{n\times n}$ is invertible if and only if $\det A \neq 0$. Theorem 5.4.10: $\det(AB) = \det A \det B$ for all $A, B \in F^{n\times n}$.

(b) Fix A, and let $D(B) = \det(AB)$. Column j of AB is $A\mathbf{b}_j$, so $D(B) = \det(A\mathbf{b}_1, \ldots, A\mathbf{b}_n)$. In column j, D is the linear map $\mathbf{x} \mapsto A\mathbf{x}$ followed by det, which is linear in column j; so D is multilinear. If two columns of B are equal, the corresponding columns of AB are equal, and $D(B) = 0$; so D is alternating. By Theorem 5.3.4, $D(B) = D(I_n) \det B = \det(A) \det B$.

If A is invertible, then $1 = \det I_n = \det\left(AA^{-1}\right) = \det A \det A^{-1}$, so $\det A \neq 0$.

(c) Suppose $A \in \mathbb{Q}^{n\times n}$ and $A^2 = 2I_n$. By (b) and Exercise 5.1.5, $(\det A)^2 = \det(2I_n) = 2^n$, and $\det A \in \mathbb{Q}$. If $n = 2k+1$ is odd, then $\left(\det A/2^k\right)^2 = 2^{2k+1}/2^{2k} = 2$, so $\sqrt{2}$ would be rational, which it is not. So n must be even. Conversely, $R = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ satisfies $R^2 = 2I_2$, and for even n the block-diagonal matrix with $n/2$ blocks R satisfies $A^2 = 2I_n$, since block-diagonal matrices multiply block by block (Theorem 2.4.34). So the answer over $\mathbb{Q}$ is: exactly the even n.

Over $\mathbb{R}$, $A = \sqrt{2}I_n$ works for every n. The obstruction over $\mathbb{Q}$ is arithmetic, the irrationality of $\sqrt{2}$, and the determinant is what detects it.

Solution to Problem 5.3

Uses. Theorem 5.5.14 (Cramer's rule), Proposition 2.4.8 (Four views of the product), Definition 5.1.1 (Determinant function), Theorem 5.4.7 (Invertibility and the determinant), Proposition 5.3.20 (Reduction modulo p), Corollary 5.5.12 (Integer inverses)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. For (b), write $\mathbf{y} = \sum_k x_k \mathbf{b}_k$ and expand $\det B_i(\mathbf{y})$ in column i.
Hint 2. For the second part of (c), if every integral $\mathbf{y}$ had an integral solution, what would that say about the columns of B^{-1}?
Sketch. (b) Linearity in column i gives $\det B_i(\mathbf{y}) = \sum_k x_k \det B_i(\mathbf{b}_k)$, and every term with $k \neq i$ has a repeated column, while $B_i(\mathbf{b}_i) = B$. (c) $\det B_i(\mathbf{y})$ is an integer. If all $B^{-1}\mathbf{e}_j$ were integral, B^{-1} would be, forcing $d = \pm 1$. For the example, $\mathbf{y} = \mathbf{e}_1$ gives $\mathbf{x} = (3/5, -1/5)$.

(a) (Theorem 5.5.14) If $B \in F^{n\times n}$ has $\det B \neq 0$ and $\mathbf{y} \in F^n$, then $B\mathbf{x} = \mathbf{y}$ has exactly one solution, and $x_i = \det B_i(\mathbf{y})/\det B$ for each i.

(b) Let $\mathbf{x}$ be a solution. Then $\mathbf{y} = B\mathbf{x} = \sum_k x_k \mathbf{b}_k$ (Proposition 2.4.8). By linearity in column i,

$$\det B_i(\mathbf{y}) = \sum_{k=1}^{n} x_k \det B_i(\mathbf{b}_k).$$

For $k \neq i$, the matrix $B_i(\mathbf{b}_k)$ has $\mathbf{b}_k$ in columns i and k, so its determinant is 0. For $k = i$, $B_i(\mathbf{b}_i) = B$. Hence $\det B_i(\mathbf{y}) = x_i \det B$.

If $\det B \neq 0$, then B is invertible (Theorem 5.4.7), so $\mathbf{x} = B^{-1}\mathbf{y}$ is the unique solution, and dividing by $\det B$ gives $x_i = \det B_i(\mathbf{y})/\det B$.

(c) If $\mathbf{y}$ is integral, then $B_i(\mathbf{y})$ has integer entries, so $\det B_i(\mathbf{y})$ is an integer (Proposition 5.3.20), and by (b), $dx_i = \det B_i(\mathbf{y}) \in \mathbb{Z}$.

Suppose that every integral $\mathbf{y}$ gives an integral solution. Then each column $B^{-1}\mathbf{e}_j$ of B^{-1}, the solution for $\mathbf{y} = \mathbf{e}_j$, is integral, so B^{-1} has integer entries, and $d = \pm 1$ by Corollary 5.5.12. So if $d \neq \pm 1$, some $\mathbf{e}_j$ has a non-integral solution.

For $B = \begin{pmatrix} 2 & 1 \\ 1 & 3 \end{pmatrix}$, $d = 5$. With $\mathbf{y} = \mathbf{e}_1$,

$$x_1 = \frac{1}{5}\det\begin{pmatrix} 1 & 1 \\ 0 & 3 \end{pmatrix} = \frac{3}{5}, \quad x_2 = \frac{1}{5}\det\begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} = -\frac{1}{5}.$$

Check: $2 \cdot 3/5 - 1/5 = 1$ and $3/5 + 3 \cdot (-1/5) = 0$. The denominators are exactly d.

Solution to Problem 5.4

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Proposition 1.1.17 (No zero divisors), Corollary 5.4.8 (Vanishing determinants), Proposition 5.3.15 (Triangular matrices)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), try diagonal matrices. For (c), the two products have different sizes when $m \neq n$.
Hint 2. For (d) and (e), what is $A(1, \ldots, 1)$?
Sketch. (a) False: $I_n + \operatorname{diag}(-1, -1, 1, \ldots, 1) = \operatorname{diag}(0, 0, 2, \ldots, 2)$. (b) True: $d^3 = d$ gives $d(d-1)(d+1) = 0$. (c) False: $A = (1 \;\; 0)$ gives $\det\left(A^{\mathsf{T}}A\right) = 0$ and $\det\left(AA^{\mathsf{T}}\right) = 1$; true when $m = n$. (d) True: $(1, \ldots, 1)$ is in the kernel. (e) False: $\begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$.

(a) False. Let $A = I_n$ and $B = \operatorname{diag}(-1, -1, 1, \ldots, 1)$. Both have determinant 1 (Proposition 5.3.15), but $A + B = \operatorname{diag}(0, 0, 2, \ldots, 2)$ has determinant 0.

(b) True. Let $d = \det A$. By Theorem 5.4.10, $d^3 = \det\left(A^3\right) = \det A = d$, so $d(d-1)(d+1) = d^3 - d = 0$. A field has no zero divisors (Proposition 1.1.17), so d is 0, 1, or -1. (Over $\mathbb{F}_2$ the set $\{-1, 0, 1\}$ is $\{0, 1\}$.)

(c) False in general. Let $A = (1 \;\; 0) \in \mathbb{R}^{1\times 2}$. Then $A^{\mathsf{T}}A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ has determinant 0, while $AA^{\mathsf{T}} = (1)$ has determinant 1. The statement is true when $m = n$: then both sides equal $\det A^{\mathsf{T}} \det A = (\det A)^2$ by Theorem 5.4.10 and Theorem 5.4.14.

(d) True. The i-th entry of $A(1, \ldots, 1)$ is the sum of row i, so $A(1, \ldots, 1) = \mathbf{0}$ with $(1, \ldots, 1) \neq \mathbf{0}$, and $\det A = 0$ by Corollary 5.4.8.

(e) False for every $n \geq 2$ (for $n = 1$ it is true). $\begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ has row sums 1 and determinant 0, and adding a diagonal block I_{n-2} gives an example for each $n \geq 2$. The hypothesis says $A(1, \ldots, 1) = (1, \ldots, 1)$, a statement about one vector, which says nothing about $\det A$.

Solution to Problem 5.5

Uses. Definition 5.1.14 (The 2×2 determinant), Definition 2.4.26 (Trace), Theorem 5.4.10 (Multiplicativity), Proposition 1.1.17 (No zero divisors)
Hint 1. For (a), count the triples (a, b, d) with $ad = b^2$, splitting into the cases $b = 0$ and $b \neq 0$.
Hint 2. In (b), $d = -a$, and the condition becomes $b(-c) = a^2$. For (c), multiply out A^2; for the converse, take determinants of $A^2 = 0$ first.
Sketch. (a) $b = 0$: $ad = 0$ has $2p - 1$ solutions. $b \neq 0$: a is any of the $p - 1$ nonzero elements and $d = b^2a^{-1}$. Total $2p - 1 + (p-1)^2 = p^2$. (b) $d = -a$ and $b(-c) = a^2$ is the same equation $xy = z^2$, so again p^2. (c) Direct computation. If $A^2 = 0$, then $(\det A)^2 = 0$, so $A^2 = (\operatorname{tr} A)A$, forcing $\operatorname{tr} A = 0$. So there are p^2 such A.

(a) By Definition 5.1.14 we count the triples $(a, b, d) \in \mathbb{F}_p^3$ with $ad - b^2 = 0$. If $b = 0$, we need $ad = 0$, that is, $a = 0$ or $d = 0$ (Proposition 1.1.17): there are p triples with $a = 0$ and p with $d = 0$, and one triple has both, so $2p - 1$ in all. If $b \neq 0$ ($p - 1$ choices), then $ad = b^2 \neq 0$, so $a \neq 0$ ($p - 1$ choices), and then $d = b^2a^{-1}$ is determined. In all there are

$$2p - 1 + (p-1)^2 = p^2$$

such matrices.

(b) Write $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Then $\operatorname{tr} A = 0$ means $d = -a$, and then $\det A = -a^2 - bc$, so the conditions say $b(-c) = a^2$, with a, b, c free otherwise. The map $(a, b, c) \mapsto (b, -c, a)$ is a bijection of $\mathbb{F}_p^3$ that turns these solutions into the solutions (x, y, z) of $xy = z^2$, and so does $(a, b, d) \mapsto (a, d, b)$ for the equation in (a). Both counts are the number of solutions of $xy = z^2$ in $\mathbb{F}_p^3$, which is p^2.

(c) With $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$,

$$A^2 = \begin{pmatrix} a^2 + bc & ab + bd \\ ca + dc & cb + d^2 \end{pmatrix},$$

$$(\operatorname{tr} A)A = \begin{pmatrix} (a+d)a & (a+d)b \\ (a+d)c & (a+d)d \end{pmatrix},$$

so $A^2 - (\operatorname{tr} A)A = \begin{pmatrix} bc-ad & 0 \\ 0 & bc-ad \end{pmatrix} = -(\det A) I_2$, as claimed.

If $\operatorname{tr} A = \det A = 0$, the identity gives $A^2 = 0$. Conversely, suppose $A^2 = 0$. Then $(\det A)^2 = \det(A^2) = 0$ by Theorem 5.4.10, so $\det A = 0$, and the identity becomes $(\operatorname{tr} A)A = A^2 = 0$. Either $\operatorname{tr} A = 0$, or $A = 0$, and the zero matrix also has trace 0. So $A^2 = 0$ exactly when $\operatorname{tr} A = \det A = 0$, and by (b) there are p^2 such matrices in $\mathbb{F}_p^{2\times 2}$, one of which is 0.

Solution to Problem 5.6

Uses. Definition 5.1.14 (The 2×2 determinant), Theorem 5.1.13 (The 2×2 determinant), Proposition 5.1.10 (Alternating implies antisymmetric), Example 5.1.15 (det is signed area)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. For (a), expand $\det(\mathbf{p}_k + \mathbf{c}, \mathbf{p}_{k+1} + \mathbf{c})$ into four terms, and sum over k. The sums $\sum_k \mathbf{p}_k$ and $\sum_k \mathbf{p}_{k+1}$ are equal.
Hint 2. For (b), apply (a) with $\mathbf{c} = -\mathbf{p}$. For (c), apply (b) to each triangle and then (a) with $-\mathbf{c}$.
Sketch. (a) The extra terms sum to $\det(\mathbf{s}, \mathbf{c}) + \det(\mathbf{c}, \mathbf{s})$ with $\mathbf{s} = \sum_k \mathbf{p}_k$, which is 0 by antisymmetry, and $\det(\mathbf{c}, \mathbf{c}) = 0$. (b) After translating by $-\mathbf{p}$, two of the three terms involve $\mathbf{0}$. (c) $\sum_k S(\mathbf{c}, \mathbf{p}_k, \mathbf{p}_{k+1}) = \frac{1}{2}\sum_k \det(\mathbf{p}_k - \mathbf{c}, \mathbf{p}_{k+1} - \mathbf{c}) = S$ by (a); for an interior $\mathbf{c}$ the triangles tile the polygon and are all counterclockwise. (d) $\frac{1}{2}(0 + 12 + 19 + 11 + 0) = 21$.

(a) By multilinearity, with $\det(\mathbf{c}, \mathbf{c}) = 0$,

$$\det(\mathbf{p}_k + \mathbf{c}, \mathbf{p}_{k+1} + \mathbf{c}) = \det(\mathbf{p}_k, \mathbf{p}_{k+1}) + \det(\mathbf{p}_k, \mathbf{c}) + \det(\mathbf{c}, \mathbf{p}_{k+1}).$$

Let $\mathbf{s} = \sum_{k=1}^m \mathbf{p}_k$. Since $\mathbf{p}_{m+1} = \mathbf{p}_1$, also $\sum_{k=1}^m \mathbf{p}_{k+1} = \mathbf{s}$. Summing over k and using linearity in each column, the extra terms add up to

$$\det(\mathbf{s}, \mathbf{c}) + \det(\mathbf{c}, \mathbf{s}) = 0$$

by antisymmetry (Proposition 5.1.10). So S is unchanged.

(b) By (a) with $\mathbf{c} = -\mathbf{p}$, and writing $\mathbf{q}' = \mathbf{q} - \mathbf{p}$ and $\mathbf{r}' = \mathbf{r} - \mathbf{p}$,

$$\begin{aligned} S(\mathbf{p}, \mathbf{q}, \mathbf{r}) &= S(\mathbf{0}, \mathbf{q}', \mathbf{r}') \\ &= \frac{1}{2}(\det(\mathbf{0}, \mathbf{q}') + \det(\mathbf{q}', \mathbf{r}') + \det(\mathbf{r}', \mathbf{0})) \\ &= \frac{1}{2}\det(\mathbf{q}', \mathbf{r}'), \end{aligned}$$

since a matrix with a zero column has determinant 0. The triangle $\mathbf{pqr}$ is half of the parallelogram spanned by $\mathbf{q}'$ and $\mathbf{r}'$, translated to $\mathbf{p}$. By Example 5.1.15, $\det(\mathbf{q}', \mathbf{r}')$ is the signed area of that parallelogram, positive exactly when the turn from $\mathbf{q}'$ to $\mathbf{r}'$ is counterclockwise, that is, when $\mathbf{p}, \mathbf{q}, \mathbf{r}$ run counterclockwise.

(c) By (b), $S(\mathbf{c}, \mathbf{p}_k, \mathbf{p}_{k+1}) = \frac{1}{2}\det(\mathbf{p}_k - \mathbf{c}, \mathbf{p}_{k+1} - \mathbf{c})$. Summing over k gives $S(\mathbf{p}_1 - \mathbf{c}, \ldots, \mathbf{p}_m - \mathbf{c})$, which is $S(\mathbf{p}_1, \ldots, \mathbf{p}_m)$ by (a).

Now let the polygon be convex with counterclockwise vertices, and let $\mathbf{c}$ be a point inside it. The segments from $\mathbf{c}$ to the vertices cut the polygon into the triangles $\mathbf{c}\mathbf{p}_k\mathbf{p}_{k+1}$, and each of these runs counterclockwise, since the boundary of the polygon does. By (b), each $S(\mathbf{c}, \mathbf{p}_k, \mathbf{p}_{k+1})$ is the area of its triangle, and their sum is the area of the polygon.

(d) The terms $\det(\mathbf{p}_k, \mathbf{p}_{k+1})$ are

$$\det\begin{pmatrix} 0 & 4 \\ 0 & 0 \end{pmatrix} = 0, \quad \det\begin{pmatrix} 4 & 5 \\ 0 & 3 \end{pmatrix} = 12,$$

$$\det\begin{pmatrix} 5 & 2 \\ 3 & 5 \end{pmatrix} = 19, \quad \det\begin{pmatrix} 2 & -1 \\ 5 & 3 \end{pmatrix} = 11,$$

$$\det\begin{pmatrix} -1 & 0 \\ 3 & 0 \end{pmatrix} = 0,$$

so $S = \frac{1}{2}(0 + 12 + 19 + 11 + 0) = 21$. The pentagon is convex and its vertices run counterclockwise: the edge vectors $(4, 0), (1, 3), (-3, 2), (-3, -2), (1, -3)$ point in the directions of about $0°$, $72°$, $146°$, $214°$, and $288°$, so the boundary turns left at every vertex and makes exactly one full turn in all. Hence the area is 21. (Left turns alone are not enough: the edges of a five-pointed star also turn left at every vertex, but they make two full turns.)

Solution to Problem 5.7

> *Uses.* Lemma 5.1.8 (Column replacement), Lemma 5.5.2 (A row or column with one nonzero entry), Corollary 5.4.8 (Vanishing determinants), Theorem 5.5.14 (Cramer's rule), Proposition 2.4.8 (Four views of the product)
> *Hint 1.* For (a), subtract column 1 from the other columns, and expand along the first row.
> *Hint 2.* For (c), the two conditions on λ are one linear system $M\boldsymbol{\lambda} = (1, \mathbf{x})$. For (d), apply (a) to M_i, which is the matrix of the same kind built from the points with $\mathbf{p}_i$ replaced by $\mathbf{x}$.
> *Sketch.* (a) Column replacements turn column $i + 1$ into $(0, \mathbf{p}_i - \mathbf{p}_0)$, after which row 1 is $\mathbf{e}_1^{\mathsf{T}}$ and the minor is the matrix with columns $\mathbf{p}_i - \mathbf{p}_0$. (b) Corollary 5.4.8. (c) The conditions read $M\boldsymbol{\lambda} = (1, \mathbf{x})$; apply Cramer's rule. (d) By (a) and Problem 5.6 (b), $\det M_i$ is twice the signed area of the triangle with $\mathbf{p}_i$ replaced by $\mathbf{x}$, and $\det M$ is twice that of $\mathbf{p}_0\mathbf{p}_1\mathbf{p}_2$. For the example, $\det M = 16$ and $\lambda = (1/4, 1/4, 1/2)$.

(a) For $i = 1, \ldots, n$, subtract column 1 from column $i + 1$. These replacements do not change the determinant (Lemma 5.1.8), and column $i + 1$ becomes $(0, \mathbf{p}_i - \mathbf{p}_0)$. Now row 1 is $(1, 0, \ldots, 0)$, so by Lemma 5.5.2 the determinant is $(-1)^{1+1} \cdot 1$ times the determinant of the matrix left after deleting row 1 and column 1, whose columns are $\mathbf{p}_1 - \mathbf{p}_0, \ldots, \mathbf{p}_n - \mathbf{p}_0$.

(b) By (a) and Corollary 5.4.8, $\det M \neq 0$ exactly when the columns $\mathbf{p}_i - \mathbf{p}_0$ are independent. For $n = 2$ this says that $\mathbf{p}_1 - \mathbf{p}_0$ and $\mathbf{p}_2 - \mathbf{p}_0$ do not lie on one line through $\mathbf{0}$, that is, the three points do not lie on one line.

(c) Let $\boldsymbol{\lambda} = (\lambda_0, \ldots, \lambda_n)$. By Proposition 2.4.8, $M\boldsymbol{\lambda} = \sum_i \lambda_i (1, \mathbf{p}_i)$, whose first entry is $\sum_i \lambda_i$ and whose other entries form $\sum_i \lambda_i \mathbf{p}_i$. So the two conditions say exactly $M\boldsymbol{\lambda} = (1, \mathbf{x})$. Since $\det M \neq 0$, Cramer's rule (Theorem 5.5.14) gives a unique solution, with $\lambda_i = \det M_i / \det M$.

(d) M_i is the matrix M built from the points $\mathbf{p}_0, \ldots, \mathbf{x}, \ldots, \mathbf{p}_n$, with $\mathbf{x}$ in place of $\mathbf{p}_i$. By (a) and Problem 5.6 (b), $\det M = 2S(\mathbf{p}_0, \mathbf{p}_1, \mathbf{p}_2)$ and

$$\begin{aligned} \det M_0 &= 2S(\mathbf{x}, \mathbf{p}_1, \mathbf{p}_2), \\ \det M_1 &= 2S(\mathbf{p}_0, \mathbf{x}, \mathbf{p}_2), \\ \det M_2 &= 2S(\mathbf{p}_0, \mathbf{p}_1, \mathbf{x}). \end{aligned}$$

So λ_i is the signed area of the triangle with $\mathbf{p}_i$ replaced by $\mathbf{x}$, divided by the signed area of $\mathbf{p}_0\mathbf{p}_1\mathbf{p}_2$. It is positive exactly when the two signed areas have the same sign, that is, the two triangles have the same orientation.

For $\mathbf{p}_0 = (0, 0)$, $\mathbf{p}_1 = (4, 0)$, $\mathbf{p}_2 = (0, 4)$, and $\mathbf{x} = (1, 2)$:

$$\det M = \det\begin{pmatrix} 4 & 0 \\ 0 & 4 \end{pmatrix} = 16,$$

$$\det M_1 = \det\begin{pmatrix} 1 & 0 \\ 2 & 4 \end{pmatrix} = 4,$$

$$\det M_2 = \det\begin{pmatrix} 4 & 1 \\ 0 & 2 \end{pmatrix} = 8,$$

and $\det M_0 = \det(\mathbf{p}_1 - \mathbf{x}, \mathbf{p}_2 - \mathbf{x}) = \det\begin{pmatrix} 3 & -1 \\ -2 & 2 \end{pmatrix} = 4$. So $\lambda = (1/4, 1/4, 1/2)$, and indeed $\frac{1}{4}(0,0) + \frac{1}{4}(4,0) + \frac{1}{2}(0,4) = (1,2)$. All three are positive, so $(1,2)$ lies inside the triangle in this sense. These λ_i are the barycentric coordinates of Section 4.7, and the sign test is the standard way to decide whether a point lies in a triangle.

Solution to Problem 5.8

Uses. Definition 5.4.18 (Determinant of an operator), Definition 1.6.1 (Basis), Proposition 5.3.15 (Triangular matrices), Proposition 5.4.20 (Properties of the determinant of an operator), Exercise 5.4.40

Hint 1. Symmetric matrices are fixed by the transpose and skew-symmetric ones are negated. What does T do to each kind?

Hint 2. For the basis in (a), $U_{ij} = \frac{1}{2}\big((U_{ij} + U_{ji}) + (U_{ij} - U_{ji})\big)$, and there are $n + 2 \cdot n(n-1)/2 = n^2$ matrices in the list.

Sketch. (a) T multiplies U_{ii} and $U_{ij} + U_{ji}$ by $\alpha + \beta$, and $U_{ij} - U_{ji}$ by $\alpha - \beta$. There are $n + n(n-1)/2 = n(n+1)/2$ basis vectors of the first kind. (b) $\alpha = 0$, $\beta = 1$ gives $(-1)^{n(n-1)/2}$. (c) The matrix is block diagonal with blocks $\alpha + \beta$, $\begin{pmatrix} \alpha & \beta \\ \beta & \alpha \end{pmatrix}$, $\alpha + \beta$, so $\det T = (\alpha+\beta)^2(\alpha^2 - \beta^2) = (\alpha+\beta)^3(\alpha - \beta)$. (d) Invertible iff $\alpha + \beta \neq 0$ and, for $n \geq 2$, $\alpha - \beta \neq 0$; for $\alpha = \beta \neq 0$ the kernel is the space of skew-symmetric matrices.

(a) Let $S_{ij} = U_{ij} + U_{ji}$ and $K_{ij} = U_{ij} - U_{ji}$ for $i < j$. The list $U_{11}, \dots, U_{nn}, S_{ij}, K_{ij}$ has $n + 2 \cdot n(n-1)/2 = n^2$ entries.

It spans. Each U_{ii} is in the list, and for $i < j$, $U_{ij} = (1+1)^{-1}\big(S_{ij} + K_{ij}\big)$ and $U_{ji} = (1+1)^{-1}\big(S_{ij} - K_{ij}\big)$. So the span contains every matrix unit, hence all of $F^{n \times n}$.

It is independent. Suppose $\sum_i a_i U_{ii} + \sum_{i<j}\big(b_{ij} S_{ij} + c_{ij} K_{ij}\big) = 0$. The (i,i) entry gives $a_i = 0$. For $i < j$, the (i,j) and (j,i) entries give $b_{ij} + c_{ij} = 0$ and $b_{ij} - c_{ij} = 0$, so $(1+1)b_{ij} = 0$, hence $b_{ij} = 0$ and $c_{ij} = 0$.

So the list is a basis (Definition 1.6.1). Since $U_{ii}^{\mathsf{T}} = U_{ii}$, $S_{ij}^{\mathsf{T}} = S_{ij}$, and $K_{ij}^{\mathsf{T}} = -K_{ij}$,

$$T(U_{ii}) = (\alpha + \beta) U_{ii},$$

$$T\big(S_{ij}\big) = (\alpha + \beta) S_{ij},$$

$$T\big(K_{ij}\big) = (\alpha - \beta) K_{ij}.$$

So the matrix of T in this basis is diagonal, with $\alpha + \beta$ appearing $n + n(n-1)/2 = n(n+1)/2$ times and $\alpha - \beta$ appearing $n(n-1)/2$ times. By Definition 5.4.18 and Proposition 5.3.15, $\det T$ is the product of these diagonal entries, as claimed.

(b) The transpose operator is the case $\alpha = 0$, $\beta = 1$, and the formula gives $1 \cdot (-1)^{n(n-1)/2}$, which is the answer of Exercise 5.4.40.

(c) For $n = 2$, $T(U_{11}) = (\alpha+\beta)U_{11}$, $T(U_{22}) = (\alpha+\beta)U_{22}$, $T(U_{12}) = \alpha U_{12} + \beta U_{21}$, and $T(U_{21}) = \beta U_{12} + \alpha U_{21}$. In the basis $U_{11}, U_{12}, U_{21}, U_{22}$ the matrix of T is

$$\begin{pmatrix} \alpha+\beta & 0 & 0 & 0 \\ 0 & \alpha & \beta & 0 \\ 0 & \beta & \alpha & 0 \\ 0 & 0 & 0 & \alpha+\beta \end{pmatrix},$$

which is block diagonal, so $\det T = (\alpha+\beta)^2(\alpha^2 - \beta^2) = (\alpha+\beta)^3(\alpha - \beta)$ (Corollary 5.4.27). This is the formula of (a) for $n = 2$, and the computation used nothing about $1 + 1$. (Over $\mathbb{F}_2$ it reads $(\alpha+\beta)^4$.)

(d) By Proposition 5.4.20, T is invertible exactly when $\det T \neq 0$, that is, when $\alpha+\beta \neq 0$ and, if $n \geq 2$, also $\alpha-\beta \neq 0$. If $\alpha=\beta \neq 0$, then in the basis of (a) the diagonal entries are $1+1$ times α for U_{ii} and S_{ij}, which is nonzero, and 0 for K_{ij}. So $\ker T = \operatorname{span}\left(K_{ij} \mid i<j\right)$, the space of skew-symmetric matrices, of dimension $n(n-1)/2$. Directly: $\alpha\left(X+X^{\mathsf{T}}\right)=0$ exactly when $X^{\mathsf{T}}=-X$.

Solution to Problem 5.9

Uses. Definition 3.4.22 (Vandermonde matrix), Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Definition 2.4.1 (Matrix product)
Techniques. Factor the matrix (Technique 5.6.1)
Hint 1. The (l,j) entry of V is x_l^{j-1}. Compute the (i,j) entry of $V^{\mathsf{T}}V$ as a sum over l.
Hint 2. For (c), a real square is nonnegative. Over $\mathbb{C}$, try $x=(i,-i)$. For (d), you do not need the x_i: compute $\det H$ from the power sums.
Sketch. (a) $\left(V^{\mathsf{T}}V\right)_{ij}=\sum_l x_l^{i-1}x_l^{j-1}=s_{i+j-2}$, so $\det H=(\det V)^2$. (b) $2\left(x_1^2+x_2^2\right)-(x_1+x_2)^2=(x_1-x_2)^2$. (c) Squares of reals; over $\mathbb{C}$, $x=(i,-i)$ gives $H=\left(\begin{smallmatrix}2&0\\0&-2\end{smallmatrix}\right)$. (d) $\det\left(\begin{smallmatrix}3&0&6\\0&6&0\\6&0&18\end{smallmatrix}\right)=108>0$, so yes.

(a) The (l,j) entry of V is x_l^{j-1} (Definition 3.4.22), so the (i,l) entry of V^{T} is x_l^{i-1}, and

$$\left(V^{\mathsf{T}}V\right)_{ij}=\sum_{l=1}^{n}x_l^{i-1}x_l^{j-1}=\sum_{l=1}^{n}x_l^{i+j-2}=s_{i+j-2}.$$

So $H=V^{\mathsf{T}}V$, and by Theorem 5.4.10, Theorem 5.4.14, and Theorem 5.5.21,

$$\det H=\det V^{\mathsf{T}}\det V=(\det V)^2=\prod_{1\leq i<j\leq n}\left(x_j-x_i\right)^2.$$

(b) For $n=2$, $H=\left(\begin{smallmatrix}2&x_1+x_2\\x_1+x_2&x_1^2+x_2^2\end{smallmatrix}\right)$, and

$$\begin{aligned}\det H&=2x_1^2+2x_2^2-(x_1+x_2)^2\\&=x_1^2-2x_1x_2+x_2^2=(x_2-x_1)^2.\end{aligned}$$

(c) Over $\mathbb{R}$, $\det H=(\det V)^2\geq 0$, with equality exactly when $\det V=0$, that is, when some factor x_j-x_i is 0 (Proposition 1.1.17). Over $\mathbb{C}$, take $n=2$, $x_1=i$, and $x_2=-i$, where i is the imaginary unit: then $s_0=2$, $s_1=0$, $s_2=i^2+(-i)^2=-2$, and $\det H=\det\left(\begin{smallmatrix}2&0\\0&-2\end{smallmatrix}\right)=-4$, which is $(x_2-x_1)^2=(-2i)^2$.

(d) Here $s_0=3$, and

$$\det H=\det\begin{pmatrix}3&0&6\\0&6&0\\6&0&18\end{pmatrix}=6(3\cdot 18-6\cdot 6)=108>0,$$

expanding along the middle row. By (c), the x_i are distinct. (Indeed $x=\left(-\sqrt{3},0,\sqrt{3}\right)$ has these power sums, and $\left(\sqrt{3}\right)^2\left(2\sqrt{3}\right)^2\left(\sqrt{3}\right)^2=108$.)

Solution to Problem 5.10

Uses. Corollary 5.4.15 (Rows), Proposition 5.3.15 (Triangular matrices), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Theorem 5.5.9 (The adjugate and the inverse), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Expose a factor with row and column operations (Technique 5.5.22)
Hint 1. Subtract a times row $i-1$ from row i, for $i=n,\ldots,2$. What happens to the entries left of the diagonal?
Hint 2. For (c), the inverse of K_3 is tridiagonal. Guess a tridiagonal T with $-a$ next to the diagonal, and check $K_nT=\left(1-a^2\right)I_n$ column by column.
Sketch. (a) The row operations make the entries left of the diagonal 0 and multiply those on and right of it by $1-a^2$ (except in row 1), leaving an upper triangular matrix with diagonal $1,1-a^2,\ldots,1-a^2$. (b) $\operatorname{adj}K_3=\left(1-a^2\right)\left(\begin{smallmatrix}1&-a&0\\-a&1+a^2&-a\\0&-a&1\end{smallmatrix}\right)$. (c) $K_n^{-1}=\left(1-a^2\right)^{-1}T$, where T is tridiagonal with diagonal $1,1+a^2,\ldots,1+a^2,1$ and $-a$ beside the diagonal.

(a) For $i = n, n-1, \ldots, 2$ in turn, subtract a times row $i-1$ from row i; working from the bottom up, row $i-1$ is still the original row when it is used. These replacements do not change the determinant (Corollary 5.4.15). For $i \geq 2$ the new (i,j) entry is $a^{|i-j|} - a \cdot a^{|i-1-j|}$. If $j \leq i-1$, this is $a^{i-j} - a \cdot a^{i-1-j} = 0$. If $j \geq i$, it is $a^{j-i} - a \cdot a^{j-i+1} = a^{j-i}\left(1-a^2\right)$. So the new matrix is upper triangular with diagonal entries $1, 1-a^2, \ldots, 1-a^2$, and $\det K_n = \left(1-a^2\right)^{n-1}$ by Proposition 5.3.15.

(b) The cofactors of K_3 are

$$c_{11} = 1-a^2, c_{12} = -\left(a-a^3\right), c_{13} = a^2 - a^2 = 0,$$
$$c_{22} = 1-a^4, c_{23} = -\left(a-a^3\right), c_{33} = 1-a^2,$$

and $c_{ji} = c_{ij}$ since K_3 is symmetric. Factoring out $1-a^2$,

$$\operatorname{adj} K_3 = \left(1-a^2\right)\begin{pmatrix} 1 & -a & 0 \\ -a & 1+a^2 & -a \\ 0 & -a & 1 \end{pmatrix}.$$

By (a), $\det K_3 = \left(1-a^2\right)^2$, so when $a^2 \neq 1$, Theorem 5.5.9 gives

$$K_3^{-1} = \frac{1}{1-a^2}\begin{pmatrix} 1 & -a & 0 \\ -a & 1+a^2 & -a \\ 0 & -a & 1 \end{pmatrix}.$$

(c) Let $T \in F^{n\times n}$ be tridiagonal with diagonal entries $1, 1+a^2, \ldots, 1+a^2, 1$ (the first and last are 1) and every entry next to the diagonal equal to $-a$. We check $K_n T = \left(1-a^2\right) I_n$ one column at a time.

Column 1 of T is $(1, -a, 0, \ldots, 0)$, so the $(i,1)$ entry of $K_n T$ is $a^{|i-1|} - a \cdot a^{|i-2|}$. For $i = 1$ it is $1-a^2$, and for $i \geq 2$ it is $a^{i-1} - a^{i-1} = 0$. *Column* n is the mirror image of column 1, with the same result.

Column j *with* $1 < j < n$ has entries $-a, 1+a^2, -a$ in rows $j-1, j, j+1$. The (i,j) entry of $K_n T$ is

$$-a \cdot a^{|i-j+1|} + \left(1+a^2\right)a^{|i-j|} - a \cdot a^{|i-j-1|}.$$

If $i = j$, this is $-a^2 + 1 + a^2 - a^2 = 1-a^2$. If $i < j$, put $d = j-i \geq 1$; the entry is $-a^d + a^d + a^{d+2} - a^{d+2} = 0$. If $i > j$, put $d = i-j \geq 1$; it is $-a^{d+2} + a^d + a^{d+2} - a^d = 0$.

So $K_n T = \left(1-a^2\right) I_n$. Taking determinants, $\det K_n \det T = \left(1-a^2\right)^n \neq 0$, so K_n is invertible (Theorem 5.4.7), and multiplying by K_n^{-1} gives $K_n^{-1} = \left(1-a^2\right)^{-1} T$.

Solution to Problem 5.11

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.7 (Invertibility and the determinant), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t), Theorem 7.1.32 (Fundamental Theorem of Algebra)
Techniques. det is a polynomial in the entries (Technique 5.3.18)
Hint 1. The product computation is fine. Test the sentence "so is $M = A^{-1}N$" on 2×2 matrices, with A a swap.
Hint 2. For (b), commuting lets you regroup $\left(A^{-1}N\right)^k$. For (c), the polynomial $\det(I_n + tN)$ never vanishes; over $\mathbb{C}$, what does that force?
Sketch. (a) $A^{-1}N$ need not be nilpotent: $A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ and $N = \left(\begin{smallmatrix} 0 & 0 \\ -1 & 0 \end{smallmatrix}\right)$ give $A+N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, singular, and $A^{-1}N = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. (b) If $AN = NA$, then $\left(A^{-1}N\right)^k = A^{-k}N^k = 0$. (c) $g(t) = \det(I_n + tN)$ is $e_0 + e_1 t + \cdots + e_n t^n$ and has no zeros, since tN is nilpotent and commutes with I_n. A nonconstant complex polynomial has a root, so g is constant, equal to $g(0) = 1$. (d) $\det(A+N) = \det A \det\left(I_n + A^{-1}N\right) = \det A$.

(a) The error is the claim that $M = A^{-1}N$ is nilpotent. (The displayed product is correct: it telescopes to $I_n - (-M)^k$.) Let

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad N = \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix}.$$

Then A is invertible ($A^{-1} = A$), $N^2 = 0$, and $A + N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has a zero row, so it is not invertible. Here $A^{-1}N = \begin{pmatrix} -1 & 0 \\ 0 & 0 \end{pmatrix}$, whose powers $\begin{pmatrix} (-1)^k & 0 \\ 0 & 0 \end{pmatrix}$ are never 0.

(b) Suppose $AN = NA$. Multiplying by A^{-1} on both sides gives $NA^{-1} = A^{-1}N$. So A^{-1} and N commute, and by induction on k, $\left(A^{-1}N\right)^k = A^{-k}N^k$ (move each A^{-1} to the left past the factors N). If $N^k = 0$, then $\left(A^{-1}N\right)^k = 0$, $M = A^{-1}N$ is nilpotent, and the argument of (a) is valid.

(c) Let $N^k = 0$ and $g(t) = \det(I_n + tN)$ for $t \in \mathbb{C}$. Since $(tN)^k = t^k N^k = 0$ and tN commutes with I_n, (b) with $A = I_n$ shows that $I_n + tN$ is invertible, so $g(t) \neq 0$ for every t (Theorem 5.4.7). Every entry of $I_n + tN$ has the form $\alpha + \beta t$, so, as in the proof of Proposition 5.3.19, $g(t) = e_0 + e_1 t + \cdots + e_n t^n$ for some $e_0, \ldots, e_n \in \mathbb{C}$ and all t, with $e_0 = g(0) = \det I_n = 1$. If $e_m \neq 0$ for some $m \geq 1$, the polynomial $e_0 + e_1 x + \cdots + e_n x^n \in \mathbb{C}[x]$ has degree at least 1, so it has a root $t_0 \in \mathbb{C}$ (Theorem 7.1.32), and $g(t_0) = 0$, which is impossible. So $e_1 = \cdots = e_n = 0$, and $g(t) = 1$ for every t. In particular $\det(I_n + N) = g(1) = 1$.

(d) By (b), $A^{-1}N$ is nilpotent, so by (c) and Theorem 5.4.10,

$$\begin{aligned} \det(A + N) &= \det\left(A\left(I_n + A^{-1}N\right)\right) \\ &= \det A \det\left(I_n + A^{-1}N\right) = \det A. \end{aligned}$$

A real matrix can be regarded as a complex one with the same determinant, since the Leibniz formula uses only sums and products of the entries, so (c) and (d) also hold over $\mathbb{R}$.

Solution to Problem 5.12

> *Uses.* Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.10 (Multiplicativity), Proposition 2.4.8 (Four views of the product), Proposition 5.3.15 (Triangular matrices), Lemma 5.5.23 (A polynomial with prescribed roots)
> *Techniques.* Factor the matrix (Technique 5.6.1)
> *Hint 1.* In $(C\mathbf{v}_m)_j = \sum_k c_{(k-j) \bmod n}\omega^{mk}$, substitute $l = (k-j) \bmod n$ and use $\omega^n = 1$.
> *Hint 2.* Put the $\mathbf{v}_m$ side by side as the columns of a matrix W. Then $CW = WD$ with D diagonal, and W is a Vandermonde matrix.
> *Hint 3.* For (d), $f(z) = 1 + z$. For the value, evaluate $t^n - 1 = \prod_m (t - \omega^m)$ at $t = -1$.
> *Sketch.* (a) $(C\mathbf{v}_m)_j = \sum_l c_l \omega^{m(j+l)} = \omega^{mj} f(\omega^m)$. (b) W with columns $\mathbf{v}_m$ is $V\left(1, \omega, \ldots, \omega^{n-1}\right)$, invertible since the nodes are distinct, and $CW = W \operatorname{diag}(f(\omega^m))$; cancel $\det W$. (c) $n = 3$ and $\omega^4 = \omega$. (d) $f(\omega^m) = 1 + \omega^m = 0$ iff $\omega^m = -1$, possible iff n is even. For odd n, $t^n - 1 = \prod_m (t - \omega^m)$ at $t = -1$ gives $-2 = -\prod_m (1 + \omega^m)$.

(a) By definition, $(C\mathbf{v}_m)_j = \sum_{k=0}^{n-1} c_{(k-j) \bmod n}\omega^{mk}$. As k runs over $0, \ldots, n-1$, so does $l = (k-j) \bmod n$, and $k = j + l$ or $k = j + l - n$. Since $\omega^n = 1$, in both cases $\omega^{mk} = \omega^{m(j+l)}$. So

$$(C\mathbf{v}_m)_j = \sum_{l=0}^{n-1} c_l \omega^{mj}\omega^{ml} = \omega^{mj} f(\omega^m),$$

which is the j-th entry of $f(\omega^m)\mathbf{v}_m$.

(b) Let W be the matrix with columns $\mathbf{v}_0, \ldots, \mathbf{v}_{n-1}$. Its (k, m) entry is $\omega^{km} = \left(\omega^k\right)^m$, so W is the Vandermonde matrix $V\left(1, \omega, \ldots, \omega^{n-1}\right)$, and $\det W \neq 0$ by Theorem 5.5.21, since the nodes are distinct. By (a) and Proposition 2.4.8, column m of CW is $f(\omega^m)\mathbf{v}_m$, which is column m of WD for $D = \operatorname{diag}\left(f(1), f(\omega), \ldots, f\left(\omega^{n-1}\right)\right)$. So $CW = WD$, and by Theorem 5.4.10 and Proposition 5.3.15,

$$\det C \det W = \det W \det D = \det W \prod_{m=0}^{n-1} f(\omega^m).$$

Dividing by $\det W \neq 0$ gives the claim.

(c) For $n = 3$ and $(c_0, c_1, c_2) = (a, b, c)$, the matrix is $\begin{pmatrix} a & b & c \\ c & a & b \\ b & c & a \end{pmatrix}$ and $f(z) = a + bz + cz^2$. So $\det = f(1)f(\omega)f\left(\omega^2\right)$ with $f\left(\omega^2\right) = a + b\omega^2 + c\omega^4 = a + b\omega^2 + c\omega$, since $\omega^3 = 1$.

(d) Here $f(z) = 1 + z$, so by (b), $\det C = 0$ exactly when $\omega^m = -1$ for some m. If n is even, $\omega^{n/2} = -1$. If n is odd, then $(-1)^n = -1$, while $(\omega^m)^n = 1$, so no ω^m equals -1. Hence C is singular exactly when n is even.

For odd n, the polynomial $x^n - 1$ has degree n, leading coefficient 1, and the n distinct roots $1, \omega, \dots, \omega^{n-1}$, so by Lemma 5.5.23, $t^n - 1 = \prod_{m=0}^{n-1}(t - \omega^m)$ for every $t \in \mathbb{C}$. At $t = -1$,

$$\begin{aligned} -2 = (-1)^n - 1 &= \prod_m (-1 - \omega^m) \\ &= (-1)^n \prod_m (1 + \omega^m) = -\det C, \end{aligned}$$

so $\det C = 2$. For $n = 3$ this is the matrix of Exercise 5.3.38 (a).

Solution to Problem 5.13

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.14 (The transpose), Proposition 5.3.15 (Triangular matrices), Proposition 5.1.10 (Alternating implies antisymmetric), Exercise 5.2.34
Techniques. Factor the matrix (Technique 5.6.1)
Hint 1. Expand $(x_i + y_j)^{n-1}$ by the binomial theorem and read the result as a product of three matrices.
Hint 2. $M = XDY$, where X has entries x_i^k, D is diagonal with the binomial coefficients, and Y has entries y_j^{n-1-k}. Up to the order of its rows, Y is $V(y_1, \dots, y_n)^{\mathsf{T}}$.
Sketch. By the binomial theorem, $M = XDY$ with $X = V(x_1, \dots, x_n)$, $D = \operatorname{diag}\left(\binom{n-1}{0}, \dots, \binom{n-1}{n-1}\right)$, and Y equal to $V(y_1, \dots, y_n)^{\mathsf{T}}$ with its rows reversed. Reversing n rows takes $\lfloor n/2 \rfloor$ interchanges, and $(-1)^{\lfloor n/2 \rfloor} = (-1)^{n(n-1)/2}$, which turns $\prod_{i<j}(y_j - y_i)$ into $\prod_{i<j}(y_i - y_j)$. (c) Over $\mathbb{Q}$: invertible iff the x_i are distinct and the y_j are distinct. Over $\mathbb{F}_2$: never, since $\binom{2}{1} = 0$.

(a) Index rows and columns of auxiliary matrices by $k = 0, \dots, n-1$ where needed. By the binomial theorem,

$$(x_i + y_j)^{n-1} = \sum_{k=0}^{n-1} x_i^k \binom{n-1}{k} y_j^{n-1-k}.$$

So $M = XDY$, where X has (i,k) entry x_i^k, $D = \operatorname{diag}\left(\binom{n-1}{0}, \dots, \binom{n-1}{n-1}\right)$, and Y has (k,j) entry y_j^{n-1-k}. Now $X = V(x_1, \dots, x_n)$. The matrix $V(y_1, \dots, y_n)^{\mathsf{T}}$ has (k,j) entry y_j^k, so Y is $V(y_1, \dots, y_n)^{\mathsf{T}}$ with its rows in reverse order. Reversing the order of n rows takes $\lfloor n/2 \rfloor$ interchanges (the first row with the last, and so on), each of which negates the determinant (Proposition 5.1.10 with Theorem 5.4.14), and $(-1)^{\lfloor n/2 \rfloor} = (-1)^{n(n-1)/2}$ by Exercise 5.2.34 (c). So, by Theorem 5.5.21 and Theorem 5.4.14,

$$\det Y = (-1)^{n(n-1)/2} \prod_{1 \le i < j \le n} (y_j - y_i) = \prod_{1 \le i < j \le n} (y_i - y_j),$$

because the product has $n(n-1)/2$ factors and each sign change flips one of them. By Theorem 5.4.10 and Proposition 5.3.15,

$$\begin{aligned} \det M &= \det X \det D \det Y \\ &= \prod_{i<j} (x_j - x_i) \cdot \prod_{k=0}^{n-1} \binom{n-1}{k} \cdot \prod_{i<j} (y_i - y_j). \end{aligned}$$

(b) For $n = 2$ the binomial coefficients are $1, 1$, and

$$\begin{aligned} \det M &= (x_1 + y_1)(x_2 + y_2) - (x_1 + y_2)(x_2 + y_1) \\ &= x_1 y_2 + x_2 y_1 - x_1 y_1 - x_2 y_2 \\ &= (x_2 - x_1)(y_1 - y_2). \end{aligned}$$

(c) For $n = 3$ the coefficients are $\binom{2}{0}, \binom{2}{1}, \binom{2}{2} = 1, 2, 1$. Over $\mathbb{Q}$ they are nonzero, so M is invertible exactly when the x_i are distinct and the y_j are distinct (Proposition 1.1.17, Theorem 5.4.7). Over $\mathbb{F}_2$, $\binom{2}{1} = 2 = 0$, so $\det M = 0$ and M is never invertible. This agrees with $(x + y)^2 = x^2 + y^2$ over $\mathbb{F}_2$: there M is the sum of

the matrix with all columns $\left(x_1^2, x_2^2, x_3^2\right)$ and the matrix with all rows $\left(y_1^2, y_2^2, y_3^2\right)$, and both have rank at most 1.

Solution to Problem 5.14

Uses. Theorem 5.3.3 (The Leibniz formula), Proposition 5.2.25 (Multiplicativity of the sign), Definition 5.2.10 (Transposition), Proposition 5.5.18 (Tridiagonal determinants)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12), Induction on matrix size (Technique 5.5.17)
Hint 1. For (a), induct on n and look at $\sigma(n)$, which is n or $n-1$. If $\sigma(n) = n-1$, which j can have $\sigma(j) = n$?
Hint 2. The same case split counts the permutations in (b). In (c), the term of σ is nonzero only if $|\sigma(j) - j| \leq 1$ for every j.
Sketch. (a) Induct on n. If $\sigma(n) = n$, restrict to $[n-1]$. If $\sigma(n) = n-1$, then $\sigma^{-1}(n) \in \{n-1, n\}$ forces $\sigma(n-1) = n$, and $(n-1\ n)\sigma$ fixes $n-1$ and n. (b) The two cases give $N_n = N_{n-1} + N_{n-2}$ with $N_0 = N_1 = 1$. (c) For the product σ of the transpositions of P, $\operatorname{sgn}(\sigma) = (-1)^{|P|}$, and each pair contributes $t_{k+1,k}t_{k,k+1} = c_k b_k$; all other terms of the Leibniz formula vanish. (d) Split by whether n is matched. In the example, every term equals 1.

(a) A product of disjoint adjacent transpositions moves each point by at most 1. For the converse we induct on n; for $n \leq 1$ the only permutation is the identity, the empty product. Let $n \geq 2$ and let σ satisfy $|\sigma(j) - j| \leq 1$ for every j. Then $\sigma(n) \in \{n-1, n\}$.

If $\sigma(n) = n$, then σ maps $[n-1]$ onto itself, and its restriction has the same property, so by induction it is a product of disjoint adjacent transpositions of $[n-1]$, and so is σ.

If $\sigma(n) = n-1$, let $j = \sigma^{-1}(n)$. Then $|n-j| \leq 1$ and $j \neq n$, so $j = n-1$, that is, $\sigma(n-1) = n$. For $j \leq n-2$ we have $\sigma(j) \leq j+1 \leq n-1$ and $\sigma(j) \neq n-1$, so σ maps $[n-2]$ onto itself. Its restriction to $[n-2]$ has the property, so by induction it is a product ρ of disjoint adjacent transpositions of $[n-2]$, and $\sigma = \rho(n-1\ n)$, where $(n-1\ n)$ is disjoint from the factors of ρ.

(b) Let N_n be the number of such permutations of $[n]$, with $N_0 = N_1 = 1$. The two cases of (a) give $N_n = N_{n-1} + N_{n-2}$ for $n \geq 2$, since in each case the restriction can be any of the permutations counted for $[n-1]$, respectively $[n-2]$. So $N_n = F_{n+1}$, by induction from $N_0 = F_1$ and $N_1 = F_2$.

(c) The term of σ in the Leibniz formula (Theorem 5.3.3) contains $t_{\sigma(j)j}$, which is 0 unless $|\sigma(j) - j| \leq 1$. So only the permutations of (a) contribute. Such a σ is the product of the transpositions $(k\ k+1)$ for the pairs of a matching P, and different matchings give different permutations, so the surviving terms correspond to the matchings. For the σ of P, $\operatorname{sgn}(\sigma) = (-1)^{|P|}$ by Proposition 5.2.25. Each unmatched i contributes $t_{ii} = a_i$, and each pair $\{k, k+1\} \in P$ contributes $t_{\sigma(k)k}t_{\sigma(k+1),k+1} = t_{k+1,k}t_{k,k+1} = c_k b_k$. So the term of σ is $\prod_P(-b_k c_k)\prod_{\text{unmatched}} a_i$, as claimed.

(d) Let d_m be the sum in (c) for T_m, the upper left $m \times m$ corner. Split the matchings of $[m]$ according to whether m is matched. If it is unmatched, the rest is any matching of $[m-1]$, and these terms add up to $a_m d_{m-1}$. If it is matched, its pair is $\{m-1, m\}$, the rest is any matching of $[m-2]$, and these terms add up to $-b_{m-1}c_{m-1}d_{m-2}$. So $d_m = a_m d_{m-1} - b_{m-1}c_{m-1}d_{m-2}$, the recurrence of Proposition 5.5.18.

In Example 5.5.19 (b), $a_k = 1$ and $-b_k c_k = -i \cdot i = 1$, so every term in (c) equals 1, and $\det T$ is the number of matchings of $[n]$, which is F_{n+1} by (b). The cofactor recurrence computes the determinants; the matching formula explains what they count.

Solution to Problem 5.15

Uses. Proposition 5.3.20 (Reduction modulo p), Exercise 5.6.13, Corollary 5.4.27 (Several diagonal blocks), Example 5.4.24 (A matrix with constant row sums)
Techniques. Reduce modulo p (Technique 5.3.21), Cancel terms in pairs (Technique 5.3.5)
Hint 1. Reduce modulo 2. What do the hypotheses say about the reduction $\overline{A}$ over $\mathbb{F}_2$?
Hint 2. $\overline{A}$ is alternating in the sense of Exercise 5.6.13. For (b), start with $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$.
Sketch. (a) Over $\mathbb{F}_2$, $\overline{a}_{ii} = 0$ and $\overline{a}_{ji} = \overline{a}_{ij} = -\overline{a}_{ij}$, so $\overline{A}$ is alternating of odd size and $\det \overline{A} = 0$; hence $\det A$ is even. (b) Block-diagonal matrices with blocks $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ satisfy the hypotheses and have determinant ± 1. (c) I_n has odd determinant; $J + I_n$ has determinant $n+1$.

(a) Let $\overline{A} \in \mathbb{F}_2^{n\times n}$ be the reduction of A modulo 2. Since a_{ii} is even, $\bar{a}_{ii} = 0$. Since $a_{ij} + a_{ji}$ is even, $\bar{a}_{ji} = -\bar{a}_{ij}$ in $\mathbb{F}_2$. So $\overline{A}$ is alternating in the sense of Exercise 5.6.13, and since n is odd, $\det \overline{A} = 0$ there. By Proposition 5.3.20, $(\det A) \bmod 2 = \det \overline{A} = 0$, so $\det A$ is even.

The argument must work in characteristic 2, which is why it uses the pairing of Exercise 5.6.13 and not the identity $\det A = -\det A$: over $\mathbb{F}_2$, $-\det A = \det A$ carries no information.

(b) Let $n = 2k$ and let A be block diagonal with k blocks $R = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Its diagonal entries are 0, and $a_{ij} + a_{ji}$ is 0 or 2, so A satisfies the hypotheses. By Corollary 5.4.27, $\det A = (\det R)^k = (-1)^k$, which is odd.

(c) For odd n, I_n has $a_{ij} + a_{ji} = 0$ for $i \neq j$ but odd diagonal entries, and $\det I_n = 1$ is odd. So the diagonal hypothesis is needed (it is not implied by the other one, which for $i = j$ only says that $2a_{ii}$ is even). The matrix $J + I_n$ has diagonal entries 2 and $a_{ij} + a_{ji} = 2$, and by Example 5.4.24 with $x = 2$, $\det(J + I_n) = (n + 1) \cdot 1^{n-1} = n + 1$, which is even for odd n, as (a) predicts.

Solution to Problem 5.16

Uses. Proposition 2.4.23 (Transpose of a product), Corollary 5.4.8 (Vanishing determinants), Theorem 5.4.7 (Invertibility and the determinant), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t), Proposition 5.3.15 (Triangular matrices)
Techniques. det is a polynomial in the entries (Technique 5.3.18)
Hint 1. A 1×1 matrix equals its own transpose. For invertibility, if $(I_n + tA)\mathbf{x} = \mathbf{0}$, multiply on the left by $\mathbf{x}^\mathsf{T}$.
Hint 2. $g(t) = \det(I_n + tA)$ is a polynomial in t, so it is continuous, it is 1 at $t = 0$, and by (a) it never vanishes.
Sketch. (a) $\mathbf{x}^\mathsf{T}A\mathbf{x} = \left(\mathbf{x}^\mathsf{T}A\mathbf{x}\right)^\mathsf{T} = -\mathbf{x}^\mathsf{T}A\mathbf{x}$, so it is 0; then $\mathbf{x}^\mathsf{T}(I_n + tA)\mathbf{x} = \sum x_i^2$ forces $\mathbf{x} = \mathbf{0}$. (b) A continuous function on $[0, 1]$ with $g(0) = 1$ and no zeros is positive at 1. (c) $1 + p^2$, and $1 + p^2 + q^2 + r^2$. (d) $A = \operatorname{diag}(-2, 2)$.

(a) The 1×1 matrix $\mathbf{x}^\mathsf{T}A\mathbf{x}$ equals its transpose, which by Proposition 2.4.23 is $\mathbf{x}^\mathsf{T}A^\mathsf{T}\mathbf{x} = -\mathbf{x}^\mathsf{T}A\mathbf{x}$. So $2\mathbf{x}^\mathsf{T}A\mathbf{x} = 0$, and $\mathbf{x}^\mathsf{T}A\mathbf{x} = 0$. Now suppose $(I_n + tA)\mathbf{x} = \mathbf{0}$. Then

$$0 = \mathbf{x}^\mathsf{T}(I_n + tA)\mathbf{x} = \mathbf{x}^\mathsf{T}\mathbf{x} + t\mathbf{x}^\mathsf{T}A\mathbf{x} = x_1^2 + \cdots + x_n^2,$$

so $\mathbf{x} = \mathbf{0}$, and $I_n + tA$ is invertible by Corollary 5.4.8.

(b) Let $g(t) = \det(I_n + tA)$. Its entries are affine in t, so as in the proof of Proposition 5.3.19, $g(t) = e_0 + e_1 t + \cdots + e_n t^n$ for real constants e_k. In particular g is continuous, $g(0) = \det I_n = 1$, and by (a) and Theorem 5.4.7, $g(t) \neq 0$ for every t. If $g(1) < 0$, the intermediate value theorem would give $t \in (0, 1)$ with $g(t) = 0$. So $\det(I_n + A) = g(1) > 0$.

(c) For $n = 2$, $A = \begin{pmatrix} 0 & p \\ -p & 0 \end{pmatrix}$ and $\det(I_2 + A) = \det\begin{pmatrix} 1 & p \\ -p & 1 \end{pmatrix} = 1 + p^2$. For $n = 3$, $A = \begin{pmatrix} 0 & p & q \\ -p & 0 & r \\ -q & -r & 0 \end{pmatrix}$, and expanding along the first row,

$$\det\begin{pmatrix} 1 & p & q \\ -p & 1 & r \\ -q & -r & 1 \end{pmatrix} = \left(1 + r^2\right) - p(-p + qr) + q(pr + q)$$
$$= 1 + p^2 + q^2 + r^2.$$

Both are at least 1. In fact $\det(I_n + A) \geq 1$ for every real skew-symmetric A, but the proof needs the spectral theory of Chapter 8.

(d) $A = \operatorname{diag}(-2, 2)$ has trace 0, and $\det(I_2 + A) = (-1) \cdot 3 = -3 < 0$ (Proposition 5.3.15). Here $I_2 + tA$ is singular at $t = 1/2$, and the argument of (b) breaks at exactly that point.

Solution to Problem 5.17

Uses. Theorem 4.1.10 (Independent lists are short), Corollary 5.4.8 (Vanishing determinants), Exercise 5.5.48, Theorem 7.1.32 (Fundamental Theorem of Algebra), Theorem 5.4.7 (Invertibility and the determinant)
Techniques. det is a polynomial in the entries (Technique 5.3.18)
Hint 1. For (a), if $\dim W > n$, a basis $X_1, \ldots, X_m$ gives more than n vectors $X_k\mathbf{e}_1$ in F^n. A relation among them produces a nonzero singular matrix in W.

Hint 2. For (c), $\det B \neq 0$, and $\det(A + tB)$ is a polynomial in t of degree n with leading coefficient $\det B$. Over $\mathbb{C}$ it has a root. For (d), use that a real polynomial of odd degree has a real root.
Sketch. (a) If $m = \dim W > n$, then $\sum_k c_k X_k \mathbf{e}_1 = \mathbf{0}$ nontrivially, and $X = \sum_k c_k X_k$ is a nonzero matrix of W with $X\mathbf{e}_1 = \mathbf{0}$. (b) $\det = a^2 + b^2$. (c) For independent $A, B \in W$, $B \neq 0$, so $\det B \neq 0$, and $\det(A + tB)$ has degree $n \geq 1$ in t; a root $t_0 \in \mathbb{C}$ gives the nonzero singular $A + t_0 B \in W$. (d) The same with a real root of an odd-degree polynomial.

(a) Suppose $m = \dim W > n$, and let $X_1, \ldots, X_m$ be a basis of W. The m vectors $X_1\mathbf{e}_1, \ldots, X_m\mathbf{e}_1$ lie in F^n, so they are dependent (Theorem 4.1.10): $\sum_k c_k X_k \mathbf{e}_1 = \mathbf{0}$ with not all $c_k = 0$. Let $X = \sum_k c_k X_k \in W$. Since the X_k are independent, $X \neq 0$; but $X\mathbf{e}_1 = \mathbf{0}$, so X is not invertible (Corollary 5.4.8). This contradicts the hypothesis, so $\dim W \leq n$.

(b) $W = \operatorname{span}(I_2, R)$ with $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, so it is a subspace, and I_2, R are independent, so $\dim W = 2$. For $X = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$, $\det X = a^2 + b^2$, which is positive unless $a = b = 0$. So every nonzero $X \in W$ is invertible.

(c) Suppose $\dim W \geq 2$, and let $A, B \in W$ be independent. Then $B \neq 0$, so B is invertible and $\det B \neq 0$. By Exercise 5.5.48 (a), there are $e_0, \ldots, e_n \in \mathbb{C}$ with $\det(A + tB) = e_0 + e_1 t + \cdots + e_n t^n$ for all t, and $e_n = \det B \neq 0$. So $e_0 + e_1 x + \cdots + e_n x^n$ has degree $n \geq 2$, and it has a root $t_0 \in \mathbb{C}$ (Theorem 7.1.32). Then $A + t_0 B \in W$ is singular, and it is nonzero because A and B are independent. This contradicts the hypothesis, so $\dim W \leq 1$. The bound is attained by $W = \operatorname{span}(I_n)$.

(d) For $n = 1$ this is (a). For odd $n \geq 3$, argue as in (c): with A, B independent in W, $g(t) = \det(A + tB) = e_0 + \cdots + e_n t^n$ with real e_k and $e_n = \det B \neq 0$. Since n is odd, $g(t)/t^n \to e_n$ as $t \to \pm\infty$ and t^n changes sign, so g takes both signs, and by the intermediate value theorem $g(t_0) = 0$ for some real t_0. Then $A + t_0 B$ is a nonzero singular matrix in W, a contradiction.

So the largest possible $\dim W$ depends on the field: 1 over $\mathbb{C}$, 1 over $\mathbb{R}$ for odd n, but 2 over $\mathbb{R}$ for $n = 2$, by (b). (For $n = 4$ over $\mathbb{R}$, a construction from the quaternions reaches $\dim W = 4$.)

Solution to Problem 5.18

Uses. Lemma 5.1.8 (Column replacement), Definition 5.1.1 (Determinant function), Proposition 5.3.15 (Triangular matrices)
Techniques. Polynomial identity arguments (Technique 5.5.24), det is a polynomial in the entries (Technique 5.3.18)
Hint 1. Every column of $T_n + tJ$ is a column of T_n plus $t(1, \ldots, 1)$. Subtract column 1 from the others.
Hint 2. An affine function $\alpha + \beta t$ is determined by two of its values. At $t = -a$ and at $t = -b$ the matrix $T_n + tJ$ is triangular.
Sketch. After subtracting column 1 from the others, only column 1 involves t, linearly, so $f(t) = \det(T_n + tJ) = \alpha + \beta t$. $T_n - aJ$ is lower triangular with diagonal $x - a$, and $T_n - bJ$ is upper triangular with diagonal $x - b$, so $f(-a) = (x - a)^n$ and $f(-b) = (x - b)^n$. Solve for $f(0) = \alpha$.

Let $\mathbf{1} = (1, \ldots, 1)$ and let $\mathbf{t}_1, \ldots, \mathbf{t}_n$ be the columns of T_n, so the columns of $T_n + tJ$ are $\mathbf{t}_j + t\mathbf{1}$. Subtracting column 1 from each other column does not change the determinant (Lemma 5.1.8), and leaves the columns $\mathbf{t}_1 + t\mathbf{1}, \mathbf{t}_2 - \mathbf{t}_1, \ldots, \mathbf{t}_n - \mathbf{t}_1$, in which only the first involves t. By linearity in column 1,

$$\begin{aligned} f(t) &= \det(T_n + tJ) \\ &= \det(\mathbf{t}_1, \mathbf{t}_2 - \mathbf{t}_1, \ldots) + t \det(\mathbf{1}, \mathbf{t}_2 - \mathbf{t}_1, \ldots) \\ &= \alpha + \beta t \end{aligned}$$

for constants $\alpha, \beta \in F$. Note $f(0) = \det T_n = \alpha$.

The matrix $T_n - aJ$ has diagonal entries $x - a$, entries 0 above the diagonal, and $b - a$ below it, so it is lower triangular and $f(-a) = (x - a)^n$ (Proposition 5.3.15). Likewise $T_n - bJ$ is upper triangular with diagonal entries $x - b$, so $f(-b) = (x - b)^n$. So

$$\alpha - a\beta = (x - a)^n, \quad \alpha - b\beta = (x - b)^n.$$

Multiplying the first equation by b, the second by a, and subtracting, $(b - a)\alpha = b(x - a)^n - a(x - b)^n$. Since $a \neq b$,

$$\det T_n = \alpha = \frac{b(x-a)^n - a(x-b)^n}{b-a}.$$

For $n = 2$ the formula gives

$$\begin{aligned}\frac{b(x-a)^2 - a(x-b)^2}{b-a} &= \frac{bx^2 + a^2 b - ax^2 - ab^2}{b-a} \\ &= \frac{(b-a)x^2 - ab(b-a)}{b-a} = x^2 - ab,\end{aligned}$$

which is $\det\begin{pmatrix} x & a \\ b & x \end{pmatrix}$. The proof never multiplied anything out: it located two values of t at which the matrix becomes triangular and used that f is determined by two values. When $a = b$ the formula breaks down, and the answer is $(x-a)^{n-1}(x + (n-1)a)$ (compare Example 5.4.24).

Solution to Problem 5.19

Uses. Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.10 (Multiplicativity), Proposition 5.3.15 (Triangular matrices), Definition 1.2.17 (Evaluation), Lemma 5.5.23 (A polynomial with prescribed roots), Proposition 5.3.20 (Reduction modulo p), Exercise 5.5.26
Techniques. Expose a factor with row and column operations (Technique 5.5.22), Factor the matrix (Technique 5.6.1)
Hint 1. For (a), column $k+1$ is column $k+1$ of the Vandermonde matrix plus a combination of earlier columns. Write the matrix as VU with U upper triangular.
Hint 2. For (b), take $p_k(t) = t(t-1)\cdots(t-k+1)$, whose values at integers $x \geq 0$ are $k!\binom{x}{k}$. Translating all x_i by the same integer does not change the product, so you may assume $x_i \geq 0$.
Sketch. (a) $p_k = x^k + \sum_{l<k} u_{lk} x^l$, so the matrix is VU with U upper triangular with 1s on the diagonal; $\det = \det V$. (b) Shift so that all $x_i \geq 0$ and use the falling factorials: the matrix has entries $k!\binom{x_i}{k}$, so $\det V = \left(\prod_k k!\right)\det\left(\binom{x_i}{k}\right)$, and the last determinant is an integer. (c) $\prod_{i<j}(j-i) = 1!2!\cdots(n-1)!$.

(a) Write $p_k = \sum_{l=0}^{k} u_{lk} x^l$ with $u_{kk} = 1$, and set $u_{lk} = 0$ for $l > k$. Let $U \in F^{n\times n}$ have $(l+1, k+1)$ entry u_{lk}; it is upper triangular with 1s on the diagonal, so $\det U = 1$ (Proposition 5.3.15). Let $V = V(x_1, \ldots, x_n)$, with $(i, l+1)$ entry x_i^l. By Definition 1.2.17,

$$p_k(x_i) = \sum_{l=0}^{n-1} x_i^l u_{lk} = (VU)_{i,k+1}.$$

So the matrix in question is VU, and its determinant is $\det V \det U = \det V = \prod_{i<j}(x_j - x_i)$ by Theorem 5.4.10 and Theorem 5.5.21.

(b) Replacing every x_i by $x_i + c$, for an integer c, does not change any difference $x_j - x_i$. So we may assume that every $x_i \geq 0$. For $k \geq 0$, multiplying out the product one factor at a time (as in the proof of Lemma 5.5.23) shows that there is a polynomial $p_k \in \mathbb{Q}[x]$ of degree k, with coefficient 1 of x^k, such that

$$p_k(t) = t(t-1)\cdots(t-k+1) \quad \text{for every } t,$$

with $p_0 = 1$. For an integer $t \geq 0$, $p_k(t) = k!\binom{t}{k}$: if $t \geq k$ this is the formula for $\binom{t}{k}$, and if $t < k$ both sides are 0. By (a),

$$\begin{aligned}\prod_{i<j}(x_j - x_i) &= \det(p_k(x_i)) = \det\left(k!\binom{x_i}{k}\right) \\ &= \left(\prod_{k=0}^{n-1} k!\right)\det\left(\binom{x_i}{k}\right),\end{aligned}$$

pulling the factor $k!$ out of column $k+1$. The matrix $\left(\binom{x_i}{k}\right)$ has integer entries, so its determinant is an integer (Proposition 5.3.20), and $0! \cdot 1! \cdots (n-1)!$ divides the product.

(c) By Exercise 5.5.26 (a), $\prod_{1\le i<j\le n}(j-i) = \det V(1,\dots,n) = 1!\cdot 2!\cdots(n-1)!$. So the quotient in (c) is $\prod_{i<j}(x_j - x_i)$ divided by $0!\cdot 1!\cdots(n-1)!$, which is an integer by (b). For $n=3$ this says that among three integers some two have the same parity; for $n=4$, that the six differences of four integers have a product divisible by 12.

Solution to Problem 5.20

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Proposition 5.3.15 (Triangular matrices), Corollary 5.5.12 (Integer inverses), Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Factor the matrix (Technique 5.6.1)
Hint 1. Apply the identity to $m = \gcd(i,j)$. The divisors of $\gcd(i,j)$ are exactly the common divisors of i and j.
Hint 2. L is lower triangular with 1s on the diagonal. For (c), when is $\prod_k \varphi(k) = 1$?
Sketch. (a) $\left(L\Phi L^{\mathsf T}\right)_{ij} = \sum_{d\mid i,\, d\mid j}\varphi(d) = \sum_{d\mid \gcd(i,j)}\varphi(d) = \gcd(i,j)$. (b) $\det L = 1$, so $\det G_n = \det\Phi$; $\det G_6 = 1\cdot 1\cdot 2\cdot 2\cdot 4\cdot 2 = 32$. (c) $\varphi(d)\ge 1$, so $\det G_n \neq 0$; the inverse is integral iff $\det G_n = \pm 1$, iff $\varphi(k)=1$ for all $k\le n$, iff $n\le 2$.

(a) The (i,j) entry of $L\Phi L^{\mathsf T}$ is

$$\sum_{d=1}^{n} l_{id}\varphi(d)l_{jd} = \sum_{d\le n,\, d\mid i,\, d\mid j}\varphi(d).$$

A common divisor of i and j is at most $i\le n$, so the condition $d\le n$ is automatic, and the common divisors of i and j are exactly the divisors of $\gcd(i,j)$. By the given identity with $m=\gcd(i,j)$, the sum is $\gcd(i,j) = g_{ij}$.

(b) If $d\mid i$ then $d\le i$, so L is lower triangular, and $l_{ii}=1$. So $\det L = \det L^{\mathsf T} = 1$ (Proposition 5.3.15, Theorem 5.4.14), and by Theorem 5.4.10,

$$\det G_n = \det L\det\Phi\det L^{\mathsf T} = \varphi(1)\varphi(2)\cdots\varphi(n).$$

Since $\varphi(1),\dots,\varphi(6) = 1,1,2,2,4,2$, we get $\det G_6 = 32$.

(c) Every $\varphi(d)\ge 1$, since $k=1$ is counted, so $\det G_n \ge 1$ and G_n is invertible (Theorem 5.4.7). By Corollary 5.5.12, G_n^{-1} has integer entries exactly when $\det G_n = \pm 1$, that is, when $\varphi(k)=1$ for every $k\le n$. Since $\varphi(1)=\varphi(2)=1$ and $\varphi(3)=2$, this happens exactly for $n\le 2$.

The factorization is the whole proof. Computing $\det G_n$ by elimination for each n gives no hint of the pattern, while the identity $m=\sum_{d\mid m}\varphi(d)$ says that each entry is a sum of products, which is what Technique 5.6.1 asks for. (This is H. J. S. Smith's determinant, from 1875.)

Section 6.1

Solution to Exercise 6.1.12

Uses. Definition 6.1.8 (Dot product), Proposition 6.1.10 (The dot product is an inner product)
Hint 1. Conjugate the coordinates of the second vector, multiply coordinatewise, and add.
Hint 2. For the last part, expand $(\mathbf{v}-c\mathbf{w})\cdot\mathbf{w}$ by linearity in the first slot; it is a linear equation in c.
Sketch. $\mathbf{v}\cdot\mathbf{w} = -i + (1+i) + (2+2i) = 3+2i$, and $\mathbf{w}\cdot\mathbf{v} = 3-2i$. The squared lengths are $1+1+4=6$ and $1+2+2=5$. Linearity gives $(\mathbf{v}-c\mathbf{w})\cdot\mathbf{w} = (3+2i) - 5c$, so $c = (3+2i)/5$.

By Definition 6.1.8,

$$\mathbf{v}\cdot\mathbf{w} = 1\cdot\bar{i} + i\cdot\overline{(1+i)} + 2\cdot\overline{(1-i)} = -i + i(1-i) + 2(1+i) = -i + (i+1) + (2+2i) = 3+2i,$$

and by conjugate symmetry $\mathbf{w}\cdot\mathbf{v} = \overline{3+2i} = 3-2i$. Directly,

$$\mathbf{w}\cdot\mathbf{v} = i\cdot 1 + (1+i)(-i) + (1-i)2 = i + (1-i) + (2-2i) = 3-2i.$$

By Proposition 6.1.10, $\mathbf{v}\cdot\mathbf{v} = 1+1+4 = 6$ and $\mathbf{w}\cdot\mathbf{w} = 1 + |1+i|^2 + |1-i|^2 = 1+2+2 = 5$.

By linearity in the first slot, $(\mathbf{v}-c\mathbf{w})\cdot\mathbf{w} = \mathbf{v}\cdot\mathbf{w} - c(\mathbf{w}\cdot\mathbf{w}) = (3+2i) - 5c$. This vanishes exactly for $c = (3+2i)/5$.

Solution to Exercise 6.1.20

Uses. Corollary 6.1.19 ($A^*A = 0$ forces $A = 0$)
Techniques. The trace of A^*A (Technique 6.1.18)
Hint 1. Rewrite A^2 using the hypothesis $A^* = A$.
Hint 2. $A^*A = AA = 0$. Now use Corollary 6.1.19.
Sketch. $A^*A = A^2 = 0$, so $A = 0$ by Corollary 6.1.19. Without $A^* = A$ the claim fails for $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.

Since $A^* = A$, we have $A^*A = AA = A^2 = 0$, so $A = 0$ by Corollary 6.1.19. The hypothesis $A^* = A$ cannot be dropped: $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ satisfies $N^2 = 0$ but $N \neq 0$. (Indeed $N^* = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \neq N$.)

Solution to Exercise 6.1.28

Uses. Proposition 6.1.27 (Basic properties of the norm)
Hint 1. By Proposition 6.1.27(b), the condition only involves $|a|$.
Hint 2. $\|a\mathbf{v}\| = 1$ if and only if $|a| = 1/\|\mathbf{v}\|$. How many real numbers, and which complex numbers, have a given modulus?
Sketch. $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$, so the condition is $|a| = 1/\|\mathbf{v}\|$. Over $\mathbb{R}$ this gives $a = \pm 1/\|\mathbf{v}\|$; over $\mathbb{C}$ it gives the circle of radius $1/\|\mathbf{v}\|$ centred at 0.

By Proposition 6.1.27, $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$, and $\|\mathbf{v}\| > 0$ since $\mathbf{v} \neq \mathbf{0}$. So $\|a\mathbf{v}\| = 1$ if and only if $|a| = 1/\|\mathbf{v}\|$. Over $\mathbb{R}$ there are exactly two such scalars, $a = 1/\|\mathbf{v}\|$ and $a = -1/\|\mathbf{v}\|$. Over $\mathbb{C}$ there are infinitely many: all $a = s + ti$ with $s^2 + t^2 = 1/\|\mathbf{v}\|^2$, a circle of radius $1/\|\mathbf{v}\|$ about 0 in the complex plane. So a nonzero vector in a complex space has a whole circle of normalizations, which differ by factors of modulus 1.

Solution to Exercise 6.1.31

Uses. Proposition 6.1.30 (Parallelogram law), Proposition 6.1.29 (Expanding a norm)
Hint 1. The parallelogram law relates the four given or unknown norms.
Hint 2. For the real part, solve the expansion of $\|\mathbf{x} + \mathbf{y}\|^2$ for $\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$.
Sketch. $\|\mathbf{x} - \mathbf{y}\|^2 = 2 \cdot 9 + 2 \cdot 16 - 36 = 14$, and $36 = 9 + 2\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle + 16$ gives $\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle = 11/2$.

By Proposition 6.1.30,

$$\|\mathbf{x} - \mathbf{y}\|^2 = 2\|\mathbf{x}\|^2 + 2\|\mathbf{y}\|^2 - \|\mathbf{x} + \mathbf{y}\|^2 = 18 + 32 - 36 = 14,$$

so $\|\mathbf{x} - \mathbf{y}\| = \sqrt{14}$. By Proposition 6.1.29, $36 = 9 + 2\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle + 16$, so $\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle = 11/2$. (As a check, Proposition 6.1.29 with the minus sign gives $9 - 11 + 16 = 14$.)

Solution to Exercise 6.1.35

Uses. Proposition 6.1.32 (Polarization identities), Proposition 6.1.30 (Parallelogram law)
Techniques. Polarization (Technique 6.1.33)
Hint 1. Substitute into Proposition 6.1.32(b).
Hint 2. For $\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2$, use the parallelogram law, for the pair $\mathbf{x}, \mathbf{y}$ or for the pair $\mathbf{x}, i\mathbf{y}$.
Sketch. $\langle \mathbf{x}, \mathbf{y}\rangle = (10 - 2 + 4i - 8i)/4 = 2 - i$. The parallelogram law gives $2\left(\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2\right) = 10 + 2 = 12$, so the sum is 6.

By Proposition 6.1.32(b),

$$\langle \mathbf{x}, \mathbf{y}\rangle = \frac{1}{4}(10 - 2 + 4i - 8i) = \frac{1}{4}(8 - 4i) = 2 - i.$$

By Proposition 6.1.30, $2\|\mathbf{x}\|^2 + 2\|\mathbf{y}\|^2 = 10 + 2 = 12$, so $\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 = 6$. The data are consistent: the parallelogram law for $\mathbf{x}$ and $i\mathbf{y}$, where $\|i\mathbf{y}\| = \|\mathbf{y}\|$, gives $4 + 8 = 12$ as well.

Solution to Exercise 6.1.42

Uses. Definition 6.1.2 (Inner product), Proposition 6.1.22 (Inner products on $\mathbb{F}^n$), Proposition 6.1.4 (Sesquilinearity), Definition 1.2.17 (Evaluation)
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. (a) and (e) have the form $\mathbf{y}^* M \mathbf{x}$; write down M and use Proposition 6.1.22. To show $\mathbf{x}^* M \mathbf{x} > 0$, complete squares.
Hint 2. (b) Look for a nonzero matrix with $\langle A, A\rangle = 0$. (c) Compute $\langle \mathbf{e}_2, \mathbf{e}_2\rangle$.
Hint 3. (d) A polynomial $a + bx + cx^2$ that vanishes at -1, 0, and 1: solve for a, b, c. (e) Try to write $\mathbf{x}^* M \mathbf{x}$ as $|x_1|^2 + |x_2 + ix_1|^2$.

Sketch. (a) Yes: M is symmetric and $\mathbf{x}^{\mathsf{T}}M\mathbf{x} = (x_1+x_3)^2 + 2x_2^2 + 2x_3^2$. (b) No: $A = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \neq 0$ has $\langle A, A\rangle = 0$. (c) No: $\langle \mathbf{e}_2, \mathbf{e}_2\rangle = i$ is not real. (d) Yes: it is symmetric, bilinear, a sum of squares on the diagonal, and a polynomial of degree at most 2 vanishing at three points is 0. (e) Yes: $M = \begin{pmatrix} 2 & -i \\ i & 1 \end{pmatrix}$ is self-conjugate-transpose and $\mathbf{x}^*M\mathbf{x} = |x_1|^2 + |x_2 + ix_1|^2$.

(a) Yes. The formula is $\mathbf{y}^{\mathsf{T}}M\mathbf{x}$ with $M = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 3 \end{pmatrix}$, which is symmetric, and

$$\mathbf{x}^{\mathsf{T}}M\mathbf{x} = x_1^2 + 2x_2^2 + 3x_3^2 + 2x_1x_3 = (x_1+x_3)^2 + 2x_2^2 + 2x_3^2.$$

This is a sum of nonnegative terms, and it is 0 only if $x_2 = x_3 = 0$ and $x_1 + x_3 = 0$, that is, $\mathbf{x} = \mathbf{0}$. By Proposition 6.1.22(b), it is an inner product.

(b) No. Definiteness fails: $A = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ is nonzero, but $\langle A, A\rangle = \operatorname{tr}(A)^2 = 0$. (The formula is symmetric, bilinear, and positive.)

(c) No. $\langle \mathbf{e}_2, \mathbf{e}_2\rangle = i$ is not a nonnegative real number, so positivity fails. (Conjugate symmetry fails as well, since $\bar{i} \neq i$.)

(d) Yes. Evaluation at a point is linear (Definition 1.2.17), so the formula is linear in p, and it is visibly symmetric. Also $\langle p, p\rangle = p(-1)^2 + p(0)^2 + p(1)^2 \geq 0$. If $\langle p, p\rangle = 0$, each term vanishes, so $p = a + bx + cx^2$ satisfies $p(0) = a = 0$, $p(1) = a + b + c = 0$, and $p(-1) = a - b + c = 0$. Then $b + c = 0$ and $-b + c = 0$, so $b = c = 0$ and $p = \mathbf{0}$.

(e) Yes. Reading off the coefficient of $\overline{y_i}x_j$ as m_{ij}, the formula is $\mathbf{y}^*M\mathbf{x}$ with $M = \begin{pmatrix} 2 & -i \\ i & 1 \end{pmatrix}$. The conjugate transpose of M is $\begin{pmatrix} \overline{2} & \overline{i} \\ \overline{-i} & \overline{1} \end{pmatrix} = \begin{pmatrix} 2 & -i \\ i & 1 \end{pmatrix} = M$. Also,

$$\mathbf{x}^*M\mathbf{x} = 2|x_1|^2 - i\overline{x_1}x_2 + ix_1\overline{x_2} + |x_2|^2.$$

On the other hand, by Proposition 6.1.29 in $\mathbb{C}^1$ (or by direct expansion), $|x_2 + ix_1|^2 = |x_2|^2 + ix_1\overline{x_2} - i\overline{x_1}x_2 + |x_1|^2$. Hence $\mathbf{x}^*M\mathbf{x} = |x_1|^2 + |x_2 + ix_1|^2$, which is 0 only if $x_1 = 0$ and then $x_2 = 0$. By Proposition 6.1.22(b), this is an inner product.

Solution to Exercise 6.1.43

Uses. Proposition 6.1.13 (Integral inner products), Lemma 6.1.14 (Nonnegative functions with zero integral)
Hint 1. In each case symmetry and bilinearity come from the integral. Only positivity and definiteness need thought.
Hint 2. (b) Find f that is large where $t < 0$ and small where $t > 0$. (c) Find a nonzero continuous function that vanishes on $[0, 1/2]$.
Hint 3. For (a) and (d), use Lemma 6.1.14 (on the relevant interval), then continuity or the mean value theorem.
Sketch. (a) Yes: $t^2 f(t)^2 = 0$ for all t forces $f = 0$ off 0, and then at 0 by continuity. (b) No: $f(t) = 1 - t$ gives $\langle f, f\rangle = -4/3$. (c) No: $f(t) = \max(0, t - 1/2)$ is nonzero with $\langle f, f\rangle = 0$. (d) Yes: $\langle f, f\rangle = 0$ gives $f(0) = 0$ and $f' = 0$, so $f = 0$.

In all four cases the formula is symmetric and bilinear, by linearity of the integral and of $f \mapsto f'$. So only positivity and definiteness are at stake.

(a) Yes. $\langle f, f\rangle = \int_{-1}^{1} t^2 f(t)^2 \, dt \geq 0$, as the integrand is continuous and nonnegative. If $\langle f, f\rangle = 0$, then Lemma 6.1.14 (on $[-1, 1]$) gives $t^2 f(t)^2 = 0$ for all t, so $f(t) = 0$ for all $t \neq 0$. By continuity, $f(0) = \lim_{t\to 0} f(t) = 0$ as well. So $f = 0$.

(b) No. Positivity fails for $f(t) = 1 - t$:

$$\langle f, f\rangle = \int_{-1}^{1} t(1-t)^2 \, dt = \int_{-1}^{1} \left(t - 2t^2 + t^3\right) dt = 0 - \frac{4}{3} + 0 = -\frac{4}{3} < 0.$$

(c) No. Definiteness fails: $f(t) = \max(0, t - 1/2)$ is continuous and nonzero, but $f = 0$ on $[0, 1/2]$, so $\langle f, f\rangle = 0$. (Positivity does hold.)

(d) Yes. $\langle f, f\rangle = f(0)^2 + \int_0^1 f'(t)^2\,dt \geq 0$. If $\langle f, f\rangle = 0$, both nonnegative terms vanish. So $f(0) = 0$, and Lemma 6.1.14 applied to the continuous function $(f')^2$ gives $f' = 0$ on $[0, 1]$. By the mean value theorem f is constant, so $f = f(0) = 0$. Without the term $f(0)g(0)$, definiteness would fail for the constant function 1.

Solution to Exercise 6.1.44

Uses. Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.29 (Expanding a norm)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Expand each inner product into the four values $\langle \mathbf{x}, \mathbf{x}\rangle = 1$, $\langle \mathbf{x}, \mathbf{y}\rangle = 1 - i$, $\langle \mathbf{y}, \mathbf{x}\rangle = 1 + i$, $\langle \mathbf{y}, \mathbf{y}\rangle = 4$. Scalars leave the second slot conjugated.
Hint 2. For (b) and (c), Proposition 6.1.29 saves work: $\|\mathbf{x} + a\mathbf{y}\|^2 = \|\mathbf{x}\|^2 + 2\,\mathrm{Re}(\bar{a}\langle \mathbf{x}, \mathbf{y}\rangle) + |a|^2\|\mathbf{y}\|^2$.
Sketch. (a) $2 - 2(1 - i) + i(1 + i) - 4i = -1 - i$. (b) $1 + 2\,\mathrm{Re}(i(1 - i)) + 4 = 7$. (c) $|1 + i|^2 + 2\,\mathrm{Re}((1 + i)(1 - i)) + 4 = 10$. (d) $c = (1 - i)/4$ and $\|\mathbf{x} - c\mathbf{y}\|^2 = 1 - 1 + 1/2 = 1/2$.

We use $\langle \mathbf{x}, \mathbf{x}\rangle = 1$, $\langle \mathbf{y}, \mathbf{y}\rangle = 4$, $\langle \mathbf{x}, \mathbf{y}\rangle = 1 - i$, and $\langle \mathbf{y}, \mathbf{x}\rangle = \overline{1 - i} = 1 + i$.

(a) Expanding,

$$\begin{aligned}\langle 2\mathbf{x} + i\mathbf{y}, \mathbf{x} - \mathbf{y}\rangle &= 2\langle \mathbf{x}, \mathbf{x}\rangle - 2\langle \mathbf{x}, \mathbf{y}\rangle + i\langle \mathbf{y}, \mathbf{x}\rangle - i\langle \mathbf{y}, \mathbf{y}\rangle \\ &= 2 - (2 - 2i) + (i - 1) - 4i = -1 - i.\end{aligned}$$

(b) By Proposition 6.1.29 with $a = -i$, $\bar{a} = i$, and $|a| = 1$,

$$\|\mathbf{x} - i\mathbf{y}\|^2 = 1 + 2\,\mathrm{Re}(i(1 - i)) + 4 = 1 + 2\,\mathrm{Re}(1 + i) + 4 = 7.$$

(c) Here the scalar sits on $\mathbf{x}$, so we expand directly:

$$\|(1 + i)\mathbf{x} + \mathbf{y}\|^2 = |1 + i|^2\langle \mathbf{x}, \mathbf{x}\rangle + (1 + i)\langle \mathbf{x}, \mathbf{y}\rangle + \overline{(1 + i)}\langle \mathbf{y}, \mathbf{x}\rangle + \langle \mathbf{y}, \mathbf{y}\rangle,$$

which is

$$2 + (1 + i)(1 - i) + (1 - i)(1 + i) + 4 = 2 + 2 + 2 + 4 = 10.$$

(d) By linearity in the first slot, $\langle \mathbf{x} - c\mathbf{y}, \mathbf{y}\rangle = (1 - i) - 4c$, which vanishes exactly for $c = (1 - i)/4$. Then $\bar{c}\langle \mathbf{x}, \mathbf{y}\rangle = (1 + i)(1 - i)/4 = 1/2$ and $|c|^2 = 2/16 = 1/8$, so by Proposition 6.1.29 with $a = -c$,

$$\|\mathbf{x} - c\mathbf{y}\|^2 = 1 - 2 \cdot \frac{1}{2} + \frac{1}{8} \cdot 4 = \frac{1}{2}.$$

Solution to Exercise 6.1.45

Uses. Proposition 6.1.22 (Inner products on $\mathbb{F}^n$), Proposition 6.1.29 (Expanding a norm), Proposition 6.1.30 (Parallelogram law)
Techniques. Polarization (Technique 6.1.33)
Hint 1. By Proposition 6.1.22(a), an inner product on $\mathbb{R}^2$ is determined by $\langle \mathbf{e}_1, \mathbf{e}_1\rangle$, $\langle \mathbf{e}_2, \mathbf{e}_2\rangle$, and $c = \langle \mathbf{e}_1, \mathbf{e}_2\rangle$. Find c from $\|\mathbf{e}_1 + \mathbf{e}_2\|^2$.
Hint 2. In (a), you must also check that the matrix you find gives an inner product: complete the square.
Hint 3. In (c), the same computation forces a value of c. Find a vector $\mathbf{x}$ with $\langle \mathbf{x}, \mathbf{x}\rangle < 0$ for that value.
Sketch. (a) $4 = 1 + 2c + 4$ forces $c = -1/2$, so $\langle \mathbf{x}, \mathbf{y}\rangle = x_1y_1 - (x_1y_2 + x_2y_1)/2 + 4x_2y_2$, which is an inner product because $x_1^2 - x_1x_2 + 4x_2^2 = (x_1 - x_2/2)^2 + 15x_2^2/4$. (b) Both give $\|\mathbf{e}_1 - \mathbf{e}_2\|^2 = 6$. (c) $16 = 5 + 2c$ forces $c = 11/2$, and then $(2, -1)$ would have $\langle \mathbf{x}, \mathbf{x}\rangle = 4 - 22 + 4 < 0$.

(a) Suppose $\langle \cdot, \cdot\rangle$ is such an inner product, and let $c = \langle \mathbf{e}_1, \mathbf{e}_2\rangle = \langle \mathbf{e}_2, \mathbf{e}_1\rangle$ (it is real and symmetric). By Proposition 6.1.29, $\|\mathbf{e}_1 + \mathbf{e}_2\|^2 = 1 + 2c + 4$, so $4 = 5 + 2c$ and $c = -1/2$. By Proposition 6.1.22(a), $\langle \mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}}M\mathbf{x}$ with $M = \begin{pmatrix} 1 & -1/2 \\ -1/2 & 4 \end{pmatrix}$, that is,

$$\langle \mathbf{x}, \mathbf{y}\rangle = x_1y_1 - \frac{1}{2}(x_1y_2 + x_2y_1) + 4x_2y_2.$$

So there is at most one such inner product. Conversely, M is symmetric and

$$\mathbf{x}^{\mathsf{T}} M\mathbf{x} = x_1^2 - x_1x_2 + 4x_2^2 = \left(x_1 - \frac{x_2}{2}\right)^2 + \frac{15}{4}x_2^2,$$

which is positive unless $x_2 = 0$ and $x_1 = x_2/2 = 0$. By Proposition 6.1.22(b), this is an inner product, and it has $\|\mathbf{e}_1\|^2 = 1$, $\|\mathbf{e}_2\|^2 = 4$, and $\|\mathbf{e}_1 + \mathbf{e}_2\|^2 = 1 - 1 + 4 = 4$, as required.

(b) From the formula, $\|\mathbf{e}_1 - \mathbf{e}_2\|^2 = 1 - 2c + 4 = 1 + 1 + 4 = 6$. From Proposition 6.1.30, $\|\mathbf{e}_1 - \mathbf{e}_2\|^2 = 2 \cdot 1 + 2 \cdot 4 - 4 = 6$. So $\|\mathbf{e}_1 - \mathbf{e}_2\| = \sqrt{6}$.

(c) Suppose such an inner product exists. The argument of (a) gives $16 = 5 + 2c$, so $c = 11/2$, and $\langle \mathbf{x}, \mathbf{x}\rangle = x_1^2 + 11x_1x_2 + 4x_2^2$ for all $\mathbf{x}$. For $\mathbf{x} = (2, -1)$ this is $4 - 22 + 4 = -14 < 0$, contradicting positivity. (In Section 6.2 this also follows from the triangle inequality, as $4 > 1 + 2$.)

Solution to Exercise 6.1.46

Uses. Proposition 6.1.22 (Inner products on $\mathbb{F}^n$)
Techniques. Plug in clever test vectors (Technique 6.1.40), A sum of nonnegative terms (Technique 6.1.9)
Hint 1. The formula is $\mathbf{y}^{\mathsf{T}} M\mathbf{x}$ for the symmetric matrix $M = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$, so by Proposition 6.1.22 the question is when $q(\mathbf{x}) = ax_1^2 + 2bx_1x_2 + cx_2^2 > 0$ for all $\mathbf{x} \neq \mathbf{0}$.
Hint 2. Necessary conditions come from test vectors: try $\mathbf{e}_1$, and then a vector that makes the cross term as harmful as possible, such as $(-b, a)$.
Hint 3. For sufficiency, when $a > 0$, complete the square in $aq(\mathbf{x})$.
Sketch. Exactly when $a > 0$ and $ac - b^2 > 0$. Necessity: $q(\mathbf{e}_1) = a$ and $q(-b, a) = a\big(ac - b^2\big)$. Sufficiency: $aq(\mathbf{x}) = (ax_1 + bx_2)^2 + \big(ac - b^2\big)x_2^2$.

The formula is $\mathbf{y}^{\mathsf{T}} M\mathbf{x}$ with $M = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$, which is symmetric. By Proposition 6.1.22(b), it is an inner product if and only if $q(\mathbf{x}) = \mathbf{x}^{\mathsf{T}} M\mathbf{x} = ax_1^2 + 2bx_1x_2 + cx_2^2$ is positive for all $\mathbf{x} \neq \mathbf{0}$. We show that this happens exactly when $a > 0$ and $ac - b^2 > 0$.

Suppose $q(\mathbf{x}) > 0$ for all $\mathbf{x} \neq \mathbf{0}$. Then $a = q(\mathbf{e}_1) > 0$. The vector $(-b, a)$ is nonzero since $a \neq 0$, and

$$q(-b, a) = ab^2 - 2b \cdot ba + ca^2 = a\big(ac - b^2\big),$$

which is positive; dividing by $a > 0$ gives $ac - b^2 > 0$.

Conversely, suppose $a > 0$ and $ac - b^2 > 0$. Completing the square,

$$aq(\mathbf{x}) = a^2x_1^2 + 2abx_1x_2 + acx_2^2 = (ax_1 + bx_2)^2 + \big(ac - b^2\big)x_2^2.$$

Both terms are nonnegative, so $aq(\mathbf{x}) \geq 0$, and it is 0 only if $x_2 = 0$ and $ax_1 + bx_2 = 0$, that is, $\mathbf{x} = \mathbf{0}$. Since $a > 0$, $q(\mathbf{x}) > 0$ for $\mathbf{x} \neq \mathbf{0}$.

The number $ac - b^2$ is $\det M$; Section 12.3 extends this test to $n \times n$ matrices.

Solution to Exercise 6.1.47

Uses. Notation 6.1.7 (Conjugate transpose), Notation 6.1.1 (Real and complex scalars)
Techniques. Plug in clever test vectors (Technique 6.1.40)
Hint 1. Compute $\mathbf{x}^* M\mathbf{x}$ for $\mathbf{x} = \mathbf{e}_j$, $\mathbf{e}_j + \mathbf{e}_k$, and $\mathbf{e}_j + i\mathbf{e}_k$.
Hint 2. With $\mathbf{x} = \mathbf{e}_j + \mathbf{e}_k$ you learn that $m_{jk} + m_{kj}$ is real; with $\mathbf{e}_j + i\mathbf{e}_k$, that $i\big(m_{jk} - m_{kj}\big)$ is real. What do these say about real and imaginary parts?
Sketch. $\mathbf{e}_j^* M\mathbf{e}_j = m_{jj}$ is real. For $j \neq k$, $\mathbf{x} = \mathbf{e}_j + \mathbf{e}_k$ gives $m_{jk} + m_{kj} \in \mathbb{R}$, so $\operatorname{Im} m_{jk} = -\operatorname{Im} m_{kj}$; and $\mathbf{x} = \mathbf{e}_j + i\mathbf{e}_k$ gives $i\big(m_{jk} - m_{kj}\big) \in \mathbb{R}$, so $\operatorname{Re} m_{jk} = \operatorname{Re} m_{kj}$. Together, $m_{jk} = \overline{m_{kj}}$.

For $\mathbf{x} \in \mathbb{C}^n$, $\mathbf{x}^* M\mathbf{x} = \sum_{p,q} \overline{x_p} m_{pq} x_q$. Fix j. For $\mathbf{x} = \mathbf{e}_j$ this is m_{jj}, so $m_{jj} \in \mathbb{R}$, that is, $m_{jj} = \overline{m_{jj}}$.

Now fix $j \neq k$. For $\mathbf{x} = \mathbf{e}_j + \mathbf{e}_k$, only the terms with $p, q \in \{j, k\}$ survive, and

$$\mathbf{x}^* M\mathbf{x} = m_{jj} + m_{jk} + m_{kj} + m_{kk}.$$

Since this and m_{jj}, m_{kk} are real, $m_{jk} + m_{kj} \in \mathbb{R}$, so $\operatorname{Im} m_{jk} = -\operatorname{Im} m_{kj}$. For $\mathbf{x} = \mathbf{e}_j + i\mathbf{e}_k$ we have $x_j = 1$ and $x_k = i$, so

$$\mathbf{x}^* M\mathbf{x} = m_{jj} + m_{jk}i + \bar{i}m_{kj} + \bar{i}m_{kk}i = m_{jj} + i\big(m_{jk} - m_{kj}\big) + m_{kk}.$$

So $i\big(m_{jk} - m_{kj}\big)$ is real, which means $m_{jk} - m_{kj}$ has real part 0: $\operatorname{Re} m_{jk} = \operatorname{Re} m_{kj}$. Together, $m_{jk} = \operatorname{Re} m_{kj} - i \operatorname{Im} m_{kj} = \overline{m_{kj}}$. Hence the (k, j) entry of M^*, which is $\overline{m_{jk}}$, equals m_{kj}, and $M^* = M$.

If $\mathbf{x}^* M\mathbf{x} > 0$ for every $\mathbf{x} \neq \mathbf{0}$, then $\mathbf{x}^* M\mathbf{x}$ is real for every $\mathbf{x}$ (it is 0 at $\mathbf{0}$), so $M^* = M$ by what we just proved.

Solution to Exercise 6.1.48

Uses. Proposition 6.1.30 (Parallelogram law), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. Write $\mathbf{z} - \mathbf{x}$ and $\mathbf{z} - \mathbf{y}$ as $\mathbf{u} + \mathbf{w}$ and $\mathbf{u} - \mathbf{w}$ for suitable $\mathbf{u}, \mathbf{w}$.
Hint 2. Take $\mathbf{u} = \mathbf{z} - \mathbf{m}$ and $\mathbf{w} = (\mathbf{y} - \mathbf{x})/2$, then apply the parallelogram law.
Sketch. With $\mathbf{u} = \mathbf{z} - \mathbf{m}$ and $\mathbf{w} = (\mathbf{y} - \mathbf{x})/2$, we have $\mathbf{z} - \mathbf{x} = \mathbf{u} + \mathbf{w}$ and $\mathbf{z} - \mathbf{y} = \mathbf{u} - \mathbf{w}$. The parallelogram law gives $2\|\mathbf{u}\|^2 + 2\|\mathbf{w}\|^2$, and $2\|\mathbf{w}\|^2 = \|\mathbf{x} - \mathbf{y}\|^2/2$.

Let $\mathbf{u} = \mathbf{z} - \mathbf{m}$ and $\mathbf{w} = (\mathbf{y} - \mathbf{x})/2$. Since $\mathbf{m} - \mathbf{x} = (\mathbf{y} - \mathbf{x})/2 = \mathbf{w}$ and $\mathbf{m} - \mathbf{y} = (\mathbf{x} - \mathbf{y})/2 = -\mathbf{w}$,

$$\mathbf{z} - \mathbf{x} = (\mathbf{z} - \mathbf{m}) + (\mathbf{m} - \mathbf{x}) = \mathbf{u} + \mathbf{w}, \quad \mathbf{z} - \mathbf{y} = \mathbf{u} - \mathbf{w}.$$

By Proposition 6.1.30 and Proposition 6.1.27(b),

$$\|\mathbf{z} - \mathbf{x}\|^2 + \|\mathbf{z} - \mathbf{y}\|^2 = 2\|\mathbf{u}\|^2 + 2\|\mathbf{w}\|^2 = 2\|\mathbf{z} - \mathbf{m}\|^2 + 2 \cdot \frac{1}{4}\|\mathbf{y} - \mathbf{x}\|^2,$$

which is the identity, since $\|\mathbf{y} - \mathbf{x}\| = \|\mathbf{x} - \mathbf{y}\|$.

In $\mathbb{R}^2$, $\mathbf{m}$ is the midpoint of the side from $\mathbf{x}$ to $\mathbf{y}$, and $\|\mathbf{z} - \mathbf{m}\|$ is the length of the median from $\mathbf{z}$. The identity expresses the length of a median through the three side lengths:

$$\|\mathbf{z} - \mathbf{m}\|^2 = \frac{1}{4}\Big(2\|\mathbf{z} - \mathbf{x}\|^2 + 2\|\mathbf{z} - \mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2\Big).$$

Solution to Exercise 6.1.49

Uses. Proposition 6.1.4 (Sesquilinearity), Notation 6.1.1 (Real and complex scalars)
Hint 1. Expand $\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle$ into four terms.
Hint 2. The two cross terms are $-\langle \mathbf{x}, \mathbf{y} \rangle$ and $\langle \mathbf{y}, \mathbf{x} \rangle = \overline{\langle \mathbf{x}, \mathbf{y} \rangle}$, whose sum is $-2i \operatorname{Im}\langle \mathbf{x}, \mathbf{y} \rangle$.
Sketch. $\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = \big(\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\big) - 2i \operatorname{Im}\langle \mathbf{x}, \mathbf{y} \rangle$. Its real part is $\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2$, and it vanishes exactly when both the real part and $\operatorname{Im}\langle \mathbf{x}, \mathbf{y} \rangle$ do. In $\mathbb{R}^2$: a parallelogram is a rhombus if and only if its diagonals are perpendicular.

Expanding with linearity in the first slot and Proposition 6.1.4,

$$\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = \|\mathbf{x}\|^2 - \langle \mathbf{x}, \mathbf{y} \rangle + \langle \mathbf{y}, \mathbf{x} \rangle - \|\mathbf{y}\|^2.$$

With $z = \langle \mathbf{x}, \mathbf{y} \rangle$, conjugate symmetry gives $-z + \bar{z} = -2i \operatorname{Im} z$, so

$$\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = \big(\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\big) - 2i \operatorname{Im}\langle \mathbf{x}, \mathbf{y} \rangle.$$

(a) The real part of the right side is $\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2$, which is 0 if and only if $\|\mathbf{x}\| = \|\mathbf{y}\|$ (norms are nonnegative). In $\mathbb{R}^2$ with the dot product, $\mathbf{x} + \mathbf{y}$ and $\mathbf{x} - \mathbf{y}$ are the diagonals of the parallelogram on $\mathbf{x}$ and $\mathbf{y}$, so (a) says that the parallelogram is a rhombus (all sides equal) if and only if its diagonals are perpendicular, provided $\mathbf{x}, \mathbf{y}$ are linearly independent so that the parallelogram is not degenerate.

(b) A complex number is 0 if and only if its real and imaginary parts are. So $\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = 0$ if and only if $\|\mathbf{x}\| = \|\mathbf{y}\|$ and $\operatorname{Im}\langle \mathbf{x}, \mathbf{y} \rangle = 0$, that is, $\langle \mathbf{x}, \mathbf{y} \rangle \in \mathbb{R}$. For instance, $\mathbf{x} = (1, 0)$ and $\mathbf{y} = (0, 1)$ in $\mathbb{C}^2$ qualify, but $\mathbf{x} = (1)$ and $\mathbf{y} = (i)$ in $\mathbb{C}^1$ do not: they have equal norms, while $\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = (1 + i)\overline{(1 - i)} = (1 + i)^2 = 2i$.

Solution to Exercise 6.1.50

Uses. Proposition 6.1.37 (Inner products distinguish vectors), Proposition 6.1.4 (Sesquilinearity), Definition 1.3.10 (Span)
Techniques. Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. By Proposition 6.1.37, it suffices to show $\langle \mathbf{x} - \mathbf{y}, \mathbf{w} \rangle = 0$ for every $\mathbf{w} \in V$.
Hint 2. Write $\mathbf{w} = \sum_j c_j \mathbf{v}_j$ and expand the second slot with Proposition 6.1.4.

Sketch. Every $\mathbf{w} = \sum_j c_j \mathbf{v}_j$, so $\langle \mathbf{x}-\mathbf{y}, \mathbf{w}\rangle = \sum_j \overline{c_j}\langle \mathbf{x}-\mathbf{y}, \mathbf{v}_j\rangle = 0$, and Proposition 6.1.37 gives $\mathbf{x} = \mathbf{y}$. In $\mathbb{R}^2$ with the list $\mathbf{e}_1$, the vectors $\mathbf{e}_2$ and $\mathbf{0}$ have the same inner product with $\mathbf{e}_1$.

Let $\mathbf{u} = \mathbf{x} - \mathbf{y}$, so that $\langle \mathbf{u}, \mathbf{v}_j\rangle = 0$ for every j. Let $\mathbf{w} \in V$. Since the list spans V, $\mathbf{w} = \sum_j c_j \mathbf{v}_j$ for some scalars c_j, and by Proposition 6.1.4,

$$\langle \mathbf{u}, \mathbf{w}\rangle = \sum_{j=1}^{k} \overline{c_j}\langle \mathbf{u}, \mathbf{v}_j\rangle = 0 = \langle \mathbf{0}, \mathbf{w}\rangle.$$

By Proposition 6.1.37, $\mathbf{u} = \mathbf{0}$, that is, $\mathbf{x} = \mathbf{y}$.

Without the spanning hypothesis the conclusion fails: in $\mathbb{R}^2$ with the list consisting of $\mathbf{e}_1$ alone, $\langle \mathbf{e}_2, \mathbf{e}_1\rangle = 0 = \langle \mathbf{0}, \mathbf{e}_1\rangle$, but $\mathbf{e}_2 \neq \mathbf{0}$.

Solution to Exercise 6.1.51

Uses. Proposition 6.1.32 (Polarization identities), Proposition 6.1.27 (Basic properties of the norm), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Polarization (Technique 6.1.33)
Hint 1. Express $\langle T\mathbf{v}, T\mathbf{w}\rangle$ through norms with Proposition 6.1.32.
Hint 2. Each norm that appears is $\|T\mathbf{v} + cT\mathbf{w}\| = \|T(\mathbf{v} + c\mathbf{w})\|$. For injectivity, look at the kernel.
Sketch. By polarization in W and linearity, $\langle T\mathbf{v}, T\mathbf{w}\rangle$ is a combination of the numbers $\|T(\mathbf{v} + c\mathbf{w})\|^2 = \|\mathbf{v} + c\mathbf{w}\|^2$, which is the same combination that polarization in V gives for $\langle \mathbf{v}, \mathbf{w}\rangle$. If $T\mathbf{v} = \mathbf{0}$, then $\|\mathbf{v}\| = \|T\mathbf{v}\| = 0$.

Suppose $\mathbb{F} = \mathbb{C}$; the real case is the same with c ranging over ± 1 and the coefficients of Proposition 6.1.32(a). For $c \in \mathbb{C}$, linearity gives $T\mathbf{v} + cT\mathbf{w} = T(\mathbf{v} + c\mathbf{w})$, so by hypothesis $\|T\mathbf{v} + cT\mathbf{w}\| = \|\mathbf{v} + c\mathbf{w}\|$. By Proposition 6.1.32 in W and then in V,

$$\langle T\mathbf{v}, T\mathbf{w}\rangle = \frac{1}{4}\sum_{k=0}^{3} i^k \left\|T\mathbf{v} + i^k T\mathbf{w}\right\|^2 = \frac{1}{4}\sum_{k=0}^{3} i^k \left\|\mathbf{v} + i^k \mathbf{w}\right\|^2 = \langle \mathbf{v}, \mathbf{w}\rangle.$$

For injectivity, if $T\mathbf{v} = \mathbf{0}$, then $\|\mathbf{v}\| = \|T\mathbf{v}\| = 0$, so $\mathbf{v} = \mathbf{0}$ by Proposition 6.1.27. So $\ker T = \{\mathbf{0}\}$, and T is injective by Theorem 2.6.11.

Solution to Exercise 6.1.52

Uses. Example 6.1.39 (A rotation), Corollary 6.1.38 (Linear maps are determined by inner products), Proposition 6.1.4 (Sesquilinearity)
Techniques. Plug in clever test vectors (Technique 6.1.40)
Hint 1. (a) Look at Example 6.1.39.
Hint 2. (b) Apply the hypothesis to $\mathbf{v} + \mathbf{w}$, and use that a real inner product is symmetric.
Hint 3. (c) Combine (b) with the hypothesis to get $\langle T\mathbf{v}, \mathbf{w}\rangle = -\langle T\mathbf{v}, \mathbf{w}\rangle$.
Sketch. (a) False: the rotation by $\pi/2$ on $\mathbb{R}^2$. (b) Expanding $\langle T(\mathbf{v}+\mathbf{w}), \mathbf{v}+\mathbf{w}\rangle = 0$ gives $\langle T\mathbf{v}, \mathbf{w}\rangle + \langle T\mathbf{w}, \mathbf{v}\rangle = 0$, and $\langle T\mathbf{w}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle$ by symmetry; conversely put $\mathbf{w} = \mathbf{v}$. (c) Then $\langle T\mathbf{v}, \mathbf{w}\rangle = -\langle T\mathbf{v}, \mathbf{w}\rangle$, so it is 0 and $T = 0$.

(a) False. The rotation $T\mathbf{x} = (-x_2, x_1)$ of $\mathbb{R}^2$ satisfies $\langle T\mathbf{x}, \mathbf{x}\rangle = 0$ for every $\mathbf{x}$ but is not 0 (Example 6.1.39).

(b) Suppose $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$. For $\mathbf{v}, \mathbf{w} \in V$, expanding as in the proof of Proposition 6.1.41,

$$0 = \langle T(\mathbf{v}+\mathbf{w}), \mathbf{v}+\mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle + \langle T\mathbf{w}, \mathbf{v}\rangle.$$

A real inner product is symmetric, so $\langle T\mathbf{w}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle$, and hence $\langle T\mathbf{v}, \mathbf{w}\rangle = -\langle \mathbf{v}, T\mathbf{w}\rangle$. Conversely, if this holds for all $\mathbf{v}, \mathbf{w}$, then taking $\mathbf{w} = \mathbf{v}$ gives $\langle T\mathbf{v}, \mathbf{v}\rangle = -\langle \mathbf{v}, T\mathbf{v}\rangle = -\langle T\mathbf{v}, \mathbf{v}\rangle$, so $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$.

(c) By (b) and the hypothesis on T, $\langle T\mathbf{v}, \mathbf{w}\rangle = -\langle \mathbf{v}, T\mathbf{w}\rangle = -\langle T\mathbf{v}, \mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w}$. So $\langle T\mathbf{v}, \mathbf{w}\rangle = 0 = \langle 0\mathbf{v}, \mathbf{w}\rangle$, and $T = 0$ by Corollary 6.1.38.

Solution to Exercise 6.1.53

Uses. Proposition 6.1.41 (Over $\mathbb{C}$, the values $\langle T\mathbf{v}, \mathbf{v}\rangle$ determine T), Proposition 6.1.4 (Sesquilinearity), Notation 6.1.1 (Real and complex scalars)
Techniques. Polarization (Technique 6.1.33)
Hint 1. One direction is a one-line computation with conjugate symmetry.

Hint 2. For the other, consider $B(\mathbf{v},\mathbf{w}) = \langle T\mathbf{v},\mathbf{w}\rangle - \langle \mathbf{v}, T\mathbf{w}\rangle$. How does B treat scalars in each slot, and what is $B(\mathbf{v},\mathbf{v})$?
Hint 3. B is linear in the first slot, conjugate-linear in the second, and $B(\mathbf{v},\mathbf{v}) = 2i\operatorname{Im}\langle T\mathbf{v},\mathbf{v}\rangle$. Use (6.1.4).
Sketch. If T satisfies the identity, then $\langle T\mathbf{v},\mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v},\mathbf{v}\rangle}$ is real. Conversely, $B(\mathbf{v},\mathbf{w}) = \langle T\mathbf{v},\mathbf{w}\rangle - \langle \mathbf{v}, T\mathbf{w}\rangle$ is linear in $\mathbf{v}$ and conjugate-linear in $\mathbf{w}$, and $B(\mathbf{v},\mathbf{v}) = 2i\operatorname{Im}\langle T\mathbf{v},\mathbf{v}\rangle = 0$. By (6.1.4), $B = 0$.

Suppose $\langle T\mathbf{v},\mathbf{w}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle$ for all $\mathbf{v},\mathbf{w}$. Then $\langle T\mathbf{v},\mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v},\mathbf{v}\rangle}$ by conjugate symmetry, so $\langle T\mathbf{v},\mathbf{v}\rangle$ is real.

Conversely, suppose $\langle T\mathbf{v},\mathbf{v}\rangle \in \mathbb{R}$ for all $\mathbf{v}$, and define

$$B(\mathbf{v},\mathbf{w}) = \langle T\mathbf{v},\mathbf{w}\rangle - \langle \mathbf{v}, T\mathbf{w}\rangle.$$

The first term is linear in $\mathbf{v}$ and conjugate-linear in $\mathbf{w}$, as in the second proof of Proposition 6.1.41. So is the second term: it is linear in $\mathbf{v}$ by linearity in the first slot, and by Proposition 6.1.4,

$$\langle \mathbf{v}, T(a\mathbf{w}+b\mathbf{z})\rangle = \langle \mathbf{v}, aT\mathbf{w}+bT\mathbf{z}\rangle = \overline{a}\langle \mathbf{v},T\mathbf{w}\rangle + \overline{b}\langle \mathbf{v},T\mathbf{z}\rangle.$$

Hence B is linear in the first slot and conjugate-linear in the second. Its diagonal values are

$$B(\mathbf{v},\mathbf{v}) = \langle T\mathbf{v},\mathbf{v}\rangle - \overline{\langle T\mathbf{v},\mathbf{v}\rangle} = 2i\operatorname{Im}\langle T\mathbf{v},\mathbf{v}\rangle = 0.$$

The identity (6.1.4) holds for every such B, as its derivation used only how B treats scalars in each slot. So $B(\mathbf{v},\mathbf{w}) = \frac{1}{4}\sum_k i^k B\big(\mathbf{v}+i^k\mathbf{w},\mathbf{v}+i^k\mathbf{w}\big) = 0$ for all $\mathbf{v},\mathbf{w}$, which is the claim.

Solution to Exercise 6.1.54

Uses. Corollary 6.1.19 ($A^*A = 0$ forces $A = 0$), Proposition 2.4.23 (Transpose of a product), Definition 2.4.1 (Matrix product)
Techniques. The trace of A^*A (Technique 6.1.18)
Hint 1. Show $(BC)^* = C^*B^*$ entrywise, and deduce $(A^m)^* = A^m$ for every $m \geq 1$.
Hint 2. If $A^{2m} = 0$, then $(A^m)^*A^m = A^{2m} = 0$. What does Corollary 6.1.19 say?
Hint 3. Choose j with $2^j \geq k$ and halve the exponent j times.
Sketch. $(A^m)^* = (A^*)^m = A^m$, so $A^{2m} = 0$ gives $(A^m)^*A^m = 0$ and $A^m = 0$. Starting from $A^{2^j} = 0$ with $2^j \geq k$, halving j times gives $A = 0$.

First, for $B, C \in \mathbb{C}^{n\times n}$, the (i,j) entry of $(BC)^*$ is

$$\overline{(BC)_{ji}} = \overline{\sum_l b_{jl}c_{li}} = \sum_l \overline{c_{li}}\,\overline{b_{jl}} = \sum_l (C^*)_{il}(B^*)_{lj},$$

which is the (i,j) entry of C^*B^* (Definition 2.4.1). So $(BC)^* = C^*B^*$. By induction on m, using $A^* = A$,

$$(A^m)^* = \big(A^{m-1}A\big)^* = A^*\big(A^{m-1}\big)^* = AA^{m-1} = A^m \quad \text{for all } m \geq 1.$$

Next, if $m \geq 1$ and $A^{2m} = 0$, then $(A^m)^*A^m = A^mA^m = A^{2m} = 0$, so $A^m = 0$ by Corollary 6.1.19.

Now choose $j \geq 0$ with $2^j \geq k$. Then $A^{2^j} = A^{2^j-k}A^k = 0$ (with $A^0 = I$). If $j = 0$, this says $A = 0$. Otherwise, applying the previous paragraph with $m = 2^{j-1}, 2^{j-2}, \ldots, 1$ in turn gives $A^{2^{j-1}} = 0$, then $A^{2^{j-2}} = 0$, and finally $A^1 = 0$.

Solution to Exercise 6.1.55

Uses. Proposition 6.1.16 (Frobenius inner product)
Techniques. The trace of A^*A (Technique 6.1.18)
Hint 1. Rewrite A^2 using $A = -A^{\mathsf{T}}$.
Hint 2. $A^2 = -A^{\mathsf{T}}A$, and $\operatorname{tr}\big(A^{\mathsf{T}}A\big)$ is a sum of squares.
Sketch. $\operatorname{tr}\big(A^2\big) = -\operatorname{tr}\big(A^{\mathsf{T}}A\big) = -\sum_{i,j} a_{ij}^2 \leq 0$, with equality only for $A = 0$. If $A^2 = I_n$, then $\operatorname{tr}\big(A^2\big) = n > 0$. The rotation $J = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ has $J^2 = -I_2$.

(a) Since $A = -A^{\mathsf{T}}$, $A^2 = \big(-A^{\mathsf{T}}\big)A = -A^{\mathsf{T}}A$. By Proposition 6.1.16 (over $\mathbb{R}$, $A^* = A^{\mathsf{T}}$),

$$\operatorname{tr}\big(A^2\big) = -\operatorname{tr}\big(A^{\mathsf{T}}A\big) = -\sum_{i,j} a_{ij}^2 \leq 0,$$

with equality only if every $a_{ij} = 0$.

(b) If $A^2 = I_n$, then $\operatorname{tr}(A^2) = n > 0$, contradicting (a). On the other hand, $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ is skew-symmetric with $J^2 = -I_2$, and indeed $\operatorname{tr}(J^2) = -2 = -\sum_{i,j} j_{ij}^2$.

Solution to Exercise 6.1.56

Uses. Proposition 6.1.16 (Frobenius inner product), Definition 6.1.8 (Dot product), Definition 2.4.1 (Matrix product)
Hint 1. The (i, j) entry of $\mathbf{u}\mathbf{v}^*$ is $u_i\overline{v_j}$.
Hint 2. Use the entrywise formula of Proposition 6.1.16; the double sum factors into a product of two single sums.
Sketch. By Proposition 6.1.16 the inner product is $\sum_{i,j} u_i\overline{v_j}\,\overline{x_i}\overline{y_j}$, and this double sum factors as $\left(\sum_i u_i\overline{x_i}\right)\left(\sum_j y_j\overline{v_j}\right)$. With $\mathbf{x} = \mathbf{u}$ and $\mathbf{y} = \mathbf{v}$ this is $\|\mathbf{u}\|^2\|\mathbf{v}\|^2$.

By Definition 2.4.1, the (i, j) entry of $\mathbf{u}\mathbf{v}^*$ is $u_i\overline{v_j}$, and that of $\mathbf{x}\mathbf{y}^*$ is $x_i\overline{y_j}$. By Proposition 6.1.16,

$$\langle \mathbf{u}\mathbf{v}^*, \mathbf{x}\mathbf{y}^* \rangle = \sum_{i=1}^{m}\sum_{j=1}^{n} u_i\overline{v_j}\,\overline{x_i\overline{y_j}} = \sum_{i,j} u_i\overline{x_i}y_j\overline{v_j} = \left(\sum_i u_i\overline{x_i}\right)\left(\sum_j y_j\overline{v_j}\right),$$

which is $(\mathbf{u}\cdot\mathbf{x})(\mathbf{y}\cdot\mathbf{v})$. Taking $\mathbf{x} = \mathbf{u}$ and $\mathbf{y} = \mathbf{v}$ gives $\|\mathbf{u}\mathbf{v}^*\|^2 = (\mathbf{u}\cdot\mathbf{u})(\mathbf{v}\cdot\mathbf{v}) = \|\mathbf{u}\|^2\|\mathbf{v}\|^2$, and taking nonnegative square roots, $\|\mathbf{u}\mathbf{v}^*\| = \|\mathbf{u}\|\|\mathbf{v}\|$.

Solution to Exercise 6.1.57

Uses. Proposition 6.1.29 (Expanding a norm), Proposition 6.1.4 (Sesquilinearity)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Sum over all ordered pairs (i, j) instead; the terms with $i = j$ are 0, and each unordered pair is counted twice.
Hint 2. Expand $\|\mathbf{x}_i - \mathbf{x}_j\|^2 = 2 - 2\operatorname{Re}\langle \mathbf{x}_i, \mathbf{x}_j\rangle$, and recognize $\sum_{i,j}\langle \mathbf{x}_i, \mathbf{x}_j\rangle$ as $\langle \mathbf{s}, \mathbf{s}\rangle$ for $\mathbf{s} = \sum_i \mathbf{x}_i$.
Sketch. Each term is $2 - 2\operatorname{Re}\langle \mathbf{x}_i, \mathbf{x}_j\rangle$, and $\sum_{i,j}\langle \mathbf{x}_i, \mathbf{x}_j\rangle = \|\mathbf{s}\|^2$, so the sum over all ordered pairs is $2n^2 - 2\|\mathbf{s}\|^2$; the sum over $i < j$ is half of this. (b) is immediate, and in (c) the maximum 9 is attained by three unit vectors at angles $2\pi/3$, which sum to $\mathbf{0}$.

(a) Let $\mathbf{s} = \mathbf{x}_1 + \cdots + \mathbf{x}_n$. By sesquilinearity, $\sum_{i,j}\langle \mathbf{x}_i, \mathbf{x}_j\rangle = \langle \mathbf{s}, \mathbf{s}\rangle = \|\mathbf{s}\|^2$, the sum running over all ordered pairs. By Proposition 6.1.29 and $\|\mathbf{x}_i\| = 1$, $\|\mathbf{x}_i - \mathbf{x}_j\|^2 = 2 - 2\operatorname{Re}\langle \mathbf{x}_i, \mathbf{x}_j\rangle$. Summing over all ordered pairs,

$$\sum_{i,j}\|\mathbf{x}_i - \mathbf{x}_j\|^2 = 2n^2 - 2\operatorname{Re}\sum_{i,j}\langle \mathbf{x}_i, \mathbf{x}_j\rangle = 2n^2 - 2\|\mathbf{s}\|^2.$$

The terms with $i = j$ vanish, and each pair $i < j$ occurs twice, as (i, j) and (j, i), with the same value. So the sum over $i < j$ is half of this, $n^2 - \|\mathbf{s}\|^2$.

(b) Since $\|\mathbf{s}\|^2 \geq 0$, the sum is at most n^2, with equality if and only if $\|\mathbf{s}\| = 0$, that is, $\mathbf{s} = \mathbf{0}$ by Proposition 6.1.27.

(c) By (b) the sum is at most 9, with equality exactly when $\mathbf{x}_1 + \mathbf{x}_2 + \mathbf{x}_3 = \mathbf{0}$. This happens for $\mathbf{x}_1 = (1, 0)$, $\mathbf{x}_2 = \left(-1/2, \sqrt{3}/2\right)$, and $\mathbf{x}_3 = \left(-1/2, -\sqrt{3}/2\right)$, the vertices of an equilateral triangle inscribed in the unit circle. Each side has squared length $(3/2)^2 + \left(\sqrt{3}/2\right)^2 = 3$, and $3 + 3 + 3 = 9$.

Solution to Exercise 6.1.58

Uses. Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Proposition 1.1.17 (No zero divisors)
Hint 1. (a) List the squares in $\mathbb{F}_5$.
Hint 2. (b) For odd p, it suffices to find $a, b \in \mathbb{F}_p$ with $a^2 + b^2 = -1$, and then take $\mathbf{x} = (a, b, 1)$. Compare the sets $\{a^2\}$ and $\{-1 - b^2\}$.
Hint 3. Count: $a^2 = c^2$ if and only if $a = \pm c$, so there are exactly $(p + 1)/2$ squares in $\mathbb{F}_p$. Two subsets of $\mathbb{F}_p$ of that size must meet.
Sketch. (a) $(1, 2)$, since $1 + 4 = 5 = 0$. (b) For $p = 2$ take $(1, 1, 0)$. For odd p, the set S of squares has $(p + 1)/2$ elements, and so does $-1 - S$; since $(p + 1)/2 + (p + 1)/2 > p$, they share an element $a^2 = -1 - b^2$, and $(a, b, 1)$ works.

(a) The squares in $\mathbb{F}_5$ are $0, 1, 4, 4, 1$ (of $0, 1, 2, 3, 4$). Since $1 + 4 = 5 = 0$, the vector $\mathbf{x} = (1, 2)$ works.

(b) For $p = 2$, $\mathbf{x} = (1, 1, 0)$ works, since $1 + 1 = 0$ in $\mathbb{F}_2$. Let p be odd. It suffices to find $a, b \in \mathbb{F}_p$ with $a^2 + b^2 + 1 = 0$, because then $\mathbf{x} = (a, b, 1) \neq \mathbf{0}$ works.

Let $S = \left\{a^2 \;\middle|\; a \in \mathbb{F}_p\right\}$. For $a, c \in \mathbb{F}_p$, $a^2 = c^2$ if and only if $(a-c)(a+c) = 0$, which by Proposition 1.1.17 means $a = c$ or $a = -c$. For $a \neq 0$ we have $a \neq -a$, since $a = -a$ would give $2a = 0$, and $2 \neq 0$ in $\mathbb{F}_p$ for odd p. So the $p-1$ nonzero elements fall into $(p-1)/2$ pairs $\{a, -a\}$, each pair having one square, and distinct pairs having distinct squares. Together with $0^2 = 0$, S has exactly $(p+1)/2$ elements.

The map $s \mapsto -1 - s$ is a bijection of $\mathbb{F}_p$, so $T = \left\{-1 - b^2 \;\middle|\; b \in \mathbb{F}_p\right\}$ also has $(p+1)/2$ elements. Since $|S| + |T| = p + 1 > p = \left|\mathbb{F}_p\right|$, the sets S and T intersect: $a^2 = -1 - b^2$ for some $a, b \in \mathbb{F}_p$. Then $a^2 + b^2 + 1 = 0$, as desired. For $n > 3$, pad with zeros: $(x_1, x_2, x_3, 0, \ldots, 0)$ is nonzero with $\sum_k x_k^2 = 0$.

Solution to Exercise 6.1.59

Uses. Proposition 6.1.32 (Polarization identities), Proposition 5.1.10 (Alternating implies antisymmetric)
Techniques. Polarization (Technique 6.1.33)
Hint 1. Which properties of an inner product did the proof of Proposition 6.1.32(a) use? Does B have them?
Hint 2. Expand $B(\mathbf{x}+\mathbf{y}, \mathbf{x}+\mathbf{y}) - B(\mathbf{x}-\mathbf{y}, \mathbf{x}-\mathbf{y})$ for a B that is only bilinear.
Hint 3. Look for a counterexample among 2×2 determinants.
Sketch. The real polarization identity needs symmetry: for a bilinear B, the right side equals $(B(\mathbf{x}, \mathbf{y}) + B(\mathbf{y}, \mathbf{x}))/2$. The claim is false: $B(\mathbf{x}, \mathbf{y}) = x_1 y_2 - x_2 y_1$ vanishes on the diagonal but $B(\mathbf{e}_1, \mathbf{e}_2) = 1$. What is true is $B(\mathbf{y}, \mathbf{x}) = -B(\mathbf{x}, \mathbf{y})$.

The error is the first equality. The real polarization identity was derived for inner products, and its proof used symmetry: the two cross terms of $\|\mathbf{x}+\mathbf{y}\|^2$ were combined into $2\langle \mathbf{x}, \mathbf{y}\rangle$. For a bilinear B without symmetry, expanding gives

$$B(\mathbf{x}+\mathbf{y}, \mathbf{x}+\mathbf{y}) - B(\mathbf{x}-\mathbf{y}, \mathbf{x}-\mathbf{y}) = 2B(\mathbf{x}, \mathbf{y}) + 2B(\mathbf{y}, \mathbf{x}),$$

so the right side of the displayed formula is $(B(\mathbf{x}, \mathbf{y}) + B(\mathbf{y}, \mathbf{x}))/2$, not $B(\mathbf{x}, \mathbf{y})$.

The claim is false. On $\mathbb{R}^2$, $B(\mathbf{x}, \mathbf{y}) = x_1 y_2 - x_2 y_1 = \det\begin{pmatrix} x_1 & y_1 \\ x_2 & y_2 \end{pmatrix}$ is linear in each slot and $B(\mathbf{v}, \mathbf{v}) = 0$ for every $\mathbf{v}$, but $B(\mathbf{e}_1, \mathbf{e}_2) = 1$. What the argument does prove, correctly read, is that $B(\mathbf{x}, \mathbf{y}) + B(\mathbf{y}, \mathbf{x}) = 0$: a bilinear function that vanishes on the diagonal is antisymmetric. This is the argument of Proposition 5.1.10, which applies to any bilinear function of two vectors (Remark 5.1.6).

Solution to Exercise 6.1.60

Uses. Lemma 6.1.14 (Nonnegative functions with zero integral), Proposition 6.1.13 (Integral inner products)
Hint 1. Which hypothesis of Lemma 6.1.14 is missing for an integrable f?
Hint 2. Find a nonzero integrable function whose square has integral 0. Change a continuous function at one point.
Sketch. The step "$\int f^2 = 0$ and $f^2 \geq 0$ imply $f^2 = 0$" needs continuity (Lemma 6.1.14). The function equal to 1 at $t = 1/2$ and 0 elsewhere is integrable, nonzero, and has $\int f^2 = 0$. So the claim is false: definiteness fails on $R[0,1]$.

The error is in the last step. A nonnegative function with integral 0 must vanish if it is continuous (Lemma 6.1.14), but not in general. Let $f(1/2) = 1$ and $f(t) = 0$ for $t \neq 1/2$. Then f is Riemann-integrable and $f^2 = f$, and $\int_0^1 f^2 = 0$, since every Riemann sum over a partition of mesh δ is at most 2δ (the point $1/2$ lies in at most two subintervals). But $f \neq 0$.

So the claim is false: the formula is symmetric, bilinear, and positive on $R[0,1]$, but not definite. This is why Proposition 6.1.13 is stated for continuous functions.

Solution to Exercise 6.1.61 BEYOND 21-242

Uses. Proposition 6.1.32 (Polarization identities), Proposition 6.1.30 (Parallelogram law), Exercise 2.1.51
Hint 1. (a) uses only $\|-\mathbf{v}\| = \|\mathbf{v}\|$ and $\|2\mathbf{x}\| = 2\|\mathbf{x}\|$.
Hint 2. (b) Apply the parallelogram law to the pairs $(\mathbf{x}+\mathbf{y}, \mathbf{z})$ and $(\mathbf{x}-\mathbf{y}, \mathbf{z})$, and subtract.
Hint 3. (c) Put $\mathbf{z} = \mathbf{x}$ in (b) to get $\langle 2\mathbf{x}, \mathbf{y}\rangle = 2\langle \mathbf{x}, \mathbf{y}\rangle$. Then choose $\mathbf{x}$ and $\mathbf{z}$ with $\mathbf{x}+\mathbf{z} = \mathbf{u}$ and $\mathbf{x}-\mathbf{z} = \mathbf{w}$.
Hint 4. (d) Additivity gives homogeneity for integers, then for rationals. For real t, show $t \mapsto \langle t\mathbf{x}, \mathbf{y}\rangle$ is continuous, using $|\|\mathbf{a}\| - \|\mathbf{b}\|| \leq \|\mathbf{a}-\mathbf{b}\|$.
Sketch. (a) is immediate. (b) Subtracting the parallelogram laws for $(\mathbf{x}+\mathbf{y}, \mathbf{z})$ and $(\mathbf{x}-\mathbf{y}, \mathbf{z})$ gives $4\langle \mathbf{x}+\mathbf{z}, \mathbf{y}\rangle + 4\langle \mathbf{x}-\mathbf{z}, \mathbf{y}\rangle = 8\langle \mathbf{x}, \mathbf{y}\rangle$. (c) $\mathbf{z} = \mathbf{x}$ gives $\langle 2\mathbf{x}, \mathbf{y}\rangle = 2\langle \mathbf{x}, \mathbf{y}\rangle$, and then $\mathbf{x} = (\mathbf{u}+\mathbf{w})/2$, $\mathbf{z} = (\mathbf{u}-\mathbf{w})/2$ give additivity. (d) $f(t) = \langle t\mathbf{x}, \mathbf{y}\rangle$ is additive and continuous, so $f(t) = tf(1)$. Symmetry, linearity in the first slot, and $\langle \mathbf{x}, \mathbf{x}\rangle = \|\mathbf{x}\|^2$ are the inner product axioms.

(a) Since $\|-\mathbf{v}\| = |-1|\|\mathbf{v}\| = \|\mathbf{v}\|$, we have $\|\mathbf{y}-\mathbf{x}\| = \|\mathbf{x}-\mathbf{y}\|$, which gives symmetry, and $\|-\mathbf{x}-\mathbf{y}\| = \|\mathbf{x}+\mathbf{y}\|$ and $\|-\mathbf{x}+\mathbf{y}\| = \|\mathbf{x}-\mathbf{y}\|$, which give $\langle -\mathbf{x},\mathbf{y}\rangle = -\langle \mathbf{x},\mathbf{y}\rangle$. Also $\langle \mathbf{x},\mathbf{x}\rangle = \big(\|2\mathbf{x}\|^2 - \|\mathbf{0}\|^2\big)/4 = \|\mathbf{x}\|^2$.

(b) The parallelogram law for the pairs $(\mathbf{x}+\mathbf{y},\mathbf{z})$ and $(\mathbf{x}-\mathbf{y},\mathbf{z})$ reads

$$\|\mathbf{x}+\mathbf{y}+\mathbf{z}\|^2 + \|\mathbf{x}+\mathbf{y}-\mathbf{z}\|^2 = 2\|\mathbf{x}+\mathbf{y}\|^2 + 2\|\mathbf{z}\|^2,$$
$$\|\mathbf{x}-\mathbf{y}+\mathbf{z}\|^2 + \|\mathbf{x}-\mathbf{y}-\mathbf{z}\|^2 = 2\|\mathbf{x}-\mathbf{y}\|^2 + 2\|\mathbf{z}\|^2.$$

Subtract the second from the first and regroup the left side:

$$\big(\|(\mathbf{x}+\mathbf{z})+\mathbf{y}\|^2 - \|(\mathbf{x}+\mathbf{z})-\mathbf{y}\|^2\big) + \big(\|(\mathbf{x}-\mathbf{z})+\mathbf{y}\|^2 - \|(\mathbf{x}-\mathbf{z})-\mathbf{y}\|^2\big)$$
$$= 2\big(\|\mathbf{x}+\mathbf{y}\|^2 - \|\mathbf{x}-\mathbf{y}\|^2\big).$$

By the definition of $\langle\cdot,\cdot\rangle$, this says $4\langle \mathbf{x}+\mathbf{z},\mathbf{y}\rangle + 4\langle \mathbf{x}-\mathbf{z},\mathbf{y}\rangle = 8\langle \mathbf{x},\mathbf{y}\rangle$.

(c) First, $\langle \mathbf{0},\mathbf{y}\rangle = \big(\|\mathbf{y}\|^2 - \|-\mathbf{y}\|^2\big)/4 = 0$. Taking $\mathbf{z} = \mathbf{x}$ in (b) gives $\langle 2\mathbf{x},\mathbf{y}\rangle + \langle \mathbf{0},\mathbf{y}\rangle = 2\langle \mathbf{x},\mathbf{y}\rangle$, so $\langle 2\mathbf{x},\mathbf{y}\rangle = 2\langle \mathbf{x},\mathbf{y}\rangle$ for all $\mathbf{x},\mathbf{y}$. Now let $\mathbf{u},\mathbf{w}\in V$, and apply (b) with $\mathbf{x} = (\mathbf{u}+\mathbf{w})/2$ and $\mathbf{z} = (\mathbf{u}-\mathbf{w})/2$, so that $\mathbf{x}+\mathbf{z} = \mathbf{u}$ and $\mathbf{x}-\mathbf{z} = \mathbf{w}$:

$$\langle \mathbf{u},\mathbf{y}\rangle + \langle \mathbf{w},\mathbf{y}\rangle = 2\left\langle \frac{\mathbf{u}+\mathbf{w}}{2},\mathbf{y}\right\rangle = \langle \mathbf{u}+\mathbf{w},\mathbf{y}\rangle,$$

the last step by the doubling rule applied to $(\mathbf{u}+\mathbf{w})/2$.

(d) Fix $\mathbf{x},\mathbf{y}$ and let $f(t) = \langle t\mathbf{x},\mathbf{y}\rangle$ for $t\in\mathbb{R}$. By (c), $f(s+t) = \langle s\mathbf{x}+t\mathbf{x},\mathbf{y}\rangle = f(s)+f(t)$, so f is additive. We show that f is continuous. The triangle inequality gives $\|\mathbf{a}\| \le \|\mathbf{a}-\mathbf{b}\| + \|\mathbf{b}\|$ and the same with $\mathbf{a},\mathbf{b}$ exchanged, so $|\|\mathbf{a}\| - \|\mathbf{b}\|| \le \|\mathbf{a}-\mathbf{b}\|$. Hence

$$|\|t\mathbf{x}\pm\mathbf{y}\| - \|s\mathbf{x}\pm\mathbf{y}\|| \le \|(t-s)\mathbf{x}\| = |t-s|\|\mathbf{x}\|,$$

so $t\mapsto \|t\mathbf{x}\pm\mathbf{y}\|$ is continuous, and so is $f(t) = \big(\|t\mathbf{x}+\mathbf{y}\|^2 - \|t\mathbf{x}-\mathbf{y}\|^2\big)/4$. A continuous additive function $\mathbb{R}\to\mathbb{R}$ satisfies $f(t) = tf(1)$ for all t (Exercise 2.1.51). Directly: additivity gives $f(mt) = mf(t)$ for positive integers m by induction, $f(0) = 0$, and $f(-t) = -f(t)$ by (a); so for $q = m/n$ with $n>0$, $nf(q) = f(m) = mf(1)$, that is, $f(q) = qf(1)$. Every real t is a limit of rationals q_k, and continuity gives $f(t) = \lim f(q_k) = \lim q_k f(1) = tf(1)$. So $\langle t\mathbf{x},\mathbf{y}\rangle = t\langle \mathbf{x},\mathbf{y}\rangle$.

Together with (c), $\langle\cdot,\cdot\rangle$ is linear in the first slot. It is symmetric by (a), which over $\mathbb{R}$ is conjugate symmetry, and $\langle \mathbf{x},\mathbf{x}\rangle = \|\mathbf{x}\|^2$ is nonnegative and vanishes only for $\mathbf{x} = \mathbf{0}$. So $\langle\cdot,\cdot\rangle$ is an inner product, and its norm $\sqrt{\langle \mathbf{x},\mathbf{x}\rangle}$ is $\|\mathbf{x}\|$.

Section 6.2

Solution to Exercise 6.2.10

Uses. Definition 6.1.8 (Dot product), (6.2.1)
Techniques. Orthogonal decomposition (Technique 6.2.4)
Hint 1. $c = (\mathbf{x}\cdot\mathbf{y})/\|\mathbf{y}\|^2$.
Hint 2. Compute $c\mathbf{y}$ coordinate by coordinate: $(3+i)i = -1+3i$ and $(3+i)(1-i) = 4-2i$.
Sketch. $c = (3+i)/3$, $c\mathbf{y} = ((-1+3i)/3, (4-2i)/3)$, and $\mathbf{w} = (4/3, (2+2i)/3)$. Then $\|\mathbf{w}\|^2 = 8/3$ and $|3+i|^2/3 = 10/3$, which add to 6.

By Technique 6.2.4, $c = (\mathbf{x}\cdot\mathbf{y})/\|\mathbf{y}\|^2 = (3+i)/3$. Since $(3+i)i = -1+3i$ and $(3+i)(1-i) = 4-2i$,

$$c\mathbf{y} = \left(\frac{-1+3i}{3}, \frac{4-2i}{3}\right), \quad \mathbf{w} = \mathbf{x} - c\mathbf{y} = \left(\frac{4}{3}, \frac{2+2i}{3}\right).$$

Check:

$$\mathbf{w}\cdot\mathbf{y} = \frac{4}{3}\bar{i} + \frac{2+2i}{3}\overline{(1-i)} = \frac{-4i}{3} + \frac{4i}{3} = 0,$$

using $(2+2i)(1+i) = 4i$. Now $\|\mathbf{w}\|^2 = 16/9 + 8/9 = 8/3$ (as $|2+2i|^2 = 8$), and $|\mathbf{x}\cdot\mathbf{y}|^2/\|\mathbf{y}\|^2 = 10/3$. Their sum is $18/3 = 6 = \|\mathbf{x}\|^2$, as (6.2.1) predicts. In particular $|\mathbf{x}\cdot\mathbf{y}|^2 = 10 \le 18 = \|\mathbf{x}\|^2\|\mathbf{y}\|^2$.

Solution to Exercise 6.2.12

Uses. Proposition 6.1.27 (Basic properties of the norm), Theorem 6.2.11 (Triangle inequality), Notation 6.1.1 (Real and complex scalars)
Hint 1. By Proposition 6.1.27, both conditions are equations between real multiples of $\|\mathbf{x}\|$. Divide by $\|\mathbf{x}\|$.
Hint 2. The first condition becomes $|1+a| = 1+|a|$, the triangle inequality in $\mathbb{C} = \mathbb{C}^1$ itself. For the second, square $|1+a| = |1-|a||$ and expand $|1+a|^2 = 1 + 2\operatorname{Re} a + |a|^2$.
Sketch. The first condition is $|1+a| = 1+|a|$, which by Theorem 6.2.11(b) in $\mathbb{C}$ means $a \ge 0$ is real. Squaring the second gives $2\operatorname{Re} a = -2|a|$, so a is a real number ≤ 0.

By Proposition 6.1.27, $\|\mathbf{x}+a\mathbf{x}\| = |1+a|\|\mathbf{x}\|$ and $\|a\mathbf{x}\| = |a|\|\mathbf{x}\|$, and $\|\mathbf{x}\| > 0$.

The first condition is $|1+a| = 1+|a|$. This is the equality case of Theorem 6.2.11 in $\mathbb{C}$ with the dot product $z\overline{w}$, for the vectors 1 and a. By (b), it holds if and only if one of $1, a$ is a nonnegative real multiple of the other, that is, if and only if a is a real number with $a \ge 0$. (If $1 = ba$ with $b \ge 0$, then $b > 0$ and $a = 1/b > 0$.)

The second condition is $|1+a| = |1-|a||$. Both sides are nonnegative, so it is equivalent to the equality of squares $1 + 2\operatorname{Re} a + |a|^2 = 1 - 2|a| + |a|^2$, that is, $\operatorname{Re} a = -|a|$. Writing $a = s + ti$, this says $s = -\sqrt{s^2+t^2}$, which holds if and only if $t = 0$ and $s \le 0$. So the second condition holds exactly for real $a \le 0$; for $a < 0$, the vectors $\mathbf{x}$ and $a\mathbf{x}$ point in opposite directions.

Solution to Exercise 6.2.20

Uses. Definition 6.2.16 (Angle), Proposition 6.1.13 (Integral inner products)
Hint 1. $\langle t, t^2\rangle = \int_0^1 t^3\,dt$, and $\|t^k\|^2 = \int_0^1 t^{2k}\,dt$.
Hint 2. For the second part, the condition is $\langle 1, t+a\rangle = (1/2)\|1\|\|t+a\|$. The left side must be positive. Square and solve.
Sketch. $\cos\theta = (1/4)/\left(\sqrt{1/3}\sqrt{1/5}\right) = \sqrt{15}/4$. For the second part, $1/2 + a = (1/2)\sqrt{1/3 + a + a^2}$ with $1/2 + a > 0$; squaring gives $9a^2 + 9a + 2 = 0$, so $a = -1/3$ or $a = -2/3$, and only $a = -1/3$ has $1/2 + a > 0$.

We have $\langle t, t^2\rangle = \int_0^1 t^3\,dt = 1/4$, $\|t\|^2 = 1/3$, and $\|t^2\|^2 = \int_0^1 t^4\,dt = 1/5$. So

$$\cos\theta = \frac{1/4}{\sqrt{\frac{1}{3}\cdot\frac{1}{5}}} = \frac{\sqrt{15}}{4} \approx 0.968.$$

For the second part, $t + a \ne 0$ for every a, $\|1\| = 1$, $\langle 1, t+a\rangle = 1/2 + a$, and

$$\|t+a\|^2 = \int_0^1 \left(t^2 + 2at + a^2\right)dt = \frac{1}{3} + a + a^2.$$

The angle is $\pi/3$ if and only if $1/2 + a = (1/2)\sqrt{1/3 + a + a^2}$. This requires $1/2 + a \ge 0$, and then it is equivalent to the squared equation $4(1/2+a)^2 = 1/3 + a + a^2$, that is, $3a^2 + 3a + 2/3 = 0$, or $9a^2 + 9a + 2 = 0$. Its roots are $a = -1/3$ and $a = -2/3$. Only $a = -1/3$ satisfies $1/2 + a \ge 0$; for $a = -2/3$ the angle is $2\pi/3$. Check: $\|t - 1/3\|^2 = 1/3 - 1/3 + 1/9 = 1/9$, so $\cos\theta = (1/6)/(1/3) = 1/2$.

Solution to Exercise 6.2.27

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), (6.2.1), Definition 6.2.16 (Angle)
Techniques. Orthogonal decomposition (Technique 6.2.4)
Hint 1. Every inner product in this exercise carries the weights $1, 2, 3$. For instance $\|\mathbf{y}\|^2 = 1 + 2 + 3\cdot 4$.
Hint 2. $c = \langle \mathbf{x}, \mathbf{y}\rangle / \|\mathbf{y}\|^2$.
Sketch. $\langle \mathbf{x}, \mathbf{y}\rangle = 5$, $\|\mathbf{x}\|^2 = 6$, $\|\mathbf{y}\|^2 = 15$, and $25 \le 90$. Then $c = 1/3$, $\mathbf{w} = (2/3, 4/3, 1/3)$, $\|\mathbf{w}\|^2 = 13/3$, and $13/3 + 25/15 = 6$. The cosine is $5/\sqrt{90} = \sqrt{10}/6$; for the dot product it is $2/\sqrt{18} = \sqrt{2}/3$.

(a) $\langle \mathbf{x}, \mathbf{y}\rangle = 1 - 2 + 6 = 5$, $\|\mathbf{x}\|^2 = 1 + 2 + 3 = 6$, and $\|\mathbf{y}\|^2 = 1 + 2 + 12 = 15$. Indeed $5^2 = 25 \le 6 \cdot 15 = 90$.

(b) By Technique 6.2.4, $c = 5/15 = 1/3$ and $\mathbf{w} = \mathbf{x} - \mathbf{y}/3 = (2/3, 4/3, 1/3)$. Check:

$$\langle \mathbf{w}, \mathbf{y} \rangle = \frac{2}{3} - 2 \cdot \frac{4}{3} + 3 \cdot \frac{2}{3} = 0.$$

Also

$$\|\mathbf{w}\|^2 = \frac{4}{9} + 2 \cdot \frac{16}{9} + 3 \cdot \frac{1}{9} = \frac{39}{9} = \frac{13}{3},$$

and

$$\|\mathbf{w}\|^2 + \frac{\langle \mathbf{x}, \mathbf{y} \rangle^2}{\|\mathbf{y}\|^2} = \frac{13}{3} + \frac{25}{15} = 6 = \|\mathbf{x}\|^2,$$

as (6.2.1) predicts.

(c) $\cos\theta = 5/\sqrt{90} = 5/\left(3\sqrt{10}\right) = \sqrt{10}/6 \approx 0.527$. For the dot product, $\mathbf{x} \cdot \mathbf{y} = 2$, $\|\mathbf{x}\|^2 = 3$, $\|\mathbf{y}\|^2 = 6$, and the cosine is $2/\sqrt{18} = \sqrt{2}/3 \approx 0.471$. The angle depends on the inner product.

Solution to Exercise 6.2.28

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Theorem 6.2.11 (Triangle inequality)
Hint 1. Both vectors are nonzero for every z. By Theorem 6.2.1(b), equality means $\mathbf{y} = a\mathbf{x}$ for some $a \in \mathbb{C}$. Compare second coordinates first.
Hint 2. For (b), Theorem 6.2.11(b) requires a nonnegative real multiple. Is the multiple from (a) real?
Sketch. (a) $\mathbf{y} = a\mathbf{x}$ forces $1 = ai$, so $a = -i$ and $z = -i$. (b) The only dependent case has $\mathbf{y} = -i\mathbf{x}$, which is not a nonnegative real multiple, so there is no such z; indeed $\|\mathbf{x} + \mathbf{y}\| = 2 < 2\sqrt{2}$ for $z = -i$.

(a) Both $\mathbf{x}$ and $\mathbf{y}$ are nonzero, so by Theorem 6.2.1(b) equality holds if and only if $\mathbf{y} = a\mathbf{x}$ for some $a \in \mathbb{C}$ (a relation $\mathbf{x} = b\mathbf{y}$ has $b \neq 0$ and can be inverted). Comparing second coordinates, $1 = ai$, so $a = -i$, and then $z = a \cdot 1 = -i$. Conversely, $z = -i$ gives $\mathbf{y} = -i\mathbf{x}$. Check: $\mathbf{x} \cdot \mathbf{y} = 1 \cdot \overline{-i} + i \cdot 1 = 2i$, and $|2i| = 2 = \sqrt{2}\sqrt{2} = \|\mathbf{x}\|\|\mathbf{y}\|$.

(b) By Theorem 6.2.11(b), equality requires one of $\mathbf{x}, \mathbf{y}$ to be a nonnegative real multiple of the other, so in particular equality in Cauchy–Schwarz. By (a), this forces $z = -i$ and $\mathbf{y} = -i\mathbf{x}$, equivalently $\mathbf{x} = i\mathbf{y}$, and neither $-i$ nor i is a nonnegative real number. So there is no such z. For $z = -i$ directly: $\mathbf{x} + \mathbf{y} = (1 - i, 1 + i)$ has norm $\sqrt{2 + 2} = 2 < 2\sqrt{2}$.

Solution to Exercise 6.2.29

Uses. Definition 6.1.8 (Dot product)
Techniques. Rotate the phase (Technique 6.2.8)
Hint 1. $\langle \mathbf{x}, \mathbf{y} \rangle = 1 \cdot \overline{1} + 1 \cdot \overline{i}$.
Hint 2. For (b), $\operatorname{Re}\langle \lambda\mathbf{x}, \mathbf{y} \rangle = \operatorname{Re}(\lambda\langle \mathbf{x}, \mathbf{y} \rangle)$ is largest when λ rotates $\langle \mathbf{x}, \mathbf{y} \rangle$ onto the positive real axis.
Sketch. $\langle \mathbf{x}, \mathbf{y} \rangle = 1 - i$ and $\|\mathbf{x}\| = \|\mathbf{y}\| = \sqrt{2}$. The two ratios are $1/2$ and $\sqrt{2}/2$, giving angles $\pi/3$ and $\pi/4$. In (b), $\lambda = (1 + i)/\sqrt{2}$ and the maximum is $\sqrt{2} = |1 - i|$.

(a) $\langle \mathbf{x}, \mathbf{y} \rangle = 1 + \overline{i} = 1 - i$, and $\|\mathbf{x}\|^2 = \|\mathbf{y}\|^2 = 2$. So

$$\frac{\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle}{\|\mathbf{x}\|\|\mathbf{y}\|} = \frac{1}{2}, \quad \frac{|\langle \mathbf{x}, \mathbf{y} \rangle|}{\|\mathbf{x}\|\|\mathbf{y}\|} = \frac{\sqrt{2}}{2},$$

with angles $\pi/3$ and $\pi/4$. The first is the angle between $\mathbf{x}$ and $\mathbf{y}$ regarded as vectors $(1, 0, 1, 0)$ and $(1, 0, 0, 1)$ of $\mathbb{R}^4$.

(b) $\operatorname{Re}\langle \lambda\mathbf{x}, \mathbf{y} \rangle = \operatorname{Re}(\lambda(1 - i)) \leq |\lambda(1 - i)| = \sqrt{2}$, with equality if and only if $\lambda(1 - i)$ is a nonnegative real number. With $1 - i = \sqrt{2}\mu$, $\mu = (1 - i)/\sqrt{2}$, this happens for $\lambda = \overline{\mu} = (1 + i)/\sqrt{2}$, and indeed $\lambda(1 - i) = (1 + i)(1 - i)/\sqrt{2} = \sqrt{2}$. So the maximum is $\sqrt{2} = |\langle \mathbf{x}, \mathbf{y} \rangle|$, and the smallest real angle between $\mathbf{y}$ and a unit-modulus multiple of $\mathbf{x}$ is $\pi/4$, as Technique 6.2.8 predicts.

Solution to Exercise 6.2.30

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Definition 6.1.8 (Dot product), Remark 6.2.2

Hint 1. The dot product on $\mathbb{C}^n$ conjugates the second vector. Which vector should play the role of $\mathbf{y}$ so that $\mathbf{z}\cdot\mathbf{y} = \sum_k z_k w_k$?
Hint 2. For the example, try $\mathbf{z} = \mathbf{w} = (1, i)$.
Sketch. With $\overline{\mathbf{w}} = (\overline{w_1}, \ldots, \overline{w_n})$, $\mathbf{z}\cdot\overline{\mathbf{w}} = \sum_k z_k w_k$ and $\|\overline{\mathbf{w}}\| = \|\mathbf{w}\|$, so this is Cauchy–Schwarz for $\mathbf{z}, \overline{\mathbf{w}}$, with equality iff they are dependent. For $\mathbf{z} = \mathbf{w} = (1, i)$, the left side is $\left|1 + i^2\right|^2 = 0 < 4$.

Let $\mathbf{z} = (z_1, \ldots, z_n)$ and $\overline{\mathbf{w}} = (\overline{w_1}, \ldots, \overline{w_n})$. Then $\mathbf{z}\cdot\overline{\mathbf{w}} = \sum_k z_k\overline{\overline{w_k}} = \sum_k z_k w_k$, and $\|\overline{\mathbf{w}}\|^2 = \sum_k |\overline{w_k}|^2 = \sum_k |w_k|^2$. So the inequality is Theorem 6.2.1 for $\mathbf{z}$ and $\overline{\mathbf{w}}$ (squared), and by Theorem 6.2.1(b) and Remark 6.2.2, equality holds if and only if $\mathbf{z}$ and $\overline{\mathbf{w}}$ are linearly dependent.

For $\mathbf{z} = \mathbf{w} = (1, i)$, the two vectors are equal, hence dependent, but $z_1 w_1 + z_2 w_2 = 1 + i^2 = 0$, while the right side is $2 \cdot 2 = 4$. Here $\overline{\mathbf{w}} = (1, -i)$ is not a multiple of $\mathbf{z}$. With $\mathbf{w} = (1, -i)$ instead, $\sum_k z_k w_k = 1 - i^2 = 2$ and equality $4 = 4$ holds.

Solution to Exercise 6.2.31

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Example 6.1.21 (Weighted dot products)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. The constraint says $\|\mathbf{v}\| \le 1$ for a weighted inner product. Which weights?
Hint 2. Write $x + y + z = \langle (x, y, z), \mathbf{u}\rangle$ in the inner product $x_1y_1 + 4x_2y_2 + 9x_3y_3$, for a suitable vector $\mathbf{u}$.
Hint 3. $\mathbf{u} = (1, 1/4, 1/9)$. For the maximizer, use the equality case together with $\|\mathbf{v}\| = 1$.
Sketch. In $\langle \mathbf{a}, \mathbf{b}\rangle_w = a_1b_1 + 4a_2b_2 + 9a_3b_3$, $x + y + z = \langle \mathbf{v}, \mathbf{u}\rangle_w$ with $\mathbf{u} = (1, 1/4, 1/9)$ and $\|\mathbf{u}\|_w = 7/6$. So $x + y + z \le \|\mathbf{v}\|_w \cdot 7/6 \le 7/6$, with equality at $\mathbf{v} = (6/7)\mathbf{u} = (6/7, 3/14, 2/21)$.

Let $\langle \mathbf{a}, \mathbf{b}\rangle_w = a_1b_1 + 4a_2b_2 + 9a_3b_3$, an inner product on $\mathbb{R}^3$ by Example 6.1.21, and let $\mathbf{v} = (x, y, z)$ and $\mathbf{u} = (1, 1/4, 1/9)$. Then $\langle \mathbf{v}, \mathbf{u}\rangle_w = x + y + z$, the constraint is $\|\mathbf{v}\|_w \le 1$, and

$$\|\mathbf{u}\|_w^2 = 1 + 4\cdot\frac{1}{16} + 9\cdot\frac{1}{81} = 1 + \frac{1}{4} + \frac{1}{9} = \frac{49}{36}.$$

By Theorem 6.2.1,

$$x + y + z \le \left|\langle \mathbf{v}, \mathbf{u}\rangle_w\right| \le \|\mathbf{v}\|_w\|\mathbf{u}\|_w \le \frac{7}{6}.$$

For $\mathbf{v} = (6/7)\mathbf{u} = (6/7, 3/14, 2/21)$ we have $\|\mathbf{v}\|_w = (6/7)(7/6) = 1$, so the constraint holds, and $x + y + z = (6/7)\|\mathbf{u}\|_w^2$, which is $(6/7)(49/36) = 7/6$. So the maximum is $7/6$.

It is attained only there: equality throughout requires $\|\mathbf{v}\|_w = 1$, equality in Cauchy–Schwarz, so $\mathbf{v} = t\mathbf{u}$ (as $\mathbf{u} \ne \mathbf{0}$), and $\langle \mathbf{v}, \mathbf{u}\rangle_w = t\|\mathbf{u}\|_w^2 \ge 0$, so $t \ge 0$; then $\|\mathbf{v}\|_w = t \cdot 7/6 = 1$ gives $t = 6/7$.

Solution to Exercise 6.2.32

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. The first equation says $\mathbf{v}\cdot(1, 2, 3) = 14$, and $\|(1, 2, 3)\|^2 = 14$. What does Cauchy–Schwarz say about $\mathbf{v}\cdot(1, 2, 3)$ when $\|\mathbf{v}\|^2 = 14$?
Hint 2. The data force equality in Cauchy–Schwarz. Use the equality case.
Sketch. With $\mathbf{v} = (x, y, z)$ and $\mathbf{u} = (1, 2, 3)$: $14 = \mathbf{v}\cdot\mathbf{u} \le \|\mathbf{v}\|\|\mathbf{u}\| = \sqrt{14}\sqrt{14} = 14$, so equality holds and $\mathbf{v} = t\mathbf{u}$; then $14t = 14$ gives $(1, 2, 3)$. In (b), $\mathbf{v}\cdot\mathbf{u} \le \sqrt{13\cdot 14} < 14$.

Let $\mathbf{v} = (x, y, z)$ and $\mathbf{u} = (1, 2, 3)$, so that $\|\mathbf{u}\|^2 = 14$ and the first equation is $\mathbf{v}\cdot\mathbf{u} = 14$.

(a) If $\|\mathbf{v}\|^2 = 14$, then by Theorem 6.2.1, $14 = \mathbf{v}\cdot\mathbf{u} \le \|\mathbf{v}\|\|\mathbf{u}\| = 14$, so equality holds. By Theorem 6.2.1(b), and since $\mathbf{u} \ne \mathbf{0}$, $\mathbf{v} = t\mathbf{u}$ for some $t \in \mathbb{R}$. Then $\mathbf{v}\cdot\mathbf{u} = 14t = 14$ gives $t = 1$, so $(x, y, z) = (1, 2, 3)$. Conversely, $(1, 2, 3)$ satisfies both equations, since $1 + 4 + 9 = 14$. So $(1, 2, 3)$ is the only solution.

(b) If $\|\mathbf{v}\|^2 = 13$, then $\mathbf{v}\cdot\mathbf{u} \le \sqrt{13}\sqrt{14} < 14$, so the first equation fails.

Geometrically, the plane $x + 2y + 3z = 14$ is at distance $14/\sqrt{14} = \sqrt{14}$ from the origin. It touches the sphere of radius $\sqrt{14}$ in exactly one point and misses the smaller sphere of radius $\sqrt{13}$.

Solution to Exercise 6.2.33

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.4 (Sesquilinearity), Remark 6.2.2, Notation 6.1.1 (Real and complex scalars)
Hint 1. Expand $\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle$. Its real part is $\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2$.
Hint 2. Then $\left|\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\right| \le |\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle|$, and Cauchy–Schwarz finishes (a).
Hint 3. For (b), equality needs $\operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle = 0$ and equality in Cauchy–Schwarz for $\mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}$. Show that $\mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}$ are dependent if and only if $\mathbf{x}, \mathbf{y}$ are.
Sketch. $\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle = \left(\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\right) - 2i \operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle$, so $\left|\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\right|$ is at most $|\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle|$, which Cauchy–Schwarz bounds by $\|\mathbf{x}+\mathbf{y}\|\|\mathbf{x}-\mathbf{y}\|$. Equality holds iff $\operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle = 0$ and $\mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}$ are dependent, iff $\mathbf{x}, \mathbf{y}$ are dependent with a real ratio.

(a) By sesquilinearity and conjugate symmetry,

$$\begin{aligned}\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle &= \|\mathbf{x}\|^2 - \langle \mathbf{x}, \mathbf{y}\rangle + \overline{\langle \mathbf{x}, \mathbf{y}\rangle} - \|\mathbf{y}\|^2 \\ &= \left(\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\right) - 2i \operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle,\end{aligned}$$

since $z - \overline{z} = 2i \operatorname{Im} z$. So $\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2$ is the real part of $\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle$, and by $|\operatorname{Re} z| \le |z|$ and Theorem 6.2.1,

$$\left|\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\right| \le |\langle \mathbf{x}+\mathbf{y}, \mathbf{x}-\mathbf{y}\rangle| \le \|\mathbf{x}+\mathbf{y}\|\|\mathbf{x}-\mathbf{y}\|.$$

(b) Equality holds if and only if both steps are equalities. The first is an equality if and only if $\operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle = 0$, since $|\operatorname{Re} z| = |z|$ exactly for real z. The second is an equality if and only if $\mathbf{x}+\mathbf{y}$ and $\mathbf{x}-\mathbf{y}$ are linearly dependent (Remark 6.2.2). These are dependent if and only if $\mathbf{x}, \mathbf{y}$ are: a nontrivial relation $a(\mathbf{x}+\mathbf{y}) + b(\mathbf{x}-\mathbf{y}) = \mathbf{0}$ is the relation $(a+b)\mathbf{x} + (a-b)\mathbf{y} = \mathbf{0}$, which is nontrivial since $a+b = a-b = 0$ forces $a = b = 0$; conversely, $\alpha\mathbf{x} + \beta\mathbf{y} = \mathbf{0}$ becomes $((\alpha+\beta)/2)(\mathbf{x}+\mathbf{y}) + ((\alpha-\beta)/2)(\mathbf{x}-\mathbf{y}) = \mathbf{0}$, again nontrivial.

So equality holds if and only if $\mathbf{x}, \mathbf{y}$ are dependent and $\langle \mathbf{x}, \mathbf{y}\rangle$ is real. If $\mathbf{x} = \mathbf{0}$ or $\mathbf{y} = \mathbf{0}$, both conditions hold, and the zero vector is the real multiple 0 of the other. If $\mathbf{y} = a\mathbf{x}$ with $\mathbf{x} \neq \mathbf{0}$, then $\langle \mathbf{x}, \mathbf{y}\rangle = \overline{a}\|\mathbf{x}\|^2$ is real if and only if a is real; the case $\mathbf{x} = b\mathbf{y}$ is the same. This proves (b).

Solution to Exercise 6.2.34

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Lemma 6.2.3 (The easy half of (b))
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Equality is the same as linear dependence. Is "is dependent with" a transitive relation? Think about the zero vector.
Hint 2. If $\mathbf{y} \neq \mathbf{0}$, both $\mathbf{x}$ and $\mathbf{z}$ are multiples of $\mathbf{y}$.
Sketch. False: take $\mathbf{y} = \mathbf{0}$ and $\mathbf{x} = \mathbf{e}_1$, $\mathbf{z} = \mathbf{e}_2$ in $\mathbb{R}^2$. If $\mathbf{y} \neq \mathbf{0}$, then $\mathbf{x} = a\mathbf{y}$ and $\mathbf{z} = b\mathbf{y}$, so one of $\mathbf{x}, \mathbf{z}$ is a multiple of the other, and equality holds by Lemma 6.2.3.

The claim is false. In $\mathbb{R}^2$ with the dot product, let $\mathbf{x} = \mathbf{e}_1$, $\mathbf{y} = \mathbf{0}$, and $\mathbf{z} = \mathbf{e}_2$. Both hypotheses hold, since both sides of the inequality are 0 for each pair containing $\mathbf{0}$. But $|\mathbf{e}_1 \cdot \mathbf{e}_2| = 0 < 1 = \|\mathbf{e}_1\|\|\mathbf{e}_2\|$.

If $\mathbf{y} \neq \mathbf{0}$, the conclusion holds. By Theorem 6.2.1(b), one of $\mathbf{x}, \mathbf{y}$ is a multiple of the other, and since $\mathbf{y} \neq \mathbf{0}$, $\mathbf{x} = a\mathbf{y}$ for some a (if $\mathbf{y} = c\mathbf{x}$, then $c \neq 0$ and $\mathbf{x} = c^{-1}\mathbf{y}$). Likewise $\mathbf{z} = b\mathbf{y}$. If $a = 0$, then $\mathbf{x} = \mathbf{0} = 0\mathbf{z}$. If $a \neq 0$, then $\mathbf{y} = a^{-1}\mathbf{x}$ and $\mathbf{z} = (b/a)\mathbf{x}$. Either way one of $\mathbf{x}, \mathbf{z}$ is a multiple of the other, and equality holds by Lemma 6.2.3.

Solution to Exercise 6.2.35

Uses. Proposition 6.1.29 (Expanding a norm), Lemma 6.2.6 (Nonnegative quadratics)
Techniques. A nonnegative quadratic has nonpositive discriminant (Technique 6.2.7)
Hint 1. Expand $\|\mathbf{x} - t\mathbf{y}\|^2$ correctly with Proposition 6.1.29. Where do conjugates and real parts appear?
Hint 2. Is the right side of the displayed formula even a real number for complex t? Does "≤ 0" make sense for $\langle \mathbf{x}, \mathbf{y}\rangle^2$?
Hint 3. Try $x = 1$, $y = i$, $t = i$ in $\mathbb{C}$.
Sketch. The correct expansion is $\|\mathbf{x}\|^2 - 2\operatorname{Re}(\overline{t}\langle \mathbf{x}, \mathbf{y}\rangle) + |t|^2\|\mathbf{y}\|^2$. The displayed expression is not real in general, so it cannot be compared with 0; the discriminant criterion is about real quadratics in a real variable; and $\langle \mathbf{x}, \mathbf{y}\rangle^2$ need not be real. In $\mathbb{C}$ with $x = 1$, $y = i$, $t = i$: the formula gives -2, but $|1 - i \cdot i|^2 = 4$. The repair is the second proof of Theorem 6.2.1.

There are three errors.

First, the expansion is wrong over $\mathbb{C}$. By Proposition 6.1.29 with $a = -t$,

$$\|\mathbf{x} - t\mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2\,\mathrm{Re}(\bar{t}\langle \mathbf{x}, \mathbf{y}\rangle) + |t|^2\|\mathbf{y}\|^2.$$

The argument's formula drops the conjugate and the real part and writes t^2 for $|t|^2$. For a numerical counterexample, take $V = \mathbb{C}$ with $\langle z, w\rangle = z\overline{w}$, $x = 1$, $y = i$, and $t = i$. Then $\langle x, y\rangle = \bar{i} = -i$, $\|x\| = \|y\| = 1$, and the formula gives $1 - 2i(-i) + i^2 = 1 - 2 - 1 = -2$, while $\|x - ty\|^2 = |1 - i \cdot i|^2 = |2|^2 = 4$.

Second, the discriminant criterion (Lemma 6.2.6) is a statement about real quadratics in a real variable. A polynomial in a complex variable t takes non-real values, and "never negative" has no meaning for it.

Third, $\langle \mathbf{x}, \mathbf{y}\rangle^2$ need not be real, so "$4\langle \mathbf{x}, \mathbf{y}\rangle^2 - 4\|\mathbf{x}\|^2\|\mathbf{y}\|^2 \le 0$" is not a meaningful inequality, and "taking square roots" of it is not a valid step. (The claim itself is true; it is Theorem 6.2.1.)

The repair is the second proof of Theorem 6.2.1: restrict to real t, and first rotate the phase of $\mathbf{x}$ so that $\langle \mathbf{x}, \mathbf{y}\rangle$ is a nonnegative real number. Then the expansion above becomes a real quadratic in t with middle coefficient $-2|\langle \mathbf{x}, \mathbf{y}\rangle|$, and the discriminant argument applies.

Solution to Exercise 6.2.36

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.13 (Integral inner products)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. The right side contains $e^t f^2 = \left(e^{t/2} f\right)^2$. Split $f = \left(e^{t/2} f\right) \cdot e^{-t/2}$.
Hint 2. Apply Cauchy–Schwarz in $C[0,1]$ to $g = e^{t/2} f$ and $h = e^{-t/2}$. Compute $\|h\|^2$.
Sketch. $\int f = \left\langle e^{t/2} f, e^{-t/2}\right\rangle$, so $\left(\int f\right)^2 \le \left(\int e^t f^2\right)\left(\int_0^1 e^{-t}\,\mathrm{d}t\right) = \left(1 - e^{-1}\right)\int e^t f^2$. Equality iff $e^{t/2} f = ce^{-t/2}$, that is, $f(t) = ce^{-t}$.

In $C[0,1]$ with $\langle g, h\rangle = \int_0^1 gh$, let $g(t) = e^{t/2} f(t)$ and $h(t) = e^{-t/2}$, both continuous. Then $gh = f$, $g^2 = e^t f^2$, and $h^2 = e^{-t}$, so

$$\langle g, h\rangle = \int_0^1 f, \quad \|g\|^2 = \int_0^1 e^t f^2,$$

and $\|h\|^2 = \int_0^1 e^{-t}\,\mathrm{d}t = 1 - e^{-1}$. By Theorem 6.2.1, $\langle g, h\rangle^2 \le \|g\|^2\|h\|^2$, which is the inequality.

Since $h \neq \mathbf{0}$, equality holds if and only if $g = ch$ for some $c \in \mathbb{R}$, that is, $e^{t/2} f(t) = ce^{-t/2}$, or $f(t) = ce^{-t}$. Check: for $f(t) = e^{-t}$, the left side is $\left(1 - e^{-1}\right)^2$ and the right side is $\left(1 - e^{-1}\right)\int_0^1 e^{-t}\,\mathrm{d}t = \left(1 - e^{-1}\right)^2$.

Solution to Exercise 6.2.37

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Definition 1.2.17 (Evaluation)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. $p(t) = \sum_k a_k t^k$ is a dot product in $\mathbb{R}^{n+1}$. Of which two vectors?
Hint 2. For equality, choose the coefficient vector proportional to $(1, t, \ldots, t^n)$. For (b), compare $\sum_{k=0}^n t^{2k}$ with a geometric series.
Sketch. $p(t) = \mathbf{a} \cdot \boldsymbol{\tau}$ with $\mathbf{a} = (a_0, \ldots, a_n)$ and $\boldsymbol{\tau} = (1, t, \ldots, t^n)$, so Cauchy–Schwarz gives (a), with equality for $\mathbf{a} = \boldsymbol{\tau}$. For $|t| < 1$, $\sum_{k=0}^n t^{2k} \le \sum_{k \ge 0} t^{2k} = 1/\left(1 - t^2\right)$.

(a) Let $\mathbf{a} = (a_0, \ldots, a_n)$ and $\boldsymbol{\tau} = \left(1, t, t^2, \ldots, t^n\right)$ in $\mathbb{R}^{n+1}$. By Definition 1.2.17, $p(t) = \sum_{k=0}^n a_k t^k = \mathbf{a} \cdot \boldsymbol{\tau}$, and $\|\boldsymbol{\tau}\|^2 = \sum_{k=0}^n t^{2k}$. So Theorem 6.2.1 gives $|p(t)| \le \|\mathbf{a}\|\|\boldsymbol{\tau}\|$, which is the inequality. For $p = \sum_{k=0}^n t^k x^k$, the coefficient vector is $\boldsymbol{\tau}$ itself, which is nonzero (its first entry is 1), and $p(t) = \|\boldsymbol{\tau}\|^2 = \|\boldsymbol{\tau}\|\|\boldsymbol{\tau}\|$, so equality holds.

(b) For $|t| < 1$, $0 \le t^2 < 1$, so $\sum_{k=0}^n t^{2k} = \left(1 - t^{2n+2}\right)/\left(1 - t^2\right) \le 1/\left(1 - t^2\right)$. Combining with (a), $|p(t)| \le \|\mathbf{a}\|/\sqrt{1 - t^2}$, and the bound does not depend on n.

Solution to Exercise 6.2.38

Uses. Proposition 6.2.22 (The square of a sum), Theorem 6.2.1 (Cauchy–Schwarz inequality)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. (a) is Proposition 6.2.22 for $a_k = \sqrt{k}$. Recall $1 + 2 + \cdots + n = n(n+1)/2$.
Hint 2. (b) The left side is $\mathbf{a} \cdot (1, 1/2, \ldots, 1/n)$. Bound $\sum_{k=1}^n 1/k^2$ by telescoping.
Sketch. (a) $\left(\sum_k \sqrt{k}\right)^2 \le n \sum_k k = n^2(n+1)/2$. (b) Cauchy–Schwarz gives $\sum_k a_k/k \le \|\mathbf{a}\|\left(\sum_k 1/k^2\right)^{1/2}$, and the bound $1/k^2 < 1/(k-1) - 1/k$ makes $\sum_{k=2}^n 1/k^2$ telescope to less than 1.

(a) By Proposition 6.2.22 with $a_k = \sqrt{k}$,

$$\left(\sum_{k=1}^{n} \sqrt{k}\right)^2 \le n \sum_{k=1}^{n} k = n \cdot n\frac{n+1}{2},$$

and taking square roots gives the claim.

(b) Let $\mathbf{a} = (a_1, \dots, a_n)$ and $\mathbf{r} = (1, 1/2, \dots, 1/n)$. By Theorem 6.2.1,

$$\sum_{k=1}^{n} \frac{a_k}{k} = \mathbf{a} \cdot \mathbf{r} \le \|\mathbf{a}\|\|\mathbf{r}\| = \|\mathbf{a}\|\left(\sum_{k=1}^{n} \frac{1}{k^2}\right)^{1/2}.$$

For $k \ge 2$, $1/k^2 < 1/(k(k-1)) = 1/(k-1) - 1/k$, so the sum telescopes:

$$\sum_{k=1}^{n} \frac{1}{k^2} \le 1 + \sum_{k=2}^{n}\left(\frac{1}{k-1} - \frac{1}{k}\right) = 2 - \frac{1}{n} < 2.$$

Hence $\sum_k a_k/k \le \sqrt{2}\|\mathbf{a}\|$.

Solution to Exercise 6.2.39

Uses. Proposition 6.1.16 (Frobenius inner product), Theorem 6.2.1 (Cauchy–Schwarz inequality), Remark 6.2.2
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. The trace is an inner product with a fixed matrix in the Frobenius inner product $\langle A, B\rangle = \operatorname{tr}(B^* A)$. Which one?
Hint 2. $\langle A, I_n\rangle = \operatorname{tr} A$ and $\|I_n\|^2 = n$. For (b), the data force equality.
Sketch. $\operatorname{tr} A = \operatorname{tr}(I_n^* A) = \langle A, I_n\rangle$ and $\|I_n\|^2 = n$, so Cauchy–Schwarz gives (a), with equality iff $A = cI_n$. In (b), $|\operatorname{tr} A|^2 = 4 = 2 \cdot 2$, so $A = cI_2$, and $\operatorname{tr} A = 2$ gives $A = I_2$.

(a) In the Frobenius inner product (Proposition 6.1.16), $\langle A, I_n\rangle = \operatorname{tr}(I_n^* A) = \operatorname{tr} A$, $\|I_n\|^2 = \operatorname{tr}(I_n) = n$, and $\|A\|^2 = \operatorname{tr}(A^* A)$. By Theorem 6.2.1, $|\operatorname{tr} A|^2 \le \|A\|^2\|I_n\|^2 = n \operatorname{tr}(A^* A)$, with equality if and only if one of A, I_n is a multiple of the other, that is (as $I_n \ne 0$), $A = cI_n$ for some $c \in \mathbb{F}$.

(b) Here $\operatorname{tr}\left(A^{\mathsf{T}} A\right) = \sum_{i,j} a_{ij}^2 = 2$, so $|\operatorname{tr} A|^2 = 4 = 2 \cdot 2 = n \operatorname{tr}\left(A^{\mathsf{T}} A\right)$, which is the equality case of (a). So $A = cI_2$, and $\operatorname{tr} A = 2c = 2$ gives $c = 1$. Conversely, I_2 satisfies both conditions. So $A = I_2$ is the only such matrix.

Solution to Exercise 6.2.40

Uses. Proposition 6.1.16 (Frobenius inner product), Definition 2.4.1 (Matrix product), Theorem 6.2.1 (Cauchy–Schwarz inequality)
Hint 1. The (i, j) entry of AB is $\sum_k a_{ik} b_{kj}$, a product of row i of A with column j of B. Bound its modulus with Cauchy–Schwarz in $\mathbb{F}^n$ (watch the conjugate).
Hint 2. Square, sum over i and j, and recognize $\|A\|_F^2 = \sum_{i,k} |a_{ik}|^2$. For (b), induct on k.
Sketch. $\left|(AB)_{ij}\right|^2 \le \left(\sum_k |a_{ik}|^2\right)\left(\sum_k |b_{kj}|^2\right)$ by Cauchy–Schwarz; summing over i, j gives $\|AB\|_F^2 \le \|A\|_F^2 \|B\|_F^2$. Then $\left|\left(A^k\right)_{ij}\right| \le \left\|A^k\right\|_F \le \|A\|_F^k$. For (c), $A = B = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ gives $AB = 0$.

(a) By Definition 2.4.1, $(AB)_{ij} = \sum_{k=1}^{n} a_{ik} b_{kj}$. Let $\mathbf{r}_i = (a_{i1}, \dots, a_{in})$ and $\mathbf{c}_j = \left(\overline{b_{1j}}, \dots, \overline{b_{nj}}\right)$ in $\mathbb{F}^n$. Then $(AB)_{ij} = \mathbf{r}_i \cdot \mathbf{c}_j$, and by Theorem 6.2.1,

$$\left|(AB)_{ij}\right|^2 \le \|\mathbf{r}_i\|^2 \|\mathbf{c}_j\|^2 = \left(\sum_k |a_{ik}|^2\right)\left(\sum_k |b_{kj}|^2\right).$$

Summing over all i and j, and using Proposition 6.1.16,

$$\begin{aligned} \|AB\|_F^2 &\le \sum_{i,j}\left(\sum_k |a_{ik}|^2\right)\left(\sum_k |b_{kj}|^2\right) \\ &= \left(\sum_{i,k} |a_{ik}|^2\right)\left(\sum_{k,j} |b_{kj}|^2\right) = \|A\|_F^2 \|B\|_F^2. \end{aligned}$$

(b) By (a) and induction on k, $\left\|A^k\right\|_F \le \|A\|_F^k$: the case $k=1$ is trivial, and $\left\|A^{k+1}\right\|_F = \left\|A^kA\right\|_F \le \left\|A^k\right\|_F\|A\|_F$. Each entry satisfies $\left|\left(A^k\right)_{ij}\right|^2 \le \sum_{i',j'}\left|\left(A^k\right)_{i'j'}\right|^2 = \left\|A^k\right\|_F^2$, so $\left|\left(A^k\right)_{ij}\right| \le \|A\|_F^k$.

(c) For $A = B = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $AB = 0$, so $\|AB\|_F = 0 < 1 = \|A\|_F\|B\|_F$.

Solution to Exercise 6.2.41

Uses. Theorem 6.2.11 (Triangle inequality), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. The triangle inequality gives ≤ 1. Equality would force $(1-s)\mathbf{x}$ and $s\mathbf{y}$ onto a common ray.
Hint 2. If $(1-s)\mathbf{x} = as\mathbf{y}$ with $a \ge 0$, take norms to find a, and conclude $\mathbf{x} = \mathbf{y}$.
Hint 3. For (b), look at $\mathbf{e}_1$ and $\mathbf{e}_2$.
Sketch. By Theorem 6.2.11, $\|(1-s)\mathbf{x} + s\mathbf{y}\| \le (1-s) + s = 1$, with equality only if one of $(1-s)\mathbf{x}, s\mathbf{y}$ is a nonnegative multiple of the other. Taking norms, the multiple is the ratio of $1-s$ and s, and then $\mathbf{x} = \mathbf{y}$. In (b), $\|(\mathbf{e}_1 + \mathbf{e}_2)/2\|_1 = 1$.

(a) By Theorem 6.2.11 and Proposition 6.1.27,

$$\|(1-s)\mathbf{x} + s\mathbf{y}\| \le (1-s)\|\mathbf{x}\| + s\|\mathbf{y}\| = 1.$$

Suppose equality holds. By Theorem 6.2.11(b), one of $(1-s)\mathbf{x}$, $s\mathbf{y}$ is a nonnegative real multiple of the other. If $(1-s)\mathbf{x} = as\mathbf{y}$ with $a \ge 0$, taking norms gives $1 - s = as$, so $(1-s)\mathbf{x} = (1-s)\mathbf{y}$, and $\mathbf{x} = \mathbf{y}$ since $1 - s \neq 0$. If $s\mathbf{y} = b(1-s)\mathbf{x}$ with $b \ge 0$, the same argument gives $\mathbf{y} = \mathbf{x}$. Both contradict $\mathbf{x} \neq \mathbf{y}$, so the inequality is strict.

(b) The vectors $\mathbf{e}_1$ and $\mathbf{e}_2$ are distinct and $\|\mathbf{e}_1\|_1 = \|\mathbf{e}_2\|_1 = 1$, but $\|(\mathbf{e}_1 + \mathbf{e}_2)/2\|_1 = 1/2 + 1/2 = 1$. (The whole segment from $\mathbf{e}_1$ to $\mathbf{e}_2$ is an edge of the diamond in Figure 6.1.4.) If $\|\cdot\|_1$ were the norm of an inner product, (a) would apply to it. So it is not.

Solution to Exercise 6.2.42

Uses. Theorem 6.2.11 (Triangle inequality), Proposition 6.1.27 (Basic properties of the norm)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For $\supseteq$, compute $\mathbf{x} - \mathbf{z}$ and $\mathbf{z} - \mathbf{y}$ for $\mathbf{z} = (1-s)\mathbf{x} + s\mathbf{y}$: both are multiples of $\mathbf{x} - \mathbf{y}$.
Hint 2. For $\subseteq$, the condition is equality in the triangle inequality for $\mathbf{u} = \mathbf{x} - \mathbf{z}$ and $\mathbf{v} = \mathbf{z} - \mathbf{y}$, whose sum is $\mathbf{x} - \mathbf{y}$.
Hint 3. If $\mathbf{v} = a\mathbf{u}$ with $a \ge 0$, then $(1+a)\mathbf{u} = \mathbf{x} - \mathbf{y}$. Solve for $\mathbf{z}$.
Sketch. For $\mathbf{z} = (1-s)\mathbf{x} + s\mathbf{y}$, $\mathbf{x} - \mathbf{z} = s(\mathbf{x} - \mathbf{y})$ and $\mathbf{z} - \mathbf{y} = (1-s)(\mathbf{x} - \mathbf{y})$, whose norms add up to $\|\mathbf{x} - \mathbf{y}\|$. Conversely, equality in the triangle inequality for $\mathbf{u} = \mathbf{x} - \mathbf{z}$, $\mathbf{v} = \mathbf{z} - \mathbf{y}$ makes one a nonnegative multiple of the other; solving $(1+a)\mathbf{u} = \mathbf{x} - \mathbf{y}$ gives $\mathbf{z} = (1-s)\mathbf{x} + s\mathbf{y}$ with $s = 1/(1+a)$, and similarly in the other case.

Let L be the set of $\mathbf{z} \in V$ satisfying the equation, and $S = \{(1-s)\mathbf{x} + s\mathbf{y} \mid s \in [0,1]\}$. We show $L = S$ by Technique 1.3.14.

$S \subseteq L$. Let $\mathbf{z} = (1-s)\mathbf{x} + s\mathbf{y}$ with $s \in [0,1]$. Then $\mathbf{x} - \mathbf{z} = s(\mathbf{x} - \mathbf{y})$ and $\mathbf{z} - \mathbf{y} = (1-s)(\mathbf{x} - \mathbf{y})$. Since $s, 1-s \ge 0$, Proposition 6.1.27 gives

$$\|\mathbf{x} - \mathbf{z}\| + \|\mathbf{z} - \mathbf{y}\| = (s + (1-s))\|\mathbf{x} - \mathbf{y}\| = \|\mathbf{x} - \mathbf{y}\|.$$

$L \subseteq S$. Let $\mathbf{z} \in L$, and put $\mathbf{u} = \mathbf{x} - \mathbf{z}$ and $\mathbf{v} = \mathbf{z} - \mathbf{y}$, so that $\mathbf{u} + \mathbf{v} = \mathbf{x} - \mathbf{y}$ and $\|\mathbf{u} + \mathbf{v}\| = \|\mathbf{u}\| + \|\mathbf{v}\|$. By Theorem 6.2.11(b), one of $\mathbf{u}, \mathbf{v}$ is a nonnegative real multiple of the other.

If $\mathbf{v} = a\mathbf{u}$ with $a \ge 0$, then $(1+a)\mathbf{u} = \mathbf{x} - \mathbf{y}$, so $\mathbf{u} = s(\mathbf{x} - \mathbf{y})$ with $s = 1/(1+a) \in (0,1]$, and $\mathbf{z} = \mathbf{x} - \mathbf{u} = (1-s)\mathbf{x} + s\mathbf{y}$. If $\mathbf{u} = b\mathbf{v}$ with $b \ge 0$, then $(1+b)\mathbf{v} = \mathbf{x} - \mathbf{y}$, so $\mathbf{v} = (1-s)(\mathbf{x} - \mathbf{y})$ with $1 - s = 1/(1+b)$, that is, $s = b/(1+b) \in [0,1)$, and $\mathbf{z} = \mathbf{y} + \mathbf{v} = (1-s)\mathbf{x} + s\mathbf{y}$. In both cases $\mathbf{z} \in S$.

Solution to Exercise 6.2.43

Uses. Remark 6.2.5 (The size of the gap), Remark 6.2.2
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. Write both products as double sums over all pairs (j,k), and subtract.
Hint 2. The terms with $j = k$ cancel. Group the term for (j,k) with the term for (k,j).
Hint 3. For the equality case in (b), all the numbers $a_jb_k - a_kb_j$ vanish. If some $a_p \neq 0$, show $\mathbf{b} = \left(b_p/a_p\right)\mathbf{a}$.

Sketch. The left side is $\sum_{j,k}\left(a_j^2 b_k^2 - a_j b_j a_k b_k\right)$. Diagonal terms vanish, and the terms for (j,k) and (k,j) with $j<k$ add to $\left(a_j b_k - a_k b_j\right)^2$. A sum of squares is nonnegative and vanishes iff each term does, which says that $\mathbf{a}, \mathbf{b}$ are dependent. For $n=2$ the right side is $(a_1 b_2 - a_2 b_1)^2$, and (6.2.2) identifies the left side with the square of base times height.

(a) Expanding the products as double sums over all pairs (j,k),

$$\left(\sum_j a_j^2\right)\left(\sum_k b_k^2\right) - \left(\sum_j a_j b_j\right)\left(\sum_k a_k b_k\right)$$
$$= \sum_{j,k}\left(a_j^2 b_k^2 - a_j b_j a_k b_k\right).$$

The terms with $j=k$ are $a_j^2 b_j^2 - a_j^2 b_j^2 = 0$. For $j<k$, the terms for (j,k) and (k,j) add to

$$a_j^2 b_k^2 + a_k^2 b_j^2 - 2 a_j b_j a_k b_k = \left(a_j b_k - a_k b_j\right)^2.$$

Summing over $j<k$ gives the identity.

(b) The right side of (a) is a sum of squares, so it is nonnegative, which is the Cauchy–Schwarz inequality $(\mathbf{a}\cdot\mathbf{b})^2 \le \|\mathbf{a}\|^2\|\mathbf{b}\|^2$. By Technique 6.1.9, equality holds if and only if $a_j b_k = a_k b_j$ for all $j<k$, hence for all j,k. We show this happens if and only if $\mathbf{a}, \mathbf{b}$ are linearly dependent. If $\mathbf{a}=\mathbf{0}$, both hold. Otherwise pick p with $a_p \neq 0$. If $a_p b_k = a_k b_p$ for all k, then $\mathbf{b} = \left(b_p/a_p\right)\mathbf{a}$. Conversely, if $\mathbf{b} = c\mathbf{a}$, then $a_j b_k - a_k b_j = c\left(a_j a_k - a_k a_j\right) = 0$, and if $\mathbf{a} = c\mathbf{b}$ the same computation applies. By Remark 6.2.2, this is the equality case of Theorem 6.2.1.

(c) For $n=2$ there is one pair $j<k$, and (a) reads $\|\mathbf{a}\|^2\|\mathbf{b}\|^2 - (\mathbf{a}\cdot\mathbf{b})^2 = (a_1 b_2 - a_2 b_1)^2$. If $\mathbf{b}\neq\mathbf{0}$, (6.2.2) says the left side is $\|\mathbf{b}\|^2\|\mathbf{a} - c\mathbf{b}\|^2$, the square of (base) × (height) for the parallelogram on $\mathbf{a}, \mathbf{b}$ with base $\mathbf{b}$. So the area is $|a_1 b_2 - a_2 b_1|$; if $\mathbf{b}=\mathbf{0}$, both are 0. This is $\left|\det\begin{pmatrix} a_1 & b_1 \\ a_2 & b_2 \end{pmatrix}\right|$.

Solution to Exercise 6.2.44

Uses. Theorem 6.2.11 (Triangle inequality), Theorem 6.2.1 (Cauchy–Schwarz inequality), Notation 6.1.1 (Real and complex scalars)
Hint 1. The "if" direction is a computation. For "only if", first show that the sum $\mathbf{s} = \mathbf{x}_1 + \cdots + \mathbf{x}_n$ is nonzero, and let $\mathbf{u} = \mathbf{s}/\|\mathbf{s}\|$.
Hint 2. Write $\|\mathbf{s}\| = \langle \mathbf{s}, \mathbf{u}\rangle = \sum_k \langle \mathbf{x}_k, \mathbf{u}\rangle$, take real parts, and bound each term by $\|\mathbf{x}_k\|$.
Hint 3. Equality throughout forces $\langle \mathbf{x}_k, \mathbf{u}\rangle = \|\mathbf{x}_k\|\|\mathbf{u}\|$ for each k. Apply Theorem 6.2.11(b).
Sketch. If $\mathbf{x}_k = r_k\mathbf{u}$, both sides equal $\sum_k r_k$. Conversely, $\mathbf{s}\neq\mathbf{0}$ because $\|\mathbf{s}\| = \sum_k \|\mathbf{x}_k\| > 0$. With $\mathbf{u} = \mathbf{s}/\|\mathbf{s}\|$, $\|\mathbf{s}\| = \sum_k \operatorname{Re}\langle \mathbf{x}_k, \mathbf{u}\rangle \le \sum_k \|\mathbf{x}_k\| = \|\mathbf{s}\|$, so $\operatorname{Re}\langle \mathbf{x}_k, \mathbf{u}\rangle = |\langle \mathbf{x}_k, \mathbf{u}\rangle| = \|\mathbf{x}_k\|$ for each k, and Theorem 6.2.11(b) makes $\mathbf{x}_k$ a nonnegative multiple of $\mathbf{u}$.

Suppose $\mathbf{x}_k = r_k\mathbf{u}$ with $\|\mathbf{u}\| = 1$ and $r_k \ge 0$. Then $\left\|\sum_k \mathbf{x}_k\right\| = \left\|\left(\sum_k r_k\right)\mathbf{u}\right\| = \sum_k r_k = \sum_k \|\mathbf{x}_k\|$.

Conversely, suppose equality holds, and let $\mathbf{s} = \mathbf{x}_1 + \cdots + \mathbf{x}_n$. Since not all $\mathbf{x}_k$ are $\mathbf{0}$, $\|\mathbf{s}\| = \sum_k \|\mathbf{x}_k\| > 0$, so $\mathbf{s} \neq \mathbf{0}$. Let $\mathbf{u} = \mathbf{s}/\|\mathbf{s}\|$, a unit vector with $\langle \mathbf{s}, \mathbf{u}\rangle = \|\mathbf{s}\|$. By linearity in the first slot, $\operatorname{Re} z \le |z|$, and Theorem 6.2.1,

$$\|\mathbf{s}\| = \operatorname{Re}\langle \mathbf{s}, \mathbf{u}\rangle = \sum_k \operatorname{Re}\langle \mathbf{x}_k, \mathbf{u}\rangle$$
$$\le \sum_k |\langle \mathbf{x}_k, \mathbf{u}\rangle| \le \sum_k \|\mathbf{x}_k\| = \|\mathbf{s}\|.$$

So equality holds throughout. Since each term satisfies $\operatorname{Re}\langle \mathbf{x}_k, \mathbf{u}\rangle \le |\langle \mathbf{x}_k, \mathbf{u}\rangle| \le \|\mathbf{x}_k\|$, equality of the sums forces equality in every term. As in the proof of Theorem 6.2.11, $\operatorname{Re} z = |z|$ means that z is a nonnegative real number, so $\langle \mathbf{x}_k, \mathbf{u}\rangle = \|\mathbf{x}_k\| = \|\mathbf{x}_k\|\|\mathbf{u}\|$. By Theorem 6.2.11(b), one of $\mathbf{x}_k, \mathbf{u}$ is a nonnegative real multiple of the other. If $\mathbf{u} = b\mathbf{x}_k$ with $b \ge 0$, then $b > 0$ since $\mathbf{u}\neq\mathbf{0}$, and $\mathbf{x}_k = b^{-1}\mathbf{u}$. So in every case $\mathbf{x}_k = r_k\mathbf{u}$ with $r_k \ge 0$.

Solution to Exercise 6.2.45

Uses. Definition 6.2.16 (Angle), Theorem 6.2.1 (Cauchy–Schwarz inequality), (6.2.1)

Techniques. Orthogonal decomposition (Technique 6.2.4)
Hint 1. Angles do not change when vectors are scaled by positive numbers, so assume $\mathbf{x}, \mathbf{y}, \mathbf{z}$ are unit vectors. Let $\alpha = \theta(\mathbf{x}, \mathbf{y})$ and $\beta = \theta(\mathbf{y}, \mathbf{z})$. If $\alpha + \beta \geq \pi$ there is nothing to prove.
Hint 2. Decompose $\mathbf{x} = (\cos\alpha)\mathbf{y} + \mathbf{w}$ and $\mathbf{z} = (\cos\beta)\mathbf{y} + \mathbf{w}'$ with $\mathbf{w}, \mathbf{w}'$ orthogonal to $\mathbf{y}$. Compute $\|\mathbf{w}\|$ and $\|\mathbf{w}'\|$.
Hint 3. Expand $\langle \mathbf{x}, \mathbf{z} \rangle$ and bound $\langle \mathbf{w}, \mathbf{w}' \rangle$ below with Cauchy–Schwarz. You should get $\langle \mathbf{x}, \mathbf{z} \rangle \geq \cos(\alpha + \beta)$.
Sketch. Normalize. With α, β as above, $\mathbf{x} = (\cos\alpha)\mathbf{y} + \mathbf{w}$ and $\mathbf{z} = (\cos\beta)\mathbf{y} + \mathbf{w}'$, where $\mathbf{w}, \mathbf{w}' \perp \mathbf{y}$, $\|\mathbf{w}\| = \sin\alpha$, $\|\mathbf{w}'\| = \sin\beta$. Then $\langle \mathbf{x}, \mathbf{z} \rangle = \cos\alpha\cos\beta + \langle \mathbf{w}, \mathbf{w}' \rangle$, and Cauchy–Schwarz bounds the last term below by $-\sin\alpha\sin\beta$, so $\langle \mathbf{x}, \mathbf{z} \rangle \geq \cos(\alpha + \beta)$. If $\alpha + \beta \leq \pi$, since cos is decreasing on $[0, \pi]$, $\theta(\mathbf{x}, \mathbf{z}) \leq \alpha + \beta$; otherwise the claim is trivial since $\theta \leq \pi$.

For $s, t > 0$, $\langle s\mathbf{x}, t\mathbf{y} \rangle / (\|s\mathbf{x}\|\|t\mathbf{y}\|) = \langle \mathbf{x}, \mathbf{y} \rangle / (\|\mathbf{x}\|\|\mathbf{y}\|)$, so angles are unchanged by positive scaling, and we may assume $\|\mathbf{x}\| = \|\mathbf{y}\| = \|\mathbf{z}\| = 1$. Let $\alpha = \theta(\mathbf{x}, \mathbf{y})$ and $\beta = \theta(\mathbf{y}, \mathbf{z})$, both in $[0, \pi]$. If $\alpha + \beta > \pi$, the claim holds because $\theta(\mathbf{x}, \mathbf{z}) \leq \pi$. Assume $\alpha + \beta \leq \pi$.

By Definition 6.2.16, $\langle \mathbf{x}, \mathbf{y} \rangle = \cos\alpha$ and $\langle \mathbf{z}, \mathbf{y} \rangle = \cos\beta$. As in Technique 6.2.4 (with $\|\mathbf{y}\| = 1$), let $\mathbf{w} = \mathbf{x} - (\cos\alpha)\mathbf{y}$ and $\mathbf{w}' = \mathbf{z} - (\cos\beta)\mathbf{y}$, so that $\langle \mathbf{w}, \mathbf{y} \rangle = \langle \mathbf{w}', \mathbf{y} \rangle = 0$. By (6.2.1), $\|\mathbf{w}\|^2 = 1 - \cos^2\alpha = \sin^2\alpha$, so $\|\mathbf{w}\| = \sin\alpha$, as $\sin\alpha \geq 0$ on $[0, \pi]$; similarly $\|\mathbf{w}'\| = \sin\beta$. Expanding, and using that the cross terms $\langle \mathbf{y}, \mathbf{w}' \rangle$ and $\langle \mathbf{w}, \mathbf{y} \rangle$ vanish,

$$\begin{aligned} \langle \mathbf{x}, \mathbf{z} \rangle &= \langle (\cos\alpha)\mathbf{y} + \mathbf{w}, (\cos\beta)\mathbf{y} + \mathbf{w}' \rangle \\ &= \cos\alpha\cos\beta + \langle \mathbf{w}, \mathbf{w}' \rangle. \end{aligned}$$

By Theorem 6.2.1, $\langle \mathbf{w}, \mathbf{w}' \rangle \geq -\|\mathbf{w}\|\|\mathbf{w}'\| = -\sin\alpha\sin\beta$. So

$$\begin{aligned} \cos\theta(\mathbf{x}, \mathbf{z}) = \langle \mathbf{x}, \mathbf{z} \rangle &\geq \cos\alpha\cos\beta - \sin\alpha\sin\beta \\ &= \cos(\alpha + \beta). \end{aligned}$$

Both $\theta(\mathbf{x}, \mathbf{z})$ and $\alpha + \beta$ lie in $[0, \pi]$, where cos is strictly decreasing, so $\theta(\mathbf{x}, \mathbf{z}) \leq \alpha + \beta$.

Solution to Exercise 6.2.46

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.13 (Integral inner products)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. The constraints say $\langle f, 1 \rangle = \langle f, t \rangle = 1$. So $\langle f, g \rangle$ is known for every $g = \alpha + \beta t$. Apply Cauchy–Schwarz to f and such a g.
Hint 2. The bound is $\|f\|^2 \geq (\alpha + \beta)^2 / \|\alpha + \beta t\|^2$. The best g should itself satisfy the constraints, by the equality case.
Hint 3. Find $g = \alpha + \beta t$ with $\langle g, 1 \rangle = \langle g, t \rangle = 1$: you get $g = 6t - 2$.
Sketch. For $g = 6t - 2$: $\langle f, g \rangle = 6 - 2 = 4$ and $\|g\|^2 = 4$, so $16 \leq 4\|f\|^2$, that is, $\int f^2 \geq 4$. The function g satisfies both constraints and has $\int g^2 = 4$. Equality forces $f = cg$, and the constraints give $c = 1$. So the minimum is 4, attained only by $f(t) = 6t - 2$.

Let $g(t) = 6t - 2$. In $C[0, 1]$ with $\langle f, h \rangle = \int_0^1 fh$,

$$\langle f, g \rangle = 6\int_0^1 tf - 2\int_0^1 f = 6 - 2 = 4,$$

$$\|g\|^2 = \int_0^1 \left(36t^2 - 24t + 4\right) \mathrm{d}t = 12 - 12 + 4 = 4,$$

for every f satisfying the constraints. By Theorem 6.2.1, $16 = \langle f, g \rangle^2 \leq \|f\|^2\|g\|^2 = 4\|f\|^2$, so $\int_0^1 f^2 \geq 4$.

The function g itself satisfies the constraints: $\int_0^1 (6t - 2)\,\mathrm{d}t = 3 - 2 = 1$ and $\int_0^1 \left(6t^2 - 2t\right)\mathrm{d}t = 2 - 1 = 1$. And $\int_0^1 g^2 = 4$. So the minimum is 4. If f attains it, equality holds in Cauchy–Schwarz, so $f = cg$ (as $g \neq \mathbf{0}$), and $1 = \int_0^1 f = c\int_0^1 g = c$. So $f = g$ is the only minimizer.

Here is how to find g. The constraints determine $\langle f, \alpha + \beta t \rangle = \alpha + \beta$ for all α, β, so each $g = \alpha + \beta t \neq \mathbf{0}$ gives the bound $\|f\|^2 \geq (\alpha + \beta)^2 / \|g\|^2$. If some such g satisfies the constraints itself, then $f = g$ attains its own bound, and no f can do better. Solving $\langle \alpha + \beta t, 1 \rangle = \alpha + \beta/2 = 1$ and $\langle \alpha + \beta t, t \rangle = \alpha/2 + \beta/3 = 1$ gives $\beta = 6$ and $\alpha = -2$. (In the language of Section 6.4, the minimizer is the vector of least norm in an affine subspace, and it lies in $\mathrm{span}(1, t)$.)

Solution to Exercise 6.2.47

Uses. Corollary 6.2.26 (Engel's form)
Techniques. A sum of nonnegative terms (Technique 6.1.9), Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. Engel's form (Corollary 6.2.26) needs squares in the numerators. Multiply the numerator and denominator of $a/(b+c)$ by a.
Hint 2. You get a lower bound $(a+b+c)^2/(2(ab+bc+ca))$. Compare $(a+b+c)^2$ with $3(ab+bc+ca)$.
Sketch. Write $a/(b+c) = a^2/(a(b+c))$. By Corollary 6.2.26, the sum is at least $(a+b+c)^2/(2(ab+bc+ca))$. Finally $(a+b+c)^2 \geq 3(ab+bc+ca)$, because the difference is half the sum of the squares $(a-b)^2$, $(b-c)^2$, $(c-a)^2$. Equality in the last step forces $a=b=c$, and then equality holds.

Since $a, b, c > 0$, the denominators $a(b+c)$, $b(c+a)$, $c(a+b)$ are positive. By Corollary 6.2.26,

$$\begin{aligned}
&\frac{a}{b+c} + \frac{b}{c+a} + \frac{c}{a+b} \\
&= \frac{a^2}{a(b+c)} + \frac{b^2}{b(c+a)} + \frac{c^2}{c(a+b)} \\
&\geq \frac{(a+b+c)^2}{2(ab+bc+ca)},
\end{aligned}$$

since the denominators add up to $2(ab+bc+ca)$. Now

$$\begin{aligned}
(a+b+c)^2 - 3(ab+bc+ca) &= a^2+b^2+c^2-ab-bc-ca \\
&= \frac{1}{2}\Big((a-b)^2+(b-c)^2+(c-a)^2\Big) \geq 0,
\end{aligned}$$

so the right side is at least $3(ab+bc+ca)/(2(ab+bc+ca)) = 3/2$.

If equality holds, the last step is an equality, so $(a-b)^2+(b-c)^2+(c-a)^2 = 0$, and $a=b=c$ by Technique 6.1.9. Conversely, for $a=b=c$ each term is $1/2$.

Solution to Exercise 6.2.48

Uses. Proposition 6.1.29 (Expanding a norm), Corollary 6.2.14 (Distances and the reverse triangle inequality), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. (a) Expand the left side squared with Proposition 6.1.29; the coefficients $1/\|\mathbf{x}\|^2$ and $1/\|\mathbf{y}\|^2$ are real.
Hint 2. (b) Translating all four points by $-\mathbf{w}$ changes no distance, so you may assume $\mathbf{w} = \mathbf{0}$. Dispose of the case where one of $\mathbf{x}, \mathbf{y}, \mathbf{z}$ is $\mathbf{0}$.
Hint 3. Apply the triangle inequality to the three points $\mathbf{v}/\|\mathbf{v}\|^2$ for $\mathbf{v} = \mathbf{x}, \mathbf{y}, \mathbf{z}$, rewrite each distance with (a), and clear denominators.
Sketch. (a) Expand the square of the left side with Proposition 6.1.29 and put everything over $\|\mathbf{x}\|^2\|\mathbf{y}\|^2$; the numerator is $\|\mathbf{x}-\mathbf{y}\|^2$. (b) Translate so that $\mathbf{w} = \mathbf{0}$; the cases with a zero vector are immediate. Otherwise, let $\iota(\mathbf{v}) = \mathbf{v}/\|\mathbf{v}\|^2$. The triangle inequality for the three points $\iota(\mathbf{x}), \iota(\mathbf{y}), \iota(\mathbf{z})$ becomes, by (a), the claim divided by $\|\mathbf{x}\|\|\mathbf{y}\|\|\mathbf{z}\|$.

(a) Let $\alpha = 1/\|\mathbf{x}\|^2$ and $\beta = 1/\|\mathbf{y}\|^2$, both real. By Proposition 6.1.29 (and linearity),

$$\begin{aligned}
\|\alpha\mathbf{x} - \beta\mathbf{y}\|^2 &= \alpha^2\|\mathbf{x}\|^2 - 2\alpha\beta\,\mathrm{Re}\langle\mathbf{x},\mathbf{y}\rangle + \beta^2\|\mathbf{y}\|^2 \\
&= \frac{1}{\|\mathbf{x}\|^2} - \frac{2\,\mathrm{Re}\langle\mathbf{x},\mathbf{y}\rangle}{\|\mathbf{x}\|^2\|\mathbf{y}\|^2} + \frac{1}{\|\mathbf{y}\|^2} \\
&= \frac{\|\mathbf{y}\|^2 - 2\,\mathrm{Re}\langle\mathbf{x},\mathbf{y}\rangle + \|\mathbf{x}\|^2}{\|\mathbf{x}\|^2\|\mathbf{y}\|^2} = \frac{\|\mathbf{x}-\mathbf{y}\|^2}{\|\mathbf{x}\|^2\|\mathbf{y}\|^2}.
\end{aligned}$$

Taking nonnegative square roots gives (a).

(b) Replacing $\mathbf{x}, \mathbf{y}, \mathbf{z}, \mathbf{w}$ by $\mathbf{x}-\mathbf{w}, \mathbf{y}-\mathbf{w}, \mathbf{z}-\mathbf{w}, \mathbf{0}$ changes none of the six differences, so we may assume $\mathbf{w} = \mathbf{0}$. The claim is then

$$\|\mathbf{x}-\mathbf{y}\|\|\mathbf{z}\| \le \|\mathbf{x}-\mathbf{z}\|\|\mathbf{y}\| + \|\mathbf{x}\|\|\mathbf{y}-\mathbf{z}\|.$$

If $\mathbf{x}=\mathbf{0}$, both sides are $\|\mathbf{y}\|\|\mathbf{z}\|$. If $\mathbf{y}=\mathbf{0}$, both sides are $\|\mathbf{x}\|\|\mathbf{z}\|$. If $\mathbf{z}=\mathbf{0}$, the left side is 0. So assume $\mathbf{x},\mathbf{y},\mathbf{z}\neq\mathbf{0}$, and write $\iota(\mathbf{v}) = \mathbf{v}/\|\mathbf{v}\|^2$ for $\mathbf{v}\neq\mathbf{0}$. By Corollary 6.2.14(a),

$$\|\iota(\mathbf{x})-\iota(\mathbf{y})\| \le \|\iota(\mathbf{x})-\iota(\mathbf{z})\| + \|\iota(\mathbf{z})-\iota(\mathbf{y})\|,$$

and by (a) this says

$$\frac{\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}\|\|\mathbf{y}\|} \le \frac{\|\mathbf{x}-\mathbf{z}\|}{\|\mathbf{x}\|\|\mathbf{z}\|} + \frac{\|\mathbf{z}-\mathbf{y}\|}{\|\mathbf{z}\|\|\mathbf{y}\|}.$$

Multiplying by $\|\mathbf{x}\|\|\mathbf{y}\|\|\mathbf{z}\| > 0$ gives the claim, since $\|\mathbf{z}-\mathbf{y}\| = \|\mathbf{y}-\mathbf{z}\|$.

The map ι is *inversion* in the unit sphere, and (a) says how it distorts distances. Ptolemy's inequality is the triangle inequality, seen after inversion.

Section 6.3

Solution to Exercise 6.3.7

Uses. Definition 6.1.8 (Dot product), Definition 6.3.1 (Orthogonality), Proposition 6.1.10 (The dot product is an inner product)
Hint 1. Conjugate the entries of the second vector, multiply entrywise, and add. You get a linear equation in a.
Hint 2. The equation is $3+i-ia=0$.
Sketch. $(1,i,a)\cdot(2,1+i,i) = 2+i(1-i)-ia = 3+i-ia$, which vanishes for $a=1-3i$. Then the squared norms are 12 and 7, and the sum $(3,1+2i,1-2i)$ has squared norm $9+5+5 = 19 = 12+7$.

By Definition 6.1.8,

$$\begin{aligned}(1,i,a)\cdot(2,1+i,i) &= 1\cdot 2 + i\cdot\overline{(1+i)} + a\cdot\bar{i}\\ &= 2+i(1-i)-ia = 3+i-ia.\end{aligned}$$

This vanishes if and only if $ia = 3+i$, that is, $a = (3+i)/i = (3+i)(-i) = 1-3i$.

With $\mathbf{u}=(1,i,1-3i)$ and $\mathbf{v}=(2,1+i,i)$, Proposition 6.1.10 gives $\|\mathbf{u}\|^2 = 1+1+10 = 12$ and $\|\mathbf{v}\|^2 = 4+2+1 = 7$. The sum is $\mathbf{u}+\mathbf{v} = (3,1+2i,1-2i)$, with $\|\mathbf{u}+\mathbf{v}\|^2 = 9+5+5 = 19 = 12+7$, as Theorem 6.3.3 predicts.

Solution to Exercise 6.3.11

Uses. Definition 6.3.8 (Vectors orthogonal to a set), Proposition 6.3.9 (Properties of $A^\perp$)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For the first identity, unwind the definitions: being orthogonal to every element of $A\cup B$ means being orthogonal to every element of A and to every element of B.
Hint 2. For $A\subseteq\left(A^\perp\right)^\perp$, take $\mathbf{a}\in A$ and $\mathbf{v}\in A^\perp$, and compute $\langle\mathbf{a},\mathbf{v}\rangle$ using symmetry of orthogonality.
Hint 3. $\left(A^\perp\right)^\perp$ is always a subspace, by Proposition 6.3.9(a).
Sketch. $\mathbf{v}\perp(A\cup B)$ if and only if $\mathbf{v}\perp A$ and $\mathbf{v}\perp B$. If $\mathbf{a}\in A$ and $\mathbf{v}\in A^\perp$, then $\langle\mathbf{a},\mathbf{v}\rangle = \overline{\langle\mathbf{v},\mathbf{a}\rangle} = 0$, so $\mathbf{a}\in\left(A^\perp\right)^\perp$. For $A=\{(1,0)\}$ in $\mathbb{R}^2$, $\left(A^\perp\right)^\perp$ is a subspace, so it is not A.

A vector $\mathbf{v}$ lies in $(A\cup B)^\perp$ if and only if $\langle\mathbf{v},\mathbf{c}\rangle = 0$ for every $\mathbf{c}$ in A or in B, that is, if and only if $\mathbf{v}\in A^\perp$ and $\mathbf{v}\in B^\perp$. So $(A\cup B)^\perp = A^\perp\cap B^\perp$.

Let $\mathbf{a}\in A$. For every $\mathbf{v}\in A^\perp$, $\langle\mathbf{a},\mathbf{v}\rangle = \overline{\langle\mathbf{v},\mathbf{a}\rangle} = \bar{0} = 0$. So $\mathbf{a}$ is orthogonal to every vector of $A^\perp$, that is, $\mathbf{a}\in\left(A^\perp\right)^\perp$.

For $A=\{(1,0)\}$ in $\mathbb{R}^2$ with the dot product, $\left(A^\perp\right)^\perp$ is a subspace by Proposition 6.3.9(a), so it contains $\mathbf{0}\notin A$. In fact $A^\perp = \operatorname{span}((0,1))$ and $\left(A^\perp\right)^\perp = \operatorname{span}((1,0))$. (Section 6.4 shows that $\left(W^\perp\right)^\perp = W$ when W is a finite-dimensional subspace.)

Solution to Exercise 6.3.23

Uses. Corollary 6.3.14 (Counting orthogonal vectors), Proposition 6.3.18 (Coordinates in an orthonormal basis), Theorem 6.3.22 (Parseval's identity)
Hint 1. Check the three dot products between different vectors, and the three norms. Then use Corollary 6.3.14.
Hint 2. The jth coordinate is $\mathbf{v} \cdot \mathbf{u}_j$.
Sketch. The pairwise dot products of $(1,1,0)$, $(1,-1,1)$, $(-1,1,2)$ vanish, and the scalings make them unit vectors. The coordinates are $4/\sqrt{2} = 2\sqrt{2}$, $4/\sqrt{3}$, and $2/\sqrt{6}$, and $8 + 16/3 + 2/3 = 14 = \|\mathbf{v}\|^2$.

The unscaled vectors $(1,1,0)$, $(1,-1,1)$, $(-1,1,2)$ have pairwise dot products $1-1+0=0$, $-1+1+0=0$, and $-1-1+2=0$, and squared norms 2, 3, 6. So $\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$ is an orthonormal list of length $3 = \dim \mathbb{R}^3$, hence an orthonormal basis by Corollary 6.3.14.

By Proposition 6.3.18,

$$\begin{aligned} \mathbf{v} \cdot \mathbf{u}_1 &= \frac{4}{\sqrt{2}} = 2\sqrt{2}, \\ \mathbf{v} \cdot \mathbf{u}_2 &= \frac{3-1+2}{\sqrt{3}} = \frac{4}{\sqrt{3}}, \\ \mathbf{v} \cdot \mathbf{u}_3 &= \frac{-3+1+4}{\sqrt{6}} = \frac{2}{\sqrt{6}}, \end{aligned}$$

so $[\mathbf{v}]_{\mathcal{O}} = \left(2\sqrt{2}, 4/\sqrt{3}, 2/\sqrt{6}\right)$. By Theorem 6.3.22(b), the sum of the squares of the coordinates should be $\|\mathbf{v}\|^2 = 9+1+4 = 14$, and indeed $8 + 16/3 + 4/6 = 8 + 16/3 + 2/3 = 14$.

Solution to Exercise 6.3.37

Uses. Definition 6.3.33 (Unitary and orthogonal matrices), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 6.3.34 (Characterizations of unitary matrices), Proposition 2.4.14 (Algebra of matrices)
Hint 1. Compute $(UW)^*(UW)$ with Proposition 6.3.27(b).
Hint 2. $U^{-1} = U^*$, and Proposition 6.3.34(iv). For the dot products, move U across with Proposition 6.3.27(d).
Sketch. $(UW)^*UW = W^*U^*UW = W^*W = I$. $U^{-1} = U^*$ is unitary by Proposition 6.3.34. And $(U\mathbf{x}) \cdot (U\mathbf{y}) = \mathbf{x} \cdot (U^*U\mathbf{y}) = \mathbf{x} \cdot \mathbf{y}$; take $\mathbf{y} = \mathbf{x}$ for the norms.

By Proposition 6.3.27(b) and associativity,

$$(UW)^*(UW) = W^*(U^*U)W = W^*I_nW = W^*W = I_n,$$

so UW is unitary. By Proposition 6.3.34, $U^{-1} = U^*$, and U^* is unitary by (iv) of the same proposition.

By Proposition 6.3.27(d) with $A = U$ and the vector $U\mathbf{y}$ in place of $\mathbf{y}$,

$$(U\mathbf{x}) \cdot (U\mathbf{y}) = \mathbf{x} \cdot (U^*U\mathbf{y}) = \mathbf{x} \cdot \mathbf{y}.$$

Taking $\mathbf{y} = \mathbf{x}$ gives $\|U\mathbf{x}\|^2 = \|\mathbf{x}\|^2$, and norms are nonnegative, so $\|U\mathbf{x}\| = \|\mathbf{x}\|$. (Section 8.4 shows that, conversely, a square matrix with $\|A\mathbf{x}\| = \|\mathbf{x}\|$ for all $\mathbf{x}$ is unitary.)

Solution to Exercise 6.3.38

Uses. Definition 6.3.33 (Unitary and orthogonal matrices), Theorem 6.3.29 (Orthonormal columns), Definition 6.1.8 (Dot product)
Hint 1. The first column $(1,i)/\sqrt{2}$ is already a unit vector. Write the two remaining conditions on the second column.
Hint 2. Orthogonality to the first column gives one linear equation; the norm gives $|a|^2 + |b|^2 = 2$.
Sketch. Orthogonality: $(a,b) \cdot (1,i) = a - ib = 0$, so $a = ib$. Unit length: $|a|^2 + |b|^2 = 2|b|^2 = 2$. So $(a,b) = (ib, b)$ with $|b| = 1$.

By Theorem 6.3.29 the matrix is unitary if and only if its columns $\mathbf{c}_1 = (1,i)/\sqrt{2}$ and $\mathbf{c}_2 = (a,b)/\sqrt{2}$ are orthonormal. Here $\|\mathbf{c}_1\|^2 = (1+1)/2 = 1$. Next,

$$\mathbf{c}_2 \cdot \mathbf{c}_1 = \frac{1}{2}\left(a \cdot 1 + b \cdot \bar{i}\right) = \frac{1}{2}(a - ib),$$

which vanishes if and only if $a = ib$. Then $\|\mathbf{c}_2\|^2 = \left(|a|^2 + |b|^2\right)/2 = |b|^2$, which is 1 if and only if $|b| = 1$. So the matrix is unitary exactly when $a = ib$ with $|b| = 1$. For $b = -i$ we recover the first matrix of Example 6.3.35(d).

Solution to Exercise 6.3.44

Uses. Definition 6.1.8 (Dot product), Corollary 6.3.14 (Counting orthogonal vectors), Proposition 6.3.18 (Coordinates in an orthonormal basis), Theorem 6.3.22 (Parseval's identity), Remark 6.3.19 (Which slot)
Hint 1. For (a), compute both squared norms and one dot product; then count.
Hint 2. For (b), the coordinates are $\mathbf{v}\cdot\mathbf{u}_1$ and $\mathbf{v}\cdot\mathbf{u}_2$. Conjugate the entries of $\mathbf{u}_j$.
Hint 3. For (c), the coefficients are the conjugates of those in (b).
Sketch. (a) $\|(1,1+i)\|^2 = \|(-1+i,1)\|^2 = 3$ and $(1,1+i)\cdot(-1+i,1) = (-1-i)+(1+i) = 0$. (b) $[\mathbf{v}]_{\mathcal{O}} = \big((5+3i)/\sqrt{3}, (-2+i)/\sqrt{3}\big)$, and $(34+5)/3 = 13 = \|\mathbf{v}\|^2$. (c) The conjugated coefficients give $((8-4i)/3, (6+i)/3) \neq \mathbf{v}$.

(a) $\|(1,1+i)\|^2 = 1+2 = 3$ and $\|(-1+i,1)\|^2 = 2+1 = 3$, so $\mathbf{u}_1$ and $\mathbf{u}_2$ are unit vectors. Also

$$\begin{aligned}(1,1+i)\cdot(-1+i,1) &= 1\cdot\overline{(-1+i)} + (1+i)\cdot 1\\ &= (-1-i)+(1+i) = 0.\end{aligned}$$

So $\mathcal{O}$ is an orthonormal list of length $2 = \dim\mathbb{C}^2$, hence an orthonormal basis by Corollary 6.3.14.

(b) By Proposition 6.3.18,

$$\begin{aligned}\langle \mathbf{v},\mathbf{u}_1\rangle &= \frac{1}{\sqrt{3}}\Big(2\cdot 1 + 3i\cdot\overline{(1+i)}\Big)\\ &= \frac{1}{\sqrt{3}}(2+3i+3) = \frac{5+3i}{\sqrt{3}},\\ \langle \mathbf{v},\mathbf{u}_2\rangle &= \frac{1}{\sqrt{3}}\Big(2\cdot\overline{(-1+i)} + 3i\cdot 1\Big)\\ &= \frac{1}{\sqrt{3}}(-2-2i+3i) = \frac{-2+i}{\sqrt{3}}.\end{aligned}$$

So $[\mathbf{v}]_{\mathcal{O}} = \big((5+3i)/\sqrt{3}, (-2+i)/\sqrt{3}\big)$. Check: $|5+3i|^2/3 + |-2+i|^2/3 = (34+5)/3 = 13 = |2|^2 + |3i|^2$, as Theorem 6.3.22(b) requires. One can also check directly that $(5+3i)(1,1+i)/3 + (-2+i)(-1+i,1)/3 = (6,9i)/3 = \mathbf{v}$, using $(5+3i)(1+i) = 2+8i$ and $(-2+i)(-1+i) = 1-3i$.

(c) The exchanged coefficients are the conjugates $\langle \mathbf{u}_1,\mathbf{v}\rangle = (5-3i)/\sqrt{3}$ and $\langle \mathbf{u}_2,\mathbf{v}\rangle = (-2-i)/\sqrt{3}$. Since $(5-3i)(1+i) = 8+2i$ and $(-2-i)(-1+i) = 3-i$,

$$\begin{aligned}&\frac{1}{3}\big((5-3i)(1,1+i) + (-2-i)(-1+i,1)\big)\\ &= \frac{1}{3}(5-3i+3-i, 8+2i-2-i) = \left(\frac{8-4i}{3}, \frac{6+i}{3}\right),\end{aligned}$$

which is not $\mathbf{v}$. Over $\mathbb{C}$ the vector belongs in the first slot (Remark 6.3.19).

Solution to Exercise 6.3.45

Uses. Example 6.3.10 (Perps are solution sets), Theorem 6.3.29 (Orthonormal columns), Definition 6.3.33 (Unitary and orthogonal matrices)
Hint 1. By Example 6.3.10, the vectors orthogonal to both are the solutions of a homogeneous system with these two rows.
Hint 2. Solve $x_1+2x_2+2x_3 = 0$, $2x_1+x_2-2x_3 = 0$, then normalize. For the matrices, the third column must be one of the vectors you found.
Sketch. Adding the equations gives $x_2 = -x_1$, and then $x_3 = x_1/2$, so the solutions are $t(2,-2,1)$, and the unit ones are $\pm\frac{1}{3}(2,-2,1)$. A 3×3 matrix is orthogonal exactly when its columns are orthonormal, so the third column must be one of these two vectors: there are exactly two such matrices.

By Example 6.3.10, $\mathbf{x}$ is orthogonal to both vectors if and only if

$$x_1+2x_2+2x_3 = 0, \quad 2x_1+x_2-2x_3 = 0.$$

Adding the equations gives $3x_1 + 3x_2 = 0$, so $x_2 = -x_1$, and then the first equation gives $-x_1 + 2x_3 = 0$, so $x_3 = x_1/2$. Conversely, every $\mathbf{x} = t(2,-2,1)$ satisfies both equations. Since $\|(2,-2,1)\| = 3$, the unit vectors among these are $\mathbf{x} = \pm\frac{1}{3}(2,-2,1)$.

By Theorem 6.3.29 and Definition 6.3.33, a real 3×3 matrix is orthogonal if and only if its columns are orthonormal. The first two given columns are orthonormal (Example 6.3.16(c)), so the matrix is orthogonal exactly when its third column is a unit vector orthogonal to both, that is, $\pm\frac{1}{3}(2,-2,1)$. So there are exactly two such matrices,

$$\frac{1}{3}\begin{pmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{pmatrix} \quad \text{and} \quad \frac{1}{3}\begin{pmatrix} 1 & 2 & -2 \\ 2 & 1 & 2 \\ 2 & -2 & -1 \end{pmatrix}.$$

Solution to Exercise 6.3.46

Uses. Definition 6.3.1 (Orthogonality), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.29 (Expanding a norm), Proposition 6.3.9 (Properties of $A^\perp$), Non-example 6.3.4 (The converse fails over $\mathbb{C}$)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a) and (b), look for counterexamples in which a vector is repeated.
Hint 2. For (d), expand both norms with Proposition 6.1.29. Do the two hypotheses say different things?
Hint 3. For (e), combine (c) and (d) of Proposition 6.3.9.
Sketch. (a) False: $\mathbf{u} = \mathbf{w} = \mathbf{e}_1$, $\mathbf{v} = \mathbf{e}_2$. (b) False: in $\mathbb{R}^3$, $\mathbf{v}_1 = \mathbf{v}_3 = \mathbf{e}_1$, $\mathbf{v}_2 = \mathbf{e}_2$. (c) True: $\langle c_i\mathbf{v}_i, c_j\mathbf{v}_j\rangle = c_i\overline{c_j}\langle \mathbf{v}_i, \mathbf{v}_j\rangle$. (d) Both hypotheses say $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = 0$; true over $\mathbb{R}$, false over $\mathbb{C}$ ($\mathbf{u} = 1$, $\mathbf{v} = i$). (e) True: $\mathbf{x} \in \mathcal{L}^\perp = \operatorname{span}(\mathcal{L})^\perp = V^\perp = \{\mathbf{0}\}$.

(a) False. In $\mathbb{R}^2$, take $\mathbf{u} = \mathbf{w} = \mathbf{e}_1$ and $\mathbf{v} = \mathbf{e}_2$. Then $\mathbf{u} \perp \mathbf{v}$ and $\mathbf{v} \perp \mathbf{w}$, but $\langle \mathbf{u}, \mathbf{w}\rangle = 1$.

(b) False. In $\mathbb{R}^3$, take $\mathbf{v}_1 = \mathbf{v}_3 = \mathbf{e}_1$ and $\mathbf{v}_2 = \mathbf{e}_2$. The hypotheses hold, but $\mathbf{v}_1 - \mathbf{v}_3 = \mathbf{0}$. The hypothesis says nothing about the pair $\mathbf{v}_1, \mathbf{v}_3$, so the list need not be orthogonal, and Proposition 6.3.13 does not apply. (The space is $\mathbb{R}^3$ so that the dependence is not merely forced by the dimension.)

(c) True. For $i \neq j$, Proposition 6.1.4 gives $\langle c_i\mathbf{v}_i, c_j\mathbf{v}_j\rangle = c_i\overline{c_j}\langle \mathbf{v}_i, \mathbf{v}_j\rangle = 0$.

(d) True over $\mathbb{R}$ and false over $\mathbb{C}$. By Proposition 6.1.29,

$$\|\mathbf{u} \pm \mathbf{v}\|^2 = \|\mathbf{u}\|^2 \pm 2\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle + \|\mathbf{v}\|^2,$$

so each hypothesis says exactly that $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = 0$; the second adds nothing to the first. Over $\mathbb{R}$ this means $\mathbf{u} \perp \mathbf{v}$ (Theorem 6.3.3(b)). Over $\mathbb{C}$, $\mathbf{u} = 1$ and $\mathbf{v} = i$ in $\mathbb{C}$ satisfy both, since $|1 \pm i|^2 = 2$, but $\langle 1, i\rangle = -i \neq 0$ (Non-example 6.3.4).

(e) True. Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$. By Proposition 6.3.9(c) and (d), $\mathbf{x} \in \mathcal{L}^\perp = \operatorname{span}(\mathcal{L})^\perp = V^\perp = \{\mathbf{0}\}$.

Solution to Exercise 6.3.47

Uses. Proposition 6.3.13 (Orthogonal lists are independent), Proposition 6.3.9 (Properties of $A^\perp$), Definition 6.1.2 (Inner product)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. In $\mathbb{F}_2$, $1 + 1 = 0$. A vector with an even number of entries 1 is orthogonal to itself.
Hint 2. Try $(1,1,0,0)$, $(0,0,1,1)$, and their sum.
Hint 3. For (c), as in Proposition 6.3.9(c), it suffices to test orthogonality to the two spanning vectors.
Sketch. (a) $(1,1,0,0)$. (b) $(1,1,0,0)$, $(0,0,1,1)$, $(1,1,1,1)$ are pairwise orthogonal and the third is the sum of the first two; the step "$a_j\mathbf{v}_j \cdot \mathbf{v}_j = 0$ forces $a_j = 0$" fails because $\mathbf{v}_j \cdot \mathbf{v}_j = 0$. (c) The conditions are $x_1 = x_2$ and $x_3 = x_4$, which describe W. So $W \cap W^\perp = W \neq \{\mathbf{0}\}$, against Proposition 6.3.9(d), whose proof used definiteness.

(a) $\mathbf{x} = (1,1,0,0)$ has $\mathbf{x} \cdot \mathbf{x} = 1 + 1 = 0$ in $\mathbb{F}_2$.

(b) Let $\mathbf{v}_1 = (1,1,0,0)$, $\mathbf{v}_2 = (0,0,1,1)$, $\mathbf{v}_3 = (1,1,1,1)$. Then $\mathbf{v}_1 \cdot \mathbf{v}_2 = 0$, $\mathbf{v}_1 \cdot \mathbf{v}_3 = 1 + 1 = 0$, and $\mathbf{v}_2 \cdot \mathbf{v}_3 = 1 + 1 = 0$. But $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 = (2,2,2,2) = \mathbf{0}$, a nontrivial relation. In the first proof of Proposition 6.3.13, taking the product with $\mathbf{v}_j$ still gives $a_j(\mathbf{v}_j \cdot \mathbf{v}_j) = 0$, but now $\mathbf{v}_j \cdot \mathbf{v}_j = 0$, so nothing follows about a_j. The proof needed $\langle \mathbf{v}_j, \mathbf{v}_j\rangle \neq 0$ for $\mathbf{v}_j \neq \mathbf{0}$, which is definiteness.

(c) Since the formula is linear in each slot, the argument of Proposition 6.3.9(c) applies: $\mathbf{x}$ is orthogonal to every vector of W if and only if it is orthogonal to $(1,1,0,0)$ and $(0,0,1,1)$, that is, $x_1 + x_2 = 0$ and $x_3 + x_4 = 0$. In $\mathbb{F}_2$ these say $x_1 = x_2$ and $x_3 = x_4$, so the set is $\{(s,s,t,t) \mid s,t \in \mathbb{F}_2\} = W$. So $W \cap W^\perp = W \neq \{\mathbf{0}\}$, and the last statement of Proposition 6.3.9(d) fails; its proof used that a vector orthogonal to itself is $\mathbf{0}$. Forms over general fields are studied in Section 12.4.

Solution to Exercise 6.3.48

Uses. Proposition 6.1.16 (Frobenius inner product), Proposition 2.4.28 (Cyclicity of the trace), Definition 2.4.26 (Trace), Theorem 6.3.3 (Pythagorean theorem), (6.3.1), Proposition 6.3.27 (Properties of the conjugate transpose)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. For (a), $\langle S, K\rangle = \operatorname{tr}\left(K^{\mathsf{T}}S\right) = -\operatorname{tr}(KS)$. Compute $\operatorname{tr}(KS)$ a second way by transposing, and use cyclicity.
Hint 2. For (b), test $H = I_n$ and $K = iI_n$.
Hint 3. For the identity in (b), only $\operatorname{Re}\langle H, K\rangle$ matters ((6.3.1)). Show that $\operatorname{tr}(KH)$ is purely imaginary by comparing it with its conjugate $\operatorname{tr}\left((KH)^*\right)$.
Sketch. (a) $\operatorname{tr}(KS) = \operatorname{tr}\left((KS)^{\mathsf{T}}\right) = \operatorname{tr}\left(S^{\mathsf{T}}K^{\mathsf{T}}\right) = -\operatorname{tr}(SK) = -\operatorname{tr}(KS)$, so $\langle S, K\rangle = -\operatorname{tr}(KS) = 0$, and Pythagoras applies to $A = S + K$. (b) False: $\langle I, iI\rangle = -in \neq 0$. But $\overline{\operatorname{tr}(KH)} = \operatorname{tr}(H^*K^*) = -\operatorname{tr}(KH)$, so $\langle H, K\rangle = -\operatorname{tr}(KH)$ is purely imaginary, $\operatorname{Re}\langle H, K\rangle = 0$, and the identity holds by (6.3.1).

(a) Let $S^{\mathsf{T}} = S$ and $K^{\mathsf{T}} = -K$. A matrix and its transpose have the same diagonal, so $\operatorname{tr}\left(M^{\mathsf{T}}\right) = \operatorname{tr} M$. Hence, using cyclicity (Proposition 2.4.28),

$$\begin{aligned}\operatorname{tr}(KS) &= \operatorname{tr}\left((KS)^{\mathsf{T}}\right) = \operatorname{tr}\left(S^{\mathsf{T}}K^{\mathsf{T}}\right)\\ &= \operatorname{tr}(S(-K)) = -\operatorname{tr}(SK) = -\operatorname{tr}(KS),\end{aligned}$$

so $\operatorname{tr}(KS) = 0$, and $\langle S, K\rangle = \operatorname{tr}\left(K^{\mathsf{T}}S\right) = -\operatorname{tr}(KS) = 0$. For $A \in \mathbb{R}^{n\times n}$, $S = \left(A + A^{\mathsf{T}}\right)/2$ is symmetric, $K = \left(A - A^{\mathsf{T}}\right)/2$ is skew-symmetric, and $A = S + K$. By Theorem 6.3.3(a), $\|A\|^2 = \|S\|^2 + \|K\|^2$.

(b) False. $H = I_n$ is Hermitian and $K = iI_n$ satisfies $K^* = -iI_n = -K$, but $\langle H, K\rangle = \operatorname{tr}(K^*H) = \operatorname{tr}(-iI_n) = -in \neq 0$.

The identity still holds. Let $H^* = H$ and $K^* = -K$. The diagonal entries of M^* are the conjugates of those of M, so $\operatorname{tr}(M^*) = \overline{\operatorname{tr} M}$. By Proposition 6.3.27(b) and cyclicity,

$$\begin{aligned}\overline{\operatorname{tr}(KH)} &= \operatorname{tr}\left((KH)^*\right) = \operatorname{tr}(H^*K^*)\\ &= \operatorname{tr}(H(-K)) = -\operatorname{tr}(HK) = -\operatorname{tr}(KH).\end{aligned}$$

So $\operatorname{tr}(KH)$ is purely imaginary, and so is $\langle H, K\rangle = \operatorname{tr}(K^*H) = -\operatorname{tr}(KH)$. Thus $\operatorname{Re}\langle H, K\rangle = 0$, and by (6.3.1), $\|H + K\|^2 = \|H\|^2 + \|K\|^2$. For $A \in \mathbb{C}^{n\times n}$, $H = (A + A^*)/2$ is Hermitian and $K = (A - A^*)/2$ satisfies $K^* = -K$ (Proposition 6.3.27(a)), and $A = H + K$, which gives the identity. This is the situation of Non-example 6.3.4: Pythagoras holds without orthogonality.

Solution to Exercise 6.3.49

Uses. Example 6.3.17 (Orthogonal polynomials), Proposition 6.3.9 (Properties of $A^\perp$), Corollary 6.3.14 (Counting orthogonal vectors), Corollary 6.3.21 (Coordinates in an orthogonal basis)
Techniques. Undetermined coefficients (Technique 3.1.9)
Hint 1. $\left\langle x^j, x^k\right\rangle = \int_{-1}^{1} t^{j+k}\,dt$ is $2/(j+k+1)$ if $j+k$ is even and 0 if it is odd. The three conditions are linear equations in a, b, c.
Hint 2. You should find $q = x^3 - (3/5)x$. For (b), $q \perp x^2 - 1/3$ follows from $q \perp 1$ and $q \perp x^2$.
Hint 3. For (c), you need $\langle p, 1\rangle$, $\langle p, x\rangle$, $\left\langle p, x^2 - 1/3\right\rangle$, $\langle p, q\rangle$ and the four squared norms.
Sketch. (a) $\langle q, 1\rangle = 2a/3 + 2c$, $\langle q, x\rangle = 2/5 + 2b/3$, $\left\langle q, x^2\right\rangle = 2a/5 + 2c/3$ force $a = c = 0$, $b = -3/5$, and $\|q\|^2 = 8/175$. (b) Four nonzero orthogonal vectors in a 4-dimensional space. (c) The coefficients are $(8/3)/2 = 4/3$, $(16/15)/(2/3) = 8/5$, $(8/45)/(8/45) = 1$, and $(8/175)/(8/175) = 1$.

Throughout, $\left\langle x^j, x^k\right\rangle = \int_{-1}^{1} t^{j+k}\,dt$, which is $2/(j+k+1)$ when $j+k$ is even and 0 when $j+k$ is odd.

(a) By linearity in the first slot,

$$\langle q,1\rangle = \frac{2}{3}a + 2c, \quad \langle q,x\rangle = \frac{2}{5} + \frac{2}{3}b, \quad \langle q,x^2\rangle = \frac{2}{5}a + \frac{2}{3}c.$$

The second equation gives $b = -3/5$. The first gives $c = -a/3$, and then the third becomes $2a/5 - 2a/9 = 8a/45 = 0$, so $a = c = 0$. Hence $q = x^3 - (3/5)x$, and

$$\begin{aligned}\|q\|^2 &= \int_{-1}^{1}\left(t^6 - \frac{6}{5}t^4 + \frac{9}{25}t^2\right)\mathrm{d}t \\ &= \frac{2}{7} - \frac{12}{25} + \frac{6}{25} = \frac{8}{175}.\end{aligned}$$

(b) By Example 6.3.17, $1, x, x^2 - 1/3$ is orthogonal. By (a), q is orthogonal to 1 and to x^2, hence to $x^2 - 1/3$ (Proposition 6.3.9(a)), and to x. So the four polynomials form an orthogonal list of nonzero vectors in the 4-dimensional space $\mathbb{R}[x]_{\le 3}$, hence an orthogonal basis (Corollary 6.3.14).

(c) We compute $\langle p, x^k\rangle = \sum_{j=0}^{3}\langle x^j, x^k\rangle$:

$$\langle p,1\rangle = 2 + \frac{2}{3} = \frac{8}{3}, \qquad \langle p,x\rangle = \frac{2}{3} + \frac{2}{5} = \frac{16}{15},$$
$$\langle p,x^2\rangle = \frac{2}{3} + \frac{2}{5} = \frac{16}{15}, \quad \langle p,x^3\rangle = \frac{2}{5} + \frac{2}{7} = \frac{24}{35}.$$

Hence $\langle p, x^2 - 1/3\rangle = 16/15 - 8/9 = 8/45$ and $\langle p, q\rangle = 24/35 - (3/5)(16/15) = 24/35 - 16/25 = 8/175$. The squared norms are 2, $2/3$, $8/45$ (Example 6.3.17), and $8/175$. By Corollary 6.3.21,

$$p = \frac{4}{3}\cdot 1 + \frac{8}{5}x + 1\cdot\left(x^2 - \frac{1}{3}\right) + 1\cdot\left(x^3 - \frac{3}{5}x\right).$$

Check: the constant term is $4/3 - 1/3 = 1$, the coefficient of x is $8/5 - 3/5 = 1$, and those of x^2 and x^3 are 1.

Solution to Exercise 6.3.50

Uses. Proposition 6.1.16 (Frobenius inner product), Proposition 2.4.28 (Cyclicity of the trace), Corollary 6.3.14 (Counting orthogonal vectors), Proposition 6.3.18 (Coordinates in an orthonormal basis)
Hint 1. Each σ_a is Hermitian, so $\langle\sigma_a,\sigma_b\rangle = \operatorname{tr}(\sigma_b\sigma_a)$. Compute σ_a^2 and the products $\sigma_1\sigma_2$, $\sigma_2\sigma_3$, $\sigma_3\sigma_1$.
Hint 2. $\sigma_a^2 = I_2$, and the three products are $i\sigma_3$, $i\sigma_1$, $i\sigma_2$, all of trace 0. Also $\operatorname{tr}\sigma_a = 0$ for $a = 1,2,3$.
Hint 3. For (b), the coordinate of A along $\sigma_a/\sqrt{2}$ is $\langle A, \sigma_a/\sqrt{2}\rangle = \operatorname{tr}(\sigma_a A)/\sqrt{2}$.
Sketch. (a) $\langle\sigma_a,\sigma_b\rangle = \operatorname{tr}(\sigma_b\sigma_a)$ is 2 for $a = b$ and 0 otherwise, and $\dim\mathbb{C}^{2\times 2} = 4$. (b) Proposition 6.3.18 with $\langle A,\sigma_a/\sqrt{2}\rangle = \operatorname{tr}(\sigma_a A)/\sqrt{2}$. (c) The traces are $5, 5, -i, -3$, so $A = (5\sigma_0 + 5\sigma_1 - i\sigma_2 - 3\sigma_3)/2$.

(a) Each σ_a satisfies $\sigma_a^* = \sigma_a$ (for σ_2: $\overline{-i} = i$ moves to position $(2,1)$). So $\langle\sigma_a,\sigma_b\rangle = \operatorname{tr}(\sigma_b^*\sigma_a) = \operatorname{tr}(\sigma_b\sigma_a)$. Direct multiplication gives $\sigma_1^2 = \sigma_2^2 = \sigma_3^2 = I_2$ and

$$\sigma_1\sigma_2 = \begin{pmatrix} i & 0 \\ 0 & -i\end{pmatrix} = i\sigma_3,$$
$$\sigma_2\sigma_3 = \begin{pmatrix} 0 & i \\ i & 0\end{pmatrix} = i\sigma_1,$$
$$\sigma_3\sigma_1 = \begin{pmatrix} 0 & 1 \\ -1 & 0\end{pmatrix} = i\sigma_2.$$

So $\langle\sigma_a,\sigma_a\rangle = \operatorname{tr} I_2 = 2$ for every a (including $a = 0$). For distinct $a, b \in \{1,2,3\}$, $\operatorname{tr}(\sigma_b\sigma_a) = \operatorname{tr}(\sigma_a\sigma_b)$ (Proposition 2.4.28) is the trace of i times a Pauli matrix with trace 0, so it is 0. Finally $\langle\sigma_a,\sigma_0\rangle = \operatorname{tr}\sigma_a = 0$ for $a = 1,2,3$. Hence the $\sigma_a/\sqrt{2}$ are orthonormal, and since $\dim\mathbb{C}^{2\times 2} = 4$, they form an orthonormal basis (Corollary 6.3.14).

(b) By Proposition 6.3.18, $A = \sum_a\langle A,\sigma_a/\sqrt{2}\rangle\sigma_a/\sqrt{2}$, and $\langle A,\sigma_a/\sqrt{2}\rangle = \operatorname{tr}(\sigma_a^* A)/\sqrt{2} = \operatorname{tr}(\sigma_a A)/\sqrt{2}$. Multiplying the two factors $1/\sqrt{2}$ gives the formula.

(c) We have $\operatorname{tr} A = 5$, and

$$\sigma_1 A = \begin{pmatrix} 3 & 4 \\ 1 & 2 \end{pmatrix}, \quad \sigma_2 A = \begin{pmatrix} -3i & -4i \\ i & 2i \end{pmatrix},$$
$$\sigma_3 A = \begin{pmatrix} 1 & 2 \\ -3 & -4 \end{pmatrix},$$

with traces $5, -i, -3$. So $A = (5\sigma_0 + 5\sigma_1 - i\sigma_2 - 3\sigma_3)/2$. Check: $5\sigma_0 + 5\sigma_1 - i\sigma_2 - 3\sigma_3 = \begin{pmatrix} 5-3 & 5-1 \\ 5+1 & 5+3 \end{pmatrix} = \begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix} = 2A$, since $-i\sigma_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.

Solution to Exercise 6.3.51

Uses. Proposition 1.6.19 (Coordinates respect linear combinations), Proposition 6.1.10 (The dot product is an inner product), Definition 6.1.2 (Inner product), Theorem 6.3.22 (Parseval's identity), Proposition 6.1.22 (Inner products on $\mathbb{F}^n$)
Hint 1. The coordinate map $\mathbf{x} \mapsto [\mathbf{x}]_{\mathcal{B}}$ is linear and injective. Transfer each axiom from the dot product.
Hint 2. For (b), if $\mathcal{B}$ is orthonormal for some inner product, what does Theorem 6.3.22 say about it?
Hint 3. For (c), $[\mathbf{x}]_{\mathcal{B}} = (x_1 - x_2, x_2)$.
Sketch. (a) Write $C(\mathbf{x}) = [\mathbf{x}]_{\mathcal{B}}$. Conjugate symmetry, linearity in the first slot, and positivity pass from the dot product through the linear map C, and $\langle \mathbf{x}, \mathbf{x} \rangle_{\mathcal{B}} = 0$ forces $C(\mathbf{x}) = \mathbf{0}$, so $\mathbf{x} = \mathbf{0}$. Since $[\mathbf{b}_j]_{\mathcal{B}} = \mathbf{e}_j$, $\mathcal{B}$ is orthonormal. (b) By Theorem 6.3.22(a), any inner product for which $\mathcal{B}$ is orthonormal equals $[\mathbf{x}]_{\mathcal{B}} \cdot [\mathbf{y}]_{\mathcal{B}}$. (c) $(x_1 - x_2)(y_1 - y_2) + x_2 y_2$, so $M = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$.

(a) Let $C(\mathbf{x}) = [\mathbf{x}]_{\mathcal{B}}$. By Proposition 1.6.19, $C : V \to \mathbb{F}^n$ is linear, and $C(\mathbf{x}) = \mathbf{0}$ only for $\mathbf{x} = 0\mathbf{b}_1 + \cdots + 0\mathbf{b}_n = \mathbf{0}$. Since the dot product is an inner product on $\mathbb{F}^n$ (Proposition 6.1.10), for all $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$ and $a, b \in \mathbb{F}$:

- $\langle \mathbf{y}, \mathbf{x} \rangle_{\mathcal{B}} = C(\mathbf{y}) \cdot C(\mathbf{x}) = \overline{C(\mathbf{x}) \cdot C(\mathbf{y})} = \overline{\langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{B}}}$;
- $\langle a\mathbf{x} + b\mathbf{y}, \mathbf{z} \rangle_{\mathcal{B}} = (aC(\mathbf{x}) + bC(\mathbf{y})) \cdot C(\mathbf{z}) = a\langle \mathbf{x}, \mathbf{z} \rangle_{\mathcal{B}} + b\langle \mathbf{y}, \mathbf{z} \rangle_{\mathcal{B}}$;
- $\langle \mathbf{x}, \mathbf{x} \rangle_{\mathcal{B}} = C(\mathbf{x}) \cdot C(\mathbf{x}) \geq 0$, with equality only if $C(\mathbf{x}) = \mathbf{0}$, that is, $\mathbf{x} = \mathbf{0}$.

So $\langle \cdot, \cdot \rangle_{\mathcal{B}}$ is an inner product. Since $[\mathbf{b}_j]_{\mathcal{B}} = \mathbf{e}_j$, we get $\langle \mathbf{b}_i, \mathbf{b}_j \rangle_{\mathcal{B}} = \mathbf{e}_i \cdot \mathbf{e}_j = \delta_{ij}$, so $\mathcal{B}$ is orthonormal.

(b) Let $\langle \cdot, \cdot \rangle$ be an inner product on V for which $\mathcal{B}$ is orthonormal. Then $\mathcal{B}$ is an orthonormal basis, and by Theorem 6.3.22(a), $\langle \mathbf{x}, \mathbf{y} \rangle = [\mathbf{x}]_{\mathcal{B}} \cdot [\mathbf{y}]_{\mathcal{B}} = \langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{B}}$ for all $\mathbf{x}, \mathbf{y}$.

(c) Writing $\mathbf{x} = a(1,0) + c(1,1) = (a + c, c)$ gives $c = x_2$ and $a = x_1 - x_2$, so $[\mathbf{x}]_{\mathcal{B}} = (x_1 - x_2, x_2)$. Hence

$$\begin{aligned} \langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{B}} &= (x_1 - x_2)(y_1 - y_2) + x_2 y_2 \\ &= x_1 y_1 - x_1 y_2 - x_2 y_1 + 2x_2 y_2 \\ &= \mathbf{y}^{\mathsf{T}} \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix} \mathbf{x}. \end{aligned}$$

For instance $\langle \mathbf{e}_1, \mathbf{e}_2 \rangle_{\mathcal{B}} = -1$: the standard basis is not orthonormal for this inner product, as anticipated after Theorem 6.3.22.

Solution to Exercise 6.3.52

Uses. Definition 6.1.8 (Dot product), Corollary 6.3.14 (Counting orthogonal vectors), Theorem 6.3.24 (Bessel's inequality), Proposition 6.3.13 (Orthogonal lists are independent)
Techniques. Plug in clever test vectors (Technique 6.1.40), A sum of nonnegative terms (Technique 6.1.9)
Hint 1. For (a), write $\mathbf{v} = (x, y)$ and expand. You need $\sum_j \cos^2 \theta_j$, $\sum_j \sin^2 \theta_j$, and $\sum_j \cos\theta_j \sin\theta_j$ for $\theta_j = 2\pi j/3$.
Hint 2. For (b), apply the hypothesis to $\mathbf{v} = \mathbf{v}_l$. The left side contains the term $|\langle \mathbf{v}_l, \mathbf{v}_l \rangle|^2 = 1$.
Hint 3. Once the list is orthonormal, the hypothesis is the equality case of Bessel's inequality for every $\mathbf{v}$.
Sketch. (a) With $\cos\theta_j = 1, -1/2, -1/2$ and $\sin\theta_j = 0, \sqrt{3}/2, -\sqrt{3}/2$, the sum is $(2/3)\big(3x^2/2 + 3y^2/2\big)$. Three nonzero vectors in $\mathbb{R}^2$ cannot be orthogonal. (b) For $\mathbf{v} = \mathbf{v}_l$: $1 = 1 + \sum_{j \neq l} |\langle \mathbf{v}_l, \mathbf{v}_j \rangle|^2$, so the cross terms vanish. Then Bessel's equality case puts every $\mathbf{v}$ in the span.

(a) For $\theta_j = 2\pi j/3$, the cosines are $1, -1/2, -1/2$ and the sines are $0, \sqrt{3}/2, -\sqrt{3}/2$. So $\sum_j \cos^2 \theta_j = 3/2$, $\sum_j \sin^2 \theta_j = 3/2$, and $\sum_j \cos\theta_j \sin\theta_j = 0 - \sqrt{3}/4 + \sqrt{3}/4 = 0$. For $\mathbf{v} = (x, y)$,

$$\sum_{j=0}^{2} \langle \mathbf{v}, \mathbf{w}_j \rangle^2 = \frac{2}{3} \sum_{j=0}^{2} \left(x \cos\theta_j + y \sin\theta_j \right)^2$$
$$= \frac{2}{3}\left(\frac{3}{2}x^2 + 0 + \frac{3}{2}y^2 \right) = \|\mathbf{v}\|^2.$$

The list is not orthonormal: each $\mathbf{w}_j$ has norm $\sqrt{2/3}$, and by Corollary 6.3.14 no three nonzero vectors in $\mathbb{R}^2$ are orthogonal.

(b) Fix l and apply the hypothesis to $\mathbf{v} = \mathbf{v}_l$. Since $\|\mathbf{v}_l\| = 1$,

$$1 = \sum_{j=1}^{k} \left| \langle \mathbf{v}_l, \mathbf{v}_j \rangle \right|^2 = 1 + \sum_{j \neq l} \left| \langle \mathbf{v}_l, \mathbf{v}_j \rangle \right|^2.$$

So the remaining sum of nonnegative terms is 0, and $\langle \mathbf{v}_l, \mathbf{v}_j \rangle = 0$ for all $j \neq l$. Thus the list is orthonormal. Now the hypothesis says that equality holds in Bessel's inequality (Theorem 6.3.24) for every $\mathbf{v} \in V$, so every $\mathbf{v}$ lies in $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$. The list spans V and is independent (Proposition 6.3.13), so it is an orthonormal basis. Part (a) shows that the hypothesis "unit vectors" cannot be dropped.

Solution to Exercise 6.3.53

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Theorem 6.3.24 (Bessel's inequality), Proposition 6.2.22 (The square of a sum)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. For (a), apply Cauchy–Schwarz in $\mathbb{R}^k$ to the vectors $\left(|\langle \mathbf{x}, \mathbf{u}_j \rangle|\right)_j$ and $\left(|\langle \mathbf{y}, \mathbf{u}_j \rangle|\right)_j$, then Bessel to each norm.
Hint 2. For (b), use Proposition 6.2.22 and then Bessel. Equality requires equality in both steps.
Sketch. (a) Cauchy–Schwarz in $\mathbb{R}^k$ bounds the sum by $\left(\sum_j |\langle \mathbf{x}, \mathbf{u}_j \rangle|^2\right)^{1/2}\left(\sum_j |\langle \mathbf{y}, \mathbf{u}_j \rangle|^2\right)^{1/2}$, and Bessel bounds the factors by $\|\mathbf{x}\|$ and $\|\mathbf{y}\|$. (b) $\left(\sum_j a_j\right)^2 \le k \sum_j a_j^2 \le k\|\mathbf{x}\|^2$ with $a_j = |\langle \mathbf{x}, \mathbf{u}_j \rangle|$. Equality: all a_j equal and $\mathbf{x} \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$, that is, $\mathbf{x} = \sum_j c_j \mathbf{u}_j$ with $|c_1| = \cdots = |c_k|$.

Write $a_j = |\langle \mathbf{x}, \mathbf{u}_j \rangle|$ and $b_j = |\langle \mathbf{y}, \mathbf{u}_j \rangle|$, nonnegative reals.

(a) By Theorem 6.2.1 for the dot product on $\mathbb{R}^k$ and then Theorem 6.3.24 twice,

$$\sum_j a_j b_j \le \left(\sum_j a_j^2 \right)^{1/2} \left(\sum_j b_j^2 \right)^{1/2} \le \|\mathbf{x}\| \|\mathbf{y}\|.$$

(b) By Proposition 6.2.22 and Theorem 6.3.24,

$$\left(\sum_j a_j \right)^2 \le k \sum_j a_j^2 \le k \|\mathbf{x}\|^2,$$

and taking nonnegative square roots gives the inequality. Equality holds if and only if both steps are equalities: all a_j are equal (Proposition 6.2.22) and $\mathbf{x} \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$ (Theorem 6.3.24). By Proposition 6.3.18, this says $\mathbf{x} = c_1 \mathbf{u}_1 + \cdots + c_k \mathbf{u}_k$ with $|c_1| = \cdots = |c_k|$. For example, in $\mathbb{R}^k$ with the standard basis, $\mathbf{x} = (1, -1, 1, \ldots)$ gives equality.

Solution to Exercise 6.3.54

Uses. Definition 6.3.28 (Gram matrix), Proposition 6.3.30 (Gram matrices detect independence), Example 1.5.7 (Monomials)
Techniques. Gram matrices (Technique 6.3.31)
Hint 1. Compute $\langle x^{j-1}, x^{i-1} \rangle$.
Hint 2. The monomials are linearly independent. Apply Proposition 6.3.30.
Sketch. $\langle x^{j-1}, x^{i-1} \rangle = \int_0^1 t^{i+j-2}\,dt = 1/(i+j-1)$. The monomials are independent, so H_n is invertible, and $\mathbf{c}^{\mathsf{T}} H_n \mathbf{c} = \left\| \sum_j c_j x^{j-1} \right\|^2 > 0$ because the polynomial is nonzero.

(a) The formula is an inner product on $\mathbb{R}[x]_{\leq n-1}$ (see Example 6.3.17 for definiteness; the interval does not matter). The (i,j) entry of the Gram matrix of $x^0, \ldots, x^{n-1}$ is

$$\left\langle x^{j-1}, x^{i-1} \right\rangle = \int_0^1 t^{i+j-2}\,dt = \frac{1}{i+j-1} = h_{ij}.$$

(b) The monomials $1, x, \ldots, x^{n-1}$ are linearly independent (Example 1.5.7), so H_n is invertible by Proposition 6.3.30. For $\mathbf{c} \neq \mathbf{0}$, the polynomial $p = c_1 + c_2 x + \cdots + c_n x^{n-1}$ is nonzero, and by Proposition 6.3.30(a), $\mathbf{c}^{\mathsf{T}} H_n \mathbf{c} = \|p\|^2 > 0$.

Computing $\det H_n$ directly is laborious already for $n = 4$; the Gram matrix point of view gives invertibility with no computation.

Solution to Exercise 6.3.55

Uses. Theorem 6.3.29 (Orthonormal columns), Proposition 6.3.34 (Characterizations of unitary matrices)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Check each step. Which one is a general claim about matrices that you have not seen proved?
Hint 2. Is $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 2 \end{smallmatrix}\right)$ diagonal? Is it similar to a diagonal matrix? For a counterexample to the claim, try 2×2 matrices with columns $(1,1)$ and $(a,-a)$.
Sketch. The false step is "similar to a diagonal matrix implies diagonal". The claim is false: $A = \left(\begin{smallmatrix} 1 & 2 \\ 1 & -2 \end{smallmatrix}\right)$ has $A^{\mathsf{T}}A = \operatorname{diag}(2,8)$ but $AA^{\mathsf{T}} = \left(\begin{smallmatrix} 5 & -3 \\ -3 & 5 \end{smallmatrix}\right)$. With orthonormal columns ($D = I$) the argument works and gives Proposition 6.3.34.

Every step is correct except "a matrix similar to a diagonal matrix is diagonal". For instance PDP^{-1} with $D = \operatorname{diag}(1,2)$ and $P = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ is $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 2 \end{smallmatrix}\right)$, which is not diagonal. (Matrices similar to diagonal ones are the diagonalizable matrices of Section 7.4.)

The claim is false. For $A = \left(\begin{smallmatrix} 1 & 2 \\ 1 & -2 \end{smallmatrix}\right)$, the columns $(1,1)$ and $(2,-2)$ are orthogonal and nonzero, and $A^{\mathsf{T}}A = \operatorname{diag}(2,8)$. But the rows $(1,2)$ and $(1,-2)$ have dot product $1 - 4 = -3$, and indeed

$$AA^{\mathsf{T}} = \begin{pmatrix} 1 & 2 \\ 1 & -2 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 2 & -2 \end{pmatrix} = \begin{pmatrix} 5 & -3 \\ -3 & 5 \end{pmatrix}.$$

The argument does prove something when $D = I$, that is, when the columns are orthonormal: then $AA^{\mathsf{T}} = AA^{-1} = I$, and the rows are orthonormal. This is (i) $\Rightarrow$ (iii) of Proposition 6.3.34.

Solution to Exercise 6.3.56

Uses. Definition 6.3.28 (Gram matrix), Proposition 6.1.4 (Sesquilinearity), Definition 2.4.1 (Matrix product), Definition 6.3.26 (Conjugate transpose), Definition 6.3.33 (Unitary and orthogonal matrices), Corollary 6.3.14 (Counting orthogonal vectors)
Techniques. Expand by multilinearity (Technique 5.1.7), Gram matrices (Technique 6.3.31)
Hint 1. Expand $\langle \mathbf{w}_j, \mathbf{w}_i \rangle$ in both slots. The coefficients from the second slot come out conjugated.
Hint 2. $\langle \mathbf{w}_j, \mathbf{w}_i \rangle = \sum_m \sum_l \overline{s_{mi}} g_{ml} s_{lj}$, and $\overline{s_{mi}}$ is the (i,m) entry of S^*.
Hint 3. For (b), $G = I_n$; a list is orthonormal exactly when its Gram matrix is I_n. Column j of S is $[\mathbf{w}_j]_{\mathcal{O}}$.
Sketch. (a) $\langle \mathbf{w}_j, \mathbf{w}_i \rangle = \sum_{l,m} s_{lj}\overline{s_{mi}}\langle \mathbf{v}_l, \mathbf{v}_m \rangle = \sum_{m,l} (S^*)_{im} g_{ml} s_{lj} = (S^*GS)_{ij}$. (b) With $G = I$, the $\mathbf{w}_j$ are orthonormal iff $S^*S = I$, and n orthonormal vectors form a basis. Column j of S is $[\mathbf{w}_j]_{\mathcal{O}}$, so S is the change-of-coordinates matrix from the $\mathbf{w}$-basis to $\mathcal{O}$.

(a) Expanding both slots (linearity in the first, Proposition 6.1.4 in the second),

$$\begin{aligned} \langle \mathbf{w}_j, \mathbf{w}_i \rangle &= \left\langle \sum_l s_{lj}\mathbf{v}_l, \sum_m s_{mi}\mathbf{v}_m \right\rangle = \sum_{m=1}^{n}\sum_{l=1}^{n} \overline{s_{mi}}\langle \mathbf{v}_l, \mathbf{v}_m \rangle s_{lj} \\ &= \sum_{m=1}^{n}\sum_{l=1}^{n} (S^*)_{im} g_{ml} s_{lj}, \end{aligned}$$

using $g_{ml} = \langle \mathbf{v}_l, \mathbf{v}_m \rangle$ and $(S^*)_{im} = \overline{s_{mi}}$. By Definition 2.4.1, the right side is the (i,j) entry of S^*GS.

(b) If $\mathcal{O}$ is orthonormal, its Gram matrix is I_n, so by (a) the Gram matrix of $\mathbf{w}_1, \ldots, \mathbf{w}_n$ is S^*S. A list is orthonormal exactly when its Gram matrix is the identity, so $\mathbf{w}_1, \ldots, \mathbf{w}_n$ is orthonormal if and only if $S^*S = I_n$, that is, S is unitary. An orthonormal list of length $n = \dim V$ is an orthonormal basis (Corollary 6.3.14).

Column j of S is the coordinate vector $[\mathbf{w}_j]_{\mathcal{O}}$, so S is the change-of-coordinates matrix that converts coordinates with respect to $\mathbf{w}_1, \ldots, \mathbf{w}_n$ into coordinates with respect to $\mathcal{O}$. Hence if both lists are orthonormal bases, this matrix is unitary, and so is its inverse, the change of coordinates in the other direction (Exercise 6.3.37).

Solution to Exercise 6.3.57

Uses. Theorem 5.3.3 (The Leibniz formula), Theorem 5.4.14 (The transpose), Theorem 5.4.10 (Multiplicativity), Theorem 6.3.29 (Orthonormal columns), Definition 6.3.26 (Conjugate transpose)
Hint 1. Conjugation respects sums and products, so it passes through the Leibniz formula: $\det \overline{A} = \overline{\det A}$. Then use $\det\left(B^{\mathsf{T}}\right) = \det B$.
Hint 2. Take determinants of $U^*U = I_n$.
Hint 3. For (c), the first column of U is $u_{11}\mathbf{e}_1$. Orthogonality of the other columns to it kills the rest of the first row. Then repeat with the second column.
Sketch. (a) $\det A^* = \det \overline{A}^{\mathsf{T}} = \det \overline{A} = \overline{\det A}$, so $1 = \det(U^*U) = \overline{\det U} \det U = |\det U|^2$; a real number of modulus 1 is ± 1. (b) $\operatorname{diag}(2, 1/2)$. (c) Induct on the row: if rows $1, \ldots, i-1$ vanish off the diagonal, column i is $u_{ii}\mathbf{e}_i$, and orthogonality of column $j > i$ to it gives $u_{ij}\overline{u_{ii}} = 0$ with $|u_{ii}| = 1$, so row i vanishes off the diagonal too.

(a) By Theorem 5.3.3, $\det \overline{A}$ is a sum of signed products of entries of $\overline{A}$, which are the conjugates of the corresponding products for A; since conjugation respects sums and products, $\det \overline{A} = \overline{\det A}$. By Theorem 5.4.14, $\det(A^*) = \det\left(\overline{A}^{\mathsf{T}}\right) = \det \overline{A} = \overline{\det A}$.

If U is unitary, then by Theorem 5.4.10,

$$\begin{aligned} 1 = \det I_n = \det(U^*U) &= \det(U^*) \det U \\ &= \overline{\det U} \det U = |\det U|^2, \end{aligned}$$

so $|\det U| = 1$. If Q is real orthogonal, $\det Q$ is a real number with $|\det Q| = 1$, so $\det Q = \pm 1$.

(b) $A = \operatorname{diag}(2, 1/2)$ has $\det A = 1$, but its first column has norm 2, so $A^{\mathsf{T}}A \neq I_2$.

(c) Let U be unitary and upper triangular, with columns $\mathbf{c}_1, \ldots, \mathbf{c}_n$; by Theorem 6.3.29 they are orthonormal. We show by induction on i that $u_{ij} = 0$ for all $j > i$. Suppose this holds for the rows $1, \ldots, i-1$. Then the entries $u_{1i}, \ldots, u_{i-1,i}$ of $\mathbf{c}_i$ vanish, and so do its entries below the diagonal, so $\mathbf{c}_i = u_{ii}\mathbf{e}_i$, and $|u_{ii}| = \|\mathbf{c}_i\| = 1$. For $j > i$,

$$0 = \mathbf{c}_j \cdot \mathbf{c}_i = u_{ij}\overline{u_{ii}},$$

and $\overline{u_{ii}} \neq 0$, so $u_{ij} = 0$. This completes the induction (the case $i = 1$ needs no hypothesis). So U is diagonal, with diagonal entries of modulus 1.

Solution to Exercise 6.3.58

Uses. Theorem 6.3.29 (Orthonormal columns), Definition 6.1.8 (Dot product), Theorem 5.1.13 (The 2×2 determinant)
Hint 1. The first column (a, c) is any unit vector. Find one unit vector orthogonal to it by inspection.
Hint 2. $(-\overline{c}, \overline{a})$ works. Show that every vector orthogonal to (a, c) is a multiple of it: solve $b\overline{a} + d\overline{c} = 0$, treating $a \neq 0$ and $a = 0$ separately.
Sketch. The given matrices have orthonormal columns by a direct check. Conversely, if (a, c) is a unit vector, the solutions of $b\overline{a} + d\overline{c} = 0$ are the multiples of $(-\overline{c}, \overline{a})$, which is a unit vector; so a unit second column is $\lambda(-\overline{c}, \overline{a})$ with $|\lambda| = 1$. Then $\det U = \lambda\left(|a|^2 + |c|^2\right) = \lambda$.

By Theorem 6.3.29, U is unitary if and only if its columns are orthonormal.

Suppose U has the given form. The first column has squared norm $|a|^2 + |c|^2 = 1$, the second has squared norm $|\lambda|^2\left(|c|^2 + |a|^2\right) = 1$, and

$$(-\lambda\overline{c}, \lambda\overline{a}) \cdot (a, c) = -\lambda\overline{c}\,\overline{a} + \lambda\overline{a}\,\overline{c} = 0.$$

So U is unitary.

Conversely, let $U = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ be unitary. Then $|a|^2 + |c|^2 = 1$, and the second column satisfies $(b,d)\cdot(a,c) = b\overline{a} + d\overline{c} = 0$. If $a \neq 0$, then $b = -d\overline{c}/\overline{a}$, so $(b,d) = (d/\overline{a})(-\overline{c},\overline{a})$. If $a = 0$, then $|c| = 1$, so $c \neq 0$ and $d = 0$, and $(b,d) = (b,0) = (-b/\overline{c})(-\overline{c},\overline{a})$ since $\overline{a} = 0$. Either way $(b,d) = \lambda(-\overline{c},\overline{a})$ for some $\lambda \in \mathbb{C}$. Since $\|(-\overline{c},\overline{a})\|^2 = |c|^2 + |a|^2 = 1$ and (b,d) is a unit vector, $|\lambda| = 1$.

Finally, by Theorem 5.1.13, $\det U = a\cdot\lambda\overline{a} - (-\lambda\overline{c})c = \lambda\left(|a|^2 + |c|^2\right) = \lambda$. The unitary matrices with determinant 1 are those with $\lambda = 1$.

Solution to Exercise 6.3.59

Uses. Definition 6.3.40 (Fourier matrix), Proposition 6.3.41 (The Fourier basis)
Hint 1. $\omega^3 = 1$, so $\omega^4 = \omega$, and $\omega^2 = \overline{\omega} = \omega^{-1}$.
Hint 2. The coefficient of $\mathbf{f}_k$ is $\langle \mathbf{x}, \mathbf{f}_k\rangle/3$ with $\langle \mathbf{x}, \mathbf{f}_k\rangle = \sum_j x_j\omega^{-jk}$.
Sketch. $\Phi_3 = \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix}$ and $\Phi_3^{-1} = (1/3)\overline{\Phi_3}$. The transform of $\mathbf{x}$ is $\left(3, -\sqrt{3}i, \sqrt{3}i\right)$, so $\mathbf{x} = \mathbf{f}_0 + \left(i/\sqrt{3}\right)(\mathbf{f}_2 - \mathbf{f}_1)$, and $1 + 4 = (9+3+3)/3$.

(a) Since $\omega^3 = 1$, $\omega^4 = \omega$, and $\overline{\omega} = \omega^2$,

$$\Phi_3 = \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix},$$

$$\Phi_3^{-1} = \frac{1}{3}\overline{\Phi_3} = \frac{1}{3}\begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega^2 & \omega \\ 1 & \omega & \omega^2 \end{pmatrix},$$

by Proposition 6.3.41(b).

(b) By Proposition 6.3.41(c), with $\omega^{-1} = \omega^2$ and $\omega^{-2} = \omega$,

$$\langle \mathbf{x}, \mathbf{f}_0\rangle = 3,$$
$$\langle \mathbf{x}, \mathbf{f}_1\rangle = 1 + 2\omega^2 = -\sqrt{3}i,$$
$$\langle \mathbf{x}, \mathbf{f}_2\rangle = 1 + 2\omega = \sqrt{3}i.$$

So $\mathbf{x} = (1/3)\left(3\mathbf{f}_0 - \sqrt{3}i\mathbf{f}_1 + \sqrt{3}i\mathbf{f}_2\right) = \mathbf{f}_0 + \left(i/\sqrt{3}\right)(\mathbf{f}_2 - \mathbf{f}_1)$. Check: $\mathbf{f}_2 - \mathbf{f}_1 = \left(0, \omega^2 - \omega, \omega - \omega^2\right) = \left(0, -\sqrt{3}i, \sqrt{3}i\right)$, so $\left(i/\sqrt{3}\right)(\mathbf{f}_2 - \mathbf{f}_1) = (0,1,-1)$, and adding $\mathbf{f}_0 = (1,1,1)$ gives $(1,2,0)$. For (d): $|1|^2 + |2|^2 + 0 = 5$ and $(9+3+3)/3 = 5$.

Solution to Exercise 6.3.60

Uses. Lemma 6.3.39 (Sums of roots of unity), Definition 5.2.29 (Permutation matrix), Theorem 5.4.10 (Multiplicativity), Proposition 5.3.15 (Triangular matrices)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. $\left(\Phi_n^2\right)_{jl} = \sum_k \omega^{jk}\omega^{kl}$. Apply Lemma 6.3.39 with $m = j + l$.
Hint 2. For each j there is exactly one $l \in \{0,\ldots,n-1\}$ with $n \mid (j+l)$. Which?
Hint 3. For (b), take determinants in $\Phi_n^4 = n^2 I_n$.
Sketch. (a) $\left(\Phi_n^2\right)_{jl} = \sum_k \omega^{k(j+l)}$ is n if $n \mid (j+l)$ and 0 otherwise. Each row and each column of P has a single 1, at $l = \sigma(j)$ where $\sigma(j)$ is $-j$ reduced mod n, and σ is its own inverse, so $P^2 = I$ and $\Phi_n^4 = n^2P^2 = n^2 I$. (b) $(\det\Phi_n)^4 = \det\left(n^2 I_n\right) = n^{2n}$, so $|\det\Phi_n| = n^{n/2}$.

(a) By the entry formula for products and Lemma 6.3.39,

$$\left(\Phi_n^2\right)_{jl} = \sum_{k=0}^{n-1}\omega^{jk}\omega^{kl} = \sum_{k=0}^{n-1}\omega^{k(j+l)} = \begin{cases} n \text{ if } n \mid (j+l) \\ 0 \text{ otherwise,} \end{cases}$$

so $\Phi_n^2 = nP$. For $j \in \{0,\ldots,n-1\}$, let $\sigma(j) = 0$ if $j = 0$ and $\sigma(j) = n - j$ otherwise. Then $\sigma(j)$ is the only $l \in \{0,\ldots,n-1\}$ with $n \mid (j+l)$, so row j of P has its only 1 in column $\sigma(j)$. Also $\sigma(\sigma(j)) = j$, so σ is a bijection

of $\{0, \dots, n-1\}$ (its own inverse), and P is the permutation matrix of σ (Definition 5.2.29). It is symmetric, since $n \mid (j+l)$ is symmetric in j and l. Finally

$$\left(P^2\right)_{jm} = \sum_l p_{jl} p_{lm} = p_{\sigma(j)m},$$

which is 1 exactly when $m = \sigma(\sigma(j)) = j$. So $P^2 = I_n$ and $\Phi_n^4 = (nP)^2 = n^2 P^2 = n^2 I_n$.

(b) By Theorem 5.4.10 and Proposition 5.3.15, $(\det \Phi_n)^4 = \det\left(\Phi_n^4\right) = \det\left(n^2 I_n\right) = n^{2n}$. Taking moduli, $|\det \Phi_n|^4 = n^{2n}$, so $|\det \Phi_n| = n^{n/2}$. (Alternatively, $\Phi_n^* \Phi_n = n I_n$ and Exercise 6.3.57(a) give $|\det \Phi_n|^2 = n^n$.)

Solution to Exercise 6.3.61

Uses. Definition 6.3.40 (Fourier matrix), Proposition 6.3.41 (The Fourier basis), Proposition 2.4.8 (Four views of the product), Theorem 5.4.10 (Multiplicativity)
Hint 1. Write $(C\mathbf{f}_k)_j = \sum_l c_{(j-l) \bmod n} \omega^{lk}$ and substitute $m = (j-l) \bmod n$. Since $\omega^n = 1$, $\omega^{lk} = \omega^{(j-m)k}$.
Hint 2. For (b), (a) says $C\Phi_n = \Phi_n D$ column by column. Diagonal matrices commute.
Hint 3. For (c), $\mathbf{c} = (2, 1, 0)$ and $\langle \mathbf{c}, \mathbf{f}_k \rangle = 2 + \omega^{-k}$.
Sketch. (a) Reindexing by $m = (j-l) \bmod n$ gives $(C\mathbf{f}_k)_j = \omega^{jk} \sum_m c_m \omega^{-mk} = \langle \mathbf{c}, \mathbf{f}_k \rangle (\mathbf{f}_k)_j$. (b) So $C\Phi_n = \Phi_n D$, and $C = \Phi_n D \Phi_n^{-1}$; then $CC' = \Phi_n D D' \Phi_n^{-1} = C'C$, and C is invertible iff D is. (c) The values $2 + \omega^{-k}$ are 3, $2 + \omega^2$, $2 + \omega$, all nonzero, and $\det C = 3|2 + \omega|^2 = 9$.

(a) Fix j and k. As l runs over $0, \dots, n-1$, so does $m = (j-l) \bmod n$, and l is congruent to $j - m$ modulo n. Since $\omega^n = 1$, $\omega^{lk} = \omega^{(j-m)k}$. Hence

$$\begin{aligned}(C\mathbf{f}_k)_j &= \sum_{l=0}^{n-1} c_{(j-l) \bmod n} \omega^{lk} = \sum_{m=0}^{n-1} c_m \omega^{(j-m)k} \\ &= \omega^{jk} \sum_{m=0}^{n-1} c_m \omega^{-mk} = \langle \mathbf{c}, \mathbf{f}_k \rangle (\mathbf{f}_k)_j,\end{aligned}$$

using $\langle \mathbf{c}, \mathbf{f}_k \rangle = \sum_m c_m \omega^{-mk}$ (Proposition 6.3.41(c)).

(b) Column k of $C\Phi_n$ is $C\mathbf{f}_k$ (Proposition 2.4.8), and column k of $\Phi_n D$ is $\langle \mathbf{c}, \mathbf{f}_k \rangle \mathbf{f}_k$. By (a), $C\Phi_n = \Phi_n D$, and since Φ_n is invertible, $C = \Phi_n D \Phi_n^{-1}$. If C' is another circulant, with diagonal matrix D', then since diagonal matrices commute,

$$CC' = \Phi_n D D' \Phi_n^{-1} = \Phi_n D' D \Phi_n^{-1} = C'C.$$

Finally, C is invertible if and only if $D = \Phi_n^{-1} C \Phi_n$ is, and a diagonal matrix is invertible if and only if its diagonal entries are nonzero.

(c) The matrix is the circulant with $\mathbf{c} = (2, 1, 0)$. With $\omega = -1/2 + \left(\sqrt{3}/2\right)i$, the entries of D are $\langle \mathbf{c}, \mathbf{f}_k \rangle = 2 + \omega^{-k}$, namely 3, $2 + \omega^2$, and $2 + \omega$. The last two are $3/2 \mp \left(\sqrt{3}/2\right)i \neq 0$, so the matrix is invertible. By Theorem 5.4.10, $\det C = \det D = 3\left(2 + \omega^2\right)(2 + \omega) = 3|2 + \omega|^2 = 3(9/4 + 3/4) = 9$, which agrees with cofactor expansion along the first row: $2 \cdot 4 - 0 + 1 \cdot 1 = 9$.

Solution to Exercise 6.3.62

Uses. Lemma 6.3.39 (Sums of roots of unity), Definition 1.2.17 (Evaluation), de Moivre's formula (Section B.1), the binomial theorem
Hint 1. Substitute $p\left(\omega^j\right) = \sum_k a_k \omega^{jk}$, exchange the two sums, and apply Lemma 6.3.39 with $m = k - r$.
Hint 2. For (b), take $p = (1 + x)^{12}$, $n = 3$, $r = 0$. Write $1 + \omega$ and $1 + \omega^2$ in the form $\cos\theta + i \sin\theta$.
Sketch. (a) $(1/n) \sum_j \omega^{-jr} \sum_k a_k \omega^{jk} = \sum_k a_k (1/n) \sum_j \omega^{j(k-r)}$, and the inner average is 1 if $n \mid (k-r)$ and 0 otherwise. (b) With $\omega = \omega_3$, $1 + \omega = \cos(\pi/3) + i \sin(\pi/3)$ and $1 + \omega^2$ is its conjugate, so their 12th powers are 1, and the sum is $\left(2^{12} + 2\right)/3 = 1366$. (c) The same computation with exponent m gives $\left(2^m + 2\cos(m\pi/3)\right)/3$.

(a) By Definition 1.2.17, $p\left(\omega^j\right) = \sum_{k=0}^{d} a_k \omega^{jk}$. Exchanging the finite sums,

$$\frac{1}{n}\sum_{j=0}^{n-1}\omega^{-jr}p\big(\omega^j\big)=\sum_{k=0}^{d}a_k\left(\frac{1}{n}\sum_{j=0}^{n-1}\omega^{j(k-r)}\right).$$

By Lemma 6.3.39 the expression in parentheses is 1 if $n \mid (k-r)$ and 0 otherwise, which gives the claim.

(b) Take $n=3$, $r=0$, and $p=(1+x)^{12}=\sum_k\binom{12}{k}x^k$. Then the left side of (a) is the requested sum, and the right side is $\big(p(1)+p(\omega)+p\big(\omega^2\big)\big)/3$. Here $\omega=-1/2+\big(\sqrt{3}/2\big)i$, so

$$1+\omega=\frac{1}{2}+\frac{\sqrt{3}}{2}i=\cos\frac{\pi}{3}+i\sin\frac{\pi}{3},$$
$$1+\omega^2=1+\overline{\omega}=\overline{1+\omega}.$$

By de Moivre's formula, $(1+\omega)^{12}=\cos 4\pi+i\sin 4\pi=1$, and $\big(1+\omega^2\big)^{12}=\overline{(1+\omega)^{12}}=1$. So the sum is $\big(2^{12}+1+1\big)/3=4098/3=1366$.

(c) With $p=(1+x)^m$, the same computation gives $(1+\omega)^m=\cos(m\pi/3)+i\sin(m\pi/3)$ and $\big(1+\omega^2\big)^m$ its conjugate, which add up to $2\cos(m\pi/3)$. So the sum is $(2^m+2\cos(m\pi/3))/3$.

Solution to Exercise 6.3.63

Uses. Theorem 6.3.29 (Orthonormal columns), Theorem 2.4.34 (Block multiplication)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Multiplying a row of H by -1, or permuting the rows, keeps the columns orthogonal. Use this to make the first column all 1s.
Hint 2. A ±1 column orthogonal to the all-1s column has as many $+1$s as -1s. Arrange the second column as $n/2$ entries $+1$ followed by $n/2$ entries -1.
Hint 3. Count the $+1$s of the third column in each half, and use its orthogonality to the first two columns.
Sketch. (a) Normalize the first column to all 1s and sort the rows so that column 2 is $+1$ in the first half and -1 in the second. If column 3 has a entries $+1$ in the first half and b in the second, orthogonality to column 1 gives $a+b=n/2$ and to column 2 gives $2a-2b=0$, so $a=n/4$. (b) Block multiplication gives $\begin{pmatrix}H & H\\ H & -H\end{pmatrix}^{\mathsf{T}}\begin{pmatrix}H & H\\ H & -H\end{pmatrix}=\operatorname{diag}\big(2H^{\mathsf{T}}H, 2H^{\mathsf{T}}H\big)=2nI_{2n}$; start from (1).

(a) Let H be a Hadamard matrix of order $n\ge 3$, with columns $\mathbf{h}_1,\dots,\mathbf{h}_n$, so $\mathbf{h}_k\cdot\mathbf{h}_l=\sum_j h_{jk}h_{jl}$. Multiplying row j by -1 multiplies both h_{jk} and h_{jl} by -1, so it leaves each term $h_{jk}h_{jl}$ unchanged, and permuting the rows only reorders the sum. So both operations produce Hadamard matrices. Multiply each row whose first entry is -1 by -1; now $\mathbf{h}_1=(1,\dots,1)$.

Every other column satisfies $0=\mathbf{h}_k\cdot\mathbf{h}_1=\sum_j h_{jk}$, so it has equally many entries $+1$ and -1; in particular n is even. Permute the rows so that $\mathbf{h}_2$ has $+1$ in rows $1,\dots,n/2$ and -1 in rows $n/2+1,\dots,n$. Let a and b be the numbers of entries $+1$ of $\mathbf{h}_3$ in the first and in the second half. From $\mathbf{h}_3\cdot\mathbf{h}_1=0$, $\mathbf{h}_3$ has $n/2$ entries $+1$ in total, so $a+b=n/2$. From $\mathbf{h}_3\cdot\mathbf{h}_2=0$,

$$0=\left(a-\left(\frac{n}{2}-a\right)\right)-\left(b-\left(\frac{n}{2}-b\right)\right)=2a-2b.$$

So $a=b=n/4$, and since a is an integer, $4\mid n$.

(b) Let $K=\begin{pmatrix}H & H\\ H & -H\end{pmatrix}$. Its entries are ±1, and by Theorem 2.4.34,

$$K^{\mathsf{T}}K=\begin{pmatrix}H^{\mathsf{T}} & H^{\mathsf{T}}\\ H^{\mathsf{T}} & -H^{\mathsf{T}}\end{pmatrix}\begin{pmatrix}H & H\\ H & -H\end{pmatrix}$$
$$=\begin{pmatrix}2H^{\mathsf{T}}H & 0\\ 0 & 2H^{\mathsf{T}}H\end{pmatrix}=\begin{pmatrix}2nI_n & 0\\ 0 & 2nI_n\end{pmatrix}=2nI_{2n}.$$

So K is a Hadamard matrix of order $2n$ (Theorem 6.3.29). Starting from the Hadamard matrix (1) of order 1 and applying this construction k times gives one of order 2^k. The first step gives $\Phi_2=\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}$. Whether Hadamard matrices exist for every order divisible by 4 is a famous open problem.

Solution to Exercise 6.3.64

Uses. Lemma 6.3.39 (Sums of roots of unity)
Hint 1. Write $|g|^2 = g\overline{g} = \sum_j \sum_k \omega^{j^2-k^2}$. The exponent $j^2 - k^2$ suggests substituting $j = k + d$.
Hint 2. Since $\omega^n = 1$, ω^{j^2} depends only on j modulo n, so for fixed k you may let d run over $0, \ldots, n-1$ with $j \equiv k + d$. Then $j^2 - k^2 \equiv d^2 + 2dk$.
Hint 3. The sum over k of ω^{2dk} is given by Lemma 6.3.39. For which d is it nonzero when n is odd?
Sketch. $|g|^2 = \sum_k \sum_d \omega^{(k+d)^2-k^2} = \sum_d \omega^{d^2} \sum_k \omega^{2dk}$. The inner sum is n if $n \mid 2d$ and 0 otherwise. For odd n, $n \mid 2d$ only for $d = 0$, so $|g|^2 = n$. For $n = 4$ the values $d = 0, 2$ contribute, giving 8; for $n = 6$, $d = 0, 3$ contribute $6\left(1 + \omega^9\right) = 0$.

(a) Since $\omega^n = 1$, ω^m depends only on m modulo n; as $(j+n)^2 = j^2 + n(2j+n)$, the term ω^{j^2} depends only on j modulo n. Since $\overline{\omega^{k^2}} = \omega^{-k^2}$,

$$|g|^2 = g\overline{g} = \sum_{k=0}^{n-1} \sum_{j=0}^{n-1} \omega^{j^2-k^2}.$$

Fix k. As d runs over $0, \ldots, n-1$, the residue of $k + d$ modulo n runs over all residues once, so we may replace j by $k + d$ in the inner sum:

$$\sum_{j=0}^{n-1} \omega^{j^2-k^2} = \sum_{d=0}^{n-1} \omega^{(k+d)^2-k^2} = \sum_{d=0}^{n-1} \omega^{d^2+2dk}.$$

Summing over k and exchanging the sums,

$$|g|^2 = \sum_{d=0}^{n-1} \omega^{d^2} \sum_{k=0}^{n-1} \omega^{k(2d)}.$$

By Lemma 6.3.39 the inner sum is n if $n \mid 2d$ and 0 otherwise. Since n is odd, $n \mid 2d$ implies $n \mid d$, which for $0 \le d \le n-1$ means $d = 0$. So $|g|^2 = \omega^0 \cdot n = n$.

(b) The computation up to the last step did not use that n is odd, so in general $|g|^2 = n \sum \omega^{d^2}$ over the $d \in \{0, \ldots, n-1\}$ with $n \mid 2d$. For $n = 4$ (where $\omega = i$) these are $d = 0, 2$, and $|g|^2 = 4\left(1 + i^4\right) = 8$; directly, $g = 1 + i + i^4 + i^9 = 2 + 2i$. For $n = 6$ they are $d = 0, 3$, and $|g|^2 = 6\left(1 + \omega^9\right) = 6\left(1 + \omega^3\right) = 0$, since $\omega^3 = -1$ for $n = 6$. The oddness of n was used only to conclude that $n \mid 2d$ forces $d = 0$.

Section 6.4

Solution to Exercise 6.4.13

Uses. Definition 6.4.1 (Projection onto the span of an orthonormal list), Definition 6.1.8 (Dot product), Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$)
Hint 1. $\langle \mathbf{v}, \mathbf{u} \rangle = \mathbf{v} \cdot \mathbf{u}$ conjugates the entries of $\mathbf{u}$.
Hint 2. You should get $\langle \mathbf{v}, \mathbf{u} \rangle = -i/\sqrt{2}$, while $\langle \mathbf{u}, \mathbf{v} \rangle$ is its conjugate.
Sketch. (a) $\langle \mathbf{v}, \mathbf{u} \rangle = \left(1 \cdot \bar{i}\right)/\sqrt{2} = -i/\sqrt{2}$, so $\mathrm{Pr}_{\mathbf{u}}(\mathbf{v}) = (-i/2)(1, i, 0) = (-i/2, 1/2, 0)$, and $\mathbf{v} - \mathrm{Pr}_{\mathbf{u}}(\mathbf{v}) = (i/2, 1/2, 1)$ has dot product $i/2 + (1/2)(-i) = 0$ with $(1, i, 0)$. (b) $\langle \mathbf{u}, \mathbf{v} \rangle \mathbf{u} = (i/2, -1/2, 0)$, and $\mathbf{v}$ minus it has dot product $-2i \neq 0$ with $(1, i, 0)$.

(a) By Definition 6.1.8, $\langle \mathbf{v}, \mathbf{u} \rangle = \left(0 \cdot 1 + 1 \cdot \bar{i} + 1 \cdot 0\right)/\sqrt{2} = -i/\sqrt{2}$. So

$$\begin{aligned} \mathrm{Pr}_{\mathbf{u}}(\mathbf{v}) &= -\frac{i}{\sqrt{2}} \cdot \frac{1}{\sqrt{2}}(1, i, 0) \\ &= -\frac{i}{2}(1, i, 0) = \left(-\frac{i}{2}, \frac{1}{2}, 0\right), \end{aligned}$$

and $\mathbf{v} - \mathrm{Pr}_{\mathbf{u}}(\mathbf{v}) = (i/2, 1/2, 1)$. Its dot product with $(1, i, 0)$ is $(i/2) \cdot 1 + (1/2) \cdot \bar{i} + 0 = i/2 - i/2 = 0$, so it is orthogonal to $\mathbf{u}$, as Proposition 6.4.4(b) says.

(b) $\langle \mathbf{u}, \mathbf{v} \rangle = \overline{\langle \mathbf{v}, \mathbf{u} \rangle} = i/\sqrt{2}$, so the student's vector is $(i/2)(1, i, 0) = (i/2, -1/2, 0)$, and $\mathbf{v}$ minus it is $(-i/2, 3/2, 1)$. Its dot product with $(1, i, 0)$ is $-i/2 + (3/2)(-i) = -2i \neq 0$. Over $\mathbb{C}$ the vector being projected belongs in the first slot.

Solution to Exercise 6.4.21

Uses. Algorithm 6.4.14 (Gram–Schmidt), Definition 6.1.8 (Dot product), Corollary 6.4.10 (Projecting with an orthogonal list)
Hint 1. Work with residuals: $\mathbf{f}_2 = \mathbf{v}_2 - \langle \mathbf{v}_2, \mathbf{f}_1\rangle / \|\mathbf{f}_1\|^2 \, \mathbf{f}_1$ with $\mathbf{f}_1 = \mathbf{v}_1$.
Hint 2. $\langle \mathbf{v}_2, \mathbf{f}_1\rangle = 1 + \bar{i} = 1 - i$ and $\|\mathbf{f}_1\|^2 = 2$.
Sketch. $\mathbf{f}_2 = (1,1,1) - ((1-i)/2)(1,i,0) = ((1+i)/2, (1-i)/2, 1)$, of squared norm 2. So $\mathbf{u}_1 = (1,i,0)/\sqrt{2}$ and $\mathbf{u}_2 = ((1+i)/2, (1-i)/2, 1)/\sqrt{2}$. With the conjugated coefficient $(1+i)/2$, the residual has dot product $-2i \neq 0$ with $\mathbf{v}_1$.

We use Remark 6.4.16. First $\mathbf{f}_1 = (1,i,0)$ with $\|\mathbf{f}_1\|^2 = 2$. Next $\langle \mathbf{v}_2, \mathbf{f}_1\rangle = 1 \cdot 1 + 1 \cdot \bar{i} + 0 = 1 - i$, so

$$\begin{aligned}\mathbf{f}_2 &= (1,1,1) - \frac{1-i}{2}(1,i,0) \\ &= \left(1 - \frac{1-i}{2}, 1 - \frac{i+1}{2}, 1\right) \\ &= \left(\frac{1+i}{2}, \frac{1-i}{2}, 1\right).\end{aligned}$$

Check: $\mathbf{f}_2 \cdot \mathbf{f}_1 = (1+i)/2 + ((1-i)/2)\bar{i} = (1+i)/2 + (-i-1)/2 = 0$. Also $\|\mathbf{f}_2\|^2 = 1/2 + 1/2 + 1 = 2$. So

$$\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1,i,0), \quad \mathbf{u}_2 = \frac{1}{\sqrt{2}}\left(\frac{1+i}{2}, \frac{1-i}{2}, 1\right).$$

With the slots exchanged, the coefficient becomes $\overline{1-i}/2 = (1+i)/2$, and the "residual" is $(1,1,1) - ((1+i)/2)(1,i,0) = ((1-i)/2, (3-i)/2, 1)$. Its dot product with $\mathbf{v}_1$ is $(1-i)/2 + ((3-i)/2)(-i) = (1 - i - 3i - 1)/2 = -2i \neq 0$, so the output would not be orthogonal.

Solution to Exercise 6.4.28

Uses. Theorem 6.4.26 (The double complement), Corollary 6.4.10 (Projecting with an orthogonal list), Theorem 6.4.6 (The projection is characterized by orthogonality), Proposition 6.3.9 (Properties of $A^\perp$)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. $W = \operatorname{span}(\mathbf{j})^\perp$ for $\mathbf{j} = (1,1,1,1)$. Apply Theorem 6.4.26.
Hint 2. $\operatorname{Pr}_{W^\perp}$ is the projection onto a line. For the closest vector, guess $\mathbf{e}_1 - \operatorname{Pr}_{W^\perp}(\mathbf{e}_1)$ and check the two conditions of Technique 6.4.7 for the subspace W.
Sketch. $W = \operatorname{span}(\mathbf{j})^\perp$, so $W^\perp = \operatorname{span}(\mathbf{j})$ by Theorem 6.4.26, and $\operatorname{Pr}_{W^\perp}(\mathbf{x}) = ((x_1 + x_2 + x_3 + x_4)/4)\mathbf{j}$. The vector $\mathbf{p} = \mathbf{e}_1 - \mathbf{j}/4 = (3/4, -1/4, -1/4, -1/4)$ lies in W, and $\mathbf{e}_1 - \mathbf{p} = \mathbf{j}/4 \in W^\perp$, so $\mathbf{p} = \operatorname{Pr}_W(\mathbf{e}_1)$.

Let $\mathbf{j} = (1,1,1,1)$. Then $W = \{\mathbf{j}\}^\perp = \operatorname{span}(\mathbf{j})^\perp$ by Proposition 6.3.9(c), and $\operatorname{span}(\mathbf{j})$ is finite-dimensional, so Theorem 6.4.26 gives $W^\perp = \left(\operatorname{span}(\mathbf{j})^\perp\right)^\perp = \operatorname{span}(\mathbf{j})$. By Corollary 6.4.10 with the single vector $\mathbf{j}$, $\|\mathbf{j}\|^2 = 4$,

$$\operatorname{Pr}_{W^\perp}(\mathbf{x}) = \frac{x_1 + x_2 + x_3 + x_4}{4}\mathbf{j}.$$

In particular $\operatorname{Pr}_{W^\perp}(\mathbf{e}_1) = \mathbf{j}/4$. Let

$$\mathbf{p} = \mathbf{e}_1 - \frac{1}{4}\mathbf{j} = \left(\frac{3}{4}, -\frac{1}{4}, -\frac{1}{4}, -\frac{1}{4}\right).$$

Its coordinates add up to 0, so $\mathbf{p} \in W$, and $\mathbf{e}_1 - \mathbf{p} = \mathbf{j}/4 \in W^\perp$. By Theorem 6.4.6 (applied with an orthonormal basis of W), $\mathbf{p} = \operatorname{Pr}_W(\mathbf{e}_1)$. By Theorem 6.4.33 below, this is the vector of W closest to $\mathbf{e}_1$, at distance $\|\mathbf{j}/4\| = 1/2$. (Proposition 6.4.29(d) below explains the shortcut: $\operatorname{Pr}_W = \mathrm{id} - \operatorname{Pr}_{W^\perp}$.)

Solution to Exercise 6.4.36

Uses. Example 6.4.17 (Gram–Schmidt in $\mathbb{R}^3$), Theorem 6.4.33 (Best approximation), Example 6.4.35 (Distance to a hyperplane)
Hint 1. Example 6.4.17 already contains an orthonormal basis of W.
Hint 2. $\mathbf{u}_1 = (1,1,0)/\sqrt{2}$ and $\mathbf{u}_2 = (1,-1,2)/\sqrt{6}$. For the check, a normal vector of W is $\mathbf{u}_3$.
Sketch. With $\mathbf{u}_1, \mathbf{u}_2$ from Example 6.4.17, $\langle \mathbf{v}, \mathbf{u}_1\rangle = 0$ and $\langle \mathbf{v}, \mathbf{u}_2\rangle = 6/\sqrt{6}$, so $\operatorname{Pr}_W(\mathbf{v}) = (1,-1,2)$ and $\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}) = (-1,1,1)$, of length $\sqrt{3}$. With $\mathbf{n} = (-1,1,1)$, $|\langle \mathbf{v}, \mathbf{n}\rangle| / \|\mathbf{n}\| = 3/\sqrt{3} = \sqrt{3}$.

By Example 6.4.17, $\mathbf{u}_1 = (1,1,0)/\sqrt{2}$, $\mathbf{u}_2 = (1,-1,2)/\sqrt{6}$ is an orthonormal basis of $\operatorname{span}(\mathbf{v}_1,\mathbf{v}_2) = W$. Here $\langle \mathbf{v}, \mathbf{u}_1\rangle = 0$ and $\langle \mathbf{v}, \mathbf{u}_2\rangle = 6/\sqrt{6}$, so by Theorem 6.4.33 the closest point is

$$\operatorname{Pr}_W(\mathbf{v}) = 0 \cdot \mathbf{u}_1 + \frac{6}{\sqrt{6}} \cdot \frac{1}{\sqrt{6}}(1,-1,2) = (1,-1,2).$$

The distance is $\|\mathbf{v} - \operatorname{Pr}_W(\mathbf{v})\| = \|(-1,1,1)\| = \sqrt{3}$. Check: $(-1,1,1)$ is orthogonal to $(1,1,0)$ and $(1,0,1)$, so $W = \{\mathbf{n}\}^\perp$ with $\mathbf{n} = (-1,1,1)$ (both are planes, and one contains the other), and Example 6.4.35 gives $|\langle \mathbf{v}, \mathbf{n}\rangle|/\|\mathbf{n}\| = 3/\sqrt{3} = \sqrt{3}$.

Solution to Exercise 6.4.40

Uses. Algorithm 6.4.14 (Gram–Schmidt), Remark 6.4.16 (Postponing the normalization), Corollary 6.4.10 (Projecting with an orthogonal list), Theorem 6.4.33 (Best approximation), Corollary 6.4.25 (Dimension of the orthogonal complement)
Hint 1. Run the algorithm with residuals only (Remark 6.4.16). The coefficients are $\langle \mathbf{v}_j, \mathbf{f}_i\rangle/\|\mathbf{f}_i\|^2$.
Hint 2. The residuals are $(1,1,1,1)$, $(1,-1,-1,1)$, $(0,1,-1,0)$. For (b), use Corollary 6.4.10 with these.
Hint 3. For (c), $\dim W^\perp = 1$, and $\mathbf{b} - \operatorname{Pr}_W(\mathbf{b})$ is a nonzero vector of $W^\perp$.
Sketch. $\mathbf{f}_1 = (1,1,1,1)$, $\mathbf{f}_2 = \mathbf{v}_2 - \mathbf{f}_1 = (1,-1,-1,1)$, $\mathbf{f}_3 = \mathbf{v}_3 - \mathbf{f}_1/2 + \mathbf{f}_2/2 = (0,1,-1,0)$. Then $\operatorname{Pr}_W(\mathbf{b}) = (10/4)\mathbf{f}_1 + 0\mathbf{f}_2 - (1/2)\mathbf{f}_3 = (5/2,2,3,5/2)$, and $\mathbf{b} - \operatorname{Pr}_W(\mathbf{b}) = (3/2)(-1,0,0,1)$, of length $3/\sqrt{2}$. $W^\perp = \operatorname{span}((1,0,0,-1))$.

(a) By Remark 6.4.16 we may work with residuals. First $\mathbf{f}_1 = (1,1,1,1)$, with $\|\mathbf{f}_1\|^2 = 4$. Next $\langle \mathbf{v}_2, \mathbf{f}_1\rangle = 4$, so

$$\mathbf{f}_2 = (2,0,0,2) - (1,1,1,1) = (1,-1,-1,1),$$

with $\|\mathbf{f}_2\|^2 = 4$. Then $\langle \mathbf{v}_3, \mathbf{f}_1\rangle = 2$ and $\langle \mathbf{v}_3, \mathbf{f}_2\rangle = -2$, so

$$\begin{aligned}\mathbf{f}_3 &= (0,2,0,0) - \frac{1}{2}(1,1,1,1) + \frac{1}{2}(1,-1,-1,1)\\ &= (0,1,-1,0),\end{aligned}$$

with $\|\mathbf{f}_3\|^2 = 2$. No residual is $\mathbf{0}$, so $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ is independent, and

$$\mathbf{u}_1 = \frac{1}{2}(1,1,1,1), \quad \mathbf{u}_2 = \frac{1}{2}(1,-1,-1,1),$$

$$\mathbf{u}_3 = \frac{1}{\sqrt{2}}(0,1,-1,0)$$

is an orthonormal basis of W (Theorem 6.4.15).

(b) We have $\langle \mathbf{b}, \mathbf{f}_1\rangle = 10$, $\langle \mathbf{b}, \mathbf{f}_2\rangle = 1 - 2 - 3 + 4 = 0$, and $\langle \mathbf{b}, \mathbf{f}_3\rangle = -1$. By Corollary 6.4.10,

$$\begin{aligned}\operatorname{Pr}_W(\mathbf{b}) &= \frac{10}{4}(1,1,1,1) + 0 - \frac{1}{2}(0,1,-1,0)\\ &= \left(\frac{5}{2}, 2, 3, \frac{5}{2}\right).\end{aligned}$$

So $\mathbf{b} - \operatorname{Pr}_W(\mathbf{b}) = (-3/2,0,0,3/2)$, which is indeed orthogonal to $\mathbf{f}_1, \mathbf{f}_2, \mathbf{f}_3$, and by Theorem 6.4.33, $\operatorname{dist}(\mathbf{b}, W) = \sqrt{9/4 + 9/4} = 3/\sqrt{2}$.

(c) By Corollary 6.4.25, $\dim W^\perp = 4 - 3 = 1$. The vector $(1,0,0,-1)$ is orthogonal to $\mathbf{f}_1$, $\mathbf{f}_2$, $\mathbf{f}_3$, which span W, so it lies in $W^\perp$ (Proposition 6.3.9(c)). Hence $W^\perp = \operatorname{span}((1,0,0,-1))$. As it must, $\mathbf{b} - \operatorname{Pr}_W(\mathbf{b}) = -(3/2)(1,0,0,-1)$ lies in $W^\perp$.

Solution to Exercise 6.4.41

Uses. Theorem 6.4.31 (The matrix of an orthogonal projection), Corollary 6.4.10 (Projecting with an orthogonal list), Proposition 6.4.29 (The orthogonal projection as a linear map), Corollary 6.4.25 (Dimension of the orthogonal complement)
Hint 1. Gram–Schmidt with residuals gives $(1,0,1)$ and $(1,2,-1)$. Use $\sum_i \mathbf{f}_i\mathbf{f}_i^{\mathsf{T}}/\|\mathbf{f}_i\|^2$.
Hint 2. For (b), find $\mathbf{n} \neq \mathbf{0}$ orthogonal to both spanning vectors; then $P = I_3 - \mathbf{n}\mathbf{n}^{\mathsf{T}}/\|\mathbf{n}\|^2$ by Proposition 6.4.29(d).

Sketch. Both ways give $P = (1/3)\begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{pmatrix}$: in (a) as $(1/2)\mathbf{f}_1\mathbf{f}_1^{\mathsf{T}} + (1/6)\mathbf{f}_2\mathbf{f}_2^{\mathsf{T}}$ with $\mathbf{f}_1 = (1,0,1)$, $\mathbf{f}_2 = (1,2,-1)$, and in (b) as $I_3 - (1/3)\mathbf{n}\mathbf{n}^{\mathsf{T}}$ with $\mathbf{n} = (-1,1,1)$. The trace is $6/3 = 2 = \dim W$.

(a) Gram–Schmidt with residuals: $\mathbf{f}_1 = (1,0,1)$, and $(1,1,0) - (1/2)(1,0,1) = (1/2, 1, -1/2)$, which we replace by $\mathbf{f}_2 = (1,2,-1)$. By Theorem 6.4.31 and Corollary 6.4.10,

$$P = \frac{1}{2}\begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{pmatrix} + \frac{1}{6}\begin{pmatrix} 1 & 2 & -1 \\ 2 & 4 & -2 \\ -1 & -2 & 1 \end{pmatrix}$$
$$= \frac{1}{3}\begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{pmatrix}.$$

(b) The vector $\mathbf{n} = (-1,1,1)$ is orthogonal to $(1,0,1)$ and $(1,1,0)$, so it lies in $W^{\perp}$, which is a line by Corollary 6.4.25. So $W^{\perp} = \operatorname{span}(\mathbf{n})$ and, by Proposition 6.4.29(d),

$$P = I_3 - \frac{\mathbf{n}\mathbf{n}^{\mathsf{T}}}{3} = I_3 - \frac{1}{3}\begin{pmatrix} 1 & -1 & -1 \\ -1 & 1 & 1 \\ -1 & 1 & 1 \end{pmatrix}$$
$$= \frac{1}{3}\begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{pmatrix}.$$

The matrix is symmetric, and $\operatorname{tr} P = (2+2+2)/3 = 2$. For $P^2 = P$, by Theorem 6.4.31 there is nothing to check, but directly: the first row of $3P$ times the columns of $3P$ gives $(4+1+1, 2+2-1, 2-1+2) = (6,3,3)$, which is 3 times the first row of $3P$, and similarly for the other rows; so $(3P)^2 = 3(3P)$, that is, $P^2 = P$.

Solution to Exercise 6.4.42

Uses. Corollary 6.4.10 (Projecting with an orthogonal list), Theorem 6.4.6 (The projection is characterized by orthogonality), Algorithm 6.4.14 (Gram–Schmidt)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. Which hypothesis of Corollary 6.4.10 does the list $\mathbf{a}, \mathbf{b}$ fail?
Hint 2. Check whether $\mathbf{v} - (5/2, 3/2, 0)$ is orthogonal to $\mathbf{a}$. To fix the computation, orthogonalize $\mathbf{a}, \mathbf{b}$ first.
Sketch. The formula needs an orthogonal list, and $\langle \mathbf{a}, \mathbf{b} \rangle = 1 \neq 0$. The student's $\mathbf{v} - \mathbf{p} = (-3/2, 1/2, 3)$ has inner product $-3/2$ with $\mathbf{a}$. Gram–Schmidt replaces $\mathbf{b}$ by $(0,1,0)$, and then $\operatorname{Pr}_W(\mathbf{v}) = (1,0,0) + (0,2,0) = (1,2,0)$.

The formula of Corollary 6.4.10 holds for orthogonal lists, and $\langle \mathbf{a}, \mathbf{b} \rangle = 1 \neq 0$. The test of Theorem 6.4.6 detects the error: for $\mathbf{p} = (5/2, 3/2, 0)$, the vector $\mathbf{v} - \mathbf{p} = (-3/2, 1/2, 3)$ has $\langle \mathbf{v} - \mathbf{p}, \mathbf{a} \rangle = -3/2 \neq 0$, so $\mathbf{v} - \mathbf{p} \notin W^{\perp}$.

Gram–Schmidt turns $\mathbf{a}, \mathbf{b}$ into the orthogonal list $\mathbf{a}$, $\mathbf{b} - \langle \mathbf{b}, \mathbf{a} \rangle \mathbf{a} = (0,1,0)$ with the same span, so W is the x_1x_2-plane. Now Corollary 6.4.10 applies:

$$\operatorname{Pr}_W(\mathbf{v}) = 1 \cdot (1,0,0) + 2 \cdot (0,1,0) = (1,2,0),$$

and $\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}) = (0,0,3)$ is orthogonal to W. The student's vector even lies in W; it is just the wrong vector of W.

Solution to Exercise 6.4.43

Uses. Algorithm 6.4.14 (Gram–Schmidt), Theorem 6.4.15 (Gram–Schmidt is correct), Remark 6.4.16 (Postponing the normalization)
Hint 1. Use residuals. $\mathbf{f}_1 = (1,0,1,0)$ and $\mathbf{f}_2$ is a multiple of $(1,2,-1,0)$.
Hint 2. The third residual is $\mathbf{0}$. Its formula expresses $\mathbf{v}_3$ through $\mathbf{f}_1$ and $\mathbf{f}_2$; rewrite those in terms of $\mathbf{v}_1$ and $\mathbf{v}_2$.

Sketch. $\mathbf{f}_1 = (1,0,1,0)$; $\mathbf{f}_2 = \mathbf{v}_2 - \mathbf{f}_1/2$, rescaled to $\mathbf{g} = (1,2,-1,0) = 2\mathbf{v}_2 - \mathbf{v}_1$; $\mathbf{v}_3 - (-1/2)\mathbf{f}_1 - (3/6)\mathbf{g} = \mathbf{0}$, so $\mathbf{v}_3$ is skipped and $\mathbf{v}_3 = -\mathbf{v}_1/2 + \mathbf{g}/2 = \mathbf{v}_2 - \mathbf{v}_1$; $\mathbf{v}_4$ is already orthogonal to the others. The dimension is 3.

With residuals (Remark 6.4.16): $\mathbf{f}_1 = (1,0,1,0)$, $\|\mathbf{f}_1\|^2 = 2$. Then $\langle \mathbf{v}_2, \mathbf{f}_1 \rangle = 1$, and

$$\mathbf{v}_2 - \frac{1}{2}\mathbf{f}_1 = \left(\frac{1}{2}, 1, -\frac{1}{2}, 0\right),$$

which we replace by $\mathbf{g} = (1,2,-1,0) = 2\mathbf{v}_2 - \mathbf{v}_1$, with $\|\mathbf{g}\|^2 = 6$. In the third pass, $\langle \mathbf{v}_3, \mathbf{f}_1 \rangle = -1$ and $\langle \mathbf{v}_3, \mathbf{g} \rangle = 2 + 1 = 3$, so

$$\begin{aligned} &\mathbf{v}_3 + \frac{1}{2}(1,0,1,0) - \frac{3}{6}(1,2,-1,0) \\ &= \left(0 + \frac{1}{2} - \frac{1}{2}, 1 - 1, -1 + \frac{1}{2} + \frac{1}{2}, 0\right) = \mathbf{0}. \end{aligned}$$

So $\mathbf{v}_3$ is skipped, and by Theorem 6.4.15(b) it lies in $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$. Explicitly, $\mathbf{v}_3 = -(1/2)\mathbf{v}_1 + (1/2)(2\mathbf{v}_2 - \mathbf{v}_1) = \mathbf{v}_2 - \mathbf{v}_1$, which is easily checked. Finally $\mathbf{v}_4$ is orthogonal to $\mathbf{f}_1$ and $\mathbf{g}$, so its residual is $\mathbf{v}_4$ itself. Three vectors are kept, so the output

$$\frac{1}{\sqrt{2}}(1,0,1,0), \quad \frac{1}{\sqrt{6}}(1,2,-1,0), \quad (0,0,0,1)$$

is an orthonormal basis of $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_4)$ (Theorem 6.4.15(c)), whose dimension is therefore 3.

Solution to Exercise 6.4.44

Uses. Theorem 6.4.33 (Best approximation), Example 6.4.19 (Legendre polynomials), Corollary 6.4.10 (Projecting with an orthogonal list)
Hint 1. Use the orthogonal basis $1, t, t^2 - 1/3$ of Example 6.4.19, with squared norms $2, 2/3, 8/45$. Each new degree adds one term to the projection.
Hint 2. $\langle |t|, 1 \rangle = 1$, $\langle |t|, t \rangle = 0$ (odd integrand), and $\langle |t|, t^2 \rangle = 2\int_0^1 t^3\,dt = 1/2$.
Hint 3. The squared distance is $\|f\|^2$ minus the squared norm of the projection, and each term contributes $\langle f, \mathbf{f}_j \rangle^2 / \|\mathbf{f}_j\|^2$.
Sketch. The coefficients are $1/2, 0$, and $(1/6)/(8/45) = 15/16$. So the best constant and the best linear function are both $1/2$, with squared distance $2/3 - 1/2 = 1/6$, and the best quadratic is $1/2 + (15/16)\left(t^2 - 1/3\right) = \left(3 + 15t^2\right)/16$, with squared distance $1/6 - (1/36)(45/8) = 1/96$.

Let $f(t) = |t|$. The polynomial functions of degree at most n form a finite-dimensional subspace W_n, and by Theorem 6.4.33 the closest one to f is $\operatorname{Pr}_{W_n}(f)$. By Example 6.4.19, 1; $1, t$; and $1, t, t^2 - 1/3$ are orthogonal bases of W_0, W_1, W_2, with squared norms 2, $2/3$, $8/45$. We need

$$\langle f, 1 \rangle = 2\int_0^1 t\,dt = 1, \quad \langle f, t \rangle = 0,$$

$$\left\langle f, t^2 - \frac{1}{3} \right\rangle = 2\int_0^1 t^3\,dt - \frac{1}{3} = \frac{1}{2} - \frac{1}{3} = \frac{1}{6},$$

where $\langle f, t \rangle = 0$ because $|t|t$ is odd. By Corollary 6.4.10,

$$\begin{aligned} \operatorname{Pr}_{W_0}(f) &= \operatorname{Pr}_{W_1}(f) = \frac{1}{2}, \\ \operatorname{Pr}_{W_2}(f) &= \frac{1}{2} + \frac{1/6}{8/45}\left(t^2 - \frac{1}{3}\right) \\ &= \frac{1}{2} + \frac{15}{16}\left(t^2 - \frac{1}{3}\right) = \frac{3 + 15t^2}{16}. \end{aligned}$$

For the distances, $\|f\|^2 = \int_{-1}^1 t^2\,dt = 2/3$, and by Theorem 6.4.33 (applied with the normalized basis, whose squared inner products with f are $\langle f, \mathbf{f}_j \rangle^2 / \|\mathbf{f}_j\|^2$),

$$\operatorname{dist}(f, W_0)^2 = \operatorname{dist}(f, W_1)^2 = \frac{2}{3} - \frac{1^2}{2} = \frac{1}{6},$$

$$\operatorname{dist}(f, W_2)^2 = \frac{1}{6} - \frac{(1/6)^2}{8/45} = \frac{1}{6} - \frac{5}{32} = \frac{1}{96}.$$

The best linear approximation is no better than the best constant, because f is even and t is odd. Allowing t^2 cuts the squared error by a factor of 16, although $|t|$ is not differentiable at 0 and has no Taylor polynomial there.

Solution to Exercise 6.4.45

Uses. Theorem 6.4.33 (Best approximation), Example 6.4.19 (Legendre polynomials), Exercise 6.3.49
Hint 1. The integral is $\|t^3 - p\|^2$ for $p = a + bt + ct^2$ in the subspace W of polynomial functions of degree at most 2. Which p minimizes it?
Hint 2. $p = \operatorname{Pr}_W(t^3)$, and $t^3 - \operatorname{Pr}_W(t^3)$ is the fourth Gram–Schmidt residual of Example 6.4.19.
Sketch. By Theorem 6.4.33 the minimizer is $p = \operatorname{Pr}_W(t^3)$, and $t^3 - \operatorname{Pr}_W(t^3)$ is the residual $t^3 - (3/5)t$ from Gram–Schmidt on $1, t, t^2, t^3$. So $a = c = 0$, $b = 3/5$, and the minimum is $\|t^3 - (3/5)t\|^2 = 8/175$ (Exercise 6.3.49).

Let W be the space of polynomial functions of degree at most 2 in $C[-1, 1]$ with $\langle f, g\rangle = \int_{-1}^{1} fg$. The integral is $\|t^3 - p\|^2$ with $p = a + bt + ct^2 \in W$, and as (a, b, c) ranges over $\mathbb{R}^3$, p ranges over all of W. By Theorem 6.4.33 the minimum is attained exactly at $p = \operatorname{Pr}_W(t^3)$.

By Example 6.4.19, $W = \operatorname{span}(1, t, t^2)$, and the fourth Gram–Schmidt residual is $t^3 - \operatorname{Pr}_W(t^3) = t^3 - (3/5)t$. So $\operatorname{Pr}_W(t^3) = (3/5)t$: the minimum is attained exactly at $a = 0$, $b = 3/5$, $c = 0$, and its value is

$$\begin{aligned}\left\|t^3 - \frac{3}{5}t\right\|^2 &= \int_{-1}^{1}\left(t^6 - \frac{6}{5}t^4 + \frac{9}{25}t^2\right)\mathrm{d}t \\ &= \frac{2}{7} - \frac{12}{25} + \frac{6}{25} = \frac{8}{175},\end{aligned}$$

as computed in Exercise 6.3.49. (Calculus would set three partial derivatives to 0 and solve a 3×3 system; the orthogonal basis does that work once and for all.)

Solution to Exercise 6.4.46

Uses. Algorithm 6.4.14 (Gram–Schmidt), Remark 6.4.16 (Postponing the normalization), Theorem 6.4.33 (Best approximation)
Hint 1. $\langle x^i, x^j\rangle = 1/(i + j + 1)$. Work with residuals.
Hint 2. The residuals are 1, $x - 1/2$, $x^2 - x + 1/6$, with squared norms 1, $1/12$, $1/180$.
Hint 3. For (b), the minimizer is $a + bx = \operatorname{Pr}(x^2)$ onto $\operatorname{span}(1, x)$, and the minimum is the squared norm of the third residual.
Sketch. $f_1 = 1$; $f_2 = x - \langle x, 1\rangle = x - 1/2$; $f_3 = x^2 - 1/3 - (1/12)/(1/12)(x - 1/2) = x^2 - x + 1/6$. Normalizing with $\|f_2\|^2 = 1/12$ and $\|f_3\|^2 = 1/180$ gives the list. (b) The minimum is $\|f_3\|^2 = 1/180$, at $a + bt = t - 1/6$.

(a) Here $\langle x^i, x^j\rangle = \int_0^1 t^{i+j}\,\mathrm{d}t = 1/(i + j + 1)$. With residuals: $f_1 = 1$, $\|f_1\|^2 = 1$, and $f_2 = x - \langle x, 1\rangle \cdot 1 = x - 1/2$, with

$$\|f_2\|^2 = \int_0^1 \left(t - \frac{1}{2}\right)^2 \mathrm{d}t = \frac{1}{12}.$$

Next, $\langle x^2, 1\rangle = 1/3$ and $\langle x^2, x - 1/2\rangle = 1/4 - 1/6 = 1/12$, so

$$f_3 = x^2 - \frac{1}{3} - \frac{1/12}{1/12}\left(x - \frac{1}{2}\right) = x^2 - x + \frac{1}{6}.$$

Expanding, $\|f_3\|^2 = \int_0^1 \left(t^4 - 2t^3 + (4/3)t^2 - t/3 + 1/36\right)\mathrm{d}t = 1/5 - 1/2 + 4/9 - 1/6 + 1/36 = 1/180$. Normalizing,

$$u_1 = 1,$$

$$u_2 = \sqrt{12}\left(x - \frac{1}{2}\right) = \sqrt{3}(2x - 1),$$
$$u_3 = \sqrt{180}\left(x^2 - x + \frac{1}{6}\right) = \sqrt{5}\left(6x^2 - 6x + 1\right).$$

The first two are the output of the lecture's example.

(b) As (a, b) ranges over $\mathbb{R}^2$, $a + bx$ ranges over $W = \operatorname{span}(1, x) = \operatorname{span}(f_1, f_2)$. By Theorem 6.4.33, the minimum is $\operatorname{dist}\left(x^2, W\right)^2 = \left\|x^2 - \operatorname{Pr}_W\left(x^2\right)\right\|^2$, and $x^2 - \operatorname{Pr}_W\left(x^2\right)$ is the residual f_3. So the minimum is $1/180$, attained at $a + bx = x^2 - f_3 = x - 1/6$, that is, $a = -1/6$, $b = 1$.

Solution to Exercise 6.4.47

Uses. Definition 6.4.22 (Orthogonal complement), Proposition 1.4.24 (The sum of two subspaces), Theorem 6.4.26 (The double complement), Proposition 6.3.9 (Properties of $A^\perp$)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For (a), unwind the definitions. One containment uses $U, W \subseteq U + W$; the other expands $\langle \mathbf{v}, \mathbf{u} + \mathbf{w} \rangle$.
Hint 2. For (b), apply (a) to the subspaces $U^\perp$ and $W^\perp$, then take $\perp$ of both sides.
Hint 3. Theorem 6.4.26 says $\left(X^\perp\right)^\perp = X$ for every subspace X of the finite-dimensional space V.
Sketch. (a) $U, W \subseteq U + W$ gives $(U + W)^\perp \subseteq U^\perp \cap W^\perp$; conversely $\langle \mathbf{v}, \mathbf{u} + \mathbf{w} \rangle = \langle \mathbf{v}, \mathbf{u} \rangle + \langle \mathbf{v}, \mathbf{w} \rangle = 0$. (b) By (a) and Theorem 6.4.26, $\left(U^\perp + W^\perp\right)^\perp = U^{\perp\perp} \cap W^{\perp\perp} = U \cap W$. Taking $\perp$ and using Theorem 6.4.26 again, $U^\perp + W^\perp = (U \cap W)^\perp$.

(a) Since $U \subseteq U + W$ and $W \subseteq U + W$ (Proposition 1.4.24), Proposition 6.3.9(b) gives $(U + W)^\perp \subseteq U^\perp$ and $(U + W)^\perp \subseteq W^\perp$. Conversely, let $\mathbf{v} \in U^\perp \cap W^\perp$. Every vector of $U + W$ is $\mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in U$ and $\mathbf{w} \in W$, and

$$\langle \mathbf{v}, \mathbf{u} + \mathbf{w} \rangle = \langle \mathbf{v}, \mathbf{u} \rangle + \langle \mathbf{v}, \mathbf{w} \rangle = 0 + 0 = 0.$$

So $\mathbf{v} \in (U + W)^\perp$.

(b) Every subspace X of the finite-dimensional space V is finite-dimensional, so $\left(X^\perp\right)^\perp = X$ by Theorem 6.4.26. Apply (a) to the subspaces $U^\perp$ and $W^\perp$:

$$\left(U^\perp + W^\perp\right)^\perp = \left(U^\perp\right)^\perp \cap \left(W^\perp\right)^\perp = U \cap W.$$

Taking orthogonal complements of both sides and applying Theorem 6.4.26 to $X = U^\perp + W^\perp$,

$$U^\perp + W^\perp = \left(\left(U^\perp + W^\perp\right)^\perp\right)^\perp = (U \cap W)^\perp,$$

as desired.

Solution to Exercise 6.4.48

Uses. Theorem 6.4.24 (Orthogonal decomposition), Proposition 6.4.4 (Properties of $\operatorname{Pr}_{\mathcal{O}}$), Remark 6.4.12 (Why "orthogonal"), Definition 4.4.4 (Direct sum)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), (c), and (e), look in $\mathbb{R}^2$, using lines that are neither equal nor perpendicular.
Hint 2. For (b), $W \subseteq U^\perp$ is clear. For the other containment, write $\mathbf{v} \in U^\perp$ as $\mathbf{u} + \mathbf{w}$ and take the inner product with $\mathbf{u}$.
Hint 3. For (d), use Proposition 6.4.4(e).
Sketch. (a) False: $\mathbb{R}^2 = \operatorname{span}(\mathbf{e}_1) \oplus \operatorname{span}((1, 1))$. (b) True: if $\mathbf{v} = \mathbf{u} + \mathbf{w} \in U^\perp$, then $0 = \langle \mathbf{v}, \mathbf{u} \rangle = \|\mathbf{u}\|^2$. (c) False: for $U = \operatorname{span}(\mathbf{e}_1)$, $W = \operatorname{span}((1, 1))$, $\operatorname{Pr}_U \operatorname{Pr}_W \mathbf{e}_1 = (1/2, 0)$ but $\operatorname{Pr}_W \operatorname{Pr}_U \mathbf{e}_1 = (1/2, 1/2)$. (d) True, by the equality case of Bessel. (e) False: $P(x, y) = (x + y, 0)$ has $P^2 = P$ and $\|P(1, 1)\| = 2 > \sqrt{2}$.

(a) False. In $\mathbb{R}^2$, let $U = \operatorname{span}(\mathbf{e}_1)$ and $W = \operatorname{span}((1, 1))$. Then $U \cap W = \{\mathbf{0}\}$ and $U + W = \mathbb{R}^2$, so $V = U \oplus W$, but $U^\perp = \operatorname{span}(\mathbf{e}_2) \neq W$. Every subspace has many complements, and $U^\perp$ is only one of them.

(b) True. By hypothesis $W \subseteq U^\perp$. Conversely, let $\mathbf{v} \in U^\perp$, and write $\mathbf{v} = \mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in U$ and $\mathbf{w} \in W$. Then

$$0 = \langle \mathbf{v}, \mathbf{u} \rangle = \langle \mathbf{u}, \mathbf{u} \rangle + \langle \mathbf{w}, \mathbf{u} \rangle = \|\mathbf{u}\|^2,$$

so $\mathbf{u} = \mathbf{0}$ and $\mathbf{v} = \mathbf{w} \in W$.

(c) False. With U and W as in (a), $\operatorname{Pr}_W(\mathbf{e}_1) = (1/2)(1, 1)$, so

$$\operatorname{Pr}_U \operatorname{Pr}_W(\mathbf{e}_1) = \operatorname{Pr}_U\left(\frac{1}{2}, \frac{1}{2}\right) = \left(\frac{1}{2}, 0\right),$$
$$\operatorname{Pr}_W \operatorname{Pr}_U(\mathbf{e}_1) = \operatorname{Pr}_W(\mathbf{e}_1) = \left(\frac{1}{2}, \frac{1}{2}\right).$$

(Exercise 6.4.58 shows when the two products agree.)

(d) True. By Proposition 6.4.4(e) applied to an orthonormal basis of W, $\|\operatorname{Pr}_W(\mathbf{v})\| = \|\mathbf{v}\|$ holds only if $\mathbf{v} \in W$.

(e) False. $P(x, y) = (x + y, 0)$ is linear with $P^2(x, y) = P(x + y, 0) = (x + y, 0) = P(x, y)$, but $\|P(1, 1)\| = \|(2, 0)\| = 2 > \sqrt{2} = \|(1, 1)\|$. Like the map of Remark 6.4.12, P projects onto the x-axis along a direction that is not perpendicular to it (here $(1, -1)$), and such projections can stretch vectors. Exercise 6.4.57 shows that this is the only way an idempotent can fail to shrink norms.

Solution to Exercise 6.4.49

Uses. Theorem 6.4.6 (The projection is characterized by orthogonality), Proposition 6.4.29 (The orthogonal projection as a linear map), Proposition 1.4.24 (The sum of two subspaces), Theorem 6.4.20 (Orthonormal bases exist)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. For (a), check the two conditions of Technique 6.4.7 for $\mathbf{p} = \operatorname{Pr}_U(\mathbf{v}) + \operatorname{Pr}_W(\mathbf{v})$ and the subspace $U + W$. ($U + W$ is finite-dimensional: concatenate orthonormal bases.)
Hint 2. For $\operatorname{Pr}_U \operatorname{Pr}_W = 0$: $\operatorname{Pr}_W(\mathbf{v}) \in W \subseteq U^\perp = \ker \operatorname{Pr}_U$.
Hint 3. For (b), compute $\langle \mathbf{w}, \mathbf{u} \rangle = \langle \operatorname{Pr}_W \mathbf{w}, \operatorname{Pr}_U \mathbf{u} \rangle$ and move Pr_U across with Proposition 6.4.29(c).
Sketch. (a) $U + W$ is spanned by the concatenation of orthonormal bases of U and W, which is orthonormal. For $\mathbf{p} = \operatorname{Pr}_U(\mathbf{v}) + \operatorname{Pr}_W(\mathbf{v}) \in U + W$, $\langle \mathbf{v} - \mathbf{p}, \mathbf{u} \rangle = \langle \mathbf{v} - \operatorname{Pr}_U(\mathbf{v}), \mathbf{u} \rangle - \langle \operatorname{Pr}_W(\mathbf{v}), \mathbf{u} \rangle = 0$ for $\mathbf{u} \in U$, and similarly for W; so $\mathbf{p} = \operatorname{Pr}_{U+W}(\mathbf{v})$. Also $\operatorname{Pr}_W(\mathbf{v}) \in W \subseteq U^\perp = \ker \operatorname{Pr}_U$. (b) $\langle \mathbf{w}, \mathbf{u} \rangle = \langle \operatorname{Pr}_W \mathbf{w}, \operatorname{Pr}_U \mathbf{u} \rangle = \langle \operatorname{Pr}_U \operatorname{Pr}_W \mathbf{w}, \mathbf{u} \rangle = 0$.

(a) Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ and $\mathbf{w}_1, \ldots, \mathbf{w}_l$ be orthonormal bases of U and W (Theorem 6.4.20). By hypothesis $\langle \mathbf{u}_i, \mathbf{w}_j \rangle = 0$, so the concatenated list is orthonormal, and it spans $U + W$. So $U + W$ is finite-dimensional and Pr_{U+W} is defined. (In fact the formula of Definition 6.4.11 for this basis already gives the claim; we give the argument of Technique 6.4.7 instead.)

Let $\mathbf{v} \in V$ and $\mathbf{p} = \operatorname{Pr}_U(\mathbf{v}) + \operatorname{Pr}_W(\mathbf{v})$, which lies in $U + W$. For $\mathbf{u} \in U$, we have $\operatorname{Pr}_W(\mathbf{v}) \in W$, so $\langle \operatorname{Pr}_W(\mathbf{v}), \mathbf{u} \rangle = 0$ by hypothesis, and

$$\begin{aligned} \langle \mathbf{v} - \mathbf{p}, \mathbf{u} \rangle &= \langle \mathbf{v} - \operatorname{Pr}_U(\mathbf{v}), \mathbf{u} \rangle - \langle \operatorname{Pr}_W(\mathbf{v}), \mathbf{u} \rangle \\ &= 0 - 0 = 0. \end{aligned}$$

In the same way $\langle \mathbf{v} - \mathbf{p}, \mathbf{w} \rangle = 0$ for $\mathbf{w} \in W$. So $\mathbf{v} - \mathbf{p}$ is orthogonal to every $\mathbf{u} + \mathbf{w}$, that is, to $U + W$, and $\mathbf{p} = \operatorname{Pr}_{U+W}(\mathbf{v})$ by Theorem 6.4.6.

The hypothesis says $W \subseteq U^\perp$, and $U^\perp = \ker \operatorname{Pr}_U$ by Proposition 6.4.29(a). Since $\operatorname{Pr}_W(\mathbf{v}) \in W$, we get $\operatorname{Pr}_U \operatorname{Pr}_W(\mathbf{v}) = \mathbf{0}$ for every $\mathbf{v}$.

(b) Let $\mathbf{u} \in U$ and $\mathbf{w} \in W$. Then $\mathbf{u} = \operatorname{Pr}_U(\mathbf{u})$ and $\mathbf{w} = \operatorname{Pr}_W(\mathbf{w})$, and by Proposition 6.4.29(c) for Pr_U,

$$\begin{aligned} \langle \mathbf{w}, \mathbf{u} \rangle &= \langle \operatorname{Pr}_W(\mathbf{w}), \operatorname{Pr}_U(\mathbf{u}) \rangle = \langle \operatorname{Pr}_U(\operatorname{Pr}_W(\mathbf{w})), \mathbf{u} \rangle \\ &= \langle \mathbf{0}, \mathbf{u} \rangle = 0. \end{aligned}$$

Solution to Exercise 6.4.50

Uses. Theorem 6.4.6 (The projection is characterized by orthogonality), Exercise 6.4.49
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Every step but one is an instance of something proved in this section. Which statement about $\operatorname{Pr}_W(\mathbf{v})$ has no justification?
Hint 2. Test the claim with $U = W$.
Sketch. The step "$\operatorname{Pr}_W(\mathbf{v}) \perp U$" is unjustified: $\operatorname{Pr}_W(\mathbf{v})$ lies in W, and W need not be orthogonal to U. The claim is false: for $U = W = \operatorname{span}(\mathbf{e}_1)$ in $\mathbb{R}^2$, $\operatorname{Pr}_U + \operatorname{Pr}_W = 2 \operatorname{Pr}_U$, which sends $\mathbf{e}_1$ to $2\mathbf{e}_1$, while $\operatorname{Pr}_{U+W}(\mathbf{e}_1) = \mathbf{e}_1$. It is true when $U \perp W$ (Exercise 6.4.49).

The error is the assertion $\mathrm{Pr}_W(\mathbf{v}) \perp U$. All we know is that $\mathrm{Pr}_W(\mathbf{v}) \in W$, and a vector of W is orthogonal to U only if, for instance, every vector of W is orthogonal to every vector of U.

The claim is false. Let $U = W = \mathrm{span}(\mathbf{e}_1)$ in $\mathbb{R}^2$. Then $U + W = U$, and

$$(\mathrm{Pr}_U + \mathrm{Pr}_W)(\mathbf{e}_1) = 2\mathbf{e}_1 \neq \mathbf{e}_1 = \mathrm{Pr}_{U+W}(\mathbf{e}_1).$$

The argument becomes correct under the extra hypothesis that every vector of U is orthogonal to every vector of W, and then it proves Exercise 6.4.49(a).

Solution to Exercise 6.4.51

Uses. Theorem 6.4.31 (The matrix of an orthogonal projection), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.4.33 (Best approximation), Theorem 6.4.20 (Orthonormal bases exist)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. By Theorem 6.4.31, $P = QQ^*$ with $Q^*Q = I_k$. Use cyclicity of the trace.
Hint 2. For (b), $p_{ii} = (P\mathbf{e}_i)\cdot\mathbf{e}_i$. Use Proposition 6.4.29(c).
Hint 3. For (c), $\mathrm{dist}(\mathbf{e}_i, W)^2 = 1 - \|\mathrm{Pr}_W(\mathbf{e}_i)\|^2$, and the n numbers $\|\mathrm{Pr}_W(\mathbf{e}_i)\|^2$ add up to k.
Sketch. (a) $\mathrm{rank}\, P = \dim \mathrm{im}\, \mathrm{Pr}_W = k$, and $\mathrm{tr}(QQ^*) = \mathrm{tr}(Q^*Q) = \mathrm{tr}\, I_k = k$. (b) $p_{ii} = \langle P\mathbf{e}_i, \mathbf{e}_i\rangle = \langle P\mathbf{e}_i, P\mathbf{e}_i\rangle$; sum over i. (c) $\mathrm{dist}(\mathbf{e}_i, W)^2 = 1 - p_{ii}$, and the average of the p_{ii} is k/n, so some $p_{ii} \geq k/n$.

(a) By Proposition 6.4.29(a), the image of Pr_W is W, so $\mathrm{rank}\, P = \dim W = k$. By Theorem 6.4.20, W has an orthonormal basis, and by Theorem 6.4.31, $P = QQ^*$ with $Q \in \mathbb{F}^{n\times k}$ and $Q^*Q = I_k$. By Proposition 2.4.28, $\mathrm{tr}\, P = \mathrm{tr}(QQ^*) = \mathrm{tr}(Q^*Q) = \mathrm{tr}\, I_k = k$.

(b) The ith entry of $P\mathbf{e}_i$ is p_{ii}, so $p_{ii} = (P\mathbf{e}_i)\cdot\mathbf{e}_i = \langle P\mathbf{e}_i, \mathbf{e}_i\rangle$. By Proposition 6.4.29(c), this equals $\langle P\mathbf{e}_i, P\mathbf{e}_i\rangle = \|P\mathbf{e}_i\|^2$. Summing over i and using (a), $\sum_i \|\mathrm{Pr}_W(\mathbf{e}_i)\|^2 = \mathrm{tr}\, P = k$.

(c) By Theorem 6.4.33, $\mathrm{dist}(\mathbf{e}_i, W)^2 = \|\mathbf{e}_i\|^2 - \|\mathrm{Pr}_W(\mathbf{e}_i)\|^2 = 1 - p_{ii}$. The n numbers p_{ii} add up to k, so the largest of them is at least k/n. For that i, $\mathrm{dist}(\mathbf{e}_i, W)^2 \leq 1 - k/n$. (For the plane of Example 6.4.32, every p_{ii} equals $2/3$, so the bound is attained by all three.)

Solution to Exercise 6.4.52

Uses. Theorem 6.4.24 (Orthogonal decomposition), Theorem 6.2.1 (Cauchy–Schwarz inequality), Definition 6.4.34 (Distance to a subspace), Exercise 6.4.45
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. For $\mathbf{x} \in W^\perp$, $\langle \mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v} - \mathrm{Pr}_W(\mathbf{v}), \mathbf{x}\rangle$. Why?
Hint 2. Apply Cauchy–Schwarz, and find when equality holds.
Hint 3. For (b), W is the space of polynomial functions of degree at most 2; the distance from t^3 to it was found in Exercise 6.4.45.
Sketch. For a unit $\mathbf{x} \in W^\perp$, $\langle \mathrm{Pr}_W(\mathbf{v}), \mathbf{x}\rangle = 0$, so $|\langle \mathbf{v}, \mathbf{x}\rangle| = |\langle \mathbf{v} - \mathrm{Pr}_W(\mathbf{v}), \mathbf{x}\rangle| \leq \|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|$ by Cauchy–Schwarz. Equality holds for $\mathbf{x} = (\mathbf{v} - \mathrm{Pr}_W(\mathbf{v}))/\mathrm{dist}(\mathbf{v}, W)$, which is a unit vector in $W^\perp$. (b) The maximum is $\mathrm{dist}(t^3, W) = \sqrt{8/175}$, at $g = (t^3 - 3t/5)/\sqrt{8/175}$.

(a) Let $\mathbf{r} = \mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$, so $\mathbf{r} \in W^\perp$ and $\|\mathbf{r}\| = \mathrm{dist}(\mathbf{v}, W) > 0$ because $\mathbf{v} \notin W$. For a unit vector $\mathbf{x} \in W^\perp$, $\langle \mathrm{Pr}_W(\mathbf{v}), \mathbf{x}\rangle = 0$ since $\mathrm{Pr}_W(\mathbf{v}) \in W$, so by Theorem 6.2.1

$$|\langle \mathbf{v}, \mathbf{x}\rangle| = |\langle \mathbf{r}, \mathbf{x}\rangle| \leq \|\mathbf{r}\|\|\mathbf{x}\| = \mathrm{dist}(\mathbf{v}, W).$$

For $\mathbf{x} = \mathbf{r}/\|\mathbf{r}\|$, which is a unit vector in $W^\perp$, we get $\langle \mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{r}, \mathbf{r}\rangle/\|\mathbf{r}\| = \|\mathbf{r}\|$. So the maximum exists and equals $\mathrm{dist}(\mathbf{v}, W)$. By the equality case of Cauchy–Schwarz, the maximizers are the unit vectors $\mathbf{x} = \lambda\mathbf{r}/\|\mathbf{r}\|$ with $|\lambda| = 1$.

(b) Let W be the space of polynomial functions of degree at most 2. A function orthogonal to $1, t, t^2$ is orthogonal to W (Proposition 6.3.9(c)), so we are maximizing $\langle t^3, g\rangle$ over unit vectors $g \in W^\perp$. By (a) and Exercise 6.4.45, the maximum of $|\langle t^3, g\rangle|$ is $\mathrm{dist}(t^3, W) = \sqrt{8/175}$, attained at $g = \pm q/\|q\|$ with $q = t^3 - (3/5)t$. Taking the plus sign makes $\langle t^3, g\rangle$ positive, so the largest value of $\int_{-1}^{1} t^3 g$ is $\sqrt{8/175} \approx 0.214$.

So the distance from $\mathbf{v}$ to W can be computed in two dual ways: as a minimum over W, or as a maximum over unit vectors of $W^\perp$.

Solution to Exercise 6.4.53

Uses. Theorem 6.4.33 (Best approximation), Proposition 3.1.19 (Solution sets are translates of the kernel), Corollary 6.4.10 (Projecting with an orthogonal list)
Hint 1. $\|\mathbf{y} - (\mathbf{x}_0 + \mathbf{u})\| = \|(\mathbf{y} - \mathbf{x}_0) - \mathbf{u}\|$. So you are approximating $\mathbf{y} - \mathbf{x}_0$ by vectors of U.
Hint 2. For (b), the solution set is $\mathbf{x}_0 + \ker A$ (Proposition 3.1.19), and the closest point to $\mathbf{y} = \mathbf{0}$ is wanted.
Sketch. (a) By Theorem 6.4.33 applied to $\mathbf{y} - \mathbf{x}_0$, $\|(\mathbf{y} - \mathbf{x}_0) - \mathbf{u}\|$ is minimized exactly at $\mathbf{u} = \operatorname{Pr}_U(\mathbf{y} - \mathbf{x}_0)$. (b) With $\mathbf{x}_0 = (2, 0, 2)$ and $\ker A = \operatorname{span}((1, -1, 1))$, the answer is $\mathbf{x}_0 - \operatorname{Pr}_{\ker A}(\mathbf{x}_0) = (2, 0, 2) - (4/3)(1, -1, 1) = (2/3, 4/3, 2/3)$, which is orthogonal to $(1, -1, 1)$.

(a) For $\mathbf{u} \in U$, $\|\mathbf{y} - (\mathbf{x}_0 + \mathbf{u})\| = \|(\mathbf{y} - \mathbf{x}_0) - \mathbf{u}\|$. By Theorem 6.4.33, applied to the vector $\mathbf{y} - \mathbf{x}_0$ and the subspace U, this is smallest exactly when $\mathbf{u} = \operatorname{Pr}_U(\mathbf{y} - \mathbf{x}_0)$. So $\mathbf{x}_0 + \operatorname{Pr}_U(\mathbf{y} - \mathbf{x}_0)$ is the unique closest vector.

(b) Let $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}$. One solution is $\mathbf{x}_0 = (2, 0, 2)$, and $\ker A = \operatorname{span}((1, -1, 1))$: the equations say $x_1 = -x_2 = x_3$. By Proposition 3.1.19 the solution set is $\mathbf{x}_0 + \ker A$. The solution of smallest norm is the one closest to $\mathbf{y} = \mathbf{0}$, which by (a) is

$$\begin{aligned} \mathbf{x}_0 + \operatorname{Pr}_{\ker A}(-\mathbf{x}_0) &= \mathbf{x}_0 - \frac{\langle \mathbf{x}_0, (1, -1, 1) \rangle}{3}(1, -1, 1) \\ &= (2, 0, 2) - \frac{4}{3}(1, -1, 1) \\ &= \left(\frac{2}{3}, \frac{4}{3}, \frac{2}{3} \right), \end{aligned}$$

using Corollary 6.4.10. Check: $2/3 + 4/3 = 2$ and $4/3 + 2/3 = 2$; the norm is $\sqrt{24/9} = \sqrt{8/3}$; and $(2/3, 4/3, 2/3) \cdot (1, -1, 1) = 0$. In general the least-norm solution is $\mathbf{x}_0 - \operatorname{Pr}_{\ker A}(\mathbf{x}_0)$, the component of any solution in $(\ker A)^\perp$, which for real A is the span of the rows (Example 6.4.23(b), Theorem 6.4.26). It is the only solution in $(\ker A)^\perp$.

Solution to Exercise 6.4.54

Uses. Example 6.3.2 (Orthogonal vectors), Proposition 6.1.27 (Basic properties of the norm), Theorem 6.3.3 (Pythagorean theorem), Definition 6.4.22 (Orthogonal complement)
Hint 1. $O \subseteq E^\perp$ because the product of an even and an odd function is odd. For $E^\perp \subseteq O$, write $f \in E^\perp$ as $f_e + f_o$ and pair f with f_e.
Hint 2. For (b), $f - f_e = f_o$ is odd, hence orthogonal to E. Run the Pythagoras argument of Theorem 6.4.33 by hand.
Sketch. (a) Odd times even is odd, with integral 0, so $O \subseteq E^\perp$. If $f \in E^\perp$, then $0 = \langle f, f_e \rangle = \|f_e\|^2 + \langle f_o, f_e \rangle = \|f_e\|^2$, so $f = f_o \in O$. The same with E and O exchanged gives $O^\perp = E$. (b) For $g \in E$, $f - g = f_o + (f_e - g)$ with $f_o \perp f_e - g$, so $\|f - g\|^2 = \|f_o\|^2 + \|f_e - g\|^2 \geq \|f_o\|^2$, with equality only for $g = f_e$.

Every $f \in C[-1, 1]$ is $f = f_e + f_o$ with $f_e(t) = (f(t) + f(-t))/2$ even and $f_o(t) = (f(t) - f(-t))/2$ odd, both continuous.

(a) If g is even and h is odd, then gh is odd, so $\langle g, h \rangle = 0$ (Example 6.3.2(c)). This gives $O \subseteq E^\perp$ and $E \subseteq O^\perp$. Conversely, let $f \in E^\perp$. Since $f_e \in E$,

$$0 = \langle f, f_e \rangle = \langle f_e, f_e \rangle + \langle f_o, f_e \rangle = \|f_e\|^2,$$

so $f_e = \mathbf{0}$ (Proposition 6.1.27) and $f = f_o \in O$. Similarly, if $f \in O^\perp$, then $0 = \langle f, f_o \rangle = \|f_o\|^2$, so $f = f_e \in E$.

(b) Let $g \in E$. Then $f - g = f_o + (f_e - g)$, where $f_o \in O = E^\perp$ and $f_e - g \in E$. By Theorem 6.3.3,

$$\|f - g\|^2 = \|f_o\|^2 + \|f_e - g\|^2 \geq \|f_o\|^2 = \|f - f_e\|^2,$$

with equality if and only if $g = f_e$. So f_e is the unique even function closest to f. The proof of Theorem 6.4.33 only needed the decomposition $f = f_e + f_o$ into a part in E and a part orthogonal to E. For finite-dimen-

sional subspaces that decomposition always exists (Theorem 6.4.24); here it exists for a reason specific to E, and Exercise 6.4.63 shows that it need not exist in general.

Solution to Exercise 6.4.55

Uses. Proposition 6.3.18 (Coordinates in an orthonormal basis), Theorem 6.4.15 (Gram–Schmidt is correct), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. $\mathbf{u}'_j \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$, so expand it with Proposition 6.3.18(a). Which coefficients vanish?
Hint 2. For $i < j$, $\mathbf{u}_i \in \operatorname{span}(\mathbf{u}'_1, \ldots, \mathbf{u}'_{j-1})$, which is orthogonal to $\mathbf{u}'_j$.
Hint 3. For (b), compare an arbitrary such list with the Gram–Schmidt output using (a), and use $\langle \mathbf{v}_j, \lambda \mathbf{u}_j \rangle = \overline{\lambda} \langle \mathbf{v}_j, \mathbf{u}_j \rangle$.
Sketch. (a) $\mathbf{u}'_j = \sum_{i \le j} \langle \mathbf{u}'_j, \mathbf{u}_i \rangle \mathbf{u}_i$, and for $i < j$, $\mathbf{u}_i \in \operatorname{span}(\mathbf{u}'_1, \ldots, \mathbf{u}'_{j-1})$, which is orthogonal to $\mathbf{u}'_j$. So $\mathbf{u}'_j = \lambda_j \mathbf{u}_j$, and $|\lambda_j| = \|\mathbf{u}'_j\| = 1$. (b) By Theorem 6.4.15(d) the output satisfies the conditions. For another such list, (a) gives $\mathbf{u}'_j = \lambda_j \mathbf{u}_j$, and $\langle \mathbf{v}_j, \mathbf{u}'_j \rangle = \overline{\lambda_j} \langle \mathbf{v}_j, \mathbf{u}_j \rangle$ with both inner products positive, so $\overline{\lambda_j} > 0$ and $|\lambda_j| = 1$ force $\lambda_j = 1$.

(a) Fix j. Since $\mathbf{u}'_j \in \operatorname{span}(\mathbf{u}'_1, \ldots, \mathbf{u}'_j) = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$, Proposition 6.3.18(a) gives

$$\mathbf{u}'_j = \sum_{i=1}^{j} \langle \mathbf{u}'_j, \mathbf{u}_i \rangle \mathbf{u}_i.$$

For $i < j$, $\mathbf{u}_i \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_{j-1}) = \operatorname{span}(\mathbf{u}'_1, \ldots, \mathbf{u}'_{j-1})$, and $\mathbf{u}'_j$ is orthogonal to each of $\mathbf{u}'_1, \ldots, \mathbf{u}'_{j-1}$, hence to their span (Proposition 6.3.9(c)). So $\langle \mathbf{u}'_j, \mathbf{u}_i \rangle = 0$ for $i < j$, and $\mathbf{u}'_j = \lambda_j \mathbf{u}_j$ with $\lambda_j = \langle \mathbf{u}'_j, \mathbf{u}_j \rangle$. Then $1 = \|\mathbf{u}'_j\| = |\lambda_j| \|\mathbf{u}_j\| = |\lambda_j|$ by Proposition 6.1.27(b).

(b) By Theorem 6.4.15(d), the output $\mathbf{u}_1, \ldots, \mathbf{u}_m$ of Gram–Schmidt has both properties. Let $\mathbf{u}'_1, \ldots, \mathbf{u}'_m$ be another orthonormal list with both properties. The two lists have the same spans $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$, so by (a), $\mathbf{u}'_j = \lambda_j \mathbf{u}_j$ with $|\lambda_j| = 1$. By Proposition 6.1.4,

$$\langle \mathbf{v}_j, \mathbf{u}'_j \rangle = \overline{\lambda_j} \langle \mathbf{v}_j, \mathbf{u}_j \rangle.$$

Both inner products are positive reals, so $\overline{\lambda_j}$ is a positive real number of modulus 1, that is, $\lambda_j = 1$. Hence $\mathbf{u}'_j = \mathbf{u}_j$ for every j.

Solution to Exercise 6.4.56

Uses. Theorem 6.4.33 (Best approximation), Example 6.4.19 (Legendre polynomials), Exercise 6.3.49
Hint 1. The polynomials of degree n with leading coefficient 1 are exactly the $x^n - q$ with $q \in \mathbb{R}[x]_{\le n-1}$.
Hint 2. Minimizing $\|x^n - q\|$ over $q \in W$ is a best-approximation problem.
Sketch. Such polynomials are $x^n - q$ with $q \in W$, and $\|x^n - q\|$ is minimized exactly at $q = \operatorname{Pr}_W(x^n)$. By Theorem 6.4.15(d), W is the span of the first n Gram–Schmidt outputs, so $x^n - \operatorname{Pr}_W(x^n)$ is the next residual. For $n = 2, 3$ these are $x^2 - 1/3$ and $x^3 - (3/5)x$, with squared norms $8/45$ and $8/175$.

A polynomial of degree n with leading coefficient 1 is $x^n - q$ with $q \in W = \mathbb{R}[x]_{\le n-1}$, and every such difference is one. The space W is finite-dimensional, so by Theorem 6.4.33, $\|x^n - q\|$ is smallest for exactly one $q \in W$, namely $q = \operatorname{Pr}_W(x^n)$. When Gram–Schmidt is run on $1, x, x^2, \ldots$, the first n outputs span $\operatorname{span}(1, \ldots, x^{n-1}) = W$ (Theorem 6.4.15(d)), so the next residual is exactly $x^n - \operatorname{Pr}_W(x^n)$.

By Example 6.4.19, for $n = 2$ the minimizer is $x^2 - 1/3$, with $\|x^2 - 1/3\|^2 = 8/45$ (Example 6.3.17), and for $n = 3$ it is $x^3 - (3/5)x$, with squared norm $8/175$ (Exercise 6.3.49). So among all monic quadratics, $x^2 - 1/3$ is the smallest on $[-1, 1]$ in the mean-square sense.

Solution to Exercise 6.4.57

Uses. Proposition 6.4.29 (The orthogonal projection as a linear map), Proposition 6.4.4 (Properties of $\operatorname{Pr}_{\mathcal{O}}$), Theorem 6.4.6 (The projection is characterized by orthogonality), Proposition 6.1.29 (Expanding a norm)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7), Orthogonal decomposition (Technique 6.2.4), Proving TFAE (Technique 2.7.1)
Hint 1. (i) $\Rightarrow$ (iii) is Bessel. For (ii) $\Rightarrow$ (i), check the two conditions of Technique 6.4.7 for $P\mathbf{v}$; note $\mathbf{v} - P\mathbf{v} \in \ker P$.
Hint 2. For (iii) $\Rightarrow$ (ii), take $\mathbf{u} \in \operatorname{im} P$ and $\mathbf{w} \in \ker P$. Then $P\mathbf{u} = \mathbf{u}$, so $P(\mathbf{u} + \lambda \mathbf{w}) = \mathbf{u}$ for every scalar λ, and (iii) gives $\|\mathbf{u}\| \le \|\mathbf{u} + \lambda \mathbf{w}\|$.
Hint 3. Choose λ to make $\mathbf{u} + \lambda \mathbf{w}$ the part of $\mathbf{u}$ orthogonal to $\mathbf{w}$, as in Technique 6.2.4.

Sketch. (i) ⇒ (iii): Proposition 6.4.4(e). (iii) ⇒ (ii): for $\mathbf{u} \in \operatorname{im} P$, $\mathbf{w} \in \ker P$, $\mathbf{w} \neq \mathbf{0}$, and $\lambda = -\langle \mathbf{u}, \mathbf{w}\rangle / \|\mathbf{w}\|^2$, we get $\|\mathbf{u}\|^2 = \|P(\mathbf{u} + \lambda \mathbf{w})\|^2 \leq \|\mathbf{u} + \lambda \mathbf{w}\|^2 = \|\mathbf{u}\|^2 - |\langle \mathbf{u}, \mathbf{w}\rangle|^2 / \|\mathbf{w}\|^2$, so $\langle \mathbf{u}, \mathbf{w}\rangle = 0$. (ii) ⇒ (i): $P\mathbf{v} \in \operatorname{im} P$ and $\mathbf{v} - P\mathbf{v} \in \ker P \subseteq (\operatorname{im} P)^\perp$, so $P\mathbf{v} = \operatorname{Pr}_{\operatorname{im} P}(\mathbf{v})$.

We prove (i) ⇒ (iii) ⇒ (ii) ⇒ (i).

(i) ⇒ (iii). This is Proposition 6.4.4(e), applied to an orthonormal basis of $\operatorname{im} P$.

(iii) ⇒ (ii). Let $\mathbf{u} \in \operatorname{im} P$ and $\mathbf{w} \in \ker P$; we may assume $\mathbf{w} \neq \mathbf{0}$. Write $\mathbf{u} = P\mathbf{x}$; then $P\mathbf{u} = P^2\mathbf{x} = P\mathbf{x} = \mathbf{u}$. So for every scalar λ, $P(\mathbf{u} + \lambda \mathbf{w}) = \mathbf{u} + \lambda \mathbf{0} = \mathbf{u}$, and (iii) gives $\|\mathbf{u}\| \leq \|\mathbf{u} + \lambda \mathbf{w}\|$. Take $\lambda = -\langle \mathbf{u}, \mathbf{w}\rangle / \|\mathbf{w}\|^2$. By Proposition 6.1.29,

$$\begin{aligned} \|\mathbf{u} + \lambda \mathbf{w}\|^2 &= \|\mathbf{u}\|^2 + 2\operatorname{Re}\left(\overline{\lambda}\langle \mathbf{u}, \mathbf{w}\rangle\right) + |\lambda|^2 \|\mathbf{w}\|^2 \\ &= \|\mathbf{u}\|^2 - 2\frac{|\langle \mathbf{u}, \mathbf{w}\rangle|^2}{\|\mathbf{w}\|^2} + \frac{|\langle \mathbf{u}, \mathbf{w}\rangle|^2}{\|\mathbf{w}\|^2} \\ &= \|\mathbf{u}\|^2 - \frac{|\langle \mathbf{u}, \mathbf{w}\rangle|^2}{\|\mathbf{w}\|^2}. \end{aligned}$$

Combined with $\|\mathbf{u}\|^2 \leq \|\mathbf{u} + \lambda \mathbf{w}\|^2$, this gives $|\langle \mathbf{u}, \mathbf{w}\rangle|^2 \leq 0$, so $\langle \mathbf{u}, \mathbf{w}\rangle = 0$.

(ii) ⇒ (i). Let $W = \operatorname{im} P$, which is finite-dimensional. For $\mathbf{v} \in V$, $P\mathbf{v} \in W$, and $P(\mathbf{v} - P\mathbf{v}) = P\mathbf{v} - P^2\mathbf{v} = \mathbf{0}$, so $\mathbf{v} - P\mathbf{v} \in \ker P$. By (ii), $\mathbf{v} - P\mathbf{v} \in W^\perp$. By Theorem 6.4.6, $P\mathbf{v} = \operatorname{Pr}_W(\mathbf{v})$.

So an idempotent operator fails to be an orthogonal projection exactly when it stretches some vector, as the map in Exercise 6.4.48(e) does.

Solution to Exercise 6.4.58

Uses. Proposition 6.4.30 (Recognizing orthogonal projections), Proposition 6.4.29 (The orthogonal projection as a linear map), Proposition 6.1.37 (Inner products distinguish vectors)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. Both directions go through Proposition 6.4.30. Compute $\langle PQ\mathbf{v}, \mathbf{x}\rangle$ by moving P and then Q to the other slot.
Hint 2. You get $\langle PQ\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, QP\mathbf{x}\rangle$. Compare this with the symmetry condition for PQ.
Hint 3. For the image: $\operatorname{im} PQ \subseteq U$ always, and $PQ = QP$ puts it inside W too. Conversely, $PQ\mathbf{z} = \mathbf{z}$ for $\mathbf{z} \in U \cap W$.
Sketch. By Proposition 6.4.29(c), $\langle PQ\mathbf{v}, \mathbf{x}\rangle = \langle Q\mathbf{v}, P\mathbf{x}\rangle = \langle \mathbf{v}, QP\mathbf{x}\rangle$. If $PQ = QP$, then $(PQ)^2 = P^2Q^2 = PQ$ and $\langle PQ\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, PQ\mathbf{x}\rangle$, so PQ is an orthogonal projection onto $\operatorname{im} PQ = U \cap W$. Conversely, if PQ is an orthogonal projection, its symmetry gives $\langle \mathbf{v}, PQ\mathbf{x}\rangle = \langle \mathbf{v}, QP\mathbf{x}\rangle$ for all $\mathbf{v}$, so $PQ = QP$.

For all $\mathbf{v}, \mathbf{x} \in V$, Proposition 6.4.29(c), applied first to P and then to Q, gives

$$\langle PQ\mathbf{v}, \mathbf{x}\rangle = \langle Q\mathbf{v}, P\mathbf{x}\rangle = \langle \mathbf{v}, QP\mathbf{x}\rangle. \tag{C.1.8}$$

Suppose $PQ = QP$. Then $(PQ)^2 = PQPQ = PPQQ = P^2Q^2 = PQ$ by Proposition 6.4.29(b), and by (C.1.8), $\langle PQ\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, QP\mathbf{x}\rangle = \langle \mathbf{v}, PQ\mathbf{x}\rangle$. By Proposition 6.4.30, $PQ = \operatorname{Pr}_{\operatorname{im} PQ}$. Its image lies in $\operatorname{im} P = U$, and since $PQ = QP$ also in $\operatorname{im} Q = W$. Conversely, if $\mathbf{z} \in U \cap W$, then $PQ\mathbf{z} = P\mathbf{z} = \mathbf{z}$, so $\mathbf{z} \in \operatorname{im} PQ$. Hence $\operatorname{im} PQ = U \cap W$ and $PQ = \operatorname{Pr}_{U \cap W}$.

Conversely, suppose PQ is an orthogonal projection. By Proposition 6.4.30, $\langle PQ\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, PQ\mathbf{x}\rangle$ for all $\mathbf{v}, \mathbf{x}$, and comparing with (C.1.8) gives $\langle \mathbf{v}, PQ\mathbf{x} - QP\mathbf{x}\rangle = 0$ for all $\mathbf{v}$. Taking $\mathbf{v} = PQ\mathbf{x} - QP\mathbf{x}$ shows that this vector has norm 0, so $PQ\mathbf{x} = QP\mathbf{x}$ for every $\mathbf{x}$.

Exercise 6.4.48(c) gives two subspaces for which PQ is not an orthogonal projection. The commuting case includes $U \subseteq W$, where $PQ = QP = P$, and $U \perp W$, where $PQ = QP = 0$ (Exercise 6.4.49).

Solution to Exercise 6.4.59

Uses. Theorem 6.4.15 (Gram–Schmidt is correct), Theorem 6.3.22 (Parseval's identity), Proposition 5.3.15 (Triangular matrices), Theorem 5.4.10 (Multiplicativity), Exercise 6.3.57, Technique 6.4.5 (Projections shrink norms), Theorem 6.3.29

(Orthonormal columns), Theorem 5.4.7 (Invertibility and the determinant), Proposition 6.4.29 (The orthogonal projection as a linear map)
Techniques. Gram matrices (Technique 6.3.31)
Hint 1. For $i > j$, $\mathbf{v}_j \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$ is orthogonal to $\mathbf{u}_i$. For the product, $(R^*R)_{ij} = \sum_l \overline{r_{li}} r_{lj}$; recognize Parseval's identity in $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_m)$.
Hint 2. For (b), take determinants: $\det R^* = \overline{\det R}$. Gram–Schmidt on $\mathbf{v}_1, \ldots, \mathbf{v}_j$ produces the same first j residuals.
Hint 3. For (c), $\mathbf{f}_j = \mathbf{v}_j - \operatorname{Pr}(\mathbf{v}_j)$, and projections shrink norms.
Sketch. (a) $r_{ij} = 0$ for $i > j$ since $\mathbf{v}_j \perp \mathbf{u}_i$, and $r_{jj} = \|\mathbf{f}_j\|$ by Theorem 6.4.15(d). By Parseval in the span of the $\mathbf{u}$'s, $(R^*R)_{ij} = \sum_l \langle \mathbf{v}_j, \mathbf{u}_l \rangle \overline{\langle \mathbf{v}_i, \mathbf{u}_l \rangle} = \langle \mathbf{v}_j, \mathbf{v}_i \rangle = g_{ij}$. (b) $\det G = |\det R|^2 = \prod_j \|\mathbf{f}_j\|^2$; the ratio of consecutive Gram determinants is $\|\mathbf{f}_m\|^2$, the squared distance. (c) $\|\mathbf{f}_j\| \le \|\mathbf{v}_j\|$ with equality iff $\mathbf{v}_j \perp \mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$. For A with independent columns, $G = A^*A$ and $\det G = |\det A|^2$.

(a) Let $U = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_m) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_m)$. For $i > j$, $\mathbf{v}_j \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$ (Theorem 6.4.15(d)), which is orthogonal to $\mathbf{u}_i$, so $r_{ij} = 0$: R is upper triangular. Also $r_{jj} = \langle \mathbf{v}_j, \mathbf{u}_j \rangle = \|\mathbf{f}_j\|$ by Theorem 6.4.15(d). Note that $r_{li} = \langle \mathbf{v}_i, \mathbf{u}_l \rangle$ for all l and i. Since $\mathbf{u}_1, \ldots, \mathbf{u}_m$ is an orthonormal basis of the inner product space U, which contains every $\mathbf{v}_i$, Theorem 6.3.22(a) gives

$$(R^*R)_{ij} = \sum_{l=1}^{m} \overline{r_{li}} r_{lj} = \sum_{l=1}^{m} \langle \mathbf{v}_j, \mathbf{u}_l \rangle \overline{\langle \mathbf{v}_i, \mathbf{u}_l \rangle} = \langle \mathbf{v}_j, \mathbf{v}_i \rangle = g_{ij}.$$

(b) By Theorem 5.4.10 and Exercise 6.3.57(a), $\det G = \det(R^*) \det R = \overline{\det R} \det R = |\det R|^2$, and by Proposition 5.3.15, $\det R = r_{11} \cdots r_{mm} = \|\mathbf{f}_1\| \cdots \|\mathbf{f}_m\|$. So $\det G = \prod_j \|\mathbf{f}_j\|^2$. Gram–Schmidt processes the list in order, so running it on $\mathbf{v}_1, \ldots, \mathbf{v}_j$ produces the residuals $\mathbf{f}_1, \ldots, \mathbf{f}_j$, and $\det G_j = \prod_{i \le j} \|\mathbf{f}_i\|^2$. Hence $\det G_m / \det G_{m-1} = \|\mathbf{f}_m\|^2$. Finally $\mathbf{f}_m = \mathbf{v}_m - \operatorname{Pr}_X(\mathbf{v}_m)$ with $X = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_{m-1}) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{m-1})$, so $\|\mathbf{f}_m\| = \operatorname{dist}(\mathbf{v}_m, X)$ by Theorem 6.4.33.

(c) Write $X_j = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$, so $\mathbf{f}_j = \mathbf{v}_j - \operatorname{Pr}_{X_j}(\mathbf{v}_j)$. By Technique 6.4.5, $\|\mathbf{f}_j\| \le \|\mathbf{v}_j\|$, with equality if and only if $\operatorname{Pr}_{X_j}(\mathbf{v}_j) = \mathbf{0}$, that is (Proposition 6.4.29(a)), if and only if $\mathbf{v}_j \perp X_j$. Multiplying these inequalities between nonnegative numbers, $\det G \le \prod_j \|\mathbf{v}_j\|^2$, with equality if and only if $\mathbf{v}_j \perp \mathbf{v}_i$ for all $i < j$, that is, if and only if the list is orthogonal.

For $A \in \mathbb{F}^{n \times n}$: if its columns are dependent, then A is not invertible and $\det A = 0$ (Theorem 5.4.7), and there is nothing to prove. Otherwise, by Theorem 6.3.29, A^*A is the Gram matrix G of the columns, so $|\det A|^2 = \overline{\det A} \det A = \det(A^*A) = \det G \le \prod_j \|\mathbf{a}_j\|^2$. Geometrically: the volume of a box is at most the product of its side lengths, with equality only for a rectangular box.

Solution to Exercise 6.4.60

Uses. Proposition 6.4.29 (The orthogonal projection as a linear map), Proposition 6.1.27 (Basic properties of the norm)
Techniques. A sum of nonnegative terms (Technique 6.1.9), Projections shrink norms (Technique 6.4.5)
Hint 1. Write $P_i = \operatorname{Pr}_{W_i}$. For any $\mathbf{v}$, compute $\|\mathbf{v}\|^2 = \langle \mathbf{v}, \sum_i P_i \mathbf{v} \rangle$ and rewrite each term with Proposition 6.4.29(c).
Hint 2. You get $\|\mathbf{v}\|^2 = \sum_i \|P_i \mathbf{v}\|^2$. Now take $\mathbf{v} \in W_1$.
Sketch. With $P_i = \operatorname{Pr}_{W_i}$, $\|\mathbf{v}\|^2 = \sum_i \langle P_i \mathbf{v}, \mathbf{v} \rangle = \sum_i \|P_i \mathbf{v}\|^2$. For $\mathbf{v} \in W_i$, the ith term is $\|\mathbf{v}\|^2$, so $P_j \mathbf{v} = \mathbf{0}$ for $j \ne i$, that is, $\mathbf{v} \in \ker P_j = W_j^\perp$. Existence of the decomposition: $\mathbf{v} = \sum_i P_i \mathbf{v}$. Uniqueness: apply P_i to $\sum_j \mathbf{w}_j$, which kills $\mathbf{w}_j$ for $j \ne i$ and fixes $\mathbf{w}_i$.

Write $P_i = \operatorname{Pr}_{W_i}$. For every $\mathbf{v} \in V$, by the hypothesis and Proposition 6.4.29(c),

$$\begin{aligned} \|\mathbf{v}\|^2 &= \left\langle \sum_{i=1}^{m} P_i \mathbf{v}, \mathbf{v} \right\rangle = \sum_{i=1}^{m} \langle P_i \mathbf{v}, \mathbf{v} \rangle \\ &= \sum_{i=1}^{m} \langle P_i \mathbf{v}, P_i \mathbf{v} \rangle = \sum_{i=1}^{m} \|P_i \mathbf{v}\|^2. \end{aligned}$$

Now let $\mathbf{v} \in W_i$. Then $P_i \mathbf{v} = \mathbf{v}$, so the identity reads $\|\mathbf{v}\|^2 = \|\mathbf{v}\|^2 + \sum_{j \ne i} \|P_j \mathbf{v}\|^2$. A sum of nonnegative terms is 0 only if each term is, so $P_j \mathbf{v} = \mathbf{0}$ for every $j \ne i$, that is, $\mathbf{v} \in \ker P_j = W_j^\perp$ (Proposition 6.4.29(a)). So every vector of W_i is orthogonal to every vector of W_j.

For $\mathbf{v} \in V$, the hypothesis gives $\mathbf{v} = P_1\mathbf{v} + \cdots + P_m\mathbf{v}$ with $P_i\mathbf{v} \in W_i$. If also $\mathbf{v} = \mathbf{w}_1 + \cdots + \mathbf{w}_m$ with $\mathbf{w}_j \in W_j$, apply P_i: for $j \neq i$, $\mathbf{w}_j \in W_j \subseteq W_i^\perp = \ker P_i$, and $P_i\mathbf{w}_i = \mathbf{w}_i$. So $P_i\mathbf{v} = \mathbf{w}_i$, and the decomposition is unique.

For example, if $\mathbf{u}_1, \ldots, \mathbf{u}_n$ is an orthonormal basis of V, then $\mathrm{Pr}_{\mathrm{span}(\mathbf{u}_1)} + \cdots + \mathrm{Pr}_{\mathrm{span}(\mathbf{u}_n)} = \mathrm{id}_V$ by Proposition 6.3.18(b). The exercise says that every decomposition of id_V into orthogonal projections looks like a grouping of such a basis.

Solution to Exercise 6.4.61

Uses. Lemma 6.1.14 (Nonnegative functions with zero integral), Proposition 7.1.22 (Counting roots), the intermediate value theorem
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Let $t_1 < \cdots < t_r$ be the points of $(-1, 1)$ where p changes sign. Build a polynomial s of degree r such that ps does not change sign on $[-1, 1]$.
Hint 2. Take $s(t) = (t - t_1)\cdots(t - t_r)$. If $r < n$, then $\int_{-1}^{1} ps = 0$ by hypothesis. Why is that impossible?
Hint 3. A continuous function that is ≥ 0 on $[-1, 1]$ and has integral 0 vanishes on $[-1, 1]$ (Lemma 6.1.14).
Sketch. p has finitely many roots, so $(-1, 1)$ splits into finitely many open intervals on which p has constant sign. Let $t_1 < \cdots < t_r$ be the roots at which the sign changes, and $s = \prod_i (t - t_i)$. Then ps has constant sign on $[-1, 1]$ and is not identically zero there, so $\int ps \neq 0$. If $r < n$, $\deg s < n$ and the hypothesis gives $\int ps = 0$, a contradiction. So p has at least n distinct roots in $(-1, 1)$, and at most n roots in all.

The polynomial p is nonzero, so it has at most n roots (Proposition 7.1.22). Let $a_1 < \cdots < a_N$ be its roots in $(-1, 1)$, and put $a_0 = -1$, $a_{N+1} = 1$. On each open interval (a_k, a_{k+1}), p has no root, so by the intermediate value theorem it has constant sign there. Say that p *changes sign* at a_k $(1 \leq k \leq N)$ if its signs on (a_{k-1}, a_k) and (a_k, a_{k+1}) differ, and let $t_1 < \cdots < t_r$ be the roots at which p changes sign. Let

$$s(t) = (t - t_1)(t - t_2)\cdots(t - t_r)$$

($s = 1$ if $r = 0$). Each factor $t - t_i$ changes sign at t_i and nowhere else, so s has constant sign on each interval (a_k, a_{k+1}) and changes sign exactly at $t_1, \ldots, t_r$. Hence the product ps has constant sign on each (a_k, a_{k+1}), and at each a_k either both factors change sign or neither does, so ps has the same sign on all of these intervals. Replacing s by $-s$ if necessary, $ps \geq 0$ on $[-1, 1]$ by continuity.

Suppose $r < n$. Then $\deg s = r < n$, so $\int_{-1}^{1} p(t)s(t)\,\mathrm{d}t = 0$ by hypothesis. Since ps is continuous and nonnegative on $[-1, 1]$, Lemma 6.1.14 gives $ps = 0$ on $[-1, 1]$. But ps is a nonzero polynomial, with finitely many roots, a contradiction. So $r \geq n$: p has at least n distinct roots in $(-1, 1)$. Since it has at most n roots, these are all of its roots.

The argument used only that p is continuous, has finitely many zeros in $[-1, 1]$, and is orthogonal to all polynomials of degree less than n. So it applies to the error $e^t - p(t)$ of Example 6.4.37 with $n = 3$: that error has at most three zeros (see the remark after Example 6.4.37), and therefore changes sign at least three times in $(-1, 1)$.

Solution to Exercise 6.4.62

Uses. Corollary 6.4.25 (Dimension of the orthogonal complement), Corollary 6.4.10 (Projecting with an orthogonal list), Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$)
Techniques. Induction on the length of a list (Technique 1.6.9), Orthogonal decomposition (Technique 6.2.4)
Hint 1. Induct on the dimension, proving the statement for every n-dimensional subspace of some $\mathbb{R}^N$. Project the first $m - 1$ vectors onto the hyperplane $\mathbf{v}_m^\perp$.
Hint 2. Let $\mathbf{w}_i = \mathbf{v}_i - c_i\mathbf{v}_m$ with $c_i = \langle \mathbf{v}_i, \mathbf{v}_m \rangle / \|\mathbf{v}_m\|^2 < 0$. Compute $\langle \mathbf{w}_i, \mathbf{w}_j \rangle$ for $i \neq j$.
Hint 3. $\langle \mathbf{w}_i, \mathbf{w}_j \rangle = \langle \mathbf{v}_i, \mathbf{v}_j \rangle - c_i c_j \|\mathbf{v}_m\|^2 < 0$, since $c_i c_j > 0$. For the example, try $\mathbf{e}_i - t(1, \ldots, 1)$ and $-(1, \ldots, 1)$.
Sketch. Prove, by induction on n, that pairwise negative inner products allow at most $n + 1$ vectors in any n-dimensional subspace V of $\mathbb{R}^N$. For $n = 0$ only $\mathbf{0}$ exists and $\langle \mathbf{0}, \mathbf{0} \rangle = 0$, so $m \leq 1$. For $n \geq 1$ and $m \geq 2$, all $\mathbf{v}_i \neq \mathbf{0}$; project $\mathbf{v}_1, \ldots, \mathbf{v}_{m-1}$ onto $U = \mathbf{v}_m^\perp \cap V$, of dimension $n - 1$. The projections $\mathbf{w}_i = \mathbf{v}_i - c_i\mathbf{v}_m$ have $\langle \mathbf{w}_i, \mathbf{w}_j \rangle = \langle \mathbf{v}_i, \mathbf{v}_j \rangle - c_i c_j \|\mathbf{v}_m\|^2 < 0$, so $m - 1 \leq n$. Example: $\mathbf{e}_i - (1/2n)\mathbf{j}$ for $i \leq n$, and $-\mathbf{j}$, with $\mathbf{j} = (1, \ldots, 1)$.

We prove, by induction on $n \geq 0$, the following statement: if V is an n-dimensional subspace of $\mathbb{R}^N$ (for some N) and $\mathbf{v}_1, \ldots, \mathbf{v}_m \in V$ satisfy $\langle \mathbf{v}_i, \mathbf{v}_j \rangle < 0$ for all $i \neq j$, then $m \leq n + 1$. The case $V = \mathbb{R}^n$ is the claim.

If $n = 0$, then $V = \{\mathbf{0}\}$ and $\langle \mathbf{0}, \mathbf{0} \rangle = 0$, so there is no pair $i \neq j$, and $m \leq 1$.

Let $n \geq 1$, and assume the statement for $(n-1)$-dimensional subspaces. If $m \leq 2$ there is nothing to prove, so let $m \geq 3$. Every $\mathbf{v}_i$ is nonzero, since $\langle \mathbf{v}_i, \mathbf{v}_j \rangle \neq 0$ for some $j \neq i$. Let $U = \{\mathbf{x} \in V \mid \langle \mathbf{x}, \mathbf{v}_m \rangle = 0\}$, the orthogonal complement of $\operatorname{span}(\mathbf{v}_m)$ inside the inner product space V, so $\dim U = n - 1$ by Corollary 6.4.25. For $i < m$ let

$$c_i = \frac{\langle \mathbf{v}_i, \mathbf{v}_m \rangle}{\|\mathbf{v}_m\|^2} < 0, \quad \mathbf{w}_i = \mathbf{v}_i - c_i \mathbf{v}_m.$$

By Corollary 6.4.10 and Proposition 6.4.4(b), $\mathbf{w}_i = \mathbf{v}_i - \operatorname{Pr}_{\operatorname{span}(\mathbf{v}_m)}(\mathbf{v}_i) \in U$. For $i \neq j$, both less than m,

$$\begin{aligned} \langle \mathbf{w}_i, \mathbf{w}_j \rangle &= \langle \mathbf{v}_i, \mathbf{v}_j \rangle - c_j \langle \mathbf{v}_i, \mathbf{v}_m \rangle - c_i \langle \mathbf{v}_m, \mathbf{v}_j \rangle + c_i c_j \|\mathbf{v}_m\|^2 \\ &= \langle \mathbf{v}_i, \mathbf{v}_j \rangle - c_i c_j \|\mathbf{v}_m\|^2 - c_i c_j \|\mathbf{v}_m\|^2 + c_i c_j \|\mathbf{v}_m\|^2 \\ &= \langle \mathbf{v}_i, \mathbf{v}_j \rangle - c_i c_j \|\mathbf{v}_m\|^2 < 0, \end{aligned}$$

because $\langle \mathbf{v}_i, \mathbf{v}_j \rangle < 0$ and $c_i c_j > 0$. So $\mathbf{w}_1, \ldots, \mathbf{w}_{m-1}$ are vectors in the $(n-1)$-dimensional space U with pairwise negative inner products, and the induction hypothesis gives $m - 1 \leq n$, that is, $m \leq n + 1$.

For an example with $m = n + 1$, let $\mathbf{j} = (1, \ldots, 1) \in \mathbb{R}^n$, $\mathbf{v}_i = \mathbf{e}_i - (1/2n)\mathbf{j}$ for $i = 1, \ldots, n$, and $\mathbf{v}_{n+1} = -\mathbf{j}$. For $i \neq k \leq n$,

$$\langle \mathbf{v}_i, \mathbf{v}_k \rangle = 0 - \frac{1}{2n} - \frac{1}{2n} + \frac{n}{4n^2} = -\frac{3}{4n} < 0,$$

$$\langle \mathbf{v}_i, \mathbf{v}_{n+1} \rangle = -1 + \frac{n}{2n} = -\frac{1}{2} < 0.$$

The proof is an induction on dimension in which projecting onto a hyperplane preserves the hypothesis. The triangularization theorems of Section 7.5 are proved by the same pattern (Technique 7.5.12).

Solution to Exercise 6.4.63

Uses. Definition 1.2.13 (Polynomials), Definition 1.2.17 (Evaluation), Proposition 1.2.18 (Degree and evaluation versus the operations), Proposition 6.3.9 (Properties of $A^{\perp}$), Theorem 6.4.24 (Orthogonal decomposition)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. The sum defining $\langle p, q \rangle$ is finite. W is the set of polynomials killed by evaluation at 1, and $1 \notin W$.
Hint 2. For $q \in W^{\perp}$, test against $x^k - x^{k+1} \in W$. What does $\langle q, x^k - x^{k+1} \rangle = 0$ say about the coefficients of q?
Hint 3. For (c), try $w_n = 1 - (1 + x + \cdots + x^n)/(n+1)$.
Sketch. (a) W is closed under the operations since evaluation respects them, and $1 \notin W$. If $q \perp W$, then $0 = \langle q, x^k - x^{k+1} \rangle = q_k - q_{k+1}$ for all k, so all coefficients of q are equal, and since almost all are 0, $q = 0$. (b) $W + W^{\perp} = W$ and $(W^{\perp})^{\perp} = V$. (c) $w_n \in W$ and $\|1 - w_n\|^2 = 1/(n+1) \to 0$, but $\|1 - w\| > 0$ for every $w \in W$ since $1 \notin W$.

(a) For each p only finitely many p_k are nonzero, so the sum is finite. It is symmetric and linear in each slot, and $\langle p, p \rangle = \sum_k p_k^2 > 0$ for $p \neq 0$, so it is an inner product (it is the dot product of coefficient sequences). By Proposition 1.2.18, $(ap + bq)(1) = ap(1) + bq(1)$, so W is a subspace, and $1 \notin W$, so $W \neq \mathbb{R}[x]$.

Let $q \in W^{\perp}$. For each $k \geq 0$, the polynomial $x^k - x^{k+1}$ vanishes at 1, so it lies in W, and

$$0 = \langle q, x^k - x^{k+1} \rangle = q_k - q_{k+1}.$$

So $q_0 = q_1 = q_2 = \cdots$. Since $q_k = 0$ for all large k, every coefficient is 0, and $q = 0$. Hence $W^{\perp} = \{\mathbf{0}\}$.

(b) $W + W^{\perp} = W \neq \mathbb{R}[x]$, so $\mathbb{R}[x]$ is not $W \oplus W^{\perp}$. And $(W^{\perp})^{\perp} = \{\mathbf{0}\}^{\perp} = \mathbb{R}[x] \neq W$ (Proposition 6.3.9(d)). Both conclusions of Theorem 6.4.24 and Theorem 6.4.26 fail. The hypothesis that breaks is finite-dimensionality: W contains the independent list $1 - x, x - x^2, x^2 - x^3, \ldots$, of every length, so it has no (finite) orthonormal basis, and Pr_W cannot be defined.

(c) Let $w_n = 1 - (1 + x + \cdots + x^n)/(n+1)$. Then $w_n(1) = 1 - 1 = 0$, so $w_n \in W$, and

$$\|1 - w_n\|^2 = \left\| \frac{1 + x + \cdots + x^n}{n+1} \right\|^2 = \frac{n+1}{(n+1)^2} = \frac{1}{n+1}.$$

So $\inf_{w \in W} \|1 - w\| = 0$. But $1 \notin W$, so $\|1 - w\| > 0$ for every $w \in W$. If some $w \in W$ were closest to 1, then $\|1 - w\| \le \|1 - w_n\| = (n+1)^{-1/2}$ for every n, forcing $\|1 - w\| = 0$, which is impossible. In the spaces of Section 15.3, which are *complete*, closest points do exist for closed subspaces, and this kind of example disappears.

Solution to Exercise 6.4.64

Uses. Theorem 6.4.38 (QR factorization), Theorem 6.4.31 (The matrix of an orthogonal projection), Algorithm 6.4.14 (Gram–Schmidt)
Hint 1. Gram–Schmidt on the columns: $\|\mathbf{a}_1\| = 3$, and $\langle \mathbf{a}_2, \mathbf{u}_1 \rangle$ is an integer.
Hint 2. $\mathbf{u}_1 = (1,2,2)/3$ and $\mathbf{u}_2 = (2,1,-2)/3$. For (b), $\mathrm{Pr}_{\mathrm{im}\,A} = QQ^{\mathsf{T}}$.
Sketch. $\mathbf{u}_1 = (1,2,2)/3$, $r_{11} = 3$; $r_{12} = \langle \mathbf{a}_2, \mathbf{u}_1 \rangle = 3$, $\mathbf{f}_2 = (3,3,0) - (1,2,2) = (2,1,-2)$, $r_{22} = 3$. So $R = \left(\begin{smallmatrix} 3 & 3 \\ 0 & 3 \end{smallmatrix}\right)$. Then $\mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{e}_1) = (1/9)(1,2,2) + (2/9)(2,1,-2) = (5,4,-2)/9$, and $A^{\mathsf{T}}A = \left(\begin{smallmatrix} 9 & 9 \\ 9 & 18 \end{smallmatrix}\right) = R^{\mathsf{T}}R$.

(a) Let $\mathbf{a}_1 = (1,2,2)$ and $\mathbf{a}_2 = (3,3,0)$. Then $\|\mathbf{a}_1\| = 3$, so $\mathbf{u}_1 = (1,2,2)/3$ and $r_{11} = 3$. Next $r_{12} = \langle \mathbf{a}_2, \mathbf{u}_1 \rangle = (3+6+0)/3 = 3$, and $\mathbf{f}_2 = \mathbf{a}_2 - 3\mathbf{u}_1 = (2,1,-2)$, with $r_{22} = \|\mathbf{f}_2\| = 3$ and $\mathbf{u}_2 = (2,1,-2)/3$. By Theorem 6.4.38,

$$A = QR, \quad Q = \frac{1}{3}\begin{pmatrix} 1 & 2 \\ 2 & 1 \\ 2 & -2 \end{pmatrix}, \quad R = \begin{pmatrix} 3 & 3 \\ 0 & 3 \end{pmatrix}.$$

(b) The columns of Q are an orthonormal basis of $\mathrm{im}\,A$, so by Theorem 6.4.31,

$$\begin{aligned} \mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{e}_1) &= \langle \mathbf{e}_1, \mathbf{u}_1 \rangle \mathbf{u}_1 + \langle \mathbf{e}_1, \mathbf{u}_2 \rangle \mathbf{u}_2 \\ &= \frac{1}{9}(1,2,2) + \frac{2}{9}(2,1,-2) = \frac{1}{9}(5,4,-2). \end{aligned}$$

(c) $A^{\mathsf{T}}A = \left(\begin{smallmatrix} 1+4+4 & 3+6+0 \\ 3+6+0 & 9+9+0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 9 & 9 \\ 9 & 18 \end{smallmatrix}\right)$ and $R^{\mathsf{T}}R = \left(\begin{smallmatrix} 3 & 0 \\ 3 & 3 \end{smallmatrix}\right)\left(\begin{smallmatrix} 3 & 3 \\ 0 & 3 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 9 & 9 \\ 9 & 18 \end{smallmatrix}\right)$. In general $A^*A = R^*Q^*QR = R^*R$, which is Exercise 6.4.59(a) for the columns of A.

Section 6.5

Solution to Exercise 6.5.8

Uses. Theorem 6.5.5 (The normal equations), Definition 6.1.8 (Dot product), Definition 6.3.26 (Conjugate transpose)
Hint 1. Here $A^*A = \mathbf{a}^*\mathbf{a} = \|\mathbf{a}\|^2$ and $A^*\mathbf{b} = \mathbf{a}^*\mathbf{b} = \langle \mathbf{b}, \mathbf{a} \rangle$, with the entries of $\mathbf{a}$ conjugated.
Hint 2. You should get $\hat{z} = (1-i)/3$. For (b), $\mathbf{a}^{\mathsf{T}}\mathbf{a} = 1 + i^2 + 1 = 1$.
Sketch. (a) $\mathbf{a}^*\mathbf{a} = 3$ and $\mathbf{a}^*\mathbf{b} = 1 - i$, so $\hat{z} = (1-i)/3$, and the residual $((2+i)/3, (2-i)/3, (-1+i)/3)$ has inner product 0 with $\mathbf{a}$. (b) $\mathbf{a}^{\mathsf{T}}\mathbf{a} = 1$ and $\mathbf{a}^{\mathsf{T}}\mathbf{b} = 1 + i$, so $z = 1 + i$, whose residual $(-i, 2-i, -1-i)$ has inner product $-2 - 4i \neq 0$ with $\mathbf{a}$; by Theorem 6.5.5 it is not a least-squares solution.

(a) With one column, the normal equations read $(\mathbf{a}^*\mathbf{a})z = \mathbf{a}^*\mathbf{b}$. Here $\mathbf{a}^* = (1, -i, 1)$, so

$$\mathbf{a}^*\mathbf{a} = 1 + (-i)(i) + 1 = 3, \quad \mathbf{a}^*\mathbf{b} = 1 + (-i) \cdot 1 + 0 = 1 - i,$$

and $\hat{z} = (1-i)/3$ by Theorem 6.5.5. The residual is

$$\begin{aligned} \mathbf{b} - \hat{z}\mathbf{a} &= \left(1 - \frac{1-i}{3}, 1 - \frac{i+1}{3}, -\frac{1-i}{3}\right) \\ &= \left(\frac{2+i}{3}, \frac{2-i}{3}, \frac{-1+i}{3}\right), \end{aligned}$$

using $i(1-i) = i + 1$. Its inner product with $\mathbf{a}$ is

$$\frac{1}{3}\big((2+i)\cdot 1+(2-i)\cdot \bar{i}+(-1+i)\cdot 1\big)$$
$$=\frac{1}{3}((2+i)+(-1-2i)+(-1+i))=0.$$

(b) $\mathbf{a}^{\mathsf{T}}\mathbf{a}=1+i^2+1=1$ and $\mathbf{a}^{\mathsf{T}}\mathbf{b}=1+i$, so the student gets $z=1+i$. Its residual is $\mathbf{b}-(1+i)\mathbf{a}=(1-(1+i),1-(i-1),-(1+i))=(-i,2-i,-1-i)$, and its inner product with $\mathbf{a}$ is $-i+(2-i)(-i)+(-1-i)=-i-2i-1-1-i=-2-4i\neq 0$. By Theorem 6.5.5, $1+i$ is not a least-squares solution. Over $\mathbb{C}$ the transpose does not compute inner products; the conjugate transpose does.

Solution to Exercise 6.5.15

Uses. Proposition 6.5.13 (Projection onto a column space), Corollary 6.5.11 (The least-squares solution for independent columns), Proposition 6.5.2 (Least squares is projection)
Hint 1. With one column, $A^{\mathsf{T}}A=\mathbf{a}^{\mathsf{T}}\mathbf{a}=9$.
Hint 2. $P=\mathbf{a}\mathbf{a}^{\mathsf{T}}/9$, and $\hat{x}=\mathbf{a}^{\mathsf{T}}\mathbf{b}/9$.
Sketch. $P=(1/9)\begin{pmatrix}1&2&2\\2&4&4\\2&4&4\end{pmatrix}$, $\hat{x}=9/9=1$, $P\mathbf{b}=(1,2,2)$, and the residual $(2,-2,1)$ has length 3.

Here $A=\mathbf{a}$ is a single nonzero column, so $A^{\mathsf{T}}A=\mathbf{a}\cdot\mathbf{a}=9$ and, by Proposition 6.5.13,

$$P=\frac{1}{9}\mathbf{a}\mathbf{a}^{\mathsf{T}}=\frac{1}{9}\begin{pmatrix}1&2&2\\2&4&4\\2&4&4\end{pmatrix}.$$

By Corollary 6.5.11, $\hat{x}=\left(\mathbf{a}^{\mathsf{T}}\mathbf{a}\right)^{-1}\mathbf{a}^{\mathsf{T}}\mathbf{b}=(3+0+6)/9=1$, and indeed $P\mathbf{b}=\hat{x}\mathbf{a}=(1,2,2)$. The residual is $\mathbf{b}-\mathbf{a}=(2,-2,1)$, which is orthogonal to $\mathbf{a}$, and the least-squares error is $\|(2,-2,1)\|=3$.

Solution to Exercise 6.5.20

Uses. Corollary 6.5.11 (The least-squares solution for independent columns), Definition 6.5.1 (Least-squares solution)
Hint 1. The design matrix has the single column $\mathbf{x}$. What are $\mathbf{x}^{\mathsf{T}}\mathbf{x}$ and $\mathbf{x}^{\mathsf{T}}\mathbf{y}$?
Hint 2. For (b), $\sum_i I_i^2=7.5$.
Sketch. (a) $A=\mathbf{x}$ has an independent column since $\mathbf{x}\neq\mathbf{0}$, so $\hat{c}=\left(\mathbf{x}^{\mathsf{T}}\mathbf{x}\right)^{-1}\mathbf{x}^{\mathsf{T}}\mathbf{y}=(\sum x_iy_i)/\left(\sum x_i^2\right)$. (b) $\sum I_iV_i=0.5+2.1+4.35+8.2=15.15$ and $\sum I_i^2=7.5$, so $R\approx 2.02$ ohms.

(a) The sum $\sum_i (y_i-cx_i)^2$ is $\|\mathbf{y}-c\mathbf{x}\|^2$, so we want the least-squares solution of $Ac=\mathbf{y}$ for the $m\times 1$ matrix A with column $\mathbf{x}$. Since $\mathbf{x}\neq\mathbf{0}$, this column is independent, and by Corollary 6.5.11

$$\hat{c}=\left(\mathbf{x}^{\mathsf{T}}\mathbf{x}\right)^{-1}\mathbf{x}^{\mathsf{T}}\mathbf{y}=\frac{\sum_i x_iy_i}{\sum_i x_i^2}.$$

(b) Here $\sum_i I_iV_i=0.5\cdot 1.0+1.0\cdot 2.1+1.5\cdot 2.9+2.0\cdot 4.1=0.5+2.1+4.35+8.2=15.15$ and $\sum_i I_i^2=0.25+1+2.25+4=7.5$. So $R\approx 15.15/7.5=2.02$ ohms. The model has no intercept, because a resistor carries no voltage at zero current; fitting $V=c_0+c_1I$ instead would let the data choose a nonzero intercept that the physics rules out.

Solution to Exercise 6.5.30

Uses. Theorem 6.5.5 (The normal equations), Proposition 6.5.9 ($\operatorname{rank}(A^*A)=\operatorname{rank}A$)
Hint 1. Form $A^{\mathsf{T}}A$ and $A^{\mathsf{T}}\mathbf{b}$ for $A=\begin{pmatrix}1&1\\1&-1\\2&1\end{pmatrix}$ and $\mathbf{b}=(2,0,5)$.
Hint 2. $A^{\mathsf{T}}A=\begin{pmatrix}6&2\\2&3\end{pmatrix}$ and $A^{\mathsf{T}}\mathbf{b}=(12,7)$.
Sketch. The normal equations $6x_1+2x_2=12$, $2x_1+3x_2=7$ give $\hat{\mathbf{x}}=(11/7,9/7)$. The residual is $(-6,-2,4)/7$, orthogonal to $(1,1,2)$ and $(1,-1,1)$, and the error is $\sqrt{56}/7=\sqrt{8/7}$.

Let $A=\begin{pmatrix}1&1\\1&-1\\2&1\end{pmatrix}$ and $\mathbf{b}=(2,0,5)$. Then

$$A^{\mathsf{T}}A = \begin{pmatrix} 1+1+4 & 1-1+2 \\ 1-1+2 & 1+1+1 \end{pmatrix} = \begin{pmatrix} 6 & 2 \\ 2 & 3 \end{pmatrix},$$
$$A^{\mathsf{T}}\mathbf{b} = \begin{pmatrix} 2+0+10 \\ 2-0+5 \end{pmatrix} = \begin{pmatrix} 12 \\ 7 \end{pmatrix}.$$

The columns of A are independent, so by Theorem 6.5.5 and Proposition 6.5.9 the unique least-squares solution solves $6x_1 + 2x_2 = 12$, $2x_1 + 3x_2 = 7$. Subtracting 3 times the second equation from the first gives $-7x_2 = -9$, so $\hat{x}_2 = 9/7$ and $\hat{x}_1 = (7 - 27/7)/2 = 11/7$. Then $A\hat{\mathbf{x}} = (20/7, 2/7, 31/7)$, and the residual is

$$\mathbf{b} - A\hat{\mathbf{x}} = \frac{1}{7}(14 - 20, 0 - 2, 35 - 31) = \frac{1}{7}(-6, -2, 4).$$

Its dot products with the columns are $(-6 - 2 + 8)/7 = 0$ and $(-6 + 2 + 4)/7 = 0$. The least-squares error is $\|\mathbf{b} - A\hat{\mathbf{x}}\| = \sqrt{36 + 4 + 16}/7 = \sqrt{56}/7 = \sqrt{8/7}$.

Solution to Exercise 6.5.31

Uses. Theorem 6.5.5 (The normal equations), Definition 6.3.26 (Conjugate transpose), Theorem 6.3.29 (Orthonormal columns)
Hint 1. The entries of A^*A are $\mathbf{a}_i^*\mathbf{a}_j$; remember to conjugate the entries of $\mathbf{a}_i$.
Hint 2. $A^*A = \left(\begin{smallmatrix} 3 & 1 \\ 1 & 3 \end{smallmatrix}\right)$ and $A^*\mathbf{b} = (3, 1 - 2i)$.
Sketch. The normal equations $3x_1 + x_2 = 3$, $x_1 + 3x_2 = 1 - 2i$ give $\hat{\mathbf{x}} = (1 + i/4, -3i/4)$. The residual is $((1 - i)/4, (-1 - i)/4, i/2)$, orthogonal to both columns, with squared norm $1/2$.

With $\mathbf{a}_1 = (1, 1, 1)$ and $\mathbf{a}_2 = (i, -i, 1)$,

$$\mathbf{a}_1^*\mathbf{a}_1 = 3, \quad \mathbf{a}_1^*\mathbf{a}_2 = i - i + 1 = 1,$$
$$\mathbf{a}_2^*\mathbf{a}_2 = 1 + 1 + 1 = 3,$$

and $\mathbf{a}_2^*\mathbf{a}_1 = \overline{\mathbf{a}_1^*\mathbf{a}_2} = 1$. So $A^*A = \left(\begin{smallmatrix} 3 & 1 \\ 1 & 3 \end{smallmatrix}\right)$ (Theorem 6.3.29). Also $A^*\mathbf{b} = \left(2 + 0 + 1, \bar{i} \cdot 2 + \overline{-i} \cdot 0 + 1\right) = (3, 1 - 2i)$. The normal equations are

$$3x_1 + x_2 = 3, \quad x_1 + 3x_2 = 1 - 2i.$$

Subtracting 3 times the second from the first gives $-8x_2 = 6i$, so $\hat{x}_2 = -3i/4$, and then $\hat{x}_1 = 1 - 3\hat{x}_2 + (-2i) = 1 + 9i/4 - 2i = 1 + i/4$. By Theorem 6.5.5 this is the least-squares solution, and it is unique since A^*A is invertible. Now

$$A\hat{\mathbf{x}} = (\hat{x}_1 + i\hat{x}_2, \hat{x}_1 - i\hat{x}_2, \hat{x}_1 + \hat{x}_2)$$
$$= \left(\frac{7}{4} + \frac{i}{4}, \frac{1}{4} + \frac{i}{4}, 1 - \frac{i}{2}\right),$$

so the residual is $\mathbf{b} - A\hat{\mathbf{x}} = ((1 - i)/4, (-1 - i)/4, i/2)$. Its inner product with $\mathbf{a}_1$ is $(1 - i - 1 - i)/4 + i/2 = 0$, and with $\mathbf{a}_2$ it is $((1 - i)/4)\bar{i} + ((-1 - i)/4)\overline{-i} + i/2 = (-i - 1)/4 + (-i + 1)/4 + i/2 = 0$. The squared error is $2/16 + 2/16 + 1/4 = 1/2$.

Solution to Exercise 6.5.32

Uses. Proposition 6.5.17 (The least-squares line)
Hint 1. Center the data: $m_x = 3$ and $m_y = 16.6$.
Hint 2. $\tilde{\mathbf{x}} = (-2, -1, 0, 1, 2)$ and $\tilde{\mathbf{y}} = (4.4, 2.4, -0.6, -1.6, -4.6)$.
Sketch. $\tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}} = -22$ and $\|\tilde{\mathbf{x}}\|^2 = 10$, so $c_1 = -2.2$ and $c_0 = 16.6 + 6.6 = 23.2$. Residuals $0, 0.2, -0.6, 0.6, -0.2$. Prediction at 6: 10.0. At 11: -1.0, a negative price.

Here $m_x = 3$ and $m_y = 83/5 = 16.6$, so $\tilde{\mathbf{x}} = (-2, -1, 0, 1, 2)$ and $\tilde{\mathbf{y}} = (4.4, 2.4, -0.6, -1.6, -4.6)$. Then

$$\tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}} = -8.8 - 2.4 + 0 - 1.6 - 9.2 = -22, \quad \|\tilde{\mathbf{x}}\|^2 = 10,$$

so by Proposition 6.5.17 $c_1 = -2.2$ and $c_0 = 16.6 + 2.2 \cdot 3 = 23.2$. The line is $y = 23.2 - 2.2x$: the car loses about 2.2 thousand dollars a year. Its values at $x = 1, \dots, 5$ are $21.0, 18.8, 16.6, 14.4, 12.2$, so the residuals are $0, 0.2, -0.6, 0.6, -0.2$, which add up to 0. At age 6 it predicts $23.2 - 13.2 = 10.0$. At age 11 it predicts $23.2 - 24.2 = -1.0$, a negative price. The fit describes the data on the range where it was measured; nothing in least squares says that the linear model stays valid outside that range, and here it clearly does not.

Solution to Exercise 6.5.33

Uses. Proposition 6.5.17 (The least-squares line), Proposition 6.5.21 (Polynomial fits), Theorem 6.5.5 (The normal equations), Proposition 6.5.2 (Least squares is projection), Theorem 6.4.33 (Best approximation)

Hint 1. For (b), $A^{\mathsf{T}}A$ has entries $\sum_i x_i^{j+k}$; here $A^{\mathsf{T}}A = \begin{pmatrix} 4 & 2 & 6 \\ 2 & 6 & 8 \\ 6 & 8 & 18 \end{pmatrix}$ and $A^{\mathsf{T}}\mathbf{y} = (8, 7, 19)$.

Hint 2. For (c), compare the column spaces of the two design matrices.

Sketch. (a) $y = 1.7 + 0.6x$ with residuals $0.9, -0.7, -1.3, 1.1$ and squared error 4.2. (b) $y = 0.7 - 0.4x + x^2$ with residuals $-0.1, 0.3, -0.3, 0.1$ and squared error 0.2. (c) $\operatorname{span}(\mathbf{1}, \mathbf{x}) \subseteq \operatorname{span}(\mathbf{1}, \mathbf{x}, \mathbf{x}^2)$, and the distance from $\mathbf{y}$ to a larger subspace is no larger; equivalently, every line is a parabola with $c_2 = 0$.

(a) For the line, $A^{\mathsf{T}}A = \begin{pmatrix} 4 & 2 \\ 2 & 6 \end{pmatrix}$ and $A^{\mathsf{T}}\mathbf{y} = (2 + 1 + 1 + 4, -2 + 0 + 1 + 8) = (8, 7)$. The normal equations $4c_0 + 2c_1 = 8$, $2c_0 + 6c_1 = 7$ give $c_1 = 3/5$ and $c_0 = 17/10$, so the line is $y = 1.7 + 0.6x$. Its values at $-1, 0, 1, 2$ are $1.1, 1.7, 2.3, 2.9$, the residuals are $0.9, -0.7, -1.3, 1.1$, and the squared error is $0.81 + 0.49 + 1.69 + 1.21 = 4.2$.

(b) For the parabola, row i of A is $\left(1, x_i, x_i^2\right)$, and with $\sum x_i = 2$, $\sum x_i^2 = 6$, $\sum x_i^3 = 8$, $\sum x_i^4 = 18$, $\sum y_i = 8$, $\sum x_i y_i = 7$, $\sum x_i^2 y_i = 19$, the normal equations are

$$\begin{aligned} 4c_0 + 2c_1 + 6c_2 &= 8, \\ 2c_0 + 6c_1 + 8c_2 &= 7, \\ 6c_0 + 8c_1 + 18c_2 &= 19. \end{aligned}$$

Row reduction gives $(c_0, c_1, c_2) = (7/10, -2/5, 1)$; check: $2.8 - 0.8 + 6 = 8$, $1.4 - 2.4 + 8 = 7$, $4.2 - 3.2 + 18 = 19$. The four x_i are distinct, so this is the unique least-squares parabola (Proposition 6.5.21). Its values are $2.1, 0.7, 1.3, 3.9$, the residuals are $-0.1, 0.3, -0.3, 0.1$, and the squared error is 0.2.

(c) Let A_1 and A_2 be the two design matrices. The columns $\mathbf{1}, \mathbf{x}$ of A_1 are also columns of A_2, so $\operatorname{im} A_1 \subseteq \operatorname{im} A_2$. By Proposition 6.5.2(d) the two errors are $\operatorname{dist}(\mathbf{y}, \operatorname{im} A_1)$ and $\operatorname{dist}(\mathbf{y}, \operatorname{im} A_2)$, and the distance from $\mathbf{y}$ to a larger set is no larger, since Theorem 6.4.33 minimizes over all its points. Concretely, the least-squares line is the parabola with $c_2 = 0$, so the best parabola does at least as well. (Exercise 6.5.39 says exactly when the error drops.)

Solution to Exercise 6.5.34

Uses. Theorem 6.5.5 (The normal equations), Lemma 6.5.4 (The orthogonal complement of a column space)

Hint 1. By Theorem 6.5.5, $(1, 1)$ is a least-squares solution exactly when $\mathbf{b} - A(1, 1) \in (\operatorname{im} A)^{\perp}$.

Hint 2. $A(1, 1) = (1, 2, 3)$, and $(\operatorname{im} A)^{\perp} = \ker A^{\mathsf{T}}$ (Lemma 6.5.4).

Sketch. $(\operatorname{im} A)^{\perp} = \ker A^{\mathsf{T}} = \operatorname{span}((1, -2, 1))$, so the answer is the line $\mathbf{b} = (1, 2, 3) + t(1, -2, 1)$, $t \in \mathbb{R}$, through $A(1, 1)$ perpendicular to the plane $\operatorname{im} A$. The data sets are $(0, 1 + t), (1, 2 - 2t), (2, 3 + t)$.

By Theorem 6.5.5, $(1, 1)$ is a least-squares solution of $A\mathbf{x} = \mathbf{b}$ if and only if $\mathbf{b} - A(1, 1) \in (\operatorname{im} A)^{\perp}$. Here $A(1, 1) = (1, 2, 3)$, and by Lemma 6.5.4, $(\operatorname{im} A)^{\perp} = \ker A^{\mathsf{T}}$, the solutions of $z_1 + z_2 + z_3 = 0$ and $z_2 + 2z_3 = 0$. These give $z_2 = -2z_3$ and $z_1 = z_3$, so $(\operatorname{im} A)^{\perp} = \operatorname{span}((1, -2, 1))$. Hence the answer is

$$\left\{\mathbf{b} \in \mathbb{R}^3 \;\middle|\; \mathbf{b} = (1, 2, 3) + t(1, -2, 1) \text{ for some } t \in \mathbb{R}\right\},$$

the line through the point $A(1, 1)$ of the plane $\operatorname{im} A$ perpendicular to that plane. The columns of A are independent, so for each such $\mathbf{b}$ the vector $(1, 1)$ is the only least-squares solution, and the least-squares error is $|t|\sqrt{6}$, which is 0 only for $\mathbf{b} = (1, 2, 3)$. In terms of data, the least-squares line of $(0, y_1), (1, y_2), (2, y_3)$ is $y = 1 + x$ exactly when $(y_1, y_2, y_3) = (1 + t, 2 - 2t, 3 + t)$ for some t: the points are pushed off the line alternately up, down, up, in the pattern $(1, -2, 1)$.

Solution to Exercise 6.5.35

Uses. Theorem 6.5.5 (The normal equations), Definition 6.3.33 (Unitary and orthogonal matrices), Proposition 6.3.27 (Properties of the conjugate transpose), Corollary 6.5.11 (The least-squares solution for independent columns)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), (b), and (d), compare normal equations.
Hint 2. For (c), multiplying one equation by 2 makes its squared error count four times as much. Try a single column $A = (1, 1)$.
Sketch. (a) True: the normal equations are linear in $\mathbf{b}$. (b) True: $(UA)^*(UA) = A^*A$ and $(UA)^*U\mathbf{b} = A^*\mathbf{b}$. (c) False: $A = (1, 1)$, $\mathbf{b} = (0, 2)$, $G = \operatorname{diag}(1, 2)$ give $\hat{x} = 1$ and $\hat{x} = 8/5$. (d) True: $\mathbf{y} \mapsto AS\mathbf{y}$ has the same values as $\mathbf{x} \mapsto A\mathbf{x}$, reached at $\mathbf{x} = S\mathbf{y}$.

(a) True. By Theorem 6.5.5, $A^*A\hat{\mathbf{x}} = A^*\mathbf{b}$ and $A^*A\hat{\mathbf{x}}' = A^*\mathbf{b}'$. Adding, $A^*A(\hat{\mathbf{x}} + \hat{\mathbf{x}}') = A^*(\mathbf{b} + \mathbf{b}')$, so $\hat{\mathbf{x}} + \hat{\mathbf{x}}'$ is a least-squares solution of $A\mathbf{x} = \mathbf{b} + \mathbf{b}'$.

(b) True. Since $U^*U = I_m$ (Definition 6.3.33) and $(UA)^* = A^*U^*$ (Proposition 6.3.27(b)),

$$(UA)^*(UA) = A^*U^*UA = A^*A,$$
$$(UA)^*(U\mathbf{b}) = A^*U^*U\mathbf{b} = A^*\mathbf{b}.$$

So the two problems have the same normal equations, and by Theorem 6.5.5 the same least-squares solutions. (Geometrically, U preserves lengths, so $\|U\mathbf{b} - UA\mathbf{x}\| = \|\mathbf{b} - A\mathbf{x}\|$.)

(c) False. Let $A = \begin{pmatrix}1\\1\end{pmatrix}$, $\mathbf{b} = (0, 2)$, and $G = \operatorname{diag}(1, 2)$. By Corollary 6.5.11, the least-squares solution of $Ax = \mathbf{b}$ is $\left(A^{\mathsf{T}}\mathbf{b}\right)/\left(A^{\mathsf{T}}A\right) = 2/2 = 1$. But $GA = \begin{pmatrix}1\\2\end{pmatrix}$ and $G\mathbf{b} = (0, 4)$, and the least-squares solution of $GAx = G\mathbf{b}$ is $8/5$. Multiplying an equation by 2 multiplies its squared error by 4, which changes the balance between the equations; this is weighted least squares (Aside (Weighted least squares)).

(d) True. As $\mathbf{y}$ runs over $\mathbb{F}^n$, so does $\mathbf{x} = S\mathbf{y}$, since S is invertible, and $(AS)\mathbf{y} = A(S\mathbf{y})$. So $\|\mathbf{b} - AS\mathbf{y}\|$ takes the same values as $\|\mathbf{b} - A\mathbf{x}\|$, and $\mathbf{y}$ minimizes the first if and only if $S\mathbf{y}$ minimizes the second. With $\mathbf{y} = S^{-1}\hat{\mathbf{x}}$, this is the claim.

Solution to Exercise 6.5.36

Uses. Proposition 2.5.17 (Algebra of inverses), Proposition 6.5.13 (Projection onto a column space), Corollary 3.5.25 (The invertible matrix theorem)
Hint 1. The rule $(BC)^{-1} = C^{-1}B^{-1}$ requires B and C to be invertible. Are A and A^*?
Hint 2. Try $A = (1, 2, 2)$, a single column. When is $\operatorname{im} A = \mathbb{F}^m$?
Sketch. $(A^*A)^{-1} = A^{-1}(A^*)^{-1}$ needs A invertible, hence square; for $m > n$, A has no inverse. For $A = (1, 2, 2)$, the projection matrix is $\mathbf{a}\mathbf{a}^{\mathsf{T}}/9 \neq I_3$. The conclusion holds exactly when $m = n$, that is, when A is invertible, and then the computation is valid.

The step $(A^*A)^{-1} = A^{-1}(A^*)^{-1}$ applies Proposition 2.5.17 to the factors A^* and A, which requires both to be invertible. An invertible matrix is square, so for $m > n$ the matrix A^{-1} does not exist, even though A^*A is invertible. For instance, for the single column $\mathbf{a} = (1, 2, 2)$ the projection matrix is $\mathbf{a}\mathbf{a}^{\mathsf{T}}/9$ (Exercise 6.5.15), which has rank 1 and is not I_3. In general $\operatorname{Pr}_{\operatorname{im} A}$ has rank $\dim \operatorname{im} A = n$, so $\operatorname{Pr}_{\operatorname{im} A} = I_m$ forces $n = m$.

Conversely, if $m = n$, then A is a square matrix with independent columns, hence invertible (Corollary 3.5.25), and so is A^*. Then the student's computation is valid, $\operatorname{Pr}_{\operatorname{im} A} = I_m$, and indeed $\operatorname{im} A = \mathbb{F}^m$.

Solution to Exercise 6.5.37

Uses. Theorem 6.5.5 (The normal equations), Exercise 6.5.20
Hint 1. By Theorem 6.5.5(ii), the residual is orthogonal to every vector of $\operatorname{im} A$.
Hint 2. For (b), two points suffice, for example $(1, 1)$ and $(2, 1)$.
Sketch. (a) The residual $\mathbf{r}$ is orthogonal to $\mathbf{1} \in \operatorname{im} A$, and $\mathbf{r} \cdot \mathbf{1} = \sum_i r_i$. (b) For $(1, 1), (2, 1)$, $c = 3/5$ and the residuals $2/5, -1/5$ add up to $1/5$.

(a) Let $\mathbf{r} = \mathbf{b} - A\hat{\mathbf{x}}$. By Theorem 6.5.5, $\mathbf{r} \perp \operatorname{im} A$, and $\mathbf{1} \in \operatorname{im} A$, so $0 = \mathbf{r} \cdot \mathbf{1} = \sum_i r_i$. Hence $\sum_i (A\hat{\mathbf{x}})_i = \sum_i b_i$, and dividing by m, the two vectors have the same mean. For a polynomial fit, $\mathbf{1}$ is the first column of the design matrix.

(b) For the data $(1,1),(2,1)$, Exercise 6.5.20 gives $c=(1+2)/(1+4)=3/5$. The residuals are $1-3/5=2/5$ and $1-6/5=-1/5$, which add up to $1/5\neq 0$. Here $\operatorname{im} A=\operatorname{span}((1,2))$ does not contain $\mathbf{1}$.

Solution to Exercise 6.5.38

Uses. Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.5.9 ($\operatorname{rank}(A^*A)=\operatorname{rank} A$)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. For (a), cancel $(A^*A)(A^*A)^{-1}$ in the middle of P^2. For P^*, note that A^*A is Hermitian.
Hint 2. For (b), $\operatorname{im} P\subseteq\operatorname{im} A$ because $P=A(\cdots)$; and $A=PA$ gives the reverse.
Hint 3. For (c), move the factor A from the front to the back with Proposition 2.4.28.
Sketch. (a) $P^2=A(A^*A)^{-1}(A^*A)(A^*A)^{-1}A^*=P$, and $P^*=A\big((A^*A)^{-1}\big)^*A^*=P$ since $(A^*A)^*=A^*A$. (b) $PA=A$; $\operatorname{im} P\subseteq\operatorname{im} A=\operatorname{im}(PA)\subseteq\operatorname{im} P$. (c) $\operatorname{tr}\big(A(A^*A)^{-1}A^*\big)=\operatorname{tr}\big((A^*A)^{-1}A^*A\big)=\operatorname{tr} I_n=n$. (d) $P=(1/10)\begin{pmatrix}7&4&1&-2\\4&3&2&1\\1&2&3&4\\-2&1&4&7\end{pmatrix}$.

The matrix A^*A is invertible by Proposition 6.5.9(c), and Hermitian, since $(A^*A)^*=A^*A^{**}=A^*A$ by Proposition 6.3.27(a) and (b).

(a) $P^2=A(A^*A)^{-1}(A^*A)(A^*A)^{-1}A^*=A(A^*A)^{-1}A^*=P$. By Proposition 6.3.27, $P^*=(A^*)^*\big((A^*A)^{-1}\big)^*A^*=A\big((A^*A)^*\big)^{-1}A^*=A(A^*A)^{-1}A^*=P$.

(b) $PA=A(A^*A)^{-1}(A^*A)=A$. Every $P\mathbf{y}=A\big((A^*A)^{-1}A^*\mathbf{y}\big)$ lies in $\operatorname{im} A$, and every $A\mathbf{x}=P(A\mathbf{x})$ lies in $\operatorname{im} P$. So $\operatorname{im} P=\operatorname{im} A$.

(c) By Proposition 2.4.28, $\operatorname{tr} P=\operatorname{tr}\big(A\cdot(A^*A)^{-1}A^*\big)=\operatorname{tr}\big((A^*A)^{-1}A^*\cdot A\big)=\operatorname{tr} I_n=n$.

(d) Here $A^{\mathsf T}A=\begin{pmatrix}4&10\\10&30\end{pmatrix}$, with determinant 20, so $\big(A^{\mathsf T}A\big)^{-1}=(1/20)\begin{pmatrix}30&-10\\-10&4\end{pmatrix}$. Row i of A is $(1,x_i)$, so

$$p_{ij}=\frac{1}{20}\big(30-10(x_i+x_j)+4x_ix_j\big),$$

so

$$P=\frac{1}{10}\begin{pmatrix}7&4&1&-2\\4&3&2&1\\1&2&3&4\\-2&1&4&7\end{pmatrix}.$$

Each row adds up to $10/10=1$, so $P\mathbf{1}=\mathbf{1}$; the rows times $(1,2,3,4)$ give $10,20,30,40$, divided by 10, so $P\mathbf{x}=\mathbf{x}$; and $\operatorname{tr} P=(7+3+3+7)/10=2$. The diagonal entries p_{ii} are largest at the ends: a data point far from m_x pulls harder on the fitted line.

Solution to Exercise 6.5.39

Uses. Theorem 6.5.5 (The normal equations), Proposition 6.5.2 (Least squares is projection), Proposition 6.1.29 (Expanding a norm), Lemma 6.5.4 (The orthogonal complement of a column space)
Techniques. Perturb a minimizer (Technique 6.5.6)
Hint 1. If $\hat{\mathbf{x}}$ is a least-squares solution for A, try $\mathbf{x}'=(\hat{\mathbf{x}},t)$ for a scalar t. What is its residual?
Hint 2. Its residual is $\mathbf{r}-t\mathbf{a}$. Expand $\|\mathbf{r}-t\mathbf{a}\|^2$ and choose $t=\langle\mathbf{r},\mathbf{a}\rangle/\|\mathbf{a}\|^2$.
Hint 3. If $\langle\mathbf{r},\mathbf{a}\rangle=0$, check that $(\hat{\mathbf{x}},0)$ satisfies condition (ii) of Theorem 6.5.5 for A'.
Sketch. For $\mathbf{x}'=(\hat{\mathbf{x}},t)$, the residual is $\mathbf{r}-t\mathbf{a}$, so $E'^2\le\|\mathbf{r}-t\mathbf{a}\|^2$ for every t; $t=0$ gives $E'\le E$. If $\langle\mathbf{r},\mathbf{a}\rangle\neq0$, then $t=\langle\mathbf{r},\mathbf{a}\rangle/\|\mathbf{a}\|^2$ gives $E'^2\le E^2-|\langle\mathbf{r},\mathbf{a}\rangle|^2/\|\mathbf{a}\|^2<E^2$. If $\langle\mathbf{r},\mathbf{a}\rangle=0$, then $\mathbf{r}$ is orthogonal to every column of A', so $(\hat{\mathbf{x}},0)$ is a least-squares solution for A' with residual $\mathbf{r}$, and $E'=E$.

Let $\hat{\mathbf{x}}$ be a least-squares solution of $A\mathbf{x}=\mathbf{b}$, so $\mathbf{r}=\mathbf{b}-A\hat{\mathbf{x}}$ and $E=\|\mathbf{r}\|$. (By Proposition 6.5.2(a), $\mathbf{r}=\mathbf{b}-\operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$ does not depend on the choice of $\hat{\mathbf{x}}$.) For $t\in\mathbb{F}$, the vector $\mathbf{x}'=(\hat{\mathbf{x}},t)$ has $A'\mathbf{x}'=A\hat{\mathbf{x}}+t\mathbf{a}$, so its residual is $\mathbf{r}-t\mathbf{a}$, and

$$E'^2\le\|\mathbf{r}-t\mathbf{a}\|^2\quad\text{for every } t\in\mathbb{F}.$$

Taking $t=0$ gives $E'\le E$.

Suppose $\langle \mathbf{r}, \mathbf{a}\rangle \neq 0$. Then $\mathbf{a} \neq \mathbf{0}$; let $t = \langle \mathbf{r}, \mathbf{a}\rangle / \|\mathbf{a}\|^2$. By Proposition 6.1.29,

$$\begin{aligned}\|\mathbf{r} - t\mathbf{a}\|^2 &= \|\mathbf{r}\|^2 - 2\,\mathrm{Re}(\bar{t}\langle \mathbf{r}, \mathbf{a}\rangle) + |t|^2\|\mathbf{a}\|^2 \\ &= \|\mathbf{r}\|^2 - 2\frac{|\langle \mathbf{r}, \mathbf{a}\rangle|^2}{\|\mathbf{a}\|^2} + \frac{|\langle \mathbf{r}, \mathbf{a}\rangle|^2}{\|\mathbf{a}\|^2} = E^2 - \frac{|\langle \mathbf{r}, \mathbf{a}\rangle|^2}{\|\mathbf{a}\|^2},\end{aligned}$$

which is less than E^2. So $E' < E$.

Suppose $\langle \mathbf{r}, \mathbf{a}\rangle = 0$. By Theorem 6.5.5(ii), $\mathbf{r}$ is orthogonal to the columns of A, and now also to $\mathbf{a}$, so to every column of A'. The vector $(\hat{\mathbf{x}}, 0)$ has residual $\mathbf{b} - A\hat{\mathbf{x}} = \mathbf{r}$ for A', so by Theorem 6.5.5 it is a least-squares solution of $A'\mathbf{x}' = \mathbf{b}$, and $E' = \|\mathbf{r}\| = E$.

In words: adding a column to the design matrix never makes the fit worse, and it makes it strictly better exactly when the new column is correlated with what the old model leaves unexplained. This is also why the error alone cannot decide between models: a model with more columns always wins.

Solution to Exercise 6.5.40

Uses. Proposition 6.5.17 (The least-squares line), Proposition 6.1.29 (Expanding a norm), Example 6.2.19 (Correlation is a cosine)
Hint 1. Write $\mathbf{y} = m_y\mathbf{1} + \tilde{\mathbf{y}}$ and $A\mathbf{c} = c_0\mathbf{1} + c_1\mathbf{x}$, and use $c_0 = m_y - c_1 m_x$.
Hint 2. Expand $\|\tilde{\mathbf{y}} - c_1\tilde{\mathbf{x}}\|^2$ and substitute $c_1 = (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})/\|\tilde{\mathbf{x}}\|^2$.
Sketch. (a) $\mathbf{y} - A\mathbf{c} = m_y\mathbf{1} + \tilde{\mathbf{y}} - \big(m_y - c_1 m_x\big)\mathbf{1} - c_1\mathbf{x} = \tilde{\mathbf{y}} - c_1\tilde{\mathbf{x}}$. (b) $\|\tilde{\mathbf{y}} - c_1\tilde{\mathbf{x}}\|^2 = \|\tilde{\mathbf{y}}\|^2 - (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})^2/\|\tilde{\mathbf{x}}\|^2 = \|\tilde{\mathbf{y}}\|^2\big(1 - r^2\big)$. (c) $\|\tilde{\mathbf{y}}\|^2 = 9.5$ and the squared error is 0.091, so $r^2 = 1 - 0.091/9.5 \approx 0.990$.

(a) By Proposition 6.5.17, $c_0 = m_y - c_1 m_x$, so

$$\begin{aligned}\mathbf{y} - A\mathbf{c} &= \big(m_y\mathbf{1} + \tilde{\mathbf{y}}\big) - \big(m_y - c_1 m_x\big)\mathbf{1} - c_1\mathbf{x} \\ &= \tilde{\mathbf{y}} - c_1(\mathbf{x} - m_x\mathbf{1}) = \tilde{\mathbf{y}} - c_1\tilde{\mathbf{x}}.\end{aligned}$$

(b) By Proposition 6.1.29 (all vectors are real) and $c_1 = (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})/\|\tilde{\mathbf{x}}\|^2$,

$$\begin{aligned}\|\tilde{\mathbf{y}} - c_1\tilde{\mathbf{x}}\|^2 &= \|\tilde{\mathbf{y}}\|^2 - 2c_1(\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}) + c_1^2\|\tilde{\mathbf{x}}\|^2 \\ &= \|\tilde{\mathbf{y}}\|^2 - \frac{(\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})^2}{\|\tilde{\mathbf{x}}\|^2} = \|\tilde{\mathbf{y}}\|^2\left(1 - \frac{(\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})^2}{\|\tilde{\mathbf{x}}\|^2\|\tilde{\mathbf{y}}\|^2}\right),\end{aligned}$$

and the last fraction is r^2. Since the left side is nonnegative, this reproves $r^2 \le 1$, with equality exactly when every residual is 0, that is, when the data lie on a line.

(c) For the spring data, $\|\tilde{\mathbf{y}}\|^2 = 1.9^2 + 1.1^2 + 0.2^2 + 0.8^2 + 2.0^2 = 9.5$, and the squared error is 0.091 (Example 6.5.18). So $1 - r^2 = 0.091/9.5$, and $r^2 \approx 0.990$: the line accounts for 99% of the variation in the lengths.

Solution to Exercise 6.5.41

Uses. Proposition 6.5.17 (The least-squares line), Example 6.2.19 (Correlation is a cosine), Theorem 6.2.1 (Cauchy–Schwarz inequality)
Hint 1. By Proposition 6.5.17 with the roles exchanged, $d_1 = (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})/\|\tilde{\mathbf{y}}\|^2$.
Hint 2. If $r \neq 0$, the second line is $y = m_y + (1/d_1)(x - m_x)$. When is $1/d_1 = c_1$?
Sketch. (a) $c_1 d_1 = (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})^2/\big(\|\tilde{\mathbf{x}}\|^2\|\tilde{\mathbf{y}}\|^2\big) = r^2$. (b) Both lines pass through the means. If $r = 0$, they are $y = m_y$ and $x = m_x$. Otherwise they agree iff $c_1 = 1/d_1$, iff $r^2 = 1$, iff the points are collinear (Example 6.2.19). (c) $c_1 = d_1 = 4/5$: $y = 3/10 + (4/5)x$ and $y = -3/8 + (5/4)x$.

(a) By Proposition 6.5.17, $c_1 = (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})/\|\tilde{\mathbf{x}}\|^2$, and, with the roles of x and y exchanged, $d_1 = (\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})/\|\tilde{\mathbf{y}}\|^2$. So

$$c_1 d_1 = \frac{(\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})^2}{\|\tilde{\mathbf{x}}\|^2\|\tilde{\mathbf{y}}\|^2} = r^2.$$

(b) By Proposition 6.5.17, $m_y = c_0 + c_1 m_x$ and $m_x = d_0 + d_1 m_y$, so both lines pass through $\left(m_x, m_y\right)$. If $r = 0$, then $c_1 = d_1 = 0$, and the lines are $y = m_y$ and $x = m_x$, which are different. If $r \neq 0$, then $d_1 \neq 0$ and the second line is $y = m_y + (1/d_1)(x - m_x)$. Two lines through the same point coincide exactly when their slopes agree, that is, when $c_1 = 1/d_1$, which by (a) means $r^2 = 1$. By Example 6.2.19, $r = \pm 1$ exactly when all data points lie on one line.

(c) Here $m_x = m_y = 3/2$, $\tilde{\mathbf{x}} = (-3, -1, 1, 3)/2$, and $\tilde{\mathbf{y}} = (-3, 1, -1, 3)/2$. So $\tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}} = (9 - 1 - 1 + 9)/4 = 4$ and $\|\tilde{\mathbf{x}}\|^2 = \|\tilde{\mathbf{y}}\|^2 = 5$. Hence $c_1 = d_1 = 4/5$ and $r^2 = 16/25$. The line of y on x is $y = 3/2 + (4/5)(x - 3/2) = 3/10 + (4/5)x$, and the line of x on y is $y = 3/2 + (5/4)(x - 3/2) = -3/8 + (5/4)x$.

Since $r^2 \leq 1$, (a) gives $|c_1 d_1| \leq 1$. So when $r \neq 0$, $|c_1| \leq 1/|d_1|$, and when $r = 0$ the line of x on y is vertical: either way, the line of y on x is never steeper than the line of x on y. Predictions of y from x are pulled toward the mean m_y, which is where the word "regression" comes from.

Solution to Exercise 6.5.42

Uses. Proposition 6.5.2 (Least squares is projection), Proposition 6.4.29 (The orthogonal projection as a linear map), Proposition 2.6.18 (The column space is spanned by the columns)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. Let A and A' be the design matrices for the old and new data. Compare $\operatorname{im} A$ and $\operatorname{im} A'$.
Hint 2. $\operatorname{im} A = \operatorname{im} A'$. The fitted values of the new data are $\Pr_{\operatorname{im} A}(\gamma \mathbf{y} + \delta \mathbf{1})$; use linearity of the projection and $\Pr_{\operatorname{im} A}(\mathbf{1}) = \mathbf{1}$.
Sketch. $\mathbf{x}' = \alpha \mathbf{x} + \beta \mathbf{1}$ and $\mathbf{x} = (\mathbf{x}' - \beta \mathbf{1})/\alpha$, so $\operatorname{im} A' = \operatorname{span}(\mathbf{1}, \mathbf{x}') = \operatorname{span}(\mathbf{1}, \mathbf{x}) = \operatorname{im} A$. By linearity, $\Pr(\mathbf{y}') = \gamma \Pr(\mathbf{y}) + \delta \mathbf{1} = \gamma(c_0 \mathbf{1} + c_1 \mathbf{x}) + \delta \mathbf{1}$; substituting $\mathbf{x} = (\mathbf{x}' - \beta \mathbf{1})/\alpha$ writes this as $A' \mathbf{c}'$ with the coefficients of the claimed line.

Let A and A' have columns $\mathbf{1}, \mathbf{x}$ and $\mathbf{1}, \mathbf{x}'$. Since $\mathbf{x}' = \alpha \mathbf{x} + \beta \mathbf{1}$ and $\mathbf{x} = (\mathbf{x}' - \beta \mathbf{1})/\alpha$, each pair of columns lies in the span of the other, so $W = \operatorname{im} A = \operatorname{im} A'$ (Proposition 2.6.18). The x_i' are not all equal, so the new least-squares line is unique, and by Proposition 6.5.2(a) its fitted values are $\Pr_W(\mathbf{y}')$. By linearity of $\Pr_W$ (Proposition 6.4.29(a)), $\Pr_W(\mathbf{1}) = \mathbf{1}$, and $\Pr_W(\mathbf{y}) = c_0 \mathbf{1} + c_1 \mathbf{x}$,

$$\begin{aligned} \Pr_W(\mathbf{y}') &= \gamma \Pr_W(\mathbf{y}) + \delta \Pr_W(\mathbf{1}) = \gamma(c_0 \mathbf{1} + c_1 \mathbf{x}) + \delta \mathbf{1} \\ &= \left(\gamma c_0 + \delta - \frac{\gamma c_1 \beta}{\alpha}\right) \mathbf{1} + \frac{\gamma c_1}{\alpha} \mathbf{x}'. \end{aligned}$$

So the new line is $y' = c_0' + c_1' x'$ with $c_1' = \gamma c_1/\alpha$ and $c_0' = \gamma c_0 + \delta - \gamma c_1 \beta/\alpha$, which is $y' = \gamma(c_0 + c_1(x' - \beta)/\alpha) + \delta$, as claimed. Measuring in other units, or from another origin, therefore gives the same fitted line. That fails for a nonlinear change such as $x' = x^2$, which changes the column space.

Solution to Exercise 6.5.43

Uses. Proposition 6.5.23 (Normal equations for a spanning list), Theorem 6.4.33 (Best approximation), Proposition 6.4.4 (Properties of $\Pr_{\mathcal{O}}$)
Techniques. Gram matrices (Technique 6.3.31)
Hint 1. The Gram matrix of $1, t, t^2$ has entries $\langle t^j, t^i \rangle = 1/(i + j + 1)$, and $\langle \sqrt{t}, t^i \rangle = 1/(i + 3/2) = 2/(2i + 3)$.
Hint 2. Clear denominators: the equations become $6c_0 + 3c_1 + 2c_2 = 4$, $6c_0 + 4c_1 + 3c_2 = 24/5$, $20c_0 + 15c_1 + 12c_2 = 120/7$. For the error, $\|f - p\|^2 = \|f\|^2 - \langle p, f \rangle$ because $f - p \perp p$.
Sketch. $G = \begin{pmatrix} 1 & 1/2 & 1/3 \\ 1/2 & 1/3 & 1/4 \\ 1/3 & 1/4 & 1/5 \end{pmatrix}$, $\mathbf{d} = (2/3, 2/5, 2/7)$, solution $p = 6/35 + (48/35)t - (4/7)t^2$. Then $\|f - p\|^2 = 1/2 - 612/1225 = 1/2450$. The best line is $4/15 + (4/5)t$, with squared error $1/450$.

Let W be the polynomials of degree at most 2. By Proposition 6.5.23 with the list $1, t, t^2$, the coefficients of $p = \Pr_W(f) = c_0 + c_1 t + c_2 t^2$ solve $G\mathbf{c} = \mathbf{d}$, where $g_{ij} = \int_0^1 t^{i+j} \, \mathrm{d}t = 1/(i + j + 1)$ (indices from 0) and $d_i = \int_0^1 t^{i+1/2} \, \mathrm{d}t = 2/(2i + 3)$:

$$\begin{aligned} c_0 + \frac{c_1}{2} + \frac{c_2}{3} &= \frac{2}{3}, \\ \frac{c_0}{2} + \frac{c_1}{3} + \frac{c_2}{4} &= \frac{2}{5}, \end{aligned}$$

$$\frac{c_0}{3}+\frac{c_1}{4}+\frac{c_2}{5}=\frac{2}{7}.$$

Multiplying by 6, 12, and 60 gives $6c_0+3c_1+2c_2=4$, $6c_0+4c_1+3c_2=24/5$, and $20c_0+15c_1+12c_2=120/7$. The second minus the first is $c_1+c_2=4/5$. The third minus $10/3$ times the first is $5c_1+(16/3)c_2=120/7-40/3=80/21$, that is, $15c_1+16c_2=80/7$. Substituting $c_1=4/5-c_2$ gives $12+c_2=80/7$, so $c_2=-4/7$, $c_1=48/35$, and $c_0=(4-144/35+8/7)/6=6/35$. So

$$p(t)=\frac{6}{35}+\frac{48}{35}t-\frac{4}{7}t^2.$$

Since $f-p\perp W$ and $p\in W$ (Proposition 6.4.4), $\|f-p\|^2=\langle f-p,f\rangle=\|f\|^2-\langle p,f\rangle$, and $\langle p,f\rangle=\sum_i c_i d_i=(6/35)(2/3)+(48/35)(2/5)-(4/7)(2/7)=612/1225$. With $\|f\|^2=\int_0^1 t\,dt=1/2$,

$$\|f-p\|^2=\frac{1}{2}-\frac{612}{1225}=\frac{1}{2450}.$$

For the best line, drop c_2 and the third equation: $c_0+c_1/2=2/3$ and $c_0/2+c_1/3=2/5$ give $4/15+(4/5)t$, with squared error $1/2-(8/45+8/25)=1/450$. Allowing t^2 reduces the squared error by a factor of 5.4, and changes the constant and linear coefficients too, because $1,t,t^2$ are not orthogonal.

Solution to Exercise 6.5.44

Uses. Theorem 6.5.5 (The normal equations), Proposition 6.5.9 ($\operatorname{rank}(A^*A)=\operatorname{rank}A$), Remark 6.5.10 (The conjugate is essential)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Look for a nonzero column $\mathbf{a}\in\mathbb{F}_2^m$ with $\mathbf{a}^{\mathsf{T}}\mathbf{a}=0$.
Hint 2. $\mathbf{a}=(1,1)$ works. For (a), choose $\mathbf{b}$ with $\mathbf{a}^{\mathsf{T}}\mathbf{b}=1$.
Sketch. (a) False: $A=\begin{pmatrix}1\\1\end{pmatrix}$ and $\mathbf{b}=(1,0)$ give $0x=1$. (b) False: the same A has an independent column and $A^{\mathsf{T}}A=0$. (c) True: over $\mathbb{R}$, $A^{\mathsf{T}}=A^*$, so these are Theorem 6.5.5 and Proposition 6.5.9(c).

(a) False. Let $A=\begin{pmatrix}1\\1\end{pmatrix}\in\mathbb{F}_2^{2\times1}$ and $\mathbf{b}=(1,0)$. Then $A^{\mathsf{T}}A=1+1=0$ and $A^{\mathsf{T}}\mathbf{b}=1$, so the system reads $0x=1$, which has no solution.

(b) False. The same A has a single nonzero, hence independent, column, but $A^{\mathsf{T}}A=0$ is not invertible.

(c) True. Over $\mathbb{R}$, $A^{\mathsf{T}}=A^*$. The system $A^{\mathsf{T}}A\mathbf{x}=A^{\mathsf{T}}\mathbf{b}$ is the normal equations, which always have a solution by Theorem 6.5.5, and $A^{\mathsf{T}}A$ is invertible when the columns are independent by Proposition 6.5.9(c). Both proofs used $\mathbf{v}^*\mathbf{v}=\|\mathbf{v}\|^2>0$ for $\mathbf{v}\neq\mathbf{0}$, which fails over $\mathbb{F}_2$ for $\mathbf{v}=(1,1)$ (Remark 6.5.10).

Solution to Exercise 6.5.45

Uses. Lemma 6.5.4 (The orthogonal complement of a column space), Proposition 6.5.9 ($\operatorname{rank}(A^*A)=\operatorname{rank}A$), Proposition 6.3.27 (Properties of the conjugate transpose), Theorem 6.4.26 (The double complement)
Hint 1. Apply Lemma 6.5.4 to $M=A^*A$ and to $M=A^*$. What are $(A^*A)^*$ and $(A^*)^*$?
Hint 2. Both complements equal $\ker A$, by Proposition 6.5.9(a). Now take complements again with Theorem 6.4.26.
Sketch. $(\operatorname{im}A^*A)^\perp=\ker(A^*A)^*=\ker(A^*A)=\ker A$ and $(\operatorname{im}A^*)^\perp=\ker A^{**}=\ker A$. Taking complements, $\operatorname{im}(A^*A)=(\ker A)^\perp=\operatorname{im}A^*$ by Theorem 6.4.26. Then $A^*\mathbf{b}\in\operatorname{im}A^*=\operatorname{im}(A^*A)$.

By Proposition 6.3.27, $(A^*A)^*=A^*A$ and $(A^*)^*=A$. By Lemma 6.5.4, applied to A^*A and to A^*, and by Proposition 6.5.9(a),

$$(\operatorname{im}(A^*A))^\perp=\ker(A^*A)=\ker A,$$
$$(\operatorname{im}A^*)^\perp=\ker A.$$

Subspaces of $\mathbb{F}^n$ are finite-dimensional, so Theorem 6.4.26 gives

$$\operatorname{im}(A^*A)=\left((\operatorname{im}(A^*A))^\perp\right)^\perp=(\ker A)^\perp$$
$$=\left((\operatorname{im}A^*)^\perp\right)^\perp=\operatorname{im}A^*.$$

Hence $A^*\mathbf{b} \in \operatorname{im} A^* = \operatorname{im}(A^*A)$, that is, $A^*A\mathbf{x} = A^*\mathbf{b}$ for some $\mathbf{x}$.

Solution to Exercise 6.5.45

Uses. Proposition 6.5.9 ($\operatorname{rank}(A^*A) = \operatorname{rank} A$), Theorem 4.2.7 (The image of T_A), Theorem 4.3.8 (Row rank equals column rank), Proposition 3.5.2 (First properties of rank), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. One containment is clear: $A^*A\mathbf{x} = A^*(A\mathbf{x})$. Compare dimensions.
Hint 2. $\dim\operatorname{im}(A^*A) = \operatorname{rank} A$ by Proposition 6.5.9(b). For $\dim\operatorname{im} A^* = \operatorname{rank} A^*$, write $A^* = \overline{A}^{\mathsf{T}}$: transposing does not change the rank, and neither does conjugating the entries.
Sketch. $\operatorname{im}(A^*A) \subseteq \operatorname{im} A^*$. Both have dimension rank A: the first by Proposition 6.5.9(b), the second because $\operatorname{rank} A^* = \operatorname{rank} \overline{A}^{\mathsf{T}} = \operatorname{rank} \overline{A} = \operatorname{rank} A$. Equal dimensions and containment give equality.

Since $A^*A\mathbf{x} = A^*(A\mathbf{x})$, $\operatorname{im}(A^*A) \subseteq \operatorname{im} A^*$. By Theorem 4.2.7 and Proposition 6.5.9(b), $\dim\operatorname{im}(A^*A) = \operatorname{rank}(A^*A) = \operatorname{rank} A$. For A^*, write $A^* = \overline{A}^{\mathsf{T}}$. By Theorem 4.3.8, $\operatorname{rank} A^* = \operatorname{rank} \overline{A}$. Conjugating the coefficients of a relation shows that $\overline{\mathbf{a}}_j \in \operatorname{span}(\overline{\mathbf{a}}_1, \ldots, \overline{\mathbf{a}}_{j-1})$ if and only if $\mathbf{a}_j \in \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_{j-1})$, so by Proposition 3.5.2(d), $\operatorname{rank} \overline{A} = \operatorname{rank} A$. Hence $\dim\operatorname{im} A^* = \operatorname{rank} A = \dim\operatorname{im}(A^*A)$, and Proposition 4.1.21 gives $\operatorname{im}(A^*A) = \operatorname{im} A^*$. As before, $A^*\mathbf{b} \in \operatorname{im}(A^*A)$.

Solution to Exercise 6.5.46

Uses. Proposition 6.5.9 ($\operatorname{rank}(A^*A) = \operatorname{rank} A$), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 3.1.19 (Solution sets are translates of the kernel), Theorem 6.3.3 (Pythagorean theorem)
Hint 1. The columns of A^* are the conjugates of the rows of A. Apply Proposition 6.5.9(c) to A^*.
Hint 2. For $\mathbf{z} \in \ker A$, $\langle A^*\mathbf{y}, \mathbf{z}\rangle = \langle \mathbf{y}, A\mathbf{z}\rangle$ by Proposition 6.3.27(d).
Hint 3. Every solution is $\mathbf{x}_0 + \mathbf{z}$ with $\mathbf{z} \in \ker A$. Use Pythagoras.
Sketch. (a) The columns of A^* are independent, so $(A^*)^*A^* = AA^*$ is invertible. (b) $A\mathbf{x}_0 = AA^*(AA^*)^{-1}\mathbf{b} = \mathbf{b}$, and $\mathbf{x}_0 = A^*\mathbf{y}$ is orthogonal to $\ker A$ since $\langle A^*\mathbf{y}, \mathbf{z}\rangle = \langle \mathbf{y}, A\mathbf{z}\rangle = 0$. (c) Solutions are $\mathbf{x}_0 + \mathbf{z}$, $\mathbf{z} \in \ker A$, with $\|\mathbf{x}_0 + \mathbf{z}\|^2 = \|\mathbf{x}_0\|^2 + \|\mathbf{z}\|^2$. (d) $AA^{\mathsf{T}} = \operatorname{diag}(3, 2)$, so $\mathbf{x}_0 = A^{\mathsf{T}}(1, 1/2) = (3/2, 1, 1/2)$.

(a) Row i of A, read as a vector, has conjugate equal to column i of A^* (Definition 6.3.26). A relation $\sum_i c_i \overline{\mathbf{r}_i} = \mathbf{0}$ among the conjugated rows gives, after conjugating, the relation $\sum_i \overline{c_i}\mathbf{r}_i = \mathbf{0}$ among the rows, so the columns of A^* are independent. By Proposition 6.5.9(c) applied to $A^* \in \mathbb{F}^{n\times m}$, the matrix $(A^*)^*A^* = AA^*$ is invertible.

(b) $A\mathbf{x}_0 = (AA^*)(AA^*)^{-1}\mathbf{b} = \mathbf{b}$. Let $\mathbf{y} = (AA^*)^{-1}\mathbf{b}$, so $\mathbf{x}_0 = A^*\mathbf{y}$. For $\mathbf{z} \in \ker A$, Proposition 6.3.27(d) and conjugate symmetry give $\langle \mathbf{x}_0, \mathbf{z}\rangle = \langle A^*\mathbf{y}, \mathbf{z}\rangle = \overline{\langle \mathbf{z}, A^*\mathbf{y}\rangle} = \overline{\langle A\mathbf{z}, \mathbf{y}\rangle} = 0$. So $\mathbf{x}_0 \in (\ker A)^{\perp}$.

(c) By Proposition 3.1.19, the solutions are the vectors $\mathbf{x}_0 + \mathbf{z}$ with $\mathbf{z} \in \ker A$. Since $\mathbf{x}_0 \perp \mathbf{z}$, Theorem 6.3.3 gives $\|\mathbf{x}_0 + \mathbf{z}\|^2 = \|\mathbf{x}_0\|^2 + \|\mathbf{z}\|^2 \geq \|\mathbf{x}_0\|^2$, with equality if and only if $\mathbf{z} = \mathbf{0}$.

(d) Here $A = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 0 & -1 \end{pmatrix}$, whose rows are independent, and $AA^{\mathsf{T}} = \begin{pmatrix} 3 & 0 \\ 0 & 2 \end{pmatrix}$. So $\left(AA^{\mathsf{T}}\right)^{-1}(3, 1) = (1, 1/2)$, and

$$\mathbf{x}_0 = A^{\mathsf{T}}\begin{pmatrix} 1 \\ 1/2 \end{pmatrix} = \begin{pmatrix} 3/2 \\ 1 \\ 1/2 \end{pmatrix}.$$

Check: $3/2 + 1 + 1/2 = 3$ and $3/2 - 1/2 = 1$, and $\mathbf{x}_0$ is orthogonal to $(1, -2, 1)$, which spans $\ker A$. In the language of Section 6.5.7, $\mathbf{x}_0 = A^+\mathbf{b}$, and $A^+ = A^*(AA^*)^{-1}$ for A with independent rows.

Solution to Exercise 6.5.47

Uses. Proposition 6.5.17 (The least-squares line)
Hint 1. Show that $\sum_{i<j}(u_j - u_i)(v_j - v_i) = m\sum_k (u_k - m_u)(v_k - m_v)$ for any $\mathbf{u}, \mathbf{v} \in \mathbb{R}^m$. Sum over all ordered pairs (i, j) first.
Hint 2. Apply this with $(\mathbf{u}, \mathbf{v}) = (\mathbf{x}, \mathbf{y})$ and $(\mathbf{x}, \mathbf{x})$, and note that $(x_j - x_i)(y_j - y_i) = (x_j - x_i)^2 s_{ij}$.
Sketch. Summing over all ordered pairs, $\sum_{i,j}(u_j - u_i)(v_j - v_i) = 2m\sum_k u_k v_k - 2\left(\sum_k u_k\right)\left(\sum_k v_k\right) = 2m\sum_k (u_k - m_u)(v_k - m_v)$, and the sum over $i < j$ is half of it. So the numerator and denominator in the claim are $m\tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}}$ and $m\|\tilde{\mathbf{x}}\|^2$, whose ratio is c_1. A weighted average with positive weights lies between the smallest and largest values.

Let $\mathbf{u}, \mathbf{v} \in \mathbb{R}^m$ with means m_u, m_v. Summing over all ordered pairs (i, j), including $i = j$, whose terms are 0,

$$\begin{aligned}&\sum_{i,j}(u_j-u_i)(v_j-v_i)\\&=\sum_{i,j}(u_jv_j+u_iv_i-u_jv_i-u_iv_j)\\&=2m\sum_k u_kv_k-2\left(\sum_k u_k\right)\left(\sum_k v_k\right).\end{aligned}$$

Since $\sum_k u_k = mm_u$ and $\sum_k v_k = mm_v$, the right side is $2m\big(\sum_k u_kv_k - mm_um_v\big) = 2m\sum_k(u_k-m_u)(v_k-m_v)$, by the identity in the proof of Proposition 6.5.17. The terms for (i,j) and (j,i) are equal, so

$$\sum_{i<j}(u_j-u_i)(v_j-v_i) = m\sum_k(u_k-m_u)(v_k-m_v).$$

With $(\mathbf{u},\mathbf{v}) = (\mathbf{x},\mathbf{y})$ and $(\mathbf{x},\mathbf{x})$, this gives $\sum_{i<j}(x_j-x_i)(y_j-y_i) = m\,\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}$ and $\sum_{i<j}(x_j-x_i)^2 = m\|\tilde{\mathbf{x}}\|^2 > 0$. In the first sum, a pair with $x_i = x_j$ contributes 0, and a pair with $x_i \neq x_j$ contributes $(x_j-x_i)^2 s_{ij}$. Dividing, and using Proposition 6.5.17,

$$\frac{\sum_{i<j}(x_j-x_i)^2 s_{ij}}{\sum_{i<j}(x_j-x_i)^2} = \frac{\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}}{\|\tilde{\mathbf{x}}\|^2} = c_1.$$

The weights $w_{ij} = (x_j-x_i)^2$ of the remaining pairs are positive. If $s_{\min}$ and $s_{\max}$ are the smallest and largest s_{ij}, then $s_{\min}\sum w_{ij} \le \sum w_{ij}s_{ij} \le s_{\max}\sum w_{ij}$, so $s_{\min} \le c_1 \le s_{\max}$. Pairs of points far apart in x get the most weight, which matches the intuition that they determine a slope most reliably.

Solution to Exercise 6.5.48

Uses. Theorem 6.5.5 (The normal equations), Proposition 6.3.27 (Properties of the conjugate transpose), Aside (Weighted least squares) (Weighted least squares)
Hint 1. $(W\mathbf{v})_i = \sqrt{w_i}v_i$. So the weighted sum is an ordinary least-squares problem for the matrix WA and the vector $W\mathbf{b}$.
Hint 2. For (b), $A^{\mathsf{T}}DA = \begin{pmatrix}13/4 & 15/4\\ 15/4 & 29/4\end{pmatrix}$ and $A^{\mathsf{T}}D\mathbf{y} = (8,14)$.
Sketch. (a) $\|W(\mathbf{b}-A\mathbf{x})\|^2 = \sum_i w_i|b_i-(A\mathbf{x})_i|^2$, so the minimizers are the least-squares solutions of $(WA)\mathbf{x} = W\mathbf{b}$, whose normal equations are $A^*W^*WA\mathbf{x} = A^*W^*W\mathbf{b}$, and $W^*W = D$. (b) Ordinary: $y = 1/5 + (11/5)x$. Weighted: $y = 11/19 + (31/19)x \approx 0.58 + 1.63x$.

(a) The ith entry of $W(\mathbf{b}-A\mathbf{x})$ is $\sqrt{w_i}(b_i-(A\mathbf{x})_i)$, so $\|W\mathbf{b}-WA\mathbf{x}\|^2 = \sum_i w_i|b_i-(A\mathbf{x})_i|^2$. Hence the minimizers are the least-squares solutions of $(WA)\mathbf{x} = W\mathbf{b}$, which by Theorem 6.5.5 are the solutions of $(WA)^*(WA)\mathbf{x} = (WA)^*W\mathbf{b}$. Since W is real and diagonal, $W^* = W$ and $W^*W = W^2 = D$, and by Proposition 6.3.27(b) the equations read $A^*DA\mathbf{x} = A^*D\mathbf{b}$. This is a second derivation of the weighted normal equations of Aside (Weighted least squares).

(b) Ordinary least squares: $A^{\mathsf{T}}A = \begin{pmatrix}4 & 6\\ 6 & 14\end{pmatrix}$ and $A^{\mathsf{T}}\mathbf{y} = (14, 0+2+6+24) = (14,32)$. The determinant is 20, and $c_0 = (14\cdot 14 - 6\cdot 32)/20 = 1/5$, $c_1 = (4\cdot 32 - 6\cdot 14)/20 = 11/5$. So the line is $y = 0.2 + 2.2x$.

Weighted, with $D = \operatorname{diag}(1,1,1,1/4)$:

$$A^{\mathsf{T}}DA = \begin{pmatrix}3+1/4 & 3+3/4\\ 3+3/4 & 5+9/4\end{pmatrix} = \frac{1}{4}\begin{pmatrix}13 & 15\\ 15 & 29\end{pmatrix},$$

$$A^{\mathsf{T}}D\mathbf{y} = \begin{pmatrix}6+2\\ 8+6\end{pmatrix} = \begin{pmatrix}8\\ 14\end{pmatrix}.$$

Multiplying by 4, the system is $13c_0 + 15c_1 = 32$, $15c_0 + 29c_1 = 56$, with determinant $377 - 225 = 152$. So $c_0 = (32\cdot 29 - 15\cdot 56)/152 = 88/152 = 11/19$ and $c_1 = (13\cdot 56 - 15\cdot 32)/152 = 248/152 = 31/19$. The weighted line is $y \approx 0.58 + 1.63x$. The first three points lie on $y = 1 + x$, and giving the unreliable fourth point less weight pulls the slope from 2.2 toward 1.

Solution to Exercise 6.5.49

Uses. Proposition 6.5.27 (The least-squares solution of minimal norm), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.4.31 (The matrix of an orthogonal projection), Proposition 6.5.2 (Least squares is projection)
Hint 1. $A^+(A\mathbf{x})$ is the least-squares solution of $A\mathbf{z} = A\mathbf{x}$ of smallest norm. This system is consistent; what are its solutions?
Hint 2. For (b), use $AA^+ = \mathrm{Pr}_{\mathrm{im}\,A}$, (a), and the fact that $A^+\mathbf{b} \in (\ker A)^\perp$. Matrices of orthogonal projections are Hermitian.
Sketch. (a) The solutions of $A\mathbf{z} = A\mathbf{x}$ are $\mathbf{x} + \ker A$, so $A^+A\mathbf{x} = \mathbf{x} - \mathrm{Pr}_{\ker A}(\mathbf{x}) = \mathrm{Pr}_{(\ker A)^\perp}(\mathbf{x})$ by Proposition 6.5.27(a) and Proposition 6.4.29(d). (b) $AA^+A = \mathrm{Pr}_{\mathrm{im}\,A}\,A = A$; $A^+AA^+ = \mathrm{Pr}_{(\ker A)^\perp}\,A^+ = A^+$; orthogonal projection matrices are Hermitian. (c) $A^+ = (1/4)\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}$, with $AA^+ = A^+A = (1/2)\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}$.

(a) Let $\mathbf{x} \in \mathbb{F}^n$. Then $A^+(A\mathbf{x})$ is the least-squares solution of smallest norm of $A\mathbf{z} = A\mathbf{x}$. This system is consistent, so its least-squares solutions are its solutions, $\mathbf{x} + \ker A$ (Proposition 6.5.2(b)). By Proposition 6.5.27(a) with $\hat{\mathbf{x}} = \mathbf{x}$, $A^+A\mathbf{x} = \mathbf{x} - \mathrm{Pr}_{\ker A}(\mathbf{x})$, and since $\mathbb{F}^n$ is finite-dimensional this is $\mathrm{Pr}_{(\ker A)^\perp}(\mathbf{x})$ by Proposition 6.4.29(d).

(b) By Proposition 6.5.2(a), $AA^+ = \mathrm{Pr}_{\mathrm{im}\,A}$, which fixes every column of A; so $AA^+A = A$. By Proposition 6.5.27(a), every $A^+\mathbf{b}$ lies in $(\ker A)^\perp$, which $\mathrm{Pr}_{(\ker A)^\perp}$ fixes; with (a), $A^+AA^+ = A^+$. Finally AA^+ and A^+A are matrices of orthogonal projections, which are Hermitian by Theorem 6.4.31.

(c) Here $\mathrm{im}\,A = \mathrm{span}((1,1))$, $\ker A = \mathrm{span}((1,-1))$, and $(\ker A)^\perp = \mathrm{span}((1,1))$. For $\mathbf{b} \in \mathbb{F}^2$, $\mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{b}) = ((b_1+b_2)/2)(1,1)$, so the least-squares solutions satisfy $x_1 + x_2 = (b_1+b_2)/2$, and the one in $(\ker A)^\perp$ is $s(1,1)$ with $2s = (b_1+b_2)/2$. So $A^+\mathbf{b} = ((b_1+b_2)/4)(1,1)$, that is, $A^+ = (1/4)\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}$. Then $AA^+ = A^+A = (1/2)\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}$, which is Hermitian, $AA^+A = (1/2)\begin{pmatrix}2 & 2\\ 2 & 2\end{pmatrix} = A$, and $A^+AA^+ = (1/8)\begin{pmatrix}2 & 2\\ 2 & 2\end{pmatrix} = A^+$.

Solution to Exercise 6.5.50

Uses. Example 6.4.35 (Distance to a hyperplane), Exercise 6.5.20, Theorem 6.3.22 (Parseval's identity), Theorem 6.2.1 (Cauchy–Schwarz inequality), Exercise 6.5.41
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. For (a), $\ell = \mathbf{q} + \{\mathbf{n}\}^\perp$ for any $\mathbf{q} \in \ell$; translate Example 6.4.35. Then $\sum_i (\langle \mathbf{p}_i, \mathbf{n}\rangle - c)^2$ is a least-squares problem for a constant.
Hint 2. For (b), $\mathbf{u}, \mathbf{n}$ is an orthonormal basis of $\mathbb{R}^2$, so $\|\tilde{\mathbf{p}}\|^2 = \langle \tilde{\mathbf{p}}, \mathbf{u}\rangle^2 + \langle \tilde{\mathbf{p}}, \mathbf{n}\rangle^2$.
Hint 3. For (c), expand $(\tilde{x}_i \cos\theta + \tilde{y}_i \sin\theta)^2$ with the double-angle formulas, and bound $\mathbf{w} \cdot (\cos 2\theta, \sin 2\theta)$ by Cauchy–Schwarz.
Sketch. (a) With $\mathbf{q} \in \ell$, $\mathrm{dist}(\mathbf{p}, \ell) = \mathrm{dist}\big(\mathbf{p} - \mathbf{q}, \{\mathbf{n}\}^\perp\big) = |\langle \mathbf{p} - \mathbf{q}, \mathbf{n}\rangle| = |\langle \mathbf{p}, \mathbf{n}\rangle - c|$; minimizing $\sum_i (\langle \mathbf{p}_i, \mathbf{n}\rangle - c)^2$ over c gives the mean $c = \langle \mathbf{g}, \mathbf{n}\rangle$. (b) Parseval in the basis $\mathbf{u}, \mathbf{n}$. (c) The double-angle formulas give the expression, and Cauchy–Schwarz bounds $\mathbf{w} \cdot (\cos 2\theta, \sin 2\theta) \le \|\mathbf{w}\|$ with equality iff $(\cos 2\theta, \sin 2\theta) = \mathbf{w}/\|\mathbf{w}\|$. (d) $\mathbf{g} = (3/2, 3/2)$, $\mathbf{w} = (0, 4)$, so $\theta = \pi/4$ and the line is $y = x$, whose slope 1 lies between $4/5$ and $5/4$.

(a) Pick $\mathbf{q} \in \ell$, so $\langle \mathbf{q}, \mathbf{n}\rangle = c$ and $\ell = \mathbf{q} + H$ with $H = \{\mathbf{n}\}^\perp$. Translating by $-\mathbf{q}$ preserves distances, so by Example 6.4.35, $\mathrm{dist}(\mathbf{p}, \ell) = \mathrm{dist}(\mathbf{p} - \mathbf{q}, H) = |\langle \mathbf{p} - \mathbf{q}, \mathbf{n}\rangle| = |\langle \mathbf{p}, \mathbf{n}\rangle - c|$. For fixed $\mathbf{n}$, $D(\ell) = \sum_i (t_i - c)^2$ with $t_i = \langle \mathbf{p}_i, \mathbf{n}\rangle$. This is the least-squares problem $c\mathbf{1} \approx \mathbf{t}$, whose solution (Exercise 6.5.20 with all $x_i = 1$) is the mean $c = (1/m)\sum_i t_i = \langle \mathbf{g}, \mathbf{n}\rangle$, and it is unique. So D is smallest when $\mathbf{g} \in \ell$.

(b) Let $\mathbf{n}$ be a unit vector orthogonal to $\mathbf{u}$, so that $\mathbf{u}, \mathbf{n}$ is an orthonormal basis of $\mathbb{R}^2$ and $\ell = \{\mathbf{p} \mid \langle \mathbf{p}, \mathbf{n}\rangle = \langle \mathbf{g}, \mathbf{n}\rangle\}$. By (a), $\mathrm{dist}(\mathbf{p}_i, \ell)^2 = \langle \tilde{\mathbf{p}}_i, \mathbf{n}\rangle^2$, and by Parseval (Theorem 6.3.22), $\|\tilde{\mathbf{p}}_i\|^2 = \langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2 + \langle \tilde{\mathbf{p}}_i, \mathbf{n}\rangle^2$. Summing over i gives the formula.

(c) We have $\langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2 = \tilde{x}_i^2 \cos^2\theta + 2\tilde{x}_i\tilde{y}_i \cos\theta \sin\theta + \tilde{y}_i^2 \sin^2\theta$. Summing, and using $\cos^2\theta = (1 + \cos 2\theta)/2$, $\sin^2\theta = (1 - \cos 2\theta)/2$, and $2\sin\theta\cos\theta = \sin 2\theta$,

$$\sum_i \langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2 = \frac{S_{xx} + S_{yy}}{2} + \frac{S_{xx} - S_{yy}}{2}\cos 2\theta + S_{xy}\sin 2\theta$$
$$= \frac{S_{xx} + S_{yy}}{2} + \mathbf{w} \cdot (\cos 2\theta, \sin 2\theta).$$

By Cauchy–Schwarz (Theorem 6.2.1), $\mathbf{w} \cdot (\cos 2\theta, \sin 2\theta) \le \|\mathbf{w}\|$, with equality if and only if the unit vector $(\cos 2\theta, \sin 2\theta)$ is a positive multiple of $\mathbf{w}$, that is, equals $\mathbf{w}/\|\mathbf{w}\|$. By (a), a minimizing line passes through $\mathbf{g}$, and by (b), among those, D is smallest exactly when $\sum_i \langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2$ is largest. The condition determines 2θ modulo 2π, hence $\mathbf{u}$ up to sign, hence the line.

(d) Here $\mathbf{g} = (3/2, 3/2)$, $S_{xx} = S_{yy} = 5$, and $S_{xy} = 4$ (Exercise 6.5.41(c)), so $\mathbf{w} = (0, 4)$, $2\theta = \pi/2$, and $\mathbf{u} = (1, 1)/\sqrt{2}$. The best line is $y = x$, with $D = 10 - (5 + 4) = 1$. Its slope 1 lies between the slope $4/5$ of the regression of y on x and the slope $5/4$ of the regression of x on y, as it treats the two coordinates symmetrically. The direction $\mathbf{u}$ maximizing $\sum_i \langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2$ is the first principal component of the points (Section 16.2).

Section 6.6

Solution to Exercise 6.6.6

Uses. Theorem 6.6.3 (Riesz representation theorem), Definition 6.1.8 (Dot product), Example 6.6.5 (Representing evaluation at 0)
Hint 1. In (a), $\mathbf{z} \cdot \mathbf{u} = \sum_j z_j \overline{u_j}$, so each u_j is the conjugate of a coefficient.
Hint 2. In (b), use the orthonormal basis $1, \sqrt{3}(2x-1)$, or write $q = c + dx$ and impose the two conditions $\langle 1, q\rangle = 1$ and $\langle x, q\rangle = 1$.
Sketch. (a) $\mathbf{u} = (2, i, 1-i)$, the conjugated coefficients. (b) $q = 1 + \sqrt{3}\cdot\sqrt{3}(2x-1) = 6x - 2$; check: $\int_0^1 (6t-2)\,dt = 1$ and $\int_0^1 t(6t-2)\,dt = 1$.

(a) For $\mathbf{u} = (2, i, 1-i)$,

$$\mathbf{z} \cdot \mathbf{u} = z_1\overline{2} + z_2\overline{i} + z_3\overline{1-i} = 2z_1 - iz_2 + (1+i)z_3,$$

as required. By Theorem 6.6.3 (or by comparing coefficients at $\mathbf{z} = \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$) it is the only such vector.

(b) With $e_1 = 1$ and $e_2 = \sqrt{3}(2x-1)$, the functional $\varphi(p) = p(1)$ has $\varphi(e_1) = 1$ and $\varphi(e_2) = \sqrt{3}$, so Theorem 6.6.3 gives

$$q = 1 + \sqrt{3}\cdot\sqrt{3}(2x-1) = 6x - 2.$$

Check: $\int_0^1 (6t-2)\,dt = 3 - 2 = 1 = \varphi(1)$ and $\int_0^1 t(6t-2)\,dt = 2 - 1 = 1 = \varphi(x)$, so $\langle p, q\rangle = p(1)$ for all $p \in \mathbb{R}[x]_{\le 1}$ by linearity. As expected from the symmetry $t \mapsto 1 - t$ of $[0,1]$, $q(x)$ is $4 - 6(1-x)$, the polynomial of Example 6.6.5 with x replaced by $1 - x$.

Solution to Exercise 6.6.17

Uses. Proposition 6.1.16 (Frobenius inner product), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.3.27 (Properties of the conjugate transpose), Definition 6.6.8 (Adjoint)
Techniques. Find the adjoint by isolating the input (Technique 6.6.11)
Hint 1. For (a), use $\operatorname{tr}(BC) = \operatorname{tr}(CB)$ to move A next to Y^*, and recognize AY^* as $(YA^*)^*$.
Hint 2. For (b), use the entrywise formula $\langle X, Y\rangle = \sum_{i,j} x_{ij}\overline{y_{ij}}$ and rename the indices.
Sketch. (a) $\operatorname{tr}(Y^*XA) = \operatorname{tr}(AY^*X) = \operatorname{tr}\big((YA^*)^*X\big)$, so $R_A^* = R_{A^*}$. (b) $\langle X^{\mathsf{T}}, Y\rangle = \sum_{i,j} x_{ji}\overline{y_{ij}} = \langle X, Y^{\mathsf{T}}\rangle$, so the transpose map is its own adjoint. (c) $(iX)^* = -iX^*$, so the map is not linear over $\mathbb{C}$, and Definition 6.6.8 applies only to linear maps.

(a) By Proposition 2.4.28 and Proposition 6.3.27,

$$\langle XA, Y\rangle = \operatorname{tr}(Y^*XA) = \operatorname{tr}(AY^*X) = \operatorname{tr}\big((YA^*)^*X\big) = \langle X, YA^*\rangle,$$

since $(YA^*)^* = (A^*)^*Y^* = AY^*$. So $R_A^*(Y) = YA^*$, that is, $R_A^* = R_{A^*}$.

(b) By Proposition 6.1.16, $\langle X, Y\rangle = \sum_{i,j} x_{ij}\overline{y_{ij}}$. The (i,j) entry of X^{T} is x_{ji}, so

$$\langle X^{\mathsf{T}}, Y\rangle = \sum_{i,j} x_{ji}\overline{y_{ij}} = \sum_{i,j} x_{ij}\overline{y_{ji}} = \langle X, Y^{\mathsf{T}}\rangle,$$

after renaming i and j. So the transpose map is its own adjoint.

(c) $(iX)^* = \bar{i}X^* = -iX^*$ (Proposition 6.3.27(a)), so $X \mapsto X^*$ is not linear over $\mathbb{C}$ (unless $n = 0$). Adjoints are defined for linear maps only. (Over $\mathbb{R}$ the map is the transpose, covered by (b).)

Solution to Exercise 6.6.19

Uses. Proposition 6.6.18 (Properties of the adjoint)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. First show $\left(T^j\right)^* = (T^*)^j$ by induction on j, using (d) and (e) of Proposition 6.6.18.
Hint 2. Then expand the left side with (a) and (b).
Sketch. $\left(T^0\right)^* = \mathrm{id}^* = \mathrm{id}$, and $\left(T^{j+1}\right)^* = \left(TT^j\right)^* = \left(T^j\right)^* T^* = (T^*)^j T^* = (T^*)^{j+1}$. Then (a) and (b) give $\left(\sum_j c_j T^j\right)^* = \sum_j \overline{c_j}\left(T^j\right)^* = \sum_j \overline{c_j}(T^*)^j$.

All adjoints exist since V is finite-dimensional (Theorem 6.6.15). We show $\left(T^j\right)^* = (T^*)^j$ by induction on $j \geq 0$. For $j = 0$, $T^0 = \mathrm{id}$ and $\mathrm{id}^* = \mathrm{id}$ by Proposition 6.6.18(e). If $\left(T^j\right)^* = (T^*)^j$, then by Proposition 6.6.18(d),

$$\left(T^{j+1}\right)^* = \left(TT^j\right)^* = \left(T^j\right)^* T^* = (T^*)^j T^* = (T^*)^{j+1}.$$

By (a) and (b) of Proposition 6.6.18, applied term by term,

$$\left(\sum_{j=0}^{k} c_j T^j\right)^* = \sum_{j=0}^{k} \overline{c_j}\left(T^j\right)^* = \sum_{j=0}^{k} \overline{c_j}(T^*)^j,$$

as desired.

Solution to Exercise 6.6.25

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Corollary 6.6.22 (T and T^* have the same rank), Proposition 2.6.18 (The column space is spanned by the columns), Proposition 6.3.9 (Properties of $A^\perp$)
Hint 1. The third row is the sum of the first two, so rank $A = 2$, and each kernel is a line.
Hint 2. Solve $A\mathbf{x} = \mathbf{0}$ and $A^{\mathsf{T}}\mathbf{y} = \mathbf{0}$, then check orthogonality against the rows and the columns of A.
Sketch. $\ker A = \mathrm{span}((1,-1,1))$ and $\mathrm{im}\, A^{\mathsf{T}} = \mathrm{span}((1,2,1),(0,1,1))$; the kernel vector is orthogonal to both rows. $\mathrm{im}\, A = \mathrm{span}((1,0,1),(2,1,3))$ and $\ker A^{\mathsf{T}} = \mathrm{span}((1,1,-1))$, orthogonal to every column. Dimensions $1+2=3$ in both cases.

Row 3 is row 1 plus row 2, and rows 1 and 2 are not proportional, so $\operatorname{rank} A = 2$ and $\mathrm{im}\, A^{\mathsf{T}} = \mathrm{span}((1,2,1),(0,1,1))$ has dimension 2. Solving $x_1 + 2x_2 + x_3 = 0$ and $x_2 + x_3 = 0$ gives $x_2 = -x_3$ and $x_1 = x_3$, so $\ker A = \mathrm{span}((1,-1,1))$. Indeed $(1,-1,1)\cdot(1,2,1) = 0$ and $(1,-1,1)\cdot(0,1,1) = 0$, so $\ker A \perp \mathrm{im}\, A^{\mathsf{T}}$ (Proposition 6.3.9(c)), and the dimensions add up to 3, as Theorem 6.6.21 predicts.

The columns are $(1,0,1)$, $(2,1,3)$, $(1,1,2)$, and the third is the second minus the first, so $\mathrm{im}\, A = \mathrm{span}((1,0,1),(2,1,3))$ (Proposition 2.6.18). The equations of $A^{\mathsf{T}}\mathbf{y} = \mathbf{0}$ are $y_1 + y_3 = 0$, $2y_1 + y_2 + 3y_3 = 0$, $y_1 + y_2 + 2y_3 = 0$; the first gives $y_3 = -y_1$, and then the second gives $y_2 = y_1$, which also satisfies the third. So $\ker A^{\mathsf{T}} = \mathrm{span}((1,1,-1))$, which is orthogonal to $(1,0,1)$ and $(2,1,3)$. Again the dimensions are 2 and 1.

Solution to Exercise 6.6.31

Uses. Example 6.6.10 (The adjoint of a matrix), Proposition 6.6.9 (Adjoints are unique and linear), Proposition 6.1.4 (Sesquilinearity), Theorem 6.6.15 (Existence of adjoints)
Techniques. Find the adjoint by isolating the input (Technique 6.6.11)
Hint 1. For (a), use Example 6.6.10 with $A = \begin{pmatrix} 1 & i \\ 1-i & 0 \end{pmatrix}$.
Hint 2. For (b), expand $\langle T\mathbf{z}, \mathbf{w}\rangle$ and collect the terms with z_1 and with z_2. The coefficient of z_2 must be written as 2 times a conjugate, to match the weight 2.
Sketch. (a) $A^* = \begin{pmatrix} 1 & 1+i \\ -i & 0 \end{pmatrix}$, so $T^*(\mathbf{w}) = (w_1 + (1+i)w_2, -iw_1)$. (b) $\langle T\mathbf{z}, \mathbf{w}\rangle = z_1\overline{w_1 + 2(1+i)w_2} + 2z_2\overline{-iw_1/2}$, so $T^*(\mathbf{w}) = (w_1 + (2+2i)w_2, -iw_1/2)$. (c) No; the standard basis is not orthonormal for the weighted inner product.

(a) The matrix of T is $A = \begin{pmatrix} 1 & i \\ 1-i & 0 \end{pmatrix}$, so by Example 6.6.10, T^* is multiplication by $A^* = \begin{pmatrix} 1 & 1+i \\ -i & 0 \end{pmatrix}$:

$$T^*(w_1, w_2) = (w_1 + (1+i)w_2, -iw_1).$$

(b) For $\mathbf{z}, \mathbf{w} \in \mathbb{C}^2$,

$$\begin{aligned} \langle T\mathbf{z}, \mathbf{w}\rangle &= (z_1 + iz_2)\overline{w_1} + 2(1-i)z_1\overline{w_2} \\ &= z_1(\overline{w_1} + 2(1-i)\overline{w_2}) + 2z_2 \cdot \frac{i\overline{w_1}}{2} \end{aligned}$$

$$= z_1\overline{w_1 + 2(1+i)w_2} + 2z_2\overline{-iw_1/2},$$

which is $\langle \mathbf{z}, \mathbf{u}\rangle$ for $\mathbf{u} = (w_1 + (2+2i)w_2, -iw_1/2)$. By Proposition 6.6.9,

$$T^*(w_1, w_2) = (w_1 + (2+2i)w_2, -(i/2)w_1).$$

(c) The matrix of this T^* in the standard basis is $\begin{pmatrix} 1 & 2+2i \\ -i/2 & 0 \end{pmatrix} \neq A^*$. There is no contradiction: Theorem 6.6.15(b) needs orthonormal bases, and $\mathbf{e}_1, \mathbf{e}_2$ is not orthonormal for the weighted inner product, since $\langle \mathbf{e}_2, \mathbf{e}_2\rangle = 2$. The adjoint depends on the inner products, not only on the map.

Solution to Exercise 6.6.32

Uses. Theorem 6.6.3 (Riesz representation theorem), Example 6.4.19 (Legendre polynomials), Corollary 6.4.10 (Projecting with an orthogonal list)
Hint 1. Use the orthogonal basis $1, x, x^2 - 1/3$ of Example 6.4.19, with squared norms $2, 2/3, 8/45$. For an orthogonal basis f_j, the formula of Theorem 6.6.3 becomes $q = \sum_j \varphi(f_j)/\|f_j\|^2 f_j$ over $\mathbb{R}$.
Hint 2. (a) $\varphi(1) = 0$, $\varphi(x) = 1$, $\varphi(x^2 - 1/3) = 0$. (b) $\varphi(1) = 1$, $\varphi(x) = 1/2$, $\varphi(x^2 - 1/3) = 0$.
Sketch. (a) $q_1 = (1/(2/3))x = 3x/2$. (b) $q_2 = 1/2 + (1/2)/(2/3)\,x = 1/2 + 3x/4$. Check both on $1, x, x^2$.

Let $f_1 = 1$, $f_2 = x$, $f_3 = x^2 - 1/3$, an orthogonal basis with $\|f_1\|^2 = 2$, $\|f_2\|^2 = 2/3$, $\|f_3\|^2 = 8/45$ (Example 6.4.19). Normalizing, $e_j = f_j/\|f_j\|$, the formula of Theorem 6.6.3 gives, over $\mathbb{R}$,

$$q = \sum_j \varphi(e_j)e_j = \sum_j \frac{\varphi(f_j)}{\|f_j\|^2} f_j.$$

(a) For $\varphi(p) = p'(0)$: $\varphi(1) = 0$, $\varphi(x) = 1$, and $\varphi(x^2 - 1/3) = 0$. So $q_1 = (3/2)x$. Check: for $p = a + bx + cx^2$, $\langle p, q_1\rangle = (3/2)\left(a\int_{-1}^{1} t\,dt + b\int_{-1}^{1} t^2\,dt + c\int_{-1}^{1} t^3\,dt\right) = (3/2)(2b/3) = b = p'(0)$.

(b) For $\varphi(p) = \int_0^1 p$: $\varphi(1) = 1$, $\varphi(x) = 1/2$, and $\varphi(x^2 - 1/3) = 1/3 - 1/3 = 0$. So

$$q_2 = \frac{1}{2} + \frac{1/2}{2/3}x = \frac{1}{2} + \frac{3}{4}x.$$

Check: $\langle 1, q_2\rangle = 1 = \int_0^1 1$, $\langle x, q_2\rangle = (3/4)(2/3) = 1/2 = \int_0^1 t\,dt$, and $\langle x^2, q_2\rangle = (1/2)(2/3) = 1/3 = \int_0^1 t^2\,dt$.

Solution to Exercise 6.6.33

Uses. Definition 6.1.8 (Dot product), Proposition 6.6.9 (Adjoints are unique and linear), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Definition 6.4.11 (Orthogonal projection)
Techniques. Find the adjoint by isolating the input (Technique 6.6.11)
Hint 1. Write $\langle R\mathbf{x}, \mathbf{y}\rangle = \sum_{j=1}^{n-1} x_j\overline{y_{j+1}}$ and read off the vector in the second slot.
Hint 2. R^* shifts the other way. For (b), C sends $\mathbf{e}_j$ to $\mathbf{e}_{j+1}$ and $\mathbf{e}_n$ to $\mathbf{e}_1$.
Sketch. (a) $R^*(\mathbf{y}) = (y_2, \ldots, y_n, 0)$. Then $R^*R\mathbf{x} = (x_1, \ldots, x_{n-1}, 0)$ projects onto $\operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{n-1})$ and $RR^*\mathbf{y} = (0, y_2, \ldots, y_n)$ projects onto $\operatorname{span}(\mathbf{e}_2, \ldots, \mathbf{e}_n)$. (b) $C^*(\mathbf{y}) = (y_2, \ldots, y_n, y_1)$, which undoes C.

(a) For $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$,

$$\langle R\mathbf{x}, \mathbf{y}\rangle = \sum_{j=1}^{n-1} x_j\overline{y_{j+1}} = \langle \mathbf{x}, (y_2, \ldots, y_n, 0)\rangle,$$

so $R^*(y_1, \ldots, y_n) = (y_2, \ldots, y_n, 0)$, the shift to the left. Then

$$R^*R\mathbf{x} = R^*(0, x_1, \ldots, x_{n-1}) = (x_1, \ldots, x_{n-1}, 0), \quad RR^*\mathbf{y} = R(y_2, \ldots, y_n, 0) = (0, y_2, \ldots, y_n).$$

The first keeps the coordinates along $\mathbf{e}_1, \ldots, \mathbf{e}_{n-1}$ and kills the last, so it is Pr_W for $W = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{n-1})$ (Definition 6.4.11, with the orthonormal basis $\mathbf{e}_1, \ldots, \mathbf{e}_{n-1}$ of W). Likewise $RR^* = \operatorname{Pr}_{\operatorname{span}(\mathbf{e}_2, \ldots, \mathbf{e}_n)}$. Note $R^*R \neq RR^*$: the shift is not normal (Section 8.1).

(b) For $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$,

$$\langle C\mathbf{x}, \mathbf{y}\rangle = x_n\overline{y_1} + \sum_{j=1}^{n-1} x_j\overline{y_{j+1}} = \langle \mathbf{x}, (y_2, ..., y_n, y_1)\rangle,$$

so $C^*(y_1, ..., y_n) = (y_2, ..., y_n, y_1)$. Then $C(C^*\mathbf{y}) = C(y_2, ..., y_n, y_1) = (y_1, y_2, ..., y_n)$ and $C^*(C\mathbf{x}) = C^*(x_n, x_1, ..., x_{n-1}) = (x_1, ..., x_n)$. So C^* is a two-sided inverse of C.

Solution to Exercise 6.6.34

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Definition 6.3.26 (Conjugate transpose), Definition 6.1.8 (Dot product), Definition 6.6.26 (Self-adjoint operator)
Hint 1. The second row is i times the first, so A has rank 1 and every subspace in question is a line.
Hint 2. $A^* = \begin{pmatrix} 1 & -i \\ -i & -1 \end{pmatrix}$. Remember to conjugate the second vector in each dot product.
Sketch. (a) $\ker A = \operatorname{span}((-i, 1))$, $\operatorname{im} A = \operatorname{span}((1, i))$, $\ker A^* = \operatorname{span}((i, 1))$, $\operatorname{im} A^* = \operatorname{span}((1, -i))$. Then $(i, 1) \cdot (1, i) = 0$ and $(-i, 1) \cdot (1, -i) = 0$, and each pair consists of two lines in $\mathbb{C}^2$, so they are orthogonal complements. (b) $(-i, 1) \cdot (1, i) = -2i$. (c) No, $A^* \neq A$.

(a) The second row of A is i times the first, and the second column is i times the first, so $\operatorname{rank} A = 1$. The kernel is given by $x_1 + ix_2 = 0$, so $\ker A = \operatorname{span}((-i, 1))$, and $\operatorname{im} A = \operatorname{span}((1, i))$. Next, $A^* = \begin{pmatrix} 1 & -i \\ -i & -1 \end{pmatrix}$, again of rank 1: $\ker A^*$ is given by $x_1 - ix_2 = 0$, so $\ker A^* = \operatorname{span}((i, 1))$, and $\operatorname{im} A^* = \operatorname{span}((1, -i))$. Now

$$(i, 1) \cdot (1, i) = i + \bar{i} = 0, \quad (-i, 1) \cdot (1, -i) = -i + \overline{-i} = 0.$$

So $\ker A^* \perp \operatorname{im} A$ and $\ker A \perp \operatorname{im} A^*$. In each case both are lines in $\mathbb{C}^2$, and the perp of a line in $\mathbb{C}^2$ is a line (Corollary 6.4.25), so $\ker A^* = (\operatorname{im} A)^\perp$ and $\ker A = (\operatorname{im} A^*)^\perp$, which are (a) and (b) of Theorem 6.6.21. Taking perps once more gives (c) and (d).

(b) $\operatorname{im} A^{\mathsf{T}} = \operatorname{im} A = \operatorname{span}((1, i))$, and $(-i, 1) \cdot (1, i) = -i + \bar{i} = -2i \neq 0$.

(c) No: $A^* = \begin{pmatrix} 1 & -i \\ -i & -1 \end{pmatrix} \neq A$. A complex symmetric matrix need not be Hermitian, and (b) shows what goes wrong: the orthogonal complement of the kernel is spanned by the conjugated rows, not by the rows.

Solution to Exercise 6.6.35

Uses. Proposition 6.6.18 (Properties of the adjoint), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents)
Hint 1. Take the adjoint of both sides of $T^*T = T$.
Hint 2. You should find that T is self-adjoint. Then $T^2 = T^*T$.
Sketch. $T^* = (T^*T)^* = T^*T^{**} = T^*T = T$, so T is self-adjoint, and $T^2 = T^*T = T$. By Corollary 6.6.29, $T = \operatorname{Pr}_{\operatorname{im} T}$.

By (c) and (d) of Proposition 6.6.18,

$$T^* = (T^*T)^* = T^*(T^*)^* = T^*T = T.$$

So T is self-adjoint, and then $T^2 = T^*T = T$. By Corollary 6.6.29, T is the orthogonal projection onto $\operatorname{im} T$.

Solution to Exercise 6.6.36

Uses. Proposition 6.6.18 (Properties of the adjoint), Corollary 6.6.28 (Self-adjointness in an orthonormal basis)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Compute each adjoint with Proposition 6.6.18 and compare with the original operator.
Hint 2. For (b), $(ST)^* = TS$. Look for two symmetric 2×2 matrices that do not commute.
Sketch. (a) True. (b) False in general: $(ST)^* = TS$, and $S = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $T = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ give $ST = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$; ST is self-adjoint exactly when $ST = TS$. (c) True: $(STS)^* = STS$. (d) False unless $T = 0$: $(iT)^* = -iT$. (e) True: $\left(T^{-1}\right)^* = (T^*)^{-1} = T^{-1}$.

(a) True: $(S + T)^* = S^* + T^* = S + T$ by Proposition 6.6.18(a).

(b) False in general. By Proposition 6.6.18(d), $(ST)^* = T^*S^* = TS$, so ST is self-adjoint exactly when $ST = TS$. On $\mathbb{R}^2$ with the dot product, $S = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $T = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ are symmetric, but $ST = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ is not, so $T_S T_T$ is not self-adjoint (Corollary 6.6.28).

(c) True: $(STS)^* = S^*T^*S^* = STS$, applying Proposition 6.6.18(d) twice.

(d) False unless $T = 0$. By Proposition 6.6.18(b), $(iT)^* = \bar{i}T^* = -iT$, which equals iT only if $2iT = 0$, that is, $T = 0$. So the self-adjoint operators on a complex space are closed under addition and real scalar multiples, but they do not form a complex subspace of $\mathrm{L}(V)$.

(e) True: by Proposition 6.6.18(f), $\left(T^{-1}\right)^* = (T^*)^{-1} = T^{-1}$.

Solution to Exercise 6.6.37

Uses. Proposition 6.6.18 (Properties of the adjoint), Definition 6.6.26 (Self-adjoint operator), Example 6.6.10 (The adjoint of a matrix)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Imitate $x = (z + \bar{z})/2$ and $y = (z - \bar{z})/(2i)$.
Hint 2. For uniqueness, if $A + iB = A' + iB'$, then $C = A - A'$ is self-adjoint and also i times a self-adjoint operator. Compute C^* in two ways.
Sketch. (a) $A = (T + T^*)/2$ and $B = (T - T^*)/(2i)$ are self-adjoint with $A + iB = T$. If also $T = A' + iB'$, then $C = A - A' = i(B' - B)$ satisfies $C^* = C$ and $C^* = -i(B' - B) = -C$, so $C = 0$. (b) $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 0 & -i \\ i & 1 \end{smallmatrix}\right)$.

(a) Let $A = (T + T^*)/2$ and $B = (T - T^*)/(2i)$. By Proposition 6.6.18, $A^* = (T^* + T)/2 = A$, and since $\overline{1/(2i)} = -1/(2i)$,

$$B^* = -\frac{1}{2i}(T^* - T) = \frac{1}{2i}(T - T^*) = B.$$

Also $A + iB = (T + T^*)/2 + (T - T^*)/2 = T$. For uniqueness, suppose $T = A' + iB'$ with A', B' self-adjoint, and let $C = A - A' = i(B' - B)$. Then C is self-adjoint, as a difference of self-adjoint operators, and also $C^* = \bar{i}(B' - B)^* = -i(B' - B) = -C$. So $C = -C$, hence $C = 0$, $A = A'$, and $B' - B = -iC = 0$.

(b) By Example 6.6.10 we may compute with matrices. Here $M^* = \left(\begin{smallmatrix} 1 & 0 \\ 2 & -i \end{smallmatrix}\right)$, so

$$A = \frac{1}{2}(M + M^*) = \frac{1}{2}\begin{pmatrix} 2 & 2 \\ 2 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix},$$

$$B = \frac{1}{2i}(M - M^*) = \frac{1}{2i}\begin{pmatrix} 0 & 2 \\ -2 & 2i \end{pmatrix} = \begin{pmatrix} 0 & -i \\ i & 1 \end{pmatrix}.$$

Both are Hermitian, and $A + iB = \left(\begin{smallmatrix} 1 & 1+1 \\ 1-1 & i \end{smallmatrix}\right) = M$.

Solution to Exercise 6.6.38

Uses. Definition 6.6.8 (Adjoint), Definition 6.4.22 (Orthogonal complement), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.4.26 (The double complement)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. Take $\mathbf{w} \in U^\perp$ and $\mathbf{u} \in U$, and move T^* across in $\langle T^*\mathbf{w}, \mathbf{u}\rangle$.
Hint 2. For the converse, apply the first direction to T^* and the subspace $U^\perp$.
Sketch. If $T(U) \subseteq U$, then for $\mathbf{w} \in U^\perp$ and $\mathbf{u} \in U$, $\langle T^*\mathbf{w}, \mathbf{u}\rangle = \langle \mathbf{w}, T\mathbf{u}\rangle = 0$, so $T^*\mathbf{w} \in U^\perp$. Conversely apply this to T^* and $U^\perp$, using $(T^*)^* = T$ and $\left(U^\perp\right)^\perp = U$.

Suppose T maps U into U. Let $\mathbf{w} \in U^\perp$ and $\mathbf{u} \in U$. Then $T\mathbf{u} \in U$, so

$$\langle T^*\mathbf{w}, \mathbf{u}\rangle = \langle \mathbf{w}, T\mathbf{u}\rangle = 0.$$

As $\mathbf{u} \in U$ was arbitrary, $T^*\mathbf{w} \in U^\perp$. Conversely, suppose T^* maps $U^\perp$ into $U^\perp$. Applying what we just proved to the operator T^* and the subspace $U^\perp$, the operator $(T^*)^* = T$ (Proposition 6.6.18(c)) maps $\left(U^\perp\right)^\perp$ into itself, and $\left(U^\perp\right)^\perp = U$ by Theorem 6.4.26. If T is self-adjoint and maps U into U, then $T^* = T$ maps $U^\perp$ into $U^\perp$. This is the step that lets the spectral theorem (Section 8.2) split V into perpendicular pieces one at a time.

Solution to Exercise 6.6.39

Uses. Proposition 6.6.9 (Adjoints are unique and linear), Theorem 6.6.15 (Existence of adjoints), Proposition 6.6.18 (Properties of the adjoint)
Hint 1. Integrate by parts: $\int_0^{2\pi} f'g = [fg]_0^{2\pi} - \int_0^{2\pi} fg'$. What is $[fg]_0^{2\pi}$ for these functions?

Hint 2. For (c), normalizing the basis divides $\cos kt$ and $\sin kt$ by the same number, so the 2×2 blocks of the matrix do not change. Then use Theorem 6.6.15(b).
Sketch. (a) D sends each spanning function into V. Every $f \in V$ satisfies $f(2\pi) = f(0)$, so integration by parts gives $\langle Df, g\rangle = -\langle f, Dg\rangle$, that is, $D^* = -D$. (b) $\langle Df, f\rangle = -\langle f, Df\rangle = -\langle Df, f\rangle$. (c) The matrix is block diagonal with blocks (0), $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$, $\begin{pmatrix} 0 & 2 \\ -2 & 0 \end{pmatrix}$; it stays the same in the orthonormal basis obtained by normalizing, and it is antisymmetric.

(a) $D1 = 0$, $D\cos kt = -k\sin kt$, and $D\sin kt = k\cos kt$, so D maps the spanning functions, and hence all of V, into V. Every $f \in V$ is 2π-periodic, so $f(2\pi) = f(0)$. For $f, g \in V$, integration by parts gives

$$\langle Df, g\rangle = \int_0^{2\pi} f'(t)g(t)\,dt = f(2\pi)g(2\pi) - f(0)g(0) - \int_0^{2\pi} f(t)g'(t)\,dt = \langle f, -Dg\rangle.$$

By Proposition 6.6.9, $D^* = -D$.

(b) For $f \in V$, $\langle Df, f\rangle = \langle f, -Df\rangle = -\langle f, Df\rangle = -\langle Df, f\rangle$, by symmetry of a real inner product. So $\langle Df, f\rangle = 0$. Since $D\sin t = \cos t \neq 0$, $D \neq 0$, so $D^* = -D \neq D$, and D is not self-adjoint.

(c) From the formulas in (a), the matrix of D in the basis $1, \cos t, \sin t, \cos 2t, \sin 2t$ is

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & -2 & 0 \end{pmatrix}.$$

The basis is orthogonal, with $\|1\| = \sqrt{2\pi}$ and $\|\cos kt\| = \|\sin kt\| = \sqrt{\pi}$. Dividing each basis function by its norm rescales $\cos kt$ and $\sin kt$ by the same factor, so in the resulting orthonormal basis the matrix is unchanged. It is antisymmetric, so by Theorem 6.6.15(b) the matrix of D^* is its transpose, which is its negative: $D^* = -D$ again.

Solution to Exercise 6.6.40

Uses. Exercise 6.1.51, Corollary 6.1.38 (Linear maps are determined by inner products), Definition 6.6.8 (Adjoint), Theorem 6.3.29 (Orthonormal columns), Example 6.6.10 (The adjoint of a matrix)
Techniques. Proving TFAE (Technique 2.7.1), Move an operator across the inner product (Technique 6.6.20)
Hint 1. (i) $\Rightarrow$ (ii) is polarization, Exercise 6.1.51.
Hint 2. For (ii) $\Rightarrow$ (iii), move T out of the second slot: $\langle T\mathbf{v}, T\mathbf{w}\rangle = \langle T^*T\mathbf{v}, \mathbf{w}\rangle$. Then use Corollary 6.1.38.
Sketch. (i) $\Rightarrow$ (ii) by polarization. (ii) $\Rightarrow$ (iii): $\langle T^*T\mathbf{v}, \mathbf{w}\rangle = \langle T\mathbf{v}, T\mathbf{w}\rangle = \langle \mathbf{v}, \mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w}$, so $T^*T = \mathrm{id}_V$. (iii) $\Rightarrow$ (i): $\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \|\mathbf{v}\|^2$. For T_A, (iii) is $A^*A = I_n$: the columns of A are orthonormal.

We prove (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (i). The first implication is Exercise 6.1.51. For the second, the conjugated form of the defining identity, $\langle \mathbf{x}, T\mathbf{w}\rangle = \langle T^*\mathbf{x}, \mathbf{w}\rangle$, with $\mathbf{x} = T\mathbf{v}$ gives

$$\langle T^*T\mathbf{v}, \mathbf{w}\rangle = \langle T\mathbf{v}, T\mathbf{w}\rangle = \langle \mathbf{v}, \mathbf{w}\rangle = \langle \mathrm{id}_V\mathbf{v}, \mathbf{w}\rangle$$

for all $\mathbf{v}, \mathbf{w} \in V$, so $T^*T = \mathrm{id}_V$ by Corollary 6.1.38. For the third, $\|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, \mathbf{v}\rangle = \|\mathbf{v}\|^2$.

For $T = T_A$, $T^*T = T_{A^*A}$ (Example 6.6.10), so (iii) says $A^*A = I_n$, that is, the columns of A are orthonormal (Theorem 6.3.29). Such maps are studied in Section 8.4.

Solution to Exercise 6.6.41

Uses. Definition 2.5.12 (Invertible), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.6.18 (Properties of the adjoint), Proposition 2.5.4 (Left inverses give uniqueness), Theorem 4.2.11 (Rank–nullity)
Hint 1. $T^*T = \mathrm{id}_V$ says that T^* is a left inverse. Try $T : \mathbb{R} \to \mathbb{R}^2$, $Tx = (x, 0)$.
Hint 2. For (b), check that $P = TT^*$ satisfies $P^2 = P = P^*$, and compare $\mathrm{im}\,P$ with $\mathrm{im}\,T$.
Hint 3. For (c), T is injective. What does rank–nullity say when $\dim V = \dim W$?
Sketch. (a) A left inverse need not be a right inverse; for $Tx = (x, 0)$, $T^*(y_1, y_2) = y_1$, $T^*T = \mathrm{id}_{\mathbb{R}}$, but $TT^*(y_1, y_2) = (y_1, 0)$. (b) $(TT^*)^2 = T(T^*T)T^* = TT^*$ and $(TT^*)^* = TT^*$, so TT^* is the orthogonal projection onto its image, which is $\mathrm{im}\,T$ because $T = (TT^*)T$. (c) T is injective, so if $\dim V = \dim W$ it is surjective, and $TT^* = \mathrm{Pr}_W = \mathrm{id}_W$.

(a) The equation $T^*T = \mathrm{id}_V$ only says that T^* is a left inverse of T; an inverse must also be a right inverse (Definition 2.5.12). Let $T : \mathbb{R} \to \mathbb{R}^2$, $Tx = (x, 0)$, with dot products. Then $\langle Tx, \mathbf{y}\rangle = xy_1 = \langle x, y_1\rangle$, so $T^*(y_1, y_2) = y_1$ and $T^*Tx = x$. But $TT^*(y_1, y_2) = (y_1, 0)$, which is not $\mathrm{id}_{\mathbb{R}^2}$.

(b) Let $P = TT^*$. By Proposition 6.6.18,

$$P^2 = T(T^*T)T^* = TT^* = P, \quad P^* = (T^*)^*T^* = TT^* = P.$$

By Corollary 6.6.29, $P = \mathrm{Pr}_{\mathrm{im}\, P}$. Clearly $\mathrm{im}\, P \subseteq \mathrm{im}\, T$, and $T = T(T^*T) = PT$ shows $\mathrm{im}\, T \subseteq \mathrm{im}\, P$. So $TT^* = \mathrm{Pr}_{\mathrm{im}\, T}$.

(c) T has a left inverse, so it is injective (Proposition 2.5.4). By Theorem 4.2.11, $\mathrm{rank}\, T = \dim V = \dim W$, so $\mathrm{im}\, T = W$, and by (b), $TT^* = \mathrm{Pr}_W = \mathrm{id}_W$.

Solution to Exercise 6.6.42

Uses. Definition 6.6.8 (Adjoint), Theorem 6.2.1 (Cauchy–Schwarz inequality), Notation 6.1.1 (Real and complex scalars), Proposition 6.6.18 (Properties of the adjoint)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. For (a), move T across and apply Cauchy–Schwarz to $\langle \mathbf{v}, T^*\mathbf{w}\rangle$.
Hint 2. For (b), write $\|T^*\mathbf{w}\|^2 = \langle TT^*\mathbf{w}, \mathbf{w}\rangle$ and bound it by Cauchy–Schwarz and the hypothesis on T.
Sketch. (a) $\mathrm{Re}\langle T\mathbf{v}, \mathbf{w}\rangle = \mathrm{Re}\langle \mathbf{v}, T^*\mathbf{w}\rangle \le |\langle \mathbf{v}, T^*\mathbf{w}\rangle| \le \|T^*\mathbf{w}\|$, with equality at $\mathbf{v} = T^*\mathbf{w}/\|T^*\mathbf{w}\|$. (b) $\|T^*\mathbf{w}\|^2 = \langle TT^*\mathbf{w}, \mathbf{w}\rangle \le \|TT^*\mathbf{w}\|\|\mathbf{w}\| \le c\|T^*\mathbf{w}\|\|\mathbf{w}\|$; divide by $\|T^*\mathbf{w}\|$. The converse is the same argument for T^*, whose adjoint is T.

(a) For a unit vector $\mathbf{v}$, by $|\mathrm{Re}\, z| \le |z|$ (Notation 6.1.1) and Cauchy–Schwarz (Theorem 6.2.1),

$$\mathrm{Re}\langle T\mathbf{v}, \mathbf{w}\rangle = \mathrm{Re}\langle \mathbf{v}, T^*\mathbf{w}\rangle \le |\langle \mathbf{v}, T^*\mathbf{w}\rangle| \le \|\mathbf{v}\|\|T^*\mathbf{w}\| = \|T^*\mathbf{w}\|.$$

If $T^*\mathbf{w} \neq \mathbf{0}$ and $\mathbf{v} = T^*\mathbf{w}/\|T^*\mathbf{w}\|$, then $\langle \mathbf{v}, T^*\mathbf{w}\rangle = \|T^*\mathbf{w}\|^2/\|T^*\mathbf{w}\| = \|T^*\mathbf{w}\|$, a real number, so equality holds.

(b) Suppose $\|T\mathbf{v}\| \le c\|\mathbf{v}\|$ for all $\mathbf{v}$, and let $\mathbf{w} \in W$. By the defining identity with $\mathbf{v} = T^*\mathbf{w}$, Cauchy–Schwarz, and the hypothesis,

$$\|T^*\mathbf{w}\|^2 = \langle TT^*\mathbf{w}, \mathbf{w}\rangle \le \|TT^*\mathbf{w}\|\|\mathbf{w}\| \le c\|T^*\mathbf{w}\|\|\mathbf{w}\|.$$

If $T^*\mathbf{w} \neq \mathbf{0}$, dividing by $\|T^*\mathbf{w}\|$ gives $\|T^*\mathbf{w}\| \le c\|\mathbf{w}\|$; if $T^*\mathbf{w} = \mathbf{0}$ this is clear. Conversely, T^* has adjoint T (Proposition 6.6.18(c)), so the same argument with the roles of T and T^* exchanged proves the other implication.

Solution to Exercise 6.6.43

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Definition 6.3.8 (Vectors orthogonal to a set), Theorem 4.2.11 (Rank–nullity), Example 6.6.10 (The adjoint of a matrix)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Every vector of $\mathrm{im}\, T$ is orthogonal to $\mathrm{im}\, T^*$ exactly when $\mathrm{im}\, T \subseteq (\mathrm{im}\, T^*)^\perp$. Which subspace is $(\mathrm{im}\, T^*)^\perp$?
Hint 2. For (b), $\mathrm{im}\, T \subseteq \ker T$; apply rank–nullity.
Sketch. (a) The condition says $\mathrm{im}\, T \subseteq (\mathrm{im}\, T^*)^\perp = \ker T$ (Theorem 6.6.21(b)), that is, $T(T\mathbf{v}) = \mathbf{0}$ for all $\mathbf{v}$. (b) $\mathrm{rank}\, T \le \dim \ker T = \dim V - \mathrm{rank}\, T$. (c) T_N with N sending $\mathbf{e}_3 \mapsto \mathbf{e}_1$ and killing $\mathbf{e}_1, \mathbf{e}_2$: $\mathrm{im}\, T_N = \mathrm{span}(\mathbf{e}_1)$ and $\mathrm{im}\, T_N^* = \mathrm{span}(\mathbf{e}_3)$.

(a) Every vector of $\mathrm{im}\, T$ is orthogonal to every vector of $\mathrm{im}\, T^*$ if and only if $\mathrm{im}\, T \subseteq (\mathrm{im}\, T^*)^\perp$, and $(\mathrm{im}\, T^*)^\perp = \ker T$ by Theorem 6.6.21(b). Now $\mathrm{im}\, T \subseteq \ker T$ means $T(T\mathbf{v}) = \mathbf{0}$ for all $\mathbf{v}$, that is, $T^2 = 0$.

(b) If $T^2 = 0$, then $\mathrm{im}\, T \subseteq \ker T$, so by Theorem 4.2.11, $\mathrm{rank}\, T \le \dim \ker T = \dim V - \mathrm{rank}\, T$, and $2\,\mathrm{rank}\, T \le \dim V$.

(c) Let $N = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$, so that $N\mathbf{e}_3 = \mathbf{e}_1$ and $N\mathbf{e}_1 = N\mathbf{e}_2 = \mathbf{0}$. Then $N^2\mathbf{e}_3 = N\mathbf{e}_1 = \mathbf{0}$, so $N^2 = 0$, while $N \neq 0$. Here $\mathrm{im}\, T_N = \mathrm{span}(\mathbf{e}_1)$, and $T_N^* = T_{N^\mathsf{T}}$ (Example 6.6.10) has $N^\mathsf{T}\mathbf{e}_1 = \mathbf{e}_3$, so $\mathrm{im}\, T_N^* = \mathrm{span}(\mathbf{e}_3)$, which is orthogonal to $\mathbf{e}_1$. Also $\mathrm{rank}\, N = 1 \le 3/2$.

Solution to Exercise 6.6.44

Uses. Proposition 6.6.23 (T^*T and T), Corollary 6.6.22 (T and T^* have the same rank), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.6.21 (Kernels and images of adjoints), Definition 6.6.8 (Adjoint)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. For (a), apply Proposition 6.6.23 to T and to T^*.
Hint 2. For (b), $\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle$ and $\|T^*\mathbf{v}\|^2 = \langle TT^*\mathbf{v}, \mathbf{v}\rangle$. For the images, use Theorem 6.6.21(d) and (c).
Sketch. (a) $\operatorname{rank}(T^*T) = \operatorname{rank} T$, and applied to T^* (whose adjoint is T), $\operatorname{rank}(TT^*) = \operatorname{rank} T^* = \operatorname{rank} T$. (b) $\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \langle TT^*\mathbf{v}, \mathbf{v}\rangle = \|T^*\mathbf{v}\|^2$, so the kernels agree, and $\operatorname{im} T = (\ker T^*)^\perp = (\ker T)^\perp = \operatorname{im} T^*$. (c) $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$.

(a) By Proposition 6.6.23(b), $\operatorname{rank}(T^*T) = \operatorname{rank} T$. Applying the same result to T^*, whose adjoint is T (Proposition 6.6.18(c)), gives $\operatorname{rank}(TT^*) = \operatorname{rank} T^*$, which is $\operatorname{rank} T$ by Corollary 6.6.22.

(b) By the defining identity of T^*, and of $(T^*)^* = T$,

$$\|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \langle TT^*\mathbf{v}, \mathbf{v}\rangle = \langle T^*\mathbf{v}, T^*\mathbf{v}\rangle = \|T^*\mathbf{v}\|^2.$$

So $T\mathbf{v} = \mathbf{0}$ if and only if $T^*\mathbf{v} = \mathbf{0}$: $\ker T = \ker T^*$. By (d) and (c) of Theorem 6.6.21, $\operatorname{im} T = (\ker T^*)^\perp = (\ker T)^\perp = \operatorname{im} T^*$.

(c) For $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $\ker N = \operatorname{span}(\mathbf{e}_1)$, while $\ker N^{\mathsf{T}} = \operatorname{span}(\mathbf{e}_2)$. Operators with $T^*T = TT^*$ are called normal; they are the subject of Section 8.1.

Solution to Exercise 6.6.45

Uses. Definition 6.6.26 (Self-adjoint operator), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.6.18 (Properties of the adjoint)
Hint 1. Substitute $s = 1 - t$ in $\int_0^1 p(1-t)q(t)\,dt$. For the second inner product, test $p = x$ and $q = 1$.
Hint 2. $S^2 = \mathrm{id}$. Check $P^2 = P = P^*$ for $P = (\mathrm{id} + S)/2$, and identify $\operatorname{im} P$.
Sketch. (a) The substitution $s = 1 - t$ maps $[0,1]$ to itself, giving $\langle Sp, q\rangle = \langle p, Sq\rangle$. On $[0,2]$, $p = x$, $q = 1$ give $\langle Sp, q\rangle = 0$ but $\langle p, Sq\rangle = 2$. (b) $S^2 = \mathrm{id}$, so $P^2 = P$, and $P^* = P$. $\operatorname{im} P = \{p \mid Sp = p\} = E$, with basis $1, x^2 - x$.

(a) For the first inner product, substituting $s = 1 - t$,

$$\langle Sp, q\rangle = \int_0^1 p(1-t)q(t)\,dt = \int_0^1 p(s)q(1-s)\,ds = \langle p, Sq\rangle.$$

For the second, take $p = x$ and $q = 1$: $\langle Sp, q\rangle = \int_0^2 (1-t)\,dt = 2 - 2 = 0$, while $\langle p, Sq\rangle = \int_0^2 t\,dt = 2$. So S is not self-adjoint for $\int_0^2$; the substitution maps $[0,2]$ to $[-1,1]$, not to itself.

(b) $S^2p(x) = p(1-(1-x)) = p(x)$, so $S^2 = \mathrm{id}$. Let $P = (\mathrm{id} + S)/2$. Then $P^2 = \left(\mathrm{id} + 2S + S^2\right)/4 = (\mathrm{id} + S)/2 = P$, and $P^* = (\mathrm{id} + S^*)/2 = P$ by (a) and Proposition 6.6.18. By Corollary 6.6.29, $P = \mathrm{Pr}_{\operatorname{im} P}$. If $Sp = p$, then $Pp = p$, so $E \subseteq \operatorname{im} P$; conversely $SP = \left(S + S^2\right)/2 = P$, so S fixes every vector of $\operatorname{im} P$. Hence $\operatorname{im} P = E$. For $p = a + bx + cx^2$,

$$p(1-x) = (a + b + c) - (b + 2c)x + cx^2,$$

which equals $p(x)$ if and only if $b = -c$. So $E = \left\{a + c\left(x^2 - x\right)\right\}$, with basis $1, x^2 - x$, and $\dim E = 2$.

Solution to Exercise 6.6.46

Uses. Proposition 6.1.4 (Sesquilinearity), Definition 6.3.28 (Gram matrix), Proposition 6.3.30 (Gram matrices detect independence), Theorem 2.3.9 (The matrix of a map computes the map), Proposition 6.3.27 (Properties of the conjugate transpose), Theorem 6.3.22 (Parseval's identity), Example 6.6.16 (The adjoint of differentiation)
Techniques. Translate between maps and matrices (Technique 2.3.27), Gram matrices (Technique 6.3.31)
Hint 1. For (a), expand $\left\langle \sum_j x_j \mathbf{b}_j, \sum_i y_i \mathbf{b}_i \right\rangle$ by sesquilinearity, as in Proposition 6.1.22(a).
Hint 2. For (b), with $A = [T]_{\mathcal{B}}$ and $C = [T^*]_{\mathcal{B}}$, (a) turns the defining identity into $\mathbf{y}^*GA\mathbf{x} = \mathbf{y}^*C^*G\mathbf{x}$ for all $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$. Conclude $GA = C^*G$; is G invertible?
Sketch. (a) $\langle \mathbf{v}, \mathbf{w}\rangle = \sum_{i,j} \overline{y_i} x_j \langle \mathbf{b}_j, \mathbf{b}_i\rangle = \mathbf{y}^*G\mathbf{x}$. (b) The defining identity reads $\mathbf{y}^*GA\mathbf{x} = \mathbf{y}^*C^*G\mathbf{x}$ for all $\mathbf{x}, \mathbf{y}$; taking standard basis vectors gives $GA = C^*G$. G is invertible (Gram matrix of an independent list) and Hermitian, so $C = G^{-1}A^*G$. (c) $G^{-1}\left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)G = \left(\begin{smallmatrix} -6 & -3 \\ 12 & 6 \end{smallmatrix}\right)$. (d) The formula $\langle \mathbf{v}, \mathbf{w}\rangle = [\mathbf{v}]_{\mathcal{B}} \cdot [\mathbf{w}]_{\mathcal{B}}$ is Parseval's identity, valid only for orthonormal $\mathcal{B}$; the claim holds whenever G is a scalar multiple of I_n.

(a) Write $\mathbf{x} = [\mathbf{v}]_{\mathcal{B}}$ and $\mathbf{y} = [\mathbf{w}]_{\mathcal{B}}$. By linearity in the first slot and Proposition 6.1.4,

$$\langle \mathbf{v}, \mathbf{w} \rangle = \left\langle \sum_j x_j \mathbf{b}_j, \sum_i y_i \mathbf{b}_i \right\rangle = \sum_{i,j} \overline{y_i} \langle \mathbf{b}_j, \mathbf{b}_i \rangle x_j = \sum_i \overline{y_i} \left(\sum_j g_{ij} x_j \right) = \mathbf{y}^* G \mathbf{x}.$$

(b) Let $A = [T]_{\mathcal{B}}$ and $C = [T^*]_{\mathcal{B}}$. For $\mathbf{v}, \mathbf{w} \in V$ with coordinates $\mathbf{x}, \mathbf{y}$, Theorem 2.3.9 gives $[T\mathbf{v}]_{\mathcal{B}} = A\mathbf{x}$ and $[T^*\mathbf{w}]_{\mathcal{B}} = C\mathbf{y}$, so by (a) and Proposition 6.3.27,

$$\langle T\mathbf{v}, \mathbf{w} \rangle = \mathbf{y}^* G A \mathbf{x}, \quad \langle \mathbf{v}, T^*\mathbf{w} \rangle = (C\mathbf{y})^* G \mathbf{x} = \mathbf{y}^* C^* G \mathbf{x}.$$

These agree for all $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$, since coordinates range over all of $\mathbb{F}^n$. Taking $\mathbf{x} = \mathbf{e}_j$ and $\mathbf{y} = \mathbf{e}_i$ shows that GA and C^*G have the same (i, j) entry, so $GA = C^*G$. The Gram matrix of the independent list $\mathcal{B}$ is invertible (Proposition 6.3.30), and $G^* = G$, so $C^* = GAG^{-1}$ and

$$C = \left(GAG^{-1}\right)^* = \left(G^{-1}\right)^* A^* G^* = G^{-1} A^* G,$$

using Proposition 6.3.27 and $\left(G^{-1}\right)^* = (G^*)^{-1} = G^{-1}$.

(c) For $\mathcal{B} = 1, x$ with $\langle p, q \rangle = \int_0^1 pq$, $G = \begin{pmatrix} 1 & 1/2 \\ 1/2 & 1/3 \end{pmatrix}$, whose determinant is $1/12$, so $G^{-1} = \begin{pmatrix} 4 & -6 \\ -6 & 12 \end{pmatrix}$. With $[D]_{\mathcal{B}}^* = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$,

$$G^{-1} \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} G = \begin{pmatrix} -6 & 0 \\ 12 & 0 \end{pmatrix} \begin{pmatrix} 1 & 1/2 \\ 1/2 & 1/3 \end{pmatrix} = \begin{pmatrix} -6 & -3 \\ 12 & 6 \end{pmatrix},$$

in agreement with Example 6.6.16.

(d) The identity $\langle \mathbf{v}, \mathbf{w} \rangle = [\mathbf{v}]_{\mathcal{B}} \cdot [\mathbf{w}]_{\mathcal{B}}$ is Parseval's identity (Theorem 6.3.22), which needs $\mathcal{B}$ orthonormal. By (a) it holds exactly when $G = I_n$. If $G = cI_n$ for some $c > 0$, that is, the basis vectors are orthogonal and of equal length, then (b) gives $[T^*]_{\mathcal{B}} = A^*$ as well. For other bases the claim can fail, as in (c).

Solution to Exercise 6.6.47

Uses. Definition 4.4.4 (Direct sum), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.6.21 (Kernels and images of adjoints), Theorem 6.4.26 (The double complement), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents)
Hint 1. Any $Q \in \mathrm{L}(V)$ with $Q^2 = Q$ satisfies $V = \operatorname{im} Q \oplus \ker Q$ and is the projection onto $\operatorname{im} Q$ along $\ker Q$: split $\mathbf{v} = Q\mathbf{v} + (\mathbf{v} - Q\mathbf{v})$.
Hint 2. Apply this to $Q = P^*$, using $(P^*)^2 = \left(P^2\right)^*$ and Theorem 6.6.21 for $\operatorname{im} P^*$ and $\ker P^*$.
Sketch. (a) is immediate from uniqueness of the decomposition. (b) An idempotent Q is the projection onto $\operatorname{im} Q$ along $\ker Q$, and $V = \operatorname{im} Q \oplus \ker Q$. Now $(P^*)^2 = \left(P^2\right)^* = P^*$, $\operatorname{im} P^* = (\ker P)^\perp = X^\perp$, and $\ker P^* = (\operatorname{im} P)^\perp = U^\perp$. (c) P is orthogonal iff $P = P^*$ (Corollary 6.6.29), iff they have the same image and kernel, iff $U = X^\perp$, iff $X = U^\perp$.

(a) For $\mathbf{u} \in U$, the decomposition of $\mathbf{u}$ is $\mathbf{u} + \mathbf{0}$, so $P\mathbf{u} = \mathbf{u}$. Hence $P(P\mathbf{v}) = P\mathbf{v}$ for every $\mathbf{v}$, since $P\mathbf{v} \in U$, and $\operatorname{im} P = U$. Finally $P(\mathbf{u} + \mathbf{x}) = \mathbf{0}$ exactly when $\mathbf{u} = \mathbf{0}$, so $\ker P = X$.

(b) First a general fact. Let $Q \in \mathrm{L}(V)$ with $Q^2 = Q$. Every $\mathbf{v}$ is $Q\mathbf{v} + (\mathbf{v} - Q\mathbf{v})$, with $Q\mathbf{v} \in \operatorname{im} Q$ and $Q(\mathbf{v} - Q\mathbf{v}) = Q\mathbf{v} - Q^2\mathbf{v} = \mathbf{0}$. If $\mathbf{y} \in \operatorname{im} Q \cap \ker Q$, say $\mathbf{y} = Q\mathbf{z}$, then $\mathbf{0} = Q\mathbf{y} = Q^2\mathbf{z} = Q\mathbf{z} = \mathbf{y}$. So $V = \operatorname{im} Q \oplus \ker Q$, and Q sends $\mathbf{v} = Q\mathbf{v} + (\mathbf{v} - Q\mathbf{v})$ to its component $Q\mathbf{v}$ in $\operatorname{im} Q$: Q is the projection onto $\operatorname{im} Q$ along $\ker Q$.

Apply this to $Q = P^*$. By Proposition 6.6.18(d), $(P^*)^2 = \left(P^2\right)^* = P^*$. By Theorem 6.6.21 and (a), $\operatorname{im} P^* = (\ker P)^\perp = X^\perp$ and $\ker P^* = (\operatorname{im} P)^\perp = U^\perp$. So $V = X^\perp \oplus U^\perp$, and P^* is the projection onto $X^\perp$ along $U^\perp$.

(c) Since $P^2 = P$, Corollary 6.6.29 says that P is an orthogonal projection if and only if $P = P^*$. A projection along a complement is determined by its image and kernel (by the general fact in (b)), so $P = P^*$ if and only if $U = X^\perp$ and $X = U^\perp$. These two conditions are equivalent to each other by Theorem 6.4.26: if $X = U^\perp$, then $X^\perp = \left(U^\perp\right)^\perp = U$, and conversely. So P is an orthogonal projection if and only if $X = U^\perp$.

Solution to Exercise 6.6.48

Uses. Proposition 6.1.22 (Inner products on $\mathbb{F}^n$), Definition 6.6.26 (Self-adjoint operator)
Techniques. Undetermined coefficients (Technique 3.1.9)
Hint 1. For $\langle \mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}} M\mathbf{x}$, show that T_A is self-adjoint if and only if MA is symmetric.
Hint 2. Write $M = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$. For (a), solve for the symmetry condition and then make M positive definite. For (b), the symmetry condition forces $c = -a$; why is that impossible?
Sketch. $\langle A\mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}} MA\mathbf{x}$ and $\langle \mathbf{x}, A\mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}} A^{\mathsf{T}} M\mathbf{x}$, so self-adjointness means $MA = A^{\mathsf{T}} M = (MA)^{\mathsf{T}}$. (a) $M = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$ gives $MA = \begin{pmatrix} a & a+2b \\ b & b+2c \end{pmatrix}$, symmetric iff $b = -a$; take $M = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$. (b) $MJ = \begin{pmatrix} b & -a \\ c & -b \end{pmatrix}$ is symmetric iff $c = -a$, but $a = \mathbf{e}_1^{\mathsf{T}} M\mathbf{e}_1 > 0$ and $c = \mathbf{e}_2^{\mathsf{T}} M\mathbf{e}_2 > 0$.

By Proposition 6.1.22, the inner products on $\mathbb{R}^2$ are exactly $\langle \mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}} M\mathbf{x}$ with $M = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$ symmetric and $\mathbf{x}^{\mathsf{T}} M\mathbf{x} > 0$ for $\mathbf{x} \neq \mathbf{0}$. For such an inner product and any $A \in \mathbb{R}^{2\times 2}$,

$$\langle A\mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}}(MA)\mathbf{x}, \quad \langle \mathbf{x}, A\mathbf{y}\rangle = (A\mathbf{y})^{\mathsf{T}} M\mathbf{x} = \mathbf{y}^{\mathsf{T}}\left(A^{\mathsf{T}} M\right)\mathbf{x}.$$

These agree for all $\mathbf{x}, \mathbf{y}$ if and only if $MA = A^{\mathsf{T}} M$ (test on standard basis vectors), that is, $MA = (MA)^{\mathsf{T}}$, since $(MA)^{\mathsf{T}} = A^{\mathsf{T}} M^{\mathsf{T}} = A^{\mathsf{T}} M$.

(a) $MA = \begin{pmatrix} a & a+2b \\ b & b+2c \end{pmatrix}$ is symmetric if and only if $a + 2b = b$, that is, $b = -a$. Take $a = 1, b = -1, c = 2$. Then $M = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$ is symmetric and $\mathbf{x}^{\mathsf{T}} M\mathbf{x} = x_1^2 - 2x_1x_2 + 2x_2^2 = (x_1 - x_2)^2 + x_2^2 > 0$ for $\mathbf{x} \neq \mathbf{0}$. So T_A is self-adjoint for

$$\langle \mathbf{x}, \mathbf{y}\rangle = x_1y_1 - x_1y_2 - x_2y_1 + 2x_2y_2.$$

For instance, $A\mathbf{e}_1 = \mathbf{e}_1$ and $A(1,1) = 2(1,1)$, and these two vectors are orthogonal for this inner product: $\langle \mathbf{e}_1, (1,1)\rangle = 1 - 1 = 0$. That is what Section 8.2 leads one to expect.

(b) $MJ = \begin{pmatrix} b & -a \\ c & -b \end{pmatrix}$ is symmetric if and only if $c = -a$. But $a = \mathbf{e}_1^{\mathsf{T}} M\mathbf{e}_1 > 0$ and $c = \mathbf{e}_2^{\mathsf{T}} M\mathbf{e}_2 > 0$, so $c \neq -a$. Hence T_J is self-adjoint for no inner product on $\mathbb{R}^2$. (By Section 8.2, a self-adjoint operator on $\mathbb{R}^2$ maps some line into itself, and a rotation by $\pi/2$ maps no line into itself.)

Solution to Exercise 6.6.49

Uses. Theorem 6.6.3 (Riesz representation theorem), Theorem 6.2.1 (Cauchy–Schwarz inequality)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. For (a), apply Cauchy–Schwarz to $p(0) = \langle p, q_n\rangle$.
Hint 2. For (c), if q worked for all polynomials, compare q with q_n for $n \geq \deg q$.
Sketch. (a) $|p(0)| = |\langle p, q_n\rangle| \leq \|p\|\|q_n\|$. (b) $p(0) = 1$ and $\|p\|^2 = \int_0^1 (1-t)^{2n}\,dt = 1/(2n+1)$. (c) Such a q would lie in P_n for $n \geq \deg q$ and represent evaluation there, so $q = q_n$ by uniqueness, and then $\|q\| \geq \sqrt{2n+1}$ for all large n.

(a) By Cauchy–Schwarz, $|p(0)| = |\langle p, q_n\rangle| \leq \|p\|\|q_n\|$. Divide by $\|p\| > 0$.

(b) For $p(t) = (1-t)^n$, $p(0) = 1$ and $\|p\|^2 = \int_0^1 (1-t)^{2n}\,dt = 1/(2n+1)$. By (a), $\|q_n\| \geq 1/\|p\| = \sqrt{2n+1}$. For $n = 1$ this gives $\|q_1\| \geq \sqrt{3}$; in fact $\|q_1\| = 2$ (Example 6.6.5).

(c) Suppose q is a polynomial with $\langle p, q\rangle = p(0)$ for all polynomials p, and let $n \geq \deg q$. Then $q \in P_n$ and $\langle p, q\rangle = p(0)$ for all $p \in P_n$, so $q = q_n$ by the uniqueness in Theorem 6.6.3. By (b), $\|q\| = \|q_n\| \geq \sqrt{2n+1}$ for every $n \geq \deg q$, which is impossible for a fixed q.

Solution to Exercise 6.6.50

Uses. Proposition 6.1.16 (Frobenius inner product), Corollary 6.1.19 ($A^*A = 0$ forces $A = 0$), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.3.27 (Properties of the conjugate transpose)
Techniques. The trace of A^*A (Technique 6.1.18)
Hint 1. It suffices to show that $B = A - A^*$ satisfies $\operatorname{tr}(B^*B) = 0$.
Hint 2. Expand $\operatorname{tr}((A^* - A)(A - A^*))$ into four traces, and express each through $\operatorname{tr}(A^*A)$ using $\operatorname{tr}(XY) = \operatorname{tr}(YX)$, $\operatorname{tr}(X^*) = \overline{\operatorname{tr} X}$, and the hypothesis.
Sketch. With $B = A - A^*$, $\operatorname{tr}(B^*B) = \operatorname{tr}(A^*A) - \operatorname{tr}\left((A^*)^2\right) - \operatorname{tr}\left(A^2\right) + \operatorname{tr}(AA^*)$. Here $\operatorname{tr}\left(A^2\right) = \operatorname{tr}(A^*A)$, which is real, so $\operatorname{tr}\left((A^*)^2\right) = \overline{\operatorname{tr}\left(A^2\right)} = \operatorname{tr}(A^*A)$, and $\operatorname{tr}(AA^*) = \operatorname{tr}(A^*A)$. So $\operatorname{tr}(B^*B) = 0$, and $B = 0$.

Let $B = A - A^*$, so that $B^* = A^* - A$ (Proposition 6.3.27(a)). Then

$$\operatorname{tr}(B^*B) = \operatorname{tr}(A^*A) - \operatorname{tr}\big((A^*)^2\big) - \operatorname{tr}\big(A^2\big) + \operatorname{tr}(AA^*).$$

We express each term through $t = \operatorname{tr}(A^*A) = \sum_{i,j} |a_{ij}|^2$, a real number (Proposition 6.1.16). By hypothesis $\operatorname{tr}\big(A^2\big) = t$. The diagonal entries of X^* are the conjugates of those of X, so $\operatorname{tr}(X^*) = \overline{\operatorname{tr} X}$, and with Proposition 6.3.27(b), $\operatorname{tr}\big((A^*)^2\big) = \operatorname{tr}\big((A^2)^*\big) = \overline{\operatorname{tr}\big(A^2\big)} = \bar{t} = t$. By Proposition 2.4.28, $\operatorname{tr}(AA^*) = \operatorname{tr}(A^*A) = t$. Hence $\operatorname{tr}(B^*B) = t - t - t + t = 0$. By Proposition 6.1.16, $\operatorname{tr}(B^*B) = \sum_{i,j} |b_{ij}|^2$, so every entry of B is 0 (as in Corollary 6.1.19). That is, $A^* = A$.

Solution to Exercise 6.6.51

Uses. Exercise 6.6.42, Proposition 6.1.29 (Expanding a norm), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.6.21 (Kernels and images of adjoints), Theorem 6.4.24 (Orthogonal decomposition), Theorem 6.2.11 (Triangle inequality)
Techniques. Show a vector is zero via its norm (Technique 6.1.36), Move an operator across the inner product (Technique 6.6.20)
Hint 1. By Exercise 6.6.42(b), $\|T^*\mathbf{w}\| \le \|\mathbf{w}\|$ as well. If $T\mathbf{v} = \mathbf{v}$, expand $\|T^*\mathbf{v} - \mathbf{v}\|^2$ and compute $\langle T^*\mathbf{v}, \mathbf{v}\rangle$ by moving T^* across.
Hint 2. For (b), (a) says $\ker(T - \mathrm{id}) = \ker(T^* - \mathrm{id}) = \ker(T - \mathrm{id})^*$. Apply Theorem 6.6.21 to $T - \mathrm{id}$.
Hint 3. For (c), write $\mathbf{v} = \mathbf{u} + (T - \mathrm{id})\mathbf{z}$ by (b). The averages fix $\mathbf{u}$, and the sum over the second part telescopes.
Sketch. (a) If $T\mathbf{v} = \mathbf{v}$, then $\langle T^*\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \|\mathbf{v}\|^2$, so $\|T^*\mathbf{v} - \mathbf{v}\|^2 = \|T^*\mathbf{v}\|^2 - \|\mathbf{v}\|^2 \le 0$. The converse is the same for T^*. (b) $\ker(T - \mathrm{id}) = \ker(T - \mathrm{id})^* = (\operatorname{im}(T - \mathrm{id}))^\perp$. (c) For $\mathbf{v} = \mathbf{u} + (T - \mathrm{id})\mathbf{z}$ with $T\mathbf{u} = \mathbf{u}$: $A_N\mathbf{u} = \mathbf{u}$, and $A_N(T - \mathrm{id})\mathbf{z} = \big(T^N\mathbf{z} - \mathbf{z}\big)/N$ has norm at most $2\|\mathbf{z}\|/N$.

(a) By Exercise 6.6.42(b) with $c = 1$, $\|T^*\mathbf{w}\| \le \|\mathbf{w}\|$ for all $\mathbf{w}$. Suppose $T\mathbf{v} = \mathbf{v}$. Moving T^* across, $\langle T^*\mathbf{v}, \mathbf{v}\rangle = \overline{\langle \mathbf{v}, T^*\mathbf{v}\rangle} = \overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \overline{\langle \mathbf{v}, \mathbf{v}\rangle} = \|\mathbf{v}\|^2$, which is real. By Proposition 6.1.29,

$$\|T^*\mathbf{v} - \mathbf{v}\|^2 = \|T^*\mathbf{v}\|^2 - 2\operatorname{Re}\langle T^*\mathbf{v}, \mathbf{v}\rangle + \|\mathbf{v}\|^2 = \|T^*\mathbf{v}\|^2 - \|\mathbf{v}\|^2 \le 0,$$

so $T^*\mathbf{v} = \mathbf{v}$. Conversely, T^* also satisfies $\|T^*\mathbf{w}\| \le \|\mathbf{w}\|$, and its adjoint is T (Proposition 6.6.18(c)), so the same argument applied to T^* shows that $T^*\mathbf{v} = \mathbf{v}$ implies $T\mathbf{v} = \mathbf{v}$.

(b) By Proposition 6.6.18, $(T - \mathrm{id})^* = T^* - \mathrm{id}$, so (a) says $\ker(T - \mathrm{id}) = \ker(T - \mathrm{id})^*$. By Theorem 6.6.21(a) applied to $T - \mathrm{id}$, this is $(\operatorname{im}(T - \mathrm{id}))^\perp$. Since $\operatorname{im}(T - \mathrm{id})$ is finite-dimensional, Theorem 6.4.24 gives $V = \operatorname{im}(T - \mathrm{id}) \oplus (\operatorname{im}(T - \mathrm{id}))^\perp = \operatorname{im}(T - \mathrm{id}) \oplus \ker(T - \mathrm{id})$, an orthogonal decomposition.

(c) Let $\mathbf{v} \in V$. By (b), $\mathbf{v} = \mathbf{u} + (T - \mathrm{id})\mathbf{z}$ with $\mathbf{u} \in \ker(T - \mathrm{id})$ and $\mathbf{z} \in V$, and $\mathbf{u} = \operatorname{Pr}_{\ker(T - \mathrm{id})}(\mathbf{v})$ because the second piece lies in $\operatorname{im}(T - \mathrm{id}) = (\ker(T - \mathrm{id}))^\perp$. Since $T\mathbf{u} = \mathbf{u}$, $A_N\mathbf{u} = \mathbf{u}$. The other piece telescopes:

$$A_N(T - \mathrm{id})\mathbf{z} = \frac{1}{N}\sum_{k=0}^{N-1}\big(T^{k+1}\mathbf{z} - T^k\mathbf{z}\big) = \frac{1}{N}\big(T^N\mathbf{z} - \mathbf{z}\big).$$

By the triangle inequality and $\big\|T^N\mathbf{z}\big\| \le \|\mathbf{z}\|$, this has norm at most $2\|\mathbf{z}\|/N$, which tends to 0. Hence $\|A_N\mathbf{v} - \mathbf{u}\| \le 2\|\mathbf{z}\|/N \to 0$. This is the finite-dimensional case of von Neumann's mean ergodic theorem.

Section 6.7

Solution to Exercise 6.7.5

Uses. Corollary 6.4.10 (Projecting with an orthogonal list), Example 6.4.35 (Distance to a hyperplane), Theorem 6.5.5 (The normal equations), Theorem 6.4.33 (Best approximation)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. In (a), compute the inner product of the two spanning vectors. In (b), the complement of the hyperplane is a line. In (c), there are only two unknowns.
Hint 2. (a) Use the projection formula for an orthogonal list. (b) $\operatorname{dist}(\mathbf{v}, H) = |\langle \mathbf{v}, \mathbf{n}\rangle|/\|\mathbf{n}\|$. (c) Solve $A^{\mathsf{T}}A\mathbf{x} = A^{\mathsf{T}}\mathbf{b}$, a 2×2 system.
Sketch. (a) The spanning vectors are orthogonal, so $\operatorname{Pr}_W(\mathbf{v}) = (9/4)\mathbf{w}_1 + (5/4)\mathbf{w}_2 = (7/2, 1, 7/2, 1)$ and the distance is $\|(-1/2, 0, 1/2, 0)\| = 1/\sqrt{2}$. (b) With $\mathbf{n} = (1, -1, 1, -1)$, the distance is $|-2|/2 = 1$. (c) $A^{\mathsf{T}}A = \begin{pmatrix} 3 & 6 \\ 6 & 14 \end{pmatrix}$ and $A^{\mathsf{T}}\mathbf{b} = (5, 11)$ give $\hat{\mathbf{x}} = (2/3, 1/2)$.

(a) The spanning vectors $\mathbf{w}_1 = (1,1,1,1)$ and $\mathbf{w}_2 = (1,-1,1,-1)$ are orthogonal, so no orthogonalization is needed and Corollary 6.4.10 applies directly. Here $\langle \mathbf{v}, \mathbf{w}_1 \rangle = 9$, $\langle \mathbf{v}, \mathbf{w}_2 \rangle = 5$, and $\|\mathbf{w}_1\|^2 = \|\mathbf{w}_2\|^2 = 4$, so

$$\operatorname{Pr}_W(\mathbf{v}) = \frac{9}{4}\mathbf{w}_1 + \frac{5}{4}\mathbf{w}_2 = (7/2, 1, 7/2, 1).$$

Then $\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}) = (-1/2, 0, 1/2, 0)$, and the distance is $1/\sqrt{2}$ by Theorem 6.4.33. As a check, $\|\mathbf{v}\|^2 - \|\operatorname{Pr}_W(\mathbf{v})\|^2 = 27 - 53/2 = 1/2$.

(b) The hyperplane is $H = \{\mathbf{n}\}^\perp$ with $\mathbf{n} = (1,-1,1,-1)$, and its complement is the line through $\mathbf{n}$, so it is quickest to project onto that line. By Example 6.4.35, $\operatorname{dist}(\mathbf{v}, H) = |\langle \mathbf{v}, \mathbf{n} \rangle| / \|\mathbf{n}\| = |1 - 2 + 3 - 4|/2 = 1$.

(c) The columns $(1,1,1)$ and $(1,2,3)$ of the coefficient matrix A are not orthogonal, and there are only two unknowns, so we solve the normal equations (Theorem 6.5.5):

$$A^{\mathsf{T}}A = \begin{pmatrix} 3 & 6 \\ 6 & 14 \end{pmatrix}, \quad A^{\mathsf{T}}\mathbf{b} = \begin{pmatrix} 5 \\ 11 \end{pmatrix}, \quad \hat{\mathbf{x}} = \frac{1}{6}\begin{pmatrix} 14 & -6 \\ -6 & 3 \end{pmatrix}\begin{pmatrix} 5 \\ 11 \end{pmatrix} = \begin{pmatrix} 2/3 \\ 1/2 \end{pmatrix}.$$

The residual $\mathbf{b} - A\hat{\mathbf{x}} = (-1/6, 1/3, -1/6)$ is orthogonal to both columns, as it must be.

Solution to Exercise 6.7.6

Uses. Proposition 6.1.29 (Expanding a norm)
Techniques. Perturb a minimizer (Technique 6.5.6), Rotate the phase (Technique 6.2.8)
Hint 1. Expand $\|\mathbf{x} + t\mathbf{y}\|^2 - \|\mathbf{x}\|^2$ as a function of t.
Hint 2. For the converse, try $t = -s\langle \mathbf{x}, \mathbf{y} \rangle$ with a small real $s > 0$. For (b), look at $V = \mathbb{C}$ with $\mathbf{x} = 1$ and $\mathbf{y} = i$.
Sketch. $\|\mathbf{x} + t\mathbf{y}\|^2 - \|\mathbf{x}\|^2 = 2\operatorname{Re}(\bar{t}\langle \mathbf{x}, \mathbf{y} \rangle) + |t|^2\|\mathbf{y}\|^2$. If $\langle \mathbf{x}, \mathbf{y} \rangle = 0$ this is ≥ 0. If $c = \langle \mathbf{x}, \mathbf{y} \rangle \neq 0$, then $t = -sc$ gives $s|c|^2\big(s\|\mathbf{y}\|^2 - 2\big)$, which is negative for small $s > 0$. (b) In $\mathbb{C}$, $|1 + ti|^2 = 1 + t^2 \geq 1$ for real t, but $\langle 1, i \rangle = -i$.

(a) By Proposition 6.1.29, for every $t \in \mathbb{F}$,

$$\|\mathbf{x} + t\mathbf{y}\|^2 - \|\mathbf{x}\|^2 = 2\operatorname{Re}(\bar{t}\langle \mathbf{x}, \mathbf{y} \rangle) + |t|^2\|\mathbf{y}\|^2.$$

If $\langle \mathbf{x}, \mathbf{y} \rangle = 0$, the right side is $|t|^2\|\mathbf{y}\|^2 \geq 0$, so the inequality holds for every t.

Conversely, suppose $c = \langle \mathbf{x}, \mathbf{y} \rangle \neq 0$, and take $t = -sc$ with $s > 0$ real. Then $\bar{t}c = -s|c|^2$, and the right side becomes

$$-2s|c|^2 + s^2|c|^2\|\mathbf{y}\|^2 = s|c|^2\big(s\|\mathbf{y}\|^2 - 2\big).$$

For $0 < s < 2/\big(\|\mathbf{y}\|^2 + 1\big)$ this is negative, so $\|\mathbf{x} + t\mathbf{y}\| < \|\mathbf{x}\|$ for that t. This proves the contrapositive. The choice of t is Technique 6.5.6 in the direction $-c\mathbf{y}$: the factor c rotates the phase so that the linear term is real and negative.

(b) Take $V = \mathbb{C}$ with $\langle z, w \rangle = z\overline{w}$, $\mathbf{x} = 1$, and $\mathbf{y} = i$. For real t, $\|1 + ti\|^2 = 1 + t^2 \geq 1$, but $\langle 1, i \rangle = \bar{i} = -i \neq 0$. Real t only see $\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle$, and the imaginary part needs $t = is$.

The condition in (a) mentions only the norm, so it makes sense in any normed space, where it is used as a definition of orthogonality (*Birkhoff–James orthogonality*). In an inner product space it is ordinary orthogonality. Exercise 6.7.13 puts it to work.

Solution to Exercise 6.7.7

Uses. Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.3.18 (Coordinates in an orthonormal basis), Theorem 2.2.1 (Linear maps are determined by a basis)
Techniques. Plug in clever test vectors (Technique 6.1.40), Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. Choose an orthonormal basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$. What does the hypothesis say about the coordinates of $T\mathbf{e}_i$?
Hint 2. Each $T\mathbf{e}_i$ is a multiple $c_i\mathbf{e}_i$. To compare c_i with c_j, find two orthogonal vectors built from $\mathbf{e}_i$ and $\mathbf{e}_j$ other than $\mathbf{e}_i, \mathbf{e}_j$ themselves.
Sketch. In an orthonormal basis, $\langle T\mathbf{e}_i, \mathbf{e}_j \rangle = 0$ for $j \neq i$, so $T\mathbf{e}_i = c_i\mathbf{e}_i$. Since $\mathbf{e}_i + \mathbf{e}_j \perp \mathbf{e}_i - \mathbf{e}_j$, $0 = \big\langle T\big(\mathbf{e}_i + \mathbf{e}_j\big), \mathbf{e}_i - \mathbf{e}_j \big\rangle = c_i - c_j$. So all c_i equal some c, and $T = c\mathrm{id}_V$ on a basis.

If $V = \{\mathbf{0}\}$, there is nothing to prove. Otherwise choose an orthonormal basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$ of V (Theorem 6.4.20). For $j \neq i$, $\mathbf{e}_i \perp \mathbf{e}_j$, so $\langle T\mathbf{e}_i, \mathbf{e}_j\rangle = 0$. By Proposition 6.3.18, $T\mathbf{e}_i = \sum_j \langle T\mathbf{e}_i, \mathbf{e}_j\rangle \mathbf{e}_j = c_i \mathbf{e}_i$, where $c_i = \langle T\mathbf{e}_i, \mathbf{e}_i\rangle$.

Now let $i \neq j$. The vectors $\mathbf{e}_i + \mathbf{e}_j$ and $\mathbf{e}_i - \mathbf{e}_j$ are orthogonal, since $\langle \mathbf{e}_i + \mathbf{e}_j, \mathbf{e}_i - \mathbf{e}_j\rangle = 1 - 0 + 0 - 1 = 0$. By the hypothesis,

$$0 = \langle T(\mathbf{e}_i + \mathbf{e}_j), \mathbf{e}_i - \mathbf{e}_j\rangle = \langle c_i\mathbf{e}_i + c_j\mathbf{e}_j, \mathbf{e}_i - \mathbf{e}_j\rangle = c_i - c_j.$$

So $c_1 = \cdots = c_n = c$, and T agrees with $c\mathrm{id}_V$ on a basis. By Theorem 2.2.1, $T = c\mathrm{id}_V$.

A basis-free version: for fixed $\mathbf{u}$, the hypothesis says $T\mathbf{u} \perp \operatorname{span}(\mathbf{u})^\perp$, so $T\mathbf{u} \in \left(\operatorname{span}(\mathbf{u})^\perp\right)^\perp = \operatorname{span}(\mathbf{u})$ by Theorem 6.4.26. A linear map that sends every vector to a multiple of itself is a multiple of the identity, by comparing $T(\mathbf{u} + \mathbf{v})$ with $T\mathbf{u} + T\mathbf{v}$ for independent $\mathbf{u}, \mathbf{v}$.

Solution to Exercise 6.7.8

Uses. Definition 6.6.8 (Adjoint), Proposition 6.6.18 (Properties of the adjoint), Proposition 6.1.41 (Over $\mathbb{C}$, the values $\langle T\mathbf{v}, \mathbf{v}\rangle$ determine T), Corollary 6.1.38 (Linear maps are determined by inner products)
Techniques. Move an operator across the inner product (Technique 6.6.20), Polarization (Technique 6.1.33), Plug in clever test vectors (Technique 6.1.40)
Hint 1. Write $\|T\mathbf{v}\|^2$ and $\|T^*\mathbf{v}\|^2$ as $\langle S\mathbf{v}, \mathbf{v}\rangle$ for suitable operators S.
Hint 2. For the converse, $S = T^*T - TT^*$ is self-adjoint with $\langle S\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$. Over $\mathbb{C}$ cite Proposition 6.1.41. Over $\mathbb{R}$, expand $\langle S(\mathbf{x} + \mathbf{y}), \mathbf{x} + \mathbf{y}\rangle$.
Sketch. $\|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2 = \langle (T^*T - TT^*)\mathbf{v}, \mathbf{v}\rangle$. So normality gives equal norms. Conversely $S = T^*T - TT^*$ is self-adjoint with zero diagonal values; expanding $\langle S(\mathbf{x} + \mathbf{y}), \mathbf{x} + \mathbf{y}\rangle = 0$ gives $2\operatorname{Re}\langle S\mathbf{x}, \mathbf{y}\rangle = 0$, and replacing $\mathbf{y}$ by $i\mathbf{y}$ over $\mathbb{C}$ kills the imaginary part. So $S = 0$.

For every $\mathbf{v}$, moving the operators across the inner product (Definition 6.6.8, with $(T^*)^* = T$ by Proposition 6.6.18),

$$\|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle - \langle TT^*\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, \mathbf{v}\rangle,$$

where $S = T^*T - TT^*$. If T is normal, then $S = 0$ and the norms agree.

Conversely, suppose $\langle S\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$. By Proposition 6.6.18, $S^* = T^*T - TT^* = S$. For $\mathbf{x}, \mathbf{y} \in V$,

$$0 = \langle S(\mathbf{x} + \mathbf{y}), \mathbf{x} + \mathbf{y}\rangle = \langle S\mathbf{x}, \mathbf{y}\rangle + \langle S\mathbf{y}, \mathbf{x}\rangle = \langle S\mathbf{x}, \mathbf{y}\rangle + \overline{\langle S\mathbf{x}, \mathbf{y}\rangle},$$

using $\langle S\mathbf{y}, \mathbf{x}\rangle = \langle \mathbf{y}, S\mathbf{x}\rangle = \overline{\langle S\mathbf{x}, \mathbf{y}\rangle}$. So $\operatorname{Re}\langle S\mathbf{x}, \mathbf{y}\rangle = 0$. Over $\mathbb{R}$ this says $\langle S\mathbf{x}, \mathbf{y}\rangle = 0$. Over $\mathbb{C}$, apply it to $i\mathbf{y}$ in place of $\mathbf{y}$: $\operatorname{Re}\langle S\mathbf{x}, i\mathbf{y}\rangle = \operatorname{Re}(-i\langle S\mathbf{x}, \mathbf{y}\rangle) = \operatorname{Im}\langle S\mathbf{x}, \mathbf{y}\rangle = 0$. Either way $\langle S\mathbf{x}, \mathbf{y}\rangle = 0$ for all $\mathbf{x}, \mathbf{y}$, so $S = 0$ by Corollary 6.1.38. (Over $\mathbb{C}$ one can instead cite Proposition 6.1.41, which does not need S to be self-adjoint.)

Over $\mathbb{R}$, self-adjointness was used to replace $\langle S\mathbf{y}, \mathbf{x}\rangle$ by $\langle S\mathbf{x}, \mathbf{y}\rangle$. Without it the argument fails, as the rotation of Example 6.1.39 shows: it has zero diagonal values and is not 0.

Solution to Exercise 6.7.9

Uses. Proposition 6.6.18 (Properties of the adjoint), Proposition 6.1.27 (Basic properties of the norm), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents)
Techniques. Move an operator across the inner product (Technique 6.6.20), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Let $S = T^2 - T$. Is S self-adjoint? Compute S^2 using $T^3 = T^2$.
Hint 2. $S^2 = 0$ and $S^* = S$. Now $\|S\mathbf{v}\|^2 = \langle S^*S\mathbf{v}, \mathbf{v}\rangle$. For (b), try a nilpotent matrix.
Sketch. $S = T^2 - T$ is self-adjoint, and $T^4 = TT^3 = T^3 = T^2$, so $S^2 = T^4 - 2T^3 + T^2 = 0$. Then $\|S\mathbf{v}\|^2 = \langle S^2\mathbf{v}, \mathbf{v}\rangle = 0$, so $S = 0$, and $T^2 = T = T^*$ is an orthogonal projection. (b) $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ has $N^3 = N^2 = 0 \neq N$.

(a) Let $S = T^2 - T$. By Proposition 6.6.18, $S^* = (T^*)^2 - T^* = S$. Since $T^4 = TT^3 = TT^2 = T^3 = T^2$,

$$S^2 = T^4 - 2T^3 + T^2 = T^2 - 2T^2 + T^2 = 0.$$

For every $\mathbf{v}$, $\|S\mathbf{v}\|^2 = \langle S\mathbf{v}, S\mathbf{v}\rangle = \langle S^*S\mathbf{v}, \mathbf{v}\rangle = \langle S^2\mathbf{v}, \mathbf{v}\rangle = 0$, so $S\mathbf{v} = \mathbf{0}$ (Proposition 6.1.27). Hence $T^2 = T$. Together with $T^* = T$, this makes T an orthogonal projection by Corollary 6.6.29.

(b) Let $N \in \mathbb{R}^{2\times 2}$ have $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_2 = \mathbf{e}_1$, that is, $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. Then $N^2 = 0$, so $N^3 = N^2$, but $N^2 = 0 \neq N$.

The proof used self-adjointness only to make $S^*S = S^2$, so that the algebraic fact $S^2 = 0$ became the positive fact $\|S\mathbf{v}\|^2 = 0$. For a general T, $S^2 = 0$ says nothing about S, as N shows.

Solution to Exercise 6.7.10

Uses. Theorem 6.3.22 (Parseval's identity), Definition 6.6.8 (Adjoint), Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 6.1.16 (Frobenius inner product)
Techniques. Move an operator across the inner product (Technique 6.6.20), The trace of A^*A (Technique 6.1.18)
Hint 1. Apply Theorem 6.3.22(b) to $T\mathbf{e}_j$ in the basis $\mathbf{f}_1, \dots, \mathbf{f}_m$, and to $T^*\mathbf{f}_i$ in the basis $\mathbf{e}_1, \dots, \mathbf{e}_n$.
Hint 2. The middle sum in (a) is symmetric in the two bases. Which of the outer sums does not mention the basis of V? For $\operatorname{tr}(A^*A)$, recall Proposition 6.1.16.
Sketch. By Parseval in W, $\|T\mathbf{e}_j\|^2 = \sum_i |\langle T\mathbf{e}_j, \mathbf{f}_i\rangle|^2$; by Parseval in V, $\|T^*\mathbf{f}_i\|^2 = \sum_j |\langle T^*\mathbf{f}_i, \mathbf{e}_j\rangle|^2 = \sum_j |\langle T\mathbf{e}_j, \mathbf{f}_i\rangle|^2$. The right side of (a) does not involve the $\mathbf{e}_j$, so the left side does not depend on them. The entries of A are $\langle T\mathbf{e}_j, \mathbf{f}_i\rangle$, so the middle sum is $\operatorname{tr}(A^*A)$.

(a) By Theorem 6.3.22(b) in W, $\|T\mathbf{e}_j\|^2 = \sum_{i=1}^m |\langle T\mathbf{e}_j, \mathbf{f}_i\rangle|^2$; summing over j gives the first equality. By Theorem 6.3.22(b) in V and the definition of the adjoint,

$$\|T^*\mathbf{f}_i\|^2 = \sum_{j=1}^n |\langle T^*\mathbf{f}_i, \mathbf{e}_j\rangle|^2 = \sum_{j=1}^n |\langle \mathbf{f}_i, T\mathbf{e}_j\rangle|^2 = \sum_{j=1}^n |\langle T\mathbf{e}_j, \mathbf{f}_i\rangle|^2,$$

using $|\overline{z}| = |z|$. Summing over i gives the second equality.

(b) Fix the basis $\mathbf{f}_1, \dots, \mathbf{f}_m$ of W. By (a), $\sum_j \|T\mathbf{e}_j\|^2 = \sum_i \|T^*\mathbf{f}_i\|^2$ for every orthonormal basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ of V, and the right side does not involve that basis. So the left side is the same for all of them. By Proposition 6.3.18, the (i,j) entry of A is the ith coordinate of $T\mathbf{e}_j$, namely $\langle T\mathbf{e}_j, \mathbf{f}_i\rangle$, so the middle sum of (a) is $\sum_{i,j} |a_{ij}|^2 = \operatorname{tr}(A^*A)$ (Proposition 6.1.16). Since the left side of (a) does not depend on the bases either, neither does $\operatorname{tr}(A^*A)$.

The number $\sum_j \|T\mathbf{e}_j\|^2$ is the squared *Hilbert–Schmidt norm* of T; for $V = \mathbb{F}^n$ and $W = \mathbb{F}^m$ with dot products it is the squared Frobenius norm of the matrix. The proof never chose a convenient basis: it compared two arbitrary ones through a double sum that is symmetric in them.

Solution to Exercise 6.7.11

Uses. Theorem 6.4.20 (Orthonormal bases exist), Theorem 6.3.22 (Parseval's identity), Proposition 6.3.30 (Gram matrices detect independence), Theorem 5.4.10 (Multiplicativity), Exercise 6.3.57, Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Pass to orthonormal coordinates (Technique 6.7.2), Gram matrices (Technique 6.3.31)
Hint 1. If the list is dependent, Proposition 6.3.30 already says that G is singular.
Hint 2. If it is independent, $W = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$ has dimension k. Let $B \in \mathbb{F}^{k\times k}$ have columns $[\mathbf{v}_j]_{\mathcal{O}}$ for an orthonormal basis $\mathcal{O}$ of W, and show $G = B^*B$.
Sketch. If the list is dependent, G is singular (Proposition 6.3.30) and $\det G = 0$. If it is independent, choose an orthonormal basis $\mathcal{O}$ of its span, which has k vectors, and let B have columns $[\mathbf{v}_j]_{\mathcal{O}}$. Parseval gives $G = B^*B$, and B is invertible, so $\det G = \overline{\det B} \det B = |\det B|^2 > 0$.

If the list is dependent, then G is not invertible by Proposition 6.3.30, so $\det G = 0$ (Theorem 5.4.7).

Suppose the list is independent. Then it is a basis of $W = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$, so $\dim W = k$, and W has an orthonormal basis $\mathcal{O}$ with k vectors (Theorem 6.4.20). Let $B \in \mathbb{F}^{k\times k}$ be the matrix with columns $[\mathbf{v}_1]_{\mathcal{O}}, \dots, [\mathbf{v}_k]_{\mathcal{O}}$. By Theorem 6.3.22, the (i,j) entry of B^*B is

$$[\mathbf{v}_i]_{\mathcal{O}}^* [\mathbf{v}_j]_{\mathcal{O}} = \langle \mathbf{v}_j, \mathbf{v}_i\rangle = g_{ij},$$

so $G = B^*B$. The columns of B are the coordinate vectors of a basis, so they are independent and B is invertible, with $\det B \neq 0$. By Theorem 5.4.10 and Exercise 6.3.57(a),

$$\det G = \det(B^*)\det B = \overline{\det B}\det B = |\det B|^2 > 0.$$

So $\det G \geq 0$ always, with equality exactly for dependent lists. This is Technique 6.7.2: the list becomes the columns of a square matrix, and the Gram determinant becomes a squared modulus. The Gram–Schmidt route of Exercise 6.4.59 gives the more precise formula $\det G = \|\mathbf{f}_1\|^2 \cdots \|\mathbf{f}_k\|^2$, and with it the geometric meaning, base times height, repeated.

Solution to Exercise 6.7.12

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.29 (Expanding a norm), Proposition 6.1.27 (Basic properties of the norm)
Techniques. A sum of nonnegative terms (Technique 6.1.9), Orthogonal decomposition (Technique 6.2.4)
Hint 1. For the lower bound, expand $\|\mathbf{v}_1 + \cdots + \mathbf{v}_n\|^2 \geq 0$.
Hint 2. For the construction, work in $\mathbb{R}^n$ with $\mathbf{u} = (1/\sqrt{n})(1, \ldots, 1)$ and $\mathbf{f}_i = \mathbf{e}_i - (1/\sqrt{n})\mathbf{u}$, which are orthogonal to $\mathbf{u}$. Try $\mathbf{v}_i = \alpha\mathbf{f}_i + \beta\mathbf{u}$.
Sketch. Necessity: $x \leq 1$ by Cauchy–Schwarz, and $0 \leq \|\sum \mathbf{v}_i\|^2 = n + n(n-1)x$. Sufficiency: with $\mathbf{f}_i = \mathbf{e}_i - (1/n)(1, \ldots, 1)$, $\langle \mathbf{f}_i, \mathbf{f}_j \rangle = \delta_{ij} - 1/n$ and $\mathbf{f}_i \perp \mathbf{u}$. Then $\mathbf{v}_i = \alpha\mathbf{f}_i + \beta\mathbf{u}$ has $\langle \mathbf{v}_i, \mathbf{v}_j \rangle = \alpha^2(\delta_{ij} - 1/n) + \beta^2$, and $\alpha^2 = 1 - x$, $\beta^2 = (1 + (n-1)x)/n$ work exactly when $-1/(n-1) \leq x \leq 1$.

Necessity. By Theorem 6.2.1, $x = \langle \mathbf{v}_1, \mathbf{v}_2 \rangle \leq \|\mathbf{v}_1\|\|\mathbf{v}_2\| = 1$. By Proposition 6.1.29 (with all $n(n-1)$ cross terms equal to x),

$$0 \leq \|\mathbf{v}_1 + \cdots + \mathbf{v}_n\|^2 = \sum_{i,j} \langle \mathbf{v}_j, \mathbf{v}_i \rangle = n + n(n-1)x,$$

so $x \geq -1/(n-1)$.

Sufficiency. Let $-1/(n-1) \leq x \leq 1$, and work in $\mathbb{R}^n$ with the dot product. Let $\mathbf{1} = (1, \ldots, 1)$, $\mathbf{u} = \mathbf{1}/\sqrt{n}$, and $\mathbf{f}_i = \mathbf{e}_i - (1/n)\mathbf{1}$, the part of $\mathbf{e}_i$ orthogonal to $\mathbf{u}$ (Technique 6.2.4). Then $\langle \mathbf{f}_i, \mathbf{u} \rangle = (1-1)/\sqrt{n} = 0$ and

$$\langle \mathbf{f}_i, \mathbf{f}_j \rangle = \delta_{ij} - \frac{1}{n} - \frac{1}{n} + \frac{n}{n^2} = \delta_{ij} - \frac{1}{n}.$$

For real α, β, let $\mathbf{v}_i = \alpha\mathbf{f}_i + \beta\mathbf{u}$. Since $\mathbf{f}_i \perp \mathbf{u}$ and $\|\mathbf{u}\| = 1$,

$$\langle \mathbf{v}_i, \mathbf{v}_j \rangle = \alpha^2\left(\delta_{ij} - \frac{1}{n}\right) + \beta^2.$$

We need $\alpha^2(1 - 1/n) + \beta^2 = 1$ and $-\alpha^2/n + \beta^2 = x$. Subtracting, $\alpha^2 = 1 - x$, and then $\beta^2 = x + (1-x)/n = (1 + (n-1)x)/n$. Both right sides are nonnegative exactly when $-1/(n-1) \leq x \leq 1$, so we can take $\alpha = \sqrt{1-x}$ and $\beta = \sqrt{(1 + (n-1)x)/n}$.

Endpoints. At $x = 1$, equality in Cauchy–Schwarz for unit vectors with $\langle \mathbf{v}_i, \mathbf{v}_j \rangle = 1$ forces $\mathbf{v}_i = \mathbf{v}_j$: all the vectors coincide. At $x = -1/(n-1)$, the expansion above gives $\|\mathbf{v}_1 + \cdots + \mathbf{v}_n\| = 0$, so the vectors sum to $\mathbf{0}$; in the construction $\beta = 0$, and the vectors $\mathbf{v}_i = \sqrt{n/(n-1)}\mathbf{f}_i$ point from the center of the regular simplex with vertices $\mathbf{e}_1, \ldots, \mathbf{e}_n$ to its vertices. For $n = 3$ these are three unit vectors in a plane at angles $2\pi/3$. Every list attaining the lower endpoint has the same Gram matrix as this one, so by Problem 6.9 it is this configuration up to an isometry of spans.

The Gram matrix of the list is $(1-x)I_n + xJ$, where J has every entry 1. The exercise therefore says for which x this matrix is a Gram matrix; Problem 6.17 answers that question for every Hermitian matrix.

Solution to Exercise 6.7.13

Uses. Theorem 6.3.3 (Pythagorean theorem), Theorem 6.4.6 (The projection is characterized by orthogonality), Exercise 6.7.6
Techniques. Recognize a projection by its two conditions (Technique 6.4.7), Perturb a minimizer (Technique 6.5.6)
Hint 1. Which hypothesis does the argument never use? What does the Pythagorean theorem require of the two pieces?
Hint 2. For a correct proof, take $\mathbf{u} \in \operatorname{im} P$ and $\mathbf{w} \in \ker P$, and compute $P(\mathbf{u} + t\mathbf{w})$. Then use Exercise 6.7.6.

Sketch. The Pythagorean theorem needs $P\mathbf{v} \perp \mathbf{v} - P\mathbf{v}$, which is what has to be proved; the argument never uses $\|P\mathbf{v}\| \le \|\mathbf{v}\|$, and the oblique projection $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ satisfies everything else. Correct proof: for $\mathbf{u} \in \operatorname{im} P$, $\mathbf{w} \in \ker P$, $P(\mathbf{u} + t\mathbf{w}) = \mathbf{u}$, so $\|\mathbf{u}\| \le \|\mathbf{u} + t\mathbf{w}\|$ for all t, and $\mathbf{u} \perp \mathbf{w}$ by Exercise 6.7.6. Then $\mathbf{v} - P\mathbf{v} \perp \operatorname{im} P$ and Theorem 6.4.6 finishes.

The error. The Pythagorean theorem (Theorem 6.3.3) applies to orthogonal vectors; its converse, which the argument uses in the form "the norms add up, so the pieces are orthogonal", needs the equation $\|\mathbf{v}\|^2 = \|P\mathbf{v}\|^2 + \|\mathbf{v} - P\mathbf{v}\|^2$, which nobody has shown. The argument assumes the conclusion. A sign of this is that the hypothesis $\|P\mathbf{v}\| \le \|\mathbf{v}\|$ is never used. Every step except the Pythagorean one holds for the oblique projection $P = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ on $\mathbb{R}^2$, which has $P^2 = P$, $\ker P = \operatorname{span}((1,-1))$, and $\operatorname{im} P = \operatorname{span}(\mathbf{e}_1)$, and for which the pieces of $\mathbf{v} = (0,1)$ are $(1,0)$ and $(-1,1)$, not orthogonal. (Consistently, this P violates the norm hypothesis: $P(1,1) = (2,0)$ is longer than $(1,1)$.) Over $\mathbb{C}$ there is a second gap: even if the norms did add up, the converse of Pythagoras fails there (Theorem 6.3.3(b) is stated for $\mathbb{F} = \mathbb{R}$ only), so orthogonality would still not follow.

A correct proof. Let $\mathbf{u} \in \operatorname{im} P$ and $\mathbf{w} \in \ker P$. Since $\mathbf{u} = P\mathbf{x}$ for some $\mathbf{x}$, $P\mathbf{u} = P^2\mathbf{x} = \mathbf{u}$, so for every $t \in \mathbb{F}$, $P(\mathbf{u} + t\mathbf{w}) = \mathbf{u} + tP\mathbf{w} = \mathbf{u}$. The norm hypothesis applied to $\mathbf{u} + t\mathbf{w}$ gives

$$\|\mathbf{u}\| = \|P(\mathbf{u} + t\mathbf{w})\| \le \|\mathbf{u} + t\mathbf{w}\| \quad \text{for all } t \in \mathbb{F},$$

so $\langle \mathbf{u}, \mathbf{w} \rangle = 0$ by Exercise 6.7.6. Thus every vector of $\ker P$ is orthogonal to $\operatorname{im} P$. Now for $\mathbf{v} \in V$, $P\mathbf{v} \in \operatorname{im} P$ and $\mathbf{v} - P\mathbf{v} \in \ker P \subseteq (\operatorname{im} P)^{\perp}$, so $P\mathbf{v} = \operatorname{Pr}_{\operatorname{im} P}(\mathbf{v})$ by Theorem 6.4.6.

Solution to Exercise 6.7.14

Uses. Definition 6.6.8 (Adjoint), Theorem 6.2.1 (Cauchy–Schwarz inequality), Exercise 6.7.8
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. Which step replaces one operator by another? When is that legitimate?
Hint 2. For a correct proof, start from $\|T^*\mathbf{v}\|^2 = \langle TT^*\mathbf{v}, \mathbf{v} \rangle$ and apply Cauchy–Schwarz, then the hypothesis to the vector $T^*\mathbf{v}$.
Sketch. The step $TT^* = T^*T$ assumes that T is normal; the argument would prove $\|T^*\mathbf{v}\| = \|T\mathbf{v}\|$ for every T, which fails for $T = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ at $\mathbf{v} = \mathbf{e}_2$. Correct proof: $\|T^*\mathbf{v}\|^2 = \langle T(T^*\mathbf{v}), \mathbf{v} \rangle \le \|TT^*\mathbf{v}\|\|\mathbf{v}\| \le \|T^*\mathbf{v}\|\|\mathbf{v}\|$, and divide by $\|T^*\mathbf{v}\|$ when it is nonzero.

The error. The middle equality replaces TT^* by T^*T. These are equal only when T is normal, and the argument, which never uses the hypothesis on T, would prove $\|T^*\mathbf{v}\| = \|T\mathbf{v}\|$ for every operator. By Exercise 6.7.8 that holds only for normal T. For $T = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ on $\mathbb{R}^2$ with the dot product, $T^* = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$, and at $\mathbf{v} = \mathbf{e}_2$: $\|T^*\mathbf{e}_2\|^2 = 0$ while $\|T\mathbf{e}_2\|^2 = \|\mathbf{e}_1\|^2 = 1$.

A correct proof. Let $\mathbf{v} \in V$. Moving T across the inner product, then using Cauchy–Schwarz (Theorem 6.2.1) and the hypothesis applied to $T^*\mathbf{v}$,

$$\|T^*\mathbf{v}\|^2 = \langle TT^*\mathbf{v}, \mathbf{v} \rangle \le \|T(T^*\mathbf{v})\|\|\mathbf{v}\| \le \|T^*\mathbf{v}\|\|\mathbf{v}\|.$$

If $T^*\mathbf{v} = \mathbf{0}$ the claim is clear; otherwise divide by $\|T^*\mathbf{v}\| > 0$. So $\|T^*\mathbf{v}\| \le \|\mathbf{v}\|$.

In terms of the operator norm of Section 9.2, the claim says $\|T^*\| \le \|T\|$, and applying it to T^* gives equality.

Solution to Exercise 6.7.15

Uses. Proposition 6.1.41 (Over $\mathbb{C}$, the values $\langle T\mathbf{v}, \mathbf{v} \rangle$ determine T), Example 6.1.39 (A rotation), Theorem 6.3.3 (Pythagorean theorem), Proposition 6.1.32 (Polarization identities), Proposition 6.6.30 (Self-adjoint means real values)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Plug in clever test vectors (Technique 6.1.40)
Hint 1. Each of the four holds over exactly one of $\mathbb{R}$ and $\mathbb{C}$. Test the complex failures on $V = \mathbb{C}$ with $\mathbf{x} = 1$ and $\mathbf{y} = i$.
Hint 2. For the real failures, use the rotation $J = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$.
Sketch. (a) True over $\mathbb{C}$ (Proposition 6.1.41), false over $\mathbb{R}$ (rotation by $\pi/2$). (b) True over $\mathbb{R}$, false over $\mathbb{C}$: $|1+i|^2 = 2 = 1 + 1$ but $\langle 1, i \rangle = -i$. (c) True over $\mathbb{R}$; over $\mathbb{C}$ the right side is $\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle$, so it fails for $1, i$. (d) True over $\mathbb{C}$ (Proposition 6.6.30); over $\mathbb{R}$ the hypothesis holds for every T, and the rotation is not self-adjoint.

(a) Over $\mathbb{C}$ this is Proposition 6.1.41. Over $\mathbb{R}$ it is false: the rotation $T\mathbf{v} = J\mathbf{v}$ with $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ has $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v} \in \mathbb{R}^2$ (Example 6.1.39), and $T \neq 0$.

(b) Over $\mathbb{R}$ this is Theorem 6.3.3(b). Over $\mathbb{C}$ it is false: in $V = \mathbb{C}$ with $\langle z, w\rangle = z\overline{w}$, $|1+i|^2 = 2 = |1|^2 + |i|^2$, but $\langle 1, i\rangle = -i \neq 0$.

(c) Over $\mathbb{R}$ this is Proposition 6.1.32(a). Over $\mathbb{C}$, Proposition 6.1.29 shows that the right side equals $\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$, so the formula fails whenever $\langle \mathbf{x}, \mathbf{y}\rangle$ is not real: for $\mathbf{x} = 1$ and $\mathbf{y} = i$ in $\mathbb{C}$ the right side is $(2-2)/4 = 0$ while $\langle 1, i\rangle = -i$.

(d) Over $\mathbb{C}$ this is Proposition 6.6.30. Over $\mathbb{R}$, every $\langle T\mathbf{v}, \mathbf{v}\rangle$ is real, so the hypothesis holds for every operator, and the rotation T of (a) is not self-adjoint: $\langle T\mathbf{e}_1, \mathbf{e}_2\rangle = 1$ while $\langle \mathbf{e}_1, T\mathbf{e}_2\rangle = -1$.

Statements (a) and (d) hold over $\mathbb{C}$ because a complex inner product can separate real and imaginary parts with the test vector $\mathbf{x} + i\mathbf{y}$; statements (b) and (c) hold over $\mathbb{R}$ because there the cross term $2\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$ is all of $2\langle \mathbf{x}, \mathbf{y}\rangle$.

Problems for Chapter 6

Solution to Problem 6.1

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.29 (Expanding a norm), Lemma 6.2.3 (The easy half of (b)), Theorem 6.2.11 (Triangle inequality)
Techniques. Orthogonal decomposition (Technique 6.2.4), A nonnegative quadratic has nonpositive discriminant (Technique 6.2.7)
Hint 1. For (b), if $\mathbf{y} \neq \mathbf{0}$, write $\mathbf{x} = c\mathbf{y} + \mathbf{w}$ with $\mathbf{w} \perp \mathbf{y}$ and expand $\|\mathbf{x}\|^2$.
Hint 2. For (c), write $a = \|\mathbf{x}\|$, $b = \|\mathbf{y}\|$, $r = \operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$, and express the squares of both sides through a, b, r.
Hint 3. After clearing denominators, the difference of the two sides of (c) factors as $(a-b)^2(ab+r)$. Why is $ab + r \geq 0$?
Sketch. (b) With $c = \langle \mathbf{x}, \mathbf{y}\rangle / \|\mathbf{y}\|^2$ and $\mathbf{w} = \mathbf{x} - c\mathbf{y} \perp \mathbf{y}$, $\|\mathbf{x}\|^2 = \|\mathbf{w}\|^2 + |\langle \mathbf{x}, \mathbf{y}\rangle|^2/\|\mathbf{y}\|^2$. (c) The left side squared is $2(ab-r)/(ab)$ and the right side squared is $4\big((a-b)^2 + 2(ab-r)\big)/(a+b)^2$. After clearing denominators, the inequality between the squares becomes $(ab-r)(a+b)^2 \leq 2ab\big((a-b)^2 + 2(ab-r)\big)$, and the right side minus the left is $(a-b)^2(ab+r) \geq 0$, since $-r \leq |\langle \mathbf{x}, \mathbf{y}\rangle| \leq ab$ by Cauchy–Schwarz. Equality iff $a = b$ or $r = -ab$, and the latter means $-\mathbf{y}$ is a positive multiple of $\mathbf{x}$.

(a) For all vectors $\mathbf{x}, \mathbf{y}$ in an inner product space, $|\langle \mathbf{x}, \mathbf{y}\rangle| \leq \|\mathbf{x}\|\|\mathbf{y}\|$, with equality if and only if one of $\mathbf{x}, \mathbf{y}$ is a scalar multiple of the other (Theorem 6.2.1).

(b) If $\mathbf{y} = \mathbf{0}$, both sides are 0 and $\mathbf{y} = 0\mathbf{x}$. Let $\mathbf{y} \neq \mathbf{0}$, $c = \langle \mathbf{x}, \mathbf{y}\rangle / \|\mathbf{y}\|^2$, and $\mathbf{w} = \mathbf{x} - c\mathbf{y}$. Then $\langle \mathbf{w}, \mathbf{y}\rangle = \langle \mathbf{x}, \mathbf{y}\rangle - c\|\mathbf{y}\|^2 = 0$, so by Proposition 6.1.29 the cross term in $\|\mathbf{w} + c\mathbf{y}\|^2$ vanishes:

$$\|\mathbf{x}\|^2 = \|\mathbf{w}\|^2 + |c|^2\|\mathbf{y}\|^2 = \|\mathbf{w}\|^2 + \frac{|\langle \mathbf{x}, \mathbf{y}\rangle|^2}{\|\mathbf{y}\|^2}.$$

Dropping $\|\mathbf{w}\|^2 \geq 0$ and multiplying by $\|\mathbf{y}\|^2$ gives the inequality. Equality holds exactly when $\mathbf{w} = \mathbf{0}$, that is, $\mathbf{x} = c\mathbf{y}$; the converse is Lemma 6.2.3.

(c) Let $a = \|\mathbf{x}\| > 0$, $b = \|\mathbf{y}\| > 0$, and $r = \operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$. By Proposition 6.1.29 with the real scalars $1/a$ and $1/b$,

$$\left\|\frac{\mathbf{x}}{a} - \frac{\mathbf{y}}{b}\right\|^2 = 1 - \frac{2r}{ab} + 1 = \frac{2(ab-r)}{ab},$$

and $\|\mathbf{x} - \mathbf{y}\|^2 = a^2 - 2r + b^2 = (a-b)^2 + 2(ab-r)$. Both sides of the claimed inequality are nonnegative, so it is equivalent to the inequality between their squares, and after multiplying by $ab(a+b)^2/2 > 0$, to

$$(ab-r)(a+b)^2 \leq 2ab\big((a-b)^2 + 2(ab-r)\big).$$

Since $(a+b)^2 = (a-b)^2 + 4ab$, the left side is $(ab-r)(a-b)^2 + 4ab(ab-r)$, and the right side minus the left side is

$$2ab(a-b)^2-(ab-r)(a-b)^2=(a-b)^2(ab+r).$$

By Cauchy–Schwarz, $-r\le|\langle\mathbf{x},\mathbf{y}\rangle|\le ab$, so $ab+r\ge 0$, which proves the inequality.

Equality holds if and only if $(a-b)^2(ab+r)=0$, that is, $a=b$ or $r=-ab$. If $r=-ab$, then $\operatorname{Re}\langle\mathbf{x},-\mathbf{y}\rangle=\|\mathbf{x}\|\|-\mathbf{y}\|$. Since $\operatorname{Re}z\le|z|$ and Cauchy–Schwarz bounds $|\langle\mathbf{x},-\mathbf{y}\rangle|$ by the same number, $\langle\mathbf{x},-\mathbf{y}\rangle=\|\mathbf{x}\|\|-\mathbf{y}\|$, and by Theorem 6.2.11(b) one of $\mathbf{x},-\mathbf{y}$ is a nonnegative real multiple of the other. Both are nonzero, so $\mathbf{y}=-s\mathbf{x}$ with $s>0$. Conversely, if $\mathbf{y}=-s\mathbf{x}$ with $s>0$, then $r=-sa^2=-ab$.

The inequality says that sending nonzero vectors to the unit sphere along rays moves them apart by at most $2/(\|\mathbf{x}\|+\|\mathbf{y}\|)$ times their distance. Its proof used only $\operatorname{Re}\langle\mathbf{x},\mathbf{y}\rangle\ge-\|\mathbf{x}\|\|\mathbf{y}\|$. In a general normed space the same inequality holds with 4 in place of 2 (Dunkl and Williams, 1964).

Solution to Problem 6.2

> *Uses.* Theorem 6.4.24 (Orthogonal decomposition), Theorem 6.4.33 (Best approximation), Proposition 6.3.9 (Properties of $A^\perp$), Theorem 6.3.3 (Pythagorean theorem), Proposition 6.1.30 (Parallelogram law), Aside (Norms that do not come from inner products) (Norms that do not come from inner products)
> *Techniques.* Projections shrink norms (Technique 6.4.5), Recognize a projection by its two conditions (Technique 6.4.7)
> *Hint 1.* For existence in (b), check $\langle\mathbf{v}-\operatorname{Pr}_W(\mathbf{v}),\mathbf{u}_j\rangle=0$ for each j. For uniqueness, what is $W\cap W^\perp$?
> *Hint 2.* For best approximation, write $\mathbf{v}-\mathbf{w}=(\mathbf{v}-\operatorname{Pr}_W(\mathbf{v}))+(\operatorname{Pr}_W(\mathbf{v})-\mathbf{w})$ and use Pythagoras. In (c), compute $\|\mathbf{e}_2-t\mathbf{e}_1\|_\infty$.
> *Sketch.* (b) $\mathbf{v}-\operatorname{Pr}_W(\mathbf{v})$ is orthogonal to each $\mathbf{u}_j$, hence to W; two decompositions differ by a vector of $W\cap W^\perp=\{\mathbf{0}\}$. For $\mathbf{w}\in W$, Pythagoras gives $\|\mathbf{v}-\mathbf{w}\|^2=\|\mathbf{v}-\operatorname{Pr}_W(\mathbf{v})\|^2+\|\operatorname{Pr}_W(\mathbf{v})-\mathbf{w}\|^2$. (c) $\|\mathbf{e}_2-t\mathbf{e}_1\|_\infty=\max(|t|,1)$, so every $t\mathbf{e}_1$ with $|t|\le1$ is closest. The Pythagorean step fails: $\|\cdot\|_\infty$ violates the parallelogram law, so it comes from no inner product.

(a) *Orthogonal decomposition* (Theorem 6.4.24): every $\mathbf{v}\in V$ can be written in exactly one way as $\mathbf{v}=\mathbf{w}+\mathbf{w}'$ with $\mathbf{w}\in W$ and $\mathbf{w}'\in W^\perp$, namely with $\mathbf{w}=\operatorname{Pr}_W(\mathbf{v})$. *Best approximation* (Theorem 6.4.33): $\|\mathbf{v}-\operatorname{Pr}_W(\mathbf{v})\|\le\|\mathbf{v}-\mathbf{w}\|$ for every $\mathbf{w}\in W$, with equality only for $\mathbf{w}=\operatorname{Pr}_W(\mathbf{v})$.

(b) *Existence.* Let $\mathbf{p}=\operatorname{Pr}_W(\mathbf{v})=\sum_i\langle\mathbf{v},\mathbf{u}_i\rangle\mathbf{u}_i\in W$. For each j, since $\langle\mathbf{u}_i,\mathbf{u}_j\rangle=\delta_{ij}$,

$$\langle\mathbf{v}-\mathbf{p},\mathbf{u}_j\rangle=\langle\mathbf{v},\mathbf{u}_j\rangle-\sum_i\langle\mathbf{v},\mathbf{u}_i\rangle\langle\mathbf{u}_i,\mathbf{u}_j\rangle=0.$$

A vector orthogonal to each $\mathbf{u}_j$ is orthogonal to their span W (Proposition 6.3.9(c)), so $\mathbf{v}-\mathbf{p}\in W^\perp$, and $\mathbf{v}=\mathbf{p}+(\mathbf{v}-\mathbf{p})$ is a decomposition.

Uniqueness. If $\mathbf{w}_1+\mathbf{w}_1'=\mathbf{w}_2+\mathbf{w}_2'$ with $\mathbf{w}_i\in W$ and $\mathbf{w}_i'\in W^\perp$, then $\mathbf{z}=\mathbf{w}_1-\mathbf{w}_2=\mathbf{w}_2'-\mathbf{w}_1'$ lies in $W\cap W^\perp$, so $\langle\mathbf{z},\mathbf{z}\rangle=0$ and $\mathbf{z}=\mathbf{0}$.

Best approximation. Let $\mathbf{w}\in W$. Then $\mathbf{v}-\mathbf{w}=(\mathbf{v}-\mathbf{p})+(\mathbf{p}-\mathbf{w})$, where the first piece lies in $W^\perp$ and the second in W. By Theorem 6.3.3,

$$\|\mathbf{v}-\mathbf{w}\|^2=\|\mathbf{v}-\mathbf{p}\|^2+\|\mathbf{p}-\mathbf{w}\|^2\ge\|\mathbf{v}-\mathbf{p}\|^2,$$

with equality if and only if $\|\mathbf{p}-\mathbf{w}\|=0$, that is, $\mathbf{w}=\mathbf{p}$.

(c) The points of W are $t\mathbf{e}_1=(t,0)$, and $\|\mathbf{e}_2-t\mathbf{e}_1\|_\infty=\|(-t,1)\|_\infty=\max(|t|,1)\ge1$, with equality if and only if $|t|\le1$. So the distance from $\mathbf{e}_2$ to W is 1, and it is attained at every point $(t,0)$ with $-1\le t\le1$.

The step with no analogue is the Pythagorean identity, which made the closest point unique: it adds the positive number $\|\mathbf{p}-\mathbf{w}\|^2$ for every $\mathbf{w}\ne\mathbf{p}$. The norm $\|\cdot\|_\infty$ does not come from any inner product, since it violates the parallelogram law (Proposition 6.1.30): $\|\mathbf{e}_1+\mathbf{e}_2\|_\infty^2+\|\mathbf{e}_1-\mathbf{e}_2\|_\infty^2=2$, while $2\|\mathbf{e}_1\|_\infty^2+2\|\mathbf{e}_2\|_\infty^2=4$. So there is no orthogonality to make the error perpendicular to W (compare Aside (Norms that do not come from inner products)). Closest points still exist here, but uniqueness, and the linear formula for Pr_W, are features of inner products.

Solution to Problem 6.3

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Definition 6.6.8 (Adjoint), Proposition 6.1.37 (Inner products distinguish vectors), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.4.26 (The double complement), Example 6.6.10 (The adjoint of a matrix), Corollary 6.6.22 (T and T^* have the same rank), Theorem 4.2.11 (Rank–nullity)
Techniques. Move an operator across the inner product (Technique 6.6.20), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. For (b), $\mathbf{w} \in \ker T^*$ if and only if $\langle \mathbf{v}, T^*\mathbf{w}\rangle = 0$ for every $\mathbf{v}$. Move T^* across.
Hint 2. For the second statement, apply the first one to T^*, whose adjoint is T, and take perps.
Hint 3. For (c), $A\mathbf{x} = \mathbf{b}$ is solvable if and only if $\mathbf{b} \in \operatorname{im} A = (\ker A^*)^\perp$. For the example, look for a combination of the three equations whose left side is 0.
Sketch. (b) $T^*\mathbf{w} = \mathbf{0}$ iff $\langle \mathbf{v}, T^*\mathbf{w}\rangle = 0$ for all $\mathbf{v}$ iff $\langle T\mathbf{v}, \mathbf{w}\rangle = 0$ for all $\mathbf{v}$ iff $\mathbf{w} \perp \operatorname{im} T$. Applied to T^*: $\ker T = (\operatorname{im} T^*)^\perp$, and the double perp gives $\operatorname{im} T^* = (\ker T)^\perp$. (c) $\mathbf{b} \in \operatorname{im} A$ iff $\mathbf{b} \perp \ker A^*$; the second alternative says exactly that this fails. For the example, $\mathbf{y} = (1, -1, -1)$ spans $\ker A^{\mathsf{T}}$; $\mathbf{y}^{\mathsf{T}}(1,1,1) = -1$, so no solution, while $\mathbf{y}^{\mathsf{T}}(1,1,0) = 0$, and $(1,0,1)$ is a solution.

(a) Let $T \in \mathrm{L}(V, W)$ have an adjoint. Then $\ker T^* = (\operatorname{im} T)^\perp$ and $\ker T = (\operatorname{im} T^*)^\perp$. If V is finite-dimensional, also $\operatorname{im} T^* = (\ker T)^\perp$ and $\operatorname{im} T = (\ker T^*)^\perp$, so that $V = \ker T \oplus \operatorname{im} T^*$ and $W = \operatorname{im} T \oplus \ker T^*$ (Theorem 6.6.21).

(b) Let $\mathbf{w} \in W$. A vector of V is $\mathbf{0}$ if and only if it is orthogonal to every vector of V (Proposition 6.1.37). So

$$\begin{aligned} T^*\mathbf{w} = \mathbf{0} &\iff \langle \mathbf{v}, T^*\mathbf{w}\rangle = 0 \text{ for all } \mathbf{v} \in V \\ &\iff \langle T\mathbf{v}, \mathbf{w}\rangle = 0 \text{ for all } \mathbf{v} \in V \iff \mathbf{w} \in (\operatorname{im} T)^\perp, \end{aligned}$$

using Definition 6.6.8 in the middle. This proves $\ker T^* = (\operatorname{im} T)^\perp$.

By Proposition 6.6.18, T^* has the adjoint T. Applying what we just proved to T^* gives $\ker T = (\operatorname{im} T^*)^\perp$. If V is finite-dimensional, so is its subspace $\operatorname{im} T^*$, and Theorem 6.4.26 gives $(\ker T)^\perp = \left((\operatorname{im} T^*)^\perp\right)^\perp = \operatorname{im} T^*$.

(c) With dot products, the map $\mathbf{x} \mapsto A\mathbf{x}$ from $\mathbb{F}^n$ to $\mathbb{F}^m$ has the adjoint $\mathbf{y} \mapsto A^*\mathbf{y}$ (Example 6.6.10). Applying (b) to the adjoint, with the finite-dimensional space $\mathbb{F}^m$ in the role of V, gives $\operatorname{im} A = (\ker A^*)^\perp$. So $A\mathbf{x} = \mathbf{b}$ has a solution if and only if $\mathbf{y}^*\mathbf{b} = \langle \mathbf{b}, \mathbf{y}\rangle = 0$ for every $\mathbf{y} \in \ker A^*$. The second alternative says precisely that this fails for some $\mathbf{y}$, so exactly one of the two holds.

For the example, $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & -1 \end{pmatrix}$ is real, so $A^* = A^{\mathsf{T}}$. Subtracting the second equation from the first gives $x_1 - x_3$, so $\mathbf{y} = (1, -1, -1)$ satisfies $A^{\mathsf{T}}\mathbf{y} = \mathbf{0}$, as one checks column by column. With $\mathbf{b} = (1,1,1)$, $\mathbf{y}^{\mathsf{T}}\mathbf{b} = 1 - 1 - 1 = -1 \neq 0$, so the system has no solution. With $\mathbf{b}' = (1,1,0)$, $\mathbf{y}^{\mathsf{T}}\mathbf{b}' = 0$. The first two rows of A are independent and the third is their difference, so $\operatorname{rank} A = 2$, $\operatorname{rank} A^{\mathsf{T}} = 2$ (Corollary 6.6.22), and $\ker A^{\mathsf{T}} = \operatorname{span}(\mathbf{y})$ by Theorem 4.2.11. So $\mathbf{b}' \perp \ker A^{\mathsf{T}}$, and the system is solvable; indeed $\mathbf{x} = (1,0,1)$ works.

The vector $\mathbf{y}$ is a certificate of inconsistency that can be checked without solving anything. Row reduction finds it too (as the combination of rows that produces $0 = -1$), but (b) explains why it must exist: the right-hand side has to be orthogonal to every relation among the rows.

Solution to Problem 6.4

Uses. Proposition 6.1.29 (Expanding a norm), Definition 6.3.28 (Gram matrix), Proposition 6.3.30 (Gram matrices detect independence), Theorem 6.4.6 (The projection is characterized by orthogonality), Theorem 6.4.33 (Best approximation)
Techniques. Gram matrices (Technique 6.3.31), Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. Write $\mathbf{c} = \mathbf{p}_0 + \mathbf{z}$. Expand $\|\mathbf{z} - \mathbf{v}_i\|^2 = \|\mathbf{z}\|^2$. What linear condition on $\mathbf{z}$ do you get?
Hint 2. The conditions are $\langle \mathbf{z}, \mathbf{v}_i\rangle = \|\mathbf{v}_i\|^2/2$. With $\mathbf{z} = \sum_j t_j\mathbf{v}_j$ they become a linear system whose matrix is the Gram matrix of $\mathbf{v}_1, \ldots, \mathbf{v}_k$.
Sketch. $\|\mathbf{c} - \mathbf{p}_i\| = \|\mathbf{c} - \mathbf{p}_0\|$ iff $\langle \mathbf{c} - \mathbf{p}_0, \mathbf{v}_i\rangle = \|\mathbf{v}_i\|^2/2$. For $\mathbf{c} - \mathbf{p}_0 = \sum_j t_j\mathbf{v}_j$ this is $G\mathbf{t} = \mathbf{d}$ with G the invertible Gram matrix, so $\mathbf{c}$ is unique. For any $\mathbf{q}$ the same conditions hold with $\mathbf{q}$; subtracting gives $\mathbf{q} - \mathbf{c} \perp \mathbf{v}_i$, so $\mathbf{c} - \mathbf{p}_0$ is the projection of $\mathbf{q} - \mathbf{p}_0$. (c) $G = \begin{pmatrix} 4 & 2 \\ 2 & 9 \end{pmatrix}$, $\mathbf{d} = (2, 9/2)$, $\mathbf{t} = (9/32, 7/16)$, $\mathbf{c} = (1, 7/8, 7/8)$, distance $9\sqrt{2}/8$.

(a) Every point of A is $\mathbf{c} = \mathbf{p}_0 + \mathbf{z}$ with $\mathbf{z} \in U = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$. Since $\mathbf{c} - \mathbf{p}_i = \mathbf{z} - \mathbf{v}_i$, Proposition 6.1.29 gives

$$\|\mathbf{c} - \mathbf{p}_i\|^2 = \|\mathbf{z}\|^2 - 2\langle \mathbf{z}, \mathbf{v}_i\rangle + \|\mathbf{v}_i\|^2 = \|\mathbf{c} - \mathbf{p}_0\|^2 - 2\langle \mathbf{z}, \mathbf{v}_i\rangle + \|\mathbf{v}_i\|^2.$$

So $\mathbf{c}$ is equidistant from all the points if and only if

$$\langle \mathbf{z}, \mathbf{v}_i \rangle = \frac{1}{2}\|\mathbf{v}_i\|^2 \quad (1 \le i \le k).$$

Write $\mathbf{z} = \sum_j t_j \mathbf{v}_j$. Then $\langle \mathbf{z}, \mathbf{v}_i \rangle = \sum_j t_j \langle \mathbf{v}_j, \mathbf{v}_i \rangle = (G\mathbf{t})_i$, where G is the Gram matrix of $\mathbf{v}_1, \dots, \mathbf{v}_k$ (Definition 6.3.28). So the conditions say $G\mathbf{t} = \mathbf{d}$ with $d_i = \|\mathbf{v}_i\|^2/2$. The $\mathbf{v}_i$ are independent, so G is invertible (Proposition 6.3.30), and there is exactly one $\mathbf{t}$, hence (by independence again) exactly one $\mathbf{z} \in U$ and one $\mathbf{c} \in A$.

(b) The computation in (a) did not use $\mathbf{z} \in U$: for every $\mathbf{q} \in \mathbb{R}^n$, $\mathbf{q}$ is equidistant from the points if and only if $\mathbf{z} = \mathbf{q} - \mathbf{p}_0$ satisfies these k conditions. Since $\mathbf{c} - \mathbf{p}_0$ satisfies it, subtracting shows that $\mathbf{q}$ is equidistant if and only if $\langle \mathbf{q} - \mathbf{c}, \mathbf{v}_i \rangle = 0$ for all i.

For such $\mathbf{q}$, the vector $\mathbf{c} - \mathbf{p}_0$ lies in U, and $(\mathbf{q} - \mathbf{p}_0) - (\mathbf{c} - \mathbf{p}_0) = \mathbf{q} - \mathbf{c}$ is orthogonal to U. By Theorem 6.4.6, $\mathbf{c} - \mathbf{p}_0 = \mathrm{Pr}_U(\mathbf{q} - \mathbf{p}_0)$. For any $\mathbf{a} = \mathbf{p}_0 + \mathbf{u} \in A$, Theorem 6.4.33 gives

$$\|\mathbf{q} - \mathbf{a}\| = \|(\mathbf{q} - \mathbf{p}_0) - \mathbf{u}\| \ge \|(\mathbf{q} - \mathbf{p}_0) - \mathrm{Pr}_U(\mathbf{q} - \mathbf{p}_0)\| = \|\mathbf{q} - \mathbf{c}\|,$$

with equality only for $\mathbf{a} = \mathbf{c}$. If $k = n$, then $U = \mathbb{R}^n$, so $U^\perp = \{\mathbf{0}\}$ and $\mathbf{q} = \mathbf{c}$.

(c) Here $\mathbf{v}_1 = (2, 0, 0)$ and $\mathbf{v}_2 = (1, 2, 2)$, so

$$G = \begin{pmatrix} 4 & 2 \\ 2 & 9 \end{pmatrix}, \quad \mathbf{d} = \begin{pmatrix} 2 \\ 9/2 \end{pmatrix}, \quad \mathbf{t} = G^{-1}\mathbf{d} = \frac{1}{32}\begin{pmatrix} 9 & -2 \\ -2 & 4 \end{pmatrix}\begin{pmatrix} 2 \\ 9/2 \end{pmatrix} = \begin{pmatrix} 9/32 \\ 7/16 \end{pmatrix}.$$

So $\mathbf{c} = (9/32)(2, 0, 0) + (7/16)(1, 2, 2) = (1, 7/8, 7/8)$. Check: $\|\mathbf{c}\|^2 = 1 + 49/32 = 81/32$, $\|\mathbf{c} - \mathbf{p}_1\|^2 = 1 + 49/32 = 81/32$, and $\|\mathbf{c} - \mathbf{p}_2\|^2 = 0 + 2 \cdot 81/64 = 81/32$. The common distance is $9/\sqrt{32} = 9\sqrt{2}/8$.

By (b), the points of $\mathbb{R}^3$ equidistant from the three vertices form the line through $\mathbf{c}$ perpendicular to the plane of the triangle; the circumcenter is where that line meets the plane.

Solution to Problem 6.5

Uses. Definition 6.1.2 (Inner product), Lemma 3.4.23 (Too many roots), Proposition 6.3.18 (Coordinates in an orthonormal basis), Corollary 6.3.14 (Counting orthogonal vectors), Proposition 6.3.30 (Gram matrices detect independence), Theorem 6.4.33 (Best approximation), Proposition 6.5.21 (Polynomial fits)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12), A sum of nonnegative terms (Technique 6.1.9)
Hint 1. For definiteness, a polynomial of degree at most n with $n+1$ roots is zero. For the Lagrange polynomials, compute $\langle L_i, L_j \rangle$ from $L_i(x_k) = \delta_{ik}$.
Hint 2. In (c), $\|p - q\|^2 = \sum_k (y_k - q(x_k))^2$ for every q. In (d), 1 and x are orthogonal for this inner product.
Sketch. (a) Positivity is a sum of squares, and $\sum_k p(x_k)^2 = 0$ forces $n+1$ roots, so $p = 0$. $\langle L_i, L_j \rangle = \sum_k \delta_{ik}\delta_{jk} = \delta_{ij}$, and $n+1$ orthonormal vectors in an $(n+1)$-dimensional space form a basis; $\langle p, L_j \rangle = p(x_j)$. (b) It is the Gram matrix of the basis $1, x, \dots, x^n$. (c) $\|p - q\|^2$ is the sum of squared residuals of q, so its minimizer is the projection. (d) $p = 1 + 3x/2 + x^2/2$; with $\|1\|^2 = 3$, $\|x\|^2 = 2$, $\langle p, 1 \rangle = 4$, $\langle p, x \rangle = 3$, the line is $y = 4/3 + 3x/2$.

(a) The formula is linear in p and symmetric, since evaluation at a point is linear. Also $\langle p, p \rangle = \sum_k p(x_k)^2 \ge 0$, and if it is 0, then every $p(x_k) = 0$ (Technique 6.1.9), so p, which has degree at most n and $n+1$ distinct roots, is 0 by Lemma 3.4.23. So this is an inner product.

Since $L_i(x_k) = \delta_{ik}$,

$$\langle L_i, L_j \rangle = \sum_{k=0}^{n} L_i(x_k) L_j(x_k) = \sum_{k=0}^{n} \delta_{ik}\delta_{jk} = \delta_{ij}.$$

So $L_0, \dots, L_n$ is orthonormal, and since $\dim V = n + 1$ it is an orthonormal basis (Corollary 6.3.14). By Proposition 6.3.18 the coordinates of p are $\langle p, L_j \rangle = \sum_k p(x_k)\delta_{jk} = p(x_j)$, that is, $p = \sum_j p(x_j) L_j$. The Lagrange interpolation formula is the coordinate formula for this orthonormal basis.

(b) The (i,j) entry is $\sum_k x_k^j x_k^i = \langle x^j, x^i \rangle$, so the matrix is the Gram matrix of $1, x, \ldots, x^n$ (Definition 6.3.28). These polynomials are independent, so the Gram matrix is invertible by Proposition 6.3.30. Problem 5.9 computes its determinant as $\prod_{i<j} (x_j - x_i)^2$; here invertibility came from the positivity of an inner product instead.

(c) For every $q \in \mathbb{R}[x]_{\le d}$,

$$\|p - q\|^2 = \sum_{k=0}^{n} (p(x_k) - q(x_k))^2 = \sum_{k=0}^{n} (y_k - q(x_k))^2,$$

the sum of squared residuals of q. By Theorem 6.4.33, this is smallest exactly for $q = \mathrm{Pr}_{\mathbb{R}[x]_{\le d}}(p)$, so that projection is the least-squares polynomial of Proposition 6.5.21, and in particular it is unique.

(d) $p = 1 + (3/2)x + (1/2)x^2$ satisfies $p(-1) = 0$, $p(0) = 1$, $p(1) = 3$. For this inner product $\langle 1, x \rangle = -1 + 0 + 1 = 0$, $\|1\|^2 = 3$, and $\|x\|^2 = 2$, while $\langle p, 1 \rangle = 0 + 1 + 3 = 4$ and $\langle p, x \rangle = 0 + 0 + 3 = 3$. By Corollary 6.4.10,

$$\mathrm{Pr}_{\mathbb{R}[x]_{\le 1}}(p) = \frac{4}{3} + \frac{3}{2}x.$$

This agrees with Proposition 6.5.17: the mean of the nodes is 0, the mean of the values is $4/3$, and the slope is $\sum_k x_k y_k / \sum_k x_k^2 = 3/2$.

Solution to Problem 6.6

> *Uses.* Proposition 6.1.41 (Over $\mathbb{C}$, the values $\langle T\mathbf{v}, \mathbf{v} \rangle$ determine T), Example 6.1.39 (A rotation), Proposition 6.6.18 (Properties of the adjoint), Proposition 6.6.30 (Self-adjoint means real values)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18), Plug in clever test vectors (Technique 6.1.40)
> *Hint 1.* Which hypotheses does Proposition 6.1.41 have? Over $\mathbb{R}$, compute $\langle S\mathbf{v}, \mathbf{v} \rangle$ for $S = T - T^*$ without using any hypothesis on T.
> *Hint 2.* Try $T = I_2 + J$ with J the rotation by $\pi/2$.
> *Sketch.* Proposition 6.1.41 needs complex scalars. Over $\mathbb{R}$, $\langle T^*\mathbf{v}, \mathbf{v} \rangle = \langle T\mathbf{v}, \mathbf{v} \rangle$ for every T, so the argument proves nothing, and $T = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ has $\langle T\mathbf{v}, \mathbf{v} \rangle = \|\mathbf{v}\|^2$ but $T^{\mathsf{T}} \neq T$. (a) Over $\mathbb{C}$ the conjugation step uses that $\langle T\mathbf{v}, \mathbf{v} \rangle$ is real, and Proposition 6.1.41 applies. (b) $\langle T^*\mathbf{v}, \mathbf{v} \rangle = \langle T\mathbf{v}, \mathbf{v} \rangle$ over $\mathbb{R}$, so averaging gives the claim.

The error. The last step cites Proposition 6.1.41, which is about complex inner product spaces. Over $\mathbb{R}$, $S = T - T^*$ satisfies $S^* = -S$ (Proposition 6.6.18), and every such operator has $\langle S\mathbf{v}, \mathbf{v} \rangle = \langle \mathbf{v}, S^*\mathbf{v} \rangle = -\langle \mathbf{v}, S\mathbf{v} \rangle = -\langle S\mathbf{v}, \mathbf{v} \rangle$, hence $\langle S\mathbf{v}, \mathbf{v} \rangle = 0$, whether or not $S = 0$. In fact over $\mathbb{R}$ the first display holds for every T, so the argument never used the hypothesis, which is a sign that something is wrong.

The claim is false. Let $T = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ on $\mathbb{R}^2$ with the dot product. Then

$$\langle T\mathbf{v}, \mathbf{v} \rangle = (v_1 - v_2)v_1 + (v_1 + v_2)v_2 = v_1^2 + v_2^2 \ge 0,$$

but $T^* = T^{\mathsf{T}} = \left(\begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix}\right) \neq T$. Here $T = I_2 + J$ with J the rotation of Example 6.1.39, and J contributes nothing to $\langle T\mathbf{v}, \mathbf{v} \rangle$.

(a) Over $\mathbb{C}$ every step is correct. The conjugation step is the definition of the adjoint followed by conjugate symmetry, and the hypothesis is used exactly where it should be: a nonnegative number equals its conjugate. Then $\langle S\mathbf{v}, \mathbf{v} \rangle = 0$ for every $\mathbf{v}$, and Proposition 6.1.41 gives $S = 0$. (This is one half of Proposition 6.6.30.)

(b) Over $\mathbb{R}$, $\langle T^*\mathbf{v}, \mathbf{v} \rangle = \langle \mathbf{v}, T\mathbf{v} \rangle = \langle T\mathbf{v}, \mathbf{v} \rangle$ by symmetry of the real inner product. So

$$\langle H\mathbf{v}, \mathbf{v} \rangle = \frac{1}{2}(\langle T\mathbf{v}, \mathbf{v} \rangle + \langle T^*\mathbf{v}, \mathbf{v} \rangle) = \langle T\mathbf{v}, \mathbf{v} \rangle.$$

The numbers $\langle T\mathbf{v}, \mathbf{v} \rangle$ see only the self-adjoint part H of a real operator, and adding any K with $K^* = -K$ to T does not change them. This is why Section 8.3 requires positive operators to be self-adjoint by definition.

Solution to Problem 6.7

Uses. Theorem 6.4.31 (The matrix of an orthogonal projection), Theorem 5.4.10 (Multiplicativity), Exercise 6.3.57, Lemma 6.5.4 (The orthogonal complement of a column space), Theorem 6.4.6 (The projection is characterized by orthogonality), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 4.2.11 (Rank–nullity), Exercise 6.4.59
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Move an operator across the inner product (Technique 6.6.20)
Hint 1. (a) Try $m > n$. (b) $\det(A^*) = \overline{\det A}$. (c) First show $\|P\mathbf{v}\| = \|P^{\mathsf{T}}\mathbf{v}\|$, and deduce $\ker P = \ker P^{\mathsf{T}}$.
Hint 2. (d) Apply rank–nullity to Pr_W restricted to U. (e) One direction is Hadamard's inequality from Exercise 6.4.59(c); for the other, try a diagonal matrix.
Sketch. (a) False: $A = \mathbf{e}_1 \in \mathbb{R}^{2\times 1}$ gives $AA^{\mathsf{T}} = \mathrm{diag}(1,0)$; in general AA^{T} is the projection onto $\mathrm{im}\, A$. (b) True: $\det(A^*A) = |\det A|^2$. (c) True: normality gives $\ker P = \ker P^{\mathsf{T}} = (\mathrm{im}\, P)^{\perp}$, so $\mathbf{v} - P\mathbf{v} \in \ker P \perp \mathrm{im}\, P$. (d) True: the restriction of Pr_W to U has kernel $U \cap W^{\perp}$ and image in W. (e) "Only if" is true by Hadamard, since the columns $A\mathbf{e}_j$ have length at most 1; "if" is false for $\mathrm{diag}(2, 1/2)$.

(a) False. $A = \begin{pmatrix}1\\0\end{pmatrix} \in \mathbb{R}^{2\times 1}$ has one orthonormal column, but $AA^{\mathsf{T}} = \begin{pmatrix}1&0\\0&0\end{pmatrix} \neq I_2$. In general AA^{T} is the matrix of $\mathrm{Pr}_{\mathrm{im}\, A}$ (Theorem 6.4.31), which is I_m only when $\mathrm{im}\, A = \mathbb{R}^m$, that is, when $m = n$.

(b) True. By Theorem 5.4.10 and Exercise 6.3.57(a), $\det(A^*A) = \det(A^*)\det A = \overline{\det A}\det A = |\det A|^2 \geq 0$.

(c) True. Let $\mathbf{v} \in \mathbb{R}^n$. Using the dot product, $\|P\mathbf{v}\|^2 = \langle P^{\mathsf{T}}P\mathbf{v}, \mathbf{v}\rangle = \langle PP^{\mathsf{T}}\mathbf{v}, \mathbf{v}\rangle = \|P^{\mathsf{T}}\mathbf{v}\|^2$, so $\ker P = \ker P^{\mathsf{T}}$, and $\ker P^{\mathsf{T}} = (\mathrm{im}\, P)^{\perp}$ by Lemma 6.5.4. Now $P\mathbf{v} \in \mathrm{im}\, P$, and $P(\mathbf{v} - P\mathbf{v}) = P\mathbf{v} - P^2\mathbf{v} = \mathbf{0}$, so $\mathbf{v} - P\mathbf{v} \in \ker P = (\mathrm{im}\, P)^{\perp}$. By Theorem 6.4.6, $P\mathbf{v} = \mathrm{Pr}_{\mathrm{im}\, P}(\mathbf{v})$ for every $\mathbf{v}$.

(d) True. Let $R : U \to W$ be the restriction of Pr_W to U; it maps into W and is linear. Its kernel is $U \cap \ker \mathrm{Pr}_W = U \cap W^{\perp}$ (Proposition 6.4.29(a)), and its image is a subspace of W. By Theorem 4.2.11,

$$\dim U = \dim\bigl(U \cap W^{\perp}\bigr) + \dim \mathrm{im}\, R \leq \dim\bigl(U \cap W^{\perp}\bigr) + \dim W.$$

In words: if U is bigger than W, then U contains $\dim U - \dim W$ independent directions perpendicular to all of W.

(e) "Only if" is true. The columns of A are $\mathbf{a}_j = A\mathbf{e}_j$, with $\|\mathbf{a}_j\| \leq \|\mathbf{e}_j\| = 1$. By Hadamard's inequality (Exercise 6.4.59(c)), $|\det A| \leq \|\mathbf{a}_1\|\cdots\|\mathbf{a}_n\| \leq 1$. "If" is false: $A = \begin{pmatrix}2&0\\0&1/2\end{pmatrix}$ has $\det A = 1$ but $\|A\mathbf{e}_1\| = 2 > 1$. The determinant measures the change of volume, and a map can stretch one direction while shrinking another.

Solution to Problem 6.8

Uses. Proposition 6.1.29 (Expanding a norm), Proposition 6.1.27 (Basic properties of the norm), Corollary 6.3.14 (Counting orthogonal vectors), Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A), Theorem 6.3.29 (Orthonormal columns)
Techniques. Polarization (Technique 6.1.33), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. (a) Put $\mathbf{y} = \mathbf{0}$, then expand $\|f(\mathbf{x}) - f(\mathbf{y})\|^2$ and compare with $\|\mathbf{x} - \mathbf{y}\|^2$.
Hint 2. (b) Expand $\|f(\mathbf{x}+\mathbf{y}) - f(\mathbf{x}) - f(\mathbf{y})\|^2$ into norms and inner products of values of f, and use (a) on every term.
Hint 3. For the second proof, $f(\mathbf{e}_1), \ldots, f(\mathbf{e}_n)$ is orthonormal. Compute the coordinates of $f(\mathbf{x})$ in it. For (d), try complex conjugation on $\mathbb{C}^n$.
Sketch. (a) $\|f(\mathbf{x})\| = \|f(\mathbf{x}) - f(\mathbf{0})\| = \|\mathbf{x}\|$, and polarization turns equal distances and equal lengths into equal inner products. (b) $\|f(\mathbf{x}+\mathbf{y}) - f(\mathbf{x}) - f(\mathbf{y})\|^2$ expands into terms that (a) lets us replace by the same terms without f, giving $\|\mathbf{0}\|^2 = 0$; likewise for $f(t\mathbf{x}) - tf(\mathbf{x})$. With an orthonormal basis: $f(\mathbf{e}_i)$ is an orthonormal basis and $f(\mathbf{x}) = \sum_i \langle \mathbf{x}, \mathbf{e}_i\rangle f(\mathbf{e}_i)$. (c) Apply (b) to $g - g(\mathbf{0})$. (d) The expansions involve only real parts, so the first proof gives real linearity; conjugation preserves distances and is not $\mathbb{C}$-linear.

(a) Taking $\mathbf{y} = \mathbf{0}$ gives $\|f(\mathbf{x})\| = \|f(\mathbf{x}) - f(\mathbf{0})\| = \|\mathbf{x}\|$. By Proposition 6.1.29 over $\mathbb{R}$,

$$\begin{aligned}\|f(\mathbf{x})\|^2 - 2\langle f(\mathbf{x}), f(\mathbf{y})\rangle + \|f(\mathbf{y})\|^2 &= \|f(\mathbf{x}) - f(\mathbf{y})\|^2 \\ &= \|\mathbf{x} - \mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2,\end{aligned}$$

and the squared lengths agree, so $\langle f(\mathbf{x}), f(\mathbf{y})\rangle = \langle \mathbf{x}, \mathbf{y}\rangle$.

(b) *First proof.* Let $\mathbf{x}, \mathbf{y} \in V$ and $\mathbf{z} = f(\mathbf{x}+\mathbf{y}) - f(\mathbf{x}) - f(\mathbf{y})$. Expanding,

$$\|\mathbf{z}\|^2 = \|f(\mathbf{x}+\mathbf{y})\|^2 + \|f(\mathbf{x})\|^2 + \|f(\mathbf{y})\|^2 \\ -2\langle f(\mathbf{x}+\mathbf{y}), f(\mathbf{x})\rangle - 2\langle f(\mathbf{x}+\mathbf{y}), f(\mathbf{y})\rangle + 2\langle f(\mathbf{x}), f(\mathbf{y})\rangle.$$

By (a), each term equals the same term with f removed, and the result is the expansion of $\|(\mathbf{x}+\mathbf{y})-\mathbf{x}-\mathbf{y}\|^2 = 0$. So $\mathbf{z} = \mathbf{0}$ (Proposition 6.1.27). Similarly, for $t \in \mathbb{R}$,

$$\|f(t\mathbf{x}) - tf(\mathbf{x})\|^2 = \|f(t\mathbf{x})\|^2 - 2t\langle f(t\mathbf{x}), f(\mathbf{x})\rangle + t^2\|f(\mathbf{x})\|^2 = \|t\mathbf{x} - t\mathbf{x}\|^2 = 0.$$

So f is additive and homogeneous, that is, linear. This proof works verbatim for $f : V \to W$ between any two real inner product spaces.

Second proof, for $\dim V = n < \infty$. Let $\mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis. By (a), $\langle f(\mathbf{e}_i), f(\mathbf{e}_j)\rangle = \delta_{ij}$, so $f(\mathbf{e}_1), \ldots, f(\mathbf{e}_n)$ is an orthonormal list of length n in V, hence an orthonormal basis (Corollary 6.3.14). By Proposition 6.3.18 and (a),

$$f(\mathbf{x}) = \sum_{i=1}^{n} \langle f(\mathbf{x}), f(\mathbf{e}_i)\rangle f(\mathbf{e}_i) = \sum_{i=1}^{n} \langle \mathbf{x}, \mathbf{e}_i\rangle f(\mathbf{e}_i),$$

and each $\mathbf{x} \mapsto \langle \mathbf{x}, \mathbf{e}_i\rangle$ is linear. This proof needs the values $f(\mathbf{e}_i)$ to span the target, which is why it asks for $f : V \to V$ with V finite-dimensional; the first proof needs nothing of the kind.

(c) Let $f(\mathbf{x}) = g(\mathbf{x}) - g(\mathbf{0})$. Then $f(\mathbf{0}) = \mathbf{0}$ and $\|f(\mathbf{x}) - f(\mathbf{y})\| = \|g(\mathbf{x}) - g(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\|$, so f is linear by (b), say $f(\mathbf{x}) = Q\mathbf{x}$ (Proposition 2.3.17). By (a), $(Q\mathbf{e}_j)\cdot(Q\mathbf{e}_i) = \delta_{ij}$, so the columns of Q are orthonormal and $Q^{\mathsf{T}}Q = I_n$ (Theorem 6.3.29). With $\mathbf{b} = g(\mathbf{0})$, $g(\mathbf{x}) = Q\mathbf{x} + \mathbf{b}$.

(d) Over $\mathbb{C}$, Proposition 6.1.29 contains $2\,\mathrm{Re}\langle\cdot,\cdot\rangle$ instead of $2\langle\cdot,\cdot\rangle$, so (a) becomes $\mathrm{Re}\langle f(\mathbf{x}), f(\mathbf{y})\rangle = \mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$, and the expansions in the first proof of (b) involve only lengths and real parts of inner products (for the second one, with t real). So they go through unchanged and show that f is additive and $f(t\mathbf{x}) = tf(\mathbf{x})$ for $t \in \mathbb{R}$. But f need not be $\mathbb{C}$-linear: on $\mathbb{C}^n$ with the dot product, let f conjugate every entry. Then $f(\mathbf{0}) = \mathbf{0}$ and $\|f(\mathbf{x}) - f(\mathbf{y})\| = \|\overline{\mathbf{x}-\mathbf{y}}\| = \|\mathbf{x}-\mathbf{y}\|$, while $f(i\mathbf{e}_1) = -i\mathbf{e}_1 \neq if(\mathbf{e}_1)$.

For surjective distance-preserving maps between real normed spaces, the conclusion of (b) still holds (the Mazur–Ulam theorem), but the proof is much harder: without an inner product there is no polarization.

Solution to Problem 6.9

> *Uses.* Proposition 6.3.30 (Gram matrices detect independence), Proposition 6.1.27 (Basic properties of the norm), Corollary 2.2.6 (Agreeing on a spanning list), Theorem 6.3.29 (Orthonormal columns), Theorem 6.4.20 (Orthonormal bases exist), Corollary 6.4.25 (Dimension of the orthogonal complement), Corollary 6.3.14 (Counting orthogonal vectors), Definition 6.3.33 (Unitary and orthogonal matrices), Exercise 6.3.37
> *Techniques.* Gram matrices (Technique 6.3.31), Show a vector is zero via its norm (Technique 6.1.36)
> *Hint 1.* (a) is Proposition 6.3.30(a) applied to both lists. Then use Technique 6.1.36.
> *Hint 2.* (b) Define $S\left(\sum_i c_i\mathbf{v}_i\right) = \sum_i c_i\mathbf{w}_i$. Why is this well defined?
> *Hint 3.* (c) The columns of A and of B have the same Gram matrix. Extend the map S of (b) from $\mathrm{im}\,A$ to all of $\mathbb{F}^m$ by matching orthonormal bases of $(\mathrm{im}\,A)^{\perp}$ and $(\mathrm{im}\,B)^{\perp}$.
> *Sketch.* (a) Both squared norms equal $\mathbf{c}^*G\mathbf{c}$. (b) Well defined because two expressions of the same vector differ by a relation, which (a) transports; inner products are preserved because they are computed from G; injective by (a). (c) A^*A is the Gram matrix of the columns. The isometry $S : \mathrm{im}\,A \to \mathrm{im}\,B$ sends an orthonormal basis $\mathbf{u}_1, \ldots, \mathbf{u}_r$ of $\mathrm{im}\,A$ to one of $\mathrm{im}\,B$; completing both with orthonormal bases of the complements (both of dimension $m-r$) gives two unitary matrices U_1, U_2, and $U = U_2U_1^*$ agrees with S on $\mathrm{im}\,A$, so $UA = B$.

(a) Let G be the common Gram matrix and $\mathbf{c} = (c_1, \ldots, c_k)$. By Proposition 6.3.30(a), $\left\|\sum_i c_i\mathbf{v}_i\right\|^2 = \mathbf{c}^*G\mathbf{c} = \left\|\sum_i c_i\mathbf{w}_i\right\|^2$. Since a vector is $\mathbf{0}$ exactly when its norm is 0 (Proposition 6.1.27), the second statement follows.

(b) *Uniqueness.* A linear map on $\mathrm{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$ is determined by its values on the spanning list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ (Corollary 2.2.6).

Existence. Every vector of $\operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$ is $\sum_i c_i \mathbf{v}_i$ for some scalars, and we set $S\big(\sum_i c_i \mathbf{v}_i\big) = \sum_i c_i \mathbf{w}_i$. If $\sum_i c_i \mathbf{v}_i = \sum_i d_i \mathbf{v}_i$, then $\sum_i (c_i - d_i)\mathbf{v}_i = \mathbf{0}$, so $\sum_i (c_i - d_i)\mathbf{w}_i = \mathbf{0}$ by (a), and the two definitions agree. So S is well defined, and it is linear because $\sum_i c_i \mathbf{v}_i + a \sum_i d_i \mathbf{v}_i = \sum_i (c_i + a d_i)\mathbf{v}_i$ is sent to $\sum_i (c_i + a d_i)\mathbf{w}_i$. Clearly $S\mathbf{v}_i = \mathbf{w}_i$.

S preserves inner products. For $\mathbf{x} = \sum_j c_j \mathbf{v}_j$ and $\mathbf{y} = \sum_i d_i \mathbf{v}_i$,

$$\langle S\mathbf{x}, S\mathbf{y} \rangle = \sum_{i,j} c_j \overline{d_i} \langle \mathbf{w}_j, \mathbf{w}_i \rangle = \sum_{i,j} c_j \overline{d_i} \langle \mathbf{v}_j, \mathbf{v}_i \rangle = \langle \mathbf{x}, \mathbf{y} \rangle.$$

S is bijective. If $S\mathbf{x} = \mathbf{0}$, then $\|\mathbf{x}\| = \|S\mathbf{x}\| = 0$, so S is injective. Its image contains every $\mathbf{w}_i$, hence their span, so S is surjective.

(c) If $B = UA$ with $U^*U = I_m$, then $B^*B = A^*U^*UA = A^*A$.

Conversely, suppose $A^*A = B^*B$. By Theorem 6.3.29, A^*A is the Gram matrix of the columns $\mathbf{a}_1, \dots, \mathbf{a}_n$ of A, and B^*B that of the columns $\mathbf{b}_1, \dots, \mathbf{b}_n$ of B. By (b) there is a bijective linear $S : \operatorname{im} A \to \operatorname{im} B$ with $S\mathbf{a}_j = \mathbf{b}_j$ that preserves inner products. In particular $r = \dim \operatorname{im} A = \dim \operatorname{im} B$.

Choose an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_r$ of $\operatorname{im} A$ (Theorem 6.4.20). Then $S\mathbf{u}_1, \dots, S\mathbf{u}_r$ is orthonormal in $\operatorname{im} B$, hence an orthonormal basis of it (Corollary 6.3.14). By Corollary 6.4.25, $(\operatorname{im} A)^\perp$ and $(\operatorname{im} B)^\perp$ both have dimension $m - r$; choose orthonormal bases $\mathbf{u}_{r+1}, \dots, \mathbf{u}_m$ and $\mathbf{u}'_{r+1}, \dots, \mathbf{u}'_m$ of them. Vectors of $\operatorname{im} A$ are orthogonal to vectors of $(\operatorname{im} A)^\perp$, so $\mathbf{u}_1, \dots, \mathbf{u}_m$ is an orthonormal list of length m, hence an orthonormal basis of $\mathbb{F}^m$, and likewise for $S\mathbf{u}_1, \dots, S\mathbf{u}_r, \mathbf{u}'_{r+1}, \dots, \mathbf{u}'_m$. Let U_1 and U_2 be the unitary matrices with these columns (Definition 6.3.33), and $U = U_2 U_1^*$, which is unitary (Exercise 6.3.37). Since $U_1^* U_1 = I_m$, $U_1^* \mathbf{u}_i = \mathbf{e}_i$, so $U\mathbf{u}_i = U_2 \mathbf{e}_i = S\mathbf{u}_i$ for $i \le r$. The linear maps $\mathbf{x} \mapsto U\mathbf{x}$ and S agree on a basis of $\operatorname{im} A$, so they agree on $\operatorname{im} A$, and $U\mathbf{a}_j = S\mathbf{a}_j = \mathbf{b}_j$ for every j. That is, $UA = B$.

Over $\mathbb{R}$, (c) says that two lists of vectors in $\mathbb{R}^m$ with the same lengths and the same pairwise angles differ by an orthogonal matrix. The unitary U is not unique when $r < m$: it can be changed freely on $(\operatorname{im} A)^\perp$.

Solution to Problem 6.10

> *Uses.* Proposition 6.4.29 (The orthogonal projection as a linear map), Proposition 6.6.9 (Adjoints are unique and linear), Definition 6.6.8 (Adjoint), Corollary 6.6.22 (T and T^* have the same rank), Corollary 4.2.18 (Injective if and only if surjective)
> *Techniques.* Move an operator across the inner product (Technique 6.6.20), Dimension counting (Technique 4.2.24)
> *Hint 1.* For (a), move Pr_W across: $\langle \operatorname{Pr}_W \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, \operatorname{Pr}_W \mathbf{w} \rangle$, and $\operatorname{Pr}_W \mathbf{w} = \mathbf{w}$.
> *Hint 2.* For (b), compute $\ker A$. Then compare the ranks of A and A^*.
> *Sketch.* (a) $\langle \operatorname{Pr}_W \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, \operatorname{Pr}_W \mathbf{w} \rangle = \langle \mathbf{u}, \mathbf{w} \rangle$, and symmetrically with U. So B satisfies the defining identity of A^*. (b) $\ker A = U \cap W^\perp$ and $\ker B = W \cap U^\perp$; with $\dim U = \dim W = k$, injective means bijective. $\operatorname{rank} A^* = \operatorname{rank} A$, so A is bijective iff B is. (c) $U = \operatorname{span}(\mathbf{e}_1)$ and $W = \mathbb{R}^2$.

(a) By Proposition 6.4.29(c) and (b), $\langle \operatorname{Pr}_W \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, \operatorname{Pr}_W \mathbf{w} \rangle = \langle \mathbf{u}, \mathbf{w} \rangle$, since $\mathbf{w} \in W$. In the same way $\langle \mathbf{u}, \operatorname{Pr}_U \mathbf{w} \rangle = \langle \operatorname{Pr}_U \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, \mathbf{w} \rangle$, since $\mathbf{u} \in U$. So $\langle A\mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, B\mathbf{w} \rangle$ for all $\mathbf{u} \in U$ and $\mathbf{w} \in W$, which says that B is an adjoint of A (Definition 6.6.8); by Proposition 6.6.9, $B = A^*$.

(b) Let $k = \dim U = \dim W$. By Proposition 6.4.29(a), $\ker \operatorname{Pr}_W = W^\perp$, so $\ker A = U \cap W^\perp$; likewise $\ker B = W \cap U^\perp$. So (i) says that A is injective, and (ii) that B is injective. Since A maps between spaces of the same dimension k, it is injective if and only if it is bijective (Corollary 4.2.18), and the same holds for B. So (i) $\iff$ (iii) and (ii) $\iff$ (iv). Finally, by (a) and Corollary 6.6.22, $\operatorname{rank} B = \operatorname{rank} A^* = \operatorname{rank} A$, and a map between k-dimensional spaces is bijective exactly when its rank is k. So (iii) $\iff$ (iv).

(c) In $V = \mathbb{R}^2$, let $U = \operatorname{span}(\mathbf{e}_1)$ and $W = \mathbb{R}^2$. Then $W^\perp = \{\mathbf{0}\}$, so $U \cap W^\perp = \{\mathbf{0}\}$, but $W \cap U^\perp = \operatorname{span}(\mathbf{e}_2) \neq \{\mathbf{0}\}$.

Condition (i) says that no nonzero vector of U is perpendicular to all of W. Part (b) says that for subspaces of equal dimension this relation is symmetric, which is not obvious from the definition; the proof gets the symmetry from $\operatorname{rank} A^* = \operatorname{rank} A$. For two lines in $\mathbb{R}^3$, both conditions say that the lines are not

perpendicular. In orthonormal bases of U and W, the matrix of A has entries $\langle \mathbf{u}_j, \mathbf{w}_i \rangle$, and its singular values (Section 9.1) are the cosines of the *principal angles* between U and W.

Solution to Problem 6.11

Uses. Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.3.9 (Properties of $A^\perp$), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 6.1.37 (Inner products distinguish vectors), Exercise 2.4.43, Theorem 6.4.26 (The double complement), Lemma 2.4.24 (Matrix units), Example 2.6.28 (The trace)
Techniques. Cyclicity of trace (Technique 2.4.29), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. (a) $\operatorname{tr}(XY) = \operatorname{tr}(YX)$, and $\langle A, I_n \rangle = \operatorname{tr} A$.
Hint 2. (b) Write $\langle XY - YX, M \rangle = \operatorname{tr}(M^* XY) - \operatorname{tr}(M^* YX)$ and move X cyclically in the second term. If the result vanishes for every Y, test with $Y = X^*M - MX^*$.
Hint 3. (c) (b) shows $C^\perp \subseteq \operatorname{span}(I_n)$. Take perps. (d) $U_{ij} = U_{ii}U_{ij} - U_{ij}U_{ii}$ for $i \neq j$.
Sketch. (a) Commutators have trace 0, and $\operatorname{tr} A = \langle A, I_n \rangle$. (b) By cyclicity, $\langle XY - YX, M \rangle = \operatorname{tr}((M^*X - XM^*)Y) = \langle Y, X^*M - MX^* \rangle$; for $M \in C^\perp$, choosing $Y = X^*M - MX^*$ gives $X^*M = MX^*$ for all X, so M is scalar. (c) $C^\perp = \operatorname{span}(I_n)$, so $C = \left(C^\perp\right)^\perp = \operatorname{span}(I_n)^\perp = Z$. (d) $U_{ij} = U_{ii}U_{ij} - U_{ij}U_{ii}$ and $U_{ii} - U_{nn} = U_{in}U_{ni} - U_{ni}U_{in}$.

(a) By Proposition 2.4.28, $\operatorname{tr}(XY - YX) = 0$, so every commutator lies in the subspace Z, and so does their span C. For every A, $\langle A, I_n \rangle = \operatorname{tr}(I_n^* A) = \operatorname{tr} A$, so $Z = \{I_n\}^\perp = \operatorname{span}(I_n)^\perp$ (Proposition 6.3.9(c)).

(b) By Proposition 2.4.28, $\operatorname{tr}(M^*YX) = \operatorname{tr}(XM^*Y)$, so

$$\langle XY - YX, M \rangle = \operatorname{tr}(M^*XY) - \operatorname{tr}(XM^*Y) = \operatorname{tr}((M^*X - XM^*)Y).$$

Let $N = X^*M - MX^*$. By Proposition 6.3.27, $N^* = M^*X - XM^*$, so the right side is $\operatorname{tr}(N^*Y) = \langle Y, N \rangle$, as claimed.

Now let $M \in C^\perp$ and fix X. Then $\langle Y, N \rangle = 0$ for every Y, and $Y = N$ gives $N = 0$ (Proposition 6.1.37), that is, $X^*M = MX^*$. As X runs over $\mathbb{F}^{n \times n}$ so does X^*, since $X = (X^*)^*$. So M commutes with every matrix.

(c) By (b) and Exercise 2.4.43 (a matrix that commutes with every upper triangular matrix is a scalar multiple of I_n; for $n = 1$ every matrix is), $C^\perp \subseteq \operatorname{span}(I_n)$. Conversely $I_n \in C^\perp$, since $\langle XY - YX, I_n \rangle = \operatorname{tr}(XY - YX) = 0$. So $C^\perp = \operatorname{span}(I_n)$, and by Theorem 6.4.26 and (a),

$$C = \left(C^\perp\right)^\perp = \operatorname{span}(I_n)^\perp = Z.$$

(d) Write $U_{ij} = \mathbf{e}_i \mathbf{e}_j^{\mathsf{T}}$, so that $U_{ij}U_{kl} = \delta_{jk}U_{il}$ (Lemma 2.4.24). For $i \neq j$,

$$U_{ii}U_{ij} - U_{ij}U_{ii} = U_{ij} - 0 = U_{ij},$$

and for $i \neq n$,

$$U_{in}U_{ni} - U_{ni}U_{in} = U_{ii} - U_{nn}.$$

By Example 2.6.28, these matrices span Z, so $Z \subseteq C$, and $C \subseteq Z$ holds over every field by Proposition 2.4.28.

The second proof is shorter and works over every field. The first illustrates a pattern: to show that a subspace C is all of a given subspace, compute $C^\perp$, and test a vector of $C^\perp$ against everything. It needs an inner product, so it works only over $\mathbb{R}$ and $\mathbb{C}$. (In fact every matrix of trace 0 over $\mathbb{R}$ or $\mathbb{C}$ is a *single* commutator, a theorem of Shoda that is much harder.)

Solution to Problem 6.12

Uses. Theorem 2.4.34 (Block multiplication), Theorem 6.3.29 (Orthonormal columns), Exercise 6.4.59, Theorem 6.4.15 (Gram–Schmidt is correct)
Techniques. Gram matrices (Technique 6.3.31), A sum of nonnegative terms (Technique 6.1.9)
Hint 1. For (b), Exercise 6.4.59 gives $\det G = \|\mathbf{f}_1\|^2 \cdots \|\mathbf{f}_n\|^2$, where $\mathbf{f}_j$ is the Gram–Schmidt residual of $\mathbf{c}_j$.
Hint 2. $\mathbf{f}_j$ is $\mathbf{c}_j$ minus a combination of $\mathbf{c}_1, \ldots, \mathbf{c}_{j-1}$. What is its jth coordinate?
Sketch. (a) $C^*C = I_n^* I_n + A^*A$ by block multiplication. (b) The columns are independent. The residual $\mathbf{f}_j = \mathbf{c}_j - \sum_{i<j} \beta_i \mathbf{c}_i$ has jth coordinate 1, since $\mathbf{c}_i$ has jth coordinate 0 for $i < j$; so $\|\mathbf{f}_j\| \geq 1$ and $\det G \geq 1$. Equality forces $\mathbf{f}_j = \mathbf{e}_j$ for all j, so $\operatorname{span}(\mathbf{c}_1, \ldots, \mathbf{c}_n) = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_n)$, and the lower block A is 0.

(a) $C^* = (I_n\ A^*)$, so by Theorem 2.4.34 $C^*C = I_nI_n + A^*A = I_n + A^*A$, and C^*C is the Gram matrix of the columns of C (Theorem 6.3.29).

(b) Write $\mathbf{c}_j = (\mathbf{e}_j, \mathbf{a}_j)$, where $\mathbf{a}_j$ is column j of A. Coordinate i of $\mathbf{c}_j$ is δ_{ij} for $i \le n$, so the columns are independent. Run Gram–Schmidt on them, with residuals $\mathbf{f}_1, \dots, \mathbf{f}_n$. By Exercise 6.4.59(b),

$$\det(I_n + A^*A) = \|\mathbf{f}_1\|^2 \cdots \|\mathbf{f}_n\|^2.$$

The residual $\mathbf{f}_j$ is $\mathbf{c}_j$ minus its projection onto $\operatorname{span}(\mathbf{c}_1, \dots, \mathbf{c}_{j-1})$, so $\mathbf{f}_j = \mathbf{c}_j - \sum_{i<j} \beta_i \mathbf{c}_i$ for some scalars β_i. Coordinate j of $\mathbf{c}_j$ is 1, and that of $\mathbf{c}_i$ is 0 for $i < j$, so coordinate j of $\mathbf{f}_j$ is 1. Since $\|\mathbf{f}_j\|^2$ is the sum of the squared moduli of its coordinates, $\|\mathbf{f}_j\|^2 \ge 1$, and $\det(I_n + A^*A) \ge 1$.

If equality holds, then every $\|\mathbf{f}_j\| = 1$, so $\mathbf{f}_j$ has no coordinate other than the jth, and $\mathbf{f}_j = \mathbf{e}_j \in \mathbb{F}^{n+m}$. By Theorem 6.4.15(a), $\operatorname{span}(\mathbf{c}_1, \dots, \mathbf{c}_n) = \operatorname{span}(\mathbf{f}_1, \dots, \mathbf{f}_n)$, which consists of vectors whose last m coordinates vanish. So every $\mathbf{a}_j = \mathbf{0}$, and $A = 0$. Conversely $\det(I_n + 0) = 1$.

Solution to Problem 6.12 BEYOND 21-242

Uses. Exercise 5.5.52, Exercise 6.3.57, Corollary 5.4.15 (Rows), Proposition 5.3.15 (Triangular matrices)
Techniques. Gram matrices (Technique 6.3.31), A sum of nonnegative terms (Technique 6.1.9)
Hint 1. Apply Cauchy–Binet to C^*C: it is a sum over the n-element sets S of rows of C.
Hint 2. The set $S = \{1, \dots, n\}$ contributes 1. For the equality case, find a set S whose minor is $\pm a_{ij}$.
Sketch. $\det(C^*C) = \sum_S |\det C_S|^2$, where C_S consists of the rows of C indexed by S; the term $S = [n]$ is $\det I_n = 1$. The rows $[n] \setminus \{j\}$ together with row $n + i$ give a minor $\pm a_{ij}$, so equality forces $A = 0$.

For an n-element set $S \subseteq [n+m]$, let C_S be the $n \times n$ matrix formed by the rows of C with indices in S. The columns of C^* with indices in S form C_S^*, so by Exercise 5.5.52 and Exercise 6.3.57(a),

$$\det(C^*C) = \sum_S \det(C_S^*) \det(C_S) = \sum_S |\det C_S|^2.$$

The term $S = \{1, \dots, n\}$ is $|\det I_n|^2 = 1$, and the others are nonnegative, so $\det(I_n + A^*A) \ge 1$. For equality, every other minor must vanish. Take $S = ([n] \setminus \{j\}) \cup \{n + i\}$. Then C_S consists of the rows $\mathbf{e}_k^{\mathsf{T}}$ for $k \ne j$, in order, followed by row i of A. Moving that last row up to position j changes $\det C_S$ by a sign, and gives I_n with row j replaced by row i of A. Subtracting a_{ik} times row k from row j for every $k \ne j$ does not change the determinant (Corollary 5.4.15) and leaves a diagonal matrix whose only diagonal entry other than 1 is a_{ij}. So $\det C_S = \pm a_{ij}$. So $|a_{ij}|^2$ occurs in the sum, and equality forces every $a_{ij} = 0$.

The first approach is the geometric one: each column $\mathbf{c}_j$ sticks out of the span of the previous ones by at least 1, because of its identity part. The second expands the determinant into squares, one of which is the 1 coming from I_n. Either way, $I_n + A^*A$ is invertible for every A, which Exercise 5.6.12(c) proved for real A through the kernel; in terms of the singular values of Section 9.1, $\det(I_n + A^*A) = \prod_i (1 + \sigma_i^2)$.

Solution to Problem 6.13

Uses. Corollary 6.4.25 (Dimension of the orthogonal complement), Proposition 6.1.29 (Expanding a norm), Exercise 6.4.62
Techniques. Orthogonal decomposition (Technique 6.2.4), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Induct on n. For the step, project $\mathbf{v}_1, \dots, \mathbf{v}_{m-1}$ onto $\mathbf{v}_m^{\perp}$, which has dimension $n - 1$.
Hint 2. The projections $\mathbf{w}_i = \mathbf{v}_i - \left(\langle \mathbf{v}_i, \mathbf{v}_m \rangle / \|\mathbf{v}_m\|^2\right)\mathbf{v}_m$ still have $\langle \mathbf{w}_i, \mathbf{w}_j \rangle \le 0$. How many of them can be $\mathbf{0}$?
Sketch. For $n = 1$, three nonzero real multiples of one vector include two of the same sign. For the step, with $\mathbf{u} = \mathbf{v}_m$, the parts $\mathbf{w}_i$ of $\mathbf{v}_i$ orthogonal to $\mathbf{u}$ satisfy $\langle \mathbf{w}_i, \mathbf{w}_j \rangle = \langle \mathbf{v}_i, \mathbf{v}_j \rangle - \langle \mathbf{v}_i, \mathbf{u} \rangle \langle \mathbf{v}_j, \mathbf{u} \rangle / \|\mathbf{u}\|^2 \le 0$. If two were $\mathbf{0}$, the corresponding $\mathbf{v}_i, \mathbf{v}_j$ would be negative multiples of $\mathbf{u}$ with $\langle \mathbf{v}_i, \mathbf{v}_j \rangle > 0$. So at least $m - 2$ nonzero vectors in the $(n-1)$-dimensional $\mathbf{u}^{\perp}$, and $m - 2 \le 2(n-1)$. Example: $\pm\mathbf{e}_1, \dots, \pm\mathbf{e}_n$.

We induct on n.

$n = 1$. Then $V = \operatorname{span}(\mathbf{u})$ for any nonzero $\mathbf{u}$, and $\mathbf{v}_i = t_i\mathbf{u}$ with $t_i \ne 0$, so $\langle \mathbf{v}_i, \mathbf{v}_j \rangle = t_i t_j \|\mathbf{u}\|^2$. If $m \ge 3$, two of t_1, t_2, t_3 have the same sign, and their vectors have a positive inner product. So $m \le 2$.

$n \ge 2$. We may assume $m \ge 2$. Let $\mathbf{u} = \mathbf{v}_m$, and for $i < m$ let

$$\mathbf{w}_i = \mathbf{v}_i - \lambda_i \mathbf{u}, \quad \lambda_i = \frac{\langle \mathbf{v}_i, \mathbf{u} \rangle}{\|\mathbf{u}\|^2} \leq 0,$$

the part of $\mathbf{v}_i$ orthogonal to $\mathbf{u}$ (Technique 6.2.4). For $i \neq j$, both less than m,

$$\langle \mathbf{w}_i, \mathbf{w}_j \rangle = \langle \mathbf{v}_i, \mathbf{v}_j \rangle - \lambda_i \langle \mathbf{u}, \mathbf{v}_j \rangle - \lambda_j \langle \mathbf{v}_i, \mathbf{u} \rangle + \lambda_i \lambda_j \|\mathbf{u}\|^2 = \langle \mathbf{v}_i, \mathbf{v}_j \rangle - \lambda_i \lambda_j \|\mathbf{u}\|^2 \leq 0,$$

since $\lambda_i \lambda_j \geq 0$. If $\mathbf{w}_i = \mathbf{0}$, then $\mathbf{v}_i = \lambda_i \mathbf{u}$ with $\lambda_i < 0$ (it is ≤ 0, and nonzero because $\mathbf{v}_i \neq \mathbf{0}$). If this happened for two indices $i \neq j$, then $\langle \mathbf{v}_i, \mathbf{v}_j \rangle = \lambda_i \lambda_j \|\mathbf{u}\|^2 > 0$, a contradiction. So at least $m - 2$ of the vectors $\mathbf{w}_1, \ldots, \mathbf{w}_{m-1}$ are nonzero. They lie in $\mathbf{u}^\perp$, a real inner product space of dimension $n - 1 \geq 1$ (Corollary 6.4.25), and have pairwise nonpositive inner products. By the induction hypothesis $m - 2 \leq 2(n-1)$, that is, $m \leq 2n$.

Example. In $\mathbb{R}^n$, the $2n$ vectors $\pm\mathbf{e}_1, \ldots, \pm\mathbf{e}_n$ have pairwise inner products 0 or -1.

With strict inequalities $\langle \mathbf{v}_i, \mathbf{v}_j \rangle < 0$, the bound drops to $n + 1$ (Exercise 6.4.62). The difference is visible in the proof: with strict inequalities, the projected vectors still have strictly negative inner products, and none of them can vanish once $m \geq 3$.

Solution to Problem 6.14

Uses. Proposition 6.5.27 (The least-squares solution of minimal norm), Theorem 6.6.21 (Kernels and images of adjoints), Example 6.6.10 (The adjoint of a matrix), Theorem 6.5.5 (The normal equations), Proposition 6.5.9 ($\operatorname{rank}(A^*A) = \operatorname{rank} A$)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. (a) $\mathbf{w}^+$ lies in $(\ker \Phi)^\perp$. Which subspace is that?
Hint 2. (b) Write both conditions with the normal equations: $\Phi^{\mathsf{T}}(K\boldsymbol{\alpha} - \mathbf{y}) = \mathbf{0}$ and $K(K\boldsymbol{\alpha} - \mathbf{y}) = \mathbf{0}$. Then compare $\ker \Phi^{\mathsf{T}}$ with $\ker K$.
Hint 3. (c) $k(s,t) = 1 + 2st + s^2t^2 = (1+st)^2$, and K turns out to be invertible.
Sketch. (a) $\mathbf{w}^+ \in (\ker \Phi)^\perp = \operatorname{im} \Phi^{\mathsf{T}}$. (b) By the normal equations the two conditions say $K\boldsymbol{\alpha} - \mathbf{y} \in \ker \Phi^{\mathsf{T}}$ and $K\boldsymbol{\alpha} - \mathbf{y} \in \ker K$, and $\ker K = \ker \Phi^{\mathsf{T}}$ by Proposition 6.5.9(a) for Φ^{T}. So $\Phi^{\mathsf{T}}\boldsymbol{\alpha}$ is a least-squares solution in $\operatorname{im} \Phi^{\mathsf{T}} = (\ker \Phi)^\perp$, which is $\mathbf{w}^+$. (c) $K = \begin{pmatrix} 4 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 4 \end{pmatrix}$, $\boldsymbol{\alpha} = (-1, 4, 5)/8$, and $\sum_i \alpha_i (1 + tt_i)^2 = 1 + 3t/2 + t^2/2$.

(a) By Proposition 6.5.27, $\mathbf{w}^+$ is the only least-squares solution in $(\ker \Phi)^\perp$. With dot products, Φ^{T} is the adjoint of Φ (Example 6.6.10), so $(\ker \Phi)^\perp = \operatorname{im} \Phi^{\mathsf{T}}$ by Theorem 6.6.21(c).

(b) By Theorem 6.5.5, $\Phi^{\mathsf{T}}\boldsymbol{\alpha}$ is a least-squares solution of $\Phi\mathbf{w} = \mathbf{y}$ if and only if $\Phi^{\mathsf{T}}\left(\Phi\Phi^{\mathsf{T}}\boldsymbol{\alpha} - \mathbf{y}\right) = \mathbf{0}$, that is, $K\boldsymbol{\alpha} - \mathbf{y} \in \ker \Phi^{\mathsf{T}}$. Since $K^{\mathsf{T}} = K$, $\boldsymbol{\alpha}$ is a least-squares solution of $K\boldsymbol{\alpha} = \mathbf{y}$ if and only if $K(K\boldsymbol{\alpha} - \mathbf{y}) = \mathbf{0}$, that is, $K\boldsymbol{\alpha} - \mathbf{y} \in \ker K$. By Proposition 6.5.9(a) applied to Φ^{T}, $\ker K = \ker\left(\left(\Phi^{\mathsf{T}}\right)^{\mathsf{T}}\Phi^{\mathsf{T}}\right) = \ker \Phi^{\mathsf{T}}$. So the two conditions agree.

If $\boldsymbol{\alpha}$ is a least-squares solution of $K\boldsymbol{\alpha} = \mathbf{y}$, then $\Phi^{\mathsf{T}}\boldsymbol{\alpha}$ is a least-squares solution of $\Phi\mathbf{w} = \mathbf{y}$ that lies in $\operatorname{im} \Phi^{\mathsf{T}} = (\ker \Phi)^\perp$, so it is $\mathbf{w}^+$ by the uniqueness in Proposition 6.5.27. Since $\Phi^{\mathsf{T}}\boldsymbol{\alpha} = \sum_i \alpha_i \boldsymbol{\varphi}_i$, we get $\boldsymbol{\varphi} \cdot \mathbf{w}^+ = \sum_i \alpha_i \, \boldsymbol{\varphi} \cdot \boldsymbol{\varphi}_i$.

(c) $k(s,t) = 1 + 2st + s^2t^2 = (1+st)^2$. For $t_1, t_2, t_3 = -1, 0, 1$,

$$K = \begin{pmatrix} 4 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 4 \end{pmatrix}, \quad \det K = 8, \quad K^{-1} = \frac{1}{8}\begin{pmatrix} 3 & -4 & 1 \\ -4 & 16 & -4 \\ 1 & -4 & 3 \end{pmatrix}.$$

K is invertible, so the least-squares solution of $K\boldsymbol{\alpha} = \mathbf{y}$ is $\boldsymbol{\alpha} = K^{-1}\mathbf{y} = (1/8)(-1, 4, 5)$. By (b), the fitted function is

$$\sum_i \alpha_i k(t, t_i) = \frac{1}{8}\left(-(1-t)^2 + 4 + 5(1+t)^2\right) = 1 + \frac{3}{2}t + \frac{1}{2}t^2,$$

which takes the values $0, 1, 3$ at $-1, 0, 1$. Explicitly, $\mathbf{w}^+ = \Phi^{\mathsf{T}}\boldsymbol{\alpha} = \left(1, 3\sqrt{2}/4, 1/2\right)$, and $\boldsymbol{\varphi}(t) \cdot \mathbf{w}^+$ is the same polynomial.

The point is that N never appeared in the computation. The fit needs the $m \times m$ matrix K and the values $k(\varphi, \varphi_i)$ only, so the feature space can be huge, or even infinite-dimensional, as long as its inner products are cheap to compute. Section 16.1 develops this.

Solution to Problem 6.15

> *Uses.* Proposition 6.1.13 (Integral inner products), Lemma 6.1.14 (Nonnegative functions with zero integral), Proposition 6.1.29 (Expanding a norm)
> *Techniques.* Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21), A sum of nonnegative terms (Technique 6.1.9)
> *Hint 1.* Find an inner product on $C[0,1]$ for which $J(f) = \|f\|^2$. Then write $I(f)$ as an inner product of f with a fixed function.
> *Hint 2.* With $\langle f, g\rangle = \int_0^1 x f(x) g(x)\,dx$ and $h(x) = x$, $I(f) - J(f) = \langle f, h\rangle - \|f\|^2$. Complete the square.
> *Sketch.* $\langle f, g\rangle = \int_0^1 xfg$ is an inner product, $J(f) = \|f\|^2$, and $I(f) = \langle f, h\rangle$ for $h(x) = x$. Then $I(f) - J(f) = \|h\|^2/4 - \|f - h/2\|^2 \le \|h\|^2/4 = (1/4)\int_0^1 x^3\,dx = 1/16$, with equality exactly for $f(x) = x/2$.

Let $\langle f, g\rangle = \int_0^1 x f(x) g(x)\,dx$ on $C[0,1]$. It is bilinear and symmetric, and $\langle f, f\rangle = \int_0^1 x f(x)^2\,dx \ge 0$. If $\langle f, f\rangle = 0$, then the continuous nonnegative function $x f(x)^2$ is 0 (Lemma 6.1.14, as in the proof of Proposition 6.1.13), so $f(x) = 0$ for $0 < x \le 1$, and $f(0) = 0$ by continuity. So this is an inner product.

With $h(x) = x$, $I(f) = \int_0^1 x \cdot x f(x)\,dx = \langle f, h\rangle$ and $J(f) = \|f\|^2$. By Proposition 6.1.29,

$$\left\| f - \frac{h}{2} \right\|^2 = \|f\|^2 - \langle f, h\rangle + \frac{1}{4}\|h\|^2,$$

so

$$I(f) - J(f) = \frac{1}{4}\|h\|^2 - \left\| f - \frac{h}{2} \right\|^2 \le \frac{1}{4}\|h\|^2 = \frac{1}{4}\int_0^1 x^3\,dx = \frac{1}{16},$$

with equality if and only if $f = h/2$, that is, $f(x) = x/2$. The largest value is $1/16$.

Pointwise, the identity is $x^2 f - x f^2 = x^3/4 - x(f - x/2)^2$, and integrating it gives the same proof without naming an inner product. The inner product explains where the identity comes from: the maximum of $\langle f, h\rangle - \|f\|^2$ over a whole inner product space is found by completing the square, and the weight x in J tells us which inner product to use. One can also use Cauchy–Schwarz, $I(f) \le \|f\|\|h\|$, and then maximize $s\|h\| - s^2$ over $s = \|f\| \ge 0$.

This is Problem B5 of the 2006 Putnam Competition.

Solution to Problem 6.16

> *Uses.* Corollary 6.2.26 (Engel's form), Theorem 6.2.1 (Cauchy–Schwarz inequality)
> *Techniques.* Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21), A sum of nonnegative terms (Technique 6.1.9)
> *Hint 1.* Substitute $x = 1/a$, $y = 1/b$, $z = 1/c$, so that $xyz = 1$. What does the first term become?
> *Hint 2.* The sum becomes $x^2/(y+z) + y^2/(z+x) + z^2/(x+y)$. Apply Corollary 6.2.26, and then show $x + y + z \ge 3$ when $xyz = 1$.
> *Hint 3.* For the last step, with $x = p^3$, $y = q^3$, $z = r^3$: $p^3 + q^3 + r^3 - 3pqr = \frac{1}{2}(p+q+r)\big((p-q)^2 + (q-r)^2 + (r-p)^2\big)$.
> *Sketch.* With $x = 1/a$ etc., $1/\big(a^3(b+c)\big) = x^3 yz/(y+z) = x^2/(y+z)$. By Engel's form of Cauchy–Schwarz, the sum is at least $(x+y+z)^2/(2(x+y+z)) = (x+y+z)/2$, and $x + y + z \ge 3\sqrt[3]{xyz} = 3$ by the sum-of-squares identity for $p^3 + q^3 + r^3 - 3pqr$. Equality iff $a = b = c = 1$.

Let $x = 1/a$, $y = 1/b$, $z = 1/c$, positive with $xyz = 1$. Then

$$\frac{1}{a^3(b+c)} = \frac{x^3}{1/y + 1/z} = \frac{x^3 yz}{y+z} = \frac{x^2}{y+z},$$

and similarly for the other terms. By Corollary 6.2.26, with numerators x, y, z and denominators $y+z$, $z+x$, $x+y$,

$$\frac{x^2}{y+z}+\frac{y^2}{z+x}+\frac{z^2}{x+y}\geq\frac{(x+y+z)^2}{2(x+y+z)}=\frac{x+y+z}{2}.$$

That is Cauchy–Schwarz for the vectors $\left(x/\sqrt{y+z},\ldots\right)$ and $\left(\sqrt{y+z},\ldots\right)$, chosen so that their inner product is $x+y+z$ (Technique 6.2.21).

It remains to show $x+y+z\geq 3$. Let $p,q,r>0$ with $p^3=x, q^3=y, r^3=z$, so that $pqr=1$. Multiplying out,

$$p^3+q^3+r^3-3pqr=(p+q+r)\big(p^2+q^2+r^2-pq-qr-rp\big)=\frac{1}{2}(p+q+r)\Big((p-q)^2+(q-r)^2+(r-p)^2\Big),$$

which is ≥ 0, with equality only if $p=q=r$ (Technique 6.1.9). So $x+y+z\geq 3pqr=3$, and the sum is at least $3/2$.

If equality holds, then $x+y+z=3$, which forces $p=q=r$, hence $x=y=z=1$ and $a=b=c=1$. Conversely, at $a=b=c=1$ every term is $1/2$.

This is Problem 2 of the 1995 International Mathematical Olympiad. The substitution is the real idea; after it, the problem is the same Engel-form estimate as Nesbitt's inequality (Exercise 6.2.47).

Solution to Problem 6.17

> *Uses.* Lemma 6.2.6 (Nonnegative quadratics), Proposition 6.3.30 (Gram matrices detect independence), Theorem 6.3.22 (Parseval's identity), Theorem 6.3.29 (Orthonormal columns), Proposition 6.5.9 ($\operatorname{rank}(A^*A)=\operatorname{rank}A$), Theorem 6.4.20 (Orthonormal bases exist)
> *Techniques.* A nonnegative quadratic has nonpositive discriminant (Technique 6.2.7), Pass to orthonormal coordinates (Technique 6.7.2)
> *Hint 1.* (a) Run the second proof of Theorem 6.2.1: rotate the phase, then look at $\beta(\lambda\mathbf{c}-t\mathbf{d},\lambda\mathbf{c}-t\mathbf{d})$ for real t. Treat $\beta(\mathbf{d},\mathbf{d})=0$ separately: a linear function of t that is never negative is constant.
> *Hint 2.* (b) If $\beta(\mathbf{c},\mathbf{c})=0$, (a) gives $\beta(\mathbf{c},\mathbf{d})=0$ for every $\mathbf{d}$. Take $\mathbf{d}=G\mathbf{c}$.
> *Hint 3.* (c) For well-definedness in the second slot, use $G^*=G$. For (d), choose an orthonormal basis of V and record the coordinates of the classes $[\mathbf{e}_j]$.
> *Sketch.* (a) With $|\lambda|=1$ and $\lambda\beta(\mathbf{c},\mathbf{d})=|\beta(\mathbf{c},\mathbf{d})|$, $0\leq\beta(\lambda\mathbf{c}-t\mathbf{d},\lambda\mathbf{c}-t\mathbf{d})=\beta(\mathbf{c},\mathbf{c})-2t|\beta(\mathbf{c},\mathbf{d})|+t^2\beta(\mathbf{d},\mathbf{d})$ for real t; the discriminant gives (a) if $\beta(\mathbf{d},\mathbf{d})>0$, and a linear function bounded below gives $\beta(\mathbf{c},\mathbf{d})=0$ otherwise. (b) Then $(G\mathbf{c})^*G\mathbf{c}=0$. (c) Changing representatives changes $\mathbf{d}^*G\mathbf{c}$ by terms with $G\mathbf{z}=\mathbf{0}$; definiteness is (b). (d) An orthonormal basis of V turns $[\mathbf{e}_1],\ldots,[\mathbf{e}_k]$ into the columns of $B\in\mathbb{F}^{r\times k}$ with $B^*B=G$, and $r=\operatorname{rank}B=\operatorname{rank}B^*B=\operatorname{rank}G$.

The function β is linear in $\mathbf{c}$, and $\beta(\mathbf{d},\mathbf{c})=\mathbf{c}^*G\mathbf{d}=(\mathbf{d}^*G^*\mathbf{c})^*=\overline{\beta(\mathbf{c},\mathbf{d})}$, using $G^*=G$. So β satisfies every axiom of an inner product except possibly definiteness.

(a) The second proof of Theorem 6.2.1 uses definiteness only to know that $\|\mathbf{y}\|^2>0$, so we follow it and handle that case separately. Choose $\lambda\in\mathbb{F}$ with $|\lambda|=1$ and $\lambda\beta(\mathbf{c},\mathbf{d})=|\beta(\mathbf{c},\mathbf{d})|$. For real t, expanding as in Proposition 6.1.29,

$$0\leq\beta(\lambda\mathbf{c}-t\mathbf{d},\lambda\mathbf{c}-t\mathbf{d})=\beta(\mathbf{c},\mathbf{c})-2t|\beta(\mathbf{c},\mathbf{d})|+t^2\beta(\mathbf{d},\mathbf{d}).$$

If $\beta(\mathbf{d},\mathbf{d})>0$, Lemma 6.2.6 gives $|\beta(\mathbf{c},\mathbf{d})|^2\leq\beta(\mathbf{c},\mathbf{c})\beta(\mathbf{d},\mathbf{d})$. If $\beta(\mathbf{d},\mathbf{d})=0$, the right side is $\beta(\mathbf{c},\mathbf{c})-2t|\beta(\mathbf{c},\mathbf{d})|$, which is nonnegative for every real t only if $|\beta(\mathbf{c},\mathbf{d})|=0$ (otherwise take t large). In both cases (a) holds. (The first proof of Theorem 6.2.1 divides by $\|\mathbf{y}\|^2$, and the third normalizes, so neither survives as it stands.)

(b) If $G\mathbf{c}=\mathbf{0}$, then $\beta(\mathbf{c},\mathbf{c})=\mathbf{c}^*G\mathbf{c}=0$. Conversely, if $\beta(\mathbf{c},\mathbf{c})=0$, then (a) gives $\beta(\mathbf{c},\mathbf{d})=0$ for every $\mathbf{d}$. With $\mathbf{d}=G\mathbf{c}$ this reads $(G\mathbf{c})^*(G\mathbf{c})=0$, the squared length of $G\mathbf{c}$ for the dot product, so $G\mathbf{c}=\mathbf{0}$.

(c) Let $[\mathbf{c}]=[\mathbf{c}']$ and $[\mathbf{d}]=[\mathbf{d}']$, that is, $G(\mathbf{c}-\mathbf{c}')=\mathbf{0}$ and $G(\mathbf{d}-\mathbf{d}')=\mathbf{0}$. Then

$$\mathbf{d}^*G\mathbf{c}-\mathbf{d}'^*G\mathbf{c}'=\mathbf{d}^*G(\mathbf{c}-\mathbf{c}')+(\mathbf{d}-\mathbf{d}')^*G\mathbf{c}'=0+(G(\mathbf{d}-\mathbf{d}'))^*\mathbf{c}'=0,$$

using $(\mathbf{d}-\mathbf{d}')^*G=(G^*(\mathbf{d}-\mathbf{d}'))^*=(G(\mathbf{d}-\mathbf{d}'))^*$. So the formula is well defined. Linearity in the first slot and conjugate symmetry come from β, and $\langle[\mathbf{c}],[\mathbf{c}]\rangle=\beta(\mathbf{c},\mathbf{c})\geq 0$. By (b), $\langle[\mathbf{c}],[\mathbf{c}]\rangle=0$ if and only if $\mathbf{c}\in\ker G$, that is, $[\mathbf{c}]=\mathbf{0}$. So this is an inner product on V, and $\langle[\mathbf{e}_j],[\mathbf{e}_i]\rangle=\mathbf{e}_i^*G\mathbf{e}_j=g_{ij}$.

(d) If G is the Gram matrix of $\mathbf{v}_1, \dots, \mathbf{v}_k$, then $\mathbf{c}^* G \mathbf{c} = \left\| \sum_i c_i \mathbf{v}_i \right\|^2 \geq 0$ (Proposition 6.3.30(a)). Conversely, if $\mathbf{c}^* G \mathbf{c} \geq 0$ for all $\mathbf{c}$, then by (c) G is the Gram matrix of $[\mathbf{e}_1], \dots, [\mathbf{e}_k]$ in V. These classes span V, so V is finite-dimensional; let $\mathcal{O}$ be an orthonormal basis (Theorem 6.4.20), $r = \dim V$, and $B \in \mathbb{F}^{r \times k}$ the matrix with columns $\left[[\mathbf{e}_j]\right]_{\mathcal{O}}$. By Theorem 6.3.22, $(B^* B)_{ij} = \langle [\mathbf{e}_j], [\mathbf{e}_i] \rangle = g_{ij}$, so $G = B^* B$ (Technique 6.7.2). Finally, if $G = B^* B$ for any B, then G is the Gram matrix of the columns of B (Theorem 6.3.29), closing the cycle. For the B constructed above, the columns span $\mathbb{F}^r$ (they are the coordinates of a spanning list of V), so $\operatorname{rank} B = r$, and $\operatorname{rank} G = \operatorname{rank}(B^* B) = \operatorname{rank} B = r$ by Proposition 6.5.9(b).

Matrices with these properties are called *positive semidefinite*. Section 8.3 produces the factorization $G = B^* B$ differently, with B a square root of G, and Exercise 6.7.12 is the case $G = (1 - x) I_n + x J$. The quotient construction, dividing a semi-inner product by its null vectors, is also how inner product spaces of functions are built in analysis, where functions that differ only on a negligible set are identified.

Solution to Problem 6.18

> *Uses.* Proposition 6.1.10 (The dot product is an inner product), Definition 6.6.8 (Adjoint), Proposition 6.6.9 (Adjoints are unique and linear), Proposition 6.6.18 (Properties of the adjoint), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.4.20 (Orthonormal bases exist), Corollary 6.4.25 (Dimension of the orthogonal complement), Proposition 2.4.28 (Cyclicity of the trace), Theorem 6.3.22 (Parseval's identity), Theorem 6.3.29 (Orthonormal columns)
> *Techniques.* Move an operator across the inner product (Technique 6.6.20), Cyclicity of trace (Technique 2.4.29)
> *Hint 1.* (a) and (b): for fixed $N \in \mathcal{G}$, the maps $M \mapsto MN$, $M \mapsto NM$, and $M \mapsto M^{-1}$ are bijections of $\mathcal{G}$, so sums over $\mathcal{G}$ can be reindexed by them.
> *Hint 2.* For self-adjointness, first show that the adjoint of $N \in \mathcal{G}$ for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$ is N^{-1}.
> *Hint 3.* (c) P is an orthogonal projection for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$. Take an orthonormal basis for that inner product whose first vectors span $\operatorname{im} P$, and compute the trace of P in it. (d) Use the same kind of basis as the columns of S.
> *Sketch.* (a) Positivity: $\langle \mathbf{x}, \mathbf{x} \rangle_{\mathcal{G}} \geq \|I_n \mathbf{x}\|^2$. Invariance: reindex by $M \mapsto MN$. (b) $NP = P$ by reindexing with $M \mapsto NM$, so $P^2 = |\mathcal{G}|^{-1} \sum_N NP = P$. For $N \in \mathcal{G}$, $\langle N\mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}} = \langle N\mathbf{x}, NN^{-1}\mathbf{y} \rangle_{\mathcal{G}} = \langle \mathbf{x}, N^{-1}\mathbf{y} \rangle_{\mathcal{G}}$, so $N^* = N^{-1}$ and $P^* = |\mathcal{G}|^{-1} \sum N^{-1} = P$. (c) $P = \operatorname{Pr}_{\operatorname{im} P}$; in an adapted orthonormal basis P is $\operatorname{diag}(1, \dots, 1, 0, \dots, 0)$, so $\operatorname{tr} P = \operatorname{rank} P$ by cyclicity of trace. If $\operatorname{tr} P = 0$, then $P = 0$. (d) The columns of S form an orthonormal basis for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$; $S^{-1} M S$ is the matrix of M in it, and M preserves $\langle \cdot, \cdot \rangle_{\mathcal{G}}$.

Fix $N \in \mathcal{G}$. The map $M \mapsto MN$ sends $\mathcal{G}$ into $\mathcal{G}$ (closure) and is injective ($MN = M'N$ implies $M = M'$), so it is a bijection of the finite set $\mathcal{G}$. The same holds for $M \mapsto NM$ and for $M \mapsto M^{-1}$, which is its own inverse. So a sum over $\mathcal{G}$ can be reindexed by any of these maps.

(a) Each term $(M\mathbf{x}) \cdot (M\mathbf{y})$ is linear in $\mathbf{x}$ and symmetric, and so is the sum. Since $I_n \in \mathcal{G}$, $\langle \mathbf{x}, \mathbf{x} \rangle_{\mathcal{G}} = \sum_M \|M\mathbf{x}\|^2 \geq \|\mathbf{x}\|^2$, which is positive for $\mathbf{x} \neq \mathbf{0}$ (Proposition 6.1.10). So $\langle \cdot, \cdot \rangle_{\mathcal{G}}$ is an inner product. Reindexing by $M \mapsto MN$,

$$\langle N\mathbf{x}, N\mathbf{y} \rangle_{\mathcal{G}} = \sum_{M \in \mathcal{G}} (MN\mathbf{x}) \cdot (MN\mathbf{y}) = \sum_{M' \in \mathcal{G}} (M'\mathbf{x}) \cdot (M'\mathbf{y}) = \langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}}.$$

(b) Reindexing by $M \mapsto NM$, $NP = |\mathcal{G}|^{-1} \sum_M NM = |\mathcal{G}|^{-1} \sum_{M'} M' = P$. Hence

$$P^2 = |\mathcal{G}|^{-1} \sum_{N \in \mathcal{G}} NP = |\mathcal{G}|^{-1} \sum_{N \in \mathcal{G}} P = P.$$

For $N \in \mathcal{G}$ and all $\mathbf{x}, \mathbf{y}$, by (a) applied with N,

$$\langle N\mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}} = \langle N\mathbf{x}, N(N^{-1}\mathbf{y}) \rangle_{\mathcal{G}} = \langle \mathbf{x}, N^{-1}\mathbf{y} \rangle_{\mathcal{G}},$$

so the adjoint of $\mathbf{x} \mapsto N\mathbf{x}$ for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$ is $\mathbf{x} \mapsto N^{-1}\mathbf{x}$ (Definition 6.6.8, Proposition 6.6.9). Adjoints of sums and real multiples are the sums and multiples of the adjoints (Proposition 6.6.18), so the adjoint of P is $|\mathcal{G}|^{-1} \sum_N N^{-1}$, which is P after reindexing by $N \mapsto N^{-1}$.

(c) By (b) and Corollary 6.6.29, P is the orthogonal projection onto $\operatorname{im} P$ for the inner product $\langle \cdot, \cdot \rangle_{\mathcal{G}}$. Let $r = \operatorname{rank} P$. By Theorem 6.4.20 and Corollary 6.4.25, there is a basis $\mathbf{u}_1, \dots, \mathbf{u}_n$ of $\mathbb{R}^n$, orthonormal for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$,

with $\mathbf{u}_1, \ldots, \mathbf{u}_r$ a basis of $\operatorname{im} P$ and $\mathbf{u}_{r+1}, \ldots, \mathbf{u}_n$ a basis of $(\operatorname{im} P)^{\perp} = \ker P$ (Proposition 6.4.29(a)). So $P\mathbf{u}_i = \mathbf{u}_i$ for $i \le r$ and $P\mathbf{u}_i = \mathbf{0}$ for $i > r$. Let S be the invertible matrix with columns $\mathbf{u}_1, \ldots, \mathbf{u}_n$. Then $PS = SD$ with $D = \operatorname{diag}(1, \ldots, 1, 0, \ldots, 0)$ (r ones), so $P = SDS^{-1}$ and, by Proposition 2.4.28, $\operatorname{tr} P = \operatorname{tr}\big(DS^{-1}S\big) = \operatorname{tr} D = r$.

If $\sum_M \operatorname{tr} M = 0$, then $\operatorname{tr} P = |\mathcal{G}|^{-1} \sum_M \operatorname{tr} M = 0$, so $\operatorname{rank} P = 0$, $P = 0$, and $\sum_M M = |\mathcal{G}| P = 0$.

(d) Take S with columns $\mathbf{u}_1, \ldots, \mathbf{u}_n$ forming any basis that is orthonormal for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$, as in (c). For $\mathbf{x} \in \mathbb{R}^n$, $S^{-1}\mathbf{x}$ is the coordinate vector of $\mathbf{x}$ in this basis, since $S\big(S^{-1}\mathbf{x}\big) = \mathbf{x}$. By Theorem 6.3.22, $\langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}} = \big(S^{-1}\mathbf{x}\big) \cdot \big(S^{-1}\mathbf{y}\big)$. Let $M \in \mathcal{G}$ and $Q = S^{-1}MS$. Then for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^n$, with $\mathbf{x} = S\mathbf{a}$ and $\mathbf{y} = S\mathbf{b}$,

$$(Q\mathbf{a}) \cdot (Q\mathbf{b}) = \big(S^{-1}M\mathbf{x}\big) \cdot \big(S^{-1}M\mathbf{y}\big) = \langle M\mathbf{x}, M\mathbf{y} \rangle_{\mathcal{G}} = \langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}} = \mathbf{a} \cdot \mathbf{b}.$$

With $\mathbf{a} = \mathbf{e}_j$ and $\mathbf{b} = \mathbf{e}_i$, the columns of Q are orthonormal, so Q is orthogonal (Theorem 6.3.29).

By (c), P is the orthogonal projection onto the vectors fixed by all of $\mathcal{G}$: if $M\mathbf{x} = \mathbf{x}$ for all M then $P\mathbf{x} = \mathbf{x}$, and conversely $MP\mathbf{y} = P\mathbf{y}$ by (b). The idempotence $P^2 = P$ alone already gives $\operatorname{tr} P = \operatorname{rank} P$, by the decomposition $\mathbb{R}^n = \operatorname{im} P \oplus \ker P$ of Section 4.4, so the inner product is not needed for the conclusion of (c). It explains what P is, and it gives (d): every finite group of real matrices is conjugate to a group of orthogonal matrices. Averaging over the group in this way is the basic tool of the representation theory of finite groups.

This is Problem B6 of the 1985 Putnam Competition, in a slightly restricted form: the original allows any finite set of real matrices that forms a group under multiplication, whose identity element need not be I_n.

Section 7.1

Solution to Exercise 7.1.8

Uses. Proposition 7.1.3 ($F[x]$ is a commutative ring), Definition 7.1.1 (Product of polynomials)
Hint 1. For the first product in (a), write the factors as $\big(x^2 + 1\big) - x$ and $\big(x^2 + 1\big) + x$. In the second, most terms cancel in pairs.
Hint 2. For (b), expand as over $\mathbb{Z}$, then reduce the coefficients modulo 2 or 3.
Sketch. (a) $\big(x^2 + 1\big)^2 - x^2 = x^4 + x^2 + 1$, and the second product telescopes to $1 - x^n$. (b) $\big(1 + x + x^2\big)^2 = 1 + 2x + 3x^2 + 2x^3 + x^4$, which is $1 + x^2 + x^4$ over $\mathbb{F}_2$; $(1 + x)^3 = 1 + 3x + 3x^2 + x^3$, which is $1 + x^3$ over $\mathbb{F}_3$.

(a) Since $F[x]$ is a commutative ring, $(u - v)(u + v) = u^2 - v^2$. With $u = x^2 + 1$ and $v = x$,

$$\begin{aligned}\big(x^2 - x + 1\big)\big(x^2 + x + 1\big) &= \big(x^2 + 1\big)^2 - x^2 \\ &= x^4 + x^2 + 1.\end{aligned}$$

For the second product,

$$(1 - x) \sum_{k=0}^{n-1} x^k = \sum_{k=0}^{n-1} x^k - \sum_{k=0}^{n-1} x^{k+1} = 1 - x^n,$$

since every x^k with $1 \le k \le n - 1$ occurs once in each sum and cancels.

(b) Expanding, $\big(1 + x + x^2\big)^2 = 1 + 2x + 3x^2 + 2x^3 + x^4$. In $\mathbb{F}_2$, $2 = 0$ and $3 = 1$, so the square is $1 + x^2 + x^4$. Similarly $(1 + x)^3 = 1 + 3x + 3x^2 + x^3$, and in $\mathbb{F}_3$ this is $1 + x^3$.

Solution to Exercise 7.1.18

Uses. Theorem 7.1.14 (Division with remainder), Algorithm 7.1.15 (Long division), Definition 7.1.16 (Divisibility)
Hint 1. Run Algorithm 7.1.15 over $\mathbb{Q}$. Since s is monic, no division by a leading coefficient is needed.
Hint 2. The computation over $\mathbb{Q}$ uses only integer arithmetic, so it can be reduced modulo 2 and modulo 3. Why does reducing give the right answer?
Sketch. Over $\mathbb{Q}$: $p - x^2 s = x^3 - x^2 + x + 2$, minus xs gives $-x^2 + 2$, plus s gives 3. So $q = x^2 + x - 1$ and $r = 3$. Reducing $p = sq + 3$ modulo 2 and 3 gives a valid division there, so by uniqueness $r = 1$ over $\mathbb{F}_2$ and $r = \mathbf{0}$ over $\mathbb{F}_3$. Only over $\mathbb{F}_3$ does s divide p.

Over $\mathbb{Q}$, long division gives

$$\begin{aligned} p - x^2 s &= x^3 - x^2 + x + 2, \\ p - (x^2 + x)s &= -x^2 + 2, \\ p - (x^2 + x - 1)s &= 3. \end{aligned}$$

So $p = (x^2+1)(x^2+x-1) + 3$, with quotient $x^2 + x - 1$ and remainder 3. Since $3 \neq 0$, s does not divide p in $\mathbb{Q}[x]$.

Every coefficient in this identity is an integer, and the identity was obtained by adding and multiplying integers, so it remains true when every coefficient is read in $\mathbb{F}_2$ or $\mathbb{F}_3$. Over $\mathbb{F}_2$, it reads $p = (x^2+1)(x^2+x+1) + 1$, and $\deg 1 = 0 < 2$, so by the uniqueness in Theorem 7.1.14 the quotient is $x^2 + x + 1$ and the remainder is 1. Over $\mathbb{F}_3$, $3 = 0$, so $p = (x^2+1)(x^2+x+2)$ (as $-1 = 2$), the remainder is $\mathbf{0}$, and $s \mid p$. So s divides p only over $\mathbb{F}_3$.

Solution to Exercise 7.1.28

> *Uses.* Theorem 7.1.20 (Factor theorem), Lemma 7.1.25 (Reading off a multiplicity), Exercise 2.1.49, Proposition 7.1.10 (Evaluation respects sums and products)
> *Hint 1.* Both conditions include that c is a root. So write $p = (x-c)q$ and compute p' with the product rule (Exercise 2.1.49).
> *Hint 2.* You should find $p'(c) = q(c)$. Compare with Lemma 7.1.25 for $m = 1$.
> *Sketch.* If c is not a root, both sides are false. If it is, $p = (x-c)q$, and the product rule gives $p' = q + (x-c)q'$, so $p'(c) = q(c)$. By Lemma 7.1.25, c is simple exactly when $q(c) \neq 0$, that is, when $p'(c) \neq 0$.

If $p(c) \neq 0$, then c is not a root, so it is not a repeated root, and both sides of the equivalence are false. So suppose $p(c) = 0$, and write $p = (x-c)q$ (Theorem 7.1.20). The formal derivative satisfies the product rule (Exercise 2.1.49(a)), and $(x-c)' = 1$, so

$$p' = q + (x-c)q', \quad \text{hence} \quad p'(c) = q(c) + 0 \cdot q'(c) = q(c)$$

by Proposition 7.1.10. By Lemma 7.1.25 with $m = 1$, the root c is simple if and only if $q(c) \neq 0$. So c is repeated if and only if $q(c) = 0$, that is, if and only if $p'(c) = 0$.

Solution to Exercise 7.1.49

> *Uses.* Theorem 7.1.20 (Factor theorem), Example 7.1.26 (Multiplicity depends on the field), Proposition 7.1.34 (Roots of a split polynomial)
> *Hint 1.* Check that 1 is a root, and split off $x - 1$ with Horner's scheme.
> *Hint 2.* The quotient is the polynomial of Example 7.1.26. The resulting identity has integer coefficients, so it can be read in $\mathbb{F}_3$ and $\mathbb{F}_2$.
> *Sketch.* $p = (x-1)(x^3 - x^2 - x + 1) = (x-1)^3(x+1)$. Over $\mathbb{Q}$: 1 with multiplicity 3 and -1 with multiplicity 1. Over $\mathbb{F}_3$, $x + 1 = x - 2$: 1 with multiplicity 3 and 2 with multiplicity 1. Over $\mathbb{F}_2$, $x + 1 = x - 1$: 1 with multiplicity 4.

Since $p(1) = 1 - 2 + 2 - 1 = 0$, Horner's scheme with $c = 1$ applies to the coefficients $1, -2, 0, 2, -1$: it gives $1, -2 + 1 = -1, 0 - 1 = -1, 2 - 1 = 1$, and remainder $-1 + 1 = 0$. So $p = (x-1)(x^3 - x^2 - x + 1)$, and by Example 7.1.26, $x^3 - x^2 - x + 1 = (x-1)^2(x+1)$. Hence

$$p = (x-1)^3(x+1).$$

This identity was derived with integer arithmetic, so it holds over every field when the integers are read in that field. By Proposition 7.1.34, the roots and multiplicities can be read off from a factorization into linear factors.

Over $\mathbb{Q}$, the roots are 1, with multiplicity 3, and -1, with multiplicity 1. Over $\mathbb{F}_3$, $x + 1 = x - 2$, so $p = (x-1)^3(x-2)$: the roots are 1, with multiplicity 3, and 2, with multiplicity 1. Over $\mathbb{F}_2$, $x + 1 = x - 1$, so $p = (x-1)^4$, and 1 is the only root, with multiplicity 4. In each case the multiplicities add up to $4 = \deg p$.

Solution to Exercise 7.1.50

Uses. Theorem 7.1.14 (Division with remainder), Proposition 7.1.10 (Evaluation respects sums and products), Corollary 7.1.17 (Division does not depend on the field), Exercise 2.1.49
Hint 1. The remainder has the form $ax + b$. Evaluate $x^{100} = sq + ax + b$ at the roots of s to get equations for a and b.
Hint 2. For (b), the roots $\pm i$ are not rational. Why may you divide in $\mathbb{C}[x]$ instead? For (c), there is only one root; differentiate to get a second equation.
Sketch. (a) At ± 1: $1 = a + b$ and $1 = -a + b$, so the remainder is 1. (b) Over $\mathbb{C}$, at $\pm i$: $i^{100} = 1 = \pm ai + b$, so the remainder is 1; by Corollary 7.1.17 it is also the remainder over $\mathbb{Q}$. (c) At 1: $a + b = 1$; differentiating, $100x^{99} = 2(x-1)q + (x-1)^2 q' + a$, so $a = 100$ and the remainder is $100x - 99$.

In each case s has degree 2, so $x^{100} = sq + ax + b$ for some q and some $a, b \in \mathbb{Q}$ (Theorem 7.1.14). We evaluate with Proposition 7.1.10.

(a) With $s = x^2 - 1$, evaluating at 1 and at -1 gives $1 = a + b$ and $1 = -a + b$. So $a = 0$, $b = 1$, and the remainder is 1.

(b) By Corollary 7.1.17, the quotient and remainder over $\mathbb{Q}$ are also those over $\mathbb{C}$, so we may evaluate at the complex roots $\pm i$ of $x^2 + 1$. Since $i^4 = 1$, $(\pm i)^{100} = 1$, so $1 = ai + b$ and $1 = -ai + b$. Adding and subtracting gives $b = 1$ and $a = 0$. The remainder is 1.

(c) With $s = (x-1)^2$, evaluating at 1 gives $1 = a + b$. To get a second equation, apply the formal derivative, using the product rule (Exercise 2.1.49):

$$100x^{99} = 2(x-1)q + (x-1)^2 q' + a.$$

Evaluating at 1 gives $100 = a$, so $b = -99$, and the remainder is $100x - 99$.

Solution to Exercise 7.1.51

Uses. Theorem 7.1.14 (Division with remainder), Proposition 1.2.18 (Degree and evaluation versus the operations), Proposition 7.1.4 (Degree of a product), Corollary 7.1.7 (No zero divisors, cancellation, and units), Theorem 4.2.11 (Rank–nullity), Example 4.1.7 (Dimensions of the standard spaces)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), add two divisions $p_1 = sq_1 + r_1$ and $p_2 = sq_2 + r_2$ (one multiplied by c), and use uniqueness in Theorem 7.1.14.
Hint 2. For (b), what is $R(r)$ when $\deg r < m$? For the kernel, $R(p) = \mathbf{0}$ means $s \mid p$; bound the degree of the quotient.
Hint 3. For (c), $q \mapsto sq$ is an injective linear map from $F[x]_{\leq n-m}$ onto $\ker R$.
Sketch. (a) $cp_1 + p_2 = s(cq_1 + q_2) + (cr_1 + r_2)$ with $\deg(cr_1 + r_2) < m$, so by uniqueness $R(cp_1 + p_2) = cR(p_1) + R(p_2)$. (b) $R(r) = r$ for $\deg r < m$. $R(p) = \mathbf{0}$ iff $p = sq$, and then $\deg q = \deg p - m \leq n - m$. (c) $\dim \ker R = n - m + 1$ and $\dim \operatorname{im} R = m$ add up to $n + 1$.

(a) Let $p_1, p_2 \in F[x]_{\leq n}$ and $c \in F$, with $p_1 = sq_1 + r_1$ and $p_2 = sq_2 + r_2$, where $r_i = R(p_i)$. Then

$$cp_1 + p_2 = s(cq_1 + q_2) + (cr_1 + r_2),$$

and $\deg(cr_1 + r_2) < m$ by Proposition 1.2.18. By the uniqueness in Theorem 7.1.14, $R(cp_1 + p_2) = cr_1 + r_2 = cR(p_1) + R(p_2)$.

(b) If $\deg r \leq m - 1$, then $r = s \cdot \mathbf{0} + r$, so $R(r) = r$; thus R is surjective onto $F[x]_{\leq m-1}$ (note $m - 1 \leq n$). Next, $R(p) = \mathbf{0}$ if and only if $p = sq$ for some q. If $p = sq \neq \mathbf{0}$ has degree at most n, then $\deg q = \deg p - m \leq n - m$ by Proposition 7.1.4. Conversely, if $\deg q \leq n - m$, then $\deg(sq) \leq n$ and $R(sq) = \mathbf{0}$. So $\ker R = \{sq \mid q \in F[x]_{\leq n-m}\}$.

(c) The map $q \mapsto sq$ from $F[x]_{\leq n-m}$ to $\ker R$ is linear, onto by (b), and injective by Corollary 7.1.7(b). So $\dim \ker R = \dim F[x]_{\leq n-m} = n - m + 1$ (Example 4.1.7), while $\dim \operatorname{im} R = \dim F[x]_{\leq m-1} = m$. Their sum is $n + 1 = \dim F[x]_{\leq n}$, as Theorem 4.2.11 requires.

Solution to Exercise 7.1.52

Uses. Proposition 7.1.22 (Counting roots), Proposition 1.1.17 (No zero divisors), Definition 1.1.19 (Integers modulo n)
Hint 1. Square each odd residue modulo 8.
Hint 2. Follow the proof with $c_1 = 1$ and $c_2 = 3$. After splitting off $x - 1$, what is q, and what is $q(3)$?

Sketch. (a) $1^2, 3^2, 5^2, 7^2$ are all 1 modulo 8, and $(x-3)(x+3) = x^2 - 9 = x^2 - 1$. (b) With $c_1 = 1$, $q = x + 1$, and $p(3) = (3-1)q(3) = 2 \cdot 4 = 0$ although $q(3) = 4 \neq 0$. The step "the product of the differences is nonzero, so $q(c_k) = 0$" uses Proposition 1.1.17, which fails in $\mathbb{Z}/8\mathbb{Z}$.

(a) Modulo 8, $1^2 = 1$, $3^2 = 9 = 1$, $5^2 = 25 = 1$, and $7^2 = 49 = 1$, so $1, 3, 5, 7$ are roots of $x^2 - 1$. Also $(x-3)(x+3) = x^2 - 9 = x^2 - 1$, since $9 = 1$ in $\mathbb{Z}/8\mathbb{Z}$. So $x^2 - 1$ has two different factorizations into monic linear factors.

(b) Take $c_1 = 1$ and $c_2 = 3$. The factor theorem still holds, because dividing by the monic polynomial $x - 1$ never requires inverting a scalar, and it gives $x^2 - 1 = (x-1)q$ with $q = x + 1$. The proof then evaluates at $c_2 = 3$:

$$0 = p(3) = (3-1)q(3) = 2 \cdot 4.$$

The next step concludes $q(3) = 0$ because $c_2 - c_1 = 2$ is nonzero, using Proposition 1.1.17. In $\mathbb{Z}/8\mathbb{Z}$ this is false: $2 \cdot 4 = 0$ while $2 \neq 0$ and $q(3) = 4 \neq 0$. That is the step that fails. (The degree formula of Proposition 7.1.4 also fails over $\mathbb{Z}/8\mathbb{Z}$, for instance $(4x+1)(2x+1) = 6x + 1$, but the proof only uses it for monic factors, where it still holds.)

Solution to Exercise 7.1.53

Uses. Corollary 7.1.23 (Polynomials and their values), Definition 7.1.16 (Divisibility), Corollary 7.1.43 (Odd degree gives a real root), Theorem 7.1.39 (Factorization over $\mathbb{R}$)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Try small cases and small fields (Technique 1.2.38)
Hint 1. Try small fields for (a), constants for (b), and repeated factors for (c).
Hint 2. For (d) and (e), use Theorem 7.1.39. What does it say about the number of real roots counted with multiplicity?
Sketch. (a) False over $\mathbb{F}_2$: $x^2 + x$ and $\mathbf{0}$; true over infinite fields. (b) False: x and $2x$ over $\mathbb{Q}$; true for monic polynomials. (c) False: $x^2 \mid x \cdot x$. (d) True by Corollary 7.1.43 (a polynomial with no real root is nonzero). (e) True: in Theorem 7.1.39, k counts the real roots with multiplicity and $k + 2l = \deg p$.

(a) False. Over $\mathbb{F}_2$, $x^2 + x$ and $\mathbf{0}$ both vanish at 0 and 1 (Aside (Polynomials versus polynomial functions)). It is true when F is infinite, by Corollary 7.1.23(b).

(b) False. Over $\mathbb{Q}$, $x \mid 2x$ and $2x \mid x$, since $x = \frac{1}{2} \cdot 2x$. Polynomials that divide each other differ by a nonzero constant factor, so the statement is true if p and q are monic (see the remarks after Definition 7.1.16).

(c) False. x^2 divides $x \cdot x$ but not x, by degrees. It is true when p is irreducible (Exercise 7.1.68).

(d) True. A polynomial with no real root is nonzero, since every real number is a root of $\mathbf{0}$. If its degree were odd, it would have a real root by Corollary 7.1.43. So its degree is even (possibly 0).

(e) True. In Theorem 7.1.39, $\lambda_1, \ldots, \lambda_k$ are the real roots of p listed with multiplicity, so the number of real roots counted with multiplicity is $k = \deg p - 2l$, which has the parity of $\deg p$.

Solution to Exercise 7.1.54

Uses. Exercise 7.1.28, Corollary 7.1.35 (Factorization over $\mathbb{C}$), Proposition 7.1.34 (Roots of a split polynomial), the binomial theorem in a commutative ring
Hint 1. For (a), use Exercise 7.1.28: can $x^n - 1$ and its derivative have a common root?
Hint 2. For (b), expand $(x-1)^p$ with the binomial theorem. Which binomial coefficients $\binom{p}{k}$ are divisible by p?
Sketch. (a) A repeated root c would satisfy $c^n = 1$ and $nc^{n-1} = 0$, which forces $c = 0$, but $0^n \neq 1$. So all n roots given by Corollary 7.1.35 are simple, hence distinct. (b) For $0 < k < p$, p divides $\binom{p}{k} = p!/(k!(p-k)!)$, so $(x-1)^p = x^p + (-1)^p = x^p - 1$ in $\mathbb{F}_p[x]$ (also for $p = 2$, where $1 = -1$).

(a) The derivative of $f = x^n - 1$ is $f' = nx^{n-1}$, where $n = 1 + \cdots + 1 \neq 0$ in $\mathbb{C}$. If c were a repeated root of f, then $f'(c) = nc^{n-1} = 0$ by Exercise 7.1.28. For $n = 1$ this is impossible, as $f' = 1$; for $n \geq 2$ it forces $c = 0$, but $f(0) = -1 \neq 0$. So every root of f is simple. By Corollary 7.1.35, f has n roots counted with multiplicity, and since each multiplicity is 1, these are n distinct roots.

(b) $\mathbb{F}_p[x]$ is a commutative ring, so the binomial theorem holds there, with the usual inductive proof:

$$(x-1)^p = \sum_{k=0}^{p} \binom{p}{k} (-1)^{p-k} x^k.$$

For $0 < k < p$, the integer $\binom{p}{k} = p!/(k!(p-k)!)$ is divisible by p, because the prime p divides the numerator but none of the factors $1, \dots, k$ and $1, \dots, p-k$ of the denominator. So these coefficients are 0 in $\mathbb{F}_p$, and $(x-1)^p = x^p + (-1)^p$. For odd p, $(-1)^p = -1$, and for $p = 2$, $(-1)^2 = 1 = -1$ in $\mathbb{F}_2$. Hence $(x-1)^p = x^p - 1$, and by Proposition 7.1.34, 1 is the only root, with multiplicity p. The test of Exercise 7.1.28 does not separate roots here, since the derivative px^{p-1} is $\mathbf{0}$ in $\mathbb{F}_p[x]$.

Solution to Exercise 7.1.55

Uses. Exercise 1.1.51, Proposition 7.1.22 (Counting roots), Proposition 7.1.4 (Degree of a product), Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 7.1.10 (Evaluation respects sums and products), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$)
Techniques. Compare degrees and leading coefficients (Technique 7.1.6)
Hint 1. By Fermat's little theorem (Exercise 1.1.51), every $a \in \mathbb{F}_p$ is a root of $x^p - x$. What does Proposition 7.1.22 then say?
Hint 2. Both sides of (a) are monic of degree p, and one divides the other.
Hint 3. For (b), cancel the factor x from both sides of (a) and compare constant terms.
Sketch. Each $a \in \mathbb{F}_p$ is a root of $x^p - x$ (for $a \neq 0$, $a^{p-1} = 1$), so $\omega = \prod_a (x-a)$ divides $x^p - x$ by Proposition 7.1.22. Both are monic of degree p, so the quotient is 1. Cancelling x gives $x^{p-1} - 1 = \prod_{a \neq 0}(x-a)$; at 0 this reads $-1 = (-1)^{p-1}(p-1)!$ in $\mathbb{F}_p$, and $(-1)^{p-1} = 1$ for odd p, while $p = 2$ is checked directly.

(a) Every $a \in \mathbb{F}_p$ is a root of $x^p - x$: for $a = 0$ this is clear, and for $a \neq 0$, $a^{p-1} = 1$ by Exercise 1.1.51, so $a^p = a$. The p elements of $\mathbb{F}_p$ are distinct roots, so by Proposition 7.1.22, $\omega = \prod_{a \in \mathbb{F}_p}(x-a)$ divides $x^p - x$, say $x^p - x = \omega h$. Both ω and $x^p - x$ are monic of degree p, so by Proposition 7.1.4 h has degree 0 and leading coefficient 1, that is, $h = 1$.

(b) Write $\omega = x\prod_{a \neq 0}(x-a)$ and $x^p - x = x\left(x^{p-1} - 1\right)$. Cancelling x (Corollary 7.1.7(b)) gives

$$x^{p-1} - 1 = \prod_{a \in \mathbb{F}_p, a \neq 0} (x-a).$$

Evaluating at 0 (Proposition 7.1.10), $-1 = \prod_{a \neq 0}(-a) = (-1)^{p-1} \cdot (1 \cdot 2 \cdots (p-1))$, where the product is computed in $\mathbb{F}_p$, so it is $(p-1)!$ mod p (Lemma 1.1.21). If p is odd, $(-1)^{p-1} = 1$, so $(p-1)! \equiv -1 \pmod p$. If $p = 2$, then $(p-1)! = 1 \equiv -1 \pmod 2$ directly.

Solution to Exercise 7.1.56

Uses. Corollary 7.1.12 (Substituting twice), Definition 1.1.28 (Characteristic), Corollary 7.1.23 (Polynomials and their values), Exercise 7.1.55, Proposition 7.1.10 (Evaluation respects sums and products)
Hint 1. Evaluate $f(x+1) = f$ at $t \in F$ with Corollary 7.1.12. What does this say about $f(0), f(1), f(1+1), \dots$?
Hint 2. In characteristic 0, the elements $k \cdot 1$ for $k = 0, 1, 2, \dots$ are distinct. For (b), substitute $x+1$ into the factorization of Exercise 7.1.55.
Sketch. (a) $f(t+1) = f(t)$ for all t, so $f(k \cdot 1) = f(0)$ for all $k \geq 0$. In characteristic 0 these are infinitely many distinct points, so $f - f(0)$ is $\mathbf{0}$. (b) $f = x^p - x = \prod_a (x-a)$; substituting $x+1$ gives $\prod_a (x-(a-1))$, the same product reordered.

(a) By Corollary 7.1.12 with $r = x+1$, for every $t \in F$ we have $f(t+1) = (f(x+1))(t) = f(t)$. By induction, $f(k \cdot 1) = f(0)$ for every integer $k \geq 0$, where $k \cdot 1 = 1 + \cdots + 1$. In characteristic 0 these elements are distinct: if $j \cdot 1 = k \cdot 1$ with $j < k$, then $(k-j) \cdot 1 = 0$ with $k - j \geq 1$, which is impossible by Definition 1.1.28. So $f - f(0)$ has infinitely many roots, hence $f - f(0) = \mathbf{0}$ by Corollary 7.1.23(b), and f is the constant $f(0)$.

(b) Let $f = x^p - x$, which has degree $p \geq 2$. By Exercise 7.1.55, $f = \prod_{a \in \mathbb{F}_p}(x-a)$. Substituting $x+1$ and using Proposition 7.1.10 for the product,

$$f(x+1) = \prod_{a \in \mathbb{F}_p} (x+1-a) = \prod_{a \in \mathbb{F}_p} (x-(a-1))$$

$$= \prod_{b \in \mathbb{F}_p} (x - b) = f,$$

because $a \mapsto a - 1$ is a bijection of $\mathbb{F}_p$, so the last two products have the same factors in a different order. (Alternatively, $(x+1)^p = x^p + 1$ in $\mathbb{F}_p[x]$ by the binomial argument of Exercise 7.1.54.)

Solution to Exercise 7.1.57

Uses. Exercise 7.1.28, Proposition 7.1.27 (Multiplicities add up to at most the degree), Corollary 4.2.18 (Injective if and only if surjective), Example 2.1.9 (Maps of polynomials), Example 4.1.7 (Dimensions of the standard spaces)
Techniques. Uniqueness gives existence (Technique 3.4.21), Dimension counting (Technique 4.2.24)
Hint 1. The map $f \mapsto (f(0), f'(0), f(1), f'(1))$ from $F[x]_{\le 3}$ to F^4 is linear, and both spaces have dimension 4. So it is enough to show that it is injective.
Hint 2. If all four values are 0, then 0 and 1 are repeated roots of f (Exercise 7.1.28). Count multiplicities.
Hint 3. For (b), 1 is a repeated root, so $f = (x-1)^2(ux+v)$.
Sketch. The map $T(f) = (f(0), f'(0), f(1), f'(1))$ is linear from a 4-dimensional space to F^4. If $T(f) = \mathbf{0}$ and $f \neq \mathbf{0}$, then 0 and 1 are roots of multiplicity at least 2, so $4 \le \deg f \le 3$ by Proposition 7.1.27, which is impossible. So T is injective, hence bijective. For (b), $f = (x-1)^2(ux+v)$ with $v = 1$ and $u - 2v = 0$, so $f = (x-1)^2(2x+1) = 2x^3 - 3x^2 + 1$.

(a) Let $T : F[x]_{\le 3} \to F^4$, $T(f) = (f(0), f'(0), f(1), f'(1))$. Evaluation and the formal derivative are linear (Example 2.1.9), so T is linear. Suppose $T(f) = \mathbf{0}$ and $f \neq \mathbf{0}$. By Exercise 7.1.28, 0 and 1 are repeated roots of f, so each has multiplicity at least 2, and Proposition 7.1.27 gives $2 + 2 \le \deg f \le 3$, which is impossible. So $\ker T = \{\mathbf{0}\}$, and T is injective. Since $\dim F[x]_{\le 3} = 4 = \dim F^4$ (Example 4.1.7), T is bijective by Corollary 4.2.18. So each (a, b, c, d) is $T(f)$ for exactly one f.

(b) Here $f(1) = f'(1) = 0$, so 1 is a repeated root (or $f = \mathbf{0}$, which is excluded by $f(0) = 1$), and $(x-1)^2$ divides f. Since $\deg f \le 3$, $f = (x-1)^2(ux+v)$ for some $u, v \in \mathbb{Q}$. Then $f(0) = v = 1$, and by the product rule $f' = 2(x-1)(ux+v) + u(x-1)^2$, so $f'(0) = -2v + u = 0$ and $u = 2$. Hence

$$f = (x-1)^2(2x+1) = 2x^3 - 3x^2 + 1.$$

Check: $f(0) = 1$, $f(1) = 0$, and $f' = 6x^2 - 6x$ vanishes at 0 and 1.

Solution to Exercise 7.1.58

Uses. Proposition 3.4.27 (Lagrange's formula), Theorem 3.4.24 (Polynomial interpolation), Proposition 7.1.29 (Lagrange polynomials in closed form), Exercise 2.1.49, Proposition 7.1.10 (Evaluation respects sums and products)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), both sides of each identity have degree at most n. Compare their values at the nodes.
Hint 2. For (b), write $\omega = (x - c_i)\omega_i$ and differentiate with the product rule.
Sketch. (a) By Proposition 3.4.27, $\sum_i d_i L_i$ is the interpolant of the values d_i. The constant 1 and the polynomial x (of degree $1 \le n$) interpolate the values 1 and c_i, so they equal $\sum_i L_i$ and $\sum_i c_i L_i$. (b) $\omega' = \omega_i + (x - c_i)\omega_{i'}$, so $\omega'(c_i) = \omega_i(c_i) = \prod_{j \neq i}(c_i - c_j)$, and Proposition 7.1.29 gives $L_i = \omega_i / \omega'(c_i)$.

(a) By Proposition 3.4.27, for any values $d_0, \ldots, d_n$, the polynomial $\sum_i d_i L_i$ is the unique element of $F[x]_{\le n}$ taking the value d_k at c_k. The constant polynomial 1 lies in $F[x]_{\le n}$ and takes the value 1 at every node, so $\sum_i L_i = 1$. Since $n \ge 1$, the polynomial x lies in $F[x]_{\le n}$ and takes the value c_k at c_k, so $\sum_i c_i L_i = x$.

(b) Write $\omega = (x - c_i)\omega_i$. By the product rule (Exercise 2.1.49), $\omega' = \omega_i + (x - c_i)\omega_{i'}$, so by Proposition 7.1.10

$$\omega'(c_i) = \omega_i(c_i) + 0 = \prod_{j \neq i}(c_i - c_j).$$

This is nonzero, and by Proposition 7.1.29, $L_i = \omega_i / \prod_{j \neq i}(c_i - c_j) = \omega_i / \omega'(c_i)$.

Solution to Exercise 7.1.59

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Proposition 7.1.36 (Sum and product of the roots)
Hint 1. Multiply out one factor at a time.
Hint 2. By Corollary 7.1.35, $x^3 - 2x + 5 = (x - \lambda_1)(x - \lambda_2)(x - \lambda_3)$. Compare coefficients. For the last sum, square $\lambda_1 + \lambda_2 + \lambda_3$.

Sketch. (a) $x^3 - e_1x^2 + e_2x - e_3$ with $e_1 = \sum \lambda_i$, $e_2 = \sum_{i<j} \lambda_i\lambda_j$, $e_3 = \lambda_1\lambda_2\lambda_3$. (b) Comparing with $x^3 - 2x + 5$: $e_1 = 0$, $e_2 = -2$, $e_3 = -5$, and $\sum \lambda_i^2 = e_1^2 - 2e_2 = 4$.

(a) First $(x - \lambda_1)(x - \lambda_2) = x^2 - (\lambda_1 + \lambda_2)x + \lambda_1\lambda_2$. Multiplying by $x - \lambda_3$,

$$(x - \lambda_1)(x - \lambda_2)(x - \lambda_3) = x^3 - e_1x^2 + e_2x - e_3,$$

where $e_1 = \lambda_1 + \lambda_2 + \lambda_3$, $e_2 = \lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3$, and $e_3 = \lambda_1\lambda_2\lambda_3$. The first and last agree with Proposition 7.1.36.

(b) By Corollary 7.1.35, $x^3 - 2x + 5 = (x - \lambda_1)(x - \lambda_2)(x - \lambda_3)$, so comparing coefficients with (a) gives $e_1 = 0$, $e_2 = -2$, and $-e_3 = 5$, that is, $e_3 = -5$. Finally, expanding the square gives $e_1^2 = \lambda_1^2 + \lambda_2^2 + \lambda_3^2 + 2e_2$, so

$$\lambda_1^2 + \lambda_2^2 + \lambda_3^2 = e_1^2 - 2e_2 = 0 - 2(-2) = 4.$$

Solution to Exercise 7.1.60

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Theorem 7.1.39 (Factorization over $\mathbb{R}$), Corollary 7.1.42 (Irreducible polynomials over $\mathbb{C}$ and $\mathbb{R}$), Proposition 7.1.34 (Roots of a split polynomial)
Hint 1. For $x^4 + 1$, find a complex number whose square is i; its fourth power is -1.
Hint 2. Over $\mathbb{R}$, pair conjugate roots as in the proof of Theorem 7.1.39. For $x^6 - 1$, start from $\big(x^3 - 1\big)\big(x^3 + 1\big)$.
Sketch. The roots of $x^4 + 1$ are $(\pm 1 \pm i)/\sqrt{2}$, and pairing conjugates gives $x^4 + 1 = \big(x^2 - \sqrt{2}x + 1\big)\big(x^2 + \sqrt{2}x + 1\big)$ over $\mathbb{R}$. Also $x^6 - 1 = (x - 1)(x + 1)\big(x^2 + x + 1\big)\big(x^2 - x + 1\big)$ over $\mathbb{R}$, and the quadratics split over $\mathbb{C}$ with roots $\big(-1 \pm i\sqrt{3}\big)/2$ and $\big(1 \pm i\sqrt{3}\big)/2$.

By Corollary 7.1.42, the irreducible factors over $\mathbb{C}$ are linear, and those over $\mathbb{R}$ are linear or quadratics with negative discriminant.

$x^4 + 1$. Let $\zeta = (1 + i)/\sqrt{2}$. Then $\zeta^2 = (1 + 2i - 1)/2 = i$, so $\zeta^4 = -1$. The same computation shows that all four numbers $(\pm 1 \pm i)/\sqrt{2}$, that is, $\pm\zeta$ and $\pm\overline{\zeta}$, have squares $\pm i$ and are roots. They are distinct, so by Corollary 7.1.35

$$x^4 + 1 = (x - \zeta)\big(x - \overline{\zeta}\big)(x + \zeta)\big(x + \overline{\zeta}\big).$$

Pairing conjugates, $(x - \zeta)\big(x - \overline{\zeta}\big) = x^2 - 2(\operatorname{Re}\zeta)x + |\zeta|^2 = x^2 - \sqrt{2}x + 1$, and similarly for $-\zeta$. So over $\mathbb{R}$,

$$x^4 + 1 = \big(x^2 - \sqrt{2}x + 1\big)\big(x^2 + \sqrt{2}x + 1\big),$$

and both quadratics have discriminant $2 - 4 < 0$. Check: the product is $\big(x^2 + 1\big)^2 - 2x^2 = x^4 + 1$.

$x^6 - 1$. Since $x^3 - 1 = (x - 1)\big(x^2 + x + 1\big)$ and $x^3 + 1 = (x + 1)\big(x^2 - x + 1\big)$,

$$x^6 - 1 = (x - 1)(x + 1)\big(x^2 + x + 1\big)\big(x^2 - x + 1\big)$$

over $\mathbb{R}$, and the two quadratics have discriminant $1 - 4 < 0$, so they are irreducible. Over $\mathbb{C}$, by the quadratic formula, $x^2 + x + 1 = (x - \omega)(x - \overline{\omega})$ with $\omega = \big(-1 + i\sqrt{3}\big)/2$, and $x^2 - x + 1 = (x + \omega)(x + \overline{\omega})$, so

$$x^6 - 1 = (x - 1)(x + 1)(x - \omega)(x - \overline{\omega})(x + \omega)(x + \overline{\omega}).$$

The six roots $\pm 1, \pm\omega, \pm\overline{\omega}$ are distinct, consistent with Exercise 7.1.54(a).

Solution to Exercise 7.1.61

Uses. Definition 7.1.41 (Irreducible polynomial), Theorem 7.1.20 (Factor theorem), Proposition 7.1.4 (Degree of a product), Example 7.1.40 ($x^4 + 4$), Exercise 7.1.8
Hint 1. If $p = gh$ with both factors of degree at least 1 and $\deg g + \deg h \le 3$, then one factor has degree 1.
Hint 2. For (b), look for a product of two quadratics without roots. Example 7.1.40 and Exercise 7.1.8 have candidates.
Sketch. (a) A root c gives $p = (x - c)q$ with $\deg q \ge 1$. Conversely, in a factorization $p = gh$ the degrees add to 2 or 3, so one factor is $ux + v$ with $u \ne 0$, and $-v/u$ is a root of p. (b) $x^4 + 4 = \big(x^2 - 2x + 2\big)\big(x^2 + 2x + 2\big)$ over $\mathbb{Q}$ and $x^4 + x^2 + 1 = \big(x^2 + x + 1\big)^2$ over $\mathbb{F}_2$. (c) The first two have no root in $\mathbb{F}_2$, so they are irreducible; $x^3 + 1$ has the root 1.

(a) If p has a root c, then $p = (x - c)q$ with $\deg q = \deg p - 1 \ge 1$ (Theorem 7.1.20), so p is reducible. Conversely, suppose $p = gh$ with $\deg g, \deg h \ge 1$. Since $\deg g + \deg h = \deg p \le 3$ (Proposition 7.1.4), one

of the factors, say g, has degree 1: $g = ux + v$ with $u \neq 0$. Then $c = -v/u$ satisfies $g(c) = 0$, so $p(c) = g(c)h(c) = 0$, and p has a root.

(b) Over $\mathbb{Q}$, $x^4 + 4 = (x^2 - 2x + 2)(x^2 + 2x + 2)$ (Example 7.1.40) is reducible, and it has no root even in $\mathbb{R}$, since $t^4 + 4 \geq 4$. Over $\mathbb{F}_2$, $(x^2 + x + 1)^2 = x^4 + x^2 + 1$ (Exercise 7.1.8), and $x^4 + x^2 + 1$ takes the value 1 at both 0 and 1, so it has no root.

(c) The polynomial $x^2 + x + 1$ takes the values 1 and $1 + 1 + 1 = 1$ at 0 and 1, and $x^3 + x + 1$ takes the values 1 and 1, so by (a) both are irreducible over $\mathbb{F}_2$. But 1 is a root of $x^3 + 1$, so it is reducible: $x^3 + 1 = (x + 1)(x^2 + x + 1)$.

Solution to Exercise 7.1.62

Uses. Exercise 7.1.61, Theorem 7.1.20 (Factor theorem), Proposition 7.1.34 (Roots of a split polynomial)
Hint 1. Count all monic quadratics, then count the reducible ones. By Exercise 7.1.61, a reducible monic quadratic has a root.
Hint 2. A reducible monic quadratic is $(x - a)(x - b)$. By Proposition 7.1.34, how many choices of a, b give the same polynomial?
Sketch. There are p^2 monic quadratics $x^2 + bx + c$. The reducible ones are the products $(x - a)(x - b)$, and by Proposition 7.1.34 two such products are equal exactly when the pairs agree up to order. There are $p + p(p-1)/2 = p(p+1)/2$ unordered pairs, so $p^2 - p(p+1)/2 = p(p-1)/2$ are irreducible. For $p = 3$: $x^2 + 1$, $x^2 + x + 2$, $x^2 + 2x + 2$.

A monic quadratic is $x^2 + bx + c$ with $b, c \in \mathbb{F}_p$, so there are p^2 of them. If one is reducible, it has a root a (Exercise 7.1.61), and then it equals $(x - a)q$ with q monic of degree 1 (Theorem 7.1.20, comparing leading coefficients), so it is $(x - a)(x - b)$ for some $a, b \in \mathbb{F}_p$. Conversely every such product is a reducible monic quadratic. By Proposition 7.1.34, $(x - a)(x - b) = (x - a')(x - b')$ if and only if the lists a, b and a', b' agree up to order. So the reducible monic quadratics correspond to unordered pairs $\{a, b\}$ with repetition allowed: p with $a = b$, and $p(p-1)/2$ with $a \neq b$. That makes $p(p+1)/2$ reducible ones, and

$$p^2 - p\frac{p+1}{2} = p\frac{p-1}{2}$$

irreducible ones.

For $p = 3$ there are 3. Checking values at $0, 1, 2$: $x^2 + 1$ takes the values $1, 2, 2$; $x^2 + x + 2$ takes $2, 1, 2$; and $x^2 + 2x + 2$ takes $2, 2, 1$. None has a root, so these are the three monic irreducible quadratics over $\mathbb{F}_3$.

Solution to Exercise 7.1.63

Uses. Lemma 7.1.37 (Conjugating polynomials), Corollary 7.1.23 (Polynomials and their values)
Hint 1. Compare f with the conjugate polynomial $\overline{f}$ at the points t_k.
Hint 2. For the example, take a polynomial that vanishes at all the t_k.
Sketch. For real t_k, $\overline{f}(t_k) = \overline{f}(\overline{t_k}) = \overline{f(t_k)} = f(t_k)$. So f and $\overline{f}$, both of degree at most n, agree at $n + 1$ points, and $f = \overline{f} \in \mathbb{R}[x]$. Without the degree bound, $i(x - t_0)\cdots(x - t_n)$ is real (zero) at every t_k.

The conjugate polynomial $\overline{f}$ has the same degree as f, so it lies in $\mathbb{C}[x]_{\leq n}$. For each k, since t_k is real and $f(t_k)$ is real, Lemma 7.1.37(b) gives

$$\overline{f}(t_k) = \overline{f}(\overline{t_k}) = \overline{f(t_k)} = f(t_k).$$

So f and $\overline{f}$ agree at the $n + 1$ distinct points $t_0, \ldots, t_n$, and $f = \overline{f}$ by Corollary 7.1.23(a). By Lemma 7.1.37(c), $f \in \mathbb{R}[x]$.

The degree bound is needed: $g = i(x - t_0)(x - t_1)\cdots(x - t_n)$ has $g(t_k) = 0 \in \mathbb{R}$ for every k, but its leading coefficient i is not real.

Solution to Exercise 7.1.64

Uses. Theorem 7.1.39 (Factorization over $\mathbb{R}$), Lemma 7.1.37 (Conjugating polynomials), Lemma 7.1.25 (Reading off a multiplicity), continuity of polynomial functions
Hint 1. First show that every real root of p has even multiplicity: a root of odd multiplicity is a point where p changes sign.

Hint 2. Then factor p as in Theorem 7.1.39, show $a > 0$, and split each quadratic factor over $\mathbb{C}$ as $(x-\mu)(x-\overline{\mu})$.
Hint 3. Find $h \in \mathbb{C}[x]$ with $p = h\overline{h}$, and write $h = f + ig$ with $f, g \in \mathbb{R}[x]$.
Sketch. If a real root λ had odd multiplicity m, then $p = (x-\lambda)^m q$ with $q(\lambda) \neq 0$, and p would change sign at λ. So $p = a\prod (x-\lambda_i)^{2k_i} \prod (x-\mu_j)(x-\overline{\mu_j})$ with $a > 0$. Let $h = \sqrt{a}\prod (x-\lambda_i)^{k_i} \prod (x-\mu_j)$. Then $\overline{h} = \sqrt{a}\prod (x-\lambda_i)^{k_i} \prod (x-\overline{\mu_j})$, so $p = h\overline{h}$, and with $h = f + ig$ this is $(f+ig)(f-ig) = f^2 + g^2$.

If $p = \mathbf{0}$, take $f = g = \mathbf{0}$. Let $p \neq \mathbf{0}$.

Real roots have even multiplicity. Let $\lambda \in \mathbb{R}$ be a root of multiplicity m, and write $p = (x-\lambda)^m q$ with $q(\lambda) \neq 0$ (Lemma 7.1.25). The function $t \mapsto q(t)$ is continuous, so it has constant sign on some interval $(\lambda - \delta, \lambda + \delta)$. If m were odd, $(t-\lambda)^m$ would be negative for $t < \lambda$ and positive for $t > \lambda$, so $p(t) = (t-\lambda)^m q(t)$ would take both signs near λ, contradicting $p \geq 0$. So m is even.

Factor. By Theorem 7.1.39, whose real linear factors are the real roots listed with multiplicity, and grouping equal linear factors,

$$p = a\prod_{i=1}^{r} (x-\lambda_i)^{2k_i} \prod_{j=1}^{l} (x^2 + b_j x + c_j),$$

with distinct real λ_i, each of even multiplicity $2k_i$ by the first step, and $b_j^2 < 4c_j$. Each quadratic factor is positive on $\mathbb{R}$, since $t^2 + b_j t + c_j = \left(t + b_j/2\right)^2 + \left(c_j - b_j^2/4\right)$. Choose $t \in \mathbb{R}$ that is not a root of p (there are finitely many roots). Then $p(t) > 0$ and every factor other than a is positive at t, so $a > 0$.

Write $p = h\overline{h}$. As in the proof of Theorem 7.1.39, $x^2 + b_j x + c_j = \left(x - \mu_j\right)\left(x - \overline{\mu_j}\right)$ for some $\mu_j \in \mathbb{C}$. Let

$$h = \sqrt{a}\prod_{i=1}^{r} (x-\lambda_i)^{k_i} \prod_{j=1}^{l} (x-\mu_j) \in \mathbb{C}[x].$$

By Lemma 7.1.37(a), and since $\sqrt{a}$ and the λ_i are real, $\overline{h} = \sqrt{a}\prod_i (x-\lambda_i)^{k_i} \prod_j \left(x - \overline{\mu_j}\right)$. Hence $h\overline{h} = p$.

Real and imaginary parts. Write $h = f + ig$, where $f, g \in \mathbb{R}[x]$ have as coefficients the real and imaginary parts of the coefficients of h. Then $\overline{h} = f - ig$, and

$$p = h\overline{h} = (f+ig)(f-ig) = f^2 + g^2.$$

Both sides lie in $\mathbb{R}[x]$, and the identity holds there because the operations of $\mathbb{R}[x]$ are those of $\mathbb{C}[x]$.

Solution to Exercise 7.1.65

Uses. Definition 7.1.9 (Substitution), Definition 7.1.1 (Product of polynomials), Proposition 7.1.4 (Degree of a product)
Techniques. Compare degrees and leading coefficients (Technique 7.1.6)
Hint 1. Try small cases: which monomials ax^n work? Compare leading coefficients.
Hint 2. Suppose $p = x^n + a_k x^k + \cdots$, where $k < n$, $a_k \neq 0$, and the omitted terms have degree less than k. Compute the coefficient of x^{n+k} on both sides.
Hint 3. On the right it is $2a_k$. On the left, $p\left(x^2\right)$ has only even powers x^{2j}, and x^{n+k} would need $j = (n+k)/2$, strictly between k and n.
Sketch. (a) The solutions are $\mathbf{0}$ and x^n, $n \geq 0$. For $p \neq \mathbf{0}$ of degree n with leading coefficient a, comparing leading coefficients gives $a = a^2$, so $a = 1$. If p had another nonzero coefficient, let a_k be the one with the largest $k < n$. The coefficient of x^{n+k} is $2a_k \neq 0$ in p^2, but 0 in $p\left(x^2\right)$. (b) Over $\mathbb{F}_2$, $p^2 = \sum a_i^2 x^{2i} + 2\sum_{i<j} a_i a_j x^{i+j} = \sum a_i x^{2i}$.

(a) The solutions are $p = \mathbf{0}$ and $p = x^n$ for $n \geq 0$; these work, since $\left(x^2\right)^n = x^{2n} = (x^n)^2$. Conversely, let $p = \sum_{j=0}^{n} a_j x^j$ with $a_n \neq 0$ satisfy $p\left(x^2\right) = p^2$. The polynomial $p\left(x^2\right) = \sum_j a_j x^{2j}$ has leading coefficient a_n, and p^2 has leading coefficient a_n^2 (Proposition 7.1.4). So $a_n^2 = a_n$, and $a_n = 1$.

Suppose $p \neq x^n$, and let $k < n$ be the largest index below n with $a_k \neq 0$. In p^2, the coefficient of x^{n+k} is $\sum_{i+j=n+k} a_i a_j$. A nonzero term needs $a_i \neq 0$ and $a_j \neq 0$, so each of i, j is n or at most k. If $i \leq k$, then $j = n + k - i \geq n$, so $j = n$ and $i = k$; similarly if $j \leq k$. So only the pairs (n,k) and (k,n) contribute, and the coefficient is $2a_n a_k = 2a_k$, which is nonzero because $1 + 1 \neq 0$ and F has no zero divisors. In $p\left(x^2\right) = \sum_j a_j x^{2j}$, the

coefficient of x^{n+k} is 0 if $n+k$ is odd, and $a_{(n+k)/2}$ if it is even. Since $k < (n+k)/2 < n$, this is 0 by the choice of k. The two sides differ, a contradiction. So $p = x^n$.

(b) Let $p = \sum_i a_i x^i \in \mathbb{F}_2[x]$. Expanding the square and grouping the pairs (i,j) and (j,i) with $i \neq j$,

$$\begin{aligned} p^2 &= \sum_{i,j} a_i a_j x^{i+j} = \sum_i a_i^2 x^{2i} + \sum_{i<j} 2a_i a_j x^{i+j} \\ &= \sum_i a_i x^{2i} = p\big(x^2\big), \end{aligned}$$

because $2 = 0$ and $a^2 = a$ for both elements a of $\mathbb{F}_2$.

Solution to Exercise 7.1.66

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Exercise 2.1.49, Proposition 7.1.10 (Evaluation respects sums and products), Notation 6.1.1 (Real and complex scalars)
Hint 1. If w is a root of p, the claim is easy. Otherwise, compute p' from $p = a\prod(x-\lambda_i)$ with the product rule.
Hint 2. You should find $p'(w) = p(w)\sum_i 1/(w-\lambda_i)$, so $\sum_i 1/(w-\lambda_i) = 0$.
Hint 3. Write $1/(w-\lambda_i) = \overline{w-\lambda_i}/\left|w-\lambda_i\right|^2$, and conjugate the equation.
Sketch. If $p(w) = 0$, then $w = \lambda_i$ for some i. Otherwise $p' = a\sum_i \prod_{j\neq i}(x-\lambda_j)$ gives $0 = p'(w) = p(w)\sum_i 1/(w-\lambda_i)$, so $\sum_i \overline{w-\lambda_i}/\left|w-\lambda_i\right|^2 = 0$. Conjugating, $\sum_i s_i(w-\lambda_i) = 0$ with $s_i = \left|w-\lambda_i\right|^{-2} > 0$, so $w = \sum_i\big(s_i/\sum_j s_j\big)\lambda_i$.

If $p(w) = 0$, then $w = \lambda_i$ for some i (Corollary 7.1.35), and $t_i = 1$, $t_j = 0$ for $j \neq i$ works. So suppose $p(w) \neq 0$.

Write $p = a(x-\lambda_1)\cdots(x-\lambda_n)$. Applying the product rule (Exercise 2.1.49) $n-1$ times, by induction on the number of factors,

$$p' = a\sum_{i=1}^{n}\prod_{j\neq i}(x-\lambda_j).$$

Evaluating at w (Proposition 7.1.10) and using $a\prod_{j\neq i}(w-\lambda_j) = p(w)/(w-\lambda_i)$, which is valid since $w \neq \lambda_i$,

$$0 = p'(w) = p(w)\sum_{i=1}^{n}\frac{1}{w-\lambda_i}.$$

Since $p(w) \neq 0$, $\sum_i 1/(w-\lambda_i) = 0$. For $z \neq 0$, $1/z = \overline{z}/\left|z\right|^2$ (Notation 6.1.1), so with $s_i = 1/\left|w-\lambda_i\right|^2 > 0$ we get $\sum_i s_i\overline{w-\lambda_i} = 0$. Conjugating, $\sum_i s_i(w-\lambda_i) = 0$, that is,

$$w = \sum_{i=1}^{n}\left(\frac{s_i}{s_1+\cdots+s_n}\right)\lambda_i.$$

The coefficients $t_i = s_i/(s_1+\cdots+s_n)$ are positive and add up to 1.

Geometrically, the roots of p' lie in the smallest convex polygon containing the roots of p. For real-rooted p this is the interval between the smallest and the largest root.

Solution to Exercise 7.1.67

Uses. Algorithm 7.1.46 (Euclidean algorithm), Theorem 7.1.45 (Bézout's identity), Definition 7.1.44 (Greatest common divisor)
Hint 1. Over $\mathbb{Q}$ the algorithm takes two divisions.
Hint 2. Over $\mathbb{F}_2$, $p = x^4+x^3+x+1$. Divide it by $s = x^3+1$.
Sketch. (a) $p = (x+1)s + 2\big(x^2+x+1\big)$ and $s = \big(\frac{1}{2}x - \frac{1}{2}\big)\cdot 2\big(x^2+x+1\big)$, so $\gcd(p,s) = x^2+x+1 = \frac{1}{2}p - \frac{1}{2}(x+1)s$. (b) Over $\mathbb{F}_2$, $p = (x+1)s$ exactly, so $\gcd(p,s) = s = x^3+1$. Reducing modulo 2 is not an inclusion of fields, so the remainders, and with them the gcd, can change.

(a) Dividing, $p = (x+1)\big(x^3-1\big) + \big(2x^2+2x+2\big)$: indeed $(x+1)\big(x^3-1\big) = x^4+x^3-x-1$, and p minus this is $2x^2+2x+2$. Next, $x^3-1 = \big(\frac{1}{2}x-\frac{1}{2}\big)\big(2x^2+2x+2\big)$ exactly, since $(x-1)\big(x^2+x+1\big) = x^3-1$. The last nonzero remainder is $2x^2+2x+2$, so $\gcd(p,s) = x^2+x+1$, and from the first division

$$x^2 + x + 1 = \frac{1}{2}(p - (x+1)s) = \frac{1}{2}p - \frac{1}{2}(x+1)s.$$

Consistently, $p = \left(x^2+1\right)\left(x^2+x+1\right)$ and $s = (x-1)\left(x^2+x+1\right)$.

(b) Over $\mathbb{F}_2$, $p = x^4 + x^3 + x + 1$ and $s = x^3 + 1$, and $(x+1)\left(x^3+1\right) = x^4 + x^3 + x + 1 = p$. So $s \mid p$, the algorithm stops after one division, and $\gcd(p, s) = x^3 + 1$. The answer has larger degree than over $\mathbb{Q}$, because in $\mathbb{F}_2[x]$ the factor $x^2 + 1$ of p becomes $(x+1)^2$, which shares the factor $x + 1 = x - 1$ with s. Reducing the coefficients modulo 2 is not a passage to a larger field, so nothing like Corollary 7.1.17 applies; already the remainders change, as in Exercise 7.1.18. For a subfield $F \subseteq K$, on the other hand, the gcd computed in $K[x]$ is the one computed in $F[x]$, since the Euclidean algorithm only takes remainders.

Solution to Exercise 7.1.68

Uses. Theorem 7.1.45 (Bézout's identity), Definition 7.1.41 (Irreducible polynomial), Definition 7.1.16 (Divisibility), Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 7.1.4 (Degree of a product)
Techniques. Strong induction and well-ordering (Technique 5.2.12)
Hint 1. For (a), let $d = \gcd(p, g)$. Since p is irreducible, d is 1 or p made monic. In the first case use Bézout and multiply by h.
Hint 2. For existence in (b), use strong induction on the degree. For uniqueness, apply (a) repeatedly to see that p_1 divides some q_j, and cancel.
Sketch. (a) $d = \gcd(p, g)$ divides the irreducible p, so $d = 1$ or d is p made monic. In the second case $p \mid g$. In the first, $up + vg = 1$, so $h = uph + vgh$ is divisible by p. (b) A reducible polynomial is a product of two of smaller degree, so strong induction gives existence. For uniqueness, compare leading coefficients, then $p_1 \mid q_1 \cdots q_l$, so $p_1 \mid q_j$ for some j by (a); both are monic irreducible, so $p_1 = q_j$; cancel and induct on k.

(a) Let $d = \gcd(p, g)$ (Theorem 7.1.45). Since $d \mid p$, write $p = de$. As p is irreducible, $\deg d = 0$ or $\deg e = 0$. If $\deg d = 0$, then $d = 1$, being monic, and Bézout gives $up + vg = 1$ for some u, v. Multiplying by h, $h = uph + vgh$. Both terms are divisible by p, the second because $p \mid gh$, so $p \mid h$. If $\deg e = 0$, then e is a nonzero constant and $p = ed$ divides g, because d does.

(b) *Existence*, by strong induction on $\deg f$ for f of degree at least 1. If f is irreducible, it is a product of one irreducible. Otherwise $f = gh$ with $1 \le \deg g, \deg h < \deg f$, and by the induction hypothesis both g and h are products of irreducibles, hence so is f. Writing each irreducible factor as a constant times a monic one, $f = ap_1 \cdots p_k$ with p_i monic irreducible.

Uniqueness. The product of monic polynomials is monic, so comparing leading coefficients gives $a = b$, and cancelling a leaves $p_1 \cdots p_k = q_1 \cdots q_l$. We induct on k. If $k = 0$, the left side is 1, so $l = 0$ by degrees. If $k \ge 1$, then $l \ge 1$, since otherwise $p_1 \cdots p_k = 1$ would have degree $0 < k$. So p_1 divides $q_1 \cdots q_l$, and by (a) applied $l - 1$ times, $p_1 \mid q_j$ for some j. Since q_j is irreducible and $\deg p_1 \ge 1$, $q_j = p_1 c$ with c constant, and as both are monic, $c = 1$. Cancelling $p_1 = q_j$ from both sides (Corollary 7.1.7(b)) leaves products of $k - 1$ and $l - 1$ monic irreducibles, and the induction hypothesis finishes the proof.

Solution to Exercise 7.1.69

Uses. Theorem 7.1.45 (Bézout's identity), Corollary 7.1.48 (Coprime polynomials), Theorem 7.1.14 (Division with remainder), Theorem 7.1.20 (Factor theorem), Proposition 7.1.4 (Degree of a product)
Techniques. Compare degrees and leading coefficients (Technique 7.1.6)
Hint 1. Use $um_1 + vm_2 = 1$. The polynomial vm_2 is 1 "modulo m_1" and 0 "modulo m_2".
Hint 2. Take $P = r_1 vm_2 + r_2 um_1$, then reduce it modulo $m_1 m_2$. For uniqueness, show that $m_1 m_2$ divides the difference of two solutions.
Sketch. With $um_1 + vm_2 = 1$, $P = r_1 vm_2 + r_2 um_1$ satisfies $P - r_1 = (r_2 - r_1)um_1$ and $P - r_2 = (r_1 - r_2)vm_2$. Its remainder p on division by $m_1 m_2$ still works and has degree less than $d_1 + d_2$. If p, p' both work, then $p - p' = m_1 g$ and $m_2 \mid m_1 g$, so $m_2 \mid g = um_1 g + vm_2 g$; hence $m_1 m_2 \mid p - p'$, and degrees force $p = p'$. For (b), $x - c_i$ divides $p - r_i$ iff $p(c_i) = r_i(c_i)$.

(a) By Theorem 7.1.45 there are u, v with $um_1 + vm_2 = 1$.

Existence. Let $P = r_1 vm_2 + r_2 um_1$. Using $vm_2 = 1 - um_1$ and $um_1 = 1 - vm_2$,

$$P - r_1 = r_1(vm_2 - 1) + r_2 um_1 = (r_2 - r_1)um_1,$$

$$P - r_2 = r_1 v m_2 + r_2(u m_1 - 1) = (r_1 - r_2) v m_2.$$

So $m_1 \mid P - r_1$ and $m_2 \mid P - r_2$. Divide P by $m_1 m_2$, which has degree $d_1 + d_2$ (Proposition 7.1.4): $P = m_1 m_2 q + p$ with $\deg p < d_1 + d_2$ (Theorem 7.1.14). Then $p - r_1 = (P - r_1) - m_1 m_2 q$ is divisible by m_1, and likewise $m_2 \mid p - r_2$.

Uniqueness. Suppose p and p' both have the property. Then m_1 and m_2 both divide $e = p - p'$, since $e = (p - r_i) - (p' - r_i)$. Write $e = m_1 g$. Then

$$g = (u m_1 + v m_2) g = u e + v m_2 g,$$

and m_2 divides both terms, so $m_2 \mid g$ and $m_1 m_2 \mid e$. But $\deg e < d_1 + d_2 = \deg(m_1 m_2)$, so $e = \mathbf{0}$ by Proposition 7.1.4. Hence $p = p'$.

(b) Let $c_1 \neq c_2$ and $y_1, y_2 \in F$, and let $m_i = x - c_i$ and $r_i = y_i$ (constants). These are coprime, since $(x - c_1) - (x - c_2) = c_2 - c_1$ is a nonzero constant and Corollary 7.1.48(a) applies after dividing by it. By Theorem 7.1.20, $x - c_i$ divides $p - y_i$ if and only if $p(c_i) = y_i$. So (a) says that there is exactly one p of degree less than 2 with $p(c_1) = y_1$ and $p(c_2) = y_2$, which is Theorem 3.4.24 for two nodes. With more coprime moduli, the same argument by induction gives interpolation at any number of nodes. Moduli $(x - c)^2$ give interpolation with prescribed values and first derivatives, as in Exercise 7.1.57; higher powers $(x - c)^k$ prescribe higher derivatives, at least in characteristic 0.

Section 7.2

Solution to Exercise 7.2.11

Uses. Definition 7.2.6 (Eigenvalue, eigenvector)
Hint 1. Multiply each vector by A and compare with the vector itself.
Hint 2. $A\mathbf{v}$ must be a scalar multiple of $\mathbf{v}$. Look at a nonzero coordinate of $\mathbf{v}$ to find the only possible scalar, then check the other coordinates.
Sketch. $A(1,1,0) = 3(1,1,0)$; $A(1,-1,0) = -(1,-1,0)$; $A(0,0,1) = -(0,0,1)$; $A(1,0,0) = (1,2,0)$, not an eigenvector; $A(1,-1,1) = -(1,-1,1)$; $A(1,1,1) = (3,3,-1)$, not an eigenvector.

We compute $A\mathbf{v}$ in each case:

$$\begin{aligned} A(1,1,0) &= (3,3,0) = 3(1,1,0), & A(1,-1,0) &= (-1,1,0) = -(1,-1,0), \\ A(0,0,1) &= (0,0,-1) = -(0,0,1), & A(1,0,0) &= (1,2,0), \\ A(1,-1,1) &= (-1,1,-1) = -(1,-1,1), & A(1,1,1) &= (3,3,-1). \end{aligned}$$

So $(1,1,0)$ is an eigenvector with eigenvalue 3, and $(1,-1,0)$, $(0,0,1)$, $(1,-1,1)$ are eigenvectors with eigenvalue -1. The vector $(1,0,0)$ is not an eigenvector: a multiple of it has second coordinate 0. Neither is $(1,1,1)$: a multiple $c(1,1,1)$ has three equal coordinates.

The sum of the two eigenvectors $(1,-1,0)$ and $(0,0,1)$ for the eigenvalue -1 is again an eigenvector for -1, but the sum $(1,1,1)$ of the eigenvectors $(1,1,0)$ and $(0,0,1)$, which have different eigenvalues, is not. The definition below and Theorem 7.2.21 explain both observations.

Solution to Exercise 7.2.12

Uses. Theorem 7.2.9 (Eigenvalues and invertibility), Definition 2.5.12 (Invertible), Definition 7.2.6 (Eigenvalue, eigenvector)
Hint 1. An invertible map is injective. What does Theorem 7.2.9 say about $\lambda = 0$?
Hint 2. Apply T^{-1} to both sides of $T\mathbf{v} = \lambda\mathbf{v}$, and divide by λ.
Sketch. $T - 0\,\mathrm{id} = T$ is injective, so 0 is not an eigenvalue. If $T\mathbf{v} = \lambda\mathbf{v}$, applying T^{-1} gives $\mathbf{v} = \lambda T^{-1}\mathbf{v}$, so $T^{-1}\mathbf{v} = \lambda^{-1}\mathbf{v}$. The converse is the same argument for T^{-1}, whose inverse is T.

Since T has a left inverse, it is injective: $T\mathbf{v} = \mathbf{0}$ gives $\mathbf{v} = T^{-1}T\mathbf{v} = \mathbf{0}$. So $T - 0\,\mathrm{id} = T$ is injective, and 0 is not an eigenvalue by Theorem 7.2.9.

Let $\lambda \neq 0$ and suppose $\mathbf{v} \neq \mathbf{0}$ and $T\mathbf{v} = \lambda\mathbf{v}$. Applying the linear map T^{-1} gives $\mathbf{v} = T^{-1}(\lambda\mathbf{v}) = \lambda T^{-1}\mathbf{v}$, and multiplying by λ^{-1} gives $T^{-1}\mathbf{v} = \lambda^{-1}\mathbf{v}$. Conversely, T^{-1} is invertible with inverse T, so the same argument with the roles of T and T^{-1} exchanged shows that $T^{-1}\mathbf{v} = \lambda^{-1}\mathbf{v}$ implies $T\mathbf{v} = \left(\lambda^{-1}\right)^{-1}\mathbf{v} = \lambda\mathbf{v}$.

Solution to Exercise 7.2.25

Uses. Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. Suppose $T(\sum \mathbf{v}_l) = \mu \sum \mathbf{v}_l$. Expand both sides in terms of the $\mathbf{v}_l$.
Hint 2. You get a linear relation with coefficients $\lambda_l - \mu$. What does independence say about them?
Sketch. If $T(\sum \mathbf{v}_l) = \mu \sum \mathbf{v}_l$, then $\sum(\lambda_l - \mu)\mathbf{v}_l = \mathbf{0}$, so $\lambda_l = \mu$ for all l by independence. This contradicts $\lambda_1 \neq \lambda_2$.

Let $\mathbf{w} = \mathbf{v}_1 + \cdots + \mathbf{v}_m$, and suppose $T\mathbf{w} = \mu\mathbf{w}$ for some $\mu \in F$. Then

$$\mathbf{0} = T\mathbf{w} - \mu\mathbf{w} = \sum_{l=1}^{m} \lambda_l \mathbf{v}_l - \sum_{l=1}^{m} \mu\mathbf{v}_l = \sum_{l=1}^{m} (\lambda_l - \mu)\mathbf{v}_l.$$

By Theorem 7.2.21 the list $\mathbf{v}_1, \ldots, \mathbf{v}_m$ is independent, so $\lambda_l - \mu = 0$ for every l (Theorem 1.5.5). Then $\lambda_1 = \mu = \lambda_2$, contradicting distinctness. So $\mathbf{w}$ is not an eigenvector. (It is nonzero, again by independence, so the only way to fail is the one we ruled out.)

Solution to Exercise 7.2.29

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 2.5.12 (Invertible)
Hint 1. T is a root of $x^2 - 5x + 6$. Factor it and apply Proposition 7.2.28.
Hint 2. For (b), divide $x^2 - 5x + 6$ by $x - 4$ with remainder, and evaluate the resulting identity at T.
Sketch. (a) $p = x^2 - 5x + 6 = (x-2)(x-3)$ satisfies $p(T) = 0$. (b) $x^2 - 5x + 6 = (x-4)(x-1) + 2$, so $0 = (T - 4\,\mathrm{id})(T - \mathrm{id}) + 2\,\mathrm{id}$, and $-(1/2)(T - \mathrm{id})$ is a two-sided inverse of $T - 4\,\mathrm{id}$ (polynomials in T commute). Over a field with $2 = 0$, (b) fails.

(a) Let $p = x^2 - 5x + 6 = (x-2)(x-3)$. By hypothesis $p(T) = T^2 - 5T + 6\,\mathrm{id} = 0$, so by Proposition 7.2.28 every eigenvalue λ satisfies $(\lambda - 2)(\lambda - 3) = 0$, that is, $\lambda \in \{2, 3\}$.

(b) In $F[x]$, $(x-4)(x-1) = x^2 - 5x + 4$, so $p = (x-4)(x-1) + 2$. Evaluating at T with Proposition 7.2.27(a),

$$0 = p(T) = (T - 4\,\mathrm{id})(T - \mathrm{id}) + 2\,\mathrm{id}, \quad \text{so} \quad (T - 4\,\mathrm{id})(T - \mathrm{id}) = -2\,\mathrm{id}.$$

Since $2 \neq 0$ in F, we may let $S = -2^{-1}(T - \mathrm{id})$. Then $(T - 4\,\mathrm{id})S = \mathrm{id}$, and $S(T - 4\,\mathrm{id}) = \mathrm{id}$ as well, because polynomials in T commute (Proposition 7.2.27(b)). So $T - 4\,\mathrm{id}$ is invertible with inverse $-2^{-1}(T - \mathrm{id})$.

The hypothesis $1 + 1 \neq 0$ is needed. Over $\mathbb{F}_2$, $5 = 1$, $6 = 0$, and $4 = 0$, so the relation reads $T^2 = T$ and $T - 4\,\mathrm{id} = T$, which is not invertible when T is, say, the zero operator on $V \neq \{\mathbf{0}\}$.

Solution to Exercise 7.2.40

Uses. Proposition 7.2.37 (Chains are independent), Corollary 7.2.38 (The span of a chain), Theorem 4.1.10 (Independent lists are short), Proposition 7.2.28 (Polynomials act on eigenvectors by their values)
Hint 1. $N\mathbf{e}_3$ is the third column of N.
Hint 2. For (b), N^3 kills a basis, so $N^3 = 0$. If $A\mathbf{w} = \mu\mathbf{w}$, what is $N^3\mathbf{w}$?
Sketch. (a) $N\mathbf{e}_3 = (1,1,0)$, $N^2\mathbf{e}_3 = (1,0,0)$, $N^3\mathbf{e}_3 = \mathbf{0}$; by Proposition 7.2.37 with $k = 2$ the chain is independent, hence a basis of F^3. (b) N^3 kills the basis, so $N^3 = 0$, and an eigenvalue μ satisfies $(\mu - 1)^3 = 0$. $E_1 = \ker N = \{y + z = 0, z = 0\} = \mathrm{span}(\mathbf{e}_1)$.

(a) $N = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$, so $N(x, y, z) = (y + z, z, 0)$. Hence

$$N\mathbf{e}_3 = (1,1,0), \quad N^2\mathbf{e}_3 = N(1,1,0) = (1,0,0), \quad N^3\mathbf{e}_3 = N(1,0,0) = \mathbf{0}.$$

By Proposition 7.2.37 with $\lambda = 1$ and $k = 2$, the list $\mathbf{e}_3, (1,1,0), (1,0,0)$ is independent. It has length $3 = \dim F^3$, so it is a basis (Theorem 4.1.10(b)).

(b) N^3 sends each of the three basis vectors $N^j\mathbf{e}_3$ to $N^{3+j}\mathbf{e}_3 = \mathbf{0}$, so $N^3 = 0$. That is, $p(A) = 0$ for $p = (x-1)^3$, and by Proposition 7.2.28 every eigenvalue μ of A satisfies $(\mu-1)^3 = 0$, so $\mu = 1$. And 1 is an eigenvalue, with eigenvector $N^2\mathbf{e}_3 = \mathbf{e}_1$ (Corollary 7.2.38(a)). Finally $E_1 = \ker N = \{(x,y,z) \mid y+z=0, z=0\} = \operatorname{span}(\mathbf{e}_1)$.

Solution to Exercise 7.2.41

Uses. Definition 7.2.6 (Eigenvalue, eigenvector), Proposition 1.2.35 (Zero products)
Hint 1. Write out $B(x,y) = \lambda(x,y)$ as two equations and eliminate x.
Hint 2. You should find $(\lambda^2-2)y = 0$ and $x = \lambda y$. So the eigenvalues are the square roots of 2 in the field. List the squares in each $\mathbb{F}_p$.
Sketch. $B(x,y) = (2y,x)$, so $B\mathbf{v} = \lambda\mathbf{v}$ means $2y = \lambda x$ and $x = \lambda y$, hence $(\lambda^2-2)y = 0$, and $y = 0$ forces $\mathbf{v} = \mathbf{0}$. So λ is an eigenvalue iff $\lambda^2 = 2$, with eigenvector $(\lambda, 1)$. $\mathbb{R}$: $\pm\sqrt{2}$. $\mathbb{F}_2$: $\lambda = 0$. $\mathbb{F}_3$, $\mathbb{F}_5$: none. $\mathbb{F}_7$: 3 and 4.

$B(x,y) = (2y,x)$, so $B(x,y) = \lambda(x,y)$ means $2y = \lambda x$ and $x = \lambda y$. Substituting the second into the first gives $(\lambda^2-2)y = 0$. If $y = 0$, then $x = \lambda y = 0$. So a nonzero solution exists only if $\lambda^2 = 2$, and conversely, if $\lambda^2 = 2$, then $B(\lambda,1) = (2,\lambda) = (\lambda^2,\lambda) = \lambda(\lambda,1)$. So the eigenvalues are the $\lambda \in F$ with $\lambda^2 = 2$, with eigenvectors $(\lambda,1)$.

- $\mathbb{R}$: $\lambda = \pm\sqrt{2}$, eigenvectors $(\pm\sqrt{2},1)$.
- $\mathbb{F}_2$: $2 = 0$, so $\lambda^2 = 0$ and $\lambda = 0$, with eigenvector $(0,1)$. (Here $B = \left(\begin{smallmatrix}0&0\\1&0\end{smallmatrix}\right)$.)
- $\mathbb{F}_3$: the squares are $0, 1, 4 = 1$, and 2 is not one of them. No eigenvalues.
- $\mathbb{F}_5$: the squares are $0, 1, 4, 9 = 4, 16 = 1$. No eigenvalues.
- $\mathbb{F}_7$: $3^2 = 9 = 2$ and $4^2 = 16 = 2$. Eigenvalues 3 and 4, with eigenvectors $(3,1)$ and $(4,1)$.

Solution to Exercise 7.2.42

Uses. Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 5.1.13 (The 2×2 determinant), Definition 7.2.6 (Eigenvalue, eigenvector)
Hint 1. By Theorem 7.2.9, λ is an eigenvalue iff $\det(R_\theta - \lambda I_2) = 0$. Compute this 2×2 determinant.
Hint 2. $(\cos\theta-\lambda)^2 + \sin^2\theta$ is a sum of two real squares. When is it 0?
Sketch. (a) $\det(R_\theta - \lambda I_2) = (\cos\theta-\lambda)^2 + \sin^2\theta$, which for real λ vanishes iff $\sin\theta = 0$ and $\lambda = \cos\theta$. So $\theta \in \pi\mathbb{Z}$: $R_\theta = I_2$ (eigenvalue 1, $E_1 = \mathbb{R}^2$) or $R_\theta = -I_2$ (eigenvalue -1, $E_{-1} = \mathbb{R}^2$). (b) Direct multiplication: $R_\theta(1,-i) = (\cos\theta + i\sin\theta, \sin\theta - i\cos\theta) = (\cos\theta + i\sin\theta)(1,-i)$, and similarly for $(1,i)$.

(a) By Theorem 7.2.9 and Theorem 5.1.13, $\lambda \in \mathbb{R}$ is an eigenvalue if and only if

$$\det(R_\theta - \lambda I_2) = (\cos\theta-\lambda)^2 + \sin^2\theta = 0.$$

A sum of two squares of real numbers is 0 only if both are 0, so this happens if and only if $\sin\theta = 0$ and $\lambda = \cos\theta$. Thus R_θ has a real eigenvalue exactly when θ is an integer multiple of π. If $\theta \in 2\pi\mathbb{Z}$, then $R_\theta = I_2$, the only eigenvalue is 1, and $E_1 = \mathbb{R}^2$. If $\theta \in \pi + 2\pi\mathbb{Z}$, then $R_\theta = -I_2$, the only eigenvalue is -1, and $E_{-1} = \mathbb{R}^2$. Geometrically: a rotation that is not by a multiple of π moves every line through $\mathbf{0}$.

(b) Write $c = \cos\theta$, $s = \sin\theta$. Then

$$R_\theta\begin{pmatrix}1\\-i\end{pmatrix} = \begin{pmatrix}c+is\\s-ic\end{pmatrix} = (c+is)\begin{pmatrix}1\\-i\end{pmatrix},$$

because $(c+is)(-i) = -ic - i^2 s = s - ic$. Similarly

$$R_\theta\begin{pmatrix}1\\i\end{pmatrix} = \begin{pmatrix}c-is\\s+ic\end{pmatrix} = (c-is)\begin{pmatrix}1\\i\end{pmatrix},$$

because $(c-is)i = ic + s$. Both vectors are nonzero, so they are eigenvectors with eigenvalues $c+is = e^{i\theta}$ and $c-is = e^{-i\theta}$. These are distinct unless $s = 0$, in agreement with (a).

Solution to Exercise 7.2.43

Uses. Definition 7.2.6 (Eigenvalue, eigenvector), Example 7.2.15 (Diagonal matrices)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)

Hint 1. For (a) and (b), try diagonal matrices whose eigenvectors are different standard basis vectors.
Hint 2. For (d), take S a projection and T with $TS \neq ST$, and look for $\mathbf{v} \in \ker(ST)$. For (e), what commutes with everything?
Sketch. (a), (b) false: $S = \operatorname{diag}(1,0)$, $T = \operatorname{diag}(0,1)$ have eigenvalue 1, but $S+T = I_2$ has only $1 \neq 2$, and $ST = 0$ has only $0 \neq 1$. (c) true: $(S+T)\mathbf{v} = (\lambda+\mu)\mathbf{v}$, $ST\mathbf{v} = \mu\lambda\mathbf{v}$. (d) false: $S = \operatorname{diag}(1,0)$, $T = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, $\mathbf{v} = (1,-1)$: $ST\mathbf{v} = \mathbf{0}$ but $TS\mathbf{v} = (1,0)$. (e) false: $S = \mathrm{id}$.

(a) False. On F^2 let $S = \operatorname{diag}(1,0)$ and $T = \operatorname{diag}(0,1)$. Both have the eigenvalue 1 (with eigenvectors $\mathbf{e}_1$ and $\mathbf{e}_2$). But $S+T = I_2$, whose only eigenvalue is $1 \neq 1+1$ when $1+1 \neq 1$, which holds in every field.

(b) False, with the same S and T: $ST = 0$, whose only eigenvalue is 0, while $1 \cdot 1 = 1$.

(c) True. If $S\mathbf{v} = \lambda\mathbf{v}$ and $T\mathbf{v} = \mu\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $(S+T)\mathbf{v} = (\lambda+\mu)\mathbf{v}$ and $ST\mathbf{v} = S(\mu\mathbf{v}) = \mu\lambda\mathbf{v}$.

(d) False. Let $S = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $T = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, so $ST = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ and $TS = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. For $\mathbf{v} = (1,-1)$, $ST\mathbf{v} = \mathbf{0} = 0\mathbf{v}$, so $\mathbf{v}$ is an eigenvector of ST. But $TS\mathbf{v} = (1,0)$, which is not a multiple of $(1,-1)$. (What is true: if $ST\mathbf{v} = \lambda\mathbf{v}$ and $T\mathbf{v} \neq \mathbf{0}$, then $T\mathbf{v}$ is an eigenvector of TS for λ.)

(e) False. $S = \mathrm{id}_V$ commutes with every T, and every nonzero vector is an eigenvector of S, but the rotation $T = R_{\pi/2}$ of $\mathbb{R}^2$ has no eigenvectors at all (Example 7.2.18). By Proposition 7.2.30, what is true is that T maps each eigenspace of S into itself.

Solution to Exercise 7.2.44

Uses. Definition 7.2.6 (Eigenvalue, eigenvector), Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 4.3.8 (Row rank equals column rank)
Hint 1. For (a), compute $A(1,1,\ldots,1)$.
Hint 2. For (b), use the rank criterion in Theorem 7.2.9, and $(A-\lambda I_n)^{\mathsf{T}} = A^{\mathsf{T}} - \lambda I_n$.
Sketch. (a) $A(1,\ldots,1)$ is the vector of row sums, $s(1,\ldots,1)$. (b) $\operatorname{rank}\left(A^{\mathsf{T}} - \lambda I_n\right) = \operatorname{rank}\left((A-\lambda I_n)^{\mathsf{T}}\right) = \operatorname{rank}(A-\lambda I_n)$, so one is less than n iff the other is. (c) Apply (a) to A^{T} and use (b). $(1,\ldots,1)$ need not be an eigenvector: $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$.

(a) The i-th coordinate of $A(1,\ldots,1)$ is $\sum_j a_{ij}$, the i-th row sum, which is s. So $A(1,\ldots,1) = s(1,\ldots,1)$, and $(1,\ldots,1) \neq \mathbf{0}$ is an eigenvector with eigenvalue s.

(b) For $\lambda \in F$, $(A-\lambda I_n)^{\mathsf{T}} = A^{\mathsf{T}} - \lambda I_n$, so by Theorem 4.3.8, $\operatorname{rank}\left(A^{\mathsf{T}} - \lambda I_n\right) = \operatorname{rank}(A - \lambda I_n)$. By Theorem 7.2.9, λ is an eigenvalue of A if and only if this rank is less than n, if and only if λ is an eigenvalue of A^{T}.

(c) The rows of A^{T} are the columns of A, so every row of A^{T} sums to s, and s is an eigenvalue of A^{T} by (a), hence of A by (b). The vector $(1,\ldots,1)$ need not be an eigenvector of A: for $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$, every column sums to 1, but $A(1,1,1) = (2,1,0)$, which is not a multiple of $(1,1,1)$ because its last two coordinates differ. An eigenvector of A for the eigenvalue 1 is $\mathbf{e}_1$. (A 2×2 example such as $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ works only when $1+1 \neq 0$: over $\mathbb{F}_2$ it sends $(1,1)$ to $\mathbf{0}$.) (Matrices with nonnegative entries and column sums 1 are the transition matrices of Markov chains, and this exercise shows they always have the eigenvalue 1; see Section 11.1.)

Solution to Exercise 7.2.45

Uses. Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Corollary 7.2.22 (At most $\dim V$ eigenvalues), Proposition 4.1.21 (Dimensions of subspaces), Example 7.2.18 (Rotations), Theorem 2.2.1 (Linear maps are determined by a basis)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. By Proposition 7.2.7, an invariant line is a line contained in some eigenspace. How many lines can an eigenspace contain?
Hint 2. If some E_λ is all of V, then $T = \lambda\,\mathrm{id}$. Otherwise each E_λ is $\{\mathbf{0}\}$ or a line, and there are at most 2 eigenvalues.
Sketch. An invariant line is $\operatorname{span}(\mathbf{v})$ for an eigenvector $\mathbf{v}$, so it lies in E_λ for its eigenvalue. If $T = c\,\mathrm{id}$, every line is invariant: infinitely many over $\mathbb{R}$, all 3 lines of $\mathbb{F}_2^2$. Otherwise every eigenspace is a proper subspace of a 2-dimensional

space, hence $\{\mathbf{0}\}$ or a line, and invariant lines correspond to eigenvalues, of which there are at most 2. Examples: rotation, shear, $\operatorname{diag}(1,2)$, id over $\mathbb{R}$; over $\mathbb{F}_2$: $\left(\begin{smallmatrix}0&1\\1&1\end{smallmatrix}\right)$, $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$, $\operatorname{diag}(0,1)$, id.

Let $V = F^2$ with $F = \mathbb{R}$ or $\mathbb{F}_2$, and $T \in \mathrm{L}(V)$. By Proposition 7.2.7, a line ℓ is invariant if and only if it is spanned by an eigenvector, and then $\ell \subseteq E_\lambda$ for the eigenvalue λ of that eigenvector. Conversely every line inside an eigenspace is invariant.

If $E_\lambda = V$ for some λ, then $T = \lambda\,\mathrm{id}$, and every line is invariant. Over $\mathbb{R}$ there are infinitely many lines. Over $\mathbb{F}_2$ there are exactly 3: each line $\{\mathbf{0}, \mathbf{v}\}$ contains one nonzero vector, and $\mathbb{F}_2^2$ has 3 nonzero vectors.

Otherwise each E_λ is a proper subspace of the 2-dimensional V, so it is $\{\mathbf{0}\}$ or a line (Proposition 4.1.21), and a line contains exactly one line. So the invariant lines are exactly the eigenspaces E_λ of the eigenvalues λ, and their number is the number of eigenvalues, which is at most 2 by Corollary 7.2.22. This proves the restrictions in (a) and (b). Examples:

(a) $R_{\pi/2}$ has no eigenvalues (Example 7.2.18): 0 lines. The shear $A = \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ satisfies $(A - I_2)^2 = 0$, so 1 is its only possible eigenvalue (Proposition 7.2.28), and $E_1 = \ker(A - I_2) = \operatorname{span}(\mathbf{e}_1)$: 1 line. $\operatorname{diag}(1,2)$ has $E_1 = \operatorname{span}(\mathbf{e}_1)$ and $E_2 = \operatorname{span}(\mathbf{e}_2)$ (Example 7.2.15): 2 lines. The identity: infinitely many.

(b) Over $\mathbb{F}_2$ the only possible eigenvalues are 0 and 1. For $A = \left(\begin{smallmatrix}0&1\\1&1\end{smallmatrix}\right)$, $A(x,y) = (y, x+y)$; $A\mathbf{v} = \mathbf{0}$ forces $y = 0$ and then $x = 0$, and $A\mathbf{v} = \mathbf{v}$ means $y = x$ and $x + y = y$, so $x = 0$ and $y = 0$. So A has no eigenvalues: 0 lines. The shear $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ is invertible, so 0 is not an eigenvalue, and $E_1 = \ker\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right) = \operatorname{span}(\mathbf{e}_1)$: 1 line. $\operatorname{diag}(0,1)$: 2 lines. The identity: 3 lines.

Solution to Exercise 7.2.46

Uses. Proposition 7.2.27 (Evaluating polynomials at an operator), Proposition 1.5.24 (Distinct degrees), Theorem 4.1.10 (Independent lists are short), Example 4.1.7 (Dimensions of the standard spaces), Example 2.1.9 (Maps of polynomials)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Let $U \neq \{\mathbf{0}\}$ be invariant and $p \in U$ of degree n. What are the degrees of $p, Dp, D^2p, \ldots, D^np$ over $\mathbb{R}$?
Hint 2. These $n+1$ polynomials have distinct degrees $n, n-1, \ldots, 0$, so they are independent, and they lie in $U \cap \mathbb{R}[x]_{\leq n}$. Count dimensions. Then split into the cases where the degrees of elements of U are bounded or not.
Sketch. If $p \in U$ has degree n, then D^jp has degree $n-j$ for $0 \leq j \leq n$ (leading coefficient $n(n-1)\cdots(n-j+1)a_n \neq 0$ in $\mathbb{R}$). These $n+1$ polynomials are independent and lie in $U \cap \mathbb{R}[x]_{\leq n}$, so $\mathbb{R}[x]_{\leq n} \subseteq U$. If degrees in U are bounded with maximum n, then $U = \mathbb{R}[x]_{\leq n}$; if unbounded, U contains every $\mathbb{R}[x]_{\leq n}$, so $U = \mathbb{R}[x]$. Over $\mathbb{F}_p$, $\operatorname{span}(x^p)$ is invariant since $D(x^p) = \mathbf{0}$.

(a) Each listed subspace is invariant: D lowers degrees (Example 7.2.2). Conversely, let U be D-invariant with $U \neq \{\mathbf{0}\}$.

Claim. If $p \in U$ has degree n, then $\mathbb{R}[x]_{\leq n} \subseteq U$. Write $p = a_nx^n + (\text{lower terms})$ with $a_n \neq 0$. By the formula for D (Example 2.1.9), $D^jp = n(n-1)\cdots(n-j+1)a_nx^{n-j} + (\text{lower terms})$ for $0 \leq j \leq n$, and the leading coefficient is nonzero in $\mathbb{R}$. So $p, Dp, \ldots, D^np$ have the distinct degrees $n, n-1, \ldots, 0$, hence are independent (Proposition 1.5.24). They lie in U by Proposition 7.2.27(d), and in $\mathbb{R}[x]_{\leq n}$, which has dimension $n+1$ (Example 4.1.7). So they form a basis of $\mathbb{R}[x]_{\leq n}$ (Theorem 4.1.10(b)), and $\mathbb{R}[x]_{\leq n} = \operatorname{span}(p, \ldots, D^np) \subseteq U$.

If the degrees of the nonzero elements of U are bounded, let n be the largest. Then $U \subseteq \mathbb{R}[x]_{\leq n}$, and the claim gives equality. If they are unbounded, then for every m there is $p \in U$ with $\deg p \geq m$, and the claim gives $\mathbb{R}[x]_{\leq m} \subseteq \mathbb{R}[x]_{\leq \deg p} \subseteq U$. Every polynomial lies in some $\mathbb{R}[x]_{\leq m}$, so $U = \mathbb{R}[x]$.

(b) Over $\mathbb{F}_p$, $D(x^p) = px^{p-1} = \mathbf{0}$, so the line $\operatorname{span}(x^p)$ is D-invariant. It is not $\{\mathbf{0}\}$, it is not $\mathbb{F}_p[x]$, and it is not $\mathbb{F}_p[x]_{\leq n}$ for any n, since it does not contain the constant 1. The proof of (a) breaks down because the leading coefficient p of $D(x^p)$ vanishes in $\mathbb{F}_p$.

Solution to Exercise 7.2.47

Uses. Corollary 7.2.23 (Eigenspaces are independent), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Theorem 7.2.21 (Eigenvectors for distinct

eigenvalues are independent), Theorem 4.1.10 (Independent lists are short), Theorem 3.4.24 (Polynomial interpolation), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Corollary 2.2.6 (Agreeing on a spanning list)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Each eigenspace $E_{\lambda_i}(T)$ is S-invariant. What is its dimension?
Hint 2. The dimensions of the n eigenspaces are each at least 1 and add up to at most n.
Hint 3. For (b), if $S\mathbf{v}_i = \mu_i\mathbf{v}_i$, choose p with $p(\lambda_i) = \mu_i$ for all i, and compare S and $p(T)$ on the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$.
Sketch. (a) By Corollary 7.2.23, $\sum \dim E_{\lambda_i} \leq n$ with each term ≥ 1, so each $E_{\lambda_i} = \operatorname{span}(\mathbf{v}_i)$ is a line. It is S-invariant by Proposition 7.2.30, so $\mathbf{v}_i$ is an eigenvector of S, say $S\mathbf{v}_i = \mu_i\mathbf{v}_i$. (b) Interpolate: $p(\lambda_i) = \mu_i$ with $\deg p < n$. Then $p(T)\mathbf{v}_i = \mu_i\mathbf{v}_i = S\mathbf{v}_i$, and the $\mathbf{v}_i$ form a basis.

(a) Each $E_{\lambda_i}(T)$ contains $\mathbf{v}_i \neq \mathbf{0}$, so $\dim E_{\lambda_i} \geq 1$, and by Corollary 7.2.23 the n dimensions add up to at most n. So each $\dim E_{\lambda_i} = 1$, and $E_{\lambda_i} = \operatorname{span}(\mathbf{v}_i)$. By Proposition 7.2.30(b) (with the roles of S and T exchanged), $E_{\lambda_i}(T)$ is S-invariant, so $\mathbf{v}_i$ is an eigenvector of S by Proposition 7.2.7. Write $S\mathbf{v}_i = \mu_i\mathbf{v}_i$.

(b) By Theorem 3.4.24 there is $p \in F[x]_{\leq n-1}$ with $p(\lambda_i) = \mu_i$ for $i = 1, \ldots, n$, since the λ_i are distinct. By Proposition 7.2.28, $p(T)\mathbf{v}_i = p(\lambda_i)\mathbf{v}_i = \mu_i\mathbf{v}_i = S\mathbf{v}_i$. The list $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is independent (Theorem 7.2.21) of length n, so it is a basis (Theorem 4.1.10(b)), and $S = p(T)$ by Corollary 2.2.6. Conversely every $p(T)$ commutes with T, so the operators commuting with T are exactly the polynomials in T.

Solution to Exercise 7.2.48

Uses. Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Theorem 4.1.10 (Independent lists are short), Definition 3.4.26 (Lagrange polynomials), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Proposition 7.2.27 (Evaluating polynomials at an operator), Proposition 7.2.4 (Invariance is checked on a spanning list)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be eigenvectors for the distinct eigenvalues $\lambda_1, \ldots, \lambda_n$; they form a basis. Guess the invariant subspaces.
Hint 2. For an invariant U and $\mathbf{u} = \sum c_i\mathbf{v}_i \in U$, find a polynomial q with $q(T)\mathbf{u} = c_i\mathbf{v}_i$. Lagrange polynomials do this.
Hint 3. Conclude that $U = \operatorname{span}(\mathbf{v}_i \mid \mathbf{v}_i \in U)$, so invariant subspaces correspond to subsets of $\{1, \ldots, n\}$.
Sketch. With an eigenbasis $\mathbf{v}_i$, each $U_I = \operatorname{span}(\mathbf{v}_i \mid i \in I)$ is invariant, and distinct I give distinct U_I. Conversely, if U is invariant and $\mathbf{u} = \sum c_i\mathbf{v}_i \in U$, then $L_i(T)\mathbf{u} = c_i\mathbf{v}_i \in U$, where L_i is the Lagrange polynomial with $L_i(\lambda_j) = [i = j]$. So $U = U_I$ for $I = \{i \mid \mathbf{v}_i \in U\}$. Hence 2^n.

Let $\lambda_1, \ldots, \lambda_n$ be the eigenvalues and $\mathbf{v}_i$ an eigenvector for λ_i. By Theorem 7.2.21 and Theorem 4.1.10(b), $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis of V. For $I \subseteq \{1, \ldots, n\}$ let $U_I = \operatorname{span}(\mathbf{v}_i \mid i \in I)$ (with $U_\emptyset = \{\mathbf{0}\}$). Each U_I is invariant by Proposition 7.2.4, since $T\mathbf{v}_i = \lambda_i\mathbf{v}_i \in U_I$ for $i \in I$. Different subsets give different subspaces: if $j \in I$ and $j \notin I'$, then $\mathbf{v}_j \in U_I$ but $\mathbf{v}_j \notin U_{I'}$, because $\mathbf{v}_j$ is not a combination of the other basis vectors.

Conversely, let U be T-invariant and $I = \{i \mid \mathbf{v}_i \in U\}$. Clearly $U_I \subseteq U$. Let $\mathbf{u} \in U$ and write $\mathbf{u} = \sum_i c_i\mathbf{v}_i$. For each i, let L_i be the Lagrange polynomial for the nodes $\lambda_1, \ldots, \lambda_n$ with $L_i(\lambda_i) = 1$ and $L_i(\lambda_j) = 0$ for $j \neq i$ (Definition 3.4.26). By Proposition 7.2.28,

$$L_i(T)\mathbf{u} = \sum_j c_j L_i(\lambda_j)\mathbf{v}_j = c_i\mathbf{v}_i,$$

and $L_i(T)\mathbf{u} \in U$ by Proposition 7.2.27(d). So $c_i\mathbf{v}_i \in U$ for every i. If $c_i \neq 0$, then $\mathbf{v}_i = c_i^{-1}(c_i\mathbf{v}_i) \in U$, so $i \in I$. Hence $\mathbf{u} = \sum_{i \in I} c_i\mathbf{v}_i \in U_I$, and $U = U_I$.

So the invariant subspaces are exactly the U_I, one for each of the 2^n subsets I. Without distinct eigenvalues the count can be infinite: every line in $\mathbb{R}^2$ is invariant under id.

Solution to Exercise 7.2.49

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Proposition 7.1.22 (Counting roots), Proposition 7.2.34 (The smallest invariant subspace containing a vector), Theorem 4.1.10 (Independent lists are short)
Hint 1. A relation $\sum_{j<n} c_j T^j\mathbf{w} = \mathbf{0}$ says $p(T)\mathbf{w} = \mathbf{0}$ for $p = \sum c_j x^j$. Compute $p(T)\mathbf{w}$ with Proposition 7.2.28.
Hint 2. $p(T)\mathbf{w} = \sum_i p(\lambda_i)\mathbf{v}_i$. Independence of the $\mathbf{v}_i$ gives n roots of p, which has degree less than n.

Sketch. If $p(T)\mathbf{w} = \mathbf{0}$ with $\deg p < n$, then $\sum_i p(\lambda_i)\mathbf{v}_i = \mathbf{0}$, so $p(\lambda_i) = 0$ for all n distinct λ_i, and $p = \mathbf{0}$ (Proposition 7.1.22). So the n vectors are independent. They lie in the invariant subspace $W = \operatorname{span}(\mathbf{v}_i)$, which has dimension n, so they span it; and $W \subseteq K_T(\mathbf{w}) \subseteq W$.

Suppose $\sum_{j=0}^{n-1} c_j T^j \mathbf{w} = \mathbf{0}$, and let $p = \sum_{j=0}^{n-1} c_j x^j$. By Proposition 7.2.28,

$$\mathbf{0} = p(T)\mathbf{w} = \sum_{i=1}^{n} p(T)\mathbf{v}_i = \sum_{i=1}^{n} p(\lambda_i)\mathbf{v}_i.$$

The $\mathbf{v}_i$ are independent by Theorem 7.2.21, so $p(\lambda_i) = 0$ for every i. Thus p has at least n distinct roots but degree less than n (if nonzero), so $p = \mathbf{0}$ by Proposition 7.1.22, and all $c_j = 0$.

Let $W = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_n)$. It is T-invariant (Proposition 7.2.4) and contains $\mathbf{w}$, so $K_T(\mathbf{w}) \subseteq W$ (Proposition 7.2.34). On the other hand, $\mathbf{w}, \ldots, T^{n-1}\mathbf{w}$ are n independent vectors of $K_T(\mathbf{w}) \subseteq W$, and $\dim W = n$, so they span W (Theorem 4.1.10(b)) and $W \subseteq K_T(\mathbf{w})$. Hence $K_T(\mathbf{w}) = W$.

The independence can also be read off a determinant: in the basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ of W, the coordinates of $T^j\mathbf{w}$ are $\left(\lambda_1^j, \ldots, \lambda_n^j\right)$, so the matrix with these columns is a Vandermonde matrix, which is invertible for distinct λ_i (Theorem 3.4.24).

Solution to Exercise 7.2.50

Uses. Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.1.10 (Independent lists are short), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 4.1.21 (Dimensions of subspaces), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Choose $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$. The chain $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ is a basis. Compute N^j on a general combination of it.
Hint 2. For (b), let U be invariant and j the least integer with $N^j(U) = \{\mathbf{0}\}$. Find a chain of length j inside U.
Hint 3. Compare $\dim U$ with $\dim \ker N^j = j$.
Sketch. (a) With $\mathbf{v}$ as in the hint, the chain is independent (Proposition 4.1.26) of length n, hence a basis, and $N^j\left(\sum_i c_i N^i \mathbf{v}\right) = \sum_{i \le n-1-j} c_i N^{i+j}\mathbf{v}$ vanishes iff $c_0 = \cdots = c_{n-1-j} = 0$; so $\ker N^j = \operatorname{span}\left(N^{n-j}\mathbf{v}, \ldots, N^{n-1}\mathbf{v}\right)$. (b) Kernels of powers are invariant. Conversely, if j is least with $U \subseteq \ker N^j$ and $j \ge 1$, some $\mathbf{u} \in U$ has $N^{j-1}\mathbf{u} \neq \mathbf{0} = N^j\mathbf{u}$, giving j independent vectors in U; so $j \le \dim U \le \dim \ker N^j = j$, and $U = \ker N^j$.

(a) Choose $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$; then $N^n\mathbf{v} = \mathbf{0}$. By Proposition 4.1.26, $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ is independent, and it has length $n = \dim V$, so it is a basis (Theorem 4.1.10(b)). Let $0 \le j \le n$. For $\mathbf{x} = \sum_{i=0}^{n-1} c_i N^i \mathbf{v}$,

$$N^j\mathbf{x} = \sum_{i=0}^{n-1} c_i N^{i+j}\mathbf{v} = \sum_{i=0}^{n-1-j} c_i N^{i+j}\mathbf{v},$$

since $N^{i+j}\mathbf{v} = \mathbf{0}$ for $i + j \ge n$. The vectors $N^{i+j}\mathbf{v}$, $0 \le i \le n-1-j$, are distinct members of the basis, so $N^j\mathbf{x} = \mathbf{0}$ if and only if $c_0 = \cdots = c_{n-1-j} = 0$. Hence $\ker N^j = \operatorname{span}\left(N^{n-j}\mathbf{v}, \ldots, N^{n-1}\mathbf{v}\right)$, which has dimension j.

(b) Each $\ker N^j$ is N-invariant by Proposition 7.2.30(a). Conversely, let U be N-invariant. Since $N^n = 0$, there is a least $j \in \{0, \ldots, n\}$ with $N^j\mathbf{u} = \mathbf{0}$ for all $\mathbf{u} \in U$, that is, $U \subseteq \ker N^j$. If $j = 0$, then $U = \{\mathbf{0}\} = \ker N^0$. If $j \ge 1$, minimality gives some $\mathbf{u} \in U$ with $N^{j-1}\mathbf{u} \neq \mathbf{0}$, while $N^j\mathbf{u} = \mathbf{0}$. By Proposition 4.1.26, $\mathbf{u}, N\mathbf{u}, \ldots, N^{j-1}\mathbf{u}$ is independent, and it lies in U because U is invariant. So

$$j \le \dim U \le \dim \ker N^j = j,$$

and $U = \ker N^j$ by Proposition 4.1.21. By (a) the $n+1$ subspaces $\ker N^0 \subsetneq \ker N^1 \subsetneq \cdots \subsetneq \ker N^n = V$ have different dimensions, so they are distinct.

Solution to Exercise 7.2.51

Uses. Theorem 1.5.5 (Independence is decided at zero), Notation 2.1.18, Proposition 7.2.37 (Chains are independent)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. For one chain this is Proposition 7.2.37. Imitate its proof by the lowest nonzero coefficient. A term $a_{ij}N^j\mathbf{u}_i$ sits $k_i - j$ steps below the top of its chain.

Hint 2. Given a nontrivial relation, let h be the largest value of $k_i - j$ over the nonzero coefficients a_{ij}, and apply N^h.
Hint 3. Terms with $k_i - j < h$ are pushed past the top and die; terms with $k_i - j = h$ land on the tops. Use independence of the tops.
Sketch. Suppose $\sum_{i,j} a_{ij} N^j \mathbf{u}_i = \mathbf{0}$ is nontrivial, and let $h = \max\{k_i - j \mid a_{ij} \neq 0\}$. Applying N^h kills every term with $k_i - j < h$ (as $j + h \geq k_i + 1$) and sends each term with $k_i - j = h$ to $a_{i,k_i-h} N^{k_i} \mathbf{u}_i$; for each i there is at most one such term. The result is a relation among the tops with at least one nonzero coefficient, a contradiction.

The hypothesis implies that each top $N^{k_i}\mathbf{u}_i$ is nonzero. Suppose, for contradiction, that

$$\sum_{i=1}^{r} \sum_{j=0}^{k_i} a_{ij} N^j \mathbf{u}_i = \mathbf{0}$$

with not all a_{ij} zero. Call $k_i - j$ the depth of the term (i, j), and let h be the largest depth among the terms with $a_{ij} \neq 0$. Then $0 \leq h$, and apply N^h to the relation. For a term with $a_{ij} \neq 0$:

- if its depth is less than h, then $j + h \geq k_i + 1$, so $N^h N^j \mathbf{u}_i = N^{j+h-k_i-1} N^{k_i+1} \mathbf{u}_i = \mathbf{0}$;
- if its depth is h, then $N^h N^j \mathbf{u}_i = N^{k_i} \mathbf{u}_i$.

Terms with $a_{ij} = 0$ contribute nothing. For each i at most one j has depth h, namely $j = k_i - h$. So, with $I = \{i \mid k_i \geq h \text{ and } a_{i,k_i-h} \neq 0\}$,

$$\sum_{i \in I} a_{i,k_i-h} N^{k_i} \mathbf{u}_i = \mathbf{0}.$$

By the choice of h, I is nonempty, so this is a nontrivial relation among the tops, contradicting their independence. Hence all $a_{ij} = 0$, and the list is independent by Theorem 1.5.5.

For $r = 1$ the depth of the deepest nonzero term is $k - m$, where m is the lowest index with $a_m \neq 0$, and the argument is the second proof of Proposition 7.2.37. The statement is the independence half of the Jordan form (Section 10.3): to build a basis out of chains, it suffices to choose their tops independent.

Solution to Exercise 7.2.52

Uses. Example 2.1.9 (Maps of polynomials), Definition 7.2.13 (Eigenspace), Definition 1.2.13 (Polynomials)
Hint 1. Compute $T(x^k)$.
Hint 2. For $p = \sum a_k x^k$, the equation $T(p) = \lambda p$ says $(k - \lambda)a_k = 0$ for every k. In $\mathbb{F}_3$, which $k \in \{0, \ldots, 5\}$ are equal to a given λ?
Sketch. $T(x^k) = kx^k$, so $T(\sum a_k x^k) = \lambda \sum a_k x^k$ iff $(k - \lambda)a_k = 0$ for all k. Over $\mathbb{R}$: eigenvalues $0, 1, \ldots, n$ with $E_k = \operatorname{span}(x^k)$. Over $\mathbb{F}_3$, $n = 5$: eigenvalues $0, 1, 2$ with $E_0 = \operatorname{span}(1, x^3)$, $E_1 = \operatorname{span}(x, x^4)$, $E_2 = \operatorname{span}(x^2, x^5)$.

For $k \geq 1$, $T(x^k) = x \cdot kx^{k-1} = kx^k$, and $T(1) = \mathbf{0} = 0 \cdot 1$. By linearity, for $p = \sum_{k=0}^{n} a_k x^k$,

$$T(p) - \lambda p = \sum_{k=0}^{n} (k - \lambda) a_k x^k,$$

which is $\mathbf{0}$ if and only if $(k - \lambda)a_k = 0$ for each k, where k means $1 + \cdots + 1$ in F. So $E_\lambda = \operatorname{span}(x^k \mid 0 \leq k \leq n, k = \lambda \text{ in } F)$, and λ is an eigenvalue exactly when λ equals some $k \in \{0, \ldots, n\}$ in F.

(a) Over $\mathbb{R}$ the integers $0, 1, \ldots, n$ are distinct, so the eigenvalues are $0, 1, \ldots, n$, with $E_k = \operatorname{span}(x^k)$. These are $n + 1 = \dim \mathbb{R}[x]_{\leq n}$ distinct eigenvalues.

(b) Over $\mathbb{F}_3$, $k = \lambda$ in $\mathbb{F}_3$ when $k \equiv \lambda \pmod 3$. For $k \in \{0, \ldots, 5\}$ the residues are $0, 1, 2, 0, 1, 2$. So the eigenvalues are $0, 1, 2$, with

$$E_0 = \operatorname{span}(1, x^3), \quad E_1 = \operatorname{span}(x, x^4), \quad E_2 = \operatorname{span}(x^2, x^5).$$

The dimensions add up to $6 = \dim \mathbb{F}_3[x]_{\leq 5}$, as Corollary 7.2.23 allows, and the monomials still form a basis of eigenvectors.

Solution to Exercise 7.2.53

Uses. Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 7.2.6 (Eigenvalue, eigenvector)

Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Let $\mathbf{w} = (T + \lambda\,\mathrm{id})\mathbf{v}$. The display says $(T - \lambda\,\mathrm{id})\mathbf{w} = \mathbf{0}$. Does that say anything about $\mathbf{v}$ when $\mathbf{w} \neq \mathbf{0}$?
Hint 2. Test the claim on $T = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, for which $T^2 = I_2$.
Sketch. The display shows $(T - \lambda\,\mathrm{id})\mathbf{w} = \mathbf{0}$ for $\mathbf{w} = (T + \lambda\,\mathrm{id})\mathbf{v}$. If $\mathbf{w} \neq \mathbf{0}$, this makes $\mathbf{w}$, not $\mathbf{v}$, an eigenvector for λ; the "either/or" step confuses $\mathbf{w}$ with $\mathbf{v}$. The claim is false: $T = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has $T^2 = I_2$, so $\mathbf{e}_1$ is an eigenvector of T^2, but $T\mathbf{e}_1 = \mathbf{e}_2$.

The first display is correct, by Proposition 7.2.27(a). Write $\mathbf{w} = (T + \lambda\,\mathrm{id})\mathbf{v}$; the display says $(T - \lambda\,\mathrm{id})\mathbf{w} = \mathbf{0}$. The next sentence treats this as if it were a statement about $\mathbf{v}$: from "$AB\mathbf{v} = \mathbf{0}$" it concludes "$B\mathbf{v} = \mathbf{0}$ or $A\mathbf{v} = \mathbf{0}$". What actually follows is: either $\mathbf{w} = \mathbf{0}$, in which case $\mathbf{v}$ is an eigenvector for $-\lambda$, or $\mathbf{w} \neq \mathbf{0}$ and $\mathbf{w}$ is an eigenvector of T for λ. In the second case nothing has been shown about $\mathbf{v}$.

The claim is false. Let $T = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) \in \mathbb{C}^{2\times 2}$, so $T^2 = I_2$ and every nonzero vector is an eigenvector of T^2. But $T\mathbf{e}_1 = \mathbf{e}_2$ is not a multiple of $\mathbf{e}_1$. Following the corrected argument with $\mu = 1$, $\lambda = 1$, $\mathbf{v} = \mathbf{e}_1$: $\mathbf{w} = (T + \mathrm{id})\mathbf{e}_1 = (1, 1)$, which is indeed an eigenvector of T for 1. Over $\mathbb{R}$ the argument fails even earlier, since μ may have no real square root: $R_{\pi/2}^2 = -\mathrm{id}$ (Example 7.2.18).

Solution to Exercise 7.2.54

Uses. Definition 7.2.1 (Invariant subspace), Corollary 4.2.18 (Injective if and only if surjective), Example 7.2.18 (Rotations)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. (a) is a generic-element check. For (b), find a T with $T^2 = -\mathrm{id}$.
Hint 2. For (c), $T|_U$ is an injective operator on the finite-dimensional U. For (d), look for an invertible shift on sequences indexed by all of $\mathbb{Z}$.
Sketch. (a) True: $T(\mathbf{u} + \mathbf{w}) = T\mathbf{u} + T\mathbf{w} \in U + W$, and T maps $U \cap W$ into both. (b) False: $R_{\pi/2}^2 = -\mathrm{id}$ leaves every line invariant, but $R_{\pi/2}$ leaves none. (c) True: $T|_U \in \mathrm{L}(U)$ is injective, hence surjective, so each $\mathbf{u} \in U$ is $T\mathbf{u}'$ with $\mathbf{u}' \in U$, and $T^{-1}\mathbf{u} = \mathbf{u}' \in U$. (d) False: on $F^{\mathbb{Z}}$ the right shift is invertible, and the sequences vanishing at negative indices form a subspace invariant under it but not under its inverse.

(a) True. If $\mathbf{u} \in U$ and $\mathbf{w} \in W$, then $T(\mathbf{u} + \mathbf{w}) = T\mathbf{u} + T\mathbf{w} \in U + W$. If $\mathbf{x} \in U \cap W$, then $T\mathbf{x} \in U$ and $T\mathbf{x} \in W$.

(b) False. Let $T = R_{\pi/2}$ on $\mathbb{R}^2$. Then $T^2 = -\mathrm{id}$, under which every subspace is invariant, but no line is T-invariant (Example 7.2.18). Take $U = \mathrm{span}(\mathbf{e}_1)$.

(c) True. Since T is injective, so is $T|_U \in \mathrm{L}(U)$, and U is finite-dimensional, so $T|_U$ is surjective onto U (Corollary 4.2.18). Given $\mathbf{u} \in U$, choose $\mathbf{u}' \in U$ with $T\mathbf{u}' = \mathbf{u}$. Then $T^{-1}\mathbf{u} = \mathbf{u}' \in U$.

(d) False. Let $V = F^{\mathbb{Z}}$ be the space of two-sided sequences $(x_n)_{n\in\mathbb{Z}}$, and let T be the right shift, $(T\mathbf{x})_n = x_{n-1}$. It is invertible, with inverse the left shift $\left(T^{-1}\mathbf{x}\right)_n = x_{n+1}$. The subspace $U = \{\mathbf{x} \mid x_n = 0 \text{ for all } n < 0\}$ is T-invariant: if $x_n = 0$ for $n < 0$, then $(T\mathbf{x})_n = x_{n-1} = 0$ for $n < 0$. But the sequence $\mathbf{x}$ with $x_0 = 1$ and all other terms 0 lies in U, while $\left(T^{-1}\mathbf{x}\right)_{-1} = x_0 = 1$, so $T^{-1}\mathbf{x} \notin U$. The proof of (c) fails because $T|_U$ is injective but not surjective onto U.

Solution to Exercise 7.2.55

Uses. Corollary 7.1.48 (Coprime polynomials), Proposition 7.2.27 (Evaluating polynomials at an operator), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Theorem 4.4.7 (Criteria for direct sums), Definition 4.4.4 (Direct sum)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. By Bézout (Corollary 7.1.48), $up + vq = 1$ for some $u, v \in F[x]$. Evaluate at T: $\mathrm{id} = u(T)p(T) + v(T)q(T)$.
Hint 2. Apply this to $\mathbf{v}$. Which kernel does $u(T)p(T)\mathbf{v}$ lie in, and which does $v(T)q(T)\mathbf{v}$ lie in?
Hint 3. For the intersection, apply the same identity to a vector killed by both $p(T)$ and $q(T)$.
Sketch. From $up + vq = 1$, $\mathrm{id} = u(T)p(T) + v(T)q(T)$. For $\mathbf{x} \in V$, $q(T)u(T)p(T)\mathbf{x} = u(T)(pq)(T)\mathbf{x} = \mathbf{0}$, so the first term lies in $\ker q(T)$, and likewise the second in $\ker p(T)$: $V = \ker p(T) + \ker q(T)$. If $\mathbf{x}$ is in both kernels, the identity gives $\mathbf{x} = \mathbf{0}$. Invariance is Proposition 7.2.30. For $T^2 = \mathrm{id}$, take $p = x - 1$, $q = x + 1$, coprime since $1 = ((x + 1) - (x - 1))/2$.

By Corollary 7.1.48 there are $u, v \in F[x]$ with $up + vq = 1$. By Proposition 7.2.27(a),

$$\mathrm{id} = u(T)p(T) + v(T)q(T). \tag{C.1.9}$$

Let $\mathbf{x} \in V$, and set $\mathbf{y} = v(T)q(T)\mathbf{x}$ and $\mathbf{z} = u(T)p(T)\mathbf{x}$, so that $\mathbf{x} = \mathbf{y} + \mathbf{z}$. Since polynomials in T commute (Proposition 7.2.27(b)),

$$p(T)\mathbf{y} = v(T)p(T)q(T)\mathbf{x} = \mathbf{0}, \quad q(T)\mathbf{z} = u(T)p(T)q(T)\mathbf{x} = \mathbf{0}.$$

So $\mathbf{y} \in \ker p(T)$ and $\mathbf{z} \in \ker q(T)$, and $V = \ker p(T) + \ker q(T)$. If $\mathbf{x} \in \ker p(T) \cap \ker q(T)$, then (C.1.9) gives $\mathbf{x} = u(T)p(T)\mathbf{x} + v(T)q(T)\mathbf{x} = \mathbf{0}$. So the sum is direct (Theorem 4.4.7). Both kernels are T-invariant by Proposition 7.2.30(a).

If $T^2 = \mathrm{id}$ and $2 \neq 0$, take $p = x - 1$ and $q = x + 1$. Then $pq = x^2 - 1$, so $p(T)q(T) = T^2 - \mathrm{id} = 0$, and $2^{-1}q - 2^{-1}p = 1$, so p and q are coprime (Corollary 7.1.48). Hence $V = \ker(T - \mathrm{id}) \oplus \ker(T + \mathrm{id}) = E_1 \oplus E_{-1}$. Over $\mathbb{F}_2$ this fails: the swap of Example 7.2.17 satisfies $\sigma^2 = \mathrm{id}$, but E_1 is a line in $\mathbb{F}_2^2$ and $E_{-1} = E_1$.

Solution to Exercise 7.2.56

Uses. Definition 7.2.6 (Eigenvalue, eigenvector), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Definition 7.2.13 (Eigenspace)
Hint 1. $Z^3 = \mathrm{id}$, so every eigenvalue is a cube root of 1 (Proposition 7.2.28). Conversely, for $\lambda^3 = 1$, solve $Z\mathbf{v} = \lambda\mathbf{v}$ starting from $x = 1$.
Hint 2. The equations are $z = \lambda x$, $x = \lambda y$, $y = \lambda z$. Try $\mathbf{v} = (1, \lambda^2, \lambda)$.
Sketch. $Z\mathbf{v} = \lambda\mathbf{v}$ means $z = \lambda x$, $y = \lambda z = \lambda^2 x$, $x = \lambda y = \lambda^3 x$, so $\mathbf{v} = x(1, \lambda^2, \lambda)$ and $(\lambda^3 - 1)x = 0$. Eigenvalues are the cube roots of 1 in F, each with eigenspace $\mathrm{span}((1, \lambda^2, \lambda))$. $\mathbb{C}$: $1, \omega, \omega^2$. $\mathbb{R}$: 1. $\mathbb{F}_7$: $1, 2, 4$. $\mathbb{F}_3$: 1 only.

$Z\mathbf{v} = \lambda\mathbf{v}$ means $(z, x, y) = (\lambda x, \lambda y, \lambda z)$, that is, $z = \lambda x$, $x = \lambda y$, $y = \lambda z$. Then $y = \lambda z = \lambda^2 x$ and $x = \lambda y = \lambda^3 x$. So every solution is $\mathbf{v} = x(1, \lambda^2, \lambda)$, and it is nonzero only if $x \neq 0$ and $\lambda^3 = 1$. Conversely, if $\lambda^3 = 1$, then

$$Z(1, \lambda^2, \lambda) = (\lambda, 1, \lambda^2) = (\lambda, \lambda^3, \lambda^2) = \lambda(1, \lambda^2, \lambda).$$

So the eigenvalues are the cube roots of 1 in F, and $E_\lambda = \mathrm{span}((1, \lambda^2, \lambda))$ for each.

- Over $\mathbb{C}$: $1, \omega, \omega^2$ with $\omega = e^{2\pi i/3} = (-1 + i\sqrt{3})/2$, and eigenvectors $(1, 1, 1)$, $(1, \omega^2, \omega)$, $(1, \omega, \omega^2)$.
- Over $\mathbb{R}$: only 1, since $t \mapsto t^3$ is injective on $\mathbb{R}$. Eigenvector $(1, 1, 1)$.
- Over $\mathbb{F}_7$: $2^3 = 8 = 1$ and $4^3 = 64 = 1$, and $3^3 = 6$, $5^3 = 6$, $6^3 = 6$ are not 1. So the eigenvalues are $1, 2, 4$, with eigenvectors $(1, 1, 1)$, $(1, 4, 2)$, and $(1, 2, 4)$.
- Over $\mathbb{F}_3$: $0^3 = 0$, $1^3 = 1$, $2^3 = 8 = 2$. Only 1, with $E_1 = \mathrm{span}((1, 1, 1))$.

Over $\mathbb{C}$ and $\mathbb{F}_7$ there are 3 distinct eigenvalues, so the three eigenvectors form a basis (Theorem 7.2.21). Over $\mathbb{F}_3$ there is only one eigenvector line.

Solution to Exercise 7.2.57

Uses. Theorem 4.1.16 (Extending to a basis), Exercise 7.2.54, Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Exercise 2.1.48
Hint 1. Show that every line $\mathrm{span}(\mathbf{v})$ is invariant. Intersections of invariant subspaces are invariant.
Hint 2. For $\mathbf{v} \neq \mathbf{0}$ and $\mathbf{w} \notin \mathrm{span}(\mathbf{v})$, build a k-dimensional subspace containing $\mathbf{v}$ but not $\mathbf{w}$ by extending $\mathbf{v}, \mathbf{w}$ to a basis.
Hint 3. So $\mathrm{span}(\mathbf{v})$ is the intersection of all k-dimensional subspaces that contain $\mathbf{v}$. Finish with Exercise 2.1.48.
Sketch. Fix $\mathbf{v} \neq \mathbf{0}$. For $\mathbf{w} \notin \mathrm{span}(\mathbf{v})$, extend $\mathbf{v}, \mathbf{w}$ to a basis $\mathbf{v}, \mathbf{w}, \mathbf{b}_3, \ldots, \mathbf{b}_n$ and let $U = \mathrm{span}(\mathbf{v}, \mathbf{b}_3, \ldots, \mathbf{b}_{k+1})$, of dimension k, containing $\mathbf{v}$ but not $\mathbf{w}$. So $\mathrm{span}(\mathbf{v})$ is the intersection of the k-dimensional subspaces containing $\mathbf{v}$, all invariant, hence invariant. Every vector is then an eigenvector or $\mathbf{0}$, so T is scalar.

Fix $\mathbf{v} \neq \mathbf{0}$, and let X be the intersection of all k-dimensional subspaces of V that contain $\mathbf{v}$. There is at least one such subspace, since $k \geq 1$ (extend $\mathbf{v}$ to a basis and take the span of $\mathbf{v}$ and $k - 1$ further basis vectors). So X is a subspace containing $\mathrm{span}(\mathbf{v})$. We show $X = \mathrm{span}(\mathbf{v})$. Let $\mathbf{w} \notin \mathrm{span}(\mathbf{v})$. Then $\mathbf{v}, \mathbf{w}$ is independent, and it extends to a basis $\mathbf{v}, \mathbf{w}, \mathbf{b}_3, \ldots, \mathbf{b}_n$ of V (Theorem 4.1.16). Since $k - 1 \leq n - 2$, the list $\mathbf{v}, \mathbf{b}_3, \ldots, \mathbf{b}_{k+1}$ makes sense; its span U has dimension k and contains $\mathbf{v}$, but not $\mathbf{w}$, because $\mathbf{w}$ is not a combination of the other basis vectors. So $\mathbf{w} \notin X$, and $X = \mathrm{span}(\mathbf{v})$.

Each of these k-dimensional subspaces is T-invariant by hypothesis, so X is T-invariant: if $\mathbf{x} \in X$, then $T\mathbf{x}$ lies in each of them, as in Exercise 7.2.54(a). So $T\mathbf{v} \in \mathrm{span}(\mathbf{v})$ for every $\mathbf{v} \neq \mathbf{0}$, and trivially for $\mathbf{v} = \mathbf{0}$.

By Exercise 2.1.48, $T = \lambda\,\mathrm{id}$ for some λ. (The converse is clear, and the hypothesis $k < n$ is needed: every operator leaves the one n-dimensional subspace V invariant.)

Solution to Exercise 7.2.58

> *Uses.* Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 2.5.28 (Inverse of a 2×2 matrix)
> *Techniques.* Construct a map by choosing it on a basis (Technique 2.2.4)
> *Hint 1.* $(1,2), (1,1)$ is a basis, so Theorem 2.2.1 gives exactly one such map.
> *Hint 2.* With $S = \begin{pmatrix} 1 & 1 \\ 2 & 1 \end{pmatrix}$, the conditions say $AS = S\,\mathrm{diag}(3,-1)$. Solve for A.
> *Sketch.* $AS = SD$ with $S = \begin{pmatrix} 1 & 1 \\ 2 & 1 \end{pmatrix}$ and $D = \mathrm{diag}(3,-1)$, so $A = SDS^{-1} = \begin{pmatrix} 3 & -1 \\ 6 & -1 \end{pmatrix}\begin{pmatrix} -1 & 1 \\ 2 & -1 \end{pmatrix} = \begin{pmatrix} -5 & 4 \\ -8 & 7 \end{pmatrix}$. It is unique because a linear map is determined by its values on a basis.

The vectors $(1,2)$ and $(1,1)$ form a basis of $\mathbb{Q}^2$, so by Theorem 2.2.1 there is exactly one linear map with the prescribed values, and A is unique. To find it, let $S = \begin{pmatrix} 1 & 1 \\ 2 & 1 \end{pmatrix}$, whose columns are the two vectors, and $D = \mathrm{diag}(3,-1)$. The conditions say $AS = SD$, column by column. By Proposition 2.5.28, $\det S = -1$ and $S^{-1} = \begin{pmatrix} -1 & 1 \\ 2 & -1 \end{pmatrix}$, so

$$A = SDS^{-1} = \begin{pmatrix} 3 & -1 \\ 6 & -1 \end{pmatrix}\begin{pmatrix} -1 & 1 \\ 2 & -1 \end{pmatrix} = \begin{pmatrix} -5 & 4 \\ -8 & 7 \end{pmatrix}.$$

Check: $A(1,2) = (-5+8, -8+14) = (3,6)$ and $A(1,1) = (-1,-1)$.

Section 7.3

Solution to Exercise 7.3.9

> *Uses.* Example 7.3.5 (Small cases), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial)
> *Hint 1.* $p_A = x^2 - (\mathrm{tr}\,A)x + \det A$. Then find the roots field by field.
> *Hint 2.* For a root λ, the first row of $A - \lambda I_2$ is $(1-\lambda, 1)$, so $(1, \lambda - 1)$ is in the kernel. Since $\lambda^2 = \lambda + 1$, this is $(1, 1/\lambda)$, or more simply the multiple $(\lambda, 1)$.
> *Sketch.* $p_A = x^2 - x - 1$. Over $\mathbb{R}$: $\left(1 \pm \sqrt{5}\right)/2$. Over $\mathbb{F}_2$: $x^2 + x + 1$ has no root. Over $\mathbb{F}_5$: $(x-3)^2$, one eigenvalue 3. Over $\mathbb{F}_{11}$: roots 4 and 8. Eigenvectors $(\lambda, 1)$ in each case.

By Example 7.3.5(a), $p_A = x^2 - x - 1$. If λ is a root, then $(A - \lambda I_2)(\lambda, 1) = \left(\lambda - \lambda^2 + 1, \lambda - \lambda\right) = (0,0)$, because $\lambda^2 = \lambda + 1$. So $(\lambda, 1)$ is an eigenvector for every root λ, and by Theorem 7.3.6 the eigenvalues are exactly the roots.

Over $\mathbb{R}$, the roots are $\left(1 \pm \sqrt{5}\right)/2$, the golden ratio and its conjugate.

Over $\mathbb{F}_2$, $p_A = x^2 + x + 1$ takes the value 1 at both 0 and 1, so A has no eigenvalues.

Over $\mathbb{F}_5$, $p_A = x^2 - x - 1 = x^2 + 4x + 4 = (x+2)^2 = (x-3)^2$, so 3 is the only eigenvalue, with eigenvector $(3,1)$. Indeed $A(3,1) = (4,3) = 3(3,1)$, as $9 = 4$ in $\mathbb{F}_5$.

Over $\mathbb{F}_{11}$, $p_A(4) = 16 - 4 - 1 = 11 = 0$ and $p_A(8) = 64 - 8 - 1 = 55 = 0$, so the eigenvalues are 4 and 8 (there are at most two), with eigenvectors $(4,1)$ and $(8,1)$. These are the two "square roots of 5 formulas" $(1 \pm 4)/2$ read in $\mathbb{F}_{11}$, since $4^2 = 5$ there.

Solution to Exercise 7.3.17

> *Uses.* Proposition 7.3.2 (Determinants over a commutative ring), Lemma 7.1.37 (Conjugating polynomials), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Definition 6.3.26 (Conjugate transpose)
> *Hint 1.* For (a), what is $(xI_n - A)^{\mathsf{T}}$? Use Proposition 7.3.2(d).
> *Hint 2.* For (b), coefficientwise conjugation $\mathbb{C}[x] \to \mathbb{C}[x]$ respects sums, products, and 1 (Lemma 7.1.37). Apply Proposition 7.3.2(g) to it.
> *Sketch.* (a) $(xI_n - A)^{\mathsf{T}} = xI_n - A^{\mathsf{T}}$, and transposing does not change det. (b) Conjugating every entry of $xI_n - A$ gives $xI_n - \overline{A}$, so $p_{\overline{A}} = \overline{p_A}$ by Proposition 7.3.2(g). With (a), $p_{A^{\mathsf{H}}} = \overline{p_A}$, whose roots are the conjugates of the roots of p_A by Lemma 7.1.37(b).

(a) The transpose of $xI_n - A$ is $xI_n - A^{\mathsf{T}}$, since xI_n is symmetric. By Proposition 7.3.2(d), $p_{A^{\mathsf{T}}} = \det\left((xI_n - A)^{\mathsf{T}}\right) = \det(xI_n - A) = p_A$.

(b) Let $\varphi : \mathbb{C}[x] \to \mathbb{C}[x]$, $\varphi(f) = \overline{f}$. By Lemma 7.1.37(a), φ respects sums and products, and $\varphi(1) = 1$. Applying φ to every entry of $xI_n - A$ gives $xI_n - \overline{A}$, because $\overline{x} = x$ and the constant $-a_{ij}$ becomes $-\overline{a_{ij}}$. By Proposition 7.3.2(g), $p_{\overline{A}} = \det \varphi(xI_n - A) = \varphi(p_A) = \overline{p_A}$.

Now $A^{\mathsf{H}} = \overline{A}^{\mathsf{T}}$, so by (a), $p_{A^{\mathsf{H}}} = p_{\overline{A}} = \overline{p_A}$. By Lemma 7.1.37(b), $\overline{p_A}\big(\overline{\lambda}\big) = \overline{p_A(\lambda)}$, so $\overline{\lambda}$ is a root of $\overline{p_A}$ if and only if λ is a root of p_A. By Theorem 7.3.6, the eigenvalues of A^{H} are exactly the conjugates $\overline{\lambda}$ of the eigenvalues λ of A.

Solution to Exercise 7.3.20

Uses. Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Remark 7.3.19 (Trace and determinant from the roots), Theorem 7.2.9 (Eigenvalues and invertibility)
Hint 1. Since $A - I_3$ is not invertible, 1 is an eigenvalue. Write $p_A = (x-1)(x-r)(x-s)$.
Hint 2. Remark 7.3.19 gives $1 + r + s = 2$ and $rs = -2$.
Sketch. 1 is a root, $r + s = 1$, $rs = -2$, so r, s are the roots of $t^2 - t - 2 = (t-2)(t+1)$. Hence $p_A = (x-1)(x-2)(x+1)$.

By Theorem 7.2.9, 1 is an eigenvalue of A, so $p_A(1) = 0$ by Theorem 7.3.6, and since p_A splits we can write $p_A = (x-1)(x-r)(x-s)$ with $r, s \in \mathbb{R}$. By Remark 7.3.19, $1 + r + s = \operatorname{tr} A = 2$ and $1 \cdot rs = \det A = -2$. So $r + s = 1$ and $rs = -2$, which makes r and s the roots of $(t-r)(t-s) = t^2 - t - 2 = (t-2)(t+1)$. Therefore $p_A = (x-1)(x-2)(x+1)$, and the eigenvalues are 1, 2, -1. (The matrix $\operatorname{diag}(1, 2, -1)$ shows that such an A exists.)

Solution to Exercise 7.3.37

Uses. Algorithm 7.3.7 (Eigenvalues by the characteristic polynomial), Proposition 7.3.2 (Determinants over a commutative ring), Proposition 7.3.15 (Block-triangular matrices), Exercise 7.3.17, Theorem 7.3.24 (Every monic polynomial is a characteristic polynomial)
Hint 1. In (a), add the second and third rows of $xI_3 - A$ to the first; a common factor appears. In (b), A is the transpose of a companion matrix. In (c), A is block diagonal.
Hint 2. The answers are $(x-5)(x+1)^2$, $(x-1)^2(x-2)$, and $(x-2)\big(x^2 - 2x + 2\big)$. Now row reduce $A - \lambda I_3$ for each root.
Sketch. (a) $p_A = (x-5)(x+1)^2$, $E_5 = \operatorname{span}((1,1,1))$, $E_{-1} = \operatorname{span}((1,-1,0),(1,0,-1))$. (b) $p_A = x^3 - 4x^2 + 5x - 2 = (x-1)^2(x-2)$, $E_1 = \operatorname{span}((1,1,1))$, $E_2 = \operatorname{span}((1,2,4))$. (c) $p_A = (x-2)\big(x^2 - 2x + 2\big)$; over $\mathbb{R}$ only $E_2 = \operatorname{span}(\mathbf{e}_3)$; over $\mathbb{C}$ also $E_{1+i} = \operatorname{span}((i,1,0))$ and $E_{1-i} = \operatorname{span}((-i,1,0))$.

(a) In $xI_3 - A$, add rows 2 and 3 to row 1; this does not change the determinant (Proposition 7.3.2(b), (d)). Row 1 becomes $(x-5, x-5, x-5)$, and pulling out the factor $x - 5$ and then adding 2 times row 1 to rows 2 and 3,

$$p_A = (x-5)\det\begin{pmatrix} 1 & 1 & 1 \\ -2 & x-1 & -2 \\ -2 & -2 & x-1 \end{pmatrix} = (x-5)\det\begin{pmatrix} 1 & 1 & 1 \\ 0 & x+1 & 0 \\ 0 & 0 & x+1 \end{pmatrix} = (x-5)(x+1)^2.$$

Next, $A - 5I_3 = \begin{pmatrix} -4 & 2 & 2 \\ 2 & -4 & 2 \\ 2 & 2 & -4 \end{pmatrix}$ has rank 2 and kills $(1,1,1)$, so $E_5 = \operatorname{span}((1,1,1))$. Every row of $A + I_3$ is $(2,2,2)$, so $E_{-1} = \{(x,y,z) \mid x + y + z = 0\} = \operatorname{span}((1,-1,0),(1,0,-1))$. As a check, $A = 2J - I_3$ with J the all-ones matrix, and J acts as 3 on $(1,1,1)$ and as 0 on the plane $x + y + z = 0$.

(b) $A^{\mathsf{T}} = \begin{pmatrix} 0 & 0 & 2 \\ 1 & 0 & -5 \\ 0 & 1 & 4 \end{pmatrix}$ is the companion matrix of $p = x^3 - 4x^2 + 5x - 2$, so $p_A = p_{A^{\mathsf{T}}} = p$ by Exercise 7.3.17 and Theorem 7.3.24. (Expanding $\det(xI_3 - A)$ along the first row gives the same.) Since $p(1) = 0$, dividing gives $p = (x-1)\big(x^2 - 3x + 2\big) = (x-1)^2(x-2)$. Then

$$A - I_3 = \begin{pmatrix} -1 & 1 & 0 \\ 0 & -1 & 1 \\ 2 & -5 & 3 \end{pmatrix}, \quad A - 2I_3 = \begin{pmatrix} -2 & 1 & 0 \\ 0 & -2 & 1 \\ 2 & -5 & 2 \end{pmatrix}.$$

The first two rows of each are independent, so both have rank 2. The first two rows of $A - I_3$ force $y = x$ and $z = y$, and $(1,1,1)$ satisfies the third row; so $E_1 = \operatorname{span}((1,1,1))$. Likewise $E_2 = \operatorname{span}((1,2,4))$. Although 1 is a double root of p_A, its eigenspace is only a line.

(c) A is block diagonal with blocks $\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ and (2), so by Proposition 7.3.15 and Example 7.3.5(a), $p_A = (x^2 - 2x + 2)(x - 2)$. Over $\mathbb{R}$, $x^2 - 2x + 2 = (x-1)^2 + 1$ has no root, so the only eigenvalue is 2, and $A - 2I_3 = \begin{pmatrix} -1 & -1 & 0 \\ 1 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$ gives $E_2 = \operatorname{span}(\mathbf{e}_3)$. Over $\mathbb{C}$, the quadratic has roots $1 \pm i$. For $\lambda = 1 + i$, the first row of $A - \lambda I_3$ is $(-i, -1, 0)$, so $(i, 1, 0)$ spans E_{1+i}; indeed $A(i,1,0) = (i-1, i+1, 0) = (1+i)(i,1,0)$. Since A is real, conjugating $A\mathbf{v} = \lambda\mathbf{v}$ entrywise gives $A\overline{\mathbf{v}} = \overline{\lambda}\overline{\mathbf{v}}$, so $E_{1-i} = \operatorname{span}((-i, 1, 0))$, and $E_2 = \operatorname{span}(\mathbf{e}_3)$ as before.

Solution to Exercise 7.3.38

Uses. Proposition 7.3.2 (Determinants over a commutative ring), Proposition 7.1.10 (Evaluation respects sums and products), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Corollary 3.5.25 (The invertible matrix theorem), Proposition 4.5.24 (Similarity is an equivalence relation)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. For (a) and (b), look at 2×2 matrices with a repeated eigenvalue.
Hint 2. For (c), $xI_n - (A + cI_n) = (x - c)I_n - A$. Which map $F[x] \to F[x]$ turns $xI_n - A$ into this matrix?
Hint 3. For (d), pick an eigenvector of A for each root. They form a basis, in which A becomes $\operatorname{diag}(\lambda_1, \ldots, \lambda_n)$. Do the same for B separately, in its own basis of eigenvectors.
Sketch. (a) False: I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. (b) False: 0 and $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. (c) True: substitute $x - c$ for x entrywise and use Proposition 7.3.2(g). (d) True: n distinct eigenvalues give a basis of eigenvectors, so A and B are both similar to $\operatorname{diag}(\lambda_1, \ldots, \lambda_n)$.

(a) False. I_2 and $N = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ both have characteristic polynomial $(x-1)^2$ (Example 7.3.5(d)). But $S^{-1}I_2S = I_2 \neq N$ for every invertible S, so they are not similar.

(b) False. $0_{2\times 2}$ and $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ both have characteristic polynomial x^2, but their ranks are 0 and 1.

(c) True. Substituting $x - c$ for x respects sums, products, and 1 (Proposition 7.1.10), and applied to every entry of $xI_n - A$ it gives $(x-c)I_n - A = xI_n - (A + cI_n)$, since the constant entries are unchanged. By Proposition 7.3.2(g), $p_{A+cI_n} = p_A(x - c)$. In particular the eigenvalues of $A + cI_n$ are the $\lambda + c$ for the eigenvalues λ of A.

(d) True. Let $\lambda_1, \ldots, \lambda_n$ be the distinct roots. By Theorem 7.3.6 each λ_i is an eigenvalue of A; choose eigenvectors $\mathbf{v}_i$. By Theorem 7.2.21 they are independent, so they form a basis of F^n, and the matrix S with columns $\mathbf{v}_i$ is invertible (Corollary 3.5.25). Column i of AS is $A\mathbf{v}_i = \lambda_i\mathbf{v}_i$, which is column i of SD for $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$. So $S^{-1}AS = D$. The same argument for B gives $R^{-1}BR = D$. Hence $A \sim D \sim B$, and $A \sim B$ by Proposition 4.5.24.

Solution to Exercise 7.3.39

Uses. Lemma 2.4.24 (Matrix units), Definition 2.3.1 (Matrix of a linear map), Proposition 7.3.15 (Block-triangular matrices), Corollary 7.3.13 (Eigenvalues of an operator)
Hint 1. For (a), order the matrix units so that U_{ij} and U_{ji} are adjacent. What does the matrix of τ look like?
Hint 2. It is block diagonal, with n blocks (1) and $n(n-1)/2$ blocks $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. For (b), compute D on each basis function; the matrix is block upper triangular.
Sketch. (a) $\tau(U_{ii}) = U_{ii}$ and τ swaps U_{ij} and U_{ji}; so $p_\tau = (x-1)^n(x^2-1)^{n(n-1)/2}$. (b) The matrix is $\begin{pmatrix} R & I_2 \\ 0 & R \end{pmatrix}$ with $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, so $p_D = (x^2+1)^2$, which has no real root.

(a) By Lemma 2.4.24, the matrix units U_{ij} form a basis of $F^{n\times n}$. Order it as $U_{11}, \ldots, U_{nn}$, followed by the pairs U_{ij}, U_{ji} for $i < j$. Since $\tau(U_{ii}) = U_{ii}$, $\tau(U_{ij}) = U_{ji}$, and $\tau(U_{ji}) = U_{ij}$, the matrix of τ is block diagonal with n blocks (1) and $n(n-1)/2$ blocks $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, whose characteristic polynomial is $x^2 - 1 = (x-1)(x+1)$. Applying Proposition 7.3.15 once for each block,

$$p_\tau = (x-1)^n\left(x^2-1\right)^{n(n-1)/2} = (x-1)^{n+n(n-1)/2}(x+1)^{n(n-1)/2},$$

and $n + n(n-1)/2 = n(n+1)/2$. This fits Example 7.2.17: $\tau^2 = \mathrm{id}$, the symmetric matrices form E_1, of dimension $n(n+1)/2$, and the antisymmetric ones form E_{-1}. When $1+1=0$ in F, the formula reads $p_\tau = (x-1)^{n^2}$.

(b) Let $\mathbf{b}_1 = \sin t$, $\mathbf{b}_2 = \cos t$, $\mathbf{b}_3 = t\sin t$, $\mathbf{b}_4 = t\cos t$. Then

$$D\mathbf{b}_1 = \mathbf{b}_2, \quad D\mathbf{b}_2 = -\mathbf{b}_1, \quad D\mathbf{b}_3 = \mathbf{b}_1 + \mathbf{b}_4, \quad D\mathbf{b}_4 = \mathbf{b}_2 - \mathbf{b}_3,$$

so D maps W to W, and its matrix (Definition 2.3.1) is

$$[D] = \begin{pmatrix} 0 & -1 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

This is block upper triangular with both diagonal blocks equal to $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, so $p_D = \left(x^2+1\right)^2$ by Proposition 7.3.15. It has no real root, so D has no real eigenvalue (Corollary 7.3.13): no nonzero $f \in W$ satisfies $f' = \lambda f$ with $\lambda \in \mathbb{R}$. The upper left block reflects the invariant plane $\mathrm{span}(\sin t, \cos t)$.

Solution to Exercise 7.3.40

Uses. Proposition 7.3.22 (AB and BA), Proposition 7.3.11 (Similar matrices have the same characteristic polynomial), Proposition 7.3.15 (Block-triangular matrices), Theorem 2.4.34 (Block multiplication), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial)
Techniques. Compare AB and BA (Technique 7.3.21)
Hint 1. Imitate the first proof of Proposition 7.3.22 with $S = \left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$. The zero blocks now have different sizes.
Hint 2. For (b), evaluate the identity of (a) at $\lambda \neq 0$.
Hint 3. For (c), why is $B\mathbf{v} \neq \mathbf{0}$? Apply A to it.
Sketch. (a) $X = \left(\begin{smallmatrix} AB & 0 \\ B & 0_{n\times n} \end{smallmatrix}\right)$ and $Y = \left(\begin{smallmatrix} 0_{m\times m} & 0 \\ B & BA \end{smallmatrix}\right)$ satisfy $XS = SY$ with $S = \left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$, and $p_X = p_{AB}x^n$, $p_Y = x^m p_{BA}$. (b) For $\lambda \neq 0$, $\lambda^n p_{AB}(\lambda) = \lambda^m p_{BA}(\lambda)$. (c) $A(B\mathbf{v}) = \lambda\mathbf{v} \neq \mathbf{0}$, and $BA(B\mathbf{v}) = B(\lambda\mathbf{v})$. (d) $A = (1,0)$, $B = (1,0)^{\mathsf{T}}$.

(a) Let $S = \left(\begin{smallmatrix} I_m & A \\ 0 & I_n \end{smallmatrix}\right)$, which is invertible with inverse $\left(\begin{smallmatrix} I_m & -A \\ 0 & I_n \end{smallmatrix}\right)$, and let

$$X = \begin{pmatrix} AB & 0 \\ B & 0_{n\times n} \end{pmatrix}, \quad Y = \begin{pmatrix} 0_{m\times m} & 0 \\ B & BA \end{pmatrix}.$$

By block multiplication (Theorem 2.4.34), $XS = \left(\begin{smallmatrix} AB & ABA \\ B & BA \end{smallmatrix}\right) = SY$. So X and Y are similar and $p_X = p_Y$ (Proposition 7.3.11). Both are block lower triangular, so by Proposition 7.3.15, $p_X = p_{AB}p_{0_{n\times n}} = p_{AB}x^n$ and $p_Y = x^m p_{BA}$.

(b) Let $\lambda \neq 0$. Evaluating (a) at λ gives $\lambda^n p_{AB}(\lambda) = \lambda^m p_{BA}(\lambda)$, and $\lambda^n, \lambda^m \neq 0$. So $p_{AB}(\lambda) = 0$ if and only if $p_{BA}(\lambda) = 0$, and Theorem 7.3.6 finishes.

(c) Suppose $AB\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$ and $\lambda \neq 0$. Then $A(B\mathbf{v}) = \lambda\mathbf{v} \neq \mathbf{0}$, so $B\mathbf{v} \neq \mathbf{0}$, and $(BA)(B\mathbf{v}) = B(AB\mathbf{v}) = \lambda B\mathbf{v}$. So every nonzero eigenvalue of AB is one of BA, and exchanging the roles of A and B gives the converse.

(d) Let $A = \begin{pmatrix} 1 & 0 \end{pmatrix} \in F^{1\times 2}$ and $B = \left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right) \in F^{2\times 1}$. Then $AB = (1)$ has the single eigenvalue 1, while $BA = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ also has the eigenvalue 0. Consistently with (a), $x^2(x-1) = x \cdot x(x-1)$.

Solution to Exercise 7.3.41

Uses. Exercise 7.3.40, Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Proposition 4.5.27 (Similarity invariants), Theorem 4.2.11 (Rank–nullity), Example 7.3.5 (Small cases)
Techniques. Compare AB and BA (Technique 7.3.21), Choose a basis adapted to a preserved subspace (Technique 4.5.36)

Hint 1. Write $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ as a product of an $n \times 1$ and a $1 \times n$ matrix, and use Exercise 7.3.40.
Hint 2. Alternatively, if $\mathbf{v} \neq \mathbf{0}$, the hyperplane $\{\mathbf{w} \mid \mathbf{v}^{\mathsf{T}}\mathbf{w} = 0\}$ lies in the kernel. Choose a basis starting with a basis of it; the matrix becomes triangular. Its last diagonal entry is the trace.
Sketch. (a) With $A = \mathbf{u} \in F^{n\times 1}$ and $B = \mathbf{v}^{\mathsf{T}} \in F^{1\times n}$, Exercise 7.3.40 gives $x p_{\mathbf{u}\mathbf{v}^{\mathsf{T}}} = x^n p_{\mathbf{v}^{\mathsf{T}}\mathbf{u}} = x^n\big(x - \mathbf{v}^{\mathsf{T}}\mathbf{u}\big)$; cancel x. (b) $J = \mathbf{1}\mathbf{1}^{\mathsf{T}}$ and $\mathbf{1}^{\mathsf{T}}\mathbf{1} = n$, so $p_J = x^{n-1}(x-n)$: eigenvalues $0, n$ over $\mathbb{Q}$, and only 0 over $\mathbb{F}_p$ when $p \mid n$.

(a) *First proof.* Let $A = \mathbf{u} \in F^{n\times 1}$ and $B = \mathbf{v}^{\mathsf{T}} \in F^{1\times n}$, so $AB = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ and $BA = \big(\mathbf{v}^{\mathsf{T}}\mathbf{u}\big)$ is 1×1, with $p_{BA} = x - \mathbf{v}^{\mathsf{T}}\mathbf{u}$. By Exercise 7.3.40, $x p_{\mathbf{u}\mathbf{v}^{\mathsf{T}}} = x^n\big(x - \mathbf{v}^{\mathsf{T}}\mathbf{u}\big)$. Cancelling x in $F[x]$ (Corollary 7.1.7) gives the claim.

Second proof. Let $M = \mathbf{u}\mathbf{v}^{\mathsf{T}}$. If $\mathbf{v} = \mathbf{0}$, then $M = 0$ and $p_M = x^n$, as claimed. Otherwise $H = \{\mathbf{w} \in F^n \mid \mathbf{v}^{\mathsf{T}}\mathbf{w} = 0\}$ is the kernel of a nonzero linear map $F^n \to F$, so $\dim H = n - 1$ (Theorem 4.2.11), and $M\mathbf{w} = \mathbf{u}\big(\mathbf{v}^{\mathsf{T}}\mathbf{w}\big) = \mathbf{0}$ for $\mathbf{w} \in H$. Extend a basis $\mathbf{w}_1, \ldots, \mathbf{w}_{n-1}$ of H to a basis $\mathcal{B}$ of F^n. The first $n-1$ columns of $[T_M]_{\mathcal{B}\mathcal{B}}$ are $\mathbf{0}$, so this matrix is upper triangular with diagonal entries $0, \ldots, 0, c$, and $p_M = x^{n-1}(x-c)$ by Example 7.3.5(d). Since the trace is a similarity invariant (Proposition 4.5.27), $c = \operatorname{tr} M = \sum_i u_i v_i = \mathbf{v}^{\mathsf{T}}\mathbf{u}$.

(b) $J = \mathbf{1}\mathbf{1}^{\mathsf{T}}$ with $\mathbf{1} = (1, \ldots, 1)$, and $\mathbf{1}^{\mathsf{T}}\mathbf{1} = n$. By (a), $p_J = x^{n-1}(x-n)$. Over $\mathbb{Q}$ the eigenvalues are 0 and n. Over $\mathbb{F}_p$ with $p \mid n$, we have $n = 0$, so $p_J = x^n$ and 0 is the only eigenvalue; indeed $J\mathbf{1} = n\mathbf{1} = \mathbf{0}$ there.

Solution to Exercise 7.3.42

Uses. Definition 7.3.1 (Determinant over a commutative ring), Definition 7.1.1 (Product of polynomials), Proposition 7.3.18 (The first and last coefficients), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial)
Hint 1. For (a), every entry of $xI_n - A$ is a polynomial with integer coefficients. What happens to such polynomials under sums and products?
Hint 2. For (b), write the eigenvalue as a/b in lowest terms with $b \geq 1$, substitute into p_A, and multiply by b^n. Which terms are divisible by b?
Sketch. (a) The Leibniz formula is a signed sum of products of polynomials with integer coefficients. (b) If $p_A(a/b) = 0$ with $\gcd(a,b) = 1$, then $a^n = -b\big(c_{n-1}a^{n-1} + \cdots + c_0 b^{n-1}\big)$, so every prime factor of b divides a; hence $b = 1$. Then a divides the constant term $(-1)^n \det A$. (c) $p_A = x^2 - 5x - 2$ has no root among $\pm 1, \pm 2$.

(a) Every entry of $xI_n - A$ is $x - a_{ii}$ or $-a_{ij}$, a polynomial with integer coefficients. By the formula for the product (Definition 7.1.1), sums and products of polynomials with integer coefficients have integer coefficients. So every Leibniz term, and hence p_A, has integer coefficients.

(b) Write $p_A = x^n + c_{n-1}x^{n-1} + \cdots + c_0$ with $c_i \in \mathbb{Z}$, and suppose $p_A(a/b) = 0$ with $a, b \in \mathbb{Z}$, $b \geq 1$, and $\gcd(a,b) = 1$. Multiplying by b^n,

$$a^n = -b\big(c_{n-1}a^{n-1} + c_{n-2}a^{n-2}b + \cdots + c_0 b^{n-1}\big).$$

If $b > 1$, a prime q dividing b divides a^n, hence divides a, contradicting $\gcd(a,b) = 1$. So $b = 1$ and the eigenvalue a is an integer. Then $0 = a^n + c_{n-1}a^{n-1} + \cdots + c_1 a + c_0$ gives $c_0 = -a\big(a^{n-1} + c_{n-1}a^{n-2} + \cdots + c_1\big)$, so a divides $c_0 = (-1)^n \det A$ (Proposition 7.3.18), and therefore divides $\det A$.

(c) Here $p_A = x^2 - 5x - 2$ and $\det A = -2$. By (b), a rational eigenvalue would be one of $\pm 1, \pm 2$, but $p_A(1) = -6$, $p_A(-1) = 4$, $p_A(2) = -8$, and $p_A(-2) = 12$. So there is none, and the eigenvalues $\big(5 \pm \sqrt{33}\big)/2$ are irrational.

Solution to Exercise 7.3.43

Uses. Theorem 5.4.10 (Multiplicativity), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Corollary 7.1.35 (Factorization over $\mathbb{C}$), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Proposition 7.1.38 (Conjugate roots)
Hint 1. For (a), take determinants of both sides. What sign does a real square have?
Hint 2. For (b), an eigenvalue λ of A over $\mathbb{C}$ satisfies $\lambda^2 = -1$. Then $p_A = (x-i)^a(x+i)^b$. Use that p_A has real coefficients.
Sketch. (a) $(\det A)^2 = \det(-I_n) = (-1)^n$, and a nonzero real square is positive, so $(-1)^n = 1$. (b) All complex eigenvalues are $\pm i$, so $p_A = (x-i)^a(x+i)^b$ with $a + b = n$; real coefficients force $a = b$ (Proposition 7.1.38). (c) Block-diagonal rotations by $\pi/2$ over $\mathbb{R}$; iI_n over $\mathbb{C}$.

(a) By Theorem 5.4.10, $(\det A)^2 = \det\big(A^2\big) = \det(-I_n) = (-1)^n$. Since $\det A \in \mathbb{R}$ and $(\det A)^2 = (-1)^n \neq 0$, we get $(-1)^n = (\det A)^2 > 0$, so n is even.

(b) Regard A as a complex matrix. If $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $-\mathbf{v} = A^2\mathbf{v} = \lambda^2\mathbf{v}$ (Proposition 7.2.28), so $\lambda^2 = -1$ and $\lambda = \pm i$. By Corollary 7.1.35, p_A is a product of n factors $x - \lambda_k$, and each λ_k is a root, hence an eigenvalue (Theorem 7.3.6), hence $\pm i$. So $p_A = (x-i)^a(x+i)^b$ with $a + b = n$. The entries of A are real, so $p_A \in \mathbb{R}[x]$, and by Proposition 7.1.38 the roots i and $-i = \bar{i}$ have the same multiplicity: $a = b$. Hence $n = 2a$ is even.

(c) Over $\mathbb{C}$, $(iI_n)^2 = -I_n$. Over $\mathbb{R}$ with $n = 2m$, the block-diagonal matrix with m blocks $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ works, since $R^2 = -I_2$.

Solution to Exercise 7.3.44

Uses. Theorem 7.3.24 (Every monic polynomial is a characteristic polynomial), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Definition 7.3.23 (Companion matrix)
Hint 1. Evaluate p at each c_j.
Hint 2. Every monic polynomial is a characteristic polynomial (Theorem 7.3.24).
Sketch. (a) $p(c_j) = 0 + 1 = 1$. (b) $C_p \in F^{q\times q}$ has $p_{C_p} = p$, which has no root. (c) Over $\mathbb{F}_2$, $p = x(x-1) + 1 = x^2 + x + 1$ and $C_p = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$; neither C_p nor $C_p - I_2$ is singular.

(a) For each j, the product $(c_j - c_1)\cdots(c_j - c_q)$ contains the factor $c_j - c_j = 0$, so $p(c_j) = 0 + 1 = 1 \neq 0$.

(b) p is monic of degree q, so by Theorem 7.3.24 the companion matrix $C_p \in F^{q\times q}$ has $p_{C_p} = p$. By (a) and Theorem 7.3.6, C_p has no eigenvalue in F.

(c) Over $\mathbb{F}_2$, $p = x(x-1) + 1 = x^2 - x + 1 = x^2 + x + 1$, and $C_p = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$. Its determinant is $-1 = 1 \neq 0$, so 0 is not an eigenvalue, and $C_p - I_2 = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$ has determinant $-1 = 1 \neq 0$, so 1 is not one either.

Solution to Exercise 7.3.45

Uses. Definition 7.3.23 (Companion matrix), Theorem 4.2.11 (Rank–nullity), Remark 7.1.11 (Polynomials in a matrix), Theorem 7.3.24 (Every monic polynomial is a characteristic polynomial), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Proposition 7.1.22 (Counting roots)
Techniques. Krylov sequences must become dependent (Technique 7.3.28)
Hint 1. For (a), look at the first $n-1$ columns of $C - \lambda I_n$.
Hint 2. For (b), $C^j\mathbf{e}_1 = \mathbf{e}_{j+1}$ for $j \leq n-1$. Compute $q(C)\mathbf{e}_1$ and $p(C)\mathbf{e}_1$.
Hint 3. For (c), a basis of eigenvectors has at most one vector in each eigenspace, by (a).
Sketch. (a) Columns $k < n$ of $C - \lambda I_n$ are $\mathbf{e}_{k+1} - \lambda\mathbf{e}_k$, which are independent (look at the last coordinate first). (b) $q(C)\mathbf{e}_1$ is the given vector, and $(C - \lambda I_n)q(C)\mathbf{e}_1 = p(C)\mathbf{e}_1 = C\mathbf{e}_n + \sum a_j\mathbf{e}_{j+1} = \mathbf{0}$. (c) Distinct roots give independent eigenvectors; conversely a basis of eigenvectors needs n different eigenvalues, all roots of p.

(a) For $k \leq n-1$, column k of $C - \lambda I_n$ is $\mathbf{e}_{k+1} - \lambda\mathbf{e}_k$. Suppose $\sum_{k=1}^{n-1} c_k(\mathbf{e}_{k+1} - \lambda\mathbf{e}_k) = \mathbf{0}$. The coordinate at $\mathbf{e}_n$ is c_{n-1}, so $c_{n-1} = 0$. If $c_{k+1} = \cdots = c_{n-1} = 0$, the coordinate at $\mathbf{e}_{k+1}$ is $c_k - \lambda c_{k+1} = c_k$, so $c_k = 0$. Hence these $n-1$ columns are independent, $\operatorname{rank}(C - \lambda I_n) \geq n-1$, and $\dim E_\lambda = n - \operatorname{rank}(C - \lambda I_n) \leq 1$ by Theorem 4.2.11.

(b) Since $C\mathbf{e}_k = \mathbf{e}_{k+1}$ for $k < n$, we have $C^j\mathbf{e}_1 = \mathbf{e}_{j+1}$ for $0 \leq j \leq n-1$. So

$$\mathbf{w} = q(C)\mathbf{e}_1 = b_0\mathbf{e}_1 + b_1\mathbf{e}_2 + \cdots + b_{n-2}\mathbf{e}_{n-1} + \mathbf{e}_n = (b_0, \ldots, b_{n-2}, 1),$$

which is nonzero. Also $C^n\mathbf{e}_1 = C\mathbf{e}_n = -\sum_{j=0}^{n-1} a_j\mathbf{e}_{j+1}$, so $p(C)\mathbf{e}_1 = C^n\mathbf{e}_1 + \sum_j a_j\mathbf{e}_{j+1} = \mathbf{0}$. By Remark 7.1.11, $(C - \lambda I_n)\mathbf{w} = ((x-\lambda)q)(C)\mathbf{e}_1 = p(C)\mathbf{e}_1 = \mathbf{0}$.

(c) By Theorem 7.3.24 and Theorem 7.3.6, the eigenvalues of C are the roots of p in F. If there are n distinct ones, eigenvectors for them are independent (Theorem 7.2.21), hence a basis of F^n. Conversely, suppose $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis of eigenvectors. Two of them with the same eigenvalue would be two independent vectors in one eigenspace, which is a line by (a). So their eigenvalues are n distinct roots of p, and p has at least, hence exactly, n distinct roots (Proposition 7.1.22). In the language of Section 7.4, C_p is diagonalizable over F exactly when p splits with distinct roots.

Solution to Exercise 7.3.46

Uses. Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 7.3.26 (Krylov subspaces and the characteristic polynomial), Remark 7.1.11 (Polynomials in a matrix)
Techniques. Krylov sequences must become dependent (Technique 7.3.28)
Hint 1. $\mathbf{v}, A\mathbf{v}, A^2\mathbf{v}$ turn out to be independent. Solve $A^3\mathbf{v} = \alpha\mathbf{v} + \beta A\mathbf{v} + \gamma A^2\mathbf{v}$.
Hint 2. $p = x^3 - 4x^2 + 6x - 4$ has the root 2. For a root λ, apply $q = p/(x - \lambda)$ at A to $\mathbf{v}$.
Sketch. (a) $\mathbf{v} = (1, 0, 1)$, $A\mathbf{v} = (1, 1, 2)$, $A^2\mathbf{v} = (0, 2, 4)$, $A^3\mathbf{v} = (-2, 2, 8) = 4\mathbf{v} - 6A\mathbf{v} + 4A^2\mathbf{v}$, so $p = x^3 - 4x^2 + 6x - 4$. (b) $p = (x - 2)(x - 1 - i)(x - 1 + i)$, with eigenvectors $(0, 0, 2)$, $(-1 - i, -1 + i, 0)$, and $(-1 + i, -1 - i, 0)$. (c) $A^2\mathbf{e}_1 = 2A\mathbf{e}_1 - 2\mathbf{e}_1$, so $p = x^2 - 2x + 2$, which misses 2; it is a proper divisor of p_A.

(a) We get $\mathbf{v} = (1, 0, 1)$, $A\mathbf{v} = (1, 1, 2)$, $A^2\mathbf{v} = (0, 2, 4)$, and $A^3\mathbf{v} = (-2, 2, 8)$. The first three are independent: the matrix with these columns has determinant $1 \cdot (4 - 4) - 1 \cdot (0 - 2) + 0 = 2 \neq 0$. Solving $A^3\mathbf{v} = \alpha\mathbf{v} + \beta A\mathbf{v} + \gamma A^2\mathbf{v}$ coordinatewise gives $\alpha + \beta = -2$, $\beta + 2\gamma = 2$, $\alpha + 2\beta + 4\gamma = 8$, so $\gamma = 4$, $\beta = -6$, $\alpha = 4$. Hence $d = 3$ and $p = x^3 - 4x^2 + 6x - 4$.

(b) $p(2) = 0$, and dividing, $p = (x - 2)\big(x^2 - 2x + 2\big) = (x - 2)(x - (1 + i))(x - (1 - i))$. For each root λ let $q = p/(x - \lambda)$; then $q(A)\mathbf{v}$ is an eigenvector for λ.

- $\lambda = 2$: $q = x^2 - 2x + 2$, and $q(A)\mathbf{v} = (0, 2, 4) - 2(1, 1, 2) + 2(1, 0, 1) = (0, 0, 2)$.
- $\lambda = 1 + i$: $q = (x - 2)(x - 1 + i) = x^2 - (3 - i)x + (2 - 2i)$, and

$$q(A)\mathbf{v} = (0, 2, 4) - (3 - i)(1, 1, 2) + (2 - 2i)(1, 0, 1) = (-1 - i, -1 + i, 0) = (-1 + i)(i, 1, 0).$$

- $\lambda = 1 - i$: conjugating the previous computation, since A and $\mathbf{v}$ are real, gives $(-1 + i, -1 - i, 0) = (-1 - i)(-i, 1, 0)$.

Check: $A(0, 0, 1) = 2(0, 0, 1)$ and $A(i, 1, 0) = (i - 1, i + 1, 0) = (1 + i)(i, 1, 0)$.

(c) For $\mathbf{v} = \mathbf{e}_1$: $A\mathbf{e}_1 = (1, 1, 0)$, which is not a multiple of $\mathbf{e}_1$, and $A^2\mathbf{e}_1 = (0, 2, 0) = 2A\mathbf{e}_1 - 2\mathbf{e}_1$. So $d = 2$ and $p = x^2 - 2x + 2$, which produces the eigenvectors $(A - (1 - i)I_3)\mathbf{e}_1 = (i, 1, 0)$ and $(A - (1 + i)I_3)\mathbf{e}_1 = (-i, 1, 0)$ but misses the eigenvalue 2. This is consistent with Proposition 7.3.26: p divides $p_A = (x - 2)\big(x^2 - 2x + 2\big)$, but need not equal it, because $K_A(\mathbf{e}_1) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ is a proper invariant subspace.

Solution to Exercise 7.3.47

Uses. Definition 7.3.4 (Characteristic polynomial), Proposition 7.3.2 (Determinants over a commutative ring), Remark 7.1.11 (Polynomials in a matrix)
Hint 1. What kind of object is each side? $p_A(A)$ is a matrix. What is det(...)?
Hint 2. Proposition 7.3.2(g) lets us substitute A for x in every entry of $xI_n - A$. What does that array look like? Is it the matrix $A - A$?
Hint 3. Apply the same reasoning to the single entry $x - a_{11}$ of $xI_n - A$, instead of to its determinant.
Sketch. The two sides have different types: $p_A(A)$ is a matrix and a determinant is a scalar. Substituting A for x entrywise turns $xI_n - A$ into an $n \times n$ array of matrices, with $A - a_{ii}I_n$ on the diagonal and $-a_{ij}I_n$ elsewhere, not into $A - A = 0$. The same move would show $A = a_{11}I_n$ for every A. The claim is true (Cayley–Hamilton) but needs a real proof.

The claim is true; it is the Cayley–Hamilton theorem (Theorem 7.6.20), and Exercise 7.3.51 proves it. The argument is not a proof.

First, the types do not match: $p_A(A) = A^n + c_{n-1}A^{n-1} + \cdots + c_0 I_n$ is an $n \times n$ matrix, while a determinant is a scalar.

Second, the substitution is done wrongly. The identity $p_A = \det(xI_n - A)$ holds in $F[x]$, and Proposition 7.3.2(g) does allow us to apply a map like "substitute A for x" to it, but entry by entry. The map $q \mapsto q(A)$ takes values in the commutative ring of polynomials in A (Remark 7.1.11), and applied to the entries of $xI_n - A$ it gives the $n \times n$ array whose (i, i) entry is the matrix $A - a_{ii}I_n$ and whose (i, j) entry is the matrix $-a_{ij}I_n$. The determinant of that array, computed in this ring, is indeed $p_A(A)$. But the array is not the zero matrix "$AI_n - A$": the scalar entries a_{ij} became the matrices $a_{ij}I_n$, not the scalars a_{ij}. For $A = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, the array is $\left(\begin{smallmatrix} A & -I_2 \\ 0 & A \end{smallmatrix}\right)$, whose determinant in this ring is $A^2 = 0$, although no entry is 0.

Third, the argument proves too much. Apply the same move to the polynomial $f = x - a_{11}$, the $(1, 1)$ entry of $xI_n - A$: "substituting $x = A$" gives $f(A) = (AI_n - A)_{11} = 0$, that is, $A = a_{11}I_n$ for every A, which is false.

Solution to Exercise 7.3.48

Uses. Proposition 7.3.2 (Determinants over a commutative ring), Theorem 7.1.20 (Factor theorem), Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 7.3.18 (The first and last coefficients), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Corollary 7.1.35 (Factorization over $\mathbb{C}$)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. For (a), multiply out; the sum telescopes.
Hint 2. For (b), take determinants: $p_A g = x^{kn}$ for some $g \in F[x]$. So p_A divides a power of x.
Hint 3. Write $p_A = x^m h$ with $h(0) \neq 0$. Show that h divides 1, by evaluating at 0 and cancelling x repeatedly.
Sketch. (a) Telescoping: $\sum_j x^{k-j}A^j - \sum_j x^{k-1-j}A^{j+1} = x^k I_n - A^k$. (b) Taking determinants, $p_A \cdot g = x^{kn}$. Write $p_A = x^m h$ with $h(0) \neq 0$; cancelling x^m gives $hg = x^{kn-m}$, and evaluating at 0 repeatedly shows that g absorbs every factor x, so $hg' = 1$ and h is a constant, hence 1. So $p_A = x^n$. (c) Over $\mathbb{C}$, every eigenvalue satisfies $\lambda^k = 0$, and p_A splits.

(a) Let $N = \sum_{j=0}^{k-1} x^{k-1-j}A^j$. By Proposition 7.3.2(a), and since the scalar matrices $x^m I_n$ commute with every matrix,

$$(xI_n - A)N = \sum_{j=0}^{k-1} x^{k-j}A^j - \sum_{j=0}^{k-1} x^{k-1-j}A^{j+1} = \sum_{j=0}^{k-1} x^{k-j}A^j - \sum_{j=1}^{k} x^{k-j}A^j = x^k I_n - A^k,$$

which is $x^k I_n$ because $A^k = 0$.

(b) Let $g = \det N \in F[x]$. Taking determinants in (a) with Proposition 7.3.2(c) and (e), $p_A g = \det\left(x^k I_n\right) = x^{kn}$. Since $p_A \neq \mathbf{0}$, write $p_A = x^m h$ with $m \geq 0$ as large as possible, so that x does not divide h, that is, $h(0) \neq 0$ (Theorem 7.1.20). Comparing degrees in $x^m hg = x^{kn}$ gives $m \leq kn$, and cancelling x^m (Corollary 7.1.7(b)) gives $hg = x^{kn-m}$.

We show by induction on $r = kn - m$ that an equation $hg = x^r$ forces h to be a nonzero constant. If $r = 0$, then $hg = 1$, so h is invertible in $F[x]$, hence a nonzero constant (Corollary 7.1.7(c)). If $r \geq 1$, evaluating at 0 gives $h(0)g(0) = 0$, so $g(0) = 0$ and $g = xg_1$ (Theorem 7.1.20). Then $x(hg_1) = x \cdot x^{r-1}$, and cancelling x gives $hg_1 = x^{r-1}$, to which the induction hypothesis applies.

So h is a constant, and $h = 1$ because p_A is monic. Thus $p_A = x^m$, and $m = \deg p_A = n$ (Proposition 7.3.18). The coefficient of x^{n-1} is $0 = -\operatorname{tr} A$, and 0 is the only root.

(c) Over $\mathbb{C}$: if $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{0} = A^k\mathbf{v} = \lambda^k\mathbf{v}$ (Proposition 7.2.28), so $\lambda = 0$. By Corollary 7.1.35, p_A is a product of factors $x - \lambda_j$ whose roots λ_j are eigenvalues, hence 0; so $p_A = x^n$. Over a general field this argument only shows that 0 is the only root of p_A in F; it cannot rule out an irreducible factor of degree at least 2, because p_A need not split. The proof of (b) never needs p_A to split.

Solution to Exercise 7.3.49

Uses. Proposition 7.3.2 (Determinants over a commutative ring), Proposition 7.1.10 (Evaluation respects sums and products), Remark 7.3.19 (Trace and determinant from the roots)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. Factor $x^2 I_n - A^2$ in $F[x]^{n\times n}$.
Hint 2. $\det\left(x^2 I_n - A^2\right)$ is p_{A^2} with x^2 substituted, by Proposition 7.3.2(g). Similarly, what is $\det(xI_n + A)$ in terms of p_A?
Hint 3. For (b), $(x-\lambda)(x+\lambda) = x^2 - \lambda^2$. A polynomial r is determined by $r\left(x^2\right)$.
Sketch. (a) $x^2 I_n - A^2 = (xI_n - A)(xI_n + A)$. Substituting x^2 into $xI_n - A^2$ gives $x^2 I_n - A^2$, so its determinant is $p_{A^2}\left(x^2\right)$; and $\det(xI_n + A) = (-1)^n \det(-xI_n - A) = (-1)^n p_A(-x)$. (b) $(-1)^n p_A(-x) = \prod(x + \lambda_i)$, so the right side is $\prod\left(x^2 - \lambda_i^2\right) = q\left(x^2\right)$ with $q = \prod\left(x - \lambda_i^2\right)$; compare coefficients. (c) $\operatorname{tr}\left(A^2\right) = \sum \lambda_i^2 = 0$ with real λ_i.

(a) In $F[x]^{n\times n}$, $(xI_n - A)(xI_n + A) = x^2 I_n + xA - xA - A^2 = x^2 I_n - A^2$. Substituting x^2 for x respects sums, products, and 1 (Proposition 7.1.10), and applied to every entry of $xI_n - A^2$ it gives $x^2 I_n - A^2$; so by Proposition 7.3.2(g), $\det\left(x^2 I_n - A^2\right) = p_{A^2}\left(x^2\right)$. In the same way, substituting $-x$ into $xI_n - A$ gives $-xI_n - A$, so $\det(-xI_n - A) = p_A(-x)$, and $\det(xI_n + A) = (-1)^n \det(-xI_n - A) = (-1)^n p_A(-x)$ by multilinearity. Taking determinants of the factorization (Proposition 7.3.2(c)) gives $p_{A^2}\left(x^2\right) = p_A(x) \cdot (-1)^n p_A(-x)$.

(b) Substituting $-x$ into the factorization gives $p_A(-x) = \prod_i(-x - \lambda_i) = (-1)^n \prod_i(x + \lambda_i)$. So by (a),

$$p_{A^2}(x^2) = \prod_i (x-\lambda_i)(x+\lambda_i) = \prod_i \left(x^2-\lambda_i^2\right) = q(x^2), \quad q = \prod_i \left(x-\lambda_i^2\right).$$

For any $r = \sum_k r_k x^k$, the coefficient of x^{2k} in $r(x^2) = \sum_k r_k x^{2k}$ is r_k. So $r(x^2) = s(x^2)$ implies $r = s$, and $p_{A^2} = q$.

(c) Let $p_A = \prod(x-\lambda_i)$ with $\lambda_i \in \mathbb{R}$. By (b) and Remark 7.3.19 applied to A^2, $\operatorname{tr}(A^2) = \lambda_1^2 + \cdots + \lambda_n^2$. If this is 0, then every $\lambda_i = 0$, since a sum of squares of reals vanishes only when each term does. So $p_A = x^n$.

Solution to Exercise 7.3.50

Uses. Proposition 7.2.35 (A basis of a Krylov subspace), Proposition 7.3.26 (Krylov subspaces and the characteristic polynomial), Theorem 4.5.25 (Similar matrices are one operator in two bases), Proposition 4.5.24 (Similarity is an equivalence relation), Proposition 7.3.11 (Similar matrices have the same characteristic polynomial), Exercise 7.3.17
Hint 1. For (a), if $K_T(\mathbf{v}) = V$, what is d in Proposition 7.2.35? Then use Proposition 7.3.26.
Hint 2. For (b), both matrices are similar to the same companion matrix.
Hint 3. For (c), C_p has the cyclic vector $\mathbf{e}_1$. For C_p^{T}, try $\mathbf{e}_n$ and show that $\left(C_p^{\mathsf{T}}\right)^j \mathbf{e}_n$ is $\mathbf{e}_{n-j}$ plus a combination of $\mathbf{e}_{n-j+1}, \ldots, \mathbf{e}_n$.
Sketch. (a) $d = n$, and in the basis $\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ the matrix is C_p with $p = p_T$ (Proposition 7.3.26). (b) Both are similar to C_f for $f = p_A = p_B$; the converse is Proposition 7.3.11. (c) $\dim K(\mathbf{v}) \le 1$ for I_2. C_p is cyclic with $\mathbf{e}_1$, C_p^{T} with $\mathbf{e}_n$ (triangular argument), and $p_{C_p} = p_{C_p^{\mathsf{T}}}$.

(a) Let $\mathbf{v}$ be cyclic, so $\mathbf{v} \neq \mathbf{0}$ (as $V \neq \{\mathbf{0}\}$). In Proposition 7.2.35, $d = \dim K_T(\mathbf{v}) = n$, so $\mathbf{v}, T\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is a basis of V, and by Proposition 7.3.26 the matrix of T in it is C_p, with $p_T = p$. So the matrix is C_{p_T}.

(b) If $A \sim B$, then $p_A = p_B$ by Proposition 7.3.11. Conversely, let $f = p_A = p_B$. By (a), T_A has matrix C_f in some basis, so $A \sim C_f$ by Theorem 4.5.25, and likewise $B \sim C_f$. By Proposition 4.5.24, $A \sim B$.

(c) For every $\mathbf{v} \in F^2$, $K_{I_2}(\mathbf{v}) = \operatorname{span}(\mathbf{v})$ has dimension at most 1, so I_2 has no cyclic vector. (Indeed I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ have the same characteristic polynomial and are not similar, so (b) needs the hypothesis.)

Now let $C = C_p$. Since $C^j \mathbf{e}_1 = \mathbf{e}_{j+1}$ for $j < n$, $\mathbf{e}_1$ is cyclic for C. For C^{T}: column j of C^{T} is row j of C, which is $-a_0 \mathbf{e}_n^{\mathsf{T}}$ for $j = 1$ and $\mathbf{e}_{j-1}^{\mathsf{T}} - a_{j-1}\mathbf{e}_n^{\mathsf{T}}$ for $j \ge 2$. So $C^{\mathsf{T}}\mathbf{e}_j = \mathbf{e}_{j-1} - a_{j-1}\mathbf{e}_n$ for $j \ge 2$. By induction on j, $\left(C^{\mathsf{T}}\right)^j \mathbf{e}_n = \mathbf{e}_{n-j} + \mathbf{r}_j$ with $\mathbf{r}_j \in \operatorname{span}(\mathbf{e}_{n-j+1}, \ldots, \mathbf{e}_n)$ for $0 \le j \le n-1$ (with $\mathbf{r}_0 = \mathbf{0}$): applying C^{T} lowers each index by one and adds a multiple of $\mathbf{e}_n$. So $\left(C^{\mathsf{T}}\right)^j \mathbf{e}_n$ has coordinate 1 at $\mathbf{e}_{n-j}$ and coordinate 0 at $\mathbf{e}_1, \ldots, \mathbf{e}_{n-j-1}$. Hence the matrix with columns $\left(C^{\mathsf{T}}\right)^{n-1}\mathbf{e}_n, \ldots, C^{\mathsf{T}}\mathbf{e}_n, \mathbf{e}_n$ is lower triangular with 1's on the diagonal, so these vectors are independent (Proposition 5.3.15, Theorem 5.4.7), and $\mathbf{e}_n$ is cyclic for C^{T}. Since $p_{C^{\mathsf{T}}} = p_C$ (Exercise 7.3.17), (b) shows $C \sim C^{\mathsf{T}}$.

Solution to Exercise 7.3.51

Uses. Proposition 7.3.26 (Krylov subspaces and the characteristic polynomial), Proposition 7.2.27 (Evaluating polynomials at an operator), Proposition 4.1.31 (Every square matrix satisfies a polynomial)
Techniques. Krylov sequences must become dependent (Technique 7.3.28)
Hint 1. It is enough to show $p_T(T)\mathbf{v} = \mathbf{0}$ for each $\mathbf{v}$. Fix $\mathbf{v} \neq \mathbf{0}$ and its Krylov polynomial p.
Hint 2. p divides p_T, so $p_T = gp$. Evaluate at T and apply to $\mathbf{v}$.
Sketch. For $\mathbf{v} \neq \mathbf{0}$ with Krylov polynomial p, $p_T = gp$ by Proposition 7.3.26(c), so $p_T(T)\mathbf{v} = g(T)p(T)\mathbf{v} = \mathbf{0}$. For matrices, apply this to T_A and use $[q(T)] = q([T])$.

(a) Let $\mathbf{v} \in V$. If $\mathbf{v} = \mathbf{0}$, then $p_T(T)\mathbf{v} = \mathbf{0}$. Otherwise let p be the polynomial of Proposition 7.2.35 for $\mathbf{v}$, so $p(T)\mathbf{v} = \mathbf{0}$. By Proposition 7.3.26(c), $p_T = gp$ for some $g \in F[x]$, and by Proposition 7.2.27(a),

$$p_T(T)\mathbf{v} = g(T)(p(T)\mathbf{v}) = g(T)\mathbf{0} = \mathbf{0}.$$

So $p_T(T)$ sends every vector to $\mathbf{0}$, that is, $p_T(T) = 0$.

(b) Apply (a) to T_A on F^n. Its matrix in the standard basis is A, so $p_{T_A} = p_A$, and by Proposition 7.2.27(c), $p_A(A)$ is the matrix of $p_A(T_A) = 0$. So $p_A(A) = 0$, and p_A is monic of degree n.

Solution to Exercise 7.3.52

Uses. Example 7.3.5 (Small cases), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Proposition 7.1.22 (Counting roots)
Techniques. Double counting (Technique 4.1.36)
Hint 1. Write $A = \left(\begin{smallmatrix} a & b \\ c & e \end{smallmatrix}\right)$. The conditions are $a+e=t$ and $ae-bc=d$. Choose a first.
Hint 2. Then $e = t-a$ and $bc = a(t-a)-d = -f(a)$. How many pairs (b,c) have a given product m? Distinguish $m=0$ and $m \neq 0$.
Hint 3. If f has r roots in $\mathbb{F}_q$, the total is $r(2q-1)+(q-r)(q-1) = q(q-1)+rq$.
Sketch. For each a, $e = t-a$ is forced and $bc = -f(a)$; there are $2q-1$ pairs (b,c) if $f(a)=0$ and $q-1$ otherwise. So the count is $q(q-1)+rq$, where $r \in \{0,1,2\}$ is the number of roots. There are $\left(q^2-q\right)/2$ monic quadratics without roots, each realized by q^2-q matrices.

(a) Write $A = \left(\begin{smallmatrix} a & b \\ c & e \end{smallmatrix}\right)$. By Example 7.3.5(a), $p_A = f$ if and only if $a+e=t$ and $ae-bc=d$. Choose $a \in \mathbb{F}_q$ arbitrarily (q ways). Then $e = t-a$ is determined, and the second condition becomes

$$bc = a(t-a)-d = -\left(a^2-ta+d\right) = -f(a).$$

The number of pairs (b,c) with $bc=m$ is $q-1$ if $m \neq 0$ (any $b \neq 0$, and then $c = m/b$), and $2q-1$ if $m=0$ ($b=0$ with c arbitrary, or $b \neq 0$ with $c=0$). So if f has r roots in $\mathbb{F}_q$, the number of matrices is

$$r(2q-1)+(q-r)(q-1) = q(q-1)+rq,$$

which is q^2+q, q^2, q^2-q for $r=2,1,0$.

(b) By Theorem 7.3.6, A has no eigenvalue exactly when p_A has no root. There are q^2 monic quadratics x^2-tx+d. Those with two distinct roots are the products $(x-\alpha)(x-\beta)$ with $\alpha \neq \beta$, and there are $\binom{q}{2} = \left(q^2-q\right)/2$ of them; those with a repeated root are the $(x-\alpha)^2$, and there are q of them (a monic quadratic is determined by its roots, by Proposition 7.1.22 and the factor theorem). So $q^2 - \left(q^2-q\right)/2 - q = \left(q^2-q\right)/2$ have no root. Each is realized by q^2-q matrices, which gives $\left(q^2-q\right)^2/2$ matrices without eigenvalues. The total is

$$\frac{q^2-q}{2}\left(q^2+q\right) + q\cdot q^2 + \frac{q^2-q}{2}\left(q^2-q\right) = \frac{q^2-q}{2}\cdot 2q^2 + q^3 = q^4 - q^3 + q^3 = q^4,$$

as it should be. For $q=2$ the two matrices without eigenvalues are $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$.

Solution to Exercise 7.3.53

Uses. Proposition 7.3.2 (Determinants over a commutative ring), Proposition 7.3.18 (The first and last coefficients)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Column j of $xI_n - A$ is $x\mathbf{e}_j - \mathbf{a}_j$, a sum of two vectors. Expand det by multilinearity in all columns at once.
Hint 2. You get 2^n terms indexed by the set S of columns where $-\mathbf{a}_j$ was chosen. In the term for S, the columns $x\mathbf{e}_j$ with $j \notin S$ have a single nonzero entry. Expand along them.
Sketch. Multilinearity gives $p_A = \sum_S \det M_S$, where column j of M_S is $-\mathbf{a}_j$ for $j \in S$ and $x\mathbf{e}_j$ otherwise. Expanding along the columns $x\mathbf{e}_j$, $j \notin S$, each contributes a factor x and deletes row and column j, leaving $-A_S$. So $\det M_S = x^{n-|S|}(-1)^{|S|}\det A_S$.

Column j of $xI_n - A$ is $x\mathbf{e}_j - \mathbf{a}_j$, where $\mathbf{a}_j$ is column j of A. Expanding by linearity in each of the n columns (Proposition 7.3.2(b), Technique 5.1.7),

$$p_A = \sum_{S \subseteq \{1,\ldots,n\}} \det M_S,$$

where column j of M_S is $-\mathbf{a}_j$ for $j \in S$ and $x\mathbf{e}_j$ for $j \notin S$.

We claim that $\det M_S = x^{n-|S|}\det(-A_S)$ (where $\det\left(-A_\varnothing\right) = 1$), by induction on $n-|S|$. If $S = \{1,\ldots,n\}$, then $M_S = -A$. If $n=1$ and $S=\varnothing$, then $M_S = (x)$ and the claim holds. Otherwise $n \geq 2$; pick $j \notin S$. Column j of M_S is $x\mathbf{e}_j$, with the single nonzero entry x in position (j,j), so cofactor expansion along it (Proposition 7.3.2(f)) gives $\det M_S = x(-1)^{j+j}\det M'$, where M' is M_S with row j and column j deleted. In M', each remaining column $x\mathbf{e}_{j'}$ still has its single entry x on the diagonal, and each column $-\mathbf{a}_{j'}$ has lost its j-th

entry. So M' is the matrix of the same form for the $(n-1)\times(n-1)$ matrix obtained from A by deleting row and column j, with the same set S, and the induction hypothesis applies. Since $\det(-A_S) = (-1)^{|S|}\det A_S$ by multilinearity,

$$p_A = \sum_S (-1)^{|S|}x^{n-|S|}\det A_S = \sum_{k=0}^{n}(-1)^k e_k(A)x^{n-k}.$$

For $k=1$, the principal 1×1 minors are the diagonal entries, so $e_1(A) = \operatorname{tr} A$; for $k=n$, $e_n(A) = \det A$. This matches Proposition 7.3.18. For $n=3$, the coefficient of x is

$$e_2(A) = (a_{11}a_{22}-a_{12}a_{21}) + (a_{11}a_{33}-a_{13}a_{31}) + (a_{22}a_{33}-a_{23}a_{32}).$$

Solution to Exercise 7.3.54

Uses. Proposition 7.3.30 (Odd dimension), Definition 7.2.1 (Invariant subspace), Proposition 7.3.15 (Block-triangular matrices), Proposition 7.2.4 (Invariance is checked on a spanning list)
Hint 1. If U is invariant of odd dimension, then $T{\restriction_U}$ is an operator on an odd-dimensional real space.
Hint 2. For (b), try two copies of the rotation $R_{\pi/2}$. Look for planes spanned by $\mathbf{w}$ and $T\mathbf{w}$.
Sketch. (a) An invariant U of odd dimension gives an eigenvector of $T{\restriction_U}$ (Proposition 7.3.30), which is an eigenvector of T. (b) $T = \begin{pmatrix} R & 0 \\ 0 & R \end{pmatrix}$ with $R = R_{\pi/2}$ has $p_T = \left(x^2+1\right)^2$; for any $\mathbf{w}\neq\mathbf{0}$, $\operatorname{span}(\mathbf{w}, T\mathbf{w})$ is invariant since $T^2 = -\mathrm{id}$.

(a) Let U be T-invariant. If $\dim U = 0$ it is even. If $\dim U$ is odd, then $T{\restriction_U}\in \mathrm{L}(U)$ has an eigenvalue by Proposition 7.3.30: there are $\mathbf{u}\in U$, $\mathbf{u}\neq\mathbf{0}$, and $\lambda\in\mathbb{R}$ with $T\mathbf{u} = \lambda\mathbf{u}$. Then λ is an eigenvalue of T, a contradiction.

(b) Let $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ and $T = \begin{pmatrix} R & 0 \\ 0 & R \end{pmatrix}$ on $\mathbb{R}^4$. By Proposition 7.3.15, $p_T = \left(x^2+1\right)^2$, which has no real root, so T has no eigenvalue. Since $R^2 = -I_2$, $T^2 = -I_4$. So for every $\mathbf{w}\neq\mathbf{0}$, $T(T\mathbf{w}) = -\mathbf{w}$, and $\operatorname{span}(\mathbf{w}, T\mathbf{w})$ is T-invariant (Proposition 7.2.4); it is a plane by (a). Three different ones: $\mathbf{w} = \mathbf{e}_1$ gives $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$; $\mathbf{w} = \mathbf{e}_3$ gives $\operatorname{span}(\mathbf{e}_3, \mathbf{e}_4)$; and $\mathbf{w} = \mathbf{e}_1 + \mathbf{e}_3$ gives $\operatorname{span}(\mathbf{e}_1+\mathbf{e}_3, \mathbf{e}_2+\mathbf{e}_4)$, which contains neither $\mathbf{e}_1$ nor $\mathbf{e}_3$.

Solution to Exercise 7.3.55

Uses. Corollary 7.2.22 (At most $\dim V$ eigenvalues), Exercise 7.3.48, Definition 7.2.6 (Eigenvalue, eigenvector)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29)
Hint 1. For (a), induct on k: write $A^{k+1}B - BA^{k+1} = A\left(A^kB - BA^k\right) + (AB-BA)A^k$.
Hint 2. For (b), consider the linear map $L(X) = XB - BX$ on $\mathbb{C}^{n\times n}$. What does (a) say about $L\left(A^k\right)$?
Hint 3. An operator on an n^2-dimensional space has at most n^2 eigenvalues, but $1, 2, 3, \ldots$ are infinitely many.
Sketch. (a) $A^{k+1}B - BA^{k+1} = A\left(A^kB - BA^k\right) + (AB-BA)A^k = kA^{k+1} + A^{k+1}$. (b) With $L(X) = XB - BX$, $L\left(A^k\right) = kA^k$, so if $A^k\neq 0$ then k is an eigenvalue of L. L has at most n^2 eigenvalues, so $A^k = 0$ for some $k\leq n^2+1$. (c) Exercise 7.3.48.

(a) For $k=1$ this is the hypothesis. If it holds for k, then

$$A^{k+1}B - BA^{k+1} = A\left(A^kB - BA^k\right) + (AB-BA)A^k = A\left(kA^k\right) + A\cdot A^k = (k+1)A^{k+1},$$

where the first equality holds because the terms $-ABA^k$ and $+ABA^k$ cancel.

(b) Let $L:\mathbb{C}^{n\times n}\to\mathbb{C}^{n\times n}$, $L(X) = XB - BX$. It is linear, and (a) says $L\left(A^k\right) = kA^k$. If $A^k\neq 0$, then k is an eigenvalue of L (Definition 7.2.6). By Corollary 7.2.22, L has at most n^2 eigenvalues, and $1, 2, \ldots, n^2+1$ are n^2+1 distinct complex numbers. So $A^k = 0$ for some $k\leq n^2+1$.

(c) By (b) and Exercise 7.3.48, $p_A = x^n$. The proof used that the integers $1, 2, 3, \ldots$ are distinct in $\mathbb{C}$; over $\mathbb{F}_p$ the scalars k repeat, and (b) breaks down.

Section 7.4

Solution to Exercise 7.4.10

Uses. Corollary 7.4.5 (Distinct eigenvalues give a diagonalization), Proposition 7.4.7 (One eigenvalue), Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 5.3.15 (Triangular matrices)
Hint 1. Find the eigenvalues from $\det(A-\lambda I) = 0$. Triangular matrices show them on the diagonal.

Hint 2. Distinct eigenvalues settle the question at once. A matrix with a single eigenvalue is diagonalizable only if it is a scalar matrix.
Sketch. A_1 has distinct eigenvalues $1, 2$: diagonalizable over both fields. A_2 has only the eigenvalue 2 and is not $2I_2$: diagonalizable over neither. A_3 has $\det(A_3 - \lambda I) = \lambda^2 + 1$: no real eigenvalues, so not over $\mathbb{R}$; distinct eigenvalues $\pm i$ over $\mathbb{C}$. $A_4 = 7I_3$ is already diagonal.

The matrices A_1 and A_2 are upper triangular, so $A - \lambda I$ is triangular with diagonal entries $a_{ii} - \lambda$, and by Proposition 5.3.15 and Theorem 7.2.9 the eigenvalues are the diagonal entries. For A_1 they are 1 and 2, which are distinct, so A_1 is diagonalizable over $\mathbb{R}$, and over $\mathbb{C}$, by Corollary 7.4.5. For A_2 the only eigenvalue is 2, over either field, and $A_2 \neq 2I_2$, so A_2 is diagonalizable over neither field (Proposition 7.4.7).

For A_3, $\det(A_3 - \lambda I_2) = (1 - \lambda)(-1 - \lambda) + 2 = \lambda^2 + 1$. Over $\mathbb{R}$ it never vanishes, so A_3 has no eigenvalues and no eigenvectors, and is not diagonalizable. Over $\mathbb{C}$ it has the two distinct eigenvalues i and $-i$, so A_3 is diagonalizable over $\mathbb{C}$.

Finally $A_4 = 7I_3$ is diagonal, so it is diagonalizable over both fields (take $S = I_3$), even though it has only one eigenvalue.

Solution to Exercise 7.4.21

Uses. Definition 7.4.11 (Algebraic multiplicity), Lemma 7.4.13 (Geometric multiplicity through a rank), Theorem 7.4.16 (Criteria for diagonalizability), Proposition 5.3.15 (Triangular matrices)
Hint 1. A is upper triangular, so p_A can be read off the diagonal.
Hint 2. For $\mathrm{gm}(2)$, compute the rank of $A - 2I_4$.
Sketch. $p_A = (x-2)^3(x-3)$, so $\mathrm{am}(2) = 3$ and $\mathrm{am}(3) = 1$. $A - 2I_4$ has rank 2 (columns $\mathbf{e}_1$ and $\mathbf{e}_4$), so $\mathrm{gm}(2) = 2 < 3$: not diagonalizable. Changing $a_{12} = 1$ to 0 makes A diagonal. Any other change above the diagonal keeps A triangular, so $\mathrm{am}(2) = 3$, and keeps columns 2 and 4 of $A - 2I_4$ independent.

The matrix $xI_4 - A$ is upper triangular with diagonal $x-2, x-2, x-2, x-3$, so $p_A = (x-2)^3(x-3)$ by Proposition 5.3.15. Hence the eigenvalues are 2 and 3, with $\mathrm{am}(2) = 3$ and $\mathrm{am}(3) = 1$. Next,

$$A - 2I_4 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

has rank 2, so $\mathrm{gm}(2) = 4 - 2 = 2$ by Lemma 7.4.13, and $1 \leq \mathrm{gm}(3) \leq \mathrm{am}(3) = 1$ gives $\mathrm{gm}(3) = 1$. Since $\mathrm{gm}(2) = 2 \neq 3 = \mathrm{am}(2)$, A is not diagonalizable (Theorem 7.4.16); equivalently, $\mathrm{gm}(2) + \mathrm{gm}(3) = 3 < 4$.

The only nonzero off-diagonal entry is $a_{12} = 1$, and replacing it by 0 gives a diagonal matrix. Changing any other entry above the diagonal keeps A upper triangular with the same diagonal, so still $p_A = (x-2)^3(x-3)$ and $\mathrm{am}(2) = 3$. It also keeps $a_{12} = 1$, and column 2 of $A - 2I_4$ is still $\mathbf{e}_1$ (the only entry above the diagonal in column 2 is a_{12}), while column 4 still has last entry 1. These two columns are independent, so the rank stays at least 2, $\mathrm{gm}(2) \leq 2 < 3$, and the matrix stays non-diagonalizable.

Below the diagonal the answer is different, because the characteristic polynomial can change. Setting $a_{21} = 1$ makes the top left block $\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$, with eigenvalues 1 and 3 (Example 7.2.8); the new matrix has the eigenvalues $1, 3, 2, 3$ and is diagonalizable, as one checks with Theorem 7.4.16.

Solution to Exercise 7.4.27

Uses. Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix), Proposition 2.4.23 (Transpose of a product), Definition 7.4.1 (Diagonalizable), Theorem 7.4.16 (Criteria for diagonalizability)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. Write $A = SDS^{-1}$ and apply Proposition 7.4.23.
Hint 2. For the transpose, transpose the factorization; the inverse of S^{T} is $\left(S^{-1}\right)^{\mathsf{T}}$.
Sketch. $p(A) = Sp(D)S^{-1}$ with $p(D)$ diagonal; $A^{-1} = SD^{-1}S^{-1}$; $A^{\mathsf{T}} = \left(S^{-1}\right)^{\mathsf{T}} DS^{\mathsf{T}} = RDR^{-1}$ with $R = \left(S^{-1}\right)^{\mathsf{T}}$. The eigenvalues of $p(A)$ are the diagonal entries $p(\lambda_i)$ of $p(D)$.

Write $A = SDS^{-1}$ with $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$. By Proposition 7.4.23, $p(A) = S\operatorname{diag}(p(\lambda_1), \ldots, p(\lambda_n))S^{-1}$, which is a diagonalization of $p(A)$. If A is invertible, every λ_i is nonzero (otherwise D, and with it $A = SDS^{-1}$, would not be invertible), and Proposition 7.4.23 gives $A^{-1} = S\operatorname{diag}\left(\lambda_1^{-1}, \ldots, \lambda_n^{-1}\right)S^{-1}$. For the transpose, Proposition 2.4.23 gives

$$A^{\mathsf{T}} = \left(S^{-1}\right)^{\mathsf{T}} D^{\mathsf{T}} S^{\mathsf{T}} = RDR^{-1}, \quad R = \left(S^{-1}\right)^{\mathsf{T}},$$

since $D^{\mathsf{T}} = D$ and $RS^{\mathsf{T}} = \left(SS^{-1}\right)^{\mathsf{T}} = I_n$, and similarly $S^{\mathsf{T}}R = I_n$.

By the last part of Theorem 7.4.16, the eigenvalues of a diagonalizable matrix are its diagonal entries in any diagonalization. So the eigenvalues of $p(A)$ are $p(\lambda_1), \ldots, p(\lambda_n)$, that is, the values $p(\lambda)$ for the eigenvalues λ of A. Distinct eigenvalues of A can have the same image: for $p = x^2$ and $A = \operatorname{diag}(1, -1)$, $p(A) = I_2$.

Solution to Exercise 7.4.35

Uses. Algorithm 7.4.18 (Diagonalizing a matrix), Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 7.4.7 (One eigenvalue)
Hint 1. Follow Algorithm 7.4.18: find the eigenvalues from $\det(A - \lambda I) = 0$, then a basis of each eigenspace.
Hint 2. In (b) there is only one eigenvalue. In (c), A swaps $\mathbf{e}_1$ and $\mathbf{e}_3$ and fixes $\mathbf{e}_2$; guess the eigenvectors.
Sketch. (a) $(\lambda - 4)(\lambda + 1)$; $E_4 = \operatorname{span}((2, 3))$, $E_{-1} = \operatorname{span}((1, -1))$; $S = \begin{pmatrix} 2 & 1 \\ 3 & -1 \end{pmatrix}$, $D = \operatorname{diag}(4, -1)$. (b) $(\lambda - 2)^2$, and $A \neq 2I$: not diagonalizable. (c) $E_1 = \operatorname{span}(\mathbf{e}_2, \mathbf{e}_1 + \mathbf{e}_3)$, $E_{-1} = \operatorname{span}(\mathbf{e}_1 - \mathbf{e}_3)$.

(a) $\det(A - \lambda I_2) = (1 - \lambda)(2 - \lambda) - 6 = \lambda^2 - 3\lambda - 4 = (\lambda - 4)(\lambda + 1)$. Then $A - 4I_2 = \begin{pmatrix} -3 & 2 \\ 3 & -2 \end{pmatrix}$ has kernel $\operatorname{span}((2, 3))$, and $A + I_2 = \begin{pmatrix} 2 & 2 \\ 3 & 3 \end{pmatrix}$ has kernel $\operatorname{span}((1, -1))$. The eigenvalues are distinct, so

$$S = \begin{pmatrix} 2 & 1 \\ 3 & -1 \end{pmatrix}, \quad D = \begin{pmatrix} 4 & 0 \\ 0 & -1 \end{pmatrix}.$$

Check: $AS = \begin{pmatrix} 8 & -1 \\ 12 & 1 \end{pmatrix} = SD$.

(b) $\det(A - \lambda I_2) = (3 - \lambda)(1 - \lambda) + 1 = \lambda^2 - 4\lambda + 4 = (\lambda - 2)^2$, so 2 is the only eigenvalue. Since $A \neq 2I_2$, A is not diagonalizable (Proposition 7.4.7). Indeed $A - 2I_2 = \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}$ has rank 1, so $E_2 = \operatorname{span}((1, -1))$ is a line.

(c) $A(x, y, z) = (z, y, x)$. The vectors $\mathbf{e}_2$ and $\mathbf{e}_1 + \mathbf{e}_3$ are fixed, and $A(\mathbf{e}_1 - \mathbf{e}_3) = \mathbf{e}_3 - \mathbf{e}_1$. The matrix S below, whose columns are these three vectors, has determinant 2 (expand along its second row), so they form an eigenbasis and

$$S = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & -1 \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

To see that nothing was missed, $\det(A - \lambda I_3) = (1 - \lambda)\left(\lambda^2 - 1\right) = -(\lambda - 1)^2(\lambda + 1)$ by cofactor expansion along the middle row, and $\operatorname{gm}(1) = 2 = \operatorname{am}(1)$.

Solution to Exercise 7.4.36

Uses. Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22), Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Diagonalize: the eigenvalues are 1 and 2.
Hint 2. For (b), any B with $B^2 = A$ commutes with A. What does that say about the eigenlines of A?
Hint 3. B preserves each eigenline of A, so it is diagonal in the eigenbasis: $S^{-1}BS = \operatorname{diag}(\beta_1, \beta_2)$ with $\beta_1^2 = 1$, $\beta_2^2 = 2$.
Sketch. $A = S\operatorname{diag}(1, 2)S^{-1}$ with $S = \begin{pmatrix} 5 & 2 \\ 3 & 1 \end{pmatrix}$, $S^{-1} = \begin{pmatrix} -1 & 2 \\ 3 & -5 \end{pmatrix}$, so $A^k = \begin{pmatrix} 6 \cdot 2^k - 5 & 10 - 10 \cdot 2^k \\ 3 \cdot 2^k - 3 & 6 - 5 \cdot 2^k \end{pmatrix}$. A square root B commutes with A, so it preserves the eigenlines E_1, E_2 and is diagonal in the eigenbasis with entries $\pm 1, \pm\sqrt{2}$: exactly four square roots.

(a) $\det(A-\lambda I_2) = (7-\lambda)(-4-\lambda)+30 = \lambda^2-3\lambda+2 = (\lambda-1)(\lambda-2)$. Then $A - I_2 = \begin{pmatrix} 6 & -10 \\ 3 & -5 \end{pmatrix}$ has kernel $\operatorname{span}((5,3))$, and $A - 2I_2 = \begin{pmatrix} 5 & -10 \\ 3 & -6 \end{pmatrix}$ has kernel $\operatorname{span}((2,1))$. So $A = SDS^{-1}$ with

$$S = \begin{pmatrix} 5 & 2 \\ 3 & 1 \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}, \quad S^{-1} = \begin{pmatrix} -1 & 2 \\ 3 & -5 \end{pmatrix},$$

and both eigenvalues are nonzero, so by Proposition 7.4.23, for every $k \in \mathbb{Z}$,

$$A^k = \begin{pmatrix} 5 & 2\cdot 2^k \\ 3 & 2^k \end{pmatrix}\begin{pmatrix} -1 & 2 \\ 3 & -5 \end{pmatrix} = \begin{pmatrix} 6\cdot 2^k - 5 & 10 - 10\cdot 2^k \\ 3\cdot 2^k - 3 & 6 - 5\cdot 2^k \end{pmatrix}.$$

At $k = 1$ this is A, and at $k = -1$ it is $\begin{pmatrix} -2 & 5 \\ -3/2 & 7/2 \end{pmatrix}$, which one checks is A^{-1}.

(b) Let $\mathbf{s}_1 = (5,3)$ and $\mathbf{s}_2 = (2,1)$. If $B^2 = A$, then $BA = B^3 = AB$. By Proposition 7.2.30(b), each eigenspace $E_1(A) = \operatorname{span}(\mathbf{s}_1)$ and $E_2(A) = \operatorname{span}(\mathbf{s}_2)$ is B-invariant, so by Proposition 7.2.7, $B\mathbf{s}_1 = \beta_1\mathbf{s}_1$ and $B\mathbf{s}_2 = \beta_2\mathbf{s}_2$ for some $\beta_1, \beta_2 \in \mathbb{R}$. Then $A\mathbf{s}_j = B^2\mathbf{s}_j = \beta_j^2\mathbf{s}_j$, so $\beta_1^2 = 1$ and $\beta_2^2 = 2$. By Theorem 7.4.2, $B = S\operatorname{diag}(\beta_1,\beta_2)S^{-1}$ with $\beta_1 = \pm 1$ and $\beta_2 = \pm\sqrt{2}$. Conversely each of these four matrices squares to $S\operatorname{diag}(1,2)S^{-1} = A$. So A has exactly four real square roots; for $\beta_1 = 1$, $\beta_2 = \sqrt{2}$,

$$B = \begin{pmatrix} 5 & 2\sqrt{2} \\ 3 & \sqrt{2} \end{pmatrix}\begin{pmatrix} -1 & 2 \\ 3 & -5 \end{pmatrix} = \begin{pmatrix} 6\sqrt{2} - 5 & 10 - 10\sqrt{2} \\ 3\sqrt{2} - 3 & 6 - 5\sqrt{2} \end{pmatrix},$$

and the four square roots are $S\operatorname{diag}(\beta_1,\beta_2)S^{-1}$ with $(\beta_1,\beta_2) \in \{\pm 1\} \times \{\pm\sqrt{2}\}$, namely B, $-B$, and the matrices obtained from B and $-B$ by replacing $\sqrt{2}$ with $-\sqrt{2}$.

Solution to Exercise 7.4.37

Uses. Theorem 7.4.16 (Criteria for diagonalizability), Lemma 7.4.13 (Geometric multiplicity through a rank), Theorem 7.4.15 (Geometric multiplicity is at most algebraic multiplicity), Proposition 5.3.15 (Triangular matrices)
Hint 1. The characteristic polynomial does not depend on a, b, c. Which eigenvalue could cause trouble?
Hint 2. Compute $\operatorname{gm}(1) = 3 - \operatorname{rank}(A - I_3)$ as a function of a, b, c.
Sketch. $p_A = (x-1)^2(x-2)$, so A is diagonalizable iff $\operatorname{gm}(1) = 2$, iff $\operatorname{rank}(A - I_3) = 1$. The rows of $A - I_3$ are $(0,a,b)$, $(0,0,c)$, $(0,0,1)$; the last is nonzero and the first is independent of it iff $a \neq 0$. So A is diagonalizable iff $a = 0$, for all b, c.

A is upper triangular, so $p_A = (x-1)^2(x-2)$ (Proposition 5.3.15), which splits, with $\operatorname{am}(1) = 2$ and $\operatorname{am}(2) = 1$. Since $1 \leq \operatorname{gm}(2) \leq \operatorname{am}(2) = 1$ (Theorem 7.4.15), $\operatorname{gm}(2) = 1$ always. By Theorem 7.4.16, A is diagonalizable if and only if $\operatorname{gm}(1) = 2$, that is, $\operatorname{rank}(A - I_3) = 1$ (Lemma 7.4.13). The rows of

$$A - I_3 = \begin{pmatrix} 0 & a & b \\ 0 & 0 & c \\ 0 & 0 & 1 \end{pmatrix}$$

are $(0,a,b)$, $(0,0,c)$, $(0,0,1)$. The second is a multiple of the third, so the rank is the rank of $(0,a,b)$, $(0,0,1)$, which is 2 if $a \neq 0$ and 1 if $a = 0$. So A is diagonalizable if and only if $a = 0$, whatever b and c are. The entries b and c couple the eigenvalue 1 to the eigenvalue 2, which does no harm because the two eigenvalues are different; the entry a couples the eigenvalue 1 to itself, as in a shear.

Solution to Exercise 7.4.38

Uses. Example 7.4.8 (Shears and nilpotent matrices), Proposition 7.4.7 (One eigenvalue), Proposition 4.5.24 (Similarity is an equivalence relation), Corollary 7.4.5 (Distinct eigenvalues give a diagonalization)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. The shear and the nilpotent matrix $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ are the usual suspects.
Hint 2. For (d), look for two diagonalizable matrices whose sum is N. For (e), similarity is transitive.
Sketch. (a) False: 0. (b) False: the shear. (c) False: $N^2 = 0$ is diagonal, N is not diagonalizable. (d) False: $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} -1 & 0 \\ 0 & 0 \end{pmatrix} = N$. (e) True: $B \sim A \sim D$.

The counterexamples below are 2×2. For $n > 2$, enlarge each to a block diagonal matrix by adding the block I_{n-2} in (b) and a zero block in (c) and (d). A block diagonal matrix with diagonalizable blocks is diagonalizable (combine eigenbases of the blocks), the enlarged shear still has 1 as its only eigenvalue without being I_n, and the enlarged nilpotent matrices are still nilpotent and nonzero.

(a) False: the zero matrix is diagonal, so diagonalizable, but not invertible.

(b) False: the shear $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ is invertible but not diagonalizable (Example 7.4.8).

(c) False: $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has $N^2 = 0$, which is diagonal, while N is nonzero and nilpotent, so not diagonalizable (Example 7.4.8).

(d) False: $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ has the distinct eigenvalues 1 and 0 (it is triangular), so it is diagonalizable (Corollary 7.4.5), and $\begin{pmatrix} -1 & 0 \\ 0 & 0 \end{pmatrix}$ is diagonal; their sum is N.

(e) True: if A is similar to a diagonal D and B is similar to A, then B is similar to D by transitivity (Proposition 4.5.24).

Solution to Exercise 7.4.39

> *Uses.* Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Example 7.4.8 (Shears and nilpotent matrices)
> *Hint 1.* The λ_i in the factorization need not be distinct. What does Theorem 7.2.21 assume?
> *Hint 2.* Run the argument on the shear $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.
> *Sketch.* The roots λ_i are listed with multiplicity, so they can repeat, and Theorem 7.2.21 only applies to distinct eigenvalues. For the shear, $\lambda_1 = \lambda_2 = 1$, and any two eigenvectors are multiples of $\mathbf{e}_1$. The argument proves only that matrices with n distinct eigenvalues are diagonalizable.

The factorization lists the roots with multiplicity, so the λ_i need not be distinct, while Theorem 7.2.21 applies only to eigenvectors for pairwise distinct eigenvalues. When $\lambda_i = \lambda_j$ for some $i \neq j$, nothing prevents $\mathbf{v}_j$ from being a multiple of $\mathbf{v}_i$, and then the list is dependent. For the shear $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, $p_J = (x-1)^2$, so $\lambda_1 = \lambda_2 = 1$, and every eigenvector is a multiple of $\mathbf{e}_1$; no choice of $\mathbf{v}_1, \mathbf{v}_2$ is independent, and J is not diagonalizable (Example 7.4.8). The argument is correct when the λ_i are distinct, and then it is the proof of Corollary 7.4.5.

Solution to Exercise 7.4.40

> *Uses.* Proposition 4.3.16 (Rank-one matrices), Example 4.3.18 (Powers of a rank-one matrix), Theorem 4.2.11 (Rank–nullity), Corollary 7.2.23 (Eigenspaces are independent), Theorem 7.4.16 (Criteria for diagonalizability), Example 7.4.8 (Shears and nilpotent matrices)
> *Techniques.* Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
> *Hint 1.* Write $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$. Compute $A\mathbf{u}$, and recall $\mathbf{v}^{\mathsf{T}}\mathbf{u} = \operatorname{tr} A$.
> *Hint 2.* $\operatorname{gm}(0) = \dim \ker A = n - 1$. If $\operatorname{tr} A \neq 0$, you have one more eigenvector. If $\operatorname{tr} A = 0$, compute A^2.
> *Sketch.* $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{v}^{\mathsf{T}}\mathbf{u} = \operatorname{tr} A$, so $A\mathbf{u} = (\operatorname{tr} A)\mathbf{u}$, and $\operatorname{gm}(0) = n - 1$. If $\operatorname{tr} A \neq 0$, then $\operatorname{gm}(0) + \operatorname{gm}(\operatorname{tr} A) \geq n$: diagonalizable, with $D = \operatorname{diag}(\operatorname{tr} A, 0, \ldots, 0)$. If $\operatorname{tr} A = 0$, $A^2 = (\operatorname{tr} A)A = 0$ and $A \neq 0$: nilpotent, not diagonalizable.

By Proposition 4.3.16, $A = \mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u}, \mathbf{v}$ nonzero, and $\mathbf{v}^{\mathsf{T}}\mathbf{u} = \operatorname{tr} A$ (Example 4.3.18). Then

$$A\mathbf{u} = \mathbf{u}\left(\mathbf{v}^{\mathsf{T}}\mathbf{u}\right) = (\operatorname{tr} A)\mathbf{u}.$$

By rank–nullity, $\operatorname{gm}_A(0) = \dim \ker A = n - 1$.

Suppose $\operatorname{tr} A \neq 0$. Then $\mathbf{u} \neq \mathbf{0}$ is an eigenvector with the nonzero eigenvalue $\operatorname{tr} A$, so $\operatorname{gm}(0) + \operatorname{gm}(\operatorname{tr} A) \geq (n-1) + 1 = n$. By Corollary 7.2.23 the sum of all geometric multiplicities is at most n, so it equals n, and A is diagonalizable by Theorem 7.4.16, (III) $\Rightarrow$ (I). An eigenbasis is $\mathbf{u}$ followed by a basis of $\ker A$, so A is similar to $\operatorname{diag}(\operatorname{tr} A, 0, \ldots, 0)$.

Suppose $\operatorname{tr} A = 0$. Then $A^2 = (\operatorname{tr} A)A = 0$ (Example 4.3.18), and $A \neq 0$, so A is a nonzero nilpotent matrix, which is not diagonalizable (Example 7.4.8).

Solution to Exercise 7.4.41

Uses. Example 7.2.17 (Reflections, and the field $\mathbb{F}_2$), Theorem 7.4.16 (Criteria for diagonalizability), Proposition 7.4.7 (One eigenvalue), Example 4.5.31 (The trace of transposition)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29)
Hint 1. $\tau^2 = \mathrm{id}$, so every eigenvalue satisfies $\lambda^2 = 1$ (Example 7.2.17). What are E_1 and E_{-1}?
Hint 2. E_1 is the space of symmetric matrices and E_{-1} the space of skew-symmetric ones. Count their dimensions when $1 + 1 \neq 0$; when $1 + 1 = 0$, there is only one eigenvalue.
Sketch. Eigenvalues satisfy $\lambda^2 = 1$. If $1 + 1 \neq 0$: E_1 (symmetric, dimension $n(n+1)/2$) and E_{-1} (skew-symmetric, with zero diagonal, dimension $n(n-1)/2$) have dimensions adding up to n^2. If $1 + 1 = 0$: $1 = -1$ is the only eigenvalue and $\tau \neq \mathrm{id}$ since $n \geq 2$.

Since $\tau^2 = \mathrm{id}$, every eigenvalue of τ satisfies $\lambda^2 = 1$, so $\lambda = \pm 1$ (Example 7.2.17). The eigenspace E_1 is the space of symmetric matrices, $X^\mathsf{T} = X$, and E_{-1} is the space of skew-symmetric matrices, $X^\mathsf{T} = -X$.

Suppose $1 + 1 \neq 0$. A symmetric matrix is determined by its entries x_{ij} with $i \leq j$, which are arbitrary, so $\dim E_1 = n(n+1)/2$; a basis is U_{ii} and $U_{ij} + U_{ji}$ for $i < j$. A skew-symmetric matrix has $x_{ii} = -x_{ii}$, so $(1+1)x_{ii} = 0$ and $x_{ii} = 0$; it is determined by its entries with $i < j$, which are arbitrary, so $\dim E_{-1} = n(n-1)/2$, with basis $U_{ij} - U_{ji}$ for $i < j$. Since $n(n+1)/2 + n(n-1)/2 = n^2 = \dim F^{n\times n}$, τ is diagonalizable by Theorem 7.4.16, with $\mathrm{gm}(1) = n(n+1)/2$ and $\mathrm{gm}(-1) = n(n-1)/2$. (This recovers $\operatorname{tr}\tau = n$ from Example 4.5.31.)

Suppose $1 + 1 = 0$. Then $-1 = 1$, so 1 is the only eigenvalue of τ. Since $n \geq 2$, $\tau(U_{12}) = U_{21} \neq U_{12}$, so $\tau \neq \mathrm{id}$, and τ is not diagonalizable by Proposition 7.4.7.

Solution to Exercise 7.4.42

Uses. Theorem 7.4.16 (Criteria for diagonalizability), Theorem 4.4.7 (Criteria for direct sums), Theorem 4.2.11 (Rank–nullity), Theorem 4.4.19 (Dimension of a sum)
Hint 1. Split an eigenbasis into the vectors with eigenvalue 0 and the others. Where do the others lie?
Hint 2. If $T\mathbf{b} = \lambda\mathbf{b}$ with $\lambda \neq 0$, then $\mathbf{b} = T\left(\lambda^{-1}\mathbf{b}\right) \in \operatorname{im} T$.
Hint 3. For (b), invertible operators have $\ker T = \{\mathbf{0}\}$ and $\operatorname{im} T = V$.
Sketch. In an eigenbasis, the vectors with eigenvalue 0 span $\ker T = E_0$ and the others lie in $\operatorname{im} T$, since $\mathbf{b} = T\left(\lambda^{-1}\mathbf{b}\right)$. So $\ker T + \operatorname{im} T = V$, and rank–nullity forces the sum to be direct. (b) The invertible shear; and $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, with $\ker N = \operatorname{im} N = \operatorname{span}(\mathbf{e}_1)$.

(a) Let $\mathcal{B}$ be an eigenbasis, and split it into the vectors with eigenvalue 0 and the vectors $\mathbf{b}$ with eigenvalue $\lambda \neq 0$. The former lie in $\ker T$. For the latter, $\mathbf{b} = \lambda^{-1}T\mathbf{b} = T\left(\lambda^{-1}\mathbf{b}\right) \in \operatorname{im} T$. So the subspace $\ker T + \operatorname{im} T$ contains the basis $\mathcal{B}$, and $\ker T + \operatorname{im} T = V$. By Theorem 4.4.19 and rank–nullity,

$$\dim(\ker T \cap \operatorname{im} T) = \dim \ker T + \dim \operatorname{im} T - \dim V = 0,$$

so $\ker T \cap \operatorname{im} T = \{\mathbf{0}\}$, and the sum is direct (Theorem 4.4.7).

(b) The shear $J = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ is invertible, so $\ker T_J = \{\mathbf{0}\}$ and $\operatorname{im} T_J = F^2$, and $F^2 = \{\mathbf{0}\} \oplus F^2$; but J is not diagonalizable. For the second, $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ has $\ker N = \operatorname{span}(\mathbf{e}_1) = \operatorname{im} N$.

Solution to Exercise 7.4.43

Uses. Theorem 7.4.16 (Criteria for diagonalizability), Example 7.4.14 (The multiplicities of a diagonal matrix), Proposition 7.1.34 (Roots of a split polynomial), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Proposition 4.5.24 (Similarity is an equivalence relation), Lemma 7.4.13 (Geometric multiplicity through a rank), Example 7.4.8 (Shears and nilpotent matrices)
Techniques. Rule out similarity with an invariant (Technique 4.5.29)
Hint 1. Similar matrices have the same characteristic polynomial (Section 7.3). For the converse, what does p_A say about the diagonal matrix D in $A = SDS^{-1}$?
Hint 2. $p_A = p_D = \prod(x - d_i)$, and the d_i are determined by p_A up to order (Proposition 7.1.34).
Sketch. If $A = SDS^{-1}$ and $B = RER^{-1}$, then $p_A = p_D$ and $p_B = p_E$, and p_D determines the diagonal of D up to order. So $p_A = p_B$ gives $E = P^{-1}DP$ for a permutation matrix P, and $A \sim D \sim E \sim B$. (b) I_2 and the shear both have characteristic polynomial $(x-1)^2$.

(a) Similar matrices have the same characteristic polynomial (Section 7.3), which proves "only if". Conversely, let $A = SDS^{-1}$ and $B = RER^{-1}$ with D, E diagonal, and suppose $p_A = p_B$. Since similar matrices have equal characteristic polynomials, $p_D = p_A = p_B = p_E$. By Example 7.4.14, $p_D = \prod_i (x - d_{ii})$, and by Proposition 7.1.34 each λ occurs on the diagonal of D as many times as its multiplicity as a root of p_D; likewise for E. So the diagonal of E is a rearrangement of the diagonal of D. Rearrange the columns of S in the same way, obtaining an invertible S' whose j-th column is an eigenvector of A with eigenvalue e_{jj}. By Theorem 7.4.2, $A = S'ES'^{-1}$. Hence $A \sim E \sim B$, and $A \sim B$ by Proposition 4.5.24.

(b) I_2 is diagonal and the shear $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ is not diagonalizable, and $p_{I_2} = p_J = (x-1)^2$. They are not similar, since the only matrix similar to I_2 is I_2. (Alternatively, $\mathrm{gm}_{I_2}(1) = 2 \neq 1 = \mathrm{gm}_J(1)$, by Lemma 7.4.13.)

Solution to Exercise 7.4.44

> *Uses.* Example 7.4.20 (The Fibonacci matrix over several fields), Theorem 7.4.30 (Recurrences with distinct characteristic roots), Exercise 1.1.51
> *Techniques.* Diagonalize, solve, conjugate back (Technique 7.4.22)
> *Hint 1.* Over $\mathbb{F}_{11}$, $x^2 - x - 1$ has the distinct roots 8 and 4. By Theorem 7.4.30, $f_k = a8^k + b4^k$; find a, b from f_0, f_1.
> *Hint 2.* For (b), Fermat's little theorem (Exercise 1.1.51) gives $8^{10} = 4^{10} = 1$.
> *Sketch.* The roots of $x^2 - x - 1$ in $\mathbb{F}_{11}$ are 8 and 4. With $f_k = a8^k + b4^k$, $f_0 = 0$ gives $b = -a$, and $f_1 = 1$ gives $4a = 1$, so $a = 3$. Since $8^{10} = 4^{10} = 1$, $f_{k+10} = f_k$.

(a) In $\mathbb{F}_{11}$, $x^2 - x - 1 = (x-4)(x+3) = (x-4)(x-8)$ (Example 7.4.20), with distinct roots 8 and 4. By Theorem 7.4.30, applied with $k = 2$ and $c_0 = c_1 = 1$ over $F = \mathbb{F}_{11}$, there are $a, b \in \mathbb{F}_{11}$ with $f_k = a8^k + b4^k$ for all k. From $f_0 = 0$, $a + b = 0$, and from $f_1 = 1$, $8a + 4b = 4a = 1$, so $a = 4^{-1} = 3$ (as $4 \cdot 3 = 12 = 1$) and $b = -3$. So $f_k = 3\left(8^k - 4^k\right)$. Check: $f_2 = 3(64 - 16) = 3 \cdot 48 = 144 = 1$ and $f_3 = 3(512 - 64) = 3 \cdot 448 = 1344 = 2$ in $\mathbb{F}_{11}$.

(b) By Fermat's little theorem (Exercise 1.1.51), $8^{10} = 4^{10} = 1$ in $\mathbb{F}_{11}$. So $f_{k+10} = 3\left(8^k 8^{10} - 4^k 4^{10}\right) = 3\left(8^k - 4^k\right) = f_k$. Indeed, modulo 11 the sequence is $0, 1, 1, 2, 3, 5, 8, 2, 10, 1, 0, 1, \ldots$, with period exactly 10.

Solution to Exercise 7.4.45

> *Uses.* Theorem 7.4.30 (Recurrences with distinct characteristic roots)
> *Hint 1.* The characteristic polynomial is $x^3 - 2x^2 - x + 2$. Look for integer roots.
> *Hint 2.* With roots $2, 1, -1$, write $s_j = a2^j + b + c(-1)^j$ and solve for a, b, c from s_0, s_1, s_2.
> *Sketch.* $x^3 - 2x^2 - x + 2 = (x-2)(x-1)(x+1)$. Solving $a + b + c = 3$, $2a + b - c = 2$, $4a + b + c = 6$ gives $a = b = c = 1$, so $s_j = 2^j + 1 + (-1)^j$.

The characteristic polynomial is $q = x^3 - 2x^2 - x + 2 = x^2(x-2) - (x-2) = (x-2)(x-1)(x+1)$, with distinct roots $2, 1, -1$. By Theorem 7.4.30, $s_j = a2^j + b + c(-1)^j$ for unique $a, b, c \in \mathbb{R}$. The initial values give

$$a + b + c = 3, \quad 2a + b - c = 2, \quad 4a + b + c = 6.$$

Subtracting the first equation from the third gives $3a = 3$, so $a = 1$; then $b + c = 2$ and $b - c = 0$, so $b = c = 1$. Hence $s_j = 2^j + 1 + (-1)^j$. Check: $s_3 = 8 + 1 - 1 = 8 = 2 \cdot 6 + 2 - 2 \cdot 3$.

Solution to Exercise 7.4.46

> *Uses.* Proposition 7.4.33 (Long-run behavior), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
> *Techniques.* Diagonalize, solve, conjugate back (Technique 7.4.22)
> *Hint 1.* The matrix is $A = \begin{pmatrix} 0.7 & 0.4 \\ 0.2 & 0.9 \end{pmatrix}$. Its eigenvalues are 1.1 and 0.5.
> *Hint 2.* Expand (x_0, y_0) in the eigenbasis $(1, 1), (-2, 1)$ and use (7.4.3).
> *Hint 3.* The $(1, 1)$-component is $(x_0 + 2y_0)/3$. When is it zero?
> *Sketch.* $A(1, 1) = 1.1(1, 1)$ and $A(-2, 1) = 0.5(-2, 1)$. With $c_1 = (x_0 + 2y_0)/3$, $c_2 = (y_0 - x_0)/3$, $(x_k, y_k) = c_1 1.1^k (1, 1) + c_2 0.5^k (-2, 1)$. If $x_0, y_0 \geq 0$, not both 0, then $c_1 > 0$ and the first term dominates. The state tends to $\mathbf{0}$ iff $c_1 = 0$, iff (x_0, y_0) is a multiple of $(-2, 1)$.

(a) The system is $\mathbf{x}_{k+1} = A\mathbf{x}_k$ with $A = \begin{pmatrix} 0.7 & 0.4 \\ 0.2 & 0.9 \end{pmatrix}$. Here $\det(A - \lambda I_2) = \lambda^2 - 1.6\lambda + 0.55 = (\lambda - 1.1)(\lambda - 0.5)$, and $A(1, 1) = (1.1, 1.1)$, $A(-2, 1) = (-1, 0.5)$, so $(1, 1)$ and $(-2, 1)$ form an eigenbasis with eigenvalues 1.1 and 0.5. Solving $(x_0, y_0) = c_1(1, 1) + c_2(-2, 1)$ gives $c_2 = (y_0 - x_0)/3$ and $c_1 = (x_0 + 2y_0)/3$. By (7.4.3),

$$\begin{pmatrix} x_k \\ y_k \end{pmatrix} = \frac{x_0 + 2y_0}{3}(1.1)^k \begin{pmatrix} 1 \\ 1 \end{pmatrix} + \frac{y_0 - x_0}{3}(0.5)^k \begin{pmatrix} -2 \\ 1 \end{pmatrix}.$$

(b) If $x_0, y_0 \geq 0$ are not both 0, then $c_1 = (x_0 + 2y_0)/3 > 0$. By Proposition 7.4.33(b) with $\mu = 1.1$, $1.1^{-k}(x_k, y_k) \to c_1(1,1)$, so $1.1^{-k}x_k \to c_1$ and $1.1^{-k}y_k \to c_1$. Hence $x_k/y_k \to c_1/c_1 = 1$ (for large k, $y_k > 0$), and $x_{k+1}/x_k = 1.1 \cdot \left(1.1^{-k-1}x_{k+1}\right)/\left(1.1^{-k}x_k\right) \to 1.1$, and likewise for y_k.

(c) If $c_1 \neq 0$, the x-coordinate is $c_1(1.1)^k - 2c_2(0.5)^k$, whose absolute value tends to ∞. If $c_1 = 0$, then $(x_k, y_k) = c_2(0.5)^k(-2, 1) \to (0, 0)$. So the state tends to $(0, 0)$ exactly when $x_0 + 2y_0 = 0$, that is, when (x_0, y_0) lies on the eigenline $\operatorname{span}((-2, 1))$ of the eigenvalue 0.5.

Solution to Exercise 7.4.47

Uses. Lemma 7.4.13 (Geometric multiplicity through a rank), Theorem 3.3.17 (Uniqueness of the reduced row echelon form), Theorem 7.4.16 (Criteria for diagonalizability), Example 3.5.3 (A rank that depends on the field)
Hint 1. By Theorem 7.4.16(III), it suffices to compare $\operatorname{gm}(\lambda)$ over $\mathbb{R}$ and over $\mathbb{C}$ for each real eigenvalue λ.
Hint 2. $\operatorname{gm}(\lambda) = n - \operatorname{rank}(A - \lambda I_n)$. Is the rank of a real matrix the same over $\mathbb{R}$ and over $\mathbb{C}$?
Sketch. For real λ, $A - \lambda I_n$ is real, and Gauss–Jordan elimination over $\mathbb{R}$ produces an RREF that is also the RREF over $\mathbb{C}$ (uniqueness), so the rank, and hence $\operatorname{gm}(\lambda)$, is the same over both fields. The complex eigenvalues are exactly the real ones, so $\sum \operatorname{gm}_{\mathbb{R}}(\lambda) = \sum \operatorname{gm}_{\mathbb{C}}(\lambda) = n$.

Let $\lambda_1, \ldots, \lambda_m \in \mathbb{R}$ be the distinct eigenvalues of A over $\mathbb{C}$; by hypothesis they are real, so they are also its eigenvalues over $\mathbb{R}$, and A has no other real eigenvalues. For each i, $B_i = A - \lambda_i I_n$ is a real matrix. Row reducing B_i over $\mathbb{R}$ produces a matrix in reduced row echelon form by a sequence of row operations with real scalars. The same operations are complex row operations, so this real matrix is also the RREF of B_i over $\mathbb{C}$ (Theorem 3.3.17). The rank is the number of pivots, so B_i has the same rank over $\mathbb{R}$ and over $\mathbb{C}$, and by Lemma 7.4.13, $\dim_{\mathbb{R}} \ker_{\mathbb{R}} B_i = \dim_{\mathbb{C}} \ker_{\mathbb{C}} B_i$.

Since A is diagonalizable over $\mathbb{C}$, $\sum_i \dim_{\mathbb{C}} \ker_{\mathbb{C}} B_i = n$ by Theorem 7.4.16. Hence $\sum_i \dim_{\mathbb{R}} \ker_{\mathbb{R}} B_i = n$, and A is diagonalizable over $\mathbb{R}$ by the same theorem. (Without the hypothesis on the eigenvalues, the rotation of Example 7.4.9 is a counterexample. Contrast Example 3.5.3, where the rank of one integer matrix depends on the field because the fields $\mathbb{Q}$ and $\mathbb{F}_p$ do different arithmetic; $\mathbb{R} \subseteq \mathbb{C}$ do the same arithmetic on real numbers.)

Solution to Exercise 7.4.48

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Exercise 7.2.55, Theorem 7.4.16 (Criteria for diagonalizability), Proposition 7.4.7 (One eigenvalue), Proposition 4.5.27 (Similarity invariants), Proposition 5.4.17 (Similar matrices have equal determinants)
Hint 1. Every eigenvalue satisfies $\lambda^2 = 1$. Show that A is diagonalizable: $\mathbf{v} = (\mathbf{v} + A\mathbf{v})/2 + (\mathbf{v} - A\mathbf{v})/2$.
Hint 2. If $A \neq \pm I_2$, then A has both eigenvalues 1 and -1. What are its trace and determinant then?
Sketch. Every $\mathbf{v}$ splits as $(\mathbf{v} + A\mathbf{v})/2 \in E_1$ plus $(\mathbf{v} - A\mathbf{v})/2 \in E_{-1}$, so A is diagonalizable with eigenvalues in $\{1, -1\}$. So $A = \pm I_2$, or $A = S\operatorname{diag}(1, -1)S^{-1}$, which happens iff $\operatorname{tr} A = 0$ and $\det A = -1$: $A = \begin{pmatrix} a & b \\ c & -a \end{pmatrix}$ with $a^2 + bc = 1$. Geometrically, the reflections across a line along another line.

If $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{v} = A^2\mathbf{v} = \lambda^2\mathbf{v}$, so $\lambda = \pm 1$. For every $\mathbf{v} \in \mathbb{R}^2$,

$$\mathbf{v} = \frac{1}{2}(\mathbf{v} + A\mathbf{v}) + \frac{1}{2}(\mathbf{v} - A\mathbf{v}),$$

and $A(\mathbf{v} + A\mathbf{v}) = A\mathbf{v} + \mathbf{v}$, $A(\mathbf{v} - A\mathbf{v}) = -(\mathbf{v} - A\mathbf{v})$. So $\mathbb{R}^2 = E_1 + E_{-1}$ (this is Exercise 7.2.55). Dropping a summand that is $\{\mathbf{0}\}$ if 1 or -1 is not an eigenvalue, $\mathbb{R}^2$ is the sum, hence the direct sum, of the eigenspaces of A, and A is diagonalizable by Theorem 7.4.16, (II) $\Rightarrow$ (I), with eigenvalues in $\{1, -1\}$.

If only one of ± 1 is an eigenvalue, then $A = \pm I_2$ by Proposition 7.4.7. Otherwise $A = S\operatorname{diag}(1, -1)S^{-1}$ for an invertible S, so $\operatorname{tr} A = \operatorname{tr}\operatorname{diag}(1, -1) = 0$ and $\det A = -1$ (Proposition 4.5.27(b), Proposition 5.4.17). Conversely, if $A = \begin{pmatrix} a & b \\ c & -a \end{pmatrix}$ with $-a^2 - bc = \det A = -1$, then

$$A^2 = \begin{pmatrix} a^2+bc & ab-ab \\ ac-ac & bc+a^2 \end{pmatrix} = I_2.$$

So the solutions are $\pm I_2$ and the matrices $\begin{pmatrix} a & b \\ c & -a \end{pmatrix}$ with $a^2+bc=1$. Geometrically, $A = S\,\mathrm{diag}(1,-1)S^{-1}$ fixes the line E_1 pointwise and negates the line E_{-1}, with $\mathbb{R}^2 = E_1 \oplus E_{-1}$: it is the reflection across E_1 along E_{-1}, and every pair of distinct lines through $\mathbf{0}$ occurs. The orthogonal reflections of Example 2.1.11 are the cases with $E_{-1} \perp E_1$.

Solution to Exercise 7.4.49

Uses. Definition 3.4.26 (Lagrange polynomials), Proposition 3.4.27 (Lagrange's formula), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 7.1.20 (Factor theorem), Proposition 7.1.27 (Multiplicities add up to at most the degree), Corollary 7.2.23 (Eigenspaces are independent), Theorem 7.4.16 (Criteria for diagonalizability), Exercise 1.1.51, Proposition 7.1.34 (Roots of a split polynomial)
Techniques. Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. $L_1 + \cdots + L_k$ and 1 both have degree less than k and take the value 1 at every node. Evaluate the identity at T: every $\mathbf{v}$ is $\sum_j L_j(T)\mathbf{v}$.
Hint 2. L_j vanishes at every r_i with $i \neq j$, so $(x-r_j)L_j$ is a multiple of q. Apply this at T to show $(T - r_j\,\mathrm{id})L_j(T) = 0$.
Hint 3. For (b), $x^m - 1$ has m distinct roots in $\mathbb{C}$, the m-th roots of unity. For (c), every $a \in \mathbb{F}_p$ is a root of $x^p - x$.
Sketch. By uniqueness of interpolation, $\sum_j L_j = 1$, so $\mathbf{v} = \sum_j L_j(T)\mathbf{v}$ for every $\mathbf{v}$. Since $L_j(r_i) = 0$ for $i \neq j$, $L_j = c_j \prod_{i\neq j}(x - r_i)$, so $(x-r_j)L_j = c_j q$ and $(T - r_j\,\mathrm{id})L_j(T) = c_j q(T) = 0$: $L_j(T)\mathbf{v} \in E_{r_j}$. So the eigenspaces span V. (b) $x^m - 1 = \prod\big(x - e^{2\pi i l/m}\big)$. (c) $x^p - x = \prod_{a\in\mathbb{F}_p}(x-a)$ by Fermat.

(a) By Proposition 3.4.27 with all values $d_j = 1$, the unique polynomial of degree at most $k-1$ with value 1 at every node is $L_1 + \cdots + L_k$; the constant 1 is such a polynomial, so $L_1 + \cdots + L_k = 1$. Evaluating at T (Proposition 7.2.27(a)),

$$\mathbf{v} = L_1(T)\mathbf{v} + \cdots + L_k(T)\mathbf{v} \quad \text{for every } \mathbf{v} \in V.$$

Next, L_j vanishes at the $k-1$ distinct nodes r_i, $i \neq j$, so by the factor theorem (applied $k-1$ times, as in Proposition 7.1.27) $\prod_{i\neq j}(x - r_i)$ divides L_j; since $\deg L_j \leq k-1$, $L_j = c_j \prod_{i\neq j}(x-r_i)$ for a scalar c_j. Hence $(x-r_j)L_j = c_j q$, and evaluating at T,

$$(T - r_j\,\mathrm{id})L_j(T) = c_j q(T) = 0.$$

So $L_j(T)\mathbf{v} \in \ker(T - r_j\,\mathrm{id}) = E_{r_j}$ for every $\mathbf{v}$. Thus $V = E_{r_1} + \cdots + E_{r_k}$. Dropping the r_j that are not eigenvalues (their eigenspaces are $\{\mathbf{0}\}$), V is the sum of the eigenspaces of T, so it is their direct sum (Corollary 7.2.23), and T is diagonalizable by Theorem 7.4.16, (II) $\Rightarrow$ (I).

(b) The m numbers $\omega_l = e^{2\pi i l/m}$, $l = 0, \ldots, m-1$, are distinct roots of $x^m - 1$, so by Proposition 7.1.34 (or the factor theorem, repeatedly) $x^m - 1 = \prod_l (x - \omega_l)$, comparing degrees and leading coefficients. Since $A^m - I_n = 0$, (a) applies with $q = x^m - 1$.

(c) By Fermat's little theorem (Exercise 1.1.51), $a^{p-1} = 1$ for $a \neq 0$ in $\mathbb{F}_p$, so $a^p = a$ for every $a \in \mathbb{F}_p$, including $a = 0$. So the p distinct elements of $\mathbb{F}_p$ are roots of $x^p - x$, and as in (b), $x^p - x = \prod_{a\in\mathbb{F}_p}(x-a)$. Since $A^p - A = 0$, (a) applies.

Solution to Exercise 7.4.50

Uses. Definition 3.4.26 (Lagrange polynomials), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 7.4.16 (Criteria for diagonalizability), Corollary 7.2.23 (Eigenspaces are independent), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 7.4.26 (Polynomials that kill a diagonalizable operator), Exercise 7.4.49
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Write $\mathbf{u} \in U$ as $\mathbf{u} = \mathbf{v}_1 + \cdots + \mathbf{v}_m$ with $\mathbf{v}_i \in E_{\lambda_i}$. You need each $\mathbf{v}_i$ to lie in U.
Hint 2. Find a polynomial L_i with $L_i(T)\mathbf{u} = \mathbf{v}_i$. Polynomials in T map U into U.
Hint 3. Alternatively, apply Exercise 7.4.49 to the restriction: it is killed by $\prod(x - \lambda_i)$.

Sketch. Let L_i be the Lagrange polynomials for the nodes $\lambda_1, \dots, \lambda_m$. For $\mathbf{u} = \sum \mathbf{v}_j$ with $\mathbf{v}_j \in E_{\lambda_j}$, $L_i(T)\mathbf{u} = \sum_j L_i(\lambda_j)\mathbf{v}_j = \mathbf{v}_i$, and $L_i(T)\mathbf{u} \in U$ since U is invariant under polynomials in T. So $\mathbf{v}_i \in U \cap E_{\lambda_i}$, and U is the (direct) sum of these. Concatenating bases gives an eigenbasis of U.

First proof. Let $L_1, \dots, L_m$ be the Lagrange polynomials for the distinct nodes $\lambda_1, \dots, \lambda_m$ (Definition 3.4.26). Let $\mathbf{u} \in U$. Since $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_m}$ (Theorem 7.4.16), $\mathbf{u} = \mathbf{v}_1 + \cdots + \mathbf{v}_m$ with $\mathbf{v}_j \in E_{\lambda_j}$, and by Proposition 7.2.28

$$L_i(T)\mathbf{u} = \sum_{j=1}^{m} L_i(\lambda_j)\mathbf{v}_j = \mathbf{v}_i.$$

Since U is T-invariant, it is $L_i(T)$-invariant (Proposition 7.2.27(d)), so $\mathbf{v}_i = L_i(T)\mathbf{u} \in U \cap E_{\lambda_i}$. Hence $U \subseteq \sum_i \big(U \cap E_{\lambda_i}\big)$, and the reverse inclusion holds because each $U \cap E_{\lambda_i}$ lies in U. The sum is direct because $E_{\lambda_1} + \cdots + E_{\lambda_m}$ is (Corollary 7.2.23). Concatenating bases of the spaces $U \cap E_{\lambda_i}$ gives a basis of U (Theorem 4.4.13) consisting of eigenvectors of T, which are eigenvectors of the restriction; so the restriction is diagonalizable.

Second proof. By Proposition 7.4.26, $q(T) = 0$ for $q = (x - \lambda_1)\cdots(x - \lambda_m)$. For $\mathbf{u} \in U$, $q(T\restriction_U)\mathbf{u} = q(T)\mathbf{u} = \mathbf{0}$, where $T\restriction_U$ is regarded as an operator on U. So the restriction is killed by a product of distinct linear factors, and it is diagonalizable by Exercise 7.4.49(a). Its eigenspaces are $\ker(T\restriction_U - \lambda_i \mathrm{id}_U) = U \cap E_{\lambda_i}$, and Theorem 7.4.16(II) for the restriction gives the decomposition of U.

Solution to Exercise 7.4.51

Uses. Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Exercise 7.4.50, Theorem 7.4.16 (Criteria for diagonalizability), Theorem 4.4.13 (Bases and dimension of a sum)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Each eigenspace $E_\lambda(T)$ is S-invariant (Proposition 7.2.30).
Hint 2. The restriction of S to $E_\lambda(T)$ is diagonalizable by Exercise 7.4.50. Its eigenvectors are eigenvectors of T too.
Hint 3. For the counterexample, a diagonal and a non-diagonal matrix with distinct eigenvalues.
Sketch. $V = \bigoplus E_{\lambda_i}(T)$, and each $E_{\lambda_i}(T)$ is S-invariant, so S restricted to it is diagonalizable (Exercise 7.4.50). An eigenbasis of each restriction consists of common eigenvectors; concatenate. Without commuting: $\mathrm{diag}(1,2)$ and $\left(\begin{smallmatrix}1 & 1\\ 0 & 2\end{smallmatrix}\right)$ are both diagonalizable but have no common eigenbasis, since common eigenvectors would make them commute.

Let $\lambda_1, \dots, \lambda_m$ be the distinct eigenvalues of T, so that $V = E_{\lambda_1}(T) \oplus \cdots \oplus E_{\lambda_m}(T)$ by Theorem 7.4.16. Since $ST = TS$, each $E_{\lambda_i}(T)$ is S-invariant (Proposition 7.2.30(b)). By Exercise 7.4.50, the restriction of S to $E_{\lambda_i}(T)$ is diagonalizable, so $E_{\lambda_i}(T)$ has a basis $\mathcal{B}_i$ of eigenvectors of S. Each vector of $\mathcal{B}_i$ is nonzero and lies in $E_{\lambda_i}(T)$, so it is also an eigenvector of T. The concatenation $\mathcal{B}_1, \dots, \mathcal{B}_m$ is a basis of V (Theorem 4.4.13), consisting of common eigenvectors.

The hypothesis is needed. If $\mathcal{B}$ is a common eigenbasis, then $[S]_{\mathcal{B}\mathcal{B}}$ and $[T]_{\mathcal{B}\mathcal{B}}$ are diagonal, hence commute, so $ST = TS$. Thus $D = \mathrm{diag}(1,2)$ and $A = \left(\begin{smallmatrix}1 & 1\\ 0 & 2\end{smallmatrix}\right)$, which are both diagonalizable (distinct eigenvalues) but do not commute ($DA = \left(\begin{smallmatrix}1 & 1\\ 0 & 4\end{smallmatrix}\right)$, $AD = \left(\begin{smallmatrix}1 & 2\\ 0 & 4\end{smallmatrix}\right)$), have no common eigenbasis.

Solution to Exercise 7.4.52

Uses. Exercise 7.4.49, Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix), Proposition 4.5.27 (Similarity invariants), Proposition 7.2.28 (Polynomials act on eigenvectors by their values)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22), Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. $x^3 - x = x(x-1)(x+1)$ has distinct roots, so A is diagonalizable (Exercise 7.4.49).
Hint 2. Write $A = SDS^{-1}$. Both sides are similarity invariants, so compute them for D.
Hint 3. The diagonal entries of D lie in $\{0, 1, -1\}$, and $d^2 = 1$ exactly when $d \neq 0$.
Sketch. A is killed by $x(x-1)(x+1)$, so $A = SDS^{-1}$ with D diagonal, entries in $\{0, \pm 1\}$. Then $\operatorname{rank} A = \operatorname{rank} D$ is the number of nonzero d_i, and $\operatorname{tr} A^2 = \operatorname{tr} D^2 = \sum d_i^2$ is the same number.

Since $A^3 - A = 0$ and $x^3 - x = x(x-1)(x+1)$ has the distinct roots $0, 1, -1$, A is diagonalizable by Exercise 7.4.49(a): $A = SDS^{-1}$ with $D = \mathrm{diag}(d_1, \dots, d_n)$. Each d_i is an eigenvalue, hence a root of $x^3 - x$ (Proposition 7.2.28), so $d_i \in \{0, 1, -1\}$. Rank and trace are similarity invariants (Proposition 4.5.27), and $A^2 = SD^2S^{-1}$ (Proposition 7.4.23), so

$$\operatorname{rank} A = \operatorname{rank} D = \#\{i \mid d_i \neq 0\}, \quad \operatorname{tr}\big(A^2\big) = \operatorname{tr}\big(D^2\big) = \sum_{i=1}^{n} d_i^2.$$

For $d_i \in \{0, 1, -1\}$, $d_i^2 = 1$ if $d_i \neq 0$ and $d_i^2 = 0$ otherwise. So both sides count the nonzero d_i, and $\operatorname{rank} A = \operatorname{tr}\big(A^2\big)$.

Solution to Exercise 7.4.53

Uses. Exercise 7.4.42, Proposition 4.4.16 (Complements exist), Definition 4.4.24 (Projection along a complement), Proposition 4.4.26 (Properties of projections), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Corollary 7.2.23 (Eigenspaces are independent), Theorem 7.4.16 (Criteria for diagonalizability)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. For "only if", $T - \lambda\,\mathrm{id}$ is diagonalizable; use Exercise 7.4.42.
Hint 2. For "if", let U be the sum of all eigenspaces and suppose $U \neq V$. Take a complement W and the projection P onto W along U. The operator $PT|_W$ on W has an eigenvector $\mathbf{w}$ over $\mathbb{C}$: $T\mathbf{w} - \lambda\mathbf{w} \in U$.
Hint 3. Write $(T - \lambda\,\mathrm{id})\mathbf{w} = \sum_\mu \mathbf{u}_\mu$ with $\mathbf{u}_\mu \in E_\mu$. For $\mu \neq \lambda$, $\mathbf{u}_\mu = (T - \lambda\,\mathrm{id})\big(\mathbf{u}_\mu/(\mu - \lambda)\big)$. Subtract these from $\mathbf{w}$ and use the hypothesis.
Sketch. "Only if": $T - \lambda\,\mathrm{id}$ is diagonalizable, so its kernel and image meet in $\mathbf{0}$. "If": let $U = \bigoplus E_\mu$ and suppose $U \neq V$; choose $V = U \oplus W$. The operator $\mathbf{w} \mapsto PT\mathbf{w}$ on W has an eigenvector $\mathbf{w} \neq \mathbf{0}$, so $(T - \lambda\,\mathrm{id})\mathbf{w} = \sum_\mu \mathbf{u}_\mu \in U$. Put $\mathbf{w}' = \mathbf{w} - \sum_{\mu\neq\lambda} \mathbf{u}_\mu/(\mu - \lambda)$; then $(T - \lambda\,\mathrm{id})\mathbf{w}' = \mathbf{u}_\lambda \in \ker \cap\, \mathrm{im}$, so $\mathbf{u}_\lambda = \mathbf{0}$ and $\mathbf{w}' \in E_\lambda \subseteq U$. Then $\mathbf{w} \in U \cap W = \{\mathbf{0}\}$, a contradiction.

Only if. If $\mathcal{B}$ is an eigenbasis for T, it is also one for $T - \lambda\,\mathrm{id}$, since $T\mathbf{b} = \mu\mathbf{b}$ gives $(T - \lambda\,\mathrm{id})\mathbf{b} = (\mu - \lambda)\mathbf{b}$. So $T - \lambda\,\mathrm{id}$ is diagonalizable, and Exercise 7.4.42(a) gives $\ker(T - \lambda\,\mathrm{id}) \cap \mathrm{im}(T - \lambda\,\mathrm{id}) = \{\mathbf{0}\}$.

If. Let U be the sum of the eigenspaces of T; it is the direct sum of the eigenspaces of the finitely many eigenvalues (Corollary 7.2.23). Suppose, for contradiction, that $U \neq V$. Choose a complement W, so $V = U \oplus W$ and $W \neq \{\mathbf{0}\}$ (Proposition 4.4.16), and let $P = \mathrm{Pr}_{W,U}$ be the projection onto W along U (Definition 4.4.24). The map $R : W \to W$, $R\mathbf{w} = PT\mathbf{w}$, is an operator on the nonzero complex space W, so it has an eigenvector $\mathbf{w} \neq \mathbf{0}$ (Theorem 7.3.27): $PT\mathbf{w} = \lambda\mathbf{w}$ for some $\lambda \in \mathbb{C}$. Since $P\mathbf{w} = \mathbf{w}$, this says $P(T\mathbf{w} - \lambda\mathbf{w}) = \mathbf{0}$, and since $\ker P = U$ and P fixes W (Proposition 4.4.26(b)), $(T - \lambda\,\mathrm{id})\mathbf{w} \in U$. Write

$$(T - \lambda\,\mathrm{id})\mathbf{w} = \sum_{\mu} \mathbf{u}_\mu, \quad \mathbf{u}_\mu \in E_\mu,$$

the sum over the eigenvalues μ of T. For $\mu \neq \lambda$, $(T - \lambda\,\mathrm{id})\mathbf{u}_\mu = (\mu - \lambda)\mathbf{u}_\mu$, so $\mathbf{u}_\mu = (T - \lambda\,\mathrm{id})\big(\mathbf{u}_\mu/(\mu - \lambda)\big)$. Let

$$\mathbf{w}' = \mathbf{w} - \sum_{\mu\neq\lambda} \frac{\mathbf{u}_\mu}{\mu - \lambda}.$$

Then $(T - \lambda\,\mathrm{id})\mathbf{w}' = \sum_\mu \mathbf{u}_\mu - \sum_{\mu\neq\lambda} \mathbf{u}_\mu = \mathbf{u}_\lambda$, where $\mathbf{u}_\lambda = \mathbf{0}$ if λ is not an eigenvalue. In any case $(T - \lambda\,\mathrm{id})\mathbf{w}'$ lies in $\ker(T - \lambda\,\mathrm{id})$ (it is $\mathbf{0}$ or in E_λ) and in $\mathrm{im}(T - \lambda\,\mathrm{id})$, so it is $\mathbf{0}$ by hypothesis. Hence $\mathbf{w}' \in \ker(T - \lambda\,\mathrm{id}) \subseteq U$, and therefore $\mathbf{w} = \mathbf{w}' + \sum_{\mu\neq\lambda} \mathbf{u}_\mu/(\mu - \lambda) \in U$. But $\mathbf{w} \in W$ and $U \cap W = \{\mathbf{0}\}$, so $\mathbf{w} = \mathbf{0}$, a contradiction. Hence $U = V$, and T is diagonalizable by Theorem 7.4.16, (II) $\Rightarrow$ (I).

The hypothesis is needed only for the one λ that the argument produces, but that λ is not known in advance. Over $\mathbb{R}$ the statement fails: the rotation by a right angle has $\ker(T - \lambda\,\mathrm{id}) = \{\mathbf{0}\}$ for every real λ and is not diagonalizable over $\mathbb{R}$.

Section 7.5

Solution to Exercise 7.5.7

Uses. Definition 2.3.1 (Matrix of a linear map), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces)
Hint 1. The (i, j) entry of $[T]_{\mathcal{B}'}$ is the coefficient of $\mathbf{b}_{n+1-i}$ in $T\mathbf{b}_{n+1-j}$. Relate it to an entry of $[T]_{\mathcal{B}}$.
Hint 2. Reversing both the rows and the columns sends position (i, j) to $(n + 1 - i, n + 1 - j)$, and $i > j$ if and only if $n + 1 - i < n + 1 - j$.

Sketch. The (i,j) entry of $[T]_{\mathcal{B}'}$ is the $(n+1-i, n+1-j)$ entry of $[T]_{\mathcal{B}}$. Below-diagonal positions of one matrix correspond to above-diagonal positions of the other. For D, $[D]_{\mathcal{B}'}$ has $3, 2, 1$ just below the diagonal.

Write $\mathbf{b}'_j = \mathbf{b}_{n+1-j}$. The (i,j) entry of $[T]_{\mathcal{B}'}$ is the coefficient of $\mathbf{b}'_i = \mathbf{b}_{n+1-i}$ in $T\mathbf{b}'_j = T\mathbf{b}_{n+1-j}$ (Definition 2.3.1), which is the $(n+1-i, n+1-j)$ entry of $[T]_{\mathcal{B}}$. Now $i < j$ if and only if $n+1-i > n+1-j$. So the entries of $[T]_{\mathcal{B}'}$ above the diagonal are exactly the entries of $[T]_{\mathcal{B}}$ below the diagonal, and one set vanishes if and only if the other does.

For D, $D(x^3) = 3x^2$, $D(x^2) = 2x$, $D(x) = 1$, and $D(1) = \mathbf{0}$, so

$$[D]_{x^3,x^2,x,1} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 3 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

This is $[D]_{1,x,x^2,x^3}$ with the order of the rows and of the columns reversed.

Solution to Exercise 7.5.10

Uses. Proposition 7.5.8 (The diagonal of a triangular matrix), Proposition 7.5.9 (Multiplicities on the diagonal), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
Hint 1. Each $T\mathbf{b}_j$ lies in $\operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$, so $[T]_{\mathcal{B}}$ is upper triangular. Read off the diagonal.
Hint 2. For the eigenvectors, solve $(T - \lambda \operatorname{id})(x\mathbf{b}_1 + y\mathbf{b}_2 + z\mathbf{b}_3) = \mathbf{0}$ coefficient by coefficient.
Sketch. The diagonal is $3, -1, 3$, so the eigenvalues are 3 (multiplicity 2) and -1 (multiplicity 1), and T is invertible. $E_3 = \operatorname{span}(\mathbf{b}_1)$ and $E_{-1} = \operatorname{span}(\mathbf{b}_1 - 4\mathbf{b}_2)$. Only two independent eigenvectors exist, so T is not diagonalizable.

The matrix

$$[T]_{\mathcal{B}} = \begin{pmatrix} 3 & 1 & 1 \\ 0 & -1 & 1 \\ 0 & 0 & 3 \end{pmatrix}$$

is upper triangular. By Proposition 7.5.8 and Proposition 7.5.9, the eigenvalues are 3, with algebraic multiplicity 2, and -1, with algebraic multiplicity 1. No diagonal entry is 0, so T is invertible.

For $\lambda = 3$: $(T - 3\operatorname{id})(x\mathbf{b}_1 + y\mathbf{b}_2 + z\mathbf{b}_3) = y(\mathbf{b}_1 - 4\mathbf{b}_2) + z(\mathbf{b}_1 + \mathbf{b}_2) = (y+z)\mathbf{b}_1 + (z - 4y)\mathbf{b}_2$. This vanishes if and only if $y + z = 0$ and $z = 4y$, that is, $y = z = 0$. So $E_3 = \operatorname{span}(\mathbf{b}_1)$.

For $\lambda = -1$: $(T + \operatorname{id})(x\mathbf{b}_1 + y\mathbf{b}_2 + z\mathbf{b}_3) = (4x + y + z)\mathbf{b}_1 + z\mathbf{b}_2 + 4z\mathbf{b}_3$, which vanishes if and only if $z = 0$ and $y = -4x$. So $E_{-1} = \operatorname{span}(\mathbf{b}_1 - 4\mathbf{b}_2)$. Check: $T(\mathbf{b}_1 - 4\mathbf{b}_2) = 3\mathbf{b}_1 - 4\mathbf{b}_1 + 4\mathbf{b}_2 = -(\mathbf{b}_1 - 4\mathbf{b}_2)$.

Every eigenvector lies in $E_3 \cup E_{-1}$, a union of two lines, so there is no basis of eigenvectors, and T is not diagonalizable (Theorem 7.4.2).

Solution to Exercise 7.5.21

Uses. Theorem 7.5.18 (Schur's theorem), Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 6.3.18 (Coordinates in an orthonormal basis)
Hint 1. Find an eigenvalue and a unit eigenvector $\mathbf{u}_1$; complete it to an orthonormal basis of $\mathbb{C}^2$.
Hint 2. The entries of R are $r_{ij} = \langle A\mathbf{u}_j, \mathbf{u}_i \rangle$.
Sketch. $\det(A - \lambda I_2) = (\lambda - 2)^2$; $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1,1)$, $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(-1,1)$; $A\mathbf{u}_2 = \frac{1}{\sqrt{2}}(-4,0)$, so $R = \begin{pmatrix} 2 & -2 \\ 0 & 2 \end{pmatrix}$.

$\det(A - \lambda I_2) = (3-\lambda)(1-\lambda) + 1 = \lambda^2 - 4\lambda + 4 = (\lambda - 2)^2$, so 2 is the only eigenvalue. From $A - 2I_2 = \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix}$, a unit eigenvector is $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1,1)$; complete it with $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(-1,1)$. Then $A\mathbf{u}_1 = 2\mathbf{u}_1$, and $A\mathbf{u}_2 = \frac{1}{\sqrt{2}}(-4,0)$, so by Proposition 6.3.18

$$r_{12} = \langle A\mathbf{u}_2, \mathbf{u}_1 \rangle = \frac{1}{2}(-4) = -2, \quad r_{22} = \langle A\mathbf{u}_2, \mathbf{u}_2 \rangle = \frac{1}{2}(4) = 2.$$

Hence $A = URU^*$ with $U = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ and $R = \begin{pmatrix} 2 & -2 \\ 0 & 2 \end{pmatrix}$. Check: $AU = \frac{1}{\sqrt{2}}\begin{pmatrix} 2 & -4 \\ 2 & 0 \end{pmatrix} = UR$.

Solution to Exercise 7.5.29

Uses. Theorem 7.5.13 (Upper-triangular form), Lemma 7.5.11 (Compressing an operator to a complement), Corollary 7.5.14 (Triangularizing a matrix)
Hint 1. $(2,1,1)$ is an eigenvector. Use the complement $\operatorname{span}(\mathbf{e}_2, \mathbf{e}_3)$ and compute the compression.
Hint 2. In the basis $(2,1,1), \mathbf{e}_2, \mathbf{e}_3$, the matrix is $\begin{pmatrix} 1 & -1 & 0 \\ 0 & 0 & -2 \\ 0 & 1 & 3 \end{pmatrix}$. Triangularize the bottom right 2×2 block, starting with an eigenvector for 1.
Sketch. $A(2,1,1) = (2,1,1)$. With M having columns $(2,1,1), \mathbf{e}_2, \mathbf{e}_3$, $M^{-1}AM = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 0 & -2 \\ 0 & 1 & 3 \end{pmatrix}$. The block $\begin{pmatrix} 0 & -2 \\ 1 & 3 \end{pmatrix}$ has eigenvector $(-2,1)$ for 1, giving $\mathbf{b}_2 = (0,-2,1)$. With S having columns $(2,1,1), (0,-2,1), \mathbf{e}_3$, $S^{-1}AS = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix}$.

First, $A(2,1,1) = (4-2, 4-1-2, -2+3) = (2,1,1)$, so $\mathbf{b}_1 = (2,1,1)$ is an eigenvector for 1. Since its first coordinate is nonzero, $\mathbf{b}_1, \mathbf{e}_2, \mathbf{e}_3$ is a basis, and $W = \operatorname{span}(\mathbf{e}_2, \mathbf{e}_3)$ is a complement of $\operatorname{span}(\mathbf{b}_1)$. Writing $(x_1, x_2, x_3) = (x_1/2)\mathbf{b}_1 + (0, x_2 - x_1/2, x_3 - x_1/2)$, the projection onto W along $\operatorname{span}(\mathbf{b}_1)$ is $(x_1, x_2, x_3) \mapsto (0, x_2 - x_1/2, x_3 - x_1/2)$. Since $A\mathbf{e}_2 = (-2,-1,0)$ and $A\mathbf{e}_3 = (0,-2,3)$, the compression sends

$$\mathbf{e}_2 \mapsto (0, -1+1, 0+1) = \mathbf{e}_3, \quad \mathbf{e}_3 \mapsto (0,-2,3) = -2\mathbf{e}_2 + 3\mathbf{e}_3,$$

so its matrix is $\begin{pmatrix} 0 & -2 \\ 1 & 3 \end{pmatrix}$, with characteristic polynomial $x^2 - 3x + 2 = (x-1)(x-2)$. An eigenvector for 1 is $(-2,1)$, that is, $\mathbf{b}_2 = -2\mathbf{e}_2 + \mathbf{e}_3 = (0,-2,1)$. Complete with $\mathbf{b}_3 = \mathbf{e}_3$. Then

$$A\mathbf{b}_2 = (4,0,3) = 2\mathbf{b}_1 + \mathbf{b}_2,$$
$$A\mathbf{b}_3 = (0,-2,3) = \mathbf{b}_2 + 2\mathbf{b}_3.$$

So with

$$S = \begin{pmatrix} 2 & 0 & 0 \\ 1 & -2 & 0 \\ 1 & 1 & 1 \end{pmatrix}, \quad R = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix},$$

we have $AS = SR$ column by column, that is, $A = SRS^{-1}$. The diagonal $1, 1, 2$ agrees with $p_A = (x-1)^2(x-2)$: the first entry comes from $\mathbf{b}_1$ and the other two from the compression. (Starting instead with the eigenvector $(1,0,1)$ for 2 gives a triangular form with diagonal $2, 1, 1$.)

Solution to Exercise 7.5.30

Uses. Theorem 7.5.13 (Upper-triangular form), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Corollary 7.1.43 (Odd degree gives a real root)
Techniques. Build a flag of invariant subspaces (Technique 7.5.4)
Hint 1. For (a), a triangularizing basis comes with an invariant flag.
Hint 2. For (b), compute T^2. Why does it follow that T has no real eigenvalue?
Hint 3. If U is invariant of dimension 3, then $T|_U$ is an operator on a 3-dimensional real space. Its characteristic polynomial has odd degree.
Sketch. (a) The flag $\operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_k)$ of a triangularizing basis. (b) $T^2 = -\mathrm{id}$, so $T\mathbf{v} = \lambda\mathbf{v}$ forces $(\lambda^2 + 1)\mathbf{v} = \mathbf{0}$ and T has no eigenvector, hence no invariant line. An invariant U of dimension 3 would give an operator $T|_U$ whose characteristic polynomial has odd degree, hence a real root, hence an eigenvector of T.

(a) By Theorem 7.5.13 there is a basis $\mathbf{b}_1, \ldots, \mathbf{b}_n$ with $[T]$ upper triangular, and by Proposition 7.5.2 the subspaces $\operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_k)$, of dimension k, are T-invariant ($k = 0$ gives $\{\mathbf{0}\}$).

(b) $T^2(x_1, x_2, x_3, x_4) = T(-x_2, x_1, -x_4, x_3) = (-x_1, -x_2, -x_3, -x_4)$, so $T^2 = -\mathrm{id}$. If $T\mathbf{v} = \lambda\mathbf{v}$ with $\lambda \in \mathbb{R}$, then $-\mathbf{v} = T^2\mathbf{v} = \lambda^2\mathbf{v}$, so $(\lambda^2 + 1)\mathbf{v} = \mathbf{0}$ and $\mathbf{v} = \mathbf{0}$, as $\lambda^2 + 1 > 0$. So T has no eigenvector, and no invariant subspace of dimension 1 (Proposition 7.2.7).

Suppose U were invariant with $\dim U = 3$. Then $T|_U$ is an operator on U, and its characteristic polynomial has degree 3, so it has a real root (Corollary 7.1.43), which is an eigenvalue of $T|_U$ (Theorem 7.3.6). An

eigenvector of $T|_U$ is an eigenvector of T, which we just showed does not exist. So no such U exists. (Invariant subspaces of dimension 2 do exist, such as $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$.)

Solution to Exercise 7.5.31

Uses. Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Theorem 4.1.16 (Extending to a basis), Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 5.1.13 (The 2×2 determinant)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. In dimension 2, triangularizable means: there is an eigenvector. Why is that enough?
Hint 2. λ is an eigenvalue if and only if $\det(A - \lambda I_2) = 0$. There are only two candidates, $\lambda = 0$ and $\lambda = 1$. Express both determinants in terms of $\operatorname{tr} A$ and $\det A$.
Sketch. A 2×2 matrix is triangularizable if and only if it has an eigenvector $\mathbf{b}_1$: extend it to a basis, and $T\mathbf{b}_2 \in \operatorname{span}(\mathbf{b}_1, \mathbf{b}_2) = \mathbb{F}_2^2$ automatically. Since $\det(A - \lambda I_2) = \lambda^2 - (\operatorname{tr} A)\lambda + \det A$, the candidates fail exactly when $\det A = 1$ and $\operatorname{tr} A = 1$, which forces $b = c = 1$ and $\{a, d\} = \{0, 1\}$. So 14 are triangularizable, and the exceptions are $\left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$.

In dimension 2, A is triangularizable if and only if it has an eigenvector. If T_A is upper triangular with respect to $\mathbf{b}_1, \mathbf{b}_2$, then $\mathbf{b}_1$ is an eigenvector. Conversely, if $\mathbf{b}_1$ is an eigenvector, extend it to a basis $\mathbf{b}_1, \mathbf{b}_2$ (Theorem 4.1.16); then $T\mathbf{b}_1 \in \operatorname{span}(\mathbf{b}_1)$ and $T\mathbf{b}_2 \in \operatorname{span}(\mathbf{b}_1, \mathbf{b}_2)$, so T_A is upper triangular by Proposition 7.5.2.

For $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, Theorem 5.1.13 gives $\det(A - \lambda I_2) = (a - \lambda)(d - \lambda) - bc = \lambda^2 - (a + d)\lambda + (ad - bc)$. By Theorem 7.2.9, A has no eigenvalue in $\mathbb{F}_2$ if and only if this is nonzero for $\lambda = 0$ and $\lambda = 1$, that is,

$$\det A = 1 \quad \text{and} \quad 1 + \operatorname{tr} A + \det A = 1,$$

using $-1 = 1$ in $\mathbb{F}_2$. Substituting $\det A = 1$ into the second condition gives $\operatorname{tr} A = 1$, since $1 + 1 = 0$. From $a + d = 1$, one of a, d is 0, so $ad = 0$ and $\det A = -bc = bc = 1$, giving $b = c = 1$. So the matrices with no eigenvalue are exactly

$$\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix},$$

whose characteristic polynomial is $x^2 + x + 1$, the one irreducible quadratic over $\mathbb{F}_2$. The other 14 matrices are triangularizable.

Solution to Exercise 7.5.32

Uses. Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Proposition 7.5.9 (Multiplicities on the diagonal), Theorem 7.2.9 (Eigenvalues and invertibility)
Hint 1. A triangularizable operator has an eigenvector. Look for a rational matrix whose eigenvalues are irrational.
Hint 2. For (b), if A is upper triangular in a real basis, its characteristic polynomial is a product of real linear factors (Proposition 7.5.9). Put a rotation block next to a 1×1 block.
Sketch. (a) $A = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ has eigenvalues $\pm\sqrt{2}$: no eigenvector in $\mathbb{Q}^2$, but an eigenvector $\left(\sqrt{2}, 1\right)$ in $\mathbb{R}^2$, which a second vector completes to a triangularizing basis. (b) $A = \left(\begin{smallmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$ has eigenvalue 1, but $p_A = (x - 1)\left(x^2 + 1\right)$ is not a product of real linear factors.

(a) Let $A = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$. Then $\det(A - \lambda I_2) = \lambda^2 - 2$, which has no rational root, so A has no eigenvalue in $\mathbb{Q}$ (Theorem 7.2.9). The first vector of a triangularizing basis would be an eigenvector, so A is not triangularizable over $\mathbb{Q}$. Over $\mathbb{R}$, $A\left(\sqrt{2}, 1\right) = \left(2, \sqrt{2}\right) = \sqrt{2}\left(\sqrt{2}, 1\right)$, and in the basis $\left(\sqrt{2}, 1\right), \mathbf{e}_2$ the first vector spans an invariant line, so the flag $\{\mathbf{0}\} \subseteq \operatorname{span}\left(\left(\sqrt{2}, 1\right)\right) \subseteq \mathbb{R}^2$ is invariant and A is triangularizable over $\mathbb{R}$.

(b) Let $A = \left(\begin{smallmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$. Then $A\mathbf{e}_3 = \mathbf{e}_3$, so 1 is an eigenvalue. By cofactor expansion along the last row, $p_A = (x - 1)\left(x^2 + 1\right)$. If $A = SRS^{-1}$ with S, R real and R upper triangular, then $p_A = (x - r_{11})(x - r_{22})(x - r_{33})$ with real r_{jj} (Proposition 7.5.9). Evaluating at i gives $0 = p_A(i) = (i - r_{11})(i - r_{22})(i - r_{33})$, a product of nonzero complex numbers, which is impossible. So A is not triangularizable over $\mathbb{R}$.

Solution to Exercise 7.5.33

Uses. Definition 7.5.1 (Triangularizable), Exercise 7.5.7, Non-example 7.5.6 (A rotation), Proposition 4.5.27 (Similarity invariants)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), transpose $A = SRS^{-1}$. The result has a lower-triangular middle factor; reverse the order of a basis.
Hint 2. For (b), add an upper-triangular and a lower-triangular nilpotent matrix.
Hint 3. For (c) and (d), look at diagonal matrices, and at the identity.
Sketch. (a) True: $A^{\mathsf{T}} = \left(S^{\mathsf{T}}\right)^{-1} R^{\mathsf{T}} S^{\mathsf{T}}$, and R^{T} is lower triangular, so with the reversal permutation matrix P, $PR^{\mathsf{T}}P$ is upper triangular and similar to A^{T}. (b) False: $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right) + \left(\begin{smallmatrix} 0 & 0 \\ -1 & 0 \end{smallmatrix}\right)$ is a rotation. (c) False: $\operatorname{diag}(1,2)$ with the bases $\mathbf{e}_1, \mathbf{e}_2$ and $\mathbf{e}_2, \mathbf{e}_1$. (d) False: I_2 and $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$.

(a) True. Write $A = SRS^{-1}$ with R upper triangular. Then $A^{\mathsf{T}} = \left(S^{-1}\right)^{\mathsf{T}} R^{\mathsf{T}} S^{\mathsf{T}}$, and R^{T} is lower triangular. Let P be the permutation matrix with $P\mathbf{e}_j = \mathbf{e}_{n+1-j}$, so $P^2 = I_n$. The (i,j) entry of $PR^{\mathsf{T}}P$ is the $(n+1-i, n+1-j)$ entry of R^{T}, which is $r_{n+1-j,n+1-i}$; it vanishes when $n+1-j > n+1-i$, that is, when $i > j$. So $R' = PR^{\mathsf{T}}P$ is upper triangular (this is Exercise 7.5.7 in matrix form), and with $M = \left(S^{-1}\right)^{\mathsf{T}} P$,

$$A^{\mathsf{T}} = \left(S^{-1}\right)^{\mathsf{T}} PR'PS^{\mathsf{T}} = MR'M^{-1},$$

since $M^{-1} = P^{-1}S^{\mathsf{T}} = PS^{\mathsf{T}}$.

(b) False. $A = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ is upper triangular, and $B = \left(\begin{smallmatrix} 0 & 0 \\ -1 & 0 \end{smallmatrix}\right)$ is lower triangular, hence triangularizable by (a). But $A + B = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ is the rotation by $-\pi/2$, which has no real eigenvalue and is not triangularizable over $\mathbb{R}$ (as in Non-example 7.5.6).

(c) False. $T = T_D$ with $D = \operatorname{diag}(1,2)$ is upper triangular (even diagonal) with respect to $\mathbf{e}_1, \mathbf{e}_2$ and with respect to $\mathbf{e}_2, \mathbf{e}_1$, and $\mathbf{e}_2$ is not a multiple of $\mathbf{e}_1$.

(d) False. I_2 and $J = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ have the same diagonal, but $S^{-1}I_2S = I_2 \neq J$ for every invertible S, so I_2 is similar only to itself.

Solution to Exercise 7.5.34

Uses. Corollary 7.5.14 (Triangularizing a matrix), Proposition 2.4.36 (Products of upper triangular matrices), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Proposition 7.5.9 (Multiplicities on the diagonal), Theorem 7.5.22 (Trace and determinant from eigenvalues), Proposition 7.5.8 (The diagonal of a triangular matrix)
Techniques. Build a flag of invariant subspaces (Technique 7.5.4), Prove it for triangular matrices first (Technique 7.5.23)
Hint 1. Write $A = SRS^{-1}$ with R upper triangular. Then $A^k = SR^kS^{-1}$ and $A^{-1} = SR^{-1}S^{-1}$.
Hint 2. Powers of R are upper triangular with the powers of the diagonal entries on the diagonal (Proposition 2.4.36). For R^{-1}, use flags: T_R maps each $\operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_j)$ into itself and is injective.
Sketch. (a) R^k is upper triangular with diagonal r_{jj}^k by Proposition 2.4.36 and induction, and $A^k = SR^kS^{-1}$, so Proposition 7.5.9 applies. (b) T_R maps $V_j = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_j)$ injectively into itself, hence onto it, so T_R^{-1} also preserves every V_j and R^{-1} is upper triangular; $RR^{-1} = I_n$ and Proposition 2.4.36 give diagonal entries r_{jj}^{-1}. Then take traces.

By Corollary 7.5.14, $A = SRS^{-1}$ with R upper triangular and diagonal entries $r_{jj} = \lambda_j$, after reordering the λ_j.

(a) $A^k = SR^kS^{-1}$, by induction on k, since $S^{-1}S = I_n$ cancels between consecutive factors. By Proposition 2.4.36 and induction on k, R^k is upper triangular with diagonal entries $\lambda_1^k, \ldots, \lambda_n^k$. So T_{A^k} is upper triangular with respect to the columns of S, with this diagonal, and by Proposition 7.5.9 these are the eigenvalues of A^k counted with multiplicity. By Theorem 7.5.22, $\operatorname{tr}\left(A^k\right) = \sum_j \lambda_j^k$.

(b) A is invertible, so $R = S^{-1}AS$ is too, and $A^{-1} = SR^{-1}S^{-1}$. Let $V_j = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_j)$. By Proposition 7.5.2, T_R maps V_j into V_j, and it is injective, so $T_R|_{V_j}$ is an injective map from V_j into itself, hence onto V_j (Corollary 4.2.18). So each $\mathbf{v} \in V_j$ is $T_R\mathbf{w}$ for some $\mathbf{w} \in V_j$, and $T_R^{-1}\mathbf{v} = \mathbf{w} \in V_j$. Thus $T_R^{-1} = T_{R^{-1}}$ preserves every V_j, and R^{-1} is upper triangular by Proposition 7.5.2. By Proposition 2.4.36, the diagonal entries of $RR^{-1} = I_n$ are $r_{jj}\left(R^{-1}\right)_{jj} = 1$, so $\left(R^{-1}\right)_{jj} = \lambda_j^{-1}$ (each $\lambda_j \neq 0$ by Proposition 7.5.8). Now argue as in (a).

Solution to Exercise 7.5.35

Uses. Theorem 7.5.22 (Trace and determinant from eigenvalues), Exercise 7.5.34, Proposition 7.5.9 (Multiplicities on the diagonal), Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
Hint 1. Let $\lambda_1, \lambda_2, \lambda_3$ be the eigenvalues. You know $\sum \lambda_i$, $\sum \lambda_i^2$, and $\prod \lambda_i$.
Hint 2. $(\lambda_1+\lambda_2+\lambda_3)^2 = \sum \lambda_i^2 + 2(\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3)$. This gives every coefficient of $p_A = (x-\lambda_1)(x-\lambda_2)(x-\lambda_3)$.
Sketch. $e_1 = \sum \lambda_i = 2$, $\sum \lambda_i^2 = 6$ gives $e_2 = \sum_{i<j} \lambda_i\lambda_j = (4-6)/2 = -1$, and $e_3 = \prod \lambda_i = -2$. So $p_A = x^3 - 2x^2 - x + 2 = (x-1)(x+1)(x-2)$, with three distinct eigenvalues, so A is diagonalizable.

Let $\lambda_1, \lambda_2, \lambda_3$ be the eigenvalues of A counted with multiplicity. By Theorem 7.5.22 and Exercise 7.5.34(a),

$$\lambda_1 + \lambda_2 + \lambda_3 = 2, \quad \lambda_1^2 + \lambda_2^2 + \lambda_3^2 = 6, \quad \lambda_1\lambda_2\lambda_3 = -2.$$

Let $e_2 = \lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3$. Expanding the square, $(\lambda_1+\lambda_2+\lambda_3)^2 = \sum \lambda_i^2 + 2e_2$, so $4 = 6 + 2e_2$ and $e_2 = -1$. Expanding the product,

$$p_A = (x-\lambda_1)(x-\lambda_2)(x-\lambda_3) = x^3 - 2x^2 + e_2 x - \lambda_1\lambda_2\lambda_3 = x^3 - 2x^2 - x + 2.$$

This factors as $x^2(x-2) - (x-2) = (x-2)(x-1)(x+1)$, so the eigenvalues are 1, -1, and 2. (Check: $1 + 1 + 4 = 6$.) Eigenvectors for the three distinct eigenvalues are linearly independent (Theorem 7.2.21), so they form a basis of $\mathbb{C}^3$, and A is diagonalizable (Theorem 7.4.2).

Solution to Exercise 7.5.36

Uses. Corollary 7.5.14 (Triangularizing a matrix), Proposition 7.5.8 (The diagonal of a triangular matrix), Example 2.8.3 (Strictly upper triangular matrices are nilpotent, three ways), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$)
Techniques. Prove it for triangular matrices first (Technique 7.5.23)
Hint 1. If 0 is the only eigenvalue, a triangular form of A has zeros on the diagonal.
Hint 2. Strictly upper-triangular $n \times n$ matrices satisfy $N^n = 0$ (Example 2.8.3). For the converse, apply A^n to an eigenvector.
Hint 3. For (b), the real eigenvalues do not see a rotation block.
Sketch. (a) $A = SRS^{-1}$ with R upper triangular and diagonal the eigenvalues, all 0; so R is strictly upper triangular, $R^n = 0$, and $A^n = SR^nS^{-1} = 0$. Conversely $A\mathbf{v} = \lambda\mathbf{v}$ gives $\mathbf{0} = A^n\mathbf{v} = \lambda^n\mathbf{v}$, so $\lambda = 0$, and an eigenvalue exists over $\mathbb{C}$. (b) $A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}$.

(a) Suppose 0 is the only eigenvalue. By Corollary 7.5.14, $A = SRS^{-1}$ with R upper triangular, and the diagonal entries of R are eigenvalues of A (Proposition 7.5.8), hence all 0. So R is strictly upper triangular, and $R^n = 0$ by Example 2.8.3. Then $A^n = SR^nS^{-1} = 0$.

Conversely, suppose $A^n = 0$, and let $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. Then $A^n\mathbf{v} = \lambda^n\mathbf{v}$ (induction), so $\lambda^n\mathbf{v} = \mathbf{0}$, $\lambda^n = 0$, and $\lambda = 0$. Since A has at least one eigenvalue (Theorem 7.3.27), 0 is the only one.

(b) Let $A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}$, which is block diagonal with blocks (0) and the rotation $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. A real eigenvector (x, y, z) with eigenvalue λ satisfies $0 = \lambda x$, $-z = \lambda y$, $y = \lambda z$, so $y = -\lambda^2 y$ and $z = -\lambda^2 z$, which forces $y = z = 0$, and then $x \neq 0$ and $\lambda = 0$. So 0 is the only real eigenvalue. But A^k is block diagonal with blocks (0) and R^k, and $R^k \neq 0$ since R is invertible. Over $\mathbb{C}$, A also has the eigenvalues $\pm i$, which is why (a) does not apply.

Solution to Exercise 7.5.37

Uses. Theorem 7.5.18 (Schur's theorem), Theorem 5.4.10 (Multiplicativity), Theorem 7.5.22 (Trace and determinant from eigenvalues)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Schur's theorem gives a unitary U for each matrix separately. Does it give one U that works for both?
Hint 2. Try $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.
Sketch. The proof uses the same U for A and B, but Schur's theorem only provides a U depending on the matrix. The claim is false: $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ have only the eigenvalue 0, but $AB = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ has the eigenvalue 1.

Schur's theorem applied to A gives some unitary U, and applied to B gives some unitary U', which in general differs from U. The argument silently takes $U' = U$. A common triangularizing basis exists only in special situations, for instance for commuting matrices (Section 7.6).

The claim itself is false. Take $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$; both have 0 as their only eigenvalue, with multiplicity 2. But $AB = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ has the eigenvalues 1 and 0, while the claim predicts $0, 0$. What survives is the product of all of them: $\det(AB) = \det A \det B$ (Theorem 5.4.10), so by Theorem 7.5.22 the product of the eigenvalues of AB is $\prod \lambda_i \prod \mu_i$.

Solution to Exercise 7.5.38

Uses. Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Lemma 7.5.11 (Compressing an operator to a complement), Theorem 5.4.26 (Block-triangular matrices), Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 4.4.16 (Complements exist), Theorem 6.4.24 (Orthogonal decomposition)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Follow the first proof of Theorem 7.5.13, but choose the first eigenvector for λ_1.
Hint 2. For the induction, you need the eigenvalues of the compression S. Show $p_T = (x - \lambda_1)p_S$ from the block form of Lemma 7.5.11(b).
Hint 3. For the orthonormal version, use $W = \operatorname{span}(\mathbf{b}_1)^\perp$ with $\mathbf{b}_1$ a unit vector, as in the second proof of Theorem 7.5.18.
Sketch. Induct on n. λ_1 is a root of p_T, hence an eigenvalue; take an eigenvector $\mathbf{b}_1$, a complement W, and the compression S. The block form $[T] = \begin{pmatrix} \lambda_1 & X \\ 0 & [S] \end{pmatrix}$ gives $p_T = (x - \lambda_1)p_S$, so $p_S = (x - \lambda_2)\cdots(x - \lambda_n)$. By induction W has a basis triangularizing S with diagonal $\lambda_2, \ldots, \lambda_n$, and the block form gives the diagonal $\lambda_1, \ldots, \lambda_n$ for T. With a unit $\mathbf{b}_1$ and $W = \operatorname{span}(\mathbf{b}_1)^\perp$ everything can be made orthonormal.

We induct on n; for $n = 1$ there is nothing to show. Let $n \geq 2$. Since $p_T = (x - \lambda_1)\cdots(x - \lambda_n)$, λ_1 is a root of p_T, hence an eigenvalue (Theorem 7.3.6). Let $\mathbf{b}_1$ be an eigenvector for λ_1, W a complement of $\operatorname{span}(\mathbf{b}_1)$ (Proposition 4.4.16), and S the compression of T to W. For a basis $\mathcal{D}$ of W and $\mathcal{B} = \mathbf{b}_1, \mathcal{D}$, Lemma 7.5.11(b) gives

$$[T]_{\mathcal{B}} = \begin{pmatrix} \lambda_1 & X \\ 0 & [S]_{\mathcal{D}} \end{pmatrix},$$

so, taking $\det(xI_n - \cdot)$ with Theorem 5.4.26, $p_T = (x - \lambda_1)p_S$. Cancelling $x - \lambda_1$ from $(x - \lambda_1)p_S = (x - \lambda_1)(x - \lambda_2)\cdots(x - \lambda_n)$ (Corollary 7.1.7) gives $p_S = (x - \lambda_2)\cdots(x - \lambda_n)$: the eigenvalues of S counted with multiplicity are $\lambda_2, \ldots, \lambda_n$. By the induction hypothesis, W has a basis $\mathcal{D} = \mathbf{b}_2, \ldots, \mathbf{b}_n$ with $[S]_{\mathcal{D}}$ upper triangular with diagonal $\lambda_2, \ldots, \lambda_n$ in this order. Then the displayed block matrix is upper triangular with diagonal $\lambda_1, \lambda_2, \ldots, \lambda_n$.

If V is an inner product space, choose $\mathbf{b}_1$ of norm 1 and $W = \operatorname{span}(\mathbf{b}_1)^\perp$, a complement by Theorem 6.4.24, and apply the inner product version of the induction hypothesis to W. Then $\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_n$ is orthonormal.

Solution to Exercise 7.5.39

Uses. Theorem 6.4.38 (QR factorization), Corollary 7.5.14 (Triangularizing a matrix), Proposition 2.4.36 (Products of upper triangular matrices), Exercise 7.5.34, Definition 6.3.33 (Unitary and orthogonal matrices)
Hint 1. S is invertible, so its columns are independent and Theorem 6.4.38 applies, with Q square.
Hint 2. Substitute $S = QR'$ into $A = SRS^{-1}$. Inverses and products of invertible upper-triangular matrices are upper triangular (Exercise 7.5.34(b), Proposition 2.4.36).
Sketch. $A = QR'RR'^{-1}Q^{-1}$ and $Q^{-1} = Q^*$. The product $R'RR'^{-1}$ is upper triangular with diagonal $r'_{jj}r_{jj}r'^{-1}_{jj} = r_{jj}$. The columns of Q are Gram–Schmidt applied to the columns of S, the triangularizing basis, which is exactly the first proof.

The columns of S form a basis of $\mathbb{C}^n$, so by Theorem 6.4.38, $S = QR'$ with $Q \in \mathbb{C}^{n\times n}$ having orthonormal columns, hence unitary (Definition 6.3.33), and R' upper triangular with positive diagonal entries, hence invertible. Then

$$A = SRS^{-1} = QR'RR'^{-1}Q^{-1} = QR''Q^*.$$

By Exercise 7.5.34(b) (whose argument applies to any invertible upper-triangular matrix), R'^{-1} is upper triangular with diagonal entries $1/r'_{jj}$, and by Proposition 2.4.36, $R'' = R'RR'^{-1}$ is upper triangular with diagonal entries $r'_{jj}r_{jj}\left(1/r'_{jj}\right) = r_{jj}$.

By Theorem 6.4.38, the columns of Q are the output of Gram–Schmidt applied to the columns of S, which form a basis triangularizing T_A. So this is the first proof of Theorem 7.5.18: Gram–Schmidt applied to a triangularizing basis. The triangular factor R' records the change of basis between the two bases with the same flag, and conjugating by it keeps R triangular.

Solution to Exercise 7.5.40

Uses. Definition 6.3.33 (Unitary and orthogonal matrices), Exercise 7.5.34, Theorem 7.5.18 (Schur's theorem), Exercise 6.3.37, Proposition 6.3.27 (Properties of the conjugate transpose)
Hint 1. $R^{-1} = R^*$. One side is upper triangular and the other lower triangular.
Hint 2. Alternatively, look at the columns: the first column $(r_{11}, 0, \ldots, 0)$ is a unit vector, and every other column is orthogonal to it.
Hint 3. For (b), apply Schur's theorem and check that $R = U^*AU$ is unitary.
Sketch. (a) $R^* = R^{-1}$ is upper triangular (Exercise 7.5.34(b)) and lower triangular (as the conjugate transpose of an upper-triangular matrix), so it is diagonal, and so is R; then $R^*R = I_n$ gives $|r_{jj}|^2 = 1$. (b) Schur gives $A = URU^*$, and $R = U^*AU$ is a product of unitary matrices.

(a) Since R is unitary, $R^{-1} = R^*$. By (the argument of) Exercise 7.5.34(b), the inverse of an invertible upper-triangular matrix is upper triangular, so R^* is upper triangular. But the (i, j) entry of R^* is $\overline{r_{ji}}$, which is 0 for $i < j$, so R^* is also lower triangular. Hence R^* is diagonal, and so is $R = (R^*)^*$. Finally the (j, j) entry of $R^*R = I_n$ is $\overline{r_{jj}}r_{jj} = |r_{jj}|^2 = 1$.

(b) By Theorem 7.5.18, $A = URU^*$ with U unitary and R upper triangular. Then $R = U^*AU$ is a product of unitary matrices, so it is unitary (Exercise 6.3.37). By (a), R is diagonal; take $D = R$.

Solution to Exercise 7.5.41

Uses. Theorem 7.5.18 (Schur's theorem), Proposition 6.1.16 (Frobenius inner product), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 7.5.8 (The diagonal of a triangular matrix)
Techniques. The trace of A^*A (Technique 6.1.18), Cyclicity of trace (Technique 2.4.29)
Hint 1. The right side is $\operatorname{tr}(A^*A)$ (Proposition 6.1.16). How does it change when A is replaced by U^*AU?
Hint 2. For a Schur form $R = U^*AU$, $\operatorname{tr}(A^*A) = \operatorname{tr}(R^*R) = \sum_{i,j}|r_{ij}|^2$, and the diagonal of R lists the eigenvalues.
Sketch. With $A = URU^*$, $A^*A = UR^*RU^*$, so $\operatorname{tr}(A^*A) = \operatorname{tr}(R^*RU^*U) = \operatorname{tr}(R^*R)$. Hence $\sum|a_{ij}|^2 = \sum|r_{ij}|^2 = \sum_j|\lambda_j|^2 + \sum_{i<j}|r_{ij}|^2$. Equality holds exactly when R is diagonal.

By Theorem 7.5.18, $A = URU^*$ with U unitary and R upper triangular with diagonal $\lambda_1, \ldots, \lambda_n$ (in some order). By Proposition 6.3.27, $A^* = UR^*U^*$, so $A^*A = UR^*U^*URU^* = UR^*RU^*$. By Proposition 6.1.16 and Proposition 2.4.28,

$$\sum_{i,j}|a_{ij}|^2 = \operatorname{tr}(A^*A) = \operatorname{tr}(U(R^*RU^*)) = \operatorname{tr}(R^*RU^*U) = \operatorname{tr}(R^*R) = \sum_{i,j}|r_{ij}|^2.$$

Since R is upper triangular,

$$\sum_{i,j}|r_{ij}|^2 = \sum_{j=1}^{n}|\lambda_j|^2 + \sum_{i<j}|r_{ij}|^2 \geq \sum_{j=1}^{n}|\lambda_j|^2,$$

which is the inequality.

If equality holds, then $r_{ij} = 0$ for all $i < j$, so R is diagonal and $A = URU^*$ has the required form. Conversely, if $A = UDU^*$ with D diagonal, then D is upper triangular, its diagonal lists the eigenvalues of A (Proposition 7.5.8, Proposition 7.5.9), and the computation above with $R = D$ gives equality. (In Section 8.2 such matrices are identified as the normal ones, $A^*A = AA^*$.)

Solution to Exercise 7.5.42

Uses. Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Lemma 7.5.11 (Compressing an operator to a complement), Theorem 5.4.26 (Block-triangular matrices), Corollary 7.1.7 (No zero divisors, cancellation, and units), Theorem 6.4.24 (Orthogonal decomposition), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Theorem 4.5.17 (Change of basis)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. The second proof of Theorem 7.5.18 only used $\mathbb{C}$ to find an eigenvalue. Over $\mathbb{R}$, with a split characteristic polynomial, an eigenvalue exists. What has to be checked for the compression?
Hint 2. Show that the compression S to $\operatorname{span}(\mathbf{u}_1)^\perp$ satisfies $p_A = (x-\lambda_1)p_S$, so p_S splits too.
Sketch. Prove the operator version on a real inner product space by induction on the dimension: a real root λ_1 of p_T gives a unit eigenvector $\mathbf{u}_1$; the compression S to $W = \operatorname{span}(\mathbf{u}_1)^\perp$ has $p_T = (x-\lambda_1)p_S$ by Lemma 7.5.11(b), so p_S splits; by induction W has an orthonormal basis triangularizing S, and $\mathbf{u}_1$ followed by it triangularizes T. Apply this to T_A on $\mathbb{R}^n$.

We prove: if V is a real inner product space with $1 \le \dim V = n < \infty$ and $T \in \mathrm{L}(V)$ has p_T splitting over $\mathbb{R}$, then V has an orthonormal basis triangularizing T. Applied to T_A on $\mathbb{R}^n$ with the dot product, with Q the matrix whose columns are that basis, this gives $Q^{\mathsf{T}}AQ = R$ upper triangular by Theorem 4.5.17, since $Q^{-1} = Q^{\mathsf{T}}$ for orthogonal Q.

Induct on n; for $n = 1$ any unit vector works. Let $n \ge 2$ and $p_T = (x-\mu_1)\cdots(x-\mu_n)$ with real μ_i. Then μ_1 is an eigenvalue (Theorem 7.3.6); let $\mathbf{u}_1$ be an eigenvector of norm 1. Let $W = \operatorname{span}(\mathbf{u}_1)^\perp$, a complement of $\operatorname{span}(\mathbf{u}_1)$ of dimension $n-1$ (Theorem 6.4.24), and let $S\mathbf{w} = T\mathbf{w} - \langle T\mathbf{w}, \mathbf{u}_1\rangle \mathbf{u}_1$, the compression of T to W (as in the second proof of Theorem 7.5.18). For any basis $\mathcal{D}$ of W, Lemma 7.5.11(b) and Theorem 5.4.26 give $p_T = (x-\mu_1)p_S$, and cancelling (Corollary 7.1.7) gives $p_S = (x-\mu_2)\cdots(x-\mu_n)$, which splits. By the induction hypothesis, W has an orthonormal basis $\mathbf{u}_2, \dots, \mathbf{u}_n$ with $S\mathbf{u}_j \in \operatorname{span}(\mathbf{u}_2, \dots, \mathbf{u}_j)$. Exactly as in the second proof of Theorem 7.5.18, $\mathbf{u}_1, \dots, \mathbf{u}_n$ is an orthonormal basis of V and $T\mathbf{u}_j = \langle T\mathbf{u}_j, \mathbf{u}_1\rangle \mathbf{u}_1 + S\mathbf{u}_j \in \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_j)$, so T is upper triangular with respect to it (Proposition 7.5.2).

Solution to Exercise 7.5.43

Uses. Exercise 7.5.34, Exercise 7.5.36, Theorem 5.5.21 (The Vandermonde determinant), Corollary 3.5.25 (The invertible matrix theorem), Theorem 5.4.14 (The transpose)
Hint 1. Group the nonzero eigenvalues: let $\mu_1, \dots, \mu_r$ be the distinct nonzero ones, with algebraic multiplicities $m_1, \dots, m_r \ge 1$. By Exercise 7.5.36 it suffices to show $r = 0$.
Hint 2. By Exercise 7.5.34(a), $\sum_j m_j \mu_j^k = 0$ for $k = 1, \dots, r$. This is a square linear system for $(m_1, \dots, m_r)$.
Hint 3. Its matrix is a Vandermonde matrix times $\operatorname{diag}(\mu_1, \dots, \mu_r)$. For $\mathbb{F}_p$, try I_p.
Sketch. If there are distinct nonzero eigenvalues $\mu_1, \dots, \mu_r$ with multiplicities m_j, then $\sum_j m_j \mu_j^k = \operatorname{tr}\left(A^k\right) = 0$ for $k = 1, \dots, r$. The coefficient matrix $\left(\mu_j^k\right)_{k,j}$ has determinant $\mu_1 \cdots \mu_r \prod_{i<j}(\mu_j - \mu_i) \neq 0$, so all $m_j = 0$ in $\mathbb{C}$, which is absurd. So 0 is the only eigenvalue, and $A^n = 0$. Over $\mathbb{F}_p$, $\operatorname{tr}\left(I_p^k\right) = p * 1 = 0$ for all k, but $I_p^p \neq 0$.

Let $\mu_1, \dots, \mu_r$ be the distinct nonzero eigenvalues of A, with algebraic multiplicities $m_1, \dots, m_r \ge 1$, and suppose $r \ge 1$. The eigenvalues of A counted with multiplicity are these, each repeated m_j times, together with 0 repeated $n - \sum m_j$ times. By Exercise 7.5.34(a), for $k = 1, \dots, r$ (note $r \le n$),

$$0 = \operatorname{tr}\left(A^k\right) = m_1\mu_1^k + m_2\mu_2^k + \cdots + m_r\mu_r^k,$$

where m_j stands for $m_j * 1 \in \mathbb{C}$. So $M\mathbf{c} = \mathbf{0}$, where $\mathbf{c} = (m_1, \dots, m_r)$ and $M \in \mathbb{C}^{r\times r}$ has entries $M_{kj} = \mu_j^k$. Factoring μ_j out of column j, $M = V' \operatorname{diag}(\mu_1, \dots, \mu_r)$ with $V'_{kj} = \mu_j^{k-1}$, the transpose of the Vandermonde matrix of $\mu_1, \dots, \mu_r$. By Theorem 5.5.21 and Theorem 5.4.14,

$$\det M = \mu_1\mu_2\cdots\mu_r \prod_{i<j}\left(\mu_j - \mu_i\right) \neq 0,$$

since the μ_j are nonzero and distinct. So M is invertible (Corollary 3.5.25), $\mathbf{c} = \mathbf{0}$, and $m_1 = 0$ in $\mathbb{C}$, contradicting $m_1 \ge 1$. Hence $r = 0$: 0 is the only eigenvalue of A, and $A^n = 0$ by Exercise 7.5.36.

Over $\mathbb{F}_p$, take $A = I_p \in \mathbb{F}_p^{p\times p}$. Then $\operatorname{tr}\left(A^k\right) = \operatorname{tr} I_p = p * 1 = 0$ for every k, but $A^p = I_p \neq 0$. The proof breaks at its last step: in $\mathbb{F}_p$, the conclusion $m_1 * 1 = 0$ is no contradiction when p divides m_1, as here, where $m_1 = p$.

Solution to Exercise 7.5.44

Uses. Proposition 2.4.28 (Cyclicity of the trace), Proposition 2.4.27 (The trace is linear), Exercise 7.5.43
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint 1. Compute $A^2B - BA^2$ in terms of A^2. Guess a formula for $A^kB - BA^k$.
Hint 2. Prove $A^kB - BA^k = kA^k$ by induction, then take the trace.
Sketch. By induction, $A^{k+1}B - BA^{k+1} = A\left(A^kB - BA^k\right) + (AB - BA)A^k = kA^{k+1} + A^{k+1}$, so $A^kB - BA^k = kA^k$. Taking traces, $k\operatorname{tr}\left(A^k\right) = 0$, so $\operatorname{tr}\left(A^k\right) = 0$ for all $k \geq 1$, and Exercise 7.5.43 gives $A^n = 0$.

We show $A^kB - BA^k = kA^k$ for $k \geq 1$ by induction. For $k = 1$ this is the hypothesis. If it holds for k, then

$$\begin{aligned} A^{k+1}B - BA^{k+1} &= A\left(A^kB - BA^k\right) + (AB - BA)A^k \\ &= A\left(kA^k\right) + AA^k = (k+1)A^{k+1}. \end{aligned}$$

Taking traces, using Proposition 2.4.27 and Proposition 2.4.28, $k\operatorname{tr}\left(A^k\right) = \operatorname{tr}\left(A^kB\right) - \operatorname{tr}\left(BA^k\right) = 0$, so $\operatorname{tr}\left(A^k\right) = 0$ for every $k \geq 1$, since $k \neq 0$ in $\mathbb{C}$. By Exercise 7.5.43, $A^n = 0$.

Solution to Exercise 7.5.44

Uses. Corollary 7.2.22 (At most $\dim V$ eigenvalues), Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29), Cyclicity of trace (Technique 2.4.29)
Hint 1. Consider the operator $L(X) = BX - XB$ on $\mathbb{C}^{n\times n}$. What does it do to A, to A^2, to A^k?
Hint 2. If no power of A were 0, L would have infinitely many eigenvalues.
Sketch. The identity $A^kB - BA^k = kA^k$ says $L\left(A^k\right) = -kA^k$ for $L(X) = BX - XB$. If $A^k \neq 0$ for every k, then $-1, -2, -3, \ldots$ are all eigenvalues of L, an operator on the n^2-dimensional space $\mathbb{C}^{n\times n}$, which has at most n^2 eigenvalues. So some $A^k = 0$, and then $A^n = 0$.

As in the first approach, $A^kB - BA^k = kA^k$ for all $k \geq 1$. Let $L \in \mathrm{L}(\mathbb{C}^{n\times n})$ be $L(X) = BX - XB$. Then $L\left(A^k\right) = -kA^k$. If $A^k \neq 0$ for every $k \geq 1$, then $-1, -2, \ldots, -\left(n^2+1\right)$ are n^2+1 distinct eigenvalues of L, which is impossible, since $\dim \mathbb{C}^{n\times n} = n^2$ (Corollary 7.2.22). So $A^k = 0$ for some k, and then $A^n = 0$ (Corollary 4.1.27).

Solution to Exercise 7.5.45

Uses. Lemma 2.4.24 (Matrix units), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Proposition 7.5.9 (Multiplicities on the diagonal), Corollary 7.5.14 (Triangularizing a matrix), Theorem 7.5.22 (Trace and determinant from eigenvalues)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29), Prove it for triangular matrices first (Technique 7.5.23)
Hint 1. Compute AU_{ij} (column i of A, moved to column j) and $U_{ij}A$ (row j of A, moved to row i), using that A is upper triangular.
Hint 2. Which matrix units appear in $L_A\left(U_{ij}\right)$ besides U_{ij}? Do they come before U_{ij} in the given order?
Hint 3. For (b), if $A = SRS^{-1}$, then L_A is conjugate to L_R by the invertible operator $X \mapsto SXS^{-1}$.
Sketch. (a) $AU_{ij} = \sum_{k\leq i} a_{ki}U_{kj}$ and $U_{ij}A = \sum_{l\geq j} a_{jl}U_{il}$, so $L_A\left(U_{ij}\right) = \left(a_{ii} - a_{jj}\right)U_{ij}$ plus units U_{kj} with $k < i$ (earlier rows) and U_{il} with $l > j$ (earlier in the same row). (b) With $A = SRS^{-1}$ and $C(X) = SXS^{-1}$, $L_A \circ C = C \circ L_R$, so L_A is upper triangular in the basis $C\left(U_{ij}\right)$ with diagonal $r_{ii} - r_{jj}$. (c) The sum of all $\lambda_i - \lambda_j$ is 0, and the terms with $i = j$ are 0, so $\det L_A = 0$.

(a) By Lemma 2.4.24, $AU_{ij} = (A\mathbf{e}_i)\mathbf{e}_j^{\mathsf{T}} = \sum_k a_{ki}U_{kj}$ and $U_{ij}A = \mathbf{e}_i\left(\mathbf{e}_j^{\mathsf{T}}A\right) = \sum_l a_{jl}U_{il}$. Since A is upper triangular, $a_{ki} = 0$ for $k > i$ and $a_{jl} = 0$ for $l < j$, so

$$L_A\left(U_{ij}\right) = \left(a_{ii} - a_{jj}\right)U_{ij} + \sum_{k<i} a_{ki}U_{kj} - \sum_{l>j} a_{jl}U_{il}.$$

In the given order, every U_{kj} with $k < i$ lies in an earlier row, and every U_{il} with $l > j$ lies earlier in the same row. So $L_A\left(U_{ij}\right)$ lies in the span of U_{ij} and the units before it, and by Proposition 7.5.2, L_A is upper triangular in this basis, with diagonal entry $a_{ii} - a_{jj}$ at U_{ij}.

(b) By Corollary 7.5.14, $A = SRS^{-1}$ with R upper triangular, $r_{ii} = \lambda_i$ after reordering. Let $C \in \mathrm{L}(\mathbb{C}^{n\times n})$ be $C(X) = SXS^{-1}$, which is invertible with inverse $X \mapsto S^{-1}XS$. For every X,

$$L_A(C(X)) = SRS^{-1}SXS^{-1} - SXS^{-1}SRS^{-1} = S(RX - XR)S^{-1} = C(L_R(X)).$$

So if $\mathcal{U}$ is the ordered basis of (a), then $C(\mathcal{U})$ is a basis (the image of a basis under an isomorphism), and L_A sends $C(U_{ij})$ to $C(L_R(U_{ij}))$, which has the same coordinates in $C(\mathcal{U})$ as $L_R(U_{ij})$ has in $\mathcal{U}$. Hence $[L_A]_{C(\mathcal{U})} = [L_R]_{\mathcal{U}}$ is upper triangular with diagonal entries $\lambda_i - \lambda_j$, and by Proposition 7.5.9 these are the eigenvalues of L_A counted with multiplicity.

(c) By Theorem 7.5.22, $\operatorname{tr} L_A = \sum_{i,j}(\lambda_i - \lambda_j) = n\sum_i \lambda_i - n\sum_j \lambda_j = 0$, and $\det L_A = \prod_{i,j}(\lambda_i - \lambda_j) = 0$, because the factors with $i = j$ vanish. So L_A is not invertible. (Directly: $L_A(I_n) = 0$.)

Solution to Exercise 7.5.46

Uses. Theorem 7.5.27 (Real block upper-triangular form), Lemma 7.5.11 (Compressing an operator to a complement)
Hint 1. Split $(1, 0, -i)$ into real and imaginary parts $\mathbf{x} + i\mathbf{y}$ and compute $A\mathbf{x}$ and $A\mathbf{y}$.
Hint 2. For (b), add a real eigenvector. For (c), the invariant plane already has an orthonormal basis; compress to its orthogonal complement.
Sketch. $A(1, 0, -i) = (i, 0, 1) = i(1, 0, -i)$. With $\mathbf{x} = \mathbf{e}_1$, $\mathbf{y} = -\mathbf{e}_3$: $A\mathbf{x} = -\mathbf{y}$, $A\mathbf{y} = \mathbf{x}$, so $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ is invariant. (b) $(3, 2, 1)$ is an eigenvector for 1, and in the basis $\mathbf{x}, \mathbf{y}, (3, 2, 1)$ the matrix is $\begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$. (c) Q with columns $\mathbf{e}_1, -\mathbf{e}_3, \mathbf{e}_2$ gives $Q^{\mathsf{T}}AQ = \begin{pmatrix} 0 & 1 & 2 \\ -1 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}$.

(a) $A(1, 0, -i) = (0 + 0 + i, 0, 1 + 0 + 0) = (i, 0, 1) = i(1, 0, -i)$, since $i(-i) = 1$. Write $(1, 0, -i) = \mathbf{x} + i\mathbf{y}$ with $\mathbf{x} = (1, 0, 0)$ and $\mathbf{y} = (0, 0, -1)$. Then

$$A\mathbf{x} = (0, 0, 1) = -\mathbf{y}, \quad A\mathbf{y} = (1, 0, 0) = \mathbf{x},$$

as in the complexification argument before Theorem 7.5.27, with $a = 0$ and $b = 1$. So $\operatorname{span}(\mathbf{x}, \mathbf{y}) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ is invariant, and A acts on it by $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ in the basis $\mathbf{x}, \mathbf{y}$, a block with eigenvalues $\pm i$.

(b) For the eigenvalue 1, $A - I_3 = \begin{pmatrix} -1 & 2 & -1 \\ 0 & 0 & 0 \\ 1 & -1 & -1 \end{pmatrix}$; adding the first and last rows gives $y - 2z = 0$, so $y = 2z$ and $x = y + z = 3z$, and $\mathbf{v} = (3, 2, 1)$ is an eigenvector. In the basis $\mathbf{x}, \mathbf{y}, \mathbf{v}$,

$$[T_A] = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

a 2×2 block without real eigenvalues followed by a 1×1 block.

(c) The plane $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ has the orthonormal basis $\mathbf{e}_1, -\mathbf{e}_3$, and $U^{\perp} = \operatorname{span}(\mathbf{e}_2)$. Let Q have columns $\mathbf{e}_1, -\mathbf{e}_3, \mathbf{e}_2$:

$$Q = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}.$$

Its columns are orthonormal, so Q is orthogonal. The columns of $Q^{\mathsf{T}}AQ$ are the coordinates of $A\mathbf{e}_1 = -(-\mathbf{e}_3)$, $A(-\mathbf{e}_3) = \mathbf{e}_1$, and $A\mathbf{e}_2 = (2, 1, -1) = 2\mathbf{e}_1 + (-\mathbf{e}_3) + \mathbf{e}_2$ in this basis:

$$Q^{\mathsf{T}}AQ = \begin{pmatrix} 0 & 1 & 2 \\ -1 & 0 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

The compression of T_A to $U^{\perp}$ is multiplication by 1 on $\operatorname{span}(\mathbf{e}_2)$, which is the bottom right entry.

Section 7.6

Solution to Exercise 7.6.6

Uses. Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Proposition 2.4.23 (Transpose of a product), Remark 7.1.11 (Polynomials in a matrix), Definition 7.1.9 (Substitution)
Hint 1. Show that A and A^{T} have exactly the same annihilating polynomials. What does that say about their minimal polynomials?
Hint 2. For (b), check on $p = x^k$ that the polynomial $q(x) = p(x - c)$ satisfies $q(A + cI_n) = p(A)$, then extend by linearity.
Sketch. (a) $p\left(A^{\mathsf{T}}\right) = p(A)^{\mathsf{T}}$, so the annihilating polynomials of A and A^{T} coincide, and so do their monic generators. (b) Substituting $x - c$ is a bijection of $F[x]$ preserving degrees and monicity, and $q(A + cI_n) = p(A)$ for $q(x) = p(x - c)$; so it maps the annihilating polynomials of A onto those of $A + cI_n$. Hence $m_{\lambda I_n + N} = (x - \lambda)^n$.

(a) By Proposition 2.4.23, $\left(A^k\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^k$ for every $k \geq 0$, and transposition respects sums and scalar multiples, so $p\left(A^{\mathsf{T}}\right) = p(A)^{\mathsf{T}}$ for every $p \in F[x]$. A matrix is 0 if and only if its transpose is, so p annihilates A^{T} if and only if it annihilates A. By Theorem 7.6.2, m_A divides every polynomial that annihilates A^{T}, in particular $m_{A^{\mathsf{T}}}$, and likewise $m_{A^{\mathsf{T}}} \mid m_A$. Two monic polynomials that divide each other have the same degree, so the quotient is a constant, which is 1 by comparing leading coefficients. Hence $m_{A^{\mathsf{T}}} = m_A$.

(b) For $p \in F[x]$ let $q(x) = p(x - c)$, the result of substituting $x - c$ into p (Definition 7.1.9). Both $p \mapsto q(A + cI_n)$ and $p \mapsto p(A)$ respect sums and scalar multiples, and for $p = x^k$, using Remark 7.1.11,

$$q(A + cI_n) = \left((x - c)^k\right)(A + cI_n) = ((A + cI_n) - cI_n)^k = A^k.$$

So $q(A + cI_n) = p(A)$ for every p. Substituting $x - c$ is a bijection of $F[x]$ (its inverse substitutes $x + c$) that preserves degrees and leading coefficients. Hence it maps the monic annihilating polynomials of A bijectively onto those of $A + cI_n$, preserving degrees, and the one of least degree goes to the one of least degree: $m_{A+cI_n}(x) = m_A(x - c)$.

For N, Example 7.6.5(b) gives $m_N = x^n$, so $m_{\lambda I_n + N} = (x - \lambda)^n$.

Solution to Exercise 7.6.19

Uses. Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial)
Techniques. Use an annihilating polynomial (Technique 7.6.17)
Hint 1. Compute the squares.
Hint 2. None of the three is a scalar matrix, so each minimal polynomial has degree at least 2.
Sketch. $A^2 = 3A$, $B^2 = 0$, $C^2 = I_2$. None is scalar, so $m_A = x(x - 3)$, $m_B = x^2$, and $m_C = (x - 1)(x + 1)$. Hence A and C are diagonalizable and B is not.

Every entry of A^2 is $1 + 1 + 1 = 3$, so $A^2 = 3A$, and $x^2 - 3x = x(x - 3)$ annihilates A. Next, $B^2 = \begin{pmatrix} 1-1 & -1+1 \\ 1-1 & -1+1 \end{pmatrix} = 0$, and $C^2 = \begin{pmatrix} 9-8 & -6+6 \\ 12-12 & -8+9 \end{pmatrix} = I_2$.

None of A, B, C is a scalar multiple of the identity, so no monic polynomial of degree 1 annihilates them, and each minimal polynomial has degree 2. Since the minimal polynomial divides the quadratic found above (Theorem 7.6.2) and both are monic of degree 2, they are equal: $m_A = x(x - 3)$, $m_B = x^2$, $m_C = (x - 1)(x + 1)$. By Theorem 7.6.15, A (eigenvalues 0 and 3) and C (eigenvalues 1 and -1) are diagonalizable over $\mathbb{Q}$, and B is not, since x^2 has a repeated root.

Solution to Exercise 7.6.27

Uses. Theorem 7.6.20 (Cayley–Hamilton), Proposition 7.3.18 (The first and last coefficients), Corollary 7.6.9 (Inverses are polynomials)
Techniques. Use an annihilating polynomial (Technique 7.6.17)
Hint 1. $p_A = x^2 - (\operatorname{tr} A)x + \det A$.
Hint 2. From $A^2 = 5A + 2I_2$, factor out A to find A^{-1}, and multiply by A to find A^3.
Sketch. $p_A = x^2 - 5x - 2$, so $A^2 = 5A + 2I_2$. Then $A(A - 5I_2) = 2I_2$ gives $A^{-1} = \frac{1}{2}(A - 5I_2)$, and $A^3 = 5A^2 + 2A = 27A + 10I_2$.

Here $\operatorname{tr} A = 5$ and $\det A = 4 - 6 = -2$, so $p_A = x^2 - 5x - 2$ (Proposition 7.3.18), and Cayley–Hamilton gives $A^2 = 5A + 2I_2$. Then $A(A - 5I_2) = 2I_2$, and since $A - 5I_2$ commutes with A,

$$A^{-1} = \frac{1}{2}(A - 5I_2) = \begin{pmatrix} -2 & 1 \\ 3/2 & -1/2 \end{pmatrix}.$$

Next, $A^3 = A \cdot A^2 = 5A^2 + 2A = 5(5A + 2I_2) + 2A = 27A + 10I_2 = \begin{pmatrix} 37 & 54 \\ 81 & 118 \end{pmatrix}$.

Solution to Exercise 7.6.40

Uses. Corollary 7.6.24 (The minimal polynomial divides the characteristic polynomial), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Proposition 7.3.15 (Block-triangular matrices)
Hint 1. The minimal polynomial divides p and has the same roots. List the candidates and test them from the smallest degree up.
Hint 2. For C, the characteristic polynomial factors along the blocks.
Sketch. $p_A = (x-1)^3$, $A - I \neq 0 = (A-I)^2$, so $m_A = (x-1)^2$. $p_B = x^3$, $B \neq 0 = B^2$, so $m_B = x^2$. $p_C = x(x-2)^2$ and $C(C - 2I) = 0$, so $m_C = x(x-2)$. Only C is diagonalizable.

The matrix A**.** It is upper triangular with diagonal $1, 1, 1$, so $p_A = (x-1)^3$. By Corollary 7.6.24(c), m_A is $(x-1)^k$ for some $1 \leq k \leq 3$. Now $A - I = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \neq 0$ and $(A-I)^2 = 0$, so $m_A = (x-1)^2$. It has a repeated root, so A is not diagonalizable (Theorem 7.6.15).

The matrix B**.** It is strictly upper triangular, so $p_B = x^3$. Since $B \neq 0$ and $B^2 = 0$ (the only nonzero row of B is the first, and it picks out the third row of B, which is zero), $m_B = x^2$, and B is not diagonalizable.

The matrix C**.** It is block diagonal with blocks (2) and $K = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$, so $p_C = (x-2)p_K = (x-2)\big(x^2 - 2x\big) = x(x-2)^2$ (Proposition 7.3.15). The candidates are $x(x-2)$ and $x(x-2)^2$. Since $K^2 = 2K$,

$$C(C - 2I) = \begin{pmatrix} 2 \cdot 0 & 0 \\ 0 & K(K - 2I_2) \end{pmatrix} = 0,$$

so $m_C = x(x-2)$, and C is diagonalizable, with eigenvalues $0, 2, 2$.

Solution to Exercise 7.6.41

Uses. Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues)
Techniques. Use an annihilating polynomial (Technique 7.6.17), Try small cases and small fields (Technique 1.2.38)
Hint 1. Every entry of J^2 is a sum of n ones. Is J a scalar matrix?
Hint 2. $R^2 = -I_2$ over every field. Factor $x^2 + 1$ over each $\mathbb{F}_p$ by trying all p values.
Sketch. (a) $J^2 = nJ$, and J is not scalar, so $m_J = x(x-n)$. If $n \neq 0$ in F, the roots $0, n$ are distinct and J is diagonalizable; if $n = 0$ in F, $m_J = x^2$ and it is not. (b) $m_R = x^2 + 1$ in each case. Over $\mathbb{F}_2$ it is $(x+1)^2$: not diagonalizable. Over $\mathbb{F}_3$ it has no roots: no eigenvalues. Over $\mathbb{F}_5$ it is $(x-2)(x-3)$: diagonalizable, with eigenvectors $(1,3)$ for 2 and $(1,2)$ for 3.

(a) The (i,j) entry of J^2 is $\sum_{l=1}^{n} 1 \cdot 1 = n$, so $J^2 = nJ$, and $x^2 - nx = x(x-n)$ annihilates J. Since $n \geq 2$, J has nonzero off-diagonal entries, so it is not a scalar matrix and $\deg m_J \geq 2$. Hence $m_J = x(x-n)$ (Theorem 7.6.2). If $n \neq 0$ in F, the roots 0 and n are distinct and J is diagonalizable, with eigenvalues 0 and n (Theorem 7.6.15). If $n = 0$ in F (for instance $F = \mathbb{F}_p$ with p dividing n), then $m_J = x^2$ and J is not diagonalizable; it is a nonzero matrix with $J^2 = 0$. For example, over $\mathbb{F}_2$, $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}^2 = 0$.

(b) Over every field $R^2 = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = -I_2$, and R is not scalar, so $m_R = x^2 + 1$.

Over $\mathbb{F}_2$, $x^2 + 1 = x^2 - 1 = (x-1)^2$, with a repeated root, so R is not diagonalizable over $\mathbb{F}_2$.

Over $\mathbb{F}_3$, $x^2 + 1$ takes the values $1, 2, 2$ at $0, 1, 2$, so it has no roots, R has no eigenvalues (Theorem 7.6.7), and R is not diagonalizable.

Over $\mathbb{F}_5$, $2^2 + 1 = 5 = 0$ and $3^2 + 1 = 10 = 0$, so $x^2 + 1 = (x-2)(x-3)$ with distinct roots, and R is diagonalizable. If $R(1,a) = (-a, 1) = \lambda(1,a)$, then $\lambda = -a$ and $1 = \lambda a = -a^2$. For $a = 3$: $\lambda = -3 = 2$, and $R(1,3) =$

$(-3,1) = (2,1) = 2(1,3)$ in $\mathbb{F}_5$. For $a = 2$: $\lambda = -2 = 3$, and $R(1,2) = (-2,1) = (3,1) = 3(1,2)$. So $(1,3),(1,2)$ is an eigenbasis, with eigenvalues $2, 3$.

Solution to Exercise 7.6.42

Uses. Corollary 7.6.24 (The minimal polynomial divides the characteristic polynomial), Theorem 7.6.20 (Cayley–Hamilton), Corollary 7.6.9 (Inverses are polynomials), Exercise 7.6.6
Techniques. Use an annihilating polynomial (Technique 7.6.17)
Hint 1. A is triangular. For m_A, test the candidate $x(x-1)$.
Hint 2. For (b), Cayley–Hamilton gives $A^3 = 2A^2 - A$. Induct on k.
Hint 3. $m_B(x) = m_A(x-1)$. Expand it, and use Corollary 7.6.9.
Sketch. (a) $p_A = x(x-1)^2$ and $A(A-I) \neq 0$, so $m_A = p_A$. (b) $A^3 = 2A^2 - A$; if $A^k = (k-1)A^2 + (2-k)A$, then $A^{k+1} = (k-1)A^3 + (2-k)A^2 = kA^2 + (1-k)A$. (c) $m_B = (x-1)(x-2)^2 = x^3 - 5x^2 + 8x - 4$, so $B^{-1} = \frac{1}{4}\big(B^2 - 5B + 8I_3\big)$.

(a) A is upper triangular with diagonal $1, 1, 0$, so $p_A = x(x-1)^2 = x^3 - 2x^2 + x$. By Corollary 7.6.24(c), m_A is $x(x-1)$ or $x(x-1)^2$. Now

$$A(A - I_3) = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \neq 0,$$

so $m_A = x(x-1)^2 = p_A$.

(b) By Cayley–Hamilton, $A^3 - 2A^2 + A = 0$. We induct on k. For $k = 1$ the formula reads $A = 0 \cdot A^2 + A$. If $A^k = (k-1)A^2 + (2-k)A$, then

$$A^{k+1} = (k-1)A^3 + (2-k)A^2 = (k-1)\big(2A^2 - A\big) + (2-k)A^2 = kA^2 + (1-k)A,$$

which is the formula for $k+1$. (Equivalently, $(k-1)x^2 + (2-k)x$ is the remainder of x^k on division by $x(x-1)^2$.)

(c) By Exercise 7.6.6(b), $m_B(x) = m_A(x-1) = (x-1)(x-2)^2 = x^3 - 5x^2 + 8x - 4$. Since $m_B(0) = -4 \neq 0$, B is invertible, and writing $m_B = x\big(x^2 - 5x + 8\big) - 4$, Corollary 7.6.9 gives

$$B^{-1} = \frac{1}{4}\big(B^2 - 5B + 8I_3\big).$$

With $B = \begin{pmatrix} 2 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix}$ and $B^2 = \begin{pmatrix} 4 & 4 & 4 \\ 0 & 4 & 3 \\ 0 & 0 & 1 \end{pmatrix}$,

$$B^{-1} = \frac{1}{4}\begin{pmatrix} 2 & -1 & -1 \\ 0 & 2 & -2 \\ 0 & 0 & 4 \end{pmatrix} = \begin{pmatrix} 1/2 & -1/4 & -1/4 \\ 0 & 1/2 & -1/2 \\ 0 & 0 & 1 \end{pmatrix}.$$

Multiplying by B confirms this.

Solution to Exercise 7.6.43

Uses. Remark 7.6.11 (Neither polynomial determines the other), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Proposition 4.5.27 (Similarity invariants)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Rule out similarity with an invariant (Technique 4.5.29), Use an annihilating polynomial (Technique 7.6.17)
Hint 1. For (b), look at 4×4 matrices with $A^2 = 0$. Which similarity invariant can still tell them apart?
Hint 2. For (c), think of a nilpotent matrix.
Hint 3. For (d), if $m_{A^2} = (x-\mu_1)\cdots(x-\mu_m)$, which polynomial annihilates A? Are its roots distinct?
Sketch. (a) False: I_2 and $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. (b) False: with $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, the block matrices $\operatorname{diag}(N, 0)$ and $\operatorname{diag}(N, N)$ both have $p = x^4$ and $m = x^2$ but ranks 1 and 2. (c) False: $N^2 = 0$. (d) True: A is killed by $\prod(x^2 - \mu_i)$, whose $2m$ roots $\pm\sqrt{\mu_i}$ are distinct because the μ_i are distinct and nonzero.

(a) False. I_2 and $J = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ both have characteristic polynomial $(x-1)^2$, but $m_{I_2} = x - 1$ and $m_J = (x-1)^2$ (Remark 7.6.11).

(b) False. Let $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, and in $F^{4\times 4}$ let $A = \begin{pmatrix} N & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} N & 0 \\ 0 & N \end{pmatrix}$ in block form. Both are strictly upper triangular, so $p_A = p_B = x^4$. Both are nonzero with $A^2 = B^2 = 0$, so $m_A = m_B = x^2$. But $\operatorname{rank} A = 1$ and $\operatorname{rank} B = 2$, and similar matrices have the same rank (Proposition 4.5.27), so A and B are not similar.

(c) False. $N^2 = 0$ is diagonal, but N is not diagonalizable, since $m_N = x^2$.

(d) True. Since A^2 is diagonalizable, $m_{A^2} = (x-\mu_1)\cdots(x-\mu_m)$ with distinct $\mu_i \in \mathbb{C}$ (Theorem 7.6.15), and every μ_i is an eigenvalue of A^2. As A is invertible, so is A^2, so every $\mu_i \neq 0$. Choose $\nu_i \in \mathbb{C}$ with $\nu_i^2 = \mu_i$. Then

$$q = (x^2-\mu_1)\cdots(x^2-\mu_m) = \prod_{i=1}^{m}(x-\nu_i)(x+\nu_i)$$

satisfies $q(A) = m_{A^2}(A^2) = 0$. Its $2m$ roots $\pm\nu_i$ are distinct: $\nu_i \neq -\nu_i$ because $\nu_i \neq 0$, and for $i \neq j$ the roots $\pm\nu_i$ and $\pm\nu_j$ have different squares $\mu_i \neq \mu_j$. By Theorem 7.6.15(III), A is diagonalizable. (Invertibility was needed: in (c), $\mu_1 = 0$ and x^2 has a double root.)

Solution to Exercise 7.6.44

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Theorem 7.6.20 (Cayley–Hamilton)
Hint 1. Every step is correct except one. Do the eigenvectors of A always span $\mathbb{C}^n$?
Hint 2. Try $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.
Sketch. The eigenvectors of A span $\mathbb{C}^n$ only if A is diagonalizable; for $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ they span only $\operatorname{span}(\mathbf{e}_1)$, and the argument says nothing about $p_N(N)\mathbf{e}_2$. So the argument proves Cayley–Hamilton exactly for diagonalizable matrices. The perturbation proof extends the diagonalizable case to all matrices.

The computation $p_A(A)\mathbf{v} = p_A(\lambda)\mathbf{v} = \mathbf{0}$ is correct, and so is the principle that a linear map vanishing on a spanning set is zero. The error is the unstated claim that the eigenvectors of A span $\mathbb{C}^n$. They do if and only if $\mathbb{C}^n$ has a basis of eigenvectors, that is, if and only if A is diagonalizable (Theorem 7.4.2). For $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ the eigenvectors are the nonzero multiples of $\mathbf{e}_1$, and the argument gives no information about $p_N(N)\mathbf{e}_2$. (Here $p_N(N) = N^2 = 0$ anyway, but the argument does not show it.)

So the argument is a valid proof for diagonalizable A. The fourth proof of Theorem 7.6.20 starts from exactly this case and then reaches every matrix: it moves A to diagonalizable matrices A_t, and uses that the entries of $p_{A_t}(A_t)$ are polynomials in t that vanish for all but finitely many t, hence also at $t = 0$.

Solution to Exercise 7.6.45

Uses. Proposition 7.6.12 (Distinct linear factors force a diagonalization), Theorem 7.6.15 (Diagonalizability and the minimal polynomial)
Techniques. Use an annihilating polynomial (Technique 7.6.17), Lagrange interpolation in T (Technique 7.6.13)
Hint 1. Factor $x^2 - x - 2$. When are its roots distinct?
Hint 2. The projection onto E_2 is $L(T)$, where L is the Lagrange polynomial with $L(2) = 1$ and $L(-1) = 0$.
Hint 3. Over $\mathbb{F}_3$, $x^2 - x - 2 = (x+1)^2$. Look for $A = -I_2 + N$ with $N^2 = 0$.
Sketch. (a) $x^2 - x - 2 = (x-2)(x+1)$, and $2 - (-1) = 3 \neq 0$, so the roots are distinct; Proposition 7.6.12 gives $V = E_2 \oplus E_{-1}$, and the projection is $L(T) = \frac{1}{3}(T + \mathrm{id}_V)$. (b) Over $\mathbb{F}_3$ the polynomial is $(x+1)^2$, and $A = \begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$ works.

(a) The polynomial $q = x^2 - x - 2 = (x-2)(x+1)$ annihilates T. Its roots 2 and -1 differ by $3 \neq 0$, so they are distinct, and Proposition 7.6.12 gives $V = E_2 \oplus E_{-1}$; T is diagonalizable with eigenvalues in $\{2, -1\}$. The Lagrange polynomial of the node 2 (with the other node -1) is $L = (x+1)/3$, so $P = L(T) = \frac{1}{3}(T + \mathrm{id}_V)$. Indeed, P acts on E_2 as $(2+1)/3 = 1$ and on E_{-1} as $(-1+1)/3 = 0$, which is the projection onto E_2 along E_{-1}.

(b) In $\mathbb{F}_3$, $-1 = 2$ and $-2 = 1$, so $x^2 - x - 2 = x^2 + 2x + 1 = (x+1)^2$. Let $A = \begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix} = -I_2 + \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. Then

$$A^2 = \begin{pmatrix} 4 & 4 \\ 0 & 4 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad A + 2I_2 = \begin{pmatrix} 4 & 1 \\ 0 & 4 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix},$$

so $A^2 = A + 2I_2$. Since $A \neq -I_2$, $m_A = (x+1)^2$, and A is not diagonalizable (Theorem 7.6.15).

Solution to Exercise 7.6.46

Uses. Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues), Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Theorem 7.6.20 (Cayley–Hamilton), Proposition 7.3.18 (The first and last coefficients)
Techniques. Use an annihilating polynomial (Technique 7.6.17)
Hint 1. $q = x^2 + x + 1$ has no root in $\mathbb{F}_2$. What does that say about m_A, given that $m_A \mid q$?
Hint 2. So $m_A = q$, and Cayley–Hamilton forces $p_A = q$. Translate $p_A = x^2 + x + 1$ into conditions on $\operatorname{tr} A$ and $\det A$.
Sketch. (a) q has no roots in $\mathbb{F}_2$, so m_A, a divisor of q of degree at least 1, cannot be linear: $m_A = q$. By Cayley–Hamilton $q \mid p_A$, so $p_A = q$, that is, $\operatorname{tr} A = 1$ and $\det A = 1$. Conversely these give $A^2 + A + I_2 = 0$. The solutions are $\left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. (b) $A^2 = A + I_2$, $A(A + I_2) = I_2$, and $(A + I_2)^2 = A$.

(a) Let $q = x^2 + x + 1 \in \mathbb{F}_2[x]$; $q(0) = q(1) = 1$, so q has no roots in $\mathbb{F}_2$. Suppose $q(A) = 0$. Then $m_A \mid q$. If m_A had degree 1, say $m_A = x - c$, then c would be a root of q. So $m_A = q$. By Theorem 7.6.20, $m_A \mid p_A$, and both are monic of degree 2, so $p_A = q$. By Proposition 7.3.18, $p_A = x^2 - (\operatorname{tr} A)x + \det A$, so $\operatorname{tr} A = -1 = 1$ and $\det A = 1$. Conversely, if $\operatorname{tr} A = \det A = 1$, then $p_A = q$, and Cayley–Hamilton gives $q(A) = 0$.

So we need $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ with $a + d = 1$ and $ad - bc = 1$. The first condition gives $(a, d) = (1, 0)$ or $(0, 1)$; in both cases $ad = 0$, so $bc = -1 = 1$, forcing $b = c = 1$. The solutions are

$$\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}.$$

(b) From $A^2 + A + I_2 = 0$ and $-1 = 1$ in $\mathbb{F}_2$ we get $A^2 = A + I_2$. Sums: $A + A = 0$, $A + I_2$ is in the list, and $A + (A + I_2) = I_2$, $I_2 + (A + I_2) = A$; the rest are clear. Products: $A^2 = A + I_2$, $A(A + I_2) = A^2 + A = I_2$, and $(A + I_2)^2 = A^2 + I_2 = A$; products with 0 and I_2 are clear. So $A^{-1} = A + I_2$, $(A + I_2)^{-1} = A$, and $I_2^{-1} = I_2$. These four matrices form a field with four elements, $\mathbb{F}_4$ (Section 14.3).

Solution to Exercise 7.6.47

Uses. Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.6.20 (Cayley–Hamilton), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Proposition 7.1.22 (Counting roots), Proposition 7.2.28 (Polynomials act on eigenvectors by their values)
Techniques. Krylov sequences must become dependent (Technique 7.3.28)
Hint 1. For (a): if $\mathbf{v}$ is cyclic, $\mathbf{v}, T\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is a basis, so no nonzero polynomial of degree less than n kills $\mathbf{v}$.
Hint 2. For "$\Rightarrow$" in (b), combine (a) with Theorem 7.6.15.
Hint 3. For "$\Leftarrow$", try the sum $\mathbf{v}$ of an eigenbasis. What is $q(T)\mathbf{v}$ in that basis?
Sketch. (a) By Proposition 7.2.35, no nonzero polynomial of degree less than n kills a cyclic $\mathbf{v}$, so $\deg m_T \geq n$; with $m_T \mid p_T$, $m_T = p_T$. (b) If T is diagonalizable and cyclic, $m_T = \prod(x - \lambda_i)$ over the distinct eigenvalues has degree n. Conversely, with an eigenbasis $\mathbf{v}_i$ for distinct λ_i and $\mathbf{v} = \sum \mathbf{v}_i$, $q(T)\mathbf{v} = \sum q(\lambda_i)\mathbf{v}_i$ vanishes only if q has the n roots λ_i, so no nonzero q of degree less than n kills $\mathbf{v}$, and $\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is independent.

(a) Let $\mathbf{v}$ be cyclic. Then $\mathbf{v} \neq \mathbf{0}$ and $\dim K_T(\mathbf{v}) = n$, so by Proposition 7.2.35 the Krylov sequence first becomes dependent at $d = n$, and no nonzero polynomial of degree less than n sends $\mathbf{v}$ to $\mathbf{0}$. Since $m_T(T)\mathbf{v} = \mathbf{0}$, $\deg m_T \geq n$. By Theorem 7.6.20, $m_T \mid p_T$, which is monic of degree n, so $m_T = p_T$.

(b) Suppose T is diagonalizable with a cyclic vector. By (a), $\deg m_T = n$, and by Theorem 7.6.15, m_T is the product of $x - \lambda$ over the distinct eigenvalues λ. So T has n distinct eigenvalues.

Conversely, let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be eigenvectors for distinct eigenvalues $\lambda_1, \ldots, \lambda_n$; they form a basis (Corollary 7.4.5). Let $\mathbf{v} = \mathbf{v}_1 + \cdots + \mathbf{v}_n$. For $q \in F[x]$, Proposition 7.2.28 gives

$$q(T)\mathbf{v} = q(\lambda_1)\mathbf{v}_1 + \cdots + q(\lambda_n)\mathbf{v}_n,$$

which is $\mathbf{0}$ only if $q(\lambda_i) = 0$ for every i. A nonzero polynomial of degree less than n has fewer than n roots (Proposition 7.1.22), so no such polynomial kills $\mathbf{v}$. A linear relation among $\mathbf{v}, T\mathbf{v}, \ldots, T^{n-1}\mathbf{v}$ is a polynomial of degree less than n killing $\mathbf{v}$, so these n vectors are independent, hence a basis of V, and $K_T(\mathbf{v}) = V$.

Solution to Exercise 7.6.48

Uses. Definition 7.2.33 (Krylov subspace), Proposition 7.2.35 (A basis of a Krylov subspace), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 7.6.4 (The minimal polynomial is the first dependence among the powers), Exercise 7.6.47
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. $S\mathbf{v}$ lies in $K_T(\mathbf{v}) = V$, so $S\mathbf{v} = q(T)\mathbf{v}$ for some q.
Hint 2. Compare S and $q(T)$ on the basis $\mathbf{v}, T\mathbf{v}, \dots, T^{n-1}\mathbf{v}$, using $ST^k = T^kS$.
Sketch. Polynomials in T commute with T. Conversely, write $S\mathbf{v} = q(T)\mathbf{v}$; then $ST^k\mathbf{v} = T^kS\mathbf{v} = q(T)T^k\mathbf{v}$, so S and $q(T)$ agree on a basis. The commutant is therefore $F[T]$, of dimension $\deg m_T = n$.

If $S = q(T)$, then $ST = TS$ by Proposition 7.2.27(b). Conversely, suppose $ST = TS$. Since $S\mathbf{v} \in V = K_T(\mathbf{v})$, there is $q \in F[x]$ with $S\mathbf{v} = q(T)\mathbf{v}$ (Definition 7.2.33). For every $k \geq 0$, $ST^k = T^kS$ (by induction on k), and $q(T)$ commutes with T^k, so

$$S\big(T^k\mathbf{v}\big) = T^k(S\mathbf{v}) = T^kq(T)\mathbf{v} = q(T)\big(T^k\mathbf{v}\big).$$

So S and $q(T)$ agree on the basis $\mathbf{v}, T\mathbf{v}, \dots, T^{n-1}\mathbf{v}$ of V (Proposition 7.2.35), and hence $S = q(T)$ (Theorem 2.2.1).

So the operators commuting with T are exactly the elements of $F[T]$. By Proposition 7.6.4, $\dim F[T] = \deg m_T$, and $m_T = p_T$ has degree n by Exercise 7.6.47(a).

Solution to Exercise 7.6.49

Uses. Corollary 7.6.16 (Restrictions of diagonalizable operators), Corollary 7.2.23 (Eigenspaces are independent), Proposition 4.4.16 (Complements exist), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$)
Techniques. Glue bases of the summands (Technique 4.4.14), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. For "$\Rightarrow$": $T{\restriction_U}$ is diagonalizable, so U is the direct sum of the pieces $U \cap E_\lambda$. Complete each piece inside E_λ.
Hint 2. For "$\Longleftarrow$": apply the hypothesis to $U = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_m}$, the sum of all eigenspaces. What happens if its invariant complement is nonzero?
Sketch. ($\Rightarrow$) $U = \oplus_\lambda (U \cap E_\lambda)$ by Corollary 7.6.16. Choose a complement W_λ of $U \cap E_\lambda$ inside E_λ and let $W = \sum W_\lambda$; T acts on W_λ as λ, so W is invariant, and concatenated bases show $V = U \oplus W$. ($\Longleftarrow$) Let U be the sum of all eigenspaces and W an invariant complement. If $W \neq \{\mathbf{0}\}$, $T{\restriction_W}$ has an eigenvector, which lies in $U \cap W = \{\mathbf{0}\}$. So $U = V$. Over $\mathbb{R}$, a rotation of $\mathbb{R}^2$ is a counterexample.

($\Rightarrow$) Let $\lambda_1, \dots, \lambda_m$ be the distinct eigenvalues of T, so $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_m}$, and let U be T-invariant. If $U = \{\mathbf{0}\}$, take $W = V$. Otherwise $T{\restriction_U}$ is diagonalizable (Corollary 7.6.16), and each of its eigenvectors lies in some $U_i = U \cap E_{\lambda_i}$, so $U = U_1 + \cdots + U_m$. For each i, choose a complement W_i of U_i inside E_{λ_i} (Proposition 4.4.16), and let $W = W_1 + \cdots + W_m$. Since T acts on $W_i \subseteq E_{\lambda_i}$ as multiplication by λ_i, W is T-invariant.

Choose bases $\mathcal{C}_i$ of U_i and $\mathcal{D}_i$ of W_i. Since $E_{\lambda_i} = U_i \oplus W_i$, the list $\mathcal{C}_i, \mathcal{D}_i$ is a basis of E_{λ_i}, and since V is the direct sum of the E_{λ_i}, all these lists together form a basis of V (Theorem 4.4.13(b)). The vectors from the $\mathcal{C}_i$ span U, and those from the $\mathcal{D}_i$ span W. A basis of V split into two parts, one spanning U and the other spanning W, shows that $U + W = V$ and that each vector has only one decomposition, so $V = U \oplus W$ (Theorem 4.4.13(b)).

($\Longleftarrow$) Let $U = E_{\lambda_1} + \cdots + E_{\lambda_m}$, the sum of all eigenspaces, which is direct (Corollary 7.2.23) and T-invariant. By hypothesis $V = U \oplus W$ with W invariant. If $W \neq \{\mathbf{0}\}$, then $T{\restriction_W}$ has an eigenvector $\mathbf{w}$ (Theorem 7.3.27), and $\mathbf{w}$ is an eigenvector of T, so $\mathbf{w} \in U \cap W = \{\mathbf{0}\}$, a contradiction. So $W = \{\mathbf{0}\}$, $V = U$, and concatenating bases of the eigenspaces gives an eigenbasis.

Over $\mathbb{R}$, "$\Longleftarrow$" fails: the rotation $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ of $\mathbb{R}^2$ has no invariant lines, so its only invariant subspaces are $\{\mathbf{0}\}$ and $\mathbb{R}^2$, which are complements of each other. Yet R is not diagonalizable over $\mathbb{R}$.

Solution to Exercise 7.6.50

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.5.22 (Trace and determinant from eigenvalues), Proposition 7.1.38 (Conjugate roots), Proposition B.1.8 (Properties of the modulus)

Techniques. Use an annihilating polynomial (Technique 7.6.17)
Hint 1. Every complex eigenvalue of A is a root of $f = x^3 - x - 1$. The determinant is the product of the complex eigenvalues with multiplicity.
Hint 2. Show that every real root of f is positive. What do the nonreal eigenvalues contribute to the product?
Sketch. The complex eigenvalues are roots of $f = x^3 - x - 1$. A real root r satisfies $r(r^2-1) = 1$; if $r < 0$ this needs $-1 < r < 0$, but then $r(r^2-1) = |r|(1-r^2) < 1$. So real eigenvalues are positive. Nonreal eigenvalues pair up with their conjugates, with equal multiplicity, contributing $|\lambda|^2 > 0$. So $\det A$, the product, is positive.

Regard A as a complex matrix, and let $\lambda_1, \ldots, \lambda_n$ be its eigenvalues counted with multiplicity, so that $\det A = \lambda_1 \cdots \lambda_n$ (Theorem 7.5.22). Since $f = x^3 - x - 1$ annihilates A, every λ_j is a root of f (Proposition 7.2.28).

Real eigenvalues are positive. Let $r \in \mathbb{R}$ with $f(r) = 0$, that is, $r(r^2-1) = 1$. Clearly $r \neq 0$. If $r < 0$, then $r^2 - 1 < 0$ is needed for the product to be positive, so $-1 < r < 0$; but then $r(r^2-1) = |r|(1-r^2) \leq |r| < 1$, a contradiction. So $r > 0$.

Nonreal eigenvalues pair up. The polynomial p_A has real coefficients, so by Proposition 7.1.38 each nonreal λ and its conjugate $\overline{\lambda} \neq \lambda$ occur in the list $\lambda_1, \ldots, \lambda_n$ equally often. Grouping each such λ with a copy of $\overline{\lambda}$, the pair contributes $\lambda\overline{\lambda} = |\lambda|^2 > 0$ to the product (Proposition B.1.8).

So $\det A$ is a product of positive real eigenvalues and positive numbers $|\lambda|^2$, and $\det A > 0$.

Solution to Exercise 7.6.51

Uses. Corollary 7.6.33 (Eigenvalues of sums and products of commuting operators), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.6.20 (Cayley–Hamilton), Proposition 7.5.9 (Multiplicities on the diagonal), Corollary 7.1.35 (Factorization over $\mathbb{C}$)
Techniques. Prove it for triangular matrices first (Technique 7.5.23)
Hint 1. A nilpotent matrix has 0 as its only eigenvalue. Use Corollary 7.6.33.
Hint 2. A complex matrix whose only eigenvalue is 0 has $p = x^n$. Then apply Cayley–Hamilton.
Hint 3. For (c), compare the diagonals of AB and BA.
Sketch. (a) All eigenvalues of A and B are 0, so by Corollary 7.6.33 all eigenvalues of $A+B$ and AB are 0; then $p = x^n$ and Cayley–Hamilton gives $(A+B)^n = 0 = (AB)^n$. (b) $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and N^{T}. (c) AB and BA have the same diagonal $a_{ii}b_{ii}$, so $AB - BA$ is strictly upper triangular, with $p = x^n$. Example: $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$.

(a) If $A^k = 0$, every eigenvalue of A is a root of x^k (Proposition 7.2.28), so 0 is the only eigenvalue of A; likewise for B. By Corollary 7.6.33, every eigenvalue of $A+B$ is a sum $0+0$ and every eigenvalue of AB is a product $0 \cdot 0$. So p_{A+B} is a monic polynomial of degree n whose only complex root is 0, that is, $p_{A+B} = x^n$ (Corollary 7.1.35), and Cayley–Hamilton gives $(A+B)^n = 0$. In the same way $(AB)^n = 0$.

(A direct argument also works: since A and B commute, the binomial theorem gives $(A+B)^{2k} = \sum_j \binom{2k}{j} A^j B^{2k-j}$, and in each term $j \geq k$ or $2k - j \geq k$. And $(AB)^k = A^k B^k = 0$.)

(b) $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and N^{T} satisfy $N^2 = \left(N^{\mathsf{T}}\right)^2 = 0$, but $N + N^{\mathsf{T}} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ squares to I_2, and $NN^{\mathsf{T}} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ is a nonzero projection; neither is nilpotent.

(c) As in the proof of Theorem 7.6.28, AB and BA are upper triangular with the same diagonal entries $a_{ii}b_{ii}$. So $C = AB - BA$ is upper triangular with zero diagonal, $p_C = x^n$ by Proposition 7.5.9, and $C^n = 0$ by Cayley–Hamilton. If $A = SRS^{-1}$ and $B = SR'S^{-1}$ with R, R' upper triangular, then $AB - BA = S(RR' - R'R)S^{-1}$, and $(AB - BA)^n = S(RR' - R'R)^n S^{-1} = 0$.

For $X = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $Y = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, $XY = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $YX = 0$. So matrices can be triangular in the same basis without commuting; the converse of Theorem 7.6.32 fails.

Solution to Exercise 7.6.52

Uses. Theorem 5.4.10 (Multiplicativity), Proposition 7.3.2 (Determinants over a commutative ring), Proposition B.1.8 (Properties of the modulus)
Hint 1. Factor $A^2 + B^2$ over $\mathbb{C}$, the way $a^2 + b^2 = (a+ib)(a-ib)$. Where is $AB = BA$ used?
Hint 2. How are $\det(A+iB)$ and $\det(A-iB)$ related when A, B are real?

Sketch. Since $AB = BA$, $(A+iB)(A-iB) = A^2+B^2$. As $A-iB$ is the entrywise conjugate of $A+iB$, $\det(A-iB) = \overline{\det(A+iB)}$, so $\det(A^2+B^2) = |\det(A+iB)|^2 \geq 0$. For $A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$, $\det(A^2+B^2) = -1$.

Regard A and B as complex matrices. Then

$$(A+iB)(A-iB) = A^2 - iAB + iBA + B^2 = A^2 + B^2,$$

because $AB = BA$. Since A and B are real, $A-iB$ is the entrywise complex conjugate of $A+iB$. Complex conjugation $\mathbb{C} \to \mathbb{C}$ respects sums and products and fixes 1, so Proposition 7.3.2(g) gives $\det(A-iB) = \overline{\det(A+iB)}$. By Theorem 5.4.10 and Proposition B.1.8,

$$\det(A^2+B^2) = \det(A+iB)\overline{\det(A+iB)} = |\det(A+iB)|^2 \geq 0.$$

Without commuting this fails. Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$. Then $A^2 = A$ and $B^2 = B$, so $A^2 + B^2 = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}$, with determinant -1. (Here $AB = \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix} \neq \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} = BA$.)

Solution to Exercise 7.6.53

Uses. Theorem 7.6.34 (Simultaneous diagonalization), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Corollary 7.4.5 (Distinct eigenvalues give a diagonalization)
Hint 1. Find the eigenspaces of A first. B must preserve them.
Hint 2. On the plane $E_2(A)$, use the basis $\mathbf{e}_1, \mathbf{f} = \mathbf{e}_2 + \mathbf{e}_3$ and write down the 2×2 matrix of B.
Hint 3. For (c), what are the eigenvalues of B?
Sketch. (a) Both products equal $\begin{pmatrix} 0 & 2 & 2 \\ 2 & 0 & 0 \\ 2 & 0 & 0 \end{pmatrix}$. $E_2(A) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2+\mathbf{e}_3)$ and $E_0(A) = \operatorname{span}(\mathbf{e}_2 - \mathbf{e}_3)$; B has the three distinct eigenvalues $0, \pm\sqrt{2}$. (b) On $E_2(A)$, B has matrix $\begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$, with eigenvectors $\pm\sqrt{2}\mathbf{e}_1 + \mathbf{f}$. The basis is $\left(\sqrt{2}, 1, 1\right), \left(-\sqrt{2}, 1, 1\right), (0, 1, -1)$. (c) No: B has irrational eigenvalues, so it is not diagonalizable over $\mathbb{Q}$.

(a) Computing,

$$AB = \begin{pmatrix} 0 & 2 & 2 \\ 2 & 0 & 0 \\ 2 & 0 & 0 \end{pmatrix} = BA.$$

For A: $A\mathbf{e}_1 = 2\mathbf{e}_1$, $A(0,1,1) = (0,2,2)$, and $A(0,1,-1) = \mathbf{0}$. These three vectors form a basis, so A is diagonalizable with $E_2(A) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2+\mathbf{e}_3)$ and $E_0(A) = \operatorname{span}(\mathbf{e}_2 - \mathbf{e}_3)$. For B, part (b) produces three eigenvectors for the distinct eigenvalues $\sqrt{2}, -\sqrt{2}, 0$, so B is diagonalizable over $\mathbb{R}$ (Corollary 7.4.5).

(b) By Proposition 7.2.30(b), B preserves the eigenspaces of A. Let $\mathbf{f} = \mathbf{e}_2 + \mathbf{e}_3$. Then $B\mathbf{e}_1 = \mathbf{f}$ and $B\mathbf{f} = 2\mathbf{e}_1$, so on $E_2(A)$, in the basis $\mathbf{e}_1, \mathbf{f}$, B has matrix $\begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$, with characteristic polynomial $x^2 - 2$. One checks

$$B\left(\sqrt{2}\mathbf{e}_1 + \mathbf{f}\right) = \sqrt{2}\mathbf{f} + 2\mathbf{e}_1 = \sqrt{2}\left(\sqrt{2}\mathbf{e}_1 + \mathbf{f}\right), \quad B\left(-\sqrt{2}\mathbf{e}_1 + \mathbf{f}\right) = -\sqrt{2}\left(-\sqrt{2}\mathbf{e}_1 + \mathbf{f}\right).$$

On $E_0(A)$, $B(\mathbf{e}_2 - \mathbf{e}_3) = \mathbf{0}$. So in the basis $\left(\sqrt{2}, 1, 1\right), \left(-\sqrt{2}, 1, 1\right), (0, 1, -1)$ of $\mathbb{R}^3$,

$$A \mapsto \operatorname{diag}(2, 2, 0), \quad B \mapsto \operatorname{diag}\left(\sqrt{2}, -\sqrt{2}, 0\right).$$

(c) No. If $\mathbf{v} \in \mathbb{Q}^3$ is an eigenvector of B with eigenvalue λ, then $\lambda = (B\mathbf{v})_i / v_i$ for any i with $v_i \neq 0$, so $\lambda \in \mathbb{Q}$. The eigenvalues of B are $\pm\sqrt{2}$ and 0, so the only rational eigenvectors of B lie in the line $E_0(B)$, and $\mathbb{Q}^3$ has no basis of eigenvectors of B. Simultaneous diagonalization needs each operator to be diagonalizable over the field at hand.

Solution to Exercise 7.6.54

Uses. Theorem 7.6.36 (Gershgorin's disk theorem), Theorem 7.5.22 (Trace and determinant from eigenvalues), Proposition 7.1.38 (Conjugate roots), Exercise 7.3.17
Techniques. Look at the largest coordinate (Technique 7.6.37)
Hint 1. Find the three disks. How far left does each reach?

Hint 2. The determinant is the product of the complex eigenvalues. What can a real eigenvalue be, and what does a conjugate pair contribute?
Hint 3. Apply Gershgorin to G^{T}, which has the same eigenvalues.
Sketch. (a) The disks have centers $6, 5, 4$ and radii $2, 3, 1$, so they lie in $\operatorname{Re} z \geq 4, 2, 3$. (b) Real eigenvalues are ≥ 2, nonreal ones pair with their conjugates, so $\det G$ is a product of positive numbers. (c) The column disks have radii $1, 2, 3$, so $|\lambda| \leq 6+1, 5+2, 4+3$; the row disks give $6+2, 5+3, 4+1$.

(a) The row disks are D_1: center 6, radius $1+1=2$; D_2: center 5, radius $1+2=3$; D_3: center 4, radius $0+1=1$. A point z of the disk with center $c \in \mathbb{R}$ and radius r has $\operatorname{Re} z \geq c - |z-c| \geq c - r$, which is 4, 2, 3 for the three disks. By Theorem 7.6.36 every eigenvalue lies in one of them, so $\operatorname{Re}\lambda \geq 2$. In particular 0 is not an eigenvalue, and G is invertible.

(b) By Theorem 7.5.22, $\det G = \lambda_1\lambda_2\lambda_3$, the product of the complex eigenvalues with multiplicity. A real eigenvalue is at least 2 by (a). A nonreal eigenvalue λ occurs as often as $\overline{\lambda}$ (Proposition 7.1.38, as p_G has real coefficients), and each such pair contributes $|\lambda|^2 > 0$. So $\det G > 0$. (In fact $\det G = 129$.)

(c) G^{T} has the same characteristic polynomial (Exercise 7.3.17), hence the same eigenvalues, and its row disks are the column disks of G: centers $6, 5, 4$ and radii $1+0=1$, $1+1=2$, $1+2=3$. A point of the disk with center c and radius r has $|z| \leq |c| + r$, which here is 7 in all three cases. So $|\lambda| \leq 7$. The row disks give $6+2=8$, $5+3=8$, and $4+1=5$, so only $|\lambda| \leq 8$.

Solution to Exercise 7.6.55

Uses. Theorem 7.6.36 (Gershgorin's disk theorem), Theorem B.1.11 (Triangle inequality in $\mathbb{C}$)
Techniques. Look at the largest coordinate (Technique 7.6.37)
Hint 1. The disk D_i has center a_{ii} and radius $1 - a_{ii}$. Which vector does A fix?
Hint 2. If $|\lambda| = 1$ and $\lambda \in D_i$, then $1 = |\lambda| \leq |\lambda - a_{ii}| + a_{ii} \leq 1$. When is the triangle inequality an equality?
Sketch. (a) D_i has center $a_{ii} \geq 0$ and radius $1 - a_{ii}$, so it lies in the closed unit disk; $A(1,\dots,1) = (1,\dots,1)$. (b) If $|\lambda| = 1$, equality holds in $|\lambda| \leq |\lambda - a_{ii}| + a_{ii}$, so $\lambda - a_{ii}$ is a nonnegative multiple of the positive number a_{ii}, and λ is a positive real with $|\lambda| = 1$. (c) $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has eigenvalue -1.

(a) Since the entries are nonnegative and row i sums to 1, $R_i = \sum_{j \neq i} a_{ij} = 1 - a_{ii}$. By Theorem 7.6.36, $\lambda \in D_i$ for some i, and by the triangle inequality

$$|\lambda| \leq |\lambda - a_{ii}| + |a_{ii}| \leq (1 - a_{ii}) + a_{ii} = 1.$$

The row sums say $A\mathbf{1} = \mathbf{1}$ for $\mathbf{1} = (1,\dots,1)$, so 1 is an eigenvalue.

(b) Suppose $|\lambda| = 1$, and let i be as in (a). Then both inequalities in (a) are equalities. Equality in the triangle inequality for $z_1 = \lambda - a_{ii}$ and $z_2 = a_{ii}$ means that $z_1 = |z_1|u$ and $z_2 = |z_2|u$ for some $u \in \mathbb{C}$ with $|u| = 1$ (Theorem B.1.11(b)). Since $z_2 = a_{ii} > 0$, $u = 1$, so $\lambda - a_{ii}$ is a nonnegative real number. Then λ is a real number with $\lambda \geq a_{ii} > 0$ and $|\lambda| = 1$, so $\lambda = 1$.

(c) $A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has nonnegative entries and row sums 1, and $A(1,-1) = -(1,-1)$, so -1 is an eigenvalue of absolute value 1.

Solution to Exercise 7.6.56

Uses. Proposition 2.4.28 (Cyclicity of the trace), Corollary 7.6.30 (Trace, determinant, and invertibility of $p(T)$), Theorem 5.5.21 (The Vandermonde determinant), Theorem 7.6.20 (Cayley–Hamilton), Corollary 7.1.35 (Factorization over $\mathbb{C}$)
Techniques. Cyclicity of trace (Technique 2.4.29), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Show that $\operatorname{tr}\left(C^k\right) = 0$ for every $k \geq 1$. Write $C^k = C^{k-1}AB - C^{k-1}BA$ and move A past C^{k-1}.
Hint 2. If $\lambda_1, \dots, \lambda_n$ are the eigenvalues of C, then $\operatorname{tr}\left(C^k\right) = \sum_j \lambda_j^k$. Suppose some are nonzero, group the distinct nonzero ones, and get a Vandermonde system.
Hint 3. Over $\mathbb{F}_p$, think of the $p \times p$ matrices of x and d/dx on polynomials of degree less than p.
Sketch. For $k \geq 1$, $\operatorname{tr}\left(C^{k-1}AB\right) = \operatorname{tr}\left(AC^{k-1}B\right) = \operatorname{tr}\left(C^{k-1}BA\right)$, using $CA = AC$ and cyclicity, so $\operatorname{tr}\left(C^k\right) = 0$. With distinct nonzero eigenvalues $\mu_1, \dots, \mu_r$ of multiplicities m_l, this gives $\sum_l m_l \mu_l^k = 0$ for $k = 1, \dots, r$, an invertible Vandermonde-type system forcing $m_l = 0$. So 0 is the only eigenvalue, $p_C = x^n$, and $C^n = 0$. Over $\mathbb{F}_p$, $AB - BA = I_p$ is possible.

Traces of powers vanish. Let $k \geq 1$. Since A commutes with C, it commutes with C^{k-1}, so

$$\operatorname{tr}\big(C^{k-1}AB\big) = \operatorname{tr}\big(AC^{k-1}B\big) = \operatorname{tr}\big(\big(C^{k-1}B\big)A\big)$$

by cyclicity of the trace (Proposition 2.4.28). Hence $\operatorname{tr}\big(C^k\big) = \operatorname{tr}\big(C^{k-1}AB\big) - \operatorname{tr}\big(C^{k-1}BA\big) = 0$.

All eigenvalues are 0**.** Let $\lambda_1, \dots, \lambda_n$ be the eigenvalues of C counted with multiplicity. By Corollary 7.6.30 with $p = x^k$, $\operatorname{tr}\big(C^k\big) = \lambda_1^k + \cdots + \lambda_n^k$. Suppose some $\lambda_j \neq 0$, let $\mu_1, \dots, \mu_r$ be the distinct nonzero values among them ($r \geq 1$), and let $m_l \geq 1$ be the number of j with $\lambda_j = \mu_l$. Then for $k = 1, \dots, r$,

$$0 = \operatorname{tr}\big(C^k\big) = m_1\mu_1^k + \cdots + m_r\mu_r^k.$$

This is $M\mathbf{m} = \mathbf{0}$ with $\mathbf{m} = (m_1, \dots, m_r)$ (as elements of $\mathbb{C}$) and $M = \big(\mu_l^k\big)_{k,l}$. Factoring μ_l out of column l leaves the Vandermonde matrix $\big(\mu_l^{k-1}\big)$, so $\det M = \mu_1 \cdots \mu_r \prod_{l<l'}(\mu_{l'} - \mu_l) \neq 0$ (Theorem 5.5.21), as the μ_l are distinct and nonzero. So $\mathbf{m} = \mathbf{0}$, contradicting $m_1 \geq 1$. Hence every $\lambda_j = 0$, $p_C = x^n$ (Corollary 7.1.35), and $C^n = 0$ by Cayley–Hamilton.

Over $\mathbb{F}_p$**.** On $V = \mathbb{F}_p[x]_{<p}$, with basis $1, x, \dots, x^{p-1}$, let D be differentiation and X the operator $f \mapsto xf$ followed by deleting the x^p term. For $j < p-1$, $(DX - XD)x^j = (j+1)x^j - jx^j = x^j$. For $j = p-1$, $Xx^{p-1} = \mathbf{0}$ and $DXx^{p-1} = \mathbf{0}$, while $XDx^{p-1} = (p-1)x^{p-1} = -x^{p-1}$; so $(DX - XD)x^{p-1} = x^{p-1}$ as well. With $A = D$, $B = X$, we get $C = AB - BA = \mathrm{id}_V$, which commutes with A and is not nilpotent. The proof breaks at the last step: over $\mathbb{F}_p$ the multiplicities m_l are elements of $\mathbb{F}_p$, and $m_l = p$ is 0 there. (Here $C = \mathrm{id}_V$ has $\operatorname{tr}\big(C^k\big) = p = 0$ for all k.)

Section 7.7

Solution to Exercise 7.7.4

Uses. Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Lemma 7.4.13 (Geometric multiplicity through a rank), Theorem 7.4.16 (Criteria for diagonalizability), Proposition 7.3.30 (Odd dimension), Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix), Corollary 7.4.5 (Distinct eigenvalues give a diagonalization)
Techniques. Use an annihilating polynomial (Technique 7.6.17), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. (a) Factor $x^3 - x$ over $\mathbb{Q}$ and over $\mathbb{F}_2$. (b) Compute $\mathrm{gm}(1)$ from a rank. (d) Diagonalize and apply the polynomial to the diagonal.
Hint 2. (a) Over $\mathbb{F}_2$, $x^3 - x = x(x+1)^2$; try $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ in a block. (e) $p_A = x^2 + \det A$.
Sketch. (a) True over $\mathbb{Q}$: $x(x-1)(x+1)$ has distinct roots. False over $\mathbb{F}_2$: $A = \left(\begin{smallmatrix}1 & 1 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{smallmatrix}\right)$ has $A^3 = A$ and $\mathrm{gm}(1) = 1 < 2 = \mathrm{am}(1)$. (b) False: $\mathrm{gm}(1) = 4 - 3 = 1 < 2$. (c) True: odd dimension. (d) True: $A = S\,\mathrm{diag}(1,2,3)S^{-1}$, so $A^2 - 3A + 2I_3 = S\,\mathrm{diag}(0,0,2)S^{-1}$. (e) True: $p_A = x^2 + \det A$ has the distinct roots $\pm\sqrt{-\det A}$.

(a) True over $\mathbb{Q}$. The polynomial $x^3 - x = x(x-1)(x+1)$ annihilates A and has the distinct roots $0, 1, -1$, so A is diagonalizable by Theorem 7.6.15. Over $\mathbb{F}_2$ it is false, because $-1 = 1$ there and $x^3 - x = x(x+1)^2$ has a repeated root. For

$$A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \in \mathbb{F}_2^{3\times 3},$$

the block $J = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ has $J^2 = \left(\begin{smallmatrix}1 & 2\\ 0 & 1\end{smallmatrix}\right) = I_2$ over $\mathbb{F}_2$, so $J^3 = J$ and $A^3 = A$. But $p_A = x(x-1)^2$ and $A - I_3 = \left(\begin{smallmatrix}0 & 1 & 0\\ 0 & 0 & 0\\ 0 & 0 & 1\end{smallmatrix}\right)$ has rank 2, so $\mathrm{gm}(1) = 1 < 2 = \mathrm{am}(1)$ (Lemma 7.4.13), and A is not diagonalizable (Theorem 7.4.16).

(b) False. By Lemma 7.4.13, $\mathrm{gm}(1) = 4 - \operatorname{rank}(A - I_4) = 1$, while $\mathrm{am}(1) = 2$, so A is not diagonalizable. Such matrices exist: the block diagonal matrix with blocks $0_{2\times 2}$ and $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ has $p_A = x^2(x-1)^2$, rank 2, and $\operatorname{rank}(A - I_4) = 2 + 1 = 3$.

(c) True by Proposition 7.3.30: p_A is a real polynomial of odd degree 5, so it has a real root.

(d) True. Three distinct eigenvalues make A diagonalizable (Corollary 7.4.5): $A = SDS^{-1}$ with $D = \operatorname{diag}(1,2,3)$. With $q = x^2 - 3x + 2 = (x-1)(x-2)$, Proposition 7.4.23 gives $q(A) = Sq(D)S^{-1} = S\operatorname{diag}(0,0,2)S^{-1}$, which has rank 1.

(e) True. By Proposition 7.3.18, $p_A = x^2 - (\operatorname{tr} A)x + \det A = x^2 - c$ with $c = -\det A > 0$. Its roots $\pm\sqrt{c}$ are real and distinct, so A is diagonalizable over $\mathbb{R}$ (Corollary 7.4.5).

Solution to Exercise 7.7.5

Uses. Definition 7.4.12 (Geometric multiplicity), Definition 7.4.11 (Algebraic multiplicity), Theorem 7.4.15 (Geometric multiplicity is at most algebraic multiplicity), Proposition 7.1.34 (Roots of a split polynomial)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Which multiplicity is $\dim E_0$, and which one does "counted with multiplicity" refer to?
Hint 2. Try the shift N with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$. For the correct version, use $\mathrm{gm} \le \mathrm{am}$.
Sketch. $\dim E_0 = \mathrm{gm}(0)$, but "counted with multiplicity" means $\mathrm{am}(0)$. The claim is false: the $n \times n$ shift ($n \ge 2$) has rank $n-1$ and no nonzero eigenvalue. Correct: the number of nonzero eigenvalues with multiplicity is $n - \mathrm{am}(0) \le n - \mathrm{gm}(0) = r$, with equality when A is diagonalizable.

The error. $\dim\ker A = \dim E_0$ is the geometric multiplicity $\mathrm{gm}(0)$. The eigenvalues "counted with multiplicity" are the roots of p_A counted with algebraic multiplicity (Proposition 7.1.34), and $\mathrm{am}(0)$ can be larger than $\mathrm{gm}(0)$. The claim is false: for $n \ge 2$, the shift $N \in \mathbb{C}^{n\times n}$ with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$ for $j \ge 2$ has rank $n-1$, but $N^n = 0$, so its only eigenvalue is 0 (Proposition 7.2.28) and no eigenvalue is nonzero.

A correct version. At most r eigenvalues, counted with multiplicity, are nonzero. Indeed p_A splits over $\mathbb{C}$, its roots with multiplicity number n, and 0 occurs $\mathrm{am}(0)$ times, so the number of nonzero ones is $n - \mathrm{am}(0) \le n - \mathrm{gm}(0) = n - (n-r) = r$ by Theorem 7.4.15. Equality holds exactly when $\mathrm{am}(0) = \mathrm{gm}(0)$, for instance when A is diagonalizable.

Solution to Exercise 7.7.6

Uses. Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Theorem 7.6.34 (Simultaneous diagonalization), Theorem 7.6.31 (Commuting operators have a common eigenvector)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Two steps need a hypothesis that is not given. Which operator must be diagonalizable for each of them?
Hint 2. Try $A = I_2$ with B a nonzero nilpotent matrix, and the other way round.
Sketch. The basis of $E_\lambda(A)$ made of eigenvectors of B exists only if $B|_{E_\lambda(A)}$ is diagonalizable, and the eigenspaces of A add up to $\mathbb{C}^n$ only if A is diagonalizable. $A = I_2$, $B = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ breaks the first step; $A = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $B = I_2$ breaks the second. With both diagonalizable the argument is correct (Theorem 7.6.34).

The first step is right: $E_\lambda(A)$ is B-invariant (Proposition 7.2.30(b)). There are two errors after it.

First, $E_\lambda(A)$ need not have a basis of eigenvectors of B: that requires the restriction of B to $E_\lambda(A)$ to be diagonalizable, which follows if B is (Corollary 7.6.16) and can fail otherwise. With $A = I_2$ and $B = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, which commute, $E_1(A) = \mathbb{C}^2$ and the only eigenvectors of B are the nonzero multiples of $\mathbf{e}_1$. So no basis of common eigenvectors exists, and the claim is false.

Second, the eigenspaces of A need not add up to $\mathbb{C}^n$; that is the statement that A is diagonalizable. With $A = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $B = I_2$, the bases chosen span only $E_0(A) = \operatorname{span}(\mathbf{e}_1)$.

When A and B are both diagonalizable, both gaps close and the argument is the proof of Theorem 7.6.34. Without that, commuting still gives one common eigenvector (Theorem 7.6.31), and a common triangular form.

Solution to Exercise 7.7.7

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Example 7.7.2 (An idempotent is diagonalizable, three ways)

Techniques. Test an identity on eigenvectors (Technique 7.4.25), Use an annihilating polynomial (Technique 7.6.17)
Hint 1. The last step needs a basis of eigenvectors. Look for a counterexample with only one eigenvector line.
Hint 2. (a) Compute A^4. (b) If A is diagonalizable, the argument above is correct. Conversely, $A^2 = A$ is an annihilating polynomial with distinct roots.
Sketch. Agreement on eigenvectors gives agreement everywhere only when the eigenvectors span. $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has $N^3 = N^2 = 0$ and $N^2 \neq N$. (a) $A^4 = AA^3 = AA^2 = A^3 = A^2$. (b) If A is diagonalizable, the argument works on an eigenbasis; if $A^2 = A$, then $x(x-1)$ annihilates A.

The error. Two linear maps that agree on a spanning list are equal, but the eigenvectors of A need not span $\mathbb{C}^n$; the last step assumes that A is diagonalizable. The claim is false: $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has $N^2 = 0$, so $N^3 = N^2$, but $N^2 = 0 \neq N$. Its eigenvectors are the nonzero multiples of $\mathbf{e}_1$, on which N^2 and N do agree.

(a) $A^4 = AA^3 = AA^2 = A^3 = A^2$, so $\left(A^2\right)^2 = A^2$.

(b) If A is diagonalizable, it has an eigenbasis, and the argument above shows that A^2 and A agree on it. So $A^2 = A$ (Technique 7.4.25). Conversely, if $A^2 = A$, then $x(x-1)$ annihilates A, and A is diagonalizable (Theorem 7.6.15, or Example 7.7.2).

In terms of polynomials: $x^2(x-1)$ annihilates A, so m_A divides it, and A is diagonalizable exactly when m_A divides $x(x-1)$. The "proof" tested the identity on eigenvectors, which sees only the roots of m_A, never their multiplicities.

Solution to Exercise 7.7.8

Uses. Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues), Proposition 7.3.30 (Odd dimension), Proposition 7.4.7 (One eigenvalue), Theorem 7.1.39 (Factorization over $\mathbb{R}$)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Use an annihilating polynomial (Technique 7.6.17)
Hint 1. The roots of m_A in $\mathbb{R}$ are the real eigenvalues. Can m_A have a factor without real roots?
Hint 2. Over $\mathbb{R}$, $x^3 - 1 = (x-1)\left(x^2 + x + 1\right)$. Look for a 2×2 integer matrix with $p = x^2 + x + 1$, and add a block 1.
Sketch. Knowing the real roots of m_A does not determine m_A: it can be $(x-1)\left(x^2 + x + 1\right)$. Counterexample: A with diagonal blocks 1 and $C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}$, where $C^3 = I_2$. (a) p_A has odd degree, so there is a real eigenvalue λ, and $\lambda^3 = 1$ forces $\lambda = 1$. (b) If A is diagonalizable over $\mathbb{R}$ with only eigenvalue 1, then $A = I_3$ by Proposition 7.4.7.

The error. By Theorem 7.6.7, the roots of m_A in $\mathbb{R}$ are exactly the real eigenvalues of A, so m_A has 1 as its only real root. That does not make $m_A = x - 1$: over $\mathbb{R}$, $x^3 - 1 = (x-1)\left(x^2 + x + 1\right)$, and $x^2 + x + 1$ has no real root, so m_A could be $(x-1)\left(x^2 + x + 1\right)$. The step "its roots are the eigenvalues, so it is $x - 1$" assumed that m_A splits over $\mathbb{R}$.

A counterexample. Let $C = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}$. Then $C^2 = \begin{pmatrix} -1 & 1 \\ -1 & 0 \end{pmatrix}$ and $C^3 = CC^2 = I_2$. The block diagonal matrix A with blocks (1) and C has $A^3 = I_3$ and $A \neq I_3$. Over $\mathbb{C}$ its eigenvalues are 1 and the two primitive cube roots of unity, the roots of $p_C = x^2 + x + 1$; geometrically, C is similar to a rotation of the plane by $2\pi/3$.

(a) A has a real eigenvalue λ by Proposition 7.3.30, and $\lambda^3 = 1$ with $\lambda \in \mathbb{R}$ forces $\lambda = 1$.

(b) If $A = I_3$, it is diagonal. Conversely, if A is diagonalizable over $\mathbb{R}$, its eigenvalues are real roots of $x^3 - 1$, so 1 is its only eigenvalue, and $A = I_3$ by Proposition 7.4.7. Over $\mathbb{C}$ the situation is different: $x^3 - 1$ has three distinct complex roots, so every A with $A^3 = I_3$ is diagonalizable over $\mathbb{C}$ (Theorem 7.6.15), and $A \neq I_3$ exactly when the eigenvalues are $1, \omega, \overline{\omega}$ with $\omega = e^{2\pi i/3}$.

Solution to Exercise 7.7.9

Uses. Corollary 4.1.27 (A nilpotent operator dies within $\dim V$ steps), Proposition 4.1.26 (Nilpotent chains are independent), Theorem 4.2.11 (Rank–nullity), Exercise 4.2.51
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Dimension counting (Technique 4.2.24)
Hint 1. If $B^k = N$, then B is nilpotent. How fast must a nilpotent $n \times n$ matrix die?
Hint 2. Powers: $N^j = B^{kj}$, and $kj \geq n$ already for $j = \lceil n/k \rceil$. Kernels: $\dim \ker N = 1$, and $\ker B \subseteq \ker B^2 \subseteq \ker N$.

Sketch. Powers: $B^{kn} = N^n = 0$, so $B^n = 0$ (Corollary 4.1.27). With $j = \lceil n/k \rceil \le n-1$, $N^j = B^{kj} = 0$, so $N^{n-1} = 0$, a contradiction. Kernels: a chain of length n shows $\dim\ker N = 1$. B is nilpotent, so $\{\mathbf{0}\} \neq \ker B \subseteq \ker B^2 \subseteq \ker B^k = \ker N$, forcing $\ker B = \ker B^2$; then all $\ker B^j$ equal $\ker B$, which is not F^n, but $B^{kn} = 0$.

Suppose $B^k = N$ with $k \ge 2$. Then $B^{kn} = N^n = 0$, so B is nilpotent.

Powers. By Corollary 4.1.27, $B^n = 0$. Let $j = \lceil n/k \rceil$, so that $kj \ge n$ and $N^j = B^{kj} = B^{kj-n}B^n = 0$. Since $k \ge 2$ and $n \ge 2$, $j \le \lceil n/2 \rceil \le n-1$, so $N^{n-1} = N^{n-1-j}N^j = 0$, a contradiction.

Kernels. Choose $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$. By Proposition 4.1.26, $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ is independent, so it is a basis of F^n, and its image under N spans $\operatorname{span}\left(N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}\right)$, of dimension $n-1$. By Theorem 4.2.11, $\dim\ker N = 1$. Since B is nilpotent and $n \ge 1$, B is not injective, so $\ker B \neq \{\mathbf{0}\}$. Also $\ker B \subseteq \ker B^2 \subseteq \ker B^k = \ker N$, because $k \ge 2$. A nonzero subspace of a line is the line, so $\ker B = \ker B^2 = \ker N$. By Exercise 4.2.51(b), $\ker B^m = \ker B$ for every $m \ge 1$. But $B^{kn} = 0$, so $\ker B^{kn} = F^n$, while $\ker B$ is a line and $n \ge 2$. This is a contradiction.

The first proof needs only the bound $B^n = 0$; the second shows where a root would have to fail: $\ker B^2$ would have to lie in the line $\ker N$ and also strictly contain the nonzero $\ker B$, because B is nilpotent and $n \ge 2$. By contrast $I_n + N$ does have a square root over $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$, namely the truncated binomial series $\sum_{j=0}^{n-1}\binom{1/2}{j}N^j$, since the series for $(1+t)^{1/2}$ squares to $1+t$ and $N^n = 0$.

Solution to Exercise 7.7.10

Uses. Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Exercise 7.3.40, Exercise 7.4.40
Techniques. Compare AB and BA (Technique 7.3.21), Use an annihilating polynomial (Technique 7.6.17)
Hint 1. $B(AB)^jA = (BA)^{j+1}$. Apply this with $f = m_{AB}$.
Hint 2. (c) Map $E_\lambda(AB)$ to $E_\lambda(BA)$ by $\mathbf{v} \mapsto B\mathbf{v}$. (d) If 0 is not a root of m_{AB}, then xm_{AB} still has distinct roots.
Sketch. (a) $B(AB)^jA = (BA)^{j+1}$, sum. With $f = m_{AB}$ the left side is 0. (b) A nonzero root of m_{BA} is a root of m_{AB}, and symmetrically. $A = \left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$: $AB = 0$, $BA = A$. (c) $\mathbf{v} \mapsto B\mathbf{v}$ is injective on $E_\lambda(AB)$ and lands in $E_\lambda(BA)$; symmetric. (d) xm_{AB} is a product of distinct linear factors and kills BA. The example in (b) has $AB = 0$ diagonalizable and BA not.

(a) By associativity, $B(AB)^jA = (BA)^{j+1}$ for every $j \ge 0$. If $f = \sum_j c_j x^j$, summing gives $Bf(AB)A = \sum_j c_j(BA)^{j+1} = (xf)(BA)$. With $f = m_{AB}$ the left side is $B0A = 0$, so xm_{AB} annihilates BA, and m_{BA} divides it (Theorem 7.6.2).

(b) By symmetry, m_{AB} also divides xm_{BA}. If $\lambda \neq 0$ is an eigenvalue of BA, it is a root of m_{BA} (Theorem 7.6.7), hence of xm_{AB}, hence of m_{AB}, so it is an eigenvalue of AB. The converse is symmetric. For $A = \begin{pmatrix}0&1\\0&0\end{pmatrix}$ and $B = \begin{pmatrix}1&0\\0&0\end{pmatrix}$, $AB = 0$ and $BA = A$, so $m_{AB} = x$ while $m_{BA} = x^2$.

(c) Let $\lambda \neq 0$ and $\mathbf{v} \in E_\lambda(AB)$. Then $BA(B\mathbf{v}) = B(AB\mathbf{v}) = \lambda B\mathbf{v}$, so $B\mathbf{v} \in E_\lambda(BA)$. If $B\mathbf{v} = \mathbf{0}$, then $\lambda\mathbf{v} = AB\mathbf{v} = \mathbf{0}$ and $\mathbf{v} = \mathbf{0}$. So $\mathbf{v} \mapsto B\mathbf{v}$ is an injective linear map $E_\lambda(AB) \to E_\lambda(BA)$, and $\operatorname{gm}_{AB}(\lambda) \le \operatorname{gm}_{BA}(\lambda)$. Exchanging the roles of A and B gives the reverse inequality.

(d) By Theorem 7.6.15, $m_{AB} = (x-\lambda_1)\cdots(x-\lambda_r)$ with distinct λ_i, and none of them is 0 since AB is invertible. So xm_{AB} is a product of distinct linear factors, and by (a) it annihilates BA. Hence BA is diagonalizable. In the example of (b), $AB = 0$ is diagonalizable but not invertible, and $BA = \begin{pmatrix}0&1\\0&0\end{pmatrix}$ is not diagonalizable.

For $m = 1$, write $A = \mathbf{v}^{\mathsf{T}}$ and $B = \mathbf{u}$. Then $AB = \mathbf{v}^{\mathsf{T}}\mathbf{u}$ is a 1×1 matrix and $BA = \mathbf{u}\mathbf{v}^{\mathsf{T}}$, and (d) says that $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is diagonalizable when $\mathbf{v}^{\mathsf{T}}\mathbf{u} \neq 0$, one half of Exercise 7.4.40. Compare the three proofs of "same nonzero eigenvalues" in Exercise 7.3.40: characteristic polynomials see multiplicities, eigenvectors see geometric multiplicities as in (c), and minimal polynomials see diagonalizability.

Solution to Exercise 7.7.11

Uses. Theorem 7.4.16 (Criteria for diagonalizability), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22), Study a linear map on a space of matrices (Technique 4.2.29)
Hint 1. Write $A = SDS^{-1}$ and $B = RER^{-1}$, and substitute $X = SYR^{-1}$.
Hint 2. $DY = YE$ says $(d_i - e_j)y_{ij} = 0$ for all i, j. Count the pairs with $d_i = e_j$.
Sketch. $X \mapsto S^{-1}XR$ is an isomorphism of $F^{m\times n}$ taking W to $\{Y \mid DY = YE\}$, whose elements have $y_{ij} = 0$ unless $d_i = e_j$. The number of such pairs is $\sum_\lambda \operatorname{gm}_A(\lambda)\operatorname{gm}_B(\lambda)$. (b) is the case $\dim W = 0$. (c) With $B = A$: $\sum \operatorname{gm}(\lambda)^2 \geq \sum \operatorname{gm}(\lambda) = m$, with equality iff every $\operatorname{gm}(\lambda) \leq 1$.

(a) Write $A = SDS^{-1}$ and $B = RER^{-1}$ with $D = \operatorname{diag}(d_1, \ldots, d_m)$ and $E = \operatorname{diag}(e_1, \ldots, e_n)$. The map $X \mapsto S^{-1}XR$ is linear on $F^{m\times n}$ with inverse $Y \mapsto SYR^{-1}$, so it is an isomorphism. For $Y = S^{-1}XR$,

$$AX = XB \iff SDS^{-1}X = XRER^{-1} \iff DY = YE,$$

multiplying on the left by S^{-1} and on the right by R. The (i, j) entry of $DY - YE$ is $(d_i - e_j)y_{ij}$. So W corresponds to the space of Y with $y_{ij} = 0$ whenever $d_i \neq e_j$, which has as a basis the matrix units at the positions with $d_i = e_j$. By Theorem 7.4.16, each λ occurs exactly $\operatorname{gm}_A(\lambda)$ times among the d_i and $\operatorname{gm}_B(\lambda)$ times among the e_j, so the number of positions is $\sum_\lambda \operatorname{gm}_A(\lambda)\operatorname{gm}_B(\lambda)$.

(b) $W = \{0\}$ exactly when every term of the sum vanishes, that is, when no λ is an eigenvalue of both.

(c) Take $B = A$. Then $\dim W = \sum_\lambda \operatorname{gm}(\lambda)^2$, where $\sum_\lambda \operatorname{gm}(\lambda) = m$ since A is diagonalizable. As each $\operatorname{gm}(\lambda)$ is a nonnegative integer, $\operatorname{gm}(\lambda)^2 \geq \operatorname{gm}(\lambda)$, with equality iff $\operatorname{gm}(\lambda) \in \{0, 1\}$. So $\dim W \geq m$, with equality iff every eigenvalue has $\operatorname{gm} = 1$, that is, iff there are m distinct eigenvalues.

The "if" direction of (b) holds for all $A \in \mathbb{C}^{m\times m}$ and $B \in \mathbb{C}^{n\times n}$, diagonalizable or not. If $AX = XB$, then $A^jX = XB^j$ for all j, so $p_B(A)X = Xp_B(B) = 0$ by Cayley–Hamilton (Theorem 7.6.20). The eigenvalues of $p_B(A)$ are the numbers $p_B(\lambda)$ for eigenvalues λ of A (Theorem 7.6.28), and these are nonzero when no eigenvalue is shared, so $p_B(A)$ is invertible and $X = 0$.

Solution to Exercise 7.7.12

Uses. Theorem 7.6.31 (Commuting operators have a common eigenvector), Proposition 7.3.34 (Eigenvalues of a complexification), Example 7.2.18 (Rotations)
Techniques. Complexify, then take real and imaginary parts (Technique 7.3.35), Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Regard A, B as commuting complex matrices and take a common eigenvector $\mathbf{z} = \mathbf{u} + i\mathbf{w}$ with $\mathbf{u}, \mathbf{w} \in \mathbb{R}^n$.
Hint 2. Compare real and imaginary parts of $A\mathbf{z} = \lambda\mathbf{z}$. For (b), a rotation has no invariant line.
Sketch. By Theorem 7.6.31 there is $\mathbf{z} = \mathbf{u} + i\mathbf{w} \neq \mathbf{0}$ with $A\mathbf{z} = \lambda\mathbf{z}$ and $B\mathbf{z} = \mu\mathbf{z}$. With $\lambda = a + bi$, real and imaginary parts give $A\mathbf{u} = a\mathbf{u} - b\mathbf{w}$ and $A\mathbf{w} = b\mathbf{u} + a\mathbf{w}$; the same for B. So $U = \operatorname{span}(\mathbf{u}, \mathbf{w})$ works. (b) $A = B = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.

(a) As complex matrices, A and B commute, so by Theorem 7.6.31 there is a nonzero $\mathbf{z} \in \mathbb{C}^n$ with $A\mathbf{z} = \lambda\mathbf{z}$ and $B\mathbf{z} = \mu\mathbf{z}$. Write $\mathbf{z} = \mathbf{u} + i\mathbf{w}$ with $\mathbf{u}, \mathbf{w} \in \mathbb{R}^n$, and $\lambda = a + bi$, $\mu = c + di$ with $a, b, c, d \in \mathbb{R}$. Since A has real entries,

$$A\mathbf{u} + iA\mathbf{w} = A\mathbf{z} = (a + bi)(\mathbf{u} + i\mathbf{w}) = (a\mathbf{u} - b\mathbf{w}) + i(b\mathbf{u} + a\mathbf{w}),$$

and comparing real and imaginary parts, $A\mathbf{u} = a\mathbf{u} - b\mathbf{w}$ and $A\mathbf{w} = b\mathbf{u} + a\mathbf{w}$. In the same way $B\mathbf{u} = c\mathbf{u} - d\mathbf{w}$ and $B\mathbf{w} = d\mathbf{u} + c\mathbf{w}$. So $U = \operatorname{span}(\mathbf{u}, \mathbf{w})$ is invariant under A and B (Proposition 7.2.4). It is nonzero because $\mathbf{z} \neq \mathbf{0}$, and it has dimension at most 2.

(b) Let $A = B = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, the rotation by $\pi/2$. An invariant line of A would be spanned by a real eigenvector (Proposition 7.2.7), and A has no real eigenvalue (Example 7.2.18). So the only common invariant subspace of dimension 1 or 2 is $\mathbb{R}^2$.

This is the real counterpart of Theorem 7.6.31, and the proof is Technique 7.3.35: solve over $\mathbb{C}$, then take real and imaginary parts. The same move with one matrix is Theorem 7.3.31.

Solution to Exercise 7.7.13

Uses. Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Lemma 7.5.11 (Compressing an operator to a complement), Lemma 7.6.21 (A triangular operator is killed by its diagonal)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. (a) $\ker A$ is nonzero and B-invariant. What is B on it?
Hint 2. (b) Induct on n. Take $U = \operatorname{span}(\mathbf{v})$ from (a) and compress A and B to a complement W. Check that $T\mathbf{w} - T'\mathbf{w} \in U$ (Lemma 7.5.11(a)) gives $(AB)' = A'B'$ and $\left(A^k\right)' = (A')^k$.
Sketch. (a) $\ker A \neq \{\mathbf{0}\}$ is B-invariant and $B|_{\ker A}$ is nilpotent, hence not injective. (b) Induct on n. Compress to a complement W of $U = \operatorname{span}(\mathbf{v})$; since U is invariant under both, compressions respect products, so A', B' commute and are nilpotent. By induction they are strictly upper triangular in a basis of W; prepend $\mathbf{v}$. (c) Sums and products of strictly upper triangular matrices are strictly upper triangular, hence nilpotent.

(a) If A were injective, so would be every power of A, but $A^k = 0$ on $F^n \neq \{\mathbf{0}\}$. So $K = \ker A \neq \{\mathbf{0}\}$. By Proposition 7.2.30, K is B-invariant, and the restriction $B|_K$ satisfies $(B|_K)^k = 0$ whenever $B^k = 0$, so it is not injective either: some $\mathbf{v} \in K$, $\mathbf{v} \neq \mathbf{0}$, has $B\mathbf{v} = \mathbf{0}$. Then $A\mathbf{v} = B\mathbf{v} = \mathbf{0}$.

(b) We induct on n. For $n = 1$, a nilpotent 1×1 matrix is 0. Let $n \geq 2$, take $\mathbf{v}$ from (a), let $U = \operatorname{span}(\mathbf{v})$, and choose a complement W of U, with projection $P = \mathrm{Pr}_{W,U}$. For $T \in \{A, B\}$, let $T' = P \circ T|_W \in \mathrm{L}(W)$ be the compression (Lemma 7.5.11).

We claim that $(T_1T_2)' = T_1'T_2'$ for all T_1, T_2 that map U into U. Let $\mathbf{w} \in W$. By Lemma 7.5.11(a), $T_2\mathbf{w} = T_2'\mathbf{w} + \mathbf{u}$ with $\mathbf{u} \in U$, and $T_1T_2'\mathbf{w} = T_1'T_2'\mathbf{w} + \mathbf{u}'$ with $\mathbf{u}' \in U$. So $T_1T_2\mathbf{w} = T_1'T_2'\mathbf{w} + \mathbf{u}' + T_1\mathbf{u}$, where $\mathbf{u}' + T_1\mathbf{u} \in U$; applying P gives the claim. Here U is killed by A and B, so the claim applies to all products of A and B. Hence $A'B' = (AB)' = (BA)' = B'A'$, and $(A')^k = \left(A^k\right)' = 0$, and likewise for B'. By the induction hypothesis, W has a basis $\mathbf{w}_2, \ldots, \mathbf{w}_n$ in which A' and B' are strictly upper triangular. In the basis $\mathbf{v}, \mathbf{w}_2, \ldots, \mathbf{w}_n$ of F^n, Lemma 7.5.11(b) gives

$$[T_A] = \begin{pmatrix} 0 & * \\ 0 & [A'] \end{pmatrix},$$

with 0 in the corner because $A\mathbf{v} = \mathbf{0}$, and $[A']$ strictly upper triangular. So $[T_A]$ is strictly upper triangular, and the same holds for B. Let S have columns $\mathbf{v}, \mathbf{w}_2, \ldots, \mathbf{w}_n$.

(c) With S from (b), $S^{-1}(A+B)S$ and $S^{-1}ABS = \left(S^{-1}AS\right)\left(S^{-1}BS\right)$ are strictly upper triangular. A strictly upper triangular $n \times n$ matrix M has $M^n = 0$ (Lemma 7.6.21 with all diagonal entries 0), so $A + B$ and AB are nilpotent.

Nothing in this proof uses eigenvalues, which is why it works over every field. Over $\mathbb{C}$, (b) is a special case of Theorem 7.6.32, and (c) also follows from the binomial theorem (Exercise 7.6.51).

Solution to Exercise 7.7.14

Uses. Theorem 7.6.20 (Cayley–Hamilton), Proposition 7.3.18 (The first and last coefficients), Theorem 5.5.9 (The adjugate and the inverse), Corollary 7.1.23 (Polynomials and their values), Aside (Rational functions) (Rational functions)
Techniques. Perturbation and density (Technique 7.6.23), Polynomial identity arguments (Technique 5.5.24)
Hint 1. For invertible A, Cayley–Hamilton gives $AQ = -c_0 I_n$ with Q the bracket. What is c_0?
Hint 2. For general A, replace A by $A - tI_n$. Both sides are matrices of polynomials in t, and they agree whenever t is not an eigenvalue of A.
Sketch. Let Q be the bracket. Cayley–Hamilton: $AQ = -c_0 I_n = (-1)^{n+1}(\det A)I_n$. Multiply by $\operatorname{adj}(A)$ on the left: $(\det A)Q = (-1)^{n+1}(\det A)\operatorname{adj}(A)$, and cancel $\det A \neq 0$. For general A, both sides for $A - tI_n$ are polynomial in t entrywise (the c_j of $p_{A-tI_n}(x) = p_A(x+t)$ are polynomials in t), and they agree for all t outside the at most n eigenvalues of A; so they agree at $t = 0$.

Write $Q(A) = A^{n-1} + c_{n-1}A^{n-2} + \cdots + c_1 I_n$, so that $p_A(A) = AQ(A) + c_0 I_n$.

Invertible A. By Cayley–Hamilton (Theorem 7.6.20), $AQ(A) = -c_0 I_n$, and $c_0 = (-1)^n \det A$ by Proposition 7.3.18, so $AQ(A) = (-1)^{n+1}(\det A)I_n$. Multiplying on the left by $\operatorname{adj}(A)$ and using $\operatorname{adj}(A)A = (\det A)I_n$ (Theorem 5.5.9),

$$(\det A)Q(A) = (-1)^{n+1}(\det A)\operatorname{adj}(A).$$

Since $\det A \neq 0$, $\operatorname{adj}(A) = (-1)^{n+1}Q(A)$.

All A, for infinite F. For $t \in F$, let $A_t = A - tI_n$. Its characteristic polynomial is $\det(xI_n - A + tI_n) = p_A(x + t)$, so each coefficient $c_j(t)$ of p_{A_t} is a polynomial in t, and every entry of

$$Q_t = A_t^{n-1} + c_{n-1}(t)A_t^{n-2} + \cdots + c_1(t)I_n$$

is a polynomial in t. So is every entry of $\operatorname{adj}(A_t)$, being a cofactor of A_t. By the first part, $\operatorname{adj}(A_t) = (-1)^{n+1}Q_t$ whenever A_t is invertible, that is, for every t that is not one of the at most n eigenvalues of A. Each entry of the difference is then a polynomial in t with infinitely many roots, hence $\mathbf{0}$ (Corollary 7.1.23). At $t = 0$ this is the claim. (For a finite field, run the same argument over the field of rational functions $F(t)$ of Aside (Rational functions), where $A - tI_n$ is invertible because its determinant $(-1)^n p_A(t)$ is nonzero, and then set $t = 0$.)

$n = 2$. Here $p_A = x^2 - (\operatorname{tr} A)x + \det A$, so $c_1 = -\operatorname{tr} A$ and the formula reads $\operatorname{adj}(A) = -(A - (\operatorname{tr} A)I_2) = (\operatorname{tr} A)I_2 - A$. For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ this is $\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$, the adjugate of Example 5.5.7.

In particular $\operatorname{adj}(A)$ commutes with every matrix that commutes with A, even when A is singular. The proof is Technique 7.6.23 in its algebraic form: prove the identity where it is easy (invertible matrices), then use that both sides are polynomials.

Problems for Chapter 7

Solution to Problem 7.1

Uses. Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Corollary 7.2.23 (Eigenspaces are independent), Proposition 7.2.28 (Polynomials act on eigenvectors by their values)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. (b) Apply $\prod_{j \neq i}(T - \lambda_j \operatorname{id})$ to $\sum c_j \mathbf{v}_j = \mathbf{0}$. For the second proof, apply a single $T - \lambda_j \operatorname{id}$ to a shortest relation.
Hint 2. (c) $D^2 \cos kx = -k^2 \cos kx$. For the full list, group $a_k \cos kx + b_k \sin kx$ into one vector of $E_{-k^2}(D^2)$ and use Corollary 7.2.23.
Sketch. (b) The product kills every term except the ith, which becomes $c_i \prod_{j \neq i}(\lambda_i - \lambda_j)\mathbf{v}_i$. Or: in a shortest relation, applying $T - \lambda_j$ id for an index j in it gives a shorter nontrivial relation. (c) The eigenvalues $0, -1, -4, \ldots, -n^2$ of D^2 are distinct. For the full list, $f_k = a_k \cos kx + b_k \sin kx \in E_{-k^2}$ and $\sum f_k = \mathbf{0}$, so each $f_k = \mathbf{0}$; evaluating at 0 and $\pi/(2k)$ gives $a_k = b_k = 0$.

(a) Let $T \in \mathrm{L}(V)$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be eigenvectors of T with distinct eigenvalues $\lambda_1, \ldots, \lambda_m$. Then $\mathbf{v}_1, \ldots, \mathbf{v}_m$ is linearly independent (Theorem 7.2.21). No hypothesis on $\dim V$ is needed.

(b) *Killing terms.* Suppose $c_1\mathbf{v}_1 + \cdots + c_m\mathbf{v}_m = \mathbf{0}$, and fix i. Apply $P_i = \prod_{j \neq i}(T - \lambda_j \operatorname{id})$. By Proposition 7.2.28, $P_i\mathbf{v}_k = \prod_{j \neq i}(\lambda_k - \lambda_j)\mathbf{v}_k$, which is $\mathbf{0}$ for $k \neq i$ (the factor $j = k$ vanishes). So $c_i \prod_{j \neq i}(\lambda_i - \lambda_j)\mathbf{v}_i = \mathbf{0}$. The product is nonzero because the λ's are distinct, and $\mathbf{v}_i \neq \mathbf{0}$, so $c_i = 0$.

A shortest relation. Suppose the list is dependent, and among all nontrivial relations choose one, $\sum_{i \in S} c_i\mathbf{v}_i = \mathbf{0}$ with every $c_i \neq 0$, for which $|S|$ is smallest. Since eigenvectors are nonzero, $|S| \geq 2$. Pick $j \in S$ and apply $T - \lambda_j$ id:

$$\sum_{i \in S, i \neq j} c_i(\lambda_i - \lambda_j)\mathbf{v}_i = \mathbf{0}.$$

The coefficients are nonzero and the index set $S \setminus \{j\}$ is nonempty, so this is a nontrivial relation that is shorter, a contradiction.

(c) V is a subspace of $\mathbb{R}^{\mathbb{R}}$, and D^2 is linear. Since $D^2 \cos kx = -k^2 \cos kx$, $D^2 \sin kx = -k^2 \sin kx$, and $D^2 1 = 0$, the functions $1, \cos x, \ldots, \cos nx$ are eigenvectors of D^2 with the distinct eigenvalues $0, -1, -4, \ldots, -n^2$, so they are independent by (a). The same holds for $\sin x, \ldots, \sin nx$.

For the full list, suppose $a_0 + \sum_{k=1}^{n}(a_k \cos kx + b_k \sin kx) = 0$ for all x. Let $f_0 = a_0$ and $f_k = a_k \cos kx + b_k \sin kx$. Each f_k lies in the eigenspace $E_{-k^2}(D^2)$, and $f_0 + \cdots + f_n = \mathbf{0}$. By Corollary 7.2.23 the eigenspaces are independent, so every $f_k = \mathbf{0}$. So $a_0 = 0$, and for $k \geq 1$, evaluating f_k at $x = 0$ gives $a_k = 0$, and then at $x = \pi/(2k)$ gives $b_k = 0$.

The theorem separates eigenvalues and nothing more. Inside one eigenspace, here the plane spanned by $\cos kx$ and $\sin kx$, independence needs a separate argument, which the two evaluations supply.

Solution to Problem 7.2

> *Uses.* Theorem 7.4.16 (Criteria for diagonalizability), Corollary 7.2.23 (Eigenspaces are independent), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 7.4.15 (Geometric multiplicity is at most algebraic multiplicity), Proposition 7.1.27 (Multiplicities add up to at most the degree), Proposition 7.1.34 (Roots of a split polynomial), Proposition 7.3.15 (Block-triangular matrices)
> *Techniques.* Dimension counting (Technique 4.2.24), Block decomposition (Technique 2.4.35)
> *Hint 1.* (b) The eigenspaces are independent, so their sum has dimension $\sum \operatorname{gm}(\lambda_i)$. Then chain $\sum \operatorname{gm} \leq \sum \operatorname{am} \leq n$.
> *Hint 2.* (c) Use criterion (IV) for M. For an eigenvalue of D, map $E_\lambda(D)$ into $E_\lambda(M)$ by $\mathbf{y} \mapsto \left(-(B - \lambda I_k)^{-1} C\mathbf{y}, \mathbf{y}\right)$.
> *Sketch.* (b) $\sum E_{\lambda_i}$ is direct, of dimension $\sum \operatorname{gm}$; it is V iff $\sum \operatorname{gm} = n$, and then glued bases are an eigenbasis; conversely an eigenbasis lies in the sum. Also $\sum \operatorname{gm} \leq \sum \operatorname{am} \leq n$ with $\sum \operatorname{am} = n$ iff p_T splits, so $\sum \operatorname{gm} = n$ iff both inequalities are equalities. (c) $p_M = p_B p_D$ splits. For an eigenvalue λ of B, $\mathbf{x} \mapsto (\mathbf{x}, \mathbf{0})$ embeds $E_\lambda(B)$ in $E_\lambda(M)$; for one of D, $\mathbf{y} \mapsto \left(-(B - \lambda I_k)^{-1} C\mathbf{y}, \mathbf{y}\right)$ embeds $E_\lambda(D)$. So $\operatorname{gm}_M \geq \operatorname{am}_M$ everywhere. Counterexample: $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$.

(a) Let $\dim V = n$, $T \in \mathrm{L}(V)$, with distinct eigenvalues $\lambda_1, \ldots, \lambda_m$. Then T is diagonalizable if and only if $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_m}$, if and only if $\sum_i \operatorname{gm}(\lambda_i) = n$, if and only if p_T splits over F and $\operatorname{gm}(\lambda_i) = \operatorname{am}(\lambda_i)$ for all i (Theorem 7.4.16).

(b) The sum $E_{\lambda_1} + \cdots + E_{\lambda_m}$ is direct (Corollary 7.2.23), so its dimension is $\sum_i \operatorname{gm}(\lambda_i)$ (Theorem 4.4.13). If $\sum_i \operatorname{gm}(\lambda_i) = n$, the sum is all of V, and a basis of each E_{λ_i}, glued together, is a basis of V (Theorem 4.4.13) consisting of eigenvectors, so T is diagonalizable. Conversely, if $\mathcal{B}$ is an eigenbasis, every vector of $\mathcal{B}$ lies in some E_{λ_i}, so $V = \operatorname{span} \mathcal{B} \subseteq \sum_i E_{\lambda_i}$ and $\sum_i \operatorname{gm}(\lambda_i) = n$.

For the second equivalence, $\operatorname{gm}(\lambda_i) \leq \operatorname{am}(\lambda_i)$ for each i (Theorem 7.4.15), and $\sum_i \operatorname{am}(\lambda_i) \leq \deg p_T = n$ (Proposition 7.1.27), with equality if and only if p_T splits: if it splits, the multiplicities add up to n (Proposition 7.1.34); if they add up to n, then $\prod (x - \lambda_i)^{\operatorname{am}(\lambda_i)}$ divides p_T and has the same degree, and both are monic, so they are equal. Hence

$$\sum_i \operatorname{gm}(\lambda_i) \leq \sum_i \operatorname{am}(\lambda_i) \leq n,$$

and $\sum \operatorname{gm} = n$ exactly when both inequalities are equalities, that is, when p_T splits and every $\operatorname{gm}(\lambda_i) = \operatorname{am}(\lambda_i)$.

(c) By Proposition 7.3.15, $p_M = p_B p_D$, which splits because p_B and p_D do (Theorem 7.4.16). Let λ be an eigenvalue of M; it is a root of exactly one of p_B, p_D, so $\operatorname{am}_M(\lambda)$ is $\operatorname{am}_B(\lambda)$ or $\operatorname{am}_D(\lambda)$.

If $p_B(\lambda) = 0$, the map $\mathbf{x} \mapsto (\mathbf{x}, \mathbf{0})$ is injective and sends $E_\lambda(B)$ into $E_\lambda(M)$, because $M(\mathbf{x}, \mathbf{0}) = (B\mathbf{x}, \mathbf{0})$. So $\operatorname{gm}_M(\lambda) \geq \operatorname{gm}_B(\lambda) = \operatorname{am}_B(\lambda) = \operatorname{am}_M(\lambda)$.

If $p_D(\lambda) = 0$, then λ is not an eigenvalue of B, so $B - \lambda I_k$ is invertible. For $\mathbf{y} \in E_\lambda(D)$ let $\mathbf{x} = -(B - \lambda I_k)^{-1} C\mathbf{y}$. Then $B\mathbf{x} + C\mathbf{y} = (B - \lambda I_k)\mathbf{x} + \lambda\mathbf{x} + C\mathbf{y} = \lambda\mathbf{x}$ and $D\mathbf{y} = \lambda\mathbf{y}$, so $(\mathbf{x}, \mathbf{y}) \in E_\lambda(M)$. The map $\mathbf{y} \mapsto (\mathbf{x}, \mathbf{y})$ is linear and injective, so $\operatorname{gm}_M(\lambda) \geq \operatorname{gm}_D(\lambda) = \operatorname{am}_M(\lambda)$.

With Theorem 7.4.15, $\operatorname{gm}_M = \operatorname{am}_M$ at every eigenvalue, and M is diagonalizable by (b). Without the hypothesis, $M = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ ($B = D = (1)$, $C = (1)$) is not diagonalizable (Example 7.4.8).

Another route: if X solves $BX - XD = -C$, then $\begin{pmatrix} I_k & X \\ 0 & I_l \end{pmatrix}^{-1} M \begin{pmatrix} I_k & X \\ 0 & I_l \end{pmatrix} = \begin{pmatrix} B & 0 \\ 0 & D \end{pmatrix}$, and with no common eigenvalue such an X always exists (Exercise 7.7.11(b) and rank–nullity on $X \mapsto BX - XD$).

Solution to Problem 7.3

Uses. Proposition 7.2.37 (Chains are independent), Corollary 7.2.38 (The span of a chain), Theorem 7.5.13 (Upper-triangular form), Proposition 7.5.9 (Multiplicities on the diagonal), Lemma 7.6.21 (A triangular operator is killed by its diagonal), Theorem 4.2.11 (Rank–nullity)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25), Dimension counting (Technique 4.2.24)
Hint 1. (b) Apply N^k to a relation $\sum c_j N^j \mathbf{v} = \mathbf{0}$, then N^{k-1}, and so on.
Hint 2. (c) First $N^n = 0$, from a triangular form. Then show $\dim\ker N^{j+1} \le \dim\ker N^j + 1$ by restricting N to $\ker N^{j+1}$.
Sketch. (b) Applying N^k to $\sum_{j=0}^{k} c_j N^j \mathbf{v} = \mathbf{0}$ leaves $c_0 N^k \mathbf{v} = \mathbf{0}$, so $c_0 = 0$; then N^{k-1} gives $c_1 = 0$, and so on. $N\left(N^k \mathbf{v}\right) = \mathbf{0}$ with $N^k \mathbf{v} \neq \mathbf{0}$. (c) In a triangular basis the diagonal is all λ, so $N^n = 0$. N maps $\ker N^{j+1}$ into $\ker N^j$ with kernel $\ker N$, so $\dim\ker N^{j+1} \le \dim\ker N^j + 1$ and $\dim\ker N^{n-1} \le n - 1$. A $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$ gives a chain of length n, a basis, and Corollary 7.2.38(c) gives the matrix.

(a) Let $T \in \mathrm{L}(V)$, $\lambda \in F$, $N = T - \lambda\,\mathrm{id}$, and suppose $N^k \mathbf{v} \neq \mathbf{0}$ and $N^{k+1}\mathbf{v} = \mathbf{0}$. Then $\mathbf{v}, N\mathbf{v}, \ldots, N^k\mathbf{v}$ is linearly independent (Proposition 7.2.37). Moreover $N^k\mathbf{v}$ is an eigenvector of T with eigenvalue λ, and the span of the chain is the Krylov subspace $K_T(\mathbf{v})$, of dimension $k+1$ (Corollary 7.2.38).

(b) Suppose $\sum_{j=0}^{k} c_j N^j \mathbf{v} = \mathbf{0}$, and suppose some c_j is nonzero; let i be the smallest such index. Apply N^{k-i}: every term with $j > i$ becomes $c_j N^{j+k-i}\mathbf{v} = \mathbf{0}$, since $j + k - i \ge k + 1$. What remains is $c_i N^k \mathbf{v} = \mathbf{0}$, so $c_i = 0$, a contradiction. For the last vector, $N\left(N^k\mathbf{v}\right) = N^{k+1}\mathbf{v} = \mathbf{0}$ and $N^k\mathbf{v} \neq \mathbf{0}$, so $TN^k\mathbf{v} = \lambda N^k\mathbf{v}$.

(c) Let $N = T - \lambda\,\mathrm{id}$. By Theorem 7.5.13, T has an upper-triangular matrix in some basis, and by Proposition 7.5.9 its diagonal entries are the roots of p_T, all equal to λ. So the matrix of N is strictly upper triangular, and $N^n = 0$ (Lemma 7.6.21).

Next, for $j \ge 0$, N maps $\ker N^{j+1}$ into $\ker N^j$, and the kernel of this restriction is $\ker N \cap \ker N^{j+1} = \ker N$. By Theorem 4.2.11,

$$\dim\ker N^{j+1} \le \dim\ker N + \dim\ker N^j = 1 + \dim\ker N^j,$$

using $\dim\ker N = \mathrm{gm}(\lambda) = 1$. Starting from $\dim\ker N^0 = 0$, induction gives $\dim\ker N^j \le j$. In particular $\dim\ker N^{n-1} \le n - 1 < n$, so $N^{n-1} \neq 0$.

Choose $\mathbf{v}$ with $N^{n-1}\mathbf{v} \neq \mathbf{0}$; also $N^n\mathbf{v} = \mathbf{0}$. By (b), the chain $\mathbf{v}, N\mathbf{v}, \ldots, N^{n-1}\mathbf{v}$ is independent, and it has n vectors, so it is a basis of V. By Corollary 7.2.38(c), in the basis $N^{n-1}\mathbf{v}, \ldots, N\mathbf{v}, \mathbf{v}$ the matrix of T is as claimed.

Conversely, that matrix has $\mathrm{gm}(\lambda) = n - \mathrm{rank}(N) = 1$. So for an operator with a single eigenvalue, "one eigenvector line" and "one chain" are the same condition. Over any field the same proof works once $N^n = 0$ is known, which Cayley–Hamilton supplies (Theorem 7.6.20). This is the simplest case of the Jordan form (Section 10.3).

Solution to Problem 7.4

Uses. Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Theorem 7.1.45 (Bézout's identity)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Find polynomials with $(x-2)^2 - (x-3)q(x) = 1$, and apply the identity in A to $\mathbf{u} \in U$.
Hint 2. $G = \mathrm{span}(\mathbf{e}_1, \mathbf{e}_2)$ and $E = \mathrm{span}(\mathbf{e}_3)$. On G, A acts as $\begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$, which has one invariant line.
Sketch. $(x-2)^2 - (x-3)(x-1) = 1$, so $\mathbf{u} = (A-2I)^2\mathbf{u} - (A-3I)(A-I)\mathbf{u}$. The first term lies in E and the second in G, because $(A-3I)(A-2I)^2 = 0$, and both lie in U. So $U = (U \cap G) \oplus (U \cap E)$. $U \cap E$ is $\{\mathbf{0}\}$ or E, and $U \cap G$ is $\{\mathbf{0}\}$, $\mathrm{span}(\mathbf{e}_1)$, or G. Six subspaces.

We have $A - 2I_3 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, $(A-2I_3)^2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, and $A - 3I_3 = \begin{pmatrix} -1 & 1 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$. So $G = \mathrm{span}(\mathbf{e}_1, \mathbf{e}_2)$, $E = \mathrm{span}(\mathbf{e}_3)$, and $(A-3I_3)(A-2I_3)^2 = 0$, since the third column of $A - 3I_3$ is zero.

The splitting. In $\mathbb{Q}[x]$, $(x-2)^2-(x-3)(x-1)=\left(x^2-4x+4\right)-\left(x^2-4x+3\right)=1$. Substituting A (Proposition 7.2.27), for every $\mathbf{u}\in\mathbb{Q}^3$,

$$\mathbf{u}=(A-2I_3)^2\mathbf{u}-(A-3I_3)(A-I_3)\mathbf{u}.$$

The first term is killed by $A-3I_3$, so it lies in E; the second is killed by $(A-2I_3)^2$, since $(A-2I_3)^2(A-3I_3)(A-I_3)=(A-I_3)(A-3I_3)(A-2I_3)^2=0$, so it lies in G. If U is invariant, it is invariant under every polynomial in A, so for $\mathbf{u}\in U$ both terms lie in U. Hence $U=(U\cap G)+(U\cap E)$, and the sum is direct because $G\cap E=\{\mathbf{0}\}$.

The pieces. $U\cap E$ is a subspace of the line E, so it is $\{\mathbf{0}\}$ or E. $U\cap G$ is an invariant subspace of G, on which A acts by $A\mathbf{e}_1=2\mathbf{e}_1$, $A\mathbf{e}_2=\mathbf{e}_1+2\mathbf{e}_2$. An invariant line is spanned by an eigenvector (Proposition 7.2.7), and the eigenvectors in G are the nonzero multiples of $\mathbf{e}_1$, since $(A-2I_3)(a\mathbf{e}_1+b\mathbf{e}_2)=b\mathbf{e}_1$. So $U\cap G$ is $\{\mathbf{0}\}$, $\operatorname{span}(\mathbf{e}_1)$, or G.

Conversely, each of the $2\cdot 3$ combinations is invariant, being a sum of invariant subspaces. The six invariant subspaces are

$$\{\mathbf{0}\},\quad \operatorname{span}(\mathbf{e}_1),\quad \operatorname{span}(\mathbf{e}_1,\mathbf{e}_2),\quad \operatorname{span}(\mathbf{e}_3),\quad \operatorname{span}(\mathbf{e}_1,\mathbf{e}_3),\quad \mathbb{Q}^3.$$

The same argument shows, for any T with $p(T)q(T)=0$ and p,q coprime, that invariant subspaces split along $\ker p(T)\oplus\ker q(T)$ (compare Exercise 7.2.55). With three distinct eigenvalues there would be $2^3=8$ invariant subspaces (Exercise 7.2.48); the chain in G is what removes two of them.

Solution to Problem 7.5

> *Uses.* Corollary 7.5.14 (Triangularizing a matrix), Proposition 7.5.8 (The diagonal of a triangular matrix), Proposition 7.3.11 (Similar matrices have the same characteristic polynomial), Proposition 7.4.7 (One eigenvalue), Proposition 7.2.28 (Polynomials act on eigenvectors by their values)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18), Prove it for triangular matrices first (Technique 7.5.23)
> *Hint 1.* (a) The eigenvalues of A^2 are the squares of those of A. Follow $\lambda,\lambda^2,\lambda^4,\dots$.
> *Hint 2.* (b) Try $A=I_n$. (c) Try $A=\begin{pmatrix}1&1\\0&1\end{pmatrix}$ and compute $A+A^{-1}$. (d) What are the eigenvalues of I_n+N?
> *Sketch.* (a) True: the set S of eigenvalues satisfies $\lambda\in S\Rightarrow\lambda^2\in S$, so $\lambda^{2^i}=\lambda^{2^j}$ for some $i<j$, giving $\lambda=0$ or $\lambda^{2^j-2^i}=1$. (b) False: $A=I_n$, $B=-I_n$. (c) False: $A=\begin{pmatrix}1&1\\0&1\end{pmatrix}$ has $A+A^{-1}=2I_2$. (d) True: I_n+N has only the eigenvalue 1, and a diagonalizable matrix with one eigenvalue is scalar.

(a) True. Write $A=SRS^{-1}$ with R upper triangular (Corollary 7.5.14). Then $A^2=SR^2S^{-1}$, and R^2 is upper triangular with diagonal entries r_{ii}^2. By Proposition 7.5.8, the eigenvalues of A are the r_{ii} and those of A^2 are the r_{ii}^2. Similar matrices have the same eigenvalues (Proposition 7.3.11), so the finite set S of eigenvalues of A equals $\{\lambda^2\mid\lambda\in S\}$. In particular $\lambda\in S$ implies $\lambda^2,\lambda^4,\lambda^8,\dots\in S$. Since S is finite, $\lambda^{2^i}=\lambda^{2^j}$ for some $i<j$, that is, $\lambda^{2^i}\left(\lambda^{2^j-2^i}-1\right)=0$. So $\lambda=0$ or $\lambda^{2^j-2^i}=1$.

(b) False. With $A=I_n$ and $B=-I_n$, $A^2=B^2=I_n$, but a matrix similar to I_n is $SI_nS^{-1}=I_n$, and $B\neq I_n$.

(c) False. Let $A=\begin{pmatrix}1&1\\0&1\end{pmatrix}$. Then $A^{-1}=\begin{pmatrix}1&-1\\0&1\end{pmatrix}$ and $A+A^{-1}=2I_2$, which is diagonal, while A is not diagonalizable (Example 7.4.8). The map $\lambda\mapsto\lambda+\lambda^{-1}$ has derivative 0 at $\lambda=1$, and that is where the shear disappears.

(d) True. If $N^k=0$, the only eigenvalue of N is 0 (Proposition 7.2.28). If $(I_n+N)\mathbf{v}=\mu\mathbf{v}$ with $\mathbf{v}\neq\mathbf{0}$, then $N\mathbf{v}=(\mu-1)\mathbf{v}$, so $\mu=1$. A diagonalizable matrix with the single eigenvalue 1 is I_n (Proposition 7.4.7), so $I_n+N=I_n$ and $N=0$. The same proof works over every field.

Solution to Problem 7.6

> *Uses.* Proposition 7.3.2 (Determinants over a commutative ring), Theorem 2.4.34 (Block multiplication), Lemma 7.4.13 (Geometric multiplicity through a rank), Theorem 7.4.16 (Criteria for diagonalizability), Proposition 7.4.7 (One eigenvalue)

Techniques. Block decomposition (Technique 2.4.35), Choose a convenient basis (Technique 4.5.33)
Hint 1. (a) In $xI_{2n} - M$, add the second block column to the first, then subtract the first block row from the second.
Hint 2. (b) Conjugate by $S = \begin{pmatrix} I_n & I_n \\ I_n & -I_n \end{pmatrix}$, which satisfies $S^2 = 2I_{2n}$. Then compare gm and am of $\begin{pmatrix} 2A & 0 \\ 0 & 0 \end{pmatrix}$ with those of $2A$.
Sketch. (a) $(xI - M)\begin{pmatrix} I & 0 \\ I & I \end{pmatrix} = \begin{pmatrix} xI-2A & -A \\ xI-2A & xI-A \end{pmatrix}$, and $\begin{pmatrix} I & 0 \\ -I & I \end{pmatrix}$ times that is $\begin{pmatrix} xI-2A & -A \\ 0 & xI \end{pmatrix}$, with determinant $p_{2A}x^n$. (b) $S^{-1}MS = \begin{pmatrix} 2A & 0 \\ 0 & 0 \end{pmatrix}$. For $\mu \neq 0$ the multiplicities of μ for this block matrix and for $2A$ agree, and for $\mu = 0$ both increase by n; so criterion (IV) holds for one iff for the other, and $2A$ is diagonalizable iff A is. (c) M^2 has blocks $2A^2 = 0$. A diagonalizable nilpotent matrix is 0.

(a) Work in $F[x]^{2n\times 2n}$, where determinants are multiplicative and block triangular matrices have determinant the product of the diagonal blocks (Proposition 7.3.2). By Theorem 2.4.34,

$$(xI_{2n} - M)\begin{pmatrix} I_n & 0 \\ I_n & I_n \end{pmatrix} = \begin{pmatrix} xI_n - 2A & -A \\ xI_n - 2A & xI_n - A \end{pmatrix}, \quad \begin{pmatrix} I_n & 0 \\ -I_n & I_n \end{pmatrix}\begin{pmatrix} xI_n - 2A & -A \\ xI_n - 2A & xI_n - A \end{pmatrix} = \begin{pmatrix} xI_n - 2A & -A \\ 0 & xI_n \end{pmatrix}.$$

The two outer factors have determinant 1, so $p_M = \det(xI_n - 2A)\det(xI_n) = x^n p_{2A}$.

(b) Let $S = \begin{pmatrix} I_n & I_n \\ I_n & -I_n \end{pmatrix}$. Then $S^2 = 2I_{2n}$, so $S^{-1} = (1/2)S$, and

$$MS = \begin{pmatrix} 2A & 0 \\ 2A & 0 \end{pmatrix}, \quad S^{-1}MS = \frac{1}{2}\begin{pmatrix} 4A & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 2A & 0 \\ 0 & 0 \end{pmatrix} =: M'.$$

For $\mu \in F$, $\ker(M' - \mu I_{2n}) = \ker(2A - \mu I_n) \times \ker(-\mu I_n)$, so $\mathrm{gm}_{M'}(\mu) = \mathrm{gm}_{2A}(\mu)$ for $\mu \neq 0$ and $\mathrm{gm}_{M'}(0) = \mathrm{gm}_{2A}(0) + n$. By (a) applied to M', or directly, $p_{M'} = x^n p_{2A}$, so $\mathrm{am}_{M'}(\mu) = \mathrm{am}_{2A}(\mu)$ for $\mu \neq 0$, $\mathrm{am}_{M'}(0) = \mathrm{am}_{2A}(0) + n$, and $p_{M'}$ splits iff p_{2A} does. By Theorem 7.4.16(IV), M' is diagonalizable iff $2A$ is. Finally $2A = S_0 D S_0^{-1}$ iff $A = S_0(D/2)S_0^{-1}$, so $2A$ is diagonalizable iff A is, and M is similar to M'.

(c) By Theorem 2.4.34 every block of M^2 is $A^2 + A^2 = 2A^2 = 0$ in characteristic 2. So M is nilpotent, and its only eigenvalue is 0. If M is diagonalizable, then $M = 0$ (Proposition 7.4.7), that is, $A = 0$; conversely $A = 0$ gives $M = 0$. This matches (a): in characteristic 2, $2A = 0$ and $p_M = x^{2n}$. The similarity of (b) fails because S is singular when $2 = 0$.

Solution to Problem 7.7

Uses. Proposition 2.4.23 (Transpose of a product), Theorem 4.3.21 (Column–row factorization), Theorem 2.4.34 (Block multiplication)
Techniques. Transpose to trade rows for columns (Technique 3.2.27), Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. (a) Compute $\mathbf{w}^{\mathsf{T}}A\mathbf{v}$ in two ways.
Hint 2. (b) Transpose $S^{-1}A = DS^{-1}$. The products $\mathbf{w}_i^{\mathsf{T}}\mathbf{v}_j$ are the entries of $S^{-1}S$. For the sum, multiply SD by S^{-1} column by row.
Sketch. (a) $\lambda\mathbf{w}^{\mathsf{T}}\mathbf{v} = \mathbf{w}^{\mathsf{T}}A\mathbf{v} = \left(A^{\mathsf{T}}\mathbf{w}\right)^{\mathsf{T}}\mathbf{v} = \mu\mathbf{w}^{\mathsf{T}}\mathbf{v}$. (b) $A^{\mathsf{T}}\left(S^{-1}\right)^{\mathsf{T}} = \left(S^{-1}\right)^{\mathsf{T}}D$; $\left(S^{-1}S\right)_{ij} = \mathbf{w}_i^{\mathsf{T}}\mathbf{v}_j$; $SDS^{-1} = \sum_i(\lambda_i\mathbf{v}_i)\mathbf{w}_i^{\mathsf{T}}$. (c) $P_iP_j = \mathbf{v}_i\left(\mathbf{w}_i^{\mathsf{T}}\mathbf{v}_j\right)\mathbf{w}_j^{\mathsf{T}}$, $\sum P_i = SS^{-1}$, and $A^k = SD^kS^{-1}$.

(a) $\lambda\mathbf{w}^{\mathsf{T}}\mathbf{v} = \mathbf{w}^{\mathsf{T}}(A\mathbf{v}) = \left(A^{\mathsf{T}}\mathbf{w}\right)^{\mathsf{T}}\mathbf{v} = \mu\mathbf{w}^{\mathsf{T}}\mathbf{v}$, using $\left(A^{\mathsf{T}}\mathbf{w}\right)^{\mathsf{T}} = \mathbf{w}^{\mathsf{T}}A$ (Proposition 2.4.23). So $(\lambda - \mu)\mathbf{w}^{\mathsf{T}}\mathbf{v} = 0$, and $\lambda \neq \mu$ gives $\mathbf{w}^{\mathsf{T}}\mathbf{v} = 0$.

(b) From $AS = SD$ we get $S^{-1}A = DS^{-1}$, and transposing, $A^{\mathsf{T}}\left(S^{-1}\right)^{\mathsf{T}} = \left(S^{-1}\right)^{\mathsf{T}}D$. The columns of $\left(S^{-1}\right)^{\mathsf{T}}$ are $\mathbf{w}_1, \ldots, \mathbf{w}_n$, so column i of this equation reads $A^{\mathsf{T}}\mathbf{w}_i = \lambda_i\mathbf{w}_i$. The (i, j) entry of $S^{-1}S = I_n$ is row i of S^{-1} times column j of S, which is $\mathbf{w}_i^{\mathsf{T}}\mathbf{v}_j$. Finally, SD has columns $\lambda_i\mathbf{v}_i$, and a product of a matrix with columns $\mathbf{a}_i$ and a matrix with rows $\mathbf{b}_i^{\mathsf{T}}$ is $\sum_i \mathbf{a}_i\mathbf{b}_i^{\mathsf{T}}$ (Theorem 2.4.34, or the column–row expansion of Theorem 4.3.21). So $A = (SD)S^{-1} = \sum_i \lambda_i\mathbf{v}_i\mathbf{w}_i^{\mathsf{T}}$.

(c) By (b), $P_iP_j = \mathbf{v}_i\left(\mathbf{w}_i^{\mathsf{T}}\mathbf{v}_j\right)\mathbf{w}_j^{\mathsf{T}}$, which is 0 for $i \neq j$ and P_i for $i = j$. By the column–row expansion again, $\sum_i P_i = SS^{-1} = I_n$. And $A^k = SD^kS^{-1} = \sum_i \lambda_i^k P_i$ by the same expansion applied to SD^k.

So a diagonalizable A is a combination of rank-one idempotents P_i, the projection onto $\mathrm{span}(\mathbf{v}_i)$ along the span of the other $\mathbf{v}_j$; the left eigenvectors $\mathbf{w}_i$ measure the $\mathbf{v}_i$-coordinate. When the λ_i are distinct, P_i is the Lagrange polynomial $L_i(A)$ of Technique 7.6.13. Over $\mathbb{R}$ the $\mathbf{w}_i$ equal the $\mathbf{v}_i$ exactly when $S^{-1} = S^{\mathsf{T}}$, which makes $A = SDS^{\mathsf{T}}$ symmetric; conversely every real symmetric matrix arises this way (Section 8.2).

Solution to Problem 7.8

Uses. Corollary 7.4.5 (Distinct eigenvalues give a diagonalization), Corollary 7.2.22 (At most $\dim V$ eigenvalues), Theorem 7.5.22 (Trace and determinant from eigenvalues), Proposition 5.5.18 (Tridiagonal determinants)
Techniques. Plug in clever test vectors (Technique 6.1.40), Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. (a) $(A_n\mathbf{v})_j = v_{j-1} + v_{j+1}$, and $\sin((j-1)\theta) + \sin((j+1)\theta) = 2\cos\theta\sin j\theta$.
Hint 2. (b) The error term vanishes when $(n+1)\theta \in \pi\mathbb{Z}$. (c) Expand along the last row: $d_m = -d_{m-2}$.
Sketch. (a) The sum formula gives the middle rows; row 1 uses $\sin 0 = 0$, and row n is short of $\sin((n+1)\theta)$. (b) $\theta_k = k\pi/(n+1)$, $1 \le k \le n$, gives eigenvectors ($v_1 = \sin\theta_k \neq 0$) with n distinct eigenvalues, since cos is injective on $(0,\pi)$. (c) $d_1 = 0$, $d_2 = -1$, $d_m = -d_{m-2}$; so $\det A_n = 0$ for odd n and $(-1)^{n/2}$ for even n, and this is the product.

(a) Let $v_j = \sin j\theta$, and set $v_0 = \sin 0 = 0$. Row j of A_n has ones in columns $j-1$ and $j+1$ (when they exist), so $(A_n\mathbf{v})_j = v_{j-1} + v_{j+1}$ for $j \le n-1$ and $(A_n\mathbf{v})_n = v_{n-1}$. By the sum formula $\sin(a-b) + \sin(a+b) = 2\sin a\cos b$,

$$v_{j-1} + v_{j+1} = \sin((j-1)\theta) + \sin((j+1)\theta) = 2\cos\theta\sin j\theta,$$

which gives the rows $1 \le j \le n-1$ (row 1 because $v_0 = 0$). For row n, $v_{n-1} = 2\cos\theta\sin n\theta - \sin((n+1)\theta)$ by the same formula. This is the claim.

(b) Let $\theta_k = k\pi/(n+1)$ for $k = 1, \dots, n$. Then $\sin((n+1)\theta_k) = \sin k\pi = 0$, so $A_n\mathbf{v}_k = 2\cos\theta_k\mathbf{v}_k$, and $\mathbf{v}_k \neq \mathbf{0}$ because its first entry is $\sin\theta_k > 0$. So each $2\cos\theta_k$ is an eigenvalue. The θ_k lie in $(0,\pi)$, where cos is strictly decreasing, so these n eigenvalues are distinct. An $n \times n$ matrix has at most n eigenvalues (Corollary 7.2.22), so these are all of them, and A_n is diagonalizable (Corollary 7.4.5).

(c) Let $d_m = \det A_m$. Directly, $d_1 = 0$ and $d_2 = \det\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = -1$. By Proposition 5.5.18 with diagonal entries 0 and off-diagonal entries 1, $d_m = 0 \cdot d_{m-1} - 1 \cdot 1 \cdot d_{m-2} = -d_{m-2}$ for $m \ge 3$. Hence $\det A_n = 0$ for odd n and $\det A_n = (-1)^{n/2}$ for even n. Since A_n is diagonalizable with the eigenvalues of (b), its determinant is their product (Theorem 7.5.22), so

$$\prod_{k=1}^{n} 2\cos\frac{k\pi}{n+1} = \begin{cases} 0 & \text{if } n \text{ is odd} \\ (-1)^{n/2} & \text{if } n \text{ is even.} \end{cases}$$

For odd n this is visible directly, since the factor with $k = (n+1)/2$ is $2\cos(\pi/2) = 0$. In the same way, $\operatorname{tr} A_n = 0$ says $\sum_k \cos(k\pi/(n+1)) = 0$, which also follows from $\cos(\pi - x) = -\cos x$.

A_n is the adjacency matrix of a path with n vertices; Section 16.5 studies such matrices. The eigenvector was guessed from the recurrence $v_{j-1} + v_{j+1} = cv_j$, whose solutions are combinations of $\sin j\theta$ and $\cos j\theta$, and the boundary rows chose sin and θ.

Solution to Problem 7.9

Uses. Theorem 7.1.14 (Division with remainder), Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Theorem 2.2.1 (Linear maps are determined by a basis), Theorem 7.6.15 (Diagonalizability and the minimal polynomial)
Techniques. Krylov sequences must become dependent (Technique 7.3.28), Check it on a basis (Technique 2.2.7)
Hint 1. (a) Divide f by $p_{\mathbf{v}}$ and apply the remainder to $\mathbf{v}$.
Hint 2. (b) Two operators agree if they agree on a basis. (c) Compute $A\mathbf{e}_j$ and $A^2\mathbf{e}_j$ and find the first dependence for each j.
Sketch. (a) $f = qp_{\mathbf{v}} + r$ with $\deg r < \deg p_{\mathbf{v}}$, and $r(T)\mathbf{v} = f(T)\mathbf{v}$; minimality forces $r = \mathbf{0}$ when this is $\mathbf{0}$. (b) $f(T) = 0$ iff $f(T)\mathbf{b}_i = \mathbf{0}$ for all i, iff each $p_{\mathbf{b}_i}$ divides f by (a). m_T is the monic annihilating polynomial of least degree. (c) Each $\mathbf{e}_j$ has $p_{\mathbf{e}_j} = (x-2)^2$, so $m_A = (x-2)^2$ and A is not diagonalizable.

(a) If $p_{\mathbf{v}}$ divides f, say $f = qp_{\mathbf{v}}$, then $f(T)\mathbf{v} = q(T)p_{\mathbf{v}}(T)\mathbf{v} = \mathbf{0}$ (Proposition 7.2.27). Conversely, suppose $f(T)\mathbf{v} = \mathbf{0}$, and divide: $f = qp_{\mathbf{v}} + r$ with $r = \mathbf{0}$ or $\deg r < \deg p_{\mathbf{v}}$ (Theorem 7.1.14). Then $r(T)\mathbf{v} = f(T)\mathbf{v} - q(T)p_{\mathbf{v}}(T)\mathbf{v} = \mathbf{0}$. If $r \neq \mathbf{0}$, dividing r by its leading coefficient gives a monic polynomial of smaller degree than $p_{\mathbf{v}}$ killing $\mathbf{v}$, which contradicts the choice of $p_{\mathbf{v}}$. So $r = \mathbf{0}$.

(b) $f(T) = 0$ if and only if $f(T)\mathbf{b}_i = \mathbf{0}$ for every i, since a linear map is determined by its values on a basis (Theorem 2.2.1). By (a), this holds if and only if every $p_{\mathbf{b}_i}$ divides f. By definition, m_T is the monic polynomial of least degree with $m_T(T) = 0$ (Theorem 7.6.2), so it is the monic polynomial of least degree divisible by all the $p_{\mathbf{b}_i}$.

(c) For $\mathbf{e}_1$: $A\mathbf{e}_1 = (3, 0, 1)$ and $A^2\mathbf{e}_1 = (8, 0, 4)$. The first two are independent, and $A^2\mathbf{e}_1 - 4A\mathbf{e}_1 + 4\mathbf{e}_1 = (8 - 12 + 4, 0, 4 - 4) = \mathbf{0}$, so $p_{\mathbf{e}_1} = x^2 - 4x + 4 = (x-2)^2$. For $\mathbf{e}_2$: $A\mathbf{e}_2 = (1, 2, 1)$ and $A^2\mathbf{e}_2 = (4, 4, 4) = 4A\mathbf{e}_2 - 4\mathbf{e}_2$, so again $p_{\mathbf{e}_2} = (x-2)^2$. For $\mathbf{e}_3$: $A\mathbf{e}_3 = (-1, 0, 1)$ and $A^2\mathbf{e}_3 = (-4, 0, 0) = 4A\mathbf{e}_3 - 4\mathbf{e}_3$, so $p_{\mathbf{e}_3} = (x-2)^2$. By (b), $m_A = (x-2)^2$. It has a repeated root, so A is not diagonalizable (Theorem 7.6.15).

This costs a few matrix–vector products per basis vector, and no determinant. Here $p_A = (x-2)^3$ (its only root is 2, and $\operatorname{tr} A = 6$), so m_A is a proper divisor of p_A, and in fact $(A - 2I_3)^2 = 0$.

Solution to Problem 7.10

Uses. Corollary 7.5.14 (Triangularizing a matrix), Proposition 7.5.8 (The diagonal of a triangular matrix), Corollary 7.4.5 (Distinct eigenvalues give a diagonalization)
Techniques. Prove it for triangular matrices first (Technique 7.5.23), Choose a convenient basis (Technique 4.5.33)
Hint 1. Triangularize, $A = SRS^{-1}$. Which diagonal matrix can you subtract from R so that the rest has distinct diagonal entries?
Hint 2. A triangular matrix with distinct diagonal entries has distinct eigenvalues. For (c), choose the diagonal entries to avoid 0 as well.
Sketch. (a) $A = SRS^{-1}$ with R triangular. Let $E = \operatorname{diag}(r_{11} - 1, r_{22} - 2, \ldots, r_{nn} - n)$. Then $R - E$ is triangular with diagonal $1, 2, \ldots, n$, so diagonalizable, and $A = S(R-E)S^{-1} + SES^{-1}$. (b) $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$. (c) Choose E diagonal with $e_{ii} \neq 0$ and $e_{ii} \neq r_{ii}$.

(a) By Corollary 7.5.14, $A = SRS^{-1}$ with S invertible and R upper triangular. Let $E = \operatorname{diag}(r_{11} - 1, r_{22} - 2, \ldots, r_{nn} - n)$. Then $R - E$ is upper triangular with diagonal entries $1, 2, \ldots, n$, which are its eigenvalues (Proposition 7.5.8); they are distinct, so $R - E$ is diagonalizable (Corollary 7.4.5). So are $S(R-E)S^{-1}$ and SES^{-1}, being similar to a diagonalizable and to a diagonal matrix, and

$$A = S(R-E)S^{-1} + SES^{-1}.$$

(b) $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$. The first summand is triangular with distinct diagonal entries $1, 0$, and the second is diagonal.

(c) With $A = SRS^{-1}$ as in (a), choose $e_i \in \mathbb{C}$ with $e_i \neq 0$ and $e_i \neq r_{ii}$, and let $E = \operatorname{diag}(e_1, \ldots, e_n)$. Then E and $R - E$ are triangular with nonzero diagonal entries, hence invertible, and $A = S(R-E)S^{-1} + SES^{-1}$.

Diagonalizable matrices are not closed under addition, so (a) says that they generate everything additively. The same construction with $E = -\varepsilon \operatorname{diag}(1, 2, \ldots, n)$ shows more: $A + \varepsilon S \operatorname{diag}(1, \ldots, n) S^{-1}$ is diagonalizable whenever $r_{ii} + i\varepsilon$ are distinct, which holds for all but finitely many ε, so every complex matrix is a limit of diagonalizable ones (Technique 7.6.23).

Solution to Problem 7.11

Uses. Proposition 7.2.4 (Invariance is checked on a spanning list), Proposition 1.5.14 (Appending a vector), Theorem 4.1.10 (Independent lists are short), Exercise 7.3.43
Techniques. Extend a basis of a subspace (Technique 4.1.18), Choose a convenient basis (Technique 4.5.33)
Hint 1. Build the list greedily: if $W_k = \operatorname{span}(\mathbf{v}_1, A\mathbf{v}_1, \ldots, \mathbf{v}_k, A\mathbf{v}_k)$ is not all of $\mathbb{R}^n$, pick $\mathbf{v}_{k+1} \notin W_k$. W_k is A-invariant.
Hint 2. To see the new list is independent, show $a\mathbf{v} + bA\mathbf{v} \in W_k$ forces $a = b = 0$: apply $a\,\mathrm{id} - bA$ and use $(a - bA)(a + bA) = (a^2 + b^2)\,\mathrm{id}$.
Sketch. Inductively build $\mathbf{v}_1, \ldots, \mathbf{v}_k$ with $\mathbf{v}_i, A\mathbf{v}_i$ independent; W_k is A-invariant since $A(A\mathbf{v}_i) = -\mathbf{v}_i$. For $\mathbf{v} \notin W_k$, if $(a + bA)\mathbf{v} \in W_k$ with $(a, b) \neq (0, 0)$, then $(a^2 + b^2)\mathbf{v} = (a - bA)(a + bA)\mathbf{v} \in W_k$, a contradiction. So the list grows by two independent vectors until it spans; $n = 2m$. In this basis $A\mathbf{v}_i = A\mathbf{v}_i$ and $A(A\mathbf{v}_i) = -\mathbf{v}_i$, which is the matrix J.

(a) We construct $\mathbf{v}_1, \mathbf{v}_2, \ldots$ such that for each k the list $\mathcal{L}_k = \mathbf{v}_1, \ldots, \mathbf{v}_k, A\mathbf{v}_1, \ldots, A\mathbf{v}_k$ is independent. The empty list ($k = 0$) is independent. Suppose $\mathcal{L}_k$ is independent and $W_k = \operatorname{span} \mathcal{L}_k \neq \mathbb{R}^n$. Since $A(\mathbf{v}_i) = A\mathbf{v}_i$ and $A(A\mathbf{v}_i) = -\mathbf{v}_i$, A maps the list into W_k, so W_k is A-invariant (Proposition 7.2.4). Choose $\mathbf{v} = \mathbf{v}_{k+1} \notin W_k$.

We claim that if $a, b \in \mathbb{R}$ and $a\mathbf{v} + bA\mathbf{v} \in W_k$, then $a = b = 0$. Since $A^2 = -I_n$,

$$(aI_n - bA)(aI_n + bA) = a^2 I_n - b^2 A^2 = \left(a^2 + b^2\right) I_n.$$

So $\left(a^2 + b^2\right)\mathbf{v} = (aI_n - bA)(a\mathbf{v} + bA\mathbf{v}) \in W_k$, because W_k is invariant under A and hence under $aI_n - bA$. As $\mathbf{v} \notin W_k$, $a^2 + b^2 = 0$, so $a = b = 0$.

Now suppose $\mathbf{w} + a\mathbf{v} + bA\mathbf{v} = \mathbf{0}$ with $\mathbf{w} \in W_k$. Then $a\mathbf{v} + bA\mathbf{v} = -\mathbf{w} \in W_k$, so $a = b = 0$ by the claim, and then $\mathbf{w} = \mathbf{0}$. So $\mathcal{L}_{k+1}$ is independent. An independent list in $\mathbb{R}^n$ has at most n vectors (Theorem 4.1.10), so the process stops, at some m with $W_m = \mathbb{R}^n$. Then $\mathcal{L}_m$ is a basis with $2m$ vectors, and $n = 2m$.

(b) Let S have columns $\mathbf{v}_1, \ldots, \mathbf{v}_m, A\mathbf{v}_1, \ldots, A\mathbf{v}_m$. For $i \le m$, A sends column i to column $m + i$, and column $m + i$ to $-\mathbf{v}_i$, which is -1 times column i. So $AS = SJ$, with J as given, and $A = SJS^{-1}$. Two real $n \times n$ matrices with square $-I_n$ are both similar to J, hence to each other.

The same argument shows that a real operator with $T^2 = -\mathrm{id}$ turns V into a complex vector space, with $i\mathbf{v} \coloneqq T\mathbf{v}$, and then (a) is the statement that a complex basis $\mathbf{v}_1, \ldots, \mathbf{v}_m$ gives the real basis $\mathbf{v}_j, i\mathbf{v}_j$. Exercise 7.3.43 proved only that n is even; the basis is what gives the similarity class.

Solution to Problem 7.12

> *Uses.* Proposition 4.1.26 (Nilpotent chains are independent), Corollary 7.2.38 (The span of a chain), Proposition 7.4.7 (One eigenvalue), Exercise A.2.8, Exercise 7.1.56, Theorem 4.2.11 (Rank–nullity)
> *Techniques.* Apply an operator to a relation to kill terms (Technique 4.1.25), Dimension counting (Technique 4.2.24), Compare degrees and leading coefficients (Technique 7.1.6)
> *Hint 1.* (a) $(x+1)^m - x^m = mx^{m-1} + \cdots$. Over $\mathbb{Q}$, $m \neq 0$. So the chain starting at x^n ends at the nonzero constant $n!$.
> *Hint 2.* (b) $T^p f = f(x + p)$. For Δ^p, use the binomial theorem and $p \mid \binom{p}{j}$ for $0 < j < p$. For $\mathrm{gm}(1)$, compare $\dim\ker\Delta^{j+1}$ with $\dim\ker\Delta^j$, or find a nonconstant f with $f(x+1) = f$.
> *Sketch.* (a) The leading term of $\Delta(ax^m + \cdots)$ is max^{m-1}, so $\Delta^n x^n = n! \neq 0$ and $\Delta^{n+1}x^n = 0$; the chain is independent of length $n + 1 = \dim V$. $\ker\Delta$ is the constants, T has only eigenvalue 1, and $T \neq \mathrm{id}$, so not diagonalizable. (b) $T^p f = f(x + p) = f$. $(T - \mathrm{id})^p = T^p - \mathrm{id}$ in characteristic p. $x^p - x$ and 1 lie in $\ker\Delta$, so $\mathrm{gm}(1) \ge 2$.

(a) For $m \ge 1$, $(x+1)^m - x^m = mx^{m-1} + (\text{terms of degree} < m-1)$ by the binomial theorem. So if $f = ax^m + (\text{lower terms})$ with $a \neq 0$ and $m \ge 1$, then $\Delta f = max^{m-1} + (\text{lower terms})$, and $ma \neq 0$ in $\mathbb{Q}$: $\deg\Delta f = m - 1$. Constants are killed by Δ. Hence $\Delta^j x^n$ has degree $n - j$ for $j \le n$, with $\Delta^n x^n = n!$, and $\Delta^{n+1}x^n = 0$. By Proposition 4.1.26 (with T there replaced by Δ), $x^n, \Delta x^n, \ldots, \Delta^n x^n$ is independent; it has $n + 1 = \dim V$ vectors, so it is a basis.

If $Tf = \lambda f$ with $f \neq \mathbf{0}$, compare leading coefficients: $f(x+1)$ has the same leading coefficient as f, so $\lambda = 1$. And 1 is an eigenvalue, with $E_1 = \ker\Delta$ = the constants, since Δ lowers the degree of every nonconstant polynomial. So $\mathrm{gm}(1) = 1$. In the chain basis, read from the end, $T = \mathrm{id} + \Delta$ has the matrix of Corollary 7.2.38(c) with $\lambda = 1$. T is not diagonalizable: its only eigenvalue is 1 and $T \neq \mathrm{id}_V$ (Proposition 7.4.7).

(b) For $f \in V$, $T^p f = f(x + 1 + \cdots + 1) = f(x + p) = f$, since $p = 0$ in $\mathbb{F}_p$. So $T^p = \mathrm{id}_V$. T and id_V commute, so by the binomial theorem (Exercise A.2.8),

$$\Delta^p = (T - \mathrm{id}_V)^p = \sum_{j=0}^{p} \binom{p}{j} (-1)^{p-j} T^j = T^p + (-1)^p \mathrm{id}_V = T^p - \mathrm{id}_V = 0,$$

because p divides $\binom{p}{j}$ for $0 < j < p$, and $(-1)^p = -1$ in $\mathbb{F}_p$ (for $p = 2$, $1 = -1$). For $\mathrm{gm}(1)$: in $\mathbb{F}_p[x]$, $(x+1)^p = x^p + 1$ (the same binomial fact), so $g = x^p - x$ satisfies $g(x+1) = x^p + 1 - x - 1 = g$. Since $n \ge p$, $g \in V$, and $1, g$ are independent elements of $\ker\Delta = E_1$. So $\mathrm{gm}(1) \ge 2$. (Compare Exercise 7.1.56.)

Over $\mathbb{Q}$, T is one long chain; over $\mathbb{F}_p$, every chain has length at most p because $\Delta^p = 0$, so V, of dimension $n + 1 > p$, needs at least two chains, and each chain contributes one eigenvector. Counting with Theorem 4.2.11 gives more: $N = \Delta$ maps $\ker N^{j+1}$ to $\ker N^j$ with kernel $\ker N$, so $n + 1 = \dim\ker N^p \le p\,\mathrm{gm}(1)$, that is, $\mathrm{gm}(1) \ge (n+1)/p$.

Solution to Problem 7.13

Uses. Lemma 2.4.24 (Matrix units), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Theorem 7.5.22 (Trace and determinant from eigenvalues), Theorem 5.4.10 (Multiplicativity), Proposition 5.3.17 (Block-diagonal matrices)
Techniques. Study a linear map on a space of matrices (Technique 4.2.29), Diagonalize, solve, conjugate back (Technique 7.4.22), Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. (b) If S and R have the eigenvectors of A and of B^{T} as columns, then $X \mapsto SXR^{\mathsf{T}}$ sends the matrix units U_{ij} to $\mathbf{v}_i\mathbf{w}_j^{\mathsf{T}}$.
Hint 2. (c) L is the composite of $X \mapsto AX$ and $X \mapsto XB$. The first acts on each column of X separately.
Sketch. (a) $A\mathbf{v}\mathbf{w}^{\mathsf{T}}B = \lambda\mathbf{v}\left(B^{\mathsf{T}}\mathbf{w}\right)^{\mathsf{T}} = \lambda\mu\mathbf{v}\mathbf{w}^{\mathsf{T}}$, nonzero. (b) $B^{\mathsf{T}} = \left(R_0^{-1}\right)^{\mathsf{T}}ER_0^{\mathsf{T}}$ is diagonalizable with eigenbasis $\mathbf{w}_j$; the n^2 matrices $\mathbf{v}_i\mathbf{w}_j^{\mathsf{T}} = SU_{ij}R^{\mathsf{T}}$ form a basis, an eigenbasis of L. Sum and product of $\lambda_i\mu_j$. (c) Ordering the matrix units column by column, $X \mapsto AX$ is block diagonal with n blocks A; ordering row by row, $X \mapsto XB$ is block diagonal with n blocks B^{T}. Multiply.

(a) $L\left(\mathbf{v}\mathbf{w}^{\mathsf{T}}\right) = (A\mathbf{v})\left(\mathbf{w}^{\mathsf{T}}B\right) = \lambda\mathbf{v}\left(B^{\mathsf{T}}\mathbf{w}\right)^{\mathsf{T}} = \lambda\mu\mathbf{v}\mathbf{w}^{\mathsf{T}}$, and $\mathbf{v}\mathbf{w}^{\mathsf{T}} \neq 0$ since its (i,j) entry v_iw_j is nonzero when $v_i \neq 0 \neq w_j$.

(b) Let S be invertible with columns $\mathbf{v}_1, \ldots, \mathbf{v}_n$, eigenvectors of A for $\lambda_1, \ldots, \lambda_n$. If $B = R_0ER_0^{-1}$ with $E = \operatorname{diag}(\mu_1, \ldots, \mu_n)$, then $B^{\mathsf{T}} = \left(R_0^{-1}\right)^{\mathsf{T}}ER_0^{\mathsf{T}}$, so the columns $\mathbf{w}_1, \ldots, \mathbf{w}_n$ of $R = \left(R_0^{-1}\right)^{\mathsf{T}}$ are eigenvectors of B^{T} for $\mu_1, \ldots, \mu_n$, and R is invertible. The map $X \mapsto SXR^{\mathsf{T}}$ is an isomorphism of $F^{n\times n}$, and it sends the matrix unit $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ (Lemma 2.4.24) to $S\mathbf{e}_i\left(R\mathbf{e}_j\right)^{\mathsf{T}} = \mathbf{v}_i\mathbf{w}_j^{\mathsf{T}}$. So the n^2 matrices $\mathbf{v}_i\mathbf{w}_j^{\mathsf{T}}$ form a basis of $F^{n\times n}$, and by (a) it is an eigenbasis of L with eigenvalues $\lambda_i\mu_j$. So L is diagonalizable (Theorem 7.4.2), and its trace and determinant are the sum and product of these eigenvalues (Theorem 7.5.22):

$$\operatorname{tr} L = \sum_{i,j}\lambda_i\mu_j = \left(\sum_i \lambda_i\right)\left(\sum_j \mu_j\right) = \operatorname{tr} A \operatorname{tr} B, \quad \det L = \prod_{i,j}\lambda_i\mu_j = \left(\prod_i \lambda_i\right)^n\left(\prod_j \mu_j\right)^n = (\det A)^n(\det B)^n.$$

(c) Write $L = L_1 \circ L_2$ with $L_1(X) = AX$ and $L_2(X) = XB$, so $\det L = \det L_1 \det L_2$ (Theorem 5.4.10). Order the matrix units column by column: $U_{11}, \ldots, U_{n1}, U_{12}, \ldots, U_{n2}, \ldots$. Column j of AX is A times column j of X, so in this basis L_1 has the block diagonal matrix with n diagonal blocks A, and $\det L_1 = (\det A)^n$ (Proposition 5.3.17). Order them row by row instead: row i of XB is $\left(B^{\mathsf{T}}(\text{row } i \text{ of } X)^{\mathsf{T}}\right)^{\mathsf{T}}$, so L_2 has the block diagonal matrix with n blocks B^{T}, and $\det L_2 = \left(\det B^{\mathsf{T}}\right)^n = (\det B)^n$. The determinant of an operator does not depend on the basis, so $\det L = (\det A)^n(\det B)^n$.

The trace formula also holds for all A, B (it is linear in each of A and B and can be checked on matrix units). Over $\mathbb{C}$, the eigenvalues of L are always the $\lambda_i\mu_j$ counted with multiplicity: triangularize A and B^{T} and order the basis $\mathbf{v}_i\mathbf{w}_j^{\mathsf{T}}$ suitably, or use Technique 7.6.23. The map $X \mapsto AX - XA$ of Exercise 7.5.45 works the same way, with $\lambda_i - \lambda_j$ in place of $\lambda_i\mu_j$.

Solution to Problem 7.14

Uses. Lemma 7.5.11 (Compressing an operator to a complement), Corollary 7.6.16 (Restrictions of diagonalizable operators), Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues)
Techniques. Use an annihilating polynomial (Technique 7.6.17), Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Is W invariant? Try $T = \operatorname{diag}(1,2)$ on F^2, $U = \operatorname{span}(\mathbf{e}_1)$, and $W = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$.
Hint 2. Show $T^k\mathbf{w} - S^k\mathbf{w} \in U$ for every $\mathbf{w} \in W$ and $k \geq 0$, so that $p(S) = \Pr_{W,U} \circ p(T)\restriction_W$ for every polynomial p. Then use m_T.
Sketch. W need not be invariant, so $S \neq T\restriction_W$ in general, and an eigenvector of S need not be one of T: with $T = \operatorname{diag}(1,2)$, $U = \operatorname{span}(\mathbf{e}_1)$, $W = \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$, $S = 2\mathrm{id}_W$ but $\mathbf{e}_1 + \mathbf{e}_2$ is not an eigenvector of T. Correct proof: induction gives $T^k\mathbf{w} - S^k\mathbf{w} \in U$, so $p(S)\mathbf{w} = \Pr_{W,U} p(T)\mathbf{w}$. With $p = m_T$, which has distinct linear factors, $m_T(S) = 0$, so S is diagonalizable with eigenvalues among the roots of m_T.

The error. Corollary 7.6.16 applies to invariant subspaces, and W need not be invariant; then $T\restriction_W$ is a map $W \to V$, not an operator on W, and S is a different map. The second sentence fails too. Let $T = \operatorname{diag}(1,2)$ on

F^2, $U = \operatorname{span}(\mathbf{e}_1)$, and $W = \operatorname{span}(\mathbf{w})$ with $\mathbf{w} = \mathbf{e}_1 + \mathbf{e}_2$. Then $T\mathbf{w} = \mathbf{e}_1 + 2\mathbf{e}_2 = -\mathbf{e}_1 + 2\mathbf{w}$, so $S\mathbf{w} = 2\mathbf{w}$, and $\mathbf{w}$ is an eigenvector of S but not of T.

A correct proof. Write $P = \Pr_{W,U}$, so that P fixes W and kills U. We first show that $T^k\mathbf{w} - S^k\mathbf{w} \in U$ for all $\mathbf{w} \in W$ and $k \geq 0$, by induction on k. For $k = 0$ the difference is $\mathbf{0}$. If $T^k\mathbf{w} = S^k\mathbf{w} + \mathbf{u}$ with $\mathbf{u} \in U$, then

$$T^{k+1}\mathbf{w} = T\big(S^k\mathbf{w}\big) + T\mathbf{u} = S^{k+1}\mathbf{w} + \mathbf{u}' + T\mathbf{u},$$

where $\mathbf{u}' = T\big(S^k\mathbf{w}\big) - S\big(S^k\mathbf{w}\big) \in U$ by Lemma 7.5.11(a) applied to $S^k\mathbf{w} \in W$, and $T\mathbf{u} \in U$ by invariance. This completes the induction. Taking linear combinations, $p(T)\mathbf{w} - p(S)\mathbf{w} \in U$ for every $p \in F[x]$, and applying P gives $p(S)\mathbf{w} = Pp(T)\mathbf{w}$.

Since T is diagonalizable, $m_T = (x - \lambda_1)\cdots(x - \lambda_m)$ with distinct eigenvalues λ_i of T (Theorem 7.6.15). Then $m_T(S)\mathbf{w} = Pm_T(T)\mathbf{w} = \mathbf{0}$ for all $\mathbf{w}$, so m_T annihilates S. A product of distinct linear factors annihilates S, so S is diagonalizable (Theorem 7.6.15), and its eigenvalues are roots of m_T (Proposition 7.2.28), which are eigenvalues of T (Theorem 7.6.7).

The compression is the quotient operator T/U on V/U in disguise (Remark 7.5.16), and the claim says that quotients of diagonalizable operators are diagonalizable. The eigenvalues are preserved, the eigenvectors are not: they are eigenvectors only modulo U.

Solution to Problem 7.15

> *Uses.* Problem 7.9, Proposition 7.2.35 (A basis of a Krylov subspace), Corollary 7.1.48 (Coprime polynomials), Definition 7.1.24 (Multiplicity of a root), Theorem 7.6.20 (Cayley–Hamilton), Exercise 7.6.47
> *Techniques.* Krylov sequences must become dependent (Technique 7.3.28), Apply an operator to a relation to kill terms (Technique 4.1.25)
> *Hint 1.* Let $q_i = m_T/(x - \lambda_i)^{k_i}$. Since $(x - \lambda_i)^{k_i - 1}q_i$ has smaller degree than m_T, some $\mathbf{u}_i$ is not killed by it. Put $\mathbf{v}_i = q_i(T)\mathbf{u}_i$ and $\mathbf{v} = \sum \mathbf{v}_i$.
> *Hint 2.* If $f(T)\mathbf{v} = \mathbf{0}$, apply $q_j(T)$: the terms $i \neq j$ die. Then use Bézout for q_j and $\big(x - \lambda_j\big)^{k_j}$ to get $\big(x - \lambda_j\big)^{k_j} \mid f$.
> *Sketch.* $\mathbf{v}_i = q_i(T)\mathbf{u}_i$ is killed by $(x - \lambda_i)^{k_i}$ but not by $(x - \lambda_i)^{k_i - 1}$. If $f(T)\mathbf{v} = \mathbf{0}$, applying $q_j(T)$ kills $\mathbf{v}_i$ for $i \neq j$, so $q_j(T)f(T)\mathbf{v}_j = \mathbf{0}$; Bézout $(aq_j + b\big(x - \lambda_j\big)^{k_j} = 1)$ gives $f(T)\mathbf{v}_j = \mathbf{0}$, so $p_{\mathbf{v}_j} = \big(x - \lambda_j\big)^{k_j}$ divides f. With $f = p_{\mathbf{v}}$, each $\big(x - \lambda_j\big)^{k_j}$ divides $p_{\mathbf{v}}$, which divides m_T; compare multiplicities. Then $\dim K_T(\mathbf{v}) = \deg p_{\mathbf{v}}$; and $\deg m_T = \deg p_T = \dim V$ iff $m_T = p_T$ by Cayley–Hamilton.

For each i let $q_i = \prod_{j \neq i} \big(x - \lambda_j\big)^{k_j}$, so $m_T = (x - \lambda_i)^{k_i}q_i$. The polynomial $(x - \lambda_i)^{k_i - 1}q_i$ has degree less than $\deg m_T$, so it does not annihilate T, and some $\mathbf{u}_i$ has $(T - \lambda_i\,\mathrm{id})^{k_i - 1}q_i(T)\mathbf{u}_i \neq \mathbf{0}$. Let $\mathbf{v}_i = q_i(T)\mathbf{u}_i$. Then $(T - \lambda_i\,\mathrm{id})^{k_i}\mathbf{v}_i = m_T(T)\mathbf{u}_i = \mathbf{0}$ and $(T - \lambda_i\,\mathrm{id})^{k_i - 1}\mathbf{v}_i \neq \mathbf{0}$. By Problem 7.9(a), $p_{\mathbf{v}_i}$ divides $(x - \lambda_i)^{k_i}$ but not $(x - \lambda_i)^{k_i - 1}$; a monic divisor of $(x - \lambda_i)^{k_i}$ has only the root λ_i, so it is $(x - \lambda_i)^e$ (Corollary 7.1.35), and $e = k_i$. So $p_{\mathbf{v}_i} = (x - \lambda_i)^{k_i}$.

Let $\mathbf{v} = \mathbf{v}_1 + \cdots + \mathbf{v}_r$ and suppose $f(T)\mathbf{v} = \mathbf{0}$. Fix j. For $i \neq j$, $(x - \lambda_i)^{k_i}$ divides q_j, so $q_j(T)\mathbf{v}_i = \mathbf{0}$. Hence

$$\mathbf{0} = q_j(T)f(T)\mathbf{v} = q_j(T)f(T)\mathbf{v}_j.$$

The polynomials q_j and $\big(x - \lambda_j\big)^{k_j}$ have no common root, so they are coprime, and $aq_j + b\big(x - \lambda_j\big)^{k_j} = 1$ for some $a, b \in \mathbb{C}[x]$ (Corollary 7.1.48). The vector $\mathbf{y} = f(T)\mathbf{v}_j$ satisfies $q_j(T)\mathbf{y} = \mathbf{0}$ and $\big(T - \lambda_j\,\mathrm{id}\big)^{k_j}\mathbf{y} = f(T)\big(T - \lambda_j\,\mathrm{id}\big)^{k_j}\mathbf{v}_j = \mathbf{0}$, so $\mathbf{y} = a(T)q_j(T)\mathbf{y} + b(T)\big(T - \lambda_j\,\mathrm{id}\big)^{k_j}\mathbf{y} = \mathbf{0}$. By Problem 7.9(a), $\big(x - \lambda_j\big)^{k_j} = p_{\mathbf{v}_j}$ divides f.

Apply this to $f = p_{\mathbf{v}}$: each $\big(x - \lambda_j\big)^{k_j}$ divides $p_{\mathbf{v}}$, so λ_j is a root of $p_{\mathbf{v}}$ of multiplicity at least k_j (Definition 7.1.24). On the other hand $m_T(T)\mathbf{v} = \mathbf{0}$, so $p_{\mathbf{v}}$ divides m_T, and its roots are among the λ_j with multiplicity at most k_j. Over $\mathbb{C}$ a monic polynomial is the product of $(x - \mu)$ over its roots with multiplicity (Corollary 7.1.35), so $p_{\mathbf{v}} = m_T$.

By Proposition 7.2.35, $\dim K_T(\mathbf{v}) = \deg p_{\mathbf{v}} = \deg m_T$. If $m_T = p_T$, this is $\dim V$, so $\mathbf{v}$ is cyclic. Conversely, if $\mathbf{w}$ is cyclic, then $\dim V = \dim K_T(\mathbf{w}) = \deg p_{\mathbf{w}} \leq \deg m_T$, since $p_{\mathbf{w}}$ divides m_T; as m_T divides p_T

(Theorem 7.6.20) and $\deg p_T = \dim V$, the monic polynomials m_T and p_T are equal. This is the converse of Exercise 7.6.47(a). The result holds over every field, with a longer proof using the factorization of m_T into irreducibles.

Solution to Problem 7.16

Uses. Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.5.22 (Trace and determinant from eigenvalues), Proposition 2.4.23 (Transpose of a product)
Techniques. Use an annihilating polynomial (Technique 7.6.17), Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. Transpose the equation to eliminate A^{T}, and find a polynomial that annihilates A.
Hint 2. $x^4 - 2x^2 + x = x(x-1)\left(x^2+x-1\right)$ has four distinct real roots. Take traces of A and of A^2.
Sketch. $A^{\mathsf{T}} = I - A^2$, so $A = I - \left(I - A^2\right)^2 = 2A^2 - A^4$, and $x(x-1)\left(x^2+x-1\right)$ annihilates A. So A is diagonalizable over $\mathbb{R}$ with eigenvalues in $\{0, 1, \alpha, \beta\}$, $\alpha, \beta = \left(-1 \pm \sqrt{5}\right)/2$. With multiplicities a, b, c, d: $\operatorname{tr} A = 0$ and irrationality of $\sqrt{5}$ give $b = c = d$; $\operatorname{tr} A^2 = \operatorname{tr} I - \operatorname{tr} A^{\mathsf{T}} = 3$ and $\alpha^2 = 1 - \alpha$, $\beta^2 = 1 - \beta$ give $2b + c + d = 3$. So $4b = 3$, impossible. No.

No. Suppose A is such a matrix. Then $A^{\mathsf{T}} = I_3 - A^2$, and transposing (Proposition 2.4.23), $A = I_3 - \left(A^{\mathsf{T}}\right)^2 = I_3 - \left(I_3 - A^2\right)^2 = 2A^2 - A^4$. So $q(A) = 0$ with

$$q = x^4 - 2x^2 + x = x(x-1)\left(x^2+x-1\right),$$

whose roots $0, 1, \alpha = \left(-1+\sqrt{5}\right)/2, \beta = \left(-1-\sqrt{5}\right)/2$ are real and distinct. By Theorem 7.6.15, A is diagonalizable over $\mathbb{R}$, and its eigenvalues lie in $\{0, 1, \alpha, \beta\}$ (Proposition 7.2.28). Let a, b, c, d be the multiplicities of $0, 1, \alpha, \beta$, so $a + b + c + d = 3$, and the eigenvalues of A^2 are their squares (diagonalize).

First trace. $0 = \operatorname{tr} A = b + c\alpha + d\beta = b - (c+d)/2 + (c-d)\sqrt{5}/2$ (Theorem 7.5.22). Since $\sqrt{5}$ is irrational and b, c, d are integers, $c = d$ and then $b = c$.

Second trace. Taking the trace of $A^2 = I_3 - A^{\mathsf{T}}$ gives $\operatorname{tr} A^2 = 3 - \operatorname{tr} A = 3$. Since $\alpha^2 = 1 - \alpha$ and $\beta^2 = 1 - \beta$,

$$\operatorname{tr} A^2 = b + c(1-\alpha) + d(1-\beta) = b + c + d - (c\alpha + d\beta) = b + c + d + b,$$

using $c\alpha + d\beta = -b$ from the first trace. So $2b + c + d = 3$, and with $b = c = d$ this gives $4b = 3$, which has no integer solution. Hence no such A exists.

The equation mixes A and A^{T}, which have the same eigenvalues but different eigenvectors; transposing it once eliminates A^{T} and leaves a polynomial identity in A alone. After that the problem is counting with multiplicities. This is Problem 2 of the 2011 International Mathematics Competition for University Students (IMC).

Solution to Problem 7.17

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Proposition 7.1.38 (Conjugate roots), Theorem 7.5.22 (Trace and determinant from eigenvalues), Theorem 5.4.10 (Multiplicativity)
Techniques. Use an annihilating polynomial (Technique 7.6.17), Complexify, then take real and imaginary parts (Technique 7.3.35)
Hint 1. Multiply $(A+B)\left(A^{-1}+B^{-1}\right) = I_n$ out and set $X = AB^{-1}$.
Hint 2. $X^2 + X + I_n = 0$. What are the complex eigenvalues of a real X with this property, and with which multiplicities?
Sketch. $(A+B)\left(A^{-1}+B^{-1}\right) = I$ gives $X + X^{-1} + I = 0$, so $X^2 + X + I = 0$ with $X = AB^{-1}$. The complex eigenvalues of X are roots of $x^2 + x + 1$, i.e. $\omega, \overline{\omega}$; p_X is real, so they occur equally often, $n = 2k$, and $\det X = (\omega\overline{\omega})^k = 1$. So $\det A = \det B$. Over $\mathbb{C}$: no; $B = I_n$, $A = \omega I_n$ (if $3 \nmid n$) or $A = \operatorname{diag}(\omega, \ldots, \omega, \overline{\omega})$ (if $3 \mid n$) satisfy the equation with $\det A \neq 1$.

Multiplying the hypothesis on the left by $A + B$ gives $I_n = (A+B)\left(A^{-1}+B^{-1}\right) = 2I_n + AB^{-1} + BA^{-1}$. With $X = AB^{-1}$, so that $X^{-1} = BA^{-1}$, this is $X + X^{-1} + I_n = 0$, and multiplying by X,

$$X^2 + X + I_n = 0.$$

By Proposition 7.2.28, every complex eigenvalue of X is a root of $x^2 + x + 1$, that is, $\omega = e^{2\pi i/3}$ or $\overline{\omega}$. Since X is real, p_X has real coefficients, so ω and $\overline{\omega}$ are roots of p_X of the same multiplicity k (Proposition 7.1.38),

and $n = 2k$. By Theorem 7.5.22 over $\mathbb{C}$, $\det X = \omega^k \overline{\omega}^k = |\omega|^{2k} = 1$. As $\det X = \det A / \det B$ (Theorem 5.4.10), $\det A = \det B$.

Over $\mathbb{C}$ the conclusion fails for every n. The computation above can be reversed: if X is invertible with $X^2 + X + I_n = 0$ and $X + I_n$ is invertible, then $A = X$ and $B = I_n$ satisfy the equation, since $(X + I_n)\left(X^{-1} + I_n\right) = X + X^{-1} + 2I_n = I_n$. Take $X = \omega I_n$ if 3 does not divide n, with $\det X = \omega^n \neq 1$, and $X = \operatorname{diag}(\omega, \ldots, \omega, \overline{\omega})$ if 3 divides n, with $\det X = \omega^{n-2} = \omega^{-2} = \omega \neq 1$. In both cases $X + I_n$ has eigenvalues $1 + \omega = -\overline{\omega}$ and $1 + \overline{\omega} = -\omega$, so it is invertible, and $\det A \neq 1 = \det B$.

The real hypothesis enters only through the pairing of conjugate eigenvalues, which makes $\det X$ a product of factors $\omega\overline{\omega} = 1$; Exercise 7.6.50 uses the pairing in the same way. This is Problem 1 of the 2015 International Mathematics Competition for University Students (IMC).

Solution to Problem 7.18

Uses. Theorem 5.4.10 (Multiplicativity), Proposition 7.3.2 (Determinants over a commutative ring), Exercise 7.3.17
Techniques. Factor the matrix (Technique 5.6.1), Conjugate the equation (Technique B.1.3)
Hint 1. With $\omega = e^{2\pi i/3}$, expand $(A + \omega B)(A + \overline{\omega} B)$ and use $A^2 + B^2 = AB$ and $1 + \omega + \overline{\omega} = 0$.
Hint 2. The product is $-\omega(AB - BA)$. Take determinants; the left side is $|\det(A + \omega B)|^2$ because A, B are real.
Sketch. $(A + \omega B)(A + \overline{\omega} B) = A^2 + B^2 + \overline{\omega} AB + \omega BA = (1 + \overline{\omega})AB + \omega BA = -\omega(AB - BA)$. Determinants: $|\det(A + \omega B)|^2 = (-\omega)^n \det(AB - BA)$. The right side has a nonzero real factor, so $(-\omega)^n = e^{-\pi i n/3}$ is real, which happens iff $3 \mid n$.

Let $\omega = e^{2\pi i/3}$, so $\omega\overline{\omega} = 1$ and $1 + \omega + \overline{\omega} = 0$. Expanding (the scalars commute with all matrices) and using $A^2 + B^2 = AB$,

$$(A + \omega B)(A + \overline{\omega} B) = A^2 + B^2 + \overline{\omega} AB + \omega BA = (1 + \overline{\omega})AB + \omega BA = -\omega(AB - BA),$$

because $1 + \overline{\omega} = -\omega$. Let $Z = A + \omega B$. Since A and B are real, $A + \overline{\omega} B$ is the entrywise conjugate $\overline{Z}$, and $\det \overline{Z} = \overline{\det Z}$ (Exercise 7.3.17, or Proposition 7.3.2(g) with complex conjugation). Taking determinants (Theorem 5.4.10),

$$|\det Z|^2 = \det Z \cdot \overline{\det Z} = (-\omega)^n \det(AB - BA).$$

Here $d = \det(AB - BA)$ is a nonzero real number, so $(-\omega)^n = |\det Z|^2 / d$ is real. Now $-\omega = e^{i\pi} e^{2\pi i/3} = e^{-\pi i/3}$, so $(-\omega)^n = e^{-\pi i n/3}$, which is real exactly when $\sin(\pi n/3) = 0$, that is, when 3 divides n.

The proof factors a real quadratic expression over $\mathbb{C}$ as $Z\overline{Z}$, and the conjugate pair forces a determinant to be a nonnegative real number; this is the device of Exercise 7.6.52, with ω in place of i because the quadratic $a^2 - ab + b^2$ has roots $-\omega, -\overline{\omega}$ instead of $\pm i$. It also gives the sign: $\det(AB - BA)$ has the sign of $(-1)^{n/3}$. This is a classical olympiad problem.

Section 8.1

Solution to Exercise 8.1.6

Uses. Definition 8.1.5 (Skew-adjoint operators, skew-Hermitian matrices), Definition 6.6.8 (Adjoint), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm)
Techniques. Move an operator across the inner product (Technique 6.6.20), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Expand the left side. The cross terms are $-c\langle K\mathbf{v}, \mathbf{v}\rangle - c\langle \mathbf{v}, K\mathbf{v}\rangle$, since c is real.
Hint 2. Move K across in the second cross term: $\langle \mathbf{v}, K\mathbf{v}\rangle = \langle K^*\mathbf{v}, \mathbf{v}\rangle = -\langle K\mathbf{v}, \mathbf{v}\rangle$.
Sketch. The cross terms are $-c(\langle K\mathbf{v}, \mathbf{v}\rangle + \langle \mathbf{v}, K\mathbf{v}\rangle) = -c(\langle K\mathbf{v}, \mathbf{v}\rangle - \langle K\mathbf{v}, \mathbf{v}\rangle) = 0$. If $K\mathbf{v} = c\mathbf{v}$ with $c \neq 0$ real and $\mathbf{v} \neq \mathbf{0}$, the identity gives $0 \geq c^2\|\mathbf{v}\|^2 > 0$. For $\mathrm{id} + K$, take $c = -1$.

Since c is real, $\overline{c} = c$, and expanding gives

$$\|K\mathbf{v} - c\mathbf{v}\|^2 = \|K\mathbf{v}\|^2 - c\langle K\mathbf{v}, \mathbf{v}\rangle - c\langle \mathbf{v}, K\mathbf{v}\rangle + c^2\|\mathbf{v}\|^2.$$

By the conjugated form of the defining identity, $\langle \mathbf{v}, K\mathbf{v}\rangle = \langle K^*\mathbf{v}, \mathbf{v}\rangle = -\langle K\mathbf{v}, \mathbf{v}\rangle$, so the two middle terms cancel, which proves the identity.

If $K\mathbf{v} = c\mathbf{v}$ with $c \in \mathbb{R}$, $c \neq 0$, and $\mathbf{v} \neq \mathbf{0}$, the identity gives $0 = \|K\mathbf{v}\|^2 + c^2\|\mathbf{v}\|^2 \geq c^2\|\mathbf{v}\|^2 > 0$, a contradiction. So no nonzero real number is an eigenvalue of K. Finally, with $c = -1$, $\|(\mathrm{id} + K)\mathbf{v}\|^2 = \|K\mathbf{v}\|^2 + \|\mathbf{v}\|^2$, which is positive for $\mathbf{v} \neq \mathbf{0}$. So $\ker(\mathrm{id} + K) = \{\mathbf{0}\}$, and $\mathrm{id} + K$ is injective.

Solution to Exercise 8.1.12

Uses. Definition 8.1.8 (Normal operator, normal matrix), Proposition 6.6.18 (Properties of the adjoint)
Hint 1. Use Proposition 6.6.18 to write down each adjoint: $(T^*)^* = T$, $(cT)^* = \bar{c}T^*$, $\left(T^k\right)^* = (T^*)^k$, $\left(T^{-1}\right)^* = (T^*)^{-1}$.
Hint 2. For T^k: since T and T^* commute, any product of copies of T and T^* can be reordered. For T^{-1}, invert both sides of $T^*T = TT^*$.
Sketch. $(T^*)^*T^* = TT^* = T^*T = T^*(T^*)^*$. $(cT)^*(cT) = |c|^2T^*T = |c|^2TT^* = (cT)(cT)^*$. $(T^*)^kT^k = T^k(T^*)^k$ because T and T^* commute. Inverting $T^*T = TT^*$ gives $T^{-1}(T^*)^{-1} = (T^*)^{-1}T^{-1}$, and $(T^*)^{-1} = \left(T^{-1}\right)^*$.

By Proposition 6.6.18(c), $(T^*)^* = T$, so $(T^*)^*T^* = TT^* = T^*T = T^*(T^*)^*$, and T^* is normal. By (b) of the same proposition, $(cT)^* = \bar{c}T^*$, so

$$(cT)^*(cT) = \bar{c}cT^*T = |c|^2TT^* = (cT)(cT)^*.$$

By (d), applied $k-1$ times, $\left(T^k\right)^* = (T^*)^k$. Since $TT^* = T^*T$, we can move each factor T^* in $(T^*)^kT^k$ past each factor T, one swap at a time, so $(T^*)^kT^k = T^k(T^*)^k$, and T^k is normal.

Finally, suppose T is invertible and T^{-1} has an adjoint. By Proposition 6.6.18(f), T^* is invertible with $(T^*)^{-1} = \left(T^{-1}\right)^*$. Taking inverses of both sides of $T^*T = TT^*$ gives $T^{-1}(T^*)^{-1} = (T^*)^{-1}T^{-1}$, that is, $T^{-1}\left(T^{-1}\right)^* = \left(T^{-1}\right)^*T^{-1}$.

Solution to Exercise 8.1.19

Uses. Theorem 8.1.18 (Eigenspaces of a normal operator are orthogonal), Theorem 8.1.16 (Eigenvectors of a normal operator and of its adjoint), Theorem 6.3.3 (Pythagorean theorem), Proposition 6.1.4 (Sesquilinearity)
Hint 1. The eigenvalues 2 and i are distinct. What does that say about $\langle \mathbf{v}, \mathbf{w}\rangle$?
Hint 2. $\mathbf{v} \perp \mathbf{w}$, and $T^*\mathbf{v} = 2\mathbf{v}$, $T^*\mathbf{w} = -i\mathbf{w}$. Then use Pythagoras.
Sketch. $\mathbf{v} \perp \mathbf{w}$. $T(\mathbf{v} + \mathbf{w}) = 2\mathbf{v} + i\mathbf{w}$ has squared norm $4 + 9 = 13$. $T^*(\mathbf{v} - \mathbf{w}) = 2\mathbf{v} + i\mathbf{w}$ too, with norm $\sqrt{13}$. Finally $\langle 2\mathbf{v} + i\mathbf{w}, \mathbf{v} - \mathbf{w}\rangle = 2 - 9i$.

Since $2 \neq i$, $\langle \mathbf{v}, \mathbf{w}\rangle = 0$ by Theorem 8.1.18, and by Theorem 8.1.16, $T^*\mathbf{v} = 2\mathbf{v}$ and $T^*\mathbf{w} = \bar{i}\mathbf{w} = -i\mathbf{w}$.

First, $T(\mathbf{v} + \mathbf{w}) = 2\mathbf{v} + i\mathbf{w}$, a sum of orthogonal vectors, so by Theorem 6.3.3 its squared norm is $4\|\mathbf{v}\|^2 + |i|^2\|\mathbf{w}\|^2 = 4 + 9 = 13$, and $\|T(\mathbf{v} + \mathbf{w})\| = \sqrt{13}$.

Next, $T^*(\mathbf{v} - \mathbf{w}) = 2\mathbf{v} - (-i)\mathbf{w} = 2\mathbf{v} + i\mathbf{w}$, so $\|T^*(\mathbf{v} - \mathbf{w})\| = \sqrt{13}$ as well.

Finally, using $\langle \mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{w}, \mathbf{v}\rangle = 0$ and Proposition 6.1.4,

$$\langle 2\mathbf{v} + i\mathbf{w}, \mathbf{v} - \mathbf{w}\rangle = 2\langle \mathbf{v}, \mathbf{v}\rangle - i\langle \mathbf{w}, \mathbf{w}\rangle = 2 - 9i.$$

As a check, this also equals $\langle \mathbf{v} + \mathbf{w}, T^*(\mathbf{v} - \mathbf{w})\rangle = \langle \mathbf{v} + \mathbf{w}, 2\mathbf{v} + i\mathbf{w}\rangle = 2 + \bar{i} \cdot 9 = 2 - 9i$.

Solution to Exercise 8.1.22

Uses. Definition 6.3.26 (Conjugate transpose), Definition 8.1.5 (Skew-adjoint operators, skew-Hermitian matrices), Definition 6.3.33 (Unitary and orthogonal matrices), Definition 8.1.8 (Normal operator, normal matrix), Example 8.1.9 (Normal operators)
Hint 1. Compute A^* first: it decides Hermitian and skew-Hermitian at once. A Hermitian or skew-Hermitian matrix is automatically normal.
Hint 2. For the rest, compute A^*A and AA^*. Unitary means $A^*A = I$.
Sketch. (a) Normal ($A^{\mathsf{T}}A = AA^{\mathsf{T}} = 5I$) and nothing else. (b) $A^* = -A$: skew-Hermitian, hence normal; not unitary. (c) $A^*A = AA^* = 5I$: normal only. (d) A permutation matrix: orthogonal, hence unitary and normal. (e) $A^*A = \begin{pmatrix} 1 & i \\ -i & 2 \end{pmatrix} \neq \begin{pmatrix} 2 & i \\ -i & 1 \end{pmatrix} = AA^*$: none.

(a) $A^{\mathsf{T}} = \begin{pmatrix} 1 & -2 \\ 2 & 1 \end{pmatrix}$ is neither A nor $-A$. This is $aI + bJ$ with $a = 1$, $b = -2$, so by Example 8.1.9(c), $A^{\mathsf{T}}A = AA^{\mathsf{T}} = 5I_2$. So A is normal, and not orthogonal since $5I_2 \neq I_2$.

(b) $A^* = \begin{pmatrix} -i & -1 \\ 1 & -2i \end{pmatrix} = -A$, so A is skew-Hermitian, hence normal. It is not Hermitian, since $A \neq 0$. It is not unitary: $A^*A = -A^2 = -\begin{pmatrix} -2 & 3i \\ -3i & -5 \end{pmatrix} = \begin{pmatrix} 2 & -3i \\ 3i & 5 \end{pmatrix} \neq I_2$.

(c) $A^* = \begin{pmatrix} 2 & -i \\ -i & 2 \end{pmatrix}$, which is neither A nor $-A$. Now

$$A^*A = \begin{pmatrix} 2 & -i \\ -i & 2 \end{pmatrix}\begin{pmatrix} 2 & i \\ i & 2 \end{pmatrix} = \begin{pmatrix} 5 & 0 \\ 0 & 5 \end{pmatrix}, \quad AA^* = \begin{pmatrix} 2 & i \\ i & 2 \end{pmatrix}\begin{pmatrix} 2 & -i \\ -i & 2 \end{pmatrix} = \begin{pmatrix} 5 & 0 \\ 0 & 5 \end{pmatrix},$$

so A is normal but not unitary. (Its parts in Proposition 8.1.21 are $S = 2I_2$ and $K = iB$ with $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, and S commutes with B, as that proposition predicts.)

(d) The columns are $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1$, an orthonormal basis, so A is orthogonal (Definition 6.3.33), hence unitary and normal. It is not symmetric, since $a_{13} = 1 \neq 0 = a_{31}$, and not skew-symmetric, since $a_{13} = 1 \neq 0 = -a_{31}$.

(e) $A^* = \begin{pmatrix} 1 & 0 \\ -i & 1 \end{pmatrix}$, and

$$A^*A = \begin{pmatrix} 1 & i \\ -i & 2 \end{pmatrix}, \quad AA^* = \begin{pmatrix} 2 & i \\ -i & 1 \end{pmatrix}.$$

These differ, so A is not normal, and therefore none of the other three.

Solution to Exercise 8.1.23

Uses. Definition 7.2.13 (Eigenspace), Corollary 7.2.23 (Eigenspaces are independent), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Algorithm 6.4.14 (Gram–Schmidt)
Hint 1. $A\mathbf{x} = \mathbf{x} + (x_1 + x_2 + x_3)\mathbf{1}$. What happens for $\mathbf{x} = \mathbf{1}$, and for $\mathbf{x}$ with $x_1 + x_2 + x_3 = 0$?
Hint 2. $E_4 = \operatorname{span}(\mathbf{1})$ and $E_1 = \{\mathbf{x} \mid x_1 + x_2 + x_3 = 0\}$. Their dimensions add up to 3, so there are no other eigenvalues.
Hint 3. For (c), run Gram–Schmidt inside E_1.
Sketch. $A\mathbf{1} = 4\mathbf{1}$, and $A\mathbf{x} = \mathbf{x}$ when $x_1 + x_2 + x_3 = 0$. So $E_4 = \operatorname{span}(\mathbf{1})$ and E_1 is the plane $x_1 + x_2 + x_3 = 0$; $E_1 \perp E_4$ since that equation says $\mathbf{x} \cdot \mathbf{1} = 0$. In E_1, $(1, -1, 0) \cdot (1, 0, -1) = 1$. Orthonormal eigenbasis: $(1, 1, 1)/\sqrt{3}$, $(1, -1, 0)/\sqrt{2}$, $(1, 1, -2)/\sqrt{6}$.

(a) For $\mathbf{x} \in \mathbb{R}^3$, $\mathbf{1}\mathbf{1}^{\mathsf{T}}\mathbf{x} = (x_1 + x_2 + x_3)\mathbf{1}$, so $A\mathbf{x} = \mathbf{x} + (x_1 + x_2 + x_3)\mathbf{1}$. Hence $(A - I_3)\mathbf{x} = \mathbf{0}$ iff $x_1 + x_2 + x_3 = 0$, so $E_1 = \{\mathbf{x} \mid x_1 + x_2 + x_3 = 0\}$, a plane. And $(A - 4I_3)\mathbf{x} = (x_1 + x_2 + x_3)\mathbf{1} - 3\mathbf{x}$ vanishes iff $\mathbf{x}$ is a multiple of $\mathbf{1}$, say $\mathbf{x} = c\mathbf{1}$, and then indeed $3c\mathbf{1} - 3c\mathbf{1} = \mathbf{0}$; so $E_4 = \operatorname{span}(\mathbf{1})$. The eigenspaces of distinct eigenvalues form a direct sum (Corollary 7.2.23), and $\dim E_1 + \dim E_4 = 3$ already, so there is no room for another eigenspace: the eigenvalues are 1 and 4.

(b) For $\mathbf{x} \in E_1$, $\mathbf{x} \cdot \mathbf{1} = x_1 + x_2 + x_3 = 0$, so $E_1 \perp E_4$, as Proposition 8.1.1(b) predicts. Inside E_1, the eigenvectors $(1, -1, 0)$ and $(1, 0, -1)$ have dot product $1 \neq 0$.

(c) Apply Gram–Schmidt (Algorithm 6.4.14) to the basis $(1, -1, 0), (1, 0, -1)$ of E_1: the second vector minus its projection onto the first is

$$(1, 0, -1) - \frac{1}{2}(1, -1, 0) = \frac{1}{2}(1, 1, -2).$$

Normalizing, and adding the normalized $\mathbf{1}$ from E_4, which is orthogonal to E_1 by (b),

$$\frac{1}{\sqrt{3}}(1, 1, 1), \quad \frac{1}{\sqrt{2}}(1, -1, 0), \quad \frac{1}{\sqrt{6}}(1, 1, -2)$$

is an orthonormal basis of $\mathbb{R}^3$ consisting of eigenvectors of A.

Solution to Exercise 8.1.24

Uses. Example 8.1.9 (Normal operators), Non-example 8.1.10 (Operators that are not normal), Proposition 6.6.18 (Properties of the adjoint), Example 6.1.39 (A rotation)
Hint 1. The nilpotent $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ is the source of counterexamples. Write it as a sum of a symmetric and a skew-symmetric matrix; compute N^2.
Hint 2. For (c), look for an invertible operator that is not normal.
Hint 3. For (d), compute $(T + cT^*)^* = T^* + \overline{c}T$ and expand both products.
Sketch. (a) False: $N = \left(N + N^{\mathsf{T}}\right)/2 + \left(N - N^{\mathsf{T}}\right)/2$. (b) False: $N^2 = 0$ is normal. (c) False: the shear is invertible, so both kernels are $\{\mathbf{0}\}$. (d) True: the two products differ by $\left(1 - |c|^2\right)(T^*T - TT^*)$. (e) False: the rotation J.

Let $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, acting on $\mathbb{F}^2$ with the dot product. It is not normal (Non-example 8.1.10).

(a) False. $N = S + K$ with $S = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ symmetric and $K = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ skew-symmetric. Both are normal (Example 8.1.9(a)), and their sum N is not.

(b) False. $N^2 = 0$, which is normal, but N is not.

(c) False. The shear $S = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ is invertible, and so is $S^* = S^{\mathsf{T}}$, so $\ker S = \ker S^* = \{\mathbf{0}\}$; but S is not normal (Non-example 8.1.10).

(d) True. By Proposition 6.6.18, $(T + cT^*)^* = T^* + \overline{c}T$. Expanding,

$$(T^* + \overline{c}T)(T + cT^*) = T^*T + c(T^*)^2 + \overline{c}T^2 + |c|^2 TT^*,$$
$$(T + cT^*)(T^* + \overline{c}T) = TT^* + \overline{c}T^2 + c(T^*)^2 + |c|^2 T^*T.$$

The difference is $(T^*T - TT^*) - |c|^2(T^*T - TT^*) = \left(1 - |c|^2\right)(T^*T - TT^*)$, which is 0 when T is normal.

(e) False. The rotation $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ is orthogonal, hence normal, and $\langle J\mathbf{x}, \mathbf{x}\rangle = 0$ for every $\mathbf{x} \in \mathbb{R}^2$ (Example 6.1.39), but $J \neq 0$. (Over $\mathbb{C}$ the statement is true for every operator, by Proposition 6.1.41.)

Solution to Exercise 8.1.25

Uses. Definition 8.1.8 (Normal operator, normal matrix), Example 8.1.9 (Normal operators), Example 7.3.5 (Small cases)
Hint 1. Write $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ and compare $A^{\mathsf{T}}A$ with AA^{T} entry by entry.
Hint 2. The diagonal entries give $b^2 = c^2$. Treat $c = b$ and $c = -b \neq b$ separately.
Sketch. $A^{\mathsf{T}}A = \begin{pmatrix} a^2+c^2 & ab+cd \\ ab+cd & b^2+d^2 \end{pmatrix}$, $AA^{\mathsf{T}} = \begin{pmatrix} a^2+b^2 & ac+bd \\ ac+bd & c^2+d^2 \end{pmatrix}$. Normal iff $b^2 = c^2$ and $ab + cd = ac + bd$. If $c = b$, A is symmetric. If $c = -b \neq 0$, the second equation gives $b(a - d) = 0$, so $a = d$. The second family is a rotation followed by a scaling, with characteristic polynomial $(x - a)^2 + b^2$.

Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Then

$$A^{\mathsf{T}}A = \begin{pmatrix} a^2 + c^2 & ab + cd \\ ab + cd & b^2 + d^2 \end{pmatrix}, \quad AA^{\mathsf{T}} = \begin{pmatrix} a^2 + b^2 & ac + bd \\ ac + bd & c^2 + d^2 \end{pmatrix}.$$

So A is normal if and only if $c^2 = b^2$ and $ab + cd = ac + bd$. The first condition says $c = b$ or $c = -b$.

If $c = b$, then A is symmetric, and the second condition holds automatically. If $c = -b$ and $b \neq 0$, the second condition reads $ab - bd = -ab + bd$, that is, $2b(a - d) = 0$, so $a = d$, and $A = \begin{pmatrix} a & b \\ -b & a \end{pmatrix}$; renaming $-b$ as b gives the stated form. Conversely, symmetric matrices are normal, and so are the matrices $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ by Example 8.1.9(c).

Writing $a + bi = r(\cos\theta + i\sin\theta)$ with $r = \sqrt{a^2 + b^2}$, the matrix $\begin{pmatrix} a & -b \\ b & a \end{pmatrix} = r\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$ is a rotation by θ followed by scaling by r; it is multiplication by $a + bi$ on $\mathbb{C} = \mathbb{R}^2$. Its characteristic polynomial is $(x - a)^2 + b^2$ (Example 7.3.5), which has no real root when $b \neq 0$. So a real normal 2×2 matrix either is symmetric (and then, by Section 8.2, has an orthonormal eigenbasis), or is a scaled rotation, with no real eigenvalues at all (unless $b = 0$, when it is aI_2).

Solution to Exercise 8.1.26

Uses. Proposition 6.3.27 (Properties of the conjugate transpose), Definition 8.1.8 (Normal operator, normal matrix), Proposition 2.4.14 (Algebra of matrices)
Techniques. Write a rank-one matrix as $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ (Technique 4.3.17)
Hint 1. $A^* = \mathbf{y}\mathbf{x}^*$. Compute A^*A and AA^*, remembering that $\mathbf{x}^*\mathbf{x} = \|\mathbf{x}\|^2$ is a scalar.
Hint 2. $A^*A = \|\mathbf{x}\|^2\mathbf{y}\mathbf{y}^*$ and $AA^* = \|\mathbf{y}\|^2\mathbf{x}\mathbf{x}^*$. If these are equal, apply both to $\mathbf{y}$.
Sketch. $A^*A = \|\mathbf{x}\|^2\mathbf{y}\mathbf{y}^*$ and $AA^* = \|\mathbf{y}\|^2\mathbf{x}\mathbf{x}^*$. If $\mathbf{y} = c\mathbf{x}$, both are $|c|^2\|\mathbf{x}\|^2\mathbf{x}\mathbf{x}^*$. Conversely, applying both to $\mathbf{y}$ gives $\|\mathbf{x}\|^2\|\mathbf{y}\|^2\mathbf{y} = \|\mathbf{y}\|^2(\mathbf{x}^*\mathbf{y})\mathbf{x}$, so $\mathbf{y}$ is a multiple of $\mathbf{x}$. Then $A = \bar{c}\mathbf{x}\mathbf{x}^*$ and $A^* = c\mathbf{x}\mathbf{x}^*$.

By Proposition 6.3.27, $A^* = (\mathbf{y}^*)^*\mathbf{x}^* = \mathbf{y}\mathbf{x}^*$. Since $\mathbf{x}^*\mathbf{x} = \|\mathbf{x}\|^2$ and $\mathbf{y}^*\mathbf{y} = \|\mathbf{y}\|^2$ are 1×1 matrices, that is, scalars,

$$A^*A = \mathbf{y}(\mathbf{x}^*\mathbf{x})\mathbf{y}^* = \|\mathbf{x}\|^2\mathbf{y}\mathbf{y}^*, \quad AA^* = \mathbf{x}(\mathbf{y}^*\mathbf{y})\mathbf{x}^* = \|\mathbf{y}\|^2\mathbf{x}\mathbf{x}^*.$$

If $\mathbf{y} = c\mathbf{x}$, then $\mathbf{y}\mathbf{y}^* = |c|^2\mathbf{x}\mathbf{x}^*$ and $\|\mathbf{y}\|^2 = |c|^2\|\mathbf{x}\|^2$, so both products equal $|c|^2\|\mathbf{x}\|^2\mathbf{x}\mathbf{x}^*$, and A is normal.

Conversely, suppose $A^*A = AA^*$, and apply both sides to $\mathbf{y}$:

$$\|\mathbf{x}\|^2\|\mathbf{y}\|^2\mathbf{y} = \|\mathbf{y}\|^2(\mathbf{x}^*\mathbf{y})\mathbf{x}.$$

Dividing by $\|\mathbf{x}\|^2\|\mathbf{y}\|^2 \neq 0$ gives $\mathbf{y} = c\mathbf{x}$ with $c = (\mathbf{x}^*\mathbf{y})/\|\mathbf{x}\|^2$.

In that case $A = \mathbf{x}(c\mathbf{x})^* = \bar{c}\mathbf{x}\mathbf{x}^*$ and $A^* = c\mathbf{x}\mathbf{x}^*$. Since $\mathbf{x}\mathbf{x}^* \neq 0$ (its (j,j) entry is $|x_j|^2$, which is nonzero for some j), $A^* = A$ if and only if $c = \bar{c}$, that is, $c \in \mathbb{R}$.

Solution to Exercise 8.1.27

Uses. Proposition 6.1.37 (Inner products distinguish vectors), Non-example 8.1.10 (Operators that are not normal), Theorem 8.1.16 (Eigenvectors of a normal operator and of its adjoint)
Hint 1. Two vectors are equal if they have the same inner product with *every* vector (Proposition 6.1.37). How many vectors does the argument test against?
Hint 2. The argument shows only that $T^*\mathbf{v} - \overline{\lambda}\mathbf{v} \perp \mathbf{v}$. Try $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ with $\mathbf{v} = \mathbf{e}_1$.
Sketch. The computation is correct but shows only $\langle T^*\mathbf{v} - \overline{\lambda}\mathbf{v}, \mathbf{v}\rangle = 0$; testing against the single vector $\mathbf{v}$ does not determine $T^*\mathbf{v}$. For N, $N\mathbf{e}_1 = 0\mathbf{e}_1$ but $N^*\mathbf{e}_1 = \mathbf{e}_2 \neq \mathbf{0}$, and indeed $\mathbf{e}_2 \perp \mathbf{e}_1$. The claim holds for normal T (Theorem 8.1.16).

The error. The displayed computation is correct, and it shows that $\langle T^*\mathbf{v} - \overline{\lambda}\mathbf{v}, \mathbf{v}\rangle = 0$, that is, $T^*\mathbf{v} - \overline{\lambda}\mathbf{v}$ is orthogonal to $\mathbf{v}$. The last sentence is wrong. To conclude that two vectors are equal, they must have the same inner product with every vector of V (Proposition 6.1.37), and the argument tests only against the single vector $\mathbf{v}$.

A counterexample. Let $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ on $\mathbb{F}^2$ with the dot product, $\mathbf{v} = \mathbf{e}_1$, and $\lambda = 0$. Then $N\mathbf{e}_1 = \mathbf{0} = 0\mathbf{e}_1$, but $N^*\mathbf{e}_1 = N^{\mathsf{T}}\mathbf{e}_1 = \mathbf{e}_2 \neq \mathbf{0}$. Consistently with what the argument does prove, $\mathbf{e}_2 \perp \mathbf{e}_1$.

A correct version. If T is normal, the conclusion holds by Theorem 8.1.16. The missing ingredient is the equality of lengths $\|(T - \lambda\,\mathrm{id})\mathbf{v}\| = \|(T^* - \overline{\lambda}\,\mathrm{id})\mathbf{v}\|$, which controls all of $T^*\mathbf{v} - \overline{\lambda}\mathbf{v}$ and not just its component along $\mathbf{v}$.

Solution to Exercise 8.1.28

Uses. Definition 6.6.26 (Self-adjoint operator), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm), Corollary 4.2.18 (Injective if and only if surjective), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$)
Techniques. Move an operator across the inner product (Technique 6.6.20), Shift by a scalar (Technique 8.1.15)
Hint 1. Let $R = T - a\,\mathrm{id}$, which is self-adjoint since a is real. Then $T - \lambda\,\mathrm{id} = R - ib\,\mathrm{id}$; expand $\|R\mathbf{v} - ib\mathbf{v}\|^2$.
Hint 2. The cross terms are $ib\langle R\mathbf{v}, \mathbf{v}\rangle - ib\langle \mathbf{v}, R\mathbf{v}\rangle$, and $\langle \mathbf{v}, R\mathbf{v}\rangle = \langle R\mathbf{v}, \mathbf{v}\rangle$.
Hint 3. For (c), (a) gives $\|(T - \lambda\,\mathrm{id})\mathbf{v}\| \geq |b|\|\mathbf{v}\|$. Apply it to $\mathbf{v} = (T - \lambda\,\mathrm{id})^{-1}\mathbf{w}$.
Sketch. With $R = T - a\,\mathrm{id}$ self-adjoint, $\|R\mathbf{v} - ib\mathbf{v}\|^2 = \|R\mathbf{v}\|^2 + ib\langle R\mathbf{v}, \mathbf{v}\rangle - ib\langle \mathbf{v}, R\mathbf{v}\rangle + b^2\|\mathbf{v}\|^2$, and the middle terms cancel. If $b \neq 0$ the right side is at least $b^2\|\mathbf{v}\|^2 > 0$ for $\mathbf{v} \neq \mathbf{0}$, so $T - \lambda\,\mathrm{id}$ is injective, hence invertible in finite dimensions, and $\|\mathbf{w}\| \geq |b|\|(T - \lambda\,\mathrm{id})^{-1}\mathbf{w}\|$.

(a) Let $R = T - a\,\mathrm{id}$. Since a is real, $R^* = T^* - a\,\mathrm{id} = R$, so R is self-adjoint. Now $T - \lambda\,\mathrm{id} = R - ib\,\mathrm{id}$, and expanding with Proposition 6.1.4,

$$\|R\mathbf{v} - ib\mathbf{v}\|^2 = \|R\mathbf{v}\|^2 + \overline{-ib}\langle R\mathbf{v}, \mathbf{v}\rangle + (-ib)\langle \mathbf{v}, R\mathbf{v}\rangle + |ib|^2\|\mathbf{v}\|^2.$$

Since $\overline{-ib} = ib$ and $\langle \mathbf{v}, R\mathbf{v}\rangle = \langle R\mathbf{v}, \mathbf{v}\rangle$ by self-adjointness, the two middle terms are $ib\langle R\mathbf{v}, \mathbf{v}\rangle - ib\langle R\mathbf{v}, \mathbf{v}\rangle = 0$. This leaves $\|R\mathbf{v}\|^2 + b^2\|\mathbf{v}\|^2$.

(b) If $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then (a) gives $0 = \|(T - a\,\mathrm{id})\mathbf{v}\|^2 + b^2\|\mathbf{v}\|^2 \geq b^2\|\mathbf{v}\|^2$, so $b = 0$ and $\lambda = a \in \mathbb{R}$.

(c) By (a), $\|(T - \lambda\,\mathrm{id})\mathbf{v}\| \geq |b|\|\mathbf{v}\|$ for every $\mathbf{v}$. If $b \neq 0$, this is positive for $\mathbf{v} \neq \mathbf{0}$, so $\ker(T - \lambda\,\mathrm{id}) = \{\mathbf{0}\}$ and $T - \lambda\,\mathrm{id}$ is injective (Theorem 2.6.11). An injective operator on a finite-dimensional space is surjective (Corollary 4.2.18), hence invertible. For $\mathbf{w} \in V$, put $\mathbf{v} = (T - \lambda\,\mathrm{id})^{-1}\mathbf{w}$; then $\|\mathbf{w}\| \geq |b|\|\mathbf{v}\|$, which is the claimed bound.

Solution to Exercise 8.1.29

Uses. Proposition 8.1.21 (Normal means commuting parts), Proposition 6.6.18 (Properties of the adjoint), Proposition 8.1.4 (Self-adjoint operators are determined by their diagonal values)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. $\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle$ and $T^* = S - K$. Expand $(S - K)(S + K)$.
Hint 2. For (b), the operator $SK - KS$ is self-adjoint. Then use Proposition 8.1.4 and Proposition 8.1.21.
Sketch. $T^*T = (S - K)(S + K) = S^2 - K^2 + (SK - KS)$, and $\langle S^2\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2$, $-\langle K^2\mathbf{v}, \mathbf{v}\rangle = \|K\mathbf{v}\|^2$. For (b), $(SK - KS)^* = K^*S^* - S^*K^* = SK - KS$, so its diagonal values all vanish iff $SK = KS$, iff T is normal.

(a) By Proposition 8.1.21, $T^* = S - K$, so

$$T^*T = (S - K)(S + K) = S^2 - K^2 + (SK - KS).$$

Now $\langle S^2\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, S^*\mathbf{v}\rangle = \|S\mathbf{v}\|^2$ and $-\langle K^2\mathbf{v}, \mathbf{v}\rangle = -\langle K\mathbf{v}, K^*\mathbf{v}\rangle = \langle K\mathbf{v}, K\mathbf{v}\rangle = \|K\mathbf{v}\|^2$. Hence

$$\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2 + \|K\mathbf{v}\|^2 + \langle (SK - KS)\mathbf{v}, \mathbf{v}\rangle.$$

(b) By Proposition 6.6.18, $(SK - KS)^* = K^*S^* - S^*K^* = (-K)S - S(-K) = SK - KS$, so $SK - KS$ is self-adjoint. By (a), the identity $\|T\mathbf{v}\|^2 = \|S\mathbf{v}\|^2 + \|K\mathbf{v}\|^2$ holds for every $\mathbf{v}$ if and only if $\langle (SK - KS)\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$, which by Proposition 8.1.4 holds if and only if $SK = KS$. By Proposition 8.1.21 this says that T is normal.

Solution to Exercise 8.1.30

Uses. Definition 6.3.33 (Unitary and orthogonal matrices), Definition 6.3.26 (Conjugate transpose), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.4.31 (The matrix of an orthogonal projection)
Hint 1. $U^2 = U^*U$.
Hint 2. $P^2 = \big(I + 2U + U^2\big)/4$. For the geometry, what does U do to $\operatorname{im} P$ and to $\ker P = (\operatorname{im} P)^\perp$?
Sketch. (a) $U^2 = U^*U = I$. (b) $P^* = P$ and $P^2 = (2I + 2U)/4 = P$. $U = 2P - I$ fixes $\operatorname{im} P$ and negates $(\operatorname{im} P)^\perp$: it is the reflection across $\operatorname{im} P$. (c) $(2P - I)^* = 2P - I$ and $(2P - I)^2 = 4P^2 - 4P + I = I$. (d) $P = \frac{1}{2}\left(\begin{smallmatrix}1 & 1\\ 1 & 1\end{smallmatrix}\right)$, $U = \left(\begin{smallmatrix}0 & 1\\ 1 & 0\end{smallmatrix}\right)$.

(a) $U^2 = U^*U = I_n$, since $U^* = U$ and U is unitary.

(b) $P^* = (I_n + U^*)/2 = P$, and by (a),

$$P^2 = \frac{I_n + 2U + U^2}{4} = \frac{2I_n + 2U}{4} = P.$$

By Corollary 6.6.29, applied to $\mathbf{x} \mapsto P\mathbf{x}$ on $\mathbb{F}^n$ with the dot product (Example 6.6.10), this map is the orthogonal projection onto $W = \operatorname{im} P$, and clearly $U = 2P - I_n$. If $\mathbf{x} \in W$, then $P\mathbf{x} = \mathbf{x}$ and $U\mathbf{x} = \mathbf{x}$; if $\mathbf{x} \in W^\perp$, then $P\mathbf{x} = \mathbf{0}$ (Proposition 6.4.29) and $U\mathbf{x} = -\mathbf{x}$. Since $\mathbb{F}^n = W \oplus W^\perp$, U is the reflection across W: it keeps the component in W and reverses the component in $W^\perp$.

(c) If $P^2 = P = P^*$, then $(2P - I_n)^* = 2P - I_n$, and $(2P - I_n)^*(2P - I_n) = 4P^2 - 4P + I_n = I_n$. So $2P - I_n$ is Hermitian and unitary.

(d) With the unit vector $\mathbf{u} = (1,1)/\sqrt{2}$, the projection matrix is $P = \mathbf{u}\mathbf{u}^{\mathsf{T}} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ (Theorem 6.4.31), so $U = 2P - I_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, the reflection across the line $x_1 = x_2$, which swaps the coordinates.

Solution to Exercise 8.1.31

> *Uses.* Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Example 7.3.5 (Small cases), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators)
> *Hint 1.* The eigenvalues are the roots of $x^2 - (\operatorname{tr} A)x + \det A$ (Example 7.3.5). Choose A so that this polynomial has no root in the field.
> *Hint 2.* Over $\mathbb{Q}$, try to get $x^2 - 2$. Over $\mathbb{F}_2$ there are only two candidates, 0 and 1; try to get $x^2 + x + 1$.
> *Hint 3.* For (c), the proof needs a field containing the complex roots of p_A, and an inner product to show that those roots lie in the original field.
> *Sketch.* (a) False: $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ has $p = x^2 - 2$. (b) False: $\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$ has $p = x^2 + x + 1$, with $p(0) = p(1) = 1$. (c) Over $\mathbb{Q}$ the proof still produces a real eigenvalue, $\pm\sqrt{2}$, but the argument only shows that it is real, not rational. Over $\mathbb{F}_2$ there is no inner product at all: the dot product has $(1,1)\cdot(1,1) = 0$, and the step $\lambda\|\mathbf{v}\|^2 = \overline{\lambda}\|\mathbf{v}\|^2 \Rightarrow \lambda = \overline{\lambda}$ has no meaning.

(a) False. $A = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ is symmetric with $p_A = (x-1)(x+1) - 1 = x^2 - 2$ (Example 7.3.5). Its roots $\pm\sqrt{2}$ are irrational, so by Theorem 7.3.6 A has no eigenvalue in $\mathbb{Q}$.

(b) False. $A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} \in \mathbb{F}_2^{2\times 2}$ is symmetric with $p_A = x(x-1) - 1 = x^2 + x + 1$ over $\mathbb{F}_2$. Since $p_A(0) = 1$ and $p_A(1) = 1 + 1 + 1 = 1$, it has no root in $\mathbb{F}_2$, and A has no eigenvalue there.

(c) Over $\mathbb{Q}$, we may still regard A as a complex Hermitian matrix, and the proof shows that its eigenvalues are real. The step that fails is the last one: the proof concludes that a real root λ of p_T lies in the field and is therefore an eigenvalue (Corollary 7.3.13), and $\mathbb{R} \subseteq \mathbb{Q}$ is false. Here the real roots $\pm\sqrt{2}$ are not rational. The theorem holds over $\mathbb{R}$ because $\mathbb{R}$ is the field in which the proof places the eigenvalue.

Over $\mathbb{F}_2$ the proof breaks at the start. There is no inner product on $\mathbb{F}_2^2$ in our sense, since positivity makes no sense in $\mathbb{F}_2$, and the dot product is degenerate: $(1,1)\cdot(1,1) = 1 + 1 = 0$. The key step of Proposition 8.1.1(a), dividing by $\|\mathbf{v}\|^2 \neq 0$ and comparing λ with $\overline{\lambda}$, has nothing to stand on. The roots of $x^2 + x + 1$ do exist in a larger field with four elements, but nothing forces them back into $\mathbb{F}_2$.

Solution to Exercise 8.1.32

> *Uses.* Proposition 8.1.14 (Kernels and images of normal operators), Theorem 6.6.21 (Kernels and images of adjoints), Theorem 6.4.6 (The projection is characterized by orthogonality)
> *Techniques.* Recognize a projection by its two conditions (Technique 6.4.7)
> *Hint 1.* First show $T^2 = T$. The operator $R = T^2 - T$ satisfies $TR = 0$. Where does $\operatorname{im} R$ lie?
> *Hint 2.* $\operatorname{im} R \subseteq \ker T$ because $TR = 0$, and $\operatorname{im} R \subseteq \operatorname{im} T$ because $R = T(T - \mathrm{id})$. Use Proposition 8.1.14(c).
> *Hint 3.* Once $T^2 = T$, check the two conditions characterizing $\operatorname{Pr}_{\operatorname{im} T}(\mathbf{v})$.
> *Sketch.* $R = T^2 - T = T(T - \mathrm{id})$ has $\operatorname{im} R \subseteq \operatorname{im} T$, and $TR = T^3 - T^2 = 0$ gives $\operatorname{im} R \subseteq \ker T$. Since $\ker T \cap \operatorname{im} T = \{0\}$ for normal T, $R = 0$. Then $T\mathbf{v} \in \operatorname{im} T$ and $T(\mathbf{v} - T\mathbf{v}) = \mathbf{0}$, so $\mathbf{v} - T\mathbf{v} \in \ker T = (\operatorname{im} T)^{\perp}$, and $T\mathbf{v} = \operatorname{Pr}_{\operatorname{im} T}(\mathbf{v})$.

Let $R = T^2 - T$. Since $R = T(T - \mathrm{id})$, every vector $R\mathbf{v} = T((T - \mathrm{id})\mathbf{v})$ lies in $\operatorname{im} T$. Since $TR = T^3 - T^2 = 0$, every vector $R\mathbf{v}$ lies in $\ker T$. By Proposition 8.1.14(c), $\ker T$ and $\operatorname{im} T$ are orthogonal, so their intersection is $\{\mathbf{0}\}$ (a vector orthogonal to itself is $\mathbf{0}$). Hence $R = 0$, that is, $T^2 = T$.

Let $W = \operatorname{im} T$ and $\mathbf{v} \in V$. Then $T\mathbf{v} \in W$, and $T(\mathbf{v} - T\mathbf{v}) = T\mathbf{v} - T^2\mathbf{v} = \mathbf{0}$, so $\mathbf{v} - T\mathbf{v} \in \ker T = \ker T^* = (\operatorname{im} T)^{\perp} = W^{\perp}$ by Proposition 8.1.14(a) and Theorem 6.6.21(a). By Theorem 6.4.6, $T\mathbf{v} = \operatorname{Pr}_W(\mathbf{v})$. So $T = \operatorname{Pr}_W$.

Solution to Exercise 8.1.33

> *Uses.* Proposition 2.4.28 (Cyclicity of the trace), Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.3.34 (Characterizations of unitary matrices), Proposition 8.1.4 (Self-adjoint operators are determined by their diagonal values), Example 6.6.10 (The adjoint of a matrix)
> *Techniques.* Cyclicity of trace (Technique 2.4.29)
> *Hint 1.* Let $S = A^*A - AA^*$. Then S is Hermitian and $\mathbf{x}^*S\mathbf{x} = \|A\mathbf{x}\|^2 - \|A^*\mathbf{x}\|^2 \geq 0$. What is $\operatorname{tr} S$?
> *Hint 2.* $\operatorname{tr} S = 0$ by cyclicity of the trace. Fix a unit vector $\mathbf{u}$, extend it to an orthonormal basis, and let Q be the unitary matrix with these columns. Compute $\operatorname{tr}(Q^*SQ)$ in two ways.
> *Hint 3.* The diagonal entries of Q^*SQ are the nonnegative numbers $\mathbf{u}_j^*S\mathbf{u}_j$, and they add up to 0.

Sketch. $S = A^*A - AA^*$ is Hermitian with $\mathbf{x}^*S\mathbf{x} = \|A\mathbf{x}\|^2 - \|A^*\mathbf{x}\|^2 \geq 0$ and $\operatorname{tr} S = 0$. For a unit vector $\mathbf{u} = \mathbf{u}_1$ completed to an orthonormal basis (columns of a unitary Q), $0 = \operatorname{tr} S = \operatorname{tr}(Q^*SQ) = \sum_j \mathbf{u}_j^* S\mathbf{u}_j$, a sum of nonnegative terms, so $\mathbf{u}^*S\mathbf{u} = 0$. By scaling, $\mathbf{x}^*S\mathbf{x} = 0$ for all $\mathbf{x}$, and $S = 0$ by Proposition 8.1.4.

Let $S = A^*A - AA^*$. Then $S^* = S$, and for $\mathbf{x} \in \mathbb{F}^n$,

$$\mathbf{x}^*S\mathbf{x} = (A\mathbf{x})^*(A\mathbf{x}) - (A^*\mathbf{x})^*(A^*\mathbf{x}) = \|A\mathbf{x}\|^2 - \|A^*\mathbf{x}\|^2 \geq 0.$$

By cyclicity of the trace (Proposition 2.4.28), $\operatorname{tr} S = \operatorname{tr}(A^*A) - \operatorname{tr}(AA^*) = 0$.

Let $\mathbf{u} \in \mathbb{F}^n$ be a unit vector. By Theorem 6.4.20(b), it extends to an orthonormal basis $\mathbf{u} = \mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n$ of $\mathbb{F}^n$; let Q be the unitary matrix with these columns. Then $QQ^* = I_n$ (Proposition 6.3.34), so by cyclicity

$$0 = \operatorname{tr} S = \operatorname{tr}(SQQ^*) = \operatorname{tr}(Q^*SQ) = \sum_{j=1}^{n} \mathbf{u}_j^* S\mathbf{u}_j.$$

Each term is ≥ 0, so each is 0; in particular $\mathbf{u}^*S\mathbf{u} = 0$. Every nonzero $\mathbf{x}$ is a positive multiple of a unit vector, so $\mathbf{x}^*S\mathbf{x} = 0$ for all $\mathbf{x}$. Now $\mathbf{x}^*S\mathbf{x} = \langle S\mathbf{x}, \mathbf{x}\rangle$ for the dot product, and $\mathbf{x} \mapsto S\mathbf{x}$ is self-adjoint since $S^* = S$ (Example 6.6.10). By Proposition 8.1.4, $S = 0$, so A is normal.

Solution to Exercise 8.1.34

Uses. Proposition 2.4.23 (Transpose of a product), Definition 8.1.8 (Normal operator, normal matrix), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Exercise 8.1.25, Theorem 6.4.31 (The matrix of an orthogonal projection)
Hint 1. Transpose the equation $A^{\mathsf{T}} = A^2$. For normality, compute $A^{\mathsf{T}}A$ and AA^{T}.
Hint 2. $A^3 = A^{\mathsf{T}}A$ is symmetric. Compute $\left(A^3\right)^2$ using $A^4 = A$.
Hint 3. For (c), use Exercise 8.1.25: A is symmetric or a scaled rotation. In the symmetric case $A = A^2$. In the other case compare A^{T} and A^2 entry by entry.
Sketch. (a) $A = \left(A^2\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^2 = A^4$, and $A^{\mathsf{T}}A = A^3 = AA^{\mathsf{T}}$. (b) $A^3 = A^{\mathsf{T}}A$ is symmetric, and $\left(A^3\right)^2 = A^4A^2 = A^3$. (c) Symmetric: $A = A^2$, so A is an orthogonal projection: 0, I_2, or $\mathbf{u}\mathbf{u}^{\mathsf{T}}$ with $\|\mathbf{u}\| = 1$. Scaled rotation $\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$, $b \neq 0$: $A^{\mathsf{T}} = A^2$ gives $a = a^2 - b^2$ and $b = -2ab$, so $a = -1/2$, $b = \pm\sqrt{3}/2$: the rotations by $\pm 2\pi/3$.

(a) Transposing $A^{\mathsf{T}} = A^2$ and using Proposition 2.4.23, $A = \left(A^2\right)^{\mathsf{T}} = \left(A^{\mathsf{T}}\right)^2 = \left(A^2\right)^2 = A^4$. Moreover $A^{\mathsf{T}}A = A^2A = A^3$ and $AA^{\mathsf{T}} = AA^2 = A^3$, so $A^{\mathsf{T}}A = AA^{\mathsf{T}}$, and A is normal.

(b) $A^3 = A^{\mathsf{T}}A$ is symmetric, since $\left(A^{\mathsf{T}}A\right)^{\mathsf{T}} = A^{\mathsf{T}}A$. And by (a), $\left(A^3\right)^2 = A^6 = A^4A^2 = AA^2 = A^3$. So $P = A^3$ satisfies $P^2 = P = P^{\mathsf{T}}$, and $\mathbf{x} \mapsto P\mathbf{x}$ is an orthogonal projection by Corollary 6.6.29.

(c) By (a) and Exercise 8.1.25, either A is symmetric or $A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ with $b \neq 0$.

If A is symmetric, then $A = A^{\mathsf{T}} = A^2$, so $A^2 = A = A^{\mathsf{T}}$ and A is the matrix of an orthogonal projection Pr_W (Corollary 6.6.29). For $W = \{\mathbf{0}\}$ or $W = \mathbb{R}^2$ this gives $A = 0$ or $A = I_2$. For a line $W = \operatorname{span}(\mathbf{u})$ with $\|\mathbf{u}\| = 1$, it gives $A = \mathbf{u}\mathbf{u}^{\mathsf{T}}$ (Theorem 6.4.31). All of these satisfy $A^{\mathsf{T}} = A = A^2$.

If $A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ with $b \neq 0$, then

$$A^{\mathsf{T}} = \begin{pmatrix} a & b \\ -b & a \end{pmatrix}, \quad A^2 = \begin{pmatrix} a^2 - b^2 & -2ab \\ 2ab & a^2 - b^2 \end{pmatrix}.$$

Equality requires $a = a^2 - b^2$ and $b = -2ab$. As $b \neq 0$, the second gives $a = -1/2$, and then the first gives $b^2 = a^2 - a = 3/4$, so $b = \pm\sqrt{3}/2$. Conversely these values satisfy both equations. They give

$$A = \begin{pmatrix} -1/2 & \mp\sqrt{3}/2 \\ \pm\sqrt{3}/2 & -1/2 \end{pmatrix},$$

the rotations by $\pm 2\pi/3$. This is consistent with (a): for a rotation R by $\pm 2\pi/3$, $R^3 = I_2$, so $R^{\mathsf{T}} = R^{-1} = R^2$.

So for $n = 2$ the solutions are 0, I_2, the matrices $\mathbf{u}\mathbf{u}^{\mathsf{T}}$ with $\mathbf{u}$ a unit vector, and the two rotations by $\pm 2\pi/3$.

Solution to Exercise 8.1.35

Uses. Exercise 8.1.6, Example 6.6.10 (The adjoint of a matrix), Corollary 3.5.25 (The invertible matrix theorem), Proposition 6.3.27 (Properties of the conjugate transpose), Definition 6.3.33 (Unitary and orthogonal matrices)
Techniques. Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. For (a), apply Exercise 8.1.6 to $\mathbf{x} \mapsto K\mathbf{x}$ and to $\mathbf{x} \mapsto -K\mathbf{x}$, both skew-adjoint for the dot product.
Hint 2. For (b), first show that $I_n - K$ and $(I_n + K)^{-1}$ commute, using $(I_n - K)(I_n + K) = I_n - K^2 = (I_n + K)(I_n - K)$. Then $Q^* = (I_n - K)^{-1}(I_n + K)$.
Hint 3. If $Q\mathbf{x} = -\mathbf{x}$, write $\mathbf{x} = (I_n + K)\mathbf{y}$.
Sketch. (a) $\|(I+K)\mathbf{x}\|^2 = \|\mathbf{x}\|^2 + \|K\mathbf{x}\|^2 > 0$ for $\mathbf{x} \neq \mathbf{0}$, and the same for $-K$. (b) $Q^* = \left((I+K)^{-1}\right)^*(I-K)^* = (I-K)^{-1}(I+K)$, and $Q^*Q = (I-K)^{-1}(I+K)(I-K)(I+K)^{-1} = I$ because $I+K$ and $I-K$ commute. If $Q\mathbf{x} = -\mathbf{x}$ with $\mathbf{x} = (I+K)\mathbf{y}$, then $(I-K)\mathbf{y} = -(I+K)\mathbf{y}$, so $\mathbf{y} = \mathbf{0}$. (c) $Q = \frac{1}{1+t^2}\begin{pmatrix} 1-t^2 & 2t \\ -2t & 1-t^2 \end{pmatrix}$, the rotation by $-2\arctan t$.

(a) By Example 6.6.10, $\mathbf{x} \mapsto K\mathbf{x}$ on $\mathbb{F}^n$ with the dot product has adjoint $\mathbf{x} \mapsto K^*\mathbf{x} = -K\mathbf{x}$, so it is skew-adjoint, and so is $\mathbf{x} \mapsto -K\mathbf{x}$. By Exercise 8.1.6, $\|(I_n + K)\mathbf{x}\|^2 = \|\mathbf{x}\|^2 + \|K\mathbf{x}\|^2$, which is positive for $\mathbf{x} \neq \mathbf{0}$, and likewise with $-K$ in place of K. So $I_n + K$ and $I_n - K$ have trivial null space and are invertible (Corollary 3.5.25).

(b) Since $(I_n - K)(I_n + K) = I_n - K^2 = (I_n + K)(I_n - K)$, multiplying on both sides by $(I_n + K)^{-1}$ gives $(I_n + K)^{-1}(I_n - K) = (I_n - K)(I_n + K)^{-1}$. By Proposition 6.3.27, $(I_n - K)^* = I_n + K$ and $\left((I_n + K)^{-1}\right)^* = \left((I_n + K)^*\right)^{-1} = (I_n - K)^{-1}$, so

$$Q^* = \left((I_n + K)^{-1}\right)^*(I_n - K)^* = (I_n - K)^{-1}(I_n + K).$$

Hence, using that $I_n + K$ and $I_n - K$ commute,

$$Q^*Q = (I_n - K)^{-1}(I_n + K)(I_n - K)(I_n + K)^{-1} = (I_n - K)^{-1}(I_n - K)(I_n + K)(I_n + K)^{-1} = I_n,$$

so Q is unitary (Definition 6.3.33). Suppose $Q\mathbf{x} = -\mathbf{x}$, and let $\mathbf{y} = (I_n + K)^{-1}\mathbf{x}$, so that $\mathbf{x} = (I_n + K)\mathbf{y}$ and $Q\mathbf{x} = (I_n - K)\mathbf{y}$. Then $(I_n - K)\mathbf{y} = -(I_n + K)\mathbf{y}$, so $2\mathbf{y} = \mathbf{0}$, hence $\mathbf{y} = \mathbf{0}$ and $\mathbf{x} = \mathbf{0}$. So -1 is not an eigenvalue of Q.

(c) Here $I_2 + K = \begin{pmatrix} 1 & -t \\ t & 1 \end{pmatrix}$ with inverse $\frac{1}{1+t^2}\begin{pmatrix} 1 & t \\ -t & 1 \end{pmatrix}$, and $I_2 - K = \begin{pmatrix} 1 & t \\ -t & 1 \end{pmatrix}$. So

$$Q = \frac{1}{1+t^2}\begin{pmatrix} 1 & t \\ -t & 1 \end{pmatrix}^2 = \frac{1}{1+t^2}\begin{pmatrix} 1-t^2 & 2t \\ -2t & 1-t^2 \end{pmatrix}.$$

With $t = \tan(\varphi/2)$, the double-angle formulas give $\cos\varphi = \left(1-t^2\right)/\left(1+t^2\right)$ and $\sin\varphi = 2t/\left(1+t^2\right)$, so $Q = \begin{pmatrix} \cos\varphi & \sin\varphi \\ -\sin\varphi & \cos\varphi \end{pmatrix}$, the rotation by $-\varphi = -2\arctan t$. As t runs over $\mathbb{R}$, φ runs over $(-\pi, \pi)$, so every rotation except the rotation by π, which is $-I_2$, arises, in line with (b).

Solution to Exercise 8.1.36

Uses. Theorem 7.4.2 (Diagonalizable means an eigenbasis), Theorem 6.4.20 (Orthonormal bases exist), Theorem 8.1.18 (Eigenspaces of a normal operator are orthogonal), Proposition 6.3.13 (Orthogonal lists are independent), Proposition 8.1.7 (What an orthonormal eigenbasis forces)
Techniques. Glue bases of the summands (Technique 4.4.14)
Hint 1. Choose an orthonormal basis of each eigenspace and put them together. Why is the result orthonormal?
Hint 2. Vectors from different eigenspaces are orthogonal by Theorem 8.1.18. Why does the combined list span V?
Sketch. Let $\lambda_1, \ldots, \lambda_k$ be the distinct eigenvalues. Concatenate orthonormal bases of $E_{\lambda_1}, \ldots, E_{\lambda_k}$. Within each piece the list is orthonormal, and across pieces orthogonal by Theorem 8.1.18. Its span contains every eigenspace, hence every vector of an eigenbasis, hence V. The converse is Proposition 8.1.7.

Let $\lambda_1, \ldots, \lambda_k$ be the distinct eigenvalues of T. By Theorem 6.4.20, each eigenspace E_{λ_j} has an orthonormal basis $\mathcal{O}_j$. Let $\mathcal{O}$ be the concatenation of $\mathcal{O}_1, \ldots, \mathcal{O}_k$. Two vectors of $\mathcal{O}$ from the same $\mathcal{O}_j$ are orthogonal unit vectors, and two vectors from different eigenspaces are orthogonal by Theorem 8.1.18. So $\mathcal{O}$ is orthonormal, hence independent (Proposition 6.3.13), and it consists of eigenvectors.

It remains to show that $\mathcal{O}$ spans V. Since T is diagonalizable, V has a basis of eigenvectors (Theorem 7.4.2). Each of its vectors lies in some $E_{\lambda_j} = \operatorname{span}\left(\mathcal{O}_j\right) \subseteq \operatorname{span}(\mathcal{O})$, so $V \subseteq \operatorname{span}(\mathcal{O})$. Thus $\mathcal{O}$ is an orthonormal basis of eigenvectors.

For the last sentence: a normal diagonalizable operator has an orthonormal eigenbasis by what we just proved, and an operator with an orthonormal eigenbasis is normal by Proposition 8.1.7. (Section 8.2 shows that over $\mathbb{C}$ the hypothesis "diagonalizable" is automatic for normal operators.)

Solution to Exercise 8.1.37

> *Uses.* Theorem 7.5.18 (Schur's theorem), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.1.16 (Frobenius inner product), Proposition 6.3.34 (Characterizations of unitary matrices), Proposition 8.1.7 (What an orthonormal eigenbasis forces)
> *Techniques.* The trace of A^*A (Technique 6.1.18), Cyclicity of trace (Technique 2.4.29)
> *Hint 1.* Triangularize A unitarily with Schur's theorem: $A = URU^*$. How do $\operatorname{tr}(A^*A)$ and $\operatorname{tr}(R^*R)$ compare?
> *Hint 2.* $\operatorname{tr}(A^*A) = \operatorname{tr}(R^*R) = \sum_{i \le j} |r_{ij}|^2$, and the diagonal of R lists the eigenvalues.
> *Hint 3.* Equality forces every entry of R above the diagonal to vanish.
> *Sketch.* $A = URU^*$ with R upper triangular and diagonal $\lambda_1, \dots, \lambda_n$ (Theorem 7.5.18). Then $\operatorname{tr}(A^*A) = \operatorname{tr}(UR^*RU^*) = \operatorname{tr}(R^*R) = \sum_{i \le j} |r_{ij}|^2 = \sum_j |\lambda_j|^2 + \sum_{i<j} |r_{ij}|^2$. Equality means R is diagonal, so $A^*A = UR^*RU^* = URR^*U^* = AA^*$.

(a) By Theorem 7.5.18(b), $A = URU^*$ with U unitary and $R = (r_{ij})$ upper triangular with diagonal entries $\lambda_1, \dots, \lambda_n$. Then $A^*A = UR^*U^*URU^* = UR^*RU^*$, and by cyclicity of the trace (Proposition 2.4.28) and $U^*U = I_n$,

$$\operatorname{tr}(A^*A) = \operatorname{tr}(R^*RU^*U) = \operatorname{tr}(R^*R).$$

By Proposition 6.1.16, $\operatorname{tr}(R^*R) = \sum_{i,j} |r_{ij}|^2$, and since $r_{ij} = 0$ for $i > j$,

$$\operatorname{tr}(A^*A) = \sum_{j=1}^{n} |\lambda_j|^2 + \sum_{i<j} |r_{ij}|^2 \ge \sum_{j=1}^{n} |\lambda_j|^2.$$

The formula $\operatorname{tr}(A^*A) = \sum_{i,j} |a_{ij}|^2$ is Proposition 6.1.16 again.

(b) If equality holds, then $\sum_{i<j} |r_{ij}|^2 = 0$, so $r_{ij} = 0$ for all $i < j$ and R is diagonal. Diagonal matrices commute with their conjugate transposes, so

$$A^*A = UR^*RU^* = URR^*U^* = AA^*.$$

(Equivalently, the columns of U are an orthonormal eigenbasis of A, and Proposition 8.1.7 applies.) The converse, that normal matrices give equality, follows from the complex spectral theorem in Section 8.2.

Solution to Exercise 8.1.38

> *Uses.* Proposition 6.4.29 (The orthogonal projection as a linear map), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 2.4.28 (Cyclicity of the trace), Proposition 6.1.16 (Frobenius inner product), Exercise 6.6.38
> *Techniques.* The trace of A^*A (Technique 6.1.18), Cyclicity of trace (Technique 2.4.29)
> *Hint 1.* $P^2 = P = P^*$, and $AW \subseteq W$ means $PAP = AP$. Taking conjugate transposes, $PA^*P = PA^*$.
> *Hint 2.* Write $PAA^*P = PA(P + (I - P))A^*P$, so $\operatorname{tr}(PAA^*P) = \operatorname{tr}(PAPA^*P) + \operatorname{tr}(XX^*)$. Compute $\operatorname{tr}(PAA^*P)$ another way, using $AA^* = A^*A$ and $AP = PAP$.
> *Hint 3.* You should find $\operatorname{tr}(XX^*) = 0$, so $X = 0$. What does $PA(I - P) = 0$ say about A^*?
> *Sketch.* With $X = PA(I - P)$, $\operatorname{tr}(PAA^*P) = \operatorname{tr}(PAPA^*P) + \operatorname{tr}(XX^*)$. On the other hand $\operatorname{tr}(PAA^*P) = \operatorname{tr}(PA^*AP) = \operatorname{tr}\big((AP)^*(AP)\big) = \operatorname{tr}\big((PAP)^*(PAP)\big) = \operatorname{tr}(PA^*PAP) = \operatorname{tr}(PAPA^*P)$ by cyclicity. So $\operatorname{tr}(XX^*) = 0$, $X = 0$, and $X^* = (I - P)A^*P = 0$ says $A^*P = PA^*P$, that is, $A^*W \subseteq W$. The last claim is Exercise 6.6.38 applied to A^*.

Since P is the matrix of an orthogonal projection, $P^2 = P = P^*$ (Corollary 6.6.29), and $\operatorname{im} P = W$, with $P\mathbf{w} = \mathbf{w}$ for $\mathbf{w} \in W$ (Proposition 6.4.29). The hypothesis $AW \subseteq W$ says that $AP\mathbf{x} \in W$ for every $\mathbf{x}$, that is, $PAP = AP$.

Let $X = PA(I_n - P)$. Inserting $I_n = P + (I_n - P)$ and using $(I_n - P)^2 = I_n - P = (I_n - P)^*$,

$$PAA^*P = PAPA^*P + PA(I_n - P)(I_n - P)A^*P = (PAP)(PAP)^* + XX^*.$$

On the other hand, by normality, then $AP = PAP$, then cyclicity of the trace (Proposition 2.4.28),

$$\operatorname{tr}(PAA^*P) = \operatorname{tr}(PA^*AP) = \operatorname{tr}\big((AP)^*(AP)\big) = \operatorname{tr}\big((PAP)^*(PAP)\big) = \operatorname{tr}\big((PAP)(PAP)^*\big).$$

Comparing the traces of the two expressions for PAA^*P gives $\operatorname{tr}(XX^*) = 0$. By Proposition 6.1.16, $\operatorname{tr}(XX^*) = \operatorname{tr}\big((X^*)^*X^*\big)$ is the sum of the squared moduli of the entries of X^*, so $X^* = 0$, that is, $(I_n - P)A^*P = 0$. So $A^*P = PA^*P$, which says that $A^*\mathbf{w} = PA^*\mathbf{w} \in W$ for every $\mathbf{w} \in W$: $A^*W \subseteq W$.

Finally, by Exercise 6.6.38 applied to A^* (whose adjoint is A), $A^*W \subseteq W$ implies $AW^\perp \subseteq W^\perp$.

Section 8.2

Solution to Exercise 8.2.9

Uses. Theorem 8.2.5 (Complex spectral theorem), Proposition 8.2.2 (Necessary conditions)
Hint 1. By Theorem 8.2.5, check $A^*A = AA^*$ for the first question. For the second, an orthogonally diagonalizable real matrix must be symmetric (Proposition 8.2.2).
Hint 2. In (e), the matrix is $I_3 + P$ for a permutation matrix P with $P^{\mathsf{T}} = P^{-1}$.
Sketch. (a) Not normal: neither. (b) Normal, not symmetric: unitarily only. (c) $A^*A = 2I_2 = AA^*$: unitarily. (d) Both: $(1,1)$ and $(1,-1)$ are orthogonal eigenvectors. (e) $I + P$ with $P^{\mathsf{T}}P = PP^{\mathsf{T}} = I$ is normal but not symmetric: unitarily only.

By Theorem 8.2.5 a complex matrix is unitarily diagonalizable if and only if it is normal. A real orthogonally diagonalizable matrix is symmetric by Proposition 8.2.2(b), since its eigenvalues are real. (The converse is Theorem 8.2.12 below.)

(a) With $A = \begin{pmatrix} 1 & 2 \\ 0 & 3 \end{pmatrix}$, $(A^*A)_{11} = 1$ but $(AA^*)_{11} = 1 + 4 = 5$. Not normal, so neither.

(b) $A = 2J$ with $J^{\mathsf{T}}J = JJ^{\mathsf{T}} = I_2$, so $A^{\mathsf{T}}A = 4I_2 = AA^{\mathsf{T}}$ and A is normal: unitarily diagonalizable. It is not symmetric, so not orthogonally diagonalizable.

(c) $A^* = \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$, and $A^*A = \begin{pmatrix} 1+1 & i-i \\ -i+i & 1+1 \end{pmatrix} = 2I_2$; similarly $AA^* = 2I_2$. Normal, so unitarily diagonalizable (although $A^* \neq A$). It is not real.

(d) $A(1,1) = 3(1,1)$ and $A(1,-1) = -(1,-1)$, and these eigenvectors are orthogonal. So $A = Q\,\operatorname{diag}(3,-1)Q^{\mathsf{T}}$ with $Q = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$: orthogonally, and in particular unitarily, diagonalizable.

(e) $A = I_3 + P$ where P is the permutation matrix with $P\mathbf{e}_1 = \mathbf{e}_3$, $P\mathbf{e}_2 = \mathbf{e}_1$, $P\mathbf{e}_3 = \mathbf{e}_2$. Its columns are orthonormal, so $P^{\mathsf{T}}P = I_3$, hence $P^{\mathsf{T}} = P^{-1}$ and $PP^{\mathsf{T}} = I_3$ as well. Then $A^{\mathsf{T}}A = I + P + P^{\mathsf{T}} + I = AA^{\mathsf{T}}$, so A is normal: unitarily diagonalizable. It is not symmetric ($a_{12} = 1 \neq 0 = a_{21}$), so not orthogonally diagonalizable.

Solution to Exercise 8.2.16

Uses. Algorithm 8.2.14 (Orthogonal diagonalization)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. The trace is 11 and the determinant is 24.
Hint 2. The eigenvalues are 3 and 8. Find one eigenvector for each and normalize; they are automatically orthogonal.
Sketch. $p = x^2 - 11x + 24 = (x-3)(x-8)$. $E_8 = \operatorname{span}((2,-1))$ and $E_3 = \operatorname{span}((1,2))$. $Q = \frac{1}{\sqrt{5}}\begin{pmatrix} 2 & 1 \\ -1 & 2 \end{pmatrix}$, $D = \operatorname{diag}(8,3)$.

$p_A = (x-7)(x-4) - 4 = x^2 - 11x + 24 = (x-3)(x-8)$. From $A - 8I_2 = \begin{pmatrix} -1 & -2 \\ -2 & -4 \end{pmatrix}$ we get $E_8 = \operatorname{span}((2,-1))$, and from $A - 3I_2 = \begin{pmatrix} 4 & -2 \\ -2 & 1 \end{pmatrix}$ we get $E_3 = \operatorname{span}((1,2))$. These are orthogonal, as they must be. Normalizing,

$$Q = \frac{1}{\sqrt{5}}\begin{pmatrix} 2 & 1 \\ -1 & 2 \end{pmatrix}, \quad D = \begin{pmatrix} 8 & 0 \\ 0 & 3 \end{pmatrix},$$

and one checks $AQ = \frac{1}{\sqrt{5}}\begin{pmatrix} 16 & 3 \\ -8 & 6 \end{pmatrix} = QD$.

Solution to Exercise 8.2.22

Uses. Proposition 8.2.20 (Spectral projections are polynomials in T), Theorem 8.2.18 (Spectral decomposition), Theorem 6.4.31 (The matrix of an orthogonal projection)
Hint 1. $p_H = (x-3)^2 - 1$.
Hint 2. With eigenvalues 2 and 4, $P_4 = (H - 2I_2)/2$ and $P_2 = (H - 4I_2)/(-2)$.
Sketch. Eigenvalues $2, 4$. $P_4 = \frac{1}{2}\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix} = \mathbf{u}\mathbf{u}^*$ with $\mathbf{u} = \frac{1}{\sqrt{2}}(i, 1)$, and $P_2 = \frac{1}{2}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}$. $P_4 P_2 = \frac{1}{4}\begin{pmatrix} 1+i^2 & -i+i \\ -i+i & i^2+1 \end{pmatrix} = 0$.

$p_H = (x-3)^2 - i(-i) = (x-3)^2 - 1 = (x-2)(x-4)$. By Proposition 8.2.20,

$$P_4 = \frac{H - 2I_2}{4-2} = \frac{1}{2}\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix}, \quad P_2 = \frac{H - 4I_2}{2-4} = \frac{1}{2}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}.$$

From eigenvectors: $H(i, 1) = (3i + i, 1 + 3) = 4(i, 1)$ and $H(-i, 1) = (-3i + i, -1 + 3) = 2(-i, 1)$. With $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(i, 1)$ and $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(-i, 1)$, Theorem 6.4.31 gives

$$\mathbf{u}_1\mathbf{u}_1^* = \frac{1}{2}\begin{pmatrix} i \\ 1 \end{pmatrix}(-i \;\; 1) = \frac{1}{2}\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix} = P_4, \quad \mathbf{u}_2\mathbf{u}_2^* = \frac{1}{2}\begin{pmatrix} -i \\ 1 \end{pmatrix}(i \;\; 1) = \frac{1}{2}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix} = P_2.$$

So $H = 4P_4 + 2P_2$. Finally

$$P_4 P_2 = \frac{1}{4}\begin{pmatrix} 1\cdot 1 + i \cdot i & 1\cdot(-i) + i \cdot 1 \\ -i \cdot 1 + 1 \cdot i & (-i)(-i) + 1 \cdot 1 \end{pmatrix} = \frac{1}{4}\begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Solution to Exercise 8.2.32

Uses. Algorithm 8.2.14 (Orthogonal diagonalization), Theorem 6.4.15 (Gram–Schmidt is correct), Theorem 7.5.22 (Trace and determinant from eigenvalues)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. One eigenvalue is -2, with eigenvector $(2, 1, -2)$. Use the trace to find the others.
Hint 2. The other eigenvalue is 7, with a two-dimensional eigenspace: the plane orthogonal to $(2, 1, -2)$. Find a basis of it and apply Gram–Schmidt.
Sketch. $A(2, 1, -2) = -2(2, 1, -2)$. Since $\operatorname{tr} A = 12$ and p_A splits with real roots, and $A - 7I_3$ has rank 1, the eigenvalues are $-2, 7, 7$. $E_7 = (2, 1, -2)^\perp$ has basis $(1, 0, 1), (1, -2, 0)$; Gram–Schmidt gives $\frac{1}{\sqrt{2}}(1, 0, 1)$ and $\frac{1}{3\sqrt{2}}(1, -4, -1)$.

Let A be the matrix. We have

$$A - 7I_3 = \begin{pmatrix} -4 & -2 & 4 \\ -2 & -1 & 2 \\ 4 & 2 & -4 \end{pmatrix},$$

whose rows are all multiples of $(2, 1, -2)$. So $\operatorname{rank}(A - 7I_3) = 1$ and $E_7 = \ker(A - 7I_3) = \{\mathbf{x} \mid 2x_1 + x_2 - 2x_3 = 0\}$ is a plane. Since $\operatorname{tr} A = 12$ and A is diagonalizable with eigenvalue 7 of multiplicity 2 (Theorem 8.2.12), the third eigenvalue is $12 - 14 = -2$ (Theorem 7.5.22). Indeed $A(2, 1, -2) = (6 - 2 - 8, -4 + 6 - 4, 8 + 2 - 6) = (-4, -2, 4) = -2(2, 1, -2)$.

For E_7, take the basis $(1, 0, 1), (1, -2, 0)$ (both satisfy $2x_1 + x_2 - 2x_3 = 0$). Gram–Schmidt: $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(1, 0, 1)$, and

$$(1, -2, 0) - \frac{1 \cdot 1 + 0 + 0}{2}(1, 0, 1) = \left(\frac{1}{2}, -2, -\frac{1}{2}\right) = \frac{1}{2}(1, -4, -1),$$

which normalizes to $\mathbf{u}_3 = \frac{1}{3\sqrt{2}}(1, -4, -1)$. With $\mathbf{u}_1 = \frac{1}{3}(2, 1, -2)$,

$$Q = \begin{pmatrix} \frac{2}{3} & \frac{1}{\sqrt{2}} & \frac{1}{3\sqrt{2}} \\ \frac{1}{3} & 0 & -\frac{4}{3\sqrt{2}} \\ -\frac{2}{3} & \frac{1}{\sqrt{2}} & -\frac{1}{3\sqrt{2}} \end{pmatrix}, \quad D = \begin{pmatrix} -2 & 0 & 0 \\ 0 & 7 & 0 \\ 0 & 0 & 7 \end{pmatrix}.$$

The columns are orthonormal: $\mathbf{u}_1 \perp E_7$ automatically, and $\mathbf{u}_2 \perp \mathbf{u}_3$ by construction.

Solution to Exercise 8.2.33

Uses. Theorem 8.2.18 (Spectral decomposition), Proposition 8.2.19 (Uniqueness of the spectral decomposition), Proposition 8.2.24 (Properties of $f(T)$), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25), Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. Write $T = \sum_j \lambda_j P_j$. Then $T^* = \sum_j \overline{\lambda_j} P_j$, $T^2 = \sum_j \lambda_j^2 P_j$, and $T^*T = \sum_j |\lambda_j|^2 P_j$.
Hint 2. Two operators $\sum a_j P_j$ and $\sum b_j P_j$ are equal if and only if $a_j = b_j$ for all j: apply both to a vector of E_{λ_j}.
Sketch. With $T = \sum \lambda_j P_j$: $T^* = T$ iff $\overline{\lambda_j} = \lambda_j$; $T^* = -T$ iff $\overline{\lambda_j} = -\lambda_j$; $T^2 = T = T^*$ iff $\lambda_j^2 = \lambda_j = \overline{\lambda_j}$, i.e. $\lambda_j \in \{0, 1\}$; $T^*T = \mathrm{id}$ iff $|\lambda_j|^2 = 1$. Counterexample to (a): $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.

Write $T = \sum_{j=1}^{k} \lambda_j P_j$ as in Theorem 8.2.18. By Proposition 8.2.24, $T^* = \sum_j \overline{\lambda_j} P_j$, $T^2 = \sum_j \lambda_j^2 P_j$, and $T^*T = \sum_j |\lambda_j|^2 P_j$, while $\mathrm{id}_V = \sum_j P_j$. Two operators $\sum_j a_j P_j$ and $\sum_j b_j P_j$ are equal if and only if $a_j = b_j$ for every j: apply both to a nonzero $\mathbf{v} \in E_{\lambda_j}$, on which $\sum_i a_i P_i$ acts as a_j (Proposition 8.2.24(a)).

(a) $T^* = T$ if and only if $\overline{\lambda_j} = \lambda_j$ for all j, that is, every λ_j is real.

(b) $T^* = -T$ if and only if $\overline{\lambda_j} = -\lambda_j$ for all j, that is, $\operatorname{Re} \lambda_j = 0$.

(c) By Corollary 6.6.29, T is an orthogonal projection if and only if $T^2 = T = T^*$, that is, $\lambda_j^2 = \lambda_j = \overline{\lambda_j}$ for all j. The first equation says $\lambda_j \in \{0, 1\}$, and then the second holds automatically.

(d) $T^*T = \mathrm{id}_V$ if and only if $|\lambda_j|^2 = 1$ for all j.

For the example, $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ has only the real eigenvalue 1, but $A^* = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \neq A$.

Solution to Exercise 8.2.34

Uses. Theorem 8.2.5 (Complex spectral theorem), Theorem 8.2.12 (Real spectral theorem), Proposition 8.2.24 (Properties of $f(T)$), Theorem 7.3.24 (Every monic polynomial is a characteristic polynomial), Proposition 8.2.2 (Necessary conditions)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25), Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a) and (b), apply the relation to an eigenvector: what equation does each eigenvalue satisfy?
Hint 2. For (c), look for a real 2×2 matrix whose characteristic polynomial is the other factor of $x^3 + x - 2 = (x - 1)(x^2 + x + 2)$.
Hint 3. For (d), think of repeated eigenvalues. For (e), choose an orthonormal basis inside each eigenspace.
Sketch. (a) True: $\lambda^m = 0$ forces every eigenvalue to be 0, and $T = \sum \lambda_j P_j = 0$. (b) True: real eigenvalues of T satisfy $\lambda^3 + \lambda - 2 = (\lambda - 1)(\lambda^2 + \lambda + 2) = 0$, so $\lambda = 1$ and $T = P_1 = \mathrm{id}$. (c) False: the companion matrix C of $x^2 + x + 2$ satisfies $C^2 = -C - 2I$, hence $C^3 + C = 2I$. (d) False: I_2 with the basis $(1, 0), (1, 1)$. (e) True: orthonormal bases of the eigenspaces combine into an orthonormal eigenbasis.

(a) True. By Theorem 8.2.5, $T = \sum_j \lambda_j P_j$. If $\mathbf{v} \in E_{\lambda_j}$ is nonzero, then $\mathbf{0} = T^m \mathbf{v} = \lambda_j^m \mathbf{v}$, so $\lambda_j = 0$. Hence the only eigenvalue is 0 and $T = 0 \cdot P_1 = 0$.

(b) True. By Theorem 8.2.12, V has an orthonormal eigenbasis $\mathbf{u}_1, \ldots, \mathbf{u}_n$, with $T\mathbf{u}_i = \mu_i \mathbf{u}_i$ and $\mu_i \in \mathbb{R}$. Applying $T^3 + T = 2\mathrm{id}_V$ to $\mathbf{u}_i$ gives $\mu_i^3 + \mu_i - 2 = 0$. Since $x^3 + x - 2 = (x - 1)(x^2 + x + 2)$ and $x^2 + x + 2$ has discriminant $1 - 8 < 0$, the only real root is 1. So $T\mathbf{u}_i = \mathbf{u}_i$ for all i, and $T = \mathrm{id}_V$.

(c) False. Let $C = \begin{pmatrix} 0 & -2 \\ 1 & -1 \end{pmatrix}$, the companion matrix of $x^2 + x + 2$ (Theorem 7.3.24); directly, $C^2 = \begin{pmatrix} -2 & 2 \\ -1 & -1 \end{pmatrix} = -C - 2I_2$. Then $C^3 = -C^2 - 2C = C + 2I_2 - 2C = 2I_2 - C$, so $C^3 + C = 2I_2$, but $C \neq I_2$. (Here C is not symmetric, and its eigenvalues are not real.)

(d) False. $A = I_2$ is symmetric, and every nonzero vector is an eigenvector, so $(1, 0), (1, 1)$ is an eigenbasis. It is not orthogonal. (What is true: eigenvectors for *different* eigenvalues are orthogonal.)

(e) True. Choose an orthonormal basis of each eigenspace (Theorem 6.4.20). Since A is diagonalizable, the eigenspaces together contain a basis, so their dimensions add up to n (Theorem 7.4.16), and the concatenation is an orthonormal list of n eigenvectors, because vectors from different eigenspaces are orthogonal. It is an orthonormal eigenbasis, so A is symmetric by Proposition 8.2.2(b) (or Theorem 8.2.12).

Solution to Exercise 8.2.35

Uses. Example 8.2.3 (Which matrices have orthonormal eigenbases), Lemma 8.2.10 (Self-adjoint operators have eigenvalues), Theorem 8.2.12 (Real spectral theorem)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Every step after the first one is the second proof of Theorem 8.2.5, which works over $\mathbb{R}$ as well. Look at the first step.
Hint 2. Does every operator on $\mathbb{R}^2$ have an eigenvector?
Sketch. The proof assumes that T has an eigenvector. Over $\mathbb{R}$ it need not: the rotation J is normal ($J^{\mathsf{T}}J = I = JJ^{\mathsf{T}}$) and has no real eigenvalue. If T is self-adjoint, Lemma 8.2.10 supplies the eigenvector, and the proof becomes that of Theorem 8.2.12.

The error is in the second sentence: "let $\mathbf{u}$ be a unit eigenvector of T". Over $\mathbb{R}$ an operator need not have any eigenvector. The rest of the argument is correct over $\mathbb{R}$: the computation $\|(T-\lambda\,\mathrm{id})\mathbf{u}\| = \|(T^*-\lambda\,\mathrm{id})\mathbf{u}\|$ for a real λ, the invariance of W, and the normality of $T{\restriction_W}$ go through as in the second proof of Theorem 8.2.5.

Counterexample: $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ satisfies $J^{\mathsf{T}}J = I_2 = JJ^{\mathsf{T}}$, so T_J is normal on $\mathbb{R}^2$, but $p_J = x^2+1$ has no real root, so T_J has no eigenvector, let alone an orthonormal eigenbasis (Example 8.2.3).

Repair: assume T is self-adjoint. Then Lemma 8.2.10 provides the eigenvector at every stage (restrictions of self-adjoint operators to invariant subspaces are self-adjoint), and the argument becomes the first proof of Theorem 8.2.12.

Solution to Exercise 8.2.36

Uses. Theorem 8.2.18 (Spectral decomposition), Proposition 8.2.20 (Spectral projections are polynomials in T), Theorem 8.2.12 (Real spectral theorem), Corollary 8.2.7 (Hermitian matrices), Definition 6.6.26 (Self-adjoint operator)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Glue bases of the summands (Technique 4.4.14)
Hint 1. The easy direction: in a common orthonormal eigenbasis both matrices are diagonal.
Hint 2. For the other, S maps each eigenspace E_{λ_j} of T into itself (Proposition 8.2.20(a)). Is $S{\restriction_{E_{\lambda_j}}}$ self-adjoint?
Hint 3. Apply the spectral theorem to $S{\restriction_{E_{\lambda_j}}}$ on each E_{λ_j}, and glue the bases.
Sketch. If both are diagonal in an orthonormal basis $\mathcal{O}$, their matrices commute, so $ST = TS$. Conversely, $V = \oplus E_{\lambda_j}$ for the eigenvalues of T, and S maps each E_{λ_j} into itself; $S{\restriction_{E_{\lambda_j}}}$ is self-adjoint, so E_{λ_j} has an orthonormal eigenbasis for it. These vectors are eigenvectors of T (with eigenvalue λ_j) and of S; the eigenspaces are orthogonal, so the concatenation is orthonormal.

If $\mathcal{O}$ is an orthonormal basis of common eigenvectors, then $[S]_{\mathcal{O}}$ and $[T]_{\mathcal{O}}$ are diagonal, so they commute, and $[ST]_{\mathcal{O}} = [S]_{\mathcal{O}}[T]_{\mathcal{O}} = [T]_{\mathcal{O}}[S]_{\mathcal{O}} = [TS]_{\mathcal{O}}$. Hence $ST = TS$.

Conversely, suppose $ST = TS$. A self-adjoint operator satisfies the spectral hypothesis (over $\mathbb{C}$ it is normal), so by Theorem 8.2.18, $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_k}$ with pairwise orthogonal eigenspaces of T. By Proposition 8.2.20(a), S maps each E_{λ_j} into itself. The restriction $S_j = S{\restriction_{E_{\lambda_j}}} \in \mathrm{L}\left(E_{\lambda_j}\right)$ is self-adjoint, because $\langle S_j\mathbf{v},\mathbf{w}\rangle = \langle S\mathbf{v},\mathbf{w}\rangle = \langle \mathbf{v}, S\mathbf{w}\rangle = \langle \mathbf{v}, S_j\mathbf{w}\rangle$ for $\mathbf{v},\mathbf{w} \in E_{\lambda_j}$. By Theorem 8.2.12 or Corollary 8.2.7, E_{λ_j} has an orthonormal basis $\mathcal{O}_j$ of eigenvectors of S_j, which are eigenvectors of S; they lie in E_{λ_j}, so they are eigenvectors of T too. The concatenation $\mathcal{O}_1, \ldots, \mathcal{O}_k$ is orthonormal, since the eigenspaces are pairwise orthogonal, and it has $\sum_j \dim E_{\lambda_j} = \dim V$ vectors. So it is an orthonormal basis of common eigenvectors.

Solution to Exercise 8.2.37

Uses. Proposition 8.2.20 (Spectral projections are polynomials in T), Proposition 7.2.27 (Evaluating polynomials at an operator), Proposition 6.6.18 (Properties of the adjoint), Definition 8.1.8 (Normal operator, normal matrix)
Hint 1. By Proposition 8.2.20(b), T^* is a polynomial in T.
Hint 2. For (b), try $T = S = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.
Hint 3. For (c), apply (a) twice, and take adjoints of $ST = TS$.
Sketch. (a) $T^* = p(T)$, and S commutes with every polynomial in T. (b) $T = S = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$: $ST^* = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \neq \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = T^*S$. (c) $ST^* = T^*S$ and (by symmetry) $TS^* = S^*T$; taking adjoints of $ST = TS$ gives $S^*T^* = T^*S^*$; normality gives the rest. Then $(ST)(ST)^* = STT^*S^*$ and $(ST)^*(ST) = T^*S^*ST$ are products of the same commuting operators.

(a) By Proposition 8.2.20(b), $T^* = p(T)$ for some $p \in \mathbb{C}[x]$. Since S commutes with T, it commutes with T^m for every m (induction on m), hence with $p(T) = T^*$.

(b) Let $T = S = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, which commute. Then $T^* = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$, and

$$ST^* = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \neq \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = T^*S.$$

(This T is not normal, since $TT^* \neq T^*T$ by the same computation.)

(c) By (a), S commutes with T^*; by (a) with the roles of S and T exchanged (now S is normal and T commutes with it), T commutes with S^*. Taking adjoints of $ST = TS$ gives $T^*S^* = S^*T^*$ (Proposition 6.6.18(d)). Finally $SS^* = S^*S$ and $TT^* = T^*T$ by normality. So the four operators pairwise commute. Then

$$(ST)(ST)^* = STT^*S^* \quad \text{and} \quad (ST)^*(ST) = T^*S^*ST$$

are products of the same four pairwise commuting operators, so they are equal, and ST is normal. Similarly $(S+T)(S+T)^* = SS^* + ST^* + TS^* + TT^*$ and $(S+T)^*(S+T) = S^*S + S^*T + T^*S + T^*T$ agree term by term.

Solution to Exercise 8.2.38

Uses. Theorem 8.2.18 (Spectral decomposition), Theorem 6.4.31 (The matrix of an orthogonal projection), Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. For a symmetric A, the eigenspace for 1 is forced to be $(1,2)^\perp$. So the spectral decomposition is determined.
Hint 2. For (b), drop the orthogonality: choose any other eigenvector for 1, such as $(1,0)$, and compute SDS^{-1}.
Sketch. (a) $E_3 = \operatorname{span}((1,2))$ and $E_1 = E_3^\perp$ are forced, so $A = 3P + (I - P)$ with $P = \frac{1}{5}\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$: $A = \frac{1}{5}\begin{pmatrix} 7 & 4 \\ 4 & 13 \end{pmatrix}$. (b) $S = \begin{pmatrix} 1 & 1 \\ 2 & 0 \end{pmatrix}$, $D = \operatorname{diag}(3,1)$: $B = SDS^{-1} = \begin{pmatrix} 1 & 1 \\ 0 & 3 \end{pmatrix}$.

(a) Let A be such a matrix. By Theorem 8.2.18, $\mathbb{R}^2 = E_3 \oplus E_1$ with $E_3 \perp E_1$. Each eigenspace is at least a line, so both are lines; $E_3 = \operatorname{span}((1,2))$ and $E_1 = E_3^\perp = \operatorname{span}((2,-1))$. So $A = 3P_3 + 1P_1$ with $P_3 = \operatorname{Pr}_{E_3}$ and $P_1 = I_2 - P_3$. With $\mathbf{u} = \frac{1}{\sqrt{5}}(1,2)$, Theorem 6.4.31 gives $P_3 = \mathbf{u}\mathbf{u}^{\mathsf{T}} = \frac{1}{5}\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$, so

$$A = I_2 + 2P_3 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \frac{2}{5}\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix} = \frac{1}{5}\begin{pmatrix} 7 & 4 \\ 4 & 13 \end{pmatrix}.$$

It is symmetric, and $A(1,2) = \frac{1}{5}(15,30) = 3(1,2)$, $A(2,-1) = \frac{1}{5}(10,-5) = (2,-1)$. The argument shows it is the only one.

(b) Take $(1,0)$ as eigenvector for 1, and let $S = \begin{pmatrix} 1 & 1 \\ 2 & 0 \end{pmatrix}$ (columns: the eigenvectors for 3 and 1) and $D = \operatorname{diag}(3,1)$. Then $S^{-1} = \begin{pmatrix} 0 & \frac{1}{2} \\ 1 & -\frac{1}{2} \end{pmatrix}$ and

$$B = SDS^{-1} = \begin{pmatrix} 3 & 1 \\ 6 & 0 \end{pmatrix}\begin{pmatrix} 0 & \frac{1}{2} \\ 1 & -\frac{1}{2} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 3 \end{pmatrix}.$$

Then $B(1,2) = (3,6)$ and $B(1,0) = (1,0)$, and B is not symmetric. Uniqueness in (a) came from the orthogonality of eigenspaces, which only symmetric matrices guarantee.

Solution to Exercise 8.2.39

Uses. Proposition 8.2.24 (Properties of $f(T)$), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Theorem 8.2.18 (Spectral decomposition)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. A has eigenvalues 16 and 4, with eigenvectors $(1,1)$ and $(1,-1)$.
Hint 2. If $B^2 = A$, then B commutes with A. What does B do to the eigenspaces of A?

Hint 3. Each eigenspace of A is a line mapped into itself by B, so it consists of eigenvectors of B. For (c), every reflection squares to I_2.
Sketch. (a) $P = \frac{1}{2}\begin{pmatrix}1&1\\1&1\end{pmatrix}$, $Q = \frac{1}{2}\begin{pmatrix}1&-1\\-1&1\end{pmatrix}$, $A = 16P + 4Q$, $\sqrt{A} = 4P + 2Q = \begin{pmatrix}3&1\\1&3\end{pmatrix}$. (b) B commutes with A, so preserves the lines E_{16} and E_4, so $B = \beta_1 P + \beta_2 Q$ with $\beta_1^2 = 16$ and $\beta_2^2 = 4$: four matrices $\pm\begin{pmatrix}3&1\\1&3\end{pmatrix}$, $\pm\begin{pmatrix}1&3\\3&1\end{pmatrix}$. (c) For I_2 the eigenspace is all of $\mathbb{R}^2$, which imposes no constraint; any reflection is a square root.

(a) $p_A = (x-10)^2 - 36 = (x-16)(x-4)$, with $E_{16} = \operatorname{span}((1,1))$ and $E_4 = \operatorname{span}((1,-1))$. With $P = \operatorname{Pr}_{E_{16}} = \frac{1}{2}\begin{pmatrix}1&1\\1&1\end{pmatrix}$ and $Q = \operatorname{Pr}_{E_4} = \frac{1}{2}\begin{pmatrix}1&-1\\-1&1\end{pmatrix}$, we have $A = 16P + 4Q$, and

$$B = \sqrt{A} = 4P + 2Q = \begin{pmatrix}3&1\\1&3\end{pmatrix}.$$

Check: $\begin{pmatrix}3&1\\1&3\end{pmatrix}^2 = \begin{pmatrix}10&6\\6&10\end{pmatrix}$.

(b) Suppose $B^2 = A$. Then $BA = B^3 = AB$, so B maps $E_{16} = \ker(A - 16I_2)$ and $E_4 = \ker(A - 4I_2)$ into themselves (Proposition 7.2.30). These are lines, so by Proposition 7.2.7, $B(1,1) = \beta_1(1,1)$ and $B(1,-1) = \beta_2(1,-1)$ for some $\beta_1, \beta_2 \in \mathbb{R}$. Then $A(1,1) = B^2(1,1) = \beta_1^2(1,1)$, so $\beta_1^2 = 16$, and similarly $\beta_2^2 = 4$. Since $(1,1), (1,-1)$ is a basis, $B = \beta_1 P + \beta_2 Q$, with $\beta_1 = \pm 4$ and $\beta_2 = \pm 2$. Conversely each of these four matrices squares to $16P + 4Q = A$ by Proposition 8.2.24. They are

$$\begin{pmatrix}3&1\\1&3\end{pmatrix}, \quad \begin{pmatrix}-3&-1\\-1&-3\end{pmatrix}, \quad \begin{pmatrix}1&3\\3&1\end{pmatrix}, \quad \begin{pmatrix}-1&-3\\-3&-1\end{pmatrix}.$$

(c) For I_2 there is a single eigenspace, $\mathbb{R}^2$ itself, and the argument of (b) gives no information. Every reflection $R_\theta = \begin{pmatrix}\cos\theta&\sin\theta\\\sin\theta&-\cos\theta\end{pmatrix}$ satisfies $R_\theta^2 = I_2$ (it is $\operatorname{Pr}_\ell - \operatorname{Pr}_{\ell^\perp}$ for a line ℓ), and these are infinitely many distinct square roots. In (b), the distinct eigenvalues of A forced every square root to have the same eigenvectors as A.

Solution to Exercise 8.2.40

Uses. Definition 8.2.23 (Functions of an operator), Example 8.2.27 (The exponential), Example 8.2.3 (Which matrices have orthonormal eigenbases), Theorem 6.4.31 (The matrix of an orthogonal projection)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. A has eigenvalues ± 1 with eigenvectors $(1, \pm 1)$. Write down P_1 and P_{-1}.
Hint 2. J has eigenvalues $\pm i$ with eigenvectors $(1, \mp i)$. Use $e^{it} + e^{-it} = 2\cos t$ and $e^{it} - e^{-it} = 2i\sin t$.
Sketch. $e^{tA} = e^t P_1 + e^{-t} P_{-1} = \begin{pmatrix}\cosh t&\sinh t\\\sinh t&\cosh t\end{pmatrix}$. $e^{tJ} = e^{it}P_i + e^{-it}P_{-i}$ with $P_{\pm i} = \frac{1}{2}\begin{pmatrix}1&\pm i\\\mp i&1\end{pmatrix}$, giving $\begin{pmatrix}\cos t&-\sin t\\\sin t&\cos t\end{pmatrix}$: rotation by t.

For A: $E_1 = \operatorname{span}((1,1))$ and $E_{-1} = \operatorname{span}((1,-1))$, so $P_1 = \frac{1}{2}\begin{pmatrix}1&1\\1&1\end{pmatrix}$ and $P_{-1} = \frac{1}{2}\begin{pmatrix}1&-1\\-1&1\end{pmatrix}$, and

$$e^{tA} = e^t P_1 + e^{-t} P_{-1} = \frac{1}{2}\begin{pmatrix}e^t + e^{-t}&e^t - e^{-t}\\e^t - e^{-t}&e^t + e^{-t}\end{pmatrix} = \begin{pmatrix}\cosh t&\sinh t\\\sinh t&\cosh t\end{pmatrix}.$$

For J: by Example 8.2.3, $E_i = \operatorname{span}((1,-i))$ and $E_{-i} = \operatorname{span}((1,i))$. With $\mathbf{u} = \frac{1}{\sqrt{2}}(1,-i)$, $P_i = \mathbf{u}\mathbf{u}^* = \frac{1}{2}\begin{pmatrix}1\\-i\end{pmatrix}(1\ \ i) = \frac{1}{2}\begin{pmatrix}1&i\\-i&1\end{pmatrix}$, and similarly $P_{-i} = \frac{1}{2}\begin{pmatrix}1&-i\\i&1\end{pmatrix}$. So

$$e^{tJ} = e^{it}P_i + e^{-it}P_{-i} = \frac{1}{2}\begin{pmatrix}e^{it} + e^{-it}&i\left(e^{it} - e^{-it}\right)\\-i\left(e^{it} - e^{-it}\right)&e^{it} + e^{-it}\end{pmatrix} = \begin{pmatrix}\cos t&-\sin t\\\sin t&\cos t\end{pmatrix},$$

using $e^{it} + e^{-it} = 2\cos t$ and $i\left(e^{it} - e^{-it}\right) = i \cdot 2i\sin t = -2\sin t$. So e^{tJ} is the rotation by the angle t: the solutions of $\mathbf{x}' = J\mathbf{x}$, that is $x_1' = -x_2$ and $x_2' = x_1$, run around circles at unit angular speed. The complex projections were only a tool; the answer is real.

Solution to Exercise 8.2.41

Uses. Corollary 8.2.28 (Principal axes), Remark 8.2.30 (Classifying conics)
Hint 1. Write each left side as $\mathbf{x}^{\mathsf{T}} A\mathbf{x}$, splitting the cross term evenly.
Hint 2. All three matrices have eigenvectors $(1,1)$ and $(1,-1)$.

Sketch. (a) $A = \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}$, eigenvalues $3, -1$: $3y_1^2 - y_2^2 = 1$, a hyperbola with vertices on the line $y = x$. (b) $A = \begin{pmatrix} 3 & 1 \\ 1 & 3 \end{pmatrix}$, eigenvalues $4, 2$: $y_1^2/2 + y_2^2/4 = 1$, an ellipse with semi-axes $\sqrt{2}$ along $(1,1)$ and 2 along $(1,-1)$. (c) $A = \begin{pmatrix} 2 & 2 \\ 2 & 2 \end{pmatrix}$, eigenvalues $4, 0$: $4y_1^2 = 1$, the lines $x + y = \pm 1/\sqrt{2}$.

In each case let $\mathbf{q}_1 = \frac{1}{\sqrt{2}}(1,1)$ and $\mathbf{q}_2 = \frac{1}{\sqrt{2}}(1,-1)$, and $y_1 = (x+y)/\sqrt{2}$, $y_2 = (x-y)/\sqrt{2}$. Every symmetric matrix $\begin{pmatrix} a & b \\ b & a \end{pmatrix}$ has $A\mathbf{q}_1 = (a+b)\mathbf{q}_1$ and $A\mathbf{q}_2 = (a-b)\mathbf{q}_2$, so Corollary 8.2.28 applies with these coordinates. The principal axes are the lines $y = x$ and $y = -x$ in all three cases.

(a) $A = \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}$, eigenvalues 3 and -1. The curve is $3y_1^2 - y_2^2 = 1$: a hyperbola, with vertices at $y_1 = \pm 1/\sqrt{3}$, $y_2 = 0$, that is, at $\pm\frac{1}{\sqrt{6}}(1,1)$ on the line $y = x$.

(b) $A = \begin{pmatrix} 3 & 1 \\ 1 & 3 \end{pmatrix}$, eigenvalues 4 and 2. The curve is $4y_1^2 + 2y_2^2 = 8$, that is, $y_1^2/2 + y_2^2/4 = 1$: an ellipse with semi-axis $\sqrt{2}$ along $y = x$ and semi-axis 2 along $y = -x$.

(c) $A = \begin{pmatrix} 2 & 2 \\ 2 & 2 \end{pmatrix}$, eigenvalues 4 and 0. The curve is $4y_1^2 = 1$, that is, $y_1 = \pm 1/2$: the two parallel lines $x + y = \pm 1/\sqrt{2}$. (Directly: $2(x+y)^2 = 1$.)

Solution to Exercise 8.2.42

Uses. Theorem 8.2.12 (Real spectral theorem), Corollary 8.2.7 (Hermitian matrices), Proposition 6.3.18 (Coordinates in an orthonormal basis), Theorem 6.3.22 (Parseval's identity)
Techniques. Pass to orthonormal coordinates (Technique 6.7.2)
Hint 1. Expand $\mathbf{v} = \sum c_i \mathbf{u}_i$ in an orthonormal eigenbasis. Then $\langle T\mathbf{v}, \mathbf{v}\rangle = \sum \mu_i |c_i|^2$ and $\|\mathbf{v}\|^2 = \sum |c_i|^2$.
Hint 2. For (b), take $\mathbf{v} = \mathbf{e}_i$. For (c), find a vector $\mathbf{v}$ with $\langle A\mathbf{v}, \mathbf{v}\rangle > 3\|\mathbf{v}\|^2$.
Sketch. (a) $\langle T\mathbf{v}, \mathbf{v}\rangle = \sum_i \mu_i |c_i|^2$ is a weighted average of the eigenvalues times $\sum |c_i|^2 = \|\mathbf{v}\|^2$; equality on the right iff $c_i = 0$ whenever $\mu_i < \lambda_{\max}$. (b) $\mathbf{e}_i^{\mathsf{T}} A \mathbf{e}_i = a_{ii}$. (c) $\mathbf{v} = (1,1,1)$: $\mathbf{v}^{\mathsf{T}} A \mathbf{v} = 3 + 2 \cdot (2+2) = 11 > 9$.

(a) Let $\mathbf{u}_1, \dots, \mathbf{u}_n$ be an orthonormal eigenbasis with $T\mathbf{u}_i = \mu_i \mathbf{u}_i$ (Theorem 8.2.12 or Corollary 8.2.7), and write $\mathbf{v} = \sum_i c_i \mathbf{u}_i$. Then $T\mathbf{v} = \sum_i \mu_i c_i \mathbf{u}_i$, and by orthonormality

$$\langle T\mathbf{v}, \mathbf{v}\rangle = \sum_i \mu_i c_i \overline{c_i} = \sum_i \mu_i |c_i|^2, \quad \|\mathbf{v}\|^2 = \sum_i |c_i|^2$$

(Theorem 6.3.22). Since $\lambda_{\min} \le \mu_i \le \lambda_{\max}$ and $|c_i|^2 \ge 0$,

$$\lambda_{\min} \sum_i |c_i|^2 \le \sum_i \mu_i |c_i|^2 \le \lambda_{\max} \sum_i |c_i|^2.$$

Equality on the right means $\sum_i (\lambda_{\max} - \mu_i)|c_i|^2 = 0$, a sum of nonnegative terms, so $c_i = 0$ whenever $\mu_i \ne \lambda_{\max}$; that is, $\mathbf{v} \in \operatorname{span}\{\mathbf{u}_i \mid \mu_i = \lambda_{\max}\} = E_{\lambda_{\max}}$ (as in the proof of Theorem 8.2.18). Conversely, $\mathbf{v} \in E_{\lambda_{\max}}$ gives $\langle T\mathbf{v}, \mathbf{v}\rangle = \lambda_{\max}\|\mathbf{v}\|^2$.

(b) Apply (a) to T_A on $\mathbb{R}^n$ with the dot product and $\mathbf{v} = \mathbf{e}_i$: $\langle A\mathbf{e}_i, \mathbf{e}_i\rangle = a_{ii}$ and $\|\mathbf{e}_i\| = 1$.

(c) With $\mathbf{v} = (1,1,1)$, $A\mathbf{v} = (3,5,3)$, so $\langle A\mathbf{v}, \mathbf{v}\rangle = 11$ while $\|\mathbf{v}\|^2 = 3$. By (a), $\lambda_{\max} \ge 11/3 > 3$. (Part (b) alone gives only $\lambda_{\max} \ge 1$. In fact $\lambda_{\max} = 1 + 2\sqrt{2} \approx 3.83$.)

Solution to Exercise 8.2.43

Uses. Theorem 8.2.12 (Real spectral theorem), Proposition 4.5.27 (Similarity invariants), Proposition 6.2.22 (The square of a sum), Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. Diagonalize: all three quantities can be read off from the eigenvalues $\mu_1, \dots, \mu_n$.
Hint 2. $\operatorname{rank} A$ is the number of nonzero μ_i, $\operatorname{tr} A = \sum \mu_i$, and $\operatorname{tr}(A^2) = \sum \mu_i^2 > 0$. Apply Cauchy–Schwarz to the nonzero μ_i.
Sketch. $A = QDQ^{\mathsf{T}}$; rank and trace are similarity invariants, and $A^2 = QD^2Q^{\mathsf{T}}$. With r nonzero eigenvalues, $(\sum \mu_i)^2 \le r \sum \mu_i^2$ by Cauchy–Schwarz (Proposition 6.2.22), with equality iff the nonzero μ_i are equal. Since $A \ne 0$, $\operatorname{tr}(A^2) > 0$.

By Theorem 8.2.12, $A = QDQ^{\mathsf{T}}$ with Q orthogonal and $D = \operatorname{diag}(\mu_1, \dots, \mu_n)$, and $A^2 = QD^2Q^{\mathsf{T}}$ (Proposition 7.4.23). Rank and trace are invariant under similarity (Proposition 4.5.27), so with r the number of nonzero μ_i,

$$\operatorname{rank} A = \operatorname{rank} D = r, \quad \operatorname{tr} A = \sum_i \mu_i, \quad \operatorname{tr}\left(A^2\right) = \sum_i \mu_i^2.$$

Since $A \neq 0$, $D \neq 0$, so $r \geq 1$ and $\operatorname{tr}\left(A^2\right) > 0$. The sum $\sum_i \mu_i$ only involves the r nonzero eigenvalues, and by Proposition 6.2.22 (Cauchy–Schwarz for the vectors $(1, \ldots, 1)$ and $(\mu_i)_{\mu_i \neq 0}$ in $\mathbb{R}^r$),

$$\left(\sum_i \mu_i\right)^2 \leq r \sum_{\mu_i \neq 0} \mu_i^2 = r \operatorname{tr}\left(A^2\right).$$

Dividing by $\operatorname{tr}\left(A^2\right) > 0$ gives the inequality. Equality holds in Cauchy–Schwarz if and only if $(\mu_i)_{\mu_i \neq 0}$ is a multiple of $(1, \ldots, 1)$, that is, if and only if all nonzero eigenvalues of A are equal. Equivalently, $A = cP$ for a scalar $c \neq 0$ and an orthogonal projection P (by Theorem 8.2.18).

Solution to Exercise 8.2.44

Uses. Theorem 8.2.5 (Complex spectral theorem), Exercise 6.6.38, Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Corollary 6.4.27 (Testing whether a subspace is everything)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Move an operator across the inner product (Technique 6.6.20)
Hint 1. One direction was shown inside the second proof of Theorem 8.2.5. For the other, imitate the third proof.
Hint 2. If every vector of E_λ is an eigenvector of T^*, then $T^*\restriction_{E_\lambda}$ is an operator all of whose nonzero vectors are eigenvectors. What kind of operator is that?
Hint 3. Show that $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$ for $\mathbf{u} \in E_\lambda$ by comparing $\langle T\mathbf{u}, \mathbf{u}\rangle$ and $\langle \mathbf{u}, T^*\mathbf{u}\rangle$. Then the third proof of Theorem 8.2.5 runs unchanged.
Sketch. ($\Rightarrow$) shown in the second proof of Theorem 8.2.5. ($\Leftarrow$) For a nonzero $\mathbf{u} \in E_\lambda$, $T^*\mathbf{u} = \nu\mathbf{u}$, and $\lambda\|\mathbf{u}\|^2 = \langle T\mathbf{u}, \mathbf{u}\rangle = \langle \mathbf{u}, T^*\mathbf{u}\rangle = \overline{\nu}\|\mathbf{u}\|^2$, so $\nu = \overline{\lambda}$. Now the third proof applies: $E = \sum E_\lambda$ is T^*-invariant, $E^\perp$ is T-invariant and contains no eigenvector, so $E = V$; eigenspaces are orthogonal. So T has an orthonormal eigenbasis and is normal.

($\Rightarrow$) If T is normal and $T\mathbf{u} = \lambda\mathbf{u}$, then $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$, as shown in the second proof of Theorem 8.2.5.

($\Leftarrow$) Let $\mathbf{u} \neq \mathbf{0}$ with $T\mathbf{u} = \lambda\mathbf{u}$. By hypothesis $T^*\mathbf{u} = \nu\mathbf{u}$ for some $\nu \in \mathbb{C}$, and

$$\lambda\|\mathbf{u}\|^2 = \langle T\mathbf{u}, \mathbf{u}\rangle = \langle \mathbf{u}, T^*\mathbf{u}\rangle = \langle \mathbf{u}, \nu\mathbf{u}\rangle = \overline{\nu}\|\mathbf{u}\|^2,$$

so $\nu = \overline{\lambda}$. Thus $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$ for every $\mathbf{u} \in E_\lambda$ (including $\mathbf{0}$). This is the only property of normal operators used in the third proof of Theorem 8.2.5, so that proof applies verbatim: $E = \sum_\lambda E_\lambda$ is T^*-invariant, so $E^\perp$ is T-invariant (Exercise 6.6.38); an eigenvector of $T\restriction_{E^\perp}$ would lie in $E \cap E^\perp = \{\mathbf{0}\}$, so $E^\perp = \{\mathbf{0}\}$ and $E = V$ (Theorem 7.3.27, Corollary 6.4.27); and $\lambda\langle \mathbf{u}, \mathbf{v}\rangle = \langle \mathbf{u}, T^*\mathbf{v}\rangle = \mu\langle \mathbf{u}, \mathbf{v}\rangle$ for $\mathbf{u} \in E_\lambda$, $\mathbf{v} \in E_\mu$ shows that the eigenspaces are orthogonal. Concatenating orthonormal bases of the eigenspaces gives an orthonormal eigenbasis, so T is normal by Theorem 8.2.5.

Solution to Exercise 8.2.45

Uses. Definition 8.1.8 (Normal operator, normal matrix), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Write $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ and compare the entries of $A^{\mathsf{T}}A$ and AA^{T}.
Hint 2. The diagonal entries give $b^2 = c^2$. Split into the cases $c = b$ and $c = -b \neq 0$.
Sketch. $A^{\mathsf{T}}A = \begin{pmatrix} a^2+c^2 & ab+cd \\ ab+cd & b^2+d^2 \end{pmatrix}$ and $AA^{\mathsf{T}} = \begin{pmatrix} a^2+b^2 & ac+bd \\ ac+bd & c^2+d^2 \end{pmatrix}$. Equality means $b^2 = c^2$ and $ab + cd = ac + bd$. If $c = b$, A is symmetric. If $c = -b \neq 0$, the second equation gives $2b(a - d) = 0$, so $d = a$. (b) $p = (x - a)^2 + b^2$ has no real root for $b \neq 0$; the matrix is $\sqrt{a^2 + b^2}$ times a rotation.

(a) Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Then

$$A^{\mathsf{T}}A = \begin{pmatrix} a^2 + c^2 & ab + cd \\ ab + cd & b^2 + d^2 \end{pmatrix}, \quad AA^{\mathsf{T}} = \begin{pmatrix} a^2 + b^2 & ac + bd \\ ac + bd & c^2 + d^2 \end{pmatrix}.$$

So A is normal if and only if $b^2 = c^2$ and $ab + cd = ac + bd$. If $c = b$, the second equation holds and A is symmetric. Otherwise $c = -b$ with $b \neq 0$, and the second equation becomes $ab - bd = -ab + bd$, that is,

$2b(a-d)=0$, so $d=a$ and $A=\begin{pmatrix} a & b \\ -b & a \end{pmatrix}$, which is of the stated form with b replaced by $-b$. Conversely, symmetric matrices are normal, and for $A=\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ both products equal $\left(a^2+b^2\right)I_2$.

(b) If A is normal and not symmetric, then $A=\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ with $b\neq 0$, and $p_A=(x-a)^2+b^2>0$ for every real x. So A has no real eigenvalue (Theorem 7.3.6). Writing $r=\sqrt{a^2+b^2}>0$ and $(a,b)=r(\cos\theta,\sin\theta)$, we get $A=r\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$: a rotation by θ followed by scaling by r. It is multiplication by $a+bi$ on $\mathbb{C}=\mathbb{R}^2$.

Solution to Exercise 8.2.46

Uses. Lemma 8.2.10 (Self-adjoint operators have eigenvalues), Exercise 6.6.38, Corollary 6.4.27 (Testing whether a subspace is everything), Theorem 6.4.20 (Orthonormal bases exist), Definition 6.6.26 (Self-adjoint operator)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Let E be the sum of the eigenspaces of T. Why is $E^\perp$ invariant? (This is easier than in the complex case.)
Hint 2. To find an eigenvector in $E^\perp$, you need $T{\restriction}_{E^\perp}$ to be an operator that has one. Which lemma provides it?
Sketch. $E=\sum E_\lambda$ is T-invariant, and $T=T^*$, so $E^\perp$ is T-invariant (Exercise 6.6.38). The restriction $T{\restriction}_{E^\perp}$ is self-adjoint, so if $E^\perp\neq\{\mathbf{0}\}$ it has an eigenvector (Lemma 8.2.10), which would lie in $E\cap E^\perp$. So $E=V$. Orthogonality: $\lambda\langle\mathbf{u},\mathbf{v}\rangle=\langle T\mathbf{u},\mathbf{v}\rangle=\langle\mathbf{u},T\mathbf{v}\rangle=\mu\langle\mathbf{u},\mathbf{v}\rangle$.

Let T be self-adjoint, let $\lambda_1,\ldots,\lambda_k$ be its distinct eigenvalues ($k\geq 1$ by Lemma 8.2.10), and let $E=E_{\lambda_1}+\cdots+E_{\lambda_k}$. Each E_{λ_j} is T-invariant, so E is T-invariant. Since $T^*=T$, Exercise 6.6.38 shows that $E^\perp$ is T^*-invariant, that is, T-invariant. (This is the first use of self-adjointness; in the complex case we needed the fact that eigenvectors of T are eigenvectors of T^*.)

Suppose $E^\perp\neq\{\mathbf{0}\}$. The restriction $S=T{\restriction}_{E^\perp}$ is self-adjoint, since $\langle S\mathbf{v},\mathbf{w}\rangle=\langle T\mathbf{v},\mathbf{w}\rangle=\langle\mathbf{v},T\mathbf{w}\rangle=\langle\mathbf{v},S\mathbf{w}\rangle$ for $\mathbf{v},\mathbf{w}\in E^\perp$. By Lemma 8.2.10 (the second use of self-adjointness, replacing the existence of eigenvalues over $\mathbb{C}$), S has an eigenvector $\mathbf{w}\in E^\perp$. It is an eigenvector of T, so $\mathbf{w}\in E\cap E^\perp=\{\mathbf{0}\}$, a contradiction. So $E^\perp=\{\mathbf{0}\}$ and $E=V$ by Corollary 6.4.27.

For $\mathbf{u}\in E_\lambda$ and $\mathbf{v}\in E_\mu$ with $\lambda\neq\mu$, $\lambda\langle\mathbf{u},\mathbf{v}\rangle=\langle T\mathbf{u},\mathbf{v}\rangle=\langle\mathbf{u},T\mathbf{v}\rangle=\mu\langle\mathbf{u},\mathbf{v}\rangle$ (the third use; the eigenvalues are real), so $\langle\mathbf{u},\mathbf{v}\rangle=0$. Concatenating orthonormal bases of the eigenspaces (Theorem 6.4.20) gives an orthonormal list spanning $E=V$, which is an orthonormal eigenbasis.

Solution to Exercise 8.2.47

Uses. Corollary 8.2.7 (Hermitian matrices), Theorem 8.2.5 (Complex spectral theorem), Proposition 8.2.24 (Properties of $f(T)$), Exercise 8.2.33
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. Write $H=UDU^*$ with D real diagonal. What are the eigenvalues of $I+iH$?
Hint 2. $C=f(H)$ for $f(\lambda)=(1-i\lambda)/(1+i\lambda)$. What is $|f(\lambda)|$ for real λ?
Hint 3. For (c), solve $z=(1-i\lambda)/(1+i\lambda)$ for λ, and apply that function to C, which is normal.
Sketch. (a) The eigenvalues of $I+iH$ are $1+i\lambda_j\neq 0$. (b) $C=Uf(D)U^*$ with $f(\lambda)=(1-i\lambda)/(1+i\lambda)$; for real λ, $|f(\lambda)|=1$ and $f(\lambda)\neq -1$; so $C^*C=I$. (c) C is normal with eigenvalues z on the unit circle, $z\neq -1$; $g(z)=i(z-1)/(z+1)$ is real there and inverts f, so $H=g(C)$ is Hermitian with $f(H)=C$. Uniqueness: $H=g(f(H))$.

By Corollary 8.2.7, $H=UDU^*$ with U unitary and $D=\operatorname{diag}(\lambda_1,\ldots,\lambda_n)$ real.

(a) $I_n+iH=U(I_n+iD)U^*$, and I_n+iD is diagonal with entries $1+i\lambda_j$, which are nonzero because λ_j is real. So I_n+iH is a product of invertible matrices.

(b) Let $f(\lambda)=(1-i\lambda)/(1+i\lambda)$ for $\lambda\in\mathbb{R}$. With the matrix form of Definition 8.2.23, $(I_n-iH)(I_n+iH)^{-1}=U(I_n-iD)(I_n+iD)^{-1}U^*=Uf(D)U^*=f(H)$. For real λ, $1-i\lambda=\overline{1+i\lambda}$, so $|f(\lambda)|=1$; and $f(\lambda)=-1$ would mean $1-i\lambda=-1-i\lambda$, which is impossible. So $C=Uf(D)U^*$ with $f(D)$ diagonal, unimodular entries, and $C^*C=U\overline{f(D)}f(D)U^*=I_n$: C is unitary, and its eigenvalues $f\left(\lambda_j\right)$ are not -1.

(c) Let C be unitary with no eigenvalue -1. Then $C^*C=I_n=CC^*$, so C is normal, and by Theorem 8.2.5, $C=VZV^*$ with V unitary and $Z=\operatorname{diag}(z_1,\ldots,z_n)$; $\left|z_j\right|=1$ by Exercise 8.2.33(d), and $z_j\neq -1$. Let $g(z)=i(z-1)/(z+1)$. For $|z|=1$, $\overline{z}=1/z$, so

$$\overline{g(z)} = -i\frac{1/z - 1}{1/z + 1} = -i\frac{1 - z}{1 + z} = g(z),$$

and $g(z)$ is real. Solving $z = (1 - i\lambda)/(1 + i\lambda)$ for λ gives $z + i\lambda z = 1 - i\lambda$, so $\lambda = i(z - 1)/(z + 1) = g(z)$: thus $f(g(z)) = z$ and $g(f(\lambda)) = \lambda$. Let $H = g(C) = Vg(Z)V^*$. It is Hermitian since $g(Z)$ is real diagonal, and $f(H) = Vf(g(Z))V^* = VZV^* = C$. For uniqueness, if $f(H') = C$ with H' Hermitian, $H' = U'D'U'^*$, then $C = U'f(D')U'^*$, and $g(C) = U'g(f(D'))U'^* = H'$ (the matrix $f(D')$ is a diagonalization of C, and $g(C)$ does not depend on the choice). So $H' = g(C) = H$.

Solution to Exercise 8.2.48

Uses. Theorem 8.2.5 (Complex spectral theorem), Exercise 8.2.45, Proposition 7.3.34 (Eigenvalues of a complexification), Exercise 6.6.38, Theorem 6.4.20 (Orthonormal bases exist), Theorem 4.5.17 (Change of basis)
Techniques. Complexify, then take real and imaginary parts (Technique 7.3.35), Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Induct on n. If A has a real eigenvalue, split off a line as in the second proof of Theorem 8.2.5; it works over $\mathbb{R}$ for a real eigenvector.
Hint 2. Otherwise take a complex eigenvector $\mathbf{z} = \mathbf{x} + i\mathbf{y}$ of A for $\lambda = a + bi$, $b \neq 0$. Since A is normal as a complex matrix, $A^{\mathsf{T}}\mathbf{z} = A^*\mathbf{z} = \overline{\lambda}\mathbf{z}$. Take real and imaginary parts.
Hint 3. $U = \operatorname{span}(\mathbf{x}, \mathbf{y})$ is a plane invariant under A and A^{T}, so $U^\perp$ is too. The restriction of T_A to U, in an orthonormal basis of U, is a real normal 2×2 matrix without real eigenvalues. Use Exercise 8.2.45.
Sketch. Induction on n, splitting off an invariant subspace U of dimension 1 or 2 that is invariant under both A and A^{T}; then $U^\perp$ is invariant under both, and both restrictions are normal. A real eigenvector gives U of dimension 1. Otherwise a complex eigenvector $\mathbf{x} + i\mathbf{y}$ for $a + bi$ ($b \neq 0$) is also an eigenvector of $A^* = A^{\mathsf{T}}$ for $a - bi$, and comparing real and imaginary parts shows $U = \operatorname{span}(\mathbf{x}, \mathbf{y})$ is invariant under A and A^{T}. In an orthonormal basis of U, the restriction is normal with no real eigenvalue, hence of the form $\left(\begin{smallmatrix} a' & -b' \\ b' & a' \end{smallmatrix}\right)$ (Exercise 8.2.45); replacing the second basis vector by its negative makes $b' > 0$.

We prove the statement for normal operators T on finite-dimensional real inner product spaces V (with "orthonormal basis" in place of Q), by strong induction on $\dim V$; for A apply it to T_A on $\mathbb{R}^n$ and let Q have the basis as columns (Theorem 4.5.17). Dimension 0 is trivial. Suppose $\dim V = n \geq 1$. It suffices to find a subspace $U \neq \{\mathbf{0}\}$ of dimension 1 or 2 that is invariant under T and T^*, and an orthonormal basis of U in which $T{\restriction}_U$ has a block of the required form. Indeed, then $W = U^\perp$ is invariant under T and T^* (Exercise 6.6.38 applied to T and to T^*), $T{\restriction}_W$ is normal with adjoint $T^*{\restriction}_W$ (as in the second proof of Theorem 8.2.5), and the induction hypothesis applies to it; the two orthonormal bases together give the required basis of $V = U \oplus W$.

Case 1: T has a real eigenvalue λ. Let $\mathbf{u}$ be a unit eigenvector. The computation $\|(T - \lambda\,\mathrm{id})\mathbf{v}\| = \|(T^* - \lambda\,\mathrm{id})\mathbf{v}\|$ from the second proof of Theorem 8.2.5 works over $\mathbb{R}$, so $T^*\mathbf{u} = \lambda\mathbf{u}$, and $U = \operatorname{span}(\mathbf{u})$ is invariant under T and T^*, with 1×1 block (λ).

Case 2: T has no real eigenvalue. Choose an orthonormal basis $\mathcal{O}$ of V and let $M = [T]_{\mathcal{O}} \in \mathbb{R}^{n \times n}$; then $M^{\mathsf{T}} = [T^*]_{\mathcal{O}}$ and M is normal. As a complex matrix, $M^* = M^{\mathsf{T}}$, so M is normal in $\mathbb{C}^{n \times n}$, and it has an eigenvalue $\lambda = a + bi$ with eigenvector $\mathbf{z} = \mathbf{x} + i\mathbf{y}$, $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$; $b \neq 0$ by assumption. By the second proof of Theorem 8.2.5, $M^{\mathsf{T}}\mathbf{z} = M^*\mathbf{z} = \overline{\lambda}\mathbf{z}$. Comparing real and imaginary parts of $M\mathbf{z} = \lambda\mathbf{z}$ and $M^{\mathsf{T}}\mathbf{z} = \overline{\lambda}\mathbf{z}$ (as in Proposition 7.3.34),

$$M\mathbf{x} = a\mathbf{x} - b\mathbf{y}, \quad M\mathbf{y} = b\mathbf{x} + a\mathbf{y}, \quad M^{\mathsf{T}}\mathbf{x} = a\mathbf{x} + b\mathbf{y}, \quad M^{\mathsf{T}}\mathbf{y} = -b\mathbf{x} + a\mathbf{y}.$$

So $U_0 = \operatorname{span}(\mathbf{x}, \mathbf{y})$ is invariant under M and M^{T}, and it has dimension 2 by Proposition 7.3.34(c). Let $U \subseteq V$ be the corresponding subspace (the vectors whose $\mathcal{O}$-coordinates lie in U_0); it is invariant under T and T^*. Let $\mathbf{f}_1, \mathbf{f}_2$ be an orthonormal basis of U and $N = [T{\restriction}_U]_{\mathbf{f}_1, \mathbf{f}_2} \in \mathbb{R}^{2\times 2}$. Since $T{\restriction}_U$ is normal with adjoint $T^*{\restriction}_U$, N is normal (Theorem 6.6.15). It has no real eigenvalue, since T has none, so by Exercise 8.2.45, $N = \left(\begin{smallmatrix} a' & -b' \\ b' & a' \end{smallmatrix}\right)$ with $b' \neq 0$. If $b' < 0$, replace $\mathbf{f}_2$ by $-\mathbf{f}_2$, which changes the signs of the off-diagonal entries. This gives the required block.

Section 8.3

Solution to Exercise 8.3.7

Uses. Theorem 8.3.5 (Characterizations of positive operators), Definition 8.3.1 (Positive operator)
Hint 1. First check self-adjointness. For the symmetric ones, compute the eigenvalues from the trace and the determinant.
Hint 2. For (c), try to write $\mathbf{x}^* A\mathbf{x}$ as $|\cdots|^2$, or A as B^*B with B a 1×2 matrix.
Sketch. (a) Positive: eigenvalues $4, 2$. (b) Not positive: eigenvalues $4, -2$, and $\mathbf{x} = (1,-1)$ gives -4. (c) Positive: $A = B^*B$ for $B = \begin{pmatrix}1 & i\end{pmatrix}$, so $\mathbf{x}^*A\mathbf{x} = |x_1 + ix_2|^2$. (d) and (e) are not symmetric, so not positive, although $\mathbf{x}^{\mathsf{T}}A\mathbf{x} = 2\|\mathbf{x}\|^2 \geq 0$ in (e).

(a) The matrix is symmetric with trace 6 and determinant 8, so its eigenvalues are 4 and 2 (the roots of $x^2 - 6x + 8$). Both are nonnegative, so it is positive by Theorem 8.3.5(II).

(b) The matrix is symmetric, but its eigenvalues are the roots of $x^2 - 2x - 8$, namely 4 and -2. So it is not positive; concretely, $\mathbf{x} = (1,-1)$ gives $\mathbf{x}^{\mathsf{T}}A\mathbf{x} = 1 - 3 - 3 + 1 = -4 < 0$.

(c) Let $B = \begin{pmatrix}1 & i\end{pmatrix} \in \mathbb{C}^{1\times 2}$. Then

$$B^*B = \begin{pmatrix}1\\ -i\end{pmatrix}\begin{pmatrix}1 & i\end{pmatrix} = \begin{pmatrix}1 & i\\ -i & -i\cdot i\end{pmatrix} = \begin{pmatrix}1 & i\\ -i & 1\end{pmatrix},$$

so the matrix is positive by Theorem 8.3.5(VI). Explicitly, $\mathbf{x}^*A\mathbf{x} = |B\mathbf{x}|^2 = |x_1 + ix_2|^2 \geq 0$. Its eigenvalues are 0 and 2.

(d) The matrix is not symmetric, so it is not positive. (Also $\mathbf{x}^{\mathsf{T}}A\mathbf{x} = x_1x_2$, which is -1 at $\mathbf{x} = (1,-1)$.)

(e) Here $\mathbf{x}^{\mathsf{T}}A\mathbf{x} = 2x_1^2 + x_1x_2 - x_2x_1 + 2x_2^2 = 2\|\mathbf{x}\|^2 \geq 0$ for every $\mathbf{x} \in \mathbb{R}^2$, but the matrix is not symmetric, so it is not positive (Remark 8.3.4).

Solution to Exercise 8.3.12

Uses. Theorem 8.3.9 (The positive square root), Proposition 8.2.20 (Spectral projections are polynomials in T)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. The eigenvalues of A are 9 and 1, with eigenvectors $(1,-1)$ and $(1,1)$.
Hint 2. For (b), A is a positive square root of A^2, while B has eigenvalues 3 and -1.
Sketch. (a) $P_9 = \frac{1}{2}\begin{pmatrix}1 & -1\\ -1 & 1\end{pmatrix}$, $P_1 = \frac{1}{2}\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}$, $\sqrt{A} = 3P_9 + P_1 = \begin{pmatrix}2 & -1\\ -1 & 2\end{pmatrix}$; $B^2 = \begin{pmatrix}5 & -4\\ -4 & 5\end{pmatrix}$. (b) A is positive and squares to A^2, so $\sqrt{A^2} = A$ by uniqueness. $B^2 = A$, so $\sqrt{B^2} = \sqrt{A} = \begin{pmatrix}2 & -1\\ -1 & 2\end{pmatrix} \neq B$; B is not positive.

(a) $p_A = (x-5)^2 - 16 = (x-9)(x-1)$. By Proposition 8.2.20,

$$P_9 = \frac{A - I_2}{8} = \frac{1}{2}\begin{pmatrix}1 & -1\\ -1 & 1\end{pmatrix}, \quad P_1 = \frac{A - 9I_2}{-8} = \frac{1}{2}\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix},$$

so by Theorem 8.3.9,

$$\sqrt{A} = 3P_9 + 1P_1 = \frac{1}{2}\begin{pmatrix}3+1 & -3+1\\ -3+1 & 3+1\end{pmatrix} = \begin{pmatrix}2 & -1\\ -1 & 2\end{pmatrix}.$$

Check: $\begin{pmatrix}2 & -1\\ -1 & 2\end{pmatrix}^2 = \begin{pmatrix}4+1 & -2-2\\ -2-2 & 1+4\end{pmatrix} = A$. Also $B^2 = \begin{pmatrix}1+4 & -2-2\\ -2-2 & 4+1\end{pmatrix} = A$.

(b) A is positive (its eigenvalues are 9 and 1) and $A^2 = A^2$, so A is a positive square root of A^2, and by uniqueness $\sqrt{A^2} = A$. On the other hand $B^2 = A$, so $\sqrt{B^2} = \sqrt{A} = \begin{pmatrix}2 & -1\\ -1 & 2\end{pmatrix} \neq B$. The difference is that B is not positive: $B = 3P_9 - P_1$ has the eigenvalue -1. In general $\sqrt{S^2} = S$ for positive S, and for a self-adjoint S the operator $\sqrt{S^2}$ replaces each eigenvalue of S by its absolute value (Exercise 8.3.37).

Solution to Exercise 8.3.18

Uses. Theorem 8.3.5 (Characterizations of positive operators), Proposition 8.3.15 (Characterizations of positive definite operators)
Hint 1. The eigenvalues of A_t are real. Their sum is 5 and their product is $4 - t^2$.
Hint 2. Alternatively, complete the square in $x^2 + 2txy + 4y^2$.

Sketch. Both eigenvalues are ≥ 0 if and only if their sum 5 and product $4 - t^2$ are ≥ 0: positive for $|t| \leq 2$. Positive definite iff both > 0, iff $|t| < 2$. Or: $x^2 + 2txy + 4y^2 = (x + ty)^2 + (4 - t^2)y^2$.

A_t is symmetric, so its eigenvalues λ_1, λ_2 are real, with $\lambda_1 + \lambda_2 = \operatorname{tr} A_t = 5$ and $\lambda_1\lambda_2 = \det A_t = 4 - t^2$. Two real numbers with a positive sum are both nonnegative exactly when their product is nonnegative, and both positive exactly when their product is positive. So by Theorem 8.3.5 and Proposition 8.3.15, A_t is positive if and only if $|t| \leq 2$, and positive definite if and only if $|t| < 2$.

The same answer comes from completing the square:

$$(x, y)A_t\begin{pmatrix} x \\ y \end{pmatrix} = x^2 + 2txy + 4y^2 = (x + ty)^2 + (4 - t^2)y^2.$$

If $|t| \leq 2$ this is ≥ 0, and if $|t| < 2$ it is 0 only when $y = 0$ and $x + ty = 0$, that is, at $(0, 0)$. If $|t| > 2$, then $(x, y) = (-t, 1)$ gives $4 - t^2 < 0$. At $t = \pm 2$, the vector $(-t, 1) \neq \mathbf{0}$ gives 0.

Solution to Exercise 8.3.28

Uses. Definition 8.3.1 (Positive operator), Proposition 6.6.18 (Properties of the adjoint)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. Check the two conditions of Definition 8.3.1 directly. For (b), move X across the inner product.
Hint 2. For (c), write $T^{2k} = \left(T^k\right)^* \mathrm{id}_V T^k$ and $T^{2k+1} = \left(T^k\right)^* TT^k$, and use (b).
Hint 3. For (d), substitute $\mathbf{v} = T\mathbf{w}$ in $\left\langle T^{-1}\mathbf{v}, \mathbf{v}\right\rangle$.
Sketch. (a) Sums and real multiples of self-adjoint operators are self-adjoint, and the forms add and scale. (b) $\langle X^*TX\mathbf{u}, \mathbf{u}\rangle = \langle TX\mathbf{u}, X\mathbf{u}\rangle \geq 0$. (c) T^k is self-adjoint, and $T^{2k} = \left(T^k\right)^* \mathrm{id}_V T^k$, $T^{2k+1} = \left(T^k\right)^* TT^k$ are positive by (b). (d) $\left(T^{-1}\right)^* = (T^*)^{-1} = T^{-1}$ and $\left\langle T^{-1}\mathbf{v}, \mathbf{v}\right\rangle = \langle \mathbf{w}, T\mathbf{w}\rangle \geq 0$ for $\mathbf{w} = T^{-1}\mathbf{v}$.

(a) By Proposition 6.6.18, $(S + T)^* = S + T$ and $(cT)^* = \bar{c}T = cT$, as c is real. For every $\mathbf{v}$, $\langle (S + T)\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, \mathbf{v}\rangle + \langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ and $\langle cT\mathbf{v}, \mathbf{v}\rangle = c\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$.

(b) $(X^*TX)^* = X^*T^*X^{**} = X^*TX$ by Proposition 6.6.18, and for $\mathbf{u} \in U$, $\langle X^*TX\mathbf{u}, \mathbf{u}\rangle = \langle TX\mathbf{u}, X\mathbf{u}\rangle \geq 0$.

(c) For $m = 0$, $T^0 = \mathrm{id}_V$ is positive. By Proposition 6.6.18(d) and induction, $\left(T^k\right)^* = (T^*)^k = T^k$. If $m = 2k$, then $T^m = \left(T^k\right)^* \mathrm{id}_V T^k$, which is positive by (b) applied to the positive operator id_V and $X = T^k$. If $m = 2k + 1$, then $T^m = \left(T^k\right)^* TT^k$, positive by (b) with $X = T^k$. (Alternatively, $T^m = \sum_j \lambda_j^m P_j$ has the nonnegative eigenvalues λ_j^m, by Proposition 8.2.24.)

(d) By Proposition 6.6.18(f), $\left(T^{-1}\right)^* = (T^*)^{-1} = T^{-1}$. For $\mathbf{v} \in V$, let $\mathbf{w} = T^{-1}\mathbf{v}$. Then

$$\left\langle T^{-1}\mathbf{v}, \mathbf{v}\right\rangle = \langle \mathbf{w}, T\mathbf{w}\rangle = \overline{\langle T\mathbf{w}, \mathbf{w}\rangle} = \langle T\mathbf{w}, \mathbf{w}\rangle \geq 0,$$

since $\langle T\mathbf{w}, \mathbf{w}\rangle$ is a nonnegative real number.

Solution to Exercise 8.3.29

Uses. Theorem 8.3.5 (Characterizations of positive operators), Definition 8.3.1 (Positive operator), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (a), the diagonal entries are nonnegative in orthonormal bases. Try $T = \mathrm{diag}(0, 1)$ on $\mathbb{R}^2$ and a basis that is far from orthogonal.
Hint 2. For (b) and (c), compare the eigenvalues of T with those of T^3 and T^2.
Hint 3. For (d), try a projection and a matrix of ones in $\mathbb{R}^{2\times 2}$. For (e), real test vectors cannot see an imaginary part: try $A = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}$.
Sketch. (a) False: $T = \mathrm{diag}(0, 1)$ and $\mathcal{B} = (1, 1), (1, 2)$ give $[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} -1 & -2 \\ 1 & 2 \end{pmatrix}$. (b) True: an eigenvalue λ of T gives the eigenvalue $\lambda^3 \geq 0$ of T^3, so $\lambda \geq 0$. (c) False: $T = -\mathrm{id}_V$. (d) False: $S = \mathrm{diag}(1, 0)$, $T = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ give $\begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}$, with determinant -1. (e) False: $\begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}$ vanishes on real vectors but has the eigenvalue -1.

(a) False. Let $T = T_A$ on $\mathbb{R}^2$ with $A = \mathrm{diag}(0, 1)$, which is positive, and let $\mathcal{B} = \mathbf{b}_1, \mathbf{b}_2$ with $\mathbf{b}_1 = (1, 1)$, $\mathbf{b}_2 = (1, 2)$. Then $T\mathbf{b}_1 = (0, 1) = -\mathbf{b}_1 + \mathbf{b}_2$ and $T\mathbf{b}_2 = (0, 2) = -2\mathbf{b}_1 + 2\mathbf{b}_2$, so

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} -1 & -2 \\ 1 & 2 \end{pmatrix},$$

whose $(1,1)$ entry is negative. For an orthonormal basis the statement is true, since the diagonal entries are $\langle T\mathbf{e}_i, \mathbf{e}_i\rangle \geq 0$.

(b) True. Let λ be an eigenvalue of T, with $T\mathbf{v} = \lambda\mathbf{v}$, $\mathbf{v} \neq \mathbf{0}$; λ is real by Proposition 8.1.1. Then $T^3\mathbf{v} = \lambda^3\mathbf{v}$, so λ^3 is an eigenvalue of the positive operator T^3, and $\lambda^3 \geq 0$ by Theorem 8.3.5. For a real number this forces $\lambda \geq 0$. So T is self-adjoint with nonnegative eigenvalues, hence positive by Theorem 8.3.5(II).

(c) False. If $\dim V \geq 1$, then $T = -\mathrm{id}_V$ is self-adjoint and $T^2 = \mathrm{id}_V$ is positive, but $\langle T\mathbf{v}, \mathbf{v}\rangle = -\|\mathbf{v}\|^2 < 0$ for $\mathbf{v} \neq \mathbf{0}$. Here the argument of (b) breaks down because $\lambda^2 \geq 0$ does not force $\lambda \geq 0$.

(d) False. Let $S = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $T = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$, both positive (a projection, and $T = \mathbf{u}\mathbf{u}^{\mathsf{T}}$ with $\mathbf{u} = (1,1)$). Then

$$ST + TS = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix},$$

and $\mathbf{x} = (1,-2)$ gives $\mathbf{x}^{\mathsf{T}}(ST+TS)\mathbf{x} = 2 - 2 - 2 + 0 = -2 < 0$.

(e) False. Let $A = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}$. Then $A^* = A$, and for real $\mathbf{x}$, $\mathbf{x}^*A\mathbf{x} = ix_1x_2 - ix_2x_1 = 0$. But $p_A = x^2 - 1$, so A has the eigenvalue -1; for instance $\mathbf{x} = (1,i)$ gives $A\mathbf{x} = (-1,-i)$ and $\mathbf{x}^*A\mathbf{x} = -1 + (-i)(-i) = -2 < 0$. Positivity of a complex matrix must be tested on complex vectors.

Solution to Exercise 8.3.30

Uses. Proposition 6.6.30 (Self-adjoint means real values), Remark 8.3.4 (Why self-adjointness is part of the definition), Corollary 6.6.28 (Self-adjointness in an orthonormal basis)
Hint 1. For (ii) $\Rightarrow$ (i), over $\mathbb{C}$ nonnegative values force self-adjointness (Proposition 6.6.30). A real Hermitian matrix is symmetric.
Hint 2. For (i) $\Rightarrow$ (ii), write $\mathbf{x} = \mathbf{u} + i\mathbf{v}$ with $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$ and expand $\mathbf{x}^*A\mathbf{x}$. Where does symmetry make the imaginary part vanish?
Hint 3. For the last part, use $B = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ of Non-example 8.3.3 and $\mathbf{x} = (1,i)$.
Sketch. (ii) $\Rightarrow$ (i): the values $\mathbf{x}^*A\mathbf{x}$ are real, so A is Hermitian, hence symmetric as it is real; restrict to real $\mathbf{x}$. (i) $\Rightarrow$ (ii): for $\mathbf{x} = \mathbf{u} + i\mathbf{v}$, $\mathbf{x}^*A\mathbf{x} = \mathbf{u}^{\mathsf{T}}A\mathbf{u} + \mathbf{v}^{\mathsf{T}}A\mathbf{v} + i\big(\mathbf{u}^{\mathsf{T}}A\mathbf{v} - \mathbf{v}^{\mathsf{T}}A\mathbf{u}\big)$, and the imaginary part is 0 by symmetry. For $B = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$, $\mathbf{x}^{\mathsf{T}}B\mathbf{x} = \|\mathbf{x}\|^2$ on $\mathbb{R}^2$ but $(1,i)^*B(1,i) = 2 - 2i$.

(ii) $\Rightarrow$ (i). All values $\mathbf{x}^*A\mathbf{x} = \langle T_A\mathbf{x}, \mathbf{x}\rangle$ on $\mathbb{C}^n$ are real, so T_A is self-adjoint on $\mathbb{C}^n$ by Proposition 6.6.30, and $A^* = A$ (Corollary 6.6.28). Since A is real, $A^* = A^{\mathsf{T}}$, so $A^{\mathsf{T}} = A$. Taking $\mathbf{x} \in \mathbb{R}^n$ in (ii) gives $\mathbf{x}^{\mathsf{T}}A\mathbf{x} \geq 0$.

(i) $\Rightarrow$ (ii). Let $\mathbf{x} = \mathbf{u} + i\mathbf{v}$ with $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$. Then $\mathbf{x}^* = \mathbf{u}^{\mathsf{T}} - i\mathbf{v}^{\mathsf{T}}$, and since A is real,

$$\mathbf{x}^*A\mathbf{x} = \mathbf{u}^{\mathsf{T}}A\mathbf{u} + \mathbf{v}^{\mathsf{T}}A\mathbf{v} + i\big(\mathbf{u}^{\mathsf{T}}A\mathbf{v} - \mathbf{v}^{\mathsf{T}}A\mathbf{u}\big).$$

The number $\mathbf{v}^{\mathsf{T}}A\mathbf{u}$ is a 1×1 matrix, so it equals its transpose $\mathbf{u}^{\mathsf{T}}A^{\mathsf{T}}\mathbf{v} = \mathbf{u}^{\mathsf{T}}A\mathbf{v}$. So the imaginary part vanishes, and $\mathbf{x}^*A\mathbf{x} = \mathbf{u}^{\mathsf{T}}A\mathbf{u} + \mathbf{v}^{\mathsf{T}}A\mathbf{v} \geq 0$.

For the last part, let $B = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$. Then $\mathbf{x}^{\mathsf{T}}B\mathbf{x} = \|\mathbf{x}\|^2 \geq 0$ for $\mathbf{x} \in \mathbb{R}^2$ (Non-example 8.3.3(b)). For $\mathbf{x} = (1,i)$, $B\mathbf{x} = (1-i, 1+i)$ and $\mathbf{x}^*B\mathbf{x} = (1-i) - i(1+i) = 2 - 2i$, which is not even real. The computation above shows exactly what was lost: without symmetry, the imaginary part $\mathbf{u}^{\mathsf{T}}A\mathbf{v} - \mathbf{v}^{\mathsf{T}}A\mathbf{u}$ need not vanish.

Solution to Exercise 8.3.31

Uses. Theorem 8.3.5 (Characterizations of positive operators), Proposition 8.3.15 (Characterizations of positive definite operators), Theorem 7.5.22 (Trace and determinant from eigenvalues)
Hint 1. A is Hermitian, so its eigenvalues λ_1, λ_2 are real, with sum $a + c$ and product $ac - |b|^2$.
Hint 2. Two real numbers are both ≥ 0 if and only if their sum and their product are ≥ 0. Then translate "$a + c \geq 0$ and $ac \geq |b|^2$" into the stated conditions.

Sketch. (a) Positive iff $\lambda_1+\lambda_2 = a+c \geq 0$ and $\lambda_1\lambda_2 = ac-|b|^2 \geq 0$. If $ac \geq |b|^2 \geq 0$, then a and c do not have opposite strict signs, so with $a+c \geq 0$ both are ≥ 0. (b) Both eigenvalues > 0 iff $ac-|b|^2 > 0$ and $a+c>0$; given the first, $a>0$ iff $c>0$ iff $a+c>0$. (c) $\operatorname{diag}(0,-1)$.

A is Hermitian, so it has real eigenvalues λ_1, λ_2 (counted with multiplicity), and by Theorem 7.5.22, $\lambda_1+\lambda_2 = a+c$ and $\lambda_1\lambda_2 = ac-|b|^2$.

(a) By Theorem 8.3.5, A is positive if and only if $\lambda_1, \lambda_2 \geq 0$. For real numbers this holds if and only if $\lambda_1+\lambda_2 \geq 0$ and $\lambda_1\lambda_2 \geq 0$: if the product is ≥ 0, the two numbers do not have opposite strict signs, and then a nonnegative sum rules out both being negative. So A is positive if and only if $a+c \geq 0$ and $ac-|b|^2 \geq 0$. These two conditions are equivalent to the three in (a). If $a, c \geq 0$, then $a+c \geq 0$. Conversely, if $ac \geq |b|^2 \geq 0$ and, say, $a<0$, then $c \leq 0$ and $a+c<0$; so $a+c \geq 0$ forces $a \geq 0$, and likewise $c \geq 0$.

(b) By Proposition 8.3.15, A is positive definite if and only if $\lambda_1, \lambda_2 > 0$, if and only if $\lambda_1\lambda_2 > 0$ and $\lambda_1+\lambda_2 > 0$, that is, $ac-|b|^2 > 0$ and $a+c>0$. If $ac > |b|^2 \geq 0$, then a and c are nonzero with the same sign, so $a+c>0$ if and only if $a>0$.

(c) $A = \operatorname{diag}(0,-1)$ has $a = 0 \geq 0$ and $\det A = 0 \geq 0$, but $\mathbf{e}_2^{\mathsf{T}} A \mathbf{e}_2 = -1 < 0$. The condition $c \geq 0$ in (a) cannot be dropped. In (b), by contrast, $a>0$ and $\det A > 0$ suffice, which is the 2×2 case of Sylvester's criterion (Section 12.3).

Solution to Exercise 8.3.31

Uses. Definition 8.3.1 (Positive operator), Definition 8.3.14 (Positive definite)
Hint 1. If $a>0$, write $\mathbf{x}^* A\mathbf{x}$ as $a|x_1+(b/a)x_2|^2 + (\det A/a)|x_2|^2$.
Hint 2. If $a=0$, positivity forces $b=0$: choose $x_2=1$ and $x_1=-tb$ with $t>0$ large.
Sketch. For $a>0$, $\mathbf{x}^*A\mathbf{x} = a|x_1+(b/a)x_2|^2 + \big((ac-|b|^2)/a\big)|x_2|^2$, which is ≥ 0 for all $\mathbf{x}$ iff $ac-|b|^2 \geq 0$, and >0 for $\mathbf{x}\neq\mathbf{0}$ iff $ac-|b|^2>0$ (test $\mathbf{x}=(-b/a,1)$). For $a=0$: $\mathbf{x}^*A\mathbf{x} = 2\operatorname{Re}(\overline{x_1}bx_2) + c|x_2|^2$ is ≥ 0 for all $\mathbf{x}$ iff $b=0$ and $c\geq 0$, and never positive definite. For $a<0$, $\mathbf{e}_1$ gives $a<0$.

Expanding, $\mathbf{x}^*A\mathbf{x} = a|x_1|^2 + 2\operatorname{Re}(\overline{x_1}bx_2) + c|x_2|^2$. We split into cases by the sign of a.

If $a<0$, then $\mathbf{e}_1^* A\mathbf{e}_1 = a<0$, so A is not positive, and the conditions in (a) and (b) fail.

If $a>0$, then expanding $a|x_1+(b/a)x_2|^2 = a|x_1|^2 + 2\operatorname{Re}(\overline{x_1}bx_2) + \big(|b|^2/a\big)|x_2|^2$ gives

$$\mathbf{x}^*A\mathbf{x} = a\left|x_1+\frac{b}{a}x_2\right|^2 + \frac{ac-|b|^2}{a}|x_2|^2.$$

If $ac-|b|^2 \geq 0$, this is ≥ 0; and if $ac-|b|^2>0$, it is 0 only when $x_2=0$ and $x_1+(b/a)x_2=0$, that is, $\mathbf{x}=\mathbf{0}$. Conversely, $\mathbf{x}=(-b/a,1)\neq\mathbf{0}$ gives the value $\big(ac-|b|^2\big)/a$, which must be ≥ 0 if A is positive and >0 if A is positive definite. Also $c\geq 0$ follows from $ac\geq|b|^2\geq 0$.

If $a=0$, then A is not positive definite ($\mathbf{e}_1^*A\mathbf{e}_1=0$), and the condition in (b) fails. If $b\neq 0$, take $x_2=1$ and $x_1=-tb$ with $t>0$: the value is $-2t|b|^2+c$, which is negative for large t; and indeed $ac-|b|^2 = -|b|^2 < 0$. If $b=0$, then $\mathbf{x}^*A\mathbf{x} = c|x_2|^2$, which is ≥ 0 for all $\mathbf{x}$ if and only if $c\geq 0$. In every case A is positive exactly when $a\geq 0$, $c\geq 0$, and $ac-|b|^2\geq 0$, which proves (a) and (b). For (c), see the first solution.

Solution to Exercise 8.3.32

Uses. Theorem 8.3.5 (Characterizations of positive operators), Theorem 6.2.1 (Cauchy–Schwarz inequality), Theorem 8.3.9 (The positive square root)
Techniques. Gram matrices (Technique 6.3.31), Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. By the proof of Theorem 8.3.5, A is the Gram matrix of $\sqrt{T}\mathbf{e}_1, \ldots, \sqrt{T}\mathbf{e}_n$.
Hint 2. Apply Cauchy–Schwarz to $a_{ij} = \langle \sqrt{T}\mathbf{e}_j, \sqrt{T}\mathbf{e}_i\rangle$.
Sketch. $a_{ij} = \langle \mathbf{w}_j, \mathbf{w}_i\rangle$ with $\mathbf{w}_i = \sqrt{T}\mathbf{e}_i$, so $a_{ii} = \|\mathbf{w}_i\|^2$ and Cauchy–Schwarz gives (a). (b) $|a_{ij}|^2 \leq 0$, and $a_{ji} = \overline{a_{ij}}$. (c) $|a_{ij}| \leq \sqrt{a_{ii}a_{jj}} \leq \max(a_{ii}, a_{jj})$.

(a) Let $\mathbf{w}_i = \sqrt{T}\mathbf{e}_i$. Since $\sqrt{T}$ is self-adjoint, $a_{ij} = \langle T\mathbf{e}_j, \mathbf{e}_i\rangle = \langle \sqrt{T}\mathbf{e}_j, \sqrt{T}\mathbf{e}_i\rangle = \langle \mathbf{w}_j, \mathbf{w}_i\rangle$, and in particular $a_{ii} = \|\mathbf{w}_i\|^2$. By Cauchy–Schwarz (Theorem 6.2.1),

$$|a_{ij}|^2 = |\langle \mathbf{w}_j, \mathbf{w}_i\rangle|^2 \le \|\mathbf{w}_j\|^2\|\mathbf{w}_i\|^2 = a_{jj}a_{ii}.$$

(b) If $a_{ii} = 0$, then $|a_{ij}|^2 \le 0$, so $a_{ij} = 0$ for every j: row i is zero. Since A is Hermitian, $a_{ji} = \overline{a_{ij}} = 0$, so column i is zero too.

(c) The diagonal entries are nonnegative reals. For all i, j, by (a),

$$|a_{ij}| \le \sqrt{a_{ii}a_{jj}} \le \max(a_{ii}, a_{jj}) \le \max_k a_{kk},$$

and $\max_k a_{kk}$ is itself one of the numbers $|a_{ij}|$.

Solution to Exercise 8.3.32

Uses. Theorem 8.3.5 (Characterizations of positive operators), Exercise 8.3.31, Proposition 6.3.18 (Coordinates in an orthonormal basis)
Techniques. Gram matrices (Technique 6.3.31), Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. Restrict the form $\langle T\mathbf{v}, \mathbf{v}\rangle$ to vectors $\mathbf{v} = x\mathbf{e}_i + y\mathbf{e}_j$ with $i \ne j$.
Hint 2. The matrix $\begin{pmatrix} a_{ii} & a_{ij} \\ a_{ji} & a_{jj}\end{pmatrix}$ is then positive, and Exercise 8.3.31 applies.
Sketch. For $i \ne j$ and $\mathbf{v} = x\mathbf{e}_i + y\mathbf{e}_j$, $\langle T\mathbf{v}, \mathbf{v}\rangle = (x, y)^* A_{ij}(x, y)$ with $A_{ij} = \begin{pmatrix} a_{ii} & a_{ij} \\ a_{ji} & a_{jj}\end{pmatrix}$, which is therefore positive (and Hermitian). By Exercise 8.3.31, $a_{ii}a_{jj} - |a_{ij}|^2 \ge 0$. For $i = j$ the inequality is $a_{ii}^2 \le a_{ii}^2$.

(a) For $i = j$ there is nothing to prove. Let $i \ne j$, and for $(x, y) \in \mathbb{F}^2$ let $\mathbf{v} = x\mathbf{e}_i + y\mathbf{e}_j$. Since $a_{kl} = \langle T\mathbf{e}_l, \mathbf{e}_k\rangle$,

$$\langle T\mathbf{v}, \mathbf{v}\rangle = \overline{x}a_{ii}x + \overline{x}a_{ij}y + \overline{y}a_{ji}x + \overline{y}a_{jj}y = \begin{pmatrix} x \\ y\end{pmatrix}^* \begin{pmatrix} a_{ii} & a_{ij} \\ a_{ji} & a_{jj}\end{pmatrix}\begin{pmatrix} x \\ y\end{pmatrix}.$$

The 2×2 matrix is Hermitian (as A is) and the left side is ≥ 0, so it is positive, and Exercise 8.3.31(a) gives $a_{ii}a_{jj} - |a_{ij}|^2 \ge 0$. Parts (b) and (c) follow as in the first solution.

Solution to Exercise 8.3.33

Uses. Theorem 8.3.9 (The positive square root), Theorem 6.2.1 (Cauchy–Schwarz inequality), Theorem 4.2.11 (Rank–nullity), Lemma 8.3.8 (Where the form vanishes)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. Write $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \sqrt{T}\mathbf{v}, \sqrt{T}\mathbf{w}\rangle$ and apply Cauchy–Schwarz.
Hint 2. For (b), take $\mathbf{w} = T\mathbf{v}$ in (a).
Hint 3. For (c), $\langle T\mathbf{v}, \mathbf{v}\rangle = \|\sqrt{T}\mathbf{v}\|^2$. For the images, one inclusion is clear and rank–nullity does the rest.
Sketch. (a) $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \sqrt{T}\mathbf{v}, \sqrt{T}\mathbf{w}\rangle$, and $\|\sqrt{T}\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle$. (b) With $\mathbf{w} = T\mathbf{v}$: $\|T\mathbf{v}\|^4 \le \langle T\mathbf{v}, \mathbf{v}\rangle\langle T^2\mathbf{v}, T\mathbf{v}\rangle$, which is 0 if $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$. (c) $\sqrt{T}\mathbf{v} = \mathbf{0} \Rightarrow T\mathbf{v} = \mathbf{0}$, and $T\mathbf{v} = \mathbf{0} \Rightarrow \|\sqrt{T}\mathbf{v}\|^2 = 0$. $\operatorname{im} T = \operatorname{im}(\sqrt{T}\sqrt{T}) \subseteq \operatorname{im}\sqrt{T}$, with equal dimensions.

Let $R = \sqrt{T}$, which is self-adjoint with $R^2 = T$ (Theorem 8.3.9). For all $\mathbf{v}, \mathbf{w}$, $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle R\mathbf{v}, R\mathbf{w}\rangle$, and in particular $\langle T\mathbf{v}, \mathbf{v}\rangle = \|R\mathbf{v}\|^2$.

(a) By Cauchy–Schwarz (Theorem 6.2.1),

$$|\langle T\mathbf{v}, \mathbf{w}\rangle|^2 = |\langle R\mathbf{v}, R\mathbf{w}\rangle|^2 \le \|R\mathbf{v}\|^2\|R\mathbf{w}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle\langle T\mathbf{w}, \mathbf{w}\rangle.$$

(b) Suppose $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$, and take $\mathbf{w} = T\mathbf{v}$ in (a):

$$\|T\mathbf{v}\|^4 = |\langle T\mathbf{v}, T\mathbf{v}\rangle|^2 \le \langle T\mathbf{v}, \mathbf{v}\rangle\langle T^2\mathbf{v}, T\mathbf{v}\rangle = 0.$$

So $T\mathbf{v} = \mathbf{0}$. (This proof uses $\sqrt{T}$ through (a); one can also prove (a) without it, by applying the argument of Theorem 6.2.1 to the form $(\mathbf{v}, \mathbf{w}) \mapsto \langle T\mathbf{v}, \mathbf{w}\rangle$.)

(c) If $R\mathbf{v} = \mathbf{0}$, then $T\mathbf{v} = R(R\mathbf{v}) = \mathbf{0}$. If $T\mathbf{v} = \mathbf{0}$, then $\|R\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle = 0$, so $R\mathbf{v} = \mathbf{0}$. Hence $\ker R = \ker T$. Next, $\operatorname{im} T = \operatorname{im}(RR) \subseteq \operatorname{im} R$, and by rank–nullity (Theorem 4.2.11) $\dim\operatorname{im} T = \dim V - \dim\ker T = \dim V - \dim\ker R = \dim\operatorname{im} R$. A subspace of $\operatorname{im} R$ with the same dimension is all of $\operatorname{im} R$ (Proposition 4.1.21), so $\operatorname{im} T = \operatorname{im} R$.

Solution to Exercise 8.3.34

Uses. Theorem 8.3.5 (Characterizations of positive operators), Proposition 7.5.25 (Cyclicity of the trace for linear maps), Theorem 8.3.9 (The positive square root), Exercise 8.3.28, Proposition 6.6.18 (Properties of the adjoint)
Techniques. Sandwich between square roots (Technique 8.3.19), Cyclicity of trace (Technique 2.4.29)
Hint 1. For (a), compute tr and det in an orthonormal eigenbasis.
Hint 2. For (b), $\operatorname{tr}(ST) = \operatorname{tr}\big(\sqrt{S}\big(\sqrt{S}T\big)\big) = \operatorname{tr}\big(\sqrt{S}T\sqrt{S}\big)$, and $\sqrt{S}T\sqrt{S}$ is positive.
Hint 3. For (c), if $\sqrt{S}T\sqrt{S} = 0$, then $\big(\sqrt{T}\sqrt{S}\big)^*\big(\sqrt{T}\sqrt{S}\big) = 0$. Deduce $TS = 0$ and take adjoints.
Sketch. (a) $[T]_{\mathcal{O}} = \operatorname{diag}(d_i)$ with $d_i \geq 0$, so $\operatorname{tr} T = \sum d_i \geq 0$, $\det T = \prod d_i \geq 0$, and $\operatorname{tr} T = 0$ forces all $d_i = 0$. (b) By cyclicity $\operatorname{tr}(ST) = \operatorname{tr}(C)$ with $C = \sqrt{S}T\sqrt{S}$ positive. (c) If $\operatorname{tr} C = 0$, then $C = 0$ by (a). Since $C = M^*M$ with $M = \sqrt{T}\sqrt{S}$, $\|M\mathbf{v}\|^2 = \langle C\mathbf{v}, \mathbf{v}\rangle = 0$, so $M = 0$, $TS = \sqrt{T}M\sqrt{S} = 0$, and $ST = (TS)^* = 0$.

(a) By Theorem 8.3.5(III), $[T]_{\mathcal{O}} = \operatorname{diag}(d_1, \ldots, d_n)$ with every $d_i \geq 0$ for some orthonormal basis $\mathcal{O}$. So $\operatorname{tr} T = \sum_i d_i \geq 0$ and $\det T = \prod_i d_i \geq 0$. If $\operatorname{tr} T = 0$, then every $d_i = 0$, so $[T]_{\mathcal{O}} = 0$ and $T = 0$.

(b) By Proposition 7.5.25, $\operatorname{tr}\big(\sqrt{S}\big(\sqrt{S}T\big)\big) = \operatorname{tr}\big(\big(\sqrt{S}T\big)\sqrt{S}\big)$, so $\operatorname{tr}(ST) = \operatorname{tr}(C)$ with $C = \sqrt{S}T\sqrt{S}$. Since $\sqrt{S}$ is self-adjoint, $C = \big(\sqrt{S}\big)^* T\sqrt{S}$ is positive by Exercise 8.3.28(b). By (a), $\operatorname{tr}(ST) = \operatorname{tr} C \geq 0$.

(c) If $ST = 0$, then $\operatorname{tr}(ST) = 0$. Conversely, suppose $\operatorname{tr}(ST) = 0$. Then $\operatorname{tr} C = 0$, so $C = 0$ by (a). Let $M = \sqrt{T}\sqrt{S}$. Since $\sqrt{S}$ and $\sqrt{T}$ are self-adjoint, $M^*M = \sqrt{S}\sqrt{T}\sqrt{T}\sqrt{S} = C = 0$, so $\|M\mathbf{v}\|^2 = \langle M^*M\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$, and $M = 0$. Then $TS = \sqrt{T}\big(\sqrt{T}\sqrt{S}\big)\sqrt{S} = \sqrt{T}M\sqrt{S} = 0$, and $ST = S^*T^* = (TS)^* = 0$ by Proposition 6.6.18.

Solution to Exercise 8.3.35

Uses. Proposition 8.3.15 (Characterizations of positive definite operators), Proposition 6.1.13 (Integral inner products), Definition 6.3.28 (Gram matrix), Proposition 7.1.22 (Counting roots), Theorem 7.5.22 (Trace and determinant from eigenvalues)
Techniques. Gram matrices (Technique 6.3.31)
Hint 1. Look for functions $f_1, \ldots, f_n$ on $[0,1]$ with $\int_0^1 f_i(t) f_j(t)\,\mathrm{d}t = 1/(i+j-1)$.
Hint 2. $f_i(t) = t^{i-1}$ works for H_n. For K_n you need $\int_0^1 f_i f_j = 1/(i+j)$; try $f_i(t) = t^{i-1/2}$.
Hint 3. A Gram matrix of a linearly independent list is positive definite (Proposition 8.3.15). Independence comes down to a polynomial with infinitely many roots.
Sketch. (a) H_n is the Gram matrix of $1, t, \ldots, t^{n-1}$ in $C[0,1]$ with $\langle f, g\rangle = \int_0^1 fg$, an independent list, so it is positive definite and $\det H_n$ is a product of positive eigenvalues. (b) K_n is the Gram matrix of $t^{1/2}, t^{3/2}, \ldots, t^{n-1/2}$; if $\sum c_i t^{i-1/2} = 0$ on $[0,1]$, multiplying by $t^{1/2}$ gives a polynomial vanishing on $[0,1]$.

Give $C[0,1]$ the inner product $\langle f, g\rangle = \int_0^1 f(t)g(t)\,\mathrm{d}t$ (Proposition 6.1.13).

(a) Let $f_i(t) = t^{i-1}$ for $i = 1, \ldots, n$. Then

$$\langle f_j, f_i\rangle = \int_0^1 t^{i+j-2}\,\mathrm{d}t = \frac{1}{i+j-1} = h_{ij},$$

so H_n is the Gram matrix of $f_1, \ldots, f_n$ (Definition 6.3.28). This list is linearly independent: if $\sum_i c_i t^{i-1} = 0$ for every $t \in [0,1]$, the polynomial $\sum_i c_i x^{i-1}$ has infinitely many roots, so it is zero (Proposition 7.1.22) and every $c_i = 0$. By Proposition 8.3.15, H_n is positive definite. Its eigenvalues are positive and $\det H_n$ is their product (Theorem 7.5.22), so $\det H_n > 0$.

(b) Let $g_i(t) = t^{i-1/2}$ for $i = 1, \ldots, n$, continuous on $[0,1]$ since $i - 1/2 > 0$. Then $\langle g_j, g_i\rangle = \int_0^1 t^{i+j-1}\,\mathrm{d}t = 1/(i+j) = k_{ij}$. If $\sum_i c_i t^{i-1/2} = 0$ for every $t \in [0,1]$, then multiplying by $t^{1/2}$ gives $\sum_i c_i t^i = 0$ on $[0,1]$, so as in (a) every $c_i = 0$. Hence K_n is the Gram matrix of an independent list and is positive definite.

No eigenvalue had to be computed. The eigenvalues of H_n are in fact tiny (the smallest is below 10^{-5} for $n = 5$), so a numerical test of positivity would be delicate, while the Gram description settles the question exactly.

Solution to Exercise 8.3.36

Uses. Theorem 8.3.9 (The positive square root), Theorem 8.3.5 (Characterizations of positive operators), Theorem 7.5.22 (Trace and determinant from eigenvalues), Exercise 8.3.31
Hint 1. Every $R \in \mathbb{F}^{2\times 2}$ satisfies $R^2 - (\operatorname{tr} R)R + (\det R)I_2 = 0$. Check it by multiplying out, and apply it to $R = \sqrt{A}$.

Hint 2. If R has eigenvalues $\mu_1, \mu_2 \geq 0$, then $A = R^2$ has eigenvalues μ_1^2, μ_2^2. Express $\det R$ and $(\operatorname{tr} R)^2$ through $\det A$ and $\operatorname{tr} A$.
Sketch. With $R = \sqrt{A}$, eigenvalues $\mu_1, \mu_2 \geq 0$: $\det R = \mu_1\mu_2 = \delta$ and $(\operatorname{tr} R)^2 = \mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 = \operatorname{tr} A + 2\delta$, so $\operatorname{tr} R = s = \sqrt{\operatorname{tr} A + 2\delta} > 0$ (as $R \neq 0$). Then $A - sR + \delta I_2 = 0$ gives $R = (A + \delta I_2)/s$. (b) $s = 1 + \sqrt{3}$ and $\sqrt{A} = \frac{1}{2}\begin{pmatrix} 1+\sqrt{3} & \sqrt{3}-1 \\ \sqrt{3}-1 & 1+\sqrt{3} \end{pmatrix}$; then $\delta = 3$, $s = 4$, $\sqrt{A} = \begin{pmatrix} 2 & i \\ -i & 2 \end{pmatrix}$.

(a) For $R = \begin{pmatrix} p & q \\ r & s' \end{pmatrix}$, multiplying out gives

$$R^2 - (p + s')R = \begin{pmatrix} p^2 + qr - p^2 - ps' & pq + qs' - pq - qs' \\ rp + s'r - pr - s'r & rq + s'^2 - ps' - s'^2 \end{pmatrix} = -(ps' - qr)I_2,$$

that is, $R^2 - (\operatorname{tr} R)R + (\det R)I_2 = 0$. Let $R = \sqrt{A}$. By Theorem 8.3.5(III), $[R]_{\mathcal{O}} = \operatorname{diag}(\mu_1, \mu_2)$ for an orthonormal basis $\mathcal{O}$ with $\mu_1, \mu_2 \geq 0$, and then $[A]_{\mathcal{O}} = \operatorname{diag}\left(\mu_1^2, \mu_2^2\right)$. By Theorem 7.5.22,

$$\det R = \mu_1\mu_2 = \sqrt{\mu_1^2\mu_2^2} = \sqrt{\det A} = \delta, \quad (\operatorname{tr} R)^2 = (\mu_1 + \mu_2)^2 = \mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 = \operatorname{tr} A + 2\delta.$$

Since $\operatorname{tr} R = \mu_1 + \mu_2 \geq 0$, $\operatorname{tr} R = s$ with $s = \sqrt{\operatorname{tr} A + 2\delta}$. If $s = 0$, then $\mu_1 = \mu_2 = 0$, so $R = 0$ and $A = 0$, which is excluded. So $s > 0$, and the identity $R^2 - sR + \delta I_2 = 0$ with $R^2 = A$ gives $R = (A + \delta I_2)/s$.

(b) For $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$: $\det A = 3$, $\operatorname{tr} A = 4$, and A is positive (Exercise 8.3.31). So $\delta = \sqrt{3}$ and $s = \sqrt{4 + 2\sqrt{3}} = 1 + \sqrt{3}$, since $\left(1 + \sqrt{3}\right)^2 = 4 + 2\sqrt{3}$. Using $\left(2 + \sqrt{3}\right)/\left(1 + \sqrt{3}\right) = \left(1 + \sqrt{3}\right)/2$ and $1/\left(1 + \sqrt{3}\right) = \left(\sqrt{3} - 1\right)/2$,

$$\sqrt{A} = \frac{1}{1 + \sqrt{3}}\begin{pmatrix} 2 + \sqrt{3} & 1 \\ 1 & 2 + \sqrt{3} \end{pmatrix} = \frac{1}{2}\begin{pmatrix} 1 + \sqrt{3} & \sqrt{3} - 1 \\ \sqrt{3} - 1 & 1 + \sqrt{3} \end{pmatrix}.$$

Check: the square of the right side is $\frac{1}{4}\begin{pmatrix} \left(1+\sqrt{3}\right)^2 + \left(\sqrt{3}-1\right)^2 & 2\left(1+\sqrt{3}\right)\left(\sqrt{3}-1\right) \\ \cdots & \cdots \end{pmatrix} = \frac{1}{4}\begin{pmatrix} 8 & 4 \\ 4 & 8 \end{pmatrix} = A$.

For $A = \begin{pmatrix} 5 & 4i \\ -4i & 5 \end{pmatrix}$: A is Hermitian with $a = 5 > 0$ and $\det A = 25 - (4i)(-4i) = 25 - 16 = 9 > 0$, so it is positive (even positive definite) by Exercise 8.3.31. Here $\delta = 3$, $s = \sqrt{10 + 6} = 4$, and

$$\sqrt{A} = \frac{1}{4}\begin{pmatrix} 8 & 4i \\ -4i & 8 \end{pmatrix} = \begin{pmatrix} 2 & i \\ -i & 2 \end{pmatrix}.$$

Check: $\begin{pmatrix} 2 & i \\ -i & 2 \end{pmatrix}^2 = \begin{pmatrix} 4+i(-i) & 2i+2i \\ -2i-2i & (-i)i+4 \end{pmatrix} = \begin{pmatrix} 5 & 4i \\ -4i & 5 \end{pmatrix}$.

Solution to Exercise 8.3.37

Uses. Proposition 8.2.24 (Properties of $f(T)$), Theorem 8.3.9 (The positive square root), Theorem 8.3.5 (Characterizations of positive operators)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. Let $f(\lambda) = |\lambda|$. Show that $f(T)$ is positive and squares to T^2, then use uniqueness of the positive square root.
Hint 2. For (b), if T is positive, then T itself is a positive square root of T^2.
Hint 3. For (c), $T_+ = \sum_j \max(\lambda_j, 0)P_j$ and $T_- = \sum_j \max(-\lambda_j, 0)P_j$.
Sketch. (a) $f(T) = \sum|\lambda_j|P_j$ is self-adjoint with eigenvalues $|\lambda_j| \geq 0$, so positive, and $f(T)^2 = \left(f^2\right)(T) = \sum \lambda_j^2 P_j = T^2$; by uniqueness it is $\sqrt{T^2}$. (b) $|T|$ is positive; conversely a positive T is a positive square root of T^2. (c) $T_\pm = g_\pm(T)$ with $g_+(\lambda) = \max(\lambda, 0)$, $g_-(\lambda) = \max(-\lambda, 0)$, which are ≥ 0 with $g_+ - g_- = \lambda$ and $g_+ g_- = 0$.

(a) Let $f(\lambda) = |\lambda|$ on the eigenvalues, which are real. By Proposition 8.2.24, $f(T) = \sum_j |\lambda_j| P_j$ is self-adjoint (its values are real) with nonnegative eigenvalues $|\lambda_j|$, so it is positive by Theorem 8.3.5, and $f(T)^2 = \left(f^2\right)(T) = \sum_j \lambda_j^2 P_j = T^2$, because $f^2(\lambda) = \lambda^2$ and $T^2 = \sum_j \lambda_j^2 P_j$ (Proposition 8.2.24(c) with $g(\lambda) = \lambda$). By uniqueness in Theorem 8.3.9, $f(T) = \sqrt{T^2} = |T|$.

(b) $|T|$ is positive, so if $|T| = T$, then T is positive. Conversely, if T is positive, then T is a positive operator whose square is T^2, so $T = \sqrt{T^2} = |T|$ by uniqueness.

(c) By (a), $T_+ = \sum_j g_+(\lambda_j)P_j$ and $T_- = \sum_j g_-(\lambda_j)P_j$, where $g_+(\lambda) = (|\lambda| + \lambda)/2 = \max(\lambda, 0)$ and $g_-(\lambda) = (|\lambda| - \lambda)/2 = \max(-\lambda, 0)$. Both functions are real and nonnegative, so T_+ and T_- are positive (Proposition 8.2.24(d), (e), and Theorem 8.3.5). Clearly $T_+ - T_- = T$. Finally $g_+(\lambda)g_-(\lambda) = 0$ for every real λ, since one of the two factors is 0, so $T_+T_- = (g_+g_-)(T) = 0$ by Proposition 8.2.24(c). This is the operator version of writing a real number as its positive part minus its negative part.

Solution to Exercise 8.3.38

Uses. Theorem 8.3.9 (The positive square root), Proposition 8.2.20 (Spectral projections are polynomials in T), Proposition 8.2.24 (Properties of $f(T)$), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Is $R^2 = \lambda\,\mathrm{id}$ on a space of dimension 2 enough to conclude $R = \sqrt{\lambda}\,\mathrm{id}$? Think of $T = \mathrm{id}_V$.
Hint 2. For (b), every eigenspace is a line, and on a line an operator is a scalar.
Sketch. (a) "$R^2 = \lambda\,\mathrm{id}$ on E_λ, so $R = \sqrt{\lambda}\,\mathrm{id}$" is wrong: R may act as $-\sqrt{\lambda}$, or on a plane as any reflection scaled by $\sqrt{\lambda}$. Counterexamples: $-\sqrt{T}$, and $\mathrm{diag}(1, -1)$ for $T = I_2$. (b) R preserves each eigenline E_{λ_j}, so acts on it as a real μ_j with $\mu_j^2 = \lambda_j$; there are two choices if $\lambda_j > 0$ and one if $\lambda_j = 0$, and every choice works. So 2^k.

(a) Everything up to "$R^2 = \lambda\,\mathrm{id}$ on E_λ" is correct. The error is the conclusion "$R = \sqrt{\lambda}\,\mathrm{id}$ on E_λ". A square root of $\lambda\,\mathrm{id}$ need not be $\sqrt{\lambda}\,\mathrm{id}$: the self-adjoint operator $R_\lambda = R|_{E_\lambda}$ is diagonal in an orthonormal basis of E_λ with entries μ satisfying $\mu^2 = \lambda$, so each entry may be $\sqrt{\lambda}$ or $-\sqrt{\lambda}$. (In the first proof of Theorem 8.3.9 the extra hypothesis $\mu \geq 0$ settles this.) The claim is false: if $T \neq 0$, then $-\sqrt{T}$ is a second self-adjoint square root, and even for $T = I_2$ on $\mathbb{R}^2$, every $\mathrm{diag}(\pm 1, \pm 1)$ and every reflection is a self-adjoint square root.

(b) Let $\lambda_1, \ldots, \lambda_n$ be the distinct eigenvalues, with eigenspaces $E_{\lambda_j} = \mathrm{span}(\mathbf{u}_j)$, which are lines because there are n of them in an n-dimensional space. Let R be self-adjoint with $R^2 = T$. As in the argument, R maps E_{λ_j} into itself, so $R\mathbf{u}_j = \mu_j\mathbf{u}_j$ for a scalar μ_j, which is real by Proposition 8.1.1, and $\mu_j^2\mathbf{u}_j = T\mathbf{u}_j = \lambda_j\mathbf{u}_j$ gives $\mu_j^2 = \lambda_j$. So $\mu_j \in \{\sqrt{\lambda_j}, -\sqrt{\lambda_j}\}$, which is two choices if $\lambda_j > 0$ and one if $\lambda_j = 0$, and R is determined by $\mu_1, \ldots, \mu_n$ because $\mathbf{u}_1, \ldots, \mathbf{u}_n$ is a basis. Conversely, for any such choice, $R = \sum_j \mu_j P_j$ is self-adjoint (its coefficients are real) and $R^2 = \sum_j \mu_j^2 P_j = T$ by Proposition 8.2.24. Different choices give different operators, as they differ on some $\mathbf{u}_j$. Hence T has exactly 2^k self-adjoint square roots, and exactly one of them, $\sqrt{T}$, is positive.

Solution to Exercise 8.3.39

Uses. Proposition 8.3.22 (Properties of the Löwner order), Theorem 8.3.9 (The positive square root), Proposition 8.3.15 (Characterizations of positive definite operators), Theorem 5.4.10 (Multiplicativity), Theorem 7.5.22 (Trace and determinant from eigenvalues)
Techniques. Sandwich between square roots (Technique 8.3.19)
Hint 1. Normalize B to the identity: let $C = B^{-1/2}AB^{-1/2}$. By Proposition 8.3.22(c), $C \preceq I_n$.
Hint 2. By Proposition 8.3.22(d), the eigenvalues of C lie in $(0, 1]$. So the eigenvalues of C^{-1} are at least 1, and $C^{-1} = B^{1/2}A^{-1}B^{1/2}$.
Hint 3. For (b), $\det C = \det A / \det B$. For (c), compute the eigenvalues, or the determinant, of $B - A$ and of $B^2 - A^2$.
Sketch. $C = B^{-1/2}AB^{-1/2} \preceq B^{-1/2}BB^{-1/2} = I_n$, and C is positive definite, so its eigenvalues lie in $(0, 1]$. (a) $C^{-1} = B^{1/2}A^{-1}B^{1/2}$ has eigenvalues ≥ 1, so $I_n \preceq C^{-1}$; congruence by $B^{-1/2}$ gives $B^{-1} \preceq A^{-1}$. (b) $\det A / \det B = \det C \leq 1$. (c) $B - A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ is positive, but $B^2 - A^2 = \begin{pmatrix} 4 & 3 \\ 3 & 2 \end{pmatrix}$ has determinant -1.

Let $B^{1/2} = \sqrt{B}$ and $B^{-1/2} = \left(\sqrt{B}\right)^{-1}$, both positive definite and Hermitian. Let $C = B^{-1/2}AB^{-1/2}$. By Proposition 8.3.22(c) with $X = B^{-1/2}$,

$$C \preceq B^{-1/2}BB^{-1/2} = I_n.$$

Also $C = X^*AX$ with X invertible, so C is positive definite: $\mathbf{x}^*C\mathbf{x} = (X\mathbf{x})^*A(X\mathbf{x}) > 0$ for $\mathbf{x} \neq \mathbf{0}$. By Proposition 8.3.22(d) and Proposition 8.3.15, every eigenvalue of C lies in $(0, 1]$.

(a) C is invertible with $C^{-1} = B^{1/2}A^{-1}B^{1/2}$, and its eigenvalues are the reciprocals of those of C (if $C\mathbf{v} = \mu\mathbf{v}$, then $C^{-1}\mathbf{v} = \mu^{-1}\mathbf{v}$, and C^{-1} is Hermitian with an orthonormal eigenbasis made of eigenvectors of C). So they are all ≥ 1, and $I_n \preceq C^{-1}$ by Proposition 8.3.22(d). Applying Proposition 8.3.22(c) with $X = B^{-1/2}$,

$$B^{-1} = B^{-1/2}I_nB^{-1/2} \preceq B^{-1/2}B^{1/2}A^{-1}B^{1/2}B^{-1/2} = A^{-1}.$$

(b) $\det C$ is the product of the eigenvalues of C (Theorem 7.5.22), which lie in $(0,1]$, so $\det C \le 1$. By Theorem 5.4.10, $\det C = \det\left(B^{-1/2}\right)^2 \det A$, and $\det\left(B^{-1/2}\right)^2 \det B = \det\left(B^{-1/2}BB^{-1/2}\right) = \det I_n = 1$. So $\det C = \det A / \det B \le 1$, and $\det A \le \det B$ because $\det B > 0$.

(c) A is a projection and B has trace 3 and determinant 1, so both are positive. $B - A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ is positive (eigenvalues 2 and 0), so $A \preceq B$. But $A^2 = A$ and $B^2 = \begin{pmatrix} 5 & 3 \\ 3 & 2 \end{pmatrix}$, so $B^2 - A^2 = \begin{pmatrix} 4 & 3 \\ 3 & 2 \end{pmatrix}$, whose determinant is $8 - 9 = -1 < 0$. Its eigenvalues have a negative product, so one of them is negative, and $A^2 \preceq B^2$ fails. The tempting argument "$B^2 - A^2 = (B - A)(B + A)$ is a product of positive operators" is wrong twice: the factorization needs $AB = BA$, and a product of positive operators need not be positive (Proposition 8.3.20).

Solution to Exercise 8.3.40

Uses. Lemma 8.3.8 (Where the form vanishes), Theorem 8.3.5 (Characterizations of positive operators), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Exercise 8.3.39
Techniques. A sum of nonnegative terms (Technique 6.1.9), Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. Imitate the third proof of uniqueness in Theorem 8.3.9. Let $X = \sqrt{B} - \sqrt{A}$, which is self-adjoint; it suffices to show that every eigenvalue of X is ≥ 0.
Hint 2. Check that $B - A = \sqrt{B}X + X\sqrt{A}$, apply both sides to an eigenvector $\mathbf{v}$ of X, and take the inner product with $\mathbf{v}$.
Hint 3. You get $\langle (B-A)\mathbf{v}, \mathbf{v}\rangle = \mu\left(\left\langle \sqrt{B}\mathbf{v}, \mathbf{v}\right\rangle + \left\langle \sqrt{A}\mathbf{v}, \mathbf{v}\right\rangle\right)$. The left side is ≥ 0. What if the bracket is 0?
Sketch. With $X = \sqrt{B} - \sqrt{A}$ and $X\mathbf{v} = \mu\mathbf{v}$, $\mathbf{v} \neq \mathbf{0}$: $B - A = \sqrt{B}X + X\sqrt{A}$ gives $0 \le \langle (B-A)\mathbf{v}, \mathbf{v}\rangle = \mu\left(\left\langle \sqrt{B}\mathbf{v}, \mathbf{v}\right\rangle + \left\langle \sqrt{A}\mathbf{v}, \mathbf{v}\right\rangle\right)$. If the bracket is positive, $\mu \ge 0$. If it is 0, then $\sqrt{B}\mathbf{v} = \sqrt{A}\mathbf{v} = \mathbf{0}$ by Lemma 8.3.8, so $\mu\mathbf{v} = X\mathbf{v} = \mathbf{0}$ and $\mu = 0$. So X is positive. Converse: square roots $\operatorname{diag}(1,0) \preceq \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$ of Exercise 8.3.39(c).

Let $X = \sqrt{B} - \sqrt{A}$, which is self-adjoint. Then

$$\sqrt{B}X + X\sqrt{A} = B - \sqrt{B}\sqrt{A} + \sqrt{B}\sqrt{A} - A = B - A.$$

Let μ be an eigenvalue of X, with $X\mathbf{v} = \mu\mathbf{v}$ and $\mathbf{v} \neq \mathbf{0}$; μ is real (Proposition 8.1.1). Using $X^* = X$,

$$\langle (B-A)\mathbf{v}, \mathbf{v}\rangle = \left\langle \sqrt{B}(\mu\mathbf{v}), \mathbf{v}\right\rangle + \left\langle \sqrt{A}\mathbf{v}, X\mathbf{v}\right\rangle = \mu\left(\left\langle \sqrt{B}\mathbf{v}, \mathbf{v}\right\rangle + \left\langle \sqrt{A}\mathbf{v}, \mathbf{v}\right\rangle\right).$$

The left side is ≥ 0 because $A \preceq B$, and the bracket β is a sum of two nonnegative numbers. If $\beta > 0$, then $\mu = \langle (B-A)\mathbf{v}, \mathbf{v}\rangle / \beta \ge 0$. If $\beta = 0$, then both terms are 0, so $\sqrt{B}\mathbf{v} = \sqrt{A}\mathbf{v} = \mathbf{0}$ by Lemma 8.3.8, hence $\mu\mathbf{v} = X\mathbf{v} = \mathbf{0}$ and $\mu = 0$. In either case $\mu \ge 0$, so X is positive by Theorem 8.3.5(II), that is, $\sqrt{A} \preceq \sqrt{B}$.

For the converse, let $A_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B_0 = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$, which are positive with $A_0 \preceq B_0$ (Exercise 8.3.39(c)). Put $A = A_0^2$ and $B = B_0^2$. Then $\sqrt{A} = A_0$ and $\sqrt{B} = B_0$ by uniqueness of positive square roots, so $\sqrt{A} \preceq \sqrt{B}$; but $A \preceq B$ fails, by Exercise 8.3.39(c).

Solution to Exercise 8.3.41

Uses. Algorithm 8.3.24 (Cholesky factorization), Proposition 8.3.25 (Correctness of the Cholesky algorithm), Theorem 8.3.23 (Cholesky factorization)
Hint 1. Work row by row: $r_{kk} = \sqrt{a_{kk} - \sum_{i<k} r_{ik}^2}$, then $r_{kj} = \left(a_{kj} - \sum_{i<k} r_{ik}r_{ij}\right)/r_{kk}$.
Hint 2. In (b) the algorithm stops at $k = 3$. For (c), look for $\mathbf{x} = (x_1, x_2, 1)$ with the first two entries of $B\mathbf{x}$ equal to 0, as in the induction proof of Theorem 8.3.23.
Sketch. (a) $R = \begin{pmatrix} 1 & 2 & 1 \\ 0 & 3 & 2 \\ 0 & 0 & 3 \end{pmatrix}$. (b) $r_{1*} = (1,2,3)$, $r_{22} = 1$, $r_{23} = -2$, then $d = 6 - 9 - 4 = -7 < 0$: not positive definite. (c) Solving $x_1 + 2x_2 = -3$, $2x_1 + 5x_2 = -4$ gives $\mathbf{x} = (-7, 2, 1)$, $B\mathbf{x} = (0, 0, -7)$, and $\mathbf{x}^{\mathsf{T}}B\mathbf{x} = -7$.

(a) $k = 1$: $r_{11} = 1$, $r_{12} = 2$, $r_{13} = 1$. $k = 2$: $d = 13 - 2^2 = 9$, so $r_{22} = 3$, and $r_{23} = (8 - 2 \cdot 1)/3 = 2$. $k = 3$: $d = 14 - 1^2 - 2^2 = 9$, so $r_{33} = 3$. Hence

$$A = R^{\mathsf{T}}R, \quad R = \begin{pmatrix} 1 & 2 & 1 \\ 0 & 3 & 2 \\ 0 & 0 & 3 \end{pmatrix}.$$

Check the last column of $R^{\mathsf{T}}R$: $(1 \cdot 1, 2 \cdot 1 + 3 \cdot 2, 1 + 4 + 9) = (1, 8, 14)$.

(b) $k=1$: $r_{11}=1$, $r_{12}=2$, $r_{13}=3$. $k=2$: $d=5-4=1$, $r_{22}=1$, $r_{23}=(4-2\cdot 3)/1=-2$. $k=3$: $d=6-3^2-(-2)^2=-7\le 0$, and the algorithm stops. By Proposition 8.3.25, B is not positive definite.

(c) Following the induction proof of Theorem 8.3.23, take $\mathbf{x}=(x_1,x_2,1)$ with x_1,x_2 chosen so that the first two entries of $B\mathbf{x}$ vanish:

$$x_1+2x_2+3=0,\quad 2x_1+5x_2+4=0.$$

This gives $x_2=2$ and $x_1=-7$. Then $B\mathbf{x}=(-7+4+3,-14+10+4,-21+8+6)=(0,0,-7)$, and $\mathbf{x}^{\mathsf{T}}B\mathbf{x}=1\cdot(-7)=-7<0$. The value -7 is exactly the number d at which the algorithm stopped: it is the Schur complement of the leading 2×2 block.

Solution to Exercise 8.3.42

Uses. Exercise 8.3.32, Exercise 8.3.28, Theorem 7.5.22 (Trace and determinant from eigenvalues), Theorem 5.4.10 (Multiplicativity)
Techniques. Sandwich between square roots (Technique 8.3.19)
Hint 1. If some $a_{ii}=0$, then $\det A=0$ (Exercise 8.3.32). Otherwise let $D=\operatorname{diag}(a_{11},\dots,a_{nn})$ and $C=D^{-1/2}AD^{-1/2}$. What are the diagonal entries of C?
Hint 2. C is positive with trace n. Apply the AM–GM inequality to its eigenvalues.
Hint 3. For (b), apply (a) to $A=B^*B$.
Sketch. If some $a_{ii}=0$, a row of A vanishes and $\det A=0$. Otherwise $C=D^{-1/2}AD^{-1/2}$ is positive with $c_{ii}=1$, so its eigenvalues $\mu_i\ge 0$ have sum n and $\det C=\prod\mu_i\le(\sum\mu_i/n)^n=1$ by AM–GM. Then $\det A=\det D\det C\le\prod a_{ii}$. (b) $A=B^*B$ has $a_{ii}=\|\mathbf{b}_i\|^2$ and $\det A=|\det B|^2$.

(a) All $a_{ii}\ge 0$. If some $a_{ii}=0$, then row i of A is zero by Exercise 8.3.32(b), so $\det A=0\le\prod_i a_{ii}$. Otherwise let $D=\operatorname{diag}(a_{11},\dots,a_{nn})$ and $D^{-1/2}=\operatorname{diag}\left(a_{11}^{-1/2},\dots,a_{nn}^{-1/2}\right)$, and $C=D^{-1/2}AD^{-1/2}$. Then C is positive by Exercise 8.3.28(b), and $c_{ij}=a_{ij}/\sqrt{a_{ii}a_{jj}}$, so every $c_{ii}=1$ and $\operatorname{tr}C=n$. Let $\mu_1,\dots,\mu_n\ge 0$ be the eigenvalues of C counted with multiplicity. By Theorem 7.5.22 and the AM–GM inequality,

$$\det C=\mu_1\cdots\mu_n\le\left(\frac{\mu_1+\cdots+\mu_n}{n}\right)^n=\left(\operatorname{tr}\frac{C}{n}\right)^n=1.$$

By Theorem 5.4.10, $\det A=\det\left(D^{1/2}\right)\det C\det\left(D^{1/2}\right)=\left(\prod_i a_{ii}\right)\det C\le\prod_i a_{ii}$.

(b) $A=B^*B$ is positive, with $a_{ii}=\mathbf{b}_i^*\mathbf{b}_i=\|\mathbf{b}_i\|^2$ and $\det A=\det(B^*)\det B=\overline{\det B}\det B=|\det B|^2$ (Theorem 5.4.14). So (a) gives $|\det B|^2\le\prod_i\|\mathbf{b}_i\|^2$. For the equality case, see the second solution.

Solution to Exercise 8.3.42

Uses. Theorem 8.3.23 (Cholesky factorization), Proposition 5.3.15 (Triangular matrices), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose)
Techniques. Sandwich between square roots (Technique 8.3.19)
Hint 1. If A is not invertible, $\det A=0$. Otherwise write $A=R^*R$ (Theorem 8.3.23) and compute $\det A$ and a_{ii} in terms of the entries of R.
Hint 2. a_{ii} is the squared length of column i of R, and $\det A=\prod_i r_{ii}^2$.
Sketch. For singular A, $\det A=0\le\prod a_{ii}$. Otherwise $A=R^*R$, $\det A=\prod r_{ii}^2$, and $a_{ii}=\sum_{k\le i}|r_{ki}|^2\ge r_{ii}^2$. Equality for all i iff R is diagonal iff A is diagonal. In (b), $A=B^*B$ is diagonal iff the columns of B are orthogonal.

(a) If A is not invertible, $\det A=0\le\prod_i a_{ii}$. Otherwise A is positive definite (Proposition 8.3.15), and $A=R^*R$ with R upper triangular with positive diagonal entries (Theorem 8.3.23). By Proposition 5.3.15 and Theorem 5.4.10, $\det A=\overline{\det R}\det R=\prod_i r_{ii}^2$. The (i,i) entry of R^*R is the squared length of column i of R, whose nonzero entries are $r_{1i},\dots,r_{ii}$:

$$a_{ii}=\sum_{k\le i}|r_{ki}|^2\ge r_{ii}^2. \tag{C.1.10}$$

Multiplying these n inequalities between nonnegative numbers gives $\prod_i a_{ii}\ge\prod_i r_{ii}^2=\det A$.

(b) As in the first solution, $A=B^*B$ is positive with $a_{ii}=\|\mathbf{b}_i\|^2$ and $\det A=|\det B|^2$, which gives the inequality. Let B be invertible. Then A is positive definite and every $r_{ii}>0$, so equality $\prod_i a_{ii}=\prod_i r_{ii}^2$ holds

if and only if equality holds in every instance of (C.1.10), that is, if and only if $r_{ki} = 0$ for all $k < i$. This means that R is diagonal, which makes $A = R^*R$ diagonal; conversely, if A is diagonal, then $\det A = \prod_i a_{ii}$. So equality holds if and only if $A = B^*B$ is diagonal, that is, $\mathbf{b}_i^*\mathbf{b}_j = 0$ for $i \neq j$: the columns are orthogonal. Geometrically, the volume $|\det B|$ of the parallelepiped spanned by the columns is at most the product of the edge lengths, with equality for a box.

Solution to Exercise 8.3.43

Uses. Theorem 8.2.12 (Real spectral theorem), Corollary 8.2.7 (Hermitian matrices), Proposition 8.3.15 (Characterizations of positive definite operators), Theorem 8.3.5 (Characterizations of positive operators), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators)
Techniques. Choose a convenient basis (Technique 4.5.33), Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. Diagonalize $A = UDU^*$ and substitute $X = UYU^*$. The equation becomes $DY + YD = U^*CU$; read it entry by entry.
Hint 2. For (b), take the conjugate transpose of the equation and use (a).
Hint 3. For (c), let $X\mathbf{v} = \mu\mathbf{v}$ and compute $\langle C\mathbf{v}, \mathbf{v}\rangle = \mathbf{v}^*(AX + XA)\mathbf{v}$ in terms of μ and $\mathbf{v}^*A\mathbf{v}$.
Hint 4. For (d), take $A = \operatorname{diag}(a_1, \dots, a_n)$ and C the matrix of all ones.
Sketch. (a) With $A = UDU^*$, $D = \operatorname{diag}(d_i)$, $d_i > 0$, the equation is $(d_i + d_j)y_{ij} = (U^*CU)_{ij}$ for $Y = U^*XU$, which has exactly one solution since $d_i + d_j > 0$. (b) X^* solves the same equation. (c) For $X\mathbf{v} = \mu\mathbf{v}$, $\mathbf{v}^*C\mathbf{v} = 2\mu\mathbf{v}^*A\mathbf{v}$, and $\mathbf{v}^*A\mathbf{v} > 0$, so $\mu \geq 0$. (d) With $A = \operatorname{diag}(a_i)$ and $C = \mathbf{1}\mathbf{1}^{\mathsf{T}}$ positive, the solution is $x_{ij} = 1/(a_i + a_j)$.

(a) By Theorem 8.2.12 or Corollary 8.2.7, $A = UDU^*$ with U unitary and $D = \operatorname{diag}(d_1, \dots, d_n)$, and $d_i > 0$ by Proposition 8.3.15. Since $X \mapsto U^*XU$ is a bijection of $\mathbb{F}^{n\times n}$ (with inverse $Y \mapsto UYU^*$), we may write $X = UYU^*$. Then

$$AX + XA = U(DY + YD)U^*,$$

so $AX + XA = C$ if and only if $DY + YD = C'$, where $C' = U^*CU$. The (i,j) entry of $DY + YD$ is $(d_i + d_j)y_{ij}$, and $d_i + d_j > 0$. So the equation holds if and only if $y_{ij} = c'_{ij}/(d_i + d_j)$ for all i, j, and there is exactly one solution.

(b) Taking conjugate transposes of $AX + XA = C$ and using $A^* = A$ gives $X^*A + AX^* = C^* = C$. So X^* is also a solution, and by (a), $X^* = X$.

(c) By (b), X is Hermitian, so its eigenvalues are real (Proposition 8.1.1). Let $X\mathbf{v} = \mu\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. Then $\mathbf{v}^*X = (X\mathbf{v})^* = \overline{\mu}\mathbf{v}^* = \mu\mathbf{v}^*$, and

$$\mathbf{v}^*C\mathbf{v} = \mathbf{v}^*A(X\mathbf{v}) + (\mathbf{v}^*X)A\mathbf{v} = \mu\mathbf{v}^*A\mathbf{v} + \mu\mathbf{v}^*A\mathbf{v} = 2\mu\mathbf{v}^*A\mathbf{v}.$$

The left side is ≥ 0 because C is positive, and $\mathbf{v}^*A\mathbf{v} > 0$ because A is positive definite. So $\mu \geq 0$. Every eigenvalue of the Hermitian matrix X is nonnegative, and X is positive by Theorem 8.3.5(II).

(d) Let $A = \operatorname{diag}(a_1, \dots, a_n)$, which is positive definite, and let $C = \mathbf{1}\mathbf{1}^{\mathsf{T}}$ be the matrix of all ones, where $\mathbf{1} = (1, \dots, 1)$; C is positive, being B^*B for the $1 \times n$ matrix $B = \mathbf{1}^{\mathsf{T}}$. The (i,j) entry of $AX + XA$ is $(a_i + a_j)x_{ij}$, so the solution of $AX + XA = C$ is $x_{ij} = 1/(a_i + a_j)$. By (c) this matrix is positive.

The heart of (c) is the trick from the third proof of Theorem 8.3.9: test the equation on an eigenvector of the unknown, not of the data.

Section 8.4

Solution to Exercise 8.4.8

Uses. Theorem 8.4.4 (Characterizations of isometries), Definition 8.4.1 (Isometry)
Hint 1. Condition (V) of Theorem 8.4.4 asks for the images to be orthonormal, not merely of length 1. Try two basis vectors with the same image.
Hint 2. For (b), every nonzero vector is a positive multiple of a unit vector.
Sketch. (a) False: $S = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ sends $\mathbf{e}_1$ and $\mathbf{e}_2$ to $\mathbf{e}_1$, but $S(\mathbf{e}_1 - \mathbf{e}_2) = \mathbf{0}$. (b) True: $\|S\mathbf{v}\| = \|\mathbf{v}\|\|S(\mathbf{v}/\|\mathbf{v}\|)\| = \|\mathbf{v}\|$ for $\mathbf{v} \neq \mathbf{0}$.

(a) False. Let $S \in \mathrm{L}(\mathbb{R}^2)$ have matrix $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$. Then $S\mathbf{e}_1 = S\mathbf{e}_2 = \mathbf{e}_1$, a unit vector, but $S(\mathbf{e}_1 - \mathbf{e}_2) = \mathbf{0}$ while $\|\mathbf{e}_1 - \mathbf{e}_2\| = \sqrt{2}$. The images of the basis have length 1 but are not orthogonal to each other, and (V) of Theorem 8.4.4 needs both.

(b) True. Let $\mathbf{v} \neq \mathbf{0}$. Then $\mathbf{v}/\|\mathbf{v}\|$ is a unit vector, so by hypothesis and homogeneity of the norm,

$$\|S\mathbf{v}\| = \|\mathbf{v}\| \cdot \left\| S\left(\frac{\mathbf{v}}{\|\mathbf{v}\|}\right) \right\| = \|\mathbf{v}\|.$$

For $\mathbf{v} = \mathbf{0}$ both sides are 0. So S is an isometry.

Solution to Exercise 8.4.17

Uses. Theorem 8.4.15 (Spectral form of unitary operators), Theorem 2.2.1 (Linear maps are determined by a basis), Proposition 6.3.34 (Characterizations of unitary matrices)
Hint 1. The vectors $(1,1)/\sqrt{2}$ and $(1,-1)/\sqrt{2}$ form an orthonormal basis. Put them in the columns of W.
Hint 2. $U = W\,\mathrm{diag}(i,-1)W^*$. Powers and adjoints act on the diagonal factor.
Sketch. U is determined by its values on a basis. With $W = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = W^*$, $U = W\,\mathrm{diag}(i,-1)W = \frac{1}{2}\begin{pmatrix} i-1 & i+1 \\ i+1 & i-1 \end{pmatrix}$. It is unitary by (III) of Theorem 8.4.15. $U^4 = W\,\mathrm{diag}(1,1)W = I_2$ and $U^* = W\,\mathrm{diag}(-i,-1)W$.

An operator is determined by its values on the basis $(1,1),(1,-1)$ (Theorem 2.2.1), so there is exactly one such U. Let $W = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$; its columns are orthonormal and $W = W^* = W^{-1}$. The columns of W are eigenvectors for i and -1, so $U = W\,\mathrm{diag}(i,-1)W$, and

$$U = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} i & 0 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \frac{1}{2}\begin{pmatrix} i & -1 \\ i & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \frac{1}{2}\begin{pmatrix} i-1 & i+1 \\ i+1 & i-1 \end{pmatrix}.$$

It has an orthonormal eigenbasis with eigenvalues i and -1 of absolute value 1, so it is unitary by (III) $\Rightarrow$ (I) of Theorem 8.4.15. Next, $U^4 = W\,\mathrm{diag}\big(i^4,(-1)^4\big)W = WW = I_2$. Finally $U^* = W^*\mathrm{diag}(i,-1)^*W^* = W\,\mathrm{diag}(-i,-1)W$, which is

$$U^* = \frac{1}{2}\begin{pmatrix} -i-1 & -i+1 \\ -i+1 & -i-1 \end{pmatrix},$$

the conjugate transpose of U, as it must be. As a check, $U^* = U^{-1} = U^3$, since $U^4 = I_2$.

Solution to Exercise 8.4.22

Uses. Proposition 8.4.21 (A reflection exchanging two vectors), Example 8.4.20 (Householder reflections)
Hint 1. Both targets have length $3 = \|(2,1,2)\|$, and all entries are real. Use Proposition 8.4.21 with $\mathbf{u}$ parallel to $\mathbf{x} - \mathbf{y}$.
Hint 2. $H_{\mathbf{u}} = I_3 - 2\mathbf{u}\mathbf{u}^{\mathsf{T}} = I_3 - \big(2/\|\mathbf{d}\|^2\big)\mathbf{d}\mathbf{d}^{\mathsf{T}}$ for any nonzero $\mathbf{d}$ parallel to $\mathbf{u}$.
Sketch. For $(3,0,0)$: $\mathbf{d} = (-1,1,2)$, $\|\mathbf{d}\|^2 = 6$, $H = \frac{1}{3}\begin{pmatrix} 2 & 1 & 2 \\ 1 & 2 & -2 \\ 2 & -2 & -1 \end{pmatrix}$. For $(-3,0,0)$: $\mathbf{d} = (5,1,2)$, $\|\mathbf{d}\|^2 = 30$, $H = \frac{1}{15}\begin{pmatrix} -10 & -5 & -10 \\ -5 & 14 & -2 \\ -10 & -2 & 11 \end{pmatrix}$.

Let $\mathbf{x} = (2,1,2)$, so $\|\mathbf{x}\| = 3$. Both targets have length 3 and real dot products with $\mathbf{x}$, so Proposition 8.4.21 applies with $\mathbf{u} = \mathbf{d}/\|\mathbf{d}\|$, $\mathbf{d} = \mathbf{x} - \mathbf{y}$, and $H = I_3 - \big(2/\|\mathbf{d}\|^2\big)\mathbf{d}\mathbf{d}^{\mathsf{T}}$.

For $\mathbf{y} = (3,0,0)$: $\mathbf{d} = (-1,1,2)$ and $\|\mathbf{d}\|^2 = 6$, so

$$H = I_3 - \frac{1}{3}\begin{pmatrix} 1 & -1 & -2 \\ -1 & 1 & 2 \\ -2 & 2 & 4 \end{pmatrix} = \frac{1}{3}\begin{pmatrix} 2 & 1 & 2 \\ 1 & 2 & -2 \\ 2 & -2 & -1 \end{pmatrix}.$$

Indeed

$$H\mathbf{x} = \frac{1}{3}(4+1+4,\, 2+2-4,\, 4-2-2) = (3,0,0).$$

The matrix is symmetric by inspection. Its columns $\frac{1}{3}(2,1,2)$, $\frac{1}{3}(1,2,-2)$, $\frac{1}{3}(2,-2,-1)$ have squared lengths $9/9 = 1$ and pairwise dot products $(2+2-4)/9$, $(4-2-2)/9$, $(2-4+2)/9$, all 0; so H is orthogonal.

For $\mathbf{y} = (-3, 0, 0)$: $\mathbf{d} = (5, 1, 2)$ and $\|\mathbf{d}\|^2 = 30$, so

$$H = I_3 - \frac{1}{15}\begin{pmatrix} 25 & 5 & 10 \\ 5 & 1 & 2 \\ 10 & 2 & 4 \end{pmatrix} = \frac{1}{15}\begin{pmatrix} -10 & -5 & -10 \\ -5 & 14 & -2 \\ -10 & -2 & 11 \end{pmatrix},$$

and

$$H\mathbf{x} = \frac{1}{15}(-20 - 5 - 20, -10 + 14 - 4, -20 - 2 + 22) = (-3, 0, 0).$$

(In floating-point computation one chooses the sign of the target that makes $\|\mathbf{d}\|$ large, here the second, to avoid subtracting nearly equal numbers.)

Solution to Exercise 8.4.32

Uses. Theorem 8.4.4 (Characterizations of isometries), Theorem 8.4.11 (Characterizations of unitary operators), Definition 8.4.1 (Isometry), Proposition 6.1.16 (Frobenius inner product)
Hint 1. For matrices, check whether the columns are orthonormal. For the polynomial maps, compute $\|Tp\|^2$ from the definition of the inner product.
Hint 2. Finite-dimensional isometries $V \to V$ are unitary; an isometry between spaces of different dimension is not even an operator.
Sketch. (a) Orthonormal columns $\frac{1}{3}(1, 2, 2)$, $\frac{1}{3}(2, 1, -2)$: an isometry, not unitary. (b) Columns $\frac{1}{\sqrt{2}}(1, i)$, $\frac{1}{\sqrt{2}}(i, 1)$ are orthonormal: unitary. (c) $\|Tp\|^2 = p(1)^2 + p(0)^2$: unitary. (d) $p = x$ has $\|Tp\|^2 = 1/4 \neq 1$: no. (e) $\left\|A^{\mathsf{T}}\right\|^2 = \sum |a_{ji}|^2 = \|A\|^2$: unitary.

(a) The matrix of T is $\frac{1}{3}\begin{pmatrix} 1 & 2 \\ 2 & 1 \\ 2 & -2 \end{pmatrix}$, with columns of squared length $(1 + 4 + 4)/9 = 1$ and $(4 + 1 + 4)/9 = 1$ and dot product $(2 + 2 - 4)/9 = 0$. So T is an isometry by Theorem 8.4.4 (with the standard bases). It maps $\mathbb{R}^2$ into $\mathbb{R}^3$, so it is not an operator, and not unitary; its image is a plane.

(b) The matrix is $\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix}$. Its columns $\frac{1}{\sqrt{2}}(1, i)$ and $\frac{1}{\sqrt{2}}(i, 1)$ have squared length $(1 + 1)/2 = 1$, and their dot product is $\frac{1}{2}\left(1 \cdot \bar{i} + i \cdot \bar{1}\right) = \frac{1}{2}(-i + i) = 0$. So T is an isometry of $\mathbb{C}^2$, hence unitary (Theorem 8.4.11).

(c) $(Tp)(0) = p(1)$ and $(Tp)(1) = p(0)$, so $\|Tp\|^2 = p(1)^2 + p(0)^2 = \|p\|^2$. So T is an isometry of the finite-dimensional space V, hence unitary.

(d) For $p = x$, $\|p\|^2 = 0^2 + 1^2 = 1$, while $Tp = x/2$ has $\|Tp\|^2 = 0 + 1/4$. So T is not an isometry.

(e) T is linear, and by Proposition 6.1.16, $\left\|A^{\mathsf{T}}\right\|^2 = \sum_{i,j} |a_{ji}|^2 = \sum_{i,j} |a_{ij}|^2 = \|A\|^2$. So T is an isometry of a finite-dimensional space, hence unitary. (It also satisfies $T^2 = \mathrm{id}$, so $T^{-1} = T = T^*$: it is self-adjoint as well.)

Solution to Exercise 8.4.33

Uses. Corollary 8.4.6 (Properties of isometries), Theorem 8.4.15 (Spectral form of unitary operators), Theorem 8.2.5 (Complex spectral theorem), Example 8.1.9 (Normal operators)
Hint 1. (a) An isometry $\mathbb{R} \to \mathbb{R}^2$ cannot have an injective adjoint. (b) Look for a non-normal operator with a single eigenvalue 1.
Hint 2. (c) The spectral theorem supplies an orthonormal basis of eigenvectors. (d) A real normal operator may have no eigenvectors at all.
Sketch. (a) False: $Sx = (x, 0)$ has $S^*(y_1, y_2) = y_1$, which kills $\mathbf{e}_2$. (b) False: the shear. (c) True: an orthonormal eigenbasis exists, and $\|T\mathbf{e}_j\| = |\lambda_j| = 1$, so (III) of Theorem 8.4.15 holds. (d) False: $\begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix}$ is normal, has no real eigenvalue, and is not orthogonal.

(a) False. Let $S : \mathbb{R} \to \mathbb{R}^2$, $Sx = (x, 0)$, an isometry. Its adjoint is $S^*(y_1, y_2) = y_1$, since $\langle Sx, (y_1, y_2)\rangle = xy_1$. Then $S^*\mathbf{e}_2 = 0$, so S^* is not injective and not an isometry (Corollary 8.4.6(a)). The statement is true when $\dim V = \dim W$, by Corollary 8.4.6(d).

(b) False. The shear $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ on $\mathbb{C}^2$ has the single eigenvalue 1 but maps $\mathbf{e}_2$ to $(1, 1)$, of length $\sqrt{2}$.

(c) True. By Theorem 8.2.5, V has an orthonormal basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ with $T\mathbf{e}_j = \lambda_j \mathbf{e}_j$. By hypothesis $1 = \|T\mathbf{e}_j\| = |\lambda_j|$, and every eigenvalue of T is one of the λ_j. So T is unitary by (III) $\Rightarrow$ (I) of Theorem 8.4.15.

(d) False. Let $T \in \mathrm{L}(\mathbb{R}^2)$ have matrix $A = \begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix}$. It is normal, since $A^{\mathsf{T}}A = 4I_2 = AA^{\mathsf{T}}$ (Example 8.1.9(c)). Its characteristic polynomial $x^2 + 4$ has no real root, so T has no eigenvectors and the hypothesis holds vacuously. But $\|T\mathbf{e}_1\| = 2$, so T is not orthogonal. In (c), the eigenvectors of a complex normal operator span V; over $\mathbb{R}$ they need not exist.

Solution to Exercise 8.4.34

Uses. Theorem 8.4.4 (Characterizations of isometries), Theorem 6.4.20 (Orthonormal bases exist)
Techniques. Plug in clever test vectors (Technique 6.1.40)
Hint 1. Fix an orthonormal basis $\mathbf{e}_1, \dots, \mathbf{e}_n$. The images are orthogonal. You want them to have equal lengths.
Hint 2. For $i \neq j$, the vectors $\mathbf{e}_i + \mathbf{e}_j$ and $\mathbf{e}_i - \mathbf{e}_j$ are orthogonal. Apply the hypothesis to them.
Sketch. The images $T\mathbf{e}_i$ are pairwise orthogonal. From $(\mathbf{e}_i + \mathbf{e}_j) \perp (\mathbf{e}_i - \mathbf{e}_j)$ we get $0 = \langle T\mathbf{e}_i + T\mathbf{e}_j, T\mathbf{e}_i - T\mathbf{e}_j \rangle = \|T\mathbf{e}_i\|^2 - \|T\mathbf{e}_j\|^2$. So all $\|T\mathbf{e}_i\|$ equal some c; if $c > 0$, T/c maps an orthonormal basis to an orthonormal list.

If $V = \{\mathbf{0}\}$, then $T = 0$. Otherwise let $\mathbf{e}_1, \dots, \mathbf{e}_n$ be an orthonormal basis of V (Theorem 6.4.20). For $i \neq j$, $\langle \mathbf{e}_i, \mathbf{e}_j \rangle = 0$, so $\langle T\mathbf{e}_i, T\mathbf{e}_j \rangle = 0$ by hypothesis. Also

$$\langle \mathbf{e}_i + \mathbf{e}_j, \mathbf{e}_i - \mathbf{e}_j \rangle = \|\mathbf{e}_i\|^2 - \langle \mathbf{e}_i, \mathbf{e}_j \rangle + \langle \mathbf{e}_j, \mathbf{e}_i \rangle - \|\mathbf{e}_j\|^2 = 1 - 0 + 0 - 1 = 0,$$

so by hypothesis and the orthogonality of $T\mathbf{e}_i$ and $T\mathbf{e}_j$,

$$0 = \langle T\mathbf{e}_i + T\mathbf{e}_j, T\mathbf{e}_i - T\mathbf{e}_j \rangle = \|T\mathbf{e}_i\|^2 - \|T\mathbf{e}_j\|^2.$$

So $\|T\mathbf{e}_i\| = c$ for one $c \geq 0$ and all i. If $c = 0$, then T vanishes on a basis and $T = 0$. If $c > 0$, let $S = c^{-1}T$. Then $S\mathbf{e}_1, \dots, S\mathbf{e}_n$ are pairwise orthogonal unit vectors, so S is an isometry by (V) $\Rightarrow$ (I) of Theorem 8.4.4, and $T = cS$. Conversely, cS preserves orthogonality since $\langle cS\mathbf{u}, cS\mathbf{v} \rangle = c^2 \langle \mathbf{u}, \mathbf{v} \rangle$.

Solution to Exercise 8.4.35

Uses. Definition 6.3.33 (Unitary and orthogonal matrices), Theorem 6.3.29 (Orthonormal columns), Definition 5.2.29 (Permutation matrix), Theorem 5.4.10 (Multiplicativity)
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. A column is a unit vector with integer entries. How can integers have squares adding up to 1?
Hint 2. Orthogonal columns with one nonzero entry each must have it in different rows. For the determinant, multiplying the first row by -1 is a bijection between the two kinds.
Sketch. Each column has integer entries with $\sum q_{ij}^2 = 1$, so exactly one entry is ± 1. Two columns with their nonzero entries in the same row would have dot product ± 1, so the rows of these entries are distinct: $Q = DP$ with P a permutation matrix and D diagonal with entries ± 1. Count: $n!$ permutations times 2^n signs. Negating the first row is a bijection between determinant 1 and -1, so $2^{n-1}n!$ have determinant 1.

(a) Let $\mathbf{q}_j$ be the jth column. It is a unit vector (Theorem 6.3.29), so $\sum_i q_{ij}^2 = 1$ with every $q_{ij} \in \mathbb{Z}$. A nonzero integer has square at least 1, so exactly one entry of $\mathbf{q}_j$ is nonzero, and it is ± 1; say it is in row $\sigma(j)$. If $\sigma(j) = \sigma(k)$ with $j \neq k$, then $\mathbf{q}_j \cdot \mathbf{q}_k = \pm 1 \neq 0$, contradicting orthogonality. So σ is injective, hence a permutation of $\{1, \dots, n\}$, and every row also contains exactly one nonzero entry.

(b) Conversely, every signed permutation matrix has orthonormal columns (they are $\pm \mathbf{e}_{\sigma(j)}$ for distinct $\sigma(j)$), so it is orthogonal with integer entries. Such a matrix is determined by the permutation σ ($n!$ choices) and the signs of its n nonzero entries (2^n choices), so there are $2^n n!$ of them. Let $D = \mathrm{diag}(-1, 1, \dots, 1)$. The map $Q \mapsto DQ$ negates the first row, so it maps signed permutation matrices to signed permutation matrices, it is its own inverse, and $\det(DQ) = -\det Q$ (Theorem 5.4.10). So it exchanges those of determinant 1 and those of determinant -1 (the only possible values), and exactly half, $2^{n-1}n!$, have determinant 1.

Solution to Exercise 8.4.36

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Theorem 8.4.11 (Characterizations of unitary operators), Definition 6.3.33 (Unitary and orthogonal matrices), Proposition 6.3.34 (Characterizations of unitary matrices)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)

Hint 1. The sum of all entries is $\mathbf{1}^{\mathsf{T}}Q\mathbf{1} = \langle Q\mathbf{1}, \mathbf{1}\rangle$, where $\mathbf{1} = (1, \ldots, 1)$.
Hint 2. Apply Cauchy–Schwarz, and use $\|Q\mathbf{1}\| = \|\mathbf{1}\| = \sqrt{n}$. For (b), apply Cauchy–Schwarz to each row, a unit vector, and the vector $\mathbf{1}$.
Sketch. (a) $\sum q_{ij} = \langle Q\mathbf{1}, \mathbf{1}\rangle$, and $|\langle Q\mathbf{1}, \mathbf{1}\rangle| \le \|Q\mathbf{1}\|\|\mathbf{1}\| = n$. Equality $= n$ holds iff $Q\mathbf{1}$ is a nonnegative multiple of $\mathbf{1}$ of the same length, i.e. $Q\mathbf{1} = \mathbf{1}$. (b) For row i, $\sum_j |q_{ij}| = (|q_{i1}|, \ldots) \cdot \mathbf{1} \le 1 \cdot \sqrt{n}$, with equality iff all $|q_{ij}|$ are equal. Example: $\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$.

Let $\mathbf{1} = (1, \ldots, 1) \in \mathbb{R}^n$, so $\|\mathbf{1}\| = \sqrt{n}$, and $\|Q\mathbf{1}\| = \sqrt{n}$ since Q is orthogonal.

(a) The ith entry of $Q\mathbf{1}$ is the ith row sum, so $\sum_{i,j} q_{ij} = (Q\mathbf{1}) \cdot \mathbf{1}$. By Cauchy–Schwarz (Theorem 6.2.1),

$$\left|\sum_{i,j} q_{ij}\right| = |(Q\mathbf{1}) \cdot \mathbf{1}| \le \|Q\mathbf{1}\|\|\mathbf{1}\| = n.$$

If every row sums to 1, then $Q\mathbf{1} = \mathbf{1}$ and the sum is $\mathbf{1} \cdot \mathbf{1} = n$. Conversely, if the sum is $n = \|Q\mathbf{1}\|\|\mathbf{1}\|$, then by Theorem 6.2.11(b) (the case of equality $\langle \mathbf{x}, \mathbf{y}\rangle = \|\mathbf{x}\|\|\mathbf{y}\|$), one of $Q\mathbf{1}$ and $\mathbf{1}$ is a nonnegative multiple of the other. They have the same nonzero length, so $Q\mathbf{1} = \mathbf{1}$: every row sums to 1.

(b) Let $\mathbf{r}_i$ be the ith row of Q, a unit vector by Proposition 6.3.34, and let $\mathbf{a}_i = (|q_{i1}|, \ldots, |q_{in}|)$, which has the same length. By Cauchy–Schwarz,

$$\sum_j |q_{ij}| = \mathbf{a}_i \cdot \mathbf{1} \le \|\mathbf{a}_i\|\|\mathbf{1}\| = \sqrt{n},$$

and summing over the n rows gives $\sum_{i,j} |q_{ij}| \le n\sqrt{n}$. Equality holds if and only if it holds for every row, that is (as $\mathbf{a}_i \neq \mathbf{0}$ and both vectors have nonnegative entries), $\mathbf{a}_i$ is a positive multiple of $\mathbf{1}$ for each i. Since $\|\mathbf{a}_i\| = 1$, this says $|q_{ij}| = 1/\sqrt{n}$ for all i, j. For $n = 2$, the matrix $\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ is orthogonal with all $|q_{ij}| = 1/\sqrt{2}$, and its entries have absolute values adding up to $4/\sqrt{2} = 2\sqrt{2}$.

Solution to Exercise 8.4.37

Uses. Theorem 8.4.15 (Spectral form of unitary operators), Theorem 7.5.22 (Trace and determinant from eigenvalues), Theorem B.1.11 (Triangle inequality in $\mathbb{C}$)
Hint 1. The trace is the sum of the eigenvalues, each on the unit circle.
Hint 2. For equality, the triangle inequality in $\mathbb{C}$ forces all λ_j to point in the same direction. Then use the spectral form.
Sketch. $\operatorname{tr} U = \sum \lambda_j$ with $|\lambda_j| = 1$, so $|\operatorname{tr} U| \le n$. Equality in the triangle inequality for complex numbers of equal modulus forces all λ_j equal to one c; then $U = W(cI_n)W^* = cI_n$. For real Q, $\operatorname{tr} Q = n$ gives $c = 1$.

By Theorem 8.4.15, $U = WDW^*$ with W unitary and $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$, $|\lambda_j| = 1$; and $\operatorname{tr} U = \lambda_1 + \cdots + \lambda_n$ (Theorem 7.5.22). By the triangle inequality in $\mathbb{C}$ (Theorem B.1.11),

$$|\operatorname{tr} U| \le |\lambda_1| + \cdots + |\lambda_n| = n.$$

If $U = cI_n$ with $|c| = 1$, then $|\operatorname{tr} U| = n|c| = n$. Conversely, if $|\operatorname{tr} U| = n$, equality holds in the triangle inequality, so by its equality case all nonzero λ_j are positive real multiples of one another. They all have absolute value 1, so they are all equal to one c with $|c| = 1$. Then $D = cI_n$ and $U = W(cI_n)W^* = cWW^* = cI_n$.

If Q is real orthogonal with $\operatorname{tr} Q = n$, it is unitary as a complex matrix, and $|\operatorname{tr} Q| = n$, so $Q = cI_n$ with $nc = \operatorname{tr} Q = n$, that is, $Q = I_n$.

Solution to Exercise 8.4.38

Uses. Theorem 8.4.15 (Spectral form of unitary operators), Theorem 8.2.18 (Spectral decomposition), Definition 8.2.23 (Functions of an operator), Proposition 8.2.24 (Properties of $f(T)$), Theorem 2.2.1 (Linear maps are determined by a basis), Definition 7.2.13 (Eigenspace)
Techniques. Apply a function to the eigenvalues (Technique 8.2.25)
Hint 1. Write $S = \sum_j \lambda_j P_j$ with distinct $\lambda_j = e^{i\theta_j}$, $\theta_j \in [0, 2\pi)$. Take $A = \sum_j \theta_j P_j$.
Hint 2. For (b), take square roots of the eigenvalues: $R = \sum_j e^{i\theta_j/2} P_j$.
Hint 3. For (c), any square root R commutes with $S = R^2$, so it maps each eigenline of S into itself.
Sketch. (a) $A = \sum \theta_j P_j$ is self-adjoint with the same eigenspaces, and $f(A) = \sum e^{i\theta_j} P_j = S$. (b) $R = \sum e^{i\theta_j/2} P_j$ is unitary by Theorem 8.4.15 and $R^2 = S$ by Proposition 8.2.24. (c) $RS = R^3 = SR$, so R preserves each eigenline $\operatorname{span}(\mathbf{e}_j)$: $R\mathbf{e}_j = r_j \mathbf{e}_j$

with $r_j^2 = \lambda_j$, two choices each. Each of the 2^n choices defines a square root with an orthonormal eigenbasis and $|r_j| = 1$, hence unitary.

(a) By Theorem 8.4.15 and Theorem 8.2.18, $S = \sum_{j=1}^{k} \lambda_j P_j$, where $\lambda_1, \ldots, \lambda_k$ are the distinct eigenvalues, $P_j = \mathrm{Pr}_{E_{\lambda_j}}$, and $|\lambda_j| = 1$. Write $\lambda_j = e^{i\theta_j}$ with $\theta_j \in [0, 2\pi)$; the θ_j are distinct since the λ_j are. Let $A = \sum_j \theta_j P_j$. By Proposition 8.2.24 (applied to S and the real-valued function $\lambda_j \mapsto \theta_j$), A is self-adjoint, its distinct eigenvalues are $\theta_1, \ldots, \theta_k$, and its eigenspaces are $E_{\lambda_j}(S)$. So by Definition 8.2.23 applied to A, $f(A) = \sum_j e^{i\theta_j} P_j = S$.

(b) Let $R = \sum_j e^{i\theta_j/2} P_j$, the function $\lambda_j \mapsto e^{i\theta_j/2}$ applied to S. By Proposition 8.2.24, $R^2 = \sum_j \left(e^{i\theta_j/2}\right)^2 P_j = S$, and R is normal with eigenvalues $e^{i\theta_j/2}$ of absolute value 1, so R is unitary by Theorem 8.4.15.

(c) Let $\mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal eigenbasis of S with $S\mathbf{e}_j = \lambda_j \mathbf{e}_j$ and distinct λ_j. Suppose $R^2 = S$. Then $RS = R^3 = SR$, so $S(R\mathbf{e}_j) = RS\mathbf{e}_j = \lambda_j R\mathbf{e}_j$. Thus $R\mathbf{e}_j \in E_{\lambda_j}(S) = \mathrm{span}(\mathbf{e}_j)$, which is one-dimensional because the eigenvalues are distinct; say $R\mathbf{e}_j = r_j \mathbf{e}_j$. Then $\lambda_j \mathbf{e}_j = R^2 \mathbf{e}_j = r_j^2 \mathbf{e}_j$, so r_j is one of the two square roots of λ_j. Conversely, for each of the 2^n choices of square roots $r_1, \ldots, r_n$, Theorem 2.2.1 gives exactly one R with $R\mathbf{e}_j = r_j \mathbf{e}_j$, and $R^2 \mathbf{e}_j = r_j^2 \mathbf{e}_j = S\mathbf{e}_j$ for all j, so $R^2 = S$. Different choices give different R, so there are exactly 2^n square roots. Each has an orthonormal eigenbasis with eigenvalues r_j, where $|r_j| = |\lambda_j|^{1/2} = 1$, so each is unitary by Theorem 8.4.15.

Solution to Exercise 8.4.39

Uses. Theorem 8.2.12 (Real spectral theorem), Theorem 8.2.5 (Complex spectral theorem), Proposition 8.4.10 (Unitary means $S^* = S^{-1}$), Corollary 8.4.13 (Eigenvalues and determinant), Proposition 8.2.2 (Necessary conditions)
Hint 1. Which spectral theorem applies over $\mathbb{R}$, and what is its hypothesis?
Hint 2. For (b), the real spectral theorem says: orthonormal eigenbasis iff self-adjoint. For orthogonal S, $S^* = S^{-1}$.
Sketch. (a) Over $\mathbb{R}$ the spectral theorem needs self-adjointness, not normality; $R_{\pi/2}$ is orthogonal with no eigenvectors. (b) S has an orthonormal eigenbasis iff $S = S^*$ (Theorem 8.2.12) iff $S = S^{-1}$ iff $S^2 = \mathrm{id}$. Such S fixes E_1 and negates $E_{-1} = E_1^{\perp}$: it is the reflection through E_1.

(a) The normal spectral theorem (Theorem 8.2.5) is a theorem about complex spaces. Over $\mathbb{R}$ the spectral theorem (Theorem 8.2.12) requires S to be self-adjoint, and an orthogonal operator need not be. The rotation $R_{\pi/2} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ is orthogonal, but its characteristic polynomial $x^2 + 1$ has no real root, so it has no eigenvectors at all.

(b) By Theorem 8.2.12 (with Proposition 8.2.2 for the forward direction), S has an orthonormal eigenbasis if and only if $S^* = S$. Since $S^* = S^{-1}$ (Proposition 8.4.10), this says $S = S^{-1}$, that is, $S^2 = \mathrm{id}$. In that case the eigenvalues are real of absolute value 1 (Corollary 8.4.13(a)), so $V = E_1 \oplus E_{-1}$ with the two eigenspaces orthogonal. So S fixes the subspace E_1 and negates its orthogonal complement E_{-1}; it is the reflection through E_1, that is, $S = 2\,\mathrm{Pr}_{E_1} - \mathrm{id}$ (compare Exercise 8.1.30).

Solution to Exercise 8.4.40

Uses. Example 8.4.12 (The shift), Definition 6.6.8 (Adjoint), Definition 7.2.6 (Eigenvalue, eigenvector), Definition 6.4.11 (Orthogonal projection)
Hint 1. Write $p = \sum a_k x^k$ and $q = \sum b_k x^k$, and compute $\langle xp, q\rangle$ and $\langle p, Lq\rangle$ coefficient by coefficient.
Hint 2. For the eigenvalues, compare degrees: M raises the degree of a nonzero polynomial by 1, and L lowers it by 1 (or kills constants).
Sketch. (a) $\langle Mp, q\rangle = \sum_k a_k \overline{b_{k+1}} = \langle p, Lq\rangle$. (b) $L(xp) = p$; $xL(q) = q - b_0$, and $b_0 = \mathrm{Pr}_{\mathrm{span}(1)}\, q$ since $1, x, x^2, \ldots$ is orthonormal. (c) $\deg(xp) = \deg p + 1$, so $xp = \lambda p$ is impossible for $p \neq \mathbf{0}$. If $Lq = \lambda q$ with $q \neq \mathbf{0}$ of degree d: for $d \geq 1$, $\deg Lq = d - 1 < d$ forces $\lambda = 0$ and $Lq = 0$, a contradiction; so q is a nonzero constant, $Lq = 0$, and $\lambda = 0$.

(a) Let $p = \sum_k a_k x^k$ and $q = \sum_k b_k x^k$ (finite sums, padded with zeros). Then $Mp = \sum_k a_k x^{k+1}$ and $Lq = \sum_k b_{k+1} x^k$, so

$$\langle Mp, q\rangle = \sum_{k \geq 0} a_k \overline{b_{k+1}} = \langle p, Lq\rangle.$$

So L is the adjoint of M (Definition 6.6.8).

(b) $L(Mp) = L\left(\sum_k a_k x^{k+1}\right) = \sum_k a_k x^k = p$, so $LM = \mathrm{id}$. For q as above, $MLq = \sum_{k\geq 1} b_k x^k = q - b_0$. Since $1, x, x^2, \ldots$ is orthonormal, $b_0 = \langle q, 1\rangle$, so $b_0 = \mathrm{Pr}_{\mathrm{span}(1)}\, q$ (Definition 6.4.11), and $ML = \mathrm{id} - \mathrm{Pr}_{\mathrm{span}(1)}$. In particular $ML \neq \mathrm{id}$, as $ML1 = \mathbf{0}$: L is a left inverse of M but not a right inverse.

(c) If $p \neq \mathbf{0}$, then $\deg(xp) = \deg p + 1$, while λp is $\mathbf{0}$ or has degree $\deg p$. So $Mp = \lambda p$ never holds with $p \neq \mathbf{0}$, and M has no eigenvalue. For L: the constant 1 satisfies $L1 = \mathbf{0} = 0 \cdot 1$, so 0 is an eigenvalue. Suppose $Lq = \lambda q$ with $q \neq \mathbf{0}$. If $\deg q = d \geq 1$, then Lq is $\mathbf{0}$ or has degree $d-1$, so λq cannot have degree d; hence $\lambda q = \mathbf{0}$, $\lambda = 0$, and $Lq = \mathbf{0}$, which forces q to be constant, contradicting $d \geq 1$. So q is a nonzero constant, $Lq = \mathbf{0}$, and $\lambda = 0$.

Solution to Exercise 8.4.41

Uses. Definition 8.4.26 (Rotation), Theorem 8.4.27 (Euler's rotation theorem), Theorem 6.3.29 (Orthonormal columns)
Hint 1. Check that the columns are orthonormal and that $\det Q = 1$.
Hint 2. The axis spans $\ker(Q - I_3)$. The angle comes from $\mathrm{tr}\, Q = 1 + 2\cos\theta$.
Sketch. The columns $\frac{1}{9}(1,8,-4)$, $\frac{1}{9}(-4,4,7)$, $\frac{1}{9}(8,1,4)$ are orthonormal and $\det(9Q) = 729$, so $\det Q = 1$. $Q(1,2,2) = (1,2,2)$, so the axis is $\frac{1}{3}(1,2,2)$, and $\mathrm{tr}\, Q = 1 = 1 + 2\cos\theta$ gives $\theta = \pi/2$.

The columns of $9Q$ are $(1,8,-4)$, $(-4,4,7)$, $(8,1,4)$, each of squared length 81, with dot products $-4 + 32 - 28 = 0$, $8 + 8 - 16 = 0$, and $-32 + 4 + 28 = 0$. So the columns of Q are orthonormal and Q is orthogonal. Expanding along the first row,

$$\det(9Q) = 1(16-7) + 4(32+4) + 8(56+16) = 9 + 144 + 576 = 729 = 9^3,$$

so $\det Q = 1$ and Q is a rotation (Definition 8.4.26).

For the axis, $9Q(1,2,2) = (1 - 8 + 16, 8 + 8 + 2, -4 + 14 + 8) = (9, 18, 18)$, so $Q(1,2,2) = (1,2,2)$, and the axis is $\mathbf{a} = \frac{1}{3}(1,2,2)$. (Since $Q \neq I_3$, the fixed space is exactly this line, by the matrix form in Theorem 8.4.27.) Finally $\mathrm{tr}\, Q = (1+4+4)/9 = 1 = 1 + 2\cos\theta$, so $\cos\theta = 0$ and Q is a quarter turn about $\mathbf{a}$.

Solution to Exercise 8.4.42

Uses. Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Definition 5.1.1 (Determinant function), Theorem 7.2.9 (Eigenvalues and invertibility), Lemma 8.4.23 (Orthogonal 2×2 matrices), Proposition 7.3.15 (Block-triangular matrices)
Hint 1. Imitate the first proof of Theorem 8.4.27: write $Q + I_n = Q + QQ^{\mathsf{T}}$.
Hint 2. For (c), use rotation blocks. For the second part, recall what every element of $\mathrm{O}(2)$ with determinant -1 is.
Sketch. (a) $\det(Q+I) = \det\left(Q\left(I + Q^{\mathsf{T}}\right)\right) = \det Q \det(I+Q) = -\det(Q+I)$, so $\det(Q+I) = 0$. (b) $\det(Q-I) = \det Q \det\left(I - Q^{\mathsf{T}}\right) = (-1)^n \det(Q-I) = -\det(Q-I)$. (c) $\mathrm{diag}\left(R_{\pi/2}, R_{\pi/2}\right)$ has characteristic polynomial $\left(x^2+1\right)^2$. Every element of $\mathrm{O}(2)$ with determinant -1 is a reflection S_θ, which has eigenvalue 1: none exists.

(a) Using $QQ^{\mathsf{T}} = I_n$, Theorem 5.4.10, and Theorem 5.4.14,

$$\det(Q + I_n) = \det\left(Q + QQ^{\mathsf{T}}\right) = \det Q \cdot \det\left(I_n + Q^{\mathsf{T}}\right) = \det Q \cdot \det(I_n + Q) = -\det(Q + I_n).$$

So $\det(Q - (-1)I_n) = 0$, and -1 is an eigenvalue (Theorem 7.2.9).

(b) Similarly, $\det(Q - I_n) = \det\left(Q - QQ^{\mathsf{T}}\right) = \det Q \cdot \det\left(I_n - Q^{\mathsf{T}}\right) = \det(I_n - Q)$. By multilinearity in the n columns (Definition 5.1.1), $\det(I_n - Q) = (-1)^n \det(Q - I_n) = -\det(Q - I_n)$ for odd n. So $\det(Q - I_n) = 0$, and 1 is an eigenvalue.

(c) Let $Q = \begin{pmatrix} R_{\pi/2} & 0 \\ 0 & R_{\pi/2} \end{pmatrix} \in \mathbb{R}^{4\times 4}$. Its columns are $\mathbf{e}_2, -\mathbf{e}_1, \mathbf{e}_4, -\mathbf{e}_3$, which are orthonormal, and $\det Q = 1 \cdot 1 = 1$. By Proposition 7.3.15, $p_Q = \left(x^2+1\right)^2$, which has no real root, so Q has no real eigenvalue. For the second request, no such matrix exists: by Lemma 8.4.23, an element of $\mathrm{O}(2)$ with determinant -1 is a reflection S_θ, which has the eigenvalue 1.

Solution to Exercise 8.4.43

Uses. Definition 2.4.1 (Matrix product)
Hint 1. Write $S_\alpha = R_\alpha D$ with $D = \mathrm{diag}(1,-1)$, and check that $DR_\beta D = R_{-\beta}$.

Hint 2. For (b), given θ and β, choose α with $\alpha - \beta = \theta$.
Sketch. $S_\alpha = R_\alpha D$, so $S_\alpha S_\beta = R_\alpha D R_\beta D = R_\alpha R_{-\beta} = R_{\alpha-\beta}$. The mirrors are at angles $\alpha/2$ and $\beta/2$, which differ by half the rotation angle. Given θ and any S_β, $R_\theta = S_{\theta+\beta} S_\beta$.

(a) Let $D = \operatorname{diag}(1, -1)$. Multiplying out, $R_\alpha D = \begin{pmatrix} \cos\alpha & \sin\alpha \\ \sin\alpha & -\cos\alpha \end{pmatrix} = S_\alpha$, and

$$DR_\beta D = \begin{pmatrix} \cos\beta & \sin\beta \\ -\sin\beta & \cos\beta \end{pmatrix} = R_{-\beta}.$$

So, since rotations compose by adding angles ($R_\alpha R_\gamma = R_{\alpha+\gamma}$, by the addition formulas),

$$S_\alpha S_\beta = R_\alpha D R_\beta D = R_\alpha R_{-\beta} = R_{\alpha-\beta}.$$

The mirror of S_α is the line at angle $\alpha/2$ (Lemma 8.4.23, or directly), and that of S_β is at angle $\beta/2$. The angle from the second mirror to the first is $(\alpha - \beta)/2$, and the composite rotates by $\alpha - \beta$, twice that.

(b) Given θ and any reflection S_β, let $\alpha = \theta + \beta$. By (a), $S_\alpha S_\beta = R_\theta$. Since every reflection of the plane through $\mathbf{0}$ is some S_β, the reflection applied first can be chosen freely.

Solution to Exercise 8.4.44

Uses. Example 8.4.20 (Householder reflections), Proposition 8.4.21 (A reflection exchanging two vectors), Corollary 6.4.25 (Dimension of the orthogonal complement), Theorem 4.2.11 (Rank–nullity), Theorem 5.4.10 (Multiplicativity), Theorem 8.4.27 (Euler's rotation theorem)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12), Parity via an invariant (Technique 5.2.19)
Hint 1. (a) A vector orthogonal to every $\mathbf{u}_j$ is fixed by every factor. How large is the set of such vectors?
Hint 2. (b) Induct on r. If $Q \neq I_n$, pick $\mathbf{v}$ with $Q\mathbf{v} \neq \mathbf{v}$, and let H be the reflection with $HQ\mathbf{v} = \mathbf{v}$ (Proposition 8.4.21). Show that HQ fixes $\mathbf{v}$ and every vector fixed by Q.
Hint 3. For the fixed vectors: if $Q\mathbf{f} = \mathbf{f}$, then $\langle Q\mathbf{v} - \mathbf{v}, \mathbf{f}\rangle = \langle Q\mathbf{v}, Q\mathbf{f}\rangle - \langle \mathbf{v}, \mathbf{f}\rangle = 0$.
Sketch. (a) Q fixes $\{\mathbf{u}_1, \ldots, \mathbf{u}_k\}^\perp$, of dimension at least $n - k$, so $n - r = \dim\ker(Q - I) \geq n - k$; and each factor has determinant -1. (b) With $\mathbf{u} \propto Q\mathbf{v} - \mathbf{v}$, HQ fixes $\mathbf{v}$ and all of $F = \ker(Q - I)$ (since $F \perp \mathbf{u}$), so $\operatorname{rank}(HQ - I) \leq r - 1$; by induction HQ is a product of at most $r - 1$ reflections, so $Q = H(HQ)$ is a product of at most r, and by (a) of exactly r. (c) For a rotation $Q \neq I_3$ of $\mathbb{R}^3$, the fixed space is the axis, so $r = 2$, and $(-1)^k = 1$ forces k even.

(a) Let $X = \{\mathbf{u}_1, \ldots, \mathbf{u}_k\}^\perp = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)^\perp$. Each $H_{\mathbf{u}_j}$ fixes every vector orthogonal to $\mathbf{u}_j$ (Example 8.4.20), so $Q\mathbf{x} = \mathbf{x}$ for $\mathbf{x} \in X$, that is, $X \subseteq \ker(Q - I_n)$. By Corollary 6.4.25, $\dim X = n - \dim\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k) \geq n - k$. By rank–nullity (Theorem 4.2.11), $\dim\ker(Q - I_n) = n - r$, so $n - r \geq n - k$, that is, $k \geq r$. Each $H_{\mathbf{u}_j}$ has determinant -1 (Example 8.4.20), so $\det Q = (-1)^k$ by Theorem 5.4.10.

(b) By (a), no product of fewer than r reflections equals Q, so it suffices to show that Q is a product of at most r reflections. We use strong induction on r. If $r = 0$, then $Q = I_n$, the empty product. Let $r \geq 1$, and let $F = \ker(Q - I_n)$, of dimension $n - r < n$. Pick $\mathbf{v} \notin F$, so $Q\mathbf{v} \neq \mathbf{v}$. Since $\|Q\mathbf{v}\| = \|\mathbf{v}\|$ and all entries are real, Proposition 8.4.21 gives a reflection $H = H_{\mathbf{u}}$, $\mathbf{u} = (Q\mathbf{v} - \mathbf{v})/\|Q\mathbf{v} - \mathbf{v}\|$, with $HQ\mathbf{v} = \mathbf{v}$. For $\mathbf{f} \in F$,

$$\langle Q\mathbf{v} - \mathbf{v}, \mathbf{f}\rangle = \langle Q\mathbf{v}, Q\mathbf{f}\rangle - \langle \mathbf{v}, \mathbf{f}\rangle = 0,$$

because $Q\mathbf{f} = \mathbf{f}$ and Q preserves inner products. So $\mathbf{f} \perp \mathbf{u}$, $H\mathbf{f} = \mathbf{f}$, and $HQ\mathbf{f} = \mathbf{f}$. Hence $Q' = HQ \in \mathrm{O}(n)$ fixes every vector of $F + \operatorname{span}(\mathbf{v})$, which has dimension $n - r + 1$ since $\mathbf{v} \notin F$. So $\operatorname{rank}(Q' - I_n) \leq r - 1$, and by the induction hypothesis Q' is a product of $\operatorname{rank}(Q' - I_n) \leq r - 1$ reflections. Since $H^2 = I_n$, $Q = HQ'$ is a product of at most r reflections.

(c) Let $Q \in \mathrm{SO}(3)$, $Q \neq I_3$. By Theorem 8.4.27, in an orthonormal basis starting with an axis Q has matrix $\operatorname{diag}(1, R_\theta)$ with $R_\theta \neq I_2$, that is, $\theta \neq 0$. Then $R_\theta - I_2$ is invertible (its determinant is $(\cos\theta - 1)^2 + \sin^2\theta = 2 - 2\cos\theta \neq 0$), so $\ker(Q - I_3)$ is the axis line and $r = 2$. By (b), Q is a product of two reflections. If $Q = H_{\mathbf{u}_1} \cdots H_{\mathbf{u}_k}$, then $1 = \det Q = (-1)^k$ by (a), so k is even.

Solution to Exercise 8.4.45

Uses. Theorem 8.4.31 (Distance-preserving maps are affine), Lemma 8.4.30 (Points between two points), Theorem 4.7.37 (Affine maps preserve affine combinations), Corollary B.1.12 (Two terms, and the reverse triangle inequality)
Hint 1. $||s| - |t|| \le |s - t|$ (the reverse triangle inequality in $\mathbb{R}$). For non-affineness, look at the midpoint of -1 and 1.
Hint 2. Lemma 8.4.30 uses equality in the triangle inequality. With the max norm, the "midpoint by distances" of $(-1, 1)$ and $(1, 1)$ is not unique.
Sketch. (a) $\|f(s) - f(t)\|_\infty = \max(|s - t|, ||s| - |t||) = |s - t|$. But $f(0) = (0, 0)$ is not the midpoint $(0, 1)$ of $f(-1) = (-1, 1)$ and $f(1) = (1, 1)$. (b) Lemma 8.4.30 fails: the points at max-distance 1 from both $(-1, 1)$ and $(1, 1)$ are $(0, y)$ with $0 \le y \le 2$, a whole segment, and $f(0)$ is one of them.

(a) For $s, t \in \mathbb{R}$, $f(s) - f(t) = (s - t, |s| - |t|)$, and $||s| - |t|| \le |s - t|$ by the reverse triangle inequality for real numbers (Corollary B.1.12). So $\|f(s) - f(t)\|_\infty = |s - t|$. If f were affine, it would preserve affine combinations (Theorem 4.7.37), in particular midpoints: $f(0) = \frac{1}{2}(f(-1) + f(1))$. But $f(0) = (0, 0)$, while $\frac{1}{2}((-1, 1) + (1, 1)) = (0, 1)$.

(b) Step 1 of the proof, which rests on Lemma 8.4.30, fails: in an inner product space the point $\mathbf{z}$ is determined by its distances to $\mathbf{a}$ and $\mathbf{b}$, but not for $\|\cdot\|_\infty$. Let $\mathbf{z} = (x, y)$. The conditions are

$$\max(|x + 1|, |y - 1|) = 1 \quad \text{and} \quad \max(|x - 1|, |y - 1|) = 1.$$

Both force $|x + 1| \le 1$ and $|x - 1| \le 1$, so $x = 0$; then $|x \pm 1| = 1$, and both conditions hold exactly when $|y - 1| \le 1$. So the solutions are the points $(0, y)$ with $0 \le y \le 2$, a whole segment; the midpoint $(0, 1)$ is one of them, and $f(0) = (0, 0)$ is another. The max norm has no strict equality case in the triangle inequality: $\|(1, 1)\|_\infty + \|(1, -1)\|_\infty = 2 = \|(2, 0)\|_\infty$, although neither vector is a multiple of the other.

Solution to Exercise 8.4.46

Uses. Theorem 8.4.31 (Distance-preserving maps are affine), Proposition 4.7.20 (Affine independence through differences), Theorem 2.2.1 (Linear maps are determined by a basis)
Techniques. Choose a base point (Technique 4.7.4)
Hint 1. By Theorem 8.4.31, $f = Q\mathbf{x} + \mathbf{b}$ and $g = Q'\mathbf{x} + \mathbf{b}'$. Measure positions from $\mathbf{p}_0$.
Hint 2. $f(\mathbf{p}_i) - f(\mathbf{p}_0) = Q(\mathbf{p}_i - \mathbf{p}_0)$. The differences $\mathbf{p}_i - \mathbf{p}_0$ form a basis.
Sketch. Write $f(\mathbf{x}) = Q\mathbf{x} + \mathbf{b}$ and $g(\mathbf{x}) = Q'\mathbf{x} + \mathbf{b}'$. Then $Q(\mathbf{p}_i - \mathbf{p}_0) = f(\mathbf{p}_i) - f(\mathbf{p}_0) = g(\mathbf{p}_i) - g(\mathbf{p}_0) = Q'(\mathbf{p}_i - \mathbf{p}_0)$, and these n differences are a basis, so $Q = Q'$; then $\mathbf{b} = f(\mathbf{p}_0) - Q\mathbf{p}_0 = \mathbf{b}'$.

By Theorem 8.4.31, $f(\mathbf{x}) = Q\mathbf{x} + \mathbf{b}$ and $g(\mathbf{x}) = Q'\mathbf{x} + \mathbf{b}'$ with Q, Q' orthogonal. For each i,

$$Q(\mathbf{p}_i - \mathbf{p}_0) = f(\mathbf{p}_i) - f(\mathbf{p}_0) = g(\mathbf{p}_i) - g(\mathbf{p}_0) = Q'(\mathbf{p}_i - \mathbf{p}_0).$$

By Proposition 4.7.20, the n vectors $\mathbf{p}_1 - \mathbf{p}_0, \dots, \mathbf{p}_n - \mathbf{p}_0$ are linearly independent, hence a basis of $\mathbb{R}^n$. The linear maps $\mathbf{x} \mapsto Q\mathbf{x}$ and $\mathbf{x} \mapsto Q'\mathbf{x}$ agree on this basis, so $Q = Q'$ (Theorem 2.2.1). Then $\mathbf{b} = f(\mathbf{p}_0) - Q\mathbf{p}_0 = g(\mathbf{p}_0) - Q'\mathbf{p}_0 = \mathbf{b}'$, so $f = g$.

In $\mathbb{R}^2$, three points are affinely independent exactly when they are not collinear. Applying the first part with $g = \mathrm{id}$ shows that a rigid motion fixing three non-collinear points is the identity. (Two points do not suffice: the reflection across the line through them fixes both.)

Section A.1

Solution to Exercise A.1.15

Uses. Theorem A.1.12 (One-sided inverses of functions), Theorem A.1.14 (Bijections and inverses)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. The construction of a left inverse is forced on $\mathrm{im}\, f$ and free elsewhere. When is the freedom not really a freedom?
Hint 2. Try X with one element.
Sketch. False. If $X = \{1\}$ and $Y = \{1, 2\}$, then every function $Y \to X$ is constant, so the inclusion $f : X \to Y$ has exactly one left inverse, but it is not surjective.

The claim is false. Let $X = \{1\}$, $Y = \{1, 2\}$, and $f(1) = 1$. There is exactly one function $Y \to X$, the constant function g with value 1, and $g(f(1)) = 1$, so f has exactly one left inverse. But $2 \notin \mathrm{im}\, f$, so f is not surjective.

The claim becomes true when X has at least two elements. A left inverse exists only if f is injective (Theorem A.1.12), and it is forced on $\operatorname{im} f$. If some $y \in Y$ is not in $\operatorname{im} f$, changing the value at y to any other element of X gives a second left inverse. So a unique left inverse forces $\operatorname{im} f = Y$, and f is bijective.

Solution to Exercise A.1.23

Uses. Definition A.1.3 (Image and preimage), Proposition A.1.5 (Images and preimages)
Hint 1. Complete the square: $f(x) = (x-1)^2 - 1$.
Hint 2. $f(x) \le 0$ means $(x-1)^2 \le 1$. On $[0,1]$, f decreases from 0 to -1.
Sketch. With $f(x) = (x-1)^2 - 1$: on $[0,3]$ the values fill $[-1,3]$; $f(x) \in [-1,0]$ iff $|x-1| \le 1$, so the preimage is $[0,2]$; $\operatorname{im}\big(f\restriction_{[0,1]}\big) = [-1,0]$, whose preimage is $[0,2] \supsetneq [0,1]$, illustrating (c) for a non-injective f.

Write $f(x) = (x-1)^2 - 1$. For $x \in [0,3]$, $x-1$ ranges over $[-1,2]$, so $(x-1)^2$ ranges over $[0,4]$ and $\operatorname{im}\big(f\restriction_{[0,3]}\big) = [-1,3]$.

Every value of f is at least -1, so $f(x) \in [-1,0]$ if and only if $(x-1)^2 \le 1$, that is, $|x-1| \le 1$. Hence $f^{-1}([-1,0]) = [0,2]$.

For $x \in [0,1]$, $(x-1)^2$ ranges over $[0,1]$, so $\operatorname{im}\big(f\restriction_{[0,1]}\big) = [-1,0]$, and by the previous computation $f^{-1}\big(\operatorname{im}\big(f\restriction_{[0,1]}\big)\big) = [0,2]$. This strictly contains $[0,1]$, as Proposition A.1.5(c) allows: f is not injective, since $f(1-t) = f(1+t)$.

Solution to Exercise A.1.24

Uses. Proposition A.1.5 (Images and preimages), Definition 2.6.1 (Injective)
Techniques. Contrapositive (Technique 1.5.4)
Hint 1. One direction is Proposition A.1.5(b).
Hint 2. For the other, suppose $f(x) = f(x')$ with $x \ne x'$, and choose A and A' as small as possible.
Sketch. If f is injective, this is Proposition A.1.5(b). If $f(x) = f(x')$ with $x \ne x'$, then $A = \{x\}$ and $A' = \{x'\}$ give $\operatorname{im}(f\restriction_{A\cap A'}) = \varnothing$ but $\operatorname{im}(f\restriction_A) \cap \operatorname{im}(f\restriction_{A'}) = \{f(x)\}$.

If f is injective, the equality is Proposition A.1.5(b). We prove the converse by contrapositive. Suppose f is not injective, say $f(x) = f(x')$ with $x \ne x'$. Let $A = \{x\}$ and $A' = \{x'\}$. Then $A \cap A' = \varnothing$, so $\operatorname{im}(f\restriction_{A\cap A'}) = \varnothing$, while

$$\operatorname{im}(f\restriction_A) \cap \operatorname{im}(f\restriction_{A'}) = \{f(x)\} \cap \{f(x')\} = \{f(x)\} \ne \varnothing.$$

So the equality fails for this pair.

Solution to Exercise A.1.25

Uses. Proposition A.1.8 (Composites, injectivity, and surjectivity)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. (b) is Proposition A.1.8. For (a) and (c), make Y bigger than X and Z.
Hint 2. Try $X = Z = \{1\}$ and $Y = \{1,2\}$.
Sketch. (a) False: $X = Z = \{1\}$, $Y = \{1,2\}$, $f(1) = 1$, g constant; $g \circ f = \mathrm{id}$ is injective, g is not. (b) True by Proposition A.1.8(b), (c). (c) False by the same example: f is not surjective and g is not injective.

Let $X = Z = \{1\}$, $Y = \{1,2\}$, $f(1) = 1$, and let $g : Y \to Z$ be the constant function with value 1. Then $g \circ f = \mathrm{id}_X$ is bijective.

(a) False: in the example, $g \circ f$ is injective but $g(1) = g(2)$.

(b) True. If $g \circ f$ is bijective, it is injective, so f is injective by Proposition A.1.8(b), and it is surjective, so g is surjective by Proposition A.1.8(c).

(c) False: in the example, f is not surjective ($2 \notin \operatorname{im} f$) and g is not injective. By (b), what is true is that f is injective and g surjective; if moreover $|X| = |Y| = |Z|$ are finite, then both are bijective by Theorem A.1.20.

Solution to Exercise A.1.26

Uses. Definition 2.6.1 (Injective), Definition 2.6.2 (Surjective), Definition A.1.2 (Function)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For "injective $\Rightarrow$ cancellable", evaluate $f \circ g = f \circ h$ at each $w \in W$.

Hint 2. For the converse, test cancellability with $W = \{0\}$: a function $\{0\} \to X$ is just a choice of one element of X.
Hint 3. For surjectivity the statement is: f is surjective iff $g \circ f = h \circ f$ implies $g = h$ for all $g, h : Y \to Z$. For the converse, if $y_0 \notin \operatorname{im} f$, compare two functions $Y \to \{0,1\}$ that differ only at y_0.
Sketch. If f is injective and $f(g(w)) = f(h(w))$, then $g(w) = h(w)$. If $f(x) = f(x')$, the functions $g, h : \{0\} \to X$ with values x, x' satisfy $f \circ g = f \circ h$, so $x = x'$. Dually, if f is surjective, every y is $f(x)$, and $g(f(x)) = h(f(x))$; if $y_0 \notin \operatorname{im} f$, the indicator function of $\{y_0\}$ and the zero function $Y \to \{0,1\}$ agree after composing with f.

Suppose f is injective and $f \circ g = f \circ h$. For each $w \in W$, $f(g(w)) = f(h(w))$, so $g(w) = h(w)$. Hence $g = h$. Conversely, suppose f can be cancelled on the left, and let $f(x) = f(x')$. Define $g, h : \{0\} \to X$ by $g(0) = x$ and $h(0) = x'$. Then $f \circ g = f \circ h$, so $g = h$, that is, $x = x'$.

The analogue: f is surjective if and only if, for every set Z and all $g, h : Y \to Z$, $g \circ f = h \circ f$ implies $g = h$. Suppose f is surjective and $g \circ f = h \circ f$. Each $y \in Y$ equals $f(x)$ for some x, so $g(y) = g(f(x)) = h(f(x)) = h(y)$. Conversely, suppose f is not surjective, and let $y_0 \in Y \setminus \operatorname{im} f$. Let $g, h : Y \to \{0,1\}$ with $g(y) = 0$ for all y, and $h(y_0) = 1$, $h(y) = 0$ for $y \neq y_0$. For every $x \in X$, $f(x) \neq y_0$, so $g(f(x)) = 0 = h(f(x))$. Thus $g \circ f = h \circ f$ but $g \neq h$, and f cannot be cancelled on the right.

For matrices, Section 2.5 shows that a left-invertible matrix can be cancelled on the left. For functions, left cancellation is in fact equivalent to having a left inverse when $X \neq \emptyset$, by Theorem A.1.12(a).

Solution to Exercise A.1.27

Uses. Theorem A.1.12 (One-sided inverses of functions), Exercise A.1.28
Hint 1. A left inverse is forced on $\operatorname{im} f$, which has m elements, and arbitrary on the other $n - m$ elements of Y.
Hint 2. A right inverse is exactly a choice of one element $g(y_i) \in f^{-1}(y_i)$ for each i, and the choices are independent.
Sketch. (a) g is determined on $\operatorname{im} f$ (m points) and free on the remaining $n - m$ points, with m options each: m^{n-m}. (b) g is a right inverse iff $g(y_i) \in f^{-1}(y_i)$ for all i, and the choices are independent. (c) $2^2 = 4$ left inverses; $2 \cdot 2 = 4$ right inverses.

(a) A function $g : Y \to X$ is a left inverse of f if and only if $g(f(x)) = x$ for all x. Since f is injective, this fixes g at each of the m elements of $\operatorname{im} f$ and says nothing about the $n - m$ elements of $Y \setminus \operatorname{im} f$, where g may take any of the m values in X. By Exercise A.1.28 there are m^{n-m} such g.

(b) A function $g : Y \to X$ is a right inverse of f if and only if $f(g(y_i)) = y_i$ for each i, that is, $g(y_i) \in f^{-1}(y_i)$. So a right inverse is a choice of an element in each of the k fibers, independently, and there are $\left|f^{-1}(y_1)\right| \cdots \left|f^{-1}(y_k)\right|$ ways to choose.

(c) For f, $m = 2$ and $n = 4$, so there are $2^{4-2} = 4$ left inverses: $g(1) = 1$, $g(2) = 2$, and $g(3), g(4) \in \{1, 2\}$ arbitrary. For p, the fibers are $p^{-1}(1) = \{1, 3\}$ and $p^{-1}(2) = \{2, 4\}$, so there are $2 \cdot 2 = 4$ right inverses.

Solution to Exercise A.1.28

Uses. Corollary A.1.18 (Cardinality is well defined), Theorem A.1.14 (Bijections and inverses), Remark 1.2.11 (Tuples and matrices are functions)
Hint 1. For the step in (a), with $X = X' \cup \{x_0\}$ and $x_0 \notin X'$, a function $X \to Y$ is a function $X' \to Y$ together with a value at x_0.
Hint 2. The map $(h, y) \mapsto$ "h extended by $x_0 \mapsto y$" is a bijection $Y^{X'} \times Y \to Y^X$, and $|A \times B| = |A||B|$ (list the pairs row by row).
Hint 3. In (b), send A to its indicator function. In (c), an element of F^n is a function $[n] \to F$.
Sketch. (a) Induction: if $X = \emptyset$, Y^X has one element. Otherwise remove x_0; restricting to X' and recording the value at x_0 is a bijection $Y^X \to Y^{X'} \times Y$, giving $|Y|^{|X|-1} \cdot |Y|$. (b) $A \mapsto \mathbb{1}_A$ with inverse $h \mapsto h^{-1}(1)$. (c) $F^n = F^{[n]}$ and $F^{m \times n} = F^{[m] \times [n]}$.

(a) If $|X| = 0$, then $X = \emptyset$, and there is exactly one function $\emptyset \to Y$, so $\left|Y^X\right| = 1 = |Y|^0$. Let $|X| = k \geq 1$, pick $x_0 \in X$, and let $X' = X \setminus \{x_0\}$, so $|X'| = k - 1$ (remove x_0 from a listing of X). The map

$$Y^X \to Y^{X'} \times Y, \quad h \mapsto (h|_{X'}, h(x_0)),$$

is a bijection, with inverse sending (h', y) to the function that agrees with h' on X' and takes the value y at x_0. If $|A| = r$ and $|B| = s$, then $|A \times B| = rs$: listing $A = \{\alpha_1, \ldots, \alpha_r\}$ and $B = \{\beta_1, \ldots, \beta_s\}$, the pair (α_i, β_j)

corresponds to $(i-1)s+j \in [rs]$. Hence, by the induction hypothesis and Corollary A.1.18, $\left|Y^X\right| = |Y|^{k-1} \cdot |Y| = |Y|^k$.

(b) For $A \subseteq X$, let $\mathbb{1}_A : X \to \{0,1\}$ be its **indicator function**: $\mathbb{1}_A(x) = 1$ if $x \in A$ and 0 otherwise. The map $A \mapsto \mathbb{1}_A$ has inverse $h \mapsto h^{-1}(1)$: indeed $\mathbb{1}_A^{-1}(1) = A$, and h and $\mathbb{1}_{h^{-1}(1)}$ agree at every x. So it is a bijection (Theorem A.1.14), and $|P(X)| = \left|\{0,1\}^X\right| = 2^{|X|}$ by (a).

(c) An element of F^n is a function $[n] \to F$, and an element of $F^{m\times n}$ is a function $[m]\times[n] \to F$ (Remark 1.2.11). So $|F^n| = q^n$ and $|F^{m\times n}| = q^{mn}$ by (a), using $|[m]\times[n]| = mn$.

Solution to Exercise A.1.29

> *Uses.* Theorem A.1.17 (Pigeonhole principle), Definition 1.1.19 (Integers modulo n)
> *Techniques.* Pigeonhole (Technique A.1.21)
> *Hint 1.* Blocks of consecutive terms are differences of partial sums $s_j = a_1 + \cdots + a_j$, with $s_0 = 0$.
> *Hint 2.* There are $n+1$ partial sums $s_0, \ldots, s_n$ and only n remainders mod n.
> *Sketch.* The $n+1$ partial sums $s_0, \ldots, s_n$ have only n possible remainders mod n, so $s_i \bmod n = s_j \bmod n$ for some $i < j$, and then n divides $s_j - s_i = a_{i+1} + \cdots + a_j$.

Let $s_0 = 0$ and $s_j = a_1 + \cdots + a_j$ for $1 \le j \le n$. The function $\{0,1,\ldots,n\} \to \{0,1,\ldots,n-1\}$, $j \mapsto s_j \bmod n$, goes from a set with $n+1$ elements to one with n elements, so it is not injective (Theorem A.1.17). Hence $s_i \bmod n = s_j \bmod n$ for some $i < j$, which means n divides $s_j - s_i = a_{i+1} + \cdots + a_j$.

The bound is sharp: for $a_1 = \cdots = a_{n-1} = 1$, which has only $n-1$ terms, every block sum lies between 1 and $n-1$.

Solution to Exercise A.1.30

> *Uses.* Definition 2.6.2 (Surjective)
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9)
> *Hint 1.* Given $f : X \to P(X)$, build a subset of X that differs from every $f(x)$, by making it disagree with $f(x)$ at the element x.
> *Hint 2.* Let $D = \{x \in X \mid x \notin f(x)\}$. Could $D = f(d)$? Ask whether $d \in D$.
> *Sketch.* Diagonal argument: $D = \{x \mid x \notin f(x)\}$ is not a value of f, since $D = f(d)$ would give $d \in D \Leftrightarrow d \notin D$.

Let $f : X \to P(X)$ and $D = \{x \in X \mid x \notin f(x)\} \in P(X)$. Suppose $D = f(d)$ for some $d \in X$. If $d \in D$, then $d \notin f(d) = D$; if $d \notin D$, then $d \notin f(d)$, so $d \in D$ by definition of D. Both cases are contradictions, so D is not a value of f, and f is not surjective. In particular there is no bijection $\mathbb{N} \to P(\mathbb{N})$, although $\mathbb{N}$ and $P(\mathbb{N})$ are both infinite.

The set D is built to disagree with $f(x)$ about the single element x. The same diagonal idea shows that the real numbers cannot be listed as a sequence.

Section A.2

Solution to Exercise A.2.7

> *Uses.* Theorem A.2.1 (Induction, strong induction, and well-ordering), Definition 2.4.1 (Matrix product)
> *Hint 1.* Induct on n. Write $J^{n+1} = J^n J$.
> *Hint 2.* Multiply out $\begin{pmatrix}\lambda^n & n\lambda^{n-1}\\ 0 & \lambda^n\end{pmatrix}\begin{pmatrix}\lambda & 1\\ 0 & \lambda\end{pmatrix}$; the top right entry is $\lambda^n + n\lambda^n$.
> *Sketch.* For $n = 1$ the formula reads J. If it holds for n, then $J^{n+1} = J^n J$ has entries λ^{n+1}, $\lambda^n + n\lambda^{n-1}\lambda = (n+1)\lambda^n$, 0, λ^{n+1}.

For $n = 1$ the right side is $\begin{pmatrix}\lambda & 1\\ 0 & \lambda\end{pmatrix} = J$, since $1\lambda^0 = 1$. Suppose the formula holds for some $n \ge 1$. Then

$$J^{n+1} = J^n J = \begin{pmatrix}\lambda^n & n\lambda^{n-1}\\ 0 & \lambda^n\end{pmatrix}\begin{pmatrix}\lambda & 1\\ 0 & \lambda\end{pmatrix} = \begin{pmatrix}\lambda^{n+1} & \lambda^n + n\lambda^n\\ 0 & \lambda^{n+1}\end{pmatrix} = \begin{pmatrix}\lambda^{n+1} & (n+1)\lambda^n\\ 0 & \lambda^{n+1}\end{pmatrix},$$

which is the formula for $n+1$. By induction it holds for all $n \ge 1$.

Over a field of characteristic p, the top right entry of J^p is $p\lambda^{p-1} = 0$, so $J^p = \lambda^p I$. For instance over $\mathbb{F}_2$, $\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}^2 = I$.

Solution to Exercise A.2.8

Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering), Definition 2.4.1 (Matrix product)
Hint 1. (a) is an induction on k: $A^{k+1}B = A\big(A^kB\big)$.
Hint 2. For (b), multiply the formula for m by $A+B$ on the left, use (a) to write $BA^kB^{m-k} = A^kB^{m-k+1}$, and combine terms with $\binom{m}{k-1} + \binom{m}{k} = \binom{m+1}{k}$.
Hint 3. For (c), compute $(A+B)^2$ and $A^2 + 2AB + B^2$.
Sketch. (a) $A^{k+1}B = ABA^k = BA^{k+1}$. (b) $(A+B)^{m+1} = \sum_k \binom{m}{k}\big(A^{k+1}B^{m-k} + A^kB^{m+1-k}\big)$ by (a), and Pascal's rule collects the terms. (c) $(A+B)^2 = I$ but $A^2 + 2AB + B^2 = 2AB = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 0 \end{smallmatrix}\right)$.

(a) For $k = 0$ both sides are B. If $A^kB = BA^k$, then $A^{k+1}B = A\big(A^kB\big) = A\big(BA^k\big) = (AB)A^k = (BA)A^k = BA^{k+1}$.

(b) For $m = 0$ both sides are I. Suppose the formula holds for m. Then

$$(A+B)^{m+1} = (A+B)\sum_{k=0}^{m}\binom{m}{k}A^kB^{m-k} = \sum_{k=0}^{m}\binom{m}{k}A^{k+1}B^{m-k} + \sum_{k=0}^{m}\binom{m}{k}BA^kB^{m-k}.$$

By (a), $BA^kB^{m-k} = A^kB^{m+1-k}$. Shifting the index in the first sum ($k+1 \to k$),

$$(A+B)^{m+1} = \sum_{k=1}^{m+1}\binom{m}{k-1}A^kB^{m+1-k} + \sum_{k=0}^{m}\binom{m}{k}A^kB^{m+1-k} = \sum_{k=0}^{m+1}\binom{m+1}{k}A^kB^{m+1-k},$$

using $\binom{m}{k-1} + \binom{m}{k} = \binom{m+1}{k}$ for $1 \le k \le m$ and $\binom{m}{m} = \binom{m+1}{m+1} = \binom{m}{0} = \binom{m+1}{0} = 1$ for the end terms.

(c) Here $A + B = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, so $(A+B)^2 = I$. On the other hand $A^2 = B^2 = 0$ and $AB = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, so $A^2 + 2AB + B^2 = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 0 \end{smallmatrix}\right) \neq I$ (also in characteristic 2, where it is 0). The induction in (b) used $AB = BA$ in (a), and indeed $BA = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right) \neq AB$.

Solution to Exercise A.2.9

Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Let 2^k be the largest power of 2 with $2^k \le n$. Apply strong induction to $n - 2^k$.
Hint 2. Why can 2^k not appear in the representation of $n - 2^k$? Use $n < 2^{k+1}$.
Hint 3. For uniqueness, show that 2^k must appear in every representation, because $1 + 2 + \cdots + 2^{k-1} = 2^k - 1 < n$.
Sketch. Strong induction. With $2^k \le n < 2^{k+1}$, the number $m = n - 2^k < 2^k$ is 0 or a sum of distinct powers of 2, each less than 2^k, so adding 2^k gives n. Every representation of n uses 2^k (smaller powers sum to at most $2^k - 1$) and no larger power, so removing 2^k leaves a representation of m, which is unique by hypothesis.

We use strong induction on $n \ge 1$. Let $k \ge 0$ be the largest integer with $2^k \le n$ (it exists because $2^j > n$ for $j \ge n$), so that $2^k \le n < 2^{k+1}$, and let $m = n - 2^k$, so $0 \le m < 2^k$.

Existence. If $m = 0$, then $n = 2^k$. Otherwise $1 \le m < n$, so by the induction hypothesis m is a sum of distinct powers of 2, each at most $m < 2^k$. Adding the term 2^k gives a representation of n with distinct terms.

Uniqueness. Take any representation of n as a sum of distinct powers of 2. No term exceeds $n < 2^{k+1}$, so all terms are among $1, 2, \ldots, 2^k$. If 2^k were not a term, the sum would be at most $1 + 2 + \cdots + 2^{k-1} = 2^k - 1 < n$, by Example A.2.2 for 1×1 matrices over $\mathbb{Q}$ with $A = 2$. So 2^k is a term, and the remaining terms form a representation of m (empty if $m = 0$). If $m \ge 1$, this representation is unique by the induction hypothesis, since $m < n$. So the representation of n is unique.

Solution to Exercise A.2.10

Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering), Proposition A.2.4 (Division with remainder)
Techniques. Double containment (Technique 1.3.14), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. First show that $0 \in S$, that S is closed under negation and addition, and that S contains a positive element.
Hint 2. Take d least positive in S by well-ordering. Show $d\mathbb{Z} \subseteq S$ by induction on $|k|$, or by closure under addition and negation.
Hint 3. For $S \subseteq d\mathbb{Z}$, divide $a \in S$ by d: $a = qd + r$ with $0 \le r < d$. Then $r = a - qd \in S$.

Sketch. $0 = a - a$, $-b = 0 - b$ and $a + b = a - (-b)$ lie in S, and some nonzero $a \in S$ gives a positive element $|a|$. Let d be the least positive element. Then $d\mathbb{Z} \subseteq S$. For $a \in S$, $a = qd + r$ with $0 \le r < d$ and $r = a - qd \in S$, so $r = 0$ by minimality of d.

Pick $a \in S$. Then $0 = a - a \in S$, so for every $b \in S$ also $-b = 0 - b \in S$, and for $a, b \in S$, $a + b = a - (-b) \in S$. Since $S \neq \{0\}$, it contains some $a \neq 0$, and one of a and $-a$ is a positive element of S. By well-ordering (Theorem A.2.1(III)), S has a least positive element d.

By closure under addition, $d, 2d, 3d, \ldots \in S$ (induction on k: $(k+1)d = kd + d$), and by closure under negation, so are $-d, -2d, \ldots$; also $0 \in S$. So $d\mathbb{Z} \subseteq S$.

Conversely, let $a \in S$. By Proposition A.2.4, $a = qd + r$ with $0 \le r < d$. Since $qd \in S$, also $r = a - qd \in S$. As d is the least positive element of S and $0 \le r < d$, we get $r = 0$, so $a = qd \in d\mathbb{Z}$.

A similar argument, with the degree in place of the absolute value, Theorem 7.1.14 in place of Proposition A.2.4, and the fact that $p(T) = 0$ implies $(qp)(T) = 0$ for every polynomial q, shows that for an operator T on a finite-dimensional space, the polynomials p with $p(T) = 0$ are exactly the multiples of one of least degree (Section 7.6).

Solution to Exercise A.2.11

Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering)
Techniques. Strengthen the induction hypothesis (Technique A.2.5)
Hint 1. Let p_n be the left side, so $p_{n+1} = p_n(2n+1)/(2n+2)$. Check that $p_n \le 1/\sqrt{3n}$ does not imply $p_{n+1} \le 1/\sqrt{3n+3}$: square and compare.
Hint 2. Prove instead the stronger bound $p_n \le 1/\sqrt{3n+1}$.
Hint 3. The step reduces to $(2n+1)^2(3n+4) \le (2n+2)^2(3n+1)$. Expand both sides.
Sketch. Strengthen to $p_n \le 1/\sqrt{3n+1}$. Base: $p_1 = 1/2$. Step: $p_{n+1} \le (2n+1)/\left((2n+2)\sqrt{3n+1}\right)$, and this is at most $1/\sqrt{3n+4}$ iff $(2n+1)^2(3n+4) \le (2n+2)^2(3n+1)$, which expands to $12n^3 + 28n^2 + 19n + 4 \le 12n^3 + 28n^2 + 20n + 4$.

Let p_n be the left side, so $p_1 = 1/2$ and $p_{n+1} = p_n(2n+1)/(2n+2)$.

The direct induction fails: from $p_n \le 1/\sqrt{3n}$ we get $p_{n+1} \le (2n+1)/\left((2n+2)\sqrt{3n}\right)$, and this is at most $1/\sqrt{3n+3}$ only if $(2n+1)^2(3n+3) \le (2n+2)^2(3n)$, that is, $12n^3 + 24n^2 + 15n + 3 \le 12n^3 + 24n^2 + 12n$, which is false. (Technique A.2.5: the hypothesis leaves no room.)

We prove instead that $p_n \le 1/\sqrt{3n+1}$ for all $n \ge 1$, which implies the claim since $3n + 1 > 3n$. For $n = 1$, $p_1 = 1/2 = 1/\sqrt{4}$. Suppose $p_n \le 1/\sqrt{3n+1}$. Then

$$p_{n+1} \le \frac{2n+1}{(2n+2)\sqrt{3n+1}},$$

and this is at most $1/\sqrt{3n+4}$ if and only if $(2n+1)^2(3n+4) \le (2n+2)^2(3n+1)$. Expanding,

$$(2n+1)^2(3n+4) = 12n^3 + 28n^2 + 19n + 4, \quad (2n+2)^2(3n+1) = 12n^3 + 28n^2 + 20n + 4,$$

and $19n \le 20n$. So $p_{n+1} \le 1/\sqrt{3(n+1)+1}$, completing the induction.

Solution to Exercise A.2.12

Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering)
Hint 1. Is the step correct? Is anything missing from the induction?
Hint 2. Try $n = 0$.
Sketch. The step is valid, but there is no base case, and it fails: $0^2 + 0 + 1 = 1$ is odd. In fact $n^2 + n = n(n+1)$ is always even, so $n^2 + n + 1$ is always odd.

The induction step is correct: it shows that $P(n)$ implies $P(n+1)$. But (I) of Theorem A.2.1 also requires $P(0)$, which was never checked, and it is false: $0^2 + 0 + 1 = 1$ is odd. In fact the claim is false for every n: $n^2 + n = n(n+1)$ is a product of consecutive integers, one of which is even, so $n^2 + n + 1$ is odd. The step proves "if $P(n)$ holds for some n, then it holds for all larger n", which is vacuous here.

Solution to Exercise A.2.13

Uses. Definition 7.2.1 (Invariant subspace), Definition 7.2.6 (Eigenvalue, eigenvector)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. The induction hypothesis is about operators on n-dimensional spaces. Is the restriction of T to W an operator on W?
Hint 2. Test the argument on the rotation of $\mathbb{R}^2$ by a right angle.
Sketch. The restriction of T to W is a map $W \to V$, and it is an operator on W only if W is invariant under T. The rotation $T(x, y) = (-y, x)$ of $\mathbb{R}^2$ has no invariant line, and no eigenvector, so the claim itself is false.

The induction hypothesis applies to operators on n-dimensional spaces, that is, to linear maps $W \to W$. The restriction of T to W is a linear map $W \to V$, and it maps W into W only if W is invariant under T (Definition 7.2.1). The argument never chooses W invariant, and in general no invariant subspace of dimension n exists. Indeed the claim is false: the rotation $T(x, y) = (-y, x)$ of $\mathbb{R}^2$ has no eigenvector, since $T(x, y) = \lambda(x, y)$ gives $-y = \lambda x$ and $x = \lambda y$, so $x = -\lambda^2 x$ and $y = -\lambda^2 y$, which forces $x = y = 0$ because $-\lambda^2 \neq 1$ for real λ.

This is the general warning of Section A.2.2. Inductions on dimension pass to a smaller space, and what is passed down must be an object of the kind the hypothesis is about. In Section 7.5 the induction works over $\mathbb{C}$ because an eigenvector exists, and the induction hypothesis is applied to an operator on a smaller space built from it.

Section A.3

Solution to Exercise A.3.14

Uses. Definition A.3.1 (Equivalence relation), Example A.3.2 (Equivalence relations)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Relations of the form "$g(x) = g(y)$" are always equivalence relations (Example A.3.2(c)). Which of these have that form?
Hint 2. Check reflexivity at the "degenerate" elements: 0 in (b) and $\emptyset$ in (e).
Sketch. (a) Yes, classes $x + \mathbb{Z}$, one for each $x \in [0, 1)$. (b) No: $0 \sim 0$ fails. (c) Yes, $\underset{\text{rank}}{\sim}$; classes are the matrices of rank r, $0 \leq r \leq \min(m, n)$. (d) Yes, $\underset{g}{\sim}$ for $g(\mathbf{v}) = \operatorname{span}(\mathbf{v})$; classes are the lines through $\mathbf{0}$ with $\mathbf{0}$ removed. (e) No: $\emptyset \sim \emptyset$ fails, and so does transitivity.

(a) Yes. $x - x = 0 \in \mathbb{Z}$; if $x - y \in \mathbb{Z}$, then $y - x \in \mathbb{Z}$; and $x - z = (x - y) + (y - z)$. The class of x is $x + \mathbb{Z}$. Each class contains exactly one element of $[0, 1)$, namely $x - \lfloor x \rfloor$, so the classes are indexed by $[0, 1)$.

(b) No: $0 \cdot 0 = 0$, so $0 \sim 0$ fails. (On $\mathbb{Z} \setminus \{0\}$ it is an equivalence relation, "same sign", with two classes.)

(c) Yes: it is $\underset{g}{\sim}$ for $g = \text{rank}$. The classes are the sets of matrices of rank r for $r = 0, 1, \ldots, \min(m, n)$, each nonempty (the matrix $\begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$ has rank r).

(d) Yes: it is $\underset{g}{\sim}$ for $g(\mathbf{v}) = \operatorname{span}(\mathbf{v})$. The class of $\mathbf{v}$ is $\operatorname{span}(\mathbf{v}) \setminus \{\mathbf{0}\} = \{c\mathbf{v} \mid c \neq 0\}$, a line through $\mathbf{0}$ with $\mathbf{0}$ removed. Compare Non-example A.3.3(b).

(e) No: $\emptyset \cap \emptyset = \emptyset$, so $\emptyset \sim \emptyset$ fails. Transitivity fails too: for distinct $a, b \in X$, $\{a\} \sim \{a, b\}$ and $\{a, b\} \sim \{b\}$, but $\{a\} \cap \{b\} = \emptyset$.

Solution to Exercise A.3.15

Uses. Theorem A.3.7 (Equivalence relations are partitions)
Hint 1. By Theorem A.3.7, count partitions instead.
Hint 2. Sort the partitions by their block sizes. For $[4]$ the possible block sizes are 4; $3 + 1$; $2 + 2$; $2 + 1 + 1$; $1 + 1 + 1 + 1$.
Sketch. Count partitions. $[3]$: one with one block, three of type $2 + 1$, one into singletons: 5. $[4]$: $1 + 4 + 3 + 6 + 1 = 15$ by block sizes 4, $3 + 1$, $2 + 2$, $2 + 1 + 1$, $1 + 1 + 1 + 1$.

By Theorem A.3.7, equivalence relations on X correspond to partitions of X, so we count partitions by their block sizes.

For $[3]$: one partition with a single block; three of type $2 + 1$ (choose the singleton); one into three singletons. Total 5.

For [4]: one of type 4; four of type $3+1$ (choose the singleton); three of type $2+2$ (the block containing 1 is $\{1,j\}$ for $j=2,3,4$); six of type $2+1+1$ (choose the pair, $\binom{4}{2}=6$); one into singletons. Total $1+4+3+6+1=15$.

Solution to Exercise A.3.16

Uses. Definition A.3.1 (Equivalence relation), Theorem A.3.7 (Equivalence relations are partitions), Exercise A.1.28, Proposition 1.2.35 (Zero products)
Hint 1. For symmetry use c^{-1}; for transitivity multiply the scalars.
Hint 2. Each class has the same number of elements. How many nonzero multiples does a nonzero vector have?
Hint 3. The classes partition a set of $q^{n+1}-1$ elements into blocks of size $q-1$.
Sketch. Reflexive ($c=1$), symmetric ($\mathbf{v}=c^{-1}\mathbf{w}$), transitive ($\mathbf{u}=cd\mathbf{v}$). The class of $\mathbf{v}$ is $\operatorname{span}(\mathbf{v})\setminus\{\mathbf{0}\}$, and the map $c\mapsto c\mathbf{v}$ from $F\setminus\{0\}$ onto it is injective, so each class has $q-1$ elements. So there are $\big(q^{n+1}-1\big)/(q-1)$ classes.

(a) Reflexivity: $\mathbf{v}=1\mathbf{v}$. Symmetry: if $\mathbf{w}=c\mathbf{v}$ with $c\neq 0$, then $\mathbf{v}=c^{-1}\mathbf{w}$. Transitivity: if $\mathbf{w}=c\mathbf{v}$ and $\mathbf{u}=d\mathbf{w}$, then $\mathbf{u}=(dc)\mathbf{v}$ with $dc\neq 0$. The class of $\mathbf{v}$ is $\{c\mathbf{v}\mid c\neq 0\}=\operatorname{span}(\mathbf{v})\setminus\{\mathbf{0}\}$, the line through $\mathbf{v}$ with $\mathbf{0}$ removed (by Proposition 1.2.35, $c\mathbf{v}=\mathbf{0}$ only for $c=0$). So the classes correspond to the one-dimensional subspaces of F^{n+1}. The quotient set is the **projective space** of F^{n+1}, and the coordinates of a representative are the homogeneous coordinates of its class (Definition 4.7.41).

(b) For $\mathbf{v}\neq\mathbf{0}$, the map $F\setminus\{0\}\to[\mathbf{v}]$, $c\mapsto c\mathbf{v}$, is surjective by definition and injective since $c\mathbf{v}=d\mathbf{v}$ gives $(c-d)\mathbf{v}=\mathbf{0}$, so $c=d$. So every class has $q-1$ elements. The set $F^{n+1}\setminus\{\mathbf{0}\}$ has $q^{n+1}-1$ elements (Exercise A.1.28), and by Theorem A.3.7 it is the disjoint union of the classes. If there are N classes, then $N(q-1)=q^{n+1}-1$, so $N=\big(q^{n+1}-1\big)/(q-1)=1+q+\cdots+q^n$. For example, $\mathbb{F}_2^3$ has 7 one-dimensional subspaces.

Solution to Exercise A.3.17

Uses. Definition A.3.1 (Equivalence relation)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Each axiom is a closure condition. Which of them survive intersections?
Hint 2. For unions, take congruence mod 2 and congruence mod 3 on $\mathbb{Z}$, and look at 0, 2, 5.
Sketch. (a) True: each axiom for $R\cap S$ follows from the same axiom for R and for S. (b) False: with R congruence mod 2 and S mod 3, $(0,2)\in R$ and $(2,5)\in S$, but $(0,5)\notin R\cup S$.

(a) True. (x,x) lies in R and in S. If $(x,y)\in R\cap S$, then $(y,x)\in R$ and $(y,x)\in S$. If $(x,y),(y,z)\in R\cap S$, then $(x,z)\in R$ by transitivity of R, and $(x,z)\in S$ likewise. In terms of classes, the class of x under $R\cap S$ is the intersection of its classes under R and S.

(b) False. On $\mathbb{Z}$, let R be congruence modulo 2 and S congruence modulo 3. Then $(0,2)\in R$ and $(2,5)\in S$, so both lie in $R\cup S$, but $5-0$ is divisible by neither 2 nor 3, so $(0,5)\notin R\cup S$. Transitivity fails. ($R\cup S$ is still reflexive and symmetric.)

Solution to Exercise A.3.18

Uses. Definition A.3.1 (Equivalence relation)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Is there always a y with $x\sim y$?
Hint 2. Try the empty relation on a nonempty set.
Sketch. The step "pick y with $x\sim y$" assumes such a y exists. The empty relation on $\{1\}$ is symmetric and transitive (vacuously) but not reflexive. The argument does show $x\sim x$ for every x related to something.

The argument assumes that some y with $x\sim y$ exists, and nothing guarantees this. For instance, the empty relation $R=\emptyset$ on $X=\{1\}$ is symmetric and transitive, since their hypotheses are never satisfied, but $1\sim 1$ fails. What the argument does prove is that a symmetric and transitive relation is reflexive on the set of elements that are related to at least one element. So in checking an equivalence relation, reflexivity cannot be skipped.

Solution to Exercise A.3.19

Uses. Theorem A.3.10 (Functions on a quotient set), Example A.3.9 ($\mathbb{Z}/n\mathbb{Z}$ as a quotient set)

Techniques. Check that a definition does not depend on the representative (Technique 4.6.18)
Hint 1. By Theorem A.3.10, the formula defines a function iff $a \equiv a' (\mathrm{mod}\, n)$ implies $a \equiv a' (\mathrm{mod}\, m)$.
Hint 2. For "only if", use the pair $a = 0$, $a' = n$.
Hint 3. Surjectivity: $[a]_m = f([a]_n)$. Count the elements for bijectivity.
Sketch. Well defined iff $n \mid a - a'$ implies $m \mid a - a'$. If $m \mid n$, this holds; conversely, $a = n$, $a' = 0$ gives $m \mid n$. f is surjective since $q_m = f \circ q_n$ is. A bijection needs $n = |\mathbb{Z}/n\mathbb{Z}| = |\mathbb{Z}/m\mathbb{Z}| = m$.

Let $g : \mathbb{Z} \to \mathbb{Z}/m\mathbb{Z}$, $g(a) = [a]_m$. By Theorem A.3.10(a), the formula defines a function f with $f([a]_n) = g(a)$ if and only if g is constant on classes mod n, that is, if and only if $n \mid a - a'$ implies $m \mid a - a'$ for all $a, a' \in \mathbb{Z}$.

If $m \mid n$ and $n \mid a - a'$, then $m \mid a - a'$. Conversely, if the implication holds, apply it to $a = n$ and $a' = 0$: since $n \mid n$, we get $m \mid n$.

Suppose $m \mid n$. Since g is surjective, so is f (Theorem A.3.10(c)). By Example A.3.9, $\mathbb{Z}/n\mathbb{Z}$ has n elements and $\mathbb{Z}/m\mathbb{Z}$ has m, so if f is bijective, then $n = m$ (Corollary A.1.18). Conversely, for $m = n$, f is the identity. For example, reduction mod 2 is a well-defined function $\mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$, but "reduction mod 3" is not: $[0]_4 = [4]_4$ while $[0]_3 \neq [4]_3$.

Solution to Exercise A.3.20

Uses. Definition A.3.1 (Equivalence relation), Definition 3.2.21 (Row equivalence), Proposition 3.2.10 (Inverses of elementary matrices)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For (a): the empty chain ($k = 0$) gives reflexivity; reversing a chain gives symmetry; concatenating gives transitivity.
Hint 2. For minimality, if $\sim$ is an equivalence relation containing R, show by induction on k that each $x_0 \sim x_k$, using symmetry for the backward steps.
Hint 3. For (b), elementary row operations can be undone by elementary row operations (Proposition 3.2.10), so a backward step is also a forward step.
Sketch. (a) Chains of length 0, reversed chains, and concatenated chains give the three axioms; a one-step chain shows $R \subseteq \approx$. If $\sim \supseteq R$ is an equivalence relation, each step of a chain is in $\sim$ (by symmetry for backward steps), and transitivity along the chain gives $x \sim y$. (b) By (a) the generated relation is the smallest equivalence relation containing R; row equivalence contains R and is an equivalence relation, and conversely a row equivalence $B = E_k \cdots E_1 A$ is a chain of forward R-steps.

(a) Reflexivity: the chain $x_0 = x$ with $k = 0$. Symmetry: a chain $x_0, \ldots, x_k$ from x to y, read backwards, is a chain from y to x, since the condition on consecutive pairs is symmetric. Transitivity: a chain from x to y followed by one from y to z is a chain from x to z. If $(x, y) \in R$, then x, y is a chain with $k = 1$, so $R \subseteq \approx$.

Now let $\sim$ be an equivalence relation with $R \subseteq \sim$, and let $x = x_0, \ldots, x_k = y$ be a chain. We show $x_0 \sim x_j$ by induction on j. For $j = 0$ this is reflexivity. If $x_0 \sim x_{j-1}$, then $(x_{j-1}, x_j) \in R$ gives $x_{j-1} \sim x_j$, and $(x_j, x_{j-1}) \in R$ gives $x_j \sim x_{j-1}$, hence $x_{j-1} \sim x_j$ by symmetry. Either way $x_0 \sim x_j$ by transitivity. So $x \approx y$ implies $x \sim y$.

(b) Row equivalence is an equivalence relation (Proposition 3.2.22) and contains R, so by (a) it contains the generated relation $\approx$. Conversely, if $B = E_k \cdots E_1 A$ with E_i elementary, then $A, E_1 A, E_2 E_1 A, \ldots, B$ is a chain in which each step is one elementary row operation, so $A \approx B$. Hence the two relations are equal. The backward steps allowed in $\approx$ add nothing here because each elementary operation is undone by another one (Proposition 3.2.10). This is exactly why row equivalence is symmetric.

Section A.4

Solution to Exercise A.4.8

Uses. Definition A.4.1 (Partial order), Definition A.4.2 (Upper bound, maximal element), Corollary A.1.18 (Cardinality is well defined)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Look at strictly increasing sequences $p_1 < p_2 < \cdots < p_k$. Why are their entries distinct, and why is $k \leq |P|$?
Hint 2. Take such a sequence with k as large as possible. Its last entry is maximal.

Sketch. The entries of a strictly increasing sequence are distinct (by transitivity and antisymmetry), so its length is at most $|P|$. A longest one exists, since one-term sequences exist, and its last entry p_k is maximal: $p_k < p$ would give a longer sequence.

In a strictly increasing sequence $p_1 < p_2 < \cdots < p_k$, the entries are distinct: if $i < j$, then $p_i < p_j$ by transitivity, and if $p_i = p_j$ this would read $p_i \leq p_{i+1}$ and $p_{i+1} \leq p_j = p_i$, so $p_i = p_{i+1}$ by antisymmetry, contradicting $p_i < p_{i+1}$. So $i \mapsto p_i$ is an injection $[k] \to P$, and $k \leq |P|$ (Corollary A.1.18). Since $P \neq \emptyset$, there are sequences of length 1, so there is a strictly increasing sequence of maximal length k. Its last entry p_k is maximal: if $p_k \leq p$ with $p \neq p_k$, then $p_1 < \cdots < p_k < p$ would be longer.

Solution to Exercise A.4.9

Uses. Theorem A.4.4 (Zorn's lemma), Example A.4.3 (Chains and maximal elements)
Hint 1. An upper bound has to be an element of P. Is the union of a chain of proper subspaces proper?
Hint 2. Look at Example A.4.3(c).
Sketch. The union is a subspace, but it need not be proper, so it need not lie in P: in $F[x]$ the union of the chain $F[x]_{\leq n}$ is $F[x]$. The claim is still true (Exercise A.4.10), but the proof must keep the union away from V, for instance by fixing a vector it must avoid.

The union of the chain is a subspace containing every member, but an upper bound must be an element of P, that is, a *proper* subspace, and the argument never checks this. It can fail: in $V = F[x]$, the subspaces $F[x]_{\leq n}$, $n \geq 0$, form a chain of proper subspaces whose union is $F[x]$ (Example A.4.3(c)). So the hypothesis of Zorn's lemma has not been verified.

The claim itself is true. One way to repair the proof is to fix $\mathbf{v} \neq \mathbf{0}$ and let P be the set of subspaces that do not contain $\mathbf{v}$. It contains $\{\mathbf{0}\}$, and the union of a nonempty chain in P is a subspace that does not contain $\mathbf{v}$, so it lies in P. Let M be a maximal element. If some $\mathbf{x}$ were not in $M + \operatorname{span}(\mathbf{v})$, then $M + \operatorname{span}(\mathbf{x})$ would not contain $\mathbf{v}$ (from $\mathbf{v} = \mathbf{m} + c\mathbf{x}$ we would get $c \neq 0$ and $\mathbf{x} = c^{-1}(\mathbf{v} - \mathbf{m}) \in M + \operatorname{span}(\mathbf{v})$), contradicting maximality. So $V = M + \operatorname{span}(\mathbf{v})$. Every subspace strictly containing M contains $\mathbf{v}$, by maximality, and hence equals V; so M is a maximal proper subspace. Exercise A.4.10 gives another route.

Solution to Exercise A.4.10

Uses. Theorem A.4.7 (Complements exist), Theorem 4.4.7 (Criteria for direct sums), Definition 4.4.4 (Direct sum), Definition 2.1.1 (Linear map)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18)
Hint 1. The sum $U + \operatorname{span}(\mathbf{v})$ is direct. Take a complement W of it.
Hint 2. Every vector is uniquely $\mathbf{u} + c\mathbf{v} + \mathbf{w}$. Let φ read off c.
Hint 3. For the last part, $\ker\varphi$ is a proper subspace. Why is it maximal?
Sketch. $U \cap \operatorname{span}(\mathbf{v}) = \{\mathbf{0}\}$, so $U' = U \oplus \operatorname{span}(\mathbf{v})$; by Theorem A.4.7, $V = U \oplus \operatorname{span}(\mathbf{v}) \oplus W$. Define $\varphi(\mathbf{u} + c\mathbf{v} + \mathbf{w}) = c$, well defined by uniqueness of decompositions and linear by comparing decompositions. With $U = \{\mathbf{0}\}$, $\ker\varphi$ is a proper subspace with $V = \ker\varphi \oplus \operatorname{span}(\mathbf{v})$, and any subspace strictly containing it contains $\mathbf{v}$.

If $c\mathbf{v} \in U$ with $c \neq 0$, then $\mathbf{v} \in U$; so $U \cap \operatorname{span}(\mathbf{v}) = \{\mathbf{0}\}$, and the sum $U' = U + \operatorname{span}(\mathbf{v})$ is direct (Theorem 4.4.7). By Theorem A.4.7 there is W with $V = U' \oplus W$. So every $\mathbf{x} \in V$ has exactly one decomposition $\mathbf{x} = \mathbf{u} + c\mathbf{v} + \mathbf{w}$ with $\mathbf{u} \in U$, $c \in F$, $\mathbf{w} \in W$ (the coefficient c is unique because $\mathbf{v} \neq \mathbf{0}$). Define $\varphi(\mathbf{x}) = c$. This is a function because the decomposition is unique. It is linear: if $\mathbf{x} = \mathbf{u} + c\mathbf{v} + \mathbf{w}$ and $\mathbf{x}' = \mathbf{u}' + c'\mathbf{v} + \mathbf{w}'$, then $a\mathbf{x} + \mathbf{x}' = (a\mathbf{u} + \mathbf{u}') + (ac + c')\mathbf{v} + (a\mathbf{w} + \mathbf{w}')$ is the decomposition of $a\mathbf{x} + \mathbf{x}'$, so $\varphi(a\mathbf{x} + \mathbf{x}') = ac + c'$. Clearly $\varphi(\mathbf{u}) = 0$ for $\mathbf{u} \in U$ and $\varphi(\mathbf{v}) = 1$.

Now let $V \neq \{\mathbf{0}\}$, pick $\mathbf{v} \neq \mathbf{0}$, and apply this with $U = \{\mathbf{0}\}$. Then $M = \ker\varphi$ is a subspace not containing $\mathbf{v}$, so it is proper. Every $\mathbf{x} \in V$ equals $(\mathbf{x} - \varphi(\mathbf{x})\mathbf{v}) + \varphi(\mathbf{x})\mathbf{v}$ with the first term in M, so $V = M + \operatorname{span}(\mathbf{v})$. If M' is a subspace with $M \subsetneq M'$, pick $\mathbf{x} \in M' \setminus M$; then $\mathbf{x} - \varphi(\mathbf{x})\mathbf{v} \in M \subseteq M'$ and $\varphi(\mathbf{x}) \neq 0$, so $\mathbf{v} \in M'$ and $M' \supseteq M + \operatorname{span}(\mathbf{v}) = V$. So M is a maximal proper subspace.

Solution to Exercise A.4.11

Uses. Theorem A.4.4 (Zorn's lemma), Lemma A.4.6 (Finitely many elements of a union of a chain), Theorem A.1.12 (One-sided inverses of functions)

Techniques. Apply Zorn's lemma (Technique A.4.5)
Hint 1. Let P be the set of partial right inverses: pairs (A, g) with $A \subseteq Y$ and $g : A \to X$ such that $f(g(a)) = a$ for all $a \in A$. Order them by extension: $(A, g) \leq (A', g')$ if $A \subseteq A'$ and g' agrees with g on A.
Hint 2. For a nonempty chain, define g^* on the union of the domains by "use any member of the chain whose domain contains the point". Why is this well defined?
Hint 3. If a maximal (A, g) has $A \neq Y$, extend g to one more point y by choosing one preimage of y. A single choice needs no axiom.
Sketch. Partial right inverses, ordered by extension, form a partially ordered set containing $(\emptyset, \text{empty function})$. The union of a chain is a partial right inverse, well defined because any two members agree where both are defined. A maximal (A, g) has $A = Y$: otherwise send one $y \notin A$ to one of its preimages, which extends g strictly.

Let P be the set of pairs (A, g) with $A \subseteq Y$ and $g : A \to X$ such that $f(g(a)) = a$ for every $a \in A$. Order P by $(A, g) \leq (A', g')$ if $A \subseteq A'$ and $g'(a) = g(a)$ for all $a \in A$. This is a partial order: reflexivity and transitivity are clear, and if $(A, g) \leq (A', g') \leq (A, g)$, then $A = A'$ and $g = g'$. P contains $(\emptyset, g_\emptyset)$ with $g_\emptyset$ the empty function, so $P \neq \emptyset$.

Let $\Gamma \subseteq P$ be a nonempty chain, and let A^* be the union of the domains A of its members. For $y \in A^*$, define $g^*(y) = g(y)$ for any $(A, g) \in \Gamma$ with $y \in A$. This does not depend on the member chosen: if $y \in A$ and $y \in A'$ for $(A, g), (A', g') \in \Gamma$, these are comparable, say $(A, g) \leq (A', g')$, and then $g'(y) = g(y)$. So $g^* : A^* \to X$ is a function with $f(g^*(y)) = f(g(y)) = y$, and $(A^*, g^*) \in P$ is an upper bound of Γ.

By Zorn's lemma, P has a maximal element (A, g). Suppose $A \neq Y$ and pick $y_0 \in Y \setminus A$. Since f is surjective, there is some x_0 with $f(x_0) = y_0$; this is one choice, which needs no axiom. Extending g by $g(y_0) = x_0$ gives an element of P strictly larger than (A, g), a contradiction. So $A = Y$, and $f \circ g = \mathrm{id}_Y$.

Section B.1

Solution to Exercise B.1.6

Uses. Proposition B.1.2 (Conjugation respects the field operations), Proposition 1.1.17 (No zero divisors)
Hint 1. Move everything to one side and factor the difference of squares.
Hint 2. $(z - \overline{z})(z + \overline{z}) = 0$. Now use Proposition B.1.2(c).
Sketch. $z^2 - \overline{z}^2 = (z - \overline{z})(z + \overline{z})$, so the equation holds if and only if $\overline{z} = z$ or $\overline{z} = -z$. The solutions are the real numbers and the purely imaginary numbers.

Since multiplication in $\mathbb{C}$ is commutative, $(z - \overline{z})(z + \overline{z}) = z^2 - \overline{z}^2$. So $z^2 = \overline{z}^2$ if and only if $(z - \overline{z})(z + \overline{z}) = 0$, which by Proposition 1.1.17 happens if and only if $\overline{z} = z$ or $\overline{z} = -z$. By Proposition B.1.2(c), the solutions are exactly the real numbers and the purely imaginary numbers, that is, the points of the two coordinate axes.

Solution to Exercise B.1.10

Uses. Proposition B.1.8 (Properties of the modulus)
Hint 1. Use Proposition B.1.8(d) for the quotient.
Hint 2. To compute z, multiply the numerator and the denominator by $\overline{2 - i} = 2 + i$; this is Proposition B.1.8(c).
Sketch. $|z| = |1 + 2i|/|2 - i| = \sqrt{5}/\sqrt{5} = 1$. And $z = (1 + 2i)(2 + i)/5 = 5i/5 = i$, which has modulus 1.

By Proposition B.1.8(d), $|z| = |1 + 2i|/|2 - i| = \sqrt{1 + 4}/\sqrt{4 + 1} = 1$. By Proposition B.1.8(c), $(2 - i)^{-1} = (2 + i)/5$, so

$$z = \frac{(1 + 2i)(2 + i)}{5} = \frac{2 + i + 4i + 2i^2}{5} = \frac{5i}{5} = i,$$

and indeed $|i| = 1$.

Solution to Exercise B.1.23

Uses. Proposition B.1.15 (Existence and uniqueness of polar form), Theorem B.1.20 (De Moivre's formula), Proposition B.1.17 (Multiplication in polar form)
Techniques. Use polar form for products, powers, and roots (Technique B.1.21)
Hint 1. The moduli are $2\sqrt{2}$ and 2. Find angles with the right cosine and sine.

Hint 2. $-2+2i = 2\sqrt{2}e^{3\pi i/4}$ and $-1-\sqrt{3}i = 2e^{-2\pi i/3}$. Now apply Theorem B.1.20 and divide.
Sketch. $(-2+2i)^5 = \left(2\sqrt{2}\right)^5 e^{15\pi i/4} = 128\sqrt{2}e^{-i\pi/4} = 128-128i$ and $\left(-1-\sqrt{3}i\right)^3 = 8e^{-2\pi i} = 8$, so the quotient is $16-16i$.

We have $|-2+2i| = \sqrt{8} = 2\sqrt{2}$ and $(-2+2i)/\left(2\sqrt{2}\right) = -1/\sqrt{2}+i/\sqrt{2} = e^{3\pi i/4}$, so $-2+2i = 2\sqrt{2}e^{3\pi i/4}$. Similarly $\left|-1-\sqrt{3}i\right| = 2$ and $-1-\sqrt{3}i = 2\left(-1/2-\left(\sqrt{3}/2\right)i\right) = 2e^{-2\pi i/3}$. By Theorem B.1.20,

$$(-2+2i)^5 = \left(2\sqrt{2}\right)^5 e^{15\pi i/4} = 128\sqrt{2}e^{-i\pi/4} = 128\sqrt{2}\left(\frac{1}{\sqrt{2}}-\frac{i}{\sqrt{2}}\right) = 128-128i,$$

using $\left(2\sqrt{2}\right)^5 = 32\cdot 4\sqrt{2}$ and $15\pi/4 = 4\pi-\pi/4$. Also $\left(-1-\sqrt{3}i\right)^3 = 8e^{-2\pi i} = 8$. So the quotient is $(128-128i)/8 = 16-16i$.

Solution to Exercise B.1.33

Uses. Proposition B.1.15 (Existence and uniqueness of polar form), Theorem B.1.20 (De Moivre's formula), Exercise 1.1.36
Techniques. Use polar form for products, powers, and roots (Technique B.1.21)
Hint 1. Write each base in polar form and apply Theorem B.1.20. Then reduce the argument modulo 2π.
Hint 2. $1-i = \sqrt{2}e^{-i\pi/4}$ and $1+\sqrt{3}i = 2e^{i\pi/3}$. For (d), first simplify the base; it is a fourth root of unity.
Sketch. (a) $32e^{-5\pi i/2} = 32e^{-i\pi/2} = -32i$. (b) $2^{-4}e^{-4\pi i/3} = (1/16)e^{2\pi i/3} = -1/32+\left(\sqrt{3}/32\right)i$. (c) $e^{4\pi i/3} = -1/2-\left(\sqrt{3}/2\right)i$. (d) The base is i, and $i^{2027} = i^3 = -i$.

(a) $1-i = \sqrt{2}e^{-i\pi/4}$, so $(1-i)^{10} = 2^5 e^{-10\pi i/4} = 32e^{-5\pi i/2}$. Since $-5\pi/2 = -\pi/2-2\pi$, this is $32e^{-i\pi/2} = -32i$.

(b) $1+\sqrt{3}i = 2e^{i\pi/3}$, so $\left(1+\sqrt{3}i\right)^{-4} = 2^{-4}e^{-4\pi i/3} = (1/16)e^{2\pi i/3} = (1/16)\left(-1/2+\left(\sqrt{3}/2\right)i\right) = -1/32+\left(\sqrt{3}/32\right)i$.

(c) By Theorem B.1.20, the power is $e^{12\pi i/9} = e^{4\pi i/3} = -1/2-\left(\sqrt{3}/2\right)i$.

(d) By Exercise 1.1.36(c), $(1+i)/(1-i) = i$. Since $i^4 = 1$ and $2027 = 4\cdot 506+3$, the power is $i^3 = -i$.

Solution to Exercise B.1.34

Uses. Theorem B.1.26 (nth roots), Proposition B.1.4 (Roots of real polynomials come in conjugate pairs)
Techniques. Use polar form for products, powers, and roots (Technique B.1.21)
Hint 1. $-64 = 64e^{i\pi}$. Apply Theorem B.1.26 with $n=6$.
Hint 2. The arguments are $\pi/6+k\pi/3$ for $k = 0,\dots,5$, and the modulus is 2.
Sketch. The solutions are $2e^{i(\pi+2\pi k)/6}$: $\pm\sqrt{3}\pm i$ and $\pm 2i$, the vertices of a regular hexagon of radius 2. Of these, $\pm 2i$ satisfy $z^2 = -4$.

Since $-64 = 64e^{i\pi}$ and $64^{1/6} = 2$, Theorem B.1.26 gives the six solutions $2e^{i(\pi+2\pi k)/6}$, $k = 0,\dots,5$, with arguments $\pi/6, \pi/2, 5\pi/6, 7\pi/6, 3\pi/2, 11\pi/6$:

$$\sqrt{3}+i, \quad 2i, \quad -\sqrt{3}+i, \quad -\sqrt{3}-i, \quad -2i, \quad \sqrt{3}-i.$$

They are the vertices of a regular hexagon inscribed in the circle of radius 2, with vertices on the imaginary axis. As z^6+64 has real coefficients, they come in conjugate pairs (Proposition B.1.4). The solutions of $z^2 = -4$ are $\pm 2i$, and both are on the list, as they must be: if $z^2 = -4$, then $z^6 = \left(z^2\right)^3 = -64$.

Solution to Exercise B.1.35

Uses. Proposition B.1.8 (Properties of the modulus), Proposition B.1.2 (Conjugation respects the field operations)
Techniques. Square the modulus (Technique B.1.9)
Hint 1. Apply Proposition B.1.8(f) to $z+w$ and to $z+(-w)$.
Hint 2. $\operatorname{Re}(z\overline{w}) = ac+bd$ for $z = a+bi$ and $w = c+di$.
Sketch. $|z\pm w|^2 = |z|^2 \pm 2\operatorname{Re}(z\overline{w})+|w|^2$. Adding gives (a): the squares of the diagonals add up to the squares of the four sides. Subtracting gives (b), and $\operatorname{Re}(z\overline{w}) = ac+bd$ is the dot product of (a,b) and (c,d), so the diagonals are equal exactly when the parallelogram is a rectangle.

By Proposition B.1.8(f), $|z+w|^2 = |z|^2+2\operatorname{Re}(z\overline{w})+|w|^2$. Applied to z and $-w$, with $\overline{-w} = -\overline{w}$ and $|-w| = |w|$, it gives $|z-w|^2 = |z|^2-2\operatorname{Re}(z\overline{w})+|w|^2$.

(a) Adding the two identities gives $|z+w|^2+|z-w|^2 = 2|z|^2+2|w|^2$. The diagonals of the parallelogram are the segments from 0 to $z+w$ and from w to z, of lengths $|z+w|$ and $|z-w|$, and its four sides have

lengths $|z|, |w|, |z|, |w|$. So the sum of the squares of the diagonals equals the sum of the squares of the sides. This is the parallelogram law, the case $V = \mathbb{C}$ of Proposition 6.1.30.

(b) Subtracting gives $|z+w|^2 - |z-w|^2 = 4\,\mathrm{Re}(z\overline{w})$. Both lengths are nonnegative, so $|z+w| = |z-w|$ if and only if $\mathrm{Re}(z\overline{w}) = 0$. For $z = a + bi$ and $w = c + di$, $z\overline{w} = (ac + bd) + (bc - ad)i$, so $\mathrm{Re}(z\overline{w}) = ac + bd$ is the dot product of (a, b) and (c, d). So the diagonals are equally long exactly when the sides z and w are perpendicular (or one of them is 0), that is, when the parallelogram is a rectangle.

Solution to Exercise B.1.36

Uses. Proposition B.1.8 (Properties of the modulus), Proposition B.1.2 (Conjugation respects the field operations)
Techniques. Square the modulus (Technique B.1.9)
Hint 1. Expand both squared moduli with Proposition B.1.8(f), or as $u\overline{u}$.
Hint 2. The cross terms are $-2\,\mathrm{Re}(\overline{z}w)$ and $-2\,\mathrm{Re}(z\overline{w})$. These are equal, because $\overline{z}w$ is the conjugate of $z\overline{w}$.
Hint 3. For (b), the right side of (a) is positive. For (c), it is zero.
Sketch. $|1 - \overline{z}w|^2 = 1 - 2\,\mathrm{Re}(\overline{z}w) + |z|^2|w|^2$ and $|z-w|^2 = |z|^2 - 2\,\mathrm{Re}(z\overline{w}) + |w|^2$; the real parts agree, and the difference is $1 - |z|^2 - |w|^2 + |z|^2|w|^2$. In (b), $|\overline{z}w| < 1$, so the denominator is nonzero, and the identity gives $|z-w|^2 < |1-\overline{z}w|^2$. In (c) the right side vanishes.

(a) By Proposition B.1.8(f) (applied to 1 and $-\overline{z}w$, and to z and $-w$) and (d),

$$|1 - \overline{z}w|^2 = 1 - 2\,\mathrm{Re}(\overline{z}w) + |z|^2|w|^2,$$
$$|z-w|^2 = |z|^2 - 2\,\mathrm{Re}(z\overline{w}) + |w|^2.$$

Since $\overline{z}w = \overline{z\overline{w}}$ (Proposition B.1.2), the two numbers have the same real part. Subtracting,

$$|1-\overline{z}w|^2 - |z-w|^2 = 1 - |z|^2 - |w|^2 + |z|^2|w|^2 = \left(1-|z|^2\right)\left(1-|w|^2\right).$$

(b) $|\overline{z}w| = |z||w| < 1$, so $\overline{z}w \neq 1$ and $1 - \overline{z}w \neq 0$. Both factors on the right of (a) are positive, so $|z-w|^2 < |1-\overline{z}w|^2$. Taking square roots and dividing by $|1-\overline{z}w| > 0$ gives the claim (Proposition B.1.8(d)).

(c) Now $1 - |w|^2 = 0$, so (a) gives $|1-\overline{z}w| = |z-w|$, and the denominator is nonzero by assumption. Hence the quotient has modulus 1.

So for fixed z with $|z| < 1$, the map $w \mapsto (z-w)/(1-\overline{z}w)$ sends the open unit disk into itself, by (b), and the unit circle into itself, by (c); the condition $\overline{z}w \neq 1$ holds automatically, since $|\overline{z}w| < 1$.

Solution to Exercise B.1.37

Uses. Proposition B.1.8 (Properties of the modulus), Proposition B.1.2 (Conjugation respects the field operations)
Techniques. Square the modulus (Technique B.1.9)
Hint 1. For (a) and (b), square both sides and write $z = x + yi$.
Hint 2. For (c), multiply the numerator and the denominator by $\overline{z+1}$. The denominator becomes a positive real number, and the numerator is $(z-1)(\overline{z}+1)$.
Sketch. (a) Squaring, $-2x + 1 = 2y + 1$: the line $y = -x$, the perpendicular bisector of 1 and $-i$. (b) Squaring gives $3x^2 + 10x + 3 + 3y^2 = 0$, the circle with centre $-5/3$ and radius $4/3$. (c) $(z-1)(\overline{z}+1) = |z|^2 - 1 + (z - \overline{z})$ has real part $|z|^2 - 1$, so the set is the unit circle without -1.

Write $z = x + yi$. Moduli are nonnegative, so each equation between moduli is equivalent to the equation between their squares.

(a) $|z-1|^2 = (x-1)^2 + y^2$ and $|z+i|^2 = x^2 + (y+1)^2$. They are equal if and only if $-2x + 1 = 2y + 1$, that is, $y = -x$. The set is the line through 0 with slope -1: the perpendicular bisector of the segment from 1 to $-i$, as it should be, since it consists of the points equidistant from 1 and $-i$.

(b) The condition is $(x-1)^2 + y^2 = 4\left((x+1)^2 + y^2\right)$, that is, $3x^2 + 10x + 3 + 3y^2 = 0$. Dividing by 3 and completing the square, $(x + 5/3)^2 + y^2 = 25/9 - 1 = 16/9$. The set is the circle with centre $-5/3$ and radius $4/3$.

(c) For $z \neq -1$,

$$\frac{z-1}{z+1} = \frac{(z-1)\overline{(z+1)}}{|z+1|^2} = \frac{(z-1)(\overline{z}+1)}{|z+1|^2}$$

by Proposition B.1.8(c), and $|z+1|^2 > 0$ is real. The numerator is $z\overline{z} + z - \overline{z} - 1 = \left(|z|^2 - 1\right) + (z - \overline{z})$, where $z - \overline{z} = 2yi$ is purely imaginary. So the real part of the quotient is $\left(|z|^2 - 1\right)/|z+1|^2$, which is 0 if and only if $|z| = 1$. The set is the unit circle with -1 removed. Geometrically, $(z-1)/(z+1)$ is purely imaginary exactly when the segments from z to 1 and to -1 are perpendicular (or $z = 1$), and the set of such z is the circle with diameter from -1 to 1 (Thales).

Solution to Exercise B.1.38

Uses. Proposition B.1.8 (Properties of the modulus), Proposition B.1.2 (Conjugation respects the field operations)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. Test each claim on $z, w \in \{1, i, 1+i\}$ before trying to prove it.
Hint 2. (b), (e), and (f) are true; for (e), expand $|z \pm w|^2$ with Proposition B.1.8(f).
Sketch. (a) False: $z = w = i$. (b) True: $|zz| = |z||z|$. (c) False: $z = i$. (d) False: $z = 1$, $w = i$. (e) True: $|z+w|^2 - |z-w|^2 = 4\,\mathrm{Re}(z\overline{w})$. (f) True: Proposition B.1.2(e).

(a) False. For $z = w = i$, $\mathrm{Re}(zw) = \mathrm{Re}(-1) = -1$, but $\mathrm{Re}\, z\, \mathrm{Re}\, w = 0$. The correct formula is $\mathrm{Re}(zw) = \mathrm{Re}\, z\, \mathrm{Re}\, w - \mathrm{Im}\, z\, \mathrm{Im}\, w$.

(b) True, by Proposition B.1.8(d) with $w = z$.

(c) False: $i^2 = -1$ is real, but i is not.

(d) False: $|1| = |i| = 1$, but $1 \neq \pm i$. Numbers of equal modulus differ by a factor of modulus 1, of which ± 1 are only two.

(e) True. By Proposition B.1.8(f), $|z \pm w|^2 = |z|^2 \pm 2\,\mathrm{Re}(z\overline{w}) + |w|^2$, so the hypothesis gives $4\,\mathrm{Re}(z\overline{w}) = 0$.

(f) True, by Proposition B.1.2(e).

Solution to Exercise B.1.39

Uses. Theorem B.1.20 (De Moivre's formula), Proposition B.1.29 (Square roots in $\mathbb{C}$), Proposition B.1.15 (Existence and uniqueness of polar form)
Hint 1. For which exponents n did we prove Theorem B.1.20? Was $z^{1/2}$ ever defined?
Hint 2. What does de Moivre's formula with $n = 2$ say about $\cos(\theta/2) + i\sin(\theta/2)$?
Sketch. Theorem B.1.20 holds for integer n only, and $1^{1/2}$ has no meaning: 1 has two square roots, ± 1. The formula $\cos(\theta/2) + i\sin(\theta/2)$ depends on the argument θ chosen, not only on the number $e^{i\theta}$, and the arguments 0 and 2π of 1 produce its two square roots.

The first sentence is the error. Theorem B.1.20 was proved for integers n, by induction and by inverting, and it says nothing for $n = 1/2$. Worse, the symbol $1^{1/2}$ was never defined: 1 has two square roots, 1 and -1 (Proposition B.1.29), and no rule has been given for choosing one.

What de Moivre's formula does give, with $n = 2$, is $(\cos(\theta/2) + i\sin(\theta/2))^2 = \cos\theta + i\sin\theta$. So $\cos(\theta/2) + i\sin(\theta/2)$ is *a* square root of $e^{i\theta}$. But it depends on θ, not only on the number $e^{i\theta}$, and a number has many arguments (Proposition B.1.15). The arguments 0 and 2π of 1 give its two different square roots, 1 and -1, exactly as in Theorem B.1.26 with $n = 2$. The rest of the computation is correct; it shows only that 1 and -1 are both square roots of 1.

Solution to Exercise B.1.40

Uses. Proposition 2.3.11 (Entries of $A\mathbf{x}$), Proposition B.1.2 (Conjugation respects the field operations)
Techniques. Conjugate the equation (Technique B.1.3)
Hint 1. Compute the ith entry of $A\overline{\mathbf{z}}$ with Proposition 2.3.11 and use that each a_{ij} is real.
Hint 2. For (b) and (c), conjugate the given equation and apply (a). For the real solution in (c), average a solution with its conjugate.
Sketch. (a) $\sum_j a_{ij}\overline{z_j} = \overline{\sum_j a_{ij} z_j}$ because $\overline{a_{ij}} = a_{ij}$. (b) $A\overline{\mathbf{v}} = \overline{A\mathbf{v}} = \overline{\lambda\mathbf{v}} = \overline{\lambda}\,\overline{\mathbf{v}}$. (c) $A\overline{\mathbf{z}} = \overline{\mathbf{b}} = \mathbf{b}$, and then $(\mathbf{z} + \overline{\mathbf{z}})/2$, which has real entries $\mathrm{Re}\, z_j$, is a solution.

(a) By Proposition 2.3.11 and Proposition B.1.2, the ith entry of $A\overline{\mathbf{z}}$ is

$$\sum_{j=1}^{n} a_{ij}\overline{z_j} = \sum_{j=1}^{n} \overline{a_{ij}z_j} = \overline{\sum_{j=1}^{n} a_{ij}z_j},$$

since $\overline{a_{ij}} = a_{ij}$ for real a_{ij}. This is the ith entry of $\overline{A\mathbf{z}}$.

(b) By (a), $A\overline{\mathbf{v}} = \overline{A\mathbf{v}} = \overline{\lambda\mathbf{v}} = \overline{\lambda}\,\overline{\mathbf{v}}$, where the last step conjugates each entry λv_j.

(c) If $A\mathbf{z} = \mathbf{b}$, then by (a), $A\overline{\mathbf{z}} = \overline{\mathbf{b}} = \mathbf{b}$, since $\mathbf{b}$ is real. So $\overline{\mathbf{z}}$ is also a solution. Then $\mathbf{x} = \frac{1}{2}(\mathbf{z} + \overline{\mathbf{z}})$ satisfies $A\mathbf{x} = \frac{1}{2}(\mathbf{b} + \mathbf{b}) = \mathbf{b}$, and its entries $\left(z_j + \overline{z_j}\right)/2 = \operatorname{Re} z_j$ are real (Proposition B.1.2(d)).

In the language of Section 7.2, (b) says that the nonreal eigenvalues of a real matrix come in conjugate pairs $\lambda, \overline{\lambda}$, with conjugate eigenvectors.

Solution to Exercise B.1.41

Uses. Proposition B.1.18 (Multiplication by w as a map of the plane), Theorem 2.4.2 (The matrix of a composite), Theorem B.1.25 (The nth roots of unity)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. By Proposition B.1.18, complex numbers act on $\mathbb{R}^2$ through the matrices $J_w = [M_w]_{\mathcal{BB}}$. How does J_wJ_z compare with J_{wz}?
Hint 2. $J_w^k = J_{w^k}$. So look for $w \in \mathbb{C}$ with $w^3 = -1$ but $w \neq -1$, and in (b), for an nth root of unity whose smaller powers are not 1.
Sketch. $M_wM_z = M_{wz}$, so $J_w^k = J_{w^k}$, and $J_w = J_{w'}$ only if $w = w'$. (a) $w = e^{i\pi/3}$ has $w^3 = -1$, giving $A = \begin{pmatrix} 1/2 & -\sqrt{3}/2 \\ \sqrt{3}/2 & 1/2 \end{pmatrix}$. (b) $w = e^{2\pi i/n}$, the rotation by $2\pi/n$.

For $w = c + di$ let $J_w = [M_w]_{\mathcal{BB}} = \begin{pmatrix} c & -d \\ d & c \end{pmatrix}$, as in Proposition B.1.18. Since $M_w \circ M_z = M_{wz}$, Theorem 2.4.2 gives $J_wJ_z = J_{wz}$, and by induction $J_w^k = J_{w^k}$ for $k \geq 1$. Also J_w determines w (its first column is (c, d)), and $J_1 = I_2$, $J_{-1} = -I_2$.

(a) Let $w = e^{i\pi/3} = 1/2 + \left(\sqrt{3}/2\right)i$. Then $w^3 = e^{i\pi} = -1$ by Theorem B.1.20, so

$$A = J_w = \begin{pmatrix} 1/2 & -\sqrt{3}/2 \\ \sqrt{3}/2 & 1/2 \end{pmatrix}$$

satisfies $A^3 = J_{-1} = -I_2$, and $A \neq -I_2$. Geometrically, A is the rotation by $\pi/3$, and three of them make a half turn.

(b) Let $\omega = e^{2\pi i/n}$ and $A = J_\omega = \begin{pmatrix} \cos(2\pi/n) & -\sin(2\pi/n) \\ \sin(2\pi/n) & \cos(2\pi/n) \end{pmatrix}$, the rotation by $2\pi/n$. Then $A^k = J_{\omega^k}$, which equals $I_2 = J_1$ if and only if $\omega^k = 1$, that is, $n \mid k$ (Theorem B.1.25(a)). So $A^n = I_2$ and $A^k \neq I_2$ for $1 \leq k < n$.

Solution to Exercise B.1.42

Uses. Definition 2.4.1 (Matrix product), Proposition 2.4.14 (Algebra of matrices), Definition 2.4.21 (Transpose), Definition 5.1.14 (The 2×2 determinant), Proposition B.1.18 (Multiplication by w as a map of the plane)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Compute $\varphi(z)\varphi(w)$ directly, or note that $\varphi(z) = [M_z]_{\mathcal{BB}}$ and $M_z \circ M_w = M_{zw}$.
Hint 2. For (c), most field axioms hold because they hold for all matrices (Proposition 2.4.14). Commutativity of multiplication and inverses can be transported from $\mathbb{C}$ with (a).
Sketch. (a) Entrywise for sums; $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}\begin{pmatrix} c & -d \\ d & c \end{pmatrix} = \begin{pmatrix} ac-bd & -(ad+bc) \\ ad+bc & ac-bd \end{pmatrix} = \varphi(zw)$. (b) Swap b and $-b$; $\det = a^2 + b^2$. (c) K contains 0 and I_2 and is closed under sums, negatives, and products; $\varphi(z)\varphi(w) = \varphi(zw) = \varphi(w)\varphi(z)$; and $\varphi(z)\varphi\left(z^{-1}\right) = \varphi(1) = I_2$.

Let $z = a + bi$ and $w = c + di$.

(a) $\varphi(z + w) = \begin{pmatrix} a+c & -(b+d) \\ b+d & a+c \end{pmatrix} = \varphi(z) + \varphi(w)$. By Definition 2.4.1,

$$\varphi(z)\varphi(w) = \begin{pmatrix} ac - bd & -ad - bc \\ bc + ad & -bd + ac \end{pmatrix} = \varphi((ac - bd) + (ad + bc)i) = \varphi(zw).$$

(Equivalently, $\varphi(z) = [M_z]_{\mathcal{BB}}$ by Proposition B.1.18, and $M_z \circ M_w = M_{zw}$.) Also $\varphi(1) = I_2$, and $\varphi(z)$ determines z through its first column (a, b), so φ is injective.

(b) $\varphi(\overline{z}) = \begin{pmatrix} a & b \\ -b & a \end{pmatrix} = \varphi(z)^{\mathsf{T}}$, and $\det \varphi(z) = a \cdot a - (-b) \cdot b = a^2 + b^2 = |z|^2$ (Definition 5.1.14).

(c) By (a), K is closed under addition and multiplication, and it contains $\varphi(0) = 0$, $\varphi(1) = I_2$, and the negative $-\varphi(z) = \varphi(-z)$ of each of its elements. Addition of matrices is commutative and associative, and multiplication is associative and distributes over addition (Proposition 2.4.14), so these laws hold in K; 0 and I_2 are identities, and $I_2 \neq 0$. Multiplication in K is commutative, because $\varphi(z)\varphi(w) = \varphi(zw) = \varphi(wz) = \varphi(w)\varphi(z)$. Finally, a nonzero element of K is $\varphi(z)$ with $z \neq 0$, because φ is injective and $\varphi(0) = 0$; then $\varphi(z)\varphi\left(z^{-1}\right) = \varphi(1) = I_2 = \varphi\left(z^{-1}\right)\varphi(z)$, so $\varphi\left(z^{-1}\right) \in K$ is its inverse. So K is a field, and $\varphi : \mathbb{C} \to K$ is a bijection that respects sums and products: K is a copy of $\mathbb{C}$ made of real matrices, in which i is the quarter turn $\varphi(i) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, and in which conjugation is transposition.

Solution to Exercise B.1.43

Uses. Exercise 1.1.44, Proposition B.1.2 (Conjugation respects the field operations)
Hint 1. σ is determined by $\sigma(i)$, since $\sigma(a + bi) = \sigma(a) + \sigma(b)\sigma(i)$.
Hint 2. Apply σ to $i^2 = -1$. Which complex numbers square to -1?
Sketch. $\sigma(i)^2 = \sigma\left(i^2\right) = \sigma(-1) = -1$, so $\sigma(i) = \pm i$. Then $\sigma(a + bi) = a + b\sigma(i)$ is $a + bi$ or $a - bi$.

Since σ respects products and fixes -1, $\sigma(i)^2 = \sigma\left(i^2\right) = \sigma(-1) = -1$. By Exercise 1.1.44(a), $\sigma(i) = i$ or $\sigma(i) = -i$. For $a, b \in \mathbb{R}$, since σ respects sums and products and fixes a and b,

$$\sigma(a + bi) = \sigma(a) + \sigma(b)\sigma(i) = a + b\sigma(i).$$

If $\sigma(i) = i$, this is $a + bi$, so σ is the identity; if $\sigma(i) = -i$, it is $a - bi$, so σ is conjugation. Both are indeed automorphisms fixing $\mathbb{R}$ (Proposition B.1.2).

The hypothesis that σ fixes $\mathbb{R}$ matters. Every automorphism fixes $\mathbb{Q}$ (it fixes 1, hence every integer and every quotient of integers), but $\mathbb{C}$ has other, very discontinuous, automorphisms that move real numbers; proving that they exist needs the axiom of choice, for instance in the form of Zorn's lemma (Section A.4).

Solution to Exercise B.1.44

Uses. Proposition B.1.8 (Properties of the modulus), Proposition B.1.28 (Sum and product of the roots of unity), Theorem B.1.25 (The nth roots of unity)
Techniques. Rotate the phase (Technique 6.2.8), Square the modulus (Technique B.1.9)
Hint 1. Rotate so that $z_1 = 1$: divide everything by z_1. The hypotheses are unchanged.
Hint 2. With $w_k = z_k/z_1$, you have $w_3 = -1 - w_2$. Take the squared modulus of both sides to find $\operatorname{Re} w_2$.
Sketch. Let $w_k = z_k/z_1$: then $w_1 = 1$, $|w_2| = |w_3| = 1$, and $1 + w_2 + w_3 = 0$. Now $1 = |w_3|^2 = |1 + w_2|^2 = 2 + 2\operatorname{Re} w_2$, so $\operatorname{Re} w_2 = -1/2$ and $w_2 \in \{\omega, \omega^2\}$; then $w_3 = -1 - w_2$ is the other one. So $z_k \in \{z_1, z_1\omega, z_1\omega^2\}$.

Since $|z_1| = 1$, $z_1 \neq 0$. Let $w_k = z_k/z_1$. Then $w_1 = 1$, $|w_2| = |w_3| = 1$ by Proposition B.1.8(d), and dividing $z_1 + z_2 + z_3 = 0$ by z_1 gives $1 + w_2 + w_3 = 0$. So $w_3 = -(1 + w_2)$, and by Proposition B.1.8(f),

$$1 = |w_3|^2 = |1 + w_2|^2 = 1 + 2\operatorname{Re} w_2 + |w_2|^2 = 2 + 2\operatorname{Re} w_2.$$

Hence $\operatorname{Re} w_2 = -1/2$, and $(\operatorname{Im} w_2)^2 = 1 - 1/4 = 3/4$, so $w_2 = -1/2 \pm \left(\sqrt{3}/2\right)i$. These two numbers are ω and $\omega^2 = \overline{\omega}$. By Proposition B.1.28, $1 + \omega + \omega^2 = 0$, so if $w_2 = \omega$ then $w_3 = -1 - \omega = \omega^2$, and if $w_2 = \omega^2$ then $w_3 = \omega$. Either way $\{w_1, w_2, w_3\} = \{1, \omega, \omega^2\}$, and multiplying by $u = z_1$ gives $\{z_1, z_2, z_3\} = \{u, u\omega, u\omega^2\}$.

For $j \neq k$ in $\{0, 1, 2\}$, $\left|u\omega^j - u\omega^k\right| = \left|\omega^j\right|\left|1 - \omega^{k-j}\right| = \left|1 - \omega^{k-j}\right|$, and $\omega^{k-j} \in \{\omega, \omega^2 = \overline{\omega}\}$, so this is $|1 - \omega| = \left|3/2 - \left(\sqrt{3}/2\right)i\right| = \sqrt{3}$ in every case (Proposition B.1.8(b)). So all three sides have length $\sqrt{3}$.

Solution to Exercise B.1.45

Uses. Proposition B.1.28 (Sum and product of the roots of unity), Proposition 7.1.22 (Counting roots), Proposition B.1.8 (Properties of the modulus), Remark B.1.13 (Facts about cos and sin)
Techniques. Polynomial identity arguments (Technique 5.5.24)

Hint 1. Approach 2 of Proposition B.1.28 shows $x^n - 1 = (x-1)(x-\omega)\cdots(x-\omega^{n-1})$. Also $x^n - 1 = (x-1)(1 + x + \cdots + x^{n-1})$. You cannot simply cancel $x - 1$ yet; compare values instead.
Hint 2. Both sides of (a) take the same value at every $c \neq 1$. Two polynomials of degree at most $n-1$ that agree at infinitely many points are equal (Proposition 7.1.22).
Hint 3. For (c), $\left|1 - e^{i\theta}\right|^2 = 2 - 2\cos\theta = 4\sin^2(\theta/2)$.
Sketch. Let $P = 1 + x + \cdots + x^{n-1}$ and $Q = \prod_{k=1}^{n-1}(x - \omega^k)$. For every $c \neq 1$, $(c-1)P(c) = c^n - 1 = (c-1)Q(c)$, so $P(c) = Q(c)$; as $P - Q$ has degree at most $n-1$ and infinitely many roots, $P = Q$. Evaluating at 1 gives (b). Taking moduli, $\prod\left|1 - \omega^k\right| = n$, and $\left|1 - \omega^k\right| = 2\sin(k\pi/n)$.

(a) Let $P = 1 + x + \cdots + x^{n-1}$ and $Q = (x-\omega)(x-\omega^2)\cdots(x-\omega^{n-1})$. By Approach 2 of Proposition B.1.28, $x^n - 1 = (x-1)Q$, and multiplying out, $x^n - 1 = (x-1)P$. Evaluating at $c \in \mathbb{C}$ (evaluation respects products, Section 7.1),

$$(c-1)P(c) = c^n - 1 = (c-1)Q(c).$$

For $c \neq 1$ we may cancel $c - 1$, so $P(c) = Q(c)$ for every $c \neq 1$. Both P and Q have degree $n-1$, so $P - Q$ has degree at most $n-1$ and infinitely many roots, and $P - Q = \mathbf{0}$ by Proposition 7.1.22.

(b) Evaluating (a) at 1 gives $n = P(1) = Q(1) = (1-\omega)(1-\omega^2)\cdots(1-\omega^{n-1})$.

(c) The vertices of a regular n-gon inscribed in the unit circle are equally spaced on it, so they are $u, u\omega, \ldots, u\omega^{n-1}$, where u is the chosen vertex and $|u| = 1$. Multiplication by $\overline{u}$ preserves distances, since $|\overline{u}a - \overline{u}b| = |\overline{u}||a-b| = |a-b|$, and it carries the vertices to $1, \omega, \ldots, \omega^{n-1}$, with the chosen vertex going to 1. Taking moduli in (b), with Proposition B.1.8(d), the product of the distances is $\prod_{k=1}^{n-1}\left|1-\omega^k\right| = n$.

For $\theta \in \mathbb{R}$, by (T1),

$$\left|1 - e^{i\theta}\right|^2 = (1-\cos\theta)^2 + \sin^2\theta = 2 - 2\cos\theta = 4\sin^2\left(\frac{\theta}{2}\right),$$

where the last step is $\cos\theta = \cos^2(\theta/2) - \sin^2(\theta/2) = 1 - 2\sin^2(\theta/2)$. For $\theta = 2\pi k/n$ with $1 \leq k \leq n-1$, we have $0 < \theta/2 < \pi$, so $\sin(\theta/2) > 0$ and $\left|1-\omega^k\right| = 2\sin(k\pi/n)$. Hence $2^{n-1}\prod_{k=1}^{n-1}\sin(k\pi/n) = n$.

Solution to Exercise B.1.46

Uses. Theorem B.1.25 (The nth roots of unity), Euclid's lemma: if $n \mid km$ and $\gcd(k,n) = 1$, then $n \mid m$
Hint 1. By Theorem B.1.25(a), $\left(\omega^k\right)^m = 1$ if and only if $n \mid km$.
Hint 2. If $g = \gcd(k,n) > 1$, try $m = n/g$. If $g = 1$, use Euclid's lemma.
Hint 3. For (b), show that the n powers are distinct, and count.
Sketch. (a) $\left(\omega^k\right)^m = 1$ if and only if $n \mid km$. If $g = \gcd(k,n) > 1$, then $m = n/g < n$ works, so ω^k is not primitive. If $g = 1$, then $n \mid km$ forces $n \mid m$, so $m \geq n$. (b) If $\zeta^j = \zeta^l$ with $0 \leq j < l < n$, then $\zeta^{l-j} = 1$, which is impossible; so the powers are n distinct nth roots of unity. (c) $k = 1, 5, 7, 11$: $\pm\sqrt{3}/2 \pm i/2$.

(a) By Theorem B.1.25(a), $\left(\omega^k\right)^m = \omega^{km} = 1$ if and only if $n \mid km$. Let $g = \gcd(k,n)$. If $g > 1$, then $m = n/g$ satisfies $1 \leq m < n$ and $km = (k/g)n$, so $\left(\omega^k\right)^m = 1$ and ω^k is not primitive. If $g = 1$ and $\left(\omega^k\right)^m = 1$ with $m \geq 1$, then $n \mid km$, so $n \mid m$ by Euclid's lemma, and $m \geq n$. So ω^k is primitive.

(b) Each ζ^j is an nth root of unity, by Theorem B.1.25(c). If $\zeta^j = \zeta^l$ with $0 \leq j < l \leq n-1$, then $\zeta^{l-j} = 1$ with $1 \leq l - j < n$, contradicting primitivity. So $1, \zeta, \ldots, \zeta^{n-1}$ are n distinct nth roots of unity, and by Theorem B.1.25(b) there are only n, so these are all of them.

(c) For $n = 12$, the k in $\{0, \ldots, 11\}$ with $\gcd(k,12) = 1$ are $1, 5, 7, 11$. So the primitive 12th roots of unity are

$$e^{i\pi/6} = \frac{\sqrt{3}}{2} + \frac{i}{2}, \quad e^{5\pi i/6} = -\frac{\sqrt{3}}{2} + \frac{i}{2}, \quad e^{7\pi i/6} = -\frac{\sqrt{3}}{2} - \frac{i}{2}, \quad e^{11\pi i/6} = \frac{\sqrt{3}}{2} - \frac{i}{2}.$$

Solution to Exercise B.1.47

Uses. Theorem 7.1.14 (Division with remainder), Proposition B.1.28 (Sum and product of the roots of unity), Theorem B.1.25 (The nth roots of unity)

Hint 1. Let $p = x^{2n} + x^n + 1$ and $\omega = e^{2\pi i/3}$, a root of $x^2 + x + 1$. Divide p by $x^2 + x + 1$ with remainder in $\mathbb{R}[x]$, and evaluate at ω.
Hint 2. The remainder is $cx + d$ with $c, d \in \mathbb{R}$, and $p(\omega) = c\omega + d$. Since ω is not real, $c\omega + d = 0$ forces $c = d = 0$.
Hint 3. Compute $p(\omega) = 1 + \zeta + \zeta^2$ with $\zeta = \omega^n$. When is $\zeta = 1$?
Sketch. Write $p = q\big(x^2 + x + 1\big) + (cx + d)$ with $q \in \mathbb{R}[x]$ and $c, d \in \mathbb{R}$. Since $\omega^2 + \omega + 1 = 0$, $p(\omega) = c\omega + d$, whose imaginary part is $c\sqrt{3}/2$; so the remainder vanishes if and only if $p(\omega) = 0$. With $\zeta = \omega^n$, $p(\omega) = 1 + \zeta + \zeta^2$, which is 3 if $3 \mid n$ and 0 otherwise, since then ζ is a cube root of unity other than 1.

Let $p = x^{2n} + x^n + 1$ and $\omega = e^{2\pi i/3} = -1/2 + \big(\sqrt{3}/2\big)i$. By Proposition B.1.28, $\omega^2 + \omega + 1 = 0$. By the division algorithm in $\mathbb{R}[x]$ (Theorem 7.1.14),

$$p = q\big(x^2 + x + 1\big) + (cx + d)$$

for some $q \in \mathbb{R}[x]$ and $c, d \in \mathbb{R}$, and $x^2 + x + 1$ divides p if and only if $c = d = 0$. Evaluating at ω (evaluation respects sums and products, Section 7.1) gives $p(\omega) = q(\omega) \cdot 0 + c\omega + d = c\omega + d$. Now $c\omega + d = (d - c/2) + \big(c\sqrt{3}/2\big)i$ is 0 if and only if $c = 0$ and $d = 0$. So $x^2 + x + 1$ divides p if and only if $p(\omega) = 0$.

Let $\zeta = \omega^n$. Then $p(\omega) = 1 + \zeta + \zeta^2$, and $\zeta^3 = \big(\omega^3\big)^n = 1$. If $3 \mid n$, then $\zeta = 1$ by Theorem B.1.25(a), and $p(\omega) = 3 \neq 0$. If $3 \nmid n$, then $\zeta \neq 1$ by Theorem B.1.25(a), so $(\zeta - 1)\big(1 + \zeta + \zeta^2\big) = \zeta^3 - 1 = 0$ gives $1 + \zeta + \zeta^2 = 0$. So $p(\omega) = 0$ if and only if $3 \nmid n$.

For instance, $x^4 + x^2 + 1 = \big(x^2 + x + 1\big)\big(x^2 - x + 1\big)$, while $x^6 + x^3 + 1$ is not divisible by $x^2 + x + 1$.

Solution to Exercise B.1.48

Uses. Proposition B.1.8 (Properties of the modulus), Definition 1.1.29 (Complex numbers)
Hint 1. For (a), use the product formula of Definition 1.1.29 and Proposition B.1.8(d).
Hint 2. For (b), take norms in $zw = 1$. Which integers a, b have $a^2 + b^2 = 1$?
Hint 3. For (c), compute $N((2 + i)(3 + 2i))$ and $N((2 + i)(3 - 2i))$.
Sketch. (a) $(a + bi)(c + di) = (ac - bd) + (ad + bc)i$ has integer coordinates, $N(a + bi) = a^2 + b^2$, and $N(zw) = |zw|^2 = |z|^2|w|^2$. (b) $N(z)N(w) = 1$ forces $N(z) = 1$, so $z \in \{\pm 1, \pm i\}$; each of these has an inverse in $\mathbb{Z}[i]$. (c) $(2 + i)(3 + 2i) = 4 + 7i$ and $(2 + i)(3 - 2i) = 8 - i$, so $65 = 4^2 + 7^2 = 8^2 + 1^2$.

(a) For $z = a + bi$ and $w = c + di$ with integer coordinates, $z + w$, $-z$, and $zw = (ac - bd) + (ad + bc)i$ have integer coordinates. $N(z) = a^2 + b^2$ is a nonnegative integer, and $N(zw) = |zw|^2 = |z|^2|w|^2 = N(z)N(w)$ by Proposition B.1.8(d).

(b) If $zw = 1$ with $z, w \in \mathbb{Z}[i]$, then $N(z)N(w) = N(1) = 1$ by (a), and $N(z), N(w)$ are nonnegative integers, so $N(z) = 1$. If $z = a + bi$, then $a^2 + b^2 = 1$ with $a, b \in \mathbb{Z}$, so one of a, b is ± 1 and the other is 0: $z \in \{1, -1, i, -i\}$. Conversely, $1 \cdot 1 = (-1)(-1) = i(-i) = 1$, so all four are units.

(c) By (a), $N((2 + i)(3 + 2i)) = 5 \cdot 13 = 65$, and $(2 + i)(3 + 2i) = 6 + 4i + 3i + 2i^2 = 4 + 7i$, so $65 = 4^2 + 7^2$. Also $N(3 - 2i) = 13$, and $(2 + i)(3 - 2i) = 6 - 4i + 3i - 2i^2 = 8 - i$, so $65 = 8^2 + 1^2$. In coordinates, (a) is the identity $\big(a^2 + b^2\big)\big(c^2 + d^2\big) = (ac - bd)^2 + (ad + bc)^2$ noted after Proposition B.1.8.

Solution to Exercise B.1.49

Uses. Proposition B.1.8 (Properties of the modulus), Notation B.1.19 ($e^{i\theta}$), integrals of continuous functions
Techniques. Rotate the phase (Technique 6.2.8)
Hint 1. For a direction $e^{i\theta}$, keep the terms that make an acute angle with it: $S_\theta = \big\{k \;\big|\; \mathrm{Re}\big(e^{-i\theta} z_k\big) > 0\big\}$. Bound $\big|\sum_{k \in S_\theta} z_k\big|$ from below by a real part.
Hint 2. $\big|\sum_{k \in S_\theta} z_k\big| \geq f(\theta) = \sum_k \max\big(0, \mathrm{Re}\big(e^{-i\theta} z_k\big)\big)$. You cannot choose the best θ directly; average f over $\theta \in [0, 2\pi]$ instead.
Hint 3. With $z_k = |z_k| e^{i\varphi_k}$, $\mathrm{Re}\big(e^{-i\theta} z_k\big) = |z_k| \cos(\theta - \varphi_k)$, and the integral of $\max(0, \cos t)$ over a period is 2.
Sketch. For each θ, $\big|\sum_{S_\theta} z_k\big| \geq \mathrm{Re}\big(e^{-i\theta} \sum_{S_\theta} z_k\big) = f(\theta)$. Since $\int_0^{2\pi} f = \sum_k |z_k| \int_{-\pi/2}^{\pi/2} \cos t \, dt = 2 \sum_k |z_k|$, the average of f over $[0, 2\pi]$ is $(1/\pi) \sum_k |z_k|$, and the continuous function f reaches its average somewhere.

For $\theta \in \mathbb{R}$ let $S_\theta = \big\{k \;\big|\; \mathrm{Re}\big(e^{-i\theta} z_k\big) > 0\big\}$ and

$$f(\theta) = \sum_{k=1}^{n} \max\big(0, \mathrm{Re}\big(e^{-i\theta} z_k\big)\big) = \sum_{k \in S_\theta} \mathrm{Re}\big(e^{-i\theta} z_k\big).$$

By Proposition B.1.8(d) and (e),

$$\left|\sum_{k\in S_\theta} z_k\right| = \left|e^{-i\theta}\sum_{k\in S_\theta} z_k\right| \geq \operatorname{Re}\left(\sum_{k\in S_\theta} e^{-i\theta} z_k\right) = f(\theta).$$

So it suffices to find a θ with $f(\theta) \geq (1/\pi)\sum_k |z_k|$.

Write $z_k = |z_k| e^{i\varphi_k}$, with any φ_k if $z_k = 0$. Then $\operatorname{Re}\left(e^{-i\theta} z_k\right) = |z_k| \operatorname{Re}\left(e^{i(\varphi_k - \theta)}\right) = |z_k| \cos(\theta - \varphi_k)$. So f is continuous and 2π-periodic, and integrating each term over a period centred at φ_k,

$$\int_0^{2\pi} f(\theta)\,\mathrm{d}\theta = \sum_{k=1}^{n} |z_k| \int_{\varphi_k-\pi}^{\varphi_k+\pi} \max(0, \cos(\theta - \varphi_k))\,\mathrm{d}\theta = \sum_{k=1}^{n} |z_k| \int_{-\pi/2}^{\pi/2} \cos t\,\mathrm{d}t = 2\sum_{k=1}^{n} |z_k|.$$

If we had $f(\theta) < (1/\pi)\sum_k |z_k|$ for every $\theta \in [0, 2\pi]$, then, as f is continuous, the integral would be less than $2\pi \cdot (1/\pi)\sum_k |z_k| = 2\sum_k |z_k|$, a contradiction. So some θ has $f(\theta) \geq (1/\pi)\sum_k |z_k|$, and $S = S_\theta$ works.

This is an averaging argument. We cannot say in advance which direction θ is best, but the average of f over all directions is computable, and some direction does at least as well as the average.
