> *Hint 1.* For normalization, the (i, j) entry of I_n is 1 if $i = j$ and 0 otherwise. Which terms of $L(I_n)$ can be nonzero?
> *Hint 2.* For linearity in column k, each term contains exactly one entry of column k, namely $a_{\sigma(k)k}$. Separate it from the other factors.
> *Sketch.* In $L(I_n)$, a term with $\sigma \neq \mathrm{id}$ contains a factor $a_{\sigma(j)j} = 0$ for some j with $\sigma(j) \neq j$, so only $t_{\mathrm{id}}(I_n) = 1$ survives. If column k is $\mathbf{x}$, then $L = \sum_\sigma b_\sigma x_{\sigma(k)}$, where $b_\sigma = \operatorname{sgn}(\sigma) \prod_{j \neq k} a_{\sigma(j)j}$ does not depend on $\mathbf{x}$, and such a function of $\mathbf{x}$ is linear.

Normalized. The (i, j) entry of I_n is 1 if $i = j$ and 0 otherwise. If $\sigma \neq \mathrm{id}$, choose j with $\sigma(j) \neq j$; then the factor $a_{\sigma(j)j}$ of $t_\sigma(I_n)$ is 0, so $t_\sigma(I_n) = 0$. Hence $L(I_n) = t_{\mathrm{id}}(I_n) = \operatorname{sgn}(\mathrm{id}) \cdot 1 \cdot \cdots \cdot 1 = 1$.

Multilinear. Fix $k \in [n]$ and the columns $\mathbf{a}_j$ for $j \neq k$. For $\mathbf{x} \in F^n$, let $A_{\mathbf{x}}$ be the matrix with $\mathbf{x}$ in column k and $\mathbf{a}_j$ in column j for every $j \neq k$. The only factor of $t_\sigma(A_{\mathbf{x}})$ that comes from column k is $x_{\sigma(k)}$, so

$$L(A_{\mathbf{x}}) = \sum_{\sigma \in S_n} b_\sigma x_{\sigma(k)}, \quad \text{where } b_\sigma = \operatorname{sgn}(\sigma) \prod_{j \neq k} a_{\sigma(j)j}$$

does not depend on $\mathbf{x}$. Hence, for $\mathbf{x}, \mathbf{y} \in F^n$ and $c \in F$,

$$\begin{aligned} L\big(A_{c\mathbf{x}+\mathbf{y}}\big) &= \sum_\sigma b_\sigma \big(c x_{\sigma(k)} + y_{\sigma(k)}\big) \\ &= c \sum_\sigma b_\sigma x_{\sigma(k)} + \sum_\sigma b_\sigma y_{\sigma(k)} = cL(A_{\mathbf{x}}) + L\big(A_{\mathbf{y}}\big). \end{aligned}$$

So L is linear in column k, and k was arbitrary.

> *Intuition (Why alternation needs care).* Suppose columns k and l of A are equal, where $k \neq l$, and let $\tau = (k\ l)$. The permutation $\sigma\tau$ uses the row $\sigma(l)$ in column k and the row $\sigma(k)$ in column l, and otherwise agrees with σ. Since columns k and l are equal, the product of entries in $t_{\sigma\tau}(A)$ is the same as in $t_\sigma(A)$, while the sign is opposite. So $t_{\sigma\tau}(A) = -t_\sigma(A)$.
>
> The quickest way to use this is to reindex the whole sum: by Proposition 5.2.8, $L(A) = \sum_\sigma t_{\sigma\tau}(A) = -\sum_\sigma t_\sigma(A) = -L(A)$. But this only shows $(1 + 1)L(A) = 0$, which gives $L(A) = 0$ when $1 + 1 \neq 0$ (compare Proposition 5.1.11). Over $\mathbb{F}_2$ it says nothing, since $-L(A) = L(A)$ there.
>
> The fix is to cancel the terms two at a time instead of summing them all at once. The permutations σ and $\sigma\tau$ are different, one is even and the other odd, and their terms are negatives of each other. Grouping the $n!$ terms into $n!/2$ such pairs writes $L(A)$ as a sum of zeros, and no division is involved.

Technique 5.3.5 (Cancel terms in pairs). To show that a finite sum $\sum_{x \in X} t(x)$ is 0, find a bijection $\varphi : X \to X$ with $\varphi(\varphi(x)) = x$ and $\varphi(x) \neq x$ for every x, such that $t(\varphi(x)) = -t(x)$. Then X splits into two-element sets $\{x, \varphi(x)\}$, and the two terms in each set cancel. To write this down, choose a set $P \subseteq X$ containing exactly one element of each pair, so that φ maps P bijectively onto $X \setminus P$; then $\sum_{x \in X} t(x) = \sum_{x \in P}(t(x) + t(\varphi(x))) = 0$. If φ has fixed points, and $t(\varphi(x)) = -t(x)$ holds for the other x, the same argument shows that the sum equals the sum over the fixed points, which is often easy to evaluate.

This is not the same as the shortcut "reindexing by φ shows $S = -S$, so $S = 0$". The shortcut divides by $1 + 1$, which is impossible in characteristic 2, while pairing never divides. Reach for pairing when the terms of a sum come with signs and a natural operation flips the sign: for sums over S_n, composing with a fixed transposition. The canonical example is the alternation of the Leibniz formula in Theorem 5.3.4.

Counting is a special case: an involution with no fixed points shows that a finite set has an even number of elements, and in general $|X|$ has the same parity as the number of fixed points of φ (Exercise 5.3.40).
Used in. Theorem 5.3.4, Exercise 5.3.27, Exercise 5.3.39, Exercise 5.3.40, Exercise 5.6.13, Problem 5.1, Problem 5.15, Proposition 7.3.2.

Proof of Theorem 5.3.4, part 3 of 3: L is alternating. STANDARD

Uses. Remark 5.2.11 (Composing with a transposition), Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.2.27 (Half of all permutations are even), Proposition 5.2.8 (Reindexing sums over S_n), Proposition 5.2.13 (Products of transpositions), Theorem 5.2.18 (Parity is well defined)
Techniques. Cancel terms in pairs (Technique 5.3.5)
Hint 1. Suppose columns $k \neq l$ of A are equal, and let $\tau = (k\ l)$. Compare the terms $t_\sigma(A)$ and $t_{\sigma\tau}(A)$.
Hint 2. $(\sigma\tau)(k) = \sigma(l)$, $(\sigma\tau)(l) = \sigma(k)$, and $\sigma\tau$ agrees with σ elsewhere. Because columns k and l are equal, the products of entries agree, while the signs are opposite.
Hint 3. Split S_n into the even and the odd permutations. The map $\sigma \mapsto \sigma\tau$ is a bijection from the even ones to the odd ones. Pair each even σ with $\sigma\tau$.
Sketch. Let columns $k \neq l$ be equal and $\tau = (k\ l)$. The permutation $\sigma\tau$ differs from σ only by exchanging the rows used in columns k and l, and these columns are equal, so the products of entries agree; since $\operatorname{sgn}(\sigma\tau) = -\operatorname{sgn}(\sigma)$, $t_{\sigma\tau}(A) = -t_\sigma(A)$. The map $\sigma \mapsto \sigma\tau$ is a bijection from the even permutations to the odd ones, so $L(A) = \sum_{\sigma \text{ even}}(t_\sigma(A) + t_{\sigma\tau}(A)) = 0$.

Let $A \in F^{n\times n}$ with $\mathbf{a}_k = \mathbf{a}_l$ for some $k \neq l$, so that $n \geq 2$ and $a_{ik} = a_{il}$ for every $i \in [n]$. Let $\tau = (k\ l)$.

Step 1: $t_{\sigma\tau}(A) = -t_\sigma(A)$ for every $\sigma \in S_n$. By Remark 5.2.11, $(\sigma\tau)(k) = \sigma(l)$, $(\sigma\tau)(l) = \sigma(k)$, and $(\sigma\tau)(j) = \sigma(j)$ for $j \notin \{k, l\}$. So the product of entries in $t_{\sigma\tau}(A)$ is

$$\begin{aligned}\prod_{j=1}^{n} a_{(\sigma\tau)(j)j} &= a_{\sigma(l)k}a_{\sigma(k)l}\prod_{j\notin\{k,l\}} a_{\sigma(j)j} \\ &= a_{\sigma(l)l}a_{\sigma(k)k}\prod_{j\notin\{k,l\}} a_{\sigma(j)j} = \prod_{j=1}^{n} a_{\sigma(j)j},\end{aligned}$$

where the second equality uses $a_{\sigma(l)k} = a_{\sigma(l)l}$ and $a_{\sigma(k)l} = a_{\sigma(k)k}$, which hold because columns k and l are equal. By Proposition 5.2.25, $\operatorname{sgn}(\sigma\tau) = \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau) = -\operatorname{sgn}(\sigma)$. Hence $t_{\sigma\tau}(A) = -t_\sigma(A)$.

Step 2: pairing. Let S_n^+ and S_n^- be the sets of even and of odd permutations. By Proposition 5.2.13 and Theorem 5.2.18, S_n is the disjoint union of S_n^+ and S_n^-. Let $\varphi(\sigma) = \sigma\tau$. As in the proof of Proposition 5.2.27, φ maps S_n^+ into S_n^- and S_n^- into S_n^+, because $\operatorname{sgn}(\sigma\tau) = -\operatorname{sgn}(\sigma)$, and $\varphi(\varphi(\sigma)) = \sigma\tau^2 = \sigma$. So the restrictions $S_n^+ \to S_n^-$ and $S_n^- \to S_n^+$ of φ are inverse to each other, and in particular φ maps S_n^+ bijectively onto S_n^-. Reindexing the sum over S_n^- along this bijection (the argument of Proposition 5.2.8 applies to any bijection between finite sets) and then using Step 1,

$$\begin{aligned}L(A) &= \sum_{\sigma\in S_n^+} t_\sigma(A) + \sum_{\rho\in S_n^-} t_\rho(A) = \sum_{\sigma\in S_n^+} t_\sigma(A) + \sum_{\sigma\in S_n^+} t_{\sigma\tau}(A) \\ &= \sum_{\sigma\in S_n^+} (t_\sigma(A) + t_{\sigma\tau}(A)) = \sum_{\sigma\in S_n^+} 0 = 0.\end{aligned}$$

So L is alternating. By Part 2, L is a determinant function, and by Part 1 it is the only one. □

Step 2 never divides by $1 + 1$, so the proof works over every field. Over $\mathbb{F}_2$, where $\operatorname{sgn}(\sigma) = 1$ for every σ, Step 1 says that the two terms of each pair are *equal*, and they cancel because $x + x = 0$ in $\mathbb{F}_2$.

Definition 5.3.6 (Determinant). The **determinant** is the unique determinant function $\det : F^{n\times n} \to F$ of Theorem 5.3.4. By Theorem 5.3.3,

$$\det A = \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) a_{\sigma(1)1}a_{\sigma(2)2}\cdots a_{\sigma(n)n}$$

for every $A \in F^{n\times n}$, and every multilinear alternating $D : F^{n\times n} \to F$ satisfies $D = D(I_n)\det$. As for D, we also write $\det(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ for the determinant of the matrix with columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$.

For $n = 2$ this is the function $ad - bc$ of Definition 5.1.14. From now on every result about multilinear alternating functions in Section 5.1 and Section 5.2 applies to det. For instance, $\det A = 0$ whenever the columns of A are linearly dependent (Proposition 5.1.17), and $\det(AE_\sigma) = \operatorname{sgn}(\sigma)\det A$ (Theorem 5.2.31).

Exercise 5.3.7. ROUTINE Let Alt_n be the vector space of multilinear alternating functions $F^{n\times n} \to F$ (Exercise 5.1.34). Show that $\operatorname{Alt}_n = \operatorname{span}(\det)$ and $\dim \operatorname{Alt}_n = 1$. Deduce that if $D \in \operatorname{Alt}_n$ and $D(A) \neq 0$ for some A, then $D = c\det$ for some $c \neq 0$, and $\det A \neq 0$.

Solution on page 1404

Exercise 5.3.8. STANDARD Show that for every $A \in F^{n\times n}$,

$$\det A = \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{n\sigma(n)}.$$

Here each term takes one entry from each *row*: row i contributes the entry in column $\sigma(i)$.

Solution on page 1404

5.3.3 The 3×3 determinant

For $n = 3$ the Leibniz formula has $3! = 6$ terms, one for each permutation in Table 5.2.1. Listing the even permutations first,

$$\begin{aligned}\det A = {} & a_{11}a_{22}a_{33} + a_{21}a_{32}a_{13} + a_{31}a_{12}a_{23} \\ & - a_{21}a_{12}a_{33} - a_{11}a_{32}a_{23} - a_{31}a_{22}a_{13}.\end{aligned} \tag{5.3.2}$$

Expanding the triple product of Exercise 5.1.32 gives the same six terms, as it must by Theorem 5.3.4. Each term takes one entry from each column, and since σ is a bijection, the rows $\sigma(1), \sigma(2), \sigma(3)$ are also different. Figure 5.3.1 marks the chosen entries. In general a term of the Leibniz formula is a choice of n entries, one in each row and one in each column, like n rooks on an $n \times n$ chessboard of which no two attack each other, together with the sign of the corresponding permutation.

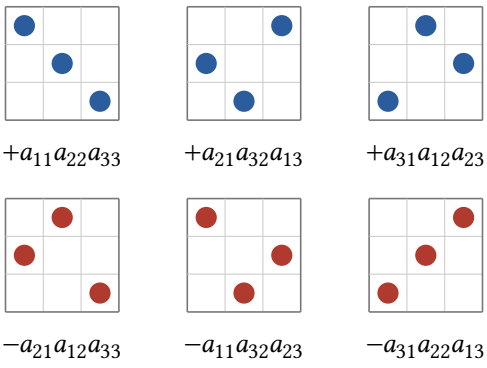

Figure 5.3.1. The six terms of (5.3.2). Each grid stands for a 3×3 matrix, and the dots mark the entries $a_{\sigma(1)1}, a_{\sigma(2)2}, a_{\sigma(3)3}$ multiplied in the term of σ. Top row (blue): the even permutations id, (1 2 3), (1 3 2). Bottom row (red): the odd permutations (1 2), (2 3), (1 3).

In the top row the dots run along the main diagonal and along its two parallels, wrapped around from the right edge to the left. In the bottom row they run along the other diagonal and its two wrapped parallels. Writing the first two columns again to the right of A unwraps these lines, as in Figure 5.3.2.

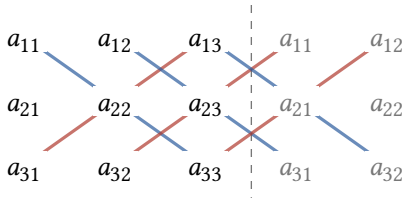

Figure 5.3.2. The rule of Sarrus. The three columns of A are followed by its first two columns again (grey). Products along the blue diagonals are added, and products along the red diagonals are subtracted.

Corollary 5.3.9 (Rule of Sarrus). Let $A \in F^{3\times 3}$, and write its three columns followed by its first two columns again, as in Figure 5.3.2. Then $\det A$ is the sum of the products along the three diagonals that run down and to the right from a_{11}, a_{12}, a_{13}, minus the sum of the products along the three diagonals that run up and to the right from a_{31}, a_{32}, a_{33}.

Proof. ROUTINE

Uses. Definition 5.3.6 (Determinant)
Hint 1. List the six diagonal products and compare them with the six terms of (5.3.2).
Hint 2. The diagonal down from a_{12} passes through a_{23} and then a_{31}, in the repeated first column.
Sketch. The down-right diagonals give $a_{11}a_{22}a_{33}$, $a_{12}a_{23}a_{31}$, $a_{13}a_{21}a_{32}$, the terms of the even permutations. The up-right diagonals give $a_{31}a_{22}a_{13}$, $a_{32}a_{23}a_{11}$, $a_{33}a_{21}a_{12}$, the terms of the transpositions.

The diagonals running down and to the right from a_{11}, a_{12}, a_{13} have products

$$a_{11}a_{22}a_{33}, \quad a_{12}a_{23}a_{31}, \quad a_{13}a_{21}a_{32},$$

and the diagonals running up and to the right from a_{31}, a_{32}, a_{33} have products

$$a_{31}a_{22}a_{13}, \quad a_{32}a_{23}a_{11}, \quad a_{33}a_{21}a_{12}.$$

After reordering the factors, the first three are the terms of id, (1 3 2), and (1 2 3) in (5.3.2), which enter with sign $+$, and the last three are the terms of (1 3), (2 3), and (1 2), which enter with sign $-$. So the rule computes exactly (5.3.2). □

Example 5.3.10 (A 3×3 determinant). Let $A = \begin{pmatrix} 2 & -1 & 3 \\ 1 & 4 & 0 \\ -2 & 1 & 5 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$. The diagonals running down to the right have products $2\cdot 4\cdot 5 = 40$, $(-1)\cdot 0\cdot(-2) = 0$, and $3\cdot 1\cdot 1 = 3$. The diagonals running up to the right have products $(-2)\cdot 4\cdot 3 = -24$, $1\cdot 0\cdot 2 = 0$, and $5\cdot 1\cdot(-1) = -5$. So

$$\det A = (40 + 0 + 3) - (-24 + 0 - 5) = 43 + 29 = 72.$$

Since $\det A \neq 0$, A is invertible by Corollary 5.1.18.

Remark 5.3.11 (Sarrus does not generalize). The rule of Sarrus works because for $n = 3$ the six diagonals happen to be the six permutations. For $n = 4$, the same picture (the four columns followed by the first three again) has four diagonals running down and four running up, so it produces 8 products, while the Leibniz formula has $4! = 24$ terms. The signs go wrong as well (Exercise 5.3.25). For $n \geq 4$ there is no shortcut of this kind. Section 5.4 computes determinants by elimination, and Section 5.5 by expanding along a row or column.

5.3.4 Triangular and block-diagonal matrices

A term of the Leibniz formula vanishes as soon as one of its n entries is 0. So a matrix with a pattern of zeros can have very few nonzero terms, and the formula becomes a practical tool.

Technique 5.3.12 (Read structure off the Leibniz expansion). A term of the Leibniz formula is $\operatorname{sgn}(\sigma)$ times n entries of A, one in each column and one in each row, and it vanishes if one of these entries is 0. So to evaluate or analyze $\det A$ for a matrix with a pattern of zeros, ask which permutations σ satisfy $a_{\sigma(j)j} \neq 0$ for every j. Often the pattern confines σ to a small, explicit set, and only those terms need to be computed. The same question asked about entries that depend on a parameter, instead of entries that vanish, tells you how $\det A$ depends on the parameter (Technique 5.3.18).

Reach for it when the matrix is sparse or structured (triangular, block-diagonal, banded, mostly zeros), or when a question asks which products of entries can occur in $\det A$. Expect to prove a small lemma about permutations along the way, such as Lemma 5.3.14. The canonical example is Proposition 5.3.15, where only the identity survives.

Used in. Proposition 5.3.15, Proposition 5.3.17, Proposition 5.3.19, Exercise 5.3.24, Exercise 5.3.29, Exercise 5.3.33, Exercise 5.3.34, Exercise 5.3.38, Theorem 5.4.26, Theorem 5.5.3, Exercise 5.6.6, Exercise 5.6.13, Problem 5.14, Proposition 7.3.18, Theorem 7.3.24, Theorem 7.5.22.

Recall (Definition 3.3.31) that $A \in F^{n\times n}$ is upper triangular if $a_{ij} = 0$ whenever $i > j$, lower triangular if $a_{ij} = 0$ whenever $i < j$, and diagonal if it is both. We call A **triangular** if it is upper or lower triangular. The entries $a_{11}, \ldots, a_{nn}$ are the **diagonal entries** of A, and $\operatorname{diag}(d_1, \ldots, d_n)$ denotes the diagonal matrix with diagonal entries $d_1, \ldots, d_n$.

Example 5.3.13 (Triangular and not). The matrices

$$\begin{pmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 6 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 \\ 2 & 0 & 0 \\ 3 & 4 & 5 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

are upper triangular, lower triangular, and neither, respectively. The transpose of an upper triangular matrix is lower triangular. I_n and the zero matrix are diagonal, and every elementary matrix that adds a multiple of one row to another (Definition 3.2.2) is triangular. The third matrix has determinant -1, while the product of its diagonal entries is 0, so the hypothesis of Proposition 5.3.15 below cannot be dropped.

For an upper triangular A, the entry $a_{\sigma(j)j}$ can be nonzero only if $\sigma(j) \leq j$. So the question of Technique 5.3.12 becomes: which permutations satisfy $\sigma(j) \leq j$ for every j?

Lemma 5.3.14 (Permutations with $\sigma(j) \leq j$). Let $\sigma \in S_n$. If $\sigma(j) \leq j$ for every $j \in [n]$, then $\sigma = \mathrm{id}$. Likewise, if $\sigma(j) \geq j$ for every $j \in [n]$, then $\sigma = \mathrm{id}$.

Proof (by induction). ROUTINE

Uses. Definition 5.2.1 (Permutation), Proposition 5.2.5 (Composition and inverses)
Techniques. Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Under the first hypothesis, what can $\sigma(1)$ be? Then $\sigma(2)$?
Hint 2. Show by induction on j that $\sigma(j) = j$: the value $\sigma(j)$ is at most j, and it differs from $\sigma(1), \ldots, \sigma(j-1)$.
Hint 3. For the second hypothesis, show that σ^{-1} satisfies the first.
Sketch. If $\sigma(j) \leq j$ for all j, then $\sigma(1) = 1$, and once $\sigma(i) = i$ for all $i < j$, injectivity rules out $\sigma(j) \in \{1, \ldots, j-1\}$, leaving $\sigma(j) = j$. If $\sigma(j) \geq j$ for all j, then $\sigma^{-1}(i) \leq i$ for all i, so $\sigma^{-1} = \mathrm{id}$.

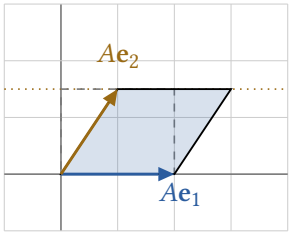
Suppose $\sigma(j) \leq j$ for every j. We show by strong induction on j that $\sigma(j) = j$. Let $j \in [n]$, and assume $\sigma(i) = i$ for every $i < j$. Since σ is injective, $\sigma(j) \neq \sigma(i) = i$ for each $i < j$, so $\sigma(j) \notin \{1, \ldots, j-1\}$. Together with $\sigma(j) \leq j$ this gives $\sigma(j) = j$. Hence $\sigma = \mathrm{id}$.

Now suppose $\sigma(j) \geq j$ for every j. Let $i \in [n]$ and $j = \sigma^{-1}(i)$. Then $\sigma^{-1}(i) = j \leq \sigma(j) = i$. So σ^{-1} satisfies the first hypothesis, $\sigma^{-1} = \mathrm{id}$, and $\sigma = \mathrm{id}$. □

Proof (by summing). ROUTINE

Uses. Definition 5.2.1 (Permutation)
Hint 1. Compare $\sum_j \sigma(j)$ with $\sum_j j$.

Hint 2. Since σ is a bijection of $[n]$, the numbers $\sigma(1), \dots, \sigma(n)$ are $1, \dots, n$ in some order, so $\sum_j (j - \sigma(j)) = 0$. What do the hypotheses say about the signs of the terms?
Sketch. $\sum_{j=1}^{n}(j - \sigma(j)) = 0$ because $\sigma(1), \dots, \sigma(n)$ is a rearrangement of $1, \dots, n$. Under either hypothesis all terms have the same sign, so all of them are 0.



Since σ is a bijection $[n] \to [n]$, the list $\sigma(1), \dots, \sigma(n)$ is a rearrangement of $1, \dots, n$, so $\sum_j \sigma(j) = \sum_j j$, that is,

$$\sum_{j=1}^{n}(j - \sigma(j)) = 0.$$

Under the first hypothesis every term $j - \sigma(j)$ is a nonnegative integer, and a sum of nonnegative integers is 0 only if every term is 0. So $\sigma(j) = j$ for every j. Under the second hypothesis every term is a nonpositive integer, and the same argument applied to the negatives of the terms gives the same conclusion. □

The second proof handles both hypotheses at once and uses only that σ rearranges $1, \dots, n$. The first uses injectivity one value at a time, which is the kind of argument Technique 5.3.12 usually calls for.

Intuition (Triangular matrices in the plane). Let $A = \begin{pmatrix} a_{11} & a_{12} \\ 0 & a_{22} \end{pmatrix} \in \mathbb{R}^{2\times 2}$. Then $A\mathbf{e}_1 = (a_{11}, 0)$ lies on the horizontal axis, and $A\mathbf{e}_2 = (a_{12}, a_{22})$ lies on the horizontal line at height a_{22}. The parallelogram spanned by them has base $|a_{11}|$ and height $|a_{22}|$, so its area is $|a_{11}a_{22}|$ whatever a_{12} is. In terms of the axioms, when $a_{11} \neq 0$, changing a_{12} slides $A\mathbf{e}_2$ parallel to $A\mathbf{e}_1$, which is a column replacement (Lemma 5.1.8). Sliding all the way to $(0, a_{22})$ turns the parallelogram into a rectangle, the image of the unit square under $\operatorname{diag}(a_{11}, a_{22})$. This is the second proof below, in the smallest case.

The upper triangular matrix $A = \begin{pmatrix} 2 & 1 \\ 0 & 3/2 \end{pmatrix}$, with $\det A = 2 \cdot 3/2 = 3$. Drag $A\mathbf{e}_2$ left or right, or focus it and use the arrow keys: A stays upper triangular, and neither the base nor the height changes, so neither does $\det A$. Moving $A\mathbf{e}_1$ off the horizontal axis makes A not triangular. (Interactive in the web version.)

Proposition 5.3.15 (Triangular matrices). Let $A \in F^{n\times n}$ be upper triangular or lower triangular. Then

$$\det A = a_{11}a_{22}\cdots a_{nn}.$$

More generally, $D(A) = a_{11}a_{22}\cdots a_{nn}D(I_n)$ for every multilinear alternating $D : F^{n\times n} \to F$.

Proof (via the Leibniz formula). ROUTINE

Uses. Definition 5.3.6 (Determinant), Lemma 5.3.14 (Permutations with $\sigma(j) \leq j$), Definition 3.3.31 (Triangular matrices), Theorem 5.3.4 (Existence and uniqueness of the determinant)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. For an upper triangular A, when can the entry $a_{\sigma(j)j}$ be nonzero?
Hint 2. Only when $\sigma(j) \leq j$. If $\sigma \neq \mathrm{id}$, Lemma 5.3.14 gives a j with $\sigma(j) > j$.
Hint 3. For the statement about D, use the last sentence of Theorem 5.3.4.
Sketch. Let A be upper triangular. If $\sigma \neq \mathrm{id}$, then $\sigma(j) > j$ for some j by Lemma 5.3.14, so $a_{\sigma(j)j} = 0$ and the term of σ vanishes. Only $\sigma = \mathrm{id}$ survives, giving $a_{11}\cdots a_{nn}$. For lower triangular A, use $\sigma(j) < j$ instead. Then $D = D(I_n)\det$.

Suppose A is upper triangular, and let $\sigma \in S_n$ with $\sigma \neq \mathrm{id}$. By Lemma 5.3.14, $\sigma(j) \leq j$ fails for some j, that is, $\sigma(j) > j$. Then $a_{\sigma(j)j} = 0$ because A is upper triangular, so the term of σ in the Leibniz formula is 0. Only the term of the identity remains:

$$\det A = \operatorname{sgn}(\mathrm{id}) a_{11}a_{22}\cdots a_{nn} = a_{11}a_{22}\cdots a_{nn}.$$

If A is lower triangular and $\sigma \neq \mathrm{id}$, then Lemma 5.3.14 gives some j with $\sigma(j) < j$, so $a_{\sigma(j)j} = 0$, and the same conclusion follows. Finally, every multilinear alternating D equals $D(I_n)\det$ by Theorem 5.3.4. □

Proof (by column replacement). STANDARD

Uses. Lemma 5.1.8 (Column replacement), Definition 5.1.1 (Determinant function), Exercise 5.1.5, Definition 3.3.31 (Triangular matrices)
Hint 1. Column j of an upper triangular matrix is $a_{jj}\mathbf{e}_j$ plus a combination of $\mathbf{e}_1, \ldots, \mathbf{e}_{j-1}$. If $a_{11} \neq 0$, how can you clear the first row outside the diagonal without changing D?
Hint 2. Work from left to right. Once columns $1, \ldots, j-1$ have become $a_{11}\mathbf{e}_1, \ldots, a_{j-1,j-1}\mathbf{e}_{j-1}$, subtract suitable multiples of them from column j. This needs $a_{ii} \neq 0$ for $i < j$.
Hint 3. If some diagonal entry is 0, let k be the least such index and stop after processing column k. What is column k then?
Sketch. If all diagonal entries are nonzero, column replacements turn columns $1, 2, \ldots, n$ in turn into $a_{jj}\mathbf{e}_j$ without changing D, so $D(A) = D(\operatorname{diag}(a_{11}, \ldots, a_{nn})) = a_{11}\cdots a_{nn}D(I_n)$. If $a_{kk} = 0$ with k least, the same replacements in columns $2, \ldots, k$ make column k equal to $\mathbf{0}$, so $D(A) = 0$. For lower triangular matrices, work from right to left.

Let D be multilinear and alternating, and let A be upper triangular. Column j of A is

$$\mathbf{a}_j = a_{jj}\mathbf{e}_j + \sum_{i<j} a_{ij}\mathbf{e}_i.$$

For $j \geq 2$, consider the following step, which may be performed when columns $1, \ldots, j-1$ of the current matrix are $a_{11}\mathbf{e}_1, \ldots, a_{j-1,j-1}\mathbf{e}_{j-1}$, column j is still $\mathbf{a}_j$, and $a_{11}, \ldots, a_{j-1,j-1}$ are nonzero: for each $i < j$, add $-a_{ij}a_{ii}^{-1}$ times column i to column j. Since column i is $a_{ii}\mathbf{e}_i$, this subtracts $a_{ij}\mathbf{e}_i$ from column j. After the step, column j is $a_{jj}\mathbf{e}_j$, the other columns are unchanged, and D has not changed, by Lemma 5.1.8.

Column 1 of A is already $a_{11}\mathbf{e}_1$. Suppose first that all diagonal entries are nonzero. Performing the step for $j = 2, 3, \ldots, n$ in turn, we reach $\operatorname{diag}(a_{11}, \ldots, a_{nn})$, whose columns are $a_{jj}\mathbf{e}_j$. Pulling the scalar a_{jj} out of each column j by multilinearity,

$$D(A) = D(\operatorname{diag}(a_{11}, \ldots, a_{nn})) = a_{11}a_{22}\cdots a_{nn}D(I_n).$$

Suppose instead that some diagonal entry is 0, and let k be the least index with $a_{kk} = 0$. If $k = 1$, column 1 of A is $\mathbf{0}$. Otherwise, perform the step for $j = 2, \ldots, k$; this uses only $a_{11}, \ldots, a_{k-1,k-1}$, which are nonzero. Afterwards column k is $a_{kk}\mathbf{e}_k = \mathbf{0}$. In both cases $D(A)$ equals the value of D at a matrix with a zero column, which is 0 by Exercise 5.1.5. And $a_{11}\cdots a_{nn}D(I_n) = 0$ as well, since the factor a_{kk} is 0.

If A is lower triangular, the same argument works with the columns processed from right to left. Column n is $a_{nn}\mathbf{e}_n$, column j is $a_{jj}\mathbf{e}_j$ plus a combination of $\mathbf{e}_{j+1}, \ldots, \mathbf{e}_n$, and the step for $j = n-1, \ldots, 1$ subtracts multiples of the columns to its right; if some diagonal entry is 0, take k to be the largest such index. □

The first proof is shorter, given the Leibniz formula. The second uses neither the formula nor permutations, only the axioms. It is the first instance of computing a determinant by column operations, which Section 5.4 turns into an algorithm.

In particular, $\det \operatorname{diag}(d_1, \ldots, d_n) = d_1d_2\cdots d_n$. If a triangular matrix has no zero diagonal entries, its determinant is nonzero, so it is invertible by Corollary 5.1.18. If it has a zero diagonal entry, its determinant is 0, and Theorem 5.4.7 will show that it is not invertible.

Exercise 5.3.16. ROUTINE

(a) Compute the determinants of

$$\begin{pmatrix} 2 & 7 & -1 & 4 \\ 0 & -1 & 3 & 5 \\ 0 & 0 & 3 & 8 \\ 0 & 0 & 0 & 1/2 \end{pmatrix} \in \mathbb{Q}^{4\times 4}$$

and

$$\begin{pmatrix} i & 0 & 0 \\ 2 & 1+i & 0 \\ -1 & 5 & 1-i \end{pmatrix} \in \mathbb{C}^{3\times 3}.$$

(b) A matrix $N \in F^{n\times n}$ is **strictly upper triangular** if its (i,j) entry is 0 whenever $i \geq j$. Show that $\det N = 0$ and $\det(cI_n + N) = c^n$ for every $c \in F$.

Solution on page 1405

The same reading of the Leibniz formula handles matrices built from square blocks along the diagonal.

Proposition 5.3.17 (Block-diagonal matrices). Let $A \in F^{k\times k}$ and $B \in F^{m\times m}$, and let

$$M = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \in F^{(k+m)\times(k+m)},$$

where the zero blocks are $k \times m$ and $m \times k$ (Definition 2.4.33). Then $\det M = \det A \det B$.

Proof (via uniqueness). STANDARD

Uses. Theorem 5.3.4 (Existence and uniqueness of the determinant), Definition 5.1.1 (Determinant function), Proposition 2.1.17 (Compositions of linear maps are linear), Definition 2.4.33 (Block matrix)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Fix B and regard $\det\begin{pmatrix} X & 0 \\ 0 & B \end{pmatrix}$ as a function of $X \in F^{k\times k}$. Which axioms does it satisfy?
Hint 2. It is multilinear and alternating in the columns of X, so by Theorem 5.3.4 it equals its value at I_k times $\det X$.
Hint 3. Then show that $Y \mapsto \det\begin{pmatrix} I_k & 0 \\ 0 & Y \end{pmatrix}$ is a determinant function on $F^{m\times m}$.
Sketch. For fixed B, $X \mapsto \det\begin{pmatrix} X & 0 \\ 0 & B \end{pmatrix}$ is multilinear and alternating in the columns of X, whose columns enter as $(\mathbf{x}_j, \mathbf{0})$. So it equals $\det X \cdot \det\begin{pmatrix} I_k & 0 \\ 0 & B \end{pmatrix}$. In turn $Y \mapsto \det\begin{pmatrix} I_k & 0 \\ 0 & Y \end{pmatrix}$ is multilinear, alternating, and 1 at I_m, so it is det by uniqueness.

Fix B, and for $X \in F^{k\times k}$ let $D(X) = \det\begin{pmatrix} X & 0 \\ 0 & B \end{pmatrix}$. For $j \leq k$, column j of $\begin{pmatrix} X & 0 \\ 0 & B \end{pmatrix}$ is $\iota(\mathbf{x}_j)$, where $\iota : F^k \to F^{k+m}$, $\mathbf{x} \mapsto (\mathbf{x}, \mathbf{0})$, is linear; the other columns do not depend on X. So when all columns of X but the j-th are fixed, $\mathbf{x} \mapsto D(\ldots, \mathbf{x}, \ldots)$ is the composite of ι with a map that is linear because det is linear in column j, and it is linear by Proposition 2.1.17. If two columns $\mathbf{x}_i, \mathbf{x}_j$ of X are equal, then columns i and j of $\begin{pmatrix} X & 0 \\ 0 & B \end{pmatrix}$ are equal, so $D(X) = 0$. Thus D is multilinear and alternating, and Theorem 5.3.4 gives

$$\det M = D(A) = D(I_k) \det A = \det\begin{pmatrix} I_k & 0 \\ 0 & B \end{pmatrix} \cdot \det A.$$

Now for $Y \in F^{m\times m}$ let $E(Y) = \det\begin{pmatrix} I_k & 0 \\ 0 & Y \end{pmatrix}$. For $j \leq m$, column $k+j$ of this matrix is $(\mathbf{0}, \mathbf{y}_j)$, the image of $\mathbf{y}_j$ under the linear map $\mathbf{y} \mapsto (\mathbf{0}, \mathbf{y})$, and the first k columns do not depend on Y. The argument above shows that E is multilinear and alternating, and $E(I_m) = \det I_{k+m} = 1$. So E is a determinant function on $F^{m\times m}$, and $E = \det$ by Theorem 5.3.4. Hence $\det M = \det B \det A$, as desired. □

Proof (via the Leibniz formula). STANDARD

Uses. Definition 5.3.6 (Determinant), Definition 5.2.23 (Sign of a permutation), Proposition 5.2.13 (Products of transpositions), Definition 5.2.10 (Transposition)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)

Hint 1. Write c_{ij} for the entries of M and $n = k + m$. If the term of σ is nonzero, where can σ send $1, \dots, k$?
Hint 2. Such a σ maps $[k]$ onto itself and $\{k+1, \dots, n\}$ onto itself, so it is made of a permutation α of $[k]$ and a permutation β of $[m]$. Show that $\operatorname{sgn}(\sigma) = \operatorname{sgn}(\alpha)\operatorname{sgn}(\beta)$ by factoring α and β into transpositions.
Hint 3. Then the sum over these σ is a sum over pairs (α, β), and it factors.
Sketch. A nonzero term needs $\sigma(j) \le k$ for every $j \le k$, so σ maps $[k]$ onto $[k]$ and the rest onto the rest. Such σ correspond to pairs $(\alpha, \beta) \in S_k \times S_m$, and factoring α and β into transpositions gives a factorization of σ, so $\operatorname{sgn}(\sigma) = \operatorname{sgn}(\alpha)\operatorname{sgn}(\beta)$. The term of σ is $\operatorname{sgn}(\alpha)\prod a_{\alpha(j)j} \cdot \operatorname{sgn}(\beta)\prod b_{\beta(i)i}$, and the double sum factors as $\det A \det B$.

Let $n = k + m$, and write c_{ij} for the (i, j) entry of M. So $c_{ij} = a_{ij}$ for $i, j \le k$, $c_{k+i,k+j} = b_{ij}$ for $i, j \le m$, and $c_{ij} = 0$ otherwise.

Let $\sigma \in S_n$ have a nonzero term. For $j \le k$, the entry $c_{\sigma(j)j}$ is nonzero, so $\sigma(j) \le k$. Thus σ maps $[k]$ into $[k]$, hence onto $[k]$, being injective, and since σ is a bijection it maps $K = \{k+1, \dots, n\}$ onto K. Call such permutations *block-preserving*. A block-preserving σ determines $\alpha \in S_k$ and $\beta \in S_m$ by

$$\alpha(j) = \sigma(j) \quad (j \le k), \qquad \beta(i) = \sigma(k+i) - k \quad (i \le m),$$

and conversely every pair $(\alpha, \beta) \in S_k \times S_m$ arises from exactly one block-preserving σ, namely the one given by these formulas.

Signs. Write $\alpha = \tau_1 \cdots \tau_r$ and $\beta = \tau_1' \cdots \tau_s'$ as products of transpositions (Proposition 5.2.13). If $\tau_q = (p\ p')$ in S_k, let $\rho_q = (p\ p')$ in S_n, and if $\tau_q' = (p\ p')$ in S_m, let $\rho_q' = (k+p\ k+p')$ in S_n. Let $\hat\alpha = \rho_1 \cdots \rho_r$ and $\hat\beta = \rho_1' \cdots \rho_s'$. Each ρ_q fixes every point of K and acts on $[k]$ as τ_q does, so $\hat\alpha$ agrees with α on $[k]$ and fixes K. Similarly, $\hat\beta$ fixes $[k]$ and sends $k+i$ to $k+\beta(i)$. Hence $\hat\alpha\hat\beta = \sigma$: for $j \le k$, $\hat\alpha\big(\hat\beta(j)\big) = \alpha(j) = \sigma(j)$, and for $i \le m$, $\hat\alpha\big(\hat\beta(k+i)\big) = \hat\alpha(k+\beta(i)) = k+\beta(i) = \sigma(k+i)$. So σ is a product of $r+s$ transpositions, and $\operatorname{sgn}(\sigma) = (-1)^{r+s} = \operatorname{sgn}(\alpha)\operatorname{sgn}(\beta)$.

The sum. For block-preserving σ, the entries in its term are $c_{\sigma(j)j} = a_{\alpha(j)j}$ for $j \le k$ and $c_{\sigma(k+i),k+i} = c_{k+\beta(i),k+i} = b_{\beta(i)i}$ for $i \le m$. Since all other terms vanish,

$$\begin{aligned}
\det M &= \sum_{\alpha \in S_k} \sum_{\beta \in S_m} \operatorname{sgn}(\alpha)\operatorname{sgn}(\beta) \prod_{j=1}^{k} a_{\alpha(j)j} \prod_{i=1}^{m} b_{\beta(i)i} \\
&= \left(\sum_{\alpha \in S_k} \operatorname{sgn}(\alpha) \prod_{j=1}^{k} a_{\alpha(j)j} \right) \left(\sum_{\beta \in S_m} \operatorname{sgn}(\beta) \prod_{i=1}^{m} b_{\beta(i)i} \right) \\
&= \det A \det B. \qquad \square
\end{aligned}$$

The first proof is an instance of a pattern we will use repeatedly: to identify a function with det, check that it is multilinear and alternating, and evaluate it at the identity. The second proof never used the upper right block of M, a point that Section 5.4 takes up for block-triangular matrices. Applying the proposition repeatedly, a block-diagonal matrix with any number of square diagonal blocks has determinant equal to the product of the determinants of the blocks.

5.3.5 The determinant as a polynomial in the entries

The Leibniz formula computes $\det A$ from the entries of A using only additions, subtractions, and multiplications: it is a sum of $n!$ terms, each ± 1 times a product of n entries. No division occurs. This has two useful consequences.

Technique 5.3.18 (det is a polynomial in the entries). By the Leibniz formula, $\det A$ is a polynomial in the n^2 entries of A with integer coefficients ± 1, each of whose monomials has degree n and uses one entry from each row and each column. So if the entries of a matrix depend polynomially on a parameter t, then so does its determinant, and the degree and the leading coefficients can be read off the formula with Technique 5.3.12. Similarly, any map that respects sums and products can be applied to

det A entry by entry: for example, complex conjugation (Exercise 5.3.28) and reduction modulo a prime (Technique 5.3.21).

Reach for it when a question asks how det varies with a parameter, as for $\det(A + tI_n)$ or $\det(A + tB)$, for how many values of t a matrix can fail to be invertible, or how det interacts with an operation on the entries. The canonical example is Proposition 5.3.19.

Used in. Proposition 5.3.19, Proposition 5.3.20, Exercise 5.3.28, Exercise 5.6.9, Exercise 5.6.12, Problem 5.11, Problem 5.16, Problem 5.17, Problem 5.18, Proposition 7.3.22, Lemma 7.6.21.

Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t). Let $A \in F^{n\times n}$. There are scalars $c_0, c_1, \ldots, c_{n-1} \in F$, depending only on A, with $c_{n-1} = \operatorname{tr} A$ and $c_0 = \det A$, such that

$$\det(A + tI_n) = t^n + c_{n-1}t^{n-1} + \cdots + c_1 t + c_0$$

for every $t \in F$.

Proof. STANDARD

Uses. Definition 5.3.6 (Determinant), Definition 2.4.26 (Trace), distributivity in F

Techniques. Read structure off the Leibniz expansion (Technique 5.3.12), det is a polynomial in the entries (Technique 5.3.18)

Hint 1. The (i, j) entry of $A + tI_n$ is a_{ij} if $i \neq j$ and $a_{jj} + t$ if $i = j$. In the term of σ, which factors contain t?

Hint 2. Only the factors $a_{jj} + t$ with $\sigma(j) = j$. Show that a permutation $\sigma \neq \mathrm{id}$ fixes at most $n - 2$ points.

Hint 3. So only the identity contributes to t^n and t^{n-1}. Expand $(a_{11} + t)\cdots(a_{nn} + t)$. For c_0, set $t = 0$.

Sketch. The term of σ has a factor $a_{jj} + t$ for each fixed point j of σ and constant factors otherwise, so expanding it gives powers of t up to the number of fixed points. If $\sigma \neq \mathrm{id}$ moves j, it also moves $\sigma(j)$, so it fixes at most $n - 2$ points. Hence t^n and t^{n-1} come only from $(a_{11} + t)\cdots(a_{nn} + t) = t^n + (a_{11} + \cdots + a_{nn})t^{n-1} + \cdots$. Setting $t = 0$ gives $c_0 = \det A$.

The (i, j) entry of $A + tI_n$ is a_{ij} if $i \neq j$ and $a_{jj} + t$ if $i = j$. For $\sigma \in S_n$, let $\operatorname{Fix}(\sigma) = \{j \in [n] \mid \sigma(j) = j\}$ and $f_\sigma = |\operatorname{Fix}(\sigma)|$. The term of σ in $\det(A + tI_n)$ is

$$T_\sigma(t) = \operatorname{sgn}(\sigma) \prod_{j \notin \operatorname{Fix}(\sigma)} a_{\sigma(j)j} \prod_{j \in \operatorname{Fix}(\sigma)} (a_{jj} + t).$$

Expanding the second product by distributivity, choosing either a_{jj} or t from each factor, gives

$$\prod_{j \in \operatorname{Fix}(\sigma)} (a_{jj} + t) = \sum_{S \subseteq \operatorname{Fix}(\sigma)} \left(\prod_{j \in S} a_{jj} \right) t^{f_\sigma - |S|}.$$

So $T_\sigma(t) = \sum_{p=0}^{f_\sigma} e_{\sigma,p} t^p$, where

$$e_{\sigma,p} = \operatorname{sgn}(\sigma) \prod_{j \notin \operatorname{Fix}(\sigma)} a_{\sigma(j)j} \sum_{S \subseteq \operatorname{Fix}(\sigma), |S| = f_\sigma - p} \prod_{j \in S} a_{jj}$$

does not depend on t. Set $e_{\sigma,p} = 0$ for $f_\sigma < p \leq n$.

If $\sigma \neq \mathrm{id}$, choose j with $\sigma(j) \neq j$, and let $i = \sigma(j)$. Then $\sigma(i) \neq i$, since otherwise $\sigma(i) = i = \sigma(j)$ with $i \neq j$, contradicting injectivity. So σ moves the two points i and j, and $f_\sigma \leq n - 2$. Hence $e_{\sigma,n} = e_{\sigma,n-1} = 0$ for $\sigma \neq \mathrm{id}$. For $\sigma = \mathrm{id}$ we have $f_{\mathrm{id}} = n$, and the subsets $S = \emptyset$ and $S = \{j\}$ show that $e_{\mathrm{id},n} = 1$ and $e_{\mathrm{id},n-1} = a_{11} + \cdots + a_{nn} = \operatorname{tr} A$.

Summing over σ, $\det(A + tI_n) = \sum_{p=0}^{n} c_p t^p$ with $c_p = \sum_\sigma e_{\sigma,p}$, and these scalars depend only on A. By the previous paragraph, $c_n = 1$ and $c_{n-1} = \operatorname{tr} A$. Finally, setting $t = 0$ gives $c_0 = \det(A + 0I_n) = \det A$. □

In particular, $A + tI_n$ fails to be invertible for at most n values of $t \in F$. Indeed, if $A + tI_n$ is not invertible, then $\det(A + tI_n) = 0$ by Corollary 5.1.18, so t is a root of the polynomial $x^n + c_{n-1}x^{n-1} + \cdots + c_0 \in F[x]$, which has degree n and therefore at most n roots (Proposition 7.1.22). For $n = 2$ the proposition is Exercise 5.1.38.

In Section 7.3, the values of t for which $\det(A + tI_n) = 0$ become, after a change of sign, the eigenvalues of A.

The proposition is about the coefficients $c_p = \sum_\sigma e_{\sigma,p}$ built in the proof, not about "the" coefficients of the function $t \mapsto \det(A + tI_n)$. Over a small field the function does not determine its coefficients: over $\mathbb{F}_2$, $t^3 = t^3 + t^2 + t$ for both elements t. From Section 7.1 on, $\det(A + xI_n)$ is a polynomial in $F[x]$ with the coefficients c_p.

The second consequence concerns matrices with integer entries. We regard such a matrix as an element of $\mathbb{Q}^{n\times n}$, and for a prime p we write $\overline{A} \in \mathbb{F}_p^{n\times n}$ for the matrix with entries $a_{ij} \bmod p$.

Proposition 5.3.20 (Reduction modulo p). Let $A \in \mathbb{Q}^{n\times n}$ have integer entries, and let p be a prime. Then $\det A$ is an integer, and $(\det A) \bmod p = \det \overline{A}$, the determinant of $\overline{A}$ computed in $\mathbb{F}_p$.

Proof. ROUTINE

Uses. Definition 5.3.6 (Determinant), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Definition 1.1.19 (Integers modulo n)
Techniques. det is a polynomial in the entries (Technique 5.3.18)
Hint 1. The Leibniz formula uses only sums, negatives, and products of the entries.
Hint 2. By Lemma 1.1.21, taking remainders modulo p respects sums and products of two integers. Extend this to sums and products of many integers, and to negatives.
Sketch. Each term of $\det A$ is $\pm$ a product of integers, so $\det A \in \mathbb{Z}$. Reduction modulo p respects sums, products, and negatives (Lemma 1.1.21, extended by induction), so reducing the Leibniz sum for A term by term gives the Leibniz sum for $\overline{A}$ in $\mathbb{F}_p$.

Each term $\operatorname{sgn}(\sigma)a_{\sigma(1)1}\cdots a_{\sigma(n)n}$ is $\pm$ a product of integers, so $\det A$ is an integer. Write $r(x) = x \bmod p$ for $x \in \mathbb{Z}$. By part (a) of Lemma 1.1.21, $r(x + y) = r(x) + r(y)$ and $r(xy) = r(x)r(y)$, with the operations on the right taken in $\mathbb{F}_p$. By induction on the number of terms or factors, r respects sums and products of any finite number of integers. It also respects negatives: $r(x) + r(-x) = r(x + (-x)) = r(0) = 0$, so $r(-x) = -r(x)$ in $\mathbb{F}_p$. Applying r to the Leibniz formula for A therefore gives

$$r(\det A) = \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) r\big(a_{\sigma(1)1}\big)\cdots r\big(a_{\sigma(n)n}\big),$$

where $\operatorname{sgn}(\sigma) = \pm 1$ is now read in $\mathbb{F}_p$. The right side is the Leibniz formula for $\overline{A}$, so $r(\det A) = \det \overline{A}$. □

Technique 5.3.21 (Reduce modulo p). To show that a matrix with integer entries has nonzero determinant, and hence is invertible (Corollary 5.1.18), it is enough to find one prime p for which $\det \overline{A} \neq 0$ in $\mathbb{F}_p$: then $(\det A) \bmod p \neq 0$ by Proposition 5.3.20, so $\det A \neq 0$. Choose p so that $\overline{A}$ is simple, for instance triangular with nonzero diagonal entries or a permutation matrix, and there is no need to compute $\det A$ itself. The converse inference is not available: $\det \overline{A} = 0$ only says that p divides $\det A$.

Reach for it when an integer matrix has a recognizable pattern modulo a small prime, most often modulo 2, where the entries are just their parities and $\operatorname{sgn}(\sigma) = 1$ for every σ. The canonical example is Example 5.3.22.

Used in. Exercise 5.3.23, Exercise 5.3.36, Exercise 5.3.40, Exercise 5.6.12, Problem 5.15.

Example 5.3.22 (Odd diagonal, even elsewhere). Let $A \in \mathbb{Q}^{n\times n}$ have integer entries, with a_{ii} odd for every i and a_{ij} even for $i \neq j$. Then $\overline{A} = I_n$ in $\mathbb{F}_2^{n\times n}$, so by Proposition 5.3.20, $(\det A) \bmod 2 = \det I_n = 1$. So $\det A$ is odd, in particular nonzero, and A is invertible by Corollary 5.1.18. For instance,

$$\det\begin{pmatrix} 3 & 2 & -4 \\ 6 & 1 & 2 \\ 0 & 8 & 5 \end{pmatrix} = -285,$$

which is odd, as predicted.

Exercises

Exercise 5.3.23. ROUTINE Let

$$A = \begin{pmatrix} 1 & 0 & 3 \\ 3 & 1 & 1 \\ 1 & 4 & 1 \end{pmatrix}.$$

(a) Compute $\det A$ over $\mathbb{Q}$ with the rule of Sarrus.

(b) Find $\det \overline{A}$ for the reductions $\overline{A}$ of A modulo 2, 3, 5, and 7.

(c) Over $\mathbb{F}_5$, find a nonzero $\mathbf{x} \in \mathbb{F}_5^3$ with $\overline{A}\mathbf{x} = \mathbf{0}$, and explain why this is consistent with (b).

Solution on page 1405

Exercise 5.3.24. ROUTINE Let

$$B = \begin{pmatrix} 0 & 2 & 0 & 1 \\ 3 & 0 & 1 & 0 \\ 0 & 1 & 0 & 4 \\ 1 & 0 & 5 & 0 \end{pmatrix}.$$

Each column of B has exactly two nonzero entries. Find the permutations $\sigma \in S_4$ whose terms in the Leibniz formula are nonzero, and compute $\det B$.

Solution on page 1405

Exercise 5.3.25. ROUTINE Find the errors in the following argument, and give a matrix for which the claim fails.

Claim. For $A \in F^{4\times 4}$, write the four columns of A followed by its first three columns again. Then $\det A$ is the sum of the products along the four diagonals running down and to the right from $a_{11}, a_{12}, a_{13}, a_{14}$, minus the sum of the products along the four diagonals running up and to the right from $a_{41}, a_{42}, a_{43}, a_{44}$.

Proof. By the Leibniz formula, $\det A$ is a signed sum of products of four entries, one from each row and one from each column. Each of the eight diagonals is such a product. The diagonals running down correspond to cyclic shifts of the columns, which have sign $+1$, and the diagonals running up have sign -1, exactly as in the rule of Sarrus.

Solution on page 1406

Exercise 5.3.26. STANDARD

(a) Find the error in the following argument.

Claim. $\det(A + B) = \det A + \det B$ for all $A, B \in F^{n\times n}$.

Proof. By the Leibniz formula,

$$\begin{aligned} \det(A+B) &= \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) \prod_{j=1}^{n} \left(a_{\sigma(j)j} + b_{\sigma(j)j}\right) \\ &= \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) \left(\prod_{j=1}^{n} a_{\sigma(j)j} + \prod_{j=1}^{n} b_{\sigma(j)j} \right) = \det A + \det B. \end{aligned}$$

(b) For $S \subseteq [n]$, let C_S be the matrix whose column j is $\mathbf{a}_j$ if $j \in S$ and $\mathbf{b}_j$ if $j \notin S$. Show that $\det(A + B) = \sum_{S \subseteq [n]} \det C_S$.

Solution on page 1406

Exercise 5.3.27. STANDARD The axioms concern columns. This exercise shows, directly from the Leibniz formula, that det behaves the same way with respect to rows.

(a) Show that det is linear in each row of A when the other rows are held fixed.

(b) Show that $\det A = 0$ if two rows of A are equal.

(c) Let $d_1, \ldots, d_n \in F$ and $\Lambda = \operatorname{diag}(d_1, \ldots, d_n)$. Show that $\det(\Lambda A) = \det(A\Lambda) = d_1 \cdots d_n \det A$.

Solution on page 1407

Exercise 5.3.28. ROUTINE For $z = x + yi \in \mathbb{C}$ with $x, y \in \mathbb{R}$, let $\overline{z} = x - yi$, and for $A \in \mathbb{C}^{n\times n}$ let $\overline{A}$ be the matrix with entries $\overline{a_{ij}}$.

(a) Show that $\det \overline{A} = \overline{\det A}$. Deduce that a matrix with real entries has a real determinant.

(b) Suppose every entry of $A \in \mathbb{C}^{n\times n}$ is purely imaginary, that is, $\overline{A} = -A$. Show that $\det A$ is real if n is even and purely imaginary if n is odd.

Solution on page 1407

Exercise 5.3.29. STANDARD Let $A \in F^{n\times n}$, and suppose there are sets $R, C \subseteq [n]$ with $|R| + |C| > n$ such that $a_{ij} = 0$ for all $i \in R$ and $j \in C$. (So A has an $|R| \times |C|$ block of zeros, after rearranging rows and columns.)

(a) Show that $\det A = 0$.

(b) Deduce from (a) that an upper triangular matrix with a zero diagonal entry has determinant 0.

(c) Show that the hypothesis $|R| + |C| > n$ cannot be weakened to $|R| + |C| = n$, for any $n \geq 2$ and any $|R| = r$ with $1 \leq r \leq n - 1$.

Solution on page 1408

Exercise 5.3.30. STANDARD Prove or disprove each statement.

(a) If every entry of $A \in \mathbb{R}^{n\times n}$ is nonzero, then $\det A \neq 0$.

(b) If $A \in F^{n\times n}$ has exactly n nonzero entries and $\det A \neq 0$, then each row and each column of A contains exactly one nonzero entry.

(c) If $A \in F^{n\times n}$ is upper triangular, then $\det A^{\mathsf{T}} = \det A$.

(d) If $N \in F^{n\times n}$ is strictly upper triangular (Exercise 5.3.16), then $\det(A + N) = \det A$ for every $A \in F^{n\times n}$.

Solution on page 1408

Exercise 5.3.31. STANDARD The **permanent** of $A \in F^{n\times n}$ is the Leibniz formula without signs:

$$\operatorname{per} A = \sum_{\sigma \in S_n} a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n}.$$

(a) Show that per is normalized and multilinear, and that $\operatorname{per}(AE_\pi) = \operatorname{per} A$ for every $\pi \in S_n$.

(b) Let $n \geq 2$. Show that per is a determinant function on $F^{n\times n}$ if and only if $1 + 1 = 0$ in F, and that in this case per = det.

(c) Let $A \in \mathbb{Q}^{n\times n}$ have all entries in $\{0, 1\}$. Show that per A is the number of permutations σ with $a_{\sigma(j)j} = 1$ for every j, and that $\det A$ and per A are both even or both odd.

Solution on page 1409

Exercise 5.3.32. STANDARD Let $A \in \mathbb{Q}^{n\times n}$ have every entry equal to 1 or -1. Show that $\det A$ is an integer divisible by 2^{n-1}.

Solution on page 1409

Exercise 5.3.33. ROUTINE Let $A = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$.

(a) Compute $\det(A + tI_3)$ from the Leibniz formula, listing the nonzero terms, and check the coefficients against Proposition 5.3.19.

(b) Find all t with $\det(A + tI_3) = 0$, for $t \in \mathbb{C}$, for $t \in \mathbb{R}$, and for $t \in \mathbb{F}_2$ (regarding A as a matrix over $\mathbb{F}_2$).

Solution on page 1410

Exercise 5.3.34. STANDARD Let $n \geq 2$ and $A \in F^{n\times n}$. Show that the coefficient $c_{n-2} = \sum_\sigma e_{\sigma,n-2}$ constructed in the proof of Proposition 5.3.19 is

$$c_{n-2} = \sum_{1\leq i<j\leq n} \big(a_{ii}a_{jj} - a_{ij}a_{ji}\big),$$

the sum of the determinants of the 2×2 matrices formed by rows i, j and columns i, j of A.

Solution on page 1410

Exercise 5.3.35. STANDARD Let V be a vector space with a basis $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$. Show that there is exactly one multilinear alternating function $f : V \times \cdots \times V \to F$ of n vectors (Remark 5.1.6) with $f(\mathbf{v}_1, \ldots, \mathbf{v}_n) = 1$, and that it is given by

$$f(\mathbf{w}_1, \ldots, \mathbf{w}_n) = \det\big([\mathbf{w}_1]_\mathcal{B}, \ldots, [\mathbf{w}_n]_\mathcal{B}\big).$$

Solution on page 1411

Exercise 5.3.36. STANDARD

(a) Show, without computing its determinant, that

$$A = \begin{pmatrix} 2 & 1 & 4 & 6 \\ 3 & 2 & 0 & 2 \\ 4 & 6 & 2 & 1 \\ 0 & 2 & 5 & 4 \end{pmatrix}$$

is invertible over $\mathbb{Q}$.

(b) Let $B = \begin{pmatrix} 4 & 1 & 3 \\ 0 & 2 & 6 \\ 3 & 3 & 1 \end{pmatrix}$. Explain why reducing B modulo 2 cannot show that B is invertible, and show that B is invertible by reducing modulo 3.

Solution on page 1411

Exercise 5.3.37. STANDARD Let $A \in F^{k\times k}$ and $B \in F^{m\times m}$. Show that

$$\det\begin{pmatrix} 0 & A \\ B & 0 \end{pmatrix} = (-1)^{km} \det A \det B,$$

where the upper left zero block is $k \times m$ and the lower right one is $m \times k$.

Solution on page 1412

Exercise 5.3.38. HARD

(a) Find a 3×3 matrix with all entries in $\{0, 1\}$ whose determinant (over $\mathbb{Q}$) is 2.

(b) Show that no 3×3 matrix with all entries in $\{0, 1\}$ has determinant greater than 2.

Solution on page 1412

Exercise 5.3.39. HARD This exercise constructs a determinant function by induction on n, without permutations. For $A \in F^{n \times n}$ with $n \geq 2$ and $i \in [n]$, let $A^{(i)} \in F^{(n-1)\times(n-1)}$ be A with row i and column 1 deleted. Define $D_1(a) = a$ and, for $n \geq 2$,

$$D_n(A) = \sum_{i=1}^{n} (-1)^{i+1} a_{i1} D_{n-1}\left(A^{(i)}\right).$$

(a) Show by induction on n that D_n is normalized and multilinear.

(b) Show by induction on n that $D_n(A) = 0$ whenever two adjacent columns of A are equal. Deduce that D_n is a determinant function, so $D_n = \det$.

(c) Explain why, with Remark 5.2.32, this gives a third proof of Theorem 5.2.18.

Solution on page 1413

Exercise 5.3.40. CHALLENGE Let n be even, and let $A \in \mathbb{Q}^{n \times n}$ have $a_{ii} = 0$ for every i and $a_{ij} \in \{1, -1\}$ for $i \neq j$. Show that A is invertible. Show by an example that the conclusion can fail for odd n.

Solution on page 1414

5.4 Determinants and invertibility

Corollary 5.1.18 says that a matrix that is not invertible has determinant 0. This section proves the converse, so that $\det A \neq 0$ exactly when A is invertible. The converse cannot follow from multilinearity and alternation alone, since the zero function has both properties, so the proof has to use normalization. Normalization only tells us that $\det I_n = 1$, and we get from I_n to an arbitrary invertible matrix by multiplying by elementary matrices (Theorem 3.5.19). So we first work out what one elementary matrix does to the determinant, and then build up. The same analysis proves $\det(AB) = \det A \det B$ and $\det A^{\mathsf{T}} = \det A$. From these we get the row versions of all the column properties, a fast way to compute determinants by row reduction, the determinant of a linear operator, and the determinants of block-triangular matrices.

5.4.1 Elementary matrices

Recall the elementary $n \times n$ matrices (Definition 3.2.2). For $i \neq j$, E_{ij} swaps rows i and j of I_n; for $c \neq 0$, E_{ic} scales row i of I_n by c; and E_{icj} adds c times row i of I_n to row j, so it is I_n with an extra entry c in position (j, i). Multiplying by E on the left performs the row operation (Proposition 3.2.7). Multiplying on the right performs a column operation (Proposition 3.2.28): AE_{ij} is A with columns i and j swapped, AE_{ic} is A with column i scaled by c, and AE_{icj} is A with c times column j added to column i.

Intuition (Why columns first). Our axioms are statements about columns, and Section 5.1 already found the effect of each column operation on a multilinear alternating function. A swap negates it (Proposition 5.1.10), scaling a column by c multiplies it by c (multilinearity), and adding a multiple of one column to another does not change it (Lemma 5.1.8). So the products we can handle now are the products AE, in which E acts on the columns of A. The products EA, which act on rows, have to wait for the product formula (Theorem 5.4.10), and the row versions of the axioms for $\det A^{\mathsf{T}} = \det A$ (Theorem 5.4.14).

The lecture passes between the two kinds of products with a trick worth remembering. By Proposition 2.4.23, $AE = \left(E^{\mathsf{T}}A^{\mathsf{T}}\right)^{\mathsf{T}}$. Here $E^{\mathsf{T}}A^{\mathsf{T}}$ performs a row operation on A^{T}, whose rows are the columns of A, and the outer transpose turns these rows back into columns. This is the first proof of Proposition 3.2.28.

Proposition 5.4.1 (Determinants of elementary matrices). Let $1 \le i, j \le n$ with $i \ne j$, and let $c \in F$. Then $\det E_{ij} = -1$, $\det E_{icj} = 1$, and $\det E_{ic} = c$ if $c \ne 0$. In particular, every elementary matrix has a nonzero determinant.

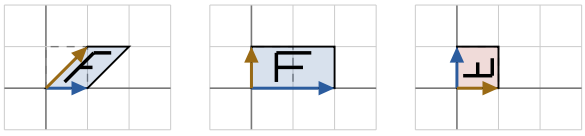
Proof. ROUTINE

Uses. Definition 3.2.2 (Elementary matrices), Definition 5.1.1 (Determinant function), Proposition 5.1.10 (Alternating implies antisymmetric)
Hint 1. Each elementary matrix is I_n with a small change. Describe the change in terms of the columns of I_n, and use the axiom that fits it.
Hint 2. E_{ij} is I_n with columns i and j interchanged, and E_{ic} is I_n with column i multiplied by c. Column i of E_{icj} is $\mathbf{e}_i + c\mathbf{e}_j$.
Hint 3. For E_{icj}, expand by linearity in column i. One of the two resulting matrices has two equal columns.
Sketch. Swapping rows i and j of I_n gives the same matrix as swapping its columns i and j, so $\det E_{ij} = -\det I_n = -1$ by antisymmetry. E_{ic} is I_n with column i scaled by c, so $\det E_{ic} = c$ by linearity in column i. Column i of E_{icj} is $\mathbf{e}_i + c\mathbf{e}_j$, so linearity in column i gives $\det I_n + c \det I'$, where I' has $\mathbf{e}_j$ in columns i and j; the value is $1 + c \cdot 0 = 1$.

Write $\mathbf{e}_1, \ldots, \mathbf{e}_n$ for the columns of I_n.

Swaps. Swapping rows i and j of I_n moves the 1 in position (i,i) to position (j,i) and the 1 in position (j,j) to position (i,j), and changes nothing else. So column i of E_{ij} is $\mathbf{e}_j$, column j is $\mathbf{e}_i$, and every other column k is $\mathbf{e}_k$. That is, E_{ij} is I_n with columns i and j interchanged, and $\det E_{ij} = -\det I_n = -1$ by Proposition 5.1.10.

Scalings. E_{ic} is I_n with column i replaced by $c\mathbf{e}_i$. By linearity in column i, $\det E_{ic} = c \det I_n = c$.



Replacements. E_{icj} is I_n with an extra entry c in position (j,i), so its column i is $\mathbf{e}_i + c\mathbf{e}_j$ and its other columns are those of I_n. Let I' be I_n with column i replaced by $\mathbf{e}_j$. By linearity in column i,

$$\det E_{icj} = \det I_n + c \det I' = 1 + c \cdot 0 = 1,$$

since columns i and j of I' are both $\mathbf{e}_j$, and det is alternating.

Finally, $-1 \ne 0$ because $1 \ne 0$, and $c \ne 0$ for a scaling, so all three values are nonzero. □

Over $\mathbb{R}$ these values are the signed areas observed in Section 3.2.6: a shear keeps the area of the unit square, the stretch E_{1c} multiplies its signed area by c (reflecting it when $c < 0$), and the swap keeps the area but reverses orientation.

$E_{2,1,1}$, $\det = 1$ $E_{1,2}$, $\det = 2$ E_{12}, $\det = -1$

The plane transformer, starting at the shear $E_{2,1,1} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. Sliding $A\mathbf{e}_2$ along the line $x_2 = 1$ gives the shears E_{2c1}, and the readout stays at $\det A = 1$. With $A\mathbf{e}_2$ back at $\mathbf{e}_2$, moving $A\mathbf{e}_1$ along the x_1-axis gives the scalings E_{1c} for $c \ne 0$, with $\det A = c$. Typing the entries $0, 1, 1, 0$ gives the swap E_{12}: the F is mirrored and $\det A = -1$. (Interactive in the web version.)

Lemma 5.4.2 (Multiplying by an elementary matrix). Let $A, E \in F^{n \times n}$, and suppose E is elementary. Then $\det(AE) = \det A \det E$.

Proof. ROUTINE

Uses. Proposition 3.2.28 (Column operations are right multiplications), Proposition 5.1.10 (Alternating implies antisymmetric), Lemma 5.1.8 (Column replacement), Definition 5.1.1 (Determinant function), Proposition 5.4.1 (Determinants of elementary matrices)
Hint 1. By Proposition 3.2.28, AE is A with one column operation performed. Treat the three types of E separately.
Hint 2. In each case, compare the factor by which the column operation changes $\det A$ with the value of $\det E$ in Proposition 5.4.1.
Sketch. AE_{ij} is A with columns i and j swapped, so its determinant is $-\det A$. AE_{ic} is A with column i scaled by c, so its determinant is $c \det A$. AE_{icj} is A with c times column j added to column i, so its determinant is $\det A$. The factors -1, c, and 1 are the determinants of the three types.

We consider the three types in turn, using Proposition 3.2.28 to describe AE and Proposition 5.4.1 for $\det E$.

Swaps. AE_{ij} is A with columns i and j interchanged, so by Proposition 5.1.10,

$$\det\big(AE_{ij}\big) = -\det A = \det A \det E_{ij}.$$

Scalings. AE_{ic} is A with column i multiplied by c, so by linearity in column i,

$$\det(AE_{ic}) = c \det A = \det A \det E_{ic}.$$

Replacements. AE_{icj} is A with c times column j added to column i, where $i \neq j$. By Lemma 5.1.8,

$$\det\big(AE_{icj}\big) = \det A = \det A \det E_{icj}.$$

□

Remark 5.4.3 (The values are no coincidence). In each case of the proof, $\det(AE) = c_E \det A$, where the factor c_E depends only on the column operation of E and not on A. Taking $A = I_n$ gives $\det E = c_E \det I_n = c_E$, because $E = I_n E$ is the result of performing its own column operation on I_n. So the lemma can be proved without computing $\det E$ first, and the computation of Proposition 5.4.1 then comes for free. (This is how LADW argues in its Lemma 3.6. We followed the lecture, which computes $\det E$ first.)

Corollary 5.4.4 (Products of elementary matrices). Let $A \in F^{n\times n}$, and let $E_1, \ldots, E_k \in F^{n\times n}$ be elementary. Then

$$\det(AE_1 \cdots E_k) = \det A \det E_1 \cdots \det E_k.$$

In particular, $\det(E_1 \cdots E_k) = \det E_1 \cdots \det E_k$, and this is nonzero.

Proof. ROUTINE

Uses. Lemma 5.4.2 (Multiplying by an elementary matrix), Proposition 5.4.1 (Determinants of elementary matrices), Proposition 1.1.17 (No zero divisors), induction on k
Hint 1. Induct on k. Group the product as $(AE_1 \cdots E_{k-1})E_k$.
Hint 2. For the last sentence, take $A = I_n$, and recall that a field has no zero divisors.
Sketch. By Lemma 5.4.2 applied to the matrix $AE_1 \cdots E_{k-1}$ and the induction hypothesis, $\det(AE_1 \cdots E_k) = \det(AE_1 \cdots E_{k-1}) \det E_k = \det A \det E_1 \cdots \det E_k$. With $A = I_n$ this is the second formula; each factor is nonzero by Proposition 5.4.1, and so is the product.

We induct on k. For $k = 0$ the product of elementary matrices is empty, that is, equal to I_n, and both sides equal $\det A$. For $k \geq 1$, apply Lemma 5.4.2 to the matrix $AE_1 \cdots E_{k-1}$ and to E_k, and then the induction hypothesis:

$$\begin{aligned}\det(AE_1 \cdots E_k) &= \det(AE_1 \cdots E_{k-1}) \det E_k \\ &= \det A \det E_1 \cdots \det E_{k-1} \det E_k.\end{aligned}$$

Taking $A = I_n$ gives $\det(E_1 \cdots E_k) = \det E_1 \cdots \det E_k$. Each $\det E_l$ is nonzero by Proposition 5.4.1, and a product of nonzero elements of a field is nonzero (Proposition 1.1.17, and induction on the number of factors). □

Exercise 5.4.5. ROUTINE Let $A \in \mathbb{Q}^{3\times 3}$ have $\det A = 5$, and let $G = E_{13}E_{2,4}E_{3,-7,1}$, a product of 3×3 elementary matrices. Find $\det G$ and $\det(AG)$. Which column operations turn A into AG, and in which order are they performed?

Solution on page 1415

5.4.2 Invertibility

We can now carry out the plan from the beginning of the section. The idea of building every invertible matrix out of elementary ones is used several times in this section, so we name it.

Technique 5.4.6 (Reduce to elementary matrices). Every invertible matrix is a product of elementary matrices (Theorem 3.5.19). So to prove a statement about all invertible matrices, it is often enough to

1. prove it for the three types of elementary matrices, by a direct computation; and
2. show that it survives multiplication: if it holds for A and E is elementary, then it holds for AE (or for EA).

Induction on the number of factors then gives the statement for every invertible matrix. A statement about all square matrices needs a separate argument for the matrices that are not invertible. Often both sides of the claimed identity are 0 there. Otherwise, write $A = G^{-1}\operatorname{rref}(A)$ (Theorem 3.3.10) and use that $\operatorname{rref}(A)$ has a zero row.

Reach for it when a statement involves products, inverses, or transposes, and is easy to check on elementary matrices, which differ from I_n in at most four entries. The fullest example is the first proof of Theorem 5.4.10; the first proof of Theorem 5.4.14 has the same shape. Remember the case split: a matrix that is not invertible is never a product of elementary matrices, since such products are invertible (Corollary 3.2.11). Forgetting this is a common error (Exercise 5.4.35).

Used in. Corollary 3.5.22, Exercise 3.6.10, Problem 3.7, Theorem 5.4.7, Theorem 5.4.10, Theorem 5.4.14, Exercise 5.4.35, Exercise 5.6.11, Exercise 5.4.49.

Theorem 5.4.7 (Invertibility and the determinant). Let $A \in F^{n\times n}$. The following are equivalent.

(I) A is invertible.
(II) $\det A \neq 0$.

Proof. STANDARD

Uses. Corollary 5.1.18 (Non-invertible matrices), Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Corollary 5.4.4 (Products of elementary matrices)
Techniques. Reduce to elementary matrices (Technique 5.4.6), Contrapositive (Technique 1.5.4)
Hint 1. One direction was proved in Section 5.1. For the other, which description of an invertible matrix makes its determinant computable?
Hint 2. Write an invertible A as a product of elementary matrices.
Hint 3. By Corollary 5.4.4, $\det A$ is then a product of determinants of elementary matrices. Can such a product be 0?
Sketch. (II) $\Rightarrow$ (I) is the contrapositive of Corollary 5.1.18. For (I) $\Rightarrow$ (II), write $A = E_1\cdots E_k$ with elementary E_i. Then $\det A = \det E_1 \cdots \det E_k$, a product of the nonzero scalars -1, c, and 1, which is nonzero.

(II) $\Rightarrow$ (I). We prove the contrapositive. If A is not invertible, then $\det A = 0$ by Corollary 5.1.18.

(I) $\Rightarrow$ (II). Suppose A is invertible. By Theorem 3.5.19 there are elementary matrices $E_1, \ldots, E_k$ with $A = E_1\cdots E_k$. By Corollary 5.4.4, $\det A = \det E_1 \cdots \det E_k$, and this is nonzero. □

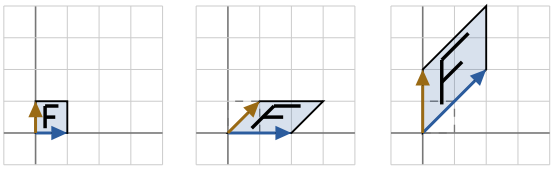
The two directions use different axioms. (II) $\Rightarrow$ (I) used only multilinearity and alternation. (I) $\Rightarrow$ (II) used normalization, through the computation $\det E_{ic} = c \det I_n = c$ and its relatives in Proposition 5.4.1. This is as it must be: the zero function is multilinear and alternating, and (I) $\Rightarrow$ (II) fails for it. Combining the theorem with the Fundamental Theorems gives several equivalent ways to say that a determinant vanishes.

Corollary 5.4.8 (Vanishing determinants). Let $A \in F^{n\times n}$. The following are equivalent.
(a) $\det A = 0$.
(b) A is not invertible.
(c) The columns of A are linearly dependent.
(d) $A\mathbf{x} = \mathbf{0}$ for some nonzero $\mathbf{x} \in F^n$.

Proof. ROUTINE

Uses. Theorem 5.4.7 (Invertibility and the determinant), Corollary 3.5.25 (The invertible matrix theorem), Theorem 3.5.12 (First Fundamental Theorem, completed), Definition 2.3.8 (Matrix–vector product), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. (a) ⇔ (b) is Theorem 5.4.7. Relate both invertibility and independence of the columns to the rank.
Hint 2. For (c) ⇔ (d), write $A\mathbf{x}$ as a linear combination of the columns of A.
Sketch. (a) ⇔ (b) by Theorem 5.4.7. By Corollary 3.5.25 and Theorem 3.5.12, A is invertible if and only if $\operatorname{rank} A = n$, if and only if its columns are independent, which gives (b) ⇔ (c). Since $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$, a nonzero solution of $A\mathbf{x} = \mathbf{0}$ is the same thing as a nontrivial linear relation among the columns.

(a) ⇔ (b) is Theorem 5.4.7. By Corollary 3.5.25, A is invertible if and only if $\operatorname{rank} A = n$, and by Theorem 3.5.12 this holds if and only if the columns of A are linearly independent. Negating both sides gives (b) ⇔ (c). Finally, $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ by Definition 2.3.8, so a nonzero $\mathbf{x}$ with $A\mathbf{x} = \mathbf{0}$ is exactly a nontrivial linear relation among the columns of A. By Theorem 1.5.5, such a relation exists if and only if the columns are linearly dependent, which is (c) ⇔ (d). □



For det, the implication (c) ⇒ (a) is Proposition 5.1.17, which holds for every multilinear alternating function. The implication (a) ⇒ (c) is the converse that Exercise 5.1.22 warned about, and it needed normalization. Together with Proposition 5.3.19, the corollary also says that $A + tI_n$ is invertible for all but at most n scalars t, and that the exceptional t are exactly the roots of $\det(A + tI_n)$. Their negatives reappear as eigenvalues in Section 7.3.

Exercise 5.4.9. ROUTINE Let $A(t) = \begin{pmatrix} 1 & t & 0 \\ t & 1 & t \\ 0 & t & 1 \end{pmatrix}$. Find all t for which $A(t)$ is invertible, when t ranges over $\mathbb{R}$, over $\mathbb{Q}$, over $\mathbb{F}_3$, and over $\mathbb{F}_7$.

Solution on page 1415

5.4.3 The product formula

Intuition (Areas multiply). Over $\mathbb{R}$, the absolute value of $\det A$ is the factor by which T_A scales areas in the plane (or volumes in space), and its sign records whether T_A preserves orientation (Section 5.1). Composition multiplies these factors. If T_B doubles areas and T_A triples them, then $T_A \circ T_B$, which is T_{AB} (Theorem 2.4.2), multiplies them by six. If both reverse orientation, the composite preserves it, matching $(-1)(-1) = 1$. So signed area predicts $\det(AB) = \det A \det B$. Figure 5.4.1 shows an example.

Q: area 1 $T_B(Q)$: area 2 $T_{AB}(Q)$: area 4

Figure 5.4.1. The unit square Q with a letter F (left), its image under T_B for $B = \begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix}$ (middle), and its image under $T_A \circ T_B = T_{AB}$ for $A = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ (right), where $AB = \begin{pmatrix} 2 & 0 \\ 2 & 2 \end{pmatrix}$. The arrows are the images of $\mathbf{e}_1$ (blue) and $\mathbf{e}_2$ (ochre). Here $\det B = 2$ and $\det A = 2$: T_B doubles the area of Q, and T_A, which rotates by 45° and stretches by $\sqrt{2}$, doubles it again, so $\det(AB) = 4$.

Theorem 5.4.10 (Multiplicativity). For all $A, B \in F^{n\times n}$,

$$\det(AB) = \det A \det B.$$

Proof (by factoring into elementary matrices). STANDARD

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Corollary 5.4.4 (Products of elementary matrices), Theorem 5.4.7 (Invertibility and the determinant), Theorem 3.5.23 (One-sided inverses of square matrices)
Techniques. Reduce to elementary matrices (Technique 5.4.6)
Hint 1. Suppose first that B is invertible, and factor it into elementary matrices. Note that Corollary 5.4.4 allows an arbitrary matrix on the left.
Hint 2. If B is not invertible, show that AB is not invertible either. What are both sides then?
Hint 3. If AB had an inverse C, then $(CA)B = I_n$. What does a one-sided inverse of a square matrix give?
Sketch. If $B = E_1 \cdots E_k$, then Corollary 5.4.4 gives $\det(AB) = \det A \det E_1 \cdots \det E_k = \det A \det B$, the last step by the same corollary with I_n in place of A. If B is not invertible, neither is AB, since an inverse C of AB would make CA a left inverse of B. So both sides are 0 by Theorem 5.4.7.

Case 1: B is invertible. By Theorem 3.5.19, $B = E_1 \cdots E_k$ for some elementary matrices $E_1, \ldots, E_k$. Applying Corollary 5.4.4 first to A and then to I_n,

$$\begin{aligned} \det(AB) &= \det(AE_1 \cdots E_k) = \det A \det E_1 \cdots \det E_k \\ &= \det A \det(E_1 \cdots E_k) = \det A \det B. \end{aligned}$$

Case 2: B is not invertible. Then $\det B = 0$ by Theorem 5.4.7, so the right side is 0. We show that AB is not invertible, so that the left side is 0 as well. Suppose instead that AB has an inverse C. Then $(CA)B = C(AB) = I_n$, so B has a left inverse. A square matrix with a one-sided inverse is invertible (Theorem 3.5.23), which contradicts our assumption on B. Hence AB is not invertible, and $\det(AB) = 0 = \det A \det B$. □

The lecture splits into cases according to whether A and B are both invertible, and factors both. Since Corollary 5.4.4 allows any matrix on the left, only B needs to be factored. The second proof avoids factoring altogether. It rests on a move that was already used for block-diagonal matrices in Proposition 5.3.17.

Technique 5.4.11 (Recognize the determinant by its axioms). By Theorem 5.3.4, every multilinear alternating function $D : F^{n\times n} \to F$ equals $D(I_n)\det$. So to prove an identity of the form $D(B) = c \det B$, where $D(B)$ is some expression built from B, check two things about D as a function of the columns of B: that it is linear in each column, and that it vanishes when two columns are equal. Then evaluate at I_n to find $c = D(I_n)$. No formula for det and no case analysis is needed.

Reach for it when an expression is visibly linear in each column of a matrix: $\det(AB)$ for a fixed A, $\det\begin{pmatrix} X & 0 \\ 0 & B \end{pmatrix}$ for a fixed B, or a function of n vectors in a space with a basis. The canonical example is the second proof of Theorem 5.4.10. The same move proved Proposition 5.3.17, and Section 13.4 uses it to define the determinant of an operator without choosing a basis.
Used in. Theorem 5.4.10, Exercise 5.6.8, Problem 5.2, Proposition 7.3.2.

Proof of Theorem 5.4.10 (by uniqueness). STANDARD

> *Uses.* Theorem 5.3.4 (Existence and uniqueness of the determinant), Definition 2.4.1 (Matrix product), Proposition 2.3.13 (Linearity of the product), Proposition 2.1.17 (Compositions of linear maps are linear), Definition 5.1.1 (Determinant function)
> *Techniques.* Recognize the determinant by its axioms (Technique 5.4.11)
> *Hint 1.* Fix A, and regard $D(B) = \det(AB)$ as a function of the columns $\mathbf{b}_1, \dots, \mathbf{b}_n$ of B. What are the columns of AB?
> *Hint 2.* Column j of AB is $A\mathbf{b}_j$. Check that D is multilinear and alternating, and apply Theorem 5.3.4.
> *Sketch.* Since column j of AB is $A\mathbf{b}_j$, $D(B) = \det(A\mathbf{b}_1, \dots, A\mathbf{b}_n)$. In each column this is det composed with the linear map $\mathbf{x} \mapsto A\mathbf{x}$, so it is linear, and equal columns of B give equal columns of AB. So D is multilinear and alternating, and $D(B) = D(I_n) \det B = \det A \det B$.

Fix A, and define $D : F^{n\times n} \to F$ by $D(B) = \det(AB)$. By Definition 2.4.1, column j of AB is $A\mathbf{b}_j$, so

$$D(\mathbf{b}_1, \dots, \mathbf{b}_n) = \det(A\mathbf{b}_1, \dots, A\mathbf{b}_n).$$

Multilinear. Fix j and all columns of B except the j-th. Then $\mathbf{x} \mapsto D(\dots, \mathbf{x}, \dots)$, with $\mathbf{x}$ in column j, is the composite of $\mathbf{x} \mapsto A\mathbf{x}$, which is linear (Proposition 2.3.13), and the map that puts a vector $\mathbf{y}$ in column j of the matrix with columns $A\mathbf{b}_k$ ($k \neq j$) and takes det, which is linear because det is linear in column j. So it is linear by Proposition 2.1.17.

Alternating. If $\mathbf{b}_i = \mathbf{b}_j$ for some $i \neq j$, then $A\mathbf{b}_i = A\mathbf{b}_j$, so AB has two equal columns and $D(B) = 0$.

By Theorem 5.3.4, $D(B) = D(I_n) \det B = \det(AI_n) \det B = \det A \det B$ for every B. □

For $n = 2$ the second proof is the first solution of Exercise 5.1.27.

> *Intuition (Two proofs compared).* The two proofs are the two basic strategies of this chapter. The first, Technique 5.4.6, builds B out of simple pieces. It needs the computation for elementary matrices, the factorization theorem that comes out of Gauss–Jordan elimination (Theorem 3.5.19), and a separate argument for matrices that are not invertible. The second, Technique 5.4.11, never looks inside B. It notices that $B \mapsto \det(AB)$ satisfies two of the three axioms, so by uniqueness it is a multiple of det, and it finds the multiple by setting $B = I_n$. It uses neither elimination nor a case split.
>
> The second proof is shorter, and it works verbatim with any multilinear alternating function in place of det, which is why the basis-free theory of Section 13.4 is built on it. It also gives (I) ⇒ (II) in Theorem 5.4.7 without elementary matrices: if A is invertible, then $1 = \det I_n = \det\left(AA^{-1}\right) = \det A \det A^{-1}$, so $\det A \neq 0$. The first proof explains where the numbers come from: the factor that each elementary matrix contributes is the effect of its column operation. Its pattern also adapts to statements that are not about columns, such as $\det A^{\mathsf{T}} = \det A$ below, where the axioms give no direct handle.

Exercise 5.4.12. ROUTINE Let $A, B \in F^{n\times n}$. Show that $\det(AB) = \det(BA)$, and that $\det\left(A^k\right) = (\det A)^k$ for every integer $k \geq 0$. Show also that if A is invertible, then $\det\left(A^{-1}\right) = (\det A)^{-1}$, and deduce that $\det\left(A^k\right) = (\det A)^k$ for negative k as well, where $A^{-k} = \left(A^{-1}\right)^k$.

Solution on page 1415

So $\det(AB) = \det(BA)$ even when $AB \neq BA$. For example, $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$ have $AB = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$ and $BA = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$, which are different matrices, both with determinant 1. In the language of Section 14.1, Theorem 5.4.7 and Theorem 5.4.10 say that det is a homomorphism from the group of invertible $n \times n$ matrices under multiplication to the group $F \setminus \{0\}$ under multiplication.

5.4.4 The transpose

The axioms single out the columns of a matrix. The transpose exchanges rows and columns (Definition 2.4.21), and the next theorem says that the determinant does not notice the exchange. First, the elementary matrices.

Lemma 5.4.13 (Transposes of elementary matrices). If $E \in F^{n\times n}$ is elementary, then E^{T} is an elementary matrix of the same type, and $\det E^{\mathsf{T}} = \det E$. Explicitly,

$$E_{ij}^{\mathsf{T}} = E_{ij}, \quad E_{ic}^{\mathsf{T}} = E_{ic}, \quad E_{icj}^{\mathsf{T}} = E_{jci}.$$

Proof. ROUTINE

Uses. Definition 3.2.2 (Elementary matrices), Definition 2.4.21 (Transpose), Proposition 5.4.1 (Determinants of elementary matrices)
Hint 1. Transposing reflects the entries in the diagonal. Which off-diagonal entries does each elementary matrix have?
Hint 2. E_{icj} has a single off-diagonal entry, c, in position (j,i). Which elementary matrix has c in position (i,j)?
Sketch. E_{ic} is diagonal. The off-diagonal entries of E_{ij} are 1s in positions (i,j) and (j,i), a symmetric pattern. E_{icj} is I_n plus c in position (j,i), so its transpose is I_n plus c in position (i,j), which is E_{jci}. Each pair has the same determinant by Proposition 5.4.1.

Transposing a matrix moves the entry in position (k,l) to position (l,k) (Definition 2.4.21), so it fixes the diagonal and the identity matrix. E_{ic} is diagonal, so $E_{ic}^{\mathsf{T}} = E_{ic}$. By the proof of Proposition 5.4.1, E_{ij} agrees with I_n except that the entries in positions (i,i) and (j,j) are 0 and those in positions (i,j) and (j,i) are 1. This pattern is unchanged by the reflection, so $E_{ij}^{\mathsf{T}} = E_{ij}$. Finally, E_{icj} is I_n with an extra entry c in position (j,i), so E_{icj}^{T} is I_n with an extra entry c in position (i,j). Since $j \neq i$, this is the elementary matrix E_{jci}, which adds c times row j to row i. In each case E and E^{T} have the same type, so they have the same determinant (-1, c, or 1) by Proposition 5.4.1. □

Theorem 5.4.14 (The transpose). For every $A \in F^{n\times n}$,

$$\det A^{\mathsf{T}} = \det A.$$

Proof (via elementary matrices). STANDARD

Uses. Theorem 3.5.19 (Invertible matrices are products of elementary matrices), Proposition 2.4.23 (Transpose of a product), Lemma 5.4.13 (Transposes of elementary matrices), Corollary 5.4.4 (Products of elementary matrices), Theorem 5.4.7 (Invertibility and the determinant), Definition 2.5.12 (Invertible)
Techniques. Reduce to elementary matrices (Technique 5.4.6), Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. First dispose of the matrices that are not invertible: show that A^{T} is invertible exactly when A is.
Hint 2. For invertible A, factor $A = E_1 \cdots E_k$. What is A^{T}, by Proposition 2.4.23?
Hint 3. $A^{\mathsf{T}} = E_k^{\mathsf{T}} \cdots E_1^{\mathsf{T}}$ is again a product of elementary matrices. Compare the two products of determinants using Lemma 5.4.13.
Sketch. If B is an inverse of A, then B^{T} is an inverse of A^{T} by Proposition 2.4.23, and conversely since $\left(A^{\mathsf{T}}\right)^{\mathsf{T}} = A$. So if A is not invertible, both determinants are 0. If $A = E_1 \cdots E_k$, then $A^{\mathsf{T}} = E_k^{\mathsf{T}} \cdots E_1^{\mathsf{T}}$, and Corollary 5.4.4 with Lemma 5.4.13 gives $\det A^{\mathsf{T}} = \prod \det E_i^{\mathsf{T}} = \prod \det E_i = \det A$.

First, A is invertible if and only if A^{T} is. Indeed, if $AB = BA = I_n$, then by Proposition 2.4.23,

$$B^{\mathsf{T}} A^{\mathsf{T}} = (AB)^{\mathsf{T}} = I_n^{\mathsf{T}} = I_n,$$
$$A^{\mathsf{T}} B^{\mathsf{T}} = (BA)^{\mathsf{T}} = I_n,$$

so A^{T} is invertible. Applying this to A^{T}, whose transpose is A, gives the converse.

If A is not invertible, then neither is A^{T}, and $\det A = 0 = \det A^{\mathsf{T}}$ by Theorem 5.4.7. Suppose that A is invertible, and write $A = E_1 E_2 \cdots E_k$ with elementary E_i (Theorem 3.5.19). By Proposition 2.4.23 and induction on k,

$$A^{\mathsf{T}} = E_k^{\mathsf{T}} \cdots E_2^{\mathsf{T}} E_1^{\mathsf{T}},$$

and each E_i^{T} is elementary by Lemma 5.4.13. So by Corollary 5.4.4 (with I_n in place of A), Lemma 5.4.13, and commutativity of multiplication in F,

$$\det A^{\mathsf{T}} = \det E_k^{\mathsf{T}} \cdots \det E_1^{\mathsf{T}} = \det E_k \cdots \det E_1$$

$$= \det E_1 \cdots \det E_k = \det A. \qquad \square$$

Proof (via the Leibniz formula). STANDARD

> *Uses.* Definition 5.3.6 (Determinant), Definition 2.4.21 (Transpose), Proposition 5.2.25 (Multiplicativity of the sign), Proposition 5.2.8 (Reindexing sums over S_n)
> *Hint 1.* Write out the Leibniz formula for A^{T}, whose (i,j) entry is a_{ji}.
> *Hint 2.* You get $\sum_\sigma \operatorname{sgn}(\sigma) a_{1\sigma(1)} \cdots a_{n\sigma(n)}$. Reorder each product by the second index: if $j = \sigma(i)$, then $i = \sigma^{-1}(j)$.
> *Hint 3.* Then use $\operatorname{sgn}(\sigma^{-1}) = \operatorname{sgn}(\sigma)$, and reindex the sum by $\sigma \mapsto \sigma^{-1}$.
> *Sketch.* The term of σ in $\det A^{\mathsf{T}}$ is $\operatorname{sgn}(\sigma) \prod_i a_{i\sigma(i)}$. Reordering the factors by $j = \sigma(i)$ turns it into $\operatorname{sgn}(\sigma^{-1}) \prod_j a_{\sigma^{-1}(j)j}$, the term of σ^{-1} in $\det A$. As σ runs over S_n, so does σ^{-1}, so the two sums agree.

Let $B = A^{\mathsf{T}}$, so that $b_{ij} = a_{ji}$ (Definition 2.4.21). By the Leibniz formula (Definition 5.3.6),

$$\begin{aligned} \det A^{\mathsf{T}} &= \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) b_{\sigma(1)1} \cdots b_{\sigma(n)n} \\ &= \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) a_{1\sigma(1)} \cdots a_{n\sigma(n)}. \end{aligned}$$

Fix σ. As i runs over $[n]$, the index $j = \sigma(i)$ runs over $[n]$, taking each value once, and $i = \sigma^{-1}(j)$. Reordering the factors by j, which is allowed since multiplication in F is commutative,

$$a_{1\sigma(1)} \cdots a_{n\sigma(n)} = a_{\sigma^{-1}(1)1} \cdots a_{\sigma^{-1}(n)n}.$$

Also $\operatorname{sgn}(\sigma) = \operatorname{sgn}(\sigma^{-1})$ by Proposition 5.2.25. So the term of σ in $\det A^{\mathsf{T}}$ is $g(\sigma^{-1})$, where

$$g(\rho) = \operatorname{sgn}(\rho) a_{\rho(1)1} \cdots a_{\rho(n)n}$$

is the term of ρ in $\det A$. By Proposition 5.2.8,

$$\det A^{\mathsf{T}} = \sum_{\sigma \in S_n} g(\sigma^{-1}) = \sum_{\sigma \in S_n} g(\sigma) = \det A. \qquad \square$$

The second proof is the computation of Exercise 5.3.8.

> *Intuition (What the two proofs see).* The lecture calls the fact $\det E^{\mathsf{T}} = \det E$ dumb luck, and in a sense it is: the axioms never mention rows. But there is a reason behind it. E^{T} performs the same kind of operation as E, on rows where E acts on columns, and the three kinds of operations scale signed volume by -1, c, and 1 whichever way they act. The second proof gives a more symmetric reason. A term of the Leibniz formula picks one entry from each row and each column, like non-attacking rooks on a chessboard (Figure 5.3.1). Transposing reflects the board in its diagonal, which turns the term of σ into the term of σ^{-1}, a permutation with the same sign.
>
> As for strategy, the first proof is Technique 5.4.6 once more, with the same case split as the first proof of Theorem 5.4.10. Technique 5.4.11 does not apply directly. To use it on $D(A) = \det A^{\mathsf{T}}$, we would need to know that D is multilinear and alternating in the columns of A, that is, that det is multilinear and alternating in rows, which is what we are trying to establish. Exercise 5.3.27 proves exactly this from the Leibniz formula, and gives a third proof.

Every statement about the columns of a determinant now has a version for rows (Technique 3.2.27).

> **Corollary 5.4.15** (Rows). Let $A \in F^{n \times n}$.
> (a) $\det A$ is multilinear and alternating as a function of the rows of A.
> (b) Swapping two rows of A negates $\det A$, multiplying a row by c multiplies $\det A$ by c, and adding a multiple of one row to a different row does not change $\det A$.
> (c) $\det A = 0$ if and only if the rows of A are linearly dependent.

Proof. ROUTINE

Uses. Theorem 5.4.14 (The transpose), Definition 2.4.21 (Transpose), Definition 5.1.1 (Determinant function), Proposition 5.1.10 (Alternating implies antisymmetric), Lemma 5.1.8 (Column replacement), Corollary 5.4.8 (Vanishing determinants)
Techniques. Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. Row i of A, written as a column, is column i of A^{T}. Apply the column statements to A^{T}.
Hint 2. For (b) you can also use Theorem 5.4.10 with the elementary matrices of Proposition 5.4.1.
Sketch. The rows of A, written as columns, are the columns of A^{T}, and $\det A = \det A^{\mathsf{T}}$. So each statement about the rows of A is the corresponding statement about the columns of A^{T}: the axioms for (a), Proposition 5.1.10, multilinearity, and Lemma 5.1.8 for (b), and Corollary 5.4.8 for (c).

For $\mathbf{r}_1, \dots, \mathbf{r}_n \in F^n$, let R be the matrix whose i-th row is $\mathbf{r}_i^{\mathsf{T}}$. Its transpose has columns $\mathbf{r}_1, \dots, \mathbf{r}_n$, so by Theorem 5.4.14,

$$\det R = \det(\mathbf{r}_1, \dots, \mathbf{r}_n).$$

(a) The right side is multilinear and alternating in $\mathbf{r}_1, \dots, \mathbf{r}_n$ (Definition 5.1.1), hence so is the left side.

(b) Each row operation on A is the corresponding column operation on A^{T}, and $\det A = \det A^{\mathsf{T}}$. By Proposition 5.1.10, linearity in a column, and Lemma 5.1.8, the three column operations multiply $\det A^{\mathsf{T}}$ by -1, by c, and by 1. (Alternatively: a row operation multiplies A on the left by an elementary matrix E (Proposition 3.2.7), and $\det(EA) = \det E \det A$ with $\det E$ given by Proposition 5.4.1.)

(c) The rows of A are linearly dependent if and only if the columns of A^{T} are, which by Corollary 5.4.8 happens if and only if $\det A^{\mathsf{T}} = \det A$ is 0. □

In particular, a matrix with a zero row or two equal rows has determinant 0, and $\det(EA) = \det E \det A$ for elementary E, which is Lemma 5.4.2 with the factors in the other order.

Exercise 5.4.16. ROUTINE Suppose that $\det\begin{pmatrix} a & b & c \\ d & e & f \\ g & h & k \end{pmatrix} = 7$, where the entries lie in a field F. Find

$$\text{(a) } \det\begin{pmatrix} d & e & f \\ a & b & c \\ g & h & k \end{pmatrix},$$

$$\text{(b) } \det\begin{pmatrix} a & b & c \\ 2d-3a & 2e-3b & 2f-3c \\ g & h & k \end{pmatrix},$$

$$\text{(c) } \det\begin{pmatrix} a & d & g+5a \\ b & e & h+5b \\ c & f & k+5c \end{pmatrix},$$

$$\text{(d) } \det\begin{pmatrix} 3a & 3b & 3c \\ 3d & 3e & 3f \\ 3g & 3h & 3k \end{pmatrix}.$$

Solution on page 1416

5.4.5 Similar matrices and the determinant of an operator

Recall (Definition 4.5.23) that $A, B \in F^{n\times n}$ are **similar** if $B = S^{-1}AS$ for some invertible $S \in F^{n\times n}$. Then also $A = SBS^{-1}$, so the relation is symmetric.

Proposition 5.4.17 (Similar matrices have equal determinants). If $A, B \in F^{n\times n}$ are similar, then $\det A = \det B$.

Proof. ROUTINE

> *Uses.* Definition 4.5.23 (Similar matrices), Theorem 5.4.10 (Multiplicativity)
> *Hint 1.* Write $B = S^{-1}AS$ and apply Theorem 5.4.10.
> *Hint 2.* Determinants are scalars, so they commute even though matrices need not. Bring $\det S^{-1}$ and $\det S$ together.
> *Sketch.* $\det B = \det S^{-1} \det A \det S = \det A \det\bigl(S^{-1}S\bigr) = \det A \det I_n = \det A$.

Write $B = S^{-1}AS$ with S invertible. By Theorem 5.4.10, applied twice, and commutativity of multiplication in F,

$$\begin{aligned}\det B &= \det S^{-1} \det A \det S = \det A\bigl(\det S^{-1} \det S\bigr)\\ &= \det A \det\bigl(S^{-1}S\bigr) = \det A \det I_n = \det A,\end{aligned}$$

as desired. □

The converse fails. $\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}$ and I_2 both have determinant 1, but they are not similar, since $S^{-1}I_2S = I_2$ for every invertible S. So the determinant can prove that two matrices are not similar, but not that they are. It joins the rank and the trace (Proposition 2.4.28) as a similarity invariant. Together with the trace, it appears among the coefficients of $\det(A + tI_n)$ (Proposition 5.3.19), and in Section 7.3 this polynomial becomes a finer invariant.

The main use of Proposition 5.4.17 is to define the determinant of a linear operator. Let V be a vector space with $\dim V = n \geq 1$, let $T \in \mathrm{L}(V)$, and let $\mathcal{B}$ and $\mathring{\mathcal{B}}$ be bases of V. By Theorem 4.5.17,

$$[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = [\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathcal{B}}[T]_{\mathcal{B}\mathcal{B}}[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}.$$

By Theorem 2.4.2, $[\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathcal{B}}[\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}} = [\mathrm{id}_V]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = I_n$, and likewise in the other order. So with $S = [\mathrm{id}_V]_{\mathcal{B}\mathring{\mathcal{B}}}$, we have $[T]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}} = S^{-1}[T]_{\mathcal{B}\mathcal{B}}S$. The two matrices are similar and have the same determinant.

Definition 5.4.18 (Determinant of an operator). Let V be a finite-dimensional vector space with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$. The **determinant** of T is

$$\det T = \det [T]_{\mathcal{B}\mathcal{B}},$$

where $\mathcal{B}$ is any basis of V. By the computation above and Proposition 5.4.17, this does not depend on the choice of $\mathcal{B}$.

For $V = F^n$ and $T = T_A$, the standard basis gives $[T_A]_{\mathcal{E}\mathcal{E}} = A$ (Proposition 2.3.16), so $\det T_A = \det A$. Translating between maps and matrices (Technique 2.3.27), the results of this section carry over to operators.

Example 5.4.19 (Two operators on matrices and polynomials).

(a) Let $T \in \mathrm{L}\big(F^{2\times 2}\big)$ be the transpose, $T(X) = X^{\mathsf{T}}$. Use the basis

$$U_{11} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad U_{12} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},$$
$$U_{21} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad U_{22} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

Then T fixes U_{11} and U_{22} and exchanges U_{12} and U_{21}, so its matrix in this basis is the 4×4 swap E_{23}, and $\det T = -1$. Over $\mathbb{R}$ this is the expected sign: T fixes the three-dimensional subspace of symmetric matrices and negates the skew-symmetric matrix $U_{12} - U_{21}$, so it is a reflection of the four-dimensional space $\mathbb{R}^{2\times 2}$. Over $\mathbb{F}_2$, $\det T = -1 = 1$.

(b) Let $D \in \mathrm{L}\big(F[x]_{\leq 2}\big)$ be differentiation. Its matrix in the basis $1, x, x^2$ is upper triangular with zero diagonal (Example 2.3.4), so $\det D = 0$. This agrees with Proposition 5.4.20 below, since D is not invertible: $D(1) = \mathbf{0}$. For $\mathrm{id} + D$, which sends $1, x, x^2$ to 1, $1 + x$, and $2x + x^2$,

$$[\mathrm{id} + D]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix}, \quad \det(\mathrm{id} + D) = 1$$

by Proposition 5.3.15, where $\mathcal{B} = 1, x, x^2$.

Proposition 5.4.20 (Properties of the determinant of an operator). Let V be a vector space with $n = \dim V \geq 1$, let $S, T \in \mathrm{L}(V)$, and let $c \in F$.
(a) $\det \mathrm{id}_V = 1$, and $\det(cT) = c^n \det T$.
(b) $\det(ST) = \det S \det T$.
(c) T is invertible if and only if $\det T \neq 0$. In that case $\det\big(T^{-1}\big) = (\det T)^{-1}$.

Proof. STANDARD

Uses. Definition 5.4.18 (Determinant of an operator), Example 2.3.6 (The zero map and the identity map), Proposition 1.6.19 (Coordinates respect linear combinations), Exercise 5.1.5, Theorem 2.4.2 (The matrix of a composite), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.7 (Invertibility and the determinant), Theorem 2.2.1 (Linear maps are determined by a basis), Definition 2.3.1 (Matrix of a linear map)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Fix one basis $\mathcal{B}$ and translate each statement into a statement about the matrices of the operators with respect to $\mathcal{B}$.
Hint 2. For (c), if T is invertible, apply (b) to $TT^{-1} = \mathrm{id}_V$. Conversely, if $\det T \neq 0$, the matrix of T has an inverse C. Find a linear map whose matrix is C.
Sketch. With one basis $\mathcal{B}$ throughout, $[\mathrm{id}_V] = I_n$, $[cT] = c[T]$, and $[ST] = [S][T]$, so (a) and (b) follow from the matrix statements. If T is invertible, (b) gives $\det T \det T^{-1} = \det \mathrm{id}_V = 1$. If $\det T \neq 0$, then $[T]$ has an inverse C, and the linear map R with $[R] = C$ has $[RT] = [TR] = I_n = [\mathrm{id}_V]$, so $RT = TR = \mathrm{id}_V$.

Fix a basis $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ of V, and write $[R]$ for $[R]_{\mathcal{B}\mathcal{B}}$ for every $R \in \mathrm{L}(V)$. A linear map is determined by its matrix: if $[R] = [R']$, then $R\big(\mathbf{v}_j\big)$ and $R'\big(\mathbf{v}_j\big)$ have the same coordinate vector for every j, so they are equal, and $R = R'$ by the uniqueness in Theorem 2.2.1.

(a) $[\mathrm{id}_V] = I_n$ (Example 2.3.6), so $\det \mathrm{id}_V = 1$. Column j of $[cT]$ is $\big[cT\big(\mathbf{v}_j\big)\big]_{\mathcal{B}} = c\big[T\big(\mathbf{v}_j\big)\big]_{\mathcal{B}}$ by Proposition 1.6.19, so $[cT] = c[T]$, and $\det(cT) = c^n \det T$ by Exercise 5.1.5.

(b) By Theorem 2.4.2, $[ST] = [S][T]$, so by Theorem 5.4.10,

$$\begin{aligned} \det(ST) &= \det([S][T]) \\ &= \det[S] \det[T] = \det S \det T. \end{aligned}$$

(c) If T is invertible, then by (b) and (a), $\det T \det\big(T^{-1}\big) = \det\big(TT^{-1}\big) = \det \mathrm{id}_V = 1$. So $\det T \neq 0$, and $\det\big(T^{-1}\big) = (\det T)^{-1}$. Conversely, suppose that $\det T \neq 0$. Then $[T]$ is invertible by Theorem 5.4.7; let C be

its inverse, with entries c_{ij}. By Theorem 2.2.1 there is a linear map $R \in \mathrm{L}(V)$ with $R(\mathbf{v}_j) = \sum_i c_{ij}\mathbf{v}_i$ for every j, and then $[R] = C$ by Definition 2.3.1. By Theorem 2.4.2, $[RT] = C[T] = I_n = [\mathrm{id}_V]$ and $[TR] = [T]C = I_n$. Since a linear map is determined by its matrix, $RT = TR = \mathrm{id}_V$, and T is invertible. □

In Section 13.4 the determinant of an operator is defined directly, without a basis, and Definition 5.4.18 becomes a theorem.

5.4.6 Computing determinants

The Leibniz formula has $n!$ terms. Corollary 5.4.15 gives a much faster method: row reduce to a triangular matrix and keep track of how each operation changes the determinant.

Proposition 5.4.21 (Determinants by row reduction). Let $A \in F^{n\times n}$, and suppose that $E_t \cdots E_2 E_1 A = U$ for elementary matrices $E_1, \ldots, E_t$. Suppose that s of the E_l are swaps, r of them are scalings by $c_1, \ldots, c_r$, and the rest are replacements. Then

$$c_1 \cdots c_r \det A = (-1)^s \det U.$$

In particular, if U is triangular, then $\det A = (-1)^s (c_1 \cdots c_r)^{-1} u_{11} \cdots u_{nn}$.

Proof. ROUTINE

Uses. Theorem 5.4.10 (Multiplicativity), Proposition 5.4.1 (Determinants of elementary matrices), Proposition 5.3.15 (Triangular matrices)
Hint 1. Take determinants of both sides of $E_t \cdots E_1 A = U$.
Hint 2. Proposition 5.4.1 gives each $\det E_l$.
Sketch. By Theorem 5.4.10, $\det U = \det E_t \cdots \det E_1 \det A$, and the product of the $\det E_l$ is $(-1)^s c_1 \cdots c_r$ by Proposition 5.4.1. If U is triangular, $\det U$ is the product of its diagonal entries.

By Theorem 5.4.10, applied t times, $\det U = \det E_t \cdots \det E_1 \det A$. By Proposition 5.4.1, $\det E_l$ is -1 for each swap, c_q for the scaling by c_q, and 1 for each replacement, so $\det U = (-1)^s c_1 \cdots c_r \det A$. Multiplying by $(-1)^s$, which is its own inverse, gives the claim. If U is triangular, then $\det U = u_{11} \cdots u_{nn}$ by Proposition 5.3.15, and we may divide by $c_1 \cdots c_r$, which is nonzero. □

Scalings are never needed to reach a triangular matrix, so the simplest version of the method uses only swaps and replacements.

Algorithm 5.4.22 (Determinant by elimination)

Input A square matrix $A \in F^{n\times n}$.
Output $\det A$.

1. Set $s = 0$. For $k = 1, 2, \ldots, n$ in turn: if column k of the current matrix has a nonzero entry in one of the rows $k, \ldots, n$, swap such a row with row k (adding 1 to s if the rows are different), and then add multiples of row k to rows $k+1, \ldots, n$ to make their entries in column k equal to 0. If there is no such entry, go on to the next k.
2. Let U be the final matrix. Output $(-1)^s u_{11} u_{22} \cdots u_{nn}$.

Proof. ROUTINE

Uses. Proposition 5.4.21 (Determinants by row reduction), Proposition 3.2.7 (Row operations are left multiplications), Definition 3.3.31 (Triangular matrices)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5)
Hint 1. By Proposition 5.4.21 it is enough to show that U is upper triangular. Which entries does stage k make 0?
Hint 2. Check that later stages never touch column k below the diagonal: which rows do they swap, and which rows do they add?
Sketch. The algorithm uses only swaps and replacements, so by Proposition 5.4.21 it outputs $\det A$ provided U is upper triangular. After stage k the entries of column k below the diagonal are 0. A later stage $k' > k$ only swaps rows numbered

> at least k' and adds multiples of row k' to rows below it, and all these rows have entry 0 in column k, so column k stays cleared.

Every operation is a swap or a replacement, so the final matrix is $U = E_t \cdots E_1 A$ with s swaps among the E_l and no scalings (Proposition 3.2.7). By Proposition 5.4.21, the output equals $\det A$ provided U is upper triangular.

We show that after stage k, the entries of columns $1, \ldots, k$ below the diagonal are 0. This holds after stage 1, since stage 1 either clears column 1 below row 1 or finds it already zero there. Suppose it holds after stage $k-1$. Stage k only swaps two rows with indices at least k, and adds multiples of row k to rows with indices greater than k. For $j < k$, all of these rows have entry 0 in column j, by the induction hypothesis, so the entries of column j below the diagonal stay 0. And stage k makes the entries of column k below the diagonal 0, or finds them 0 already. After stage n, U is upper triangular (Definition 3.3.31). □

If some stage finds no nonzero entry, say at column k, then $u_{kk} = 0$, so $\det A = 0$ and A is not invertible. In practice one also uses scalings to pull a common factor out of a row, and one may mix in column operations freely: each row or column operation multiplies the determinant by the determinant of its elementary matrix (Corollary 5.4.15, Lemma 5.4.2).

Example 5.4.23 (A 4×4 determinant by elimination). Let

$$A = \begin{pmatrix} 1 & 2 & -1 & 3 \\ 2 & 4 & 1 & 4 \\ -1 & -3 & 3 & -2 \\ 3 & 8 & -1 & 9 \end{pmatrix} \in \mathbb{Q}^{4\times 4}.$$

Stage 1 adds -2, 1, and -3 times row 1 to rows 2, 3, and 4. In column 2, the new row 2 has a 0, so stage 2 swaps rows 2 and 3 and then adds 2 times the new row 2 to row 4:

$$A \xrightarrow{\text{stage } 1} \begin{pmatrix} 1 & 2 & -1 & 3 \\ 0 & 0 & 3 & -2 \\ 0 & -1 & 2 & 1 \\ 0 & 2 & 2 & 0 \end{pmatrix},$$

$$\xrightarrow{\text{stage } 2} \begin{pmatrix} 1 & 2 & -1 & 3 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & 3 & -2 \\ 0 & 0 & 6 & 2 \end{pmatrix}.$$

Stage 3 adds -2 times row 3 to row 4, and stage 4 does nothing:

$$\xrightarrow{\text{stage } 3} \begin{pmatrix} 1 & 2 & -1 & 3 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & 3 & -2 \\ 0 & 0 & 0 & 6 \end{pmatrix} = U.$$

There was one swap, so

$$\det A = (-1)^1 \cdot 1 \cdot (-1) \cdot 3 \cdot 6 = 18.$$

The Leibniz formula would have needed 24 terms. Since $18 = 2 \cdot 3^2$, Proposition 5.3.20 shows that the reduction of A modulo a prime p is invertible over $\mathbb{F}_p$ for every p except 2 and 3.

$$\det A = (-1)^1 \cdot 1 \cdot (-1) \cdot 3 \cdot 6 = 18$$

Gauss–Jordan elimination on the matrix A of Example 5.4.23, one elementary matrix at a time. It also scales each pivot to 1, by the factor $1/p$ for a pivot p, so by Proposition 5.4.21, $\det A$ is $(-1)^s$ times the product of the pivots before scaling, where s is the number of swaps. Here this is $(-1) \cdot 1 \cdot (-1) \cdot 3 \cdot 6 = 18$. Edit the matrix to try others. When some column has no pivot, $\operatorname{rref}(A)$ has a zero row and $\det A = 0$. (Interactive in the web version.)

Structure in a matrix can often be exploited before any elimination. A common trick: if every row has the same sum, add all columns to the first, or all rows to the first if every column has the same sum.

Example 5.4.24 (A matrix with constant row sums). For $n \geq 1$ and $x \in F$, let $M_n(x) \in F^{n \times n}$ have every diagonal entry equal to x and every other entry equal to 1. Then

$$\det M_n(x) = (x + n - 1)(x - 1)^{n-1}.$$

Every column of $M_n(x)$ sums to $x + n - 1$. Adding rows $2, \ldots, n$ to row 1 does not change the determinant (Corollary 5.4.15), and makes every entry of row 1 equal to $x + n - 1$. Pulling this factor out of row 1 leaves the row $(1, 1, \ldots, 1)$. Now subtract the new row 1 from each of rows $2, \ldots, n$. Row i had x in position i and 1 elsewhere, so it becomes $(x - 1)\mathbf{e}_i^{\mathsf{T}}$. The result is upper triangular with diagonal entries $1, x - 1, \ldots, x - 1$, so by Proposition 5.3.15,

$$\det M_n(x) = (x + n - 1) \cdot 1 \cdot (x - 1)^{n-1}.$$

So for $n \geq 2$, $M_n(x)$ is invertible unless $x = 1$ or $x = 1 - n$. These two values coincide when $n = 0$ in F: over $\mathbb{F}_3$, $\det M_3(x) = (x + 2)(x - 1)^2 = (x - 1)^3$.

Remark 5.4.25 (How much faster). Each term of the Leibniz formula is a product of n entries, which takes $n - 1$ multiplications, so evaluating the formula term by term takes $(n - 1)n!$ multiplications. Algorithm 5.4.22 takes about $n^3/3$: stage k computes a multiplier for each of the $n - k$ rows below row k and updates the $n - k$ remaining entries of each, for $(n - k)(n - k + 1)$ multiplications and divisions, and summing over k gives $\left(n^3 - n\right)/3$ (Remark 3.3.35). Multiplying the diagonal entries adds $n - 1$ more.

n	Leibniz: $(n-1)n!$	Elimination: $\left(n^3 - n\right)/3$
3	12	8
5	480	40
10	32 659 200	330
20	$\approx 4.6 \cdot 10^{19}$	2660

Table 5.4.1. Multiplications (and divisions) needed to evaluate an $n \times n$ determinant.

At 10^9 multiplications per second, the Leibniz formula for a single 20×20 matrix would take about 1500 years, while elimination takes a few microseconds. Cofactor expansion (Section 5.5) also takes on the order of $n!$ operations for a general matrix, although it is convenient for matrices with many zeros. The Leibniz formula remains the tool for theory (Technique 5.3.12, Technique 5.3.18), and elimination the tool for computation.

5.4.7 Block-triangular matrices

Proposition 5.3.17 computed the determinant of $\begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix}$. Its second proof never used that the upper right block is 0, only the lower left one, which suggests the following theorem. Recall (Definition 2.4.33) that a

square block matrix with square diagonal blocks is block upper triangular if all blocks below the diagonal blocks are 0; it is **block lower triangular** if all blocks above them are 0.

Theorem 5.4.26 (Block-triangular matrices). Let $A \in F^{k\times k}$, $B \in F^{k\times m}$, $C \in F^{m\times k}$, and $D \in F^{m\times m}$. Then

$$\det\begin{pmatrix} A & B \\ 0 & D \end{pmatrix} = \det A \det D,$$

$$\det\begin{pmatrix} A & 0 \\ C & D \end{pmatrix} = \det A \det D.$$

Proof (by factoring). STANDARD

Uses. Theorem 2.4.34 (Block multiplication), Theorem 5.4.10 (Multiplicativity), Proposition 5.3.17 (Block-diagonal matrices), Lemma 5.1.8 (Column replacement), Theorem 5.4.14 (The transpose), Definition 2.4.21 (Transpose)
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Write $\begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$ as a product of two block matrices, one of which is block diagonal.
Hint 2. Check that $\begin{pmatrix} I_k & B \\ 0 & D \end{pmatrix}\begin{pmatrix} A & 0 \\ 0 & I_m \end{pmatrix} = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$.
Hint 3. To find $\det\begin{pmatrix} I_k & B \\ 0 & D \end{pmatrix}$, use the first k columns, which are standard basis vectors, to clear B by column replacements.
Hint 4. For the second identity, take transposes.
Sketch. Block multiplication gives $\begin{pmatrix} A & B \\ 0 & D \end{pmatrix} = \begin{pmatrix} I_k & B \\ 0 & D \end{pmatrix}\begin{pmatrix} A & 0 \\ 0 & I_m \end{pmatrix}$. The second factor has determinant $\det A$ by Proposition 5.3.17. In the first, column $k+j$ is $\sum_i b_{ij}\mathbf{e}_i$ plus column j of D placed below, and subtracting b_{ij} times column i for each $i \le k$ clears B without changing the determinant, leaving $\begin{pmatrix} I_k & 0 \\ 0 & D \end{pmatrix}$ with determinant $\det D$. For the lower block-triangular case, transpose.

Let $n = k + m$ and $M = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$. By block multiplication (Theorem 2.4.34),

$$\begin{pmatrix} I_k & B \\ 0 & D \end{pmatrix}\begin{pmatrix} A & 0 \\ 0 & I_m \end{pmatrix} = \begin{pmatrix} I_k A + B0 & I_k 0 + BI_m \\ 0A + D0 & 00 + DI_m \end{pmatrix} = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}.$$

So by Theorem 5.4.10 and Proposition 5.3.17,

$$\det M = \det N \det\begin{pmatrix} A & 0 \\ 0 & I_m \end{pmatrix} = \det N \det A,$$

where $N = \begin{pmatrix} I_k & B \\ 0 & D \end{pmatrix}$. For $i \le k$, column i of N is $\mathbf{e}_i \in F^n$. For $j \le m$, column $k+j$ of N is $\sum_{i=1}^{k} b_{ij}\mathbf{e}_i + \mathbf{d}'_j$, where $\mathbf{d}'_j \in F^n$ has k zeros followed by the entries of column j of D. Subtracting b_{ij} times column i from column $k+j$, for every $i \le k$ and $j \le m$, does not change $\det N$ (Lemma 5.1.8), does not change the first k columns, and turns column $k+j$ into $\mathbf{d}'_j$. The result is $\begin{pmatrix} I_k & 0 \\ 0 & D \end{pmatrix}$, so by Proposition 5.3.17, $\det N = \det I_k \det D = \det D$. Hence $\det M = \det A \det D$.

For the second identity, transposing exchanges the entries in positions (i,j) and (j,i) (Definition 2.4.21), so the transpose of $\begin{pmatrix} A & 0 \\ C & D \end{pmatrix}$ is $\begin{pmatrix} A^{\mathsf{T}} & C^{\mathsf{T}} \\ 0 & D^{\mathsf{T}} \end{pmatrix}$. By Theorem 5.4.14 and the first identity,

$$\det\begin{pmatrix} A & 0 \\ C & D \end{pmatrix} = \det\begin{pmatrix} A^{\mathsf{T}} & C^{\mathsf{T}} \\ 0 & D^{\mathsf{T}} \end{pmatrix} = \det A^{\mathsf{T}} \det D^{\mathsf{T}} = \det A \det D.$$ □

Proof (via the Leibniz formula). STANDARD

Uses. Definition 5.3.6 (Determinant), Proposition 5.3.17 (Block-diagonal matrices), Theorem 5.4.14 (The transpose)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. Compare the Leibniz terms of $M = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$ with those of $M' = \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix}$. For which σ can they differ?

Hint 2. If σ sends some $j \le k$ to a row below k, the term of σ contains an entry of the lower left block, in both matrices. Otherwise σ maps $[k]$ onto $[k]$, and its term never touches the upper right block.
Sketch. Let $M' = \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix}$. If $\sigma(j) > k$ for some $j \le k$, the terms of σ in $\det M$ and $\det M'$ both contain a 0 from the lower left block. Otherwise σ maps $[k]$ onto $[k]$, hence the rest onto the rest, and every factor of its term lies in A or in D, where M and M' agree. So $\det M = \det M' = \det A \det D$.

Let $n = k + m$, $K = \{k+1, \dots, n\}$, $M = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$, and $M' = \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix}$. Write c_{ij} and c'_{ij} for the entries of M and M'. They agree unless $i \le k < j$, that is, unless position (i, j) lies in the upper right block. We compare the terms of a fixed $\sigma \in S_n$ in the Leibniz formulas for $\det M$ and $\det M'$.

If $\sigma(j) \in K$ for some $j \le k$, then position $(\sigma(j), j)$ lies in the lower left block, so $c_{\sigma(j)j} = c'_{\sigma(j)j} = 0$, and both terms are 0. Otherwise σ maps $[k]$ into $[k]$, hence onto $[k]$ since it is injective, and then it maps K onto K since it is a bijection. Then every position $(\sigma(j), j)$ lies in one of the two diagonal blocks, where M and M' agree, so the two terms are equal. Hence $\det M = \det M' = \det A \det D$ by Proposition 5.3.17. The second identity follows by transposing, as in the first proof. □

The first proof shows how block matrices can be manipulated like matrices of numbers, as long as the order of factors is respected (Technique 2.4.35). The second proof is the shorter one here, because the work was done in Proposition 5.3.17. Grouping the diagonal blocks two at a time extends the theorem to any number of blocks.

Corollary 5.4.27 (Several diagonal blocks). Let M be block upper triangular (or block lower triangular) with square diagonal blocks $A_1, \dots, A_r$. Then

$$\det M = \det A_1 \det A_2 \cdots \det A_r.$$

Proof. ROUTINE

Uses. Theorem 5.4.26 (Block-triangular matrices), Definition 2.4.33 (Block matrix), induction on r
Techniques. Block decomposition (Technique 2.4.35)
Hint 1. Induct on r. Regard M as a 2×2 block matrix whose upper left block is A_1.
Hint 2. The lower right block is block triangular with diagonal blocks $A_2, \dots, A_r$.
Sketch. For $r \ge 2$, group the last $r-1$ block rows and columns: $M = \begin{pmatrix} A_1 & X \\ 0 & M' \end{pmatrix}$, where M' is block upper triangular with diagonal blocks $A_2, \dots, A_r$. Then $\det M = \det A_1 \det M'$ by Theorem 5.4.26, and induction finishes. The lower triangular case is the same with $\begin{pmatrix} A_1 & 0 \\ Y & M' \end{pmatrix}$.

We induct on r; for $r = 1$ there is nothing to prove. Let $r \ge 2$, and suppose M is block upper triangular. Grouping the block rows and block columns $2, \dots, r$ together, $M = \begin{pmatrix} A_1 & X \\ 0 & M' \end{pmatrix}$, where the lower left block is 0 because all blocks below the diagonal are, and M' is block upper triangular with diagonal blocks $A_2, \dots, A_r$. By Theorem 5.4.26 and the induction hypothesis,

$$\det M = \det A_1 \det M' = \det A_1 \det A_2 \cdots \det A_r.$$

The block lower triangular case is identical, with $M = \begin{pmatrix} A_1 & 0 \\ Y & M' \end{pmatrix}$. □

With 1×1 blocks this is Proposition 5.3.15. For example, the matrix

$$M = \begin{pmatrix} 1 & 2 & 5 & 7 \\ 3 & 4 & 6 & 8 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix}$$

is block upper triangular with diagonal blocks $\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$ and $\begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$, so $\det M = (-2) \cdot 1 = -2$. A 2×2 block matrix does not behave like a 2×2 matrix of numbers, though: in general $\det \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ is neither $\det A \det D - \det B \det C$ (Exercise 5.4.36) nor $\det(AD - BC)$ (the example in Exercise 5.4.50).

Block elimination BEYOND 21-242

Schur complements are standard in numerical linear algebra and statistics, but they are not part of the course.

When the upper left block is invertible, a general 2×2 block matrix can be reduced to the block-triangular case by one step of elimination with blocks.

Technique 5.4.28 (Block elimination). Row reduction works with blocks in place of entries, as long as the order of the factors in each product is respected. By Theorem 2.4.34, multiplying $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ on the left by $\begin{pmatrix} I & 0 \\ X & I \end{pmatrix}$ adds X times the first block row to the second, giving $\begin{pmatrix} A & B \\ XA+C & XB+D \end{pmatrix}$. Multiplying on the right by $\begin{pmatrix} I & Y \\ 0 & I \end{pmatrix}$ adds the first block column times Y to the second, giving $\begin{pmatrix} A & AY+B \\ C & CY+D \end{pmatrix}$. Both multipliers have determinant 1 by Theorem 5.4.26, so these operations do not change the determinant. Choose X or Y to create a zero block, and finish with Theorem 5.4.26.

Reach for it when you want the determinant or the inverse of a 2×2 block matrix and one of the blocks is invertible, or when two block matrices are related by such operations. The canonical example is Proposition 5.4.29.

Used in. Proposition 5.4.29, Exercise 5.4.50, Theorem 5.5.27.

Proposition 5.4.29 (Schur complement). Let $A \in F^{k\times k}$ be invertible, and let $B \in F^{k\times m}$, $C \in F^{m\times k}$, and $D \in F^{m\times m}$. Then

$$\det\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det A \det\big(D - CA^{-1}B\big).$$

Proof. STANDARD

Uses. Theorem 2.4.34 (Block multiplication), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.26 (Block-triangular matrices)

Techniques. Block elimination (Technique 5.4.28)

Hint 1. Imitate the first stage of elimination, with the block A as the pivot: clear the block C below it.

Hint 2. Multiply on the left by $\begin{pmatrix} I_k & 0 \\ X & I_m \end{pmatrix}$, and choose X so that the lower left block becomes 0.

Sketch. With $X = -CA^{-1}$, block multiplication gives $\begin{pmatrix} I_k & 0 \\ X & I_m \end{pmatrix}\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} A & B \\ 0 & D-CA^{-1}B \end{pmatrix}$. The left factor has determinant 1, and the right side has determinant $\det A \det\big(D - CA^{-1}B\big)$, both by Theorem 5.4.26.

Let $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ and $X = -CA^{-1} \in F^{m\times k}$. By Theorem 2.4.34,

$$\begin{aligned} \begin{pmatrix} I_k & 0 \\ X & I_m \end{pmatrix} M &= \begin{pmatrix} A & B \\ XA + C & XB + D \end{pmatrix} \\ &= \begin{pmatrix} A & B \\ 0 & D - CA^{-1}B \end{pmatrix}. \end{aligned}$$

By Theorem 5.4.26, the left factor has determinant $\det I_k \det I_m = 1$, and the right side has determinant $\det A \det\big(D - CA^{-1}B\big)$. So Theorem 5.4.10 gives the claim. □

The matrix $D - CA^{-1}B$ is the **Schur complement** of A in M. For $k = m = 1$ the proposition reads $\det\begin{pmatrix} a & b \\ c & d \end{pmatrix} = a\big(d - ca^{-1}b\big) = ad - bc$. If also $AC = CA$, then $A\big(D - CA^{-1}B\big) = AD - CB$, and the proposition becomes $\det M = \det(AD - CB)$ (Exercise 5.4.50).

Exercises

Exercise 5.4.30. ROUTINE Let

$$A = \begin{pmatrix} 1 & 3 & 0 & 2 \\ -2 & -6 & 2 & -3 \\ 3 & 10 & -1 & 9 \\ 1 & 1 & 4 & 12 \end{pmatrix} \in \mathbb{Q}^{4\times 4}.$$

(a) Compute $\det A$ with Algorithm 5.4.22.

(b) For which primes p is the reduction of A modulo p invertible over $\mathbb{F}_p$?

Solution on page 1416

Exercise 5.4.31. ROUTINE Let $A, B \in \mathbb{R}^{3\times 3}$ with $\det A = 2$ and $\det B = -3$. Compute

Exercise 5.4.32. STANDARD For which $n \geq 1$ is there a matrix $A \in F^{n\times n}$ with $A^2 = -I_n$, when (a) $F = \mathbb{R}$, (b) $F = \mathbb{C}$, (c) $F = \mathbb{F}_3$, (d) $F = \mathbb{F}_5$?

Solution on page 1417

Exercise 5.4.33. STANDARD A matrix $A \in F^{n\times n}$ is **skew-symmetric** if $A^{\mathsf{T}} = -A$.

(a) Suppose that $1 + 1 \neq 0$ in F and that n is odd. Show that every skew-symmetric $A \in F^{n\times n}$ has $\det A = 0$.

(b) Keep the assumption $1 + 1 \neq 0$. Show that the skew-symmetric 3×3 matrices are exactly the matrices $\begin{pmatrix} 0 & a & b \\ -a & 0 & c \\ -b & -c & 0 \end{pmatrix}$ with $a, b, c \in F$, and for such a matrix $A \neq 0$, find a nonzero $\mathbf{x}$ with $A\mathbf{x} = \mathbf{0}$.

(c) Show that (a) fails over $\mathbb{F}_2$.

Solution on page 1417

Exercise 5.4.34. STANDARD Let $n \geq 1$. In each case, find all possible values of $\det A$, and show that each of them occurs.

(a) $A \in F^{n\times n}$ with $A^2 = A$.

(b) $A \in F^{n\times n}$ with $A^k = 0$ for some $k \geq 1$.

(c) $A \in F^{n\times n}$ with $A^2 = I_n$.

(d) $A \in \mathbb{R}^{n\times n}$ with $A^{\mathsf{T}}A = I_n$.

Solution on page 1418

Exercise 5.4.35. STANDARD Find the error in the following argument, and repair it.

Claim. $\det(AB) = \det A \det B$ for all $A, B \in F^{n\times n}$.

Proof. By Theorem 3.5.19, we can write $A = E_1 \cdots E_k$ and $B = E_1' \cdots E_l'$ with elementary matrices E_i and E_j'. By Corollary 5.4.4,

$$\begin{aligned} \det(AB) &= \det\left(E_1 \cdots E_k E_1' \cdots E_l'\right) \\ &= \det E_1 \cdots \det E_k \det E_1' \cdots \det E_l' \end{aligned}$$

$$= \det A \det B.$$

Solution on page 1418

Exercise 5.4.36. STANDARD Let $A, B, C, D \in F^{m\times m}$ and $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$.

(a) Find the error in the following argument.

Claim. $\det M = \det A \det D - \det B \det C$.

Proof. By Theorem 2.4.34, block matrices multiply like 2×2 matrices whose entries are the blocks. So M is a 2×2 matrix with entries A, B, C, D, and Theorem 5.1.13 gives $\det M = \det A \det D - \det B \det C$.

(b) Show that the claim is false for $m = 2$, over every field.

(c) Show that the claim is true when $C = 0$.

Solution on page 1418

Exercise 5.4.37. STANDARD For $n \geq 1$, let $P_n, Q_n \in \mathbb{Q}^{n\times n}$ have entries $\min(i,j)$ and $\max(i,j)$, respectively, in position (i,j). For example,

$$P_3 = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 3 \end{pmatrix}, \quad Q_3 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 2 & 3 \\ 3 & 3 & 3 \end{pmatrix}.$$

Show that $\det P_n = 1$ and $\det Q_n = (-1)^{n-1}n$.

Solution on page 1419

Exercise 5.4.38. STANDARD Let $m < n$, $A \in F^{n\times m}$, and $B \in F^{m\times n}$. Show that $\det(AB) = 0$. Does the same hold when $m \geq n$?

Solution on page 1419

Exercise 5.4.39. STANDARD Let $A \in F^{n\times n}$, and define $L_A, R_A \in \mathrm{L}(F^{n\times n})$ by $L_A(X) = AX$ and $R_A(X) = XA$. Show that $\det L_A = \det R_A = (\det A)^n$.

Solution on page 1420

Exercise 5.4.40. STANDARD Let $T \in \mathrm{L}(F^{n\times n})$ be the transpose, $T(X) = X^{\mathsf{T}}$. Show that $\det T = (-1)^{n(n-1)/2}$. For which n is $\det T = 1$, when $1 + 1 \neq 0$ in F?

Solution on page 1420

Exercise 5.4.41. STANDARD Prove or disprove each statement, where $A, B \in F^{n\times n}$ and $n \geq 2$.

(a) If $\det A = \det B$ and $\operatorname{tr} A = \operatorname{tr} B$, then A and B are similar.

(b) If A and B are invertible, then $\det\left(ABA^{-1}B^{-1}\right) = 1$.

(c) If $F = \mathbb{R}$, n is odd, and $AB = -BA$, then A or B is not invertible.

(d) If $\det A = \det B$, then $\det(A + C) = \det(B + C)$ for every $C \in F^{n\times n}$.

Solution on page 1421

Exercise 5.4.42. ROUTINE Let $A \in \mathbb{Q}^{n\times n}$ have integer entries. Show that if A is invertible and A^{-1} also has integer entries, then $\det A = \pm 1$. (The converse holds as well; see Section 5.5.)

Solution on page 1421

Exercise 5.4.43. STANDARD Let $A, B \in F^{m\times m}$. Show that

$$\det\begin{pmatrix} A & B \\ B & A \end{pmatrix} = \det(A+B)\det(A-B).$$

Solution on page 1421

Exercise 5.4.44. STANDARD Let

$$C(z) = \begin{pmatrix} 1 & z & z^2 \\ z^2 & 1 & z \\ z & z^2 & 1 \end{pmatrix}.$$

(a) Show that $\det C(z) = \left(1-z^3\right)^2$, for z in any field.

(b) Find all z for which $C(z)$ is not invertible, for $z \in \mathbb{C}$, for $z \in \mathbb{R}$, and for $z \in \mathbb{F}_7$.

Solution on page 1422

Exercise 5.4.45. HARD Let $B, C \in \mathbb{R}^{n\times n}$, and let $A = B + iC \in \mathbb{C}^{n\times n}$. Show that

$$\det\begin{pmatrix} B & -C \\ C & B \end{pmatrix} = |\det A|^2.$$

In particular, the real $2n \times 2n$ matrix on the left has a nonnegative determinant. (For $n = 1$ and $A = (a + bi)$, the matrix $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ is the matrix of multiplication by $a + bi$ on $\mathbb{C}$, regarded as a real vector space with basis $1, i$.)

Solution on page 1423

Exercise 5.4.46. HARD Let $A, B \in \mathbb{R}^{n\times n}$ with $AB = BA$. Show that $\det\left(A^2 + B^2\right) \geq 0$. Show by an example that the hypothesis $AB = BA$ cannot be dropped.

Solution on page 1423

Exercise 5.4.47. HARD Let p be a prime, let G be the set of invertible matrices in $\mathbb{F}_p^{n\times n}$, and let $H = \{A \in G \mid \det A = 1\}$.

(a) For $c \in \mathbb{F}_p$ with $c \neq 0$, show that $X \mapsto XE_{1c}$ is a bijection from H onto $\{A \in G \mid \det A = c\}$. Deduce that $|H| = |G|/(p-1)$.

(b) For $n = 2$, show that $|G| = \left(p^2-1\right)\left(p^2-p\right)$, and conclude that $|H| = p\left(p^2-1\right)$.

(c) Check (b) for $p = 2$ by listing H.

Solution on page 1424

Exercise 5.4.48. HARD Let $n \geq 2$.

(a) Let $A \in F^{n\times n}$ be invertible. Show that there are elementary matrices $E_1, \ldots, E_t$ of type 3 (replacements) with $E_t \cdots E_1 A = \operatorname{diag}(1, \ldots, 1, \det A)$.

(b) Deduce that every $A \in F^{n\times n}$ with $\det A = 1$ is a product of elementary matrices of type 3, and that every invertible A is such a product times the single scaling $E_{n,\det A}$.

Solution on page 1424

Exercise 5.4.49. CHALLENGE Let $n \geq 2$, and let $f : F^{n\times n} \to F$ satisfy $f(AB) = f(A)f(B)$ for all A, B, and $f(\operatorname{diag}(t, 1, \ldots, 1)) = t$ for all $t \in F$. Show that $f = \det$. (This extends Exercise 5.1.42 to all n and all fields.)

Solution on page 1425

Exercise 5.4.50. HARD BEYOND 21-242 Let $A, B, C, D \in F^{m\times m}$ with A invertible and $AC = CA$. Show that

$$\det\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det(AD - CB).$$

Then show by an example with $m = 2$ that the formula can fail when A is invertible but $AC \neq CA$.

Solution on page 1426

5.5 Cofactor expansion

Expanding the Leibniz formula takes $n!$ products, and elimination computes a determinant in about $n^3/3$ operations (Remark 5.4.25). This section gives a third description of det, which is recursive: a **cofactor expansion** writes an $n \times n$ determinant as a combination of n determinants of size $n - 1$, one for each entry of a chosen row or column. For a general matrix this still takes on the order of $n!$ operations. Its strength lies elsewhere. It is quick for matrices with many zeros, and it sets up induction on the size of a matrix, which computes the determinants of whole families of matrices at once: tridiagonal matrices, companion matrices, and the Vandermonde matrices of Section 3.4. It also has a theoretical payoff. The coefficients in the expansions, the cofactors, assemble into a matrix that inverts B up to the scalar factor $\det B$. This gives explicit formulas for B^{-1} and for the solution of $B\mathbf{x} = \mathbf{y}$ (Cramer's rule).

5.5.1 Expansion along a row or a column

We start where Intuition (What the proof did, and where it leads) and Lemma 5.3.2 started, with multilinearity, but this time we expand only one row. Row i of $B \in F^{n\times n}$ is $\sum_j b_{ij}\mathbf{e}_j^{\mathsf{T}}$, so by linearity of det in row i (Corollary 5.4.15),

$$\det B = \sum_{j=1}^{n} b_{ij} \det B^{(j)},$$

where $B^{(j)}$ is B with row i replaced by $\mathbf{e}_j^{\mathsf{T}}$. Each $B^{(j)}$ has a row with a single nonzero entry. The lecture computes the determinant of such a matrix by comparing it with a matrix of size one less. We first name that smaller matrix.

Notation 5.5.1 (Minors). Let $n \geq 2$, $B \in F^{n\times n}$, and $i, j \in [n]$. We write $B_{\hat{i}\hat{j}} \in F^{(n-1)\times(n-1)}$ for the matrix obtained from B by deleting row i and column j. Its determinant $\det B_{\hat{i}\hat{j}}$ is the (i, j) **minor** of B. The hat marks the row and the column that are left out.

For instance, if $B = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{pmatrix}$, then $B_{\hat{2}\hat{3}} = \begin{pmatrix} 1 & 2 \\ 7 & 8 \end{pmatrix}$, with minor $8 - 14 = -6$, and $B_{\hat{1}\hat{1}} = \begin{pmatrix} 5 & 6 \\ 8 & 10 \end{pmatrix}$, with minor $50 - 48 = 2$. Two facts are used again and again. First, $B_{\hat{i}\hat{j}}$ involves no entry of row i and no entry of column j, so changing B in row i or in column j does not change $B_{\hat{i}\hat{j}}$. Second, deleting row j and column i of B^{T} gives the transpose of $B_{\hat{i}\hat{j}}$, that is, $\left(B^{\mathsf{T}}\right)_{\hat{j}\hat{i}} = \left(B_{\hat{i}\hat{j}}\right)^{\mathsf{T}}$.

$$B = \begin{pmatrix} b_{11} & b_{12} & b_{13} & b_{14} \\ b_{21} & b_{22} & b_{23} & b_{24} \\ b_{31} & b_{32} & b_{33} & b_{34} \\ b_{41} & b_{42} & b_{43} & b_{44} \end{pmatrix} \longrightarrow B_{\widehat{23}} = \begin{pmatrix} b_{11} & b_{12} & b_{14} \\ b_{31} & b_{32} & b_{34} \\ b_{41} & b_{42} & b_{44} \end{pmatrix}$$

$$\begin{pmatrix} + & - & + & - \\ - & + & - & + \\ + & - & + & - \\ - & + & - & + \end{pmatrix}$$

Figure 5.5.1. Top: deleting row 2 and column 3 of a 4×4 matrix B (the entries in grey) leaves the 3×3 matrix $B_{\widehat{23}}$. The remaining rows and columns keep their order. Bottom: the signs $(-1)^{i+j}$ that accompany the minors in Theorem 5.5.3 form a checkerboard, with + on the diagonal.

Intuition (Moving an entry into the corner). The lecture's starting point is the case $B = \begin{pmatrix} 1 & 0 \\ 0 & A \end{pmatrix}$, in block form, where $\det B = \det A$. More generally, if the first row of B is $(b_{11}, 0, \ldots, 0)$, then B is block lower triangular with diagonal blocks (b_{11}) and $B_{\widehat{11}}$, and Theorem 5.4.26 gives $\det B = b_{11} \det B_{\widehat{11}}$. The entries below b_{11} play no role.

If the single nonzero entry of row i sits in column j, we move it into the corner. This must be done so that the rest of the matrix becomes exactly $B_{\hat{ij}}$. Swapping rows 1 and i directly does not achieve this: old row 1 would land in position i, out of order. Instead, move row i up one step at a time, swapping it with the row just above it. After $i-1$ swaps it is on top, and the other rows are still in their original order. Do the same with column j. Each swap changes the sign, so the price is $(-1)^{(i-1)+(j-1)} = (-1)^{i+j}$.

Lemma 5.5.2 (A row or column with one nonzero entry). Let $n \geq 2$, $B \in F^{n \times n}$, and $i, j \in [n]$. If every entry of row i of B other than b_{ij} is 0, then

$$\det B = (-1)^{i+j} b_{ij} \det B_{\hat{ij}}.$$

The same holds if every entry of column j other than b_{ij} is 0.

Proof. STANDARD

Uses. Corollary 5.4.15 (Rows), Proposition 5.1.10 (Alternating implies antisymmetric), Theorem 5.4.26 (Block-triangular matrices), Theorem 5.4.14 (The transpose)
Hint 1. Settle the case $i = j = 1$ first. Which block structure does B have then?
Hint 2. For general i and j, move row i to the top and column j to the front so that the remaining rows and columns stay in their original order. How many swaps does this take?
Hint 3. Use only swaps of adjacent rows (and adjacent columns). For the column statement, transpose.
Sketch. Swap row i successively with rows $i-1, \ldots, 1$, and then column j with columns $j-1, \ldots, 1$. The result B' has first row $(b_{ij}, 0, \ldots, 0)$ and lower right block $B_{\hat{ij}}$, because the other rows and columns keep their order. So B' is block lower triangular and $\det B' = b_{ij} \det B_{\hat{ij}}$, while $\det B' = (-1)^{(i-1)+(j-1)} \det B$. For a column with one nonzero entry, apply the row case to B^{T}.

Suppose first that row i has the given form. Let B'' be the matrix obtained from B by swapping row i with row $i-1$, then with row $i-2$, and so on, up to row 1. These are $i-1$ swaps, and each multiplies the determinant by -1 (Corollary 5.4.15), so $\det B'' = (-1)^{i-1} \det B$. The rows of B'' are row i of B, followed by rows $1, \ldots, i-1, i+1, \ldots, n$ of B in this order. Next, let B' be obtained from B'' by swapping column j with column $j-1$, then with column $j-2$, and so on, up to column 1. By Proposition 5.1.10, $\det B' = (-1)^{j-1} \det B''$. The columns of B' are column j of B'', followed by its other columns in their original order.

So the first row of B' is row i of B rearranged, namely $(b_{ij}, 0, \ldots, 0)$, and deleting the first row and the first column of B' leaves the rows of B other than row i, in their original order, restricted to the columns other than column j, in their original order. That is exactly $B_{\hat{ij}}$. Hence, in block form,

$$B' = \begin{pmatrix} b_{ij} & 0 \\ \mathbf{w} & B_{\hat{i}\hat{j}} \end{pmatrix}$$

for some $\mathbf{w} \in F^{n-1}$, which is block lower triangular. By Theorem 5.4.26, $\det B' = b_{ij} \det B_{\hat{i}\hat{j}}$. Combining,

$$\det B = (-1)^{i-1}(-1)^{j-1} \det B' = (-1)^{i+j} b_{ij} \det B_{\hat{i}\hat{j}},$$

since $(-1)^{i+j-2} = (-1)^{i+j}$.

Now suppose instead that every entry of column j other than b_{ij} is 0. Then row j of B^{T} has the single nonzero entry b_{ij}, in column i. By the case already proved, Theorem 5.4.14, and $\left(B^{\mathsf{T}}\right)_{\hat{j}\hat{i}} = \left(B_{\hat{i}\hat{j}}\right)^{\mathsf{T}}$,

$$\det B = \det B^{\mathsf{T}} = (-1)^{j+i} b_{ij} \det \left(B_{\hat{i}\hat{j}}\right)^{\mathsf{T}} = (-1)^{i+j} b_{ij} \det B_{\hat{i}\hat{j}}.$$

□

The lecture states the case $i = 1$ and proves the case $j = 1$ (with $b_{11} = 1$) by observing that Gauss–Jordan elimination on $\begin{pmatrix} 1 & 0 \\ 0 & A \end{pmatrix}$ performs the same steps as on A. We had Theorem 5.4.26 available, which already contains that case.

The sign $(-1)^{i+j}$ depends only on the position, and it alternates like the colors of a checkerboard (Figure 5.5.1). Now we expand.

Theorem 5.5.3 (Cofactor expansion). Let $n \geq 2$ and $B \in F^{n \times n}$. For every $i \in [n]$,

$$\det B = \sum_{j=1}^{n} (-1)^{i+j} b_{ij} \det B_{\hat{i}\hat{j}} \tag{5.5.1}$$

(**expansion along row** i), and for every $j \in [n]$,

$$\det B = \sum_{i=1}^{n} (-1)^{i+j} b_{ij} \det B_{\hat{i}\hat{j}} \tag{5.5.2}$$

(**expansion along column** j).

Proof (by linearity in one row). ROUTINE

Uses. Corollary 5.4.15 (Rows), Lemma 5.5.2 (A row or column with one nonzero entry), Theorem 5.4.14 (The transpose)
Techniques. Expand by multilinearity (Technique 5.1.7), Transpose to trade rows for columns (Technique 3.2.27)
Hint 1. Write row i as a linear combination of $\mathbf{e}_1^{\mathsf{T}}, \ldots, \mathbf{e}_n^{\mathsf{T}}$, and use that det is linear in row i.
Hint 2. Each resulting matrix has a row with a single nonzero entry. Apply Lemma 5.5.2, and check that the minor is the same as for B.
Hint 3. For columns, expand B^{T} along row j.
Sketch. Row i of B is $\sum_j b_{ij} \mathbf{e}_j^{\mathsf{T}}$. By linearity in row i, $\det B = \sum_j b_{ij} \det B^{(j)}$, where $B^{(j)}$ is B with row i replaced by $\mathbf{e}_j^{\mathsf{T}}$. By Lemma 5.5.2, $\det B^{(j)} = (-1)^{i+j} \det B^{(j)}_{\hat{i}\hat{j}}$, and $B^{(j)}_{\hat{i}\hat{j}} = B_{\hat{i}\hat{j}}$ since the two matrices differ only in row i. The expansion of B along column j is the expansion of B^{T} along row j.

Fix i. For $j \in [n]$, let $B^{(j)}$ be the matrix obtained from B by replacing row i with $\mathbf{e}_j^{\mathsf{T}}$. Since row i of B is $\sum_j b_{ij} \mathbf{e}_j^{\mathsf{T}}$ and det is linear in row i (Corollary 5.4.15),

$$\det B = \sum_{j=1}^{n} b_{ij} \det B^{(j)}.$$

The only nonzero entry of row i of $B^{(j)}$ is the 1 in column j, so $\det B^{(j)} = (-1)^{i+j} \det B^{(j)}_{\hat{i}\hat{j}}$ by Lemma 5.5.2. The matrices $B^{(j)}$ and B differ only in row i, which is deleted, so $B^{(j)}_{\hat{i}\hat{j}} = B_{\hat{i}\hat{j}}$. This proves (5.5.1).

For (5.5.2), fix j. Row j of B^{T} has entries $b_{1j}, \ldots, b_{nj}$, and $\left(B^{\mathsf{T}}\right)_{\hat{j}\hat{i}} = \left(B_{\hat{i}\hat{j}}\right)^{\mathsf{T}}$. By Theorem 5.4.14 and (5.5.1) for B^{T},

$$\det B = \det B^{\mathsf{T}} = \sum_{i=1}^{n} (-1)^{j+i} b_{ij} \det\left(B_{\hat{ij}}\right)^{\mathsf{T}} = \sum_{i=1}^{n} (-1)^{i+j} b_{ij} \det B_{\hat{ij}}.$$

□

Proof (via the Leibniz formula). HARD

> *Uses.* Definition 5.3.6 (Determinant), Proposition 5.2.26 (Sign of a cycle), Proposition 5.2.25 (Multiplicativity of the sign), Theorem 5.2.31 (Alternating functions and permutations), Proposition 5.3.17 (Block-diagonal matrices), Theorem 5.4.14 (The transpose)
> *Techniques.* Read structure off the Leibniz expansion (Technique 5.3.12)
> *Hint 1.* Every term of the Leibniz formula contains exactly one entry of column j. Group the terms according to which entry b_{ij} it is, that is, according to $i = \sigma(j)$.
> *Hint 2.* The terms with $\sigma(j) = i$ use one entry from each row other than i and each column other than j, like the terms of $\det B_{\hat{ij}}$. Match them with the permutations of $[n-1]$.
> *Hint 3.* To compare signs, write $\sigma = \rho_i \sigma' \rho_j^{-1}$ with $\sigma'(1) = 1$, where $\rho_m(1) = m$ and $\rho_m(p) = p - 1$ for $2 \le p \le m$ (and ρ_m fixes the rest). This ρ_m is an m-cycle.
> *Sketch.* Grouping by $i = \sigma(j)$ gives $\det B = \sum_i b_{ij} s_i$, where s_i is the sum of $\operatorname{sgn}(\sigma) \prod_{k \ne j} b_{\sigma(k)k}$ over the σ with $\sigma(j) = i$. The cycle ρ_m lists $[n] \setminus \{m\}$ in order on $2, \dots, n$, so $\sigma \mapsto \rho_i^{-1} \sigma \rho_j$ is a bijection onto the permutations fixing 1, which correspond to S_{n-1}; it multiplies signs by $\operatorname{sgn}(\rho_i)\operatorname{sgn}(\rho_j) = (-1)^{i+j}$ and turns the product into the Leibniz term of $B_{\hat{ij}}$. So $s_i = (-1)^{i+j} \det B_{\hat{ij}}$. Rows follow by transposing.

We prove (5.5.2); then (5.5.1) follows by applying it to B^{T}, using Theorem 5.4.14 and $\left(B^{\mathsf{T}}\right)_{\hat{ji}} = \left(B_{\hat{ij}}\right)^{\mathsf{T}}$.

Fix j. Each term $\operatorname{sgn}(\sigma) b_{\sigma(1)1} \cdots b_{\sigma(n)n}$ of the Leibniz formula (Definition 5.3.6) contains exactly one factor from column j, namely $b_{\sigma(j)j}$. Grouping the terms by the value $i = \sigma(j)$,

$$\det B = \sum_{i=1}^{n} b_{ij} s_i, \quad \text{where } s_i = \sum_{\sigma \in S_n,\, \sigma(j) = i} \operatorname{sgn}(\sigma) \prod_{k \ne j} b_{\sigma(k)k}.$$

We show that $s_i = (-1)^{i+j} \det B_{\hat{ij}}$.

For $m \in [n]$, let $\rho_m \in S_n$ be given by $\rho_m(1) = m$, $\rho_m(p) = p - 1$ for $2 \le p \le m$, and $\rho_m(p) = p$ for $p > m$. For $m \ge 2$ this is the m-cycle $(1\ m\ m-1 \cdots 2)$, and $\rho_1 = \mathrm{id}$, so $\operatorname{sgn}(\rho_m) = (-1)^{m-1}$ by Proposition 5.2.26. As q runs through $1, \dots, n-1$, the values $\rho_m(q+1)$ run through $[n] \setminus \{m\}$ in increasing order. So row q of $B_{\hat{ij}}$ is row $\rho_i(q+1)$ of B, column q of $B_{\hat{ij}}$ is column $\rho_j(q+1)$ of B, and

$$\left(B_{\hat{ij}}\right)_{pq} = b_{\rho_i(p+1),\, \rho_j(q+1)}.$$

If $\sigma(j) = i$, then $\sigma' = \rho_i^{-1} \sigma \rho_j$ satisfies $\sigma'(1) = \rho_i^{-1}(\sigma(j)) = 1$. Conversely, if $\sigma' \in S_n$ fixes 1, then $\sigma = \rho_i \sigma' \rho_j^{-1}$ satisfies $\sigma(j) = \rho_i(\sigma'(1)) = i$. So $\sigma \mapsto \sigma'$ is a bijection from $\{\sigma \mid \sigma(j) = i\}$ onto the permutations fixing 1. These in turn correspond to the $\tau \in S_{n-1}$ via $\sigma'(q+1) = \tau(q) + 1$. By Proposition 5.2.25,

$$\operatorname{sgn}(\sigma) = \operatorname{sgn}(\rho_i)\operatorname{sgn}(\sigma')\operatorname{sgn}\left(\rho_j\right)^{-1} = (-1)^{i+j} \operatorname{sgn}(\sigma').$$

Also $\operatorname{sgn}(\sigma') = \operatorname{sgn}(\tau)$: if $\tau = \tau_1 \cdots \tau_r$ with transpositions $\tau_l = (a_l\ b_l)$ of $[n-1]$, then σ' is the product of the r transpositions $(a_l + 1\ b_l + 1)$ of $[n]$, since both sides fix 1 and send $q+1$ to $\tau(q) + 1$.

For the product, the index $k = \rho_j(q+1)$ runs through $[n] \setminus \{j\}$ as q runs through $[n-1]$, and $\sigma\left(\rho_j(q+1)\right) = \rho_i(\sigma'(q+1)) = \rho_i(\tau(q)+1)$. Hence

$$\prod_{k \ne j} b_{\sigma(k)k} = \prod_{q=1}^{n-1} b_{\rho_i(\tau(q)+1),\, \rho_j(q+1)} = \prod_{q=1}^{n-1} \left(B_{\hat{ij}}\right)_{\tau(q)q}.$$

Summing over $\tau \in S_{n-1}$,

$$s_i = (-1)^{i+j} \sum_{\tau \in S_{n-1}} \operatorname{sgn}(\tau) \prod_{q=1}^{n-1} \left(B_{\hat{ij}}\right)_{\tau(q)q} = (-1)^{i+j} \det B_{\hat{ij}},$$

as desired. □

Intuition (Two proofs compared). The first proof is Technique 5.1.7 stopped after one row. Lemma 5.3.2 expanded all n columns at once and needed permutations to sort out the n^n terms; expanding a single row produces only n terms, and the lemma about one nonzero entry evaluates each of them. The second proof reads the expansion off the Leibniz formula (Technique 5.3.12): every term uses exactly one entry of column j, and the terms that use b_{ij} are, up to the sign $(-1)^{i+j}$, the Leibniz terms of $B_{\hat{ij}}$. All of the work is in the bookkeeping of signs, which the first proof gets for free from the adjacent swaps.

A third route is Exercise 5.3.39. It takes the expansion along the first column as a *definition*, by induction on n, and checks the axioms directly.

For $n = 3$, expanding along row 1 gives

$$\det\begin{pmatrix} a & b & c \\ d & e & f \\ g & h & k \end{pmatrix} = a(ek - fh) - b(dk - fg) + c(dh - eg),$$

whose six terms are those of the rule of Sarrus (Corollary 5.3.9). Expansion pays off when a row or column has many zeros, since every zero entry removes a minor from the sum.

Example 5.5.4 (A sparse 4×4 determinant). Let

$$A = \begin{pmatrix} 2 & 0 & 1 & 3 \\ 1 & 0 & 0 & 2 \\ 5 & 4 & 2 & 1 \\ 3 & 0 & 1 & 1 \end{pmatrix} \in \mathbb{Q}^{4\times 4}.$$

Column 2 has a single nonzero entry, $a_{32} = 4$, so expanding along column 2 (or applying Lemma 5.5.2 directly) gives

$$\det A = (-1)^{3+2} \cdot 4 \det A_{\hat{32}} = -4 \det\begin{pmatrix} 2 & 1 & 3 \\ 1 & 0 & 2 \\ 3 & 1 & 1 \end{pmatrix}.$$

In the 3×3 minor, row 2 contains a zero. Expanding along row 2,

$$\det\begin{pmatrix} 2 & 1 & 3 \\ 1 & 0 & 2 \\ 3 & 1 & 1 \end{pmatrix} = -1 \cdot \det\begin{pmatrix} 1 & 3 \\ 1 & 1 \end{pmatrix} + 0 - 2 \det\begin{pmatrix} 2 & 1 \\ 3 & 1 \end{pmatrix} = -(-2) - 2(-1) = 4.$$

Hence $\det A = -16$.

In practice, expansion is combined with elimination. Row and column replacements do not change the determinant (Corollary 5.4.15, Lemma 5.1.8), so one first creates zeros in some row or column, and then expands along it. This reduces the size by one at the cost of one round of replacements. For a general matrix with no zeros, though, a full cofactor expansion computes n minors of size $n - 1$, each of these $n - 1$ minors of size $n - 2$, and so on, about $n!$ products in all; elimination is the better algorithm (Remark 5.4.25).

Exercise 5.5.5. ROUTINE Compute the determinant of

$$M = \begin{pmatrix} i & 0 & 2 & 0 \\ 1 & 3 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 2 & 1 & i & 1 \end{pmatrix} \in \mathbb{C}^{4\times 4}$$

with two cofactor expansions. Along which rows or columns should you expand?

Solution on page 1426

5.5.2 The cofactor matrix and the inverse

The numbers $(-1)^{i+j} \det B_{\hat{i}\hat{j}}$ appear in both expansions, so we give them a name and arrange them in a matrix.

Definition 5.5.6 (Cofactors, cofactor matrix, adjugate). Let $n \geq 2$ and $B \in F^{n\times n}$. The (i,j) **cofactor** of B is

$$c_{ij} = (-1)^{i+j} \det B_{\hat{i}\hat{j}}.$$

The **cofactor matrix** of B is $C_B = (c_{ij}) \in F^{n\times n}$, and the **adjugate** of B is its transpose,

$$\operatorname{adj} B = C_B^{\mathsf{T}},$$

whose (i,j) entry is c_{ji}. For $n = 1$ we set $\operatorname{adj}(b) = (1)$.

In this notation, Theorem 5.5.3 says that $\det B = \sum_j b_{ij}c_{ij}$ for each row i, and $\det B = \sum_i b_{ij}c_{ij}$ for each column j: multiply each entry of a row or column by its own cofactor and add. The lecture writes the adjugate as C_B^{T}, and we use both. The adjugate is sometimes called the classical adjoint, but it is unrelated to the adjoints of Section 6.6, so we avoid that name. (The convention for $n = 1$ makes the theorems below true for $n = 1$ as well. It corresponds to declaring the determinant of the empty 0×0 matrix to be 1.)

Example 5.5.7 (The 2×2 case). Let $B = \begin{pmatrix} p & q \\ r & s \end{pmatrix}$. Deleting a row and a column leaves a single entry, so

$$c_{11} = s, \quad c_{12} = -r, \quad c_{21} = -q, \quad c_{22} = p,$$

and

$$C_B = \begin{pmatrix} s & -r \\ -q & p \end{pmatrix}, \quad \operatorname{adj} B = \begin{pmatrix} s & -q \\ -r & p \end{pmatrix}.$$

Then $B \operatorname{adj} B = \begin{pmatrix} ps-qr & -pq+qp \\ rs-sr & -rq+sp \end{pmatrix} = (ps-qr)I_2$, and similarly $(\operatorname{adj} B)B = (ps-qr)I_2$. So when $ps - qr \neq 0$, the inverse of B is $(ps-qr)^{-1}\begin{pmatrix} s & -q \\ -r & p \end{pmatrix}$: swap the diagonal entries, negate the others, and divide by the determinant. The theorem below says that the same pattern holds for every n.

The product $B \operatorname{adj} B$ in the example has the determinant on the diagonal, which is expected: its (i,i) entry is $\sum_j b_{ij}c_{ij}$, the expansion along row i. Its off-diagonal entries pair row i of B with the cofactors of a different row k. The cofactors of row k do not involve row k at all, so pairing them with a vector $\mathbf{x}$ computes the determinant of B with row k replaced by $\mathbf{x}^{\mathsf{T}}$. When $\mathbf{x}^{\mathsf{T}}$ is another row of B, that matrix has two equal rows.

Lemma 5.5.8 (Replacing a row or a column). Let $n \geq 2$, let $B \in F^{n\times n}$ have cofactors c_{ij}, let $k \in [n]$, and let $\mathbf{x} \in F^n$.

(a) If B' is obtained from B by replacing row k with $\mathbf{x}^{\mathsf{T}}$, then $\det B' = \sum_{j=1}^n x_j c_{kj}$.

(b) If $B_k(\mathbf{x})$ is obtained from B by replacing column k with $\mathbf{x}$, then $\det B_k(\mathbf{x}) = \sum_{i=1}^n x_i c_{ik}$.

In particular, for all $i, k \in [n]$,

$$\sum_{j=1}^{n} b_{ij}c_{kj} = \delta_{ik} \det B \quad \text{and} \quad \sum_{j=1}^{n} b_{ji}c_{jk} = \delta_{ik} \det B,$$

where δ_{ik} is 1 if $i = k$ and 0 otherwise.

Proof. ROUTINE

Uses. Theorem 5.5.3 (Cofactor expansion), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Corollary 5.4.15 (Rows), Definition 5.1.1 (Determinant function)
Hint 1. Expand $\det B'$ along row k. What are the cofactors of row k of B'?
Hint 2. B' and B differ only in row k, which is deleted when forming the minors of row k.
Hint 3. For the last statement, take $\mathbf{x}^{\mathsf{T}}$ to be row i of B. If $i \neq k$, what does B' look like?
Sketch. The minors $B'_{\widehat{kj}}$ do not involve row k, so they equal $B_{\widehat{kj}}$, and the row k cofactors of B' are $c_{k1}, \ldots, c_{kn}$. Expanding along row k gives (a); (b) is the same with columns. With $\mathbf{x}^{\mathsf{T}}$ equal to row i of B, $B' = B$ if $i = k$, and B' has two equal rows if $i \neq k$. Likewise for columns.

(a) For each j, the matrices B' and B agree outside row k, so $B'_{\widehat{kj}} = B_{\widehat{kj}}$, and the (k, j) cofactor of B' is c_{kj}. Expanding $\det B'$ along row k (Theorem 5.5.3), whose entries are $x_1, \ldots, x_n$, gives $\det B' = \sum_j x_j c_{kj}$.

(b) Similarly, $B_k(\mathbf{x})$ agrees with B outside column k, so its (i, k) cofactor is c_{ik}, and expanding along column k gives $\det B_k(\mathbf{x}) = \sum_i x_i c_{ik}$.

For the last statement, let $\mathbf{x}^{\mathsf{T}}$ be row i of B, so that $x_j = b_{ij}$. If $i = k$, then $B' = B$, and (a) gives $\sum_j b_{kj}c_{kj} = \det B$. If $i \neq k$, then rows i and k of B' are both equal to row i of B, so $\det B' = 0$ (Corollary 5.4.15), and (a) gives $\sum_j b_{ij}c_{kj} = 0$. For the column version, let $\mathbf{x}$ be column i of B, so $x_j = b_{ji}$. If $i = k$, then $B_k(\mathbf{x}) = B$; if $i \neq k$, then $B_k(\mathbf{x})$ has equal columns i and k, so its determinant is 0 (Definition 5.1.1). Now apply (b). □

The sums with $i \neq k$ are often called expansions by *alien cofactors*. Part (b) will give Cramer's rule, and the last statement gives the main theorem of this subsection.

Theorem 5.5.9 (The adjugate and the inverse). For every $B \in F^{n\times n}$,

$$B \operatorname{adj} B = (\operatorname{adj} B)B = (\det B)I_n.$$

Consequently, if $\det B \neq 0$, then B is invertible and

$$B^{-1} = \frac{1}{\det B} \operatorname{adj} B = \frac{1}{\det B} C_B^{\mathsf{T}}.$$

Proof. STANDARD

Uses. Lemma 5.5.8 (Replacing a row or a column), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Definition 2.4.1 (Matrix product), Definition 2.5.12 (Invertible)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Compute the (i, k) entry of $B \operatorname{adj} B$. The (j, k) entry of $\operatorname{adj} B$ is c_{kj}.
Hint 2. You get $\sum_j b_{ij}c_{kj}$, which Lemma 5.5.8 evaluates. For $(\operatorname{adj} B)B$, use the column version.
Sketch. The (i, k) entry of $B \operatorname{adj} B$ is $\sum_j b_{ij}c_{kj} = \delta_{ik} \det B$, and that of $(\operatorname{adj} B)B$ is $\sum_j c_{ji}b_{jk} = \delta_{ik} \det B$, both by Lemma 5.5.8. Dividing by $\det B \neq 0$ shows that $(\det B)^{-1} \operatorname{adj} B$ is a two-sided inverse.

For $n = 1$, $B = (b)$ and $\operatorname{adj} B = (1)$, so both products are $(b) = (\det B)I_1$. Let $n \geq 2$. The (j, k) entry of $\operatorname{adj} B = C_B^{\mathsf{T}}$ is c_{kj}. So by Definition 2.4.1 and Lemma 5.5.8, the (i, k) entry of $B \operatorname{adj} B$ is

$$\sum_{j=1}^{n} b_{ij}c_{kj} = \delta_{ik} \det B,$$

which is the (i, k) entry of $(\det B)I_n$. Similarly, the (i, k) entry of $(\operatorname{adj} B)B$ is

$$\sum_{j=1}^{n} c_{ji}b_{jk} = \sum_{j=1}^{n} b_{jk}c_{ji} = \delta_{ki} \det B,$$

by the column version in Lemma 5.5.8 (with the roles of i and k exchanged). Since $\delta_{ki} = \delta_{ik}$, this is again the (i,k) entry of $(\det B)I_n$.

If $\det B \neq 0$, multiplying both identities by $(\det B)^{-1}$ gives

$$B\big((\det B)^{-1}\operatorname{adj} B\big) = \big((\det B)^{-1}\operatorname{adj} B\big)B = I_n,$$

so $(\det B)^{-1}\operatorname{adj} B$ is a two-sided inverse of B (Definition 2.5.12). □

The theorem gives a second proof of (II) ⇒ (I) in Theorem 5.4.7 that uses no elimination, and it produces the inverse explicitly. The identity $B\operatorname{adj} B = (\det B)I_n$ holds for every B, invertible or not; for instance, if $\det B = 0$, it says that every column of $\operatorname{adj} B$ lies in $\ker B$.

The lecture calls the formula for B^{-1} more of a curiosity than a useful way to compute inverses. For computing, that is right: it needs n^2 determinants of size $n-1$, while row reducing $(B \mid I_n)$ (Algorithm 3.3.24) takes on the order of n^3 operations, the same order as a single determinant. Its value is that it describes B^{-1} by a formula. Every entry of B^{-1} is a polynomial in the entries of B, divided by $\det B$. Two consequences follow below: integer matrices with determinant ± 1 have integer inverses, and the solution of $B\mathbf{x} = \mathbf{y}$ is given by Cramer's rule. The formula also shows how $\det B$ depends on a single entry (Remark 5.5.11), which leads to formulas for derivatives of determinants (Section 5.5.6).

Example 5.5.10 (A 3×3 inverse). Let $B = \begin{pmatrix} 2 & 1 & 1 \\ 3 & 2 & 1 \\ 2 & 1 & 2 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$. The nine cofactors are

$$c_{11} = +\det\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} = 3, \quad c_{12} = -\det\begin{pmatrix} 3 & 1 \\ 2 & 2 \end{pmatrix} = -4, c_{13} = +\det\begin{pmatrix} 3 & 2 \\ 2 & 1 \end{pmatrix} = -1,$$

$$c_{21} = -\det\begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} = -1, c_{22} = +\det\begin{pmatrix} 2 & 1 \\ 2 & 2 \end{pmatrix} = 2, \quad c_{23} = -\det\begin{pmatrix} 2 & 1 \\ 2 & 1 \end{pmatrix} = 0,$$

$$c_{31} = +\det\begin{pmatrix} 1 & 1 \\ 2 & 1 \end{pmatrix} = -1, c_{32} = -\det\begin{pmatrix} 2 & 1 \\ 3 & 1 \end{pmatrix} = 1, \quad c_{33} = +\det\begin{pmatrix} 2 & 1 \\ 3 & 2 \end{pmatrix} = 1.$$

Expanding along row 1, $\det B = 2 \cdot 3 + 1 \cdot (-4) + 1 \cdot (-1) = 1$. Transposing C_B,

$$B^{-1} = \operatorname{adj} B = \begin{pmatrix} 3 & -1 & -1 \\ -4 & 2 & 1 \\ -1 & 0 & 1 \end{pmatrix}.$$

Multiplying out confirms $B\operatorname{adj} B = I_3$. The inverse has integer entries because $\det B = 1$.

Remark 5.5.11 (Cofactors measure sensitivity). Let $B \in F^{n\times n}$ with $n \geq 2$, and let $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ be the matrix unit (Lemma 2.4.24). Adding tU_{ij} to B changes only the entry b_{ij}, which becomes $b_{ij} + t$. Expanding along row i, whose cofactors do not change,

$$\det\big(B + tU_{ij}\big) = \det B + tc_{ij} \quad \text{for all } t \in F.$$

So $\det B$ is an affine function of each single entry, and the cofactor c_{ij} is its slope. Over $\mathbb{R}$, $c_{ij} = \partial \det B/\partial b_{ij}$. For instance, if $c_{ij} \neq 0$, then changing b_{ij} to $b_{ij} - \det B/c_{ij}$ makes B singular, while if $c_{ij} = 0$, no change of b_{ij} alone affects $\det B$.

> **Corollary 5.5.12** (Integer inverses). Let $A \in \mathbb{Q}^{n\times n}$ have integer entries. Then $\operatorname{adj} A$ has integer entries, and so does $(\det A)A^{-1}$ if A is invertible. In particular, A is invertible with A^{-1} having integer entries if and only if $\det A = \pm 1$.

Proof. ROUTINE

Uses. Theorem 5.5.9 (The adjugate and the inverse), Proposition 5.3.20 (Reduction modulo p), Exercise 5.4.42, Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Each cofactor is $\pm$ the determinant of a matrix with integer entries.
Hint 2. For the converse direction, take determinants of $AA^{-1} = I_n$, as in Exercise 5.4.42.
Sketch. Determinants of integer matrices are integers (Proposition 5.3.20), so all cofactors and hence $\operatorname{adj} A$ are integral, and $(\det A)A^{-1} = \operatorname{adj} A$. If $\det A = \pm 1$, then $A^{-1} = \pm \operatorname{adj} A$ is integral. Conversely, if A^{-1} is integral, $\det A \det A^{-1} = 1$ with both factors integers forces $\det A = \pm 1$.

Each cofactor of A is $\pm$ the determinant of a matrix with integer entries, hence an integer by Proposition 5.3.20. So $\operatorname{adj} A$ has integer entries. If A is invertible, then $\det A \neq 0$ (Theorem 5.4.7), and $(\det A)A^{-1} = \operatorname{adj} A$ by Theorem 5.5.9. If $\det A = \pm 1$, then A is invertible and $A^{-1} = (\det A)^{-1} \operatorname{adj} A = \pm \operatorname{adj} A$ has integer entries. The converse is Exercise 5.4.42. □

So the denominators in A^{-1} always divide $\det A$. To manufacture integer matrices with integer inverses, start from an upper triangular matrix with 1s on the diagonal and apply row and column replacements with integer multipliers. These keep the entries integral and the determinant equal to 1.

Exercise 5.5.13. ROUTINE Let $A = \begin{pmatrix} 1 & 2 & 0 \\ 3 & 1 & 1 \\ 0 & 4 & 3 \end{pmatrix} \in \mathbb{F}_7^{3\times 3}$. Compute $\det A$ and $\operatorname{adj} A$ over $\mathbb{F}_7$, and use them to find A^{-1}. Check your answer by multiplying.

Solution on page 1427

5.5.3 Cramer's rule

Intuition (Coefficients as ratios of areas). Suppose $\mathbf{a}_1, \mathbf{a}_2 \in \mathbb{R}^2$ are independent and $\mathbf{y} = x_1\mathbf{a}_1 + x_2\mathbf{a}_2$. Replace $\mathbf{a}_1$ by $\mathbf{y}$ in the parallelogram spanned by $\mathbf{a}_1$ and $\mathbf{a}_2$. The part $x_2\mathbf{a}_2$ of $\mathbf{y}$ is parallel to the other side, and shearing along $\mathbf{a}_2$ does not change signed area (Lemma 5.1.8). What remains, $x_1\mathbf{a}_1$, scales the area by x_1. So

$$\det(\mathbf{y}, \mathbf{a}_2) = \det(x_1\mathbf{a}_1 + x_2\mathbf{a}_2, \mathbf{a}_2) = x_1 \det(\mathbf{a}_1, \mathbf{a}_2),$$

and x_1 is the ratio $\det(\mathbf{y}, \mathbf{a}_2)/\det(\mathbf{a}_1, \mathbf{a}_2)$ of two signed areas (Figure 5.5.2). The same computation works for every coordinate and in every dimension.

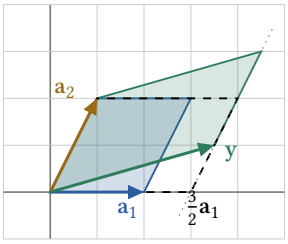

Figure 5.5.2. Here $\mathbf{a}_1 = (2, 0)$, $\mathbf{a}_2 = (1, 2)$, and $\mathbf{y} = \frac{3}{2}\mathbf{a}_1 + \frac{1}{2}\mathbf{a}_2 = \left(\frac{7}{2}, 1\right)$. The parallelogram on $\mathbf{a}_1, \mathbf{a}_2$ (blue) has signed area $\det(\mathbf{a}_1, \mathbf{a}_2) = 4$. The parallelogram on $\mathbf{y}, \mathbf{a}_2$ (green) has the same base $\mathbf{a}_2$ as the parallelogram on $\frac{3}{2}\mathbf{a}_1, \mathbf{a}_2$ (dashed), and its far side lies on the same dotted line, parallel to $\mathbf{a}_2$. So both have area $6 = \frac{3}{2} \cdot 4$, and $x_1 = \det(\mathbf{y}, \mathbf{a}_2)/\det(\mathbf{a}_1, \mathbf{a}_2) = \frac{3}{2}$.

Theorem 5.5.14 (Cramer's rule). Let $B \in F^{n\times n}$ with $\det B \neq 0$, and let $\mathbf{y} \in F^n$. Then the system $B\mathbf{x} = \mathbf{y}$ has exactly one solution $\mathbf{x} \in F^n$, and its entries are

$$x_i = \frac{\det B_i(\mathbf{y})}{\det B} \quad (i = 1, \ldots, n),$$

where $B_i(\mathbf{y})$ is the matrix obtained from B by replacing column i with $\mathbf{y}$.

Proof (by multilinearity). ROUTINE

Uses. Theorem 5.4.7 (Invertibility and the determinant), Definition 2.3.8 (Matrix–vector product), Definition 5.1.1 (Determinant function)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Existence and uniqueness come from invertibility. For the formula, write $\mathbf{y} = B\mathbf{x}$ as a combination of the columns of B.
Hint 2. Substitute $\mathbf{y} = \sum_k x_k \mathbf{b}_k$ into column i of $B_i(\mathbf{y})$ and expand by linearity in column i. Which terms survive?
Sketch. B is invertible, so $\mathbf{x} = B^{-1}\mathbf{y}$ is the only solution. Since $\mathbf{y} = \sum_k x_k \mathbf{b}_k$, linearity in column i gives $\det B_i(\mathbf{y}) = \sum_k x_k \det B_i(\mathbf{b}_k)$. For $k \neq i$, the matrix $B_i(\mathbf{b}_k)$ has $\mathbf{b}_k$ in columns i and k, so only $k = i$ survives, and $B_i(\mathbf{b}_i) = B$. So $\det B_i(\mathbf{y}) = x_i \det B$.

By Theorem 5.4.7, B is invertible. If $B\mathbf{x} = \mathbf{y}$, then $\mathbf{x} = B^{-1}B\mathbf{x} = B^{-1}\mathbf{y}$; conversely $B\big(B^{-1}\mathbf{y}\big) = \mathbf{y}$. So $\mathbf{x} = B^{-1}\mathbf{y}$ is the unique solution.

Let $\mathbf{b}_1, \dots, \mathbf{b}_n$ be the columns of B. By Definition 2.3.8, $\mathbf{y} = B\mathbf{x} = \sum_k x_k \mathbf{b}_k$. Fix i. By linearity in column i,

$$\det B_i(\mathbf{y}) = \sum_{k=1}^{n} x_k \det B_i(\mathbf{b}_k).$$

If $k \neq i$, then $B_i(\mathbf{b}_k)$ has $\mathbf{b}_k$ both in column i and in column k, so its determinant is 0 since det is alternating. If $k = i$, then $B_i(\mathbf{b}_i) = B$. So $\det B_i(\mathbf{y}) = x_i \det B$, and dividing by $\det B \neq 0$ gives the formula. □

Proof (via the adjugate). ROUTINE

Uses. Theorem 5.5.9 (The adjugate and the inverse), Lemma 5.5.8 (Replacing a row or a column), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate)
Hint 1. Write the solution as $\mathbf{x} = B^{-1}\mathbf{y}$ and use the formula for B^{-1}.
Hint 2. The i-th entry of $(\operatorname{adj} B)\mathbf{y}$ is $\sum_j c_{ji} y_j$. Compare with part (b) of Lemma 5.5.8.
Sketch. $\mathbf{x} = B^{-1}\mathbf{y} = (\det B)^{-1}(\operatorname{adj} B)\mathbf{y}$, and the i-th entry of $(\operatorname{adj} B)\mathbf{y}$ is $\sum_j c_{ji} y_j = \det B_i(\mathbf{y})$, the expansion of $\det B_i(\mathbf{y})$ along column i.

As in the first proof, the unique solution is $\mathbf{x} = B^{-1}\mathbf{y}$, which equals $(\det B)^{-1}(\operatorname{adj} B)\mathbf{y}$ by Theorem 5.5.9. For $n = 1$ this reads $x_1 = y_1/b_{11}$, which is the claim. For $n \geq 2$, the (i, j) entry of $\operatorname{adj} B$ is c_{ji}, so the i-th entry of $(\operatorname{adj} B)\mathbf{y}$ is $\sum_j y_j c_{ji}$, which is $\det B_i(\mathbf{y})$ by part (b) of Lemma 5.5.8. □

The two proofs reverse each other's logic. The second derives Cramer's rule from the inverse formula. The first needs nothing but the axioms, and running it backwards gives the inverse formula: column j of B^{-1} solves $B\mathbf{x} = \mathbf{e}_j$, so Cramer's rule computes its entries (Exercise 5.5.16). The first proof also shows more than the theorem states. Its computation never used that $\det B \neq 0$: for every $B \in F^{n\times n}$ and every solution $\mathbf{x}$ of $B\mathbf{x} = \mathbf{y}$,

$$x_i \det B = \det B_i(\mathbf{y}) \quad (i = 1, \dots, n). \tag{5.5.3}$$

So if $\det B = 0$ but $\det B_i(\mathbf{y}) \neq 0$ for some i, the system has no solution. The converse fails, as Exercise 5.5.35 shows.

Example 5.5.15 (One unknown at a time). Let B be the matrix of Example 5.5.10, with $\det B = 1$, and $\mathbf{y} = (1, 0, 4)$. To find only x_3 in the solution of $B\mathbf{x} = \mathbf{y}$, we need a single determinant:

$$x_3 = \det B_3(\mathbf{y}) = \det\begin{pmatrix} 2 & 1 & 1 \\ 3 & 2 & 0 \\ 2 & 1 & 4 \end{pmatrix} = 2(8-0) - 1(12-0) + 1(3-4) = 3.$$

The full solution, from $\mathbf{x} = (\operatorname{adj} B)\mathbf{y}$, is $\mathbf{x} = (-1, 0, 3)$, and indeed $B\mathbf{x} = (-2+3, -3+3, -2+6) = (1, 0, 4)$.

As a method for solving systems, Cramer's rule needs $n + 1$ determinants and is far slower than elimination. Its value is theoretical: it expresses each x_i as a ratio of two polynomials in the entries of B and $\mathbf{y}$, linear

in $\mathbf{y}$, so that, for instance, an integer system with $\det B = \pm 1$ has an integer solution. It also explains the geometry of Intuition (Coefficients as ratios of areas).

Exercise 5.5.16. ROUTINE Let $B \in F^{n\times n}$ with $\det B \neq 0$ and $n \geq 2$. Use Cramer's rule, applied to the systems $B\mathbf{x} = \mathbf{e}_j$, to show that the (i,j) entry of B^{-1} is $c_{ji}/\det B$. This proves the second half of Theorem 5.5.9 again.

Solution on page 1427

5.5.4 Determinants of structured matrices

Cofactor expansion reduces the size of a determinant by one. When the smaller determinants have the same shape as the original one, this sets up an induction.

Technique 5.5.17 (Induction on matrix size). Suppose a family of matrices $M_1, M_2, M_3, \ldots$, with $M_n \in F^{n\times n}$, has the property that expanding M_n along a well-chosen row or column produces minors that are earlier members of the family, or are triangular, or are otherwise known. Then the expansion gives a recurrence for $d_n = \det M_n$. Expand along the row or column with the fewest nonzero entries, identify each minor that appears, and write down the recurrence. Then either solve it, or compute d_1, d_2, d_3, guess a closed form, and prove it by induction on n.

Reach for it when a matrix has a pattern that repeats along the diagonal, so that deleting the last (or first) row and column gives the same kind of matrix. The canonical example is Proposition 5.5.18. Proposition 5.5.20 and the first proof of Theorem 5.5.21 induct in the same way, and Exercise 5.5.34 reproves Proposition 5.3.15.

Used in. Proposition 5.5.18, Proposition 5.5.20, Theorem 5.5.21, Exercise 5.5.34, Exercise 5.5.45, Exercise 5.5.53, Exercise 5.6.7, Problem 5.14, Theorem 8.3.23, Lemma 8.4.24.

Proposition 5.5.18 (Tridiagonal determinants). Let $a_1, \ldots, a_n$, $b_1, \ldots, b_{n-1}$, and $c_1, \ldots, c_{n-1}$ be elements of F. For $1 \leq m \leq n$ let

$$T_m = \begin{pmatrix} a_1 & b_1 & 0 & \cdots & 0 \\ c_1 & a_2 & b_2 & \ddots & \vdots \\ 0 & c_2 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & a_{m-1} & b_{m-1} \\ 0 & \cdots & 0 & c_{m-1} & a_m \end{pmatrix} \in F^{m\times m},$$

with b_k in position $(k, k+1)$, c_k in position $(k+1, k)$, and zeros away from the three middle diagonals. Let $d_m = \det T_m$, and put $d_0 = 1$. Then $d_1 = a_1$, and

$$d_m = a_m d_{m-1} - b_{m-1}c_{m-1}d_{m-2} \quad (2 \leq m \leq n).$$

Proof. ROUTINE

Uses. Theorem 5.5.3 (Cofactor expansion), Lemma 5.5.2 (A row or column with one nonzero entry)
Techniques. Induction on matrix size (Technique 5.5.17)
Hint 1. Expand $\det T_m$ along its last row. It has at most two nonzero entries.
Hint 2. One minor is T_{m-1}. In the other, the last column has a single nonzero entry; apply Lemma 5.5.2 once more.
Sketch. The last row of T_m is $(0, \ldots, 0, c_{m-1}, a_m)$. Deleting row m and column m leaves T_{m-1}, with sign $+$. Deleting row m and column $m-1$ leaves a matrix whose last column is $(0, \ldots, 0, b_{m-1})$, with sign $-$; expanding along that column leaves T_{m-2}. So $d_m = a_m d_{m-1} - c_{m-1}b_{m-1}d_{m-2}$.

$T_1 = (a_1)$, so $d_1 = a_1$. Let $2 \leq m \leq n$. The last row of T_m is $(0, \ldots, 0, c_{m-1}, a_m)$, so expanding along it (Theorem 5.5.3),

$$d_m = (-1)^{m+m} a_m \det T_{\widehat{mm}} + (-1)^{m+m-1} c_{m-1} \det N = a_m d_{m-1} - c_{m-1} \det N,$$

where $T_{m\widehat{m}m} = T_{m-1}$ and $N = T_{m\widehat{mm-1}}$. The matrix N consists of rows $1, \dots, m-1$ and columns $1, \dots, m-2, m$ of T_m. Its last column is column m of T_m without the last entry, namely $(0, \dots, 0, b_{m-1})$. If $m = 2$, then $N = (b_1)$ and $\det N = b_1 = b_1 d_0$. If $m \geq 3$, the only nonzero entry of the last column of N is b_{m-1}, in position $(m-1, m-1)$, and deleting row $m-1$ and column $m-1$ of N leaves rows and columns $1, \dots, m-2$ of T_m, which form T_{m-2}. By Lemma 5.5.2, $\det N = b_{m-1} d_{m-2}$. In both cases $d_m = a_m d_{m-1} - b_{m-1} c_{m-1} d_{m-2}$. □

Only the products $b_k c_k$ enter, so the entries above and below the diagonal can be traded against each other without changing any d_m.

Example 5.5.19 (Two tridiagonal families).

(a) Let $a_k = 2$ and $b_k = c_k = -1$ for all k. This is the matrix of second differences, which approximates $-f''$ when f is sampled at equally spaced points. The recurrence reads $d_m = 2d_{m-1} - d_{m-2}$ with $d_0 = 1$ and $d_1 = 2$, so $d_2 = 3$, $d_3 = 4$, and by induction $d_m = m + 1$: if $d_{m-1} = m$ and $d_{m-2} = m - 1$, then $d_m = 2m - (m-1) = m + 1$. So the $n \times n$ matrix is invertible over $\mathbb{Q}$, and over $\mathbb{F}_p$ exactly when p does not divide $n + 1$ (Proposition 5.3.20).

(b) Over $\mathbb{C}$, let $a_k = 1$ and $b_k = c_k = i$. Then $-b_k c_k = -i^2 = 1$, so $d_m = d_{m-1} + d_{m-2}$ with $d_0 = d_1 = 1$. The determinants are the Fibonacci numbers $1, 1, 2, 3, 5, 8, 13, \dots$, although every off-diagonal entry is imaginary.

The next family has a single row with more than two nonzero entries. Its determinant is a polynomial chosen in advance.

Proposition 5.5.20 (Companion matrices). Let $n \geq 1$, let $a_0, \dots, a_{n-1} \in F$, let $p = a_0 + a_1 x + \cdots + a_{n-1} x^{n-1} + x^n \in F[x]$, and let

$$C = \begin{pmatrix} 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & \cdots & 0 & -a_1 \\ 0 & 1 & \cdots & 0 & -a_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & -a_{n-1} \end{pmatrix} \in F^{n \times n},$$

whose column k is $\mathbf{e}_{k+1}$ for $k < n$, and whose last column is $-(a_0, \dots, a_{n-1})$. Then

$$\det(tI_n - C) = p(t) = t^n + a_{n-1} t^{n-1} + \cdots + a_1 t + a_0 \quad \text{for every } t \in F.$$

In particular, $\det C = (-1)^n a_0$.

Written out,

$$tI_n - C = \begin{pmatrix} t & 0 & \cdots & 0 & a_0 \\ -1 & t & \cdots & 0 & a_1 \\ 0 & -1 & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & t & a_{n-2} \\ 0 & \cdots & 0 & -1 & t + a_{n-1} \end{pmatrix}.$$

For $n = 1$ this is $(t + a_0)$, and for $n = 2$ it is $\begin{pmatrix} t & a_0 \\ -1 & t + a_1 \end{pmatrix}$, with determinant $t^2 + a_1 t + a_0$, as claimed. We give two proofs. The first is an induction in which the polynomial is built up by Horner's scheme $p(t) = a_0 + t(a_1 + t(a_2 + \cdots))$; the second performs the same scheme with row operations.

Proof (by expansion and induction). STANDARD

Uses. Theorem 5.5.3 (Cofactor expansion), Proposition 5.3.15 (Triangular matrices), Definition 1.2.17 (Evaluation), Exercise 5.1.5, induction on n

Techniques. Induction on matrix size (Technique 5.5.17)

Hint 1. Expand $\det(tI_n - C)$ along the first row, which has at most two nonzero entries.

Hint 2. Deleting row 1 and column 1 gives a matrix of the same kind, for the polynomial $a_1 + a_2x + \cdots + x^{n-1}$. Deleting row 1 and column n gives a triangular matrix.
Hint 3. You should find $\det(tI_n - C) = tq(t) + a_0$, where $q = a_1 + a_2x + \cdots + a_{n-1}x^{n-2} + x^{n-1}$.
Sketch. Induct on n; for $n = 1$ both sides are $t + a_0$. Let $M = tI_n - C$. Its first row is $(t, 0, \ldots, 0, a_0)$. The minor $M_{\widehat{11}}$ is $tI_{n-1} - C'$ for the companion matrix C' of $q = a_1 + a_2x + \cdots + x^{n-1}$, so its determinant is $q(t)$. The minor $M_{\widehat{1n}}$ is upper triangular with diagonal entries -1, so its determinant is $(-1)^{n-1}$. Hence $\det M = tq(t) + (-1)^{1+n}(-1)^{n-1}a_0 = tq(t) + a_0 = p(t)$.

We induct on n. For $n = 1$, $C = (-a_0)$ and $\det(tI_1 - C) = t + a_0 = p(t)$.

Let $n \geq 2$, assume the claim for $n - 1$, and let $M = tI_n - C$. Row k of M has -1 in column $k - 1$ (if $k \geq 2$), t in column k (if $k < n$), and a_{k-1} in column n, plus an extra t in position (n, n); all other entries are 0. The first row is $(t, 0, \ldots, 0, a_0)$, so expanding along it,

$$\det M = t \det M_{\widehat{11}} + (-1)^{1+n}a_0 \det M_{\widehat{1n}}.$$

The matrix $M_{\widehat{11}}$ consists of rows and columns $2, \ldots, n$ of M. Renumbering them as $1, \ldots, n - 1$, its row k has -1 in column $k - 1$ (if $k \geq 2$), t in column k (if $k < n - 1$), and a_k in its last column, plus an extra t in the last position. So $M_{\widehat{11}} = tI_{n-1} - C'$, where C' is the matrix of the proposition for the polynomial $q = a_1 + a_2x + \cdots + a_{n-1}x^{n-2} + x^{n-1}$. By the induction hypothesis, $\det M_{\widehat{11}} = q(t)$.

The matrix $M_{\widehat{1n}}$ consists of rows $2, \ldots, n$ and columns $1, \ldots, n - 1$ of M. Renumbered, its row k has -1 in column k and t in column $k + 1$ (if $k + 1 \leq n - 1$), and zeros elsewhere. It is upper triangular with every diagonal entry -1, so $\det M_{\widehat{1n}} = (-1)^{n-1}$ by Proposition 5.3.15.

Therefore, by Definition 1.2.17,

$$\begin{aligned}\det M &= tq(t) + (-1)^{1+n}(-1)^{n-1}a_0 = t\big(a_1 + a_2t + \cdots + a_{n-1}t^{n-2} + t^{n-1}\big) + a_0 \\ &= a_0 + a_1t + \cdots + a_{n-1}t^{n-1} + t^n = p(t),\end{aligned}$$

since $(-1)^{1+n}(-1)^{n-1} = (-1)^{2n} = 1$. Finally, with $t = 0$, $\det(-C) = p(0) = a_0$, and $\det(-C) = (-1)^n \det C$ by Exercise 5.1.5, so $\det C = (-1)^n a_0$. □

Proof (by row operations). STANDARD

Uses. Corollary 5.4.15 (Rows), Lemma 5.5.2 (A row or column with one nonzero entry), Proposition 5.3.15 (Triangular matrices), Definition 1.2.17 (Evaluation)
Hint 1. Use the -1 below each t to clear the t: add t times row $k + 1$ to row k. In which order should the rows be processed?
Hint 2. Work from the bottom up. Track the last entry of each row: if q_{k+1} is the last entry of the new row $k + 1$, the new last entry of row k is $a_{k-1} + tq_{k+1}$.
Hint 3. At the end, row 1 is $(0, \ldots, 0, p(t))$. Expand along it.
Sketch. For $k = n - 1, n - 2, \ldots, 1$, add t times the current row $k + 1$ to row k. This clears the t in position (k, k) and makes the last entry of row k equal to $q_k = a_{k-1} + tq_{k+1}$, where $q_n = t + a_{n-1}$; so $q_1 = p(t)$ by Horner's scheme. The determinant is unchanged, row 1 becomes $(0, \ldots, 0, p(t))$, and the minor of its last entry is $-I_{n-1}$. So $\det(tI_n - C) = (-1)^{1+n}p(t)(-1)^{n-1} = p(t)$.

For $n = 1$ both sides are $t + a_0$, so let $n \geq 2$ and $M = tI_n - C$. Put $q_n = t + a_{n-1}$ and, for $k = n - 1, \ldots, 1$, $q_k = a_{k-1} + tq_{k+1}$. Then

$$q_1 = a_0 + t(a_1 + t(a_2 + \cdots + t(a_{n-1} + t))) = p(t)$$

by expanding the nested products (Horner's scheme).

For $k = n - 1, n - 2, \ldots, 1$ in this order, add t times the current row $k + 1$ to row k. We claim that afterwards, for each $k \geq 2$, row k has -1 in column $k - 1$, q_k in column n, and zeros elsewhere, and row 1 is $(0, \ldots, 0, q_1)$. Row n is never changed, and it has -1 in column $n - 1$ and $q_n = t + a_{n-1}$ in column n. Suppose row $k + 1$ already has its final form, with -1 in column k and q_{k+1} in column n. Row k of M has -1 in column $k - 1$ (if $k \geq 2$), t in column k, and a_{k-1} in column n. Adding t times row $k + 1$ changes only columns k and n: the entry in column k becomes $t + t(-1) = 0$, and the entry in column n becomes $a_{k-1} + tq_{k+1} = q_k$. This

proves the claim. Each operation adds a multiple of one row to another, so the determinant is unchanged (Corollary 5.4.15).

In the final matrix, row 1 has the single nonzero entry $q_1 = p(t)$, in column n. Deleting row 1 and column n leaves the matrix whose row $k-1$ is $-\mathbf{e}_{k-1}^{\mathsf{T}}$ for $k = 2, \ldots, n$, that is, $-I_{n-1}$, with determinant $(-1)^{n-1}$ (Proposition 5.3.15). By Lemma 5.5.2,

$$\det M = (-1)^{1+n} p(t) (-1)^{n-1} = p(t),$$

as desired. The value of $\det C$ follows as in the first proof. □

So every monic polynomial of degree n arises as $t \mapsto \det(tI_n - C)$ for some $C \in F^{n \times n}$. In Section 7.3, $\det(tI_n - A)$ becomes the characteristic polynomial of A, and C (or its transpose, which has the same determinant by Theorem 5.4.14; conventions differ) is called the companion matrix of p. There the identity of the proposition is upgraded to an identity in $F[x]$.

5.5.5 The Vandermonde determinant

Recall from Definition 3.4.22 that for $c_0, \ldots, c_n \in F$ the Vandermonde matrix $V(c_0, \ldots, c_n) \in F^{(n+1)\times(n+1)}$ has row $i+1$ equal to $\left(1, c_i, c_i^2, \ldots, c_i^n\right)$. In Section 3.4 we showed that it is invertible when the c_i are distinct (Theorem 3.4.24), by an argument about roots of polynomials. Now we compute its determinant.

Theorem 5.5.21 (The Vandermonde determinant). Let $n \geq 0$ and $c_0, c_1, \ldots, c_n \in F$. Then

$$\det V(c_0, \ldots, c_n) = \det \begin{pmatrix} 1 & c_0 & c_0^2 & \cdots & c_0^n \\ 1 & c_1 & c_1^2 & \cdots & c_1^n \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & c_n & c_n^2 & \cdots & c_n^n \end{pmatrix} = \prod_{0 \leq i < j \leq n} (c_j - c_i).$$

In particular, $V(c_0, \ldots, c_n)$ is invertible if and only if $c_0, \ldots, c_n$ are distinct.

For $n = 0$ both sides are 1 (the product is empty). For $n = 1$, $\det\begin{pmatrix} 1 & c_0 \\ 1 & c_1 \end{pmatrix} = c_1 - c_0$, and for $n = 2$ the product is $(c_1 - c_0)(c_2 - c_0)(c_2 - c_1)$, which matches the rule of Sarrus after expanding. The last sentence follows from the formula: by Proposition 1.1.17 the product is nonzero exactly when every factor is, and then Theorem 5.4.7 applies.

The first proof creates the factors $c_j - c_0$ with column operations. The following technique describes the move.

Technique 5.5.22 (Expose a factor with row and column operations). When the entries of a matrix are polynomial expressions in some parameters and the determinant is expected to have a factor such as $c_1 - c_0$, look for replacements that make this factor appear in every entry of one row (or column). Replacements do not change the determinant (Corollary 5.4.15, Lemma 5.1.8), and linearity in that row then pulls the factor out. Choose the replacements so that they also create zeros, so that a cofactor expansion reduces the size at the same step. Repeating this, usually by induction on the size, peels off the factors one at a time.

Reach for it when consecutive columns (or rows) are related by a common multiplier, as the powers c^k and c^{k+1} are related by c, or when all rows have a common sum. The canonical example is the first proof of Theorem 5.5.21. Example 5.4.24 and Exercise 5.4.44 used the same idea with row sums.

Used in. Theorem 5.5.21, Exercise 5.5.42, Exercise 5.5.53, Exercise 5.6.6, Exercise 5.6.7, Problem 5.10, Problem 5.19.

Proof (by column operations). STANDARD

Uses. Lemma 5.1.8 (Column replacement), Lemma 5.5.2 (A row or column with one nonzero entry), Corollary 5.4.15 (Rows), induction on n
Techniques. Expose a factor with row and column operations (Technique 5.5.22), Induction on matrix size (Technique 5.5.17)
Hint 1. Use the first node c_0: subtract c_0 times each column from the column to its right. In which order must this be done so that each step uses an unchanged column?
Hint 2. Process the columns from right to left. Row 1 becomes $(1, 0, \dots, 0)$, and in every other row $i+1$, each entry except the first acquires the factor $c_i - c_0$.
Hint 3. After expanding along row 1 and pulling out the factors, what remains is a smaller Vandermonde matrix.
Sketch. For $m = n+1, n, \dots, 2$, subtract c_0 times column $m-1$ from column m. Row $i+1$ becomes $\big(1, (c_i - c_0), (c_i - c_0)c_i, \dots, (c_i - c_0)c_i^{n-1}\big)$, and row 1 becomes $(1, 0, \dots, 0)$. Expanding along row 1 and pulling $c_i - c_0$ out of row i of the minor gives $\det V(c_0, \dots, c_n) = \prod_{i=1}^{n}(c_i - c_0) \det V(c_1, \dots, c_n)$, and induction finishes.

We induct on n. For $n = 0$, both sides equal 1. Let $n \geq 1$, assume the formula for n nodes, and let $V = V(c_0, \dots, c_n)$. Number the columns $1, \dots, n+1$, so that the entry of column m in row $i+1$ is c_i^{m-1}.

For $m = n+1, n, \dots, 2$, in this order, subtract c_0 times column $m-1$ from column m. When column m is changed, column $m-1$ has not been changed yet, so the new entry of column m in row $i+1$ is

$$c_i^{m-1} - c_0 c_i^{m-2} = (c_i - c_0)c_i^{m-2}.$$

Each step adds a multiple of one column to another, so the determinant does not change (Lemma 5.1.8). The new matrix V' has first row $(1, 0, \dots, 0)$, since $c_0 - c_0 = 0$, and for $i = 1, \dots, n$ its row $i+1$ is

$$\big(1, (c_i - c_0), (c_i - c_0)c_i, \dots, (c_i - c_0)c_i^{n-1}\big).$$

By Lemma 5.5.2 applied to row 1, $\det V = \det V'_{\widehat{11}}$. Row i of $V'_{\widehat{11}}$ is $(c_i - c_0)\big(1, c_i, \dots, c_i^{n-1}\big)$, so pulling the factor $c_i - c_0$ out of each row (Corollary 5.4.15) gives

$$\det V = (c_1 - c_0)(c_2 - c_0)\cdots(c_n - c_0) \det V(c_1, \dots, c_n).$$

By the induction hypothesis, $\det V(c_1, \dots, c_n) = \prod_{1 \leq i < j \leq n}\big(c_j - c_i\big)$. The factors $c_j - c_0$ are the factors of $\prod_{0 \leq i < j \leq n}\big(c_j - c_i\big)$ with $i = 0$, so $\det V$ is the full product, as desired. □

Intuition (Where the factors come from). Regard the last node c_n as a variable t, and the other nodes as fixed. Expanding $\det V(c_0, \dots, c_{n-1}, t)$ along the last row $\big(1, t, t^2, \dots, t^n\big)$ shows that it is a polynomial in t of degree at most n. If $t = c_i$ for some $i < n$, then two rows are equal and the determinant is 0. So when the nodes $c_0, \dots, c_{n-1}$ are distinct, the polynomial has these n roots, and a polynomial of degree at most n with n prescribed roots is pinned down by one more number, its coefficient of t^n. That coefficient is the cofactor of the entry t^n, a smaller Vandermonde determinant. The first proof found the factors by computing; this argument predicts them from the places where the matrix collapses.

To make this precise, we need the fact that a polynomial is determined by its roots and its leading coefficient. Polynomials cannot be multiplied until Section 7.1, so we state it for values.

Lemma 5.5.23 (A polynomial with prescribed roots). Let $n \geq 0$, let $P \in F[x]_{\leq n}$, and let a be its coefficient of x^n. If $c_1, \dots, c_n \in F$ are distinct and $P(c_1) = \cdots = P(c_n) = 0$, then

$$P(t) = a(t - c_1)(t - c_2)\cdots(t - c_n) \quad \text{for every } t \in F.$$

Proof. STANDARD

Uses. Lemma 3.4.23 (Too many roots), Proposition 1.2.18 (Degree and evaluation versus the operations), Definition 1.2.17 (Evaluation), induction on n
Hint 1. First show that $t \mapsto a(t - c_1)\cdots(t - c_n)$ is the evaluation of a polynomial $Q \in F[x]_{\leq n}$ whose coefficient of x^n is a.
Hint 2. Then $P - Q$ has degree at most $n - 1$. How many roots does it have?

Sketch. Multiplying out one factor at a time shows $(t-c_1)\cdots(t-c_n) = t^n + e_{n-1}t^{n-1} + \cdots + e_0$ for scalars e_k that do not depend on t. So $a\prod(t-c_k) = Q(t)$ for some $Q \in F[x]_{\le n}$ with coefficient a of x^n. Then $P - Q \in F[x]_{\le n-1}$ vanishes at the n distinct points c_k, so $P = Q$ by Lemma 3.4.23.

For $n = 0$, P is the constant a and the product is empty, so there is nothing to prove. Let $n \ge 1$.

First, there are $e_0, \ldots, e_{n-1} \in F$, depending only on $c_1, \ldots, c_n$, such that

$$(t-c_1)\cdots(t-c_n) = t^n + e_{n-1}t^{n-1} + \cdots + e_1 t + e_0 \quad \text{for every } t \in F.$$

We show this by induction on the number m of factors. For $m = 1$, take $e_0 = -c_1$. If $(t-c_1)\cdots(t-c_m) = t^m + \sum_{k<m} e_k t^k$, then multiplying by $t - c_{m+1}$ and distributing gives

$$t^{m+1} + \sum_{k<m} e_k t^{k+1} - c_{m+1}t^m - \sum_{k<m} c_{m+1}e_k t^k,$$

which is t^{m+1} plus a combination of $1, t, \ldots, t^m$ with coefficients that do not depend on t.

Let $Q = ae_0 + ae_1 x + \cdots + ae_{n-1}x^{n-1} + ax^n \in F[x]_{\le n}$. Then $Q(t) = a(t-c_1)\cdots(t-c_n)$ for every t. The coefficients of x^n in P and Q are both a, so $R = P - Q$ lies in $F[x]_{\le n-1}$, and for each k, $R(c_k) = P(c_k) - Q(c_k) = 0 - 0 = 0$ (Proposition 1.2.18), because the product $Q(c_k)$ contains the factor $c_k - c_k = 0$. So R has degree at most $n-1$ and vanishes at the n distinct points $c_1, \ldots, c_n$. By Lemma 3.4.23 (with $n-1$ in place of n), $R = \mathbf{0}$. Hence $P = Q$, and $P(t) = Q(t) = a(t-c_1)\cdots(t-c_n)$ for every t. □

Once polynomials can be multiplied, the lemma says $P = a(x-c_1)\cdots(x-c_n)$ in $F[x]$; it is the factor theorem of Section 7.1 (compare Proposition 7.1.22).

Technique 5.5.24 (Polynomial identity arguments). To prove that two quantities depending on a scalar t are equal, show that both are values $P(t)$ and $Q(t)$ of polynomials $P, Q \in F[x]_{\le n}$, and then show $P = Q$ by counting. Two polynomials of degree at most n that agree at $n+1$ distinct points are equal, since their difference has $n+1$ roots (Lemma 3.4.23). When zeros are easier to find than values, use Lemma 5.5.23 instead: a polynomial of degree at most n with n known distinct roots is determined by its coefficient of x^n. Then the proof splits into independent checks: a bound on the degree, the roots, and one coefficient.

Determinants are a rich source of such polynomials. If a parameter t occurs in only one row, the expansion along that row (Theorem 5.5.3) shows that the determinant is a polynomial in t; if the top power of t occurs in only one entry of that row, as in $(1, t, \ldots, t^n)$, its coefficient is a single cofactor. More generally, see Technique 5.3.18. Roots come from coincidences: a value of t that makes two rows equal, or the rows dependent, is a root.

Reach for it when the expected answer is a product of linear factors, or when an identity is easy to check for many special values of a parameter. Two pitfalls: forgetting the leading coefficient (roots determine a polynomial only up to a scalar factor; see Exercise 5.5.42), and counting roots that are not distinct. Over an infinite field, an identity between polynomials in t that holds for all but finitely many t holds for all t. This extends identities from invertible matrices to all matrices by way of $A + tI_n$ (Exercise 5.5.41). The canonical example is the second proof of Theorem 5.5.21. The technique returns in Section 7.3.

Used in. Theorem 5.5.21, Exercise 5.5.40, Exercise 5.5.41, Exercise 5.5.42, Exercise 5.5.45, Exercise 5.6.9, Exercise 5.6.10, Problem 5.18, Proposition 7.3.11, Proposition 7.3.22, Exercise 7.3.48, Exercise 7.3.49, Theorem 7.5.22, Lemma 7.6.21, Exercise 7.7.14, Proposition B.1.28, Exercise B.1.45.

Proof of Theorem 5.5.21 (by a polynomial identity). STANDARD

Uses. Theorem 5.5.3 (Cofactor expansion), Lemma 5.5.23 (A polynomial with prescribed roots), Corollary 5.4.15 (Rows), induction on n

Techniques. Polynomial identity arguments (Technique 5.5.24)

Hint 1. Induct on n. Fix $c_0, \ldots, c_{n-1}$ and consider $f(t) = \det V(c_0, \ldots, c_{n-1}, t)$ as a function of t.

Hint 2. Expand along the last row to see that f is a polynomial of degree at most n. What is its coefficient of t^n? Where does f vanish?

Hint 3. If $c_0, \dots, c_{n-1}$ are distinct, Lemma 5.5.23 applies. If not, both sides are 0.
Sketch. Let $f(t) = \det V(c_0, \dots, c_{n-1}, t)$. Expanding along the last row, f is a polynomial of degree at most n whose coefficient of t^n is the cofactor of the entry t^n, namely $D = \det V(c_0, \dots, c_{n-1})$. It vanishes at $c_0, \dots, c_{n-1}$ (equal rows). If these are distinct, Lemma 5.5.23 gives $f(t) = D\prod_{i<n}(t - c_i)$; put $t = c_n$ and use induction for D. If two of them coincide, both sides are 0.

We induct on n; for $n = 0$ both sides are 1. Let $n \geq 1$, and assume the formula for n nodes. Fix $c_0, \dots, c_{n-1}$, and for $t \in F$ let $f(t) = \det V(c_0, \dots, c_{n-1}, t)$.

f is a polynomial. The last row of $V(c_0, \dots, c_{n-1}, t)$ is $\left(1, t, t^2, \dots, t^n\right)$, with t^k in column $k+1$. Expanding along it (Theorem 5.5.3),

$$f(t) = \sum_{k=0}^{n} (-1)^{(n+1)+(k+1)} t^k m_k,$$

where m_k is the determinant of the matrix obtained by deleting the last row and column $k+1$. These matrices do not involve the last row, so the m_k do not depend on t. Hence $f(t) = P(t)$ for the polynomial $P = \sum_{k=0}^{n} (-1)^{n+k} m_k x^k \in F[x]_{\leq n}$. Its coefficient of x^n is m_n, and deleting the last row and the last column of $V(c_0, \dots, c_{n-1}, t)$ leaves $V(c_0, \dots, c_{n-1})$, so $m_n = D$, where $D = \det V(c_0, \dots, c_{n-1})$.

Roots. For $i < n$, the matrix $V(c_0, \dots, c_{n-1}, c_i)$ has rows $i+1$ and $n+1$ equal, so $P(c_i) = f(c_i) = 0$ (Corollary 5.4.15).

Conclusion. Suppose first that $c_0, \dots, c_{n-1}$ are distinct. By Lemma 5.5.23, $f(t) = D(t - c_0)\cdots(t - c_{n-1})$ for every $t \in F$. Taking $t = c_n$ and using the induction hypothesis for D,

$$\det V(c_0, \dots, c_n) = \prod_{0 \leq i < j \leq n-1} (c_j - c_i) \cdot \prod_{i=0}^{n-1} (c_n - c_i) = \prod_{0 \leq i < j \leq n} (c_j - c_i).$$

If instead $c_i = c_k$ for some $i < k < n$, then $V(c_0, \dots, c_n)$ has two equal rows, so its determinant is 0, and the product is 0 as well, since it contains the factor $c_k - c_i = 0$. □

Intuition (Two proofs compared). The first proof is a computation organized by induction: column operations expose all factors that involve c_0 at once, and what is left is a smaller Vandermonde matrix. It is the proof to imitate for determinants with a similar pattern of powers. The second proof hardly computes. It identifies the determinant as a polynomial in one node, locates its roots by asking when the matrix collapses, and pins down the one remaining constant with a cofactor. It explains why the answer is a product of differences: the factor $c_j - c_i$ is there because the matrix becomes singular when $c_j = c_i$. The second proof needs the nodes $c_0, \dots, c_{n-1}$ to be distinct and treats the degenerate case separately, while the first does not split into cases at all.

Remark 5.5.25 (Back to permutations and interpolation). The polynomial $\Delta(\mathbf{x}) = \prod_{1 \leq i < j \leq n}(x_j - x_i)$ of Approach 1: a product of differences is $\det V(x_1, \dots, x_n)$. Rearranging the entries of $\mathbf{x}$ by σ rearranges the rows of V: row k of $V\left(x_{\sigma(1)}, \dots, x_{\sigma(n)}\right)$ is row $\sigma(k)$ of $V(x_1, \dots, x_n)$, so $V(\mathbf{x}^\sigma) = E_\sigma^{\mathsf{T}} V(\mathbf{x})$, and $\Delta(\mathbf{x}^\sigma) = \operatorname{sgn}(\sigma)\Delta(\mathbf{x})$. For a transposition this is Lemma 5.2.20. This is not a new proof of Theorem 5.2.18, since the existence of det relied on it, but it explains why Δ was the right invariant.

The theorem also completes the second proof of invertibility promised in Section 3.4. For distinct nodes, $\det V(c_0, \dots, c_n) \neq 0$, so V is invertible and the interpolation problem has exactly one solution.

Exercise 5.5.26. ROUTINE

(a) Show that $\det V(1, 2, \dots, n) = 1! \cdot 2! \cdots (n-1)!$, and evaluate it for $n = 4$.

(b) Compute $\det V(0, 1, 2, 3, 4)$ in $\mathbb{F}_5$. Deduce that every function $g : \mathbb{F}_5 \to \mathbb{F}_5$ is of the form $t \mapsto P(t)$ for exactly one $P \in \mathbb{F}_5[x]_{\leq 4}$.

Solution on page 1427

5.5.6 Rank-one updates BEYOND 21-242

Not covered in lecture. The matrix determinant lemma is a standard application of the adjugate in statistics and numerical linear algebra.

Remark 5.5.11 computed $\det(B + tU_{ij})$, where $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ has rank one. The same computation works for every matrix of rank one, that is, for every $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ with $\mathbf{u}, \mathbf{v} \in F^n$.

Theorem 5.5.27 (Matrix determinant lemma). Let $A \in F^{n\times n}$ and $\mathbf{u}, \mathbf{v} \in F^n$. Then

$$\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det A + \mathbf{v}^{\mathsf{T}}(\operatorname{adj} A)\mathbf{u}.$$

In particular, if A is invertible, then $\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det A\left(1 + \mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u}\right)$.

Proof (by multilinearity). STANDARD

Uses. Definition 2.4.1 (Matrix product), Definition 5.1.1 (Determinant function), Lemma 5.5.8 (Replacing a row or a column), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Theorem 5.5.9 (The adjugate and the inverse)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Column j of $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $v_j\mathbf{u}$. Expand $\det(\mathbf{a}_1 + v_1\mathbf{u}, \ldots, \mathbf{a}_n + v_n\mathbf{u})$ by multilinearity. Which terms vanish?
Hint 2. Every term that uses $\mathbf{u}$ in two columns vanishes. The terms that use $\mathbf{u}$ in exactly one column j are $v_j \det A_j(\mathbf{u})$; evaluate them with Lemma 5.5.8.
Sketch. Expanding every column $\mathbf{a}_j + v_j\mathbf{u}$ gives a sum over the sets S of columns in which $\mathbf{u}$ is chosen. Sets with two or more elements give a matrix with two columns equal to $\mathbf{u}$. So $\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det A + \sum_j v_j \det A_j(\mathbf{u})$, and $\det A_j(\mathbf{u}) = \sum_i u_i c_{ij}$. The double sum $\sum_{i,j} v_j c_{ij} u_i$ is $\mathbf{v}^{\mathsf{T}} C_A^{\mathsf{T}} \mathbf{u}$.

For $n = 1$ both sides are $a + vu$, since $\operatorname{adj}(a) = (1)$. Let $n \geq 2$. Column j of $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $v_j\mathbf{u}$ (Definition 2.4.1), so column j of $A + \mathbf{u}\mathbf{v}^{\mathsf{T}}$ is $\mathbf{a}_j + v_j\mathbf{u}$. Expanding by linearity in each column, $\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right)$ is the sum, over all subsets $S \subseteq [n]$, of $\left(\prod_{j\in S} v_j\right) \det A_S$, where A_S has column $\mathbf{u}$ in the positions $j \in S$ and column $\mathbf{a}_j$ in the other positions. If S has two or more elements, then A_S has two equal columns and $\det A_S = 0$. The set $S = \emptyset$ contributes $\det A$, and $S = \{j\}$ contributes $v_j \det A_j(\mathbf{u})$, where $A_j(\mathbf{u})$ is A with column j replaced by $\mathbf{u}$. By part (b) of Lemma 5.5.8, $\det A_j(\mathbf{u}) = \sum_i u_i c_{ij}$, where the c_{ij} are the cofactors of A. Hence

$$\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det A + \sum_{j=1}^{n}\sum_{i=1}^{n} v_j c_{ij} u_i = \det A + \mathbf{v}^{\mathsf{T}} C_A^{\mathsf{T}} \mathbf{u},$$

since the (j, i) entry of $C_A^{\mathsf{T}} = \operatorname{adj} A$ is c_{ij}. If A is invertible, then $\operatorname{adj} A = (\det A)A^{-1}$ by Theorem 5.5.9, and the right side is $\det A + \det A \cdot \mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u}$. □

Proof (by block matrices, for invertible A). STANDARD

Uses. Theorem 2.4.34 (Block multiplication), Theorem 5.4.26 (Block-triangular matrices), Theorem 5.4.10 (Multiplicativity)
Techniques. Block elimination (Technique 5.4.28)
Hint 1. Consider the $(n + 1) \times (n + 1)$ matrix $M = \begin{pmatrix} A & -\mathbf{u} \\ \mathbf{v}^{\mathsf{T}} & 1 \end{pmatrix}$, and compute $\det M$ in two ways.
Hint 2. Clear $\mathbf{v}^{\mathsf{T}}$ using the entry 1, or clear it using A. Each is a multiplication by a block triangular matrix with determinant 1.
Sketch. With $M = \begin{pmatrix} A & -\mathbf{u} \\ \mathbf{v}^{\mathsf{T}} & 1 \end{pmatrix}$, block multiplication gives $\begin{pmatrix} I_n & \mathbf{u} \\ 0 & 1 \end{pmatrix} M = \begin{pmatrix} A+\mathbf{u}\mathbf{v}^{\mathsf{T}} & 0 \\ \mathbf{v}^{\mathsf{T}} & 1 \end{pmatrix}$ and $\begin{pmatrix} I_n & 0 \\ -\mathbf{v}^{\mathsf{T}}A^{-1} & 1 \end{pmatrix} M = \begin{pmatrix} A & -\mathbf{u} \\ 0 & 1+\mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u} \end{pmatrix}$. Both multipliers have determinant 1, so $\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det M = \det A\left(1 + \mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u}\right)$.

Let $M = \begin{pmatrix} A & -\mathbf{u} \\ \mathbf{v}^{\mathsf{T}} & 1 \end{pmatrix} \in F^{(n+1)\times(n+1)}$. By Theorem 2.4.34,

$$\begin{pmatrix} I_n & \mathbf{u} \\ 0 & 1 \end{pmatrix} M = \begin{pmatrix} A + \mathbf{u}\mathbf{v}^{\mathsf{T}} & -\mathbf{u} + \mathbf{u} \\ \mathbf{v}^{\mathsf{T}} & 1 \end{pmatrix} = \begin{pmatrix} A + \mathbf{u}\mathbf{v}^{\mathsf{T}} & 0 \\ \mathbf{v}^{\mathsf{T}} & 1 \end{pmatrix}$$

and

$$\begin{pmatrix} I_n & 0 \\ -\mathbf{v}^{\mathsf{T}}A^{-1} & 1 \end{pmatrix} M = \begin{pmatrix} A & -\mathbf{u} \\ -\mathbf{v}^{\mathsf{T}} + \mathbf{v}^{\mathsf{T}} & \mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u} + 1 \end{pmatrix} = \begin{pmatrix} A & -\mathbf{u} \\ 0 & 1 + \mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u} \end{pmatrix}.$$

The two multipliers are block triangular with diagonal blocks I_n and (1), so they have determinant 1 by Theorem 5.4.26. The right sides are block triangular as well. Taking determinants with Theorem 5.4.10 and Theorem 5.4.26,

$$\det\left(A + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det M = \det A\left(1 + \mathbf{v}^{\mathsf{T}}A^{-1}\mathbf{u}\right),$$

as desired. □

The first proof is shorter, works for every A, and shows that $\det\left(A + t\mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = \det A + t\mathbf{v}^{\mathsf{T}}(\operatorname{adj} A)\mathbf{u}$ is affine in t. The second is an instance of Technique 5.4.28 and needs A^{-1}. For example, let $J \in F^{n\times n}$ be the matrix of all 1s, so $J = \mathbf{1}\mathbf{1}^{\mathsf{T}}$ with $\mathbf{1} = (1, \ldots, 1)$. For $a, b \in F$, since $\operatorname{adj}(aI_n) = a^{n-1}I_n$,

$$\det(aI_n + bJ) = a^n + b\mathbf{1}^{\mathsf{T}}a^{n-1}I_n\mathbf{1} = a^{n-1}(a + nb).$$

With $a = x - 1$ and $b = 1$ this is Example 5.4.24 again.

Remark 5.5.28 (Derivatives of determinants). Let $A(s)$ be an $n \times n$ matrix whose entries are differentiable functions of $s \in \mathbb{R}$. Applying Remark 5.5.11 entry by entry with the chain rule (or Exercise 5.5.48) gives **Jacobi's formula**

$$\frac{d}{ds}\det A(s) = \sum_{i,j} c_{ij}(s)a'_{ij}(s) = \operatorname{tr}(\operatorname{adj}(A(s))A'(s)),$$

where $c_{ij}(s)$ are the cofactors of $A(s)$ and $A'(s)$ is the entrywise derivative. At an invertible $A(s)$ this reads $(\det A)' = \det A \cdot \operatorname{tr}\left(A^{-1}A'\right)$. For $A(s) = I_n + sH$ at $s = 0$ it gives $\operatorname{tr} H$, the coefficient of s in $\det(I_n + sH)$ found in Exercise 5.5.48 (with $A = I_n$ and $B = H$).

5.5.7 Minors and rank

BEYOND 21-242

Minors of arbitrary order appear in LADW 3.6 and in Cauchy–Binet, but not in the course.

The minors $\det B_{\hat{i}\hat{j}}$ come from square submatrices one size smaller than B. Submatrices of every size describe the rank.

Definition 5.5.29 (Minors of order k). Let $A \in F^{m\times n}$ and $1 \le k \le \min(m, n)$. For sets $I \subseteq [m]$ and $J \subseteq [n]$ with k elements each, the **submatrix** $A_{IJ} \in F^{k\times k}$ consists of the entries a_{ij} with $i \in I$ and $j \in J$, with rows and columns in increasing order. Its determinant $\det A_{IJ}$ is a **minor of order** k of A.

So $B_{\hat{i}\hat{j}} = B_{IJ}$ with $I = [n] \setminus \{i\}$ and $J = [n] \setminus \{j\}$, and the 1×1 minors are the entries.

Theorem 5.5.30 (Rank via minors). Let $A \in F^{m\times n}$ be nonzero. Then $\operatorname{rank} A$ is the largest k such that A has a nonzero minor of order k. In particular, every minor of order greater than $\operatorname{rank} A$ is 0.

Proof. HARD

Uses. Theorem 4.2.7 (The image of T_A), Theorem 4.1.10 (Independent lists are short), Theorem 1.6.10 (Every spanning list contains a basis), Theorem 4.3.8 (Row rank equals column rank), Corollary 5.4.8 (Vanishing determinants), Corollary 5.4.15 (Rows)

Hint 1. If A_{IJ} has nonzero determinant, its columns are independent. What does that say about the columns $j \in J$ of A?

Hint 2. Conversely, with $r = \operatorname{rank} A$, choose r independent columns of A. The $m \times r$ matrix they form has rank r, so its transpose does too. Choose r independent rows of it.

Sketch. If $\det A_{IJ} \neq 0$, the columns of A_{IJ} are independent, so the columns of A indexed by J are independent (a relation among them restricts to the rows in I). They lie in the column space, of dimension $\operatorname{rank} A$, so $k \le \operatorname{rank} A$.

Conversely, $r = \operatorname{rank} A$ columns of A form a basis of its column space; the $m \times r$ matrix A' they form has rank r, so by Theorem 4.3.8 some r rows of A' are independent, and the $r \times r$ submatrix they form has nonzero determinant.

The columns of A span $\operatorname{im} T_A$, which has dimension $\operatorname{rank} A$ by Theorem 4.2.7.

Suppose $\det A_{IJ} \neq 0$ for some I, J with k elements. By Corollary 5.4.8, the columns of A_{IJ} are linearly independent. For $j \in J$, the column of A_{IJ} that comes from column j of A is $\mathbf{a}'_j \in F^k$, the vector of entries a_{ij} with $i \in I$. We claim that the columns $\mathbf{a}_j$, $j \in J$, of A are linearly independent. If $\sum_{j\in J} x_j \mathbf{a}_j = \mathbf{0}$, then in particular the entries in the rows $i \in I$ vanish, that is, $\sum_{j\in J} x_j \mathbf{a}'_j = \mathbf{0}$; so all $x_j = 0$. Hence $\operatorname{im} T_A$ contains k independent vectors, and $k \leq \operatorname{rank} A$ by Theorem 4.1.10. This proves the last sentence of the theorem.

Now let $r = \operatorname{rank} A \geq 1$. By Theorem 1.6.10, the list of columns of A, which spans $\operatorname{im} T_A$, contains a basis of $\operatorname{im} T_A$; it has r elements, say the columns indexed by J. Let $A' \in F^{m\times r}$ be the matrix with these columns. Its columns are independent, so $\operatorname{rank} A' = r$ (Theorem 4.2.7), and $\operatorname{rank} A'^{\mathsf{T}} = r$ by Theorem 4.3.8. Applying the same argument to A'^{T}, some r columns of A'^{T} are independent, that is, some r rows of A', indexed by a set I, are independent. These rows form the $r \times r$ matrix A_{IJ}, which therefore has independent rows, so $\det A_{IJ} \neq 0$ by Corollary 5.4.15. So A has a nonzero minor of order r, and none of larger order. □

The theorem is not a practical way to find the rank, since row reduction is much faster than evaluating minors. Its value is that minors are polynomials in the entries, so statements about rank become statements about polynomials.

Corollary 5.5.31 (Rank does not depend on the field). Let K be a subfield of F (Definition 1.1.32), and let $A \in K^{m\times n}$. Then the rank of A is the same whether A is regarded as a matrix over K or over F.

Proof. ROUTINE

Uses. Theorem 5.5.30 (Rank via minors), Definition 5.3.6 (Determinant), Definition 1.1.32 (Subfield)
Hint 1. Is a minor of A computed over K the same element as the minor computed over F?
Hint 2. The Leibniz formula uses only sums and products, and K inherits these from F.
Sketch. Each minor is given by the Leibniz formula, which uses only the operations of K, and these agree with those of F. So A has the same minors over K and over F, and by Theorem 5.5.30 the same rank.

If $A = 0$, its rank is 0 over both fields. Otherwise, each minor $\det A_{IJ}$ is the sum in the Leibniz formula (Definition 5.3.6), a combination of sums, negatives, and products of entries of A. These operations in K are the restrictions of those in F (Definition 1.1.32), so the minor is the same element whether computed in K or in F. In particular, the minors that are nonzero are the same, and Theorem 5.5.30 gives the same rank. □

For example, a matrix with rational entries has the same rank over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$. (Exercise 3.3.54 proves this with Gauss–Jordan elimination instead: the reduced row echelon form computed in K is also the one over F.) By contrast, reducing an integer matrix modulo a prime can lower its rank, because nonzero integer minors can become 0 in $\mathbb{F}_p$.

Remark 5.5.32 (The Cauchy–Binet formula). For $A \in F^{m\times n}$ and $B \in F^{n\times m}$, the determinant of the $m \times m$ matrix AB is a sum of products of minors of order m:

$$\det(AB) = \sum_{S\subseteq[n],\,|S|=m} \det A_{[m]S} \det B_{S[m]}.$$

If $m > n$, the sum is empty and $\det(AB) = 0$, in line with $\operatorname{rank}(AB) \leq n < m$. If $m = n$, there is one term, $\det A \det B$. For $A = B^{\mathsf{T}}$ over $\mathbb{R}$, it gives $\det\left(B^{\mathsf{T}}B\right) = \sum_S \left(\det B_{S[m]}\right)^2 \geq 0$. Exercise 5.5.52 proves the formula.

Exercises

Exercise 5.5.33. ROUTINE Let

$$A = \begin{pmatrix} 3 & 1 & 0 & 2 \\ 0 & 2 & 0 & 0 \\ 1 & 4 & 5 & 1 \\ 2 & 0 & 0 & 1 \end{pmatrix} \in \mathbb{Q}^{4\times 4}.$$

(a) Compute $\det A$ with cofactor expansions, choosing each row or column to keep the work small.

(b) For which primes p is the reduction of A modulo p invertible over $\mathbb{F}_p$?

Solution on page 1428

Exercise 5.5.34. ROUTINE Use cofactor expansion and induction on n to give another proof of Proposition 5.3.15: the determinant of an upper or lower triangular matrix is the product of its diagonal entries.

Solution on page 1428

Exercise 5.5.35. STANDARD For $t \in \mathbb{Q}$, consider the system $B(t)\mathbf{x} = \mathbf{y}$ with

$$B(t) = \begin{pmatrix} 1 & 1 & t \\ 1 & t & 1 \\ t & 1 & 1 \end{pmatrix}, \quad \mathbf{y} = (1, 2, 3).$$

(a) Show that $\det B(t) = -(t-1)^2(t+2)$. For which t does the system have exactly one solution?

(b) For those t, find x_2 with Cramer's rule.

(c) Show that for $t = 1$, every determinant $\det B_i(\mathbf{y})$ is 0, but the system has no solution. What happens for $t = -2$?

Solution on page 1429

Exercise 5.5.36. ROUTINE Construct a matrix $A \in \mathbb{Q}^{3\times 3}$ with integer entries, none of them 0, such that A^{-1} also has integer entries. Compute A^{-1} with the adjugate.

Solution on page 1429

Exercise 5.5.37. STANDARD Let $n \geq 2$ and let $B \in F^{n\times n}$ be upper triangular.

(a) Show that $\operatorname{adj} B$ is upper triangular, with diagonal entries $\prod_{k\neq i} b_{kk}$ for $i = 1, \ldots, n$.

(b) Deduce that if B is invertible, then B^{-1} is upper triangular with diagonal entries $b_{11}^{-1}, \ldots, b_{nn}^{-1}$.

Solution on page 1430

Exercise 5.5.38. STANDARD Let $n \geq 2$, $A, B \in F^{n\times n}$, and $c \in F$. Prove or disprove each statement. Where the answer depends on n, say how.

(a) $\operatorname{adj}\left(A^{\mathsf{T}}\right) = (\operatorname{adj} A)^{\mathsf{T}}$.

(b) $\operatorname{adj}(cA) = c^{n-1} \operatorname{adj} A$.

(c) $\operatorname{adj}(A + B) = \operatorname{adj} A + \operatorname{adj} B$.

(d) The map $\operatorname{adj} : F^{n\times n} \to F^{n\times n}$ is injective.

Solution on page 1431

Exercise 5.5.39. STANDARD Let $n \geq 2$ and $A \in F^{n\times n}$. Show that $\det(\operatorname{adj} A) = (\det A)^{n-1}$, including when A is not invertible.

Solution on page 1431

Exercise 5.5.40. HARD Let $n \geq 2$ and $A \in F^{n\times n}$. Show that

$$\operatorname{adj}(\operatorname{adj} A) = (\det A)^{n-2} A,$$

with the convention $0^0 = 1$ when $n = 2$. Prove it first for invertible A, and then for all A when F is infinite.

Solution on page 1432

Solution on page 1432

Exercise 5.5.41. HARD Let F be an infinite field and $A, B \in F^{n\times n}$. Show that $\operatorname{adj}(AB) = (\operatorname{adj} B)(\operatorname{adj} A)$. (The identity holds over every field, but the proof suggested here needs infinitely many scalars.)

Solution on page 1433

Exercise 5.5.42. STANDARD Here is a "proof" that for all $a, b, c \in F$,

$$D(a,b,c) = \det\begin{pmatrix} 1 & a & a^3 \\ 1 & b & b^3 \\ 1 & c & c^3 \end{pmatrix} = (b-a)(c-a)(c-b).$$

Fix distinct a and b. Expanding along the last row, $D(a,b,c)$ is a polynomial in c of degree at most 3. It vanishes at $c = a$ and at $c = b$, since the matrix then has two equal rows. The right side also vanishes exactly at $c = a$ and $c = b$. Two polynomials with the same roots are equal, so $D(a,b,c) = (b-a)(c-a)(c-b)$. If $a = b$, both sides are 0.

(a) Find the errors, and show that the claimed formula is false for $F = \mathbb{Q}$.

(b) Find and prove the correct formula.

Solution on page 1433

Exercise 5.5.43. ROUTINE Use Theorem 5.5.21 to give short proofs of the following, which Section 1.5 proved without determinants.

(a) If $\lambda_1, \ldots, \lambda_k \in F$ are distinct, then the sequences $\mathbf{s}_{\lambda_i} = \left(1, \lambda_i, \lambda_i^2, \ldots\right)$ are linearly independent (Exercise 1.5.44).

(b) If $\lambda_1, \ldots, \lambda_k \in \mathbb{R}$ are distinct, then the functions $t \mapsto e^{\lambda_i t}$ are linearly independent in $\mathbb{R}^{\mathbb{R}}$ (Exercise 1.5.45).

Solution on page 1434

Exercise 5.5.44. HARD Let $c_0, \ldots, c_n \in F$ be distinct and $d_0, \ldots, d_n \in F$, and let $p \in F[x]_{\leq n}$ be the polynomial with $p(c_i) = d_i$ for all i (Theorem 3.4.24).

(a) Use Cramer's rule to show that the coefficient of x^n in p is

$$\sum_{i=0}^{n} \frac{d_i}{\prod_{j\neq i}(c_i - c_j)}.$$

(b) Deduce that $\sum_{i=0}^{n} c_i^m / \prod_{j\neq i}(c_i - c_j)$ is 0 for $0 \leq m < n$ and 1 for $m = n$.

Solution on page 1434

Exercise 5.5.45. HARD For $x \in \mathbb{R}$ and $n \geq 1$, let $M_n(x) \in \mathbb{R}^{n\times n}$ be tridiagonal with every diagonal entry equal to x and every entry directly above or below the diagonal equal to 1. Let $d_n(x) = \det M_n(x)$ and $d_0(x) = 1$.

(a) Show that $d_n(x) = xd_{n-1}(x) - d_{n-2}(x)$ for $n \geq 2$, and that $d_n(x) = P_n(x)$ for a polynomial $P_n \in \mathbb{R}[x]_{\leq n}$ with coefficient 1 of x^n.

(b) Show that if $x = 2\cos\theta$ with $0 < \theta < \pi$, then $d_n(x) = \sin((n+1)\theta)/\sin\theta$.

(c) Deduce that $M_n(x)$ is singular exactly for the n values $x = 2\cos(k\pi/(n+1))$, $k = 1, \ldots, n$, and that $d_n(x) = \prod_{k=1}^{n}(x - 2\cos(k\pi/(n+1)))$ for every $x \in \mathbb{R}$.

Solution on page 1435

Exercise 5.5.46. ROUTINE Find a matrix $A \in \mathbb{F}_3^{4\times 4}$ such that $\det(tI_4 - A) = t^4 + t + 2$ for every $t \in \mathbb{F}_3$. Then show that $tI_4 - A$ is invertible for every $t \in \mathbb{F}_3$.

Solution on page 1435

Exercise 5.5.47. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$.

(a) Show that $\det(I_m + AB) = \det(I_n + BA)$ (**Sylvester's determinant identity**). Hint: compute the determinant of $M = \begin{pmatrix} I_m & -A \\ B & I_n \end{pmatrix}$ in two ways.

(b) Deduce that $\det\left(I_n + \mathbf{u}\mathbf{v}^{\mathsf{T}}\right) = 1 + \mathbf{v}^{\mathsf{T}}\mathbf{u}$ for $\mathbf{u}, \mathbf{v} \in F^n$, and compute $\det(I_n + J)$, where every entry of J is 1.

Solution on page 1436

Exercise 5.5.48. HARD Let $n \geq 2$ and $A, B \in F^{n\times n}$.

(a) Show that there are scalars $e_0, \ldots, e_n \in F$, depending only on A and B, such that $\det(A + tB) = e_0 + e_1 t + \cdots + e_n t^n$ for every $t \in F$, with $e_0 = \det A$, $e_n = \det B$, and

$$e_1 = \operatorname{tr}(\operatorname{adj}(A)B).$$

(b) Deduce that the coefficient of t in $\det(A + tI_n)$ (in the sense of Proposition 5.3.19) is $\sum_{i=1}^{n} \det A_{\hat{i}\hat{i}}$, the sum of the minors along the diagonal.

Solution on page 1436

Exercise 5.5.49. STANDARD Let $n \geq 2$, $B \in F^{n\times n}$, and $\mathbf{y} \in F^n$. Prove or disprove:

(a) If $\det B = 0$ and $\det B_i(\mathbf{y}) \neq 0$ for some i, then $B\mathbf{x} = \mathbf{y}$ has no solution.

(b) If $\det B = 0$ and $\det B_i(\mathbf{y}) = 0$ for every i, then $B\mathbf{x} = \mathbf{y}$ has a solution.

(c) If $F = \mathbb{Q}$, B and $\mathbf{y}$ have integer entries, and $\det B \neq 0$, then the solution of $B\mathbf{x} = \mathbf{y}$ has integer entries.

(d) If $\det B \neq 0$ and $\det B_i(\mathbf{y}) = 0$ for every i, then $\mathbf{y} = \mathbf{0}$.

Solution on page 1437

Exercise 5.5.50. STANDARD

(a) Compute $\det V(1, i, -1, -i)$ over $\mathbb{C}$ with Theorem 5.5.21.

(b) Let $V = V(1, i, -1, -i)$ and $\omega = i$, so V has $(j+1, k+1)$ entry ω^{jk} for $0 \leq j, k \leq 3$. Show that $V^2 = 4P$ for a permutation matrix P with $\det P = -1$, and use this to check (a) up to sign.

(c) In $\mathbb{F}_5$, the element 2 satisfies $2^4 = 1$, and its powers are $1, 2, 4, 3$. Compute $\det V(1, 2, 4, 3)$ in $\mathbb{F}_5$.

Solution on page 1437

Exercise 5.5.51. HARD BEYOND 21-242 Let $n \geq 2$ and $A \in F^{n\times n}$. Show that

$$\operatorname{rank}(\operatorname{adj} A) = \begin{cases} n \text{ if } \operatorname{rank} A = n \\ 1 \text{ if } \operatorname{rank} A = n-1 \\ 0 \text{ if } \operatorname{rank} A \leq n-2. \end{cases}$$

Solution on page 1438

Exercise 5.5.52. HARD BEYOND 21-242 Prove the Cauchy–Binet formula of Remark 5.5.32: for $A \in F^{m\times n}$ and $B \in F^{n\times m}$,

$$\det(AB) = \sum_{S\subseteq[n],\,|S|=m} \det A_{[m]S} \det B_{S[m]}.$$

Solution on page 1438

Exercise 5.5.53. CHALLENGE Let $x_1, \ldots, x_n, y_1, \ldots, y_n \in F$ with $x_i + y_j \neq 0$ for all i, j, and let $C_n \in F^{n\times n}$ have entries $1/(x_i + y_j)$.

(a) Show that

$$\det C_n = \frac{\prod_{1\leq i<j\leq n}(x_j - x_i)(y_j - y_i)}{\prod_{i,j=1}^{n}(x_i + y_j)}.$$

(b) Deduce that the Hilbert matrix $H_n \in \mathbb{Q}^{n\times n}$, with entries $1/(i+j-1)$, is invertible, and compute $\det H_3$.

Solution on page 1439

5.6 Proof patterns

The chapter described the determinant in four ways: as the only function satisfying three axioms (Definition 5.1.1, Theorem 5.3.4), as the Leibniz sum over permutations (Theorem 5.3.3), as the product of the factors collected while eliminating (Proposition 5.4.21), and as a cofactor expansion (Theorem 5.5.3). Most proofs in the chapter start by choosing one of these descriptions, and the choice decides how long the proof is. This section sorts the chapter's arguments by the question they answer, compares the descriptions on examples from the chapter, and says when each one is the wrong tool. The exercises at the end practice one move at a time, and the problem set (Problems for Chapter 5) mixes them.

5.6.1 Computing a determinant

For a matrix of numbers with no visible structure, use elimination (Algorithm 5.4.22). It takes about $n^3/3$ operations, while the Leibniz formula and a full cofactor expansion take on the order of $n!$ (Remark 5.4.25). Structure changes this, so look for it first. Roughly in order of how quickly they finish:

- *A known form.* Triangular and block-triangular matrices (Proposition 5.3.15, Corollary 5.4.27), permutation and monomial matrices (Theorem 5.2.31, Exercise 5.2.44), Vandermonde matrices (Theorem 5.5.21), and companion matrices (Proposition 5.5.20). Sometimes the form appears only after the rows or columns are reordered, which costs a sign (Exercise 5.3.37).
- *Few nonzero entries.* Ask which permutations avoid every zero (Technique 5.3.12). Often only a few terms survive: one in Example 5.6.2 below, and four of the 24 in Exercise 5.3.24. A row or column with one or

two nonzero entries calls for a cofactor expansion along it (Example 5.5.4), possibly after replacements that create the zeros.
- *A family.* If deleting the last row and column leaves a smaller member of the same family, expand to get a recurrence (Technique 5.5.17), as for tridiagonal and companion matrices (Proposition 5.5.18, Proposition 5.5.20).
- *Parameters.* When the entries are polynomials in some parameters, use replacements that expose a common factor (Technique 5.5.22), as for constant row sums (Example 5.4.24) and powers of a node (Theorem 5.5.21). If the answer should be a product of linear factors, its roots can be found before any computation (Technique 5.5.24).
- *A product.* If every entry is a sum of products, the matrix may factor, and then so does its determinant.

The last item has not been named yet, although several exercises of the chapter rely on it.

Technique 5.6.1 (Factor the matrix). To compute $\det M$, write M as a product of matrices whose determinants are known, and multiply (Theorem 5.4.10). There are two common sources of factorizations. If every entry is a sum of products, $m_{ij} = \sum_k x_{ik} d_k y_{kj}$, then $M = XDY$ with $D = \operatorname{diag}(d_1, \ldots, d_r)$, and X and Y are often triangular or Vandermonde matrices. If M is a block matrix, block row and column operations (Theorem 2.4.34) multiply it by matrices of determinant 1 until it is block triangular. When the inner size r is smaller than the size of M, the same factorization shows $\det M = 0$ instead (Exercise 5.4.38). For instance, the matrix with entries $1 + x_i y_j$ is XY with rows $(1, x_i)$ in X and columns $(1, y_j)$ in Y. For two rows this gives $(x_2 - x_1)(y_2 - y_1)$, and for three or more rows it gives 0.

Reach for it when the entries are power sums, binomial expansions, or sums over divisors, or when one block of a block matrix can be cleared. The chapter used it in Exercise 5.4.43, Exercise 5.4.46, and Exercise 5.5.47. The canonical example is the Hankel matrix of power sums, which is $V^{\mathsf{T}}V$ for a Vandermonde matrix V (Problem 5.9).

Used in. Exercise 5.6.7, Problem 5.9, Problem 5.12, Problem 5.13, Problem 5.19, Problem 5.20, Problem 7.18.

Example 5.6.2 (One determinant, three ways). Let

$$A = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 2 & 0 & 3 & 0 \\ 0 & 4 & 0 & 5 \\ 0 & 0 & 6 & 0 \end{pmatrix} \in \mathbb{Q}^{4\times 4}.$$

Counting the surviving terms. A term $\operatorname{sgn}(\sigma) a_{\sigma(1)1} \cdots a_{\sigma(4)4}$ is nonzero only if all four entries are. The only nonzero entry of column 1 is in row 2, so $\sigma(1) = 2$, and column 4 forces $\sigma(4) = 3$. Then column 2, with nonzero entries in rows 1 and 3, must use row 1, and column 3 must use row 4. Exactly one permutation survives, $\sigma = (1\ 2)(3\ 4)$, which is even. So

$$\det A = a_{21} a_{12} a_{43} a_{34} = 2 \cdot 1 \cdot 6 \cdot 5 = 60.$$

A recurrence. A is the tridiagonal matrix of Proposition 5.5.18 with every $a_k = 0$, $(b_1, b_2, b_3) = (1, 3, 5)$, and $(c_1, c_2, c_3) = (2, 4, 6)$. The recurrence becomes $d_m = -b_{m-1} c_{m-1} d_{m-2}$, so $d_1 = 0$, $d_2 = -2$, $d_3 = 0$, and $d_4 = -30 \cdot (-2) = 60$.

Elimination. Swap rows 1 and 2. Subtracting 4 times the new row 2 from row 3 turns row 3 into $(0, 0, 0, 5)$, and swapping rows 3 and 4 leaves an upper triangular matrix with diagonal $2, 1, 6, 5$. There were two swaps, so $\det A = 60$.

Elimination always works, but here it spends its steps on swaps and does not explain why the answer is a product of entries. The recurrence treats the whole family at once, and shows for example that $d_n = 0$ for every odd n. The count explains why: since the only nonzero entries are next to the diagonal, a surviving σ sends every odd index to an even one and every even index to an odd one, and when n is odd there are

more odd indices than even ones. On a dense matrix the same count lists all $n!$ permutations, and there it is the wrong tool.

Practice: Exercise 5.6.6 and Exercise 5.6.7.

5.6.2 Proving an identity for every matrix

Four arguments recur in the chapter. They differ in what they ask of the identity, and in how they deal with matrices that are not invertible.

- *Recognize the determinant by its axioms* (Technique 5.4.11). If one side, as a function of the columns of a matrix B, is multilinear and alternating, then it is its value at I_n times $\det B$. There are no cases and no formulas. This proved Theorem 5.4.10 (second proof) and Proposition 5.3.17 (first proof). It needs an expression that is visibly linear in each column of something.
- *Reduce to elementary matrices* (Technique 5.4.6). Check the identity on the three types and show that it survives multiplication. It handles transposes, which the axioms do not reach, but it only reaches invertible matrices, and the others need a separate argument (Exercise 5.4.35).
- *Manipulate the Leibniz formula.* Reindex the sum over S_n (Proposition 5.2.8), or apply an operation to every term: transposing (second proof of Theorem 5.4.14), conjugating (Exercise 5.3.28), reducing modulo p (Proposition 5.3.20). It works when the identity matches the terms of one sum with the terms of another.
- *Polynomial identities* (Technique 5.5.24). Prove the identity for invertible matrices, replace A by $A + tI_n$, and observe that both sides are polynomial in t and agree for all but finitely many t. This needs more scalars than the degree plus the number of bad values of t, which is automatic only over an infinite field (Exercise 5.6.10).

Example 5.6.3 (Multiplicativity, three ways). The text proved $\det(AB) = \det A \det B$ twice. The first proof (Technique 5.4.6) factors B into elementary matrices and needs a separate argument when B is not invertible: then AB is not invertible either, and both sides are 0. The second (Technique 5.4.11) notices that $B \mapsto \det(AB)$ is multilinear and alternating in the columns of B, so it equals $\det(AI_n)\det B$.

A third proof makes the second one explicit. Column j of AB is $A\mathbf{b}_j = \sum_k b_{kj}\mathbf{a}_k$ (Proposition 2.4.8). Expanding every column as in Lemma 5.3.2, but with $\mathbf{a}_k$ in place of $\mathbf{e}_k$,

$$\det(AB) = \sum_{f\in[n]^{[n]}} b_{f(1)1}\cdots b_{f(n)n}\det\bigl(\mathbf{a}_{f(1)},\dots,\mathbf{a}_{f(n)}\bigr).$$

The terms with f not injective have a repeated column and vanish. For a permutation σ, $\det\bigl(\mathbf{a}_{\sigma(1)},\dots,\mathbf{a}_{\sigma(n)}\bigr) = \operatorname{sgn}(\sigma)\det A$ by Theorem 5.2.31. So

$$\begin{aligned}\det(AB) &= \det A \sum_{\sigma\in S_n} \operatorname{sgn}(\sigma) b_{\sigma(1)1}\cdots b_{\sigma(n)n}\\ &= \det A \det B.\end{aligned}$$

The same computation, with $\mathbf{e}_k$ in place of $\mathbf{a}_k$, proved Theorem 5.3.3; the second proof quotes its outcome, Theorem 5.3.4, instead of repeating it. Run on a rectangular A and B, the same expansion gives the Cauchy–Binet formula (Exercise 5.5.52), which neither of the first two proofs reaches.

The wrong tool here is the Leibniz formula applied to the entries of AB: each entry is a sum of n products, each of the $n!$ terms multiplies out into n^n products, and the cancellation is invisible. For $\det A^{\mathsf{T}} = \det A$ the roles change. There the axioms are the wrong tool, since the multilinearity in rows that Technique 5.4.11 would need is what the theorem is supposed to establish, while elementary matrices and the Leibniz formula both work (Intuition (What the two proofs see)).

Matrices that are not invertible were handled in three ways. In Theorem 5.4.10, both sides are 0 on them. In Exercise 5.5.40, a polynomial in t carries the identity from $A + tI_n$ to A, provided the field is infinite, and a separate rank argument covers every field. Proofs by the axioms never meet the case at all, which is one reason to prefer them when they apply. Practice: Exercise 5.6.8, Exercise 5.6.9, and Exercise 5.6.11.

5.6.3 Showing that a determinant is nonzero

By Theorem 5.4.7, "$\det A \neq 0$" and "A is invertible" are the same statement, so either can be proved by proving the other.

- *A product of nonzero factors.* A triangular matrix with nonzero diagonal, a Vandermonde matrix with distinct nodes, or any product of such matrices has nonzero determinant, since a field has no zero divisors (Proposition 1.1.17).
- *Reduce modulo a prime* (Technique 5.3.21). For an integer matrix, one prime p with $\det \overline{A} \neq 0$ in $\mathbb{F}_p$ suffices (Example 5.3.22). The converse inference fails: $\det \overline{A} = 0$ says only that p divides $\det A$.
- *A polynomial in a parameter* (Technique 5.3.18). A polynomial of degree n has at most n roots, so $A + tI_n$ is invertible for all but at most n values of t (Proposition 5.3.19). To show that such a polynomial is not the zero polynomial, one nonzero coefficient or one nonzero value is enough.
- *The kernel instead of the determinant.* Show that $A\mathbf{x} = \mathbf{0}$ forces $\mathbf{x} = \mathbf{0}$ (Corollary 5.4.8). This is often the shortest route, and sometimes the only one available.
- *A single surviving term.* If exactly one permutation avoids the zeros of A, then $\det A$ is $\pm$ a product of nonzero entries (Exercise 5.3.30).

To show $\det A = 0$, exhibit a dependence among the rows or columns, possibly after replacements; find a block of zeros that is too large (Exercise 5.3.29); factor A through a smaller size (Exercise 5.4.38); or use a symmetry, such as $\det A = \det A^{\mathsf{T}} = -\det A$ for skew-symmetric A of odd size (Exercise 5.4.33). The symmetry argument divides by $1 + 1$, and Exercise 5.6.13 replaces it by a pairing that does not.

Example 5.6.4 (One matrix, four certificates). Let $n \geq 2$, let $J \in \mathbb{Q}^{n\times n}$ have every entry equal to 1, and let $A = J - I_n$, with 0 on the diagonal and 1 elsewhere.

The determinant. Example 5.4.24 with $x = 0$ gives $\det A = (n-1)(-1)^{n-1} \neq 0$.

The kernel. Suppose $A\mathbf{x} = \mathbf{0}$, and let $s = x_1 + \cdots + x_n$. Row i of the system says $s - x_i = 0$. So every x_i equals s, hence $s = ns$, that is, $(n-1)s = 0$, and $s = 0$. So $\mathbf{x} = \mathbf{0}$.

An inverse. Since $J^2 = nJ$,

$$\begin{aligned}(J - I_n)(J - (n-1)I_n) &= nJ - (n-1)J - J + (n-1)I_n \\ &= (n-1)I_n,\end{aligned}$$

so $A^{-1} = (n-1)^{-1}(J - (n-1)I_n)$ (Technique 2.5.16).

Modulo 2. For even n, the reduction of A is invertible over $\mathbb{F}_2$ (Exercise 5.3.40), so $\det A$ is odd. For odd n, every row of A has the even sum $n - 1$, so the reduction sends $(1, \ldots, 1)$ to $\mathbf{0}$, and this route gives no information.

The determinant contains the most information. The kernel argument is the shortest, needs no formula, and shows exactly where the hypothesis enters: over a field in which $n - 1 = 0$, the vector $(1, \ldots, 1)$ lies in the kernel. The inverse is the strongest certificate, and finding it used the algebra of J, not determinants. Reducing modulo a prime suits matrices whose pattern is simple modulo that prime, and this one is simple modulo 2 only for even n.

Practice: Exercise 5.6.12 and Exercise 5.6.13.

5.6.4 Signs of permutations

There are three ways to compute $\operatorname{sgn}(\sigma)$: count the factors of any factorization into transpositions, count inversions (Corollary 5.2.24), or read off the lengths of the cycles (Proposition 5.2.26). Cycles are the quickest when σ is given in cycle notation, and inversions when it is given by its bottom row. In determinant computations, signs come from reordering rows or columns, and there it usually pays to count adjacent interchanges. That is how the cofactor sign $(-1)^{i+j}$ arose (Lemma 5.5.2), and how a cyclic shift of n columns costs $(-1)^{n-1}$ (Exercise 5.2.34).

Example 5.6.5 (Moving a block, three ways). Let $n = k + m$, and let $\pi \in S_n$ have bottom row $m+1, \ldots, m+k, 1, \ldots, m$, the permutation that moves the block $\begin{pmatrix} 0 & A \\ B & 0 \end{pmatrix}$ into block-diagonal form in Exercise 5.3.37.

Inversions. A pair of positions is out of order exactly when the first lies among the first k positions and the second among the last m, so $\operatorname{inv}(\pi) = km$ and $\operatorname{sgn}(\pi) = (-1)^{km}$.

Adjacent interchanges. Each of the m entries $1, \ldots, m$ moves to the front past each of the k larger entries, one adjacent interchange at a time: km interchanges.

Cycles. π adds m modulo n, so its cycles all have length $n/\gcd(n,m)$, there are $\gcd(n,m)$ of them, and $\operatorname{sgn}(\pi) = (-1)^{n-\gcd(n,m)}$. This is correct, but it depends on number theory, and checking that it agrees with $(-1)^{km}$ takes a parity argument about greatest common divisors. Cycle notation is the wrong tool for this permutation.

The definition of sgn through transpositions makes multiplicativity a one-line proof (Proposition 5.2.25), while proving it from inversions takes real work (Exercise 5.2.49). In general, define an invariant through the description in which its main property is easy, and compute it through the description in which it is quick.

Sums over S_n with signs are evaluated by pairing terms of opposite sign (Technique 5.3.5). Pairing σ with $\sigma\tau$ for a fixed transposition τ proved that L is alternating (Theorem 5.3.4) and that half of all permutations are even (Proposition 5.2.27). Pairing σ with σ^{-1} handles alternating matrices (Exercise 5.6.13). Parity also proves that some configurations cannot be reached (Technique 5.2.19): the 15 puzzle (Exercise 5.2.47) and the rotation puzzle (Exercise 5.2.48). Practice: Exercise 5.6.14.

5.6.5 Reading the chapter's proofs

Uniqueness first, then existence. The existence proof was found backwards. We assumed that a determinant function exists and asked what it would have to be. Expanding every column (Lemma 5.3.2), letting alternation kill the terms with a repeated column, and sorting the survivors (Theorem 5.2.31) produced Theorem 5.3.3: at most one candidate, given by a formula. Only then did Section 5.3.2 verify that the candidate satisfies the axioms. The 2×2 case went the same way (Theorem 5.1.13). The derivation also showed what existence requires: sorting the columns must produce a well-defined sign, which is the parity theorem (Remark 5.2.32). This is the "derive the formula" move of Section 1.7.2 on a larger scale. The verification also shows where the difficulty lay. Normalization and multilinearity can be checked one term at a time, but alternation cannot, because equal columns do not force any single term to vanish.

Pairing instead of reindexing. Reindexing the Leibniz sum by $\sigma \mapsto \sigma\tau$ shows $L(A) = -L(A)$, which gives $L(A) = 0$ only after dividing by $1 + 1$. Pairing each σ with $\sigma\tau$ writes $L(A)$ as a sum of pairs that cancel, and never divides (Intuition (Why alternation needs care)). The same distinction separates antisymmetry from alternation (Proposition 5.1.11, Example 5.1.12), and it is the reason the definition asks for alternation. An argument that ends with "$x = -x$, so $x = 0$" has used $1 + 1 \neq 0$ and should say so.

Tracking which axiom is used. Theorem 5.1.13 kept $D(I_2)$ as an unknown and obtained a statement about every multilinear alternating function at no extra cost. The same bookkeeping showed that dependent columns force $D(A) = 0$ without normalization (Proposition 5.1.17), while the converse fails for $D = 0$. So

every proof of Theorem 5.4.7 must use normalization somewhere, and the proof in the text uses it through Proposition 5.4.1.

Columns first. The axioms speak about columns, so every statement about rows waited for Theorem 5.4.14 (Corollary 5.4.15, Technique 3.2.27). Statements that mix rows and columns, such as cofactor expansion, were proved for rows and transposed, or proved with whichever kind of operation was convenient.

5.6.6 Common errors

Most of these appear in the chapter as find-the-error exercises.

- *det is not linear.* In general $\det(A+B) \neq \det A + \det B$, and $\det(cA) = c^n \det A$ (Exercise 5.1.21, Exercise 5.3.26, Remark 5.1.4). Multilinear means linear in one column at a time. In the same way, a 2×2 block matrix is not a 2×2 matrix of numbers (Exercise 5.4.36).
- *Sarrus for larger matrices.* The rule of Sarrus is a coincidence of size 3 (Remark 5.3.11, Exercise 5.3.25).
- *The sign of a cofactor.* The sign $(-1)^{i+j}$ comes from $i-1$ and $j-1$ adjacent interchanges. Interchanging row i with row 1 directly puts the old row 1 out of order, and for $i \geq 3$ what remains is not the minor $B_{\hat{i}\hat{j}}$ (Exercise 5.6.15). Forgetting the checkerboard altogether is the commoner version.
- *Row operations that scale.* Replacing row i by 2 times row i minus 3 times row 1 doubles the determinant (Exercise 5.4.16).
- *Factoring a singular matrix.* Only invertible matrices are products of elementary matrices (Exercise 5.4.35).
- *A converse for arbitrary D.* A multilinear alternating D can vanish on invertible matrices (Exercise 5.1.22).
- *Circularity.* The existence proof in Section 5.3.2 rests on the parity theorem, so quoting Theorem 5.3.4 to prove that theorem is circular (Exercise 5.2.38).
- *Inversions under a transposition.* They change by an odd number, not always by 1 (Exercise 5.2.35).
- *Polynomial arguments.* Roots determine a polynomial only together with its leading coefficient (Exercise 5.5.42), and agreement at "all but finitely many points" proves nothing over a small finite field (Exercise 5.6.10).
- *Reducing modulo p in the wrong direction.* $\det \overline{A} = 0$ in $\mathbb{F}_p$ does not make A singular over $\mathbb{Q}$ (Technique 5.3.21, Exercise 5.3.36).
- *Hidden division by* $1+1$. Antisymmetry does not imply alternation over $\mathbb{F}_2$ (Example 5.1.12), and neither does $\det A = -\det A$ imply $\det A = 0$ (Exercise 5.4.33).

Exercises

Exercise 5.6.6. ROUTINE For each matrix, choose a method, say why it fits, and compute the determinant.

(a) $A = \begin{pmatrix} 2 & 1 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 & 0 \\ 7 & 3 & 1 & 2 & 0 \\ -4 & 5 & 0 & 1 & 3 \\ 9 & 9 & 4 & 0 & 1 \end{pmatrix} \in \mathbb{Q}^{5\times 5}$.

(b) $B(x) = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & x & 1 & 1 \\ 1 & 1 & x & 1 \\ 1 & 1 & 1 & x \end{pmatrix}$, for $x \in F$.

(c) $C = \begin{pmatrix} 0 & 0 & 0 & 3 \\ 0 & 0 & 2 & 0 \\ 0 & 5 & 0 & 0 \\ 1 & 0 & 0 & 7 \end{pmatrix} \in \mathbb{Q}^{4\times 4}$.

Solution on page 1440

Exercise 5.6.7. STANDARD For $n \geq 1$, let $P_n \in \mathbb{Q}^{n\times n}$ have entries $p_{ij} = \binom{i+j-2}{i-1}$, so that

$$P_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{pmatrix}.$$

(a) Show that $\det P_n = 1$ for every n. You may use Pascal's rule $\binom{m}{k} = \binom{m-1}{k} + \binom{m-1}{k-1}$ for $m, k \geq 1$, and $\binom{m}{k} = 0$ for $0 \leq m < k$.

(b) Deduce that P_n^{-1} has integer entries, and compute P_3^{-1}.

Solution on page 1440

Solution on page 1441

Exercise 5.6.8. STANDARD Let $A \in F^{n\times n}$. For $X \in F^{n\times n}$ with columns $\mathbf{x}_1, \ldots, \mathbf{x}_n$, let

$$D(X) = \sum_{j=1}^{n} \det\bigl(\mathbf{x}_1, \ldots, \mathbf{x}_{j-1}, A\mathbf{x}_j, \mathbf{x}_{j+1}, \ldots, \mathbf{x}_n\bigr),$$

the sum of the determinants obtained by applying A to one column at a time.

(a) Show that $D(X) = (\operatorname{tr} A)\det X$ for every $X \in F^{n\times n}$.

(b) Deduce that for every multilinear alternating $E : F^{n\times n} \to F$,

$$\sum_{j=1}^{n} E\bigl(\mathbf{x}_1, \ldots, A\mathbf{x}_j, \ldots, \mathbf{x}_n\bigr) = (\operatorname{tr} A)E(\mathbf{x}_1, \ldots, \mathbf{x}_n).$$

Solution on page 1442

Exercise 5.6.9. HARD Let $A, B \in F^{n\times n}$ and $t \in F$. We show that

$$\det(tI_n - AB) = \det(tI_n - BA).$$

(a) Prove this when A is invertible.

(b) Let F be infinite. Fix t, and show that $g(s) = \det(tI_n - (A + sI_n)B) - \det(tI_n - B(A + sI_n))$ satisfies $g(s) = e_0 + e_1 s + \cdots + e_n s^n$ for some $e_0, \ldots, e_n \in F$ and all $s \in F$, and that $g(s) = 0$ for all but at most n values of s. Conclude that the identity holds for every A.

(c) Prove the identity over every field, using Exercise 5.5.47 when $t \neq 0$.

Solution on page 1443

Exercise 5.6.10. STANDARD Find the error in the following argument, and give a matrix $A \in \mathbb{F}_2^{2\times 2}$ for which its key step fails. (The claim itself is true over every field; see the second approach to Exercise 5.5.40.)

Claim. For every field F, every $n \geq 2$, and every $A \in F^{n\times n}$, $\operatorname{adj}(\operatorname{adj} A) = (\det A)^{n-2}A$, with the convention $0^0 = 1$ when $n = 2$.

Proof. For invertible A this is a short computation (Exercise 5.5.40). For general A, the entries of $\operatorname{adj}(\operatorname{adj}(A + tI_n))$ and of $\det(A + tI_n)^{n-2}(A + tI_n)$ are polynomial functions of t. They agree whenever $A + tI_n$ is invertible, that is, for all but at most n values of t. Polynomial functions that agree at all but finitely many points are equal, so they also agree at $t = 0$.

Solution on page 1443

Exercise 5.6.11. STANDARD

(a) Let $A \in \mathbb{R}^{n\times n}$ be invertible. Show that $\det A > 0$ if and only if A is a product of replacement matrices E_{icj} and scaling matrices E_{ic} with $c > 0$.

(b) Write the swap $E_{12} \in \mathbb{R}^{2\times 2}$ as a product of three replacements and one scaling, and explain why some factor must be a scaling by a negative number.

Solution on page 1444

Exercise 5.6.12. STANDARD Prove each statement, choosing a suitable certificate of invertibility.

(a) The matrix $A \in \mathbb{Q}^{4\times 4}$ with entries $a_{ij} = i^j$ is invertible.

(b) For $x \in \mathbb{R}$, let $M(x) = \begin{pmatrix} x & 1 & 0 \\ 1 & x & 1 \\ 0 & 1 & x+1 \end{pmatrix}$. Then $M(x)$ is invertible for every integer x, but not for every real x.

(c) For every $A \in \mathbb{R}^{m\times n}$, the matrix $I_n + A^{\mathsf{T}}A$ is invertible. (For $\mathbf{v} \in \mathbb{R}^n$, $\mathbf{v}^{\mathsf{T}}\mathbf{v} = v_1^2 + \cdots + v_n^2$.)

(d) For every $A \in \mathbb{Q}^{n\times n}$, the matrix $A + tI_n$ is invertible for some integer t with $0 \le t \le n$.

Solution on page 1444

Exercise 5.6.13. HARD Call $A \in F^{n\times n}$ *alternating* if $a_{ii} = 0$ and $a_{ji} = -a_{ij}$ for all i, j. (When $1 + 1 \neq 0$ this means skew-symmetric; over $\mathbb{F}_2$ it means symmetric with zero diagonal.) Let n be odd and A alternating, and write $t_\sigma(A) = \operatorname{sgn}(\sigma) a_{\sigma(1)1} \cdots a_{\sigma(n)n}$ for the terms of the Leibniz formula.

(a) Show that $t_{\sigma^{-1}}(A) = -t_\sigma(A)$ for every $\sigma \in S_n$.

(b) Show that if $\sigma^2 = \mathrm{id}$, then σ has a fixed point, and $t_\sigma(A) = 0$.

(c) Deduce that $\det A = 0$, over every field.

(d) Exercise 5.4.33 proved (c) when $1 + 1 \neq 0$ by showing $\det A = -\det A$. Explain why that argument fails over $\mathbb{F}_2$, why this one does not, and where the hypothesis $a_{ii} = 0$ is used.

Solution on page 1445

Exercise 5.6.14. STANDARD Let $n \ge 1$, and let $\pi \in S_{2n}$ have $\pi(2i-1) = i$ and $\pi(2i) = n + i$ for $i = 1, \ldots, n$. Its bottom row is $1, n+1, 2, n+2, \ldots, n, 2n$, so the columns of ME_π interleave the first n columns of M with the last n (Proposition 5.2.30).

(a) Show that $\operatorname{inv}(\pi) = n(n-1)/2$.

(b) Write π in cycle notation for $n = 3$ and $n = 4$, and check (a) against Proposition 5.2.26.

(c) Let $A, B, C, D \in F^{n\times n}$ be diagonal, with diagonal entries a_i, b_i, c_i, d_i. Show that

$$\det \begin{pmatrix} A & B \\ C & D \end{pmatrix} = \prod_{i=1}^{n} (a_i d_i - b_i c_i).$$

Does the sign of π enter?

Solution on page 1446

Exercise 5.6.15. ROUTINE Find the error in the following argument, and show that its conclusion fails for

$$B = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \quad i = 3, \quad j = 1.$$

Claim. Let $n \ge 2$ and $B \in F^{n\times n}$. If every entry of row i of B other than b_{ij} is 0, then $\det B = \varepsilon b_{ij} \det B_{\hat{i}\hat{j}}$, where $\varepsilon = -1$ if exactly one of i and j equals 1, and $\varepsilon = 1$ otherwise.

Proof. Interchange rows 1 and i (if $i \neq 1$), and then columns 1 and j (if $j \neq 1$). Each interchange negates the determinant. The resulting matrix has b_{ij} in position $(1,1)$ and zeros in the rest of row 1, so it is block lower triangular, and by Theorem 5.4.26 its determinant is b_{ij} times the determinant of its lower right block, which is $B_{\hat{i}\hat{j}}$.

Solution on page 1447

Problems for Chapter 5

These problems combine the sections of Chapter 5 with each other and with earlier chapters. The first three are review prompts: state the result, prove it without looking, and then answer a follow-up question that the text did not ask. The rest are ordered roughly by difficulty. Problems of kind "competition" are harder than anything the course expects. Section 5.6 compares the methods these problems call for.

Review: state and prove

Problem 5.1. STANDARD

(a) State the theorem on the existence and uniqueness of determinant functions, including its description of all multilinear alternating functions on $F^{n\times n}$.

(b) Prove that the function L of (5.3.1) is alternating, by an argument that works over every field.

(c) Let $n \geq 2$ and $F = \mathbb{F}_2$, and define $D(A) = \det A + a_{11}a_{12}\cdots a_{1n}$ for $A \in \mathbb{F}_2^{n\times n}$. Show that D is normalized, multilinear, and antisymmetric (Definition 5.1.9), but not alternating. Explain why no such D exists over a field in which $1 + 1 \neq 0$.

Solution on page 1447

Problem 5.2. STANDARD

(a) State Theorem 5.4.7 and Theorem 5.4.10.

(b) Prove $\det(AB) = \det A \det B$ by recognizing the determinant by its axioms. Then deduce the implication "A invertible $\Rightarrow \det A \neq 0$" from it, without elementary matrices.

(c) For which $n \geq 1$ is there a matrix $A \in \mathbb{Q}^{n\times n}$ with $A^2 = 2I_n$? What changes over $\mathbb{R}$?

Solution on page 1448

Problem 5.3. STANDARD

(a) State Cramer's rule.

(b) Let $B \in F^{n\times n}$ and $\mathbf{y} \in F^n$, with no assumption on $\det B$. Prove that every solution of $B\mathbf{x} = \mathbf{y}$ satisfies $x_i \det B = \det B_i(\mathbf{y})$ for $i = 1, \ldots, n$, where $B_i(\mathbf{y})$ is B with column i replaced by $\mathbf{y}$. Deduce Cramer's rule.

(c) Let $B \in \mathbb{Q}^{n\times n}$ have integer entries and $d = \det B \neq 0$. Show that for every $\mathbf{y}$ with integer entries, the solution of $B\mathbf{x} = \mathbf{y}$ has $d\mathbf{x}$ integral. Show also that if $d \neq \pm 1$, then some $\mathbf{y}$ with integer entries has a solution that is not integral, and find one for $B = \begin{pmatrix} 2 & 1 \\ 1 & 3 \end{pmatrix}$.

Solution on page 1449

Synthesis problems

Problem 5.4. STANDARD Prove or disprove each statement.

(a) If $A, B \in \mathbb{R}^{n\times n}$, with $n \geq 2$, have positive determinants, then so does $A + B$.

(b) If $A \in F^{n\times n}$ satisfies $A^3 = A$, then $\det A \in \{-1, 0, 1\}$.

(c) If $A \in F^{m\times n}$, then $\det\left(A^{\mathsf{T}}A\right) = \det\left(AA^{\mathsf{T}}\right)$.

(d) If every row of $A \in F^{n\times n}$ sums to 0, then $\det A = 0$.

(e) If every row of $A \in F^{n\times n}$ sums to 1, then $\det A = 1$.

Solution on page 1450

Problem 5.5. STANDARD Let p be a prime.

(a) Count the symmetric matrices $\begin{pmatrix} a & b \\ b & d \end{pmatrix} \in \mathbb{F}_p^{2\times 2}$ with determinant 0.

(b) Count the matrices $A \in \mathbb{F}_p^{2\times 2}$ with $\operatorname{tr} A = 0$ and $\det A = 0$. Explain why the answers to (a) and (b) agree.

(c) Show that $A^2 - (\operatorname{tr} A)A + (\det A)I_2 = 0$ for every $A \in F^{2\times 2}$. Deduce that $A^2 = 0$ if and only if $\operatorname{tr} A = \det A = 0$, and count the $A \in \mathbb{F}_p^{2\times 2}$ with $A^2 = 0$.

Solution on page 1450

Problem 5.6. STANDARD For points $\mathbf{p}_1, \ldots, \mathbf{p}_m \in \mathbb{R}^2$ with $m \geq 3$, put $\mathbf{p}_{m+1} = \mathbf{p}_1$ and

$$S(\mathbf{p}_1, \ldots, \mathbf{p}_m) = \frac{1}{2}\sum_{k=1}^{m} \det(\mathbf{p}_k, \mathbf{p}_{k+1}),$$

where $\det(\mathbf{u}, \mathbf{v})$ is the determinant of the matrix with columns $\mathbf{u}$ and $\mathbf{v}$.

(a) Show that S does not change when every $\mathbf{p}_k$ is replaced by $\mathbf{p}_k + \mathbf{c}$, for a fixed $\mathbf{c} \in \mathbb{R}^2$.

(b) Show that $S(\mathbf{p}, \mathbf{q}, \mathbf{r}) = \frac{1}{2}\det(\mathbf{q} - \mathbf{p}, \mathbf{r} - \mathbf{p})$. This is the signed area of the triangle $\mathbf{pqr}$: its area, with a plus sign when $\mathbf{p}, \mathbf{q}, \mathbf{r}$ run counterclockwise (Example 5.1.15).

(c) Show that $S(\mathbf{p}_1, \ldots, \mathbf{p}_m) = \sum_{k=1}^{m} S(\mathbf{c}, \mathbf{p}_k, \mathbf{p}_{k+1})$ for every $\mathbf{c} \in \mathbb{R}^2$. Explain why S is the area of a convex polygon whose vertices $\mathbf{p}_1, \ldots, \mathbf{p}_m$ are listed counterclockwise. (Take for granted that the area of a region cut into triangles is the sum of their areas.)

(d) Find the area of the pentagon with vertices $(0, 0), (4, 0), (5, 3), (2, 5), (-1, 3)$.

Solution on page 1451

Problem 5.7. STANDARD Let $\mathbf{p}_0, \ldots, \mathbf{p}_n \in F^n$, and let $M \in F^{(n+1)\times(n+1)}$ have column $i + 1$ equal to $(1, \mathbf{p}_i)$, the entry 1 followed by the entries of $\mathbf{p}_i$.

(a) Show that $\det M = \det(\mathbf{p}_1 - \mathbf{p}_0, \ldots, \mathbf{p}_n - \mathbf{p}_0)$.

(b) Deduce that $\det M \neq 0$ if and only if $\mathbf{p}_1 - \mathbf{p}_0, \ldots, \mathbf{p}_n - \mathbf{p}_0$ are linearly independent.

(c) Suppose $\det M \neq 0$. Show that for each $\mathbf{x} \in F^n$ there are unique $\lambda_0, \ldots, \lambda_n \in F$ with $\lambda_0 + \cdots + \lambda_n = 1$ and $\lambda_0\mathbf{p}_0 + \cdots + \lambda_n\mathbf{p}_n = \mathbf{x}$, namely $\lambda_i = \det M_i / \det M$, where M_i is M with column $i + 1$ replaced by $(1, \mathbf{x})$.

(d) Let $F = \mathbb{R}$ and $n = 2$. Using Problem 5.6 (b), express each λ_i as a ratio of signed areas of triangles. Deduce that $\lambda_0, \lambda_1, \lambda_2 > 0$ exactly when the triangles $\mathbf{x}\mathbf{p}_1\mathbf{p}_2$, $\mathbf{p}_0\mathbf{x}\mathbf{p}_2$, and $\mathbf{p}_0\mathbf{p}_1\mathbf{x}$ have the same orientation as $\mathbf{p}_0\mathbf{p}_1\mathbf{p}_2$, and compute the λ_i for $\mathbf{x} = (1, 2)$ and the triangle with vertices $(0, 0), (4, 0), (0, 4)$.

Solution on page 1452

Problem 5.8. STANDARD Let $\alpha, \beta \in F$, and let $T \in \mathrm{L}(F^{n\times n})$ be $T(X) = \alpha X + \beta X^{\mathsf{T}}$. Write U_{ij} for the matrix units (Lemma 2.4.24).

(a) Suppose $1 + 1 \neq 0$ in F. Show that the matrices U_{ii}, $U_{ij} + U_{ji}$, and $U_{ij} - U_{ji}$ (for $i < j$) form a basis of $F^{n\times n}$ in which the matrix of T is diagonal, and deduce that

$$\det T = (\alpha + \beta)^{n(n+1)/2}(\alpha - \beta)^{n(n-1)/2}.$$

(b) Check (a) against Exercise 5.4.40.

(c) Show that the formula holds for $n = 2$ over every field, including $\mathbb{F}_2$, by using the basis $U_{11}, U_{12}, U_{21}, U_{22}$.

(d) Keep $1 + 1 \neq 0$. For which α, β is T invertible? Describe $\ker T$ when $\alpha = \beta \neq 0$.

Solution on page 1453

Problem 5.9. STANDARD Let $x_1, \ldots, x_n \in F$, let $s_k = x_1^k + \cdots + x_n^k$ for $k \geq 0$ (so $s_0 = 1 + \cdots + 1$, with n terms), and let $H \in F^{n\times n}$ be the *Hankel matrix* with (i, j) entry s_{i+j-2}:

$$H = \begin{pmatrix} s_0 & s_1 & \cdots & s_{n-1} \\ s_1 & s_2 & \cdots & s_n \\ \vdots & \vdots & \ddots & \vdots \\ s_{n-1} & s_n & \cdots & s_{2n-2} \end{pmatrix}.$$

(a) Show that $H = V^{\mathsf{T}}V$ for the Vandermonde matrix $V = V(x_1, \ldots, x_n)$, and deduce that $\det H = \prod_{1\leq i<j\leq n} (x_j - x_i)^2$.

(b) Check (a) directly for $n = 2$.

(c) Let $F = \mathbb{R}$. Show that $\det H \geq 0$, with equality exactly when two of the x_i coincide. Show by an example that $\det H$ can be negative when $F = \mathbb{C}$.

(d) Real numbers x_1, x_2, x_3 have $s_1 = 0$, $s_2 = 6$, $s_3 = 0$, and $s_4 = 18$. Are they distinct?

Solution on page 1454

Problem 5.10. STANDARD For $a \in F$ and $n \geq 1$, let $K_n \in F^{n\times n}$ have (i, j) entry $a^{|i-j|}$, where $a^0 = 1$. For example,

$$K_3 = \begin{pmatrix} 1 & a & a^2 \\ a & 1 & a \\ a^2 & a & 1 \end{pmatrix}.$$

(a) Show that $\det K_n = \left(1 - a^2\right)^{n-1}$.

(b) Compute $\operatorname{adj} K_3$, and find K_3^{-1} when $a^2 \neq 1$.

(c) Let $n \geq 2$ and $a^2 \neq 1$. Guess K_n^{-1} from (b), and verify your guess.

Solution on page 1454

Problem 5.11. HARD Call $N \in F^{n\times n}$ *nilpotent* if $N^k = 0$ for some $k \geq 1$.

(a) Find the error in the following argument, and show that its claim is false.

Claim. If $A \in F^{n\times n}$ is invertible and $N \in F^{n\times n}$ is nilpotent, then $A+N$ is invertible.

Proof. Write $A+N = A\big(I_n + A^{-1}N\big)$. Since N is nilpotent, so is $M = A^{-1}N$, say $M^k = 0$. Then

$$(I_n + M)\Big(I_n - M + M^2 - \cdots + (-1)^{k-1}M^{k-1}\Big)$$
$$= I_n + (-1)^{k-1}M^k = I_n,$$

so $I_n + M$ is invertible, and $A+N$ is a product of invertible matrices.

(b) Show that the claim is true when $AN = NA$.

(c) Let $N \in \mathbb{C}^{n\times n}$ be nilpotent. Show that $\det(I_n + N) = 1$. (Hint: $t \mapsto \det(I_n + tN)$ is a polynomial function of t with no zeros.)

(d) Deduce that if $A \in \mathbb{C}^{n\times n}$ is invertible, N is nilpotent, and $AN = NA$, then $\det(A+N) = \det A$.

Solution on page 1455

Problem 5.12. HARD Let $n \geq 2$ and $c_0, \ldots, c_{n-1} \in \mathbb{C}$, and let $C \in \mathbb{C}^{n\times n}$ be the *circulant* matrix whose rows are the successive cyclic shifts of $(c_0, c_1, \ldots, c_{n-1})$ to the right. With rows and columns indexed by $0, \ldots, n-1$, its (j,k) entry is $c_{(k-j) \bmod n}$; for $n = 3$,

$$C = \begin{pmatrix} c_0 & c_1 & c_2 \\ c_2 & c_0 & c_1 \\ c_1 & c_2 & c_0 \end{pmatrix}.$$

Let $f(z) = c_0 + c_1 z + \cdots + c_{n-1}z^{n-1}$ and $\omega = \cos(2\pi/n) + i\sin(2\pi/n)$. You may use that $1, \omega, \ldots, \omega^{n-1}$ are distinct, that each of them satisfies $z^n = 1$, and that $\omega^{n/2} = -1$ when n is even (Section B.1).

(a) For $0 \leq m \leq n-1$, let $\mathbf{v}_m = \big(1, \omega^m, \omega^{2m}, \ldots, \omega^{(n-1)m}\big)$. Show that $C\mathbf{v}_m = f(\omega^m)\mathbf{v}_m$.

(b) Deduce that $\det C = f(1)f(\omega)\cdots f\big(\omega^{n-1}\big)$.

(c) Deduce that $\det\begin{pmatrix} a & b & c \\ c & a & b \\ b & c & a \end{pmatrix} = (a+b+c)\big(a+\omega b+\omega^2 c\big)\big(a+\omega^2 b+\omega c\big)$, where $\omega = -\frac{1}{2} + \big(\sqrt{3}/2\big)i$.

(d) Let C have first row $(1, 1, 0, \ldots, 0)$. Show that C is singular if and only if n is even, and that $\det C = 2$ when n is odd.

Solution on page 1456

Problem 5.13. HARD Let $n \geq 1$, let $x_1, \ldots, x_n, y_1, \ldots, y_n \in F$, and let $M \in F^{n\times n}$ have entries $m_{ij} = \big(x_i + y_j\big)^{n-1}$.

(a) Show that

$$\det M = \prod_{k=0}^{n-1}\binom{n-1}{k} \cdot \prod_{1\leq i<j\leq n}(x_j - x_i)(y_i - y_j),$$

where the binomial coefficients are read as elements of F.

(b) Check (a) directly for $n = 2$.

(c) For $n = 3$, decide when M is invertible, over $\mathbb{Q}$ and over $\mathbb{F}_2$.

Solution on page 1457

Problem 5.14. HARD Let $T \in F^{n\times n}$ be tridiagonal, with diagonal entries $a_1, \ldots, a_n$, entries b_k in positions $(k, k+1)$, and entries c_k in positions $(k+1, k)$, as in Proposition 5.5.18.

(a) Show that the permutations $\sigma \in S_n$ with $|\sigma(j) - j| \le 1$ for every j are exactly the products of disjoint adjacent transpositions $(k\ k+1)$ (the empty product included).

(b) Show that there are F_{n+1} such permutations, where $F_1 = F_2 = 1$ and $F_{m+1} = F_m + F_{m-1}$ are the Fibonacci numbers.

(c) Call a set P of pairwise disjoint pairs $\{k, k+1\}$ a *matching* of $[n]$, and call i *unmatched* if it lies in no pair of P. Show that

$$\det T = \sum_{P} \prod_{\{k,k+1\}\in P} (-b_k c_k) \prod_{i \text{ unmatched}} a_i,$$

the sum over all matchings P of $[n]$.

(d) Derive the recurrence of Proposition 5.5.18 from (c). Explain the Fibonacci numbers in Example 5.5.19 (b) without computing.

Solution on page 1458

Problem 5.15. HARD Let $A \in \mathbb{Q}^{n\times n}$ have integer entries, with a_{ii} even for every i and $a_{ij} + a_{ji}$ even for all i, j. (For example, A could be symmetric with even diagonal, or skew-symmetric.)

(a) Show that if n is odd, then $\det A$ is even.

(b) Show that the conclusion of (a) fails for every even n.

(c) Show that the hypothesis on the diagonal cannot be dropped, and check (a) on $J + I_n$, where every entry of J is 1.

Solution on page 1458

Problem 5.16. HARD Let $A \in \mathbb{R}^{n\times n}$ be skew-symmetric, $A^{\mathsf{T}} = -A$.

(a) Show that $\mathbf{x}^{\mathsf{T}} A\mathbf{x} = 0$ for every $\mathbf{x} \in \mathbb{R}^n$, and deduce that $I_n + tA$ is invertible for every $t \in \mathbb{R}$.

(b) Show that $\det(I_n + A) > 0$. (Consider $t \mapsto \det(I_n + tA)$ on $[0, 1]$.)

(c) Compute $\det(I_n + A)$ for $n = 2$ and $n = 3$ in terms of the entries above the diagonal.

(d) Show that the conclusion of (b) can fail if A is only assumed to have $\operatorname{tr} A = 0$.

Solution on page 1459

Problem 5.17. HARD Let W be a subspace of $F^{n\times n}$ in which every nonzero matrix is invertible.

(a) Show that $\dim W \le n$. (Consider the vectors $X\mathbf{e}_1$ for X in a basis of W.)

(b) Show that $W = \left\{ \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \;\middle|\; a, b \in \mathbb{R} \right\}$ is a subspace of $\mathbb{R}^{2\times 2}$ with this property and $\dim W = 2$.

(c) Let $F = \mathbb{C}$ and $n \ge 2$. Show that $\dim W \le 1$. (Take independent $A, B \in W$ and look at $\det(A + tB)$.)

(d) Let $F = \mathbb{R}$ and let n be odd. Show that $\dim W \le 1$.

Solution on page 1459

Problem 5.18. HARD Let $x, a, b \in F$ with $a \ne b$, and let $T_n \in F^{n\times n}$ have every diagonal entry equal to x, every entry above the diagonal equal to a, and every entry below the diagonal equal to b. Show that

$$\det T_n = \frac{b(x-a)^n - a(x-b)^n}{b-a},$$

and check the formula for $n = 2$. (Hint: let J be the matrix with every entry 1, and show that $t \mapsto \det(T_n + tJ)$ is affine in t.)

Solution on page 1460

Problem 5.19. CHALLENGE

(a) Let $x_1, \dots, x_n \in F$, and for $k = 0, \dots, n-1$ let $p_k \in F[x]$ have degree k and coefficient 1 of x^k. Show that the $n \times n$ matrix with $(i, k+1)$ entry $p_k(x_i)$ has determinant $\prod_{1 \le i < j \le n} (x_j - x_i)$.

(b) Let $x_1, \dots, x_n$ be integers. Show that $\prod_{1 \le i < j \le n} (x_j - x_i)$ is divisible by $0! \cdot 1! \cdots (n-1)!$.

(c) Deduce that $\prod_{1 \le i < j \le n} \frac{x_j - x_i}{j - i}$ is an integer for all integers $x_1, \dots, x_n$.

Solution on page 1461

Problem 5.20. CHALLENGE Let $G_n \in \mathbb{Q}^{n \times n}$ have entries $g_{ij} = \gcd(i, j)$. For $d \ge 1$, let $\varphi(d)$ be the number of $k \in \{1, \dots, d\}$ with $\gcd(k, d) = 1$. You may use that $\sum_{d \mid m} \varphi(d) = m$ for every integer $m \ge 1$.

(a) Show that $G_n = L \Phi L^{\mathsf{T}}$, where $\Phi = \operatorname{diag}(\varphi(1), \dots, \varphi(n))$ and $L \in \mathbb{Q}^{n \times n}$ has (i, d) entry 1 if $d \mid i$ and 0 otherwise.

(b) Deduce that $\det G_n = \varphi(1)\varphi(2) \cdots \varphi(n)$, and evaluate $\det G_6$.

(c) Show that G_n is invertible for every n, and that G_n^{-1} has integer entries only for $n \le 2$.

Solution on page 1462

Chapter 6

Inner product spaces

Inner products and norms, Cauchy–Schwarz, orthonormal bases, projections, least squares, and adjoints.

6.1 Inner products and norms

In $\mathbb{R}^2$ the dot product $\mathbf{v} \cdot \mathbf{w} = v_1 w_1 + v_2 w_2$ knows the length of every vector and the angle between any two. This section takes the algebraic properties of the dot product that are responsible for this and makes them axioms. A vector space over $\mathbb{R}$ or $\mathbb{C}$ equipped with a product satisfying them, an inner product, acquires lengths and angles, even when its vectors are functions or matrices and there is no picture to look at.

6.1.1 Length and angle in $\mathbb{R}^2$

For $\mathbf{v} = (v_1, v_2)$ and $\mathbf{w} = (w_1, w_2)$ in $\mathbb{R}^2$, the **dot product** is

$$\mathbf{v} \cdot \mathbf{w} = v_1 w_1 + v_2 w_2 \in \mathbb{R}.$$

Draw $\mathbf{v}$ as an arrow from the origin. Its length $\|\mathbf{v}\|$ is the hypotenuse of a right triangle with legs $|v_1|$ and $|v_2|$, so by Pythagoras

$$\|\mathbf{v}\|^2 = v_1^2 + v_2^2 = \mathbf{v} \cdot \mathbf{v}.$$

Now let $\mathbf{v}$ and $\mathbf{w}$ be nonzero, and let $\theta \in [0, \pi]$ be the angle between them. The arrows $\mathbf{v}$ and $\mathbf{w}$, together with the arrow $\mathbf{v} - \mathbf{w}$ from the tip of $\mathbf{w}$ to the tip of $\mathbf{v}$, form a triangle (Figure 6.1.1), and the law of cosines says

$$\|\mathbf{v} - \mathbf{w}\|^2 = \|\mathbf{v}\|^2 + \|\mathbf{w}\|^2 - 2\|\mathbf{v}\|\|\mathbf{w}\| \cos\theta.$$

We can also expand the left side algebraically. The dot product is symmetric, $\mathbf{v} \cdot \mathbf{w} = \mathbf{w} \cdot \mathbf{v}$, and it is linear in each slot, so

$$\|\mathbf{v} - \mathbf{w}\|^2 = (\mathbf{v} - \mathbf{w}) \cdot (\mathbf{v} - \mathbf{w}) = \mathbf{v} \cdot \mathbf{v} - 2\mathbf{v} \cdot \mathbf{w} + \mathbf{w} \cdot \mathbf{w}.$$

Comparing the two expressions, and using $\|\mathbf{v}\|^2 = \mathbf{v} \cdot \mathbf{v}$ and $\|\mathbf{w}\|^2 = \mathbf{w} \cdot \mathbf{w}$, we get

$$\mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|\|\mathbf{w}\| \cos\theta. \tag{6.1.1}$$

So lengths and angles can both be read off from the dot product. In particular, $\mathbf{v}$ and $\mathbf{w}$ are perpendicular exactly when $\mathbf{v} \cdot \mathbf{w} = 0$, which is where Section 6.3 starts.

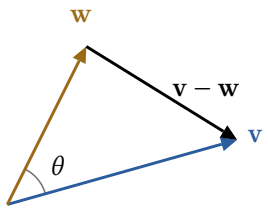

Figure 6.1.1. The triangle behind (6.1.1). Its sides have lengths $\|\mathbf{v}\|$, $\|\mathbf{w}\|$, and $\|\mathbf{v}-\mathbf{w}\|$, and the angle between the first two is θ.

Look at what the computation used: symmetry, linearity in each slot, and the fact that $\mathbf{v}\cdot\mathbf{v}$ is a nonnegative real number that vanishes only for $\mathbf{v}=\mathbf{0}$, so that $\|\mathbf{v}\|=\sqrt{\mathbf{v}\cdot\mathbf{v}}$ makes sense and is positive when $\mathbf{v}\neq\mathbf{0}$. Turned around, any product with these properties, on any vector space, lets us *define* the length of a vector as $\sqrt{\mathbf{v}\cdot\mathbf{v}}$, and (6.1.1) suggests a definition of the angle between two vectors. (Section 6.2 shows that the resulting value of $\cos\theta$ lies in $[-1,1]$.)

Which scalars?

The axioms will compare $\mathbf{v}\cdot\mathbf{v}$ with 0, and lengths are square roots. So the scalars need an order and square roots of their nonnegative elements. $\mathbb{R}$ has both, and the lack of either causes real trouble.

- In $\mathbb{Q}^2$, the vector $(1,1)$ would have length $\sqrt{2}\notin\mathbb{Q}$.
- In $\mathbb{F}_2^2$, the same formula gives $(1,1)\cdot(1,1)=1+1=0$, so a nonzero vector would have length 0. Ordering $\mathbb{F}_p$ cannot help: an order compatible with the field operations would force $0<1<1+1<\cdots<p\cdot 1=0$.
- In $\mathbb{C}^2$, $(1,i)\cdot(1,i)=1+i^2=0$, and $(1,1+i)\cdot(1,1+i)=1+2i$ is not even real.

$\mathbb{C}$ has no useful order either, but it contains $\mathbb{R}$, and the case $n=1$ shows how to land in $\mathbb{R}$. Viewing $z=a+bi$ as the point (a,b) of the plane, its length is $\sqrt{a^2+b^2}$, and $a^2+b^2=z\overline{z}$, not z^2. So on $\mathbb{C}^n$ we conjugate the second factor and use $\sum_k v_k\overline{w_k}$. Then $\mathbf{v}\cdot\mathbf{v}=\sum_k|v_k|^2$ is real and nonnegative, and the price is that symmetry becomes "conjugate symmetry". In this chapter the scalars are always real or complex.

Notation 6.1.1 (Real and complex scalars). Throughout Chapter 6, $\mathbb{F}$ denotes $\mathbb{R}$ or $\mathbb{C}$. For $z=a+bi\in\mathbb{C}$ with $a,b\in\mathbb{R}$, the **conjugate** of z is $\overline{z}=a-bi$, its **modulus** is $|z|=\sqrt{a^2+b^2}$, and its **real** and **imaginary parts** are $\operatorname{Re}z=a$ and $\operatorname{Im}z=b$. For all $z,w\in\mathbb{C}$,

$$\overline{z+w}=\overline{z}+\overline{w},\quad \overline{zw}=\overline{z}\,\overline{w},\quad \overline{\overline{z}}=z,$$
$$z\overline{z}=|z|^2,\quad z+\overline{z}=2\operatorname{Re}z,\quad \operatorname{Re}(-iz)=\operatorname{Im}z,$$

$|\operatorname{Re}z|\le|z|$, and $\overline{z}=z$ if and only if $z\in\mathbb{R}$. Each of these is checked by writing z and w in coordinates; Section B.1 develops conjugation and the modulus further. For real z, $\overline{z}=z$ and $|z|$ is the absolute value, so every formula in this chapter specializes to $\mathbb{R}$ by erasing the bars.

6.1.2 Inner products

Definition 6.1.2 (Inner product). Let V be a vector space over $\mathbb{F}$. An **inner product** on V is a function $V\times V\to\mathbb{F}$, written $(\mathbf{v},\mathbf{w})\mapsto\langle\mathbf{v},\mathbf{w}\rangle$, such that for all $\mathbf{v},\mathbf{w},\mathbf{x}\in V$ and all $a,b\in\mathbb{F}$:

- *Conjugate symmetry.* $\langle\mathbf{v},\mathbf{w}\rangle=\overline{\langle\mathbf{w},\mathbf{v}\rangle}$.
- *Linearity in the first slot.* $\langle a\mathbf{v}+b\mathbf{w},\mathbf{x}\rangle=a\langle\mathbf{v},\mathbf{x}\rangle+b\langle\mathbf{w},\mathbf{x}\rangle$.
- *Positivity.* $\langle\mathbf{v},\mathbf{v}\rangle\ge 0$.
- *Definiteness* (or *non-degeneracy*). $\langle\mathbf{v},\mathbf{v}\rangle=0$ if and only if $\mathbf{v}=\mathbf{0}$.

An **inner product space** is a vector space over $\mathbb{F}$ together with a specified inner product on it.

Remark 6.1.3. Taking $\mathbf{w} = \mathbf{v}$ in conjugate symmetry gives $\langle \mathbf{v}, \mathbf{v} \rangle = \overline{\langle \mathbf{v}, \mathbf{v} \rangle}$, so $\langle \mathbf{v}, \mathbf{v} \rangle$ is real for every $\mathbf{v}$, and positivity makes sense even when $\mathbb{F} = \mathbb{C}$. Over $\mathbb{R}$ conjugation does nothing, and conjugate symmetry is plain symmetry.

Half of definiteness is automatic: linearity gives $\langle \mathbf{0}, \mathbf{0} \rangle = \langle 0\mathbf{0}, \mathbf{0} \rangle = 0\langle \mathbf{0}, \mathbf{0} \rangle = 0$. So to verify definiteness one only has to show that $\langle \mathbf{v}, \mathbf{v} \rangle = 0$ forces $\mathbf{v} = \mathbf{0}$.

A vector space usually carries many inner products, and lengths and angles depend on the choice (Example 6.1.21). So we always say which inner product we use.

Linearity is required only in the first slot. The second slot inherits a twisted version of it from conjugate symmetry.

Proposition 6.1.4 (Sesquilinearity). Let V be an inner product space. For all $\mathbf{v}, \mathbf{w}, \mathbf{x} \in V$ and $a, b \in \mathbb{F}$:

(a) $\langle \mathbf{v}, a\mathbf{w} + b\mathbf{x} \rangle = \overline{a}\langle \mathbf{v}, \mathbf{w} \rangle + \overline{b}\langle \mathbf{v}, \mathbf{x} \rangle$;

(b) $\langle \mathbf{0}, \mathbf{v} \rangle = \langle \mathbf{v}, \mathbf{0} \rangle = 0$.

Proof. ROUTINE

Uses. Definition 6.1.2 (Inner product), Notation 6.1.1 (Real and complex scalars)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. The only axiom that says anything about the second slot is conjugate symmetry. Use it to move the second slot into the first.
Hint 2. Flip with conjugate symmetry, expand with linearity in the first slot, and flip back. Conjugation turns a sum into a sum and a product into a product.
Hint 3. For (b), write $\mathbf{0} = \mathbf{0} + \mathbf{0}$ in the first slot.
Sketch. Conjugate symmetry turns $\langle \mathbf{v}, a\mathbf{w} + b\mathbf{x} \rangle$ into the conjugate of $a\langle \mathbf{w}, \mathbf{v} \rangle + b\langle \mathbf{x}, \mathbf{v} \rangle$, which is $\overline{a}\langle \mathbf{v}, \mathbf{w} \rangle + \overline{b}\langle \mathbf{v}, \mathbf{x} \rangle$. For (b), $\langle \mathbf{0}, \mathbf{v} \rangle = \langle \mathbf{0} + \mathbf{0}, \mathbf{v} \rangle = 2\langle \mathbf{0}, \mathbf{v} \rangle$, and conjugate symmetry handles $\langle \mathbf{v}, \mathbf{0} \rangle$.

(a) We compute

$$\begin{aligned}
\langle \mathbf{v}, a\mathbf{w} + b\mathbf{x} \rangle &= \overline{\langle a\mathbf{w} + b\mathbf{x}, \mathbf{v} \rangle} && \text{(conjugate symmetry)} \\
&= \overline{a\langle \mathbf{w}, \mathbf{v} \rangle + b\langle \mathbf{x}, \mathbf{v} \rangle} && \text{(linearity in the first slot)} \\
&= \overline{a}\,\overline{\langle \mathbf{w}, \mathbf{v} \rangle} + \overline{b}\,\overline{\langle \mathbf{x}, \mathbf{v} \rangle} && \text{(conjugation respects } + \text{ and } \cdot\text{)} \\
&= \overline{a}\langle \mathbf{v}, \mathbf{w} \rangle + \overline{b}\langle \mathbf{v}, \mathbf{x} \rangle && \text{(conjugate symmetry),}
\end{aligned}$$

as desired.

(b) By linearity in the first slot, $\langle \mathbf{0}, \mathbf{v} \rangle = \langle \mathbf{0} + \mathbf{0}, \mathbf{v} \rangle = \langle \mathbf{0}, \mathbf{v} \rangle + \langle \mathbf{0}, \mathbf{v} \rangle$. Subtracting $\langle \mathbf{0}, \mathbf{v} \rangle$ from both sides gives $\langle \mathbf{0}, \mathbf{v} \rangle = 0$. Then $\langle \mathbf{v}, \mathbf{0} \rangle = \overline{\langle \mathbf{0}, \mathbf{v} \rangle} = \overline{0} = 0$. □

A function of two vectors that is linear in the first slot and satisfies (a) in the second is called **sesquilinear** ("one and a half times linear"). Over $\mathbb{R}$ the bars disappear: a real inner product is linear in each slot, that is, **bilinear**, and symmetric. Over $\mathbb{C}$, scalars leave the second slot conjugated, as in $\langle \mathbf{v}, i\mathbf{w} \rangle = -i\langle \mathbf{v}, \mathbf{w} \rangle$. Forgetting the bar is the most common error in computations with complex inner products.

Example 6.1.5 (Expanding an inner product). Let $\mathbf{x}, \mathbf{y}$ be vectors in a complex inner product space with $\langle \mathbf{x}, \mathbf{x} \rangle = 1$, $\langle \mathbf{y}, \mathbf{y} \rangle = 2$, and $\langle \mathbf{x}, \mathbf{y} \rangle = i$, so that $\langle \mathbf{y}, \mathbf{x} \rangle = \overline{i} = -i$. To compute the inner product below, expand each slot, pulling scalars out of the first slot as they are and out of the second slot conjugated:

$$\begin{aligned}
&\langle (1+i)\mathbf{x} + \mathbf{y}, 2\mathbf{x} - i\mathbf{y} \rangle \\
&= (1+i)\cdot 2\langle \mathbf{x}, \mathbf{x} \rangle + (1+i)\overline{-i}\langle \mathbf{x}, \mathbf{y} \rangle \\
&\quad + 2\langle \mathbf{y}, \mathbf{x} \rangle + \overline{-i}\langle \mathbf{y}, \mathbf{y} \rangle \\
&= 2(1+i) + (1+i)i \cdot i + 2(-i) + i \cdot 2
\end{aligned}$$

$$= (2+2i) + (-1-i) - 2i + 2i = 1 + i.$$

Here $(1+i)i \cdot i = (1+i)(-1)$. This is Technique 5.1.7 for a sesquilinear function: each slot is split into its terms, and the four resulting values are known.

Over $\mathbb{C}$ the conjugation is forced on us, because positivity and definiteness together are incompatible with linearity in both slots.

Proposition 6.1.6 (Bilinear forms over $\mathbb{C}$ are not positive definite). Let $V \neq \{\mathbf{0}\}$ be a complex vector space, and let $B : V \times V \to \mathbb{C}$ be linear in each slot when the other is fixed. If $B(\mathbf{v}, \mathbf{v})$ is real and nonnegative for every $\mathbf{v} \in V$, then $B(\mathbf{v}, \mathbf{v}) = 0$ for every $\mathbf{v} \in V$. In particular, B cannot satisfy both positivity and definiteness.

Proof. ROUTINE

Uses. Definition 6.1.2 (Inner product)
Hint 1. Compare $B(\mathbf{v}, \mathbf{v})$ with $B(c\mathbf{v}, c\mathbf{v})$ for a scalar c.
Hint 2. Take $c = i$. What is $i \cdot i$?
Sketch. $B(i\mathbf{v}, i\mathbf{v}) = i^2 B(\mathbf{v}, \mathbf{v}) = -B(\mathbf{v}, \mathbf{v})$, and a real number whose negative is also nonnegative is 0. A nonzero $\mathbf{v}$ then violates definiteness.

Let $\mathbf{v} \in V$. Linearity in each slot gives $B(i\mathbf{v}, i\mathbf{v}) = i \cdot iB(\mathbf{v}, \mathbf{v}) = -B(\mathbf{v}, \mathbf{v})$. Both $B(\mathbf{v}, \mathbf{v})$ and $B(i\mathbf{v}, i\mathbf{v}) = -B(\mathbf{v}, \mathbf{v})$ are nonnegative real numbers, so $B(\mathbf{v}, \mathbf{v}) = 0$. Since $V \neq \{\mathbf{0}\}$, there is some $\mathbf{v} \neq \mathbf{0}$, and $B(\mathbf{v}, \mathbf{v}) = 0$ violates definiteness. □

With the conjugate in the second slot the problem disappears: $\langle i\mathbf{v}, i\mathbf{v}\rangle = \bar{i}i\langle \mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, \mathbf{v}\rangle$. This is what it should be, since multiplying by i rotates each coordinate of $\mathbf{v} \in \mathbb{C}^n$ without changing its modulus, so it should not change the length of $\mathbf{v}$.

6.1.3 Examples and non-examples

The dot product

The dot product on $\mathbb{C}^n$ is most compactly written with the conjugate transpose, which Section 6.3 studies in detail.

Notation 6.1.7 (Conjugate transpose). For $A = (a_{ij}) \in \mathbb{C}^{m \times n}$, the **conjugate transpose** of A is the matrix $A^* \in \mathbb{C}^{n \times m}$ whose (i, j) entry is $\overline{a_{ji}}$. That is, $A^* = \overline{A}^{\mathsf{T}}$, where $\overline{A} = (\overline{a_{ij}})$ conjugates every entry (Definition 2.4.21). For a real matrix, $A^* = A^{\mathsf{T}}$. For $\mathbf{w} \in \mathbb{F}^n$, $\mathbf{w}^*$ is the row $(\overline{w_1}, \ldots, \overline{w_n})$, and for $\mathbf{v} \in \mathbb{F}^n$ the product $\mathbf{w}^*\mathbf{v}$ is a 1×1 matrix, which we identify with its entry $\sum_k \overline{w_k} v_k$.

Definition 6.1.8 (Dot product). The **dot product** on $\mathbb{F}^n$ is

$$\mathbf{v} \cdot \mathbf{w} = \sum_{k=1}^{n} v_k \overline{w_k} = \mathbf{w}^* \mathbf{v}$$

for $\mathbf{v} = (v_1, \ldots, v_n)$ and $\mathbf{w} = (w_1, \ldots, w_n)$ in $\mathbb{F}^n$. Over $\mathbb{R}$ it is $\sum_k v_k w_k = \mathbf{w}^{\mathsf{T}}\mathbf{v}$.

Checking the axioms for the dot product comes down to one elementary fact about real numbers, which we name because it is used constantly in this chapter.

Technique 6.1.9 (A sum of nonnegative terms). A sum of nonnegative real numbers is 0 only if every term is 0: if $t_1, \ldots, t_n \geq 0$ and some $t_j > 0$, then $t_1 + \cdots + t_n \geq t_j > 0$. So to show that many quantities vanish, it suffices to exhibit them as squares, or squared moduli $|z_k|^2$, in a single sum, and to show that the sum is 0.

Reach for it when a positivity or definiteness axiom must be verified for a concrete formula, and whenever one equation should force many. The canonical example is definiteness of the dot product (Proposition 6.1.10), where $\sum_k |v_k|^2 = 0$ forces every $v_k = 0$. Integrals of nonnegative continuous functions behave the same way (Lemma 6.1.14), and Technique 6.1.18 applies the idea to the entries of a matrix.
Used in. Exercise 1.5.48, Problem 3.15, Exercise 4.3.33, Proposition 6.1.10, Lemma 6.1.14, Proposition 6.1.13, Exercise 6.1.46, Lemma 6.2.6, Exercise 6.2.43, Proposition 6.3.13, Exercise 6.3.52, Theorem 6.4.33, Exercise 6.7.12, Problem 6.5, Problem 6.12, Problem 6.15, Problem 6.16, Theorem 8.1.3, Lemma 8.2.4, Lemma 8.3.8, Notation 8.3.10, Exercise 8.3.40, Lemma 8.4.24, Exercise 6.1.42, Exercise 6.2.47, Exercise 6.4.60, Exercise 8.4.35.

Proposition 6.1.10 (The dot product is an inner product). The dot product is an inner product on $\mathbb{F}^n$, and $\mathbf{v} \cdot \mathbf{v} = \sum_{k=1}^{n} |v_k|^2$ for all $\mathbf{v} \in \mathbb{F}^n$.

Proof. ROUTINE

Uses. Definition 6.1.2 (Inner product), Definition 6.1.8 (Dot product), Notation 6.1.1 (Real and complex scalars)
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. Check the axioms one at a time with the coordinate formula $\sum_k v_k \overline{w_k}$.
Hint 2. Conjugate symmetry is $\overline{w_k \overline{v_k}} = \overline{w_k} v_k$ for each term. For positivity, $v_k \overline{v_k} = |v_k|^2$.
Hint 3. For definiteness, a sum of nonnegative real numbers is 0 only if each term is.
Sketch. Conjugating $\mathbf{w} \cdot \mathbf{v}$ term by term gives $\mathbf{v} \cdot \mathbf{w}$, and linearity in $\mathbf{v}$ is visible from the formula. Then $\mathbf{v} \cdot \mathbf{v} = \sum_k |v_k|^2 \geq 0$, and it vanishes only if every $|v_k| = 0$, that is, $\mathbf{v} = \mathbf{0}$.

Let $\mathbf{v}, \mathbf{w}, \mathbf{x} \in \mathbb{F}^n$ and $a, b \in \mathbb{F}$.

Conjugate symmetry. $\overline{\mathbf{w} \cdot \mathbf{v}} = \overline{\sum_k w_k \overline{v_k}} = \sum_k \overline{w_k} v_k = \mathbf{v} \cdot \mathbf{w}$.

Linearity in the first slot. The kth coordinate of $a\mathbf{v} + b\mathbf{w}$ is $av_k + bw_k$, so

$$(a\mathbf{v} + b\mathbf{w}) \cdot \mathbf{x} = \sum_k (av_k + bw_k)\overline{x_k} = a \sum_k v_k \overline{x_k} + b \sum_k w_k \overline{x_k} = a(\mathbf{v} \cdot \mathbf{x}) + b(\mathbf{w} \cdot \mathbf{x}).$$

Positivity. $\mathbf{v} \cdot \mathbf{v} = \sum_k v_k \overline{v_k} = \sum_k |v_k|^2 \geq 0$.

Definiteness. Suppose $\mathbf{v} \cdot \mathbf{v} = 0$. Then $\sum_k |v_k|^2 = 0$ is a sum of nonnegative real numbers, so $|v_k|^2 = 0$ for every k. Writing $v_k = a_k + b_k i$, this says $a_k^2 + b_k^2 = 0$, so $a_k = b_k = 0$ and $v_k = 0$. Hence $\mathbf{v} = \mathbf{0}$. By Remark 6.1.3, this is all that definiteness requires. □

Unless another inner product is specified, $\mathbb{F}^n$ carries the dot product. The lecture calls it "the dot product" precisely to distinguish it from the other inner products on $\mathbb{F}^n$ below.

Example 6.1.11 (Computing in $\mathbb{C}^2$). Let $\mathbf{v} = (1 + i, 2)$ and $\mathbf{w} = (i, 1 - i)$. Then

$$\mathbf{v} \cdot \mathbf{w} = (1+i)\bar{i} + 2\overline{(1-i)} = (1+i)(-i) + 2(1+i) = (1-i) + (2+2i) = 3 + i,$$
$$\mathbf{w} \cdot \mathbf{v} = i\overline{(1+i)} + (1-i)\overline{2} = i(1-i) + 2 - 2i = 3 - i,$$

as conjugate symmetry predicts. Also $\mathbf{v} \cdot \mathbf{v} = |1+i|^2 + |2|^2 = 2 + 4 = 6$ and $\mathbf{w} \cdot \mathbf{w} = 1 + 2 = 3$. Without the conjugate, $\mathbf{v}$ would have "squared length" $(1+i)^2 + 4 = 4 + 2i$.

Exercise 6.1.12. ROUTINE In $\mathbb{C}^3$, let $\mathbf{v} = (1, i, 2)$ and $\mathbf{w} = (i, 1 + i, 1 - i)$. Compute $\mathbf{v} \cdot \mathbf{w}$, $\mathbf{w} \cdot \mathbf{v}$, $\mathbf{v} \cdot \mathbf{v}$, and $\mathbf{w} \cdot \mathbf{w}$, and find $c \in \mathbb{C}$ with $(\mathbf{v} - c\mathbf{w}) \cdot \mathbf{w} = 0$.

Solution on page 1462

Continuous functions

Let $C([0,1], \mathbb{C})$ be the set of continuous functions $f : [0,1] \to \mathbb{C}$, that is, of functions $f = u + iv$ with $u, v \in C[0,1]$ (Example 1.2.12). It is a complex vector space under the pointwise operations, by the argument of Example 1.2.12. Such functions are integrated part by part, $\int_0^1 f = \int_0^1 u + i \int_0^1 v$. This integral is $\mathbb{C}$-linear and commutes with conjugation:

$$\int_0^1 (af+bg) = a\int_0^1 f + b\int_0^1 g \quad (a,b\in\mathbb{C}), \qquad \int_0^1 \overline{f} = \overline{\int_0^1 f}.$$

Both follow from the real case by splitting into real and imaginary parts. For instance, for $a = p+qi$ we have $af = (pu-qv)+i(pv+qu)$, whose integral is $(p+qi)\big(\int u + i\int v\big)$.

Proposition 6.1.13 (Integral inner products). The formula

$$\langle f, g\rangle = \int_0^1 f(t)\overline{g(t)}\,\mathrm{d}t$$

defines an inner product on $C([0,1],\mathbb{C})$. On the real vector space $C[0,1]$ it reads $\langle f,g\rangle = \int_0^1 f(t)g(t)\,\mathrm{d}t$, and it is an inner product there as well.

Intuition. Conjugate symmetry and linearity are properties of the integral, and positivity holds because $f\overline{f} = |f|^2 \geq 0$. Definiteness is the one place where continuity matters. A function that is nonzero at only a single point has integral 0, so $\int_0^1 |f|^2 = 0$ does not force $f = 0$ for arbitrary integrable f. A continuous function that is positive at one point, however, is positive on a whole interval around it, and so has positive integral. This is Technique 6.1.9 with an integral in place of a sum.

Lemma 6.1.14 (Nonnegative functions with zero integral). Let $h \in C[0,1]$ with $h(t) \geq 0$ for all $t \in [0,1]$. If $\int_0^1 h = 0$, then $h = 0$.

Proof. STANDARD

Uses. continuity of h, monotonicity of the integral: if $g_1 \leq g_2$ on an interval, then their integrals compare the same way
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. Prove the contrapositive: if $h(c) > 0$ for some c, then $\int_0^1 h > 0$.
Hint 2. By continuity, $h > h(c)/2$ on all points of $[0,1]$ close enough to c. Find an interval $I \subseteq [0,1]$ of positive length on which this holds.
Hint 3. Bound $\int_0^1 h$ below by the integral over I, using $h \geq 0$ off I.
Sketch. If $h(c) > 0$, continuity gives an interval $I \subseteq [0,1]$ of positive length ℓ on which $h > h(c)/2$. Since $h \geq 0$ everywhere, $\int_0^1 h \geq \int_I h \geq \ell h(c)/2 > 0$.

We prove the contrapositive. Suppose $h(c) > 0$ for some $c \in [0,1]$, and let $\varepsilon = h(c)/2 > 0$. By continuity of h at c, there is $\delta > 0$ such that $h(t) > \varepsilon$ for all $t \in [0,1]$ with $|t-c| < \delta$. Let $\ell = \min(\delta/2, 1/2)$. Either $c+\ell \leq 1$ or $c-\ell \geq 0$, since otherwise $1 < c+\ell$ and $c < \ell$, which give $1 < 2\ell \leq 1$. So one of the intervals $I = [c, c+\ell]$ or $I = [c-\ell, c]$ lies in $[0,1]$. Every $t \in I$ satisfies $|t-c| \leq \ell < \delta$, so $h > \varepsilon$ on I. Since $h \geq 0$ on all of $[0,1]$, monotonicity of the integral gives

$$\int_0^1 h \geq \int_I h \geq \ell\varepsilon > 0.$$

So if $\int_0^1 h = 0$, then $h(c) > 0$ for no c, and as $h \geq 0$, $h = 0$. □

Proof of Proposition 6.1.13. STANDARD

Uses. Definition 6.1.2 (Inner product), Lemma 6.1.14 (Nonnegative functions with zero integral), Notation 6.1.1 (Real and complex scalars), $\mathbb{C}$-linearity of the integral, and $\int \overline{f} = \overline{\int f}$
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. The products $f\overline{g}$ are continuous, so all the integrals exist. Check conjugate symmetry and linearity with the two properties of the integral above.
Hint 2. For positivity, $f\overline{f} = |f|^2$ is a nonnegative continuous real function.
Hint 3. For definiteness, apply Lemma 6.1.14 to $h = |f|^2$.
Sketch. $\langle g, f\rangle = \int g\overline{f} = \int \overline{f\overline{g}} = \overline{\langle f, g\rangle}$, and linearity in f is linearity of the integral. Then $\langle f, f\rangle = \int |f|^2 \geq 0$, and if it is 0, Lemma 6.1.14 gives $|f|^2 = 0$, so $f = 0$.

For $f, g \in C([0,1], \mathbb{C})$, the function $f\overline{g}$ is continuous, so $\langle f, g\rangle$ is defined. Let $f, g, h \in C([0,1], \mathbb{C})$ and $a, b \in \mathbb{C}$.

Conjugate symmetry. $\langle g, f\rangle = \int_0^1 g\overline{f} = \int_0^1 \overline{f\overline{g}} = \overline{\int_0^1 f\overline{g}} = \overline{\langle f, g\rangle}$.

Linearity in the first slot. $\langle af + bg, h\rangle = \int_0^1 \left(af\overline{h} + bg\overline{h}\right) = a\langle f, h\rangle + b\langle g, h\rangle$.

Positivity. Writing $f = u + iv$, we have $f\overline{f} = |f|^2 = u^2 + v^2$, a continuous function with values in $[0, \infty)$. So $\langle f, f\rangle = \int_0^1 |f|^2 \geq 0$.

Definiteness. If $\langle f, f\rangle = 0$, then Lemma 6.1.14 applied to $h = |f|^2$ gives $|f(t)|^2 = 0$, hence $f(t) = 0$, for every t. So $f = \mathbf{0}$.

For $C[0,1]$, the same argument applies with every bar erased. □

Nothing here depends on the interval being $[0,1]$. For any $a < b$, the proofs of Lemma 6.1.14 and Proposition 6.1.13 go through on $[a,b]$, with $(b-a)/2$ in place of $1/2$ in the choice of ℓ, so $\int_a^b f\overline{g}$ is an inner product on $C([a,b], \mathbb{C})$, and on $C[a,b]$ with the bars erased.

> *Intuition (Infinitely many coordinates).* Riemann sums explain why this integral behaves like a dot product. For large N,
>
> $$\langle f, g\rangle \approx \frac{1}{N}\sum_{k=1}^{N} f\left(\frac{k}{N}\right)\overline{g\left(\frac{k}{N}\right)} = \frac{1}{N}(\mathbf{f}_N \cdot \mathbf{g}_N),$$
>
> where $\mathbf{f}_N = (f(1/N), f(2/N), \ldots, f(1)) \in \mathbb{C}^N$ records the values of f at N sample points. So $\langle f, g\rangle$ is a limit of rescaled dot products of longer and longer vectors, with one coordinate for each point of $[0,1]$, and $\langle f, f\rangle$ is the average of $|f|^2$.

Example 6.1.15 (Computing with functions). In $C[0,1]$, $\langle t, t^2\rangle = \int_0^1 t^3\,dt = 1/4$ and $\langle 1, 2t-1\rangle = \int_0^1 (2t-1)\,dt = 0$. In $C([0,1], \mathbb{C})$, let $f(t) = t + i$ and $g(t) = 1 + it$. Then $f\overline{g} = (t+i)(1-it)$, which expands to $2t + i(1-t^2)$, so

$$\langle f, g\rangle = \int_0^1 2t\,dt + i\int_0^1 (1-t^2)\,dt = 1 + \frac{2i}{3},$$

and $\langle f, f\rangle = \int_0^1 (t^2+1)\,dt = 4/3$.

Matrices

The space $\mathbb{F}^{m\times n}$ is $\mathbb{F}^{mn}$ with the coordinates arranged in a rectangle, so it inherits a dot product: multiply corresponding entries, conjugating those of the second matrix, and add. The trace expresses this sum compactly.

Proposition 6.1.16 (Frobenius inner product). For $A = (a_{ij})$ and $B = (b_{ij})$ in $\mathbb{F}^{m\times n}$,

$$\operatorname{tr}(B^*A) = \sum_{i=1}^{m}\sum_{j=1}^{n} a_{ij}\overline{b_{ij}}.$$

Consequently $\langle A, B\rangle = \operatorname{tr}(B^*A)$ is an inner product on $\mathbb{F}^{m\times n}$, the **Frobenius inner product**, and $\langle A, A\rangle = \sum_{i,j} |a_{ij}|^2$.

Proof. ROUTINE

Uses. Definition 2.4.26 (Trace), Definition 2.4.1 (Matrix product), Notation 6.1.7 (Conjugate transpose), Proposition 6.1.10 (The dot product is an inner product)
Hint 1. Compute the diagonal entries of B^*A from the definition of the matrix product.
Hint 2. The (j,j) entry of B^*A is $\sum_i \overline{b_{ij}}a_{ij}$: the dot product of column j of A with column j of B.
Hint 3. For the axioms, notice that the double sum is the formula of Definition 6.1.8 applied to mn coordinates.

Sketch. The jth diagonal entry of B^*A is the dot product of the jth columns of A and B; summing over j gives $\sum_{i,j} a_{ij}\overline{b_{ij}}$. That is the dot product of A and B regarded as vectors with mn coordinates, so the axioms hold by Proposition 6.1.10.

The (j,i) entry of $B^* \in \mathbb{F}^{n\times m}$ is $\overline{b_{ij}}$. By Definition 2.4.1, the (j,j) entry of $B^*A \in \mathbb{F}^{n\times n}$ is

$$(B^*A)_{jj} = \sum_{i=1}^{m} (B^*)_{ji} a_{ij} = \sum_{i=1}^{m} a_{ij}\overline{b_{ij}},$$

and summing over j (Definition 2.4.26) gives the formula.

The right side of the formula is the dot product formula of Definition 6.1.8, with the mn pairs (i,j) in place of the indices k. The proof of Proposition 6.1.10 checks each axiom from that formula alone, term by term, so it applies verbatim: $\langle A, B\rangle = \operatorname{tr}(B^*A)$ is an inner product on $\mathbb{F}^{m\times n}$, and $\langle A, A\rangle = \sum_{i,j} |a_{ij}|^2$. □

Example 6.1.17 (A Frobenius inner product). For $A = \begin{pmatrix} 1 & 2 \\ 0 & -1 \end{pmatrix}$ and $B = \begin{pmatrix} 3 & 0 \\ 1 & 1 \end{pmatrix}$ in $\mathbb{R}^{2\times 2}$, the entrywise formula gives $\langle A, B\rangle = 1\cdot 3 + 2\cdot 0 + 0\cdot 1 + (-1)\cdot 1 = 2$. With the trace,

$$B^{\mathsf{T}}A = \begin{pmatrix} 3 & 1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 2 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 3 & 5 \\ 0 & -1 \end{pmatrix}, \quad \operatorname{tr}\left(B^{\mathsf{T}}A\right) = 3 - 1 = 2.$$

The identity $\langle A, A\rangle = \operatorname{tr}(A^*A) = \sum_{i,j} |a_{ij}|^2$ is useful well beyond computing lengths.

Technique 6.1.18 (The trace of A^*A). For every $A \in \mathbb{F}^{m\times n}$, $\operatorname{tr}(A^*A) = \sum_{i,j} |a_{ij}|^2$ (Proposition 6.1.16). So $\operatorname{tr}(A^*A) \geq 0$, with equality only for $A = 0$, and one scalar equation controls every entry of A. To show that a matrix A is zero, it suffices to show $\operatorname{tr}(A^*A) = 0$; in particular, it suffices to show $A^*A = 0$.

Reach for it when a matrix identity involves A^*A or AA^* (or $A^{\mathsf{T}}A$ over $\mathbb{R}$) and the goal is a conclusion about A itself. It is Technique 6.1.9 applied to the entries of a matrix. The canonical example is Corollary 6.1.19.

Used in. Corollary 6.1.19, Exercise 6.1.20, Exercise 6.1.54, Exercise 6.1.55, Exercise 6.6.50, Exercise 6.7.10, Exercise 7.5.41, Exercise 8.1.37, Exercise 8.1.38.

Corollary 6.1.19 ($A^*A = 0$ forces $A = 0$). Let $A \in \mathbb{F}^{m\times n}$. If $A^*A = 0$ or $AA^* = 0$, then $A = 0$.

Proof. ROUTINE

Uses. Proposition 6.1.16 (Frobenius inner product), Notation 6.1.7 (Conjugate transpose)
Techniques. The trace of A^*A (Technique 6.1.18)
Hint 1. Take the trace of $A^*A = 0$.
Hint 2. For $AA^* = 0$, apply the first case to A^*, using $(A^*)^* = A$.
Sketch. If $A^*A = 0$, then $\sum_{i,j} |a_{ij}|^2 = \operatorname{tr}(A^*A) = 0$, so every $a_{ij} = 0$. Since $(A^*)^* = A$, the case $AA^* = 0$ is the first case for A^*.

If $A^*A = 0$, then by Proposition 6.1.16, $\sum_{i,j} |a_{ij}|^2 = \operatorname{tr}(A^*A) = \operatorname{tr}(0) = 0$. This is a sum of nonnegative real numbers, so every $|a_{ij}|^2 = 0$, and $A = 0$.

The (i,j) entry of $(A^*)^*$ is the conjugate of the (j,i) entry of A^*, which is $\overline{\overline{a_{ij}}} = a_{ij}$, so $(A^*)^* = A$. If $AA^* = 0$, then $(A^*)^*A^* = 0$, and the first case applied to A^* gives $A^* = 0$. Hence $A = (A^*)^* = 0$. □

The conjugate transpose is essential here. The nilpotent matrix $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ is nonzero with $N^2 = 0$, so $A^2 = 0$ does not force $A = 0$. Over $\mathbb{C}$, the transpose alone does not suffice either: the column $\mathbf{a} = (1, i)$ is nonzero, but $\mathbf{a}^{\mathsf{T}}\mathbf{a} = 1 + i^2 = 0$. This is the failure of $(1,i)\cdot(1,i)$ without conjugation that we met at the start of the section.

Exercise 6.1.20. ROUTINE Let $A \in \mathbb{C}^{n\times n}$ satisfy $A^* = A$ and $A^2 = 0$. Show that $A = 0$. Does the conclusion still hold if the hypothesis $A^* = A$ is dropped?

Solution on page 1462

Inner products on $\mathbb{F}^n$ from matrices

The dot product is not the only inner product on $\mathbb{F}^n$. Weighting the coordinates already gives others.

Example 6.1.21 (Weighted dot products). Let $c_1, \dots, c_n$ be positive real numbers. Then

$$\langle \mathbf{v}, \mathbf{w} \rangle_c = \sum_{k=1}^{n} c_k v_k \overline{w_k}$$

is an inner product on $\mathbb{F}^n$. The proof of Proposition 6.1.10 goes through with $c_k|v_k|^2$ in place of $|v_k|^2$, since $c_k|v_k|^2 \geq 0$, with equality only if $v_k = 0$. The weights must be positive: if $c_k \leq 0$, then $\langle \mathbf{e}_k, \mathbf{e}_k \rangle_c = c_k \leq 0$ while $\mathbf{e}_k \neq \mathbf{0}$.

Different weights give different geometry on the same set. With weights $(1, 4)$ on $\mathbb{R}^2$, the vector $\mathbf{e}_2$ has $\langle \mathbf{e}_2, \mathbf{e}_2 \rangle_c = 4$, so it is "twice as long" as $\mathbf{e}_1$, and the vectors with $\langle \mathbf{x}, \mathbf{x} \rangle_c = 1$ form the ellipse $x_1^2 + 4x_2^2 = 1$ rather than the unit circle (Figure 6.1.2).

In fact every inner product on $\mathbb{F}^n$ is given by a matrix. By sesquilinearity, $\langle \mathbf{x}, \mathbf{y} \rangle$ is determined by the n^2 numbers $\langle \mathbf{e}_j, \mathbf{e}_i \rangle$, and the question is which arrays of n^2 numbers occur.

Proposition 6.1.22 (Inner products on $\mathbb{F}^n$).

(a) Let $\langle \cdot, \cdot \rangle$ be an inner product on $\mathbb{F}^n$, and let $M \in \mathbb{F}^{n \times n}$ have entries $m_{ij} = \langle \mathbf{e}_j, \mathbf{e}_i \rangle$. Then $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{y}^* M \mathbf{x}$ for all $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$.

(b) Conversely, let $M \in \mathbb{F}^{n \times n}$. The formula $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{y}^* M \mathbf{x}$ defines an inner product on $\mathbb{F}^n$ if and only if $M^* = M$ and $\mathbf{x}^* M \mathbf{x} > 0$ for every nonzero $\mathbf{x} \in \mathbb{F}^n$.

Proof. STANDARD

Uses. Proposition 6.1.4 (Sesquilinearity), Definition 1.6.8 (Standard bases), Definition 2.3.8 (Matrix–vector product), Notation 6.1.7 (Conjugate transpose), Remark 6.1.3
Techniques. Expand by multilinearity (Technique 5.1.7), Check it on a basis (Technique 2.2.7)
Hint 1. For (a), write $\mathbf{x} = \sum_j x_j \mathbf{e}_j$ and $\mathbf{y} = \sum_i y_i \mathbf{e}_i$, and expand using linearity in the first slot and Proposition 6.1.4 in the second.
Hint 2. For (b), the formula is linear in $\mathbf{x}$ for every M, and positivity together with definiteness says exactly that $\mathbf{x}^* M \mathbf{x} > 0$ for $\mathbf{x} \neq \mathbf{0}$. So only conjugate symmetry needs thought.
Hint 3. Conjugate symmetry at the pair $(\mathbf{e}_j, \mathbf{e}_i)$ reads $m_{ij} = \overline{m_{ji}}$. For the converse, write $\mathbf{y}^* M \mathbf{x} = \sum_{i,j} \overline{y_i} m_{ij} x_j$, conjugate, and rename the indices.
Sketch. Expanding by sesquilinearity, $\langle \mathbf{x}, \mathbf{y} \rangle = \sum_{i,j} \overline{y_i} \langle \mathbf{e}_j, \mathbf{e}_i \rangle x_j = \mathbf{y}^* M \mathbf{x}$. For (b), linearity in $\mathbf{x}$ is automatic, and positivity plus definiteness is the condition $\mathbf{x}^* M \mathbf{x} > 0$ for $\mathbf{x} \neq \mathbf{0}$. Conjugate symmetry tested at $(\mathbf{e}_j, \mathbf{e}_i)$ gives $M = M^*$; conversely, if $M = M^*$, conjugating the double sum for $\langle \mathbf{y}, \mathbf{x} \rangle$ and swapping i and j gives $\langle \mathbf{x}, \mathbf{y} \rangle$.

(a) Write $\mathbf{x} = \sum_j x_j \mathbf{e}_j$ and $\mathbf{y} = \sum_i y_i \mathbf{e}_i$. Linearity in the first slot and Proposition 6.1.4 give

$$\langle \mathbf{x}, \mathbf{y} \rangle = \sum_{j=1}^{n} x_j \langle \mathbf{e}_j, \mathbf{y} \rangle = \sum_{j=1}^{n} \sum_{i=1}^{n} x_j \overline{y_i} \langle \mathbf{e}_j, \mathbf{e}_i \rangle = \sum_{i=1}^{n} \overline{y_i} \left(\sum_{j=1}^{n} m_{ij} x_j \right).$$

The inner sum is the ith coordinate of $M\mathbf{x}$ (Definition 2.3.8), so the whole expression is $\mathbf{y}^*(M\mathbf{x})$.

(b) Write $\langle \mathbf{x}, \mathbf{y} \rangle_M = \mathbf{y}^* M \mathbf{x} = \sum_{i,j} \overline{y_i} m_{ij} x_j$. For fixed $\mathbf{y}$ this is linear in $\mathbf{x}$, for every M, so linearity in the first slot always holds. Positivity and definiteness together say that $\langle \mathbf{x}, \mathbf{x} \rangle_M \geq 0$ for all $\mathbf{x}$, with equality only for $\mathbf{x} = \mathbf{0}$ (Remark 6.1.3); since $\langle \mathbf{0}, \mathbf{0} \rangle_M = 0$ in any case, this is the condition $\mathbf{x}^* M \mathbf{x} > 0$ for all $\mathbf{x} \neq \mathbf{0}$. It remains to show that conjugate symmetry holds if and only if $M^* = M$.

Suppose conjugate symmetry holds. For all i, j,

$$m_{ij} = \mathbf{e}_i^* M \mathbf{e}_j = \langle \mathbf{e}_j, \mathbf{e}_i \rangle_M = \overline{\langle \mathbf{e}_i, \mathbf{e}_j \rangle_M} = \overline{\mathbf{e}_j^* M \mathbf{e}_i} = \overline{m_{ji}},$$

which says $M^* = M$. Conversely, suppose $m_{ij} = \overline{m_{ji}}$ for all i, j. Then for all $\mathbf{x}, \mathbf{y}$,

$$\overline{\langle \mathbf{y}, \mathbf{x} \rangle_M} = \overline{\sum_{i,j} \overline{x_i} m_{ij} y_j} = \sum_{i,j} x_i \overline{m_{ij} y_j} = \sum_{i,j} \overline{y_j} m_{ji} x_i = \langle \mathbf{x}, \mathbf{y} \rangle_M,$$

where the last step renames the summation indices i and j as j and i. So conjugate symmetry holds. □

A matrix M with $M^* = M$ and $\mathbf{x}^* M \mathbf{x} > 0$ for all $\mathbf{x} \neq \mathbf{0}$ is called **positive definite**, and Section 12.3 gives practical tests for it. Parts (a) and (b) say that every inner product on $\mathbb{F}^n$ is $\mathbf{y}^* M \mathbf{x}$ for a positive definite M. The dot product is the case $M = I_n$, and the weighted dot products are the diagonal M with positive diagonal entries.

Example 6.1.23 (A tilted inner product on $\mathbb{R}^2$). Let $M = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$. Then $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{y}^\mathsf{T} M \mathbf{x} = 2x_1 y_1 + x_1 y_2 + x_2 y_1 + 2x_2 y_2$. Here $M^\mathsf{T} = M$, and for $\mathbf{x} \neq \mathbf{0}$,

$$\mathbf{x}^\mathsf{T} M \mathbf{x} = 2x_1^2 + 2x_1 x_2 + 2x_2^2 = x_1^2 + x_2^2 + (x_1 + x_2)^2 > 0,$$

a sum of squares that is not all zero. So Proposition 6.1.22 makes this an inner product. Measured with it, $(1, -1)$ has $\langle \mathbf{x}, \mathbf{x} \rangle = 2 - 2 + 2 = 2$ while $(1, 1)$ has $\langle \mathbf{x}, \mathbf{x} \rangle = 6$, and the vectors with $\langle \mathbf{x}, \mathbf{x} \rangle = 1$ form a tilted ellipse (Figure 6.1.2).

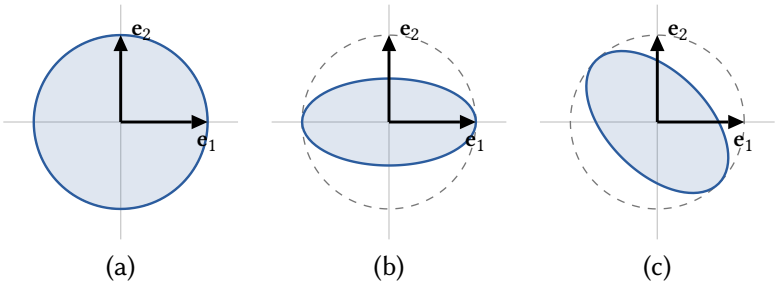

Figure 6.1.2. The vectors $\mathbf{x} \in \mathbb{R}^2$ with $\langle \mathbf{x}, \mathbf{x} \rangle = 1$ (solid) for three inner products on $\mathbb{R}^2$: (a) the dot product; (b) the weighted dot product $x_1 y_1 + 4x_2 y_2$ of Example 6.1.21, in which $\mathbf{e}_2$ lies outside the curve because it has length 2; (c) the inner product of Example 6.1.23. The dashed circle is the unit circle of the dot product.

Remark 6.1.24. Over $\mathbb{R}$, positivity of $\mathbf{x}^\mathsf{T} M \mathbf{x}$ does not force M to be symmetric. For $M = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$, $\mathbf{x}^\mathsf{T} M \mathbf{x} = x_1^2 + x_1 x_2 - x_2 x_1 + x_2^2 = x_1^2 + x_2^2 > 0$ for $\mathbf{x} \neq \mathbf{0}$, but $\mathbf{y}^\mathsf{T} M \mathbf{x}$ is not an inner product, since $\langle \mathbf{e}_2, \mathbf{e}_1 \rangle = m_{12} = 1$ while $\langle \mathbf{e}_1, \mathbf{e}_2 \rangle = m_{21} = -1$. Over $\mathbb{C}$ this cannot happen: if $\mathbf{x}^* M \mathbf{x}$ is real for every $\mathbf{x} \in \mathbb{C}^n$, then $M^* = M$ (Exercise 6.1.47).

Non-examples

Non-example 6.1.25 (Formulas that are not inner products).

(a) On $\mathbb{C}^2$, $\langle \mathbf{x}, \mathbf{y}\rangle = x_1 y_1 + x_2 y_2$ is bilinear and symmetric, but $\langle (i,0),(i,0)\rangle = i^2 = -1 < 0$. This is Proposition 6.1.6 in action.

(b) On $\mathbb{C}^n$, $\langle \mathbf{x}, \mathbf{y}\rangle = \sum_k \overline{x_k} y_k = \mathbf{x}^* \mathbf{y}$ is conjugate symmetric, positive, and definite, and it is linear in the *second* slot. But $\langle i\mathbf{x}, \mathbf{y}\rangle = -i\langle \mathbf{x}, \mathbf{y}\rangle$, so it is not linear in the first slot, and by our definition it is not an inner product. Many physics texts use this convention instead. It is the dot product with its arguments exchanged, $\langle \mathbf{x}, \mathbf{y}\rangle = \mathbf{y} \cdot \mathbf{x}$, so results translate by swapping the slots.

(c) On $\mathbb{R}^{2\times 2}$, $\langle A, B\rangle = \operatorname{tr}(AB)$ is bilinear and symmetric (as $\operatorname{tr}(AB) = \operatorname{tr}(BA)$, Proposition 2.4.28). But $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ has $J^2 = -I_2$, so $\langle J, J\rangle = -2 < 0$. In the Frobenius inner product $\operatorname{tr}\left(B^{\mathsf{T}} A\right)$, the transpose is what turns $\langle A, A\rangle$ into a sum of squares.

(d) On $\mathbb{R}[x]_{\leq 2}$, $\langle p, q\rangle = p(0)q(0) + p(1)q(1)$ is symmetric, bilinear, and positive, but the nonzero polynomial $p = x^2 - x$ has $\langle p, p\rangle = 0$. On $\mathbb{R}[x]_{\leq 1}$, the same formula *is* an inner product: if $p = a + bx$ and $p(0)^2 + p(1)^2 = 0$, then $p(0) = a = 0$ and $p(1) = a + b = 0$, so $p = \mathbf{0}$. Whether a formula defines an inner product depends on the space it is defined on.

6.1.4 The norm

Definition 6.1.26 (Norm). Let V be an inner product space. The **norm** of $\mathbf{v} \in V$ is

$$\|\mathbf{v}\| = \sqrt{\langle \mathbf{v}, \mathbf{v}\rangle},$$

the nonnegative square root of the nonnegative real number $\langle \mathbf{v}, \mathbf{v}\rangle$. A **unit vector** is a vector $\mathbf{u}$ with $\|\mathbf{u}\| = 1$.

The norm is the length of $\mathbf{v}$ as measured by the chosen inner product, and $\|\mathbf{v} - \mathbf{w}\|$ is the distance between $\mathbf{v}$ and $\mathbf{w}$. For the dot product on $\mathbb{F}^n$, $\|\mathbf{v}\|^2 = \sum_k |v_k|^2$, so $\|\mathbf{v}\|$ is the Euclidean length. For the Frobenius inner product, $\|A\|^2 = \sum_{i,j} |a_{ij}|^2$, and $\|A\|$ is often written $\|A\|_F$. For the integral inner product, $\|f\|^2 = \int_0^1 |f|^2$. A different inner product on the same space gives different lengths: with the weights $(1, 4)$ of Example 6.1.21, $\|\mathbf{e}_2\| = 2$.

Proposition 6.1.27 (Basic properties of the norm). Let V be an inner product space, $\mathbf{v} \in V$, and $a \in \mathbb{F}$.

(a) $\|\mathbf{v}\| \geq 0$, and $\|\mathbf{v}\| = 0$ if and only if $\mathbf{v} = \mathbf{0}$.

(b) $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$.

Proof. ROUTINE

Uses. Definition 6.1.26 (Norm), Definition 6.1.2 (Inner product), Proposition 6.1.4 (Sesquilinearity), Notation 6.1.1 (Real and complex scalars)
Hint 1. Part (a) is a restatement of two axioms.
Hint 2. For (b), compare squares: compute $\|a\mathbf{v}\|^2 = \langle a\mathbf{v}, a\mathbf{v}\rangle$ by taking a out of each slot.
Hint 3. The second slot contributes $\bar{a}$, and $a\bar{a} = |a|^2$. Two nonnegative reals with the same square are equal.
Sketch. (a) is positivity and definiteness. For (b), $\|a\mathbf{v}\|^2 = a\bar{a}\langle \mathbf{v}, \mathbf{v}\rangle = |a|^2\|\mathbf{v}\|^2$; take nonnegative square roots.

(a) The square root of a nonnegative real number is nonnegative. Also $\|\mathbf{v}\| = 0$ if and only if $\langle \mathbf{v}, \mathbf{v}\rangle = 0$, which by definiteness happens if and only if $\mathbf{v} = \mathbf{0}$.

(b) By linearity in the first slot and Proposition 6.1.4,

$$\|a\mathbf{v}\|^2 = \langle a\mathbf{v}, a\mathbf{v}\rangle = a\bar{a}\langle \mathbf{v}, \mathbf{v}\rangle = |a|^2\|\mathbf{v}\|^2.$$

Both $\|a\mathbf{v}\|$ and $|a|\|\mathbf{v}\|$ are nonnegative real numbers, and their squares are equal, so they are equal. □

In particular, if $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{v}/\|\mathbf{v}\|$ (that is, $(1/\|\mathbf{v}\|)\mathbf{v}$) is a unit vector, since by (b) its norm is $\|\mathbf{v}\|/\|\mathbf{v}\| = 1$. Replacing $\mathbf{v}$ by $\mathbf{v}/\|\mathbf{v}\|$ is called **normalizing** $\mathbf{v}$.

Exercise 6.1.28. ROUTINE Let $\mathbf{v} \neq \mathbf{0}$ be a vector in an inner product space. Find all scalars $a \in \mathbb{F}$ with $\|a\mathbf{v}\| = 1$, separately for $\mathbb{F} = \mathbb{R}$ and for $\mathbb{F} = \mathbb{C}$.

Solution on page 1463

Expanding norms

The computation that produced (6.1.1) expanded $\|\mathbf{v} - \mathbf{w}\|^2$. In a general inner product space the same expansion works, with one change over $\mathbb{C}$.

Proposition 6.1.29 (Expanding a norm). Let V be an inner product space, $\mathbf{x}, \mathbf{y} \in V$, and $a \in \mathbb{F}$. Then

$$\|\mathbf{x} + a\mathbf{y}\|^2 = \|\mathbf{x}\|^2 + 2\,\mathrm{Re}(\overline{a}\langle \mathbf{x}, \mathbf{y}\rangle) + |a|^2\|\mathbf{y}\|^2.$$

In particular,

$$\|\mathbf{x} \pm \mathbf{y}\|^2 = \|\mathbf{x}\|^2 \pm 2\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2.$$

Proof. ROUTINE

Uses. Definition 6.1.26 (Norm), Definition 6.1.2 (Inner product), Proposition 6.1.4 (Sesquilinearity), Notation 6.1.1 (Real and complex scalars)
Techniques. Expand by multilinearity (Technique 5.1.7)
Hint 1. Write $\|\mathbf{x} + a\mathbf{y}\|^2 = \langle \mathbf{x} + a\mathbf{y}, \mathbf{x} + a\mathbf{y}\rangle$ and expand both slots, the second with Proposition 6.1.4.
Hint 2. Of the four terms, the two cross terms are complex conjugates of each other. Use $z + \overline{z} = 2\,\mathrm{Re}\,z$.
Sketch. Expanding gives $\|\mathbf{x}\|^2 + \overline{a}\langle \mathbf{x}, \mathbf{y}\rangle + a\langle \mathbf{y}, \mathbf{x}\rangle + |a|^2\|\mathbf{y}\|^2$, and by conjugate symmetry the cross terms are z and $\overline{z}$ for $z = \overline{a}\langle \mathbf{x}, \mathbf{y}\rangle$. They add to $2\,\mathrm{Re}\,z$. Take $a = \pm 1$ for the second formula.

By linearity in the first slot and Proposition 6.1.4,

$$\begin{aligned}\|\mathbf{x} + a\mathbf{y}\|^2 &= \langle \mathbf{x} + a\mathbf{y}, \mathbf{x} + a\mathbf{y}\rangle \\ &= \langle \mathbf{x}, \mathbf{x}\rangle + \overline{a}\langle \mathbf{x}, \mathbf{y}\rangle + a\langle \mathbf{y}, \mathbf{x}\rangle + a\overline{a}\langle \mathbf{y}, \mathbf{y}\rangle.\end{aligned}$$

Let $z = \overline{a}\langle \mathbf{x}, \mathbf{y}\rangle$. By conjugate symmetry, $a\langle \mathbf{y}, \mathbf{x}\rangle = a\overline{\langle \mathbf{x}, \mathbf{y}\rangle} = \overline{\overline{a}\langle \mathbf{x}, \mathbf{y}\rangle} = \overline{z}$, so the two middle terms add to $z + \overline{z} = 2\,\mathrm{Re}\,z$. Since $a\overline{a} = |a|^2$, this is the first formula. For $a = 1$ it reads $\|\mathbf{x} + \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + 2\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2$, and for $a = -1$ the middle term is $2\,\mathrm{Re}(-\langle \mathbf{x}, \mathbf{y}\rangle) = -2\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$. □

Intuition (The law of cosines, everywhere). Over $\mathbb{R}$ the cross term is $2\langle \mathbf{x}, \mathbf{y}\rangle$, and in $\mathbb{R}^2$ with the dot product, (6.1.1) turns $\|\mathbf{x} - \mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2\mathbf{x} \cdot \mathbf{y} + \|\mathbf{y}\|^2$ back into the law of cosines. So Proposition 6.1.29 is the law of cosines of an arbitrary inner product space; the computation at the start of the section, run backwards.

Over $\mathbb{C}$, only the real part of $\langle \mathbf{x}, \mathbf{y}\rangle$ affects $\|\mathbf{x} \pm \mathbf{y}\|$. The imaginary part appears once $\mathbf{y}$ is multiplied by i: with $a = i$, $\mathrm{Re}\big(\overline{i}\langle \mathbf{x}, \mathbf{y}\rangle\big) = \mathrm{Re}(-i\langle \mathbf{x}, \mathbf{y}\rangle) = \mathrm{Im}\langle \mathbf{x}, \mathbf{y}\rangle$, so

$$\|\mathbf{x} + i\mathbf{y}\|^2 = \|\mathbf{x}\|^2 + 2\,\mathrm{Im}\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2.$$

When $\langle \mathbf{x}, \mathbf{y}\rangle = 0$, the expansion gives $\|\mathbf{x} + \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2$, the Pythagorean theorem of Section 6.3.

The parallelogram law

Vectors $\mathbf{x}$ and $\mathbf{y}$ span a parallelogram whose diagonals are $\mathbf{x} + \mathbf{y}$ and $\mathbf{x} - \mathbf{y}$ (Figure 6.1.3). In a rectangle the two diagonals are equally long, and Pythagoras says that each has squared length $\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2$. Skewing the rectangle lengthens one diagonal and shortens the other. Adding the two expansions in Proposition 6.1.29 shows that the changes in their squares cancel exactly.

Proposition 6.1.30 (Parallelogram law). For all $\mathbf{x}, \mathbf{y}$ in an inner product space,

$$\|\mathbf{x} + \mathbf{y}\|^2 + \|\mathbf{x} - \mathbf{y}\|^2 = 2\|\mathbf{x}\|^2 + 2\|\mathbf{y}\|^2.$$

Proof. ROUTINE

Uses. Proposition 6.1.29 (Expanding a norm)
Hint 1. Expand each term on the left with Proposition 6.1.29.
Hint 2. The cross terms $\pm 2\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$ have opposite signs.
Sketch. Add the expansions of $\|\mathbf{x}+\mathbf{y}\|^2$ and $\|\mathbf{x}-\mathbf{y}\|^2$; the cross terms cancel.

By Proposition 6.1.29,

$$\begin{aligned}\|\mathbf{x}+\mathbf{y}\|^2 + \|\mathbf{x}-\mathbf{y}\|^2 &= \left(\|\mathbf{x}\|^2 + 2\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2\right) + \left(\|\mathbf{x}\|^2 - 2\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2\right) \\ &= 2\|\mathbf{x}\|^2 + 2\|\mathbf{y}\|^2,\end{aligned}$$

as desired. □

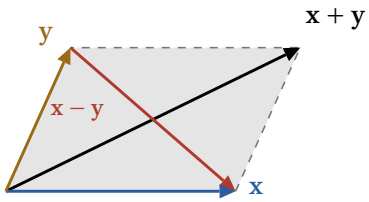

Figure 6.1.3. The parallelogram law: the squares of the diagonals $\mathbf{x}+\mathbf{y}$ and $\mathbf{x}-\mathbf{y}$ add up to the squares of the four sides, $2\|\mathbf{x}\|^2 + 2\|\mathbf{y}\|^2$.

Unlike Proposition 6.1.29, the parallelogram law mentions only norms, not the inner product. That makes it a test: a notion of length that violates it cannot be the norm of any inner product (Aside (Norms that do not come from inner products)).

Exercise 6.1.31. ROUTINE In an inner product space, $\|\mathbf{x}\| = 3$, $\|\mathbf{y}\| = 4$, and $\|\mathbf{x}+\mathbf{y}\| = 6$. Find $\|\mathbf{x}-\mathbf{y}\|$ and $\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$.

Solution on page 1463

Polarization

The norm is defined from the inner product. Polarization goes the other way. Over $\mathbb{R}$, subtracting the two expansions in Proposition 6.1.29 isolates the cross term: $\|\mathbf{x}+\mathbf{y}\|^2 - \|\mathbf{x}-\mathbf{y}\|^2 = 4\langle \mathbf{x}, \mathbf{y}\rangle$. Over $\mathbb{C}$ the same subtraction yields only $4\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$, but the imaginary part is also a real part, since $\mathrm{Im}\langle \mathbf{x}, \mathbf{y}\rangle = \mathrm{Re}(-i\langle \mathbf{x}, \mathbf{y}\rangle) = \mathrm{Re}\langle \mathbf{x}, i\mathbf{y}\rangle$.

Proposition 6.1.32 (Polarization identities). Let V be an inner product space and $\mathbf{x}, \mathbf{y} \in V$.

(a) If $\mathbb{F} = \mathbb{R}$, then

$$\langle \mathbf{x}, \mathbf{y}\rangle = \frac{1}{4}\left(\|\mathbf{x}+\mathbf{y}\|^2 - \|\mathbf{x}-\mathbf{y}\|^2\right).$$

(b) If $\mathbb{F} = \mathbb{C}$, then

$$\begin{aligned}\langle \mathbf{x}, \mathbf{y}\rangle &= \frac{1}{4}\sum_{k=0}^{3} i^k \left\|\mathbf{x} + i^k \mathbf{y}\right\|^2 \\ &= \frac{1}{4}\left(\|\mathbf{x}+\mathbf{y}\|^2 - \|\mathbf{x}-\mathbf{y}\|^2 + i\|\mathbf{x}+i\mathbf{y}\|^2 - i\|\mathbf{x}-i\mathbf{y}\|^2\right).\end{aligned}$$

Proof (via real and imaginary parts). STANDARD

Uses. Proposition 6.1.29 (Expanding a norm), Proposition 6.1.4 (Sesquilinearity), Notation 6.1.1 (Real and complex scalars)

Hint 1. Subtract the two identities of Proposition 6.1.29.
Hint 2. Over $\mathbb{C}$ this gives only $\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$. Write $\operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle$ as the real part of another inner product.
Hint 3. $\langle \mathbf{x}, i\mathbf{y}\rangle = -i\langle \mathbf{x}, \mathbf{y}\rangle$ and $\operatorname{Re}(-iz) = \operatorname{Im} z$. Apply the real-part formula with $i\mathbf{y}$ in place of $\mathbf{y}$.
Sketch. Subtracting the expansions of $\|\mathbf{x} \pm \mathbf{y}\|^2$ gives $4\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle$, which is $4\langle \mathbf{x}, \mathbf{y}\rangle$ over $\mathbb{R}$. Over $\mathbb{C}$, applying this to the pair $\mathbf{x}, i\mathbf{y}$ gives $4\operatorname{Re}\langle \mathbf{x}, i\mathbf{y}\rangle = 4\operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle = \|\mathbf{x} + i\mathbf{y}\|^2 - \|\mathbf{x} - i\mathbf{y}\|^2$. Then combine $\langle \mathbf{x}, \mathbf{y}\rangle = \operatorname{Re} + i \operatorname{Im}$.

Subtracting the two identities of Proposition 6.1.29 gives, for all $\mathbf{x}, \mathbf{y}$ in any inner product space,

$$\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle = \frac{1}{4}\Big(\|\mathbf{x} + \mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2\Big). \tag{6.1.2}$$

(a) If $\mathbb{F} = \mathbb{R}$, then $\langle \mathbf{x}, \mathbf{y}\rangle$ is real, so it equals its real part, and (6.1.2) is (a).

(b) Let $\mathbb{F} = \mathbb{C}$. By Proposition 6.1.4, $\langle \mathbf{x}, i\mathbf{y}\rangle = \bar{i}\langle \mathbf{x}, \mathbf{y}\rangle = -i\langle \mathbf{x}, \mathbf{y}\rangle$, and $\operatorname{Re}(-iz) = \operatorname{Im} z$ for every $z \in \mathbb{C}$. So (6.1.2) applied to $\mathbf{x}$ and $i\mathbf{y}$ gives

$$\operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle = \operatorname{Re}\langle \mathbf{x}, i\mathbf{y}\rangle = \frac{1}{4}\Big(\|\mathbf{x} + i\mathbf{y}\|^2 - \|\mathbf{x} - i\mathbf{y}\|^2\Big).$$

Since $\langle \mathbf{x}, \mathbf{y}\rangle = \operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle + i \operatorname{Im}\langle \mathbf{x}, \mathbf{y}\rangle$, adding (6.1.2) to i times this identity gives the second line of (b). The terms of $\sum_{k=0}^{3} i^k \|\mathbf{x} + i^k\mathbf{y}\|^2$ for $k = 0, 1, 2, 3$ are $\|\mathbf{x} + \mathbf{y}\|^2$, $i\|\mathbf{x} + i\mathbf{y}\|^2$, $-\|\mathbf{x} - \mathbf{y}\|^2$, and $-i\|\mathbf{x} - i\mathbf{y}\|^2$, so the two lines agree. □

Proof (by averaging over powers of i). STANDARD

Uses. Proposition 6.1.29 (Expanding a norm), Notation 6.1.1 (Real and complex scalars)
Hint 1. Expand each $\|\mathbf{x} + i^k\mathbf{y}\|^2$ with Proposition 6.1.29, writing $2\operatorname{Re} w$ as $w + \overline{w}$.
Hint 2. After multiplying by i^k, the terms carry the factors i^k, 1, and i^{2k}. Which of these survive summing over $k = 0, 1, 2, 3$?
Sketch. With $z = \langle \mathbf{x}, \mathbf{y}\rangle$, $i^k\|\mathbf{x} + i^k\mathbf{y}\|^2 = i^k\big(\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2\big) + z + i^{2k}\bar{z}$. Summing over k kills the first and last terms, because $1 + i + i^2 + i^3 = 0$ and $1 - 1 + 1 - 1 = 0$, and leaves $4z$.

Let $\mathbb{F} = \mathbb{C}$, let $z = \langle \mathbf{x}, \mathbf{y}\rangle$, and let $c = i^k$ for some $k \in \{0, 1, 2, 3\}$, so that $|c| = 1$ and $\bar{c} = c^{-1}$. By Proposition 6.1.29, and since $2\operatorname{Re} w = w + \overline{w}$,

$$\|\mathbf{x} + c\mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 + \bar{c}z + c\bar{z}.$$

Multiplying by c and using $c\bar{c} = 1$,

$$c\|\mathbf{x} + c\mathbf{y}\|^2 = c\Big(\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2\Big) + z + c^2\bar{z}.$$

Now sum over $c = 1, i, -1, -i$. The coefficients c add to $1 + i - 1 - i = 0$, and the coefficients c^2 add to $1 - 1 + 1 - 1 = 0$, so

$$\sum_{k=0}^{3} i^k\|\mathbf{x} + i^k\mathbf{y}\|^2 = 4z = 4\langle \mathbf{x}, \mathbf{y}\rangle,$$

which is (b). Part (a) is the same computation with $c = \pm 1$ and z real: then $c\|\mathbf{x} + c\mathbf{y}\|^2 = c\Big(\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2\Big) + 2z$, and summing over $c = \pm 1$ gives $\|\mathbf{x} + \mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2 = 4z$. □

The first proof explains why there are four terms: two give the real part, and two more give the imaginary part. The second explains the coefficients. Multiplying by i^k and summing over k is a filter: it keeps the term that carries no power of i and discards the terms that carry i^k and i^{2k}, because the powers of i add to 0. The same filter works with any $m \geq 3$ equally spaced points on the unit circle in place of $1, i, -1, -i$, and it is the idea behind the discrete Fourier transform.

Technique 6.1.33 (Polarization). An inner product is determined by its values $\langle \mathbf{v}, \mathbf{v}\rangle$ on single vectors: by Proposition 6.1.32, $\langle \mathbf{x}, \mathbf{y}\rangle$ is a combination of the numbers $\|\mathbf{x} + c\mathbf{y}\|^2$ with $c \in \{\pm 1, \pm i\}$. So a statement

about all pairs $(\mathbf{x}, \mathbf{y})$ can often be reduced to a statement about single vectors, applied to $\mathbf{x} + c\mathbf{y}$ for a few scalars c.

Reach for it when the hypothesis or the conclusion involves only lengths, or only "quadratic" quantities such as $\langle T\mathbf{v}, \mathbf{v}\rangle$, and you need information about two different vectors at once. The canonical example is Proposition 6.1.32 itself. Over $\mathbb{R}$ there is a caveat: a *symmetric* function $B(\mathbf{x}, \mathbf{y})$ that is linear in each slot is determined by its diagonal values $B(\mathbf{v}, \mathbf{v})$, but without symmetry this fails. For instance, $B(\mathbf{x}, \mathbf{y}) = x_1 y_2 - x_2 y_1$ on $\mathbb{R}^2$ satisfies $B(\mathbf{v}, \mathbf{v}) = 0$ for all $\mathbf{v}$ without being 0. Over $\mathbb{C}$ no symmetry is needed (Proposition 6.1.41).

Used in. Corollary 6.1.34, Exercise 6.1.35, Proposition 6.1.41, Exercise 6.1.45, Exercise 6.1.51, Exercise 6.1.53, Exercise 6.1.59, Exercise 6.7.8, Problem 6.8, Proposition 8.1.4, Proposition 8.1.13, Theorem 8.4.4.

Corollary 6.1.34 (The norm determines the inner product). Let $\langle\cdot,\cdot\rangle_1$ and $\langle\cdot,\cdot\rangle_2$ be inner products on V with $\langle \mathbf{v}, \mathbf{v}\rangle_1 = \langle \mathbf{v}, \mathbf{v}\rangle_2$ for all $\mathbf{v} \in V$. Then $\langle \mathbf{x}, \mathbf{y}\rangle_1 = \langle \mathbf{x}, \mathbf{y}\rangle_2$ for all $\mathbf{x}, \mathbf{y} \in V$.

Proof. ROUTINE

Uses. Proposition 6.1.32 (Polarization identities)
Techniques. Polarization (Technique 6.1.33)
Hint 1. Write both $\langle \mathbf{x}, \mathbf{y}\rangle_1$ and $\langle \mathbf{x}, \mathbf{y}\rangle_2$ with Proposition 6.1.32.
Hint 2. The right sides of the polarization identities only involve norms, and the two norms agree.
Sketch. Both inner products equal the same combination of the numbers $\|\mathbf{x} + c\mathbf{y}\|^2$, $c \in \{\pm 1, \pm i\}$, and these do not depend on which inner product defines the norm.

The two inner products define the same norm, $\|\mathbf{v}\| = \sqrt{\langle \mathbf{v}, \mathbf{v}\rangle_1} = \sqrt{\langle \mathbf{v}, \mathbf{v}\rangle_2}$. By Proposition 6.1.32, applied once to each inner product, both $\langle \mathbf{x}, \mathbf{y}\rangle_1$ and $\langle \mathbf{x}, \mathbf{y}\rangle_2$ equal $\frac{1}{4}\left(\|\mathbf{x} + \mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2\right)$ if $\mathbb{F} = \mathbb{R}$, and $\frac{1}{4}\sum_{k=0}^{3} i^k \|\mathbf{x} + i^k \mathbf{y}\|^2$ if $\mathbb{F} = \mathbb{C}$. So they are equal. □

Combined with Proposition 6.1.27(b), the inner product is even determined by its unit sphere $\{\mathbf{v} \in V \mid \|\mathbf{v}\| = 1\}$: for $\mathbf{v} \neq \mathbf{0}$, $\|\mathbf{v}\|$ is the unique $t > 0$ for which $\mathbf{v}/t$ lies on the sphere. So each curve in Figure 6.1.2 determines its inner product completely.

Exercise 6.1.35. ROUTINE Vectors $\mathbf{x}, \mathbf{y}$ in a complex inner product space satisfy

$$\|\mathbf{x} + \mathbf{y}\|^2 = 10, \quad \|\mathbf{x} - \mathbf{y}\|^2 = 2, \quad \|\mathbf{x} + i\mathbf{y}\|^2 = 4, \quad \|\mathbf{x} - i\mathbf{y}\|^2 = 8.$$

Find $\langle \mathbf{x}, \mathbf{y}\rangle$ and $\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2$.

Solution on page 1463

6.1.5 Inner products distinguish vectors

The lecture's next observation is that a vector is determined by its inner products with all vectors. The proof is a one-line instance of a move used throughout this chapter, so we name it first.

Technique 6.1.36 (Show a vector is zero via its norm). By definiteness, $\mathbf{v} = \mathbf{0}$ as soon as $\langle \mathbf{v}, \mathbf{v}\rangle = 0$. So to prove that a vector is zero, compute $\langle \mathbf{v}, \mathbf{v}\rangle$, or $\|\mathbf{v}\|^2$, and show that it vanishes. Often one knows that $\langle \mathbf{v}, \mathbf{x}\rangle = 0$ for many $\mathbf{x}$, and the move is to take $\mathbf{x} = \mathbf{v}$. To prove $\mathbf{v} = \mathbf{w}$, apply this to $\mathbf{v} - \mathbf{w}$, expanding $\|\mathbf{v} - \mathbf{w}\|^2$ with Proposition 6.1.29 if necessary.

Reach for it when the hypotheses are statements about inner products and the conclusion is an equation between vectors. The canonical example is Proposition 6.1.37. In Section 6.5 the same move shows that $A^*A\mathbf{x} = \mathbf{0}$ implies $A\mathbf{x} = \mathbf{0}$.

Used in. Proposition 6.1.37, Corollary 6.1.38, Exercise 6.1.50, Proposition 6.3.30, Theorem 6.5.5, Proposition 6.5.9, Theorem 6.6.21, Proposition 6.6.23, Exercise 6.7.9, Problem 6.3, Problem 6.8, Problem 6.9, Problem 6.11, Proposition 8.1.4, Exercise 8.1.6, Proposition 8.1.14, Theorem 8.2.5, Lemma 8.3.8, Exercise 6.6.51.

Proposition 6.1.37 (Inner products distinguish vectors). Let V be an inner product space and $\mathbf{v}, \mathbf{w} \in V$. If $\langle \mathbf{v}, \mathbf{x} \rangle = \langle \mathbf{w}, \mathbf{x} \rangle$ for all $\mathbf{x} \in V$, then $\mathbf{v} = \mathbf{w}$.

Proof. ROUTINE

Uses. Definition 6.1.2 (Inner product), Proposition 6.1.4 (Sesquilinearity)
Techniques. Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Reduce to the case $\mathbf{w} = \mathbf{0}$ by looking at $\mathbf{v} - \mathbf{w}$.
Hint 2. If $\langle \mathbf{u}, \mathbf{x} \rangle = 0$ for every $\mathbf{x}$, which choice of $\mathbf{x}$ tells you the most about $\mathbf{u}$?
Hint 3. Take $\mathbf{x} = \mathbf{u}$ and use definiteness.
Sketch. By linearity, $\langle \mathbf{v} - \mathbf{w}, \mathbf{x} \rangle = 0$ for every $\mathbf{x}$. Choosing $\mathbf{x} = \mathbf{v} - \mathbf{w}$ gives $\|\mathbf{v} - \mathbf{w}\|^2 = 0$, so $\mathbf{v} = \mathbf{w}$.

First suppose $\mathbf{w} = \mathbf{0}$. By Proposition 6.1.4, $\langle \mathbf{v}, \mathbf{x} \rangle = \langle \mathbf{0}, \mathbf{x} \rangle = 0$ for all $\mathbf{x} \in V$. In particular, for $\mathbf{x} = \mathbf{v}$ we get $\langle \mathbf{v}, \mathbf{v} \rangle = 0$, and $\mathbf{v} = \mathbf{0}$ by definiteness.

For the general case, linearity in the first slot gives $\langle \mathbf{v} - \mathbf{w}, \mathbf{x} \rangle = \langle \mathbf{v}, \mathbf{x} \rangle - \langle \mathbf{w}, \mathbf{x} \rangle = 0 = \langle \mathbf{0}, \mathbf{x} \rangle$ for all $\mathbf{x} \in V$. By the first case, $\mathbf{v} - \mathbf{w} = \mathbf{0}$, that is, $\mathbf{v} = \mathbf{w}$, as desired. □

The same holds with the vectors in the second slot: if $\langle \mathbf{x}, \mathbf{v} \rangle = \langle \mathbf{x}, \mathbf{w} \rangle$ for all $\mathbf{x}$, conjugating gives $\langle \mathbf{v}, \mathbf{x} \rangle = \langle \mathbf{w}, \mathbf{x} \rangle$ for all $\mathbf{x}$. Nor do we need every $\mathbf{x}$: the vectors of a spanning list suffice (Exercise 6.1.50).

Corollary 6.1.38 (Linear maps are determined by inner products). Let V be a vector space over $\mathbb{F}$, let W be an inner product space, and let $S, T : V \to W$ be linear. If $\langle S\mathbf{v}, \mathbf{w} \rangle = \langle T\mathbf{v}, \mathbf{w} \rangle$ for all $\mathbf{v} \in V$ and all $\mathbf{w} \in W$, then $S = T$.

Proof. ROUTINE

Uses. Proposition 6.1.37 (Inner products distinguish vectors)
Techniques. Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Fix $\mathbf{v} \in V$. What does the hypothesis say about the two vectors $S\mathbf{v}$ and $T\mathbf{v}$ of W?
Hint 2. Apply Proposition 6.1.37 in W.
Sketch. For each fixed $\mathbf{v}$, $\langle S\mathbf{v}, \mathbf{w} \rangle = \langle T\mathbf{v}, \mathbf{w} \rangle$ for all $\mathbf{w} \in W$, so $S\mathbf{v} = T\mathbf{v}$ by Proposition 6.1.37.

Here and below we write $T\mathbf{v}$ for $T(\mathbf{v})$. Fix $\mathbf{v} \in V$. By hypothesis, the vectors $S\mathbf{v}$ and $T\mathbf{v}$ of W satisfy $\langle S\mathbf{v}, \mathbf{w} \rangle = \langle T\mathbf{v}, \mathbf{w} \rangle$ for all $\mathbf{w} \in W$, so $S\mathbf{v} = T\mathbf{v}$ by Proposition 6.1.37. Since $\mathbf{v}$ was arbitrary, $S = T$. □

The proof never used that S and T are linear, so the corollary holds for arbitrary functions $V \to W$. It is how adjoints will be shown to be unique (Section 6.6).

Testing on the diagonal

Corollary 6.1.38 tests $\langle T\mathbf{v}, \mathbf{w} \rangle$ on all pairs of vectors. For an operator $T \in \mathrm{L}(V)$, it is natural to ask whether the values $\langle T\mathbf{v}, \mathbf{v} \rangle$, with the same vector in both slots, are already enough. Over $\mathbb{R}$ they are not.

Example 6.1.39 (A rotation). Let $T : \mathbb{R}^2 \to \mathbb{R}^2$ be $T\mathbf{x} = J\mathbf{x} = (-x_2, x_1)$, where $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$; this is the rotation by $\pi/2$. With the dot product,

$$\langle T\mathbf{x}, \mathbf{x} \rangle = (-x_2)x_1 + x_1 x_2 = 0 \quad \text{for every } \mathbf{x} \in \mathbb{R}^2,$$

as a rotation by a right angle moves every vector to a perpendicular one. But $T \neq 0$.

Over $\mathbb{C}$, however, the values $\langle T\mathbf{v}, \mathbf{v} \rangle$ do determine T. The proof feeds the hypothesis well-chosen vectors, a move that polarization has already used.

Technique 6.1.40 (Plug in clever test vectors). A hypothesis that holds for all vectors holds in particular for sums and multiples of the vectors you care about. Applying it to $\mathbf{v} = \mathbf{x} + \mathbf{y}$, $\mathbf{x} - \mathbf{y}$, $\mathbf{x} + i\mathbf{y}$, or to the very vector you want to control, turns one identity into a system of equations, which can then be solved for the quantity you want.

Reach for it when a hypothesis is quantified over all vectors but involves each vector only quadratically, like $\|\mathbf{v}\|$ or $\langle T\mathbf{v},\mathbf{v}\rangle$, and you need information about pairs of vectors. Over $\mathbb{C}$, the pair $\mathbf{x}+\mathbf{y}$ and $\mathbf{x}+i\mathbf{y}$ is usually the right choice, because together they separate real and imaginary parts. The canonical example is Proposition 6.1.41. The polarization identities (Proposition 6.1.32) and the choice $\mathbf{x}=\mathbf{v}-\mathbf{w}$ in Proposition 6.1.37 are instances of the same move.
Used in. Proposition 6.1.41, Exercise 6.1.46, Exercise 6.1.47, Exercise 6.1.52, Proposition 6.3.5, Exercise 6.3.52, Exercise 6.7.7, Exercise 6.7.8, Exercise 6.7.15, Problem 6.6, Problem 7.8, Proposition 8.1.4, Theorem 8.3.23, Exercise 8.4.34.

Proposition 6.1.41 (Over $\mathbb{C}$, the values $\langle T\mathbf{v},\mathbf{v}\rangle$ determine T). Let V be a complex inner product space and $T\in \mathrm{L}(V)$. If $\langle T\mathbf{v},\mathbf{v}\rangle=0$ for all $\mathbf{v}\in V$, then $T=0$. Consequently, if $S,T\in\mathrm{L}(V)$ satisfy $\langle S\mathbf{v},\mathbf{v}\rangle=\langle T\mathbf{v},\mathbf{v}\rangle$ for all $\mathbf{v}\in V$, then $S=T$.

Intuition. By Corollary 6.1.38 it suffices to show $\langle T\mathbf{x},\mathbf{y}\rangle=0$ for all $\mathbf{x},\mathbf{y}$, but the hypothesis only speaks about one vector at a time. Plugging $\mathbf{v}=\mathbf{x}+\mathbf{y}$ into it isolates the sum $\langle T\mathbf{x},\mathbf{y}\rangle+\langle T\mathbf{y},\mathbf{x}\rangle$. Over $\mathbb{R}$ that is all one can get, and for the rotation of Example 6.1.39 this sum is 0 for all $\mathbf{x},\mathbf{y}$ although its terms are not. Over $\mathbb{C}$, plugging in $\mathbf{v}=\mathbf{x}+i\mathbf{y}$ produces a second combination, $-i$ times the difference $\langle T\mathbf{x},\mathbf{y}\rangle-\langle T\mathbf{y},\mathbf{x}\rangle$, and two independent equations in the two unknowns can be solved.

Proof (with test vectors). STANDARD

Uses. Corollary 6.1.38 (Linear maps are determined by inner products), Proposition 6.1.4 (Sesquilinearity), Proposition 2.1.23 ($\mathrm{L}(V,W)$ is a vector space)
Techniques. Plug in clever test vectors (Technique 6.1.40)
Hint 1. It suffices to show $\langle T\mathbf{x},\mathbf{y}\rangle=0$ for all $\mathbf{x},\mathbf{y}\in V$. Apply the hypothesis to a vector built from $\mathbf{x}$ and $\mathbf{y}$.
Hint 2. $\mathbf{v}=\mathbf{x}+\mathbf{y}$ gives $\langle T\mathbf{x},\mathbf{y}\rangle+\langle T\mathbf{y},\mathbf{x}\rangle=0$. That alone cannot suffice, since the rotation satisfies it. Find a second equation.
Hint 3. Try $\mathbf{v}=\mathbf{x}+i\mathbf{y}$, and remember that i leaves the second slot as $-i$.
Sketch. Expanding $\langle T\mathbf{v},\mathbf{v}\rangle=0$ at $\mathbf{v}=\mathbf{x}+\mathbf{y}$ and at $\mathbf{v}=\mathbf{x}+i\mathbf{y}$ gives $\langle T\mathbf{x},\mathbf{y}\rangle+\langle T\mathbf{y},\mathbf{x}\rangle=0$ and $-i\langle T\mathbf{x},\mathbf{y}\rangle+i\langle T\mathbf{y},\mathbf{x}\rangle=0$. Dividing the second by $-i$ and adding, $\langle T\mathbf{x},\mathbf{y}\rangle=0$ for all $\mathbf{x},\mathbf{y}$, so $T=0$. Apply this to $S-T$ for the last claim.

Let $\mathbf{x},\mathbf{y}\in V$. Since T is linear and the inner product is sesquilinear,

$$\langle T(\mathbf{x}+\mathbf{y}),\mathbf{x}+\mathbf{y}\rangle=\langle T\mathbf{x},\mathbf{x}\rangle+\langle T\mathbf{x},\mathbf{y}\rangle+\langle T\mathbf{y},\mathbf{x}\rangle+\langle T\mathbf{y},\mathbf{y}\rangle.$$

The left side and the first and last terms on the right are 0 by hypothesis, so

$$\langle T\mathbf{x},\mathbf{y}\rangle+\langle T\mathbf{y},\mathbf{x}\rangle=0. \tag{6.1.3}$$

Similarly, $T(\mathbf{x}+i\mathbf{y})=T\mathbf{x}+iT\mathbf{y}$, and Proposition 6.1.4 gives

$$\langle T\mathbf{x}+iT\mathbf{y},\mathbf{x}+i\mathbf{y}\rangle=\langle T\mathbf{x},\mathbf{x}\rangle+\bar{i}\langle T\mathbf{x},\mathbf{y}\rangle+i\langle T\mathbf{y},\mathbf{x}\rangle+i\bar{i}\langle T\mathbf{y},\mathbf{y}\rangle.$$

Again the left side and the first and last terms vanish, so $-i\langle T\mathbf{x},\mathbf{y}\rangle+i\langle T\mathbf{y},\mathbf{x}\rangle=0$. Dividing by $-i$,

$$\langle T\mathbf{x},\mathbf{y}\rangle-\langle T\mathbf{y},\mathbf{x}\rangle=0.$$

Adding this to (6.1.3) gives $2\langle T\mathbf{x},\mathbf{y}\rangle=0$, so $\langle T\mathbf{x},\mathbf{y}\rangle=0=\langle 0\mathbf{x},\mathbf{y}\rangle$ for all $\mathbf{x},\mathbf{y}\in V$. By Corollary 6.1.38, $T=0$.

For the last statement, $S-T\in\mathrm{L}(V)$ (Proposition 2.1.23), and $\langle (S-T)\mathbf{v},\mathbf{v}\rangle=\langle S\mathbf{v},\mathbf{v}\rangle-\langle T\mathbf{v},\mathbf{v}\rangle=0$ for all $\mathbf{v}$. So $S-T=0$. □

Proof (by polarizing a sesquilinear function). STANDARD

Uses. Corollary 6.1.38 (Linear maps are determined by inner products), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.32 (Polarization identities)
Techniques. Polarization (Technique 6.1.33)
Hint 1. The function $B(\mathbf{x},\mathbf{y})=\langle T\mathbf{x},\mathbf{y}\rangle$ is linear in $\mathbf{x}$ and conjugate-linear in $\mathbf{y}$, like an inner product, but it need not be conjugate symmetric or positive. Try to redo the second proof of Proposition 6.1.32 for B; where that proof wrote $\bar{z}$ for $\langle\mathbf{y},\mathbf{x}\rangle$, keep $B(\mathbf{y},\mathbf{x})$ instead.
Hint 2. Expand $B\big(\mathbf{x}+i^k\mathbf{y},\mathbf{x}+i^k\mathbf{y}\big)$, multiply by i^k, and sum over $k=0,\dots,3$.

Sketch. Redo the roots-of-unity computation of Proposition 6.1.32 with $B(\mathbf{y},\mathbf{x})$ in place of $\overline{z}$; that term still carries the factor c^2, which sums to 0. So any B that is linear in the first slot and conjugate-linear in the second satisfies $B(\mathbf{x},\mathbf{y}) = \frac{1}{4}\sum_k i^k B\big(\mathbf{x}+i^k\mathbf{y},\mathbf{x}+i^k\mathbf{y}\big)$. For $B(\mathbf{x},\mathbf{y}) = \langle T\mathbf{x},\mathbf{y}\rangle$, every term on the right is 0.

Let $B(\mathbf{x},\mathbf{y}) = \langle T\mathbf{x},\mathbf{y}\rangle$. It is linear in $\mathbf{x}$, as T is linear and the inner product is linear in the first slot, and it satisfies $B(\mathbf{x},a\mathbf{y}+b\mathbf{z}) = \overline{a}B(\mathbf{x},\mathbf{y}) + \overline{b}B(\mathbf{x},\mathbf{z})$ by Proposition 6.1.4. For $c\in\mathbb{C}$ with $|c|=1$, expanding gives

$$B(\mathbf{x}+c\mathbf{y},\mathbf{x}+c\mathbf{y}) = B(\mathbf{x},\mathbf{x}) + \overline{c}B(\mathbf{x},\mathbf{y}) + cB(\mathbf{y},\mathbf{x}) + B(\mathbf{y},\mathbf{y}),$$

using $c\overline{c}=1$. Multiply by c and sum over $c=i^k$, $k=0,1,2,3$. Since $\sum_k i^k = 0$, $\sum_k i^k\overline{i^k} = 4$, and $\sum_k i^{2k} = 0$,

$$B(\mathbf{x},\mathbf{y}) = \frac{1}{4}\sum_{k=0}^{3} i^k B\big(\mathbf{x}+i^k\mathbf{y},\mathbf{x}+i^k\mathbf{y}\big). \tag{6.1.4}$$

We never used conjugate symmetry or positivity, only how B treats scalars in each slot. For our B, every term on the right is of the form $\langle T\mathbf{v},\mathbf{v}\rangle = 0$. So $\langle T\mathbf{x},\mathbf{y}\rangle = 0$ for all $\mathbf{x},\mathbf{y}$, and $T=0$ by Corollary 6.1.38. The last statement follows as in the first proof. □

The second proof shows more. Over $\mathbb{C}$, every function $B: V\times V\to\mathbb{C}$ that is linear in the first slot and conjugate-linear in the second is determined by its diagonal values $B(\mathbf{v},\mathbf{v})$, through (6.1.4), with no symmetry assumption. Over $\mathbb{R}$ the analogous computation gives

$$\frac{1}{4}(B(\mathbf{x}+\mathbf{y},\mathbf{x}+\mathbf{y}) - B(\mathbf{x}-\mathbf{y},\mathbf{x}-\mathbf{y})) = \frac{1}{2}(B(\mathbf{x},\mathbf{y}) + B(\mathbf{y},\mathbf{x})),$$

which recovers only the symmetric part of B. For the rotation of Example 6.1.39, $B(\mathbf{x},\mathbf{y}) = (J\mathbf{x})\cdot\mathbf{y} = x_1y_2 - x_2y_1$ is antisymmetric, so its symmetric part is 0 although B is not.

ASIDE: *Norms that do not come from inner products* BEYOND 21-242

The properties of $\|\cdot\|$ that matter in analysis are (a) and (b) of Proposition 6.1.27, together with the triangle inequality $\|\mathbf{v}+\mathbf{w}\| \le \|\mathbf{v}\| + \|\mathbf{w}\|$, which Section 6.2 proves for the norm of an inner product. Any function $V\to\mathbb{R}$ with these three properties is called a norm on V, and a vector space with a norm is a **normed space**. Every inner product space is a normed space, but $\mathbb{F}^n$ carries many norms that do not come from inner products, for instance

$$\|\mathbf{x}\|_1 = \sum_{k=1}^{n}|x_k|, \quad \|\mathbf{x}\|_\infty = \max_k |x_k|.$$

The first is the *taxicab norm*, the distance driven along a grid of streets; the second is the *maximum norm*. Checking the three properties for each is a short exercise. Their unit spheres in $\mathbb{R}^2$ are a diamond and a square (Figure 6.1.4), while those of inner products look like the ellipses of Figure 6.1.2.

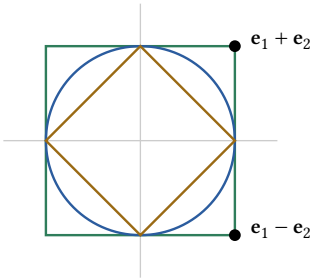

Figure 6.1.4. The unit spheres of $\|\cdot\|_1$ (diamond), of the Euclidean norm (circle), and of $\|\cdot\|_\infty$ (square) in $\mathbb{R}^2$. The marked points $\mathbf{e}_1\pm\mathbf{e}_2$ test the parallelogram law.

Corners suggest that no inner product is involved, and the parallelogram law (Proposition 6.1.30) makes this precise. In $\mathbb{R}^2$,

$$\|\mathbf{e}_1 + \mathbf{e}_2\|_1^2 + \|\mathbf{e}_1 - \mathbf{e}_2\|_1^2 = 4 + 4 = 8,$$
$$\|\mathbf{e}_1 + \mathbf{e}_2\|_\infty^2 + \|\mathbf{e}_1 - \mathbf{e}_2\|_\infty^2 = 1 + 1 = 2,$$

while $2\|\mathbf{e}_1\|^2 + 2\|\mathbf{e}_2\|^2 = 4$ for both norms. So neither satisfies the parallelogram law, and neither is the norm of any inner product on $\mathbb{R}^2$.

The parallelogram law is the only obstruction. The **Jordan–von Neumann theorem** says that a norm on a real or complex vector space is the norm of an inner product if and only if it satisfies the parallelogram law. The inner product is then given by the polarization identities, as it must be by Corollary 6.1.34. The real case is Exercise 6.1.61.

Exercises

Exercise 6.1.42. STANDARD Decide which of the following define inner products.

(a) On $\mathbb{R}^3$: $\langle \mathbf{x}, \mathbf{y} \rangle = x_1y_1 + 2x_2y_2 + 3x_3y_3 + x_1y_3 + x_3y_1$.

(b) On $\mathbb{R}^{2\times 2}$: $\langle A, B \rangle = \operatorname{tr}(A)\operatorname{tr}(B)$.

(c) On $\mathbb{C}^2$: $\langle \mathbf{x}, \mathbf{y} \rangle = x_1\overline{y_1} + ix_2\overline{y_2}$.

(d) On $\mathbb{R}[x]_{\le 2}$: $\langle p, q \rangle = p(-1)q(-1) + p(0)q(0) + p(1)q(1)$.

(e) On $\mathbb{C}^2$: $\langle \mathbf{x}, \mathbf{y} \rangle = 2x_1\overline{y_1} - ix_2\overline{y_1} + ix_1\overline{y_2} + x_2\overline{y_2}$.

Solution on page 1463

Exercise 6.1.43. STANDARD The proof of Proposition 6.1.13 works on any closed interval $[a, b]$ in place of $[0, 1]$. Decide which of the following are inner products.

(a) $\langle f, g \rangle = \int_{-1}^{1} t^2 f(t)g(t)\,dt$ on $C[-1, 1]$.

(b) $\langle f, g \rangle = \int_{-1}^{1} t f(t)g(t)\,dt$ on $C[-1, 1]$.

(c) $\langle f, g \rangle = \int_{0}^{1/2} f(t)g(t)\,dt$ on $C[0, 1]$.

(d) $\langle f, g \rangle = f(0)g(0) + \int_0^1 f'(t)g'(t)\,dt$ on the space $C^1[0, 1]$ of continuously differentiable functions $[0, 1] \to \mathbb{R}$.

Solution on page 1464

Exercise 6.1.44. ROUTINE In a complex inner product space, $\|\mathbf{x}\| = 1$, $\|\mathbf{y}\| = 2$, and $\langle \mathbf{x}, \mathbf{y} \rangle = 1 - i$. Compute

(a) $\langle 2\mathbf{x} + i\mathbf{y}, \mathbf{x} - \mathbf{y} \rangle$;

(b) $\|\mathbf{x} - i\mathbf{y}\|^2$;

(c) $\|(1 + i)\mathbf{x} + \mathbf{y}\|^2$.

(d) Find $c \in \mathbb{C}$ with $\langle \mathbf{x} - c\mathbf{y}, \mathbf{y} \rangle = 0$, and compute $\|\mathbf{x} - c\mathbf{y}\|^2$.

Solution on page 1465

Exercise 6.1.45. STANDARD

(a) An inner product on $\mathbb{R}^2$ satisfies $\|\mathbf{e}_1\| = 1$, $\|\mathbf{e}_2\| = 2$, and $\|\mathbf{e}_1 + \mathbf{e}_2\| = 2$. Show that there is exactly one such inner product, and find a formula for $\langle \mathbf{x}, \mathbf{y} \rangle$.

(b) Compute $\|\mathbf{e}_1 - \mathbf{e}_2\|$ for the inner product of (a) in two ways: from your formula, and from the parallelogram law.

(c) Show that no inner product on $\mathbb{R}^2$ satisfies $\|\mathbf{e}_1\| = 1$, $\|\mathbf{e}_2\| = 2$, and $\|\mathbf{e}_1 + \mathbf{e}_2\| = 4$.

Solution on page 1465

Exercise 6.1.46. STANDARD For which $a, b, c \in \mathbb{R}$ is

$$\langle \mathbf{x}, \mathbf{y} \rangle = ax_1y_1 + b(x_1y_2 + x_2y_1) + cx_2y_2$$

an inner product on $\mathbb{R}^2$?

Solution on page 1466

Exercise 6.1.47. STANDARD Let $M \in \mathbb{C}^{n\times n}$, and suppose $\mathbf{x}^*M\mathbf{x} \in \mathbb{R}$ for every $\mathbf{x} \in \mathbb{C}^n$. Show that $M^* = M$. Conclude that over $\mathbb{C}$, the condition $M^* = M$ in Proposition 6.1.22(b) is implied by the condition $\mathbf{x}^*M\mathbf{x} > 0$ for $\mathbf{x} \neq \mathbf{0}$. (By Remark 6.1.24, this fails over $\mathbb{R}$.)

Solution on page 1466

Exercise 6.1.48. STANDARD Let $\mathbf{x}, \mathbf{y}, \mathbf{z}$ be vectors in an inner product space, and let $\mathbf{m} = (\mathbf{x} + \mathbf{y})/2$. Prove **Apollonius's identity**

$$\|\mathbf{z} - \mathbf{x}\|^2 + \|\mathbf{z} - \mathbf{y}\|^2 = \frac{1}{2}\|\mathbf{x} - \mathbf{y}\|^2 + 2\|\mathbf{z} - \mathbf{m}\|^2.$$

In $\mathbb{R}^2$, what does it say about the triangle with vertices $\mathbf{x}, \mathbf{y}, \mathbf{z}$?

Solution on page 1467

Exercise 6.1.49. STANDARD Let $\mathbf{x}, \mathbf{y}$ be vectors in an inner product space.

(a) Show that $\|\mathbf{x}\| = \|\mathbf{y}\|$ if and only if $\operatorname{Re}\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = 0$. Interpret the case $\mathbb{F} = \mathbb{R}$, $V = \mathbb{R}^2$ geometrically.

(b) Over $\mathbb{C}$, show that $\langle \mathbf{x} + \mathbf{y}, \mathbf{x} - \mathbf{y} \rangle = 0$ if and only if $\|\mathbf{x}\| = \|\mathbf{y}\|$ and $\langle \mathbf{x}, \mathbf{y} \rangle \in \mathbb{R}$.

Solution on page 1467

Exercise 6.1.50. ROUTINE Let V be an inner product space, and let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ span V. Show that if $\mathbf{x}, \mathbf{y} \in V$ satisfy $\langle \mathbf{x}, \mathbf{v}_j \rangle = \langle \mathbf{y}, \mathbf{v}_j \rangle$ for $j = 1, \ldots, k$, then $\mathbf{x} = \mathbf{y}$. Give an example showing that the spanning hypothesis cannot be dropped.

Solution on page 1467

Exercise 6.1.51. STANDARD Let V, W be inner product spaces over the same $\mathbb{F}$, and let $T : V \to W$ be linear with $\|T\mathbf{v}\| = \|\mathbf{v}\|$ for all $\mathbf{v} \in V$. Show that $\langle T\mathbf{v}, T\mathbf{w} \rangle = \langle \mathbf{v}, \mathbf{w} \rangle$ for all $\mathbf{v}, \mathbf{w} \in V$, and that T is injective. (Maps of this kind are studied in Section 8.4.)

Solution on page 1468

Exercise 6.1.52. STANDARD Let V be a real inner product space and $T \in \mathrm{L}(V)$.

(a) Prove or disprove: if $\langle T\mathbf{v}, \mathbf{v} \rangle = 0$ for all $\mathbf{v} \in V$, then $T = 0$.

(b) Show that $\langle T\mathbf{v}, \mathbf{v} \rangle = 0$ for all $\mathbf{v} \in V$ if and only if $\langle T\mathbf{v}, \mathbf{w} \rangle = -\langle \mathbf{v}, T\mathbf{w} \rangle$ for all $\mathbf{v}, \mathbf{w} \in V$.

(c) Suppose $\langle T\mathbf{v}, \mathbf{w} \rangle = \langle \mathbf{v}, T\mathbf{w} \rangle$ for all $\mathbf{v}, \mathbf{w} \in V$. Show that if $\langle T\mathbf{v}, \mathbf{v} \rangle = 0$ for all $\mathbf{v}$, then $T = 0$.

Solution on page 1468

Exercise 6.1.53. HARD Let V be a complex inner product space and $T \in \mathrm{L}(V)$. Show that $\langle T\mathbf{v}, \mathbf{v} \rangle \in \mathbb{R}$ for all $\mathbf{v} \in V$ if and only if $\langle T\mathbf{v}, \mathbf{w} \rangle = \langle \mathbf{v}, T\mathbf{w} \rangle$ for all $\mathbf{v}, \mathbf{w} \in V$. (Such operators are called self-adjoint; see Section 6.6.)

Solution on page 1468

Exercise 6.1.54. HARD Let $A \in \mathbb{C}^{n\times n}$ satisfy $A^* = A$ and $A^k = 0$ for some $k \geq 1$. Show that $A = 0$. (Start by proving $(BC)^* = C^*B^*$ for square matrices B, C.)

Solution on page 1469

Exercise 6.1.55. ROUTINE Let $A \in \mathbb{R}^{n\times n}$ be skew-symmetric, $A^{\mathsf{T}} = -A$.

(a) Show that $\operatorname{tr}(A^2) \leq 0$, with equality only if $A = 0$.

(b) Deduce that no real skew-symmetric matrix satisfies $A^2 = I_n$. Show that $A^2 = -I_2$ is possible.

Solution on page 1469

Exercise 6.1.56. STANDARD For $\mathbf{u}, \mathbf{x} \in \mathbb{F}^m$ and $\mathbf{v}, \mathbf{y} \in \mathbb{F}^n$, the products $\mathbf{u}\mathbf{v}^*$ and $\mathbf{x}\mathbf{y}^*$ are $m \times n$ matrices. Show that, with the Frobenius inner product on $\mathbb{F}^{m\times n}$ and dot products on $\mathbb{F}^m$ and $\mathbb{F}^n$,

$$\langle \mathbf{u}\mathbf{v}^*, \mathbf{x}\mathbf{y}^* \rangle = (\mathbf{u} \cdot \mathbf{x})(\mathbf{y} \cdot \mathbf{v}),$$

and deduce that $\|\mathbf{u}\mathbf{v}^*\| = \|\mathbf{u}\|\|\mathbf{v}\|$.

Solution on page 1470

Exercise 6.1.57. HARD Let $\mathbf{x}_1, \ldots, \mathbf{x}_n$ be unit vectors in an inner product space.

(a) Show that

$$\sum_{1 \leq i < j \leq n} \|\mathbf{x}_i - \mathbf{x}_j\|^2 = n^2 - \|\mathbf{x}_1 + \cdots + \mathbf{x}_n\|^2.$$

(b) Deduce that $\sum_{i<j} \|\mathbf{x}_i - \mathbf{x}_j\|^2 \leq n^2$, with equality if and only if $\mathbf{x}_1 + \cdots + \mathbf{x}_n = \mathbf{0}$.

(c) For three unit vectors in $\mathbb{R}^2$, find the largest possible value of $\sum_{i<j} \|\mathbf{x}_i - \mathbf{x}_j\|^2$ and a configuration attaining it.

Solution on page 1470

Exercise 6.1.58. HARD This exercise shows that for $n \geq 3$, the formula $\sum_k x_k y_k$ on $\mathbb{F}_p^n$ is never definite. (For $n = 1$ it is, since $x^2 = 0$ forces $x = 0$.)

(a) Find a nonzero $\mathbf{x} \in \mathbb{F}_5^2$ with $x_1^2 + x_2^2 = 0$.

(b) Show that for every prime p there is a nonzero $\mathbf{x} \in \mathbb{F}_p^3$ with $x_1^2 + x_2^2 + x_3^2 = 0$, and deduce the same in $\mathbb{F}_p^n$ for every $n \geq 3$.

Solution on page 1470

Exercise 6.1.59. STANDARD Find the error in the following argument, and decide whether the claim is true.

Claim. If $B : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is linear in each slot and $B(\mathbf{v}, \mathbf{v}) = 0$ for all $\mathbf{v} \in \mathbb{R}^n$, then $B = 0$.

Proof. By the polarization identity, for all $\mathbf{x}, \mathbf{y}$,

$$B(\mathbf{x}, \mathbf{y}) = \frac{1}{4}(B(\mathbf{x}+\mathbf{y}, \mathbf{x}+\mathbf{y}) - B(\mathbf{x}-\mathbf{y}, \mathbf{x}-\mathbf{y})) = \frac{1}{4}(0 - 0) = 0.$$

Solution on page 1471

Exercise 6.1.60. STANDARD Let $R[0,1]$ be the real vector space of Riemann-integrable functions $[0,1] \to \mathbb{R}$. Find the error in the following argument, and decide whether the claim is true.

Claim. $\langle f, g\rangle = \int_0^1 f(t)g(t)\,dt$ is an inner product on $R[0,1]$.

Proof. Products of integrable functions are integrable, so $\langle f, g\rangle$ is defined. Symmetry and linearity follow from the properties of the integral, and $\langle f, f\rangle = \int_0^1 f^2 \geq 0$ since $f^2 \geq 0$. Finally, if $\int_0^1 f^2 = 0$, then since $f^2 \geq 0$ we must have $f^2 = 0$, so $f = 0$.

Solution on page 1471

Exercise 6.1.61. CHALLENGE BEYOND 21-242 (*Jordan–von Neumann, real case.*) Let V be a real vector space with a function $\|\cdot\| : V \to \mathbb{R}$ satisfying, for all $\mathbf{v}, \mathbf{w} \in V$ and $a \in \mathbb{R}$: $\|\mathbf{v}\| \geq 0$ with equality only for $\mathbf{v} = \mathbf{0}$; $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$; $\|\mathbf{v} + \mathbf{w}\| \leq \|\mathbf{v}\| + \|\mathbf{w}\|$; and the parallelogram law $\|\mathbf{v} + \mathbf{w}\|^2 + \|\mathbf{v} - \mathbf{w}\|^2 = 2\|\mathbf{v}\|^2 + 2\|\mathbf{w}\|^2$. Define

$$\langle \mathbf{x}, \mathbf{y}\rangle = \frac{1}{4}\Big(\|\mathbf{x} + \mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2\Big).$$

(a) Show that $\langle \mathbf{x}, \mathbf{y}\rangle = \langle \mathbf{y}, \mathbf{x}\rangle$, $\langle \mathbf{x}, \mathbf{x}\rangle = \|\mathbf{x}\|^2$, and $\langle -\mathbf{x}, \mathbf{y}\rangle = -\langle \mathbf{x}, \mathbf{y}\rangle$.

(b) Show that $\langle \mathbf{x} + \mathbf{z}, \mathbf{y}\rangle + \langle \mathbf{x} - \mathbf{z}, \mathbf{y}\rangle = 2\langle \mathbf{x}, \mathbf{y}\rangle$ for all $\mathbf{x}, \mathbf{y}, \mathbf{z}$.

(c) Deduce that $\langle \mathbf{u} + \mathbf{w}, \mathbf{y}\rangle = \langle \mathbf{u}, \mathbf{y}\rangle + \langle \mathbf{w}, \mathbf{y}\rangle$ for all $\mathbf{u}, \mathbf{w}, \mathbf{y}$.

(d) Show that $\langle t\mathbf{x}, \mathbf{y}\rangle = t\langle \mathbf{x}, \mathbf{y}\rangle$ for all $t \in \mathbb{R}$, and conclude that $\langle \cdot, \cdot\rangle$ is an inner product on V whose norm is $\|\cdot\|$.

Solution on page 1471

6.2 Cauchy–Schwarz and the triangle inequality

In Section 6.1.1 we found that the dot product on $\mathbb{R}^2$ records angles, $\mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|\|\mathbf{w}\| \cos\theta$, and proposed to turn this around: in any real inner product space, define the angle θ between nonzero vectors $\mathbf{x}$ and $\mathbf{y}$ by

$$\cos\theta = \frac{\langle \mathbf{x}, \mathbf{y}\rangle}{\|\mathbf{x}\|\|\mathbf{y}\|}.$$

This defines an angle only if the right side lies in $[-1, 1]$. In $\mathbb{R}^2$ that is a property of the cosine, but for functions or matrices it is a claim about the inner product, and it needs a proof. The claim is the Cauchy–Schwarz inequality. It also gives the triangle inequality, which is what makes $\|\mathbf{x} - \mathbf{y}\|$ behave like a distance, and applied to the inner products of Section 6.1.3 it produces inequalities between sums and between integrals that have no visible connection to geometry.

Throughout, V is an inner product space over $\mathbb{F}$, where $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ (Notation 6.1.1).

6.2.1 The Cauchy–Schwarz inequality

Intuition (The shadow is shorter than the vector). Take $\mathbf{x}, \mathbf{y} \in \mathbb{R}^2$ with $\mathbf{y} \neq \mathbf{0}$, and drop a perpendicular from the tip of $\mathbf{x}$ to the line through $\mathbf{y}$ (Figure 6.2.1). Its foot is a multiple $c\mathbf{y}$, the *shadow* of $\mathbf{x}$ on the line, and the rest of $\mathbf{x}$, namely $\mathbf{w} = \mathbf{x} - c\mathbf{y}$, is perpendicular to $\mathbf{y}$. By (6.1.1), the shadow has length

$$\|c\mathbf{y}\| = \|\mathbf{x}\||\cos\theta| = \frac{|\mathbf{x} \cdot \mathbf{y}|}{\|\mathbf{y}\|}.$$

The vectors $c\mathbf{y}$, $\mathbf{w}$, and $\mathbf{x}$ form a right triangle with hypotenuse $\mathbf{x}$, and a leg is never longer than the hypotenuse. So

$$\frac{|\mathbf{x}\cdot\mathbf{y}|}{\|\mathbf{y}\|}\le\|\mathbf{x}\|.$$

Multiplying by $\|\mathbf{y}\|$ gives $|\mathbf{x}\cdot\mathbf{y}|\le\|\mathbf{x}\|\|\mathbf{y}\|$, with equality exactly when the other leg $\mathbf{w}$ is $\mathbf{0}$, that is, when $\mathbf{x}$ lies on the line through $\mathbf{y}$.

In $\mathbb{R}^2$ this is just $|\cos\theta|\le 1$. But the argument never used cosines. It used the decomposition $\mathbf{x}=c\mathbf{y}+\mathbf{w}$ and Pythagoras, and both make sense in every inner product space. All we need is the right c. The requirement that $\mathbf{w}$ be perpendicular to $\mathbf{y}$ is $\langle\mathbf{x}-c\mathbf{y},\mathbf{y}\rangle=0$, which by linearity in the first slot reads $\langle\mathbf{x},\mathbf{y}\rangle=c\|\mathbf{y}\|^2$. So

$$c=\frac{\langle\mathbf{x},\mathbf{y}\rangle}{\|\mathbf{y}\|^2}.$$

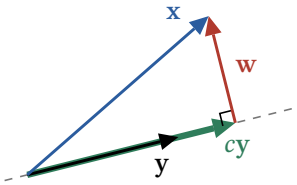

Figure 6.2.1. The shadow of $\mathbf{x}$ on the line through $\mathbf{y}$ is $c\mathbf{y}$, where $c=\langle\mathbf{x},\mathbf{y}\rangle/\|\mathbf{y}\|^2$, and $\mathbf{w}=\mathbf{x}-c\mathbf{y}$ is perpendicular to $\mathbf{y}$. By Pythagoras, $\|\mathbf{x}\|^2=\|c\mathbf{y}\|^2+\|\mathbf{w}\|^2$, so the shadow is no longer than $\mathbf{x}$.

Theorem 6.2.1 (Cauchy–Schwarz inequality). Let V be an inner product space and $\mathbf{x},\mathbf{y}\in V$.

(a) $|\langle\mathbf{x},\mathbf{y}\rangle|\le\|\mathbf{x}\|\|\mathbf{y}\|$.

(b) Equality holds in (a) if and only if one of $\mathbf{x},\mathbf{y}$ is a scalar multiple of the other.

Both sides of (a) are nonnegative, so (a) is equivalent to its square, $|\langle\mathbf{x},\mathbf{y}\rangle|^2\le\langle\mathbf{x},\mathbf{x}\rangle\langle\mathbf{y},\mathbf{y}\rangle$, which avoids square roots. For the dot product on $\mathbb{F}^n$ it says that

$$\left|\sum_{k=1}^{n}x_k\overline{y_k}\right|^2\le\left(\sum_{k=1}^{n}|x_k|^2\right)\left(\sum_{k=1}^{n}|y_k|^2\right)$$

for all complex numbers $x_1,\dots,x_n,y_1,\dots,y_n$, which is not obvious even for $n=2$.

Remark 6.2.2. In (b), "one of $\mathbf{x},\mathbf{y}$" cannot be shortened to "$\mathbf{x}$": if $\mathbf{x}\neq\mathbf{0}$ and $\mathbf{y}=\mathbf{0}$, both sides of (a) are 0, but $\mathbf{x}$ is not a multiple of $\mathbf{0}$. The condition in (b) says exactly that the list $\mathbf{x},\mathbf{y}$ is linearly dependent (Definition 1.5.1). Indeed, $\mathbf{x}=a\mathbf{y}$ gives the nontrivial relation $1\mathbf{x}-a\mathbf{y}=\mathbf{0}$, and $\mathbf{y}=b\mathbf{x}$ gives $b\mathbf{x}-1\mathbf{y}=\mathbf{0}$. Conversely, suppose $a\mathbf{x}+b\mathbf{y}=\mathbf{0}$ with a,b not both 0. If $a\neq 0$, then $\mathbf{x}=-(b/a)\mathbf{y}$. If $a=0$, then $b\neq 0$ and $b\mathbf{y}=\mathbf{0}$, so $\mathbf{y}=\mathbf{0}=0\mathbf{x}$ by Proposition 1.2.35.

Over $\mathbb{C}$ the scalar may be complex. For $\mathbf{x}\neq\mathbf{0}$, $|\langle\mathbf{x},i\mathbf{x}\rangle|=|-i|\|\mathbf{x}\|^2=\|\mathbf{x}\|\|i\mathbf{x}\|$, so $\mathbf{x}$ and $i\mathbf{x}$ give equality, even though in $\mathbb{C}=\mathbb{R}^2$ the numbers 1 and i are perpendicular arrows. We return to this in Section 6.2.3.

One direction of (b) is a direct computation, which we record first.

Lemma 6.2.3 (The easy half of (b)). If one of $\mathbf{x},\mathbf{y}\in V$ is a scalar multiple of the other, then $|\langle\mathbf{x},\mathbf{y}\rangle|=\|\mathbf{x}\|\|\mathbf{y}\|$.

Proof. ROUTINE

Uses. Proposition 6.1.27 (Basic properties of the norm), Proposition 6.1.4 (Sesquilinearity), Definition 6.1.26 (Norm)

Hint 1. Substitute $\mathbf{x} = a\mathbf{y}$ and take a out of the inner product.
Hint 2. Compare $|a|\|\mathbf{y}\|^2$ with $\|a\mathbf{y}\|\|\mathbf{y}\|$, using Proposition 6.1.27. For $\mathbf{y} = b\mathbf{x}$, the scalar leaves the second slot conjugated, and $|\overline{b}| = |b|$.
Sketch. If $\mathbf{x} = a\mathbf{y}$, both sides equal $|a|\|\mathbf{y}\|^2$. If $\mathbf{y} = b\mathbf{x}$, both sides equal $|b|\|\mathbf{x}\|^2$.

If $\mathbf{x} = a\mathbf{y}$, then by linearity in the first slot and Proposition 6.1.27,

$$|\langle a\mathbf{y}, \mathbf{y}\rangle| = |a|\|\mathbf{y}\|^2 = \|a\mathbf{y}\|\|\mathbf{y}\| = \|\mathbf{x}\|\|\mathbf{y}\|.$$

If $\mathbf{y} = b\mathbf{x}$, then by Proposition 6.1.4 and Proposition 6.1.27, $|\langle \mathbf{x}, b\mathbf{x}\rangle| = |\overline{b}|\|\mathbf{x}\|^2 = \|\mathbf{x}\|\|b\mathbf{x}\|$, since $|\overline{b}| = |b|$. □

So the content of the theorem is (a), together with the converse of Lemma 6.2.3: equality forces one vector to be a multiple of the other. We give three proofs. Each one finds a squared norm that is nonnegative for an obvious reason, expands it, and reads off (a). Each one gets the equality case by asking when that squared norm is 0.

First proof: the shadow

The first proof is the picture of Figure 6.2.1, carried out in V. The move it makes is used again and again in this chapter, so we name it.

Technique 6.2.4 (Orthogonal decomposition). To compare a vector $\mathbf{x}$ with a nonzero vector $\mathbf{y}$, split $\mathbf{x}$ into a part along $\mathbf{y}$ and a part perpendicular to $\mathbf{y}$:

$$\mathbf{x} = c\mathbf{y} + \mathbf{w}, \quad c = \frac{\langle \mathbf{x}, \mathbf{y}\rangle}{\|\mathbf{y}\|^2}, \quad \mathbf{w} = \mathbf{x} - c\mathbf{y}.$$

This choice of c is exactly the one that makes $\langle \mathbf{w}, \mathbf{y}\rangle = 0$. Then the cross term in Proposition 6.1.29 vanishes, and $\|\mathbf{x}\|^2 = |c|^2\|\mathbf{y}\|^2 + \|\mathbf{w}\|^2$. So the length of $\mathbf{x}$ splits into a contribution from the direction $\mathbf{y}$ and a contribution from everything else. Dropping $\|\mathbf{w}\|^2 \geq 0$ gives a lower bound for $\|\mathbf{x}\|$ that is sharp exactly when $\mathbf{w} = \mathbf{0}$.

Reach for it when a statement compares $\mathbf{x}$ with one fixed direction, or asks how close $\mathbf{x}$ comes to the line through $\mathbf{y}$. The canonical example is the first proof of Theorem 6.2.1. In Section 6.4 the line is replaced by an arbitrary subspace, the part along $\mathbf{y}$ becomes the orthogonal projection, and the same computation solves best-approximation problems (Theorem 6.4.33) and least squares (Section 6.5).
Used in. Theorem 6.2.1, Exercise 6.2.10, Exercise 6.2.27, Exercise 6.2.45, Theorem 6.3.24, Theorem 6.4.33, Proposition 6.5.27, Theorem 6.6.3, Exercise 6.7.12, Problem 6.1, Problem 6.13, Proposition 8.4.21, Exercise 6.4.57, Exercise 6.4.62.

Proof of Theorem 6.2.1 (by orthogonal decomposition). STANDARD

Uses. Proposition 6.1.29 (Expanding a norm), Proposition 6.1.27 (Basic properties of the norm), Proposition 6.1.4 (Sesquilinearity), Lemma 6.2.3 (The easy half of (b))
Techniques. Orthogonal decomposition (Technique 6.2.4)
Hint 1. Dispose of $\mathbf{y} = \mathbf{0}$ first. For $\mathbf{y} \neq \mathbf{0}$, write $\mathbf{x}$ as a multiple of $\mathbf{y}$ plus a vector $\mathbf{w}$ with $\langle \mathbf{w}, \mathbf{y}\rangle = 0$.
Hint 2. The multiple is $c\mathbf{y}$ with $c = \langle \mathbf{x}, \mathbf{y}\rangle/\|\mathbf{y}\|^2$. Expand $\|\mathbf{x}\|^2 = \|\mathbf{w} + c\mathbf{y}\|^2$ with Proposition 6.1.29.
Hint 3. You should get $\|\mathbf{x}\|^2 = \|\mathbf{w}\|^2 + |\langle \mathbf{x}, \mathbf{y}\rangle|^2/\|\mathbf{y}\|^2$. Drop $\|\mathbf{w}\|^2$. For the equality case, ask when that term is 0.
Sketch. If $\mathbf{y} = \mathbf{0}$, both sides vanish. Otherwise put $c = \langle \mathbf{x}, \mathbf{y}\rangle/\|\mathbf{y}\|^2$ and $\mathbf{w} = \mathbf{x} - c\mathbf{y}$, so that $\langle \mathbf{w}, \mathbf{y}\rangle = 0$. Expanding $\|\mathbf{w} + c\mathbf{y}\|^2$, the cross term vanishes, and $\|\mathbf{x}\|^2 = \|\mathbf{w}\|^2 + |\langle \mathbf{x}, \mathbf{y}\rangle|^2/\|\mathbf{y}\|^2$. This gives (a), with equality if and only if $\mathbf{w} = \mathbf{0}$, that is, $\mathbf{x} = c\mathbf{y}$.

If $\mathbf{y} = \mathbf{0}$, then $\langle \mathbf{x}, \mathbf{y}\rangle = 0$ by Proposition 6.1.4 and $\|\mathbf{y}\| = 0$, so both sides of (a) are 0. Equality holds, and $\mathbf{y} = 0\mathbf{x}$ is a multiple of $\mathbf{x}$, so (b) holds as well.

Suppose $\mathbf{y} \neq \mathbf{0}$, so that $\|\mathbf{y}\| > 0$ by Proposition 6.1.27. Let

$$c = \frac{\langle \mathbf{x}, \mathbf{y}\rangle}{\|\mathbf{y}\|^2} \quad \text{and} \quad \mathbf{w} = \mathbf{x} - c\mathbf{y}.$$

By linearity in the first slot, $\langle \mathbf{w}, \mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle - c\langle \mathbf{y}, \mathbf{y} \rangle = 0$. Since $\mathbf{x} = \mathbf{w} + c\mathbf{y}$, Proposition 6.1.29 with $a = c$ gives

$$\begin{aligned} \|\mathbf{x}\|^2 &= \|\mathbf{w}\|^2 + 2\,\mathrm{Re}(\bar{c}\langle \mathbf{w}, \mathbf{y} \rangle) + |c|^2\|\mathbf{y}\|^2 \\ &= \|\mathbf{w}\|^2 + \frac{|\langle \mathbf{x}, \mathbf{y} \rangle|^2}{\|\mathbf{y}\|^4}\|\mathbf{y}\|^2 \\ &= \|\mathbf{w}\|^2 + \frac{|\langle \mathbf{x}, \mathbf{y} \rangle|^2}{\|\mathbf{y}\|^2}. \end{aligned} \tag{6.2.1}$$

Since $\|\mathbf{w}\|^2 \geq 0$, it follows that $|\langle \mathbf{x}, \mathbf{y} \rangle|^2 / \|\mathbf{y}\|^2 \leq \|\mathbf{x}\|^2$. Multiplying by $\|\mathbf{y}\|^2 > 0$ gives $|\langle \mathbf{x}, \mathbf{y} \rangle|^2 \leq \|\mathbf{x}\|^2\|\mathbf{y}\|^2$, and taking nonnegative square roots gives (a).

For (b), (6.2.1) shows that equality holds in (a) if and only if $\|\mathbf{w}\|^2 = 0$, that is (by Proposition 6.1.27), if and only if $\mathbf{x} = c\mathbf{y}$. So if equality holds, then $\mathbf{x}$ is a multiple of $\mathbf{y}$. The converse is Lemma 6.2.3. □

Remark 6.2.5 (The size of the gap). Multiplying (6.2.1) by $\|\mathbf{y}\|^2$ gives, for $\mathbf{y} \neq \mathbf{0}$,

$$\|\mathbf{x}\|^2\|\mathbf{y}\|^2 - |\langle \mathbf{x}, \mathbf{y} \rangle|^2 = \|\mathbf{y}\|^2\|\mathbf{x} - c\mathbf{y}\|^2. \tag{6.2.2}$$

So the first proof yields more than an inequality: it computes the gap, and the gap measures how far $\mathbf{x}$ is from the line through $\mathbf{y}$. In $\mathbb{R}^2$ with the dot product, $\|\mathbf{y}\|$ is the base and $\|\mathbf{x} - c\mathbf{y}\|$ the height of the parallelogram spanned by $\mathbf{x}$ and $\mathbf{y}$, so the right side is the square of its area. A direct expansion shows that the left side is $(x_1y_2 - x_2y_1)^2$, and Exercise 6.2.43 extends this to $\mathbb{R}^n$.

Second proof: a quadratic in t

The second proof needs no picture and no clever choice. It needs one fact about real quadratics.

Lemma 6.2.6 (Nonnegative quadratics). Let $a, b, c \in \mathbb{R}$ with $a > 0$, and let $q(t) = at^2 - 2bt + c$ for $t \in \mathbb{R}$.

(a) $q(t) \geq 0$ for all $t \in \mathbb{R}$ if and only if $b^2 \leq ac$.

(b) If $b^2 \leq ac$, then q has a real root if and only if $b^2 = ac$, and in that case its only root is $t = b/a$.

Proof. ROUTINE

Uses. completing the square
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. Complete the square. Multiplying by a first avoids fractions.
Hint 2. Check that $aq(t) = (at - b)^2 + (ac - b^2)$ for all t. For the converse in (a), evaluate at the t that kills the square.
Sketch. $aq(t) = (at - b)^2 + (ac - b^2)$. If $b^2 \leq ac$, both terms are nonnegative, so $q \geq 0$; conversely $aq(b/a) = ac - b^2$. A sum of two nonnegative terms vanishes only if both do, which happens only for $t = b/a$ and $b^2 = ac$.

For every $t \in \mathbb{R}$,

$$(at - b)^2 + (ac - b^2) = a^2t^2 - 2abt + ac = aq(t).$$

(a) If $b^2 \leq ac$, then $aq(t)$ is a sum of two nonnegative numbers, so $aq(t) \geq 0$, and $q(t) \geq 0$ since $a > 0$. Conversely, if $q(t) \geq 0$ for all t, then in particular $aq(b/a) = 0 + (ac - b^2) \geq 0$.

(b) Suppose $b^2 \leq ac$. Then $aq(t)$ is the sum of the nonnegative numbers $(at - b)^2$ and $ac - b^2$, so $q(t) = 0$ if and only if both are 0, that is, if and only if $t = b/a$ and $b^2 = ac$. So if $b^2 = ac$, then b/a is a root and the only one, and if $b^2 < ac$, there is no root. □

Technique 6.2.7 (A nonnegative quadratic has nonpositive discriminant). If a real quadratic $at^2 - 2bt + c$ with $a > 0$ is nonnegative for every real t, then $b^2 \leq ac$, with equality exactly when the quadratic has a real root (Lemma 6.2.6). So to prove an inequality of the shape $b^2 \leq ac$, look for an expression that is nonnegative for every real t for an obvious reason, usually a squared norm $\|\mathbf{x} - t\mathbf{y}\|^2$ or a sum of squares,

and that expands to $at^2 - 2bt + c$. The equality case comes for free: it says that the nonnegative expression vanishes for some t.

Reach for it when the target has the shape $b^2 \le ac$ with $a, c \ge 0$, especially when no geometric picture suggests a decomposition. The parameter t must be real; over $\mathbb{C}$, first make the middle coefficient real (Technique 6.2.8). The canonical example is the second proof of Theorem 6.2.1.

Used in. Theorem 6.2.1, Exercise 6.2.35, Problem 6.1, Problem 6.17, Lemma 8.2.10.

Over $\mathbb{C}$ there is a complication. For real t, Proposition 6.1.29 gives $\|\mathbf{x} - t\mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2t\,\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle + t^2\|\mathbf{y}\|^2$, in which only the real part of $\langle \mathbf{x}, \mathbf{y}\rangle$ appears. The cure is to rotate $\mathbf{x}$ first.

Technique 6.2.8 (Rotate the phase). Every $z \in \mathbb{C}$ can be written $z = |z|\mu$ with $|\mu| = 1$: take $\mu = z/|z|$ if $z \neq 0$, and $\mu = 1$ if $z = 0$. Then $\overline{\mu} z = |z|$, so multiplying by $\overline{\mu}$ rotates z onto the nonnegative real axis without changing its modulus. In an inner product space, replacing $\mathbf{x}$ by $\overline{\mu}\mathbf{x}$ changes no norm, since $|\overline{\mu}| = 1$, and it turns $\langle \mathbf{x}, \mathbf{y}\rangle$ into $\overline{\mu}\langle \mathbf{x}, \mathbf{y}\rangle$. So in a statement that involves only $\|\mathbf{x}\|$, $\|\mathbf{y}\|$, and $|\langle \mathbf{x}, \mathbf{y}\rangle|$, we may assume that $\langle \mathbf{x}, \mathbf{y}\rangle$ is a nonnegative real number, and real-variable arguments apply. The same observation gives

$$|z| = \max_{|\lambda|=1} \mathrm{Re}(\lambda z),$$

since $\mathrm{Re}(\lambda z) \le |\lambda z| = |z|$ for $|\lambda| = 1$, with equality at $\lambda = \overline{\mu}$.

Reach for it when a real-variable argument, such as a discriminant argument, must be run over $\mathbb{C}$, or when $\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$ and $|\langle \mathbf{x}, \mathbf{y}\rangle|$ must be compared. The canonical example is the second proof of Theorem 6.2.1.

Used in. Theorem 6.2.1, Exercise 6.2.29, Exercise 6.7.6, Theorem B.1.11, Exercise B.1.44, Exercise B.1.49.

Proof of Theorem 6.2.1 (by a quadratic in t). STANDARD

Uses. Lemma 6.2.6 (Nonnegative quadratics), Proposition 6.1.29 (Expanding a norm), Proposition 6.1.27 (Basic properties of the norm), Lemma 6.2.3 (The easy half of (b)), Notation 6.1.1 (Real and complex scalars)
Techniques. A nonnegative quadratic has nonpositive discriminant (Technique 6.2.7), Rotate the phase (Technique 6.2.8)
Hint 1. For real t, the number $\|\mathbf{x} - t\mathbf{y}\|^2$ is nonnegative. Expand it as a function of t.
Hint 2. Over $\mathbb{R}$ you get $\|\mathbf{x}\|^2 - 2t\langle \mathbf{x}, \mathbf{y}\rangle + t^2\|\mathbf{y}\|^2 \ge 0$ for all t, and Lemma 6.2.6 applies when $\mathbf{y} \neq \mathbf{0}$. Over $\mathbb{C}$ the middle coefficient is only $\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle$.
Hint 3. Over $\mathbb{C}$, first replace $\mathbf{x}$ by $\lambda\mathbf{x}$, with $|\lambda| = 1$ chosen so that $\langle \lambda\mathbf{x}, \mathbf{y}\rangle = |\langle \mathbf{x}, \mathbf{y}\rangle|$. This changes neither side of (a).
Sketch. Assume $\mathbf{y} \neq \mathbf{0}$. Choose $|\lambda| = 1$ with $\lambda\langle \mathbf{x}, \mathbf{y}\rangle = |\langle \mathbf{x}, \mathbf{y}\rangle|$. For real t, $0 \le \|\lambda\mathbf{x} - t\mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2t|\langle \mathbf{x}, \mathbf{y}\rangle| + t^2\|\mathbf{y}\|^2$. A quadratic with positive leading coefficient that is never negative has $b^2 \le ac$, which is (a). Equality means that the quadratic has a real root t_0, so $\lambda\mathbf{x} = t_0\mathbf{y}$.

If $\mathbf{y} = \mathbf{0}$, both sides of (a) are 0, and $\mathbf{y} = 0\mathbf{x}$, so (a) and (b) hold. Suppose $\mathbf{y} \neq \mathbf{0}$. By Lemma 6.2.3, it remains to prove (a) and to show that equality forces one vector to be a multiple of the other.

Write $\langle \mathbf{x}, \mathbf{y}\rangle = |\langle \mathbf{x}, \mathbf{y}\rangle|\mu$ with $|\mu| = 1$, and let $\lambda = \overline{\mu}$ and $\mathbf{x}' = \lambda\mathbf{x}$. Since $\lambda\mu = |\mu|^2 = 1$,

$$\langle \mathbf{x}', \mathbf{y}\rangle = \lambda\langle \mathbf{x}, \mathbf{y}\rangle = |\langle \mathbf{x}, \mathbf{y}\rangle|,$$

a nonnegative real number, and $\|\mathbf{x}'\| = |\lambda|\|\mathbf{x}\| = \|\mathbf{x}\|$ by Proposition 6.1.27. Let $t \in \mathbb{R}$. By Proposition 6.1.29 with the scalar $-t$, using $\overline{-t} = -t$ and that $\langle \mathbf{x}', \mathbf{y}\rangle$ is real,

$$0 \le \|\mathbf{x}' - t\mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2t|\langle \mathbf{x}, \mathbf{y}\rangle| + t^2\|\mathbf{y}\|^2.$$

The right side is $q(t) = at^2 - 2bt + c$ with

$$a = \|\mathbf{y}\|^2 > 0, \quad b = |\langle \mathbf{x}, \mathbf{y}\rangle|, \quad c = \|\mathbf{x}\|^2,$$

and it is nonnegative for every real t. By Lemma 6.2.6, $b^2 \le ac$, that is, $|\langle \mathbf{x}, \mathbf{y}\rangle|^2 \le \|\mathbf{x}\|^2\|\mathbf{y}\|^2$. Taking nonnegative square roots gives (a).

If equality holds in (a), then $b^2 = ac$, so q has a real root t_0 by Lemma 6.2.6. Then $\|\mathbf{x}' - t_0\mathbf{y}\| = 0$, so $\lambda\mathbf{x} = t_0\mathbf{y}$ by Proposition 6.1.27. Multiplying by $\overline{\lambda}$ and using $\overline{\lambda}\lambda = 1$ gives $\mathbf{x} = \overline{\lambda}t_0\mathbf{y}$, a multiple of $\mathbf{y}$. □

Over $\mathbb{R}$, $\lambda = \pm 1$, and the rotation only flips the sign of $\mathbf{x}$ when $\langle \mathbf{x}, \mathbf{y} \rangle < 0$; one could instead apply Lemma 6.2.6 with $b = \langle \mathbf{x}, \mathbf{y} \rangle$ directly. Over $\mathbb{C}$ the rotation cannot be skipped. Run on $\mathbf{x}$ itself, the argument proves only $(\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle)^2 \le \|\mathbf{x}\|^2 \|\mathbf{y}\|^2$, which is weaker than (a) whenever $\langle \mathbf{x}, \mathbf{y} \rangle$ is not real. Rotating moves all of $|\langle \mathbf{x}, \mathbf{y} \rangle|$ into the real part. (One can also let t be complex. The best t is then c from the first proof, and the computation becomes the first proof.)

Third proof: normalizing

> *Intuition (Balancing the two sides).* The cheapest inequality available is $\|\mathbf{x} - \mathbf{y}\|^2 \ge 0$, which by Proposition 6.1.29 says
>
> $$2 \operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle \le \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2.$$
>
> It bounds a product by a sum, and when $\|\mathbf{x}\|$ and $\|\mathbf{y}\|$ are very different it is far from sharp. But both sides of (a) are *homogeneous*: replacing $\mathbf{x}$ by $s\mathbf{x}$ with $s > 0$ multiplies both $|\langle \mathbf{x}, \mathbf{y} \rangle|$ and $\|\mathbf{x}\|\|\mathbf{y}\|$ by s, and similarly for $\mathbf{y}$. So it suffices to prove (a) after rescaling $\mathbf{x}$ and $\mathbf{y}$, and we can rescale them to unit vectors. For unit vectors the right side above is $1 + 1$, which is twice the product $\|\mathbf{x}\|\|\mathbf{y}\| = 1$, and the cheap inequality becomes sharp enough.
>
> Equivalently, apply the cheap inequality to $s\mathbf{x}$ and $\mathbf{y}/s$, and choose $s > 0$ to make the bound $s^2\|\mathbf{x}\|^2 + \|\mathbf{y}\|^2/s^2$ as small as possible. The choice $s^2 = \|\mathbf{y}\|/\|\mathbf{x}\|$ makes the two terms equal, each $\|\mathbf{x}\|\|\mathbf{y}\|$, and the bound becomes $2\|\mathbf{x}\|\|\mathbf{y}\|$.

Proof of Theorem 6.2.1 (by normalizing). STANDARD

> *Uses.* Proposition 6.1.29 (Expanding a norm), Proposition 6.1.27 (Basic properties of the norm), Proposition 6.1.4 (Sesquilinearity), Lemma 6.2.3 (The easy half of (b))
> *Techniques.* Rotate the phase (Technique 6.2.8)
> *Hint 1.* Dispose of the case where $\mathbf{x}$ or $\mathbf{y}$ is $\mathbf{0}$. Otherwise, compare $\mathbf{x}/\|\mathbf{x}\|$ and $\mathbf{y}/\|\mathbf{y}\|$.
> *Hint 2.* For unit vectors $\mathbf{u}, \mathbf{v}$, expand $0 \le \|\mathbf{u} - \mathbf{v}\|^2$. You get $\operatorname{Re}\langle \mathbf{u}, \mathbf{v} \rangle \le 1$.
> *Hint 3.* To get $|\langle \mathbf{u}, \mathbf{v} \rangle| \le 1$, first rotate $\mathbf{u}$ by a scalar of modulus 1 so that $\langle \mathbf{u}, \mathbf{v} \rangle$ is a nonnegative real number.
> *Sketch.* For nonzero $\mathbf{x}, \mathbf{y}$, let $\mathbf{u} = \lambda\mathbf{x}/\|\mathbf{x}\|$ and $\mathbf{v} = \mathbf{y}/\|\mathbf{y}\|$, where $|\lambda| = 1$ makes $\langle \mathbf{u}, \mathbf{v} \rangle = |\langle \mathbf{x}, \mathbf{y} \rangle|/(\|\mathbf{x}\|\|\mathbf{y}\|)$ real and nonnegative. Then $0 \le \|\mathbf{u} - \mathbf{v}\|^2 = 2 - 2\langle \mathbf{u}, \mathbf{v} \rangle$ gives (a), and equality forces $\mathbf{u} = \mathbf{v}$, so $\mathbf{y}$ is a multiple of $\mathbf{x}$.

If $\mathbf{x} = \mathbf{0}$ or $\mathbf{y} = \mathbf{0}$, both sides of (a) are 0 by Proposition 6.1.4, and one vector is 0 times the other, so (a) and (b) hold. Suppose $\mathbf{x}, \mathbf{y} \neq \mathbf{0}$. By Lemma 6.2.3, it remains to prove (a) and to show that equality forces one vector to be a multiple of the other.

Choose $\lambda \in \mathbb{F}$ with $|\lambda| = 1$ and $\lambda\langle \mathbf{x}, \mathbf{y} \rangle = |\langle \mathbf{x}, \mathbf{y} \rangle|$, as in Technique 6.2.8, and let

$$\mathbf{u} = \frac{\lambda}{\|\mathbf{x}\|}\mathbf{x}, \quad \mathbf{v} = \frac{1}{\|\mathbf{y}\|}\mathbf{y}.$$

By Proposition 6.1.27, $\|\mathbf{u}\| = \|\mathbf{v}\| = 1$. Since $1/\|\mathbf{y}\|$ is real, it leaves the second slot unconjugated, and

$$\langle \mathbf{u}, \mathbf{v} \rangle = \frac{\lambda}{\|\mathbf{x}\|\|\mathbf{y}\|}\langle \mathbf{x}, \mathbf{y} \rangle = \frac{|\langle \mathbf{x}, \mathbf{y} \rangle|}{\|\mathbf{x}\|\|\mathbf{y}\|},$$

a nonnegative real number. By Proposition 6.1.29,

$$0 \le \|\mathbf{u} - \mathbf{v}\|^2 = \|\mathbf{u}\|^2 - 2\operatorname{Re}\langle \mathbf{u}, \mathbf{v} \rangle + \|\mathbf{v}\|^2 = 2 - 2\frac{|\langle \mathbf{x}, \mathbf{y} \rangle|}{\|\mathbf{x}\|\|\mathbf{y}\|}.$$

Rearranging gives (a).

If equality holds in (a), the right side is 0, so $\|\mathbf{u} - \mathbf{v}\| = 0$ and $\mathbf{u} = \mathbf{v}$ by Proposition 6.1.27. That is, $\lambda\mathbf{x}/\|\mathbf{x}\| = \mathbf{y}/\|\mathbf{y}\|$, so $\mathbf{y} = (\lambda\|\mathbf{y}\|/\|\mathbf{x}\|)\mathbf{x}$ is a multiple of $\mathbf{x}$. □

Intuition (Comparing the three proofs). All three proofs come from one fact: $\|\mathbf{x}-t\mathbf{y}\|^2 \geq 0$ for a scalar t (in the second and third proofs, after rotating the phase of $\mathbf{x}$). They differ in how t is chosen.

The first proof takes the best t, namely $t = c = \langle \mathbf{x}, \mathbf{y}\rangle / \|\mathbf{y}\|^2$. It makes $\mathbf{x} - t\mathbf{y}$ perpendicular to $\mathbf{y}$, so $c\mathbf{y}$ is the point of the line through $\mathbf{y}$ closest to $\mathbf{x}$. Finding c takes the picture or a computation, but once it is found the proof is one expansion, and it produces the identity (6.2.2) rather than just an inequality.

The second proof does not choose t at all. It uses every real t at once and lets the discriminant do the optimizing: $b^2 \leq ac$ says that the minimum value of the quadratic, attained at $t = b/a$, is nonnegative. For $\mathbf{x}$ rotated so that $\langle \mathbf{x}, \mathbf{y}\rangle \geq 0$, that minimizer $b/a = \langle \mathbf{x}, \mathbf{y}\rangle / \|\mathbf{y}\|^2$ is exactly the coefficient of the first proof. This is the proof to remember when an inequality has the shape $b^2 \leq ac$ and there is no picture: find a quantity that is nonnegative and quadratic in a real parameter.

The third proof rescales so that $\|\mathbf{x}\| = \|\mathbf{y}\| = 1$, after which the crude choice $t = 1$ already suffices. It needs a separate zero case and a normalization step, but its idea, that a homogeneous inequality can be checked on normalized vectors, applies far beyond inner products.

The equality case works the same way in all three: equality means that the nonnegative quantity is 0 for the chosen t, and that says one vector is a multiple of the other.

Example 6.2.9 (Instances of Cauchy–Schwarz). Each inner product of Section 6.1.3 gives an inequality.

(a) For the dot product on $\mathbb{R}^n$: $\left(\sum_k a_k b_k\right)^2 \leq \left(\sum_k a_k^2\right)\left(\sum_k b_k^2\right)$ for all real a_k, b_k. For $(1,2,3)$ and $(4,5,6)$ this reads $32^2 = 1024 \leq 14 \cdot 77 = 1078$.

(b) For the integral inner product on $C[a,b]$ (Proposition 6.1.13 and the paragraph after it):

$$\left(\int_a^b f(t)g(t)\,dt\right)^2 \leq \left(\int_a^b f(t)^2\,dt\right)\left(\int_a^b g(t)^2\,dt\right).$$

For $f(t) = 1$ and $g(t) = t$ on $[0,1]$, this reads $1/4 \leq 1/3$.

(c) For the Frobenius inner product on $\mathbb{F}^{m\times n}$ (Proposition 6.1.16): $|\operatorname{tr}(B^*A)|^2 \leq \operatorname{tr}(A^*A)\operatorname{tr}(B^*B)$.

In each case equality holds exactly for proportional data. In (b), that means $g = cf$ or $f = cg$ as functions on $[a,b]$.

Exercise 6.2.10. ROUTINE In $\mathbb{C}^2$ with the dot product, let $\mathbf{x} = (1+i, 2)$ and $\mathbf{y} = (i, 1-i)$, as in Example 6.1.11, where we found $\mathbf{x}\cdot\mathbf{y} = 3+i$, $\|\mathbf{x}\|^2 = 6$, and $\|\mathbf{y}\|^2 = 3$. Find $c \in \mathbb{C}$ and $\mathbf{w} \in \mathbb{C}^2$ with $\mathbf{x} = c\mathbf{y} + \mathbf{w}$ and $\mathbf{w}\cdot\mathbf{y} = 0$, and check (6.2.1) numerically.

Solution on page 1472

6.2.2 The triangle inequality

In a triangle, each side is at most as long as the other two together. The sides of the triangle with vertices $\mathbf{0}$, $\mathbf{x}$, and $\mathbf{x}+\mathbf{y}$ are $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{x}+\mathbf{y}$ (Figure 6.2.2), so the statement to prove is $\|\mathbf{x}+\mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|$. Both sides are nonnegative, so we may compare squares:

$$\|\mathbf{x}+\mathbf{y}\|^2 = \|\mathbf{x}\|^2 + 2\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle + \|\mathbf{y}\|^2,$$
$$(\|\mathbf{x}\| + \|\mathbf{y}\|)^2 = \|\mathbf{x}\|^2 + 2\|\mathbf{x}\|\|\mathbf{y}\| + \|\mathbf{y}\|^2.$$

So the triangle inequality is the statement $\operatorname{Re}\langle \mathbf{x}, \mathbf{y}\rangle \leq \|\mathbf{x}\|\|\mathbf{y}\|$, and Cauchy–Schwarz gives this with room to spare, since $\operatorname{Re} z \leq |z|$.

(a) (b)

Figure 6.2.2. (a) The triangle inequality: the side $\mathbf{x}+\mathbf{y}$ is no longer than the path $\mathbf{x}$ followed by $\mathbf{y}$. (b) Equality: when $\mathbf{y}$ is a positive multiple of $\mathbf{x}$, the triangle is flat. (The arrow $\mathbf{x}+\mathbf{y}$ is drawn slightly offset.)

Theorem 6.2.11 (Triangle inequality). Let V be an inner product space and $\mathbf{x}, \mathbf{y} \in V$.

(a) $\|\mathbf{x}+\mathbf{y}\| \le \|\mathbf{x}\| + \|\mathbf{y}\|$.

(b) The following are equivalent:
  (i) $\|\mathbf{x}+\mathbf{y}\| = \|\mathbf{x}\| + \|\mathbf{y}\|$;
  (ii) $\langle \mathbf{x}, \mathbf{y} \rangle = \|\mathbf{x}\|\|\mathbf{y}\|$;
  (iii) one of $\mathbf{x}, \mathbf{y}$ is a nonnegative real multiple of the other.

Proof. STANDARD

Uses. Proposition 6.1.29 (Expanding a norm), Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.27 (Basic properties of the norm), Proposition 6.1.4 (Sesquilinearity), Notation 6.1.1 (Real and complex scalars)
Hint 1. Both sides of (a) are nonnegative, so compare their squares. Expand $\|\mathbf{x}+\mathbf{y}\|^2$ with Proposition 6.1.29.
Hint 2. The squared inequality reduces to $\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle \le \|\mathbf{x}\|\|\mathbf{y}\|$. Pass through $|\langle \mathbf{x}, \mathbf{y} \rangle|$.
Hint 3. For (b), equality in (a) forces both steps $\operatorname{Re} z \le |z|$ and Cauchy–Schwarz to be equalities. When is $\operatorname{Re} z = |z|$? For (ii) $\Rightarrow$ (iii), use Theorem 6.2.1(b) and then compare $\langle a\mathbf{y}, \mathbf{y} \rangle$ with $\|a\mathbf{y}\|\|\mathbf{y}\|$.
Sketch. In the expansion of $\|\mathbf{x}+\mathbf{y}\|^2$, the cross term $2\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle$ is at most $2|\langle \mathbf{x}, \mathbf{y} \rangle|$, which is at most $2\|\mathbf{x}\|\|\mathbf{y}\|$ by Cauchy–Schwarz; so $\|\mathbf{x}+\mathbf{y}\|^2 \le (\|\mathbf{x}\| + \|\mathbf{y}\|)^2$. Equality holds if and only if both steps are equalities, that is, $\langle \mathbf{x}, \mathbf{y} \rangle$ is a nonnegative real number equal to $\|\mathbf{x}\|\|\mathbf{y}\|$. By Cauchy–Schwarz, this forces $\mathbf{x} = a\mathbf{y}$ (when $\mathbf{y} \neq \mathbf{0}$), and then $a\|\mathbf{y}\|^2 = |a|\|\mathbf{y}\|^2$ gives $a \ge 0$. The converse is a direct computation.

(a) By Proposition 6.1.29, $\operatorname{Re} z \le |z|$ (Notation 6.1.1), and Theorem 6.2.1,

$$\begin{aligned} \|\mathbf{x}+\mathbf{y}\|^2 &= \|\mathbf{x}\|^2 + 2\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle + \|\mathbf{y}\|^2 \\ &\le \|\mathbf{x}\|^2 + 2|\langle \mathbf{x}, \mathbf{y} \rangle| + \|\mathbf{y}\|^2 \\ &\le \|\mathbf{x}\|^2 + 2\|\mathbf{x}\|\|\mathbf{y}\| + \|\mathbf{y}\|^2 = (\|\mathbf{x}\| + \|\mathbf{y}\|)^2. \end{aligned} \tag{6.2.3}$$

Both $\|\mathbf{x}+\mathbf{y}\|$ and $\|\mathbf{x}\| + \|\mathbf{y}\|$ are nonnegative, so taking square roots gives (a).

(b) We prove (i) $\Leftrightarrow$ (ii) and (ii) $\Leftrightarrow$ (iii).

(i) $\Leftrightarrow$ (ii). Since both sides of (a) are nonnegative, (i) holds if and only if the first and last expressions in (6.2.3) are equal. Their difference is the sum of the two nonnegative gaps in the chain, so this happens if and only if both inequalities in the chain are equalities:

$$\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle = |\langle \mathbf{x}, \mathbf{y} \rangle| \quad \text{and} \quad |\langle \mathbf{x}, \mathbf{y} \rangle| = \|\mathbf{x}\|\|\mathbf{y}\|.$$

For $z \in \mathbb{C}$, $\operatorname{Re} z = |z|$ if and only if z is a nonnegative real number. Indeed, writing $z = a + bi$ with $a, b \in \mathbb{R}$, we have $\operatorname{Re} z = a \le |a| \le \sqrt{a^2 + b^2} = |z|$, with equality in the first step if and only if $a \ge 0$ and in the second if and only if $b = 0$. So the two equalities together say that $\langle \mathbf{x}, \mathbf{y} \rangle$ is a nonnegative real number equal to $\|\mathbf{x}\|\|\mathbf{y}\|$, which is (ii). Conversely, (ii) gives both equalities.

(iii) $\Rightarrow$ (ii). If $\mathbf{x} = a\mathbf{y}$ with $a \ge 0$, then $|a| = a$, and by Proposition 6.1.27, $\langle \mathbf{x}, \mathbf{y} \rangle = a\|\mathbf{y}\|^2 = \|a\mathbf{y}\|\|\mathbf{y}\| = \|\mathbf{x}\|\|\mathbf{y}\|$. If $\mathbf{y} = b\mathbf{x}$ with $b \ge 0$, then $\overline{b} = b$, and by Proposition 6.1.4, $\langle \mathbf{x}, \mathbf{y} \rangle = b\|\mathbf{x}\|^2 = \|\mathbf{x}\|\|\mathbf{y}\|$ in the same way.

(ii) ⇒ (iii). Assume (ii). If $\mathbf{y} = \mathbf{0}$, then $\mathbf{y} = 0\mathbf{x}$ and (iii) holds. Suppose $\mathbf{y} \neq \mathbf{0}$. By (ii), $|\langle \mathbf{x}, \mathbf{y}\rangle| = \|\mathbf{x}\|\|\mathbf{y}\|$, so by Theorem 6.2.1(b) one of $\mathbf{x}, \mathbf{y}$ is a multiple of the other. In fact $\mathbf{x}$ is a multiple of $\mathbf{y}$: if $\mathbf{y} = b\mathbf{x}$, then $b \neq 0$ because $\mathbf{y} \neq \mathbf{0}$, and $\mathbf{x} = b^{-1}\mathbf{y}$. Write $\mathbf{x} = a\mathbf{y}$ with $a \in \mathbb{F}$. Then

$$a\|\mathbf{y}\|^2 = \langle \mathbf{x}, \mathbf{y}\rangle = \|\mathbf{x}\|\|\mathbf{y}\| = |a|\|\mathbf{y}\|^2,$$

and dividing by $\|\mathbf{y}\|^2 > 0$ gives $a = |a|$, a nonnegative real number. □

Intuition (Same line versus same direction). Equality in Cauchy–Schwarz asks that $\mathbf{x}$ and $\mathbf{y}$ lie on a common line $\mathbb{F}\mathbf{v}$ through $\mathbf{0}$. Equality in the triangle inequality asks for more, a common ray $\{t\mathbf{v} \mid t \geq 0\}$. Over $\mathbb{R}$, if $\mathbf{y} = -\mathbf{x} \neq \mathbf{0}$, then $|\langle \mathbf{x}, \mathbf{y}\rangle| = \|\mathbf{x}\|\|\mathbf{y}\|$ but $\|\mathbf{x} + \mathbf{y}\| = 0 < 2\|\mathbf{x}\|$. Over $\mathbb{C}$, $\mathbf{y} = i\mathbf{x}$ gives equality in Cauchy–Schwarz, but $\|\mathbf{x} + i\mathbf{x}\| = |1 + i|\|\mathbf{x}\| = \sqrt{2}\|\mathbf{x}\|$. In the proof, it is the first inequality of (6.2.3), $\mathrm{Re}\langle \mathbf{x}, \mathbf{y}\rangle \leq |\langle \mathbf{x}, \mathbf{y}\rangle|$, that detects the direction.

Exercise 6.2.12. ROUTINE Let $\mathbf{x} \neq \mathbf{0}$ be a vector in a complex inner product space. Find all $a \in \mathbb{C}$ with $\|\mathbf{x} + a\mathbf{x}\| = \|\mathbf{x}\| + \|a\mathbf{x}\|$, and all $a \in \mathbb{C}$ with $\|\mathbf{x} + a\mathbf{x}\| = |\|\mathbf{x}\| - \|a\mathbf{x}\||$.

Solution on page 1473

The triangle inequality extends to any number of vectors, and it has a reversed form.

Corollary 6.2.13 (Sums of several vectors). For $\mathbf{x}_1, \ldots, \mathbf{x}_n \in V$,

$$\|\mathbf{x}_1 + \cdots + \mathbf{x}_n\| \leq \|\mathbf{x}_1\| + \cdots + \|\mathbf{x}_n\|.$$

Proof. ROUTINE

Uses. Theorem 6.2.11 (Triangle inequality)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Induct on n.
Hint 2. Write $\mathbf{x}_1 + \cdots + \mathbf{x}_n = (\mathbf{x}_1 + \cdots + \mathbf{x}_{n-1}) + \mathbf{x}_n$ and apply Theorem 6.2.11 to these two vectors.
Sketch. The case $n = 1$ is trivial. For $n \geq 2$, the triangle inequality splits off $\|\mathbf{x}_n\|$, and the induction hypothesis bounds the norm of the remaining sum.

We induct on n. For $n = 1$ there is nothing to prove. Let $n \geq 2$, and assume the claim for $n - 1$ vectors. With $\mathbf{s} = \mathbf{x}_1 + \cdots + \mathbf{x}_{n-1}$, Theorem 6.2.11 and the induction hypothesis give

$$\|\mathbf{s} + \mathbf{x}_n\| \leq \|\mathbf{s}\| + \|\mathbf{x}_n\| \leq \|\mathbf{x}_1\| + \cdots + \|\mathbf{x}_{n-1}\| + \|\mathbf{x}_n\|,$$

as desired. □

Corollary 6.2.14 (Distances and the reverse triangle inequality). For all $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$:

(a) $\|\mathbf{x} - \mathbf{z}\| \leq \|\mathbf{x} - \mathbf{y}\| + \|\mathbf{y} - \mathbf{z}\|$;

(b) $|\|\mathbf{x}\| - \|\mathbf{y}\|| \leq \|\mathbf{x} - \mathbf{y}\|$.

Proof. ROUTINE

Uses. Theorem 6.2.11 (Triangle inequality), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. For (a), write $\mathbf{x} - \mathbf{z}$ as a sum of two vectors.
Hint 2. For (b), write $\mathbf{x} = (\mathbf{x} - \mathbf{y}) + \mathbf{y}$ and apply the triangle inequality. This bounds $\|\mathbf{x}\| - \|\mathbf{y}\|$. Then exchange the roles of $\mathbf{x}$ and $\mathbf{y}$.
Sketch. (a) is the triangle inequality for $(\mathbf{x} - \mathbf{y}) + (\mathbf{y} - \mathbf{z})$. For (b), $\|\mathbf{x}\| \leq \|\mathbf{x} - \mathbf{y}\| + \|\mathbf{y}\|$ and $\|\mathbf{y}\| \leq \|\mathbf{y} - \mathbf{x}\| + \|\mathbf{x}\|$, and $\|\mathbf{y} - \mathbf{x}\| = \|\mathbf{x} - \mathbf{y}\|$.

(a) Apply Theorem 6.2.11 to $\mathbf{x} - \mathbf{z} = (\mathbf{x} - \mathbf{y}) + (\mathbf{y} - \mathbf{z})$.

(b) By Theorem 6.2.11, $\|\mathbf{x}\| = \|(\mathbf{x} - \mathbf{y}) + \mathbf{y}\| \leq \|\mathbf{x} - \mathbf{y}\| + \|\mathbf{y}\|$, so $\|\mathbf{x}\| - \|\mathbf{y}\| \leq \|\mathbf{x} - \mathbf{y}\|$. Exchanging $\mathbf{x}$ and $\mathbf{y}$, $\|\mathbf{y}\| - \|\mathbf{x}\| \leq \|\mathbf{y} - \mathbf{x}\| = \|\mathbf{x} - \mathbf{y}\|$, where the last step is Proposition 6.1.27 with $a = -1$. Since $|r|$ is the larger of r and $-r$, (b) follows. □

Part (a) is the triangle inequality for the triangle with vertices $\mathbf{x}$, $\mathbf{y}$, $\mathbf{z}$: going from $\mathbf{x}$ to $\mathbf{z}$ directly is never longer than going through $\mathbf{y}$. Part (b) says that a side of a triangle is at least the difference of the other two. Read as a statement about the function $\mathbf{v} \mapsto \|\mathbf{v}\|$, it says that moving $\mathbf{v}$ by a vector of norm δ changes $\|\mathbf{v}\|$ by at most δ; in particular, the norm is a continuous function. (Exercise 6.1.61 used exactly this.)

Remark 6.2.15. By Proposition 6.1.27 and Theorem 6.2.11, the norm of an inner product satisfies the three properties of a norm in the sense of Aside (Norms that do not come from inner products), so every inner product space is a normed space. By Corollary 6.2.14(a), the distance $d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x} - \mathbf{y}\|$ also behaves as a distance should: $d(\mathbf{x}, \mathbf{y}) \geq 0$ with equality only for $\mathbf{x} = \mathbf{y}$, $d(\mathbf{x}, \mathbf{y}) = d(\mathbf{y}, \mathbf{x})$, and $d(\mathbf{x}, \mathbf{z}) \leq d(\mathbf{x}, \mathbf{y}) + d(\mathbf{y}, \mathbf{z})$.

6.2.3 Angles

Let V be a real inner product space and $\mathbf{x}, \mathbf{y} \in V$ nonzero. By Theorem 6.2.1,

$$-1 \leq \frac{\langle \mathbf{x}, \mathbf{y} \rangle}{\|\mathbf{x}\|\|\mathbf{y}\|} \leq 1,$$

and the cosine is a strictly decreasing continuous function from $[0, \pi]$ onto $[-1, 1]$, hence a bijection. So the following definition makes sense, and the motivation at the start of the section is justified.

Definition 6.2.16 (Angle). Let V be a real inner product space, and let $\mathbf{x}, \mathbf{y} \in V$ be nonzero. The **angle** between $\mathbf{x}$ and $\mathbf{y}$ is the unique $\theta \in [0, \pi]$ with

$$\cos\theta = \frac{\langle \mathbf{x}, \mathbf{y} \rangle}{\|\mathbf{x}\|\|\mathbf{y}\|}.$$

For the dot product on $\mathbb{R}^2$, this is the usual angle, by (6.1.1). The familiar properties of angles follow from what we have proved.

Proposition 6.2.17 (Properties of angles). Let V be a real inner product space, let $\mathbf{x}, \mathbf{y} \in V$ be nonzero, and let θ be the angle between them.

(a) (Law of cosines.)

$$\|\mathbf{x} - \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 - 2\|\mathbf{x}\|\|\mathbf{y}\| \cos\theta.$$

(b) $\theta = 0$ if and only if $\mathbf{y} = a\mathbf{x}$ for some $a > 0$, and $\theta = \pi$ if and only if $\mathbf{y} = a\mathbf{x}$ for some $a < 0$.

(c) $\theta = \pi/2$ if and only if $\langle \mathbf{x}, \mathbf{y} \rangle = 0$.

Proof. ROUTINE

Uses. Definition 6.2.16 (Angle), Proposition 6.1.29 (Expanding a norm), Theorem 6.2.11 (Triangle inequality), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. For (a), expand $\|\mathbf{x} - \mathbf{y}\|^2$ and substitute the definition of θ.
Hint 2. For (b), $\theta = 0$ means $\langle \mathbf{x}, \mathbf{y} \rangle = \|\mathbf{x}\|\|\mathbf{y}\|$. Which result characterizes that equation? For $\theta = \pi$, replace $\mathbf{y}$ by $-\mathbf{y}$.
Sketch. (a) is Proposition 6.1.29 with $\langle \mathbf{x}, \mathbf{y} \rangle = \|\mathbf{x}\|\|\mathbf{y}\| \cos\theta$. In (b), $\cos\theta = 1$ means $\langle \mathbf{x}, \mathbf{y} \rangle = \|\mathbf{x}\|\|\mathbf{y}\|$, which by Theorem 6.2.11(b) means one vector is a nonnegative multiple of the other; as both are nonzero, the multiple is positive. The case $\theta = \pi$ is the case $\theta = 0$ for $\mathbf{x}$ and $-\mathbf{y}$. (c) is $\cos\theta = 0$.

(a) By Proposition 6.1.29, $\|\mathbf{x} - \mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2\langle \mathbf{x}, \mathbf{y} \rangle + \|\mathbf{y}\|^2$ (over $\mathbb{R}$, $\mathrm{Re}\langle \mathbf{x}, \mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$), and $\langle \mathbf{x}, \mathbf{y} \rangle = \|\mathbf{x}\|\|\mathbf{y}\| \cos\theta$ by Definition 6.2.16.

(b) Since cos is injective on $[0, \pi]$ with $\cos 0 = 1$, we have $\theta = 0$ if and only if $\langle \mathbf{x}, \mathbf{y} \rangle = \|\mathbf{x}\|\|\mathbf{y}\|$. By Theorem 6.2.11(b), this holds if and only if one of $\mathbf{x}, \mathbf{y}$ is a nonnegative multiple of the other. As both are nonzero, the multiple is nonzero, hence positive, and if $\mathbf{x} = b\mathbf{y}$ with $b > 0$, then $\mathbf{y} = b^{-1}\mathbf{x}$ with $b^{-1} > 0$. So $\theta = 0$ if and only if $\mathbf{y} = a\mathbf{x}$ with $a > 0$.

Similarly, $\theta = \pi$ if and only if $\langle \mathbf{x}, \mathbf{y} \rangle = -\|\mathbf{x}\|\|\mathbf{y}\|$, that is, $\langle \mathbf{x}, -\mathbf{y} \rangle = \|\mathbf{x}\|\|-\mathbf{y}\|$, using Proposition 6.1.4 and Proposition 6.1.27. By the first case applied to $\mathbf{x}$ and $-\mathbf{y}$, this holds if and only if $-\mathbf{y} = a\mathbf{x}$ with $a > 0$, that is, $\mathbf{y} = (-a)\mathbf{x}$ with $-a < 0$.

(c) $\cos\theta = 0$ for $\theta \in [0, \pi]$ if and only if $\theta = \pi/2$. □

Part (c) is why perpendicularity is defined by $\langle \mathbf{x}, \mathbf{y} \rangle = 0$ in Section 6.3. In spaces without a picture, the angle still measures how far two vectors are from being proportional, and its values can be surprising.

Example 6.2.18 (Angles in $\mathbb{R}^n$ and in $C[0,1]$).

(a) In $\mathbb{R}^n$ with the dot product, let $\mathbf{d} = (1, 1, \ldots, 1)$, the diagonal of the unit cube, and $\mathbf{e}_1$, one of its edges. Then $\langle \mathbf{d}, \mathbf{e}_1 \rangle = 1$, $\|\mathbf{d}\| = \sqrt{n}$, and $\|\mathbf{e}_1\| = 1$, so the angle θ_n between them satisfies $\cos\theta_n = 1/\sqrt{n}$. For $n = 2, 3, 4$ this gives $\theta_n = \pi/4$, about $54.7°$, and $\pi/3$. As $n \to \infty$, $\cos\theta_n \to 0$ and $\theta_n \to \pi/2$: in high dimension the diagonal of a cube is almost perpendicular to every edge.

(b) In $C[0,1]$ with the integral inner product, $\langle 1, t \rangle = \int_0^1 t\,dt = 1/2$, $\|1\| = 1$, and $\|t\| = \left(\int_0^1 t^2\,dt\right)^{1/2} = 1/\sqrt{3}$. So the angle between the functions 1 and t satisfies $\cos\theta = \sqrt{3}/2$, that is, $\theta = \pi/6$.

Example 6.2.19 (Correlation is a cosine). Given data points $(x_1, y_1), \ldots, (x_m, y_m) \in \mathbb{R}^2$, let m_x and m_y be the means of the x_k and of the y_k, and let

$$\tilde{\mathbf{x}} = (x_1 - m_x, \ldots, x_m - m_x), \quad \tilde{\mathbf{y}} = \left(y_1 - m_y, \ldots, y_m - m_y\right)$$

be the centered data in $\mathbb{R}^m$. If both are nonzero, the **correlation coefficient** of the data is

$$r = \frac{\tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}}}{\|\tilde{\mathbf{x}}\|\|\tilde{\mathbf{y}}\|},$$

the cosine of the angle between $\tilde{\mathbf{x}}$ and $\tilde{\mathbf{y}}$. Cauchy–Schwarz says $-1 \le r \le 1$, and Proposition 6.2.17(b) says that $r = \pm 1$ exactly when $\tilde{\mathbf{y}} = a\tilde{\mathbf{x}}$ with a of the same sign as r, that is, when all data points lie on the line $y = m_y + a(x - m_x)$. For the points $(0,1)$, $(1,1)$, $(2,4)$, we get $\tilde{\mathbf{x}} = (-1, 0, 1)$ and $\tilde{\mathbf{y}} = (-1, -1, 2)$, so $r = 3/\left(\sqrt{2}\sqrt{6}\right) = \sqrt{3}/2$. Least squares (Section 6.5) finds the line that comes closest to such data.

> **Exercise 6.2.20.** ROUTINE In $C[0,1]$ with the integral inner product, find $\cos\theta$ for the angle θ between t and t^2. Then find all $a \in \mathbb{R}$ for which the angle between the functions 1 and $t + a$ is $\pi/3$.

Solution on page 1473

Over $\mathbb{C}$

Let V be a complex inner product space and $\mathbf{x}, \mathbf{y} \in V$ nonzero. Now $\langle \mathbf{x}, \mathbf{y} \rangle$ is a complex number, and there are two natural real candidates for a cosine:

$$\operatorname{Re}\frac{\langle \mathbf{x}, \mathbf{y} \rangle}{\|\mathbf{x}\|\|\mathbf{y}\|} \in [-1, 1] \quad \text{and} \quad \frac{|\langle \mathbf{x}, \mathbf{y} \rangle|}{\|\mathbf{x}\|\|\mathbf{y}\|} \in [0, 1].$$

Both lie in the stated intervals by Theorem 6.2.1, since $|\operatorname{Re} z| \le |z|$. They measure different things.

The first is the cosine of an honest real angle. Regard V as a real vector space, forgetting multiplication by non-real scalars. Then $\operatorname{Re}\langle \cdot, \cdot \rangle$ is a real inner product on it: it is symmetric because $\operatorname{Re}\overline{z} = \operatorname{Re} z$, linear in the first slot for real scalars, and $\operatorname{Re}\langle \mathbf{x}, \mathbf{x} \rangle = \|\mathbf{x}\|^2$. For $V = \mathbb{C}^n$ this is the dot product of $\mathbb{R}^{2n}$, and it is the inner product that appears in the expansion $\|\mathbf{x} - \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 - 2\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle$. But it does not see complex scalars: $\operatorname{Re}\langle \mathbf{x}, i\mathbf{x} \rangle = \operatorname{Re}\left(-i\|\mathbf{x}\|^2\right) = 0$, so $\mathbf{x}$ and $i\mathbf{x}$ are perpendicular in this sense, although $i\mathbf{x}$ is a multiple of $\mathbf{x}$.

The second ignores phases. By Technique 6.2.8, $|\langle \mathbf{x}, \mathbf{y} \rangle| = \max_{|\lambda|=1} \operatorname{Re}\langle \lambda\mathbf{x}, \mathbf{y} \rangle$, so it is the cosine of the smallest real angle between $\mathbf{y}$ and a unit-modulus multiple $\lambda\mathbf{x}$. It does not change when $\mathbf{x}$ and $\mathbf{y}$ are

multiplied by arbitrary nonzero scalars (by Proposition 6.1.27, $|\langle a\mathbf{x}, b\mathbf{y}\rangle| = |a||b||\langle \mathbf{x}, \mathbf{y}\rangle|$ and the norms scale the same way), so it depends only on the complex lines $\mathbb{C}\mathbf{x}$ and $\mathbb{C}\mathbf{y}$, and it is really an angle between them. By Theorem 6.2.1(b) it equals 1 exactly when these lines coincide.

Neither number is "the" angle, and we do not define one over $\mathbb{C}$. What both notions agree on is the right angle in the strong sense: $\langle \mathbf{x}, \mathbf{y}\rangle = 0$ if and only if $\mathrm{Re}\langle \lambda\mathbf{x}, \mathbf{y}\rangle = 0$ for every λ with $|\lambda| = 1$, that is, $\mathbf{y}$ is perpendicular, in the real sense, to every unit-modulus multiple of $\mathbf{x}$. (For the "if", take $\lambda = \overline{\mu}$ as in Technique 6.2.8.) This is the notion of orthogonality used from Section 6.3 on.

6.2.4 Choosing the inner product

Every inner product gives an instance of Theorem 6.2.1, and Section 6.1.3 has many, so the theorem is a machine for producing inequalities between numbers. Using it well is a skill of its own.

Technique 6.2.21 (Apply Cauchy–Schwarz to a well-chosen inner product). To prove an inequality between sums or integrals, recognize one side as $|\langle \mathbf{x}, \mathbf{y}\rangle|$ and the other as $\|\mathbf{x}\|\|\mathbf{y}\|$ for some inner product. The work is in the choices. Pick the space and the inner product (the dot product, a weighted dot product, an integral, the Frobenius inner product), and split each term of the quantity to be bounded as a product of two factors, one belonging to $\mathbf{x}$ and one to $\mathbf{y}$. A useful move is to insert weights: write $a_k b_k$ as $\left(\sqrt{w_k}a_k\right)\left(b_k/\sqrt{w_k}\right)$ with $w_k > 0$ chosen so that the resulting norms are quantities you control.

Then check the equality case. Equality holds exactly when one of $\mathbf{x}, \mathbf{y}$ is a multiple of the other, so it tells you whether the bound is sharp and which data attain it. If the data that would attain it violate your constraints, the bound is not sharp, and a different split may do better.

Reach for it when the target has the shape $\left(\sum_k a_k b_k\right)^2 \le \left(\sum_k a_k^2\right)\left(\sum_k b_k^2\right)$ after renaming, when a linear quantity such as $\sum_k a_k$ or $\int f$ must be bounded by a quadratic one such as $\sum_k a_k^2$ or $\int f^2$, or when a quadratic quantity must be minimized subject to a linear constraint. The canonical example is Proposition 6.2.22.

Used in. Proposition 6.2.22, Proposition 6.2.24, Corollary 6.2.26, Exercise 6.2.31, Exercise 6.2.32, Exercise 6.2.36, Exercise 6.2.37, Exercise 6.2.38, Exercise 6.2.39, Exercise 6.2.46, Exercise 6.2.47, Exercise 6.4.52, Exercise 6.5.50, Problem 6.15, Problem 6.16, Exercise 8.2.43, Exercise 8.3.32, Exercise 8.3.33, Exercise 8.4.36, Exercise 6.3.53, Exercise 6.6.49.

Proposition 6.2.22 (The square of a sum). For $a_1, \dots, a_n \in \mathbb{F}$,

$$|a_1 + \cdots + a_n|^2 \le n\left(|a_1|^2 + \cdots + |a_n|^2\right),$$

with equality if and only if $a_1 = a_2 = \cdots = a_n$.

Proof. ROUTINE

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.10 (The dot product is an inner product)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. A sum $a_1 + \cdots + a_n$ is an inner product of $(a_1, \dots, a_n)$ with a fixed vector. Which one?
Hint 2. Take $\mathbf{1} = (1, \dots, 1)$. Then $\mathbf{a} \cdot \mathbf{1} = \sum_k a_k$ and $\|\mathbf{1}\|^2 = n$. For the equality case, $\mathbf{1} \neq \mathbf{0}$.
Sketch. Apply Cauchy–Schwarz to $\mathbf{a} = (a_1, \dots, a_n)$ and $\mathbf{1} = (1, \dots, 1)$ in $\mathbb{F}^n$: $|\mathbf{a} \cdot \mathbf{1}|^2 \le \|\mathbf{a}\|^2\|\mathbf{1}\|^2$ is the claim. Equality holds if and only if $\mathbf{a}$ is a multiple of $\mathbf{1}$, that is, all a_k are equal.

Let $\mathbf{a} = (a_1, \dots, a_n)$ and $\mathbf{1} = (1, \dots, 1)$ in $\mathbb{F}^n$, with the dot product. Then $\mathbf{a} \cdot \mathbf{1} = \sum_k a_k \overline{1} = \sum_k a_k$, $\|\mathbf{1}\|^2 = n$, and $\|\mathbf{a}\|^2 = \sum_k |a_k|^2$ by Proposition 6.1.10. By Theorem 6.2.1,

$$\left|\sum_k a_k\right|^2 = |\mathbf{a} \cdot \mathbf{1}|^2 \le \|\mathbf{a}\|^2\|\mathbf{1}\|^2 = n\sum_k |a_k|^2.$$

By Theorem 6.2.1(b), equality holds if and only if one of $\mathbf{a}, \mathbf{1}$ is a multiple of the other. Since $\mathbf{1} \neq \mathbf{0}$, this means $\mathbf{a} = c\mathbf{1}$ for some $c \in \mathbb{F}$ (if $\mathbf{1} = b\mathbf{a}$, then $b \neq 0$ and $\mathbf{a} = b^{-1}\mathbf{1}$). And $\mathbf{a} = c\mathbf{1}$ says that every a_k equals c. □

Corollary 6.2.23 (Arithmetic mean and quadratic mean). For $a_1, \dots, a_n \in \mathbb{R}$,

$$\frac{a_1 + \cdots + a_n}{n} \le \sqrt{\frac{a_1^2 + \cdots + a_n^2}{n}},$$

with equality if and only if $a_1 = \cdots = a_n \ge 0$.

Proof. ROUTINE

Uses. Proposition 6.2.22 (The square of a sum)
Hint 1. Bound the left side by its absolute value, then use Proposition 6.2.22.
Hint 2. For equality, both steps must be equalities: when is $r = |r|$?
Sketch. $\sum_k a_k/n \le |\sum_k a_k|/n \le \sqrt{n \sum_k a_k^2}/n$, and the right side is the quadratic mean. Equality requires $\sum_k a_k \ge 0$ and all a_k equal, hence all a_k equal to a common value $c \ge 0$.

By Proposition 6.2.22,

$$\frac{\sum_k a_k}{n} \le \frac{|\sum_k a_k|}{n} \le \frac{\sqrt{n \sum_k a_k^2}}{n} = \sqrt{\frac{\sum_k a_k^2}{n}}.$$

Equality holds if and only if both steps are equalities, that is, $\sum_k a_k \ge 0$ and (by Proposition 6.2.22) all a_k are equal to some c. Together these say that all a_k equal c with $nc \ge 0$, that is, $c \ge 0$. □

Intuition (Mean plus deviation). The proof applied Cauchy–Schwarz with $\mathbf{y} = \mathbf{1}$, and the first proof of Theorem 6.2.1 computes the gap. Here $c = (\mathbf{a} \cdot \mathbf{1})/\|\mathbf{1}\|^2 = (a_1 + \cdots + a_n)/n$ is the mean m of the a_k, the shadow $m\mathbf{1}$ is the constant vector with that mean, and $\mathbf{w} = \mathbf{a} - m\mathbf{1}$ is the vector of deviations from the mean. So (6.2.1) reads

$$\sum_{k=1}^{n} |a_k|^2 = n|m|^2 + \sum_{k=1}^{n} |a_k - m|^2.$$

Dividing by n: the mean of the squares is the square of the mean plus the variance $(1/n)\sum_k |a_k - m|^2$. So the gap in the squared inequality $|m|^2 \le (1/n)\sum_k |a_k|^2$ is exactly the variance, and it vanishes exactly for constant data.

The same choice of $\mathbf{y}$ works for integrals. The following inequality is used constantly in analysis.

Proposition 6.2.24 ($\int|f|$ versus $\int|f|^2$). Let $a < b$ and $f \in C([a,b], \mathbb{C})$. Then

$$\left(\int_a^b |f(t)|\,dt\right)^2 \le (b-a)\int_a^b |f(t)|^2\,dt,$$

with equality if and only if $|f|$ is constant. In particular, $\left(\int_0^1 |f|\right)^2 \le \int_0^1 |f|^2$.

Proof. ROUTINE

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.13 (Integral inner products)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. Work in the real space $C[a,b]$ with $\langle g, h\rangle = \int_a^b gh$, applied to the real function $g = |f|$.
Hint 2. $\int_a^b |f| = \langle |f|, 1\rangle$, and $\|1\|^2 = b - a$.
Sketch. Apply Cauchy–Schwarz in $C[a,b]$ to $g = |f|$ and the constant function 1: $\langle g, 1\rangle^2 \le \|g\|^2\|1\|^2$ is the claim. Equality holds if and only if g is a multiple of 1, that is, $|f|$ is constant.

Write $f = u + iv$ with $u, v \in C[a,b]$. Then $g = |f| = \sqrt{u^2 + v^2}$ is continuous and real-valued, so $g \in C[a,b]$. Give $C[a,b]$ the integral inner product $\langle g, h\rangle = \int_a^b gh$ (Proposition 6.1.13 and the paragraph after it), and let 1 denote the constant function. Then

$$\langle g, 1\rangle = \int_a^b |f|, \quad \|g\|^2 = \int_a^b |f|^2, \quad \|1\|^2 = b - a,$$

and Theorem 6.2.1 gives $\langle g, 1\rangle^2 \le \|g\|^2\|1\|^2$, which is the inequality. By Theorem 6.2.1(b), equality holds if and only if one of $g, 1$ is a multiple of the other; since $1 \neq \mathbf{0}$, this means $g = c \cdot 1$ for some $c \in \mathbb{R}$, that is, $|f|$ is constant. □

Weights let the same idea handle unequal coefficients. The next example also shows the equality case doing real work: it finds the minimizer.

Example 6.2.25 (A constrained minimum). We find the minimum of $a^2 + 2b^2 + 3c^2$ over all $(a, b, c) \in \mathbb{R}^3$ with $a + b + c = 1$. The quantity to be minimized is $\|\mathbf{v}\|^2$ for $\mathbf{v} = (a, b, c)$ in the weighted inner product $\langle \mathbf{x}, \mathbf{y}\rangle_w = x_1y_1 + 2x_2y_2 + 3x_3y_3$ (Example 6.1.21). So we write the constraint as an inner product in the same space: $a + b + c = \langle \mathbf{v}, \mathbf{z}\rangle_w$ for $\mathbf{z} = (1, 1/2, 1/3)$; the weights 2 and 3 cancel the entries $1/2$ and $1/3$. Since

$$\|\mathbf{z}\|_w^2 = 1 + 2 \cdot \frac{1}{4} + 3 \cdot \frac{1}{9} = \frac{11}{6},$$

Cauchy–Schwarz gives $1 = \langle \mathbf{v}, \mathbf{z}\rangle_w^2 \le \|\mathbf{v}\|_w^2 \cdot 11/6$, that is,

$$a^2 + 2b^2 + 3c^2 \ge \frac{6}{11}.$$

Equality requires $\mathbf{v} = t\mathbf{z}$, and the constraint then gives $t \cdot 11/6 = 1$, so $t = 6/11$ and $(a, b, c) = (6/11, 3/11, 2/11)$. This point satisfies the constraint, and indeed

$$\left(\frac{6}{11}\right)^2 + 2\left(\frac{3}{11}\right)^2 + 3\left(\frac{2}{11}\right)^2 = \frac{36 + 18 + 12}{121} = \frac{6}{11}.$$

So the minimum is $6/11$. Geometrically, we found the point of the plane $a + b + c = 1$ closest to $\mathbf{0}$ in the geometry of $\langle \cdot, \cdot \rangle_w$.

A variant of Cauchy–Schwarz with weights in denominators is a standard tool in competition problems.

Corollary 6.2.26 (Engel's form). Let $a_1, \dots, a_n \in \mathbb{R}$ and $b_1, \dots, b_n > 0$. Then

$$\frac{a_1^2}{b_1} + \cdots + \frac{a_n^2}{b_n} \ge \frac{(a_1 + \cdots + a_n)^2}{b_1 + \cdots + b_n},$$

with equality if and only if $a_1/b_1 = a_2/b_2 = \cdots = a_n/b_n$.

Proof. ROUTINE

Uses. Theorem 6.2.1 (Cauchy–Schwarz inequality), Proposition 6.1.10 (The dot product is an inner product)
Techniques. Apply Cauchy–Schwarz to a well-chosen inner product (Technique 6.2.21)
Hint 1. Write $a_k = \left(a_k/\sqrt{b_k}\right) \cdot \sqrt{b_k}$.
Hint 2. Apply Cauchy–Schwarz in $\mathbb{R}^n$ to $\mathbf{x} = \left(a_k/\sqrt{b_k}\right)_k$ and $\mathbf{y} = \left(\sqrt{b_k}\right)_k$.
Sketch. With $\mathbf{x} = \left(a_k/\sqrt{b_k}\right)_k$ and $\mathbf{y} = \left(\sqrt{b_k}\right)_k$, we have $\mathbf{x} \cdot \mathbf{y} = \sum_k a_k$, $\|\mathbf{x}\|^2 = \sum_k a_k^2/b_k$, and $\|\mathbf{y}\|^2 = \sum_k b_k$. Cauchy–Schwarz gives the claim after dividing by $\sum_k b_k$. Equality holds if and only if $\mathbf{x} = c\mathbf{y}$, that is, $a_k = cb_k$ for all k.

Let $\mathbf{x} = \left(a_1/\sqrt{b_1}, \dots, a_n/\sqrt{b_n}\right)$ and $\mathbf{y} = \left(\sqrt{b_1}, \dots, \sqrt{b_n}\right)$ in $\mathbb{R}^n$. Then

$$\mathbf{x} \cdot \mathbf{y} = \sum_k a_k, \quad \|\mathbf{x}\|^2 = \sum_k \frac{a_k^2}{b_k}, \quad \|\mathbf{y}\|^2 = \sum_k b_k > 0.$$

By Theorem 6.2.1, $\left(\sum_k a_k\right)^2 \le \left(\sum_k a_k^2/b_k\right)\left(\sum_k b_k\right)$, and dividing by $\sum_k b_k$ gives the inequality. Since $\mathbf{y} \neq \mathbf{0}$, equality holds if and only if $\mathbf{x} = c\mathbf{y}$ for some $c \in \mathbb{R}$ (as in the proof of Proposition 6.2.22), that is, $a_k/\sqrt{b_k} = c\sqrt{b_k}$, or $a_k/b_k = c$, for every k. □

For instance, for positive reals a, b, c, Corollary 6.2.26 with numerators a, b, c and denominators b, c, a gives

$$\frac{a^2}{b} + \frac{b^2}{c} + \frac{c^2}{a} \geq \frac{(a+b+c)^2}{b+c+a} = a + b + c.$$

Equality requires $a/b = b/c = c/a$. The product of these three ratios is 1, so the common value is 1, and $a = b = c$.

Exercises

Exercise 6.2.27. ROUTINE Give $\mathbb{R}^3$ the inner product $\langle \mathbf{x}, \mathbf{y} \rangle = x_1 y_1 + 2x_2 y_2 + 3x_3 y_3$ (Example 6.1.21), and let $\mathbf{x} = (1, 1, 1)$ and $\mathbf{y} = (1, -1, 2)$.

(a) Verify the Cauchy–Schwarz inequality for $\mathbf{x}$ and $\mathbf{y}$.

(b) Find $c \in \mathbb{R}$ and $\mathbf{w} \in \mathbb{R}^3$ with $\mathbf{x} = c\mathbf{y} + \mathbf{w}$ and $\langle \mathbf{w}, \mathbf{y} \rangle = 0$, and check (6.2.1).

(c) Find the cosine of the angle between $\mathbf{x}$ and $\mathbf{y}$ in this inner product, and compare it with the cosine for the dot product.

Solution on page 1473

Exercise 6.2.28. ROUTINE In $\mathbb{C}^2$ with the dot product, let $\mathbf{x} = (1, i)$ and $\mathbf{y} = (z, 1)$ with $z \in \mathbb{C}$.

(a) For which z does equality hold in the Cauchy–Schwarz inequality for $\mathbf{x}, \mathbf{y}$?

(b) For which z does $\|\mathbf{x} + \mathbf{y}\| = \|\mathbf{x}\| + \|\mathbf{y}\|$ hold?

Solution on page 1474

Exercise 6.2.29. ROUTINE In $\mathbb{C}^2$ with the dot product, let $\mathbf{x} = (1, 1)$ and $\mathbf{y} = (1, i)$.

(a) Compute $\operatorname{Re}\langle \mathbf{x}, \mathbf{y} \rangle / (\|\mathbf{x}\|\|\mathbf{y}\|)$ and $|\langle \mathbf{x}, \mathbf{y} \rangle| / (\|\mathbf{x}\|\|\mathbf{y}\|)$, and the corresponding angles in $[0, \pi]$.

(b) Find $\lambda \in \mathbb{C}$ with $|\lambda| = 1$ that maximizes $\operatorname{Re}\langle \lambda\mathbf{x}, \mathbf{y} \rangle$, and the maximum value.

Solution on page 1474

Exercise 6.2.30. ROUTINE Let $z_1, \ldots, z_n, w_1, \ldots, w_n \in \mathbb{C}$. Show that

$$\left| \sum_{k=1}^{n} z_k w_k \right|^2 \leq \left(\sum_{k=1}^{n} |z_k|^2 \right) \left(\sum_{k=1}^{n} |w_k|^2 \right),$$

and that equality holds if and only if $(z_1, \ldots, z_n)$ and $(\overline{w_1}, \ldots, \overline{w_n})$ are linearly dependent. Give an example where $(z_1, \ldots, z_n)$ and $(w_1, \ldots, w_n)$ are linearly dependent but the inequality is strict.

Solution on page 1474

Exercise 6.2.31. STANDARD Find the largest value of $x + y + z$ over all $(x, y, z) \in \mathbb{R}^3$ with $x^2 + 4y^2 + 9z^2 \leq 1$, and the point where it is attained.

Solution on page 1475

Exercise 6.2.32. STANDARD

(a) Find all $(x, y, z) \in \mathbb{R}^3$ with $x + 2y + 3z = 14$ and $x^2 + y^2 + z^2 = 14$.

(b) Show that there is no $(x, y, z) \in \mathbb{R}^3$ with $x + 2y + 3z = 14$ and $x^2 + y^2 + z^2 = 13$.

Solution on page 1475

Exercise 6.2.33. STANDARD Let $\mathbf{x}, \mathbf{y}$ be vectors in an inner product space.

(a) Show that $\left|\|\mathbf{x}\|^2 - \|\mathbf{y}\|^2\right| \le \|\mathbf{x}+\mathbf{y}\|\|\mathbf{x}-\mathbf{y}\|$.

(b) Show that equality holds if and only if one of $\mathbf{x}, \mathbf{y}$ is a *real* multiple of the other. (Over $\mathbb{R}$ this just says that $\mathbf{x}, \mathbf{y}$ are linearly dependent.)

Solution on page 1475

Exercise 6.2.34. STANDARD Let $\mathbf{x}, \mathbf{y}, \mathbf{z}$ be vectors in an inner product space such that equality holds in the Cauchy–Schwarz inequality for the pair $\mathbf{x}, \mathbf{y}$ and for the pair $\mathbf{y}, \mathbf{z}$. Prove or disprove: equality holds for the pair $\mathbf{x}, \mathbf{z}$. What changes if $\mathbf{y} \neq \mathbf{0}$?

Solution on page 1476

Exercise 6.2.35. STANDARD Find the errors in the following argument, and give a numerical example in $\mathbb{C}$ (with the inner product $\langle z, w\rangle = z\overline{w}$) showing that its first displayed formula is false.

Claim. For $\mathbf{x}, \mathbf{y}$ in a complex inner product space, $|\langle \mathbf{x}, \mathbf{y}\rangle| \le \|\mathbf{x}\|\|\mathbf{y}\|$.

Proof. We may assume $\mathbf{y} \neq \mathbf{0}$. For every $t \in \mathbb{C}$,

$$0 \le \|\mathbf{x} - t\mathbf{y}\|^2 = \|\mathbf{x}\|^2 - 2t\langle \mathbf{x}, \mathbf{y}\rangle + t^2\|\mathbf{y}\|^2.$$

A quadratic in t that is never negative has nonpositive discriminant, so $4\langle \mathbf{x}, \mathbf{y}\rangle^2 - 4\|\mathbf{x}\|^2\|\mathbf{y}\|^2 \le 0$. Taking square roots, $|\langle \mathbf{x}, \mathbf{y}\rangle| \le \|\mathbf{x}\|\|\mathbf{y}\|$.

Solution on page 1476

Exercise 6.2.36. STANDARD Show that for every $f \in C[0,1]$,

$$\left(\int_0^1 f(t)\,dt\right)^2 \le \left(1 - e^{-1}\right)\int_0^1 e^t f(t)^2\,dt,$$

and find all f for which equality holds.

Solution on page 1477

Exercise 6.2.37. STANDARD Let $p = a_0 + a_1 x + \cdots + a_n x^n \in \mathbb{R}[x]$ and $t \in \mathbb{R}$.

(a) Show that

$$|p(t)| \le \left(a_0^2 + \cdots + a_n^2\right)^{1/2}\left(1 + t^2 + \cdots + t^{2n}\right)^{1/2},$$

and that for each t and n some nonzero p of degree at most n attains equality.

(b) Deduce that if $|t| < 1$, then $|p(t)| \le \left(a_0^2 + \cdots + a_n^2\right)^{1/2}/\sqrt{1-t^2}$ for every polynomial p, whatever its degree.

Solution on page 1477

Exercise 6.2.38. STANDARD

(a) Show that $\sqrt{1}+\sqrt{2}+\cdots+\sqrt{n} \le n\sqrt{(n+1)/2}$ for every $n \ge 1$.

(b) Show that for all real $a_1, \ldots, a_n$,

$$\frac{a_1}{1}+\frac{a_2}{2}+\cdots+\frac{a_n}{n} \le \sqrt{2}\left(a_1^2+\cdots+a_n^2\right)^{1/2}.$$

(You may use $1/k^2 < 1/(k-1) - 1/k$ for $k \ge 2$.)

Solution on page 1477

Exercise 6.2.39. STANDARD

(a) Show that for every $A \in \mathbb{F}^{n\times n}$, $|\operatorname{tr} A|^2 \le n \operatorname{tr}(A^*A)$, with equality if and only if A is a scalar multiple of I_n.

(b) Find all $A \in \mathbb{R}^{2\times 2}$ with $\operatorname{tr} A = 2$ and $\sum_{i,j} a_{ij}^2 = 2$.

Solution on page 1478

Exercise 6.2.40. STANDARD Write $\|A\|_F = \operatorname{tr}(A^*A)^{1/2}$ for the Frobenius norm (Proposition 6.1.16).

(a) Show that $\|AB\|_F \le \|A\|_F \|B\|_F$ for all $A \in \mathbb{F}^{m\times n}$ and $B \in \mathbb{F}^{n\times p}$.

(b) Deduce that every entry of A^k has modulus at most $\|A\|_F^k$, for $A \in \mathbb{F}^{n\times n}$ and $k \ge 1$.

(c) Give $A, B \in \mathbb{R}^{2\times 2}$, both nonzero, with $\|AB\|_F < \|A\|_F \|B\|_F$.

Solution on page 1478

Exercise 6.2.41. STANDARD

(a) Let $\mathbf{x}, \mathbf{y}$ be unit vectors in an inner product space with $\mathbf{x} \ne \mathbf{y}$, and let $0 < s < 1$. Show that $\|(1-s)\mathbf{x} + s\mathbf{y}\| < 1$. (So the segment between two points of the unit sphere lies strictly inside it, except at its endpoints.)

(b) Show that (a) fails for the taxicab norm $\|\mathbf{x}\|_1 = |x_1| + |x_2|$ on $\mathbb{R}^2$ (Aside (Norms that do not come from inner products)). Conclude again that the taxicab norm does not come from an inner product.

Solution on page 1479

Exercise 6.2.42. STANDARD Let $\mathbf{x}, \mathbf{y}$ be vectors in an inner product space V. Show that $\mathbf{z} \in V$ satisfies

$$\|\mathbf{x}-\mathbf{z}\| + \|\mathbf{z}-\mathbf{y}\| = \|\mathbf{x}-\mathbf{y}\|$$

if and only if $\mathbf{z} = (1-s)\mathbf{x} + s\mathbf{y}$ for some $s \in [0,1]$. That is, the points for which the detour through $\mathbf{z}$ costs nothing are exactly the points of the segment from $\mathbf{x}$ to $\mathbf{y}$.

Solution on page 1479

Exercise 6.2.43. STANDARD

(a) Prove *Lagrange's identity*: for real numbers $a_1, \dots, a_n, b_1, \dots, b_n$,

$$\left(\sum_{k=1}^{n} a_k^2\right)\left(\sum_{k=1}^{n} b_k^2\right) - \left(\sum_{k=1}^{n} a_k b_k\right)^2 = \sum_{1 \le j < k \le n} (a_j b_k - a_k b_j)^2.$$

(b) Deduce the Cauchy–Schwarz inequality for the dot product on $\mathbb{R}^n$, including its equality case, without using Theorem 6.2.1.

(c) For $n = 2$, compare (a) with (6.2.2), and conclude that the parallelogram spanned by $\mathbf{a}, \mathbf{b} \in \mathbb{R}^2$ has area $|a_1 b_2 - a_2 b_1|$.

Solution on page 1479

Exercise 6.2.44. HARD Let $\mathbf{x}_1, \dots, \mathbf{x}_n$ be vectors in an inner product space, not all $\mathbf{0}$. Show that

$$\|\mathbf{x}_1 + \cdots + \mathbf{x}_n\| = \|\mathbf{x}_1\| + \cdots + \|\mathbf{x}_n\|$$

if and only if there is a unit vector $\mathbf{u}$ and real numbers $r_1, \dots, r_n \ge 0$ with $\mathbf{x}_k = r_k \mathbf{u}$ for every k.

Solution on page 1480

Exercise 6.2.45. HARD Let V be a real inner product space, and write $\theta(\mathbf{x}, \mathbf{y})$ for the angle between nonzero vectors (Definition 6.2.16). Show that for all nonzero $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$,

$$\theta(\mathbf{x}, \mathbf{z}) \le \theta(\mathbf{x}, \mathbf{y}) + \theta(\mathbf{y}, \mathbf{z}).$$

(Angles measure distances on the unit sphere, and this is their triangle inequality.)

Solution on page 1480

Exercise 6.2.46. HARD Find the minimum of $\int_0^1 f(t)^2 \, dt$ over all $f \in C[0,1]$ with

$$\int_0^1 f(t)\, dt = 1 \quad \text{and} \quad \int_0^1 t f(t)\, dt = 1,$$

and all functions attaining it.

Solution on page 1481

Exercise 6.2.47. HARD (*Nesbitt's inequality.*) Show that for all positive real numbers a, b, c,

$$\frac{a}{b+c} + \frac{b}{c+a} + \frac{c}{a+b} \ge \frac{3}{2},$$

with equality if and only if $a = b = c$.

Solution on page 1482

Exercise 6.2.48. CHALLENGE (*Ptolemy's inequality.*)

(a) Show that for nonzero vectors $\mathbf{x}, \mathbf{y}$ in an inner product space,

$$\left\| \frac{\mathbf{x}}{\|\mathbf{x}\|^2} - \frac{\mathbf{y}}{\|\mathbf{y}\|^2} \right\| = \frac{\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}\|\|\mathbf{y}\|}.$$

(b) Deduce that for all $\mathbf{x}, \mathbf{y}, \mathbf{z}, \mathbf{w}$ in an inner product space,

$$\|\mathbf{x}-\mathbf{y}\|\|\mathbf{z}-\mathbf{w}\| \le \|\mathbf{x}-\mathbf{z}\|\|\mathbf{y}-\mathbf{w}\| + \|\mathbf{x}-\mathbf{w}\|\|\mathbf{y}-\mathbf{z}\|.$$

(For four points in the plane: the product of the diagonals of a quadrilateral is at most the sum of the products of opposite sides.)

Solution on page 1482

6.3 Orthogonality and orthonormal bases

For nonzero $\mathbf{v}, \mathbf{w} \in \mathbb{R}^2$, $\mathbf{v} \cdot \mathbf{w} = 0$ exactly when $\mathbf{v}$ and $\mathbf{w}$ are perpendicular ((6.1.1)), and in every real inner product space the angle between nonzero vectors (Definition 6.2.16) is a right angle exactly when $\langle \mathbf{v}, \mathbf{w} \rangle = 0$ (Proposition 6.2.17). This section takes the condition $\langle \mathbf{v}, \mathbf{w} \rangle = 0$ as the definition of perpendicularity, now over $\mathbb{R}$ and $\mathbb{C}$ alike, and studies bases made of perpendicular unit vectors. For such a basis, finding the coordinates of a vector requires no linear system: each coordinate is a single inner product, computed without reference to the others. Once the coordinates are known, lengths and inner products are computed from them exactly as in $\mathbb{F}^n$ with the dot product. In $\mathbb{F}^n$ these bases are the columns of the matrices U with $U^*U = I$, and we end with the most important example after the standard basis, the Fourier basis of $\mathbb{C}^n$.

Throughout, V is an inner product space over $\mathbb{F}$, where $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ (Notation 6.1.1).

6.3.1 Orthogonality

Definition 6.3.1 (Orthogonality). Let V be an inner product space. Vectors $\mathbf{u}, \mathbf{v} \in V$ are **orthogonal**, written $\mathbf{u} \perp \mathbf{v}$, if $\langle \mathbf{u}, \mathbf{v} \rangle = 0$. A list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ in V is **orthogonal** if $\mathbf{v}_i \perp \mathbf{v}_j$ whenever $i \neq j$.

Orthogonality is symmetric: $\langle \mathbf{v}, \mathbf{u} \rangle = \overline{\langle \mathbf{u}, \mathbf{v} \rangle}$, and a complex number vanishes exactly when its conjugate does. By Proposition 6.1.4(b), $\mathbf{0}$ is orthogonal to every vector, itself included, and by definiteness it is the only vector orthogonal to itself. It is also the only vector orthogonal to every vector of V: if $\mathbf{v} \perp \mathbf{x}$ for all $\mathbf{x}$, take $\mathbf{x} = \mathbf{v}$. (This is Proposition 6.1.37 with $\mathbf{w} = \mathbf{0}$.)

In the definition of an orthogonal list only entries in different positions are compared. So a list of length 0 or 1 is orthogonal, an orthogonal list may contain $\mathbf{0}$ any number of times, and a nonzero vector cannot occur twice in an orthogonal list, since $\langle \mathbf{v}, \mathbf{v} \rangle \neq 0$.

Example 6.3.2 (Orthogonal vectors).

(a) In $\mathbb{R}^2$, $(a, b) \perp (-b, a)$ for all a, b, since $a(-b) + ba = 0$. The second vector is the first rotated by $\pi/2$. For instance $(1, 2) \perp (-2, 1)$.

(b) In $\mathbb{C}^2$, $(1, i) \cdot (1, -i) = 1 \cdot 1 + i \cdot \overline{-i} = 1 + i \cdot i = 0$, so $(1, i) \perp (1, -i)$. Forgetting the conjugate gives $1 + i(-i) = 2$ instead.

(c) Give $C[-1, 1]$ the inner product $\langle f, g \rangle = \int_{-1}^{1} f(t)g(t)\,\mathrm{d}t$ (Proposition 6.1.13, on $[-1, 1]$). If f is even and g is odd, then fg is odd, so $\langle f, g \rangle = 0$. For instance $1 \perp t$ and $t \perp t^2$. On the other hand $\langle 1, t^2 \rangle = 2/3 \neq 0$.

Orthogonality depends on the inner product as well as on the vectors. For the inner product $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{y}^{\mathsf{T}} M \mathbf{x}$ on $\mathbb{R}^2$ with $M = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$ (Example 6.1.23), $\langle \mathbf{e}_1, \mathbf{e}_2 \rangle = m_{21} = 1$, so $\mathbf{e}_1$ and $\mathbf{e}_2$ are not orthogonal. The vectors $(1, 1)$ and $(1, -1)$ are orthogonal for both inner products: $M(1, 1) = (3, 3)$, and $(1, -1) \cdot (3, 3) = 0$.

Over $\mathbb{C}$, orthogonality is more demanding than perpendicularity of arrows. In $\mathbb{C} = \mathbb{C}^1$ with $\langle z, w\rangle = z\overline{w}$, the numbers 1 and i are perpendicular as arrows in the plane, but $\langle 1, i\rangle = \bar{i} = -i \neq 0$. They are not orthogonal, and they should not be, since $i = i \cdot 1$ is a scalar multiple of 1. As we saw at the end of Section 6.2.3, $\langle \mathbf{u}, \mathbf{v}\rangle = 0$ says that $\mathbf{v}$ is perpendicular, in the real sense, to $\lambda\mathbf{u}$ for *every* λ with $|\lambda| = 1$.

The Pythagorean theorem

Theorem 6.3.3 (Pythagorean theorem). Let $\mathbf{u}, \mathbf{v} \in V$.

(a) If $\mathbf{u} \perp \mathbf{v}$, then $\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2$.

(b) If $\mathbb{F} = \mathbb{R}$, the converse holds: if $\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2$, then $\mathbf{u} \perp \mathbf{v}$.

Proof. ROUTINE

Uses. Proposition 6.1.29 (Expanding a norm), Definition 6.3.1 (Orthogonality)
Hint 1. Expand $\|\mathbf{u} + \mathbf{v}\|^2$ with Proposition 6.1.29. Which term has to vanish?
Hint 2. The identity holds if and only if $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = 0$. Over $\mathbb{R}$, what is $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle$?
Sketch. By Proposition 6.1.29, $\|\mathbf{u} + \mathbf{v}\|^2 - \|\mathbf{u}\|^2 - \|\mathbf{v}\|^2 = 2\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle$. So the identity holds exactly when $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = 0$. This follows from $\langle \mathbf{u}, \mathbf{v}\rangle = 0$, and over $\mathbb{R}$, where $\langle \mathbf{u}, \mathbf{v}\rangle$ is real, it is equivalent to it.

By Proposition 6.1.29,

$$\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + 2\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle + \|\mathbf{v}\|^2, \tag{6.3.1}$$

so the identity $\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2$ holds if and only if $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = 0$.

(a) If $\mathbf{u} \perp \mathbf{v}$, then $\langle \mathbf{u}, \mathbf{v}\rangle = 0$, so its real part is 0.

(b) If $\mathbb{F} = \mathbb{R}$, then $\langle \mathbf{u}, \mathbf{v}\rangle$ is real and equals its real part. So $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = 0$ says that $\mathbf{u} \perp \mathbf{v}$. □

In $\mathbb{R}^2$ with the dot product, (a) is the theorem about the right triangle with legs $\mathbf{u}$, $\mathbf{v}$ and hypotenuse $\mathbf{u} + \mathbf{v}$, and (b) is its converse. In other spaces it says new things. In $C[-1, 1]$, $1 \perp t$ by Example 6.3.2(c), so

$$\int_{-1}^{1} (1 + t)^2 \, dt = \|1\|^2 + \|t\|^2 = 2 + \frac{2}{3} = \frac{8}{3},$$

which agrees with the direct computation $\int_{-1}^{1}\left(1 + 2t + t^2\right) dt = 2 + 0 + 2/3$.

Non-example 6.3.4 (The converse fails over $\mathbb{C}$). In $\mathbb{C}$ with $\langle z, w\rangle = z\overline{w}$, take $\mathbf{u} = 1$ and $\mathbf{v} = i$. Then $|1 + i|^2 = 2 = |1|^2 + |i|^2$, but $\langle 1, i\rangle = -i \neq 0$. More generally, let $\mathbf{x} \neq \mathbf{0}$ be a vector in any complex inner product space. By Proposition 6.1.27,

$$\|\mathbf{x} + i\mathbf{x}\|^2 = |1 + i|^2\|\mathbf{x}\|^2 = 2\|\mathbf{x}\|^2 = \|\mathbf{x}\|^2 + \|i\mathbf{x}\|^2,$$

while $\langle \mathbf{x}, i\mathbf{x}\rangle = \bar{i}\|\mathbf{x}\|^2 = -i\|\mathbf{x}\|^2 \neq 0$. The proof of Theorem 6.3.3 shows what goes wrong: the Pythagorean identity only sees $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle$, and here $\langle \mathbf{u}, \mathbf{v}\rangle$ is purely imaginary.

The imaginary part becomes visible once $\mathbf{v}$ is multiplied by i. With $a = i$, Proposition 6.1.29 gives $\|\mathbf{u} + i\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + 2\operatorname{Im}\langle \mathbf{u}, \mathbf{v}\rangle + \|\mathbf{v}\|^2$, as computed after that proposition. So over $\mathbb{C}$ two Pythagorean identities together detect orthogonality.

Proposition 6.3.5 (Orthogonality over $\mathbb{C}$ through Pythagoras). Let V be a complex inner product space and $\mathbf{u}, \mathbf{v} \in V$. Then $\mathbf{u} \perp \mathbf{v}$ if and only if both

$$\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 \quad \text{and}$$
$$\|\mathbf{u} + i\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|i\mathbf{v}\|^2.$$

In that case $\|\mathbf{u} + a\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|a\mathbf{v}\|^2$ for every $a \in \mathbb{C}$.

Proof. ROUTINE

> *Uses.* Proposition 6.1.29 (Expanding a norm), Proposition 6.1.27 (Basic properties of the norm), Notation 6.1.1 (Real and complex scalars)
> *Techniques.* Plug in clever test vectors (Technique 6.1.40)
> *Hint 1.* Expand $\|\mathbf{u}+a\mathbf{v}\|^2$ with Proposition 6.1.29 for a general scalar a. The Pythagorean identity for $\mathbf{u}$ and $a\mathbf{v}$ says that one term vanishes.
> *Hint 2.* For $a=1$ that term is $2\,\mathrm{Re}\langle\mathbf{u},\mathbf{v}\rangle$. For $a=i$ it is $2\,\mathrm{Re}(-i\langle\mathbf{u},\mathbf{v}\rangle)$; which part of $\langle\mathbf{u},\mathbf{v}\rangle$ is that?
> *Sketch.* By Proposition 6.1.29 and $\|a\mathbf{v}\|^2=|a|^2\|\mathbf{v}\|^2$, the identity for $\mathbf{u}$ and $a\mathbf{v}$ holds exactly when $\mathrm{Re}(\overline{a}\langle\mathbf{u},\mathbf{v}\rangle)=0$. For $a=1$ and $a=i$ this says $\mathrm{Re}\langle\mathbf{u},\mathbf{v}\rangle=0$ and $\mathrm{Im}\langle\mathbf{u},\mathbf{v}\rangle=0$, which together say $\langle\mathbf{u},\mathbf{v}\rangle=0$. If $\langle\mathbf{u},\mathbf{v}\rangle=0$, then $\mathrm{Re}(\overline{a}\cdot 0)=0$ for every a.

Let $a\in\mathbb{C}$. By Proposition 6.1.29 and Proposition 6.1.27,

$$\|\mathbf{u}+a\mathbf{v}\|^2-\|\mathbf{u}\|^2-\|a\mathbf{v}\|^2=2\,\mathrm{Re}(\overline{a}\langle\mathbf{u},\mathbf{v}\rangle).$$

For $a=1$ the right side is $2\,\mathrm{Re}\langle\mathbf{u},\mathbf{v}\rangle$, and for $a=i$ it is $2\,\mathrm{Re}(-i\langle\mathbf{u},\mathbf{v}\rangle)=2\,\mathrm{Im}\langle\mathbf{u},\mathbf{v}\rangle$ (Notation 6.1.1). So the two displayed identities hold together if and only if the real and imaginary parts of $\langle\mathbf{u},\mathbf{v}\rangle$ both vanish, that is, if and only if $\mathbf{u}\perp\mathbf{v}$. Finally, if $\langle\mathbf{u},\mathbf{v}\rangle=0$, the right side is 0 for every a. □

The last statement also follows from Theorem 6.3.3(a): if $\mathbf{u}\perp\mathbf{v}$, then $\langle\mathbf{u},a\mathbf{v}\rangle=\overline{a}\langle\mathbf{u},\mathbf{v}\rangle=0$, so $\mathbf{u}\perp a\mathbf{v}$ for every scalar a. Over $\mathbb{C}$, then, orthogonality is "Pythagoras for $\mathbf{u}$ and every multiple of $\mathbf{v}$", which matches the description of orthogonality through unit-modulus multiples above.

The Pythagorean theorem extends to any number of vectors, and pairwise orthogonality is all it needs.

Corollary 6.3.6 (Pythagoras for orthogonal lists). Let $\mathbf{v}_1,\dots,\mathbf{v}_k$ be an orthogonal list in V, and let $a_1,\dots,a_k\in\mathbb{F}$. Then

$$\|a_1\mathbf{v}_1+\cdots+a_k\mathbf{v}_k\|^2=|a_1|^2\|\mathbf{v}_1\|^2+\cdots+|a_k|^2\|\mathbf{v}_k\|^2.$$

Proof (by expanding). ROUTINE

> *Uses.* Proposition 6.1.4 (Sesquilinearity), Definition 6.1.26 (Norm), Definition 6.3.1 (Orthogonality)
> *Techniques.* Expand by multilinearity (Technique 5.1.7)
> *Hint 1.* Write the left side as an inner product of a sum with itself and expand both slots.
> *Hint 2.* You get $\sum_j\sum_l a_j\overline{a_l}\langle\mathbf{v}_j,\mathbf{v}_l\rangle$. Which terms survive?
> *Sketch.* Expanding both slots gives k^2 terms $a_j\overline{a_l}\langle\mathbf{v}_j,\mathbf{v}_l\rangle$. Those with $j\neq l$ vanish by orthogonality, and those with $j=l$ are $|a_j|^2\|\mathbf{v}_j\|^2$.

By linearity in the first slot and Proposition 6.1.4 in the second,

$$\left\|\sum_{j=1}^{k}a_j\mathbf{v}_j\right\|^2=\left\langle\sum_{j=1}^{k}a_j\mathbf{v}_j,\sum_{l=1}^{k}a_l\mathbf{v}_l\right\rangle=\sum_{j=1}^{k}\sum_{l=1}^{k}a_j\overline{a_l}\langle\mathbf{v}_j,\mathbf{v}_l\rangle.$$

For $j\neq l$ the term is 0 because $\mathbf{v}_j\perp\mathbf{v}_l$. For $j=l$ it is $a_j\overline{a_j}\langle\mathbf{v}_j,\mathbf{v}_j\rangle=|a_j|^2\|\mathbf{v}_j\|^2$. Adding these gives the claim. □

Proof (by induction on k). ROUTINE

> *Uses.* Theorem 6.3.3 (Pythagorean theorem), Proposition 6.1.27 (Basic properties of the norm), Proposition 6.1.4 (Sesquilinearity)
> *Techniques.* Induction on the length of a list (Technique 1.6.9)
> *Hint 1.* Split off the last term: $\mathbf{w}=a_1\mathbf{v}_1+\cdots+a_{k-1}\mathbf{v}_{k-1}$ and $a_k\mathbf{v}_k$.
> *Hint 2.* Check that $\mathbf{w}\perp a_k\mathbf{v}_k$ by expanding $\langle\mathbf{w},a_k\mathbf{v}_k\rangle$, then apply Theorem 6.3.3.
> *Sketch.* The case $k=1$ is Proposition 6.1.27. For $k\geq 2$, the vector $\mathbf{w}=\sum_{j<k}a_j\mathbf{v}_j$ satisfies $\langle\mathbf{w},a_k\mathbf{v}_k\rangle=\sum_{j<k}a_j\overline{a_k}\langle\mathbf{v}_j,\mathbf{v}_k\rangle=0$, so Theorem 6.3.3 splits off $|a_k|^2\|\mathbf{v}_k\|^2$, and the induction hypothesis handles $\|\mathbf{w}\|^2$.

We induct on k. For $k=1$ the claim is $\|a_1\mathbf{v}_1\|^2=|a_1|^2\|\mathbf{v}_1\|^2$, which is Proposition 6.1.27. Let $k\geq 2$ and assume the claim for orthogonal lists of length $k-1$. Let $\mathbf{w}=a_1\mathbf{v}_1+\cdots+a_{k-1}\mathbf{v}_{k-1}$. Then

$$\langle \mathbf{w}, a_k \mathbf{v}_k \rangle = \sum_{j=1}^{k-1} a_j \overline{a_k} \langle \mathbf{v}_j, \mathbf{v}_k \rangle = 0,$$

so $\mathbf{w} \perp a_k \mathbf{v}_k$, and by Theorem 6.3.3(a), Proposition 6.1.27, and the induction hypothesis applied to the orthogonal list $\mathbf{v}_1, \ldots, \mathbf{v}_{k-1}$,

$$\|\mathbf{w} + a_k \mathbf{v}_k\|^2 = \|\mathbf{w}\|^2 + |a_k|^2 \|\mathbf{v}_k\|^2 = \sum_{j=1}^{k} |a_j|^2 \|\mathbf{v}_j\|^2,$$

as desired. □

The second proof explains why pairwise orthogonality is enough: a vector orthogonal to each of $\mathbf{v}_1, \ldots, \mathbf{v}_{k-1}$ is orthogonal to every linear combination of them. We record this fact in Proposition 6.3.9.

Exercise 6.3.7. ROUTINE In $\mathbb{C}^3$ with the dot product, find all $a \in \mathbb{C}$ with $(1, i, a) \perp (2, 1+i, i)$. For that a, verify Theorem 6.3.3(a) for the two vectors by computing all three norms.

Solution on page 1483

Orthogonality to a set

We often need all vectors orthogonal to a given collection of vectors.

Definition 6.3.8 (Vectors orthogonal to a set). Let $A \subseteq V$ be any subset. A vector $\mathbf{v} \in V$ is **orthogonal to** A, written $\mathbf{v} \perp A$, if $\mathbf{v} \perp \mathbf{a}$ for every $\mathbf{a} \in A$. The set of all such vectors is

$$A^\perp = \{\mathbf{v} \in V \mid \langle \mathbf{v}, \mathbf{a} \rangle = 0 \text{ for all } \mathbf{a} \in A\},$$

read "A perp". For a list $\mathcal{L}$, $\mathcal{L}^\perp$ is the perp of the set of entries of $\mathcal{L}$.

When A is a subspace, $A^\perp$ is called the *orthogonal complement* of A, and Section 6.4 shows that in finite dimensions it is a complement of A in the sense of Section 4.4. For now A is arbitrary.

Proposition 6.3.9 (Properties of $A^\perp$). Let $A, B \subseteq V$.

(a) $A^\perp$ is a subspace of V.

(b) If $A \subseteq B$, then $B^\perp \subseteq A^\perp$.

(c) For a list $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ in V, $\operatorname{span}(\mathcal{L})^\perp = \mathcal{L}^\perp$. That is, a vector is orthogonal to every linear combination of $\mathbf{v}_1, \ldots, \mathbf{v}_k$ if and only if it is orthogonal to each $\mathbf{v}_j$.

(d) $\{\mathbf{0}\}^\perp = V$, $V^\perp = \{\mathbf{0}\}$, and $A \cap A^\perp \subseteq \{\mathbf{0}\}$.

Proof. ROUTINE

Uses. Theorem 1.4.3 (Subspace criterion), Proposition 6.1.4 (Sesquilinearity), Proposition 1.3.17 (A list lies in its span), Definition 1.3.10 (Span), Definition 6.1.2 (Inner product)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. For (a), check the conditions of Theorem 1.4.3 using linearity in the first slot.
Hint 2. For (c), one containment is (b). For the other, take $\mathbf{v} \perp \mathbf{v}_j$ for all j and expand $\left\langle \mathbf{v}, \sum_j c_j \mathbf{v}_j \right\rangle$ in the second slot.
Hint 3. For (d), a vector in $V^\perp$ or in $A \cap A^\perp$ is orthogonal to itself.
Sketch. (a) $\mathbf{0} \in A^\perp$, and $\langle c\mathbf{v} + \mathbf{w}, \mathbf{a} \rangle = c\langle \mathbf{v}, \mathbf{a} \rangle + \langle \mathbf{w}, \mathbf{a} \rangle$ shows closure. (b) Orthogonality to all of B includes orthogonality to all of A. (c) $\mathcal{L} \subseteq \operatorname{span}(\mathcal{L})$ gives one containment by (b); conversely $\left\langle \mathbf{v}, \sum_j c_j \mathbf{v}_j \right\rangle = \sum_j \overline{c_j} \langle \mathbf{v}, \mathbf{v}_j \rangle = 0$. (d) Everything is orthogonal to $\mathbf{0}$, and a vector orthogonal to itself is $\mathbf{0}$.

(a) By Proposition 6.1.4(b), $\langle \mathbf{0}, \mathbf{a} \rangle = 0$ for all $\mathbf{a} \in A$, so $\mathbf{0} \in A^\perp$. Let $\mathbf{v}, \mathbf{w} \in A^\perp$ and $c \in \mathbb{F}$. For every $\mathbf{a} \in A$, linearity in the first slot gives

$$\langle c\mathbf{v} + \mathbf{w}, \mathbf{a} \rangle = c\langle \mathbf{v}, \mathbf{a} \rangle + \langle \mathbf{w}, \mathbf{a} \rangle = c \cdot 0 + 0 = 0,$$

so $c\mathbf{v}+\mathbf{w}\in A^\perp$. By Theorem 1.4.3, $A^\perp$ is a subspace.

(b) If $\mathbf{v}\in B^\perp$, then $\mathbf{v}\perp\mathbf{b}$ for every $\mathbf{b}\in B$, in particular for every element of $A\subseteq B$. So $\mathbf{v}\in A^\perp$.

(c) Each $\mathbf{v}_j$ lies in $\operatorname{span}(\mathcal{L})$ (Proposition 1.3.17), so (b) gives $\operatorname{span}(\mathcal{L})^\perp\subseteq\mathcal{L}^\perp$. Conversely, let $\mathbf{v}\in\mathcal{L}^\perp$, and let $\mathbf{w}=c_1\mathbf{v}_1+\cdots+c_k\mathbf{v}_k$ be any element of $\operatorname{span}(\mathcal{L})$. By Proposition 6.1.4,

$$\langle\mathbf{v},\mathbf{w}\rangle=\overline{c_1}\langle\mathbf{v},\mathbf{v}_1\rangle+\cdots+\overline{c_k}\langle\mathbf{v},\mathbf{v}_k\rangle=0,$$

so $\langle\mathbf{w},\mathbf{v}\rangle=\overline{\langle\mathbf{v},\mathbf{w}\rangle}=0$ as well, and $\mathbf{v}\in\operatorname{span}(\mathcal{L})^\perp$.

(d) Every $\mathbf{v}\in V$ satisfies $\langle\mathbf{v},\mathbf{0}\rangle=0$ by Proposition 6.1.4(b), so $\{\mathbf{0}\}^\perp=V$. If $\mathbf{v}\in V^\perp$, then in particular $\langle\mathbf{v},\mathbf{v}\rangle=0$, so $\mathbf{v}=\mathbf{0}$ by definiteness; and $\mathbf{0}\in V^\perp$ by (a). Finally, if $\mathbf{v}\in A\cap A^\perp$, then $\mathbf{v}\perp\mathbf{v}$, so $\mathbf{v}=\mathbf{0}$. □

Part (c) is how $A^\perp$ is computed in practice: to test orthogonality to a subspace, test it on a spanning list. The same argument shows $A^\perp=\operatorname{span}(A)^\perp$ for an arbitrary subset A, with $\operatorname{span}(A)$ as in Aside (Spans of infinite sets). Part (a) holds even when A itself is not a subspace.

Example 6.3.10 (Perps are solution sets).

(a) In $\mathbb{R}^3$, $\{(1,1,1)\}^\perp=\{\mathbf{x}\in\mathbb{R}^3\mid x_1+x_2+x_3=0\}$, the plane through $\mathbf{0}$ with normal vector $(1,1,1)$.

(b) Let $A\in\mathbb{F}^{m\times n}$. The ith entry of $A\mathbf{x}$ is $\sum_j a_{ij}x_j=\mathbf{x}\cdot\mathbf{r}_i$, where $\mathbf{r}_i=(\overline{a_{i1}},\ldots,\overline{a_{in}})\in\mathbb{F}^n$ is the ith row of A with its entries conjugated. So

$$\ker A=\{\mathbf{r}_1,\ldots,\mathbf{r}_m\}^\perp.$$

Over $\mathbb{R}$, $\mathbf{r}_i$ is just the ith row of A, and solving a homogeneous system means finding all vectors orthogonal to the rows of its coefficient matrix. For instance, for $A=\begin{pmatrix}1&2&0\\0&1&-1\end{pmatrix}$, solving $A\mathbf{x}=\mathbf{0}$ gives $\ker A=\operatorname{span}((-2,1,1))$, and indeed $(-2,1,1)$ is orthogonal to $(1,2,0)$ and to $(0,1,-1)$. The vectors $\mathbf{r}_i$ are the columns of the matrix A^* of Definition 6.3.26 below, so by Proposition 6.3.9(c) this says $\ker A=(\operatorname{im}A^*)^\perp$; Section 6.6 proves the analogous statement for linear maps.

Exercise 6.3.11. ROUTINE Let $A,B\subseteq V$. Show that $(A\cup B)^\perp=A^\perp\cap B^\perp$ and that $A\subseteq\left(A^\perp\right)^\perp$. Give an example with $A\neq\left(A^\perp\right)^\perp$.

Solution on page 1483

6.3.2 Orthonormal lists and bases

Orthogonal lists are independent

Three mutually perpendicular nonzero arrows in $\mathbb{R}^3$ cannot lie in a common plane, so they are linearly independent. To prove the general version, start from a linear relation $a_1\mathbf{v}_1+\cdots+a_k\mathbf{v}_k=\mathbf{0}$ among orthogonal vectors and try to show that one coefficient, say a_j, is 0. The inner product with $\mathbf{v}_j$ is the natural thing to apply: it is linear, so it can be applied term by term, and it annihilates every $\mathbf{v}_l$ with $l\neq j$. This move is used throughout the rest of the book.

Technique 6.3.12 (Take an inner product to isolate a coefficient). If a vector is written as a combination $\mathbf{w}=a_1\mathbf{v}_1+\cdots+a_k\mathbf{v}_k$ of an orthogonal list, take the inner product of both sides with $\mathbf{v}_j$. Linearity in the first slot distributes it over the sum, and orthogonality removes every term except the jth:

$$\langle\mathbf{w},\mathbf{v}_j\rangle=\sum_{l=1}^{k}a_l\langle\mathbf{v}_l,\mathbf{v}_j\rangle=a_j\|\mathbf{v}_j\|^2.$$

So each coefficient is determined by one inner product, with no reference to the other coefficients. Put $\mathbf{v}_j$ in the *second* slot; in the first slot it produces $\langle\mathbf{v}_j,\mathbf{w}\rangle=\overline{a_j}\|\mathbf{v}_j\|^2$, the conjugate.

Reach for it when a vector or a linear relation is expressed through an orthogonal list and you need the coefficients, or need to show that they vanish. It is the inner-product form of Technique 4.1.25: the linear map $\mathbf{x} \mapsto \langle \mathbf{x}, \mathbf{v}_j \rangle$ from V to $\mathbb{F}$ kills every $\mathbf{v}_l$ with $l \neq j$. The canonical example is Proposition 6.3.13. The coordinate formula Proposition 6.3.18, the Fourier inversion formula (Proposition 6.3.41), and Gram–Schmidt (Algorithm 6.4.14) use it again.

Used in. Proposition 6.3.13, Proposition 6.3.18, Corollary 6.3.21, Theorem 6.3.24, Proposition 6.4.4, Theorem 6.4.6, Corollary 6.4.25, Theorem 6.6.3, Theorem 6.6.15, Exercise 6.7.7, Problem 6.5, Lemma 8.4.23, Exercise 6.4.55.

Proposition 6.3.13 (Orthogonal lists are independent). An orthogonal list of nonzero vectors is linearly independent.

Proof (by isolating coefficients). ROUTINE

Uses. Theorem 1.5.5 (Independence is decided at zero), Definition 6.3.1 (Orthogonality), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. Start from a linear relation $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. You must show that every a_j is 0.
Hint 2. Fix j and take the inner product of both sides with $\mathbf{v}_j$.
Hint 3. You get $a_j\|\mathbf{v}_j\|^2 = 0$. Why is $\|\mathbf{v}_j\| \neq 0$?
Sketch. If $\sum_l a_l\mathbf{v}_l = \mathbf{0}$, then for each j, $0 = \langle \sum_l a_l\mathbf{v}_l, \mathbf{v}_j \rangle = a_j\|\mathbf{v}_j\|^2$ by orthogonality. Since $\mathbf{v}_j \neq \mathbf{0}$, $\|\mathbf{v}_j\|^2 > 0$, so $a_j = 0$. Only the trivial relation exists.

Let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ be an orthogonal list of nonzero vectors, and suppose $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. Fix $j \in \{1, \ldots, k\}$. By Proposition 6.1.4(b) and linearity in the first slot,

$$0 = \langle \mathbf{0}, \mathbf{v}_j \rangle = \left\langle \sum_{l=1}^{k} a_l\mathbf{v}_l, \mathbf{v}_j \right\rangle = \sum_{l=1}^{k} a_l \langle \mathbf{v}_l, \mathbf{v}_j \rangle$$
$$= a_j \langle \mathbf{v}_j, \mathbf{v}_j \rangle = a_j\|\mathbf{v}_j\|^2,$$

where the fourth step uses $\langle \mathbf{v}_l, \mathbf{v}_j \rangle = 0$ for $l \neq j$. Since $\mathbf{v}_j \neq \mathbf{0}$, $\|\mathbf{v}_j\|^2 > 0$ by Proposition 6.1.27, so $a_j = 0$. As j was arbitrary, the only linear relation among $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is the trivial one, and the list is independent by Theorem 1.5.5. □

Proof (by Pythagoras). ROUTINE

Uses. Corollary 6.3.6 (Pythagoras for orthogonal lists), Theorem 1.5.5 (Independence is decided at zero), Proposition 6.1.27 (Basic properties of the norm)
Techniques. A sum of nonnegative terms (Technique 6.1.9)
Hint 1. Take the squared norm of both sides of a relation $\sum_l a_l\mathbf{v}_l = \mathbf{0}$.
Hint 2. Corollary 6.3.6 turns the left side into a sum of nonnegative terms.
Sketch. If $\sum_l a_l\mathbf{v}_l = \mathbf{0}$, then $0 = \|\sum_l a_l\mathbf{v}_l\|^2 = \sum_l |a_l|^2\|\mathbf{v}_l\|^2$. A sum of nonnegative terms vanishes only if each does, and $\|\mathbf{v}_l\| > 0$, so every $a_l = 0$.

Suppose $a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k = \mathbf{0}$. By Corollary 6.3.6,

$$0 = \|\mathbf{0}\|^2 = |a_1|^2\|\mathbf{v}_1\|^2 + \cdots + |a_k|^2\|\mathbf{v}_k\|^2.$$

Each term is a nonnegative real number, so each term is 0. Since $\|\mathbf{v}_l\|^2 > 0$ for every l, it follows that $|a_l|^2 = 0$, that is, $a_l = 0$, for every l. By Theorem 1.5.5 the list is independent. □

The first proof extracts the coefficients one at a time; the second shows with a single number that they all vanish. The second also says more: by Corollary 6.3.6, a combination of orthogonal unit vectors has length $\left(\sum_l |a_l|^2\right)^{1/2}$, so it is short only when all its coefficients are small. Both proofs use that $\|\mathbf{v}_j\|^2 \neq 0$ for $\mathbf{v}_j \neq \mathbf{0}$. For the "dot product" $\sum_k x_k y_k$ on $\mathbb{F}_2^n$ with $n \geq 2$, which is not an inner product, this fails, and so does the proposition (Exercise 6.3.47). The hypothesis that the vectors are nonzero is needed too, since the orthogonal list $\mathbf{v}, \mathbf{0}$ is dependent.

Corollary 6.3.14 (Counting orthogonal vectors). Let V be finite-dimensional with $\dim V = n$. An orthogonal list of nonzero vectors in V has length at most n, and if its length is exactly n, it is a basis of V.

Proof. ROUTINE

Uses. Proposition 6.3.13 (Orthogonal lists are independent), Theorem 4.1.10 (Independent lists are short), an independent list of length $\dim V$ is a basis (Section 4.1)
Hint 1. By Proposition 6.3.13, such a list is independent. What does Section 4.1 say about independent lists?
Hint 2. Independent lists have length at most $\dim V$, and an independent list of length $\dim V$ is a basis.
Sketch. The list is independent by Proposition 6.3.13. Independent lists in V have length at most n, and independent lists of length n are bases.

By Proposition 6.3.13 the list is linearly independent. By Theorem 4.1.10 its length is at most n, and an independent list of length $n = \dim V$ is a basis of V (Section 4.1). □

So $\mathbb{R}^n$ contains at most n mutually orthogonal nonzero vectors, and to check that n of them form a basis it suffices to check orthogonality.

Orthonormal lists

Definition 6.3.15 (Orthonormal list, orthonormal basis). A list $\mathbf{u}_1, \ldots, \mathbf{u}_k$ in V is **orthonormal** if it is orthogonal and every $\mathbf{u}_j$ is a unit vector. That is,

$$\langle \mathbf{u}_i, \mathbf{u}_j \rangle = \delta_{ij} \quad \text{for all } i, j \in \{1, \ldots, k\},$$

with the Kronecker delta of Notation 2.4.7. An **orthonormal basis** of V is an orthonormal list that is a basis of V.

Unit vectors are nonzero, so an orthonormal list is linearly independent by Proposition 6.3.13, and by Corollary 6.3.14 an orthonormal list in an n-dimensional space is an orthonormal basis exactly when its length is n. An orthogonal list of nonzero vectors $\mathbf{v}_1, \ldots, \mathbf{v}_k$ becomes orthonormal after normalizing (Section 6.1.4): the vectors $\mathbf{v}_j / \|\mathbf{v}_j\|$ are unit vectors, and scaling does not affect orthogonality, as $\langle a\mathbf{v}, b\mathbf{w} \rangle = a\bar{b}\langle \mathbf{v}, \mathbf{w} \rangle$. We write $\mathcal{O}$ for orthonormal lists, as the lecture does.

Example 6.3.16 (Orthonormal bases).

(a) The standard basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$ is an orthonormal basis of $\mathbb{F}^n$ with the dot product, since $\mathbf{e}_i \cdot \mathbf{e}_j = \delta_{ij}$.

(b) For every $\theta \in \mathbb{R}$, $\mathbf{u}_1 = (\cos\theta, \sin\theta)$, $\mathbf{u}_2 = (-\sin\theta, \cos\theta)$ is an orthonormal basis of $\mathbb{R}^2$: the standard basis rotated by θ.

(c) In $\mathbb{R}^3$, let

$$\mathbf{u}_1 = \frac{1}{3}(1, 2, 2), \quad \mathbf{u}_2 = \frac{1}{3}(2, 1, -2), \quad \mathbf{u}_3 = \frac{1}{3}(2, -2, 1).$$

Each has squared norm $(1 + 4 + 4)/9 = 1$, and $\mathbf{u}_1 \cdot \mathbf{u}_2 = (2 + 2 - 4)/9 = 0$, $\mathbf{u}_1 \cdot \mathbf{u}_3 = (2 - 4 + 2)/9 = 0$, $\mathbf{u}_2 \cdot \mathbf{u}_3 = (4 - 2 - 2)/9 = 0$. So this is an orthonormal list of length $3 = \dim \mathbb{R}^3$, hence an orthonormal basis.

(d) In $\mathbb{C}^2$, $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1, i)$ and $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(1, -i)$ form an orthonormal basis: $\|\mathbf{u}_j\|^2 = (1 + 1)/2 = 1$, and $\mathbf{u}_1 \cdot \mathbf{u}_2 = 0$ by Example 6.3.2(b).

(e) With the Frobenius inner product (Proposition 6.1.16), the matrix units E_{ij}, which have entry 1 in position (i, j) and 0 elsewhere, form an orthonormal basis of $\mathbb{F}^{m \times n}$: $\langle E_{ij}, E_{kl} \rangle$ is the sum of the products of corresponding entries, which is 1 if $(i, j) = (k, l)$ and 0 otherwise.

Example 6.3.17 (Orthogonal polynomials). Give $\mathbb{R}[x]_{\leq 2}$ the inner product $\langle p, q\rangle = \int_{-1}^{1} p(t)q(t)\,dt$. (Definiteness: if $\int_{-1}^{1} p(t)^2\,dt = 0$, then p vanishes on $[-1,1]$ by Lemma 6.1.14, so it has infinitely many roots and $p = \mathbf{0}$ by Proposition 7.1.22.) The monomials $1, x, x^2$ are not orthogonal, since $\langle 1, x^2\rangle = 2/3$. But $1, x, x^2 - 1/3$ is an orthogonal list: $\langle 1, x\rangle = 0$ and $\langle x, x^2 - 1/3\rangle = 0$ because the integrands are odd, and

$$\left\langle 1, x^2 - \frac{1}{3}\right\rangle = \int_{-1}^{1}\left(t^2 - \frac{1}{3}\right)dt = \frac{2}{3} - \frac{2}{3} = 0.$$

The squared norms are $\|1\|^2 = 2$, $\|x\|^2 = 2/3$, and

$$\left\|x^2 - \frac{1}{3}\right\|^2 = \int_{-1}^{1}\left(t^4 - \frac{2}{3}t^2 + \frac{1}{9}\right)dt = \frac{2}{5} - \frac{4}{9} + \frac{2}{9} = \frac{8}{45}.$$

So $\frac{1}{\sqrt{2}}, \sqrt{3/2}\,x, \sqrt{45/8}\,(x^2 - 1/3)$ is an orthonormal basis of $\mathbb{R}[x]_{\leq 2}$, by Corollary 6.3.14. Up to scaling these are the first three *Legendre polynomials*. Section 6.4 explains how to produce them from $1, x, x^2$ systematically.

Coordinates are inner products

Intuition (Why orthonormal coordinates come for free). For a general basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of V, finding $[\mathbf{v}]_{\mathcal{B}}$ means solving $\mathbf{v} = a_1\mathbf{b}_1 + \cdots + a_n\mathbf{b}_n$ for $a_1, \ldots, a_n$. In $\mathbb{F}^n$ this is a linear system of n equations in which, in general, every equation involves every unknown, solved by row reducing the augmented matrix with columns $\mathbf{b}_1, \ldots, \mathbf{b}_n, \mathbf{v}$. Geometrically, in $\mathbb{R}^2$ the coordinate a_1 is found by drawing the line through the tip of $\mathbf{v}$ parallel to $\mathbf{b}_2$ and seeing where it meets the line through $\mathbf{b}_1$ (Figure 6.3.1(a)). So a_1 depends on $\mathbf{b}_2$ as well as on $\mathbf{b}_1$: tilting $\mathbf{b}_2$ moves the point of intersection.

For an orthonormal basis $\mathbf{u}_1, \mathbf{u}_2$, the line through the tip of $\mathbf{v}$ parallel to $\mathbf{u}_2$ is perpendicular to $\mathbf{u}_1$, so $a_1\mathbf{u}_1$ is the foot of the perpendicular from $\mathbf{v}$ to the line through $\mathbf{u}_1$ (Figure 6.3.1(b)). That foot is the shadow of Technique 6.2.4, $c\mathbf{u}_1$ with $c = \langle \mathbf{v}, \mathbf{u}_1\rangle / \|\mathbf{u}_1\|^2 = \langle \mathbf{v}, \mathbf{u}_1\rangle$. So each coordinate is one inner product. It does not involve the other basis vectors, and computing it involves no system at all.

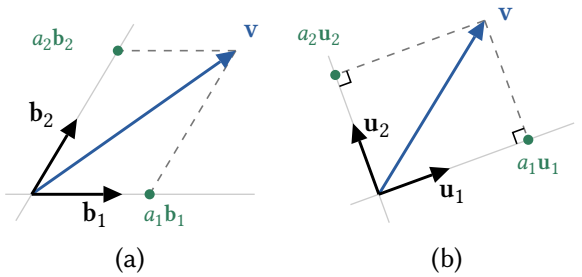

Figure 6.3.1. Reading off coordinates. (a) For a general basis, $a_1\mathbf{b}_1$ is found by moving from the tip of $\mathbf{v}$ parallel to $\mathbf{b}_2$, so it depends on both basis vectors. (b) For an orthonormal basis, $a_j\mathbf{u}_j$ is the foot of the perpendicular from $\mathbf{v}$ to the line through $\mathbf{u}_j$, and $a_j = \langle \mathbf{v}, \mathbf{u}_j\rangle$.

Proposition 6.3.18 (Coordinates in an orthonormal basis). Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$ be an orthonormal list in V.

(a) If $\mathbf{v} \in \operatorname{span}(\mathcal{O})$, then

$$\mathbf{v} = \langle \mathbf{v}, \mathbf{u}_1\rangle\mathbf{u}_1 + \cdots + \langle \mathbf{v}, \mathbf{u}_k\rangle\mathbf{u}_k.$$

(b) In particular, if $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ is an orthonormal basis of V, then every $\mathbf{v} \in V$ satisfies (a), that is,

$$[\mathbf{v}]_{\mathcal{O}} = (\langle \mathbf{v}, \mathbf{u}_1\rangle, \ldots, \langle \mathbf{v}, \mathbf{u}_n\rangle).$$

Proof. ROUTINE

> *Uses.* Definition 1.3.10 (Span), Definition 6.3.15 (Orthonormal list, orthonormal basis), Definition 1.6.14 (Coordinates)
> *Techniques.* Take an inner product to isolate a coefficient (Technique 6.3.12)
> *Hint 1.* Since $\mathbf{v} \in \operatorname{span}(\mathcal{O})$, write $\mathbf{v} = a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k$. You need to identify a_j.
> *Hint 2.* Take the inner product of both sides with $\mathbf{u}_j$, with $\mathbf{u}_j$ in the second slot.
> *Sketch.* Write $\mathbf{v} = \sum_l a_l\mathbf{u}_l$. Then $\langle \mathbf{v}, \mathbf{u}_j\rangle = \sum_l a_l\langle \mathbf{u}_l, \mathbf{u}_j\rangle = \sum_l a_l\delta_{lj} = a_j$, so the coefficients are the inner products. For (b), $\operatorname{span}(\mathcal{O}) = V$ and coordinates are the unique coefficients.

(a) Since $\mathbf{v} \in \operatorname{span}(\mathcal{O})$, there are scalars with $\mathbf{v} = a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k$. For each j, linearity in the first slot gives

$$\langle \mathbf{v}, \mathbf{u}_j\rangle = \sum_{l=1}^{k} a_l\langle \mathbf{u}_l, \mathbf{u}_j\rangle = \sum_{l=1}^{k} a_l\delta_{lj} = a_j.$$

Substituting $a_j = \langle \mathbf{v}, \mathbf{u}_j\rangle$ into $\mathbf{v} = \sum_j a_j\mathbf{u}_j$ gives (a).

(b) If $\mathcal{O}$ is a basis, then $\operatorname{span}(\mathcal{O}) = V$, so (a) applies to every $\mathbf{v} \in V$. The coordinates $[\mathbf{v}]_{\mathcal{O}}$ are the unique coefficients $a_1, \ldots, a_n$ with $\mathbf{v} = \sum_j a_j\mathbf{u}_j$ (Definition 1.6.14), and we have just seen that $a_j = \langle \mathbf{v}, \mathbf{u}_j\rangle$. □

Remark 6.3.19 (Which slot). The coefficient of $\mathbf{u}_j$ is $\langle \mathbf{v}, \mathbf{u}_j\rangle$, with $\mathbf{v}$ in the first slot, the slot in which the inner product is linear. The other order gives $\langle \mathbf{u}_j, \mathbf{v}\rangle = \overline{\langle \mathbf{v}, \mathbf{u}_j\rangle}$. Over $\mathbb{R}$ the two agree, but over $\mathbb{C}$ the conjugated numbers are the wrong coordinates. Take the orthonormal basis $\mathbf{u}_1 = (1, i)/\sqrt{2}$, $\mathbf{u}_2 = (1, -i)/\sqrt{2}$ of Example 6.3.16(d) and $\mathbf{v} = (0, 1)$. Then

$$\langle \mathbf{v}, \mathbf{u}_1\rangle = \frac{1}{\sqrt{2}}\big(0 \cdot 1 + 1 \cdot \bar{i}\big) = -\frac{i}{\sqrt{2}},$$
$$\langle \mathbf{v}, \mathbf{u}_2\rangle = \frac{1}{\sqrt{2}}\big(0 \cdot 1 + 1 \cdot \overline{-i}\big) = \frac{i}{\sqrt{2}},$$

and indeed $(-i/2)(1, i) + (i/2)(1, -i) = (0, 1)$. The conjugated coefficients give $(i/2)(1, i) - (i/2)(1, -i) = (0, -1)$ instead. Texts that make inner products linear in the second slot, as in Non-example 6.1.25(b), write the coefficient as $\langle \mathbf{u}_j, \mathbf{v}\rangle$; it is the same number.

Example 6.3.20 (Coordinates without a linear system). Take the orthonormal basis $\mathcal{O} = \mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$ of $\mathbb{R}^3$ from Example 6.3.16(c) and $\mathbf{v} = (1, 2, 3)$. By Proposition 6.3.18,

$$\langle \mathbf{v}, \mathbf{u}_1\rangle = \frac{1 + 4 + 6}{3} = \frac{11}{3},$$
$$\langle \mathbf{v}, \mathbf{u}_2\rangle = \frac{2 + 2 - 6}{3} = -\frac{2}{3},$$
$$\langle \mathbf{v}, \mathbf{u}_3\rangle = \frac{2 - 4 + 3}{3} = \frac{1}{3},$$

so $[\mathbf{v}]_{\mathcal{O}} = (11/3, -2/3, 1/3)$. Check:

$$\frac{11}{9}(1, 2, 2) - \frac{2}{9}(2, 1, -2) + \frac{1}{9}(2, -2, 1)$$
$$= \frac{1}{9}(9, 18, 27) = (1, 2, 3).$$

Three dot products replaced the row reduction of a 3×4 augmented matrix.

The same isolation works for orthogonal bases that are not normalized; each coefficient just picks up the factor $1/\|\mathbf{v}_j\|^2$.

> **Corollary 6.3.21** (Coordinates in an orthogonal basis). Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be an orthogonal basis of V, that is, an orthogonal list of nonzero vectors that is a basis. Then every $\mathbf{v} \in V$ satisfies

$$\mathbf{v} = \sum_{j=1}^{n} \frac{\langle \mathbf{v}, \mathbf{v}_j \rangle}{\|\mathbf{v}_j\|^2} \mathbf{v}_j.$$

Proof. ROUTINE

Uses. Definition 1.6.1 (Basis), Definition 6.3.1 (Orthogonality)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. Write $\mathbf{v} = \sum_l a_l \mathbf{v}_l$ and take the inner product with $\mathbf{v}_j$.
Hint 2. You get $\langle \mathbf{v}, \mathbf{v}_j \rangle = a_j \|\mathbf{v}_j\|^2$, and $\|\mathbf{v}_j\| \neq 0$.
Sketch. With $\mathbf{v} = \sum_l a_l \mathbf{v}_l$, isolating coefficients gives $\langle \mathbf{v}, \mathbf{v}_j \rangle = a_j \|\mathbf{v}_j\|^2$; divide by $\|\mathbf{v}_j\|^2 > 0$.

Since $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a basis, $\mathbf{v} = a_1 \mathbf{v}_1 + \cdots + a_n \mathbf{v}_n$ for some scalars. Taking the inner product with $\mathbf{v}_j$ and using orthogonality,

$$\langle \mathbf{v}, \mathbf{v}_j \rangle = \sum_{l=1}^{n} a_l \langle \mathbf{v}_l, \mathbf{v}_j \rangle = a_j \|\mathbf{v}_j\|^2.$$

As $\mathbf{v}_j \neq \mathbf{0}$, we may divide by $\|\mathbf{v}_j\|^2 > 0$, which gives $a_j = \langle \mathbf{v}, \mathbf{v}_j \rangle / \|\mathbf{v}_j\|^2$. □

Each term $\langle \mathbf{v}, \mathbf{v}_j \rangle / \|\mathbf{v}_j\|^2 \mathbf{v}_j$ is the shadow of $\mathbf{v}$ on the line through $\mathbf{v}_j$ (Technique 6.2.4). So in an orthogonal basis a vector is the sum of its shadows on the basis lines. For a basis that is not orthogonal this fails. In $\mathbb{R}^2$ with $\mathbf{v}_1 = (1, 0)$, $\mathbf{v}_2 = (1, 1)$, and $\mathbf{v} = (0, 1) = -\mathbf{v}_1 + \mathbf{v}_2$, the shadows are $0 \cdot \mathbf{v}_1$ and $(1/2)\mathbf{v}_2$, which add up to $(1/2, 1/2) \neq \mathbf{v}$.

Parseval's identity

Coordinates with respect to an orthonormal basis do more than locate a vector. They compute lengths and inner products, by the same formulas as in $\mathbb{F}^n$.

Theorem 6.3.22 (Parseval's identity). Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ be an orthonormal basis of V, and let $\mathbf{v}, \mathbf{w} \in V$.

(a) $\langle \mathbf{v}, \mathbf{w} \rangle = \sum_{j=1}^{n} \langle \mathbf{v}, \mathbf{u}_j \rangle \overline{\langle \mathbf{w}, \mathbf{u}_j \rangle}$. In coordinates,

$$\langle \mathbf{v}, \mathbf{w} \rangle = [\mathbf{v}]_{\mathcal{O}} \cdot [\mathbf{w}]_{\mathcal{O}} = [\mathbf{w}]_{\mathcal{O}}^{*} [\mathbf{v}]_{\mathcal{O}}.$$

(b) $\|\mathbf{v}\|^2 = \sum_{j=1}^{n} |\langle \mathbf{v}, \mathbf{u}_j \rangle|^2$, which is the squared norm of $[\mathbf{v}]_{\mathcal{O}}$ in $\mathbb{F}^n$.

Proof. ROUTINE

Uses. Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 6.1.4 (Sesquilinearity), Definition 6.1.8 (Dot product), Notation 6.1.7 (Conjugate transpose), Proposition 6.1.10 (The dot product is an inner product)
Hint 1. It suffices to expand one of the two vectors in the basis. Which one?
Hint 2. Write $\mathbf{w} = \sum_j \langle \mathbf{w}, \mathbf{u}_j \rangle \mathbf{u}_j$ by Proposition 6.3.18 and pull the coefficients out of the second slot, remembering the conjugates.
Sketch. Substituting $\mathbf{w} = \sum_j \langle \mathbf{w}, \mathbf{u}_j \rangle \mathbf{u}_j$ into the second slot gives $\langle \mathbf{v}, \mathbf{w} \rangle = \sum_j \overline{\langle \mathbf{w}, \mathbf{u}_j \rangle} \langle \mathbf{v}, \mathbf{u}_j \rangle$, which is the dot product of the coordinate vectors. Take $\mathbf{w} = \mathbf{v}$ for (b).

(a) By Proposition 6.3.18, $\mathbf{w} = \sum_{j=1}^{n} \langle \mathbf{w}, \mathbf{u}_j \rangle \mathbf{u}_j$. By Proposition 6.1.4,

$$\langle \mathbf{v}, \mathbf{w} \rangle = \left\langle \mathbf{v}, \sum_{j=1}^{n} \langle \mathbf{w}, \mathbf{u}_j \rangle \mathbf{u}_j \right\rangle = \sum_{j=1}^{n} \overline{\langle \mathbf{w}, \mathbf{u}_j \rangle} \langle \mathbf{v}, \mathbf{u}_j \rangle.$$

By Proposition 6.3.18(b), the jth entries of $[\mathbf{v}]_{\mathcal{O}}$ and $[\mathbf{w}]_{\mathcal{O}}$ are $\langle \mathbf{v}, \mathbf{u}_j \rangle$ and $\langle \mathbf{w}, \mathbf{u}_j \rangle$, so by Definition 6.1.8 and Notation 6.1.7 this sum is $[\mathbf{v}]_{\mathcal{O}} \cdot [\mathbf{w}]_{\mathcal{O}} = [\mathbf{w}]_{\mathcal{O}}^{*} [\mathbf{v}]_{\mathcal{O}}$.

(b) Take $\mathbf{w} = \mathbf{v}$ in (a) and use $z\bar{z} = |z|^2$. By Proposition 6.1.10 the result is the squared norm of $[\mathbf{v}]_{\mathcal{O}}$ for the dot product. □

Part (b) is also Corollary 6.3.6 applied to $\mathbf{v} = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$. For the basis of Example 6.3.20, it says $(121 + 4 + 1)/9 = 14 = \|(1, 2, 3)\|^2$, and since $[\mathbf{e}_3]_{\mathcal{O}} = (2/3, -2/3, 1/3)$, part (a) says

$$\mathbf{v} \cdot \mathbf{e}_3 = \frac{11}{3} \cdot \frac{2}{3} + \left(-\frac{2}{3}\right)\left(-\frac{2}{3}\right) + \frac{1}{3} \cdot \frac{1}{3} = \frac{27}{9} = 3,$$

which is indeed the third entry of $\mathbf{v}$.

Intuition (An orthonormal basis turns V into $\mathbb{F}^n$). The coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{O}}$ is a linear bijection $V \to \mathbb{F}^n$ (Proposition 1.6.19), and Parseval's identity says that it carries the inner product of V to the dot product of $\mathbb{F}^n$. So once an orthonormal basis is chosen, every question about lengths, angles, and orthogonality in V can be answered in coordinates, with the formulas of $\mathbb{F}^n$. Gram–Schmidt (Theorem 6.4.20) shows that every finite-dimensional inner product space has an orthonormal basis, so every n-dimensional inner product space looks like $\mathbb{F}^n$ with the dot product; Section 8.4 makes "looks like" precise.

This is special to orthonormal bases. For the basis $\mathcal{B} = (1,0),(1,1)$ of $\mathbb{R}^2$, the orthogonal vectors $\mathbf{e}_1 = (1,0)$ and $\mathbf{e}_2 = -(1,0) + (1,1)$ have coordinate vectors $(1,0)$ and $(-1,1)$, whose dot product is -1. In fact $[\mathbf{x}]_{\mathcal{B}} \cdot [\mathbf{y}]_{\mathcal{B}}$ is a different inner product on $\mathbb{R}^2$, the unique one for which $\mathcal{B}$ is orthonormal (Exercise 6.3.51).

Exercise 6.3.23. ROUTINE Show that $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1,1,0)$, $\mathbf{u}_2 = \frac{1}{\sqrt{3}}(1,-1,1)$, $\mathbf{u}_3 = \frac{1}{\sqrt{6}}(-1,1,2)$ is an orthonormal basis of $\mathbb{R}^3$. Find the coordinates of $\mathbf{v} = (3,1,2)$ in this basis, and check your answer with Theorem 6.3.22(b).

Solution on page 1483

Bessel's inequality

Parseval's identity needs a basis. For an orthonormal list that does not span V, the sum $\sum_j |\langle \mathbf{v}, \mathbf{u}_j \rangle|^2$ misses part of $\mathbf{v}$, and an inequality remains.

Intuition (What is left over). In $\mathbb{R}^3$ with $\mathbf{u}_1 = \mathbf{e}_1$ and $\mathbf{u}_2 = \mathbf{e}_2$, the sum is $v_1^2 + v_2^2$, which falls short of $\|\mathbf{v}\|^2$ by v_3^2, the squared length of the part of $\mathbf{v}$ perpendicular to the plane of $\mathbf{u}_1, \mathbf{u}_2$. In general, split $\mathbf{v} = \mathbf{p} + \mathbf{w}$, where $\mathbf{p} = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$ is what the formula of Proposition 6.3.18 produces and $\mathbf{w} = \mathbf{v} - \mathbf{p}$ is the remainder. Isolating coefficients shows that $\mathbf{w}$ is orthogonal to every $\mathbf{u}_j$, hence to $\mathbf{p}$, and Pythagoras gives $\|\mathbf{v}\|^2 = \|\mathbf{p}\|^2 + \|\mathbf{w}\|^2$. For a single unit vector $\mathbf{u}_1$, this is the decomposition of the first proof of Theorem 6.2.1, and the inequality below is the Cauchy–Schwarz inequality $|\langle \mathbf{v}, \mathbf{u}_1 \rangle| \le \|\mathbf{v}\|$.

Theorem 6.3.24 (Bessel's inequality). Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be an orthonormal list in V, and let $\mathbf{v} \in V$. Then

$$\sum_{j=1}^{k} |\langle \mathbf{v}, \mathbf{u}_j \rangle|^2 \le \|\mathbf{v}\|^2,$$

with equality if and only if $\mathbf{v} \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$.

Proof. STANDARD

Uses. Corollary 6.3.6 (Pythagoras for orthogonal lists), Theorem 6.3.3 (Pythagorean theorem), Proposition 6.3.9 (Properties of $A^\perp$), Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 6.1.27 (Basic properties of the norm)
Techniques. Orthogonal decomposition (Technique 6.2.4), Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. Let $\mathbf{p} = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$ and $\mathbf{w} = \mathbf{v} - \mathbf{p}$. Compute $\langle \mathbf{w}, \mathbf{u}_l \rangle$ for each l.
Hint 2. $\mathbf{w}$ is orthogonal to every $\mathbf{u}_l$, hence to $\mathbf{p}$. Apply Theorem 6.3.3 to $\mathbf{v} = \mathbf{p} + \mathbf{w}$, and compute $\|\mathbf{p}\|^2$ with Corollary 6.3.6.
Hint 3. Equality means $\mathbf{w} = \mathbf{0}$. For the converse, use Proposition 6.3.18(a).
Sketch. With $\mathbf{p} = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$ and $\mathbf{w} = \mathbf{v} - \mathbf{p}$, we get $\langle \mathbf{w}, \mathbf{u}_l \rangle = \langle \mathbf{v}, \mathbf{u}_l \rangle - \langle \mathbf{v}, \mathbf{u}_l \rangle = 0$, so $\mathbf{w} \perp \mathbf{p}$. Pythagoras gives $\|\mathbf{v}\|^2 = \|\mathbf{p}\|^2 + \|\mathbf{w}\|^2 \ge \|\mathbf{p}\|^2 = \sum_j |\langle \mathbf{v}, \mathbf{u}_j \rangle|^2$. Equality holds iff $\mathbf{w} = \mathbf{0}$, that is, $\mathbf{v} = \mathbf{p}$. If $\mathbf{v} = \mathbf{p}$, then $\mathbf{v}$ lies in the span; conversely, if $\mathbf{v}$ lies in the span, then $\mathbf{v} = \mathbf{p}$ by Proposition 6.3.18.

Let $\mathbf{p} = \sum_{j=1}^{k} \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$ and $\mathbf{w} = \mathbf{v} - \mathbf{p}$. For each l,

$$\langle \mathbf{w}, \mathbf{u}_l \rangle = \langle \mathbf{v}, \mathbf{u}_l \rangle - \sum_{j=1}^{k} \langle \mathbf{v}, \mathbf{u}_j \rangle \langle \mathbf{u}_j, \mathbf{u}_l \rangle$$
$$= \langle \mathbf{v}, \mathbf{u}_l \rangle - \langle \mathbf{v}, \mathbf{u}_l \rangle = 0.$$

So $\mathbf{w} \in \{\mathbf{u}_1, \ldots, \mathbf{u}_k\}^\perp = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)^\perp$ by Proposition 6.3.9(c), and in particular $\mathbf{w} \perp \mathbf{p}$. By Theorem 6.3.3(a) applied to $\mathbf{v} = \mathbf{p} + \mathbf{w}$, and Corollary 6.3.6 applied to $\mathbf{p}$,

$$\|\mathbf{v}\|^2 = \|\mathbf{p}\|^2 + \|\mathbf{w}\|^2 = \sum_{j=1}^{k} \left| \langle \mathbf{v}, \mathbf{u}_j \rangle \right|^2 + \|\mathbf{w}\|^2. \tag{6.3.2}$$

Since $\|\mathbf{w}\|^2 \geq 0$, the inequality follows.

By (6.3.2), equality holds if and only if $\|\mathbf{w}\| = 0$, that is (Proposition 6.1.27), if and only if $\mathbf{v} = \mathbf{p}$. If $\mathbf{v} = \mathbf{p}$, then $\mathbf{v}$ is a linear combination of $\mathbf{u}_1, \ldots, \mathbf{u}_k$. Conversely, if $\mathbf{v} \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$, then $\mathbf{v} = \mathbf{p}$ by Proposition 6.3.18(a). □

The space V need not be finite-dimensional here. The vector $\mathbf{p}$ is the *orthogonal projection* of $\mathbf{v}$ onto $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$, the subject of Section 6.4, where we will also see that $\|\mathbf{w}\| = \|\mathbf{v} - \mathbf{p}\|$ is the distance from $\mathbf{v}$ to that span (Theorem 6.4.33). Bessel's inequality says that projecting onto a subspace cannot increase length, and its equality case gives a membership test: $\mathbf{v}$ lies in the span of an orthonormal list exactly when the list captures all of $\|\mathbf{v}\|^2$.

Example 6.3.25 (Bessel in $\mathbb{R}^3$). Keep $\mathbf{v} = (1, 2, 3)$ and the vectors $\mathbf{u}_1, \mathbf{u}_2$ of Example 6.3.16(c), but drop $\mathbf{u}_3$. Then

$$|\langle \mathbf{v}, \mathbf{u}_1 \rangle|^2 + |\langle \mathbf{v}, \mathbf{u}_2 \rangle|^2 = \frac{121}{9} + \frac{4}{9} = \frac{125}{9} < 14,$$

and the deficit $1/9 = \langle \mathbf{v}, \mathbf{u}_3 \rangle^2$ is the part that $\mathbf{u}_3$ would have contributed. So $(1, 2, 3) \notin \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$. On the other hand $\mathbf{x} = (1, 1, 0)$ has $\langle \mathbf{x}, \mathbf{u}_1 \rangle = \langle \mathbf{x}, \mathbf{u}_2 \rangle = 1$, so the sum is $2 = \|\mathbf{x}\|^2$, and therefore $\mathbf{x} \in \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$; indeed $\mathbf{x} = \mathbf{u}_1 + \mathbf{u}_2$.

ASIDE: *Fourier coefficients* BEYOND 21-242

Bessel's inequality matters most in infinite-dimensional spaces, where an orthonormal list can never be a basis. On $C([0, 2\pi], \mathbb{C})$, take the inner product $\langle f, g \rangle = \frac{1}{2\pi} \int_0^{2\pi} f(t)\overline{g(t)}\, dt$ (Proposition 6.1.13 on $[0, 2\pi]$, scaled by a positive constant), and let $e_k(t) = \cos kt + i \sin kt$ for $k \in \mathbb{Z}$. The angle subtraction formulas give $e_j \overline{e_k} = e_{j-k}$, and $\int_0^{2\pi} \cos mt\, dt = \int_0^{2\pi} \sin mt\, dt = 0$ for $m \neq 0$, so $\langle e_j, e_k \rangle = \delta_{jk}$. Bessel's inequality for the orthonormal list $e_{-N}, \ldots, e_N$ says that the *Fourier coefficients* $c_k = \langle f, e_k \rangle$ of f satisfy

$$\sum_{k=-N}^{N} |c_k|^2 \leq \frac{1}{2\pi} \int_0^{2\pi} |f(t)|^2\, dt \quad \text{for every } N.$$

The bound does not depend on N, so the series $\sum_k |c_k|^2$ converges, and in particular $c_k \to 0$ as $|k| \to \infty$. Parseval's identity, with equality, also holds for the full infinite sum, but proving it takes analysis (Section 15.3). Both names come from this setting: the identity and the inequality were first found for Fourier series.

6.3.3 Matrices with orthonormal columns

In $\mathbb{F}^m$ with the dot product, a list of n vectors is the same thing as an $m \times n$ matrix, whose columns are the vectors. Orthonormality of the list is a statement about the dot products of the columns with each other, and these are the entries of a single matrix product.

Definition 6.3.26 (Conjugate transpose). Let $A = (a_{ij}) \in \mathbb{F}^{m\times n}$. The **conjugate transpose** of A is the matrix $A^* \in \mathbb{F}^{n\times m}$ with entries

$$(A^*)_{ij} = \overline{a_{ji}} \quad (1 \le i \le n, 1 \le j \le m).$$

That is, $A^* = \overline{A}^{\mathsf{T}}$, where $\overline{A} = (\overline{a_{ij}})$ conjugates every entry (Definition 2.4.21). If A is real, $A^* = A^{\mathsf{T}}$. A square matrix A with $A^* = A$ is called **Hermitian**; a real Hermitian matrix is a symmetric matrix.

This is the matrix of Notation 6.1.7. In particular, for $\mathbf{w} \in \mathbb{F}^n$, $\mathbf{w}^*$ is the row $(\overline{w_1}, \dots, \overline{w_n})$, and $\mathbf{w}^*\mathbf{v} = \mathbf{v} \cdot \mathbf{w}$ for $\mathbf{v} \in \mathbb{F}^n$ (Definition 6.1.8). For example,

$$\begin{pmatrix} 1 & i & 2 \\ 0 & 1-i & 3i \end{pmatrix}^* = \begin{pmatrix} 1 & 0 \\ -i & 1+i \\ 2 & -3i \end{pmatrix}.$$

Proposition 6.3.27 (Properties of the conjugate transpose). Let $A, A' \in \mathbb{F}^{m\times n}$, $B \in \mathbb{F}^{n\times p}$, and $c \in \mathbb{F}$.

(a) $(A^*)^* = A$ and $(cA + A')^* = \bar{c}A^* + A'^*$.

(b) $(AB)^* = B^*A^*$.

(c) If $m = n$ and A is invertible, then A^* is invertible and $(A^*)^{-1} = (A^{-1})^*$.

(d) $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{x} \cdot (A^*\mathbf{y})$ for all $\mathbf{x} \in \mathbb{F}^n$ and $\mathbf{y} \in \mathbb{F}^m$.

Proof. ROUTINE

Uses. Definition 6.3.26 (Conjugate transpose), Proposition 2.4.22 (Transpose is a linear involution), Proposition 2.4.23 (Transpose of a product), Proposition 2.4.14 (Algebra of matrices), Definition 2.5.12 (Invertible), Definition 6.1.8 (Dot product), Notation 6.1.1 (Real and complex scalars)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. (a) is entrywise. For (b), first show $\overline{AB} = \overline{A}\,\overline{B}$ entry by entry, then transpose with Proposition 2.4.23.
Hint 2. For (c), apply $*$ to $AA^{-1} = I$ and $A^{-1}A = I$ using (b).
Hint 3. For (d), write both sides as matrix products: $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{y}^*(A\mathbf{x})$. Regroup and use (a) and (b) to recognize $\mathbf{y}^*A$ as $(A^*\mathbf{y})^*$.
Sketch. (a) Conjugating twice and transposing twice undo themselves, and conjugation respects sums and products. (b) $\overline{AB} = \overline{A}\,\overline{B}$ entrywise, and $(\overline{A}\,\overline{B})^{\mathsf{T}} = \overline{B}^{\mathsf{T}}\overline{A}^{\mathsf{T}}$. (c) $A^*(A^{-1})^* = (A^{-1}A)^* = I^* = I$, and similarly on the other side. (d) $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{y}^*A\mathbf{x} = (A^*\mathbf{y})^*\mathbf{x} = \mathbf{x} \cdot (A^*\mathbf{y})$.

(a) The (i,j) entry of $(A^*)^*$ is $\overline{(A^*)_{ji}} = \overline{\overline{a_{ij}}} = a_{ij}$. The (i,j) entry of $(cA + A')^*$ is $\overline{ca_{ji} + a'_{ji}} = \bar{c}\,\overline{a_{ji}} + \overline{a'_{ji}}$, the (i,j) entry of $\bar{c}A^* + A'^*$.

(b) Since conjugation respects sums and products (Notation 6.1.1), the (i,j) entry of $\overline{AB}$ is $\overline{\sum_l a_{il}b_{lj}} = \sum_l \overline{a_{il}}\,\overline{b_{lj}}$, the (i,j) entry of $\overline{A}\,\overline{B}$. So $\overline{AB} = \overline{A}\,\overline{B}$, and by Proposition 2.4.23,

$$(AB)^* = (\overline{A}\,\overline{B})^{\mathsf{T}} = \overline{B}^{\mathsf{T}}\,\overline{A}^{\mathsf{T}} = B^*A^*.$$

(c) By (b), $A^*(A^{-1})^* = (A^{-1}A)^* = I^* = I$ and $(A^{-1})^*A^* = (AA^{-1})^* = I^* = I$, since I is real and symmetric. So $(A^{-1})^*$ is a two-sided inverse of A^* (Definition 2.5.12).

(d) Identifying 1×1 matrices with scalars, $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{y}^*(A\mathbf{x}) = (\mathbf{y}^*A)\mathbf{x}$ by associativity (Proposition 2.4.14). By (b) and (a), $(A^*\mathbf{y})^* = \mathbf{y}^*(A^*)^* = \mathbf{y}^*A$. Hence $(A\mathbf{x}) \cdot \mathbf{y} = (A^*\mathbf{y})^*\mathbf{x} = \mathbf{x} \cdot (A^*\mathbf{y})$. □

Part (d) is what makes A^* useful: it moves a matrix from one side of the dot product to the other, at the price of a star. Section 6.6 turns this property into the definition of the adjoint of a linear map.

Gram matrices

All the inner products among the vectors of a list fit into one matrix.

Definition 6.3.28 (Gram matrix). The **Gram matrix** of a list $\mathbf{v}_1, \dots, \mathbf{v}_k$ in V is the matrix $G \in \mathbb{F}^{k\times k}$ with entries

$$g_{ij} = \langle \mathbf{v}_j, \mathbf{v}_i \rangle.$$

The order of the indices, with j in the first slot, matches Proposition 6.1.22 and keeps conjugates out of the next results. By conjugate symmetry $G^* = G$, and the diagonal entries are the squared norms $\|\mathbf{v}_i\|^2$. The list is orthogonal if and only if G is diagonal, and orthonormal if and only if $G = I_k$.

Theorem 6.3.29 (Orthonormal columns). Let $A \in \mathbb{F}^{m\times n}$ have columns $\mathbf{a}_1, \dots, \mathbf{a}_n$. Then

$$(A^*A)_{ij} = \mathbf{a}_j \cdot \mathbf{a}_i \quad (1 \le i, j \le n),$$

so A^*A is the Gram matrix of the columns of A. In particular, the columns of A are orthonormal if and only if $A^*A = I_n$, and orthogonal if and only if A^*A is diagonal.

Proof. ROUTINE

Uses. Proposition 2.4.8 (Four views of the product), Definition 6.3.26 (Conjugate transpose), Definition 6.1.8 (Dot product), Definition 6.3.28 (Gram matrix), Definition 6.3.15 (Orthonormal list, orthonormal basis), Definition 2.3.5 (Identity matrix)
Hint 1. Compute the (i, j) entry of A^*A as row i of A^* times column j of A.
Hint 2. Row i of A^* is $\mathbf{a}_i^*$. What is $\mathbf{a}_i^*\mathbf{a}_j$?
Sketch. Row i of A^* is $\mathbf{a}_i^*$ and column j of A is $\mathbf{a}_j$, so $(A^*A)_{ij} = \mathbf{a}_i^*\mathbf{a}_j = \mathbf{a}_j \cdot \mathbf{a}_i$. Orthonormality says $\mathbf{a}_j \cdot \mathbf{a}_i = \delta_{ij}$, which is the statement $A^*A = I_n$.

By Definition 6.3.26, row i of A^* is $(\overline{a_{1i}}, \dots, \overline{a_{mi}}) = \mathbf{a}_i^*$. By Proposition 2.4.8(a),

$$(A^*A)_{ij} = \mathbf{a}_i^*\mathbf{a}_j = \sum_{l=1}^{m} a_{lj}\overline{a_{li}} = \mathbf{a}_j \cdot \mathbf{a}_i,$$

which is the (i, j) entry of the Gram matrix of $\mathbf{a}_1, \dots, \mathbf{a}_n$ for the dot product. The columns are orthonormal if and only if $\mathbf{a}_j \cdot \mathbf{a}_i = \delta_{ij}$ for all i, j (Definition 6.3.15), that is, if and only if $A^*A = (\delta_{ij}) = I_n$ (Definition 2.3.5). Similarly, they are orthogonal if and only if every off-diagonal entry of A^*A is 0. □

For example, the matrix with the columns $\mathbf{u}_1 = (1, i)/\sqrt{2}$ and $\mathbf{u}_2 = (1, -i)/\sqrt{2}$ of Example 6.3.16(d) satisfies

$$\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ 1 & i \end{pmatrix} \cdot \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix} = \frac{1}{2}\begin{pmatrix} 1+1 & 1-1 \\ 1-1 & 1+1 \end{pmatrix} = I_2.$$

The condition $A^*A = I_n$ does not require A to be square. The 3×2 matrix with columns $\mathbf{u}_1, \mathbf{u}_2$ from Example 6.3.16(c) has $A^*A = I_2$. But $AA^* \neq I_3$, since AA^* has rank at most 2 (Theorem 4.3.3); Section 6.4 identifies AA^* as the projection onto the plane spanned by the columns.

Gram matrices are useful beyond orthonormality. They detect linear independence of any list.

Proposition 6.3.30 (Gram matrices detect independence). Let G be the Gram matrix of a list $\mathbf{v}_1, \dots, \mathbf{v}_k$ in V, and let $\mathbf{c} = (c_1, \dots, c_k) \in \mathbb{F}^k$. Then:

(a) $\mathbf{c}^*G\mathbf{c} = \|c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k\|^2$;

(b) $G\mathbf{c} = \mathbf{0}$ if and only if $c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k = \mathbf{0}$.

Consequently, G is invertible if and only if $\mathbf{v}_1, \dots, \mathbf{v}_k$ is linearly independent.

Proof. STANDARD

Uses. Definition 6.3.28 (Gram matrix), Definition 2.3.8 (Matrix–vector product), Proposition 6.1.4 (Sesquilinearity), Definition 6.1.2 (Inner product), Theorem 1.5.5 (Independence is decided at zero), a square matrix whose kernel is $\{\mathbf{0}\}$ is invertible (Section 3.5)

Techniques. Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Let $\mathbf{w} = \sum_j c_j \mathbf{v}_j$. Show that the ith entry of $G\mathbf{c}$ is $\langle \mathbf{w}, \mathbf{v}_i \rangle$.
Hint 2. For (a), $\mathbf{c}^* G\mathbf{c} = \sum_i \overline{c_i} (G\mathbf{c})_i$; recognize this as $\left\langle \mathbf{w}, \sum_i c_i \mathbf{v}_i \right\rangle$.
Hint 3. For (b), one direction is immediate from the formula for $(G\mathbf{c})_i$. For the other, use (a) and definiteness.
Sketch. With $\mathbf{w} = \sum_j c_j \mathbf{v}_j$, $(G\mathbf{c})_i = \sum_j \langle \mathbf{v}_j, \mathbf{v}_i \rangle c_j = \langle \mathbf{w}, \mathbf{v}_i \rangle$, and then $\mathbf{c}^* G\mathbf{c} = \sum_i \overline{c_i} \langle \mathbf{w}, \mathbf{v}_i \rangle = \langle \mathbf{w}, \mathbf{w} \rangle$. If $\mathbf{w} = \mathbf{0}$, then $G\mathbf{c} = \mathbf{0}$; if $G\mathbf{c} = \mathbf{0}$, then $\|\mathbf{w}\|^2 = \mathbf{c}^* \mathbf{0} = 0$. So $\ker G$ is the set of coefficient vectors of linear relations, which is $\{\mathbf{0}\}$ exactly when the list is independent.

Let $\mathbf{w} = c_1 \mathbf{v}_1 + \cdots + c_k \mathbf{v}_k$. By Definition 2.3.8 and linearity in the first slot,

$$(G\mathbf{c})_i = \sum_{j=1}^{k} g_{ij} c_j = \sum_{j=1}^{k} c_j \langle \mathbf{v}_j, \mathbf{v}_i \rangle = \langle \mathbf{w}, \mathbf{v}_i \rangle.$$

(a) By the formula above and Proposition 6.1.4,

$$\begin{aligned} \mathbf{c}^* G\mathbf{c} &= \sum_{i=1}^{k} \overline{c_i} (G\mathbf{c})_i = \sum_{i=1}^{k} \overline{c_i} \langle \mathbf{w}, \mathbf{v}_i \rangle \\ &= \left\langle \mathbf{w}, \sum_{i=1}^{k} c_i \mathbf{v}_i \right\rangle = \|\mathbf{w}\|^2. \end{aligned}$$

(b) If $\mathbf{w} = \mathbf{0}$, every entry $\langle \mathbf{w}, \mathbf{v}_i \rangle$ of $G\mathbf{c}$ is 0. Conversely, if $G\mathbf{c} = \mathbf{0}$, then by (a), $\|\mathbf{w}\|^2 = \mathbf{c}^* \mathbf{0} = 0$, so $\mathbf{w} = \mathbf{0}$ by definiteness.

By (b), $\ker G$ consists of the coefficient vectors of linear relations among $\mathbf{v}_1, \ldots, \mathbf{v}_k$. So $\ker G = \{\mathbf{0}\}$ if and only if the list is linearly independent (Theorem 1.5.5). Since G is square, $\ker G = \{\mathbf{0}\}$ if and only if G is invertible (Section 3.5). □

Technique 6.3.31 (Gram matrices). To study a list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ in an inner product space, record all the inner products $\langle \mathbf{v}_j, \mathbf{v}_i \rangle$ in its Gram matrix G. Questions about the list become questions about one matrix: the list is orthonormal if and only if $G = I$, orthogonal if and only if G is diagonal, and independent if and only if G is invertible, and the combination with coefficient vector $\mathbf{c}$ has squared length $\mathbf{c}^* G\mathbf{c}$. When the vectors are the columns of $A \in \mathbb{F}^{m \times n}$, $G = A^* A$, so these become statements about $A^* A$.

Reach for it when the hypotheses are about inner products among the vectors of a list (lengths, angles, orthogonality) and the conclusion is about the list itself, or when the product $A^* A$ appears. The canonical example is Proposition 6.3.30. In Section 6.5 the normal equations have the coefficient matrix $A^* A$, and Proposition 6.3.30 shows that they have a unique solution exactly when the columns of A are independent.
Used in. Proposition 6.3.41, Exercise 6.3.54, Exercise 6.3.56, Exercise 6.4.59, Proposition 6.5.23, Exercise 6.5.43, Exercise 6.7.11, Problem 6.4, Problem 6.9, Problem 6.12, Theorem 8.3.5, Proposition 8.3.15, Exercise 8.3.32, Exercise 8.3.35, Exercise 6.6.46.

Example 6.3.32 (A relation read off from a Gram matrix). In $\mathbb{R}^3$, let $\mathbf{v}_1 = (1, 0, 1)$, $\mathbf{v}_2 = (0, 1, 1)$, $\mathbf{v}_3 = (1, -1, 0)$. Their Gram matrix is

$$G = \begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{pmatrix},$$

and $G(1, -1, -1) = (2 - 1 - 1, 1 - 2 + 1, 1 + 1 - 2) = \mathbf{0}$. By Proposition 6.3.30(b), $\mathbf{v}_1 - \mathbf{v}_2 - \mathbf{v}_3 = \mathbf{0}$, which is easily checked. So the list is dependent, and G is not invertible.

Unitary and orthogonal matrices

Definition 6.3.33 (Unitary and orthogonal matrices). A square matrix $U \in \mathbb{F}^{n\times n}$ is **unitary** if $U^*U = I_n$, that is (Theorem 6.3.29), if its columns form an orthonormal basis of $\mathbb{F}^n$. A real unitary matrix, that is, a matrix $Q \in \mathbb{R}^{n\times n}$ with $Q^{\mathsf{T}}Q = I_n$, is called **orthogonal**.

An $n \times n$ matrix has n columns, so by Corollary 6.3.14 its columns are an orthonormal basis of $\mathbb{F}^n$ as soon as they are orthonormal. The name "orthogonal matrix" is traditional but misleading: the columns of an orthogonal matrix are orthonormal, not merely orthogonal. The matrix $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ has orthogonal columns of length $\sqrt{2}$ and is not orthogonal; dividing it by $\sqrt{2}$ makes it orthogonal.

Proposition 6.3.34 (Characterizations of unitary matrices). For $U \in \mathbb{F}^{n\times n}$, the following are equivalent:

(i) $U^*U = I_n$, that is, the columns of U are orthonormal;
(ii) U is invertible and $U^{-1} = U^*$;
(iii) $UU^* = I_n$, that is, the rows of U, read as vectors of $\mathbb{F}^n$, are orthonormal;
(iv) U^* is unitary.

Proof. ROUTINE

Uses. Theorem 3.5.23 (One-sided inverses of square matrices), Proposition 6.3.27 (Properties of the conjugate transpose), Theorem 6.3.29 (Orthonormal columns), Definition 2.5.12 (Invertible), Definition 6.1.8 (Dot product)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. (i) says that U^* is a left inverse of the square matrix U. What do you know about one-sided inverses of square matrices?
Hint 2. Prove (i) ⇒ (ii) ⇒ (iii) ⇒ (i), then compare (iii) and (iv) using $(U^*)^* = U$.
Hint 3. For the reading of (iii), compute the (i, j) entry of UU^* as a dot product of two rows.
Sketch. For a square matrix a one-sided inverse is two-sided, so $U^*U = I$ and $UU^* = I$ each imply $U^{-1} = U^*$, which implies both. Statement (iv) says $(U^*)^*U^* = I$, which is $UU^* = I$. Finally $(UU^*)_{ij} = \sum_l u_{il}\overline{u_{jl}}$ is the dot product of rows i and j.

We prove (i) ⇒ (ii) ⇒ (iii) ⇒ (i) and (iii) ⇔ (iv).

(i) ⇒ (ii). U^* is a left inverse of the square matrix U, so it is a two-sided inverse by Theorem 3.5.23. That is, U is invertible with $U^{-1} = U^*$.

(ii) ⇒ (iii). $UU^* = UU^{-1} = I_n$.

(iii) ⇒ (i). U^* is a right inverse of the square matrix U, so again it is a two-sided inverse by Theorem 3.5.23, and $U^*U = I_n$.

(iii) ⇔ (iv). By Proposition 6.3.27(a), $(U^*)^*U^* = UU^*$, so U^* is unitary exactly when $UU^* = I_n$.

Finally, the (i, j) entry of UU^* is $\sum_l u_{il}\overline{u_{jl}}$, which is the dot product of $\mathbf{r}_i = (u_{i1}, \ldots, u_{in})$ with $\mathbf{r}_j$ (Definition 6.1.8). So $UU^* = I_n$ says that $\mathbf{r}_i \cdot \mathbf{r}_j = \delta_{ij}$, that is, the rows are orthonormal. □

That the rows of a square matrix are orthonormal whenever its columns are is not visible from either list by itself; it comes from the fact that one-sided inverses of square matrices are two-sided. For non-square matrices it fails: the columns of $\begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$ are orthonormal, but its rows $(1, 0)$, $(0, 1)$, $(0, 0)$ are not.

Example 6.3.35 (Unitary and orthogonal matrices).

(a) For every $\theta \in \mathbb{R}$, the rotation and the reflection

$$R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}, \quad S_\theta = \begin{pmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{pmatrix}$$

are orthogonal. The columns of R_θ are the orthonormal basis of Example 6.3.16(b), and those of S_θ are the same two vectors up to the sign of the second.

(b) Every permutation matrix (Definition 5.2.29) is orthogonal, since its columns are the standard basis vectors in some order.

(c) A diagonal matrix $\operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ is unitary if and only if $|\lambda_j| = 1$ for every j, since its columns $\lambda_j \mathbf{e}_j$ are orthogonal with norms $|\lambda_j|$.

(d) The matrices

$$\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix} \quad \text{and} \quad \frac{1}{3}\begin{pmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{pmatrix}$$

are unitary and orthogonal respectively, by Example 6.3.16(d) and (c).

The definition only asks for orthonormal columns. What unitary matrices do geometrically, namely preserve lengths and inner products, and what they look like (rotations and reflections, in the real case) is the subject of Section 8.4. Here we only record why they belong in this section: they are the matrices whose linear systems are solved by the method of Proposition 6.3.18.

Corollary 6.3.36 (Orthonormal coordinates in $\mathbb{F}^n$). Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ be an orthonormal basis of $\mathbb{F}^n$, and let U be the unitary matrix with columns $\mathbf{u}_1, \ldots, \mathbf{u}_n$. Then $[\mathbf{x}]_\mathcal{O} = U^*\mathbf{x}$ for every $\mathbf{x} \in \mathbb{F}^n$.

Proof (by inner products). ROUTINE

Uses. Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 2.4.8 (Four views of the product), Definition 6.3.26 (Conjugate transpose)
Hint 1. By Proposition 6.3.18, the jth coordinate is $\mathbf{x} \cdot \mathbf{u}_j$. Write it as a matrix product.
Hint 2. $\mathbf{x} \cdot \mathbf{u}_j = \mathbf{u}_j^*\mathbf{x}$, and $\mathbf{u}_j^*$ is row j of U^*.
Sketch. The jth coordinate is $\mathbf{x} \cdot \mathbf{u}_j = \mathbf{u}_j^*\mathbf{x}$, and row j of U^* is $\mathbf{u}_j^*$, so this is the jth entry of $U^*\mathbf{x}$.

By Proposition 6.3.18(b), the jth entry of $[\mathbf{x}]_\mathcal{O}$ is $\mathbf{x} \cdot \mathbf{u}_j = \mathbf{u}_j^*\mathbf{x}$. Row j of U^* is $\mathbf{u}_j^*$ (Definition 6.3.26), so by Proposition 2.4.8 this is the jth entry of $U^*\mathbf{x}$. □

Proof (by solving the system). ROUTINE

Uses. Definition 1.6.14 (Coordinates), Definition 2.3.8 (Matrix–vector product), Proposition 6.3.34 (Characterizations of unitary matrices)
Hint 1. The coordinate vector $\mathbf{c} = [\mathbf{x}]_\mathcal{O}$ is the unique solution of $c_1\mathbf{u}_1 + \cdots + c_n\mathbf{u}_n = \mathbf{x}$. Write this as a matrix equation.
Hint 2. The equation is $U\mathbf{c} = \mathbf{x}$. Solve it with U^{-1}.
Sketch. $[\mathbf{x}]_\mathcal{O}$ is the solution of $U\mathbf{c} = \mathbf{x}$, and $U^{-1} = U^*$ by Proposition 6.3.34, so $\mathbf{c} = U^*\mathbf{x}$.

By Definition 1.6.14 and Definition 2.3.8, $\mathbf{c} = [\mathbf{x}]_\mathcal{O}$ is the unique vector with $U\mathbf{c} = c_1\mathbf{u}_1 + \cdots + c_n\mathbf{u}_n = \mathbf{x}$. By Proposition 6.3.34, U is invertible with $U^{-1} = U^*$, so $\mathbf{c} = U^{-1}\mathbf{x} = U^*\mathbf{x}$. □

The first proof computes the coordinates one at a time as inner products. The second says that the linear system $U\mathbf{c} = \mathbf{x}$, which computing coordinates always requires, is solved for unitary U by a single multiplication by U^*, with no elimination. In the notation of Section 4.5, $U = [\mathrm{id}]_{\mathcal{E}\mathcal{O}}$ and $U^* = [\mathrm{id}]_{\mathcal{O}\mathcal{E}}$, and the general fact that these two change-of-coordinates matrices are inverse to each other becomes $U^{-1} = U^*$.

Exercise 6.3.37. ROUTINE Let $U, W \in \mathbb{F}^{n\times n}$ be unitary. Show that UW and U^{-1} are unitary, and that $(U\mathbf{x}) \cdot (U\mathbf{y}) = \mathbf{x} \cdot \mathbf{y}$ and $\|U\mathbf{x}\| = \|\mathbf{x}\|$ for all $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$.

Solution on page 1484

Exercise 6.3.38. ROUTINE Find all $a, b \in \mathbb{C}$ for which $\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & a \\ i & b \end{pmatrix}$ is unitary.

Solution on page 1484

6.3.4 The discrete Fourier basis

After the standard basis, the most useful orthonormal basis of $\mathbb{C}^n$ consists of sampled waves. Computing coordinates in it is the *discrete Fourier transform* of signal processing. Its orthogonality rests on one computation with roots of unity.

Fix $n \geq 1$ and let

$$\omega = \cos\frac{2\pi}{n} + i\sin\frac{2\pi}{n}.$$

By de Moivre's formula (Section B.1), $\omega^m = \cos(2\pi m/n) + i\sin(2\pi m/n)$ for every integer m. So $|\omega| = 1$, which gives $\overline{\omega^m} = \omega^{-m}$, and $\omega^m = 1$ if and only if m/n is an integer, that is, $n \mid m$. In particular $\omega^n = 1$, so ω^m depends only on the remainder of m modulo n.

Lemma 6.3.39 (Sums of roots of unity). For every integer m,

$$\sum_{j=0}^{n-1} \omega^{jm} = \begin{cases} n \text{ if } n \mid m \\ 0 \text{ if } n \nmid m. \end{cases}$$

Intuition. The numbers ω^{jm}, $j = 0, \ldots, n-1$, go around the unit circle in equal steps, and when $n \nmid m$ they are spread evenly around it. Rotating them all by the step $z = \omega^m$ permutes them, so their sum S satisfies $zS = S$; as $z \neq 1$, this forces $S = 0$. When $n \mid m$ every step is a full turn, and all n terms are 1.

Proof. ROUTINE

Uses. $\omega^m = 1$ if and only if $n \mid m$, Proposition 1.1.17 (No zero divisors)
Hint 1. If $n \mid m$, what is each term? If not, let $z = \omega^m \neq 1$ and $S = \sum_{j=0}^{n-1} z^j$. Compare zS with S.
Hint 2. $zS = z + z^2 + \cdots + z^n$, and $z^n = (\omega^n)^m = 1$.
Sketch. If $n \mid m$, every term is 1. Otherwise $z = \omega^m \neq 1$, and $zS = \sum_{j=1}^{n} z^j = S$ because $z^n = 1 = z^0$. So $(z-1)S = 0$ with $z - 1 \neq 0$, and $S = 0$. (Equivalently, sum the geometric series: $S = (z^n - 1)/(z - 1) = 0$.)

If $n \mid m$, then $\omega^m = 1$, so $\omega^{jm} = (\omega^m)^j = 1$ for every j, and the sum is n. Suppose $n \nmid m$, and let $z = \omega^m$, so $z \neq 1$ and $z^n = (\omega^n)^m = 1$. Let $S = \sum_{j=0}^{n-1} z^j$. Then

$$\begin{aligned} zS &= z + z^2 + \cdots + z^{n-1} + z^n \\ &= z + z^2 + \cdots + z^{n-1} + 1 = S. \end{aligned}$$

So $(z-1)S = 0$, and since $z - 1 \neq 0$, Proposition 1.1.17 gives $S = 0$. □

Definition 6.3.40 (Fourier matrix). The $n \times n$ **Fourier matrix** is the matrix $\Phi_n \in \mathbb{C}^{n\times n}$ with entries

$$(\Phi_n)_{jk} = \omega^{jk},$$

where, unlike elsewhere in the book, rows and columns are indexed by $j, k = 0, 1, \ldots, n-1$. Its columns are $\mathbf{f}_0, \ldots, \mathbf{f}_{n-1} \in \mathbb{C}^n$, where

$$\mathbf{f}_k = \left(1, \omega^k, \omega^{2k}, \ldots, \omega^{(n-1)k}\right).$$

For example, $\Phi_1 = (1)$, $\Phi_2 = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$, and since $\omega = i$ for $n = 4$,

$$\Phi_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{pmatrix}.$$

Since $jk = kj$, Φ_n is symmetric, so its rows are also $\mathbf{f}_0, \ldots, \mathbf{f}_{n-1}$.

Intuition (The columns are waves). The jth entry of $\mathbf{f}_k$ is $\omega^{jk} = \cos(2\pi kj/n) + i\sin(2\pi kj/n)$. So $\mathbf{f}_k$ records the values of $t \mapsto \cos(2\pi kt) + i\sin(2\pi kt)$, which winds k times around the unit circle as t runs over $[0, 1]$, at the n sample points $t = j/n$. Its real part samples a cosine wave with k full periods (Figure 6.3.2). The coordinate of a vector $\mathbf{x} \in \mathbb{C}^n$ along $\mathbf{f}_k$ measures how much of the wave of frequency k the data $\mathbf{x}$ contains. Since $\omega^{j(n-k)} = \omega^{-jk}$, we have $\mathbf{f}_{n-k} = \overline{\mathbf{f}_k}$: at only n sample points, frequency $n-k$ looks exactly like frequency $-k$.

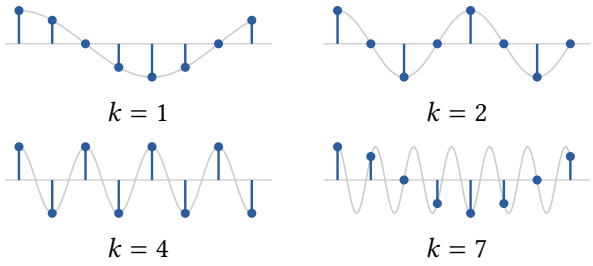

Figure 6.3.2. Real parts of four columns $\mathbf{f}_k$ of Φ_8: the samples $\cos(2\pi kj/8)$ at $j = 0, \ldots, 7$, joined by the curve $s \mapsto \cos(2\pi ks/8)$. Frequency 4 is the fastest oscillation that 8 samples can show. The samples for $k = 7$ coincide with those for $k = 1$, because $\mathbf{f}_7 = \overline{\mathbf{f}_1}$ has the same real part as $\mathbf{f}_1$.

Proposition 6.3.41 (The Fourier basis). The columns $\mathbf{f}_0, \ldots, \mathbf{f}_{n-1}$ of Φ_n are orthogonal, and $\|\mathbf{f}_k\|^2 = n$ for every k. Consequently:

(a) $\Phi_n^*\Phi_n = nI_n$, and $\Phi_n/\sqrt{n}$ is unitary;

(b) Φ_n is invertible, with $\Phi_n^{-1} = \frac{1}{n}\Phi_n^* = \frac{1}{n}\overline{\Phi_n}$;

(c) every $\mathbf{x} \in \mathbb{C}^n$ satisfies

$$\mathbf{x} = \frac{1}{n}\sum_{k=0}^{n-1}\langle \mathbf{x}, \mathbf{f}_k\rangle \mathbf{f}_k, \quad \text{where} \quad \langle \mathbf{x}, \mathbf{f}_k\rangle = \sum_{j=0}^{n-1} x_j \omega^{-jk};$$

(d) every $\mathbf{x} \in \mathbb{C}^n$ satisfies $\sum_{j=0}^{n-1} |x_j|^2 = \frac{1}{n}\sum_{k=0}^{n-1} |\langle \mathbf{x}, \mathbf{f}_k\rangle|^2$.

Proof. STANDARD

Uses. Lemma 6.3.39 (Sums of roots of unity), Theorem 6.3.29 (Orthonormal columns), Proposition 6.3.34 (Characterizations of unitary matrices), Corollary 6.3.21 (Coordinates in an orthogonal basis), Theorem 6.3.22 (Parseval's identity), Corollary 6.3.14 (Counting orthogonal vectors)
Techniques. Gram matrices (Technique 6.3.31)
Hint 1. Compute $\mathbf{f}_k \cdot \mathbf{f}_l$ using $\overline{\omega^{jl}} = \omega^{-jl}$. You get a sum of the kind in Lemma 6.3.39.
Hint 2. The sum is $\sum_j \omega^{j(k-l)}$. For $0 \le k, l \le n-1$, when does n divide $k-l$?
Hint 3. For (a), use Theorem 6.3.29. For (c) and (d), $\mathbf{f}_0, \ldots, \mathbf{f}_{n-1}$ is an orthogonal basis; apply Corollary 6.3.21 and Theorem 6.3.22 to $\mathbf{f}_k/\sqrt{n}$.
Sketch. $\mathbf{f}_k \cdot \mathbf{f}_l = \sum_j \omega^{jk}\omega^{-jl} = \sum_j \omega^{j(k-l)}$, which is n if $k = l$ and 0 otherwise by Lemma 6.3.39, as $|k-l| < n$. So $\Phi_n^*\Phi_n = nI_n$ by Theorem 6.3.29, $\Phi_n/\sqrt{n}$ is unitary, and its inverse is its conjugate transpose. The vectors $\mathbf{f}_k$ form an orthogonal basis with $\|\mathbf{f}_k\|^2 = n$, which gives (c) by Corollary 6.3.21, and (d) is Parseval for the orthonormal basis $\mathbf{f}_k/\sqrt{n}$.

For $0 \le k, l \le n-1$, since $\overline{\omega^{jl}} = \omega^{-jl}$,

$$\mathbf{f}_k \cdot \mathbf{f}_l = \sum_{j=0}^{n-1} \omega^{jk}\overline{\omega^{jl}} = \sum_{j=0}^{n-1} \omega^{j(k-l)}.$$

Since $|k-l| \le n-1$, $n \mid (k-l)$ only when $k = l$. By Lemma 6.3.39, $\mathbf{f}_k \cdot \mathbf{f}_l = n$ if $k = l$ and 0 otherwise. So the columns are orthogonal with $\|\mathbf{f}_k\|^2 = n$.

(a) By Theorem 6.3.29, $(\Phi_n^*\Phi_n)_{kl} = \mathbf{f}_l \cdot \mathbf{f}_k = n\delta_{kl}$, so $\Phi_n^*\Phi_n = nI_n$. Hence $\left(\Phi_n/\sqrt{n}\right)^*\left(\Phi_n/\sqrt{n}\right) = (1/n)\Phi_n^*\Phi_n = I_n$ (Proposition 6.3.27(a)), and $\Phi_n/\sqrt{n}$ is unitary.

(b) By Proposition 6.3.34, $\Phi_n/\sqrt{n}$ is invertible with inverse $\left(\Phi_n/\sqrt{n}\right)^* = \Phi_n^*/\sqrt{n}$. So Φ_n is invertible, and $\Phi_n^{-1} = (1/n)\Phi_n^*$. Since Φ_n is symmetric, $\Phi_n^* = \overline{\Phi_n}^{\mathsf{T}} = \overline{\Phi_n}$.

(c) The vectors $\mathbf{f}_0, \ldots, \mathbf{f}_{n-1}$ are n orthogonal nonzero vectors in $\mathbb{C}^n$, hence an orthogonal basis (Corollary 6.3.14). By Corollary 6.3.21, $\mathbf{x} = \sum_k \langle \mathbf{x}, \mathbf{f}_k\rangle / \|\mathbf{f}_k\|^2 \mathbf{f}_k$, and $\|\mathbf{f}_k\|^2 = n$. Finally $\langle \mathbf{x}, \mathbf{f}_k\rangle = \mathbf{x} \cdot \mathbf{f}_k = \sum_j x_j \overline{\omega^{jk}} = \sum_j x_j \omega^{-jk}$.

(d) The vectors $\mathbf{f}_k/\sqrt{n}$ form an orthonormal basis of $\mathbb{C}^n$, so by Theorem 6.3.22(b),

$$\|\mathbf{x}\|^2 = \sum_{k=0}^{n-1} \left|\left\langle \mathbf{x}, \frac{\mathbf{f}_k}{\sqrt{n}}\right\rangle\right|^2 = \frac{1}{n}\sum_{k=0}^{n-1} |\langle \mathbf{x}, \mathbf{f}_k\rangle|^2,$$

using that $1/\sqrt{n}$ is real. □

The vector $\hat{\mathbf{x}} = \Phi_n^*\mathbf{x} = (\langle \mathbf{x}, \mathbf{f}_0\rangle, \ldots, \langle \mathbf{x}, \mathbf{f}_{n-1}\rangle)$ is called the **discrete Fourier transform** of $\mathbf{x}$. (Conventions differ in where the factor $1/n$ goes and in the sign of the exponent.) Part (c) is the inversion formula $\mathbf{x} = (1/n)\Phi_n\hat{\mathbf{x}}$, and (d) is Parseval's identity for the transform. Both are instances of what we proved for general orthogonal bases; the only computation specific to Φ_n is Lemma 6.3.39.

Example 6.3.42 (A transform with $n = 4$). Let $\mathbf{x} = (1, 2, 3, 4)$. With $\omega = i$, $\langle \mathbf{x}, \mathbf{f}_k\rangle = \sum_j x_j i^{-jk}$:

$$\begin{aligned}
\langle \mathbf{x}, \mathbf{f}_0\rangle &= 1 + 2 + 3 + 4 = 10,\\
\langle \mathbf{x}, \mathbf{f}_1\rangle &= 1 - 2i - 3 + 4i = -2 + 2i,\\
\langle \mathbf{x}, \mathbf{f}_2\rangle &= 1 - 2 + 3 - 4 = -2,\\
\langle \mathbf{x}, \mathbf{f}_3\rangle &= 1 + 2i - 3 - 4i = -2 - 2i.
\end{aligned}$$

By Proposition 6.3.41(c),

$$\mathbf{x} = \frac{1}{4}(10\mathbf{f}_0 + (-2+2i)\mathbf{f}_1 - 2\mathbf{f}_2 + (-2-2i)\mathbf{f}_3).$$

The first term is the constant vector $(5/2)\mathbf{f}_0$ whose entries are the mean of the entries of $\mathbf{x}$, and the other three terms add up to the deviations $(-3/2, -1/2, 1/2, 3/2)$ from the mean. Since $\mathbf{x}$ is real, $\langle \mathbf{x}, \mathbf{f}_3\rangle = \overline{\langle \mathbf{x}, \mathbf{f}_1\rangle} = \overline{\langle \mathbf{x}, \mathbf{f}_1\rangle}$. As a check of (d), $1 + 4 + 9 + 16 = 30$ and $(100 + 8 + 4 + 8)/4 = 30$.

The invertibility of Φ_n can also be proved without orthogonality, and comparing the two proofs shows what orthogonality buys.

Corollary 6.3.43 (Φ_n is invertible). The Fourier matrix Φ_n is invertible.

Proof (by orthogonality). ROUTINE

Uses. Proposition 6.3.41 (The Fourier basis)
Hint 1. Use Proposition 6.3.41(b).
Hint 2. It even gives the inverse.
Sketch. $(1/n)\overline{\Phi_n}$ is a two-sided inverse, by Proposition 6.3.41(b).

This is Proposition 6.3.41(b): $\Phi_n^{-1} = (1/n)\overline{\Phi_n}$. □

Proof (by the Vandermonde determinant). STANDARD

> *Uses.* Theorem 5.5.21 (The Vandermonde determinant), Theorem 5.4.7 (Invertibility and the determinant), $\omega^m = 1$ if and only if $n \mid m$
> *Hint 1.* Row j of Φ_n is $\left(1, z_j, z_j^2, \ldots, z_j^{n-1}\right)$ with $z_j = \omega^j$. What kind of matrix is that?
> *Hint 2.* Φ_n is a Vandermonde matrix. Its determinant is nonzero when the nodes $z_0, \ldots, z_{n-1}$ are distinct; check that they are.
> *Sketch.* Φ_n is the Vandermonde matrix of the nodes $1, \omega, \ldots, \omega^{n-1}$ (it is symmetric, so the orientation does not matter). These are distinct, since $\omega^j = \omega^{j'}$ with $0 \le j < j' \le n-1$ would give $\omega^{j'-j} = 1$ with $0 < j' - j < n$. So $\det \Phi_n \neq 0$, and Φ_n is invertible.

Let $z_j = \omega^j$ for $j = 0, \ldots, n-1$. The entry of Φ_n in row j and column k is $\omega^{jk} = z_j^k$, so Φ_n is the Vandermonde matrix of the nodes $z_0, \ldots, z_{n-1}$; since Φ_n is symmetric, this holds whichever of rows or columns carries the powers in Theorem 5.5.21. The nodes are distinct: if $z_j = z_{j'}$ with $0 \le j < j' \le n-1$, then $\omega^{j'-j} = 1$ with $0 < j' - j < n$, which is impossible since $n \nmid (j' - j)$. By Theorem 5.5.21, $\det \Phi_n = \prod_{0 \le j < j' \le n-1} \left(z_{j'} - z_j\right) \neq 0$, and by Theorem 5.4.7, Φ_n is invertible. □

The Vandermonde proof uses only that the nodes ω^j are distinct, so it applies to any distinct nodes, but it says nothing about the inverse. The orthogonality proof uses the special position of the nodes on the unit circle, and in return it produces the inverse $(1/n)\overline{\Phi_n}$, the inversion formula, and Parseval's identity. It also shows that $|\det \Phi_n| = n^{n/2}$ (Exercise 6.3.60), which the product formula for the Vandermonde determinant hides.

Exercises

Exercise 6.3.44. ROUTINE In $\mathbb{C}^2$ with the dot product, let $\mathbf{u}_1 = \frac{1}{\sqrt{3}}(1, 1+i)$ and $\mathbf{u}_2 = \frac{1}{\sqrt{3}}(-1+i, 1)$.

(a) Show that $\mathcal{O} = \mathbf{u}_1, \mathbf{u}_2$ is an orthonormal basis of $\mathbb{C}^2$.

(b) Find $[\mathbf{v}]_{\mathcal{O}}$ for $\mathbf{v} = (2, 3i)$, and check your answer with Theorem 6.3.22(b).

(c) Compute $\langle \mathbf{u}_1, \mathbf{v} \rangle \mathbf{u}_1 + \langle \mathbf{u}_2, \mathbf{v} \rangle \mathbf{u}_2$, with the slots exchanged, and compare it with $\mathbf{v}$.

Solution on page 1485

Exercise 6.3.45. ROUTINE Find all unit vectors $\mathbf{x} \in \mathbb{R}^3$ that are orthogonal to both $(1, 2, 2)$ and $(2, 1, -2)$. Then find all 3×3 orthogonal matrices whose first two columns are $\frac{1}{3}(1, 2, 2)$ and $\frac{1}{3}(2, 1, -2)$.

Solution on page 1485

Exercise 6.3.46. STANDARD Let V be an inner product space. Prove or disprove each statement.

(a) If $\mathbf{u} \perp \mathbf{v}$ and $\mathbf{v} \perp \mathbf{w}$, then $\mathbf{u} \perp \mathbf{w}$.

(b) If $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ are nonzero with $\mathbf{v}_1 \perp \mathbf{v}_2$ and $\mathbf{v}_2 \perp \mathbf{v}_3$, then $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ is linearly independent.

(c) If $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is orthogonal and $c_1, \ldots, c_k \in \mathbb{F}$, then $c_1\mathbf{v}_1, \ldots, c_k\mathbf{v}_k$ is orthogonal.

(d) If $\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2$ and $\|\mathbf{u} - \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2$, then $\mathbf{u} \perp \mathbf{v}$.

(e) If $\mathbf{v}_1, \ldots, \mathbf{v}_k$ spans V and $\mathbf{x} \perp \mathbf{v}_j$ for every j, then $\mathbf{x} = \mathbf{0}$.

Solution on page 1486

Exercise 6.3.47. STANDARD On $\mathbb{F}_2^4$, let $\mathbf{x} \cdot \mathbf{y} = x_1y_1 + x_2y_2 + x_3y_3 + x_4y_4$. This formula is linear in each slot and symmetric, but it is not an inner product, since the scalars are not real or complex. Call $\mathbf{x}$ and $\mathbf{y}$ orthogonal if $\mathbf{x} \cdot \mathbf{y} = 0$.

(a) Find a nonzero $\mathbf{x} \in \mathbb{F}_2^4$ with $\mathbf{x} \cdot \mathbf{x} = 0$.

(b) Find three nonzero vectors in $\mathbb{F}_2^4$ that are pairwise orthogonal but linearly dependent. Which step of the first proof of Proposition 6.3.13 fails?

(c) Let $W = \operatorname{span}((1,1,0,0),(0,0,1,1))$. Show that $\left\{\mathbf{x} \in \mathbb{F}_2^4 \;\middle|\; \mathbf{x} \cdot \mathbf{w} = 0 \text{ for all } \mathbf{w} \in W\right\} = W$. Which part of Proposition 6.3.9 fails?

Solution on page 1486

Exercise 6.3.48. STANDARD Give $\mathbb{R}^{n\times n}$ and $\mathbb{C}^{n\times n}$ the Frobenius inner product $\langle A, B\rangle = \operatorname{tr}(B^* A)$ (Proposition 6.1.16).

(a) Show that every symmetric $S \in \mathbb{R}^{n\times n}$ is orthogonal to every skew-symmetric $K \in \mathbb{R}^{n\times n}$, and deduce that $\|A\|^2 = \left\|\left(A + A^{\mathsf{T}}\right)/2\right\|^2 + \left\|\left(A - A^{\mathsf{T}}\right)/2\right\|^2$ for every $A \in \mathbb{R}^{n\times n}$.

(b) Prove or disprove: every Hermitian $H \in \mathbb{C}^{n\times n}$ is orthogonal to every $K \in \mathbb{C}^{n\times n}$ with $K^* = -K$. Does the identity $\|A\|^2 = \|(A + A^*)/2\|^2 + \|(A - A^*)/2\|^2$ hold for every $A \in \mathbb{C}^{n\times n}$?

Solution on page 1487

Exercise 6.3.49. STANDARD Give $\mathbb{R}[x]_{\leq 3}$ the inner product $\langle p, q\rangle = \int_{-1}^{1} p(t)q(t)\,\mathrm{d}t$, as in Example 6.3.17.

(a) Find the polynomial $q = x^3 + ax^2 + bx + c$ that is orthogonal to 1, x, and x^2, and compute $\|q\|^2$.

(b) Show that $1, x, x^2 - 1/3, q$ is an orthogonal basis of $\mathbb{R}[x]_{\leq 3}$.

(c) Use Corollary 6.3.21 to write $p = 1 + x + x^2 + x^3$ in this basis, and check the result.

Solution on page 1487

Exercise 6.3.50. STANDARD The *Pauli matrices* are

$$\sigma_0 = I_2, \quad \sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$
$$\sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Give $\mathbb{C}^{2\times 2}$ the Frobenius inner product $\langle A, B\rangle = \operatorname{tr}(B^* A)$.

(a) Show that $\sigma_0/\sqrt{2}, \ldots, \sigma_3/\sqrt{2}$ is an orthonormal basis of $\mathbb{C}^{2\times 2}$.

(b) Deduce that every $A \in \mathbb{C}^{2\times 2}$ satisfies $A = \frac{1}{2}\sum_{a=0}^{3} \operatorname{tr}(\sigma_a A)\sigma_a$.

(c) Write $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$ in this form.

Solution on page 1488

Exercise 6.3.51. STANDARD Let V be a vector space over $\mathbb{F}$ with a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$.

(a) Show that $\langle \mathbf{x}, \mathbf{y}\rangle_{\mathcal{B}} = [\mathbf{x}]_{\mathcal{B}} \cdot [\mathbf{y}]_{\mathcal{B}}$ is an inner product on V for which $\mathcal{B}$ is orthonormal.

(b) Show that it is the only inner product on V for which $\mathcal{B}$ is orthonormal.

(c) For $V = \mathbb{R}^2$ and $\mathcal{B} = (1,0),(1,1)$, find the matrix M with $\langle \mathbf{x}, \mathbf{y}\rangle_{\mathcal{B}} = \mathbf{y}^{\mathsf{T}} M \mathbf{x}$.

Solution on page 1489

Exercise 6.3.52. STANDARD

(a) In $\mathbb{R}^2$, let $\mathbf{w}_j = \sqrt{2/3}(\cos(2\pi j/3), \sin(2\pi j/3))$ for $j = 0, 1, 2$. Show that $\sum_{j=0}^{2} \langle \mathbf{v}, \mathbf{w}_j \rangle^2 = \|\mathbf{v}\|^2$ for every $\mathbf{v} \in \mathbb{R}^2$, although $\mathbf{w}_0, \mathbf{w}_1, \mathbf{w}_2$ is not orthonormal.

(b) Let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ be *unit* vectors in an inner product space V such that $\sum_{j=1}^{k} |\langle \mathbf{v}, \mathbf{v}_j \rangle|^2 = \|\mathbf{v}\|^2$ for every $\mathbf{v} \in V$. Show that $\mathbf{v}_1, \ldots, \mathbf{v}_k$ is an orthonormal basis of V.

Solution on page 1489

Exercise 6.3.53. STANDARD Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be an orthonormal list in V, and let $\mathbf{x}, \mathbf{y} \in V$.

(a) Show that $\sum_{j=1}^{k} |\langle \mathbf{x}, \mathbf{u}_j \rangle| |\langle \mathbf{y}, \mathbf{u}_j \rangle| \leq \|\mathbf{x}\| \|\mathbf{y}\|$.

(b) Show that $\sum_{j=1}^{k} |\langle \mathbf{x}, \mathbf{u}_j \rangle| \leq \sqrt{k} \|\mathbf{x}\|$, and find when equality holds.

Solution on page 1490

Exercise 6.3.54. STANDARD The $n \times n$ *Hilbert matrix* H_n has entries $h_{ij} = 1/(i + j - 1)$.

(a) Show that H_n is the Gram matrix of $1, x, \ldots, x^{n-1}$ in $\mathbb{R}[x]_{\leq n-1}$ with $\langle p, q \rangle = \int_0^1 p(t)q(t)\,dt$.

(b) Deduce that H_n is invertible and that $\mathbf{c}^{\mathsf{T}} H_n \mathbf{c} > 0$ for every nonzero $\mathbf{c} \in \mathbb{R}^n$.

Solution on page 1490

Exercise 6.3.55. STANDARD Find the error in the following argument, and decide whether the claim is true.

Claim. If the columns of $A \in \mathbb{R}^{n \times n}$ are orthogonal and nonzero, then the rows of A are orthogonal.

Argument. By Theorem 6.3.29, $A^{\mathsf{T}}A = D$ is diagonal with positive diagonal entries, so D is invertible. The columns are independent (Proposition 6.3.13), so A is invertible, and $A^{\mathsf{T}} = DA^{-1}$. Hence $AA^{\mathsf{T}} = ADA^{-1}$. A matrix similar to a diagonal matrix is diagonal, so AA^{T} is diagonal, which says that the rows of A are orthogonal.

Solution on page 1491

Exercise 6.3.56. STANDARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be a list in V with Gram matrix G, let $S = (s_{ij}) \in \mathbb{F}^{n \times n}$, and let $\mathbf{w}_j = \sum_{i=1}^{n} s_{ij}\mathbf{v}_i$ for $j = 1, \ldots, n$.

(a) Show that the Gram matrix of $\mathbf{w}_1, \ldots, \mathbf{w}_n$ is S^*GS.

(b) Suppose $\mathcal{O} = \mathbf{v}_1, \ldots, \mathbf{v}_n$ is an orthonormal basis of V. Show that $\mathbf{w}_1, \ldots, \mathbf{w}_n$ is an orthonormal basis of V if and only if S is unitary. Conclude that the change-of-coordinates matrix between two orthonormal bases (Section 4.5) is unitary.

Solution on page 1491

Exercise 6.3.57. STANDARD

(a) Show that $\det(A^*) = \overline{\det A}$ for every $A \in \mathbb{F}^{n \times n}$. Deduce that $|\det U| = 1$ for every unitary U, and that $\det Q = \pm 1$ for every real orthogonal Q.

(b) Show by example that a real matrix with determinant 1 need not be orthogonal.

(c) Show that an upper triangular unitary matrix is diagonal.

Solution on page 1492

Exercise 6.3.58. STANDARD Show that $U \in \mathbb{C}^{2 \times 2}$ is unitary if and only if

$$U = \begin{pmatrix} a & -\lambda\bar{c} \\ c & \lambda\bar{a} \end{pmatrix}$$

for some $a, c, \lambda \in \mathbb{C}$ with $|a|^2 + |c|^2 = 1$ and $|\lambda| = 1$, and that then $\det U = \lambda$.

Solution on page 1492

Exercise 6.3.59. ROUTINE Let $n = 3$, so that $\omega = -1/2 + \left(\sqrt{3}/2\right)i$.

(a) Write down Φ_3 and Φ_3^{-1}.

(b) Write $\mathbf{x} = (1, 2, 0)$ as a linear combination of $\mathbf{f}_0, \mathbf{f}_1, \mathbf{f}_2$, and check Proposition 6.3.41(d).

Solution on page 1493

Exercise 6.3.60. STANDARD Index rows and columns by $0, \ldots, n-1$, as for Φ_n.

(a) Show that $\Phi_n^2 = nP$, where P has entries $p_{jl} = 1$ if $n \mid (j + l)$ and $p_{jl} = 0$ otherwise. Show that P is a permutation matrix with $P^2 = I_n$, and deduce that $\Phi_n^4 = n^2 I_n$.

(b) Show that $|\det \Phi_n| = n^{n/2}$.

Solution on page 1493

Exercise 6.3.61. HARD For $\mathbf{c} = (c_0, \ldots, c_{n-1}) \in \mathbb{C}^n$, the *circulant matrix* C has entries $C_{jl} = c_{(j-l) \bmod n}$, with indices $0, \ldots, n-1$. For $n = 3$,

$$C = \begin{pmatrix} c_0 & c_2 & c_1 \\ c_1 & c_0 & c_2 \\ c_2 & c_1 & c_0 \end{pmatrix}.$$

(a) Show that $C\mathbf{f}_k = \langle \mathbf{c}, \mathbf{f}_k \rangle \mathbf{f}_k$ for $k = 0, \ldots, n-1$.

(b) Deduce that $C = \Phi_n D \Phi_n^{-1}$, where D is the diagonal matrix with entries $\langle \mathbf{c}, \mathbf{f}_0 \rangle, \ldots, \langle \mathbf{c}, \mathbf{f}_{n-1} \rangle$. Conclude that any two $n \times n$ circulant matrices commute, and that C is invertible if and only if $\langle \mathbf{c}, \mathbf{f}_k \rangle \neq 0$ for every k.

(c) Using (b), decide whether the following matrix is invertible, and find its determinant:

$$\begin{pmatrix} 2 & 0 & 1 \\ 1 & 2 & 0 \\ 0 & 1 & 2 \end{pmatrix}.$$

Solution on page 1494

Exercise 6.3.62. HARD Let $n \geq 1$, let ω be as in Section 6.3.4, and let $r \in \{0, \ldots, n-1\}$.

(a) Let $p(x) = a_0 + a_1 x + \cdots + a_d x^d \in \mathbb{C}[x]$. Show that

$$\sum_{0 \leq k \leq d,\, n \mid (k-r)} a_k = \frac{1}{n} \sum_{j=0}^{n-1} \omega^{-jr} p\left(\omega^j\right).$$

(b) Compute $\binom{12}{0} + \binom{12}{3} + \binom{12}{6} + \binom{12}{9} + \binom{12}{12}$ without adding these numbers.

(c) Show that for every $m \geq 0$, $\sum_{k \equiv 0 \pmod 3} \binom{m}{k} = (2^m + 2\cos(m\pi/3))/3$.

Solution on page 1494

Exercise 6.3.63. HARD A *Hadamard matrix* of order n is a matrix $H \in \mathbb{R}^{n\times n}$ whose entries are all ± 1 and whose columns are orthogonal; equivalently, $H^{\mathsf{T}}H = nI_n$.

(a) Show that if a Hadamard matrix of order $n \geq 3$ exists, then $4 \mid n$.

(b) Show that if H is a Hadamard matrix of order n, then $\begin{pmatrix} H & H \\ H & -H \end{pmatrix}$ is a Hadamard matrix of order $2n$. Deduce that Hadamard matrices of order 2^k exist for every $k \geq 0$.

Solution on page 1495

Exercise 6.3.64. CHALLENGE Let n be odd, let ω be as in Section 6.3.4, and let $g = \sum_{j=0}^{n-1} \omega^{j^2}$.

(a) Show that $|g|^2 = n$.

(b) Compute $|g|^2$ for $n = 4$ and for $n = 6$ (with the same definition of g), and explain where the proof of (a) used that n is odd.

Solution on page 1496

6.4 Orthogonal projection and Gram–Schmidt

Let W be a subspace of an inner product space V, and let $\mathbf{v} \in V$. Which vector of W is closest to $\mathbf{v}$? When W is a plane through $\mathbf{0}$ in $\mathbb{R}^3$, geometry gives the answer: drop the perpendicular from $\mathbf{v}$ to W, and take its foot. This section turns that answer into a theorem about every inner product space, provided W is finite-dimensional. The foot of the perpendicular is the *orthogonal projection* $\mathrm{Pr}_W(\mathbf{v})$. If W has an orthonormal basis, it is given by the formula from the proof of Bessel's inequality (Theorem 6.3.24), and the Gram–Schmidt algorithm produces an orthonormal basis of every finite-dimensional subspace. The leftover vectors $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$ make up the orthogonal complement $W^{\perp}$, which turns out to be a complement of W in the sense of Section 4.4. Since distances also make sense between functions, the same theorem answers questions such as: which quadratic polynomial is closest to e^t on $[-1, 1]$?

Throughout, V is an inner product space over $\mathbb{F}$, where $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ (Notation 6.1.1). We do not assume that V is finite-dimensional. The subspaces we project onto will be finite-dimensional, but the ambient space is often a space of functions.

6.4.1 Projecting onto the span of an orthonormal list

Intuition (From a line to a plane). In Section 6.2.1 we split a vector $\mathbf{x}$ against a nonzero vector $\mathbf{y}$ as $\mathbf{x} = c\mathbf{y} + \mathbf{w}$, where $c\mathbf{y}$ lies on the line $\mathrm{span}(\mathbf{y})$ and $\mathbf{w} \perp \mathbf{y}$ (Figure 6.2.1). The vector $c\mathbf{y}$ is the foot of the perpendicular from $\mathbf{x}$ to the line, and the requirement $\mathbf{w} \perp \mathbf{y}$ forced $c = \langle \mathbf{x}, \mathbf{y} \rangle / \|\mathbf{y}\|^2$.

Now replace the line by a plane W in $\mathbb{R}^3$ spanned by orthonormal vectors $\mathbf{u}_1, \mathbf{u}_2$, and look for the foot $\mathbf{p}$ of the perpendicular from $\mathbf{v}$ to W. That is, we want $\mathbf{p} \in W$ such that $\mathbf{v} - \mathbf{p}$ is perpendicular to W. Write $\mathbf{p} = a_1\mathbf{u}_1 + a_2\mathbf{u}_2$. By Proposition 6.3.9(c), $\mathbf{v} - \mathbf{p} \perp W$ means that $\mathbf{v} - \mathbf{p} \perp \mathbf{u}_j$ for $j = 1, 2$, and taking the inner product with $\mathbf{u}_j$ isolates the coefficient a_j (Technique 6.3.12):

$$0 = \langle \mathbf{v} - \mathbf{p}, \mathbf{u}_j \rangle = \langle \mathbf{v}, \mathbf{u}_j \rangle - a_j.$$

So $\mathbf{p} = \langle \mathbf{v}, \mathbf{u}_1 \rangle \mathbf{u}_1 + \langle \mathbf{v}, \mathbf{u}_2 \rangle \mathbf{u}_2$. Each term is the shadow of $\mathbf{v}$ on one of the lines $\mathrm{span}(\mathbf{u}_1)$ and $\mathrm{span}(\mathbf{u}_2)$. So the foot of the perpendicular to the plane is the sum of the feet of the perpendiculars to the two lines (Figure 6.4.1).

The shadows can be computed separately and then added because $\mathbf{u}_1 \perp \mathbf{u}_2$. For a basis of W that is not orthogonal, the sum of the shadows is not the foot; see the example after Corollary 6.3.21.

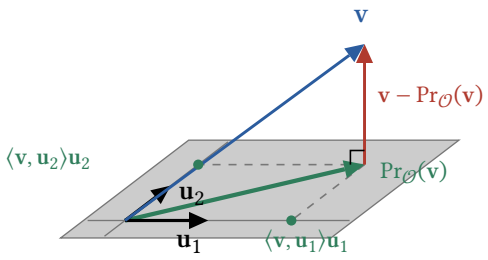

Figure 6.4.1. Projecting $\mathbf{v}$ onto the shaded plane $W = \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$, for orthonormal $\mathbf{u}_1, \mathbf{u}_2$. The foot $\operatorname{Pr}_{\mathcal{O}}(\mathbf{v})$ of the perpendicular is the sum of the shadows $\langle \mathbf{v}, \mathbf{u}_1\rangle \mathbf{u}_1$ and $\langle \mathbf{v}, \mathbf{u}_2\rangle \mathbf{u}_2$ of $\mathbf{v}$ on the two axes, and $\mathbf{v} - \operatorname{Pr}_{\mathcal{O}}(\mathbf{v})$ is perpendicular to W.

Definition 6.4.1 (Projection onto the span of an orthonormal list). Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$ be an orthonormal list in V. The **projection onto** $\operatorname{span}(\mathcal{O})$ is the function $\operatorname{Pr}_{\mathcal{O}} : V \to V$ given by

$$\operatorname{Pr}_{\mathcal{O}}(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}_1\rangle \mathbf{u}_1 + \cdots + \langle \mathbf{v}, \mathbf{u}_k\rangle \mathbf{u}_k.$$

If $k = 0$, the sum is empty and $\operatorname{Pr}_{\mathcal{O}}(\mathbf{v}) = \mathbf{0}$.

This is the vector $\mathbf{p}$ from the proof of Bessel's inequality (Theorem 6.3.24). As with coordinates (Remark 6.3.19), $\mathbf{v}$ goes in the first slot. For a single unit vector $\mathbf{u}$, $\operatorname{Pr}_{\mathbf{u}}(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}\rangle \mathbf{u}$ is the shadow of Technique 6.2.4, since there $c = \langle \mathbf{v}, \mathbf{u}\rangle / \|\mathbf{u}\|^2 = \langle \mathbf{v}, \mathbf{u}\rangle$.

Example 6.4.2 (A projection in $\mathbb{R}^3$). Take the orthonormal list $\mathcal{O} = \mathbf{u}_1, \mathbf{u}_2$ with $\mathbf{u}_1 = \frac{1}{3}(1, 2, 2)$ and $\mathbf{u}_2 = \frac{1}{3}(2, 1, -2)$ from Example 6.3.16(c), and $\mathbf{v} = (1, 2, 3)$. In Example 6.3.20 we computed $\langle \mathbf{v}, \mathbf{u}_1\rangle = 11/3$ and $\langle \mathbf{v}, \mathbf{u}_2\rangle = -2/3$. So

$$\operatorname{Pr}_{\mathcal{O}}(\mathbf{v}) = \frac{11}{9}(1, 2, 2) - \frac{2}{9}(2, 1, -2) = \frac{1}{9}(7, 20, 26),$$

and $\mathbf{v} - \operatorname{Pr}_{\mathcal{O}}(\mathbf{v}) = \frac{1}{9}(2, -2, 1)$. This vector is orthogonal to $(1, 2, 2)$ and to $(2, 1, -2)$, as the intuition above predicts. Its squared length is $9/81 = 1/9$, the deficit in Bessel's inequality found in Example 6.3.25.

Example 6.4.3 (Projecting a function). Give $C[-1, 1]$ the inner product $\langle f, g\rangle = \int_{-1}^{1} f(t)g(t)\,dt$ (Proposition 6.1.13). By Example 6.3.17, $\mathcal{O} = 1/\sqrt{2}, \sqrt{3/2}\,t$ is orthonormal. Since $\int_{-1}^{1} t^2\,dt = 2/3$ and $\int_{-1}^{1} t^3\,dt = 0$,

$$\begin{aligned}\operatorname{Pr}_{\mathcal{O}}(t^2) &= \left\langle t^2, \frac{1}{\sqrt{2}}\right\rangle \frac{1}{\sqrt{2}} + \left\langle t^2, \sqrt{\frac{3}{2}}\,t\right\rangle \sqrt{\frac{3}{2}}\,t \\ &= \frac{1}{2}\cdot\frac{2}{3} + 0 = \frac{1}{3}.\end{aligned}$$

So $t^2 - 1/3$ is orthogonal to 1 and to t. The polynomial $x^2 - 1/3$ of Example 6.3.17 arises in exactly this way, and Section 6.4.2 turns the computation into an algorithm.

The next proposition collects what we know about $\operatorname{Pr}_{\mathcal{O}}$. Most of it was proved along the way to Bessel's inequality.

Proposition 6.4.4 (Properties of $\operatorname{Pr}_{\mathcal{O}}$). Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$ be an orthonormal list in V, let $W = \operatorname{span}(\mathcal{O})$, and let $\mathbf{v} \in V$.

(a) $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) \in W$.

(b) $\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) \in W^{\perp}$.

(c) $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) = \mathbf{v}$ if and only if $\mathbf{v} \in W$.

(d) $\mathrm{Pr}_{\mathcal{O}}$ is linear.

(e) $\|\mathbf{v}\|^2 = \|\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\|^2 + \|\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\|^2$, and $\|\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\|^2 = \sum_{j=1}^{k} \left|\langle \mathbf{v}, \mathbf{u}_j \rangle\right|^2$. In particular $\|\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\| \le \|\mathbf{v}\|$, with equality if and only if $\mathbf{v} \in W$.

Proof. ROUTINE

Uses. Definition 6.4.1 (Projection onto the span of an orthonormal list), Definition 6.3.15 (Orthonormal list, orthonormal basis), Proposition 6.3.9 (Properties of $A^{\perp}$), Proposition 6.3.18 (Coordinates in an orthonormal basis), Theorem 6.3.3 (Pythagorean theorem), Corollary 6.3.6 (Pythagoras for orthogonal lists), Proposition 6.1.27 (Basic properties of the norm)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. For (b), compute $\langle \mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}), \mathbf{u}_l \rangle$ for each l; then pass from the $\mathbf{u}_l$ to all of W.
Hint 2. For (c), one direction is (a), and the other is Proposition 6.3.18(a). For (d), each coefficient $\langle \mathbf{v}, \mathbf{u}_j \rangle$ depends linearly on $\mathbf{v}$.
Hint 3. For (e), apply the Pythagorean theorem to $\mathbf{v} = \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) + (\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}))$, using (a) and (b).
Sketch. (a) $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ is a combination of the $\mathbf{u}_j$. (b) $\langle \mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}), \mathbf{u}_l \rangle = \langle \mathbf{v}, \mathbf{u}_l \rangle - \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \delta_{jl} = 0$, and Proposition 6.3.9(c) upgrades orthogonality to each $\mathbf{u}_l$ to orthogonality to W. (c) follows from (a) and Proposition 6.3.18(a). (d) follows from linearity of the inner product in the first slot. (e) is Pythagoras for the orthogonal pieces in (a) and (b), plus Corollary 6.3.6; equality means $\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) = \mathbf{0}$, which is (c).

(a) $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ is a linear combination of $\mathbf{u}_1, \ldots, \mathbf{u}_k$.

(b) For each l, linearity in the first slot and orthonormality give

$$\begin{aligned} \langle \mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}), \mathbf{u}_l \rangle &= \langle \mathbf{v}, \mathbf{u}_l \rangle - \sum_{j=1}^{k} \langle \mathbf{v}, \mathbf{u}_j \rangle \langle \mathbf{u}_j, \mathbf{u}_l \rangle \\ &= \langle \mathbf{v}, \mathbf{u}_l \rangle - \langle \mathbf{v}, \mathbf{u}_l \rangle = 0. \end{aligned}$$

So $\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) \in \mathcal{O}^{\perp}$, and $\mathcal{O}^{\perp} = \mathrm{span}(\mathcal{O})^{\perp} = W^{\perp}$ by Proposition 6.3.9(c).

(c) If $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) = \mathbf{v}$, then $\mathbf{v} \in W$ by (a). Conversely, if $\mathbf{v} \in W$, then $\mathbf{v} = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j = \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ by Proposition 6.3.18(a).

(d) For $\mathbf{v}, \mathbf{v}' \in V$ and $a, b \in \mathbb{F}$, linearity in the first slot gives $\langle a\mathbf{v} + b\mathbf{v}', \mathbf{u}_j \rangle = a\langle \mathbf{v}, \mathbf{u}_j \rangle + b\langle \mathbf{v}', \mathbf{u}_j \rangle$ for each j. Multiplying by $\mathbf{u}_j$ and summing over j gives $\mathrm{Pr}_{\mathcal{O}}(a\mathbf{v} + b\mathbf{v}') = a\,\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) + b\,\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}')$.

(e) By (a) and (b), $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) \perp \mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$, and these two vectors add up to $\mathbf{v}$. So the first identity is Theorem 6.3.3(a). The second is Corollary 6.3.6 applied to $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$. Since $\|\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\|^2 \ge 0$, the first identity gives $\|\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\|^2 \le \|\mathbf{v}\|^2$, with equality if and only if $\|\mathbf{v} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})\| = 0$. By Proposition 6.1.27(a), that happens if and only if $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) = \mathbf{v}$, that is, by (c), if and only if $\mathbf{v} \in W$. □

Part (e) is (6.3.2), and its inequality is Bessel's inequality. The move behind it deserves a name, since it is the main source of upper bounds in this chapter.

Technique 6.4.5 (Projections shrink norms). Suppose $\mathbf{x} = \mathbf{p} + \mathbf{q}$, where $\mathbf{p}$ lies in a subspace W and $\mathbf{q} \perp W$, as for $\mathbf{p} = \mathrm{Pr}_{\mathcal{O}}(\mathbf{x})$ and $\mathbf{q} = \mathbf{x} - \mathrm{Pr}_{\mathcal{O}}(\mathbf{x})$. By Pythagoras,

$$\|\mathbf{x}\|^2 = \|\mathbf{p}\|^2 + \|\mathbf{q}\|^2.$$

So each piece is at most as long as $\mathbf{x}$. Moreover $\|\mathbf{p}\| = \|\mathbf{x}\|$ exactly when $\mathbf{q} = \mathbf{0}$, that is, when $\mathbf{x} \in W$, and $\|\mathbf{q}\| = \|\mathbf{x}\|$ exactly when $\mathbf{p} = \mathbf{0}$.

Reach for it when you need an upper bound for a sum $\sum_j |\langle \mathbf{x}, \mathbf{u}_j \rangle|^2$ over an orthonormal list, which is $\|\mathrm{Pr}_{\mathcal{O}}(\mathbf{x})\|^2$, or more generally when the quantity to be bounded is the length of one orthogonal piece of a vector whose length you know. The equality case turns the bound into a test for membership in W. The canonical example is Bessel's inequality (Theorem 6.3.24). In Theorem 6.4.33 the error $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$ turns out to be the piece of $\mathbf{v} - \mathbf{w}$ orthogonal to W, for every $\mathbf{w} \in W$; and in infinite dimensions (Section 15.3) Bessel's inequality survives where Parseval's identity needs more work.
Used in. Theorem 6.4.33, Problem 6.2, Exercise 6.4.60.

The projection is determined by orthogonality

Part (b) of Proposition 6.4.4 is the property that made $\mathbf{p}$ the foot of the perpendicular in the intuition above. It determines $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ completely. This matters because the condition "$\mathbf{p} \in W$ and $\mathbf{v} - \mathbf{p} \perp W$" mentions only the subspace W, not the orthonormal list $\mathcal{O}$ that the formula uses.

Theorem 6.4.6 (The projection is characterized by orthogonality). Let $\mathcal{O}$ be an orthonormal list in V, let $W = \mathrm{span}(\mathcal{O})$, and let $\mathbf{v} \in V$. Then $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ is the unique vector $\mathbf{p} \in V$ such that

$$\mathbf{p} \in W \quad \text{and} \quad \mathbf{v} - \mathbf{p} \in W^{\perp}.$$

Proof (by two candidates). ROUTINE

Uses. Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$), Proposition 6.3.9 (Properties of $A^{\perp}$)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Existence is (a) and (b) of Proposition 6.4.4. For uniqueness, suppose that $\mathbf{p}$ and $\mathbf{p}'$ both have the two properties, and look at $\mathbf{p} - \mathbf{p}'$.
Hint 2. $\mathbf{p} - \mathbf{p}'$ lies in W. It is also the difference of $\mathbf{v} - \mathbf{p}'$ and $\mathbf{v} - \mathbf{p}$, which lie in $W^{\perp}$. What is $W \cap W^{\perp}$?
Sketch. $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ has both properties by Proposition 6.4.4. If $\mathbf{p}$ and $\mathbf{p}'$ both have them, then $\mathbf{p} - \mathbf{p}' \in W$, and $\mathbf{p} - \mathbf{p}' = (\mathbf{v} - \mathbf{p}') - (\mathbf{v} - \mathbf{p}) \in W^{\perp}$ because $W^{\perp}$ is a subspace. So $\mathbf{p} - \mathbf{p}' \in W \cap W^{\perp} = \{\mathbf{0}\}$.

By (a) and (b) of Proposition 6.4.4, $\mathbf{p} = \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ has both properties. Suppose $\mathbf{p}$ and $\mathbf{p}'$ both have them. Since W is a subspace, $\mathbf{p} - \mathbf{p}' \in W$. Since $W^{\perp}$ is a subspace (Proposition 6.3.9(a)),

$$\mathbf{p} - \mathbf{p}' = (\mathbf{v} - \mathbf{p}') - (\mathbf{v} - \mathbf{p}) \in W^{\perp}.$$

So $\mathbf{p} - \mathbf{p}' \in W \cap W^{\perp}$, which is $\{\mathbf{0}\}$ by Proposition 6.3.9(d). Hence $\mathbf{p} = \mathbf{p}'$. □

Proof (by computing coordinates). ROUTINE

Uses. Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$), Definition 6.4.1 (Projection onto the span of an orthonormal list)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. Let $\mathbf{p} \in W$ with $\mathbf{v} - \mathbf{p} \perp W$. Since $\mathbf{p} \in \mathrm{span}(\mathcal{O})$, Proposition 6.3.18(a) expresses $\mathbf{p}$ through the numbers $\langle \mathbf{p}, \mathbf{u}_j \rangle$.
Hint 2. Write $\langle \mathbf{p}, \mathbf{u}_j \rangle = \langle \mathbf{v}, \mathbf{u}_j \rangle - \langle \mathbf{v} - \mathbf{p}, \mathbf{u}_j \rangle$.
Sketch. Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$. If $\mathbf{p} \in W$ and $\mathbf{v} - \mathbf{p} \perp W$, then $\mathbf{p} = \sum_j \langle \mathbf{p}, \mathbf{u}_j \rangle \mathbf{u}_j$ and $\langle \mathbf{p}, \mathbf{u}_j \rangle = \langle \mathbf{v}, \mathbf{u}_j \rangle - 0$. So $\mathbf{p} = \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$. Existence is Proposition 6.4.4(a) and (b).

Write $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$. Existence is (a) and (b) of Proposition 6.4.4. Conversely, let $\mathbf{p} \in W$ with $\mathbf{v} - \mathbf{p} \in W^{\perp}$. Since $\mathbf{u}_j \in W$, we have $\langle \mathbf{v} - \mathbf{p}, \mathbf{u}_j \rangle = 0$, so

$$\langle \mathbf{p}, \mathbf{u}_j \rangle = \langle \mathbf{v}, \mathbf{u}_j \rangle - \langle \mathbf{v} - \mathbf{p}, \mathbf{u}_j \rangle = \langle \mathbf{v}, \mathbf{u}_j \rangle.$$

Since $\mathbf{p} \in \mathrm{span}(\mathcal{O})$, Proposition 6.3.18(a) gives

$$\mathbf{p} = \sum_{j=1}^{k} \langle \mathbf{p}, \mathbf{u}_j \rangle \mathbf{u}_j = \sum_{j=1}^{k} \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j = \mathrm{Pr}_{\mathcal{O}}(\mathbf{v}),$$

as desired. □

The first proof never uses the formula for $\mathrm{Pr}_{\mathcal{O}}$. It shows that any two vectors with the two properties agree, whatever produced them, and all it needs is $W \cap W^{\perp} = \{\mathbf{0}\}$. The second proof computes the coordinates of

such a vector and recognizes them as those of $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$; this is how the lecture argues. The first proof is the one that generalizes, and it gives the following technique.

Technique 6.4.7 (Recognize a projection by its two conditions). To show that a vector $\mathbf{p}$ is the projection of $\mathbf{v}$ onto W, do not compute the projection. Check the two conditions of Theorem 6.4.6: $\mathbf{p} \in W$, and $\mathbf{v} - \mathbf{p} \perp W$. By Proposition 6.3.9(c), the second condition only has to be checked against a spanning list of W. Uniqueness then does the rest, much as a two-sided inverse is recognized by checking two products (Technique 2.5.16).

Reach for it when a formula or a vector is proposed as a projection, when projections onto related subspaces are compared, and when you need to know that a projection does not depend on the choices made to compute it. The canonical example is Corollary 6.4.8. Later examples are the projection onto $W^{\perp}$ (Proposition 6.4.29), the recognition of orthogonal projections among all linear maps (Proposition 6.4.30), and the projection formula of Section 6.5.

Used in. Corollary 6.4.8, Proposition 6.4.29, Proposition 6.4.30, Exercise 6.4.49, Theorem 6.5.5, Proposition 6.5.13, Proposition 6.5.17, Proposition 6.5.23, Corollary 6.6.29, Exercise 6.7.5, Exercise 6.7.13, Problem 6.2, Problem 6.4, Exercise 6.4.28, Exercise 6.4.42, Exercise 6.4.57, Exercise 6.4.58, Exercise 6.5.42, Exercise 8.1.32.

Corollary 6.4.8 (The projection depends only on the span). If $\mathcal{O}$ and $\mathcal{O}'$ are orthonormal lists in V with $\mathrm{span}(\mathcal{O}) = \mathrm{span}(\mathcal{O}')$, then $\mathrm{Pr}_{\mathcal{O}} = \mathrm{Pr}_{\mathcal{O}'}$.

Proof. ROUTINE

Uses. Theorem 6.4.6 (The projection is characterized by orthogonality), Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. Let W be the common span and fix $\mathbf{v} \in V$. Which two properties does $\mathrm{Pr}_{\mathcal{O}'}(\mathbf{v})$ have?
Hint 2. Both properties mention only W. Apply the uniqueness in Theorem 6.4.6 for the list $\mathcal{O}$.
Sketch. With $W = \mathrm{span}(\mathcal{O}) = \mathrm{span}(\mathcal{O}')$, the vector $\mathrm{Pr}_{\mathcal{O}'}(\mathbf{v})$ lies in W and $\mathbf{v} - \mathrm{Pr}_{\mathcal{O}'}(\mathbf{v}) \in W^{\perp}$, by Proposition 6.4.4 for $\mathcal{O}'$. These are the conditions that characterize $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ in Theorem 6.4.6.

Let $W = \mathrm{span}(\mathcal{O}) = \mathrm{span}(\mathcal{O}')$ and $\mathbf{v} \in V$. By (a) and (b) of Proposition 6.4.4, applied to the list $\mathcal{O}'$, the vector $\mathbf{p} = \mathrm{Pr}_{\mathcal{O}'}(\mathbf{v})$ lies in W and satisfies $\mathbf{v} - \mathbf{p} \in W^{\perp}$. By Theorem 6.4.6, applied to the list $\mathcal{O}$, the only vector with these two properties is $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$. Hence $\mathrm{Pr}_{\mathcal{O}'}(\mathbf{v}) = \mathrm{Pr}_{\mathcal{O}}(\mathbf{v})$ for every $\mathbf{v}$. □

Example 6.4.9 (Two orthonormal bases, one projection). Let $W = \{\mathbf{x} \in \mathbb{R}^3 \mid x_1 + x_2 + x_3 = 0\}$. Both

$$\mathcal{O}: \quad \mathbf{a} = \frac{1}{\sqrt{2}}(1,-1,0), \quad \mathbf{b} = \frac{1}{\sqrt{6}}(1,1,-2),$$
$$\mathcal{O}': \quad \mathbf{a}' = \frac{1}{\sqrt{2}}(1,0,-1), \quad \mathbf{b}' = \frac{1}{\sqrt{6}}(1,-2,1)$$

are orthonormal lists of two vectors in the 2-dimensional plane W, so both are orthonormal bases of W (Corollary 6.3.14). For $\mathbf{v} = (3,0,0)$,

$$\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}) = \frac{3}{2}(1,-1,0) + \frac{3}{6}(1,1,-2) = (2,-1,-1),$$
$$\mathrm{Pr}_{\mathcal{O}'}(\mathbf{v}) = \frac{3}{2}(1,0,-1) + \frac{3}{6}(1,-2,1) = (2,-1,-1).$$

The individual shadows differ, because they depend on the axes, but their sums agree. As a check, $\mathbf{v} - (2,-1,-1) = (1,1,1)$ is orthogonal to W.

By hand it is often easier to work with an orthogonal list and postpone normalizing.

Corollary 6.4.10 (Projecting with an orthogonal list). Let $\mathbf{f}_1, \ldots, \mathbf{f}_k$ be an orthogonal list of nonzero vectors in V, and let $\mathcal{O}$ be the orthonormal list $\mathbf{f}_1/\|\mathbf{f}_1\|, \ldots, \mathbf{f}_k/\|\mathbf{f}_k\|$. Then

$$\Pr_{\mathcal{O}}(\mathbf{v}) = \sum_{j=1}^{k} \frac{\langle \mathbf{v}, \mathbf{f}_j \rangle}{\|\mathbf{f}_j\|^2} \mathbf{f}_j \quad \text{for all } \mathbf{v} \in V.$$

Each term is unchanged if $\mathbf{f}_j$ is replaced by $c\mathbf{f}_j$ for a scalar $c \neq 0$.

Proof. ROUTINE

Uses. Definition 6.4.1 (Projection onto the span of an orthonormal list), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. Substitute $\mathbf{u}_j = \mathbf{f}_j/\|\mathbf{f}_j\|$ into Definition 6.4.1. Is $1/\|\mathbf{f}_j\|$ real?
Hint 2. For the last claim, take c out of both slots of $\langle \mathbf{v}, c\mathbf{f}_j \rangle$ and out of $\|c\mathbf{f}_j\|^2$.
Sketch. Since $\|\mathbf{f}_j\|$ is real, $\langle \mathbf{v}, \mathbf{f}_j/\|\mathbf{f}_j\| \rangle \mathbf{f}_j/\|\mathbf{f}_j\| = \langle \mathbf{v}, \mathbf{f}_j \rangle / \|\mathbf{f}_j\|^2 \, \mathbf{f}_j$. Replacing $\mathbf{f}_j$ by $c\mathbf{f}_j$ multiplies the term by $\bar{c}c/|c|^2 = 1$.

Since $\|\mathbf{f}_j\|$ is a positive real number, it equals its conjugate, and Proposition 6.1.4 gives

$$\left\langle \mathbf{v}, \frac{\mathbf{f}_j}{\|\mathbf{f}_j\|} \right\rangle \frac{\mathbf{f}_j}{\|\mathbf{f}_j\|} = \frac{\langle \mathbf{v}, \mathbf{f}_j \rangle}{\|\mathbf{f}_j\|^2} \mathbf{f}_j.$$

Summing over j gives the formula. If $\mathbf{f}_j$ is replaced by $c\mathbf{f}_j$, the jth term becomes

$$\frac{\langle \mathbf{v}, c\mathbf{f}_j \rangle}{\|c\mathbf{f}_j\|^2} c\mathbf{f}_j = \frac{\bar{c}c}{|c|^2} \cdot \frac{\langle \mathbf{v}, \mathbf{f}_j \rangle}{\|\mathbf{f}_j\|^2} \mathbf{f}_j = \frac{\langle \mathbf{v}, \mathbf{f}_j \rangle}{\|\mathbf{f}_j\|^2} \mathbf{f}_j,$$

by Proposition 6.1.4 and Proposition 6.1.27(b). □

For $k = 1$ this is the shadow $\langle \mathbf{v}, \mathbf{f}_1 \rangle / \|\mathbf{f}_1\|^2 \, \mathbf{f}_1$ of Technique 6.2.4, and for an orthogonal basis of V it is Corollary 6.3.21.

Orthogonal projection onto a subspace

By Corollary 6.4.8, $\Pr_{\mathcal{O}}$ depends only on the subspace spanned by $\mathcal{O}$. So we may name it after the subspace.

Definition 6.4.11 (Orthogonal projection). Let W be a subspace of V that has an orthonormal basis $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$. The **orthogonal projection onto** W is the map $\Pr_W = \Pr_{\mathcal{O}} : V \to V$, that is,

$$\Pr_W(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}_1 \rangle \mathbf{u}_1 + \cdots + \langle \mathbf{v}, \mathbf{u}_k \rangle \mathbf{u}_k.$$

By Corollary 6.4.8 this does not depend on the choice of the orthonormal basis $\mathcal{O}$. By Theorem 6.4.6, $\Pr_W(\mathbf{v})$ is the unique vector $\mathbf{p} \in W$ with $\mathbf{v} - \mathbf{p} \perp W$.

A basis is a finite list, so only a finite-dimensional subspace can have an orthonormal basis. Conversely, Theorem 6.4.20 below shows that every finite-dimensional subspace has one. So $\Pr_W$ is defined exactly for the finite-dimensional subspaces W of V, while V itself may be infinite-dimensional. In Example 6.4.3, for instance, $\Pr_W(t^2) = 1/3$ for $W = \operatorname{span}(1, t) \subseteq C[-1, 1]$.

Remark 6.4.12 (Why "orthogonal"). The map $P : \mathbb{R}^2 \to \mathbb{R}^2$, $P(x, y) = (x - y, 0)$, also sends every vector into the x-axis W and fixes every vector of W. It slides each point onto W along the direction $(1, 1)$, not along the perpendicular. For instance $P(0, 1) = (-1, 0)$, and $(0, 1) - P(0, 1) = (1, 1)$ is not orthogonal to W, whereas $\Pr_W(0, 1) = \mathbf{0}$. Maps like P, which project onto one subspace along another, exist in every vector space, with or without an inner product, and they belong with the direct sums of Section 4.4. Among them, the orthogonal projection is the one that moves every vector perpendicularly to W. Proposition 6.4.30 shows how to recognize it.

Exercise 6.4.13. ROUTINE In $\mathbb{C}^3$ with the dot product, let $\mathbf{u} = \frac{1}{\sqrt{2}}(1, i, 0)$ and $\mathbf{v} = (0, 1, 1)$.

(a) Compute $\mathrm{Pr}_{\mathbf{u}}(\mathbf{v})$, and check that $\mathbf{v} - \mathrm{Pr}_{\mathbf{u}}(\mathbf{v}) \perp \mathbf{u}$.

(b) A student uses $\langle \mathbf{u}, \mathbf{v} \rangle \mathbf{u}$ instead. Show that this vector does not have the property in (a).

Solution on page 1496

6.4.2 The Gram–Schmidt algorithm

To use Definition 6.4.11 we need orthonormal bases. A subspace usually arrives as the span of some list $\mathbf{v}_1, \ldots, \mathbf{v}_m$, such as the columns of a matrix or the monomials $1, x, \ldots, x^n$, and that list is rarely orthonormal. The Gram–Schmidt algorithm converts it into an orthonormal basis of the same span.

Intuition (Keep only what is new). Process the vectors one at a time, and keep an orthonormal list $\mathbf{u}_1, \ldots, \mathbf{u}_k$ with the same span as the vectors processed so far. When $\mathbf{v}_j$ arrives, split it as in Figure 6.4.1: $\mathbf{v}_j$ is its projection onto $\mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$ plus the remainder

$$\mathbf{f} = \mathbf{v}_j - \mathrm{Pr}_{\mathbf{u}_1, \ldots, \mathbf{u}_k}(\mathbf{v}_j).$$

The projection lies in the span we already have, so it contributes nothing new. The remainder is orthogonal to $\mathbf{u}_1, \ldots, \mathbf{u}_k$ by Proposition 6.4.4(b), so after normalizing it can be appended to the orthonormal list, and it carries exactly the direction that $\mathbf{v}_j$ adds (Figure 6.4.2). If the remainder is $\mathbf{0}$, then $\mathbf{v}_j$ lies in the span of the earlier vectors and adds no new direction, so we skip it.

Algorithm 6.4.14 (Gram–Schmidt)

Input A list $\mathbf{v}_1, \ldots, \mathbf{v}_m$ in V.
Output An orthonormal list $\mathbf{u}_1, \ldots, \mathbf{u}_k$, where $k \le m$, with $\mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k) = \mathrm{span}(\mathbf{v}_1, \ldots, \mathbf{v}_m)$.

Start with no vectors kept ($k = 0$) and $j = 1$.

1. **Project.** Subtract from $\mathbf{v}_j$ its projection onto the span of the vectors kept so far:
$$\mathbf{f} = \mathbf{v}_j - \sum_{i=1}^{k} \langle \mathbf{v}_j, \mathbf{u}_i \rangle \mathbf{u}_i.$$
2. **Keep or skip.** If $\mathbf{f} \neq \mathbf{0}$, increase k by 1, and set $\mathbf{f}_k = \mathbf{f}$ and $\mathbf{u}_k = \mathbf{f}_k / \|\mathbf{f}_k\|$. If $\mathbf{f} = \mathbf{0}$, keep nothing.
3. **Repeat.** If $j < m$, increase j by 1 and return to step 1. Otherwise output $\mathbf{u}_1, \ldots, \mathbf{u}_k$.

The sum in step 1 is $\mathrm{Pr}_{\mathcal{O}}(\mathbf{v}_j)$ for the current list $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_k$; when $k = 0$ it is empty and $\mathbf{f} = \mathbf{v}_j$. We call $\mathbf{f}_1, \mathbf{f}_2, \ldots$ the **residuals**. If no vector is skipped, then $k = j$ after the jth pass, and the algorithm is the recursion

$$\begin{aligned} \mathbf{f}_j &= \mathbf{v}_j - \sum_{i=1}^{j-1} \langle \mathbf{v}_j, \mathbf{u}_i \rangle \mathbf{u}_i, \\ \mathbf{u}_j &= \frac{\mathbf{f}_j}{\|\mathbf{f}_j\|} \quad (j = 1, \ldots, m). \end{aligned} \tag{6.4.1}$$

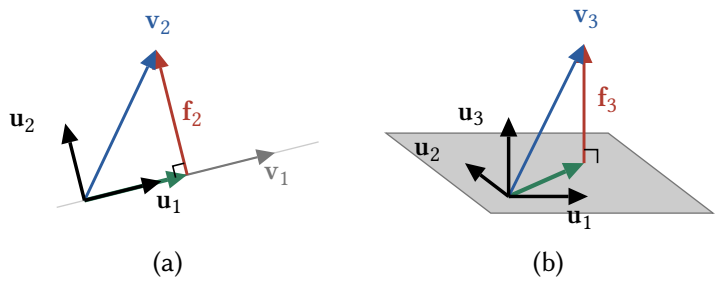

Figure 6.4.2. Two passes of Gram–Schmidt. (a) The residual $\mathbf{f}_2$ is what remains of $\mathbf{v}_2$ after subtracting its shadow on the line through $\mathbf{v}_1$; normalizing $\mathbf{v}_1$ and $\mathbf{f}_2$ gives $\mathbf{u}_1$ and $\mathbf{u}_2$. (b) In the next pass, $\mathbf{v}_3$ is projected onto the shaded plane $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2) = \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2)$, and the residual $\mathbf{f}_3$, normalized, gives $\mathbf{u}_3$.

That the output is orthonormal and has the right span is a statement about what the algorithm keeps true from one pass to the next, so we prove it as in Technique 3.3.5.

Theorem 6.4.15 (Gram–Schmidt is correct). Run Algorithm 6.4.14 on a list $\mathbf{v}_1, \ldots, \mathbf{v}_m$ in V. For $0 \le j \le m$, let $\mathcal{O}_j$ be the list of vectors kept after the first j passes, so that $\mathcal{O}_0$ is empty.

(a) For every j, $\mathcal{O}_j$ is orthonormal and $\operatorname{span}(\mathcal{O}_j) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$.

(b) In pass j, the vector $\mathbf{v}_j$ is skipped if and only if $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$.

(c) The output is an orthonormal basis of $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_m)$.

(d) If $\mathbf{v}_1, \ldots, \mathbf{v}_m$ is linearly independent, then no vector is skipped, and the output $\mathbf{u}_1, \ldots, \mathbf{u}_m$ satisfies $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$ and $\langle \mathbf{v}_j, \mathbf{u}_j \rangle = \|\mathbf{f}_j\| > 0$ for every j.

Proof. STANDARD

Uses. Proposition 6.4.4 (Properties of $\operatorname{Pr}_{\mathcal{O}}$), Proposition 1.3.18 (Comparing spans), Proposition 6.3.13 (Orthogonal lists are independent), Theorem 1.5.5 (Independence is decided at zero), Definition 6.3.15 (Orthonormal list, orthonormal basis)

Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5), Induction on the length of a list (Technique 1.6.9), Double containment (Technique 1.3.14)

Hint 1. Prove (a) by induction on j. In pass j, let $W = \operatorname{span}(\mathcal{O}_{j-1})$. What do you know about $\mathbf{f} = \mathbf{v}_j - \operatorname{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j)$?

Hint 2. By Proposition 6.4.4, $\mathbf{f} \perp W$, and $\mathbf{f} = \mathbf{0}$ exactly when $\mathbf{v}_j \in W$. In the case $\mathbf{f} \neq \mathbf{0}$, the new unit vector is orthogonal to the old ones.

Hint 3. For the spans, compare with Proposition 1.3.18 in both directions, using $\mathbf{v}_j = \operatorname{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j) + \|\mathbf{f}\|\mathbf{u}$.

Sketch. Induct on j; $\mathcal{O}_0$ is empty and spans $\{\mathbf{0}\}$. In pass j, let $W = \operatorname{span}(\mathcal{O}_{j-1}) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$. By Proposition 6.4.4, $\mathbf{f} \perp W$, and $\mathbf{f} = \mathbf{0}$ if and only if $\mathbf{v}_j \in W$; this gives (b). If $\mathbf{f} = \mathbf{0}$, nothing changes, and $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j) = W$. Otherwise $\mathbf{u} = \mathbf{f}/\|\mathbf{f}\|$ is a unit vector orthogonal to $\mathcal{O}_{j-1}$, and $\mathbf{u} \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$ and $\mathbf{v}_j = \operatorname{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j) + \|\mathbf{f}\|\mathbf{u}$ give equal spans. (c) is (a) for $j = m$, with Proposition 6.3.13. For (d), independence rules out $\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$, and $\langle \mathbf{v}_j, \mathbf{u}_j \rangle = \langle \Pr(\mathbf{v}_j) + \|\mathbf{f}_j\|\mathbf{u}_j, \mathbf{u}_j \rangle = \|\mathbf{f}_j\|$.

(a) We induct on j. For $j = 0$, the empty list is orthonormal, and both sides equal $\{\mathbf{0}\}$.

Let $1 \le j \le m$, and suppose that $\mathcal{O}_{j-1} = \mathbf{u}_1, \ldots, \mathbf{u}_k$ is orthonormal with $\operatorname{span}(\mathcal{O}_{j-1}) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$. Call this subspace W. Pass j computes $\mathbf{f} = \mathbf{v}_j - \operatorname{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j)$. By (a) and (c) of Proposition 6.4.4, $\operatorname{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j) \in W$, and $\mathbf{f} = \mathbf{0}$ if and only if $\mathbf{v}_j \in W$.

Suppose $\mathbf{f} = \mathbf{0}$. Then $\mathcal{O}_j = \mathcal{O}_{j-1}$ is orthonormal. Since $\mathbf{v}_j \in W = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1})$, Proposition 1.3.18 gives $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}) = W = \operatorname{span}(\mathcal{O}_j)$.

Suppose $\mathbf{f} \neq \mathbf{0}$. Then $\mathcal{O}_j$ is $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{u}$ with $\mathbf{u} = \mathbf{f}/\|\mathbf{f}\|$, a unit vector. By Proposition 6.4.4(b), $\mathbf{f} \in W^\perp$, so $\langle \mathbf{u}, \mathbf{u}_i \rangle = \langle \mathbf{f}, \mathbf{u}_i \rangle / \|\mathbf{f}\| = 0$ for $i \le k$. Hence $\mathcal{O}_j$ is orthonormal. For the spans we prove both containments with Proposition 1.3.18. Each $\mathbf{u}_i$ with $i \le k$ lies in $W \subseteq \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$, and so does

$$\mathbf{u} = \frac{1}{\|\mathbf{f}\|}\Big(\mathbf{v}_j - \mathrm{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j)\Big),$$

because $\mathrm{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j) \in W$. So $\mathrm{span}\big(\mathcal{O}_j\big) \subseteq \mathrm{span}\big(\mathbf{v}_1, \ldots, \mathbf{v}_j\big)$. Conversely, $\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}$ lie in $W = \mathrm{span}\big(\mathcal{O}_{j-1}\big) \subseteq \mathrm{span}\big(\mathcal{O}_j\big)$, and so does

$$\mathbf{v}_j = \mathrm{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j) + \|\mathbf{f}\|\mathbf{u}.$$

So $\mathrm{span}\big(\mathbf{v}_1, \ldots, \mathbf{v}_j\big) \subseteq \mathrm{span}\big(\mathcal{O}_j\big)$, and the induction is complete.

(b) We saw in the proof of (a) that pass j keeps nothing exactly when $\mathbf{v}_j \in W = \mathrm{span}\big(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}\big)$.

(c) The output is $\mathcal{O}_m$. By (a) it is orthonormal, hence linearly independent (Proposition 6.3.13), and it spans $\mathrm{span}(\mathbf{v}_1, \ldots, \mathbf{v}_m)$.

(d) If $\mathbf{v}_j = c_1\mathbf{v}_1 + \cdots + c_{j-1}\mathbf{v}_{j-1}$ for some j, then $c_1\mathbf{v}_1 + \cdots + c_{j-1}\mathbf{v}_{j-1} - \mathbf{v}_j = \mathbf{0}$ is a linear relation with a nonzero coefficient, so the list is dependent (Theorem 1.5.5). So if the list is independent, (b) shows that nothing is skipped. Then $\mathcal{O}_j = \mathbf{u}_1, \ldots, \mathbf{u}_j$ for every j, and (a) gives the equality of spans. Finally,

$$\mathbf{v}_j = \mathrm{Pr}_{\mathcal{O}_{j-1}}(\mathbf{v}_j) + \|\mathbf{f}_j\|\mathbf{u}_j,$$

where the first term lies in $\mathrm{span}\big(\mathbf{u}_1, \ldots, \mathbf{u}_{j-1}\big)$ and is therefore orthogonal to $\mathbf{u}_j$. Hence $\langle \mathbf{v}_j, \mathbf{u}_j \rangle = \|\mathbf{f}_j\|\langle \mathbf{u}_j, \mathbf{u}_j \rangle = \|\mathbf{f}_j\|$, which is positive because $\mathbf{f}_j \neq \mathbf{0}$. □

The invariant (a) is exactly what makes step 1 the right move. Because $\mathrm{span}\big(\mathcal{O}_{j-1}\big)$ is the span of all the earlier vectors, the residual is orthogonal to each earlier output, not only to the most recent one. Subtracting only the shadow on $\mathbf{u}_{j-1}$ would leave components along $\mathbf{u}_1, \ldots, \mathbf{u}_{j-2}$.

Remark 6.4.16 (Postponing the normalization). By Corollary 6.4.10, the projection in step 1 can be computed from the residuals instead of the normalized vectors:

$$\mathbf{f} = \mathbf{v}_j - \sum_{i=1}^{k} \frac{\langle \mathbf{v}_j, \mathbf{f}_i \rangle}{\|\mathbf{f}_i\|^2}\mathbf{f}_i,$$

and each $\mathbf{f}_i$ may be replaced by any nonzero multiple of itself without changing this sum. So by hand one runs the algorithm with residuals only, clears denominators in each residual as it appears, and normalizes once at the end. Square roots then appear only in the last step.

Example 6.4.17 (Gram–Schmidt in $\mathbb{R}^3$). Let $\mathbf{v}_1 = (1, 1, 0)$, $\mathbf{v}_2 = (1, 0, 1)$, $\mathbf{v}_3 = (0, 1, 1)$. Following Remark 6.4.16:

$$\begin{aligned} \mathbf{f}_1 &= (1, 1, 0), \\ \mathbf{f}_2 &= (1, 0, 1) - \frac{1}{2}(1, 1, 0) = \frac{1}{2}(1, -1, 2), \end{aligned}$$

which we replace by $(1, -1, 2)$. Since $\langle \mathbf{v}_3, \mathbf{f}_1 \rangle = 1$ with $\|\mathbf{f}_1\|^2 = 2$, and $\langle \mathbf{v}_3, (1, -1, 2) \rangle = 1$ with $\|(1, -1, 2)\|^2 = 6$,

$$\begin{aligned} \mathbf{f}_3 &= (0, 1, 1) - \frac{1}{2}(1, 1, 0) - \frac{1}{6}(1, -1, 2) \\ &= \frac{2}{3}(-1, 1, 1), \end{aligned}$$

which we replace by $(-1, 1, 1)$. The rescaled residuals $(1, 1, 0)$, $(1, -1, 2)$, $(-1, 1, 1)$ are pairwise orthogonal, and normalizing them gives the orthonormal basis

$$\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1, 1, 0), \quad \mathbf{u}_2 = \frac{1}{\sqrt{6}}(1, -1, 2),$$

$$\mathbf{u}_3 = \frac{1}{\sqrt{3}}(-1,1,1)$$

of $\mathbb{R}^3$. As Theorem 6.4.15(d) predicts, $\langle \mathbf{v}_2, \mathbf{u}_2 \rangle = 3/\sqrt{6} = \sqrt{3/2}$ is the length of the unrescaled residual $\frac{1}{2}(1,-1,2)$.

$$\mathbf{f}_1 = (1,1,0), \quad \mathbf{f}_2 = \frac{1}{2}(1,-1,2),$$
$$\mathbf{f}_3 = \frac{2}{3}(-1,1,1)$$

Gram–Schmidt on the vectors of Example 6.4.17, one step at a time, keeping the residuals unnormalized as in Remark 6.4.16; normalizing them gives $\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$. In the interactive version, drag or type the inputs; a vector typed into the span of the earlier ones is skipped. (Interactive in the web version.)

Example 6.4.18 (A dependent list). Run the algorithm on $\mathbf{v}_1 = (1,1,1)$, $\mathbf{v}_2 = (1,2,3)$, $\mathbf{v}_3 = (3,4,5)$, $\mathbf{v}_4 = (0,0,1)$ in $\mathbb{R}^3$, again with residuals only. First $\mathbf{f}_1 = (1,1,1)$, and

$$\mathbf{f}_2 = (1,2,3) - \frac{6}{3}(1,1,1) = (-1,0,1).$$

In the third pass, $\langle \mathbf{v}_3, \mathbf{f}_1 \rangle = 12$ and $\langle \mathbf{v}_3, \mathbf{f}_2 \rangle = 2$, so

$$\begin{aligned} &\mathbf{v}_3 - \frac{12}{3}(1,1,1) - \frac{2}{2}(-1,0,1) \\ &= (3-4+1, 4-4-0, 5-4-1) = \mathbf{0}. \end{aligned}$$

So $\mathbf{v}_3$ is skipped: by Theorem 6.4.15(b) it lies in $\operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$, and the computation even exhibits the relation $\mathbf{v}_3 = 4\mathbf{f}_1 + \mathbf{f}_2 = 4\mathbf{v}_1 + (\mathbf{v}_2 - 2\mathbf{v}_1) = 2\mathbf{v}_1 + \mathbf{v}_2$. In the fourth pass,

$$(0,0,1) - \frac{1}{3}(1,1,1) - \frac{1}{2}(-1,0,1) = \frac{1}{6}(1,-2,1),$$

which we replace by $(1,-2,1)$. The output, after normalizing, is $(1,1,1)/\sqrt{3}$, $(-1,0,1)/\sqrt{2}$, $(1,-2,1)/\sqrt{6}$: an orthonormal basis of $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_4) = \mathbb{R}^3$.

So Gram–Schmidt also detects linear dependence, much as row reduction does, and the number of vectors it keeps is the dimension of the span.

Example 6.4.19 (Legendre polynomials). Give $\mathbb{R}[x]_{\leq 3}$ the inner product $\langle p, q \rangle = \int_{-1}^{1} p(t)q(t)\,dt$ of Example 6.3.17, and run Gram–Schmidt on $1, x, x^2, x^3$. Since $\langle x^i, x^j \rangle = \int_{-1}^{1} t^{i+j}\,dt$ is $2/(i+j+1)$ when $i+j$ is even and 0 when $i+j$ is odd,

$$f_1 = 1, \quad f_2 = x - \frac{\langle x, 1 \rangle}{\|1\|^2} 1 = x,$$
$$f_3 = x^2 - \frac{\langle x^2, 1 \rangle}{\|1\|^2} 1 - \frac{\langle x^2, x \rangle}{\|x\|^2} x = x^2 - \frac{2/3}{2} = x^2 - \frac{1}{3},$$

which recovers the orthogonal basis of Example 6.3.17. The next pass gives $f_4 = x^3 - (3/5)x$, the polynomial of Exercise 6.3.49. By Theorem 6.4.15(d), $\operatorname{span}(f_1, \ldots, f_j) = \operatorname{span}(1, x, \ldots, x^{j-1})$. So $f_{j+1} = x^j - \Pr(x^j)$, where the projection is onto the polynomials of degree less than j: it has degree j, leading coefficient 1, and is orthogonal to every polynomial of degree less than j. Rescaled so that their value at 1 is 1, these are the **Legendre polynomials**

$$P_0 = 1, \quad P_1 = x,$$

$$P_2 = \frac{1}{2}(3x^2 - 1), \quad P_3 = \frac{1}{2}(5x^3 - 3x).$$

The output depends on the inner product. The lecture's example uses $\langle p, q\rangle = \int_0^1 p(t)q(t)\,dt$ instead, and Gram–Schmidt applied to $1, x$ then gives $1, \sqrt{3}(2x-1)$ (compare Exercise 6.4.46).

Now we can show that the hypothesis of Definition 6.4.11 holds for every finite-dimensional subspace.

Theorem 6.4.20 (Orthonormal bases exist).

(a) Every finite-dimensional inner product space has an orthonormal basis.

(b) In a finite-dimensional inner product space, every orthonormal list extends to an orthonormal basis.

(c) Every finite-dimensional subspace W of an inner product space V has an orthonormal basis. In particular, Pr_W is defined.

Proof. ROUTINE

Uses. Theorem 6.4.15 (Gram–Schmidt is correct), Corollary 1.6.24 (Bases exist in finite dimensions), Definition 6.4.11 (Orthogonal projection), Definition 6.1.2 (Inner product)
Hint 1. Run Gram–Schmidt on a basis, or on any spanning list.
Hint 2. For (b), put the orthonormal list in front of a basis of V. What does Gram–Schmidt do to vectors that are already orthonormal?
Sketch. (a) Gram–Schmidt turns a basis of V into an orthonormal basis of its span, which is V (Theorem 6.4.15(c)). (b) Run it on $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{b}_1, \ldots, \mathbf{b}_n$ for a basis $\mathbf{b}_1, \ldots, \mathbf{b}_n$ of V: the first k residuals are $\mathbf{u}_1, \ldots, \mathbf{u}_k$ themselves, and the output is an orthonormal basis of V that starts with them. (c) The inner product restricted to W is an inner product on W; apply (a).

(a) Let V be finite-dimensional. It has a basis $\mathbf{b}_1, \ldots, \mathbf{b}_n$ (Corollary 1.6.24). By Theorem 6.4.15(c), Gram–Schmidt turns it into an orthonormal basis of $\mathrm{span}(\mathbf{b}_1, \ldots, \mathbf{b}_n) = V$.

(b) Let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be orthonormal, and let $\mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V. Run Gram–Schmidt on the list $\mathbf{u}_1, \ldots, \mathbf{u}_k, \mathbf{b}_1, \ldots, \mathbf{b}_n$. In pass $j \le k$, the vectors kept so far are $\mathbf{u}_1, \ldots, \mathbf{u}_{j-1}$ (by induction on j), so the residual is

$$\mathbf{u}_j - \sum_{i=1}^{j-1} \langle \mathbf{u}_j, \mathbf{u}_i\rangle \mathbf{u}_i = \mathbf{u}_j,$$

a unit vector, which is kept unchanged. So the output begins with $\mathbf{u}_1, \ldots, \mathbf{u}_k$, and by Theorem 6.4.15(c) it is an orthonormal basis of the span of the whole list, which is V because the list contains a basis.

(c) The inner product of V, restricted to pairs of vectors of W, satisfies the axioms of Definition 6.1.2 on W. So W is a finite-dimensional inner product space, and it has an orthonormal basis by (a). Then Pr_W is defined by Definition 6.4.11. □

Part (b) is the orthonormal version of extending an independent list to a basis (Theorem 4.1.16). Together with Parseval's identity, part (a) completes the picture sketched after Theorem 6.3.22: every n-dimensional inner product space has an orthonormal basis, and its coordinates carry the inner product to the dot product of $\mathbb{F}^n$.

Exercise 6.4.21. ROUTINE In $\mathbb{C}^3$ with the dot product, apply Gram–Schmidt to $\mathbf{v}_1 = (1, i, 0)$, $\mathbf{v}_2 = (1, 1, 1)$. What goes wrong if $\langle \mathbf{v}_2, \mathbf{u}_1\rangle$ is replaced by $\langle \mathbf{u}_1, \mathbf{v}_2\rangle$ in step 1?

Solution on page 1497

6.4.3 Orthogonal complements

In Orthogonality to a set we defined $A^\perp$ for every subset A of V. When A is a subspace, $A^\perp$ deserves a name of its own, which we now justify.

Definition 6.4.22 (Orthogonal complement). Let W be a subspace of V. The **orthogonal complement** of W is the subspace

$$W^\perp = \{\mathbf{v} \in V \mid \langle \mathbf{v}, \mathbf{w} \rangle = 0 \text{ for all } \mathbf{w} \in W\}$$

of Definition 6.3.8.

By Proposition 6.3.9, $W^\perp$ is a subspace of V, $W \cap W^\perp = \{\mathbf{0}\}$, and $U \subseteq W$ implies $W^\perp \subseteq U^\perp$. By Exercise 6.3.11, $W \subseteq (W^\perp)^\perp$. Note that $W^\perp$ depends on the ambient space: the perp of the x-axis is a line in $\mathbb{R}^2$ and a plane in $\mathbb{R}^3$.

Example 6.4.23 (Orthogonal complements).

(a) In $\mathbb{R}^3$, $\operatorname{span}((1,1,1))^\perp$ is the plane $W = \{\mathbf{x} \mid x_1 + x_2 + x_3 = 0\}$ of Example 6.4.9 (Example 6.3.10). Conversely $W^\perp = \operatorname{span}((1,1,1))$. Indeed $(1,1,1)$ is orthogonal to the spanning vectors $(1,-1,0)$ and $(1,1,-2)$ of W, so $\operatorname{span}((1,1,1)) \subseteq W^\perp$, and Theorem 6.4.26 below gives equality.

(b) For $A \in \mathbb{R}^{m\times n}$, let $R \subseteq \mathbb{R}^n$ be the span of the rows of A. By Example 6.3.10 and Proposition 6.3.9(c), $\ker A = R^\perp$: solving $A\mathbf{x} = \mathbf{0}$ means finding the vectors orthogonal to every row.

(c) In $C[-1,1]$ with $\langle f, g\rangle = \int_{-1}^{1} f(t)g(t)\,dt$, every odd function is orthogonal to every even function (Example 6.3.2(c)). Exercise 6.4.54 shows that the odd functions form exactly the orthogonal complement of the even functions.

The main theorem says that $W^\perp$ really is a complement of W, as soon as W is finite-dimensional. The proof is already contained in Proposition 6.4.4: every vector is its projection onto W plus something orthogonal to W.

Theorem 6.4.24 (Orthogonal decomposition). Let W be a finite-dimensional subspace of V. Every $\mathbf{v} \in V$ can be written in exactly one way as

$$\mathbf{v} = \mathbf{w} + \mathbf{w}' \quad \text{with } \mathbf{w} \in W \text{ and } \mathbf{w}' \in W^\perp,$$

namely with $\mathbf{w} = \operatorname{Pr}_W(\mathbf{v})$ and $\mathbf{w}' = \mathbf{v} - \operatorname{Pr}_W(\mathbf{v})$. That is, $V = W \oplus W^\perp$.

Proof. ROUTINE

Uses. Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.4.4 (Properties of $\operatorname{Pr}_{\mathcal{O}}$), Proposition 6.3.9 (Properties of $A^\perp$), Definition 4.4.4 (Direct sum), Theorem 4.4.7 (Criteria for direct sums)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For existence, Pr_W is defined because W has an orthonormal basis. Which properties of $\operatorname{Pr}_W(\mathbf{v})$ do you need?
Hint 2. For uniqueness, suppose $\mathbf{w} + \mathbf{w}' = \mathbf{x} + \mathbf{x}'$ with $\mathbf{w}, \mathbf{x} \in W$ and $\mathbf{w}', \mathbf{x}' \in W^\perp$, and rearrange.
Sketch. By Theorem 6.4.20, Pr_W is defined, and $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) + (\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}))$ has its first piece in W and its second in $W^\perp$ by Proposition 6.4.4. If $\mathbf{w} + \mathbf{w}' = \mathbf{x} + \mathbf{x}'$ are two such decompositions, then $\mathbf{w} - \mathbf{x} = \mathbf{x}' - \mathbf{w}'$ lies in $W \cap W^\perp = \{\mathbf{0}\}$.

By Theorem 6.4.20, W has an orthonormal basis, so Pr_W is defined. For $\mathbf{v} \in V$, (a) and (b) of Proposition 6.4.4 give $\operatorname{Pr}_W(\mathbf{v}) \in W$ and $\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}) \in W^\perp$, and these two vectors add up to $\mathbf{v}$. So a decomposition exists.

Suppose $\mathbf{v} = \mathbf{w} + \mathbf{w}' = \mathbf{x} + \mathbf{x}'$ with $\mathbf{w}, \mathbf{x} \in W$ and $\mathbf{w}', \mathbf{x}' \in W^\perp$. Then

$$\mathbf{w} - \mathbf{x} = \mathbf{x}' - \mathbf{w}'.$$

The left side lies in W and the right side in $W^\perp$, since both are subspaces. So both sides lie in $W \cap W^\perp = \{\mathbf{0}\}$ (Proposition 6.3.9(d)), and $\mathbf{w} = \mathbf{x}$, $\mathbf{w}' = \mathbf{x}'$. In the language of Section 4.4, $V = W + W^\perp$ and $W \cap W^\perp = \{\mathbf{0}\}$, so the sum is direct (Theorem 4.4.7, Definition 4.4.4). □

Uniqueness can also be read off from Theorem 6.4.6: if $\mathbf{v} = \mathbf{w} + \mathbf{w}'$ with $\mathbf{w} \in W$ and $\mathbf{w}' \in W^\perp$, then $\mathbf{w} \in W$ and $\mathbf{v} - \mathbf{w} = \mathbf{w}' \perp W$, so $\mathbf{w} = \operatorname{Pr}_W(\mathbf{v})$. In $\mathbb{R}^3$ the theorem says that every vector is the sum of a vector in a given plane through $\mathbf{0}$ and a vector along the normal line, which is how one splits a force into the part along a surface and the part pushing against it.

Note what was assumed: W is finite-dimensional, but V need not be. When W is infinite-dimensional the theorem can fail. Exercise 6.4.63 gives a proper subspace W of an inner product space V with $W^\perp = \{\mathbf{0}\}$, so that $W + W^\perp = W \neq V$; Section 15.3 explains what survives in infinite dimensions.

Corollary 6.4.25 (Dimension of the orthogonal complement). Let V be finite-dimensional and W a subspace of V. Then $\dim W^\perp = \dim V - \dim W$. More precisely, if $\mathbf{u}_1, \dots, \mathbf{u}_n$ is an orthonormal basis of V whose first k vectors form an orthonormal basis of W, then $\mathbf{u}_{k+1}, \dots, \mathbf{u}_n$ is an orthonormal basis of $W^\perp$.

Proof (by the dimension formula). ROUTINE

Uses. Theorem 6.4.24 (Orthogonal decomposition), Theorem 4.4.19 (Dimension of a sum), Proposition 6.3.9 (Properties of $A^\perp$), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. W and $W^\perp$ are finite-dimensional because V is. What does Theorem 6.4.24 say about $W + W^\perp$ and $W \cap W^\perp$?
Hint 2. Apply $\dim\big(W + W^\perp\big) = \dim W + \dim W^\perp - \dim\big(W \cap W^\perp\big)$.
Sketch. $V = W + W^\perp$ and $W \cap W^\perp = \{\mathbf{0}\}$, so the dimension formula gives $\dim V = \dim W + \dim W^\perp - 0$.

Subspaces of the finite-dimensional space V are finite-dimensional (Proposition 4.1.21). By Theorem 6.4.24, $W + W^\perp = V$, and $W \cap W^\perp = \{\mathbf{0}\}$ by Proposition 6.3.9(d). By Theorem 4.4.19,

$$\begin{aligned} \dim V &= \dim\big(W + W^\perp\big) \\ &= \dim W + \dim W^\perp - \dim\big(W \cap W^\perp\big) \\ &= \dim W + \dim W^\perp, \end{aligned}$$

which gives the dimension formula. The statement about bases is proved in the second approach. □

Proof (by extending an orthonormal basis). ROUTINE

Uses. Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 6.3.9 (Properties of $A^\perp$), Definition 6.3.15 (Orthonormal list, orthonormal basis)
Techniques. Double containment (Technique 1.3.14), Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. Take an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of W and extend it to an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_n$ of V with Theorem 6.4.20(b). Guess $W^\perp$.
Hint 2. Show $\operatorname{span}(\mathbf{u}_{k+1}, \dots, \mathbf{u}_n) = W^\perp$ by double containment. For $\subseteq$, test against the spanning list $\mathbf{u}_1, \dots, \mathbf{u}_k$ of W. For $\supseteq$, expand $\mathbf{v} \in W^\perp$ in the basis.
Sketch. Extend an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of W to one of V. Each $\mathbf{u}_j$ with $j > k$ is orthogonal to $\mathbf{u}_1, \dots, \mathbf{u}_k$, hence to W. Conversely, $\mathbf{v} \in W^\perp$ has $\langle \mathbf{v}, \mathbf{u}_j \rangle = 0$ for $j \le k$, so its expansion $\sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$ involves only $\mathbf{u}_{k+1}, \dots, \mathbf{u}_n$. So $\mathbf{u}_{k+1}, \dots, \mathbf{u}_n$ is an orthonormal basis of $W^\perp$, and $\dim W^\perp = n - k$.

By Theorem 6.4.20, W has an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_k$, and it extends to an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_n$ of V, where $n = \dim V$. (Conversely, every orthonormal basis of V whose first k vectors span W arises this way.) Let $U = \operatorname{span}(\mathbf{u}_{k+1}, \dots, \mathbf{u}_n)$. We show $U = W^\perp$ by double containment.

For $j > k$, $\mathbf{u}_j$ is orthogonal to $\mathbf{u}_1, \dots, \mathbf{u}_k$, so $\mathbf{u}_j \in W^\perp$ by Proposition 6.3.9(c). As $W^\perp$ is a subspace, $U \subseteq W^\perp$. Conversely, let $\mathbf{v} \in W^\perp$. Then $\langle \mathbf{v}, \mathbf{u}_j \rangle = 0$ for $j \le k$, so by Proposition 6.3.18(b),

$$\mathbf{v} = \sum_{j=1}^{n} \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j = \sum_{j=k+1}^{n} \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j \in U.$$

So $W^\perp = U$. The list $\mathbf{u}_{k+1}, \dots, \mathbf{u}_n$ is orthonormal and spans $W^\perp$, so it is an orthonormal basis of $W^\perp$, and $\dim W^\perp = n - k = \dim V - \dim W$. □

The first proof counts. The second builds the basis of $W^\perp$, and it shows that, in coordinates with respect to an orthonormal basis adapted to W, the decomposition $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) + (\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}))$ simply splits the coordinate vector into its first k entries and the rest.

For the matrix A of Example 6.4.23(b), the corollary gives $\dim R = n - \dim\ker A$, and rank–nullity (Theorem 4.2.11) gives $\dim \operatorname{im} A = n - \dim\ker A$. So the rows of a real matrix span a space of the same dimension as its columns. This is Theorem 4.3.8 for real matrices, obtained here by a dimension count.

Since $W \subseteq \left(W^\perp\right)^\perp$ always holds, the next question is whether taking the complement twice returns W. In $\mathbb{R}^3$ the complement of a plane is its normal line, and the complement of that line is the plane again.

Theorem 6.4.26 (The double complement). Let W be a finite-dimensional subspace of V. Then $\left(W^\perp\right)^\perp = W$.

Proof (by the orthogonal decomposition). STANDARD

Uses. Theorem 6.4.24 (Orthogonal decomposition), Proposition 6.3.9 (Properties of $A^\perp$), Exercise 6.3.11
Techniques. Double containment (Technique 1.3.14)
Hint 1. One containment, $W \subseteq \left(W^\perp\right)^\perp$, holds for every subset (Exercise 6.3.11). For the other, take $\mathbf{v} \in \left(W^\perp\right)^\perp$ and decompose it with Theorem 6.4.24.
Hint 2. Write $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) + \mathbf{w}'$ with $\mathbf{w}' \in W^\perp$. Show that $\mathbf{w}'$ also lies in $\left(W^\perp\right)^\perp$.
Sketch. $W \subseteq \left(W^\perp\right)^\perp$ always. Conversely, if $\mathbf{v} \in \left(W^\perp\right)^\perp$, write $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) + \mathbf{w}'$ with $\mathbf{w}' \in W^\perp$. Both $\mathbf{v}$ and $\operatorname{Pr}_W(\mathbf{v}) \in W$ lie in the subspace $\left(W^\perp\right)^\perp$, so $\mathbf{w}' \in W^\perp \cap \left(W^\perp\right)^\perp = \{\mathbf{0}\}$, and $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) \in W$.

By Exercise 6.3.11, $W \subseteq \left(W^\perp\right)^\perp$. Conversely, let $\mathbf{v} \in \left(W^\perp\right)^\perp$. By Theorem 6.4.24, $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) + \mathbf{w}'$ with $\mathbf{w}' \in W^\perp$. Here $\mathbf{v} \in \left(W^\perp\right)^\perp$ by assumption and $\operatorname{Pr}_W(\mathbf{v}) \in W \subseteq \left(W^\perp\right)^\perp$, so $\mathbf{w}' = \mathbf{v} - \operatorname{Pr}_W(\mathbf{v}) \in \left(W^\perp\right)^\perp$, since $\left(W^\perp\right)^\perp$ is a subspace. So $\mathbf{w}'$ lies in $W^\perp$ and in $\left(W^\perp\right)^\perp$, and Proposition 6.3.9(d), applied to the subspace $W^\perp$, gives $\mathbf{w}' = \mathbf{0}$. Hence $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) \in W$. □

Proof (by counting dimensions, when V is finite-dimensional). ROUTINE

Uses. Corollary 6.4.25 (Dimension of the orthogonal complement), Proposition 4.1.21 (Dimensions of subspaces), Exercise 6.3.11
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. You know $W \subseteq \left(W^\perp\right)^\perp$. Compare dimensions.
Hint 2. Apply Corollary 6.4.25 twice: once to W and once to $W^\perp$.
Sketch. $W \subseteq \left(W^\perp\right)^\perp$, and $\dim\left(W^\perp\right)^\perp = n - (n - \dim W) = \dim W$ by Corollary 6.4.25 applied twice. A subspace of the same finite dimension as a space containing it is that space.

Suppose V is finite-dimensional, with $n = \dim V$. By Corollary 6.4.25, applied to W and then to $W^\perp$,

$$\dim\left(W^\perp\right)^\perp = n - \dim W^\perp = n - (n - \dim W) = \dim W.$$

Since $W \subseteq \left(W^\perp\right)^\perp$ (Exercise 6.3.11) and the dimensions agree, $W = \left(W^\perp\right)^\perp$ by Proposition 4.1.21. □

The second proof is shorter but needs V finite-dimensional, so that $W^\perp$ has a dimension at all. The first needs only that W is finite-dimensional, which is the setting of the approximation problems below, where V is a space of functions.

Corollary 6.4.27 (Testing whether a subspace is everything). Let W be a finite-dimensional subspace of V. Then $W = V$ if and only if $W^\perp = \{\mathbf{0}\}$.

Proof. ROUTINE

Uses. Theorem 6.4.24 (Orthogonal decomposition), Proposition 6.3.9 (Properties of $A^\perp$)
Hint 1. One direction is $V^\perp = \{\mathbf{0}\}$ (Proposition 6.3.9(d)).
Hint 2. For the other, decompose an arbitrary $\mathbf{v} \in V$ with Theorem 6.4.24.
Sketch. If $W = V$, then $W^\perp = V^\perp = \{\mathbf{0}\}$. If $W^\perp = \{\mathbf{0}\}$, then every $\mathbf{v}$ equals $\operatorname{Pr}_W(\mathbf{v}) + \mathbf{0} \in W$.

If $W = V$, then $W^\perp = V^\perp = \{\mathbf{0}\}$ by Proposition 6.3.9(d). Conversely, suppose $W^\perp = \{\mathbf{0}\}$, and let $\mathbf{v} \in V$. By Theorem 6.4.24, $\mathbf{v} - \operatorname{Pr}_W(\mathbf{v}) \in W^\perp = \{\mathbf{0}\}$, so $\mathbf{v} = \operatorname{Pr}_W(\mathbf{v}) \in W$. Hence $W = V$. □

So to show that a finite-dimensional subspace W is all of V, it suffices to show that the only vector orthogonal to W is $\mathbf{0}$.

Exercise 6.4.28. ROUTINE Let $W = \{\mathbf{x} \in \mathbb{R}^4 \mid x_1 + x_2 + x_3 + x_4 = 0\}$. Find $W^\perp$, a formula for $\mathrm{Pr}_{W^\perp}$, and the vector of W closest to $\mathbf{e}_1$.

Solution on page 1497

The projection as a linear map

We now collect the properties of Pr_W as a map $V \to V$.

Proposition 6.4.29 (The orthogonal projection as a linear map). Let W be a finite-dimensional subspace of V, and let $P = \mathrm{Pr}_W$.

(a) P is linear, $\operatorname{im} P = W$, and $\ker P = W^\perp$.

(b) $P^2 = P$. In fact $P(\mathbf{w}) = \mathbf{w}$ for every $\mathbf{w} \in W$.

(c) $\langle P\mathbf{v}, \mathbf{x}\rangle = \langle P\mathbf{v}, P\mathbf{x}\rangle = \langle \mathbf{v}, P\mathbf{x}\rangle$ for all $\mathbf{v}, \mathbf{x} \in V$.

(d) If V is finite-dimensional, then $\mathrm{id}_V - P = \mathrm{Pr}_{W^\perp}$.

Proof. ROUTINE

Uses. Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$), Theorem 6.4.6 (The projection is characterized by orthogonality), Definition 6.4.11 (Orthogonal projection), Theorem 6.4.20 (Orthonormal bases exist), Proposition 4.1.21 (Dimensions of subspaces), Exercise 6.3.11
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. For $\ker P$, apply Theorem 6.4.6: when is $\mathbf{0}$ the vector $\mathbf{p}$ with $\mathbf{p} \in W$ and $\mathbf{v} - \mathbf{p} \perp W$?
Hint 2. For (c), split the vector in the second slot as $\mathbf{x} = P\mathbf{x} + (\mathbf{x} - P\mathbf{x})$, and the vector in the first slot similarly.
Hint 3. For (d), check that $\mathbf{v} - P\mathbf{v}$ satisfies the two conditions that characterize $\mathrm{Pr}_{W^\perp}(\mathbf{v})$.
Sketch. (a) Linearity is Proposition 6.4.4(d). The image lies in W and contains every $\mathbf{w} = P\mathbf{w}$. $P\mathbf{v} = \mathbf{0}$ if and only if $\mathbf{0} \in W$ and $\mathbf{v} - \mathbf{0} \perp W$, that is, $\mathbf{v} \in W^\perp$. (b) $P\mathbf{v} \in W$ is fixed. (c) $\langle P\mathbf{v}, \mathbf{x} - P\mathbf{x}\rangle = 0$ and $\langle \mathbf{v} - P\mathbf{v}, P\mathbf{x}\rangle = 0$. (d) $\mathbf{v} - P\mathbf{v} \in W^\perp$, and $\mathbf{v} - (\mathbf{v} - P\mathbf{v}) = P\mathbf{v} \in W$ is orthogonal to $W^\perp$.

(a) P is linear by Proposition 6.4.4(d), and $\operatorname{im} P \subseteq W$ by part (a) of the same proposition. If $\mathbf{w} \in W$, then $P\mathbf{w} = \mathbf{w}$ by part (c), so $W \subseteq \operatorname{im} P$. For the kernel: by Theorem 6.4.6, $P\mathbf{v} = \mathbf{0}$ if and only if $\mathbf{0}$ satisfies $\mathbf{0} \in W$ and $\mathbf{v} - \mathbf{0} \in W^\perp$, that is, if and only if $\mathbf{v} \in W^\perp$.

(b) For $\mathbf{v} \in V$, $P\mathbf{v} \in W$, so $P(P\mathbf{v}) = P\mathbf{v}$ by Proposition 6.4.4(c).

(c) Let $\mathbf{v}, \mathbf{x} \in V$. Since $P\mathbf{v} \in W$ and $\mathbf{x} - P\mathbf{x} \in W^\perp$,

$$\langle P\mathbf{v}, \mathbf{x}\rangle = \langle P\mathbf{v}, P\mathbf{x}\rangle + \langle P\mathbf{v}, \mathbf{x} - P\mathbf{x}\rangle = \langle P\mathbf{v}, P\mathbf{x}\rangle.$$

Similarly, since $\mathbf{v} - P\mathbf{v} \in W^\perp$ and $P\mathbf{x} \in W$,

$$\langle \mathbf{v}, P\mathbf{x}\rangle = \langle P\mathbf{v}, P\mathbf{x}\rangle + \langle \mathbf{v} - P\mathbf{v}, P\mathbf{x}\rangle = \langle P\mathbf{v}, P\mathbf{x}\rangle.$$

(d) Since V is finite-dimensional, so is $W^\perp$ (Proposition 4.1.21), so $\mathrm{Pr}_{W^\perp}$ is defined (Theorem 6.4.20). Let $\mathbf{v} \in V$ and $\mathbf{p} = \mathbf{v} - P\mathbf{v}$. Then $\mathbf{p} \in W^\perp$ by Proposition 6.4.4(b), and $\mathbf{v} - \mathbf{p} = P\mathbf{v} \in W \subseteq \left(W^\perp\right)^\perp$ (Exercise 6.3.11). These are the two conditions of Theorem 6.4.6 for the subspace $W^\perp$, so $\mathbf{p} = \mathrm{Pr}_{W^\perp}(\mathbf{v})$. □

In (d), finite-dimensionality of V was used only to know that $\mathrm{Pr}_{W^\perp}$ is defined. For any V, the map $\mathbf{v} \mapsto \mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$ is linear, has image $W^\perp$, and picks out the $W^\perp$-component in Theorem 6.4.24.

Parts (b) and (c) characterize orthogonal projections among all linear maps. Part (b) alone does not: the map P of Remark 6.4.12 satisfies $P^2 = P$, but $\langle P\mathbf{e}_2, \mathbf{e}_1\rangle = \langle (-1, 0), (1, 0)\rangle = -1$ while $\langle \mathbf{e}_2, P\mathbf{e}_1\rangle = \langle \mathbf{e}_2, \mathbf{e}_1\rangle = 0$.

Proposition 6.4.30 (Recognizing orthogonal projections). Let V be finite-dimensional and $P \in \mathrm{L}(V)$. Then $P = \mathrm{Pr}_W$ for some subspace W of V if and only if

$$P^2 = P \quad \text{and} \quad \langle P\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, P\mathbf{x}\rangle \text{ for all } \mathbf{v}, \mathbf{x} \in V.$$

In that case $W = \operatorname{im} P$.

Proof. STANDARD

Uses. Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.4.6 (The projection is characterized by orthogonality), Theorem 6.4.20 (Orthonormal bases exist), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. One direction is Proposition 6.4.29(a)–(c). For the other, the only candidate is $W = \operatorname{im} P$. Check the two conditions that characterize $\operatorname{Pr}_W(\mathbf{v})$ for the vector $P\mathbf{v}$.
Hint 2. Every vector of W has the form $P\mathbf{x}$. Move P across the inner product: $\langle \mathbf{v} - P\mathbf{v}, P\mathbf{x}\rangle = \langle P(\mathbf{v} - P\mathbf{v}), \mathbf{x}\rangle$.
Sketch. If $P = \operatorname{Pr}_W$, then $P^2 = P$, the symmetry holds, and $\operatorname{im} P = W$, by Proposition 6.4.29. Conversely, let $W = \operatorname{im} P$. Then $P\mathbf{v} \in W$, and for every $P\mathbf{x} \in W$, $\langle \mathbf{v} - P\mathbf{v}, P\mathbf{x}\rangle = \langle P\mathbf{v} - P^2\mathbf{v}, \mathbf{x}\rangle = 0$. So $P\mathbf{v} = \operatorname{Pr}_W(\mathbf{v})$ by Theorem 6.4.6.

If $P = \operatorname{Pr}_W$, then $P^2 = P$ and $\langle P\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, P\mathbf{x}\rangle$ by (b) and (c) of Proposition 6.4.29, and $\operatorname{im} P = W$ by part (a).

Conversely, suppose P has the two properties, and let $W = \operatorname{im} P$. It is a subspace of the finite-dimensional space V, so it is finite-dimensional (Proposition 4.1.21) and Pr_W is defined (Theorem 6.4.20). Let $\mathbf{v} \in V$. Then $P\mathbf{v} \in W$. Every vector of W has the form $P\mathbf{x}$ for some $\mathbf{x} \in V$, and by the second property, applied to the vectors $\mathbf{v} - P\mathbf{v}$ and $\mathbf{x}$,

$$\begin{aligned}\langle \mathbf{v} - P\mathbf{v}, P\mathbf{x}\rangle &= \langle P(\mathbf{v} - P\mathbf{v}), \mathbf{x}\rangle \\ &= \langle P\mathbf{v} - P^2\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{0}, \mathbf{x}\rangle = 0.\end{aligned}$$

So $\mathbf{v} - P\mathbf{v} \in W^\perp$. By Theorem 6.4.6, $P\mathbf{v} = \operatorname{Pr}_W(\mathbf{v})$. As $\mathbf{v}$ was arbitrary, $P = \operatorname{Pr}_W$. □

The second condition says that P can be moved from one slot of the inner product to the other. In the language of Section 6.6, it says that P equals its adjoint, $P^* = P$, that is, P is self-adjoint (Definition 6.6.26). So the orthogonal projections are exactly the operators with $P^2 = P = P^*$. For $V = \mathbb{F}^n$ with the dot product, Proposition 6.3.27(d) shows that the condition says that the matrix of P is Hermitian.

Projection matrices

In $\mathbb{F}^n$ with the dot product, Pr_W is a linear map $\mathbb{F}^n \to \mathbb{F}^n$, so it is multiplication by a matrix. The matrix is built from an orthonormal basis of W and its conjugate transpose.

Theorem 6.4.31 (The matrix of an orthogonal projection). Let W be a subspace of $\mathbb{F}^n$ with the dot product, let $\mathbf{u}_1, \ldots, \mathbf{u}_k$ be an orthonormal basis of W, and let $Q \in \mathbb{F}^{n\times k}$ be the matrix with columns $\mathbf{u}_1, \ldots, \mathbf{u}_k$. Then

$$\operatorname{Pr}_W(\mathbf{x}) = QQ^*\mathbf{x} \quad \text{for all } \mathbf{x} \in \mathbb{F}^n,$$

and $QQ^* = \mathbf{u}_1\mathbf{u}_1^* + \cdots + \mathbf{u}_k\mathbf{u}_k^*$. Moreover $Q^*Q = I_k$, while the $n \times n$ matrix $P = QQ^*$ satisfies $P^2 = P$ and $P^* = P$.

Proof. ROUTINE

Uses. Definition 6.3.26 (Conjugate transpose), Proposition 2.4.8 (Four views of the product), Definition 6.1.8 (Dot product), Theorem 6.3.29 (Orthonormal columns), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 2.4.14 (Algebra of matrices)
Hint 1. Compute $Q^*\mathbf{x}$ entry by entry. Row i of Q^* is $\mathbf{u}_i^*$.
Hint 2. The entries of $Q^*\mathbf{x}$ are the coefficients $\langle \mathbf{x}, \mathbf{u}_i\rangle$, and multiplying by Q combines the columns of Q with these coefficients.
Sketch. The ith entry of $Q^*\mathbf{x}$ is $\mathbf{u}_i^*\mathbf{x} = \mathbf{x} \cdot \mathbf{u}_i = \langle \mathbf{x}, \mathbf{u}_i\rangle$, so $Q(Q^*\mathbf{x}) = \sum_i \langle \mathbf{x}, \mathbf{u}_i\rangle \mathbf{u}_i = \operatorname{Pr}_W(\mathbf{x})$. Columns times rows gives $QQ^* = \sum_i \mathbf{u}_i\mathbf{u}_i^*$. Then $Q^*Q = I_k$ is Theorem 6.3.29, so $(QQ^*)^2 = Q(Q^*Q)Q^* = QQ^*$, and $(QQ^*)^* = QQ^*$.

Row i of Q^* is $\mathbf{u}_i^*$ (Definition 6.3.26), so the ith entry of $Q^*\mathbf{x}$ is $\mathbf{u}_i^*\mathbf{x} = \mathbf{x} \cdot \mathbf{u}_i = \langle \mathbf{x}, \mathbf{u}_i\rangle$ (Definition 6.1.8). By the column view of Proposition 2.4.8, $Q(Q^*\mathbf{x})$ is the combination of the columns of Q with these coefficients:

$$QQ^*\mathbf{x} = \sum_{i=1}^{k} \langle \mathbf{x}, \mathbf{u}_i \rangle \mathbf{u}_i = \mathrm{Pr}_W(\mathbf{x}).$$

The columns-times-rows view of Proposition 2.4.8 gives $QQ^* = \sum_i \mathbf{u}_i \mathbf{u}_i^*$, since column i of Q is $\mathbf{u}_i$ and row i of Q^* is $\mathbf{u}_i^*$. Next, $Q^*Q = I_k$ by Theorem 6.3.29. Hence, by associativity and Proposition 6.3.27,

$$(QQ^*)^2 = Q(Q^*Q)Q^* = QQ^*,$$
$$(QQ^*)^* = (Q^*)^*Q^* = QQ^*.$$

□

The two products of Q and Q^* play different roles. $Q^*Q = I_k$ records that the columns are orthonormal. QQ^* is the projection onto their span, and it equals I_n only when $k = n$, that is, when Q is unitary. This is the identification promised after Theorem 6.3.29. Each term $\mathbf{u}_i \mathbf{u}_i^*$ is the projection onto the line $\mathrm{span}(\mathbf{u}_i)$, so Pr_W is the sum of the projections onto the lines of an orthonormal basis, as in Figure 6.4.1. By Corollary 6.4.10, for an orthogonal basis $\mathbf{f}_1, \ldots, \mathbf{f}_k$ of W the matrix is

$$\sum_{i=1}^{k} \frac{\mathbf{f}_i \mathbf{f}_i^*}{\mathbf{f}_i^* \mathbf{f}_i}.$$

In particular, the projection onto the line spanned by a nonzero $\mathbf{a} \in \mathbb{F}^n$ has matrix $\mathbf{a}\mathbf{a}^*/(\mathbf{a}^*\mathbf{a})$. For a general basis of W the formula needs an inverse, $A(A^*A)^{-1}A^*$, which is the subject of Section 6.5.

Example 6.4.32 (Projecting onto a plane in $\mathbb{R}^3$). Let W be the plane $x_1 + x_2 + x_3 = 0$ of Example 6.4.9, and $\mathbf{j} = (1, 1, 1)$, so that $W^\perp = \mathrm{span}(\mathbf{j})$ (Example 6.4.23(a)). By Proposition 6.4.29(d) and the formula for lines,

$$\mathrm{Pr}_W = I_3 - \frac{\mathbf{j}\mathbf{j}^\mathsf{T}}{3} = \frac{1}{3}\begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix}.$$

For instance $\mathrm{Pr}_W(3, 0, 0) = (2, -1, -1)$, as in Example 6.4.9. The same matrix comes from Theorem 6.4.31 with Q built from either orthonormal basis of Example 6.4.9. Projecting onto $W^\perp$ and subtracting needed one rank-one matrix instead of two, a trick worth remembering when $W^\perp$ is smaller than W.

6.4.4 Best approximation

We return to the question that opened the section: which vector of W is closest to $\mathbf{v}$?

Intuition (The right triangle). Let W be a plane through $\mathbf{0}$ in $\mathbb{R}^3$, and $\mathbf{w}$ any point of W. The three points $\mathbf{v}$, $\mathrm{Pr}_W(\mathbf{v})$, and $\mathbf{w}$ form a triangle with a right angle at $\mathrm{Pr}_W(\mathbf{v})$: one leg, $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$, is perpendicular to W, and the other, $\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w}$, lies in W (Figure 6.4.3). The distance from $\mathbf{v}$ to $\mathbf{w}$ is the hypotenuse, which is longer than the leg $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$ unless the other leg is $\mathbf{0}$. So no point of W is closer to $\mathbf{v}$ than $\mathrm{Pr}_W(\mathbf{v})$, and every other point of W is farther away.

This is the shadow argument of Figure 6.2.1, with the line replaced by a subspace. It uses only Pythagoras, so it works in every inner product space.

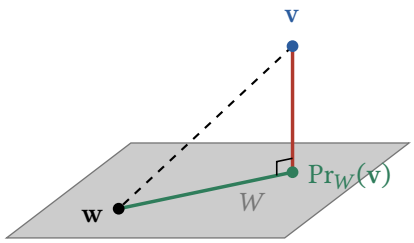

Figure 6.4.3. For every $\mathbf{w} \in W$, the points $\mathbf{v}$, $\mathrm{Pr}_W(\mathbf{v})$, $\mathbf{w}$ form a right triangle. Its hypotenuse $\mathbf{v} - \mathbf{w}$ is longer than the leg $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$ unless $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$.

Theorem 6.4.33 (Best approximation). Let W be a finite-dimensional subspace of V, and let $\mathbf{v} \in V$. Then

$$\|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\| \leq \|\mathbf{v} - \mathbf{w}\| \quad \text{for every } \mathbf{w} \in W,$$

with equality if and only if $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$. That is, $\mathrm{Pr}_W(\mathbf{v})$ is the unique vector of W closest to $\mathbf{v}$. If $\mathbf{u}_1, \ldots, \mathbf{u}_k$ is an orthonormal basis of W, the least distance is given by

$$\|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|^2 = \|\mathbf{v}\|^2 - \sum_{j=1}^{k} |\langle \mathbf{v}, \mathbf{u}_j \rangle|^2.$$

Proof (by Pythagoras). ROUTINE

Uses. Proposition 6.4.4 (Properties of $\mathrm{Pr}_{\mathcal{O}}$), Theorem 6.3.3 (Pythagorean theorem), Proposition 6.1.27 (Basic properties of the norm), Theorem 6.4.20 (Orthonormal bases exist)
Techniques. Orthogonal decomposition (Technique 6.2.4), Projections shrink norms (Technique 6.4.5)
Hint 1. Write $\mathbf{v} - \mathbf{w} = (\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})) + (\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w})$. Where do the two pieces lie?
Hint 2. The first piece is in $W^\perp$ and the second is in W, so they are orthogonal. Apply the Pythagorean theorem.
Hint 3. The formula for the least distance is Proposition 6.4.4(e).
Sketch. For $\mathbf{w} \in W$, $\mathbf{v} - \mathbf{w} = (\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})) + (\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w})$, with the first piece in $W^\perp$ and the second in W. By Pythagoras, $\|\mathbf{v} - \mathbf{w}\|^2 = \|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|^2 + \|\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w}\|^2$, which is at least $\|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|^2$, with equality exactly when $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$. The distance formula is Proposition 6.4.4(e).

Pr_W is defined by Theorem 6.4.20. Let $\mathbf{w} \in W$. Then

$$\mathbf{v} - \mathbf{w} = (\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})) + (\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w}),$$

where $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v}) \in W^\perp$ by Proposition 6.4.4(b), and $\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w} \in W$ because both terms lie in W. So the two pieces are orthogonal, and by Theorem 6.3.3(a),

$$\begin{aligned} \|\mathbf{v} - \mathbf{w}\|^2 &= \|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|^2 + \|\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w}\|^2 \\ &\geq \|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|^2. \end{aligned} \tag{6.4.2}$$

Taking nonnegative square roots gives the inequality. By (6.4.2), equality holds if and only if $\|\mathrm{Pr}_W(\mathbf{v}) - \mathbf{w}\| = 0$, that is (Proposition 6.1.27(a)), if and only if $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$. Finally, by Proposition 6.4.4(e),

$$\begin{aligned} \|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|^2 &= \|\mathbf{v}\|^2 - \|\mathrm{Pr}_W(\mathbf{v})\|^2 \\ &= \|\mathbf{v}\|^2 - \sum_{j=1}^{k} |\langle \mathbf{v}, \mathbf{u}_j \rangle|^2. \end{aligned}$$

□

Proof (by completing the square). STANDARD

Uses. Proposition 6.1.29 (Expanding a norm), Proposition 6.1.4 (Sesquilinearity), Corollary 6.3.6 (Pythagoras for orthogonal lists), Theorem 6.4.20 (Orthonormal bases exist), Definition 6.4.11 (Orthogonal projection)
Techniques. A sum of nonnegative terms (Technique 6.1.9)

Hint 1. Fix an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ of W, write $\mathbf{w} = \sum_j c_j \mathbf{u}_j$ and $a_j = \langle \mathbf{v}, \mathbf{u}_j \rangle$, and expand $\|\mathbf{v} - \mathbf{w}\|^2$ as a function of $c_1, \dots, c_k$.
Hint 2. You should get $\|\mathbf{v}\|^2 + \sum_j \big(|c_j|^2 - 2\,\mathrm{Re}(\overline{c_j} a_j) \big)$. Complete the square in each c_j, using $|c - a|^2 = |c|^2 - 2\,\mathrm{Re}(\overline{c}a) + |a|^2$.
Sketch. With $\mathbf{w} = \sum_j c_j \mathbf{u}_j$ and $a_j = \langle \mathbf{v}, \mathbf{u}_j \rangle$: $\|\mathbf{v} - \mathbf{w}\|^2 = \|\mathbf{v}\|^2 - 2\,\mathrm{Re}\langle \mathbf{v}, \mathbf{w} \rangle + \|\mathbf{w}\|^2 = \|\mathbf{v}\|^2 + \sum_j \big(|c_j|^2 - 2\,\mathrm{Re}(\overline{c_j} a_j) \big) = \|\mathbf{v}\|^2 - \sum_j |a_j|^2 + \sum_j |c_j - a_j|^2$. The last sum is nonnegative and vanishes exactly when every $c_j = a_j$, that is, when $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$.

By Theorem 6.4.20, W has an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_k$. Let $a_j = \langle \mathbf{v}, \mathbf{u}_j \rangle$, so that $\mathrm{Pr}_W(\mathbf{v}) = \sum_j a_j \mathbf{u}_j$. Every $\mathbf{w} \in W$ is $\mathbf{w} = \sum_j c_j \mathbf{u}_j$ for unique scalars c_j. By Proposition 6.1.29 with $a = -1$,

$$\|\mathbf{v} - \mathbf{w}\|^2 = \|\mathbf{v}\|^2 - 2\,\mathrm{Re}\langle \mathbf{v}, \mathbf{w} \rangle + \|\mathbf{w}\|^2.$$

By Proposition 6.1.4, $\langle \mathbf{v}, \mathbf{w} \rangle = \sum_j \overline{c_j} \langle \mathbf{v}, \mathbf{u}_j \rangle = \sum_j \overline{c_j} a_j$, and by Corollary 6.3.6, $\|\mathbf{w}\|^2 = \sum_j |c_j|^2$. For complex numbers c and a, $|c - a|^2 = (c - a)\overline{(c - a)} = |c|^2 - 2\,\mathrm{Re}(\overline{c}a) + |a|^2$. Hence

$$\begin{aligned} \|\mathbf{v} - \mathbf{w}\|^2 &= \|\mathbf{v}\|^2 + \sum_{j=1}^{k} \big(|c_j|^2 - 2\,\mathrm{Re}(\overline{c_j} a_j) \big) \\ &= \|\mathbf{v}\|^2 - \sum_{j=1}^{k} |a_j|^2 + \sum_{j=1}^{k} |c_j - a_j|^2. \end{aligned}$$

The first two terms do not depend on $\mathbf{w}$, and the last sum is a sum of nonnegative terms, which is 0 if and only if $c_j = a_j$ for every j. So $\|\mathbf{v} - \mathbf{w}\|^2$ is smallest exactly when $\mathbf{w} = \sum_j a_j \mathbf{u}_j = \mathrm{Pr}_W(\mathbf{v})$, and the smallest value is $\|\mathbf{v}\|^2 - \sum_j |a_j|^2$. □

The first proof starts from the candidate $\mathrm{Pr}_W(\mathbf{v})$ and shows that it wins. The second does not need to know the answer in advance: completing the square produces the minimizing coefficients $c_j = \langle \mathbf{v}, \mathbf{u}_j \rangle$ and the minimum at the same time, and it shows that the squared error grows like $\sum_j |c_j - a_j|^2$ as $\mathbf{w}$ moves away from the optimum. In the language of Technique 6.4.5, the first proof says that for every $\mathbf{w} \in W$, the error $\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})$ is the piece of $\mathbf{v} - \mathbf{w}$ orthogonal to W: moving $\mathbf{w}$ around W changes only the piece in W, and dropping that piece can only shorten a vector.

The theorem gives a third reason why Pr_W does not depend on the orthonormal basis used to compute it: "the closest vector of W" is defined by distances alone. Putting Theorem 6.4.6 and Theorem 6.4.33 together, for $\mathbf{p} \in W$ the following are equivalent:

(i) $\mathbf{p} = \mathrm{Pr}_W(\mathbf{v})$, the formula computed from an orthonormal basis of W;
(ii) $\mathbf{v} - \mathbf{p} \perp W$;
(iii) $\|\mathbf{v} - \mathbf{p}\| \le \|\mathbf{v} - \mathbf{w}\|$ for every $\mathbf{w} \in W$.

In proofs one usually checks (ii), in computations one uses (i), and in applications the reason to care is (iii).

Definition 6.4.34 (Distance to a subspace). Let W be a finite-dimensional subspace of V and $\mathbf{v} \in V$. The **distance** from $\mathbf{v}$ to W is

$$\mathrm{dist}(\mathbf{v}, W) = \min_{\mathbf{w} \in W} \|\mathbf{v} - \mathbf{w}\| = \|\mathbf{v} - \mathrm{Pr}_W(\mathbf{v})\|.$$

The minimum exists by Theorem 6.4.33. So $\mathrm{dist}(\mathbf{v}, W) = 0$ if and only if $\mathbf{v} \in W$, and by Theorem 6.4.24, $\mathrm{dist}(\mathbf{v}, W)$ is the length of the component of $\mathbf{v}$ in $W^\perp$. When V is finite-dimensional, that component is $\mathrm{Pr}_{W^\perp}(\mathbf{v})$ (Proposition 6.4.29(d)).

Example 6.4.35 (Distance to a hyperplane). Let $\mathbf{n} \in \mathbb{F}^n$ be nonzero and $H = \{\mathbf{n}\}^\perp = \{\mathbf{x} \in \mathbb{F}^n \mid \mathbf{x} \cdot \mathbf{n} = 0\}$. Then $H = \mathrm{span}(\mathbf{n})^\perp$ (Proposition 6.3.9(c)), so $H^\perp = \mathrm{span}(\mathbf{n})$ by Theorem 6.4.26. By Proposition 6.4.29(d), $\mathbf{v} - \mathrm{Pr}_H(\mathbf{v}) = \mathrm{Pr}_{\mathrm{span}(\mathbf{n})}(\mathbf{v}) = \big(\langle \mathbf{v}, \mathbf{n} \rangle / \|\mathbf{n}\|^2 \big) \mathbf{n}$, and therefore

$$\mathrm{dist}(\mathbf{v}, H) = \frac{|\langle \mathbf{v}, \mathbf{n} \rangle|}{\|\mathbf{n}\|}.$$

For the plane $2x_1 - x_2 + 2x_3 = 0$ in $\mathbb{R}^3$ and $\mathbf{v} = (1,1,1)$, with $\mathbf{n} = (2,-1,2)$: $\langle \mathbf{v}, \mathbf{n} \rangle = 3$ and $\|\mathbf{n}\| = 3$, so $\operatorname{dist}(\mathbf{v}, H) = 1$, and the closest point of the plane is $\mathbf{v} - (3/9)\mathbf{n} = (1/3, 4/3, 1/3)$. This is the point-to-plane formula of multivariable calculus, now proved in every dimension and over $\mathbb{C}$.

Exercise 6.4.36. ROUTINE Find the point of the plane $W = \operatorname{span}((1,1,0),(1,0,1))$ in $\mathbb{R}^3$ closest to $\mathbf{v} = (0,0,3)$, and the distance from $\mathbf{v}$ to W. Check your answer with Example 6.4.35.

Solution on page 1497

Approximating functions

In a space of functions, Theorem 6.4.33 solves approximation problems. The inner product decides what "close" means. For $\langle f, g \rangle = \int_{-1}^{1} f(t)g(t)\,dt$, the distance $\|f - p\| = \left(\int_{-1}^{1} (f(t) - p(t))^2 \,dt \right)^{1/2}$ measures the error on average over the interval: it is small when $f - p$ is small on most of $[-1,1]$, even if it is larger at a few points.

Example 6.4.37 (The quadratic closest to e^t). In $C[-1,1]$ with $\langle f, g \rangle = \int_{-1}^{1} f(t)g(t)\,dt$, let W be the subspace of polynomial functions of degree at most 2. Which $p \in W$ makes $\int_{-1}^{1} \left(e^t - p(t)\right)^2 dt$ as small as possible? By Theorem 6.4.33 the answer is $p = \operatorname{Pr}_W(e^t)$. The orthogonal basis $1, t, t^2 - 1/3$ of Example 6.4.19, whose squared norms are 2, $2/3$, and $8/45$, and Corollary 6.4.10 give

$$p = \frac{\langle e^t, 1 \rangle}{2} + \frac{\langle e^t, t \rangle}{2/3} t + \frac{\langle e^t, t^2 - 1/3 \rangle}{8/45} \left(t^2 - \frac{1}{3} \right).$$

Integrating by parts,

$$\int_{-1}^{1} e^t \,dt = e - e^{-1},$$
$$\int_{-1}^{1} t e^t \,dt = 2e^{-1},$$
$$\int_{-1}^{1} t^2 e^t \,dt = e - 5e^{-1},$$

so $\langle e^t, t^2 - 1/3 \rangle = e - 5e^{-1} - (e - e^{-1})/3 = (2/3)(e - 7e^{-1})$. Therefore

$$p(t) = \frac{e - e^{-1}}{2} + 3e^{-1}t + \frac{15}{4}(e - 7e^{-1})\left(t^2 - \frac{1}{3}\right)$$
$$\approx 0.9963 + 1.1036t + 0.5367t^2.$$

Compare the Taylor polynomial $T(t) = 1 + t + t^2/2$, which is also quadratic. Figure 6.4.4 plots both errors. Near 0, T is better: it agrees with e^t to second order there. Over the whole interval, p is better. Its squared distance from e^t is $\int_{-1}^{1} (e^t - p)^2 \approx 0.0014$, against $\int_{-1}^{1} (e^t - T)^2 \approx 0.0090$ for T, and even its largest error on $[-1,1]$ is smaller: about 0.082 at $t = 1$, against 0.218 for T.

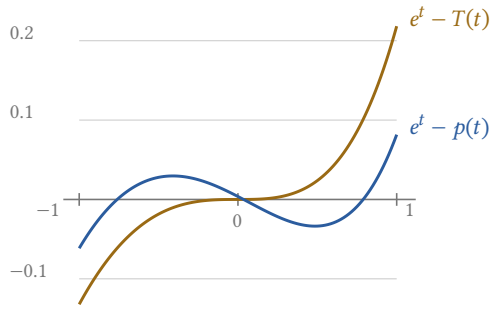

Figure 6.4.4. The errors $e^t - p(t)$ of the best quadratic approximation in the sense of Example 6.4.37, and $e^t - T(t)$ of the Taylor polynomial $T(t) = 1 + t + t^2/2$, on $[-1, 1]$. The Taylor error is tiny near 0 and large near the ends; the projection spreads the error over the interval and changes sign three times.

The error $g(t) = e^t - p(t)$ is orthogonal to 1, t, and t^2. It has at most three zeros, since $g''' = e^t > 0$ and, by Rolle's theorem, four zeros of g would give a zero of g'''. With this, the argument of Exercise 6.4.61 shows that g changes sign at least three times in $(-1, 1)$, as Figure 6.4.4 shows. The same recipe works for any continuous f and any degree n: run Gram–Schmidt on $1, t, \ldots, t^n$ once, and then each approximation costs $n + 1$ integrals. A function need not be differentiable to have a best approximation; Exercise 6.4.44 finds the quadratic closest to $|t|$, which has no Taylor polynomial at 0.

ASIDE: *Fourier truncation* BEYOND 21-242

Take the inner product $\langle f, g\rangle = \frac{1}{2\pi}\int_0^{2\pi} f(t)\overline{g(t)}\,dt$ on $C([0, 2\pi], \mathbb{C})$ and the orthonormal functions $e_k(t) = \cos kt + i \sin kt$ of Aside (Fourier coefficients), and let $W_N = \operatorname{span}(e_{-N}, \ldots, e_N)$, the *trigonometric polynomials* of degree at most N. By Theorem 6.4.33, the trigonometric polynomial of degree at most N closest to f is the *partial Fourier sum*

$$S_N f = \operatorname{Pr}_{W_N}(f) = \sum_{k=-N}^{N} c_k e_k, \quad c_k = \langle f, e_k\rangle,$$

and $\|f - S_N f\|^2 = \|f\|^2 - \sum_{k=-N}^{N} |c_k|^2$. Since $W_N \subseteq W_{N+1}$, the error can only decrease as N grows. For $f(t) = t$, integration by parts gives $c_0 = \pi$ and $c_k = i/k$ for $k \neq 0$, so

$$S_N f(t) = \pi - 2\sum_{k=1}^{N} \frac{\sin kt}{k},$$

$$\|f - S_N f\|^2 = \frac{4\pi^2}{3} - \pi^2 - 2\sum_{k=1}^{N} \frac{1}{k^2}.$$

The left side is nonnegative, so $\sum_{k=1}^{N} 1/k^2 \leq \pi^2/6$ for every N. In fact the error tends to 0 as $N \to \infty$ (Section 15.3), which gives Euler's formula $\sum_{k=1}^{\infty} 1/k^2 = \pi^2/6$.

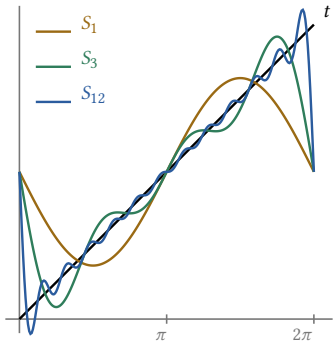

Figure 6.4.5. The function t on $[0, 2\pi]$ and its partial Fourier sums S_1, S_3, S_{12}. Each S_N is the closest trigonometric polynomial of degree at most N in the mean-square sense, and the fit improves with N except near the ends of the interval.

Best approximation in $\mathbb{F}^m$ is the subject of Section 6.5. There W is the image of a matrix A, and $\mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{b})$ is the closest one can come to solving an inconsistent system $A\mathbf{x} = \mathbf{b}$.

6.4.5 QR factorization BEYOND 21-242

QR factorization is Gram–Schmidt in matrix form. It is not covered in lecture; see LADR 7D.

Gram–Schmidt applied to the columns of a matrix factors the matrix. If A has linearly independent columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$ and Gram–Schmidt turns them into $\mathbf{u}_1, \ldots, \mathbf{u}_n$, then $\mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j) = \mathrm{span}(\mathbf{a}_1, \ldots, \mathbf{a}_j)$ for each j. So each $\mathbf{a}_j$ is a combination of $\mathbf{u}_1, \ldots, \mathbf{u}_j$ only, and recording the coefficients produces an upper triangular matrix.

Theorem 6.4.38 (QR factorization). Let $A \in \mathbb{F}^{m\times n}$ have linearly independent columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$. Then there are unique matrices $Q \in \mathbb{F}^{m\times n}$ with orthonormal columns and $R \in \mathbb{F}^{n\times n}$ upper triangular with positive real diagonal entries such that $A = QR$. The columns of Q are the output $\mathbf{u}_1, \ldots, \mathbf{u}_n$ of Gram–Schmidt applied to $\mathbf{a}_1, \ldots, \mathbf{a}_n$, and $r_{ij} = \langle \mathbf{a}_j, \mathbf{u}_i \rangle$ for $i \le j$.

Proof. HARD

Uses. Theorem 6.4.15 (Gram–Schmidt is correct), Proposition 6.3.18 (Coordinates in an orthonormal basis), Proposition 2.4.8 (Four views of the product), Lemma 3.3.32 (Products and inverses of triangular matrices), Theorem 6.3.29 (Orthonormal columns), Exercise 6.3.57, Proposition 6.3.27 (Properties of the conjugate transpose)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For existence, by Theorem 6.4.15(d), $\mathbf{a}_j \in \mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$. Expand it with Proposition 6.3.18(a), and read the coefficients as column j of R.
Hint 2. For uniqueness, suppose $QR = Q'R'$. Then $Q = Q'U$ with $U = R'R^{-1}$. What kind of matrix is U, and what does $Q^*Q = I_n$ say about it?
Hint 3. An upper triangular unitary matrix is diagonal (Exercise 6.3.57(c)).
Sketch. Existence: $\mathbf{a}_j = \sum_{i\le j}\langle \mathbf{a}_j, \mathbf{u}_i\rangle \mathbf{u}_i$, so column j of A is Q times the column $(r_{1j}, \ldots, r_{jj}, 0, \ldots, 0)$, and $r_{jj} = \|\mathbf{f}_j\| > 0$ by Theorem 6.4.15(d). Uniqueness: if $QR = Q'R'$, then $U = R'R^{-1}$ is upper triangular with positive diagonal and $Q = Q'U$; then $I_n = Q^*Q = U^*U$, so U is unitary and upper triangular, hence diagonal with entries of modulus 1, hence $U = I_n$.

Existence. By Theorem 6.4.15(d), Gram–Schmidt applied to $\mathbf{a}_1, \ldots, \mathbf{a}_n$ skips nothing, and its output $\mathbf{u}_1, \ldots, \mathbf{u}_n$ is orthonormal with $\mathbf{a}_j \in \mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$. By Proposition 6.3.18(a),

$$\mathbf{a}_j = \sum_{i=1}^{j} \langle \mathbf{a}_j, \mathbf{u}_i \rangle \mathbf{u}_i.$$

Let Q have columns $\mathbf{u}_1, \dots, \mathbf{u}_n$, and let $r_{ij} = \langle \mathbf{a}_j, \mathbf{u}_i \rangle$ for $i \le j$ and $r_{ij} = 0$ for $i > j$. Then R is upper triangular, $r_{jj} = \|\mathbf{f}_j\| > 0$ by Theorem 6.4.15(d), and by the column view of Proposition 2.4.8, column j of QR is $\sum_i r_{ij}\mathbf{u}_i = \mathbf{a}_j$. So $A = QR$.

Uniqueness. Suppose $A = QR = Q'R'$, where both pairs have the stated properties. An upper triangular matrix R with nonzero diagonal entries is invertible with upper triangular inverse, whose diagonal entries are $1/r_{jj}$: write $R = DN$ with D the diagonal matrix of the r_{jj} and $N = D^{-1}R$ unit upper triangular, and apply Lemma 3.3.32 to get $R^{-1} = N^{-1}D^{-1}$. So $U = R'R^{-1}$ is upper triangular with diagonal entries $r'_{jj}/r_{jj} > 0$, again by Lemma 3.3.32. Multiplying $QR = Q'R'$ on the right by R^{-1} gives $Q = Q'U$. Since Q and Q' have orthonormal columns, Theorem 6.3.29 and Proposition 6.3.27 give

$$I_n = Q^*Q = U^*Q'^*Q'U = U^*U.$$

So the square matrix U is unitary and upper triangular. By Exercise 6.3.57(c) it is diagonal with diagonal entries of modulus 1, and these entries are positive, so $U = I_n$. Hence $R' = UR = R$ and $Q' = QU^{-1} = Q$.□

The factorization repackages several earlier facts. The columns of Q are an orthonormal basis of $\operatorname{im} A$, so $\operatorname{Pr}_{\operatorname{im} A} = QQ^*$ by Theorem 6.4.31. If A is square, then Q is unitary, so $|\det A| = |\det Q| \det R = r_{11}\cdots r_{nn}$ (Theorem 5.4.10, Proposition 5.3.15, Exercise 6.3.57), and the system $A\mathbf{x} = \mathbf{b}$ becomes $R\mathbf{x} = Q^*\mathbf{b}$, which is solved by back substitution. Section 6.5 uses the same reduction for inconsistent systems.

Example 6.4.39 (A QR factorization). Let A have the columns $\mathbf{a}_1 = (1,1,0)$, $\mathbf{a}_2 = (1,0,1)$, $\mathbf{a}_3 = (0,1,1)$ of Example 6.4.17. The output of Gram–Schmidt was $\mathbf{u}_1 = (1,1,0)/\sqrt{2}$, $\mathbf{u}_2 = (1,-1,2)/\sqrt{6}$, $\mathbf{u}_3 = (-1,1,1)/\sqrt{3}$, and the entries of R are the inner products $r_{ij} = \langle \mathbf{a}_j, \mathbf{u}_i \rangle$:

$$A = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{pmatrix} = QR,$$

where

$$Q = \begin{pmatrix} 1/\sqrt{2} & 1/\sqrt{6} & -1/\sqrt{3} \\ 1/\sqrt{2} & -1/\sqrt{6} & 1/\sqrt{3} \\ 0 & 2/\sqrt{6} & 1/\sqrt{3} \end{pmatrix},$$

$$R = \begin{pmatrix} \sqrt{2} & 1/\sqrt{2} & 1/\sqrt{2} \\ 0 & 3/\sqrt{6} & 1/\sqrt{6} \\ 0 & 0 & 2/\sqrt{3} \end{pmatrix}.$$

The diagonal entries $\sqrt{2}, 3/\sqrt{6}, 2/\sqrt{3}$ are the lengths of the residuals, and their product is $2 = |\det A|$.

In floating-point arithmetic, Algorithm 6.4.14 as written can lose orthogonality badly when the columns are nearly dependent. Practical codes reorder the same computation (*modified Gram–Schmidt*) or build Q from reflections instead (Section 9.3).

Exercises

Exercise 6.4.40. ROUTINE In $\mathbb{R}^4$, let $W = \operatorname{span}(\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3)$ with $\mathbf{v}_1 = (1,1,1,1)$, $\mathbf{v}_2 = (2,0,0,2)$, $\mathbf{v}_3 = (0,2,0,0)$.

(a) Find an orthonormal basis of W with Gram–Schmidt.

(b) Find $\operatorname{Pr}_W(\mathbf{b})$ for $\mathbf{b} = (1,2,3,4)$, and $\operatorname{dist}(\mathbf{b}, W)$.

(c) Find $W^{\perp}$.

Solution on page 1498

Exercise 6.4.41. ROUTINE Let $W = \operatorname{span}((1,0,1),(1,1,0))$ in $\mathbb{R}^3$. Find the matrix P of Pr_W in two ways: (a) by Gram–Schmidt and Theorem 6.4.31, and (b) from a vector $\mathbf{n}$ spanning $W^\perp$. Check that $P^2 = P$, $P^{\mathsf{T}} = P$, and $\operatorname{tr} P = 2$.

Solution on page 1498

Exercise 6.4.42. ROUTINE To project $\mathbf{v} = (1,2,3)$ onto $W = \operatorname{span}(\mathbf{a},\mathbf{b})$, where $\mathbf{a} = (1,0,0)$ and $\mathbf{b} = (1,1,0)$, a student adds the shadows of $\mathbf{v}$ on the two spanning vectors:

$$\frac{\langle \mathbf{v},\mathbf{a}\rangle}{\|\mathbf{a}\|^2}\mathbf{a} + \frac{\langle \mathbf{v},\mathbf{b}\rangle}{\|\mathbf{b}\|^2}\mathbf{b} = (1,0,0) + \frac{3}{2}(1,1,0) = \left(\frac{5}{2},\frac{3}{2},0\right).$$

Find the error, show that the answer fails the test of Theorem 6.4.6, and compute $\mathrm{Pr}_W(\mathbf{v})$ correctly.

Solution on page 1499

Exercise 6.4.43. ROUTINE Run Gram–Schmidt on $\mathbf{v}_1 = (1,0,1,0)$, $\mathbf{v}_2 = (1,1,0,0)$, $\mathbf{v}_3 = (0,1,-1,0)$, $\mathbf{v}_4 = (0,0,0,1)$ in $\mathbb{R}^4$. Which vector is skipped? Use the computation to write the skipped vector as a combination of the earlier ones, and give $\dim \operatorname{span}(\mathbf{v}_1,\dots,\mathbf{v}_4)$.

Solution on page 1499

Exercise 6.4.44. STANDARD In $C[-1,1]$ with $\langle f,g\rangle = \int_{-1}^{1} f(t)g(t)\,dt$, find the polynomial functions of degree at most 0, at most 1, and at most 2 closest to $f(t) = |t|$, and the squared distance from f to each.

Solution on page 1500

Exercise 6.4.45. STANDARD Find the minimum of $\int_{-1}^{1} \left(t^3 - a - bt - ct^2\right)^2 dt$ over all $a,b,c \in \mathbb{R}$, and the values of a,b,c that attain it.

Solution on page 1501

Exercise 6.4.46. STANDARD Give $\mathbb{R}[x]_{\le 2}$ the inner product $\langle p,q\rangle = \int_0^1 p(t)q(t)\,dt$ used in lecture.

(a) Apply Gram–Schmidt to $1, x, x^2$, and show that the output is 1, $\sqrt{3}(2x-1)$, $\sqrt{5}\left(6x^2-6x+1\right)$.

(b) Find $\min_{a,b\in\mathbb{R}} \int_0^1 \left(t^2 - a - bt\right)^2 dt$.

Solution on page 1501

Exercise 6.4.47. STANDARD Let U and W be subspaces of V.

(a) Show that $(U+W)^\perp = U^\perp \cap W^\perp$.

(b) Suppose V is finite-dimensional. Show that $(U \cap W)^\perp = U^\perp + W^\perp$.

Solution on page 1502

Exercise 6.4.48. STANDARD Let V be a finite-dimensional inner product space and U, W subspaces of V. Prove or disprove each statement.

(a) If $V = U \oplus W$, then $W = U^\perp$.

(b) If every vector of U is orthogonal to every vector of W and $U + W = V$, then $W = U^\perp$.

(c) $\mathrm{Pr}_U \mathrm{Pr}_W = \mathrm{Pr}_W \mathrm{Pr}_U$.

(d) If $\|\mathrm{Pr}_W(\mathbf{v})\| = \|\mathbf{v}\|$, then $\mathbf{v} \in W$.

(e) Every $P \in \mathrm{L}(V)$ with $P^2 = P$ satisfies $\|P\mathbf{v}\| \leq \|\mathbf{v}\|$ for all $\mathbf{v} \in V$.

Solution on page 1502

Exercise 6.4.49. STANDARD Let U and W be finite-dimensional subspaces of V.

(a) Suppose every vector of U is orthogonal to every vector of W. Show that $\mathrm{Pr}_{U+W} = \mathrm{Pr}_U + \mathrm{Pr}_W$ and $\mathrm{Pr}_U \mathrm{Pr}_W = 0$.

(b) Conversely, show that if $\mathrm{Pr}_U \mathrm{Pr}_W = 0$, then every vector of U is orthogonal to every vector of W.

Solution on page 1503

Exercise 6.4.50. STANDARD Find the error in the following argument, and decide whether the claim is true.

Claim. If U and W are finite-dimensional subspaces of V, then $\mathrm{Pr}_{U+W} = \mathrm{Pr}_U + \mathrm{Pr}_W$.

Argument. Let $\mathbf{v} \in V$ and $\mathbf{p} = \mathrm{Pr}_U(\mathbf{v}) + \mathrm{Pr}_W(\mathbf{v})$, which lies in $U + W$. We have $\mathbf{v} - \mathrm{Pr}_U(\mathbf{v}) \perp U$ and $\mathrm{Pr}_W(\mathbf{v}) \perp U$, so $\mathbf{v} - \mathbf{p} = (\mathbf{v} - \mathrm{Pr}_U(\mathbf{v})) - \mathrm{Pr}_W(\mathbf{v}) \perp U$. In the same way $\mathbf{v} - \mathbf{p} \perp W$, so $\mathbf{v} - \mathbf{p} \perp U + W$. By Theorem 6.4.6, $\mathbf{p} = \mathrm{Pr}_{U+W}(\mathbf{v})$.

Solution on page 1503

Exercise 6.4.51. STANDARD Let W be a k-dimensional subspace of $\mathbb{F}^n$, and let P be the matrix of Pr_W.

(a) Show that $\operatorname{rank} P = \operatorname{tr} P = k$.

(b) Show that $p_{ii} = \|P\mathbf{e}_i\|^2$ for each i, and deduce that $\sum_{i=1}^n \|\mathrm{Pr}_W(\mathbf{e}_i)\|^2 = k$.

(c) Deduce that some standard basis vector $\mathbf{e}_i$ satisfies $\operatorname{dist}(\mathbf{e}_i, W)^2 \leq 1 - k/n$.

Solution on page 1504

Exercise 6.4.52. STANDARD Let W be a finite-dimensional subspace of V and $\mathbf{v} \in V$ with $\mathbf{v} \notin W$.

(a) Show that

$$\operatorname{dist}(\mathbf{v}, W) = \max\bigl\{|\langle \mathbf{v}, \mathbf{x}\rangle| \;\bigm|\; \mathbf{x} \in W^\perp, \|\mathbf{x}\| = 1\bigr\},$$

and find the $\mathbf{x}$ attaining the maximum.

(b) In $C[-1,1]$ with $\langle f, g\rangle = \int_{-1}^1 fg$, find the largest value of $\int_{-1}^1 t^3 g(t)\,\mathrm{d}t$ over all g with $\int_{-1}^1 g^2 = 1$ that are orthogonal to $1, t, t^2$.

Solution on page 1504

Exercise 6.4.53. STANDARD

(a) Let U be a finite-dimensional subspace of V, and let $\mathbf{x}_0, \mathbf{y} \in V$. Show that among the vectors of $\mathbf{x}_0 + U = \{\mathbf{x}_0 + \mathbf{u} \mid \mathbf{u} \in U\}$, the one closest to $\mathbf{y}$ is $\mathbf{x}_0 + \mathrm{Pr}_U(\mathbf{y} - \mathbf{x}_0)$, and that it is unique.

(b) Find the solution of smallest norm of the system $x_1 + x_2 = 2$, $x_2 + x_3 = 2$ in $\mathbb{R}^3$, and check that it is orthogonal to every solution of the homogeneous system.

Solution on page 1505

Exercise 6.4.54. STANDARD In $C[-1,1]$ with $\langle f,g\rangle = \int_{-1}^{1} f(t)g(t)\,\mathrm{d}t$, let E be the subspace of even functions and O the subspace of odd functions.

(a) Show that $E^\perp = O$ and $O^\perp = E$.

(b) Let $f \in C[-1,1]$ and $f_e(t) = (f(t)+f(-t))/2$. Show that f_e is the unique even function closest to f, although E is infinite-dimensional.

Solution on page 1505

Exercise 6.4.55. STANDARD

(a) Let $\mathbf{u}_1,\dots,\mathbf{u}_m$ and $\mathbf{u}'_1,\dots,\mathbf{u}'_m$ be orthonormal lists in V with $\operatorname{span}(\mathbf{u}_1,\dots,\mathbf{u}_j) = \operatorname{span}(\mathbf{u}'_1,\dots,\mathbf{u}'_j)$ for every j. Show that $\mathbf{u}'_j = \lambda_j \mathbf{u}_j$ for scalars λ_j with $|\lambda_j| = 1$.

(b) Let $\mathbf{v}_1,\dots,\mathbf{v}_m$ be linearly independent. Show that the output of Gram–Schmidt is the only orthonormal list $\mathbf{u}_1,\dots,\mathbf{u}_m$ such that, for every j, $\operatorname{span}(\mathbf{u}_1,\dots,\mathbf{u}_j) = \operatorname{span}(\mathbf{v}_1,\dots,\mathbf{v}_j)$ and $\langle \mathbf{v}_j, \mathbf{u}_j\rangle$ is a positive real number.

Solution on page 1506

Exercise 6.4.56. STANDARD Give $\mathbb{R}[x]$ the inner product $\langle p,q\rangle = \int_{-1}^{1} p(t)q(t)\,\mathrm{d}t$, and let $n \geq 1$. Among all polynomials of degree n with leading coefficient 1, show that exactly one has the smallest norm, namely $x^n - \operatorname{Pr}_W(x^n)$ with $W = \mathbb{R}[x]_{\leq n-1}$, the $(n+1)$st Gram–Schmidt residual of $1, x, x^2, \dots$. Find the smallest value of $\int_{-1}^{1} p(t)^2\,\mathrm{d}t$ for $n = 2$ and $n = 3$.

Solution on page 1506

Exercise 6.4.57. HARD Let V be finite-dimensional and let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$. Show that the following are equivalent:

(i) P is an orthogonal projection, that is, $P = \operatorname{Pr}_{\operatorname{im} P}$;

(ii) every vector of $\ker P$ is orthogonal to every vector of $\operatorname{im} P$;

(iii) $\|P\mathbf{v}\| \leq \|\mathbf{v}\|$ for every $\mathbf{v} \in V$.

Solution on page 1506

Exercise 6.4.58. HARD Let V be finite-dimensional, let U and W be subspaces, and let $P = \operatorname{Pr}_U$ and $Q = \operatorname{Pr}_W$. Show that PQ is an orthogonal projection if and only if $PQ = QP$, and that in this case $PQ = \operatorname{Pr}_{U\cap W}$.

Solution on page 1507

Exercise 6.4.59. HARD Let $\mathbf{v}_1,\dots,\mathbf{v}_m$ be linearly independent in V, with Gram matrix G (Definition 6.3.28). Run Gram–Schmidt, with residuals $\mathbf{f}_j$ and output $\mathbf{u}_j$, and let $R \in \mathbb{F}^{m\times m}$ have entries $r_{ij} = \langle \mathbf{v}_j, \mathbf{u}_i\rangle$.

(a) Show that R is upper triangular with diagonal entries $\|\mathbf{f}_1\|,\dots,\|\mathbf{f}_m\|$, and that $G = R^*R$.

(b) Deduce that $\det G = \|\mathbf{f}_1\|^2 \cdots \|\mathbf{f}_m\|^2$, and that $\operatorname{dist}(\mathbf{v}_m, \operatorname{span}(\mathbf{v}_1,\dots,\mathbf{v}_{m-1}))^2 = \det G_m / \det G_{m-1}$, where G_j is the Gram matrix of $\mathbf{v}_1,\dots,\mathbf{v}_j$ and $\det G_0 = 1$.

(c) (*Hadamard's inequality.*) Show that $\det G \leq \|\mathbf{v}_1\|^2 \cdots \|\mathbf{v}_m\|^2$, with equality if and only if the list is orthogonal. Deduce that $|\det A| \leq \|\mathbf{a}_1\| \cdots \|\mathbf{a}_n\|$ for every $A \in \mathbb{F}^{n\times n}$ with columns $\mathbf{a}_1,\dots,\mathbf{a}_n$.

Solution on page 1507

Exercise 6.4.60. HARD Let V be finite-dimensional, and let $W_1,\dots,W_m$ be subspaces of V with

$$\mathrm{Pr}_{W_1} + \cdots + \mathrm{Pr}_{W_m} = \mathrm{id}_V.$$

Show that every vector of W_i is orthogonal to every vector of W_j for $i \neq j$, and that every $\mathbf{v} \in V$ can be written in exactly one way as $\mathbf{v} = \mathbf{w}_1 + \cdots + \mathbf{w}_m$ with $\mathbf{w}_i \in W_i$.

Solution on page 1508

Exercise 6.4.61. HARD Let $n \geq 1$, and let $p \in \mathbb{R}[x]$ be a polynomial of degree n with $\int_{-1}^{1} p(t)q(t)\,dt = 0$ for every polynomial q of degree less than n. (For example, the Legendre polynomial P_n of Example 6.4.19.) Show that p has n distinct roots, all in the open interval $(-1, 1)$.

Solution on page 1509

Exercise 6.4.62. CHALLENGE Let $\mathbf{v}_1, \ldots, \mathbf{v}_m \in \mathbb{R}^n$ satisfy $\langle \mathbf{v}_i, \mathbf{v}_j \rangle < 0$ for all $i \neq j$. Show that $m \leq n + 1$, and find $n + 1$ such vectors in $\mathbb{R}^n$.

Solution on page 1509

Exercise 6.4.63. HARD BEYOND 21-242 Give $\mathbb{R}[x]$ the inner product $\langle p, q \rangle = \sum_{k \geq 0} p_k q_k$, where $p = \sum_k p_k x^k$ and $q = \sum_k q_k x^k$, and let $W = \{p \in \mathbb{R}[x] \mid p(1) = 0\}$.

(a) Show that W is a subspace with $W \neq \mathbb{R}[x]$, but $W^\perp = \{\mathbf{0}\}$.

(b) Deduce that $\mathbb{R}[x] \neq W \oplus W^\perp$ and $\left(W^\perp\right)^\perp \neq W$.

(c) Show that no vector of W is closest to the constant polynomial 1, although $\inf_{w \in W} \|1 - w\| = 0$.

Solution on page 1510

Exercise 6.4.64. ROUTINE BEYOND 21-242 Let $A = \begin{pmatrix} 1 & 3 \\ 2 & 3 \\ 2 & 0 \end{pmatrix}$.

(a) Find the QR factorization of A.

(b) Use it to find $\mathrm{Pr}_{\mathrm{im}\, A}(\mathbf{e}_1)$.

(c) Check that $A^\mathsf{T} A = R^\mathsf{T} R$.

Solution on page 1511

6.5 Least squares

A linear system with more equations than unknowns usually has no solution, and that is the normal situation with measured data. Suppose the length of a spring is measured under five different loads. Hooke's law says that the five data points lie on a line $y = c_0 + c_1 x$, which gives five linear equations in the two unknowns c_0, c_1, and small measurement errors make them inconsistent. When no $\mathbf{x}$ satisfies $A\mathbf{x} = \mathbf{b}$, the natural substitute is an $\mathbf{x}$ for which $A\mathbf{x}$ is as close to $\mathbf{b}$ as possible. As $\mathbf{x}$ varies, $A\mathbf{x}$ runs over the column space $\mathrm{im}\, A$, so this asks for the point of $\mathrm{im}\, A$ closest to $\mathbf{b}$, and Theorem 6.4.33 says that this point is $\mathrm{Pr}_{\mathrm{im}\, A}(\mathbf{b})$. This section turns the observation into a computation, the *normal equations* $A^* A\mathbf{x} = A^*\mathbf{b}$, which find the best $\mathbf{x}$ without an orthonormal basis of $\mathrm{im}\, A$, and applies it to fitting lines and curves to data.

Throughout, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$, $A \in \mathbb{F}^{m \times n}$ has columns $\mathbf{a}_1, \ldots, \mathbf{a}_n$, and $\mathbf{b} \in \mathbb{F}^m$. The spaces $\mathbb{F}^m$ and $\mathbb{F}^n$ carry the dot product (Definition 6.1.8), so $\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{v}^* \mathbf{u}$ and $\|\mathbf{u}\|^2 = \sum_i |u_i|^2$. Only Section 6.5.5 and the exercises built on it use other inner products.

6.5.1 The least-squares problem

Intuition (Solving as well as possible). As $\mathbf{x}$ ranges over $\mathbb{F}^n$, the vector $A\mathbf{x} = x_1\mathbf{a}_1 + \cdots + x_n\mathbf{a}_n$ ranges over the column space $\operatorname{im} A = \operatorname{span}(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ (Proposition 2.6.18). So $A\mathbf{x} = \mathbf{b}$ has a solution exactly when $\mathbf{b} \in \operatorname{im} A$. If $\mathbf{b} \notin \operatorname{im} A$, every $A\mathbf{x}$ misses $\mathbf{b}$, and the best we can ask for is that the miss $\|\mathbf{b} - A\mathbf{x}\|$ be as small as possible. That is, we want the point of the subspace $\operatorname{im} A$ nearest to $\mathbf{b}$.

Picture $m = 3$, with $\operatorname{im} A$ a plane through $\mathbf{0}$ and $\mathbf{b}$ off the plane (Figure 6.5.1). The nearest point of the plane is the foot of the perpendicular from $\mathbf{b}$, which is $\operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$. It lies in $\operatorname{im} A$, so it equals $A\hat{\mathbf{x}}$ for some $\hat{\mathbf{x}}$, and that $\hat{\mathbf{x}}$ is the best we can do. So the problem splits into a geometric step, projecting $\mathbf{b}$ onto $\operatorname{im} A$, and an algebraic one, solving $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$, a system that is consistent by construction. The normal equations of Section 6.5.2 merge the two steps.

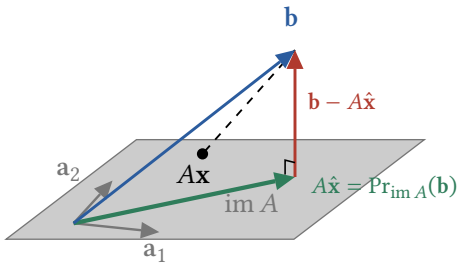

Figure 6.5.1. The column space $\operatorname{im} A = \operatorname{span}(\mathbf{a}_1, \mathbf{a}_2)$ (shaded) and a vector $\mathbf{b} \notin \operatorname{im} A$. The point of $\operatorname{im} A$ closest to $\mathbf{b}$ is the foot $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$ of the perpendicular, and the residual $\mathbf{b} - A\hat{\mathbf{x}}$ is orthogonal to $\operatorname{im} A$. Every other point $A\mathbf{x}$ of $\operatorname{im} A$ is farther from $\mathbf{b}$ (dashed).

Definition 6.5.1 (Least-squares solution). Let $A \in \mathbb{F}^{m\times n}$ and $\mathbf{b} \in \mathbb{F}^m$. A **least-squares solution** of $A\mathbf{x} = \mathbf{b}$ is a vector $\hat{\mathbf{x}} \in \mathbb{F}^n$ such that

$$\|\mathbf{b} - A\hat{\mathbf{x}}\| \le \|\mathbf{b} - A\mathbf{x}\| \quad \text{for every } \mathbf{x} \in \mathbb{F}^n.$$

For such an $\hat{\mathbf{x}}$, the vector $\mathbf{b} - A\hat{\mathbf{x}}$ is the **residual**, and $\|\mathbf{b} - A\hat{\mathbf{x}}\|$ is the **least-squares error**.

The name comes from the quantity being minimized. In coordinates,

$$\|\mathbf{b} - A\mathbf{x}\|^2 = \sum_{i=1}^{m} |b_i - (A\mathbf{x})_i|^2,$$

the sum of the squares of the errors in the m equations. If $A\mathbf{x} = \mathbf{b}$ has a solution, its least-squares solutions are exactly its solutions: the solutions have error 0, and by definiteness only they do. The course writes $A\mathbf{x} \approx \mathbf{b}$ for the problem of finding a least-squares solution.

The intuition above becomes the following proposition, which is Theorem 6.4.33 read for the subspace $\operatorname{im} A$.

Proposition 6.5.2 (Least squares is projection). Let $A \in \mathbb{F}^{m\times n}$ and $\mathbf{b} \in \mathbb{F}^m$.

(a) $\hat{\mathbf{x}} \in \mathbb{F}^n$ is a least-squares solution of $A\mathbf{x} = \mathbf{b}$ if and only if $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$.

(b) Least-squares solutions exist. If $\hat{\mathbf{x}}$ is one, the set of all of them is $\hat{\mathbf{x}} + \ker A = \{\hat{\mathbf{x}} + \mathbf{z} \mid \mathbf{z} \in \ker A\}$.

(c) The least-squares solution is unique if and only if the columns of A are linearly independent.

(d) The least-squares error is $\operatorname{dist}(\mathbf{b}, \operatorname{im} A)$.

Proof. ROUTINE

Uses. Proposition 2.6.18 (The column space is spanned by the columns), Theorem 6.4.20 (Orthonormal bases exist), Theorem 6.4.33 (Best approximation), Corollary 2.6.31 (Fibers are translates of the kernel), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Corollary 2.6.24 (The columns decide), Definition 6.4.34 (Distance to a subspace)
Hint 1. Every vector of $\operatorname{im} A$ has the form $A\mathbf{x}$. So minimizing $\|\mathbf{b} - A\mathbf{x}\|$ over $\mathbf{x} \in \mathbb{F}^n$ is minimizing $\|\mathbf{b} - \mathbf{w}\|$ over $\mathbf{w} \in \operatorname{im} A$.
Hint 2. For (a), use both halves of Theorem 6.4.33: the inequality and its equality case.
Hint 3. For (b), $\operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$ lies in $\operatorname{im} A$. And $A\mathbf{x} = A\hat{\mathbf{x}}$ exactly when $\mathbf{x} - \hat{\mathbf{x}} \in \ker A$.
Sketch. Let $\mathbf{p} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$. If $A\hat{\mathbf{x}} = \mathbf{p}$, then $\|\mathbf{b} - \mathbf{p}\| \le \|\mathbf{b} - A\mathbf{x}\|$ for all $\mathbf{x}$ by Theorem 6.4.33, since $A\mathbf{x} \in \operatorname{im} A$. Conversely, a least-squares solution does at least as well as any $\mathbf{x}_0$ with $A\mathbf{x}_0 = \mathbf{p}$, so $A\hat{\mathbf{x}}$ is a point of $\operatorname{im} A$ at least as close to $\mathbf{b}$ as $\mathbf{p}$, and the equality case forces $A\hat{\mathbf{x}} = \mathbf{p}$. The least-squares solutions are then the solutions of the consistent system $A\mathbf{x} = \mathbf{p}$, which form $\hat{\mathbf{x}} + \ker A$; this is a single point exactly when $\ker A = \{\mathbf{0}\}$.

The column space $W = \operatorname{im} A$ is a subspace of the finite-dimensional space $\mathbb{F}^m$, so it has an orthonormal basis and Pr_W is defined (Theorem 6.4.20). Let $\mathbf{p} = \operatorname{Pr}_W(\mathbf{b})$. By Proposition 2.6.18, every vector of W has the form $A\mathbf{x}$.

(a) Suppose $A\hat{\mathbf{x}} = \mathbf{p}$, and let $\mathbf{x} \in \mathbb{F}^n$. Since $A\mathbf{x} \in W$, Theorem 6.4.33 gives

$$\|\mathbf{b} - A\hat{\mathbf{x}}\| = \|\mathbf{b} - \mathbf{p}\| \le \|\mathbf{b} - A\mathbf{x}\|.$$

Conversely, suppose $\hat{\mathbf{x}}$ is a least-squares solution. Since $\mathbf{p} \in W$, there is $\mathbf{x}_0$ with $A\mathbf{x}_0 = \mathbf{p}$, and so $\|\mathbf{b} - A\hat{\mathbf{x}}\| \le \|\mathbf{b} - A\mathbf{x}_0\| = \|\mathbf{b} - \mathbf{p}\|$. On the other hand, $A\hat{\mathbf{x}} \in W$, so $\|\mathbf{b} - \mathbf{p}\| \le \|\mathbf{b} - A\hat{\mathbf{x}}\|$ by Theorem 6.4.33. So equality holds, and by the equality case of Theorem 6.4.33, $A\hat{\mathbf{x}} = \mathbf{p}$.

(b) Since $\mathbf{p} \in W$, there is $\hat{\mathbf{x}}$ with $A\hat{\mathbf{x}} = \mathbf{p}$, and it is a least-squares solution by (a). By (a), the least-squares solutions are exactly the solutions of the consistent system $A\mathbf{x} = \mathbf{p}$, and by Corollary 2.6.31 (applied to T_A) these form the set $\hat{\mathbf{x}} + \ker A$.

(c) By (b), the least-squares solution is unique if and only if $\ker A = \{\mathbf{0}\}$, that is, if and only if T_A is injective (Theorem 2.6.11). By Corollary 2.6.24, this happens if and only if the columns of A are linearly independent.

(d) By (a) and Definition 6.4.34, $\|\mathbf{b} - A\hat{\mathbf{x}}\| = \|\mathbf{b} - \operatorname{Pr}_W(\mathbf{b})\| = \operatorname{dist}(\mathbf{b}, W)$. □

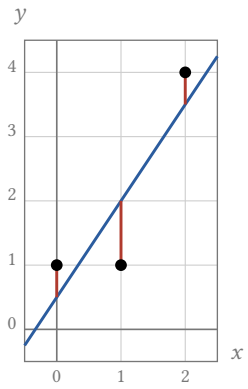
By (b), the set of least-squares solutions has the same shape as the solution set of a consistent system (Proposition 3.1.19), and for a good reason: it is the solution set of the consistent system $A\mathbf{x} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$. Note also that the vector $A\hat{\mathbf{x}}$ is always unique, even when $\hat{\mathbf{x}}$ is not.

Example 6.5.3 (Three points and a line). No line passes through the three points $(0, 1), (1, 1), (2, 4)$. Let us find the line $y = c_0 + c_1 x$ that comes closest, in the sense that the sum of the squared vertical gaps between the points and the line is as small as possible. The line passes through all three points exactly when

$$c_0 + 0c_1 = 1, \quad c_0 + 1c_1 = 1, \quad c_0 + 2c_1 = 4,$$

that is, when $A\mathbf{c} = \mathbf{y}$ for the unknown $\mathbf{c} = (c_0, c_1)$, where

$$A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 1 & 2 \end{pmatrix}, \quad \mathbf{y} = \begin{pmatrix} 1 \\ 1 \\ 4 \end{pmatrix}.$$



The first two equations force $c_1 = 0$ and $c_0 = 1$, and then the third says $1 = 4$, so the system is inconsistent. The ith entry of $\mathbf{y} - A\mathbf{c}$ is the vertical gap $y_i - (c_0 + c_1 x_i)$ at the ith point, so the best line comes from the least-squares solution of $A\mathbf{c} = \mathbf{y}$.

The column space is the plane in $\mathbb{R}^3$ spanned by $\mathbf{1} = (1, 1, 1)$ and $\mathbf{x} = (0, 1, 2)$. These are not orthogonal, so we first run Gram–Schmidt (Algorithm 6.4.14): $\mathbf{x} - (\langle \mathbf{x}, \mathbf{1} \rangle / 3)\mathbf{1} = (0, 1, 2) - (1, 1, 1) = (-1, 0, 1)$. With the orthogonal basis $\mathbf{1}, (-1, 0, 1)$ of $\operatorname{im} A$, Corollary 6.4.10 gives

$$\operatorname{Pr}_{\operatorname{im} A}(\mathbf{y}) = \frac{6}{3}(1, 1, 1) + \frac{3}{2}(-1, 0, 1) = \left(\frac{1}{2}, 2, \frac{7}{2}\right).$$

Solving $A\mathbf{c} = (1/2, 2, 7/2)$ gives $c_0 = 1/2$ and $c_1 = 3/2$, and the third equation checks: $1/2 + 2 \cdot 3/2 = 7/2$. The columns of A are independent, so by Proposition 6.5.2 the least-squares line is unique: it is $y = \frac{1}{2} + \frac{3}{2}x$.

The residual is $\mathbf{y} - A\mathbf{c} = (1/2, -1, 1/2)$. Its entries are the three vertical gaps, the red segments in the plot below, and the sum of their squares is $3/2$. In $\mathbb{R}^3$ it is a single vector, orthogonal to the plane $\operatorname{im} A$: indeed $(1/2, -1, 1/2) \cdot (1, 1, 1) = 0$ and $(1/2, -1, 1/2) \cdot (0, 1, 2) = 0$. Minimizing the sum of the squared gaps in the plot is the same as minimizing the length of one vector in $\mathbb{R}^3$.

The line of Example 6.5.3 and its residuals (red). In the interactive version, "Column space" shows the same fit in $\mathbb{R}^3$: the data vector $\mathbf{y}$, its projection $A\mathbf{c}$ onto the plane spanned by $\mathbf{1}$ and $\mathbf{x}$, and the residual, whose three coordinates are the three red gaps in the plot. Drag the points and watch the residual vector stay perpendicular to the plane. (Interactive in the web version.)

The computation in Example 6.5.3 took a detour. We wanted the coefficients $\mathbf{c}$, but we first computed an orthogonal basis of $\operatorname{im} A$ and the vector $A\mathbf{c}$, and only then solved for $\mathbf{c}$. The normal equations go to $\mathbf{c}$ directly.

6.5.2 The normal equations

Intuition (Why the residual is perpendicular). Here is a direct reason, without Theorem 6.4.33, why the best $A\mathbf{x}$ must be the foot of the perpendicular. Take any candidate $A\mathbf{x}$ and its residual $\mathbf{r} = \mathbf{b} - A\mathbf{x}$. Suppose $\mathbf{r}$ is not perpendicular to $\operatorname{im} A$, so that $\langle \mathbf{r}, \mathbf{w} \rangle \neq 0$ for some $\mathbf{w} \in \operatorname{im} A$; replacing $\mathbf{w}$ by a scalar multiple, we may take $\langle \mathbf{r}, \mathbf{w} \rangle$ real and positive. Slide the candidate a little in the direction $\mathbf{w}$, to $A\mathbf{x} + t\mathbf{w}$ with $t > 0$, which is still in $\operatorname{im} A$. Its distance to $\mathbf{b}$ satisfies

$$\|\mathbf{r} - t\mathbf{w}\|^2 = \|\mathbf{r}\|^2 - 2t\langle \mathbf{r}, \mathbf{w} \rangle + t^2\|\mathbf{w}\|^2$$

by Proposition 6.1.29. For small $t > 0$ the term $-2t\langle \mathbf{r}, \mathbf{w} \rangle$ beats $t^2\|\mathbf{w}\|^2$, so the new candidate is strictly closer. A candidate whose residual has any component along $\operatorname{im} A$ can be improved by sliding toward that component. So the best candidate, if there is one, has a residual orthogonal to all of $\operatorname{im} A$, which is the condition of Theorem 6.4.6.

The condition $\mathbf{r} \perp \operatorname{im} A$ is checked one column at a time, since $\operatorname{im} A$ is spanned by the columns. And "$\mathbf{r} \perp \mathbf{a}_j$ for every j" is a single matrix equation: $\mathbf{a}_j^* \mathbf{r}$ is the jth entry of $A^* \mathbf{r}$. With $\mathbf{r} = \mathbf{b} - A\mathbf{x}$, the condition $A^*(\mathbf{b} - A\mathbf{x}) = \mathbf{0}$ is a linear system for $\mathbf{x}$. Here "normal" means perpendicular: the equations say that the residual is normal to the column space.

The column-by-column test deserves to be recorded for any matrix.

Lemma 6.5.4 (The orthogonal complement of a column space). For every $M \in \mathbb{F}^{m\times n}$, $(\operatorname{im} M)^\perp = \ker M^*$. That is, a vector $\mathbf{y} \in \mathbb{F}^m$ is orthogonal to every column of M if and only if $M^*\mathbf{y} = \mathbf{0}$.

Proof. ROUTINE

Uses. Definition 6.3.26 (Conjugate transpose), Proposition 2.4.8 (Four views of the product), Definition 6.1.8 (Dot product), Proposition 6.3.9 (Properties of $A^\perp$), Proposition 2.6.18 (The column space is spanned by the columns)
Hint 1. Compute the jth entry of $M^*\mathbf{y}$. What is row j of M^*?
Hint 2. The jth entry is $\mathbf{m}_j^*\mathbf{y} = \langle \mathbf{y}, \mathbf{m}_j\rangle$, where $\mathbf{m}_j$ is column j of M. Then pass from the columns to their span with Proposition 6.3.9(c).
Sketch. Row j of M^* is $\mathbf{m}_j^*$, so the jth entry of $M^*\mathbf{y}$ is $\mathbf{m}_j^*\mathbf{y} = \langle \mathbf{y}, \mathbf{m}_j\rangle$. So $M^*\mathbf{y} = \mathbf{0}$ if and only if $\mathbf{y}$ is orthogonal to each column, and by Proposition 6.3.9(c) that means $\mathbf{y} \perp \operatorname{span}(\mathbf{m}_1, \ldots, \mathbf{m}_n) = \operatorname{im} M$.

Let $\mathbf{m}_1, \ldots, \mathbf{m}_n$ be the columns of M. By Definition 6.3.26, row j of M^* is $\mathbf{m}_j^*$, so by Proposition 2.4.8 and Definition 6.1.8 the jth entry of $M^*\mathbf{y}$ is

$$\mathbf{m}_j^*\mathbf{y} = \mathbf{y} \cdot \mathbf{m}_j = \langle \mathbf{y}, \mathbf{m}_j\rangle.$$

Hence $M^*\mathbf{y} = \mathbf{0}$ if and only if $\mathbf{y} \perp \mathbf{m}_j$ for every j. By Proposition 6.3.9(c) and Proposition 2.6.18, that holds if and only if $\mathbf{y} \perp \operatorname{span}(\mathbf{m}_1, \ldots, \mathbf{m}_n) = \operatorname{im} M$. □

For real M this says $(\operatorname{im} M)^\perp = \ker M^\mathsf{T}$; applied to M^T, it is the statement $\ker A = R^\perp$ of Example 6.4.23(b), where R is the span of the rows. Theorem 6.6.21 extends the lemma to linear maps between arbitrary inner product spaces.

Theorem 6.5.5 (The normal equations). Let $A \in \mathbb{F}^{m\times n}$, $\mathbf{b} \in \mathbb{F}^m$, and $\hat{\mathbf{x}} \in \mathbb{F}^n$. The following are equivalent:

(i) $\hat{\mathbf{x}}$ is a least-squares solution of $A\mathbf{x} = \mathbf{b}$;
(ii) $\mathbf{b} - A\hat{\mathbf{x}} \perp \operatorname{im} A$, that is, the residual is orthogonal to every column of A;
(iii) $A^*A\hat{\mathbf{x}} = A^*\mathbf{b}$.

In particular, the **normal equations** $A^*A\mathbf{x} = A^*\mathbf{b}$ always have a solution, and their solutions are exactly the least-squares solutions of $A\mathbf{x} = \mathbf{b}$.

Proof (by projection). ROUTINE

Uses. Proposition 6.5.2 (Least squares is projection), Theorem 6.4.6 (The projection is characterized by orthogonality), Theorem 6.4.20 (Orthonormal bases exist), Lemma 6.5.4 (The orthogonal complement of a column space)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. By Proposition 6.5.2(a), (i) says that $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$. Which two conditions characterize this projection?
Hint 2. $A\hat{\mathbf{x}}$ lies in $\operatorname{im} A$ no matter what, so only the second condition of Theorem 6.4.6 is in question.
Hint 3. For (ii) ⇔ (iii), apply Lemma 6.5.4 to the vector $\mathbf{b} - A\hat{\mathbf{x}}$.
Sketch. (i) holds iff $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$ (Proposition 6.5.2(a)). Since $A\hat{\mathbf{x}} \in \operatorname{im} A$ automatically, Theorem 6.4.6 says this holds iff $\mathbf{b} - A\hat{\mathbf{x}} \perp \operatorname{im} A$, which is (ii). By Lemma 6.5.4, (ii) holds iff $A^*(\mathbf{b} - A\hat{\mathbf{x}}) = \mathbf{0}$, which is (iii). Existence is Proposition 6.5.2(b).

(i) ⇔ (ii). By Proposition 6.5.2(a), (i) holds if and only if $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$. Fix an orthonormal basis of $\operatorname{im} A$ (Theorem 6.4.20). By Theorem 6.4.6, $\operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$ is the unique vector $\mathbf{p}$ with $\mathbf{p} \in \operatorname{im} A$ and $\mathbf{b} - \mathbf{p} \perp \operatorname{im} A$. The vector $\mathbf{p} = A\hat{\mathbf{x}}$ lies in $\operatorname{im} A$ in any case, so $A\hat{\mathbf{x}} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$ if and only if $\mathbf{b} - A\hat{\mathbf{x}} \perp \operatorname{im} A$.

(ii) ⇔ (iii). By Lemma 6.5.4, $\mathbf{b} - A\hat{\mathbf{x}} \perp \operatorname{im} A$ if and only if $A^*(\mathbf{b} - A\hat{\mathbf{x}}) = \mathbf{0}$, that is, $A^*A\hat{\mathbf{x}} = A^*\mathbf{b}$.

Finally, least-squares solutions exist by Proposition 6.5.2(b), and by (i) ⇔ (iii) they are exactly the solutions of the normal equations. □

The second proof does not use projections at all. It makes the sliding argument of the intuition precise, and the move it uses applies to many minimization problems.

Technique 6.5.6 (Perturb a minimizer). Suppose $\hat{\mathbf{x}}$ minimizes a real-valued quantity $f(\mathbf{x})$ over a vector space. Then for every direction $\mathbf{h}$, the function $t \mapsto f(\hat{\mathbf{x}} + t\mathbf{h})$ of a real variable t has a minimum at $t = 0$. When f is the squared norm of a vector that depends linearly (or affinely) on $\mathbf{x}$, this function is a

quadratic polynomial $\alpha + \beta t + \gamma t^2$ with $\gamma \geq 0$, and a minimum at $t = 0$ forces the linear coefficient β to vanish: if $\beta \neq 0$, a small t of the opposite sign makes $\beta t + \gamma t^2 < 0$. Doing this for every $\mathbf{h}$ gives an equation that $\hat{\mathbf{x}}$ must satisfy. Choosing $\mathbf{h}$ cleverly, usually equal to the vector you want to show is zero, turns "$\beta = 0$" into a statement $\|\mathbf{s}\|^2 = 0$ (Technique 6.1.36). In the other direction, if the linear coefficient vanishes for every $\mathbf{h}$, the expansion shows that $f(\hat{\mathbf{x}} + \mathbf{h}) \geq f(\hat{\mathbf{x}})$, so $\hat{\mathbf{x}}$ is a minimizer.

This is "the derivative vanishes at a minimum" without derivatives, and with the converse built in. Reach for it when a vector is defined as the minimizer (or maximizer) of something and you need an equation it satisfies. The canonical example is the second proof of Theorem 6.5.5. The same move gives the minimal-norm solution in Section 6.5.7, and in Section 12.3 it shows that a maximizer of $\langle T\mathbf{v}, \mathbf{v}\rangle$ over unit vectors is an eigenvector.

Used in. Theorem 6.5.5, Exercise 6.5.39, Exercise 6.7.6, Exercise 6.7.13.

Proof of Theorem 6.5.5 (by perturbation). STANDARD

Uses. Proposition 6.1.29 (Expanding a norm), Proposition 6.3.27 (Properties of the conjugate transpose), Definition 6.1.2 (Inner product), Lemma 6.5.4 (The orthogonal complement of a column space), Proposition 6.5.2 (Least squares is projection)
Techniques. Perturb a minimizer (Technique 6.5.6), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Let $\mathbf{r} = \mathbf{b} - A\hat{\mathbf{x}}$ and $\mathbf{s} = A^*\mathbf{r}$. Expand $\|\mathbf{b} - A(\hat{\mathbf{x}} + \mathbf{h})\|^2 = \|\mathbf{r} - A\mathbf{h}\|^2$ for an arbitrary $\mathbf{h} \in \mathbb{F}^n$.
Hint 2. Move A across the inner product: $\langle \mathbf{r}, A\mathbf{h}\rangle = \langle A^*\mathbf{r}, \mathbf{h}\rangle = \langle \mathbf{s}, \mathbf{h}\rangle$. You should get $\|\mathbf{r}\|^2 - 2\,\mathrm{Re}\langle \mathbf{s}, \mathbf{h}\rangle + \|A\mathbf{h}\|^2$.
Hint 3. If $\mathbf{s} = \mathbf{0}$, the middle term is gone. If $\hat{\mathbf{x}}$ is a minimizer, take $\mathbf{h} = t\mathbf{s}$ with $t > 0$ small.
Sketch. With $\mathbf{r} = \mathbf{b} - A\hat{\mathbf{x}}$ and $\mathbf{s} = A^*\mathbf{r}$, for every $\mathbf{h}$: $\|\mathbf{b} - A(\hat{\mathbf{x}} + \mathbf{h})\|^2 = \|\mathbf{r}\|^2 - 2\,\mathrm{Re}\langle \mathbf{s}, \mathbf{h}\rangle + \|A\mathbf{h}\|^2$. If $\mathbf{s} = \mathbf{0}$, this is at least $\|\mathbf{r}\|^2$, so $\hat{\mathbf{x}}$ is a minimizer. If $\hat{\mathbf{x}}$ is a minimizer, put $\mathbf{h} = t\mathbf{s}$: then $2t\|\mathbf{s}\|^2 \leq t^2\|A\mathbf{s}\|^2$ for all $t > 0$, so $\|\mathbf{s}\|^2 \leq (t/2)\|A\mathbf{s}\|^2$ for all $t > 0$, which forces $\mathbf{s} = \mathbf{0}$. So (i) $\Leftrightarrow$ (iii); and (ii) $\Leftrightarrow$ (iii) is Lemma 6.5.4.

Let $\mathbf{r} = \mathbf{b} - A\hat{\mathbf{x}}$ and $\mathbf{s} = A^*\mathbf{r} = A^*\mathbf{b} - A^*A\hat{\mathbf{x}}$, so that (iii) says $\mathbf{s} = \mathbf{0}$. Every $\mathbf{x} \in \mathbb{F}^n$ has the form $\hat{\mathbf{x}} + \mathbf{h}$, and $\mathbf{b} - A(\hat{\mathbf{x}} + \mathbf{h}) = \mathbf{r} - A\mathbf{h}$. By Proposition 6.3.27(d) and conjugate symmetry,

$$\langle \mathbf{r}, A\mathbf{h}\rangle = \overline{\langle A\mathbf{h}, \mathbf{r}\rangle} = \overline{\langle \mathbf{h}, A^*\mathbf{r}\rangle} = \langle \mathbf{s}, \mathbf{h}\rangle,$$

so Proposition 6.1.29 gives, for every $\mathbf{h} \in \mathbb{F}^n$,

$$\|\mathbf{b} - A(\hat{\mathbf{x}} + \mathbf{h})\|^2 = \|\mathbf{r}\|^2 - 2\,\mathrm{Re}\langle \mathbf{s}, \mathbf{h}\rangle + \|A\mathbf{h}\|^2. \tag{6.5.1}$$

(iii) $\Rightarrow$ (i). If $\mathbf{s} = \mathbf{0}$, then (6.5.1) reads $\|\mathbf{b} - A(\hat{\mathbf{x}} + \mathbf{h})\|^2 = \|\mathbf{r}\|^2 + \|A\mathbf{h}\|^2 \geq \|\mathbf{r}\|^2$ for every $\mathbf{h}$. So $\hat{\mathbf{x}}$ is a least-squares solution.

(i) $\Rightarrow$ (iii). Suppose $\hat{\mathbf{x}}$ is a least-squares solution, and take $\mathbf{h} = t\mathbf{s}$ with t real and positive. Then $\langle \mathbf{s}, \mathbf{h}\rangle = t\|\mathbf{s}\|^2$, and (6.5.1) together with minimality gives

$$\|\mathbf{r}\|^2 \leq \|\mathbf{r}\|^2 - 2t\|\mathbf{s}\|^2 + t^2\|A\mathbf{s}\|^2, \quad \text{that is,} \quad 2\|\mathbf{s}\|^2 \leq t\|A\mathbf{s}\|^2$$

after dividing by $t > 0$. If $\mathbf{s} \neq \mathbf{0}$, choose $t > 0$ so small that $t\|A\mathbf{s}\|^2 < 2\|\mathbf{s}\|^2$ (any $t > 0$ works if $A\mathbf{s} = \mathbf{0}$); this contradicts the inequality. So $\mathbf{s} = \mathbf{0}$.

(ii) $\Leftrightarrow$ (iii) is Lemma 6.5.4 applied to $\mathbf{r}$, as in the first proof. The perturbation argument characterizes the least-squares solutions but does not produce one, so existence still comes from Proposition 6.5.2(b); Exercise 6.5.45 gives an algebraic existence proof instead. □

The first proof is the picture of Figure 6.5.1: least squares is projection, and projections are recognized by orthogonality. The second is the calculus approach of "set the gradient to zero", done without derivatives: $\mathbf{s} = A^*(\mathbf{b} - A\hat{\mathbf{x}})$ is, up to a factor -2, the gradient of $\|\mathbf{b} - A\mathbf{x}\|^2$. It does not use Theorem 6.4.33, and it gives a sharper statement. If $\hat{\mathbf{x}}$ solves the normal equations, then by (6.5.1) with $\mathbf{h} = \mathbf{x} - \hat{\mathbf{x}}$,

$$\begin{aligned}\|\mathbf{b} - A\mathbf{x}\|^2 &= \|\mathbf{b} - A\hat{\mathbf{x}}\|^2 \\ &\quad + \|A(\mathbf{x} - \hat{\mathbf{x}})\|^2\end{aligned} \tag{6.5.2}$$

for every $\mathbf{x} \in \mathbb{F}^n$. This is Pythagoras for the right triangle of Figure 6.5.1 with vertices $\mathbf{b}$, $A\hat{\mathbf{x}}$, $A\mathbf{x}$, and it says exactly how fast the error grows as $\mathbf{x}$ moves away from $\hat{\mathbf{x}}$.

Example 6.5.7 (Three points, by the normal equations). Return to Example 6.5.3, with $A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 1 & 2 \end{pmatrix}$ and $\mathbf{y} = (1, 1, 4)$. The entries of $A^{\mathsf{T}}A$ are the dot products of the columns $\mathbf{1} = (1, 1, 1)$ and $\mathbf{x} = (0, 1, 2)$ (Theorem 6.3.29), and $A^{\mathsf{T}}\mathbf{y}$ lists their dot products with $\mathbf{y}$:

$$A^{\mathsf{T}}A = \begin{pmatrix} \mathbf{1}\cdot\mathbf{1} & \mathbf{x}\cdot\mathbf{1} \\ \mathbf{1}\cdot\mathbf{x} & \mathbf{x}\cdot\mathbf{x} \end{pmatrix} = \begin{pmatrix} 3 & 3 \\ 3 & 5 \end{pmatrix}, \qquad A^{\mathsf{T}}\mathbf{y} = \begin{pmatrix} \mathbf{y}\cdot\mathbf{1} \\ \mathbf{y}\cdot\mathbf{x} \end{pmatrix} = \begin{pmatrix} 6 \\ 9 \end{pmatrix}.$$

The normal equations $3c_0 + 3c_1 = 6$, $3c_0 + 5c_1 = 9$ give $2c_1 = 3$, so $c_1 = 3/2$ and $c_0 = 1/2$, as before. This time no orthogonal basis was needed: only the inner products of the columns with each other and with $\mathbf{y}$.

Exercise 6.5.8. ROUTINE In $\mathbb{C}^3$, let $\mathbf{a} = (1, i, 1)$ and $\mathbf{b} = (1, 1, 0)$, and let A be the 3×1 matrix with column $\mathbf{a}$.

(a) Find the least-squares solution $\hat{z} \in \mathbb{C}$ of $Az = \mathbf{b}$, that is, of $z\mathbf{a} = \mathbf{b}$, and check that the residual is orthogonal to $\mathbf{a}$.

(b) A student solves $A^{\mathsf{T}}Az = A^{\mathsf{T}}\mathbf{b}$ instead. Show that the resulting z is not a least-squares solution.

Solution on page 1511

When is the solution unique?

Intuition (Same kernel). The coefficient matrix A^*A of the normal equations is the Gram matrix of the columns of A (Theorem 6.3.29). By Proposition 6.5.2(c) and Theorem 6.5.5, the normal equations have exactly one solution precisely when the columns of A are independent. Since A^*A is square, we expect it to be invertible exactly when the columns of A are independent, and the underlying statement is that A^*A and A have the same kernel.

One containment is free: if $A\mathbf{x} = \mathbf{0}$, then $A^*A\mathbf{x} = \mathbf{0}$. For the other we must get from $A^*(A\mathbf{x}) = \mathbf{0}$ back to $A\mathbf{x} = \mathbf{0}$, and A^* can have a large kernel, so we cannot cancel it. Two things rescue us. Multiplying by $\mathbf{x}^*$ turns $\mathbf{x}^*A^*A\mathbf{x}$ into $\|A\mathbf{x}\|^2$, so the norm vanishes (Technique 6.1.36). Geometrically, $A^*(A\mathbf{x}) = \mathbf{0}$ says that $A\mathbf{x}$ is orthogonal to $\operatorname{im} A$ (Lemma 6.5.4), while $A\mathbf{x}$ lies in $\operatorname{im} A$.

Proposition 6.5.9 ($\operatorname{rank}(A^*A) = \operatorname{rank} A$). Let $A \in \mathbb{F}^{m\times n}$.

(a) $\ker(A^*A) = \ker A$.

(b) $\operatorname{rank}(A^*A) = \operatorname{rank} A$.

(c) A^*A is invertible if and only if the columns of A are linearly independent, that is, if and only if $\operatorname{rank} A = n$.

Proof (by the norm). STANDARD

Uses. Proposition 6.3.27 (Properties of the conjugate transpose), Definition 6.1.8 (Dot product), Definition 6.1.2 (Inner product), Theorem 4.2.11 (Rank–nullity), Corollary 3.5.25 (The invertible matrix theorem), Corollary 2.6.24 (The columns decide), Theorem 3.5.12 (First Fundamental Theorem, completed)
Techniques. Show a vector is zero via its norm (Technique 6.1.36), Double containment (Technique 1.3.14)
Hint 1. For (a), the containment $\ker A \subseteq \ker(A^*A)$ is immediate. For the other, suppose $A^*A\mathbf{x} = \mathbf{0}$ and multiply on the left by $\mathbf{x}^*$.
Hint 2. $\mathbf{x}^*A^*A\mathbf{x} = (A\mathbf{x})^*(A\mathbf{x}) = \|A\mathbf{x}\|^2$.
Hint 3. For (b), both matrices have n columns; apply rank–nullity to each. For (c), a square matrix is invertible exactly when its kernel is $\{\mathbf{0}\}$.

Sketch. If $A^*A\mathbf{x} = \mathbf{0}$, then $\|A\mathbf{x}\|^2 = \mathbf{x}^*A^*A\mathbf{x} = 0$, so $A\mathbf{x} = \mathbf{0}$; the reverse containment is clear. Both matrices have n columns, so rank–nullity turns equal kernels into equal ranks. The square matrix A^*A is invertible iff its kernel, which is $\ker A$, is $\{\mathbf{0}\}$, iff the columns of A are independent.

(a) If $A\mathbf{x} = \mathbf{0}$, then $A^*A\mathbf{x} = A^*\mathbf{0} = \mathbf{0}$. Conversely, suppose $A^*A\mathbf{x} = \mathbf{0}$. By Proposition 6.3.27(b) and (a), $\mathbf{x}^*A^* = (A\mathbf{x})^*$, so, identifying 1×1 matrices with scalars (Definition 6.1.8),

$$\|A\mathbf{x}\|^2 = (A\mathbf{x})^*(A\mathbf{x}) = \mathbf{x}^*(A^*A\mathbf{x}) = \mathbf{x}^*\mathbf{0} = 0.$$

By definiteness, $A\mathbf{x} = \mathbf{0}$. So $\ker(A^*A) = \ker A$.

(b) Both $A^*A \in \mathbb{F}^{n\times n}$ and A have n columns, so by Theorem 4.2.11 and (a),

$$\begin{aligned}\operatorname{rank}(A^*A) &= n - \dim\ker(A^*A)\\ &= n - \dim\ker A = \operatorname{rank} A.\end{aligned}$$

(c) The matrix A^*A is square, so it is invertible if and only if $\ker(A^*A) = \{\mathbf{0}\}$ (Corollary 3.5.25). By (a), that is $\ker A = \{\mathbf{0}\}$, which holds if and only if the columns of A are linearly independent (Corollary 2.6.24), and if and only if $\operatorname{rank} A = n$ (Theorem 3.5.12). □

Proof (by orthogonality). ROUTINE

Uses. Lemma 6.5.4 (The orthogonal complement of a column space), Proposition 6.3.9 (Properties of $A^\perp$), Theorem 4.2.11 (Rank–nullity), Corollary 3.5.25 (The invertible matrix theorem), Corollary 2.6.24 (The columns decide)
Techniques. Double containment (Technique 1.3.14)
Hint 1. Suppose $A^*(A\mathbf{x}) = \mathbf{0}$. What does Lemma 6.5.4 say about the vector $A\mathbf{x}$?
Hint 2. $A\mathbf{x}$ lies in $\operatorname{im} A$ and in $(\operatorname{im} A)^\perp$.
Sketch. If $A^*(A\mathbf{x}) = \mathbf{0}$, then $A\mathbf{x} \in \ker A^* = (\operatorname{im} A)^\perp$ by Lemma 6.5.4, and also $A\mathbf{x} \in \operatorname{im} A$. So $A\mathbf{x} \in \operatorname{im} A \cap (\operatorname{im} A)^\perp = \{\mathbf{0}\}$. Parts (b) and (c) follow from (a) as in the first proof.

As before, $\ker A \subseteq \ker(A^*A)$. Conversely, let $A^*A\mathbf{x} = \mathbf{0}$, and put $\mathbf{y} = A\mathbf{x}$. Then $A^*\mathbf{y} = \mathbf{0}$, so $\mathbf{y} \in (\operatorname{im} A)^\perp$ by Lemma 6.5.4. But also $\mathbf{y} \in \operatorname{im} A$. Hence $\mathbf{y} \in \operatorname{im} A \cap (\operatorname{im} A)^\perp = \{\mathbf{0}\}$ (Proposition 6.3.9(d)), that is, $A\mathbf{x} = \mathbf{0}$. This proves (a), and (b) and (c) follow from (a) exactly as in the first proof. □

The first proof is the one that generalizes to operators: the same computation shows $\ker(T^*T) = \ker T$ for a linear map T between inner product spaces (Section 6.6). It is also Proposition 6.3.30(b) for the columns of A, whose Gram matrix is A^*A. The second proof is Theorem 6.5.5 with $\mathbf{b} = \mathbf{0}$: the least-squares solutions of $A\mathbf{x} = \mathbf{0}$ are the solutions of $A\mathbf{x} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{0}) = \mathbf{0}$.

Remark 6.5.10 (The conjugate is essential). Both proofs used that $\mathbf{v}^*\mathbf{v} = \|\mathbf{v}\|^2$ vanishes only for $\mathbf{v} = \mathbf{0}$. Without the conjugate the proposition fails. For $A = \begin{pmatrix}1\\ i\end{pmatrix}$ over $\mathbb{C}$, $\operatorname{rank} A = 1$ but $A^{\mathsf{T}}A = 1 + i^2 = 0$. Over $\mathbb{F}_2$, where there is no inner product at all (Section 6.1), $A = \begin{pmatrix}1\\ 1\end{pmatrix}$ has $A^{\mathsf{T}}A = 1 + 1 = 0$. Over $\mathbb{R}$, $A^* = A^{\mathsf{T}}$, and the proposition says $\operatorname{rank}\left(A^{\mathsf{T}}A\right) = \operatorname{rank} A$.

Corollary 6.5.11 (The least-squares solution for independent columns). If the columns of $A \in \mathbb{F}^{m\times n}$ are linearly independent, then for every $\mathbf{b} \in \mathbb{F}^m$ the system $A\mathbf{x} = \mathbf{b}$ has exactly one least-squares solution,

$$\hat{\mathbf{x}} = (A^*A)^{-1}A^*\mathbf{b}.$$

If moreover $m = n$, then A is invertible and $\hat{\mathbf{x}} = A^{-1}\mathbf{b}$.

Proof. ROUTINE

Uses. Proposition 6.5.9 ($\operatorname{rank}(A^*A) = \operatorname{rank} A$), Theorem 6.5.5 (The normal equations), Corollary 3.5.25 (The invertible matrix theorem), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 2.5.17 (Algebra of inverses)
Hint 1. By Proposition 6.5.9(c), A^*A is invertible. What does that say about the normal equations?
Hint 2. For $m = n$, write $(A^*A)^{-1} = A^{-1}(A^*)^{-1}$.

Sketch. A^*A is invertible (Proposition 6.5.9(c)), so the normal equations have the single solution $(A^*A)^{-1}A^*\mathbf{b}$, and by Theorem 6.5.5 it is the unique least-squares solution. If A is square, it is invertible, and $(A^*A)^{-1}A^* = A^{-1}(A^*)^{-1}A^* = A^{-1}$.

By Proposition 6.5.9(c), A^*A is invertible, so the normal equations $A^*A\mathbf{x} = A^*\mathbf{b}$ have exactly one solution, $(A^*A)^{-1}A^*\mathbf{b}$. By Theorem 6.5.5, the least-squares solutions are exactly the solutions of the normal equations.

If $m = n$, then A is a square matrix with independent columns, so it is invertible (Corollary 2.6.24, Corollary 3.5.25), and so is A^* (Proposition 6.3.27(c)). By Proposition 2.5.17, $(A^*A)^{-1} = A^{-1}(A^*)^{-1}$, so $\hat{\mathbf{x}} = A^{-1}(A^*)^{-1}A^*\mathbf{b} = A^{-1}\mathbf{b}$, which is no surprise: $A\mathbf{x} = \mathbf{b}$ then has an exact solution. □

The formula is good for theory, but to compute $\hat{\mathbf{x}}$ by hand one solves the normal equations by row reduction rather than inverting A^*A, as in Example 6.5.7.

Example 6.5.12 (Dependent columns). Let

$$A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \\ 2 & 4 \end{pmatrix}, \quad \mathbf{b} = \begin{pmatrix} 1 \\ 2 \\ 0 \end{pmatrix}.$$

The second column is twice the first, so rank $A = 1$ and the least-squares solution is not unique. The normal equations are

$$A^{\mathsf{T}}A = \begin{pmatrix} 6 & 12 \\ 12 & 24 \end{pmatrix}, \quad A^{\mathsf{T}}\mathbf{b} = \begin{pmatrix} 3 \\ 6 \end{pmatrix},$$

so they reduce to $6x_1 + 12x_2 = 3$ (the second equation is twice the first). Their solutions are $\hat{\mathbf{x}} = (1/2, 0) + t(-2, 1)$ for $t \in \mathbb{R}$, a line in $\mathbb{R}^2$ parallel to $\ker A = \operatorname{span}((-2, 1))$, as Proposition 6.5.2(b) predicts. Each of them gives the same vector $A\hat{\mathbf{x}} = (1/2)(1, 1, 2)$, which is the projection of $\mathbf{b}$ onto the line $\operatorname{im} A = \operatorname{span}((1, 1, 2))$, namely $(3/6)(1, 1, 2)$. Section 6.5.7 singles out one of these solutions.

6.5.3 Projection onto a column space

Theorem 6.4.31 computes the matrix of Pr_W from an orthonormal basis of W. The normal equations give a formula from any basis, with no Gram–Schmidt step.

Proposition 6.5.13 (Projection onto a column space). Let $A \in \mathbb{F}^{m\times n}$ have linearly independent columns. Then

$$\mathrm{Pr}_{\operatorname{im} A}(\mathbf{b}) = A(A^*A)^{-1}A^*\mathbf{b} \quad \text{for every } \mathbf{b} \in \mathbb{F}^m.$$

That is, the matrix of $\mathrm{Pr}_{\operatorname{im} A}$ is $P = A(A^*A)^{-1}A^*$.

Proof (by the two conditions). ROUTINE

Uses. Proposition 6.5.9 ($\operatorname{rank}(A^*A) = \operatorname{rank} A$), Theorem 6.4.6 (The projection is characterized by orthogonality), Lemma 6.5.4 (The orthogonal complement of a column space), Theorem 6.4.20 (Orthonormal bases exist)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. A^*A is invertible by Proposition 6.5.9(c). Let $\mathbf{p} = A(A^*A)^{-1}A^*\mathbf{b}$. Check the two conditions of Theorem 6.4.6.
Hint 2. $\mathbf{p} = A\mathbf{c}$ for $\mathbf{c} = (A^*A)^{-1}A^*\mathbf{b}$, so $\mathbf{p} \in \operatorname{im} A$. For the other condition, compute $A^*(\mathbf{b} - \mathbf{p})$ and use Lemma 6.5.4.
Sketch. With $\mathbf{c} = (A^*A)^{-1}A^*\mathbf{b}$, the vector $\mathbf{p} = A\mathbf{c}$ lies in $\operatorname{im} A$, and $A^*(\mathbf{b} - \mathbf{p}) = A^*\mathbf{b} - (A^*A)(A^*A)^{-1}A^*\mathbf{b} = \mathbf{0}$, so $\mathbf{b} - \mathbf{p} \perp \operatorname{im} A$ (Lemma 6.5.4). By Theorem 6.4.6, $\mathbf{p} = \mathrm{Pr}_{\operatorname{im} A}(\mathbf{b})$.

By Proposition 6.5.9(c), A^*A is invertible, so P is defined. Let $\mathbf{b} \in \mathbb{F}^m$ and $\mathbf{p} = P\mathbf{b} = A\mathbf{c}$, where $\mathbf{c} = (A^*A)^{-1}A^*\mathbf{b}$. Then $\mathbf{p} \in \operatorname{im} A$, and

$$A^*(\mathbf{b} - \mathbf{p}) = A^*\mathbf{b} - (A^*A)(A^*A)^{-1}A^*\mathbf{b}$$

$$= A^*\mathbf{b} - A^*\mathbf{b} = \mathbf{0},$$

so $\mathbf{b} - \mathbf{p} \in (\operatorname{im} A)^\perp$ by Lemma 6.5.4. These are the two conditions of Theorem 6.4.6 (for an orthonormal basis of $\operatorname{im} A$, which exists by Theorem 6.4.20), so $\mathbf{p} = \operatorname{Pr}_{\operatorname{im} A}(\mathbf{b})$. □

Proof (by reduction to an orthonormal basis). STANDARD

> *Uses.* Theorem 6.4.31 (The matrix of an orthogonal projection), Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.3.29 (Orthonormal columns), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 2.5.17 (Algebra of inverses), Corollary 3.5.25 (The invertible matrix theorem), Corollary 2.6.24 (The columns decide)
> *Techniques.* Test injectivity at $\mathbf{0}$ (Technique 2.6.12)
> *Hint 1.* Let Q have orthonormal columns forming a basis of $\operatorname{im} A$, so that $\operatorname{Pr}_{\operatorname{im} A} = QQ^*$. How many columns does Q have?
> *Hint 2.* Each column of A is fixed by QQ^*, so $A = QS$ with $S = Q^*A \in \mathbb{F}^{n\times n}$. Show that S is invertible, and substitute $A = QS$ into $A(A^*A)^{-1}A^*$.
> *Sketch.* The columns of A are a basis of $\operatorname{im} A$, so an orthonormal basis of $\operatorname{im} A$ has n vectors; let $Q \in \mathbb{F}^{m\times n}$ have them as columns, so $\operatorname{Pr}_{\operatorname{im} A} = QQ^*$ and $Q^*Q = I_n$. Since QQ^* fixes $\operatorname{im} A$, $A = QQ^*A = QS$ with $S = Q^*A$, which is invertible because $S\mathbf{x} = \mathbf{0}$ gives $A\mathbf{x} = \mathbf{0}$. Then $A^*A = S^*S$ and $A(A^*A)^{-1}A^* = QSS^{-1}(S^*)^{-1}S^*Q^* = QQ^*$.

The columns of A are a basis of $\operatorname{im} A$, so $\dim \operatorname{im} A = n$. By Theorem 6.4.20, $\operatorname{im} A$ has an orthonormal basis, which therefore has n vectors $\mathbf{u}_1, \ldots, \mathbf{u}_n$. Let $Q \in \mathbb{F}^{m\times n}$ have these columns. By Theorem 6.4.31, $\operatorname{Pr}_{\operatorname{im} A} = QQ^*$, and $Q^*Q = I_n$ by Theorem 6.3.29. Since $\operatorname{Pr}_{\operatorname{im} A}$ fixes every vector of $\operatorname{im} A$ (Proposition 6.4.29(b)), it fixes each column of A, so

$$A = QQ^*A = QS \quad \text{with } S = Q^*A \in \mathbb{F}^{n\times n}.$$

The square matrix S is invertible: if $S\mathbf{x} = \mathbf{0}$, then $A\mathbf{x} = QS\mathbf{x} = \mathbf{0}$, so $\mathbf{x} = \mathbf{0}$ because the columns of A are independent (Corollary 2.6.24), and Corollary 3.5.25 applies. So S^* is invertible too (Proposition 6.3.27(c)). Now $A^*A = S^*Q^*QS = S^*S$, so $(A^*A)^{-1} = S^{-1}(S^*)^{-1}$ by Proposition 2.5.17, and

$$A(A^*A)^{-1}A^* = QSS^{-1}(S^*)^{-1}S^*Q^* = QQ^* = \operatorname{Pr}_{\operatorname{im} A},$$

as desired. □

The first proof is Technique 6.4.7, the method Section 6.4 promised for this formula. The second shows how the formula relates to QQ^*: an arbitrary basis of $\operatorname{im} A$ is $A = QS$ for an invertible change-of-basis matrix S, and the factor $(A^*A)^{-1} = S^{-1}(S^*)^{-1}$ undoes it. When the columns of A are already orthonormal, $A^*A = I_n$ and the formula is AA^*, which is Theorem 6.4.31. For a single nonzero column $\mathbf{a}$ it is $\mathbf{a}(\mathbf{a}^*\mathbf{a})^{-1}\mathbf{a}^* = \mathbf{a}\mathbf{a}^*/(\mathbf{a}^*\mathbf{a})$, the projection onto a line from Section 6.4.

Some consequences can be read off directly. The matrix P satisfies $P^2 = A(A^*A)^{-1}(A^*A)(A^*A)^{-1}A^* = P$ and $P^* = P$, since A^*A is Hermitian, as Proposition 6.4.30 requires. The matrix $I_m - P$ is the projection onto $(\operatorname{im} A)^\perp = \ker A^*$ (Proposition 6.4.29(d), Lemma 6.5.4); it sends $\mathbf{b}$ to the residual. The formula needs independent columns, since otherwise A^*A is not invertible. For a matrix with dependent columns, apply it to the matrix of pivot columns of A, which are a basis of $\operatorname{im} A$ (Corollary 3.3.19). In statistics, P is called the *hat matrix*, because it turns the data $\mathbf{y}$ into the fitted values $\hat{\mathbf{y}} = P\mathbf{y}$.

Example 6.5.14 (A projection matrix from a non-orthogonal basis). The plane $W = \{\mathbf{x} \in \mathbb{R}^3 \mid x_1 + x_2 + x_3 = 0\}$ of Example 6.4.32 has the basis $(1, -1, 0)$, $(0, 1, -1)$, which is not orthogonal. With these as the columns of A,

$$A^{\mathsf{T}}A = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \quad \left(A^{\mathsf{T}}A\right)^{-1} = \frac{1}{3}\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix},$$

and

$$A\left(A^{\mathsf{T}}A\right)^{-1}A^{\mathsf{T}} = \frac{1}{3}\begin{pmatrix}1&0\\-1&1\\0&-1\end{pmatrix}\begin{pmatrix}2&1\\1&2\end{pmatrix}\begin{pmatrix}1&-1&0\\0&1&-1\end{pmatrix}$$
$$= \frac{1}{3}\begin{pmatrix}2&1\\-1&1\\-1&-2\end{pmatrix}\begin{pmatrix}1&-1&0\\0&1&-1\end{pmatrix}$$
$$= \frac{1}{3}\begin{pmatrix}2&-1&-1\\-1&2&-1\\-1&-1&2\end{pmatrix},$$

the matrix found in Example 6.4.32 from the normal vector $(1,1,1)$.

Exercise 6.5.15. ROUTINE Let $\mathbf{a} = (1,2,2)$ and $\mathbf{b} = (3,0,3)$. Find the matrix P of the projection onto $\operatorname{span}(\mathbf{a})$ with Proposition 6.5.13, the least-squares solution of $x\mathbf{a} = \mathbf{b}$, and the least-squares error.

Solution on page 1512

6.5.4 Linear regression

The most common source of inconsistent systems is data. Suppose we have measured two real quantities m times, with results $(x_1, y_1), \ldots, (x_m, y_m)$, and have reason to expect y to be a linear function of x.

Definition 6.5.16 (Least-squares line). Let $(x_1, y_1), \ldots, (x_m, y_m) \in \mathbb{R}^2$ be data points. A **least-squares line**, or **regression line**, for the data is a line $y = c_0 + c_1 x$ for which

$$\sum_{i=1}^{m} (y_i - c_0 - c_1 x_i)^2$$

is as small as possible. The numbers $y_i - (c_0 + c_1 x_i)$ are the **residuals** of the line.

To turn this into a least-squares problem, let $\mathbf{1} = (1, \ldots, 1)$, $\mathbf{x} = (x_1, \ldots, x_m)$, and $\mathbf{y} = (y_1, \ldots, y_m)$ in $\mathbb{R}^m$, and let $A \in \mathbb{R}^{m\times 2}$ be the matrix with columns $\mathbf{1}$ and $\mathbf{x}$. For $\mathbf{c} = (c_0, c_1)$, the ith entry of $A\mathbf{c}$ is $c_0 + c_1 x_i$, so the sum in Definition 6.5.16 is $\|\mathbf{y} - A\mathbf{c}\|^2$. Hence $y = c_0 + c_1 x$ is a least-squares line if and only if $\mathbf{c}$ is a least-squares solution of $A\mathbf{c} = \mathbf{y}$, and the residuals of the line are the entries of the residual vector $\mathbf{y} - A\mathbf{c}$. (The lecture writes the line as $y = a + bx$, so $a = c_0$ and $b = c_1$. We keep the letter $\mathbf{b}$ for right-hand sides, and the indices match the interactive figures.)

As in Example 6.2.19, the answer is best expressed through the means $m_x = (x_1 + \cdots + x_m)/m$ and $m_y = (y_1 + \cdots + y_m)/m$ and the centered data

$$\tilde{\mathbf{x}} = \mathbf{x} - m_x\mathbf{1} = (x_1 - m_x, \ldots, x_m - m_x),$$
$$\tilde{\mathbf{y}} = \mathbf{y} - m_y\mathbf{1} = \left(y_1 - m_y, \ldots, y_m - m_y\right).$$

Proposition 6.5.17 (The least-squares line). Let $(x_1, y_1), \ldots, (x_m, y_m) \in \mathbb{R}^2$ be data points whose x_i are not all equal. Then there is exactly one least-squares line $y = c_0 + c_1 x$, given by

$$c_1 = \frac{\sum_{i=1}^{m}(x_i - m_x)\left(y_i - m_y\right)}{\sum_{i=1}^{m}(x_i - m_x)^2} = \frac{\tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}}}{\tilde{\mathbf{x}} \cdot \tilde{\mathbf{x}}},$$
$$c_0 = m_y - c_1 m_x.$$

In particular, the line passes through the point $\left(m_x, m_y\right)$, and its residuals add up to 0. If all x_i are equal, there are infinitely many least-squares lines.

Proof (by solving the normal equations). ROUTINE

> *Uses.* Theorem 6.5.5 (The normal equations), Theorem 6.3.29 (Orthonormal columns), Technique 6.1.9 (A sum of nonnegative terms), Proposition 6.5.2 (Least squares is projection), Corollary 2.6.24 (The columns decide)
> *Hint 1.* Write out $A^{\mathsf{T}}A$ and $A^{\mathsf{T}}\mathbf{y}$ with sums: the entries are $\mathbf{1}\cdot\mathbf{1} = m$, $\mathbf{1}\cdot\mathbf{x} = \sum_i x_i$, and so on.
> *Hint 2.* Divide the first normal equation by m to get $c_0 = m_y - c_1 m_x$, and substitute it into the second.
> *Hint 3.* You will need $\sum_i (x_i - m_x)^2 = \sum_i x_i^2 - m m_x^2$ and $\sum_i (x_i - m_x)\big(y_i - m_y\big) = \sum_i x_i y_i - m m_x m_y$.
> *Sketch.* The normal equations are $m c_0 + (\sum x_i) c_1 = \sum y_i$ and $(\sum x_i) c_0 + \big(\sum x_i^2\big) c_1 = \sum x_i y_i$. The first is $c_0 + c_1 m_x = m_y$; substituting into the second gives $c_1\big(\sum x_i^2 - m m_x^2\big) = \sum x_i y_i - m m_x m_y$, that is, $c_1 \|\tilde{\mathbf{x}}\|^2 = \tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}$, and $\|\tilde{\mathbf{x}}\|^2 > 0$. The first equation also says that $\big(m_x, m_y\big)$ lies on the line, and that $\mathbf{1}\cdot(\mathbf{y} - A\mathbf{c}) = 0$.

By Theorem 6.3.29, the entries of $A^{\mathsf{T}}A$ and $A^{\mathsf{T}}\mathbf{y}$ are dot products:

$$A^{\mathsf{T}}A = \begin{pmatrix} m & \sum_i x_i \\ \sum_i x_i & \sum_i x_i^2 \end{pmatrix}, \quad A^{\mathsf{T}}\mathbf{y} = \begin{pmatrix} \sum_i y_i \\ \sum_i x_i y_i \end{pmatrix}.$$

So the normal equations are

$$m c_0 + \left(\sum_i x_i\right) c_1 = \sum_i y_i,$$
$$\left(\sum_i x_i\right) c_0 + \left(\sum_i x_i^2\right) c_1 = \sum_i x_i y_i.$$

Dividing the first by m gives $c_0 + c_1 m_x = m_y$, that is, $c_0 = m_y - c_1 m_x$. Substituting this into the second, and using $\sum_i x_i = m m_x$, gives

$$c_1\left(\sum_i x_i^2 - m m_x^2\right) = \sum_i x_i y_i - m m_x m_y.$$

Expanding the squares and products,

$$\begin{aligned} &\sum_i (x_i - m_x)^2 \\ &= \sum_i x_i^2 - 2 m_x \sum_i x_i + m m_x^2 \\ &= \sum_i x_i^2 - m m_x^2 \end{aligned}$$

and

$$\begin{aligned} &\sum_i (x_i - m_x)\big(y_i - m_y\big) \\ &= \sum_i x_i y_i - m_x \sum_i y_i - m_y \sum_i x_i + m m_x m_y \\ &= \sum_i x_i y_i - m m_x m_y, \end{aligned}$$

so the second equation reads $c_1 \|\tilde{\mathbf{x}}\|^2 = \tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}$. Since the x_i are not all equal, $\tilde{\mathbf{x}} \neq \mathbf{0}$, and $\|\tilde{\mathbf{x}}\|^2 > 0$ (Technique 6.1.9). So the normal equations have exactly one solution, the one in the statement, and by Theorem 6.5.5 it is the unique least-squares solution. The first normal equation, $m_y = c_0 + c_1 m_x$, says that $\big(m_x, m_y\big)$ lies on the line. It is also the equation $\mathbf{1}\cdot(\mathbf{y} - A\mathbf{c}) = 0$, so the residuals add up to 0.

If all x_i are equal, then $\mathbf{x}$ is a multiple of $\mathbf{1}$, the columns of A are dependent, and by Proposition 6.5.2 the least-squares solutions form a translate of the line $\ker A$. Different vectors $\mathbf{c}$ give different lines, so there are infinitely many least-squares lines. □

Proof (by centering, which orthogonalizes the columns). STANDARD

Uses. Corollary 6.4.10 (Projecting with an orthogonal list), Proposition 6.3.13 (Orthogonal lists are independent), Proposition 6.5.2 (Least squares is projection), Theorem 6.5.5 (The normal equations)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. Compute $\mathbf{1}\cdot\tilde{\mathbf{x}}$. What does Gram–Schmidt do to the list $\mathbf{1},\mathbf{x}$?
Hint 2. $\mathbf{1}$ and $\tilde{\mathbf{x}}$ are an orthogonal basis of $\operatorname{im} A$. Project $\mathbf{y}$ onto $\operatorname{im} A$ with Corollary 6.4.10, and rewrite the result in terms of $\mathbf{1}$ and $\mathbf{x}$.
Sketch. $\mathbf{1}\cdot\tilde{\mathbf{x}}=\sum_i(x_i-m_x)=0$, and $\tilde{\mathbf{x}}=\mathbf{x}-m_x\mathbf{1}$ is the second vector Gram–Schmidt produces from $\mathbf{1},\mathbf{x}$. So $\mathbf{1},\tilde{\mathbf{x}}$ is an orthogonal basis of $\operatorname{im} A$, and $\operatorname{Pr}_{\operatorname{im} A}(\mathbf{y})=m_y\mathbf{1}+c_1\tilde{\mathbf{x}}=\big(m_y-c_1m_x\big)\mathbf{1}+c_1\mathbf{x}$ with $c_1=(\mathbf{y}\cdot\tilde{\mathbf{x}})/\|\tilde{\mathbf{x}}\|^2=(\tilde{\mathbf{y}}\cdot\tilde{\mathbf{x}})/\|\tilde{\mathbf{x}}\|^2$. This is $A\mathbf{c}$, so $\mathbf{c}$ is the least-squares solution, unique since the columns are independent.

First, $\mathbf{1}\cdot\tilde{\mathbf{x}}=\sum_i(x_i-m_x)=mm_x-mm_x=0$, so $\tilde{\mathbf{x}}\perp\mathbf{1}$. In fact $\tilde{\mathbf{x}}=\mathbf{x}-\big(\langle\mathbf{x},\mathbf{1}\rangle/\|\mathbf{1}\|^2\big)\mathbf{1}$ is what Gram–Schmidt produces from $\mathbf{1},\mathbf{x}$. Since the x_i are not all equal, $\tilde{\mathbf{x}}\neq\mathbf{0}$; so $\mathbf{1},\tilde{\mathbf{x}}$ is an orthogonal list of nonzero vectors, hence independent (Proposition 6.3.13). It spans $\operatorname{im} A=\operatorname{span}(\mathbf{1},\mathbf{x})$, because $\tilde{\mathbf{x}}\in\operatorname{span}(\mathbf{1},\mathbf{x})$ and $\mathbf{x}=\tilde{\mathbf{x}}+m_x\mathbf{1}$. So $\mathbf{1},\mathbf{x}$ is independent too.

By Corollary 6.4.10, with $\mathbf{y}\cdot\mathbf{1}=mm_y$ and $\mathbf{y}\cdot\tilde{\mathbf{x}}=\big(\tilde{\mathbf{y}}+m_y\mathbf{1}\big)\cdot\tilde{\mathbf{x}}=\tilde{\mathbf{y}}\cdot\tilde{\mathbf{x}}$,

$$\begin{aligned}\operatorname{Pr}_{\operatorname{im} A}(\mathbf{y})&=\frac{\mathbf{y}\cdot\mathbf{1}}{m}\mathbf{1}+\frac{\mathbf{y}\cdot\tilde{\mathbf{x}}}{\|\tilde{\mathbf{x}}\|^2}\tilde{\mathbf{x}}=m_y\mathbf{1}+c_1(\mathbf{x}-m_x\mathbf{1})\\&=\big(m_y-c_1m_x\big)\mathbf{1}+c_1\mathbf{x}=A\mathbf{c},\end{aligned}$$

with $c_1=(\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}})/\|\tilde{\mathbf{x}}\|^2$ and $c_0=m_y-c_1m_x$. By Proposition 6.5.2, $\mathbf{c}$ is a least-squares solution, and the only one, since the columns of A are independent. The residual $\mathbf{y}-\operatorname{Pr}_{\operatorname{im} A}(\mathbf{y})$ is orthogonal to $\mathbf{1}$ (Theorem 6.5.5), so its entries add up to 0, and $c_0+c_1m_x=m_y$ says that $\big(m_x,m_y\big)$ is on the line. The case of equal x_i is handled as in the first proof. □

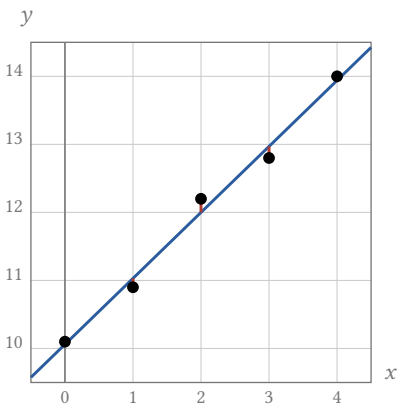
The second proof explains the shape of the formula. Centering the x-data is Gram–Schmidt applied to the columns $\mathbf{1},\mathbf{x}$, and once the columns are orthogonal, the projection splits into two one-dimensional problems: the best constant fit to the data is the mean m_y, and the slope is the coefficient of the shadow of $\tilde{\mathbf{y}}$ on $\tilde{\mathbf{x}}$. In the plane of the data, centering moves the origin to $\big(m_x,m_y\big)$, and c_1 is then the slope of the best line through the new origin (Exercise 6.5.20). When the y_i are not all equal, Example 6.2.19 gives $\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}=r\|\tilde{\mathbf{x}}\|\|\tilde{\mathbf{y}}\|$, where r is the correlation coefficient, so $c_1=r\|\tilde{\mathbf{y}}\|/\|\tilde{\mathbf{x}}\|$: the slope is the correlation scaled by the ratio of the spreads. Exercise 6.5.40 shows that the squared least-squares error is $\big(1-r^2\big)\|\tilde{\mathbf{y}}\|^2$.

Example 6.5.18 (A spring). A spring hangs from a hook, and its length y (in cm) is measured under loads $x=0,1,2,3,4$ (in newtons):

$$(0,10.1),\quad(1,10.9),\quad(2,12.2),\quad(3,12.8),\quad(4,14.0).$$

Hooke's law predicts $y=c_0+c_1x$, where c_0 is the natural length and $1/c_1$ is the stiffness. Here $m_x=2$ and $m_y=60/5=12$, so

$$\tilde{\mathbf{x}}=(-2,-1,0,1,2),\quad\tilde{\mathbf{y}}=(-1.9,-1.1,0.2,0.8,2.0).$$



Then $\tilde{\mathbf{x}}\cdot\tilde{\mathbf{y}}=3.8+1.1+0+0.8+4.0=9.7$ and $\tilde{\mathbf{x}}\cdot\tilde{\mathbf{x}}=10$, so by Proposition 6.5.17

$$c_1=0.97,\quad c_0=12-0.97\cdot2=10.06,$$

and the least-squares line is $y=10.06+0.97x$: a natural length of about 10.06 cm and a stiffness of about $1/0.97\approx1.03$ N/cm. In matrix form, the normal equations were

$$A^{\mathsf{T}}A\mathbf{c}=\begin{pmatrix}5&10\\10&30\end{pmatrix}\begin{pmatrix}c_0\\c_1\end{pmatrix}=\begin{pmatrix}60\\129.7\end{pmatrix}=A^{\mathsf{T}}\mathbf{y}.$$

The residuals are 0.04, −0.13, 0.20, −0.17, 0.06. They add up to 0, as Proposition 6.5.17 says, and the least-squares error is $\sqrt{0.091}\approx0.30$ cm.

The spring data of Example 6.5.18 and the least-squares line $y = 10.06 + 0.97x$; the residuals (red) are short. In the interactive version, drag a point to see the normal equations, the coefficients $\mathbf{c}$, and the sum of squared residuals change; add or remove points; and switch to a parabola or a cubic (Other models). (Interactive in the web version.)

Remark 6.5.19 (The calculus derivation). Statistics courses usually find the least-squares line with calculus. The function $S(c_0, c_1) = \sum_i (y_i - c_0 - c_1 x_i)^2$ has partial derivatives

$$\frac{\partial S}{\partial c_0} = -2 \sum_i (y_i - c_0 - c_1 x_i),$$
$$\frac{\partial S}{\partial c_1} = -2 \sum_i x_i (y_i - c_0 - c_1 x_i),$$

and setting both to 0 gives $\mathbf{1} \cdot (\mathbf{y} - A\mathbf{c}) = 0$ and $\mathbf{x} \cdot (\mathbf{y} - A\mathbf{c}) = 0$. These are the normal equations, in form (ii) of Theorem 6.5.5. The second proof of Theorem 6.5.5 is this computation without derivatives, and it shows at the same time that the critical point is a minimum, which the calculus argument has to check separately.

Exercise 6.5.20. ROUTINE

(a) Show that the line through the origin $y = cx$ that best fits data $(x_1, y_1), \ldots, (x_m, y_m)$, with the x_i not all 0, in the least-squares sense has $c = \left(\sum_i x_i y_i\right) / \left(\sum_i x_i^2\right)$.

(b) Currents $I = 0.5, 1.0, 1.5, 2.0$ (in amperes) through a resistor produce voltages $V = 1.0, 2.1, 2.9, 4.1$ (in volts). Ohm's law says $V = RI$. Estimate R.

Solution on page 1512

Other models

Nothing in the line-fitting problem was special to lines. What made it a least-squares problem is that the unknown coefficients enter linearly. A model

$$y \approx c_0 f_0(x) + c_1 f_1(x) + \cdots + c_n f_n(x),$$

with fixed functions $f_0, \ldots, f_n$ and unknown coefficients c_j, leads to the system $A\mathbf{c} \approx \mathbf{y}$ with entries $a_{ij} = f_j(x_i)$, however nonlinear the f_j are. The most important case is fitting a polynomial of degree at most d, where $f_j(x) = x^j$ and row i of A is $\left(1, x_i, x_i^2, \ldots, x_i^d\right)$. For $m = d + 1$ data points this is the square Vandermonde matrix of Definition 3.4.22.

Proposition 6.5.21 (Polynomial fits). Let $(x_1, y_1), \dots, (x_m, y_m) \in \mathbb{R}^2$, let $d \geq 0$, and let $A \in \mathbb{R}^{m \times (d+1)}$ have rows $\left(1, x_i, x_i^2, \dots, x_i^d\right)$.

(a) A polynomial $p = c_0 + c_1 x + \cdots + c_d x^d$ of degree at most d minimizes $\sum_i (y_i - p(x_i))^2$ among all such polynomials if and only if $\mathbf{c} = (c_0, \dots, c_d)$ is a least-squares solution of $A\mathbf{c} = \mathbf{y}$.

(b) The minimizing polynomial is unique if and only if at least $d + 1$ of the numbers $x_1, \dots, x_m$ are distinct.

(c) If $x_1, \dots, x_m$ are distinct and $m = d + 1$, the minimizer is the interpolating polynomial of Theorem 3.4.24, and every residual is 0.

Proof. STANDARD

Uses. Definition 1.2.17 (Evaluation), Definition 1.2.13 (Polynomials), Proposition 6.5.2 (Least squares is projection), Lemma 3.4.23 (Too many roots), Corollary 3.4.19 (More unknowns than equations), Theorem 3.4.24 (Polynomial interpolation)
Techniques. Test injectivity at **0** (Technique 2.6.12)
Hint 1. The ith entry of $A\mathbf{c}$ is $p(x_i)$. By Proposition 6.5.2(c), uniqueness means $\ker A = \{\mathbf{0}\}$; what does $A\mathbf{c} = \mathbf{0}$ say about p?
Hint 2. If $d + 1$ of the x_i are distinct, use Lemma 3.4.23. If at most d are distinct, the system $A\mathbf{c} = \mathbf{0}$ has repeated equations; how many different ones?
Sketch. (a) $(A\mathbf{c})_i = p(x_i)$, so the sum is $\|\mathbf{y} - A\mathbf{c}\|^2$. (b) Uniqueness means $\ker A = \{\mathbf{0}\}$, and $A\mathbf{c} = \mathbf{0}$ says p vanishes at every x_i. With $d + 1$ distinct x_i, Lemma 3.4.23 forces $p = \mathbf{0}$. With $k \leq d$ distinct values, $A\mathbf{c} = \mathbf{0}$ is equivalent to a system of k equations in $d + 1 > k$ unknowns, which has a nonzero solution. (c) The interpolating polynomial has error 0, so it is a minimizer, the only one by (b).

(a) By Definition 1.2.17, the ith entry of $A\mathbf{c}$ is $c_0 + c_1 x_i + \cdots + c_d x_i^d = p(x_i)$, so $\sum_i (y_i - p(x_i))^2 = \|\mathbf{y} - A\mathbf{c}\|^2$. Polynomials of degree at most d correspond bijectively to their coefficient vectors $\mathbf{c} \in \mathbb{R}^{d+1}$ (Definition 1.2.13), so minimizing over p is minimizing over $\mathbf{c}$.

(b) By (a) and Proposition 6.5.2(c), the minimizer is unique if and only if $\ker A = \{\mathbf{0}\}$. A vector $\mathbf{c}$ lies in $\ker A$ exactly when the corresponding p satisfies $p(x_i) = 0$ for every i.

Suppose $d + 1$ of the x_i are distinct. If $\mathbf{c} \in \ker A$, then p has degree at most d and vanishes at $d + 1$ distinct points, so $p = \mathbf{0}$ by Lemma 3.4.23, and $\mathbf{c} = \mathbf{0}$.

Suppose instead that the x_i take only $k \leq d$ distinct values $z_1, \dots, z_k$. Rows of A with the same x_i are equal, so $A\mathbf{c} = \mathbf{0}$ has the same solutions as the system of k equations $c_0 + c_1 z_l + \cdots + c_d z_l^d = 0$, $l = 1, \dots, k$, in the $d + 1 > k$ unknowns $c_0, \dots, c_d$. By Corollary 3.4.19 it has a nonzero solution, so $\ker A \neq \{\mathbf{0}\}$.

(c) By Theorem 3.4.24 there is a polynomial p of degree at most $d = m - 1$ with $p(x_i) = y_i$ for every i. Its residuals are all 0, so it is a minimizer, and by (b) it is the only one. □

So the polynomial of degree at most d closest to the data is unique as soon as there are $d + 1$ distinct x-values, and it interpolates the data when there are exactly that many points. With more points it does not interpolate in general, and it is usually the better model: the high-degree interpolating polynomial passes through every measurement error as well.

Example 6.5.22 (A thrown ball). A ball is thrown upward, and its height h (in meters) is read off a video every half second:

$$t = 0, 0.5, 1, 1.5, 2, 2.5, \quad h = 1.0, 5.9, 8.1, 7.9, 5.4, 0.4.$$

Without air resistance, $h = h_0 + v_0 t - (g/2)t^2$ with initial height h_0, initial speed v_0, and gravitational acceleration g, so we fit $h \approx c_0 + c_1 t + c_2 t^2$. Row i of A is $\left(1, t_i, t_i^2\right)$, and the entries of $A^{\mathsf{T}}A$ and $A^{\mathsf{T}}\mathbf{h}$ are the sums $\sum_i t_i^k$ and $\sum_i t_i^k h_i$:

$$A^{\mathsf{T}}A = \begin{pmatrix} 6 & 7.5 & 13.75 \\ 7.5 & 13.75 & 28.125 \\ 13.75 & 28.125 & 61.1875 \end{pmatrix}, \quad A^{\mathsf{T}}\mathbf{h} = \begin{pmatrix} 28.7 \\ 34.7 \\ 51.45 \end{pmatrix}.$$

There are six distinct t_i, so by Proposition 6.5.21 the solution is unique; row reduction gives

$$c_0 = \frac{59}{56} \approx 1.054, \quad c_1 = \frac{16699}{1400} \approx 11.93,$$
$$c_2 = -\frac{683}{140} \approx -4.879.$$

So the ball left the hand at about 1.05 m with speed about 11.9 m/s, and $g \approx -2c_2 \approx 9.76\text{m/s}^2$, close to the true 9.81. The residuals are all smaller than 0.11 m in absolute value (Figure 6.5.2).

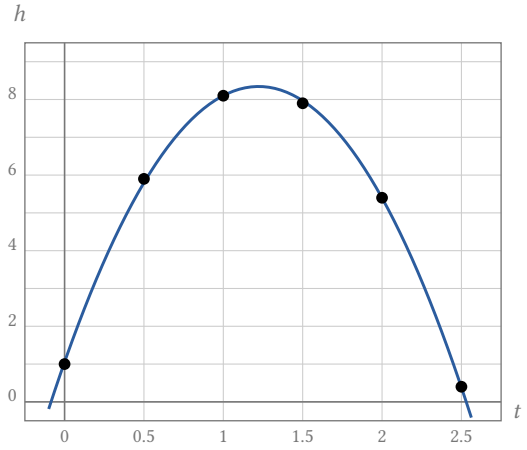


Figure 6.5.2. The heights of Example 6.5.22 and the least-squares parabola $h \approx 1.054 + 11.93t - 4.879t^2$. The residuals (red) are barely visible.

Two further variations use the same machinery. With several explanatory variables, say $y \approx c_0 + c_1u + c_2v$ with data (u_i, v_i, y_i), the matrix A has the columns $\mathbf{1}$, $\mathbf{u}$, $\mathbf{v}$; this is *multiple regression*. And some nonlinear models become linear after a change of variables. Exponential growth $y = Ce^{kx}$ is not linear in C and k, but $\ln y = \ln C + kx$ is linear in $\ln C$ and k, so one fits a line to the points $(x_i, \ln y_i)$. This minimizes the squared errors of $\ln y$, not of y, which roughly means relative rather than absolute errors; it is a different problem with a slightly different answer. How to choose the functions f_j, and how to keep a fit with many of them from following the noise, is taken up in Section 16.1.

6.5.5 Normal equations in an inner product space

The only place where the proof of Theorem 6.5.5 used $\mathbb{F}^m$ was in writing the inner products of the columns as the entries of A^*A. In a general inner product space, the Gram matrix (Definition 6.3.28) takes the place of A^*A.

Proposition 6.5.23 (Normal equations for a spanning list). Let V be an inner product space, let $\mathbf{v}_1, \dots, \mathbf{v}_n \in V$ have Gram matrix G, let $W = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_n)$, and let $\mathbf{v} \in V$. For $\mathbf{c} = (c_1, \dots, c_n) \in \mathbb{F}^n$,

$$c_1\mathbf{v}_1 + \cdots + c_n\mathbf{v}_n = \operatorname{Pr}_W(\mathbf{v}) \quad \text{if and only if} \quad G\mathbf{c} = \mathbf{d},$$

where $\mathbf{d} = (\langle \mathbf{v}, \mathbf{v}_1 \rangle, \dots, \langle \mathbf{v}, \mathbf{v}_n \rangle)$. The system $G\mathbf{c} = \mathbf{d}$ always has a solution, and the solution is unique if and only if $\mathbf{v}_1, \dots, \mathbf{v}_n$ is linearly independent.

Proof. ROUTINE

Uses. Theorem 6.4.20 (Orthonormal bases exist), Theorem 6.4.6 (The projection is characterized by orthogonality), Proposition 6.3.9 (Properties of $A^\perp$), Definition 6.3.28 (Gram matrix), Proposition 6.3.30 (Gram matrices detect independence), Corollary 3.5.25 (The invertible matrix theorem)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7), Gram matrices (Technique 6.3.31)

Hint 1. Let $\mathbf{w} = \sum_j c_j \mathbf{v}_j$. By Theorem 6.4.6, $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$ if and only if $\mathbf{v} - \mathbf{w} \perp W$. It suffices to test against $\mathbf{v}_1, \ldots, \mathbf{v}_n$.
Hint 2. Expand $\langle \mathbf{w}, \mathbf{v}_i \rangle = \sum_j c_j \langle \mathbf{v}_j, \mathbf{v}_i \rangle$ and recognize the ith entry of $G\mathbf{c}$.
Sketch. With $\mathbf{w} = \sum_j c_j \mathbf{v}_j$: $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$ iff $\langle \mathbf{v} - \mathbf{w}, \mathbf{v}_i \rangle = 0$ for all i, iff $\langle \mathbf{w}, \mathbf{v}_i \rangle = \langle \mathbf{v}, \mathbf{v}_i \rangle$ for all i, and $\langle \mathbf{w}, \mathbf{v}_i \rangle = \sum_j g_{ij} c_j = (G\mathbf{c})_i$. A solution exists because $\mathrm{Pr}_W(\mathbf{v}) \in W$ is some combination of the $\mathbf{v}_j$; it is unique iff G is invertible, iff the list is independent (Proposition 6.3.30).

The subspace W is finite-dimensional, so Pr_W is defined (Theorem 6.4.20). Let $\mathbf{w} = c_1\mathbf{v}_1 + \cdots + c_n\mathbf{v}_n \in W$. By Theorem 6.4.6, $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$ if and only if $\mathbf{v} - \mathbf{w} \perp W$, and by Proposition 6.3.9(c) it suffices to test this against the spanning list: $\langle \mathbf{v} - \mathbf{w}, \mathbf{v}_i \rangle = 0$, that is, $\langle \mathbf{w}, \mathbf{v}_i \rangle = \langle \mathbf{v}, \mathbf{v}_i \rangle$, for $i = 1, \ldots, n$. By linearity in the first slot and Definition 6.3.28,

$$\langle \mathbf{w}, \mathbf{v}_i \rangle = \sum_{j=1}^{n} c_j \langle \mathbf{v}_j, \mathbf{v}_i \rangle = \sum_{j=1}^{n} g_{ij} c_j = (G\mathbf{c})_i.$$

So $\mathbf{w} = \mathrm{Pr}_W(\mathbf{v})$ if and only if $G\mathbf{c} = \mathbf{d}$.

Since $\mathrm{Pr}_W(\mathbf{v}) \in W$, it equals $\sum_j c_j \mathbf{v}_j$ for some $\mathbf{c}$, which then solves $G\mathbf{c} = \mathbf{d}$. The solution is unique if and only if the square matrix G is invertible (Corollary 3.5.25), that is, by Proposition 6.3.30, if and only if $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is linearly independent. □

For $V = \mathbb{F}^m$ with the dot product and $\mathbf{v}_j = \mathbf{a}_j$, the columns of A, the Gram matrix is $G = A^*A$ (Theorem 6.3.29) and $d_i = \langle \mathbf{b}, \mathbf{a}_i \rangle = \mathbf{a}_i^* \mathbf{b}$ is the ith entry of $A^*\mathbf{b}$. So $G\mathbf{c} = \mathbf{d}$ is the system $A^*A\mathbf{c} = A^*\mathbf{b}$, and by Proposition 6.5.2(a) the proposition is Theorem 6.5.5 again. The general version applies when V is a space of functions, where it finds best approximations without orthogonalizing first.

Example 6.5.24 (The line closest to t^2). In $C[0,1]$ with $\langle f, g \rangle = \int_0^1 f(t)g(t)\,dt$ (Proposition 6.1.13), which line $c_0 + c_1 t$ minimizes $\int_0^1 \left(t^2 - c_0 - c_1 t\right)^2 dt$? Here $W = \mathrm{span}(1, t)$, and

$$G = \begin{pmatrix} \langle 1,1 \rangle & \langle t,1 \rangle \\ \langle 1,t \rangle & \langle t,t \rangle \end{pmatrix} = \begin{pmatrix} 1 & 1/2 \\ 1/2 & 1/3 \end{pmatrix},$$

$$\mathbf{d} = \begin{pmatrix} \langle t^2, 1 \rangle \\ \langle t^2, t \rangle \end{pmatrix} = \begin{pmatrix} 1/3 \\ 1/4 \end{pmatrix}.$$

The system $c_0 + c_1/2 = 1/3$, $c_0/2 + c_1/3 = 1/4$ gives $c_1 = 1$ and $c_0 = -1/6$. So the best line is $t - 1/6$, and its squared error is

$$\int_0^1 \left(t^2 - t + \frac{1}{6}\right)^2 dt = \frac{1}{180}.$$

The chord t through the endpoints of the graph has squared error $\int_0^1 \left(t^2 - t\right)^2 dt = 1/30$, six times as large: the best line is the chord lowered by $1/6$.

For polynomials of higher degree the Gram matrix of $1, t, \ldots, t^n$ is the Hilbert matrix of Exercise 6.3.54. It is invertible, but so close to singular that solving $G\mathbf{c} = \mathbf{d}$ numerically loses most of the accuracy for moderate n. That is why Approximating functions projects onto orthogonal polynomials instead.

ASIDE: *Weighted least squares* BEYOND 21-242

Sometimes the equations of an inconsistent system deserve different amounts of trust, for instance measurements made with instruments of different precision. Then one minimizes a weighted sum $\sum_i w_i |b_i - (A\mathbf{x})_i|^2$ with weights $w_i > 0$. With $D = \mathrm{diag}(w_1, \ldots, w_m)$, this sum is $\|\mathbf{b} - A\mathbf{x}\|_D^2$ for the weighted dot product $\langle \mathbf{u}, \mathbf{v} \rangle_D = \mathbf{v}^* D \mathbf{u}$ of Example 6.1.21. So the argument of Proposition 6.5.2, run in the inner product space $\left(\mathbb{F}^m, \langle \cdot, \cdot \rangle_D\right)$, shows that the minimizers are the $\mathbf{x}$ with $A\mathbf{x} = \mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{b})$, where the projection is now taken with respect to $\langle \cdot, \cdot \rangle_D$. Since $\langle \mathbf{a}_j, \mathbf{a}_i \rangle_D = \mathbf{a}_i^* D \mathbf{a}_j$ and $\langle \mathbf{b}, \mathbf{a}_i \rangle_D = \mathbf{a}_i^* D \mathbf{b}$, Proposition 6.5.23 turns this into the **weighted normal equations**

$$A^*DA\mathbf{x} = A^*D\mathbf{b}.$$

The same works with D replaced by any positive definite matrix M, since $\mathbf{v}^*M\mathbf{u}$ is then an inner product (Proposition 6.1.22). In statistics one takes $w_i = 1/\sigma_i^2$, where σ_i is the standard deviation of the error in the i th measurement, so that precise measurements count for more. Exercise 6.5.48 gives a second derivation and a computation.

6.5.6 Least squares via QR

BEYOND 21-242

QR factorization is not covered in lecture (Section 6.4.5).

If $A = QR$ is the QR factorization of a matrix with independent columns (Theorem 6.4.38), the normal equations simplify, because $Q^*Q = I_n$.

Proposition 6.5.25 (Least squares via QR). Let $A \in \mathbb{F}^{m\times n}$ have linearly independent columns, and let $A = QR$ be its QR factorization. Then the least-squares solution of $A\mathbf{x} = \mathbf{b}$ is the unique solution of the upper triangular system

$$R\hat{\mathbf{x}} = Q^*\mathbf{b}.$$

Proof. ROUTINE

Uses. Theorem 6.4.38 (QR factorization), Theorem 6.3.29 (Orthonormal columns), Proposition 6.3.27 (Properties of the conjugate transpose), Corollary 3.5.25 (The invertible matrix theorem), Theorem 6.5.5 (The normal equations), Corollary 2.6.24 (The columns decide)
Hint 1. Substitute $A = QR$ into A^*A and $A^*\mathbf{b}$, using $Q^*Q = I_n$.
Hint 2. You get $R^*R\mathbf{x} = R^*Q^*\mathbf{b}$. Why may you cancel R^*?
Sketch. $A^*A = R^*Q^*QR = R^*R$ and $A^*\mathbf{b} = R^*Q^*\mathbf{b}$. R is invertible, since $R\mathbf{x} = \mathbf{0}$ gives $A\mathbf{x} = \mathbf{0}$, and then so is R^*. Multiplying by $(R^*)^{-1}$, the normal equations become $R\mathbf{x} = Q^*\mathbf{b}$.

By Theorem 6.4.38, Q has orthonormal columns, so $Q^*Q = I_n$ (Theorem 6.3.29), and by Proposition 6.3.27(b),

$$A^*A = R^*Q^*QR = R^*R, \quad A^*\mathbf{b} = R^*Q^*\mathbf{b}.$$

The square matrix R is invertible: if $R\mathbf{x} = \mathbf{0}$, then $A\mathbf{x} = QR\mathbf{x} = \mathbf{0}$, so $\mathbf{x} = \mathbf{0}$ by independence of the columns of A (Corollary 2.6.24, Corollary 3.5.25). Hence R^* is invertible (Proposition 6.3.27(c)), and $R^*R\mathbf{x} = R^*Q^*\mathbf{b}$ holds if and only if $R\mathbf{x} = Q^*\mathbf{b}$. By Theorem 6.5.5, the least-squares solution is the unique solution of $R\mathbf{x} = Q^*\mathbf{b}$. □

The two sides have a meaning. $Q^*\mathbf{b}$ is the coordinate vector of $\mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{b}) = QQ^*\mathbf{b}$ with respect to the orthonormal basis formed by the columns of Q, and R converts coordinates with respect to the columns of A into coordinates with respect to the columns of Q, since $A\mathbf{x} = Q(R\mathbf{x})$. So $R\hat{\mathbf{x}} = Q^*\mathbf{b}$ says that $A\hat{\mathbf{x}}$ and $\mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{b})$ have the same coordinates. The system is upper triangular and is solved by back substitution.

Example 6.5.26 (Least squares by QR). For $A = \begin{pmatrix} 1 & 3 \\ 2 & 3 \\ 2 & 0 \end{pmatrix}$, Exercise 6.4.64 found $Q = \frac{1}{3}\begin{pmatrix} 1 & 2 \\ 2 & 1 \\ 2 & -2 \end{pmatrix}$ and $R = \begin{pmatrix} 3 & 3 \\ 0 & 3 \end{pmatrix}$. Let $\mathbf{b} = (3, 3, 3)$. Then $Q^{\mathsf{T}}\mathbf{b} = (1/3)(3 + 6 + 6, 6 + 3 - 6) = (5, 1)$, and $R\hat{\mathbf{x}} = (5, 1)$ gives $3\hat{x}_2 = 1$ and $3\hat{x}_1 + 3\hat{x}_2 = 5$, so $\hat{\mathbf{x}} = (4/3, 1/3)$. The residual $\mathbf{b} - A\hat{\mathbf{x}} = (2/3, -2/3, 1/3)$ is orthogonal to both columns of A, and the least-squares error is 1.

In exact arithmetic there is no reason to prefer QR to the normal equations. In floating-point arithmetic there is: forming A^*A can destroy information that A still contains. Let $A = \begin{pmatrix} 1 & 1 \\ \varepsilon & 0 \\ 0 & \varepsilon \end{pmatrix}$ with $\varepsilon = 10^{-8}$. Its columns are independent, and $A^{\mathsf{T}}A = \begin{pmatrix} 1+\varepsilon^2 & 1 \\ 1 & 1+\varepsilon^2 \end{pmatrix}$. But $\varepsilon^2 = 10^{-16}$ is smaller than half the spacing between double-precision numbers near 1 (about $2.2 \cdot 10^{-16}$), so the computer stores $1 + \varepsilon^2$ as 1 and $A^{\mathsf{T}}A$

as the singular matrix $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$. A QR factorization computed from A itself, with reflections as in Section 9.3, does not square the small entries. Numerical libraries solve least-squares problems this way, or with the singular value decomposition (Section 9.2).

6.5.7 The pseudoinverse BEYOND 21-242

The pseudoinverse is not covered in lecture; see LADR 6C. Section 9.2 completes the picture with the SVD.

When the columns of A are dependent, the least-squares solutions form a translate $\hat{\mathbf{x}} + \ker A$ of the kernel (Example 6.5.12). A natural way to pick one is to take the shortest.

Proposition 6.5.27 (The least-squares solution of minimal norm). Let $A \in \mathbb{F}^{m\times n}$ and $\mathbf{b} \in \mathbb{F}^m$, and let $K = \ker A$.

(a) Among the least-squares solutions of $A\mathbf{x} = \mathbf{b}$ there is exactly one of smallest norm, $\mathbf{x}^+$. It is the only least-squares solution in $K^\perp$, and $\mathbf{x}^+ = \hat{\mathbf{x}} - \mathrm{Pr}_K(\hat{\mathbf{x}})$ for every least-squares solution $\hat{\mathbf{x}}$.

(b) The map $\mathbb{F}^m \to \mathbb{F}^n$, $\mathbf{b} \mapsto \mathbf{x}^+$, is linear.

Proof. STANDARD

Uses. Proposition 6.5.2 (Least squares is projection), Theorem 6.4.24 (Orthogonal decomposition), Theorem 6.3.3 (Pythagorean theorem), Proposition 6.3.9 (Properties of $A^\perp$), Theorem 6.5.5 (The normal equations)
Techniques. Orthogonal decomposition (Technique 6.2.4), Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Fix one least-squares solution $\hat{\mathbf{x}}$, so that all of them form $\hat{\mathbf{x}} + K$. Split $\hat{\mathbf{x}} = \mathrm{Pr}_K(\hat{\mathbf{x}}) + \mathbf{q}$ with $\mathbf{q} \in K^\perp$ (Theorem 6.4.24).
Hint 2. Every least-squares solution is $\mathbf{q} + \mathbf{z}$ with $\mathbf{z} \in K$. Compute $\|\mathbf{q} + \mathbf{z}\|^2$ with Pythagoras.
Hint 3. For (b), $\mathbf{x}^+$ is the only vector $\mathbf{x}$ with $\mathbf{x} \in K^\perp$ and $A^*A\mathbf{x} = A^*\mathbf{b}$. Check that $a\mathbf{x}^+ + \mathbf{x}'^+$ has both properties for $a\mathbf{b} + \mathbf{b}'$.
Sketch. The least-squares solutions are $\hat{\mathbf{x}} + K = \mathbf{q} + K$, where $\mathbf{q} = \hat{\mathbf{x}} - \mathrm{Pr}_K(\hat{\mathbf{x}}) \in K^\perp$. For $\mathbf{z} \in K$, $\|\mathbf{q} + \mathbf{z}\|^2 = \|\mathbf{q}\|^2 + \|\mathbf{z}\|^2$, smallest exactly at $\mathbf{z} = \mathbf{0}$. A least-squares solution in $K^\perp$ differs from $\mathbf{q}$ by a vector of $K \cap K^\perp = \{\mathbf{0}\}$. Linearity: $\mathbf{x}^+$ is characterized by $\mathbf{x}^+ \in K^\perp$ and the normal equations, and both conditions are preserved by linear combinations.

(a) Let $\hat{\mathbf{x}}$ be a least-squares solution (Proposition 6.5.2(b)). The kernel K is a subspace of the finite-dimensional space $\mathbb{F}^n$, so by Theorem 6.4.24 $\hat{\mathbf{x}} = \mathrm{Pr}_K(\hat{\mathbf{x}}) + \mathbf{q}$ with $\mathbf{q} = \hat{\mathbf{x}} - \mathrm{Pr}_K(\hat{\mathbf{x}}) \in K^\perp$. By Proposition 6.5.2(b), the least-squares solutions are the vectors $\hat{\mathbf{x}} + \mathbf{z} = \mathbf{q} + (\mathrm{Pr}_K(\hat{\mathbf{x}}) + \mathbf{z})$ with $\mathbf{z} \in K$; as $\mathbf{z}$ runs over K, so does $\mathrm{Pr}_K(\hat{\mathbf{x}}) + \mathbf{z}$. So the least-squares solutions are the vectors $\mathbf{q} + \mathbf{z}'$ with $\mathbf{z}' \in K$. Since $\mathbf{q} \perp \mathbf{z}'$, Theorem 6.3.3 gives

$$\|\mathbf{q} + \mathbf{z}'\|^2 = \|\mathbf{q}\|^2 + \|\mathbf{z}'\|^2 \geq \|\mathbf{q}\|^2,$$

with equality if and only if $\mathbf{z}' = \mathbf{0}$. So $\mathbf{x}^+ = \mathbf{q}$ is the unique least-squares solution of smallest norm, and $\mathbf{q} \in K^\perp$. If $\mathbf{x}$ is any least-squares solution in $K^\perp$, then $\mathbf{x} - \mathbf{q}$ lies in K (both are in $\mathbf{q} + K$) and in $K^\perp$ (a subspace), so $\mathbf{x} = \mathbf{q}$ by Proposition 6.3.9(d). Since $\hat{\mathbf{x}}$ was arbitrary, $\mathbf{x}^+ = \hat{\mathbf{x}} - \mathrm{Pr}_K(\hat{\mathbf{x}})$ for every least-squares solution $\hat{\mathbf{x}}$.

(b) By (a) and Theorem 6.5.5, $\mathbf{x}^+$ is the only vector $\mathbf{x}$ with $\mathbf{x} \in K^\perp$ and $A^*A\mathbf{x} = A^*\mathbf{b}$. Let $\mathbf{b}, \mathbf{b}' \in \mathbb{F}^m$ have minimal solutions $\mathbf{x}^+, \mathbf{x}'^+$, and let $a \in \mathbb{F}$. Then $a\mathbf{x}^+ + \mathbf{x}'^+ \in K^\perp$, since $K^\perp$ is a subspace, and $A^*A\big(a\mathbf{x}^+ + \mathbf{x}'^+\big) = aA^*\mathbf{b} + A^*\mathbf{b}' = A^*(a\mathbf{b} + \mathbf{b}')$. So $a\mathbf{x}^+ + \mathbf{x}'^+$ is the minimal least-squares solution for $a\mathbf{b} + \mathbf{b}'$, which is linearity. □

Definition 6.5.28 (Pseudoinverse). The **pseudoinverse** of $A \in \mathbb{F}^{m\times n}$ is the matrix $A^+ \in \mathbb{F}^{n\times m}$ of the linear map $\mathbf{b} \mapsto \mathbf{x}^+$ of Proposition 6.5.27. That is, $A^+\mathbf{b}$ is the least-squares solution of $A\mathbf{x} = \mathbf{b}$ of smallest norm.

It is also called the *Moore–Penrose inverse*. By Proposition 6.5.2(a), $AA^+ = \mathrm{Pr}_{\mathrm{im}\, A}$. If the columns of A are independent, the least-squares solution is unique, so $A^+ = (A^*A)^{-1}A^*$ by Corollary 6.5.11; in particular

$A^+ = A^{-1}$ when A is invertible. Exercise 6.5.49 shows $A^+A = \mathrm{Pr}_{(\ker A)^\perp}$. LADR defines A^+ differently, as the inverse of the restriction of T_A to $(\ker A)^\perp$, composed with $\mathrm{Pr}_{\mathrm{im}\,A}$; by Proposition 6.5.27(a) it is the same matrix.

Example 6.5.29 (A pseudoinverse). Let $A = \begin{pmatrix} 1 & 2 \\ 1 & 2 \\ 2 & 4 \end{pmatrix}$ as in Example 6.5.12, and $\mathbf{a} = (1, 1, 2)$, so that $A\mathbf{x} = (x_1 + 2x_2)\mathbf{a}$ and $\mathrm{im}\,A = \mathrm{span}(\mathbf{a})$. For $\mathbf{b} \in \mathbb{R}^3$, $\mathrm{Pr}_{\mathrm{im}\,A}(\mathbf{b}) = ((\mathbf{b}\cdot\mathbf{a})/6)\mathbf{a}$, so the least-squares solutions are the $\mathbf{x}$ with $x_1 + 2x_2 = (\mathbf{b}\cdot\mathbf{a})/6$. Here $\ker A = \mathrm{span}((-2, 1))$, and $(\ker A)^\perp = \mathrm{span}((1, 2))$. The least-squares solution in $(\ker A)^\perp$ is $s(1, 2)$ with $5s = (\mathbf{b}\cdot\mathbf{a})/6$. So

$$\mathbf{x}^+ = \frac{\mathbf{b}\cdot\mathbf{a}}{30}\begin{pmatrix} 1 \\ 2 \end{pmatrix}, \quad A^+ = \frac{1}{30}\begin{pmatrix} 1 & 1 & 2 \\ 2 & 2 & 4 \end{pmatrix}.$$

For $\mathbf{b} = (1, 2, 0)$, $\mathbf{x}^+ = (1/10, 1/5)$, the point of the line of solutions $(1/2, 0) + t(-2, 1)$ of Example 6.5.12 closest to $\mathbf{0}$.

Computing A^+ from the definition means solving a least-squares problem for every $\mathbf{b}$. The singular value decomposition gives A^+ by a formula, and Section 9.2 finishes the story there.

Exercises

Exercise 6.5.30. ROUTINE Find the least-squares solution and the least-squares error of the system

$$x_1 + x_2 = 2, \quad x_1 - x_2 = 0, \quad 2x_1 + x_2 = 5,$$

and check that the residual is orthogonal to both columns of the coefficient matrix.

Solution on page 1512

Exercise 6.5.31. ROUTINE Find the least-squares solution of $A\mathbf{x} = \mathbf{b}$ in $\mathbb{C}^3$, where

$$A = \begin{pmatrix} 1 & i \\ 1 & -i \\ 1 & 1 \end{pmatrix}, \quad \mathbf{b} = \begin{pmatrix} 2 \\ 0 \\ 1 \end{pmatrix},$$

and the least-squares error.

Solution on page 1513

Exercise 6.5.32. ROUTINE A used car of a certain model sells for the following prices y (in thousands of dollars) at ages x (in years):

$$(1, 21), \quad (2, 19), \quad (3, 16), \quad (4, 15), \quad (5, 12).$$

Find the least-squares line and its residuals, and use it to predict the price at age 6. What does it predict at age 11, and what does that say about extrapolating?

Solution on page 1513

Exercise 6.5.33. STANDARD For the data $(-1, 2)$, $(0, 1)$, $(1, 1)$, $(2, 4)$:

(a) find the least-squares line and its squared error;

(b) find the least-squares parabola $y = c_0 + c_1x + c_2x^2$ and its squared error;

(c) explain without computing why the error in (b) can be no larger than the one in (a).

Solution on page 1514

Exercise 6.5.34. STANDARD Let $A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 1 & 2 \end{pmatrix}$, the matrix of Example 6.5.3. Find all $\mathbf{b} \in \mathbb{R}^3$ for which $(1, 1)$ is a least-squares solution of $A\mathbf{x} = \mathbf{b}$, and describe them geometrically. In terms of data, which data sets $(0, y_1), (1, y_2), (2, y_3)$ have the least-squares line $y = 1 + x$?

Solution on page 1514

Exercise 6.5.35. STANDARD Let $A \in \mathbb{F}^{m\times n}$ and $\mathbf{b}, \mathbf{b}' \in \mathbb{F}^m$. Prove or disprove:

(a) If $\hat{\mathbf{x}}$ is a least-squares solution of $A\mathbf{x} = \mathbf{b}$ and $\hat{\mathbf{x}}'$ is one of $A\mathbf{x} = \mathbf{b}'$, then $\hat{\mathbf{x}} + \hat{\mathbf{x}}'$ is a least-squares solution of $A\mathbf{x} = \mathbf{b} + \mathbf{b}'$.

(b) If $U \in \mathbb{F}^{m\times m}$ is unitary, then $UA\mathbf{x} = U\mathbf{b}$ and $A\mathbf{x} = \mathbf{b}$ have the same least-squares solutions.

(c) If $G \in \mathbb{F}^{m\times m}$ is invertible, then $GA\mathbf{x} = G\mathbf{b}$ and $A\mathbf{x} = \mathbf{b}$ have the same least-squares solutions.

(d) If $S \in \mathbb{F}^{n\times n}$ is invertible, then $\hat{\mathbf{x}}$ is a least-squares solution of $A\mathbf{x} = \mathbf{b}$ if and only if $S^{-1}\hat{\mathbf{x}}$ is a least-squares solution of $(AS)\mathbf{y} = \mathbf{b}$.

Solution on page 1515

Exercise 6.5.36. ROUTINE Let $A \in \mathbb{F}^{m\times n}$ have independent columns. A student computes

$$A(A^*A)^{-1}A^* = AA^{-1}(A^*)^{-1}A^* = I_m,$$

and concludes from Proposition 6.5.13 that $\mathrm{Pr}_{\mathrm{im}\, A} = I_m$, so that every vector of $\mathbb{F}^m$ lies in $\mathrm{im}\, A$ and every system $A\mathbf{x} = \mathbf{b}$ is consistent. Find the error. For which A is the conclusion correct?

Solution on page 1515

Exercise 6.5.37. ROUTINE

(a) Let $A \in \mathbb{F}^{m\times n}$, and suppose $\mathbf{1} = (1, \ldots, 1) \in \mathrm{im}\, A$. Show that the residual of a least-squares solution of $A\mathbf{x} = \mathbf{b}$ has entries adding up to 0, so that the entries of $A\hat{\mathbf{x}}$ have the same mean as those of $\mathbf{b}$.

(b) Part (a) applies to every polynomial fit. Show by an example that the residuals of the least-squares line through the origin, $y = cx$, need not add up to 0.

Solution on page 1515

Exercise 6.5.38. STANDARD Let $A \in \mathbb{F}^{m\times n}$ have independent columns, and let $P = A(A^*A)^{-1}A^*$. Without using Proposition 6.5.13, show:

(a) $P^2 = P$ and $P^* = P$;

(b) $PA = A$, and $\mathrm{im}\, P = \mathrm{im}\, A$;

(c) $\mathrm{tr}\, P = n$.

(d) Compute P for the regression matrix A with columns $\mathbf{1}$ and $\mathbf{x} = (1, 2, 3, 4)$, and check that $P\mathbf{1} = \mathbf{1}$, $P\mathbf{x} = \mathbf{x}$, and $\mathrm{tr}\, P = 2$.

Solution on page 1516

Exercise 6.5.39. STANDARD Let $A \in \mathbb{F}^{m\times n}$, $\mathbf{a}, \mathbf{b} \in \mathbb{F}^m$, and let $A' \in \mathbb{F}^{m\times(n+1)}$ be A with $\mathbf{a}$ appended as a last column. Let E and E' be the least-squares errors of $A\mathbf{x} = \mathbf{b}$ and $A'\mathbf{x}' = \mathbf{b}$, and let $\mathbf{r}$ be the residual of a least-squares solution of $A\mathbf{x} = \mathbf{b}$. Show that $E' \le E$, with $E' < E$ if and only if $\langle \mathbf{r}, \mathbf{a} \rangle \neq 0$.

Solution on page 1516

Exercise 6.5.40. STANDARD Let $(x_1, y_1), \ldots, (x_m, y_m)$ be data with the x_i not all equal and the y_i not all equal, let r be their correlation coefficient (Example 6.2.19), and let $y = c_0 + c_1 x$ be their least-squares line.

(a) Show that the residual vector is $\tilde{\mathbf{y}} - c_1 \tilde{\mathbf{x}}$.

(b) Show that the squared least-squares error is $\left(1 - r^2\right)\|\tilde{\mathbf{y}}\|^2$. So the line accounts for the fraction r^2 of the spread $\|\tilde{\mathbf{y}}\|^2$ of the y-values about their mean.

(c) Compute r^2 for the spring data of Example 6.5.18.

Solution on page 1517

Exercise 6.5.41. STANDARD Let $(x_1, y_1), \ldots, (x_m, y_m)$ be data with the x_i not all equal and the y_i not all equal, with correlation coefficient r. Let $y = c_0 + c_1 x$ be the least-squares line of y on x, and $x = d_0 + d_1 y$ the least-squares line of x on y (the roles of the coordinates exchanged).

(a) Show that $c_1 d_1 = r^2$.

(b) Show that both lines pass through $\left(m_x, m_y\right)$, and that they are the same line if and only if all data points lie on one line.

(c) Find both lines for the data $(0, 0), (1, 2), (2, 1), (3, 3)$.

Solution on page 1517

Exercise 6.5.42. STANDARD Let $y = c_0 + c_1 x$ be the least-squares line for data $(x_1, y_1), \ldots, (x_m, y_m)$ with the x_i not all equal. Let $\alpha, \gamma \neq 0$ and $\beta, \delta \in \mathbb{R}$, and change units and origins: $x_i' = \alpha x_i + \beta$ and $y_i' = \gamma y_i + \delta$. Show that the least-squares line for the new data is the image of the old line under $(x, y) \mapsto (\alpha x + \beta, \gamma y + \delta)$, namely

$$y' = \gamma\left(c_0 + c_1 \frac{x' - \beta}{\alpha}\right) + \delta.$$

Solution on page 1518

Exercise 6.5.43. STANDARD In $C[0, 1]$ with $\langle f, g \rangle = \int_0^1 f(t) g(t)\, \mathrm{d}t$, find the polynomial p of degree at most 2 closest to $f(t) = \sqrt{t}$, using Proposition 6.5.23, and compute $\|f - p\|^2$. Compare with the best line.

Solution on page 1518

Exercise 6.5.44. STANDARD Over any field F, the equations $A^{\mathsf{T}} A\mathbf{x} = A^{\mathsf{T}}\mathbf{b}$ make sense for $A \in F^{m \times n}$ and $\mathbf{b} \in F^m$, even though there is no inner product. Prove or disprove:

(a) For every $A \in \mathbb{F}_2^{m \times n}$ and $\mathbf{b} \in \mathbb{F}_2^m$, the system $A^{\mathsf{T}} A\mathbf{x} = A^{\mathsf{T}}\mathbf{b}$ has a solution.

(b) If $A \in \mathbb{F}_2^{m \times n}$ has independent columns, then $A^{\mathsf{T}} A$ is invertible.

(c) Both statements hold over $\mathbb{R}$.

Solution on page 1519

Exercise 6.5.45. HARD Give a second proof that the normal equations $A^* A\mathbf{x} = A^*\mathbf{b}$ always have a solution, by showing that $\operatorname{im}(A^* A) = \operatorname{im} A^*$.

Solution on page 1519

Solution on page 1520

Exercise 6.5.46. HARD Let $A \in \mathbb{F}^{m \times n}$ have linearly independent rows, and let $\mathbf{b} \in \mathbb{F}^m$.

(a) Show that AA^* is invertible.

(b) Show that $\mathbf{x}_0 = A^*(AA^*)^{-1}\mathbf{b}$ solves $A\mathbf{x} = \mathbf{b}$ and lies in $(\ker A)^\perp$.

(c) Show that $\mathbf{x}_0$ is the unique solution of $A\mathbf{x} = \mathbf{b}$ of smallest norm.

(d) Find the solution of smallest norm of $x_1 + x_2 + x_3 = 3$, $x_1 - x_3 = 1$.

Solution on page 1520

Exercise 6.5.47. HARD Let $(x_1, y_1), \dots, (x_m, y_m)$ be data with the x_i not all equal. For $i < j$ with $x_i \neq x_j$, let $s_{ij} = (y_j - y_i)/(x_j - x_i)$ be the slope of the line through the ith and jth points. Show that the slope of the least-squares line is a weighted average of these slopes:

$$c_1 = \frac{\sum_{i<j} (x_j - x_i)^2 s_{ij}}{\sum_{i<j} (x_j - x_i)^2},$$

where pairs with $x_i = x_j$ are omitted (they would have weight 0). Deduce that c_1 lies between the smallest and the largest of the s_{ij}.

Solution on page 1520

Exercise 6.5.48. STANDARD BEYOND 21-242

(a) Let $w_1, \dots, w_m > 0$, let $W = \operatorname{diag}(\sqrt{w_1}, \dots, \sqrt{w_m})$, and let $D = W^2$. Show that $\sum_i w_i |b_i - (A\mathbf{x})_i|^2 = \|W\mathbf{b} - WA\mathbf{x}\|^2$, and deduce from Theorem 6.5.5 that the minimizers of this sum are the solutions of $A^*DA\mathbf{x} = A^*D\mathbf{b}$.

(b) Four measurements give $(0,1), (1,2), (2,3), (3,8)$, but the last one was made with an instrument whose errors have twice the standard deviation of the others, so it gets weight $1/4$. Find the ordinary and the weighted least-squares lines.

Solution on page 1521

Exercise 6.5.49. STANDARD BEYOND 21-242 Let $A \in \mathbb{F}^{m \times n}$ with pseudoinverse A^+ (Definition 6.5.28).

(a) Show that $A^+A = \Pr_{(\ker A)^\perp}$.

(b) Deduce the *Penrose equations* $AA^+A = A$, $A^+AA^+ = A^+$, $(AA^+)^* = AA^+$, and $(A^+A)^* = A^+A$.

(c) Find A^+ for $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ and check the four equations.

Solution on page 1522

Exercise 6.5.50. CHALLENGE BEYOND 21-242 Least squares measures vertical distances to the line. *Orthogonal regression* measures perpendicular distances instead. Let $\mathbf{p}_1, \dots, \mathbf{p}_m \in \mathbb{R}^2$ be points, not all equal, with centroid $\mathbf{g}$, and write $\tilde{\mathbf{p}}_i = \mathbf{p}_i - \mathbf{g} = (\tilde{x}_i, \tilde{y}_i)$, $S_{xx} = \sum_i \tilde{x}_i^2$, $S_{yy} = \sum_i \tilde{y}_i^2$, $S_{xy} = \sum_i \tilde{x}_i \tilde{y}_i$. For a line ℓ and a point $\mathbf{p}$, let $\operatorname{dist}(\mathbf{p}, \ell) = \min_{\mathbf{q} \in \ell} \|\mathbf{p} - \mathbf{q}\|$, and let $D(\ell) = \sum_i \operatorname{dist}(\mathbf{p}_i, \ell)^2$.

(a) Every line is $\ell = \{\mathbf{p} \mid \langle \mathbf{p}, \mathbf{n}\rangle = c\}$ for a unit vector $\mathbf{n}$ and some $c \in \mathbb{R}$. Show that $\operatorname{dist}(\mathbf{p}, \ell) = |\langle \mathbf{p}, \mathbf{n}\rangle - c|$, and that for fixed $\mathbf{n}$, $D(\ell)$ is smallest when ℓ passes through $\mathbf{g}$.

(b) For a line through $\mathbf{g}$ with unit direction $\mathbf{u}$, show that $D(\ell) = \sum_i \|\tilde{\mathbf{p}}_i\|^2 - \sum_i \langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2$.

(c) With $\mathbf{u} = (\cos\theta, \sin\theta)$, show that $\sum_i \langle \tilde{\mathbf{p}}_i, \mathbf{u}\rangle^2 = \big(S_{xx} + S_{yy}\big)/2 + \Big(\big(S_{xx} - S_{yy}\big)/2\Big)\cos 2\theta + S_{xy}\sin 2\theta$. Deduce that, if $\mathbf{w} = \Big(\big(S_{xx} - S_{yy}\big)/2, S_{xy}\Big) \neq \mathbf{0}$, the lines minimizing D are exactly the line through $\mathbf{g}$ with $(\cos 2\theta, \sin 2\theta) = \mathbf{w}/\|\mathbf{w}\|$.

(d) Find the best line in this sense for $(0,0), (1,2), (2,1), (3,3)$, and compare it with the two lines of Exercise 6.5.41(c).

Solution on page 1522

6.6 Adjoints

The conjugate transpose moves a matrix from one side of the dot product to the other: $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{x} \cdot (A^*\mathbf{y})$ (Proposition 6.3.27(d)). That identity is what made the normal equations and the projection matrices of the last two sections work. This section asks for the same thing for a linear map $T : V \to W$ between inner product spaces: a map $T^* : W \to V$ with $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T^*\mathbf{w}\rangle$ for all $\mathbf{v}$ and $\mathbf{w}$. When V and W are finite-dimensional there is exactly one such map, the *adjoint* of T. It is defined without coordinates, and in orthonormal coordinates it is the conjugate transpose, so it is what the transpose of a matrix really is. Its kernel and image are the orthogonal complements of the image and kernel of T, which explains the orthogonality among the four fundamental subspaces of a matrix. The operators that equal their own adjoint, the self-adjoint operators, are the subject of Chapter 8. To construct T^* we first answer a simpler question: which linear functions $V \to \mathbb{F}$ are inner products with a fixed vector?

Throughout, V and W are inner product spaces over $\mathbb{F}$, where $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ (Notation 6.1.1), and we write $T\mathbf{v}$ for $T(\mathbf{v})$.

6.6.1 Linear functionals and the Riesz representation theorem

Definition 6.6.1 (Linear functional). A **linear functional** on a vector space V over a field F is a linear map $\varphi : V \to F$.

The linear functionals on V form the vector space $\mathrm{L}(V, F)$, the *dual space* of V, which Section 13.1 studies for its own sake. Here we need only a few examples.

Example 6.6.2 (Linear functionals).

(a) For scalars $a_1, \ldots, a_n \in F$, the map $\varphi(\mathbf{x}) = a_1x_1 + \cdots + a_nx_n$ is a linear functional on F^n. Every linear functional on F^n has this form, with $a_j = \varphi(\mathbf{e}_j)$, since $\varphi(\mathbf{x}) = \varphi\big(\sum_j x_j\mathbf{e}_j\big) = \sum_j x_j\varphi(\mathbf{e}_j)$ (Corollary 2.2.17).

(b) The trace $\operatorname{tr} : F^{n\times n} \to F$ (Proposition 2.4.27) and evaluation $p \mapsto p(c)$ on $F[x]$ (Example 2.1.9) are linear functionals, and so is $f \mapsto \int_0^1 f(t)\,dt$ on $C[0,1]$.

(c) Let V be an inner product space and $\mathbf{u} \in V$. Then $\mathbf{v} \mapsto \langle \mathbf{v}, \mathbf{u}\rangle$ is a linear functional on V, by linearity in the first slot. With $\mathbf{u}$ in the first slot instead, $\mathbf{v} \mapsto \langle \mathbf{u}, \mathbf{v}\rangle$ is not linear when $\mathbb{F} = \mathbb{C}$, since $\langle \mathbf{u}, i\mathbf{v}\rangle = -i\langle \mathbf{u}, \mathbf{v}\rangle$ (Proposition 6.1.4).

The Riesz representation theorem says that in a finite-dimensional inner product space, (c) is the only example: every linear functional is an inner product with a fixed vector.

Intuition (Level sets and the normal vector). Start with $V = \mathbb{R}^2$ and a nonzero functional $\varphi(\mathbf{x}) = a_1x_1 + a_2x_2$. Here $\varphi(\mathbf{x}) = \mathbf{x} \cdot \mathbf{u}$ with $\mathbf{u} = (a_1, a_2)$, so a representing vector exists, and the picture shows why it had

to. The level sets $\{\mathbf{x} \mid \varphi(\mathbf{x}) = c\}$ are parallel lines, the translates of the line $\ker\varphi$ (Corollary 2.6.31). A vector $\mathbf{u}$ with $\varphi(\mathbf{x}) = \langle \mathbf{x}, \mathbf{u}\rangle$ for all $\mathbf{x}$ must be orthogonal to every vector of $\ker\varphi$, so it lies on the line $(\ker\varphi)^\perp$, normal to the level sets. That fixes $\mathbf{u}$ up to a scalar, and one value of φ fixes the scalar: $\varphi(\mathbf{u}) = \langle \mathbf{u}, \mathbf{u}\rangle = \|\mathbf{u}\|^2$. Geometrically, $\langle \mathbf{x}, \mathbf{u}\rangle$ is $\|\mathbf{u}\|$ times the signed distance from $\mathbf{x}$ to the line $\ker\varphi$ (Example 6.4.35), so $\mathbf{u}$ points in the direction in which φ grows fastest, and $\|\mathbf{u}\|$ is the rate of growth (Figure 6.6.1). In the language of calculus, $\mathbf{u}$ is the gradient of φ.

The same reasoning works in every finite-dimensional inner product space: the representing vector is normal to the kernel. Over $\mathbb{C}$ there is one twist. In $\mathbb{C}^n$, the functional $\varphi(\mathbf{x}) = \sum_j a_j x_j$ equals $\mathbf{x} \cdot \mathbf{u} = \sum_j x_j \overline{u_j}$ only for $u_j = \overline{a_j}$. The coefficients of φ enter $\mathbf{u}$ conjugated, because $\mathbf{u}$ sits in the conjugate-linear slot.

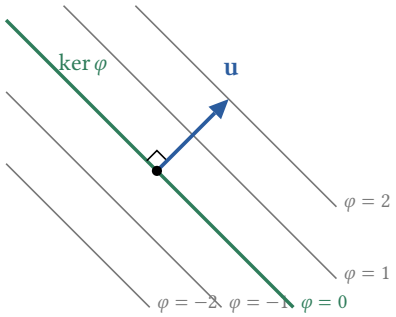

Figure 6.6.1. The level sets $\varphi = c$ of $\varphi(\mathbf{x}) = x_1 + x_2$ on $\mathbb{R}^2$ are parallel lines. The vector $\mathbf{u} = (1, 1)$ with $\varphi(\mathbf{x}) = \langle \mathbf{x}, \mathbf{u}\rangle$ is perpendicular to all of them, and its tip lies on the level set $\varphi = \|\mathbf{u}\|^2 = 2$.

The lecture does not prove the next theorem; it constructs adjoints of matrices directly, as in the second proof of Theorem 6.6.15 below. We include it because it explains what an adjoint is, and because its two proofs illustrate two ways of producing a vector with prescribed inner products.

Theorem 6.6.3 (Riesz representation theorem). BEYOND 21-242 Let V be a finite-dimensional inner product space, and let φ be a linear functional on V. There is exactly one vector $\mathbf{u} \in V$ such that

$$\varphi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}\rangle \quad \text{for all } \mathbf{v} \in V.$$

If $\mathbf{e}_1, \ldots, \mathbf{e}_n$ is an orthonormal basis of V, then $\mathbf{u} = \overline{\varphi(\mathbf{e}_1)}\mathbf{e}_1 + \cdots + \overline{\varphi(\mathbf{e}_n)}\mathbf{e}_n$.

Proof (with an orthonormal basis). STANDARD

Uses. Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.1.4 (Sesquilinearity), Definition 6.3.15 (Orthonormal list, orthonormal basis), Corollary 2.2.6 (Agreeing on a spanning list), Proposition 6.1.37 (Inner products distinguish vectors)
Techniques. Uniqueness via two candidates (Technique 1.1.8), Take an inner product to isolate a coefficient (Technique 6.3.12), Check it on a basis (Technique 2.2.7)
Hint 1. For uniqueness, suppose $\mathbf{u}$ and $\mathbf{u}'$ both work, and compare $\langle \mathbf{v}, \mathbf{u}\rangle$ with $\langle \mathbf{v}, \mathbf{u}'\rangle$. For existence, first find the only possible candidate.
Hint 2. If $\mathbf{u}$ works, its coefficient on $\mathbf{e}_j$ is $\langle \mathbf{u}, \mathbf{e}_j\rangle = \overline{\langle \mathbf{e}_j, \mathbf{u}\rangle} = \overline{\varphi(\mathbf{e}_j)}$.
Hint 3. To check the candidate, note that φ and $\mathbf{v} \mapsto \langle \mathbf{v}, \mathbf{u}\rangle$ are both linear in $\mathbf{v}$, so it suffices to compare them on the basis.
Sketch. Uniqueness: if $\langle \mathbf{v}, \mathbf{u}\rangle = \langle \mathbf{v}, \mathbf{u}'\rangle$ for all $\mathbf{v}$, then $\mathbf{u} = \mathbf{u}'$ by Proposition 6.1.37. Existence: for $\mathbf{u} = \sum_j \overline{\varphi(\mathbf{e}_j)}\mathbf{e}_j$, pulling the coefficients out of the second slot conjugates them back, so $\langle \mathbf{e}_k, \mathbf{u}\rangle = \sum_j \varphi(\mathbf{e}_j)\langle \mathbf{e}_k, \mathbf{e}_j\rangle = \varphi(\mathbf{e}_k)$. Two linear functionals that agree on a basis are equal.

Uniqueness. Suppose $\langle \mathbf{v}, \mathbf{u}\rangle = \langle \mathbf{v}, \mathbf{u}'\rangle$ for all $\mathbf{v} \in V$. Taking conjugates, $\langle \mathbf{u}, \mathbf{v}\rangle = \langle \mathbf{u}', \mathbf{v}\rangle$ for all $\mathbf{v}$, so $\mathbf{u} = \mathbf{u}'$ by Proposition 6.1.37.

Existence. By Theorem 6.4.20, V has an orthonormal basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$. Let $\mathbf{u} = \sum_{j=1}^n \overline{\varphi(\mathbf{e}_j)}\mathbf{e}_j$, and let $\psi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}\rangle$, a linear functional by linearity in the first slot. For each k, Proposition 6.1.4 and orthonormality give

$$\psi(\mathbf{e}_k) = \left\langle \mathbf{e}_k, \sum_{j=1}^{n} \overline{\varphi(\mathbf{e}_j)}\mathbf{e}_j \right\rangle = \sum_{j=1}^{n} \varphi(\mathbf{e}_j)\langle \mathbf{e}_k, \mathbf{e}_j\rangle = \varphi(\mathbf{e}_k),$$

since the conjugate of $\overline{\varphi(\mathbf{e}_j)}$ is $\varphi(\mathbf{e}_j)$ and $\langle \mathbf{e}_k, \mathbf{e}_j\rangle = \delta_{kj}$. So the linear maps φ and ψ agree on a basis of V, and $\varphi = \psi$ by Corollary 2.2.6. That is, $\varphi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}\rangle$ for every $\mathbf{v}$, as desired. □

Proof (via the orthogonal complement of the kernel). STANDARD

> *Uses.* Proposition 2.6.8 (Kernels and images are subspaces), Proposition 4.1.21 (Dimensions of subspaces), Corollary 6.4.27 (Testing whether a subspace is everything), Proposition 6.3.9 (Properties of $A^{\perp}$), Proposition 6.1.4 (Sesquilinearity)
> *Techniques.* Orthogonal decomposition (Technique 6.2.4)
> *Hint 1.* If $\mathbf{u}$ works, it is orthogonal to every vector of $\ker\varphi$. Where does that put it?
> *Hint 2.* For $\varphi \neq 0$, pick $\mathbf{z} \neq \mathbf{0}$ in $(\ker\varphi)^{\perp}$ (why does one exist?) and look for $\mathbf{u}$ as a multiple of $\mathbf{z}$. Testing at $\mathbf{v} = \mathbf{z}$ determines the multiple.
> *Hint 3.* To check the candidate at a general $\mathbf{v}$, subtract the multiple of $\mathbf{z}$ that lies on the same level set of φ: $\mathbf{v} - (\varphi(\mathbf{v})/\varphi(\mathbf{z}))\mathbf{z} \in \ker\varphi$.
> *Sketch.* Uniqueness is as in the first proof. If $\varphi \neq 0$, then $\ker\varphi \neq V$, so some $\mathbf{z} \neq \mathbf{0}$ is orthogonal to $\ker\varphi$ (Corollary 6.4.27), and $\varphi(\mathbf{z}) \neq 0$. Every $\mathbf{v}$ is $(\varphi(\mathbf{v})/\varphi(\mathbf{z}))\mathbf{z}$ plus a vector of $\ker\varphi$, which is orthogonal to $\mathbf{z}$. So $\langle \mathbf{v}, \mathbf{z}\rangle = (\varphi(\mathbf{v})/\varphi(\mathbf{z}))\|\mathbf{z}\|^2$, and $\mathbf{u} = \left(\overline{\varphi(\mathbf{z})}/\|\mathbf{z}\|^2\right)\mathbf{z}$ works.

Uniqueness is proved as in the first proof. For existence, if $\varphi = 0$, take $\mathbf{u} = \mathbf{0}$. Suppose $\varphi \neq 0$, and let $K = \ker\varphi$. It is a subspace of V (Proposition 2.6.8), finite-dimensional (Proposition 4.1.21), and $K \neq V$. By Corollary 6.4.27, $K^{\perp} \neq \{\mathbf{0}\}$, so we may choose $\mathbf{z} \in K^{\perp}$ with $\mathbf{z} \neq \mathbf{0}$. Since $K \cap K^{\perp} = \{\mathbf{0}\}$ (Proposition 6.3.9(d)), $\mathbf{z} \notin K$, that is, $\varphi(\mathbf{z}) \neq 0$. Let

$$\mathbf{u} = \frac{\overline{\varphi(\mathbf{z})}}{\|\mathbf{z}\|^2}\mathbf{z}.$$

Let $\mathbf{v} \in V$ and $c = \varphi(\mathbf{v})/\varphi(\mathbf{z})$. Then $\varphi(\mathbf{v} - c\mathbf{z}) = \varphi(\mathbf{v}) - c\varphi(\mathbf{z}) = 0$, so $\mathbf{v} - c\mathbf{z} \in K$. As $\mathbf{z} \in K^{\perp}$, conjugate symmetry gives $\langle \mathbf{v} - c\mathbf{z}, \mathbf{z}\rangle = 0$, and therefore

$$\langle \mathbf{v}, \mathbf{z}\rangle = c\langle \mathbf{z}, \mathbf{z}\rangle = \frac{\varphi(\mathbf{v})}{\varphi(\mathbf{z})}\|\mathbf{z}\|^2.$$

Pulling the real number $\|\mathbf{z}\|^2$ and the scalar $\overline{\varphi(\mathbf{z})}$ out of the second slot (Proposition 6.1.4),

$$\langle \mathbf{v}, \mathbf{u}\rangle = \frac{\varphi(\mathbf{z})}{\|\mathbf{z}\|^2}\langle \mathbf{v}, \mathbf{z}\rangle = \varphi(\mathbf{v}),$$

as desired. □

The first proof computes $\mathbf{u}$, and uniqueness shows that the formula, although written with an orthonormal basis, does not depend on which one. The second proof chooses no basis. It says where $\mathbf{u}$ lives, on the line $(\ker\varphi)^{\perp}$ normal to the level sets, and it uses finite-dimensionality only to know that $\ker\varphi$ has a nonzero orthogonal complement. In infinite-dimensional spaces, where no finite orthonormal basis exists, that is the step that can sometimes be rescued (Section 15.3).

Remark 6.6.4 (Where the conjugate comes from). The representing vector must sit in the second slot, since $\mathbf{v} \mapsto \langle \mathbf{u}, \mathbf{v}\rangle$ is not linear over $\mathbb{C}$ (Example 6.6.2(c)). Moving the coefficients $\varphi(\mathbf{e}_j)$ into the second slot conjugates them, which is why $\mathbf{u}$ has coefficients $\overline{\varphi(\mathbf{e}_j)}$. For the same reason the assignment $\mathbf{u} \mapsto \langle \cdot, \mathbf{u}\rangle$, from V to the linear functionals on V, is additive but conjugates scalars: $\langle \cdot, c\mathbf{u}\rangle = \overline{c}\langle \cdot, \mathbf{u}\rangle$. So Theorem 6.6.3 matches the vectors of V one to one with the linear functionals on V, by a map that is linear when $\mathbb{F} = \mathbb{R}$ and conjugate-linear when $\mathbb{F} = \mathbb{C}$. Section 13.2 returns to this identification.

Example 6.6.5 (Representing evaluation at 0). Give $\mathbb{R}[x]_{\le 1}$ the inner product $\langle p, q\rangle = \int_0^1 p(t)q(t)\,dt$, and let $\varphi(p) = p(0)$. Gram–Schmidt on $1, x$ gives the orthonormal basis $e_1 = 1, e_2 = \sqrt{3}(2x-1)$ (Example 6.4.19). Here $\varphi(e_1) = 1$ and $\varphi(e_2) = -\sqrt{3}$, so Theorem 6.6.3 gives the representing polynomial

$$q = 1 - \sqrt{3}\cdot\sqrt{3}(2x-1) = 4 - 6x.$$

Check on the basis $1, x$: $\int_0^1 (4-6t)\,dt = 4 - 3 = 1 = \varphi(1)$, and $\int_0^1 t(4-6t)\,dt = 2 - 2 = 0 = \varphi(x)$. So $\int_0^1 p(t)(4-6t)\,dt = p(0)$ for every p of degree at most 1.

The answer depends on the space, not only on the formula for φ. On $\mathbb{R}[x]_{\le 2}$ with the same inner product, evaluation at 0 is represented by $9 - 36x + 30x^2$, as one checks on $1, x, x^2$. The representing polynomials also grow: $\|4-6x\|^2 = \langle q, q\rangle = \varphi(q) = q(0) = 4$, and $\|9 - 36x + 30x^2\|^2 = 9$. (On $\mathbb{R}[x]_{\le n}$ the representing polynomial has norm $n+1$; Exercise 6.6.49 shows that its norm is at least $\sqrt{2n+1}$.) A polynomial that integrates against every p to give $p(0)$ has to concentrate its weight near $t = 0$, and higher degrees allow more concentration.

Exercise 6.6.6. ROUTINE

(a) Find $\mathbf{u} \in \mathbb{C}^3$ with $2z_1 - iz_2 + (1+i)z_3 = \mathbf{z}\cdot\mathbf{u}$ for all $\mathbf{z} \in \mathbb{C}^3$.

(b) With the inner product of Example 6.6.5 on $\mathbb{R}[x]_{\le 1}$, find the polynomial q with $\langle p, q\rangle = p(1)$ for all p.

Solution on page 1523

Finite-dimensionality cannot be dropped from Theorem 6.6.3.

Non-example 6.6.7 (Riesz fails in infinite dimensions). BEYOND 21-242 Let P be the space of real polynomial functions on $[0,1]$, a subspace of $C[0,1]$, with $\langle f, g\rangle = \int_0^1 f(t)g(t)\,dt$ (Proposition 6.1.13). We show that the linear functional $\varphi(p) = p(0)$ is not of the form $\langle \cdot, q\rangle$ for any $q \in P$. Suppose that $\int_0^1 p(t)q(t)\,dt = p(0)$ for every $p \in P$. Apply this to $p(t) = tq(t)$, which vanishes at 0:

$$\int_0^1 tq(t)^2\,dt = 0.$$

The integrand is continuous and nonnegative on $[0,1]$, so it is identically 0 (Lemma 6.1.14). Hence $q(t) = 0$ for $0 < t \le 1$, and $q(0) = 0$ by continuity. But then $p(0) = \langle p, q\rangle = 0$ for every p, which fails for $p = 1$.

Restricted to the polynomials of degree at most n, the same functional is represented by a polynomial of norm $n+1$ (Example 6.6.5). As n grows, these representatives pile up near $t = 0$ without converging to any polynomial. Section 15.3 explains which functionals do have representatives in infinite dimensions.

6.6.2 The adjoint

Intuition (Moving a map across the inner product). For a matrix A, read the identity $(A\mathbf{x})\cdot\mathbf{y} = \mathbf{x}\cdot(A^*\mathbf{y})$ as follows. Fix $\mathbf{y}$. The left side is a measurement of the output $A\mathbf{x}$: for a unit vector $\mathbf{y}$, it is the component of $A\mathbf{x}$ along $\mathbf{y}$. The right side computes the same number from the input $\mathbf{x}$ alone, as its component along the vector $A^*\mathbf{y}$. So A^* turns a measurement on the output side into a measurement on the input side.

For a linear map $T : V \to W$ we ask for the same conversion. Fix $\mathbf{w} \in W$. The function $\mathbf{v} \mapsto \langle T\mathbf{v}, \mathbf{w}\rangle$ is a linear functional on V, and when V is finite-dimensional, Theorem 6.6.3 says that it is $\mathbf{v} \mapsto \langle \mathbf{v}, \mathbf{u}\rangle$ for exactly one $\mathbf{u} \in V$. Calling this vector $T^*\mathbf{w}$ defines a function $T^* : W \to V$. The definition records the property that T^* is meant to have, without presupposing that such a function exists.

Definition 6.6.8 (Adjoint). Let V and W be inner product spaces and $T \in \mathrm{L}(V, W)$. A function $S : W \to V$ is an **adjoint** of T if

$$\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, S\mathbf{w}\rangle \quad \text{for all } \mathbf{v} \in V \text{ and } \mathbf{w} \in W.$$

By Proposition 6.6.9 below, T has at most one adjoint. When it exists, it is denoted T^* ("T star").

The inner product on the left is that of W, and the one on the right is that of V; we use the same notation for both. Taking conjugates of both sides gives the equivalent form

$$\langle \mathbf{w}, T\mathbf{v}\rangle = \langle T^*\mathbf{w}, \mathbf{v}\rangle,$$

which is how the lecture writes the definition. So T can be moved out of either slot into the other, at the price of a star. We did not ask S to be linear; linearity comes for free.

Proposition 6.6.9 (Adjoints are unique and linear). Let V and W be inner product spaces and $T \in \mathrm{L}(V, W)$.

(a) T has at most one adjoint.

(b) Every adjoint of T is linear. So $T^* \in \mathrm{L}(W, V)$ whenever T^* exists.

Proof. ROUTINE

Uses. Definition 6.6.8 (Adjoint), Proposition 6.1.37 (Inner products distinguish vectors), Proposition 6.1.4 (Sesquilinearity)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), let S and S' be adjoints and fix $\mathbf{w}$. What do you know about $\langle \mathbf{v}, S\mathbf{w}\rangle$ and $\langle \mathbf{v}, S'\mathbf{w}\rangle$ as $\mathbf{v}$ varies?
Hint 2. Proposition 6.1.37 says that a vector is determined by its inner products with all vectors. Here the unknown vectors sit in the second slot, so conjugate first.
Hint 3. For (b), compute $\langle \mathbf{v}, S(a\mathbf{w} + b\mathbf{w}')\rangle$ with the defining identity and Proposition 6.1.4, and compare it with $\langle \mathbf{v}, aS\mathbf{w} + bS\mathbf{w}'\rangle$.
Sketch. (a) For each $\mathbf{w}$, $\langle \mathbf{v}, S\mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, S'\mathbf{w}\rangle$ for every $\mathbf{v}$, so $S\mathbf{w} = S'\mathbf{w}$ by Proposition 6.1.37. (b) Both $\langle \mathbf{v}, S(a\mathbf{w} + b\mathbf{w}')\rangle$ and $\langle \mathbf{v}, aS\mathbf{w} + bS\mathbf{w}'\rangle$ equal $\overline{a}\langle T\mathbf{v}, \mathbf{w}\rangle + \overline{b}\langle T\mathbf{v}, \mathbf{w}'\rangle$ for every $\mathbf{v}$; apply Proposition 6.1.37 again.

(a) Let $S, S' : W \to V$ be adjoints of T, and fix $\mathbf{w} \in W$. For every $\mathbf{v} \in V$,

$$\langle \mathbf{v}, S\mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, S'\mathbf{w}\rangle.$$

Taking conjugates, $\langle S\mathbf{w}, \mathbf{v}\rangle = \langle S'\mathbf{w}, \mathbf{v}\rangle$ for every $\mathbf{v} \in V$, so $S\mathbf{w} = S'\mathbf{w}$ by Proposition 6.1.37. As $\mathbf{w}$ was arbitrary, $S = S'$.

(b) Let S be an adjoint of T, and let $\mathbf{w}, \mathbf{w}' \in W$ and $a, b \in \mathbb{F}$. For every $\mathbf{v} \in V$, the defining identity and Proposition 6.1.4 give

$$\begin{aligned}\langle \mathbf{v}, S(a\mathbf{w} + b\mathbf{w}')\rangle &= \langle T\mathbf{v}, a\mathbf{w} + b\mathbf{w}'\rangle \\ &= \overline{a}\langle T\mathbf{v}, \mathbf{w}\rangle + \overline{b}\langle T\mathbf{v}, \mathbf{w}'\rangle \\ &= \overline{a}\langle \mathbf{v}, S\mathbf{w}\rangle + \overline{b}\langle \mathbf{v}, S\mathbf{w}'\rangle \\ &= \langle \mathbf{v}, aS\mathbf{w} + bS\mathbf{w}'\rangle.\end{aligned}$$

As in (a), taking conjugates and applying Proposition 6.1.37 gives $S(a\mathbf{w} + b\mathbf{w}') = aS\mathbf{w} + bS\mathbf{w}'$. □

Neither part used a dimension: uniqueness and linearity hold in every inner product space, and this is the order in which the lecture proceeds. In practice it means that adjoints are found by guessing a formula and checking the defining identity; uniqueness does the rest.

Example 6.6.10 (The adjoint of a matrix). Let $A \in \mathbb{F}^{m\times n}$, and give $\mathbb{F}^n$ and $\mathbb{F}^m$ the dot product. By Proposition 6.3.27(d), $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{x} \cdot (A^*\mathbf{y})$ for all $\mathbf{x}$ and $\mathbf{y}$; that is, T_{A^*} is an adjoint of T_A. By Proposition 6.6.9,

$$(T_A)^* = T_{A^*}.$$

Over $\mathbb{R}$ this is $T_{A^{\mathsf{T}}}$. Over $\mathbb{C}$ the transpose would be wrong. For $A = (i) \in \mathbb{C}^{1\times 1}$, T_A is multiplication by i on $\mathbb{C}$, and $(ix)\cdot y = ix\overline{y}$, while $x\cdot(iy) = x\overline{iy} = -ix\overline{y}$. The adjoint of multiplication by i is multiplication by $\overline{i} = -i$, in line with $A^* = \left(\overline{i}\right)$.

So the star on a matrix and the star on a map agree, as long as $\mathbb{F}^n$ and $\mathbb{F}^m$ carry the dot product. The adjoint depends on the inner products as well as on the map (Exercise 6.6.31).

Technique 6.6.11 (Find the adjoint by isolating the input). To compute $T^*\mathbf{w}$, start from $\langle T\mathbf{v}, \mathbf{w}\rangle$, substitute the formula for T, and rearrange until the expression reads $\langle \mathbf{v}, \mathbf{u}\rangle$, with $\mathbf{v}$ alone in the first slot and $\mathbf{u}$ built from $\mathbf{w}$ only. Then $T^*\mathbf{w} = \mathbf{u}$ by Proposition 6.6.9. Scalars that move into the second slot pick up a bar. The same move proves identities: to show that a given map S is T^*, check $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, S\mathbf{w}\rangle$ for all $\mathbf{v}$ and $\mathbf{w}$, without ever writing a formula for T^*. This is the analogue for adjoints of Technique 2.5.16 and Technique 6.4.7.

Reach for it when computing the adjoint of an explicit map, and when proving identities such as $(RT)^* = T^*R^*$. The canonical example is Example 6.6.13.

Used in. Exercise 6.6.17, Proposition 6.6.18, Exercise 6.6.31, Exercise 6.6.33, Proposition 8.4.10.

Example 6.6.12 (An adjoint from $\mathbb{C}^3$ to $\mathbb{C}^2$). Let $T : \mathbb{C}^3 \to \mathbb{C}^2$, $T(z_1, z_2, z_3) = (z_1 + iz_3, 2z_2 - z_3)$, with dot products. For $\mathbf{z} \in \mathbb{C}^3$ and $\mathbf{w} \in \mathbb{C}^2$,

$$\begin{aligned}\langle T\mathbf{z}, \mathbf{w}\rangle &= (z_1 + iz_3)\overline{w_1} + (2z_2 - z_3)\overline{w_2}\\ &= z_1\overline{w_1} + z_2\cdot 2\overline{w_2} + z_3(\overline{iw_1} - \overline{w_2})\\ &= z_1\overline{w_1} + z_2\overline{2w_2} + z_3\overline{-iw_1 - w_2},\end{aligned}$$

which is $\langle \mathbf{z}, (w_1, 2w_2, -iw_1 - w_2)\rangle$. So $T^*(w_1, w_2) = (w_1, 2w_2, -iw_1 - w_2)$. As Example 6.6.10 predicts, this is multiplication by the conjugate transpose of the matrix of T:

$$\begin{pmatrix}1 & 0 & i\\ 0 & 2 & -1\end{pmatrix}^* = \begin{pmatrix}1 & 0\\ 0 & 2\\ -i & -1\end{pmatrix}.$$

Example 6.6.13 (Rank-one maps). Fix $\mathbf{u} \in V$ and $\mathbf{x} \in W$, and let $T\mathbf{v} = \langle \mathbf{v}, \mathbf{u}\rangle\mathbf{x}$. For $\mathbf{v} \in V$ and $\mathbf{w} \in W$,

$$\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, \mathbf{u}\rangle\langle \mathbf{x}, \mathbf{w}\rangle = \left\langle \mathbf{v}, \overline{\langle \mathbf{x}, \mathbf{w}\rangle}\mathbf{u}\right\rangle = \langle \mathbf{v}, \langle \mathbf{w}, \mathbf{x}\rangle\mathbf{u}\rangle,$$

using Proposition 6.1.4 to move the scalar $\langle \mathbf{x}, \mathbf{w}\rangle$ into the second slot. So

$$T^*\mathbf{w} = \langle \mathbf{w}, \mathbf{x}\rangle\mathbf{u}.$$

The map T reads off the component of its input along $\mathbf{u}$ and writes the result along $\mathbf{x}$; its adjoint reads along $\mathbf{x}$ and writes along $\mathbf{u}$. For $V = \mathbb{F}^n$ and $W = \mathbb{F}^m$ with dot products, $T\mathbf{v} = (\mathbf{u}^*\mathbf{v})\mathbf{x} = \mathbf{x}\mathbf{u}^*\mathbf{v}$ is multiplication by the rank-one matrix $\mathbf{x}\mathbf{u}^*$, and T^* is multiplication by $\mathbf{u}\mathbf{x}^* = (\mathbf{x}\mathbf{u}^*)^*$. No dimension assumption was needed.

Example 6.6.14 (Multiplication operators). Let $V = C([0,1], \mathbb{C})$ with $\langle f, g\rangle = \int_0^1 f(t)\overline{g(t)}\,dt$ (Proposition 6.1.13). For a continuous function $h : [0,1] \to \mathbb{C}$, let $M_h f = hf$, the pointwise product. Then

$$\langle hf, g\rangle = \int_0^1 h(t)f(t)\overline{g(t)}\,dt = \int_0^1 f(t)\overline{\overline{h(t)}g(t)}\,dt = \left\langle f, \overline{h}g\right\rangle,$$

so M_h has an adjoint, $M_h^* = M_{\overline{h}}$, although V is infinite-dimensional. This is the continuous version of $\operatorname{diag}(d_1, \ldots, d_n)^* = \operatorname{diag}\left(\overline{d_1}, \ldots, \overline{d_n}\right)$: M_h scales the value at each point t by $h(t)$, as a diagonal matrix scales each coordinate.

Existence, and the matrix of the adjoint

In finite dimensions adjoints always exist, and orthonormal bases compute them.

Theorem 6.6.15 (Existence of adjoints). Let V and W be finite-dimensional inner product spaces and $T \in \mathrm{L}(V, W)$.

(a) T has exactly one adjoint T^*, and $T^* \in \mathrm{L}(W, V)$.

(b) If $\mathcal{B} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ and $\mathcal{C} = \mathbf{f}_1, \ldots, \mathbf{f}_m$ are orthonormal bases of V and W, then

$$[T^*]_{\mathcal{B}\mathcal{C}} = \big([T]_{\mathcal{C}\mathcal{B}}\big)^*.$$

Proof (via the Riesz representation theorem). STANDARD BEYOND 21-242

Uses. Theorem 6.6.3 (Riesz representation theorem), Proposition 6.6.9 (Adjoints are unique and linear), Proposition 6.3.18 (Coordinates in an orthonormal basis), Definition 2.3.1 (Matrix of a linear map), Definition 6.3.26 (Conjugate transpose)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. For (a), fix $\mathbf{w}$ and look at $\mathbf{v} \mapsto \langle T\mathbf{v}, \mathbf{w}\rangle$. What kind of function of $\mathbf{v}$ is it?
Hint 2. Apply Theorem 6.6.3 to that functional and call the resulting vector $T^*\mathbf{w}$. Linearity and uniqueness are Proposition 6.6.9.
Hint 3. For (b), the (i, j) entry of $[T]_{\mathcal{C}\mathcal{B}}$ is the ith coordinate of $T\mathbf{e}_j$ in the orthonormal basis $\mathcal{C}$, which is an inner product (Proposition 6.3.18).
Sketch. For fixed $\mathbf{w}$, $\mathbf{v} \mapsto \langle T\mathbf{v}, \mathbf{w}\rangle$ is a linear functional on V; Theorem 6.6.3 represents it as $\langle \cdot, \mathbf{u}\rangle$, and $T^*\mathbf{w} = \mathbf{u}$ satisfies the defining identity. In orthonormal bases, $[T]_{\mathcal{C}\mathcal{B}}$ has entries $\langle T\mathbf{e}_j, \mathbf{f}_i\rangle$, and $[T^*]_{\mathcal{B}\mathcal{C}}$ has entries $\langle T^*\mathbf{f}_i, \mathbf{e}_j\rangle = \overline{\langle T\mathbf{e}_j, \mathbf{f}_i\rangle}$.

(a) Fix $\mathbf{w} \in W$. The function $\varphi_{\mathbf{w}} : V \to \mathbb{F}$, $\varphi_{\mathbf{w}}(\mathbf{v}) = \langle T\mathbf{v}, \mathbf{w}\rangle$, is a linear functional, since T is linear and the inner product is linear in its first slot. By Theorem 6.6.3 there is exactly one vector of V, which we call $T^*\mathbf{w}$, with

$$\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T^*\mathbf{w}\rangle \quad \text{for all } \mathbf{v} \in V.$$

Doing this for every $\mathbf{w}$ defines a function $T^* : W \to V$ that satisfies Definition 6.6.8. By Proposition 6.6.9 it is the only adjoint of T, and it is linear.

(b) Let $A = [T]_{\mathcal{C}\mathcal{B}}$. Its jth column is $\big[T\mathbf{e}_j\big]_{\mathcal{C}}$, so by Proposition 6.3.18(b) its (i, j) entry is $a_{ij} = \langle T\mathbf{e}_j, \mathbf{f}_i\rangle$. In the same way, the (j, i) entry of $[T^*]_{\mathcal{B}\mathcal{C}}$ is the jth coordinate of $T^*\mathbf{f}_i$ in $\mathcal{B}$, namely

$$\langle T^*\mathbf{f}_i, \mathbf{e}_j\rangle = \overline{\langle \mathbf{e}_j, T^*\mathbf{f}_i\rangle} = \overline{\langle T\mathbf{e}_j, \mathbf{f}_i\rangle} = \overline{a_{ij}}.$$

So $[T^*]_{\mathcal{B}\mathcal{C}} = A^*$ (Definition 6.3.26). □

Proof (via the conjugate transpose). ROUTINE

Uses. Theorem 6.4.20 (Orthonormal bases exist), Theorem 2.3.20 (Linear maps correspond to matrices), Theorem 2.3.9 (The matrix of a map computes the map), Theorem 6.3.22 (Parseval's identity), Proposition 6.3.27 (Properties of the conjugate transpose), Proposition 6.6.9 (Adjoints are unique and linear)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Fix orthonormal bases. In coordinates, inner products become dot products (Theorem 6.3.22), and T becomes multiplication by $A = [T]_{\mathcal{C}\mathcal{B}}$. For matrices you already know an adjoint.
Hint 2. Let $S \in \mathrm{L}(W, V)$ be the map with $[S]_{\mathcal{B}\mathcal{C}} = A^*$, and compute $\langle T\mathbf{v}, \mathbf{w}\rangle$ in coordinates.
Sketch. Let S be the linear map with $[S]_{\mathcal{B}\mathcal{C}} = A^*$. With $\mathbf{x} = [\mathbf{v}]_{\mathcal{B}}$ and $\mathbf{y} = [\mathbf{w}]_{\mathcal{C}}$, Parseval's identity gives $\langle T\mathbf{v}, \mathbf{w}\rangle = (A\mathbf{x}) \cdot \mathbf{y} = \mathbf{x} \cdot (A^*\mathbf{y}) = \langle \mathbf{v}, S\mathbf{w}\rangle$. So S is an adjoint, it is the only one by Proposition 6.6.9, and (b) holds by construction.

Orthonormal bases of V and W exist by Theorem 6.4.20. We prove (a) and (b) together, for arbitrary orthonormal bases $\mathcal{B}$ and $\mathcal{C}$. Let $A = [T]_{\mathcal{C}\mathcal{B}} \in \mathbb{F}^{m \times n}$. By Theorem 2.3.20 there is a linear map $S : W \to V$ with $[S]_{\mathcal{B}\mathcal{C}} = A^*$. Let $\mathbf{v} \in V$ and $\mathbf{w} \in W$, and write $\mathbf{x} = [\mathbf{v}]_{\mathcal{B}}$ and $\mathbf{y} = [\mathbf{w}]_{\mathcal{C}}$. By Theorem 2.3.9, $[T\mathbf{v}]_{\mathcal{C}} = A\mathbf{x}$ and $[S\mathbf{w}]_{\mathcal{B}} = A^*\mathbf{y}$. Parseval's identity (Theorem 6.3.22(a)) computes the inner products of V and of W as dot products of coordinate vectors, so

$$\langle T\mathbf{v}, \mathbf{w}\rangle = (A\mathbf{x}) \cdot \mathbf{y} = \mathbf{x} \cdot (A^*\mathbf{y}) = \langle \mathbf{v}, S\mathbf{w}\rangle,$$

where the middle step is Proposition 6.3.27(d). So S is an adjoint of T. By Proposition 6.6.9 it is the only one, so $T^* = S \in \mathrm{L}(W, V)$ and $[T^*]_{\mathcal{BC}} = A^*$. □

The second proof is the lecture's route: orthonormal coordinates turn V and W into $\mathbb{F}^n$ and $\mathbb{F}^m$ with their dot products, and there the adjoint is the conjugate transpose (Example 6.6.10). The first proof never chooses a basis of W, so it shows that (a) holds whenever V alone is finite-dimensional. Without any finite-dimensionality, adjoints can fail to exist: on the space P of Non-example 6.6.7, the operator $Tp = p(0) \cdot 1$ has none, since an adjoint would give $\langle p, T^*1\rangle = \langle Tp, 1\rangle = p(0)$ for every p, so that T^*1 would represent evaluation at 0.

Intuition (Reading and writing). Here is a formula for T^* that needs only an orthonormal basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$ of V. Every $\mathbf{v} \in V$ is $\sum_j \langle \mathbf{v}, \mathbf{e}_j\rangle \mathbf{e}_j$ (Proposition 6.3.18), so

$$T\mathbf{v} = \sum_{j=1}^{n} \langle \mathbf{v}, \mathbf{e}_j\rangle T\mathbf{e}_j.$$

That is, T is a sum of n rank-one maps, the jth of which reads the $\mathbf{e}_j$-coordinate of its input and writes it along $T\mathbf{e}_j$. By Example 6.6.13, the adjoint of the jth map reads along $T\mathbf{e}_j$ and writes along $\mathbf{e}_j$, and the adjoint of a sum is the sum of the adjoints (Proposition 6.6.18(a) below). So

$$T^*\mathbf{w} = \sum_{j=1}^{n} \langle \mathbf{w}, T\mathbf{e}_j\rangle \mathbf{e}_j.$$

One can also read this off directly: the $\mathbf{e}_j$-coordinate of $T^*\mathbf{w}$ is $\langle T^*\mathbf{w}, \mathbf{e}_j\rangle = \overline{\langle \mathbf{e}_j, T^*\mathbf{w}\rangle} = \overline{\langle T\mathbf{e}_j, \mathbf{w}\rangle} = \langle \mathbf{w}, T\mathbf{e}_j\rangle$. For $T = T_A$ on $\mathbb{F}^n$ with the standard basis, the vectors $T\mathbf{e}_j$ are the columns $\mathbf{a}_j$ of A, and the formula says that the jth entry of $A^*\mathbf{w}$ is $\mathbf{w} \cdot \mathbf{a}_j$: the rows of A^* are the conjugated columns of A.

The hypothesis that the bases are orthonormal in Theorem 6.6.15(b) cannot be dropped. In other bases the matrix of T^* is usually not the conjugate transpose of the matrix of T.

Example 6.6.16 (The adjoint of differentiation). Give $V = \mathbb{R}[x]_{\leq 1}$ the inner product $\langle p, q\rangle = \int_0^1 p(t)q(t)\,\mathrm{d}t$, and let $D(a + bx) = b$ be differentiation (Example 2.1.9). In the basis $\mathcal{B} = 1, x$,

$$[D]_{\mathcal{B}} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \text{and} \quad ([D]_{\mathcal{B}})^{\mathsf{T}} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

is the matrix of the map $a + bx \mapsto ax$. That map is not D^*: for $p = x$ and $q = 1$, $\langle Dp, q\rangle = \langle 1, 1\rangle = 1$, while $\langle p, 1 \cdot x\rangle = \langle x, x\rangle = 1/3$. The basis $\mathcal{B}$ is not orthonormal, since $\langle 1, x\rangle = 1/2$. To find D^*, use the orthonormal basis $\mathcal{O} = e_1, e_2$ with $e_1 = 1$ and $e_2 = \sqrt{3}(2x - 1)$ of Example 6.6.5. Since $De_1 = 0$ and $De_2 = 2\sqrt{3} = 2\sqrt{3}e_1$,

$$[D]_{\mathcal{O}} = \begin{pmatrix} 0 & 2\sqrt{3} \\ 0 & 0 \end{pmatrix}, \quad [D^*]_{\mathcal{O}} = \begin{pmatrix} 0 & 0 \\ 2\sqrt{3} & 0 \end{pmatrix}$$

by Theorem 6.6.15(b). So $D^*e_1 = 2\sqrt{3}e_2 = 6(2x - 1)$ and $D^*e_2 = 0$. Writing $a + bx = (a + b/2)e_1 + \big(b/\big(2\sqrt{3}\big)\big)e_2$ gives

$$D^*(a + bx) = (2a + b)(6x - 3), \quad [D^*]_{\mathcal{B}} = \begin{pmatrix} -6 & -3 \\ 12 & 6 \end{pmatrix}.$$

As a check, for $p = a + bx$ and $q = c + dx$, $\langle Dp, q\rangle = \int_0^1 b(c + dt)\,\mathrm{d}t = b(c + d/2)$, and since $\int_0^1 (6t - 3)\,\mathrm{d}t = 0$ and $\int_0^1 t(6t - 3)\,\mathrm{d}t = 1/2$, $\langle p, D^*q\rangle = (2c + d)b/2$, the same number.

So $[D^*]_{\mathcal{B}}$ has nothing to do with $([D]_{\mathcal{B}})^{\mathsf{T}}$. Nor is D^* a differentiation-like map, such as $-D$: integrating by parts, $\langle Dp, q\rangle = p(1)q(1) - p(0)q(0) - \langle p, Dq\rangle$, and the boundary terms are what D^* has to absorb (compare

Exercise 6.6.39, where there are no boundary terms). Exercise 6.6.46 gives the general rule for a basis that is not orthonormal: $[T^*]_{\mathcal{B}} = G^{-1}([T]_{\mathcal{B}})^* G$, where G is the Gram matrix of $\mathcal{B}$.

Intuition (What the adjoint is). In coordinates. In orthonormal bases, T^* is the conjugate transpose (Theorem 6.6.15(b)). The transpose of a matrix is defined by moving entries around, so it depends on the basis, and in other bases it describes some unrelated map (Example 6.6.16). The adjoint is defined by the inner product alone, and the conjugate transpose is what it looks like in orthonormal coordinates. This is the sense in which the adjoint is the right generalization of the transpose. What makes the transpose useful, in the normal equations, in A^*A, in projection matrices, is the identity $(A\mathbf{x}) \cdot \mathbf{y} = \mathbf{x} \cdot (A^*\mathbf{y})$, and that identity is the definition of T^*. The index shuffle is a consequence that holds only in orthonormal bases. Over $\mathbb{C}$ the conjugate is forced, as Example 6.6.10 shows.

As a measurement. For a unit vector $\mathbf{w}$, $\langle T\mathbf{v}, \mathbf{w}\rangle$ is the component of the output $T\mathbf{v}$ along $\mathbf{w}$, and the definition says that it is also the component of the input $\mathbf{v}$ along $T^*\mathbf{w}$. By Cauchy–Schwarz, among unit vectors $\mathbf{v}$ the real part of $\langle T\mathbf{v}, \mathbf{w}\rangle$ is largest when $\mathbf{v}$ points along $T^*\mathbf{w}$ (Exercise 6.6.42). So $T^*\mathbf{w}$ points toward the inputs that T pushes furthest in the direction $\mathbf{w}$, and its length says how far.

Reading and writing. By Example 6.6.13, T^* exchanges the vectors along which T reads and writes. Every T is a sum of such rank-one maps, and T^* exchanges the roles in each.

Without an inner product. A matrix $A \in F^{m\times n}$ over any field still has a transpose, and Section 13.1 gives it a meaning: it is the matrix of the dual map, which acts on linear functionals rather than on vectors. In an inner product space, Theorem 6.6.3 identifies functionals with vectors, and the dual map becomes the adjoint (Section 13.2).

ASIDE: *Gradients flow backward through the adjoint* BEYOND 21-242

Over $\mathbb{R}$, the derivative of a differentiable function $f : \mathbb{R}^n \to \mathbb{R}$ at $\mathbf{v}$ is a linear functional, $\mathbf{h} \mapsto \nabla f(\mathbf{v}) \cdot \mathbf{h}$, and its Riesz vector is the gradient: $f(\mathbf{v} + \mathbf{h}) \approx f(\mathbf{v}) + \nabla f(\mathbf{v}) \cdot \mathbf{h}$ for small $\mathbf{h}$. Now let $f(\mathbf{v}) = g(A\mathbf{v})$ for a matrix A and a differentiable $g : \mathbb{R}^m \to \mathbb{R}$. Then

$$f(\mathbf{v} + \mathbf{h}) = g(A\mathbf{v} + A\mathbf{h}) \approx g(A\mathbf{v}) + \nabla g(A\mathbf{v}) \cdot (A\mathbf{h}) = f(\mathbf{v}) + \left(A^{\mathsf{T}} \nabla g(A\mathbf{v})\right) \cdot \mathbf{h},$$

so $\nabla f(\mathbf{v}) = A^{\mathsf{T}} \nabla g(A\mathbf{v})$. The map A carries inputs forward, and its adjoint carries gradients backward. A neural network composes many linear maps with simple nonlinear ones, and training it requires the gradient of a loss with respect to the inputs of every layer. These are computed from the last layer to the first, multiplying by transposed weight matrices along the way; this is *backpropagation* (Section 16.6).

Exercise 6.6.17. ROUTINE Give $\mathbb{F}^{n\times n}$ the Frobenius inner product $\langle X, Y\rangle = \operatorname{tr}(Y^*X)$ (Proposition 6.1.16), and fix $A \in \mathbb{F}^{n\times n}$.

(a) Find the adjoint of $R_A(X) = XA$.

(b) Find the adjoint of $X \mapsto X^{\mathsf{T}}$.

(c) For $\mathbb{F} = \mathbb{C}$, explain why $X \mapsto X^*$ has no adjoint in the sense of Definition 6.6.8.

Solution on page 1523

6.6.3 The algebra of adjoints

The rules for computing with adjoints are those of Proposition 6.3.27 for matrices. We state them with as few hypotheses as possible: each part asks only that the adjoints on its right-hand side exist, which is automatic in finite dimensions (Theorem 6.6.15).

Proposition 6.6.18 (Properties of the adjoint). Let U, V, W be inner product spaces, let $S, T \in \mathrm{L}(V, W)$ and $R \in \mathrm{L}(W, U)$, and let $a \in \mathbb{F}$. Suppose that S, T, and R have adjoints. Then:

(a) $S + T$ has an adjoint, and $(S+T)^* = S^* + T^*$;

(b) aT has an adjoint, and $(aT)^* = \overline{a}T^*$;

(c) T^* has an adjoint, and $(T^*)^* = T$;

(d) RT has an adjoint, and $(RT)^* = T^*R^*$;

(e) id_V has an adjoint, and $\mathrm{id}_V^* = \mathrm{id}_V$;

(f) if T is invertible and T^{-1} has an adjoint, then T^* is invertible and $(T^*)^{-1} = \left(T^{-1}\right)^*$.

Proof (from the defining identity). ROUTINE

Uses. Definition 6.6.8 (Adjoint), Proposition 6.6.9 (Adjoints are unique and linear), Proposition 6.1.4 (Sesquilinearity), Definition 2.5.12 (Invertible)
Techniques. Find the adjoint by isolating the input (Technique 6.6.11), Guess the inverse, then check both products (Technique 2.5.16)
Hint 1. Each part names a candidate for the adjoint. Check the defining identity $\langle Xv, w\rangle = \langle v, Yw\rangle$ for the candidate Y and let uniqueness do the rest.
Hint 2. For (b), pulling $\overline{a}$ out of the second slot produces $\overline{\overline{a}} = a$. For (c), the defining identity of an adjoint of $T^* : W \to V$ reads $\langle T^*w, v\rangle = \langle w, Sv\rangle$; conjugate the identity for T.
Hint 3. For (f), apply (d) and (e) to $T^{-1}T = \mathrm{id}_V$ and $TT^{-1} = \mathrm{id}_W$.
Sketch. (a) $\langle (S+T)v, w\rangle = \langle v, S^*w\rangle + \langle v, T^*w\rangle$. (b) $\langle aTv, w\rangle = a\langle v, T^*w\rangle = \langle v, \overline{a}T^*w\rangle$. (c) $\langle T^*w, v\rangle = \overline{\langle v, T^*w\rangle} = \overline{\langle Tv, w\rangle} = \langle w, Tv\rangle$. (d) $\langle RTv, u\rangle = \langle Tv, R^*u\rangle = \langle v, T^*R^*u\rangle$. (e) is immediate. (f) By (d) and (e), $T^*\left(T^{-1}\right)^* = \left(T^{-1}T\right)^* = \mathrm{id}_V$ and $\left(T^{-1}\right)^*T^* = \left(TT^{-1}\right)^* = \mathrm{id}_W$.

In each part we check the defining identity for the proposed adjoint; by Proposition 6.6.9 it is then the adjoint. Let $v \in V$, $w \in W$, and $u \in U$.

(a) $\langle (S+T)v, w\rangle = \langle Sv, w\rangle + \langle Tv, w\rangle = \langle v, S^*w\rangle + \langle v, T^*w\rangle = \langle v, (S^*+T^*)w\rangle$.

(b) By Proposition 6.1.4, $\langle v, \overline{a}T^*w\rangle = a\langle v, T^*w\rangle$, so $\langle (aT)v, w\rangle = a\langle Tv, w\rangle = a\langle v, T^*w\rangle = \langle v, \overline{a}T^*w\rangle$.

(c) An adjoint of $T^* : W \to V$ is a function $S : V \to W$ with $\langle T^*w, v\rangle = \langle w, Sv\rangle$ for all w, v. By conjugate symmetry and the identity for T,

$$\langle T^*w, v\rangle = \overline{\langle v, T^*w\rangle} = \overline{\langle Tv, w\rangle} = \langle w, Tv\rangle,$$

so $S = T$ works.

(d) $\langle RTv, u\rangle = \langle Tv, R^*u\rangle = \langle v, T^*R^*u\rangle$, using the identity for R and then for T.

(e) $\langle \mathrm{id}_V v, v'\rangle = \langle v, \mathrm{id}_V v'\rangle$ for all $v, v' \in V$.

(f) By (d) and (e), applied to $T^{-1}T = \mathrm{id}_V$ and to $TT^{-1} = \mathrm{id}_W$,

$$T^*\left(T^{-1}\right)^* = \left(T^{-1}T\right)^* = \mathrm{id}_V, \quad \left(T^{-1}\right)^*T^* = \left(TT^{-1}\right)^* = \mathrm{id}_W.$$

So $\left(T^{-1}\right)^*$ is a two-sided inverse of T^* (Definition 2.5.12). □

Proof (via matrices, in finite dimensions). ROUTINE

Uses. Theorem 6.6.15 (Existence of adjoints), Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 2.4.12 (Matrices of sums and scalar multiples), Theorem 2.4.2 (The matrix of a composite), Proposition 2.5.20 (Inverses and matrices), Proposition 6.3.27 (Properties of the conjugate transpose), Theorem 6.4.20 (Orthonormal bases exist)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Assume U, V, W are finite-dimensional and fix orthonormal bases. By Theorem 6.6.15(b), every adjoint has the conjugate transpose of the original matrix.
Hint 2. Two maps are equal if their matrices are (Theorem 2.3.20). Translate each identity into one about matrices and quote Proposition 6.3.27.

Sketch. In orthonormal bases, $[X^*] = [X]^*$ for every map X. So, for instance, $\big[(RT)^*\big] = [RT]^* = ([R][T])^* = [T]^*[R]^* = [T^*][R^*] = [T^*R^*]$, and the maps agree because their matrices do. The other parts translate in the same way into (a)–(c) of Proposition 6.3.27.

Suppose U, V, W are finite-dimensional, so that all the adjoints in question exist (Theorem 6.6.15), and fix orthonormal bases of the three spaces (Theorem 6.4.20). We write $[X]$ for the matrix of a map with respect to these bases. By Theorem 6.6.15(b), $[X^*] = [X]^*$ for every linear map X between two of the spaces, and by Theorem 2.3.20, two maps with the same matrix are equal. Now, using Proposition 2.4.12, Theorem 2.4.2, and Proposition 6.3.27,

$$\begin{aligned}\big[(S+T)^*\big] &= ([S]+[T])^* = [S]^* + [T]^* = [S^* + T^*],\\ \big[(aT)^*\big] &= (a[T])^* = \overline{a}[T]^* = [\overline{a}T^*],\\ \big[(T^*)^*\big] &= \big([T]^*\big)^* = [T],\\ \big[(RT)^*\big] &= ([R][T])^* = [T]^*[R]^* = [T^*R^*],\end{aligned}$$

and $[\mathrm{id}_V^*] = I^* = I = [\mathrm{id}_V]$. For (f), $\big[T^{-1}\big] = [T]^{-1}$ (Proposition 2.5.20), and $\big([T]^{-1}\big)^* = \big([T]^*\big)^{-1}$ by Proposition 6.3.27(c), so $\big[\big(T^{-1}\big)^*\big] = \big([T]^*\big)^{-1} = [T^*]^{-1}$, which is the matrix of $(T^*)^{-1}$. □

The two proofs run in opposite directions. The second derives the rules for maps from those for matrices, and needs finite dimensions and orthonormal bases. The first needs neither, and applied to T_A, T_B on $\mathbb{F}^n$ it reproves Proposition 6.3.27 without a single index: for instance $(AB)^* = B^*A^*$ because $(T_AT_B)^* = T_B^*T_A^*$. Part (c) is the lecture's observation that T is an adjoint of T^*.

By (a)–(c), the map $T \mapsto T^*$ from $\mathrm{L}(V,W)$ to $\mathrm{L}(W,V)$ is additive, conjugates scalars, and is undone by the same operation in the other direction. In finite dimensions it is therefore a bijection; it is linear when $\mathbb{F} = \mathbb{R}$ and conjugate-linear when $\mathbb{F} = \mathbb{C}$, just like $z \mapsto \overline{z}$.

Exercise 6.6.19. ROUTINE Let V be finite-dimensional, $T \in \mathrm{L}(V)$, and $c_0, \dots, c_k \in \mathbb{F}$. Show that

$$\big(c_0\,\mathrm{id} + c_1T + \cdots + c_kT^k\big)^* = \overline{c_0}\,\mathrm{id} + \overline{c_1}T^* + \cdots + \overline{c_k}(T^*)^k.$$

Solution on page 1524

6.6.4 Kernels and images

For a matrix M we already know two orthogonality relations. One is $(\mathrm{im}\,M)^\perp = \ker M^*$ (Lemma 6.5.4). The other is $\ker M = (\mathrm{im}\,M^*)^\perp$: solving $M\mathbf{x} = \mathbf{0}$ means finding the vectors orthogonal to the conjugated rows of M, which are the columns of M^* (Example 6.3.10). Both were proved by looking at entries. For linear maps between inner product spaces they follow from a single move, which the rest of the book uses constantly.

Technique 6.6.20 (Move an operator across the inner product). When a map acts on one argument of an inner product, move it to the other argument as its adjoint: $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T^*\mathbf{w}\rangle$ and $\langle \mathbf{w}, T\mathbf{v}\rangle = \langle T^*\mathbf{w}, \mathbf{v}\rangle$. Do this so that the map lands on the vector you know more about, or so that two vectors you want to compare end up in the same inner product. Typical outcomes:

- "$\mathbf{w}$ is orthogonal to $T\mathbf{v}$ for every $\mathbf{v}$" becomes "$T^*\mathbf{w}$ is orthogonal to every vector", so $T^*\mathbf{w} = \mathbf{0}$;
- $\langle T^*T\mathbf{v}, \mathbf{v}\rangle$ becomes $\langle T\mathbf{v}, T\mathbf{v}\rangle = \|T\mathbf{v}\|^2$, which is where Technique 6.1.36 takes over;
- a hypothesis on T becomes a statement about T^*, or, for a self-adjoint T, about T itself acting on the other vector.

Reach for it whenever an inner product contains $T\mathbf{v}$ and the hypotheses or the goal concern T^*, or concern the vector in the other slot. The canonical example is part (a) of Theorem 6.6.21. In Chapter 8

the same move shows that the eigenvalues of a self-adjoint operator are real and that its eigenvectors for different eigenvalues are orthogonal.

Used in. Theorem 6.6.21, Proposition 6.6.23, Proposition 6.6.30, Exercise 6.6.38, Exercise 6.6.40, Exercise 6.6.42, Exercise 6.6.44, Exercise 6.7.8, Exercise 6.7.9, Exercise 6.7.10, Exercise 6.7.14, Problem 6.3, Problem 6.7, Problem 6.10, Problem 6.14, Problem 6.18, Proposition 8.1.1, Exercise 8.1.6, Proposition 8.1.13, Lemma 8.1.17, Exercise 8.1.28, Theorem 8.2.5, Lemma 8.2.10, Exercise 8.2.44, Lemma 8.3.8, Proposition 8.3.22, Exercise 8.3.28, Theorem 8.4.4, Lemma 8.4.14, Exercise 6.6.51, Exercise 8.1.29.

Theorem 6.6.21 (Kernels and images of adjoints). Let V and W be inner product spaces, and let $T \in \mathrm{L}(V, W)$ have an adjoint. Then

(a) $\ker T^* = (\operatorname{im} T)^\perp$;

(b) $\ker T = (\operatorname{im} T^*)^\perp$.

If moreover V is finite-dimensional, then also

(c) $\operatorname{im} T^* = (\ker T)^\perp$;

(d) $\operatorname{im} T = (\ker T^*)^\perp$;

and there are orthogonal decompositions $V = \ker T \oplus \operatorname{im} T^*$ and $W = \operatorname{im} T \oplus \ker T^*$.

Intuition. Part (a) is a chain of rewritings. A vector $\mathbf{w}$ is in $(\operatorname{im} T)^\perp$ when $\langle T\mathbf{v}, \mathbf{w}\rangle = 0$ for every $\mathbf{v}$; moving T across, that says $\langle \mathbf{v}, T^*\mathbf{w}\rangle = 0$ for every $\mathbf{v}$, and the only vector orthogonal to everything is $\mathbf{0}$. Part (b) is (a) for T^*, whose adjoint is T. Parts (c) and (d) take orthogonal complements of (b) and (a), which is allowed once the subspaces are finite-dimensional (Theorem 6.4.26).

Proof. STANDARD

Uses. Definition 6.6.8 (Adjoint), Definition 6.3.8 (Vectors orthogonal to a set), Proposition 6.1.4 (Sesquilinearity), Definition 6.1.2 (Inner product), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.4.26 (The double complement), Proposition 4.1.21 (Dimensions of subspaces), Theorem 4.2.11 (Rank–nullity), Theorem 6.4.24 (Orthogonal decomposition)

Techniques. Move an operator across the inner product (Technique 6.6.20), Show a vector is zero via its norm (Technique 6.1.36)

Hint 1. For (a), write out what $\mathbf{w} \in (\operatorname{im} T)^\perp$ means, move T to the other slot, and decide when a vector is orthogonal to every vector of V.

Hint 2. For (b), apply (a) to T^*; what is the adjoint of T^*?

Hint 3. For (c) and (d), take orthogonal complements in (b) and (a). Why are $\operatorname{im} T^*$ and $\operatorname{im} T$ finite-dimensional when V is?

Sketch. (a) $\mathbf{w} \in \ker T^*$ iff $\langle \mathbf{v}, T^*\mathbf{w}\rangle = 0$ for all $\mathbf{v}$ (take $\mathbf{v} = T^*\mathbf{w}$ for one direction) iff $\langle T\mathbf{v}, \mathbf{w}\rangle = 0$ for all $\mathbf{v}$ iff $\mathbf{w} \perp \operatorname{im} T$. (b) is (a) for T^*, since $(T^*)^* = T$. If V is finite-dimensional, so are $\operatorname{im} T^* \subseteq V$ and $\operatorname{im} T$, and Theorem 6.4.26 turns (b) and (a) into (c) and (d). The decompositions are Theorem 6.4.24 for $\ker T$ and $\operatorname{im} T$.

(a) Let $\mathbf{w} \in W$. We claim that

$$\begin{aligned} T^*\mathbf{w} = \mathbf{0} &\iff \langle \mathbf{v}, T^*\mathbf{w}\rangle = 0 \text{ for all } \mathbf{v} \in V \\ &\iff \langle T\mathbf{v}, \mathbf{w}\rangle = 0 \text{ for all } \mathbf{v} \in V \\ &\iff \mathbf{w} \in (\operatorname{im} T)^\perp. \end{aligned}$$

In the first line, if $T^*\mathbf{w} = \mathbf{0}$, then every $\langle \mathbf{v}, T^*\mathbf{w}\rangle$ is 0 by Proposition 6.1.4(b); conversely, taking $\mathbf{v} = T^*\mathbf{w}$ gives $\|T^*\mathbf{w}\|^2 = 0$, so $T^*\mathbf{w} = \mathbf{0}$ by definiteness. The second equivalence is the defining identity of T^*. For the third, the elements of $\operatorname{im} T$ are the vectors $T\mathbf{v}$, and $\langle \mathbf{w}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v}, \mathbf{w}\rangle}$ vanishes exactly when $\langle T\mathbf{v}, \mathbf{w}\rangle$ does (Definition 6.3.8). So $\ker T^* = (\operatorname{im} T)^\perp$.

(b) By Proposition 6.6.18(c), T^* has an adjoint, namely T. Applying (a) to $T^* \in \mathrm{L}(W, V)$ gives $\ker T = \ker (T^*)^* = (\operatorname{im} T^*)^\perp$.

(c) Suppose V is finite-dimensional. Then its subspace $\operatorname{im} T^*$ is finite-dimensional (Proposition 4.1.21), so by (b) and Theorem 6.4.26,

$$(\ker T)^\perp = \left((\operatorname{im} T^*)^\perp\right)^\perp = \operatorname{im} T^*.$$

(d) By Theorem 4.2.11, $\dim \operatorname{im} T \le \dim V$, so $\operatorname{im} T$ is a finite-dimensional subspace of W. By (a) and Theorem 6.4.26, $(\ker T^*)^\perp = \left((\operatorname{im} T)^\perp\right)^\perp = \operatorname{im} T$.

Finally, $\ker T$ and $\operatorname{im} T$ are finite-dimensional, so Theorem 6.4.24 gives $V = \ker T \oplus (\ker T)^\perp = \ker T \oplus \operatorname{im} T^*$ by (c), and $W = \operatorname{im} T \oplus (\operatorname{im} T)^\perp = \operatorname{im} T \oplus \ker T^*$ by (a). □

For $T = T_M$, part (a) is Lemma 6.5.4 and part (b) is the computation of Example 6.3.10. The lecture proves the weaker statement that $\operatorname{im} T^*$ is orthogonal to $\ker T$, which is half of (b) and (c): if $\mathbf{v} = T^*\mathbf{w}$ and $T\mathbf{z} = \mathbf{0}$, then $\langle \mathbf{v}, \mathbf{z}\rangle = \langle T^*\mathbf{w}, \mathbf{z}\rangle = \langle \mathbf{w}, T\mathbf{z}\rangle = 0$.

In infinite dimensions, (a) and (b) survive but (c) and (d) can fail, because a subspace can have a zero orthogonal complement without being everything (Exercise 6.4.63).

Corollary 6.6.22 (T and T^* have the same rank). Let V and W be finite-dimensional and $T \in \mathrm{L}(V, W)$.

(a) The restriction $T\restriction_{\operatorname{im} T^*}$ is injective with image $\operatorname{im} T$. So T maps $\operatorname{im} T^*$ bijectively onto $\operatorname{im} T$, and likewise T^* maps $\operatorname{im} T$ bijectively onto $\operatorname{im} T^*$.

(b) $\operatorname{rank} T^* = \operatorname{rank} T$.

(c) For every $A \in \mathbb{F}^{m\times n}$, $\operatorname{rank} A^* = \operatorname{rank} A$.

Proof (by restriction). STANDARD

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Definition 4.2.1 (Restriction), Proposition 6.3.9 (Properties of $A^\perp$), Proposition 4.2.6 (Injective maps preserve dimension), Proposition 6.6.18 (Properties of the adjoint), Example 6.6.10 (The adjoint of a matrix), Theorem 4.2.7 (The image of T_A)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. The kernel of $T\restriction_{\operatorname{im} T^*}$ is $\ker T \cap \operatorname{im} T^*$. Use Theorem 6.6.21(c).
Hint 2. For the image, decompose $\mathbf{v} = \mathbf{z} + \mathbf{r}$ with $\mathbf{z} \in \ker T$ and $\mathbf{r} \in \operatorname{im} T^*$, and compute $T\mathbf{v}$.
Hint 3. For (c), apply (b) to T_A, using $(T_A)^* = T_{A^*}$.
Sketch. $\ker(T\restriction_{\operatorname{im} T^*}) = \ker T \cap \operatorname{im} T^* = \ker T \cap (\ker T)^\perp = \{\mathbf{0}\}$. Writing $\mathbf{v} = \mathbf{z} + \mathbf{r}$ with $\mathbf{z} \in \ker T$ and $\mathbf{r} \in \operatorname{im} T^*$ gives $T\mathbf{v} = T\mathbf{r}$, so the restriction already hits all of $\operatorname{im} T$. An injective map preserves dimension, so $\operatorname{rank} T = \dim \operatorname{im} T^* = \operatorname{rank} T^*$. The statement for T^* follows by symmetry, and (c) is (b) for T_A.

(a) Let $R = T\restriction_{\operatorname{im} T^*} : \operatorname{im} T^* \to W$. Its kernel is $\ker T \cap \operatorname{im} T^*$, which by Theorem 6.6.21(c) is $\ker T \cap (\ker T)^\perp = \{\mathbf{0}\}$ (Proposition 6.3.9(d)). So R is injective. Clearly $\operatorname{im} R \subseteq \operatorname{im} T$. Conversely, let $\mathbf{v} \in V$. By Theorem 6.6.21, $\mathbf{v} = \mathbf{z} + \mathbf{r}$ with $\mathbf{z} \in \ker T$ and $\mathbf{r} \in \operatorname{im} T^*$, so $T\mathbf{v} = T\mathbf{z} + T\mathbf{r} = R\mathbf{r} \in \operatorname{im} R$. Hence $\operatorname{im} R = \operatorname{im} T$, and R is a bijection from $\operatorname{im} T^*$ onto $\operatorname{im} T$. Since T^* has adjoint T (Proposition 6.6.18(c)), the same argument applied to T^* shows that T^* maps $\operatorname{im} T$ bijectively onto $\operatorname{im} T^*$.

(b) By (a) and Proposition 4.2.6(a), applied to the injective map R, $\dim \operatorname{im} T = \dim \operatorname{im} R = \dim \operatorname{im} T^*$.

(c) With dot products, $(T_A)^* = T_{A^*}$ (Example 6.6.10), and $\operatorname{rank} A = \dim \operatorname{im} T_A$ (Theorem 4.2.7). So (c) is (b) for $T = T_A$. □

Proof (by counting dimensions). ROUTINE

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Corollary 6.4.25 (Dimension of the orthogonal complement), Theorem 4.2.11 (Rank–nullity), Example 6.6.10 (The adjoint of a matrix)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Compute $\dim \operatorname{im} T^*$ from Theorem 6.6.21(c) and Corollary 6.4.25.
Hint 2. Compare with rank–nullity for T.
Sketch. $\operatorname{rank} T^* = \dim (\ker T)^\perp = \dim V - \dim \ker T = \operatorname{rank} T$. This proves (b), and (c) as before; it does not give the bijection in (a).

By Theorem 6.6.21(c), Corollary 6.4.25, and Theorem 4.2.11,

$$\operatorname{rank} T^* = \dim (\ker T)^\perp = \dim V - \dim \ker T = \operatorname{rank} T.$$

This is (b), and (c) follows as in the first proof. This argument does not give (a). □

The counting proof is shorter; the first proof shows where the equality comes from. A linear map T throws away $\ker T$ and is injective on the rest of V, and Theorem 6.6.21 identifies "the rest" as $\operatorname{im} T^*$. The two bijections in (a) are not inverse to each other in general: for $T = 2\mathrm{id}_V$, both are multiplication by 2.

The four fundamental subspaces

For a matrix $A \in \mathbb{F}^{m\times n}$, apply Theorem 6.6.21 to $T_A : \mathbb{F}^n \to \mathbb{F}^m$, whose adjoint is T_{A^*} (Example 6.6.10). It gives the orthogonal decompositions

$$\mathbb{F}^n = \ker A \oplus \operatorname{im} A^*, \quad \mathbb{F}^m = \operatorname{im} A \oplus \ker A^*.$$

Over $\mathbb{R}$, $A^* = A^\mathsf{T}$, and these are the four fundamental subspaces of Definition 4.3.12: the null space $\ker A$ and the row space $\operatorname{im} A^\mathsf{T}$ are orthogonal complements in $\mathbb{R}^n$, and the column space $\operatorname{im} A$ and the left null space $\ker A^\mathsf{T}$ are orthogonal complements in $\mathbb{R}^m$. So $\mathbb{R}^n = \operatorname{im} A^\mathsf{T} \oplus \ker A$. Every $\mathbf{x} \in \mathbb{R}^n$ splits as $\mathbf{x} = \mathbf{x}_r + \mathbf{x}_n$ with $\mathbf{x}_r$ in the row space and $\mathbf{x}_n \in \ker A$, and $A\mathbf{x} = A\mathbf{x}_r$; by Corollary 6.6.22, A maps the row space bijectively onto the column space. In particular $\operatorname{rank} A^\mathsf{T} = \operatorname{rank} A$, which is Theorem 4.3.8 for real matrices. Figure 6.6.2 shows the picture.

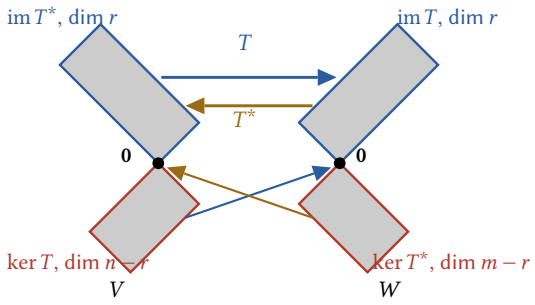

Figure 6.6.2. The four subspaces of $T \in \mathrm{L}(V, W)$, with $n = \dim V$, $m = \dim W$, and $r = \operatorname{rank} T$. In V, the subspaces $\operatorname{im} T^*$ and $\ker T$ are orthogonal complements, and in W so are $\operatorname{im} T$ and $\ker T^*$. The map T (blue) sends $\ker T$ to $\mathbf{0}$ and $\operatorname{im} T^*$ bijectively onto $\operatorname{im} T$; its adjoint T^* (ochre) sends $\ker T^*$ to $\mathbf{0}$ and $\operatorname{im} T$ bijectively onto $\operatorname{im} T^*$. For $T = T_A$ with A real, these are the row space, null space, column space, and left null space of A.

Over $\mathbb{C}$ the orthogonal complement of $\ker A$ is $\operatorname{im} A^*$, the span of the conjugated rows, and the conjugation matters. For $A = \begin{pmatrix} 1 & i \end{pmatrix}$, $\ker A = \operatorname{span}((-i, 1))$, and the conjugated row $(1, -i)$ is orthogonal to $(-i, 1)$: $(1, -i) \cdot (-i, 1) = \overline{-i} + (-i) = 0$. The row $(1, i)$ itself is not: $(1, i) \cdot (-i, 1) = i + i = 2i$. (The rank of A^T still equals the rank of A, since conjugating every entry does not change which columns are independent.)

The lecture's other result about adjoints generalizes Proposition 6.5.9 from matrices to maps, with the same two proofs.

Proposition 6.6.23 (T^*T and T). Let V and W be inner product spaces, and let $T \in \mathrm{L}(V, W)$ have an adjoint.

(a) $\ker(T^*T) = \ker T$.

(b) If V is finite-dimensional, then $\operatorname{rank}(T^*T) = \operatorname{rank} T$ and $\operatorname{im}(T^*T) = \operatorname{im} T^*$.

Proof (by the norm). ROUTINE

Uses. Definition 6.6.8 (Adjoint), Definition 6.1.2 (Inner product), Theorem 4.2.11 (Rank–nullity), Corollary 6.6.22 (T and T^* have the same rank), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Move an operator across the inner product (Technique 6.6.20), Show a vector is zero via its norm (Technique 6.1.36), Double containment (Technique 1.3.14)
Hint 1. One containment in (a) is immediate. For the other, suppose $T^*T\mathbf{v} = \mathbf{0}$ and take the inner product with $\mathbf{v}$.
Hint 2. Move T^* across: $\langle T^*T\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, T\mathbf{v}\rangle$.
Hint 3. For (b), use rank–nullity for T^*T and T, which have the same domain, and then compare $\operatorname{im}(T^*T) \subseteq \operatorname{im} T^*$ by dimension.
Sketch. If $T^*T\mathbf{v} = \mathbf{0}$, then $\|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = 0$, so $T\mathbf{v} = \mathbf{0}$; the other containment is clear. Equal kernels and rank–nullity give $\operatorname{rank}(T^*T) = \operatorname{rank} T$, which equals $\operatorname{rank} T^*$ by Corollary 6.6.22; since $\operatorname{im}(T^*T) \subseteq \operatorname{im} T^*$, the images agree.

(a) If $T\mathbf{v} = \mathbf{0}$, then $T^*T\mathbf{v} = T^*\mathbf{0} = \mathbf{0}$. Conversely, suppose $T^*T\mathbf{v} = \mathbf{0}$. By the defining identity of T^* with $\mathbf{w} = T\mathbf{v}$,

$$\|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = \langle \mathbf{v}, T^*T\mathbf{v}\rangle = \langle \mathbf{v}, \mathbf{0}\rangle = 0,$$

so $T\mathbf{v} = \mathbf{0}$ by definiteness. Hence $\ker(T^*T) = \ker T$.

(b) Both T^*T and T have domain V, so by Theorem 4.2.11 and (a),

$$\operatorname{rank}(T^*T) = \dim V - \dim\ker(T^*T) = \dim V - \dim\ker T = \operatorname{rank} T.$$

By Corollary 6.6.22 this is $\operatorname{rank} T^* = \dim\operatorname{im} T^*$, and $\operatorname{im}(T^*T) \subseteq \operatorname{im} T^*$. A subspace of $\operatorname{im} T^*$ of the same dimension is all of $\operatorname{im} T^*$ (Proposition 4.1.21(b)), so $\operatorname{im}(T^*T) = \operatorname{im} T^*$. □

Proof (by orthogonality). ROUTINE

Uses. Theorem 6.6.21 (Kernels and images of adjoints), Proposition 6.3.9 (Properties of $A^\perp$)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint. Suppose $T^*(T\mathbf{v}) = \mathbf{0}$. Which two subspaces of W contain $T\mathbf{v}$?
Sketch. If $T^*(T\mathbf{v}) = \mathbf{0}$, then $T\mathbf{v} \in \ker T^* = (\operatorname{im} T)^\perp$ by Theorem 6.6.21(a), and also $T\mathbf{v} \in \operatorname{im} T$, so $T\mathbf{v} \in \operatorname{im} T \cap (\operatorname{im} T)^\perp = \{\mathbf{0}\}$. Part (b) follows from (a) as in the first proof.

As before, $\ker T \subseteq \ker(T^*T)$. Conversely, if $T^*(T\mathbf{v}) = \mathbf{0}$, then $T\mathbf{v} \in \ker T^* = (\operatorname{im} T)^\perp$ by Theorem 6.6.21(a), and $T\mathbf{v} \in \operatorname{im} T$. So $T\mathbf{v} \in \operatorname{im} T \cap (\operatorname{im} T)^\perp = \{\mathbf{0}\}$ (Proposition 6.3.9(d)). This proves (a), and (b) follows from (a) exactly as in the first proof. □

The first proof is the lecture's. Both proofs move T^* somewhere useful: the first next to $T\mathbf{v}$, to produce a norm, and the second into the description of $\ker T^*$ as an orthogonal complement.

The next example shows the theorem at work on a map that is not self-adjoint.

Example 6.6.24 (An oblique projection and its adjoint). Let $P : \mathbb{R}^2 \to \mathbb{R}^2$, $P(x, y) = (x - y, 0)$, the projection onto the x-axis along the line $y = x$ from Remark 6.4.12. Its matrix is $\begin{pmatrix} 1 & -1 \\ 0 & 0 \end{pmatrix}$, so P^* has matrix $\begin{pmatrix} 1 & 0 \\ -1 & 0 \end{pmatrix}$, that is, $P^*(x, y) = (x, -x)$. Then

$$\operatorname{im} P = \operatorname{span}(\mathbf{e}_1), \qquad \ker P = \operatorname{span}((1, 1)),$$
$$\operatorname{im} P^* = \operatorname{span}((1, -1)) = (\ker P)^\perp, \quad \ker P^* = \operatorname{span}(\mathbf{e}_2) = (\operatorname{im} P)^\perp,$$

as Theorem 6.6.21 predicts. Moreover $(P^*)^2 = \left(P^2\right)^* = P^*$, so P^* is again a projection: it moves each point onto the line $y = -x$ along the vertical direction (Figure 6.6.3). In general, the adjoint of the projection onto U along X is the projection onto $X^\perp$ along $U^\perp$ (Exercise 6.6.47). The two coincide exactly when $X = U^\perp$, which is when the projection is orthogonal.

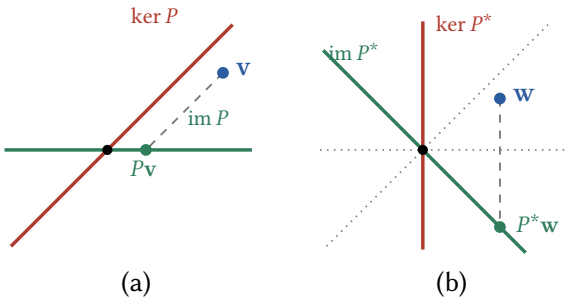

Figure 6.6.3. (a) The projection $P(x, y) = (x - y, 0)$ moves each point onto $\operatorname{im} P$ (the x-axis) along $\ker P$ (the line $y = x$). (b) Its adjoint $P^*(x, y) = (x, -x)$ moves each point onto $\operatorname{im} P^* = (\ker P)^\perp$ along $\ker P^* = (\operatorname{im} P)^\perp$. The dotted lines are $\operatorname{im} P$ and $\ker P$ from (a).

Exercise 6.6.25. ROUTINE Let $A = \begin{pmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 1 & 3 & 2 \end{pmatrix} \in \mathbb{R}^{3\times 3}$. Find bases of $\ker A$, $\operatorname{im} A^\mathsf{T}$, $\operatorname{im} A$, and $\ker A^\mathsf{T}$, and check that $\mathbb{R}^3 = \ker A \oplus \operatorname{im} A^\mathsf{T}$ and $\mathbb{R}^3 = \operatorname{im} A \oplus \ker A^\mathsf{T}$ are orthogonal decompositions.

Solution on page 1524

6.6.5 Self-adjoint operators

For an operator $T \in \mathrm{L}(V)$, the maps T and T^* act on the same space, so they can be compared. The operators that equal their adjoint are the subject of Chapter 8. Here we define them, collect examples, and characterize them over $\mathbb{C}$.

Definition 6.6.26 (Self-adjoint operator). Let V be an inner product space. An operator $T \in \mathrm{L}(V)$ is **self-adjoint** if

$$\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle \quad \text{for all } \mathbf{v}, \mathbf{w} \in V,$$

that is, if T has an adjoint and $T^* = T$.

By Example 6.6.10, T_A is self-adjoint for the dot product on $\mathbb{F}^n$ exactly when $A^* = A$, that is, when A is Hermitian (Definition 6.3.26), and over $\mathbb{R}$ when A is symmetric. One says "self-adjoint" for operators and "Hermitian" for matrices; in orthonormal coordinates they are the same condition (Corollary 6.6.28).

Example 6.6.27 (Self-adjoint operators).

(a) The matrices $\begin{pmatrix} 2 & 1-i \\ 1+i & 3 \end{pmatrix}$ and $\begin{pmatrix} 1 & 2 \\ 2 & -1 \end{pmatrix}$ are Hermitian, so they give self-adjoint operators on $\mathbb{C}^2$ and $\mathbb{R}^2$.

(b) Let W be a finite-dimensional subspace of V. By Proposition 6.4.29(c), $\langle \mathrm{Pr}_W \mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, \mathrm{Pr}_W \mathbf{x}\rangle$ for all $\mathbf{v}, \mathbf{x}$, so Pr_W is self-adjoint.

(c) For a continuous $h : [0, 1] \to \mathbb{R}$, the multiplication operator M_h on $C([0, 1], \mathbb{C})$ is self-adjoint, since $M_h^* = M_{\overline{h}} = M_h$ (Example 6.6.14).

(d) If $T \in \mathrm{L}(V, W)$ has an adjoint, then $T^*T \in \mathrm{L}(V)$ and $TT^* \in \mathrm{L}(W)$ are self-adjoint: $(T^*T)^* = T^*(T^*)^* = T^*T$ by (c) and (d) of Proposition 6.6.18, and similarly for TT^*. In particular A^*A is Hermitian for every matrix A, as we knew from its description as a Gram matrix (Theorem 6.3.29). Similarly $T + T^*$ is self-adjoint for every $T \in \mathrm{L}(V)$ with an adjoint.

Some operators that are not self-adjoint: the rotation $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ of Example 6.1.39, with $J^\mathsf{T} = -J$; multiplication by i on $\mathbb{C}$, whose adjoint is multiplication by $-i$ (Example 6.6.10); the oblique projection of Example 6.6.24; and T_A for the complex symmetric matrix $A = \begin{pmatrix} 1 & i \\ i & -1 \end{pmatrix}$, for which $A^\mathsf{T} = A$ but $A^* \neq A$ (Exercise 6.6.34).

Corollary 6.6.28 (Self-adjointness in an orthonormal basis). Let V be finite-dimensional, let $\mathcal{O}$ be an orthonormal basis of V, and let $T \in \mathrm{L}(V)$. Then T is self-adjoint if and only if $[T]_{\mathcal{O}}$ is Hermitian.

Proof. ROUTINE

Uses. Theorem 6.6.15 (Existence of adjoints), Theorem 2.3.20 (Linear maps correspond to matrices), Definition 6.6.26 (Self-adjoint operator)
Hint. Compare the matrices of T and T^* in the basis $\mathcal{O}$.
Sketch. $[T^*]_{\mathcal{O}} = \big([T]_{\mathcal{O}}\big)^*$ by Theorem 6.6.15(b), and maps with equal matrices are equal. So $T^* = T$ iff $\big([T]_{\mathcal{O}}\big)^* = [T]_{\mathcal{O}}$.

By Theorem 6.6.15, T^* exists and $[T^*]_{\mathcal{O}} = \big([T]_{\mathcal{O}}\big)^*$. By Theorem 2.3.20, $T^* = T$ if and only if $[T^*]_{\mathcal{O}} = [T]_{\mathcal{O}}$, that is, if and only if $\big([T]_{\mathcal{O}}\big)^* = [T]_{\mathcal{O}}$. □

Orthonormality is essential here. The projection Pr of $\mathbb{R}^2$ onto the x-axis is self-adjoint by (b) above, but in the basis $\mathbf{b}_1 = (1,0)$, $\mathbf{b}_2 = (1,1)$ we have $\mathrm{Pr}\,\mathbf{b}_1 = \mathbf{b}_1$ and $\mathrm{Pr}\,\mathbf{b}_2 = (1,0) = \mathbf{b}_1$, so its matrix is $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$, which is not symmetric.

The next result completes Proposition 6.4.30, which characterized orthogonal projections without naming the adjoint.

Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents). Let V be finite-dimensional and $P \in \mathrm{L}(V)$. Then P is an orthogonal projection, that is, $P = \mathrm{Pr}_W$ for some subspace W of V, if and only if

$$P^2 = P = P^*.$$

In that case $W = \operatorname{im} P$.

Proof (from the earlier characterization). ROUTINE

Uses. Proposition 6.4.30 (Recognizing orthogonal projections), Definition 6.6.26 (Self-adjoint operator)
Hint. Read the second condition of Proposition 6.4.30 in the language of Definition 6.6.26.
Sketch. The condition $\langle P\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, P\mathbf{x}\rangle$ for all $\mathbf{v}, \mathbf{x}$ in Proposition 6.4.30 says exactly that P is self-adjoint.

The second condition in Proposition 6.4.30, $\langle P\mathbf{v}, \mathbf{x}\rangle = \langle \mathbf{v}, P\mathbf{x}\rangle$ for all $\mathbf{v}, \mathbf{x} \in V$, says exactly that P is self-adjoint (Definition 6.6.26). So the corollary is Proposition 6.4.30 restated. □

Proof (via kernels and images). ROUTINE

Uses. Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 6.6.21 (Kernels and images of adjoints), Theorem 6.4.6 (The projection is characterized by orthogonality), Theorem 6.4.20 (Orthonormal bases exist), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Recognize a projection by its two conditions (Technique 6.4.7)
Hint 1. One direction is (b) and (c) of Proposition 6.4.29. For the other, let $W = \operatorname{im} P$ and split $\mathbf{v} = P\mathbf{v} + (\mathbf{v} - P\mathbf{v})$. Where does each piece lie?
Hint 2. $P(\mathbf{v} - P\mathbf{v}) = \mathbf{0}$, and for a self-adjoint P, Theorem 6.6.21(a) says $\ker P = (\operatorname{im} P)^{\perp}$.
Sketch. Orthogonal projections satisfy $P^2 = P$ and are self-adjoint (Proposition 6.4.29). Conversely, $P\mathbf{v} \in \operatorname{im} P$ and $P(\mathbf{v} - P\mathbf{v}) = P\mathbf{v} - P^2\mathbf{v} = \mathbf{0}$, so $\mathbf{v} - P\mathbf{v} \in \ker P = \ker P^* = (\operatorname{im} P)^{\perp}$. These are the two conditions that characterize $\mathrm{Pr}_{\operatorname{im} P}(\mathbf{v})$.

If $P = \mathrm{Pr}_W$, then $P^2 = P$ by Proposition 6.4.29(b), P is self-adjoint by (c) of the same proposition, and $\operatorname{im} P = W$ by part (a).

Conversely, suppose $P^2 = P = P^*$, and let $W = \operatorname{im} P$, a finite-dimensional subspace (Proposition 4.1.21), so that Pr_W is defined (Theorem 6.4.20). Let $\mathbf{v} \in V$. Then $P\mathbf{v} \in W$, and $P(\mathbf{v} - P\mathbf{v}) = P\mathbf{v} - P^2\mathbf{v} = \mathbf{0}$, so by Theorem 6.6.21(a),

$$\mathbf{v} - P\mathbf{v} \in \ker P = \ker P^* = (\operatorname{im} P)^{\perp} = W^{\perp}.$$

By Theorem 6.4.6, $P\mathbf{v} = \mathrm{Pr}_W(\mathbf{v})$. □

The second proof separates the roles of the two conditions. Any P with $P^2 = P$ projects onto $\operatorname{im} P$ along $\ker P$, since $\mathbf{v} = P\mathbf{v} + (\mathbf{v} - P\mathbf{v})$ with $\mathbf{v} - P\mathbf{v} \in \ker P$; this is how the oblique projections of Remark 6.4.12 and

Example 6.6.24 work. Self-adjointness is what makes $\ker P = (\operatorname{im} P)^{\perp}$, so that the direction of projection is perpendicular to the target.

Over $\mathbb{C}$, self-adjointness can be read off the "diagonal" values $\langle T\mathbf{v}, \mathbf{v}\rangle$ alone. This is the operator version of the fact that a complex number z is real exactly when $z = \overline{z}$.

Proposition 6.6.30 (Self-adjoint means real values). Let V be a finite-dimensional complex inner product space and $T \in \mathrm{L}(V)$. Then T is self-adjoint if and only if $\langle T\mathbf{v}, \mathbf{v}\rangle \in \mathbb{R}$ for every $\mathbf{v} \in V$.

Proof. STANDARD

Uses. Theorem 6.6.15 (Existence of adjoints), Definition 6.6.8 (Adjoint), Proposition 6.1.41 (Over $\mathbb{C}$, the values $\langle T\mathbf{v}, \mathbf{v}\rangle$ determine T), Notation 6.1.1 (Real and complex scalars), Proposition 2.1.23 ($\mathrm{L}(V, W)$ is a vector space)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. A complex number z is real iff $z - \overline{z} = 0$. Write $\overline{\langle T\mathbf{v}, \mathbf{v}\rangle}$ as an inner product with T^* in it.
Hint 2. $\overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \langle \mathbf{v}, T\mathbf{v}\rangle = \langle T^*\mathbf{v}, \mathbf{v}\rangle$. So $\langle T\mathbf{v}, \mathbf{v}\rangle - \overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \langle (T - T^*)\mathbf{v}, \mathbf{v}\rangle$.
Hint 3. Over $\mathbb{C}$, an operator S with $\langle S\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$ is 0 (Proposition 6.1.41).
Sketch. For every $\mathbf{v}$, $\langle T\mathbf{v}, \mathbf{v}\rangle - \overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \langle T\mathbf{v}, \mathbf{v}\rangle - \langle T^*\mathbf{v}, \mathbf{v}\rangle = \langle (T - T^*)\mathbf{v}, \mathbf{v}\rangle$. So all values $\langle T\mathbf{v}, \mathbf{v}\rangle$ are real iff $\langle (T - T^*)\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$, iff $T - T^* = 0$ by Proposition 6.1.41.

By Theorem 6.6.15, T has an adjoint. For every $\mathbf{v} \in V$, conjugate symmetry and the conjugated form of the defining identity give

$$\overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \langle \mathbf{v}, T\mathbf{v}\rangle = \langle T^*\mathbf{v}, \mathbf{v}\rangle,$$

and therefore

$$\langle T\mathbf{v}, \mathbf{v}\rangle - \overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \langle (T - T^*)\mathbf{v}, \mathbf{v}\rangle.$$

A complex number is real exactly when it equals its conjugate (Notation 6.1.1). So $\langle T\mathbf{v}, \mathbf{v}\rangle \in \mathbb{R}$ for every $\mathbf{v}$ if and only if $\langle (T - T^*)\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$. By Proposition 6.1.41, applied to $T - T^* \in \mathrm{L}(V)$ (Proposition 2.1.23), this holds if and only if $T - T^* = 0$, that is, T is self-adjoint. □

Finite-dimensionality was used only to know that T^* exists. Exercise 6.1.53 proves the same equivalence on every complex inner product space, without adjoints, by polarization. Over $\mathbb{R}$ the proposition fails, since every $\langle T\mathbf{v}, \mathbf{v}\rangle$ is real; the rotation J is not self-adjoint. Over $\mathbb{R}$, the values $\langle T\mathbf{v}, \mathbf{v}\rangle$ see only the self-adjoint part $(T + T^*)/2$ of T (Exercise 6.1.52).

Intuition (Self-adjoint operators as real numbers). The analogy between $T \mapsto T^*$ and $z \mapsto \overline{z}$ runs through Chapter 8. Both are additive, conjugate scalars, and undo themselves, and adjoints also reverse products, which for numbers is invisible. Self-adjoint operators play the role of real numbers: their values $\langle T\mathbf{v}, \mathbf{v}\rangle$ are real (Proposition 6.6.30), and every operator on a complex space splits uniquely as $A + iB$ with A and B self-adjoint, like $z = x + iy$ (Exercise 6.6.37). Operators of the form T^*T play the role of $|z|^2 = \overline{z}z$: they are self-adjoint with $\langle T^*T\mathbf{v}, \mathbf{v}\rangle = \|T\mathbf{v}\|^2 \geq 0$ (Section 8.3). Operators with $T^*T = \mathrm{id}$ play the role of the unit circle; they are the maps that preserve lengths (Exercise 6.6.40, Section 8.4). The analogy is imperfect because operators need not commute, and it works best for the normal operators, those with $T^*T = TT^*$ (Section 8.1).

The main theorem about self-adjoint operators, proved in Section 8.2, is that on a finite-dimensional space they are exactly the operators that are diagonal, with real diagonal entries, in some orthonormal basis. Geometrically, a self-adjoint operator stretches V by real factors along mutually perpendicular axes. An orthogonal projection is the case in which every factor is 0 or 1. The oblique projection of Example 6.6.24 also fixes one line and kills another, but the two lines are not perpendicular, and that is exactly the failure of self-adjointness.

Exercises

Exercise 6.6.31. ROUTINE Let $T : \mathbb{C}^2 \to \mathbb{C}^2$, $T(z_1, z_2) = (z_1 + iz_2, (1-i)z_1)$.

(a) Find T^* when $\mathbb{C}^2$ has the dot product.

(b) Find T^* when $\mathbb{C}^2$ has the weighted inner product $\langle \mathbf{z}, \mathbf{w} \rangle = z_1\overline{w_1} + 2z_2\overline{w_2}$ (Example 6.1.21).

(c) In (b), is T^* multiplication by the conjugate transpose of the matrix of T? Why does this not contradict Theorem 6.6.15(b)?

Solution on page 1524

Exercise 6.6.32. ROUTINE Give $\mathbb{R}[x]_{\leq 2}$ the inner product $\langle p, q \rangle = \int_{-1}^{1} p(t)q(t)\,dt$. Find the polynomials $q_1, q_2 \in \mathbb{R}[x]_{\leq 2}$ such that, for every $p \in \mathbb{R}[x]_{\leq 2}$,

(a) $\langle p, q_1 \rangle = p'(0)$;

(b) $\langle p, q_2 \rangle = \int_0^1 p(t)\,dt$.

Solution on page 1525

Exercise 6.6.33. ROUTINE On $\mathbb{F}^n$ with the dot product ($n \geq 2$), let

$$R(x_1, ..., x_n) = (0, x_1, ..., x_{n-1}), \quad C(x_1, ..., x_n) = (x_n, x_1, ..., x_{n-1}).$$

(a) Find R^*, and compute R^*R and RR^*. Identify each as an orthogonal projection.

(b) Find C^*, and show that $C^* = C^{-1}$.

Solution on page 1525

Exercise 6.6.34. ROUTINE Let $A = \begin{pmatrix} 1 & i \\ i & -1 \end{pmatrix} \in \mathbb{C}^{2\times 2}$, and give $\mathbb{C}^2$ the dot product.

(a) Find $\ker A$, $\operatorname{im} A$, $\ker A^*$, and $\operatorname{im} A^*$, and check the four statements of Theorem 6.6.21.

(b) Show that $\ker A$ is not orthogonal to $\operatorname{im} A^{\mathsf{T}}$, although $A^{\mathsf{T}} = A$.

(c) Is T_A self-adjoint?

Solution on page 1526

Exercise 6.6.35. STANDARD Let V be finite-dimensional and $T \in \mathrm{L}(V)$ with $T^*T = T$. Show that T is an orthogonal projection.

Solution on page 1526

Exercise 6.6.36. STANDARD Let V be a finite-dimensional inner product space, and let $S, T \in \mathrm{L}(V)$ be self-adjoint. Prove or disprove each statement.

(a) $S + T$ is self-adjoint.

(b) ST is self-adjoint.

(c) STS is self-adjoint.

(d) If $\mathbb{F} = \mathbb{C}$, then iT is self-adjoint.

(e) If T is invertible, then T^{-1} is self-adjoint.

Solution on page 1526

Exercise 6.6.37. STANDARD Let V be a finite-dimensional complex inner product space.

(a) Show that every $T \in \mathrm{L}(V)$ can be written in exactly one way as $T = A + iB$ with $A, B \in \mathrm{L}(V)$ self-adjoint.

(b) Find A and B for $T = T_M$ on $\mathbb{C}^2$ with the dot product, where $M = \begin{pmatrix} 1 & 2 \\ 0 & i \end{pmatrix}$.

Solution on page 1527

Exercise 6.6.38. STANDARD Let V be finite-dimensional, $T \in \mathrm{L}(V)$, and U a subspace of V. Show that T maps U into U if and only if T^* maps $U^\perp$ into $U^\perp$. Deduce that if T is self-adjoint and maps U into U, then T also maps $U^\perp$ into $U^\perp$.

Solution on page 1527

Exercise 6.6.39. STANDARD Let V be the real vector space spanned by $1, \cos t, \sin t, \cos 2t, \sin 2t$ (as functions on $[0, 2\pi]$), with $\langle f, g\rangle = \int_0^{2\pi} f(t)g(t)\,\mathrm{d}t$, an inner product by the proof of Proposition 6.1.13. Let $Df = f'$.

(a) Show that D maps V into V and that $D^* = -D$.

(b) Deduce that $\langle Df, f\rangle = 0$ for every $f \in V$, and that D is not self-adjoint.

(c) Find the matrix of D in the basis $1, \cos t, \sin t, \cos 2t, \sin 2t$. Using that this basis is orthogonal with $\|\cos kt\| = \|\sin kt\|$, explain how the matrix also shows $D^* = -D$.

Solution on page 1527

Exercise 6.6.40. STANDARD Let V and W be finite-dimensional and $T \in \mathrm{L}(V, W)$. Show that the following are equivalent:

(i) $\|T\mathbf{v}\| = \|\mathbf{v}\|$ for all $\mathbf{v} \in V$;
(ii) $\langle T\mathbf{v}, T\mathbf{w}\rangle = \langle \mathbf{v}, \mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w} \in V$;
(iii) $T^*T = \mathrm{id}_V$.

What does (iii) say about A when $T = T_A$ with $A \in \mathbb{F}^{m\times n}$ and dot products?

Solution on page 1528

Exercise 6.6.41. STANDARD Let V and W be finite-dimensional and $T \in \mathrm{L}(V, W)$ with $T^*T = \mathrm{id}_V$. A student argues: "Since $T^*T = \mathrm{id}_V$, T^* is the inverse of T, so also $TT^* = \mathrm{id}_W$."

(a) Find the error, and give a counterexample to the conclusion.

(b) Show that $TT^* = \mathrm{Pr}_{\mathrm{im}\, T}$.

(c) Show that the conclusion is correct when $\dim V = \dim W$.

Solution on page 1528

Exercise 6.6.42. STANDARD Let V and W be inner product spaces, let $T \in \mathrm{L}(V, W)$ have an adjoint, and let $\mathbf{w} \in W$.

(a) Show that $\mathrm{Re}\langle T\mathbf{v}, \mathbf{w}\rangle \le \|T^*\mathbf{w}\|$ for every unit vector $\mathbf{v} \in V$, with equality for $\mathbf{v} = T^*\mathbf{w}/\|T^*\mathbf{w}\|$ when $T^*\mathbf{w} \neq \mathbf{0}$. So $T^*\mathbf{w}$ points along the input that T pushes furthest in the direction of $\mathbf{w}$.

(b) Let $c \ge 0$. Show that $\|T\mathbf{v}\| \le c\|\mathbf{v}\|$ for all $\mathbf{v} \in V$ if and only if $\|T^*\mathbf{w}\| \le c\|\mathbf{w}\|$ for all $\mathbf{w} \in W$.

Solution on page 1529

Exercise 6.6.43. STANDARD Let V be finite-dimensional and $T \in \mathrm{L}(V)$.

(a) Show that every vector of $\operatorname{im} T$ is orthogonal to every vector of $\operatorname{im} T^*$ if and only if $T^2 = 0$.

(b) Deduce that if $T^2 = 0$, then $\operatorname{rank} T \le (\dim V)/2$.

(c) Find a nonzero operator T on $\mathbb{R}^3$ with $T^2 = 0$, and check (a) for it.

Solution on page 1529

Exercise 6.6.44. STANDARD Let V be finite-dimensional and $T \in \mathrm{L}(V)$.

(a) Show that $\operatorname{rank}(TT^*) = \operatorname{rank}(T^*T) = \operatorname{rank} T$.

(b) Suppose $T^*T = TT^*$. Show that $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$ for all $\mathbf{v} \in V$, and deduce that $\ker T = \ker T^*$ and $\operatorname{im} T = \operatorname{im} T^*$.

(c) Find an operator T on $\mathbb{R}^2$ with $\ker T \neq \ker T^*$.

Solution on page 1529

Exercise 6.6.45. STANDARD On $V = \mathbb{R}[x]_{\le 2}$, let $(Sp)(x) = p(1-x)$.

(a) Show that S is self-adjoint for $\langle p, q\rangle = \int_0^1 p(t)q(t)\,dt$, but not for $\langle p, q\rangle = \int_0^2 p(t)q(t)\,dt$.

(b) For the first inner product, show that $(\mathrm{id} + S)/2$ is the orthogonal projection onto the subspace E of polynomials with $p(1-x) = p(x)$, and find a basis of E.

Solution on page 1530

Exercise 6.6.46. HARD Let V be finite-dimensional with a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$, not necessarily orthonormal, and let G be its Gram matrix, $g_{ij} = \langle \mathbf{b}_j, \mathbf{b}_i\rangle$ (Definition 6.3.28).

(a) Show that $\langle \mathbf{v}, \mathbf{w}\rangle = [\mathbf{w}]_{\mathcal{B}}^* G [\mathbf{v}]_{\mathcal{B}}$ for all $\mathbf{v}, \mathbf{w} \in V$.

(b) Show that $[T^*]_{\mathcal{B}} = G^{-1}([T]_{\mathcal{B}})^* G$ for every $T \in \mathrm{L}(V)$.

(c) Recompute $[D^*]_{\mathcal{B}}$ of Example 6.6.16 with (b).

(d) A student claims that $[T^*]_{\mathcal{B}} = ([T]_{\mathcal{B}})^*$ for every basis, "since $\langle \mathbf{v}, \mathbf{w}\rangle = [\mathbf{v}]_{\mathcal{B}} \cdot [\mathbf{w}]_{\mathcal{B}}$, so the second proof of Theorem 6.6.15 applies." Which step fails, and for which bases is the claim true?

Solution on page 1530

Exercise 6.6.47. HARD Let V be finite-dimensional, and suppose $V = U \oplus X$ for subspaces U and X (Definition 4.4.4). Let $P \in \mathrm{L}(V)$ be the projection onto U along X: $P(\mathbf{u} + \mathbf{x}) = \mathbf{u}$ for $\mathbf{u} \in U$ and $\mathbf{x} \in X$.

(a) Show that $P^2 = P$, $\operatorname{im} P = U$, and $\ker P = X$.

(b) Show that $V = X^\perp \oplus U^\perp$ and that P^* is the projection onto $X^\perp$ along $U^\perp$.

(c) Deduce that P is an orthogonal projection if and only if $X = U^\perp$.

Solution on page 1531

Exercise 6.6.48. HARD

(a) Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$. Find an inner product on $\mathbb{R}^2$ for which T_A is self-adjoint. (Look for $\langle \mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^{\mathsf{T}} M \mathbf{x}$ as in Proposition 6.1.22.)

(b) Show that the rotation T_J, $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, is not self-adjoint for any inner product on $\mathbb{R}^2$.

Solution on page 1531

Exercise 6.6.49. HARD BEYOND 21-242 Let $P_n = \mathbb{R}[x]_{\le n}$ with $\langle p, q\rangle = \int_0^1 p(t)q(t)\,dt$, and let $q_n \in P_n$ represent evaluation at 0: $\langle p, q_n\rangle = p(0)$ for all $p \in P_n$ (Theorem 6.6.3).

(a) Show that $\|q_n\| \ge |p(0)|/\|p\|$ for every nonzero $p \in P_n$.

(b) Using $p(t) = (1-t)^n$, deduce that $\|q_n\| \ge \sqrt{2n+1}$.

(c) Deduce again (Non-example 6.6.7) that no polynomial q satisfies $\int_0^1 p(t)q(t)\,dt = p(0)$ for all polynomials p.

Solution on page 1532

Exercise 6.6.50. HARD Let $A \in \mathbb{C}^{n\times n}$ satisfy $A^*A = A^2$. Show that $A^* = A$.

Solution on page 1532

Exercise 6.6.51. CHALLENGE BEYOND 21-242 Let V be a finite-dimensional inner product space and $T \in \mathrm{L}(V)$ with $\|T\mathbf{v}\| \le \|\mathbf{v}\|$ for all $\mathbf{v} \in V$.

(a) Show that $T\mathbf{v} = \mathbf{v}$ if and only if $T^*\mathbf{v} = \mathbf{v}$.

(b) Deduce that $V = \ker(T - \mathrm{id}) \oplus \mathrm{im}(T - \mathrm{id})$, with the two subspaces orthogonal.

(c) Show that for every $\mathbf{v} \in V$, the averages $A_N\mathbf{v} = (1/N)\sum_{k=0}^{N-1} T^k\mathbf{v}$ converge to $\mathrm{Pr}_{\ker(T-\mathrm{id})}(\mathbf{v})$ as $N \to \infty$, in the sense that $\left\|A_N\mathbf{v} - \mathrm{Pr}_{\ker(T-\mathrm{id})}(\mathbf{v})\right\| \to 0$.

Solution on page 1533

6.7 Proof patterns

An inner product adds one number $\langle \mathbf{v}, \mathbf{w}\rangle$ to every pair of vectors, and the chapter turned that number into lengths, angles, projections, least-squares solutions, and adjoints. Most of its proofs use a small number of moves to get from a hypothesis about inner products to a conclusion about vectors or maps: expand a squared norm and use positivity, test a vector against everything, move an operator to the other slot, choose an orthonormal basis, or split a vector into orthogonal pieces. This section sorts the chapter's arguments by the question they answer, solves a few problems in several ways to compare the moves, and lists the errors that the chapter's exercises warn against. The exercises at the end practice one move at a time, and the problem set (Problems for Chapter 6) mixes them with earlier chapters.

6.7.1 Proving an inequality

Almost every inequality in the chapter is a squared norm that was dropped because it is nonnegative. The work is in choosing the vector whose norm to drop.

- *Expand a squared norm.* Write $0 \le \|\mathbf{x} - t\mathbf{y}\|^2$, or the norm of some other combination, and expand with Proposition 6.1.29. All three proofs of Theorem 6.2.1 start this way and differ only in the choice of t (Section 6.2.1). The same move gives the reverse triangle inequality (Corollary 6.2.14) and identities such as Exercise 6.1.57.
- *Drop an orthogonal piece* (Technique 6.2.4, Technique 6.4.5). If $\mathbf{x} = \mathbf{p} + \mathbf{q}$ with $\mathbf{p} \perp \mathbf{q}$, then $\|\mathbf{p}\| \le \|\mathbf{x}\|$. This is Bessel's inequality (Theorem 6.3.24), the best-approximation property (Theorem 6.4.33), and, with $\mathbf{p}$ the part of $\mathbf{x}$ along $\mathbf{y}$, Cauchy–Schwarz again.
- *Cauchy–Schwarz for a well-chosen inner product* (Technique 6.2.21). For inequalities between sums or integrals, the choice of space, weights, and splitting of each term is the whole proof (Proposition 6.2.22, Corollary 6.2.26, Exercise 6.2.36).
- *A discriminant* (Technique 6.2.7). When the target has the shape $b^2 \le ac$ and there is no picture, look for a quadratic in a real parameter that is nonnegative for an obvious reason.

- *Normalize.* Both sides of a homogeneous inequality scale the same way, so it suffices to check it on unit vectors (third proof of Theorem 6.2.1). Over $\mathbb{C}$, rotating the phase (Technique 6.2.8) makes an inner product real before a real-variable argument is run.

The equality case comes from the same computation: equality holds exactly when the dropped quantity is 0. That is why it pays to keep the dropped term written down, as in (6.2.2), instead of replacing it by "≥ 0" at once. The triangle inequality (Theorem 6.2.11(b)), Bessel's inequality, and best approximation all get their equality cases this way.

Example 6.7.1 (The Cauchy–Schwarz gap, three ways). Let $\mathbf{x}, \mathbf{y}$ be vectors in an inner product space V, and let

$$D = \|\mathbf{x}\|^2\|\mathbf{y}\|^2 - |\langle \mathbf{x}, \mathbf{y}\rangle|^2,$$

the amount by which Cauchy–Schwarz fails to be an equality. Here are three formulas for D.

By orthogonal decomposition. If $\mathbf{y} \neq \mathbf{0}$, (6.2.2) says $D = \|\mathbf{y}\|^2\|\mathbf{x} - c\mathbf{y}\|^2$ with $c = \langle \mathbf{x}, \mathbf{y}\rangle / \|\mathbf{y}\|^2$. Since $c\mathbf{y}$ is the projection of $\mathbf{x}$ onto the line $\operatorname{span}(\mathbf{y})$, this reads $D = \|\mathbf{y}\|^2 \operatorname{dist}(\mathbf{x}, \operatorname{span}(\mathbf{y}))^2$ (Definition 6.4.34).

In orthonormal coordinates. If $\mathbf{x}, \mathbf{y}$ are linearly dependent, $D = 0$ by Lemma 6.2.3. Otherwise $W = \operatorname{span}(\mathbf{x}, \mathbf{y})$ has an orthonormal basis $\mathcal{O} = \mathbf{u}_1, \mathbf{u}_2$ (Theorem 6.4.20). Write $\mathbf{x} = a_1\mathbf{u}_1 + a_2\mathbf{u}_2$ and $\mathbf{y} = b_1\mathbf{u}_1 + b_2\mathbf{u}_2$. By Theorem 6.3.22, $\langle \mathbf{x}, \mathbf{y}\rangle = a_1\overline{b_1} + a_2\overline{b_2}$, $\|\mathbf{x}\|^2 = |a_1|^2 + |a_2|^2$, and $\|\mathbf{y}\|^2 = |b_1|^2 + |b_2|^2$. Multiplying out,

$$\|\mathbf{x}\|^2\|\mathbf{y}\|^2 = |a_1b_1|^2 + |a_1b_2|^2 + |a_2b_1|^2 + |a_2b_2|^2,$$
$$|\langle \mathbf{x}, \mathbf{y}\rangle|^2 = |a_1b_1|^2 + |a_2b_2|^2 + 2\operatorname{Re}\left(a_1b_2\overline{a_2b_1}\right),$$

and the difference is $|a_1b_2|^2 - 2\operatorname{Re}\left(a_1b_2\overline{a_2b_1}\right) + |a_2b_1|^2$. So

$$D = |a_1b_2 - a_2b_1|^2.$$

As a determinant. By definition (Definition 6.3.28), the Gram matrix of $\mathbf{x}, \mathbf{y}$ is

$$G = \begin{pmatrix} \langle \mathbf{x}, \mathbf{x}\rangle & \langle \mathbf{y}, \mathbf{x}\rangle \\ \langle \mathbf{x}, \mathbf{y}\rangle & \langle \mathbf{y}, \mathbf{y}\rangle \end{pmatrix},$$

and $\det G = \|\mathbf{x}\|^2\|\mathbf{y}\|^2 - \langle \mathbf{y}, \mathbf{x}\rangle\langle \mathbf{x}, \mathbf{y}\rangle = D$. In the coordinates above, let $B = \begin{pmatrix} a_1 & b_1 \\ a_2 & b_2 \end{pmatrix}$, with columns $[\mathbf{x}]_{\mathcal{O}}$ and $[\mathbf{y}]_{\mathcal{O}}$. By Theorem 6.3.22, the (i, j) entry of B^*B is $[\mathbf{v}_i]_{\mathcal{O}}^*[\mathbf{v}_j]_{\mathcal{O}} = \langle \mathbf{v}_j, \mathbf{v}_i\rangle$, where $\mathbf{v}_1 = \mathbf{x}$ and $\mathbf{v}_2 = \mathbf{y}$; so $G = B^*B$. Then $\det G = \det(B^*)\det B = |\det B|^2$ (Theorem 5.4.10, Exercise 6.3.57), which is the second formula again.

Each formula proves Cauchy–Schwarz with its equality case: $D \geq 0$, and $D = 0$ exactly when $\mathbf{x} \in \operatorname{span}(\mathbf{y})$, or $\det B = 0$, or G is singular, all of which say that $\mathbf{x}, \mathbf{y}$ are dependent (Proposition 6.3.30). They lead in different directions. The first measures the gap by a distance, and Section 6.4 replaces the line by any subspace. The second writes D as one squared modulus, a certificate of nonnegativity in the sense of Technique 6.1.9; over $\mathbb{R}^n$ with the dot product it is Lagrange's identity (Exercise 6.2.43), and the orthonormal basis is what reduces every inner product space to $n = 2$. The third gives the equality case without any basis (Proposition 6.3.30), but its sign comes from $\det G = |\det B|^2$, that is, from the coordinates. It extends to k vectors: the Gram determinant of any list is nonnegative and vanishes exactly for dependent lists, by orthonormal coordinates again (Exercise 6.7.11) or by Gram–Schmidt residuals (Exercise 6.4.59). In $\mathbb{R}^2$, $|\det B|$ is the area of the parallelogram spanned by $\mathbf{x}$ and $\mathbf{y}$ (Remark 6.2.5).

The last two proofs could not have been given in Section 6.2, since they use orthonormal bases, but they are not circular: Gram–Schmidt and Parseval's identity never use Cauchy–Schwarz.

The middle formula is an instance of a move that the chapter used several times without naming it.

Technique 6.7.2 (Pass to orthonormal coordinates). A statement about finitely many vectors $\mathbf{v}_1, \ldots, \mathbf{v}_k$ of an inner product space V involves only $W = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$, which is finite-dimensional even when V is not. Choose an orthonormal basis $\mathcal{O}$ of W (Theorem 6.4.20). By Theorem 6.3.22, the coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{O}}$ preserves inner products, so W behaves exactly like $\mathbb{F}^r$ with the dot product, where $r = \dim W \leq k$. The list becomes the columns of a matrix $B \in \mathbb{F}^{r \times k}$ with $B^*B = G$, the Gram matrix of the list, and the statement can be checked with entries, sums of squares, and determinants.

Reach for it when a statement about a fixed finite list is easy to verify in $\mathbb{F}^r$ but awkward without coordinates, or when you need a matrix whose Gram matrix is prescribed. The canonical example is the second formula of Example 6.7.1. It also shows that Gram determinants are nonnegative (Exercise 6.7.11) and produces the matrix B in Problem 6.17. It does not apply as stated to a map on an infinite-dimensional V, since the map need not preserve W.

Used in. Exercise 6.7.11, Problem 6.17, Theorem 8.1.3, Proposition 8.1.7, Theorem 8.2.18, Exercise 8.2.42, Theorem 8.3.5, Lemma 8.3.8.

Practice: Exercise 6.7.6 and Exercise 6.7.12.

6.7.2 Showing that a vector or a map is zero

An inner product gives several ways to prove $\mathbf{v} = \mathbf{0}$, or $S = T$, which a bare vector space does not have.

- *Its norm* (Technique 6.1.36). Show $\langle \mathbf{v}, \mathbf{v} \rangle = 0$. If $\mathbf{v}$ is a matrix, show $\operatorname{tr}(\mathbf{v}^*\mathbf{v}) = 0$ (Technique 6.1.18). If the norm is a sum of squares, every term vanishes (Technique 6.1.9).
- *Test against everything.* If $\langle \mathbf{v}, \mathbf{x} \rangle = 0$ for every $\mathbf{x}$ in V, or in a spanning list, then $\mathbf{v} = \mathbf{0}$: take $\mathbf{x} = \mathbf{v}$ (Proposition 6.1.37, Exercise 6.1.50). For a finite-dimensional subspace W this is $W^\perp = \{\mathbf{0}\} \Rightarrow W = V$ (Corollary 6.4.27), and for maps it is Corollary 6.1.38.
- *Test on the diagonal.* Over $\mathbb{C}$, the numbers $\langle T\mathbf{v}, \mathbf{v} \rangle$ already determine T (Proposition 6.1.41). Over $\mathbb{R}$ they determine only self-adjoint operators, and the rotation by $\pi/2$ shows why (Example 6.1.39).
- *Move the operator across* (Technique 6.6.20), to turn the hypothesis into one of the forms above. The standard instance is $\langle T^*T\mathbf{v}, \mathbf{v} \rangle = \|T\mathbf{v}\|^2$, which gives $\ker T^*T = \ker T$ (Proposition 6.6.23).
- *Orthogonal pieces.* A vector in $W \cap W^\perp$ is orthogonal to itself, hence $\mathbf{0}$. This is how uniqueness of orthogonal decompositions is proved (Theorem 6.4.24), and how $\ker T^* = (\operatorname{im} T)^\perp$ is used (Theorem 6.6.21).

Example 6.7.3 (A normal matrix with square zero, three certificates). Let $A \in \mathbb{C}^{n \times n}$ satisfy $A^*A = AA^*$ and $A^2 = 0$. (Matrices with $A^*A = AA^*$ are called *normal*; Section 8.1 studies them.) We show that $A = 0$ in three ways.

Norms. With the dot product, A^* is the adjoint of $\mathbf{v} \mapsto A\mathbf{v}$ (Example 6.6.10). For every $\mathbf{v} \in \mathbb{C}^n$,

$$\|A\mathbf{v}\|^2 = \langle A^*A\mathbf{v}, \mathbf{v} \rangle = \langle AA^*\mathbf{v}, \mathbf{v} \rangle = \|A^*\mathbf{v}\|^2.$$

Applied to $A\mathbf{v}$ this gives $\|A^*A\mathbf{v}\| = \|A^2\mathbf{v}\| = 0$, so $A^*A\mathbf{v} = \mathbf{0}$, and then $\|A\mathbf{v}\|^2 = \langle A^*A\mathbf{v}, \mathbf{v} \rangle = 0$. So $A\mathbf{v} = \mathbf{0}$ for every $\mathbf{v}$.

The trace of B^*B. Let $B = A^*A$. Then $B^* = B$, and $B^2 = A^*(AA^*)A = A^*(A^*A)A = (A^*)^2A^2 = 0$. So $\operatorname{tr}(B^*B) = \operatorname{tr}(B^2) = 0$, which forces $B = 0$ (Technique 6.1.18), and $A^*A = 0$ forces $A = 0$ (Corollary 6.1.19).

Subspaces. $A^2 = 0$ says $\operatorname{im} A \subseteq \ker A$. By Proposition 6.5.9(a), applied to A and to A^*, $\ker A = \ker(A^*A) = \ker(AA^*) = \ker A^*$, and $\ker A^* = (\operatorname{im} A)^\perp$ by Lemma 6.5.4. So $\operatorname{im} A \subseteq (\operatorname{im} A)^\perp$: every $\mathbf{w} \in \operatorname{im} A$ is orthogonal to itself, and $\operatorname{im} A = \{\mathbf{0}\}$.

The norm argument is the shortest; it uses nothing but moving A across the inner product twice. The trace argument never mentions a vector, and it is the one to try when all hypotheses are matrix identities: one nonnegative number controls every entry. The subspace argument shows what normality does: it makes

$\ker A = \ker A^*$, so the image of A, which is orthogonal to $\ker A^*$, is also orthogonal to $\ker A$, and an A with $A^2 = 0$ would need its image inside that kernel.

Each argument breaks at the same hypothesis for $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, which has $N^2 = 0$ but is not normal: $\|N\mathbf{e}_2\| = 1$ while $\|N^*\mathbf{e}_2\| = 0$, and $\ker N = \operatorname{span}(\mathbf{e}_1)$ while $\ker N^* = \operatorname{span}(\mathbf{e}_2)$. The norm argument proves more than was asked. It shows that $\ker A^2 = \ker A$ for every normal A, so by induction $\ker A^k = \ker A$ for all $k \geq 1$, and a normal matrix with $A^k = 0$ is 0.

Practice: Exercise 6.7.7, Exercise 6.7.9, and Exercise 6.7.8.

6.7.3 Projections, distances, and least squares

The projection $\operatorname{Pr}_W(\mathbf{v})$, the closest point of W to $\mathbf{v}$, and the fitted values of a least-squares problem are the same vector (Theorem 6.4.33, Proposition 6.5.2). There are several ways to find it, or to use it without finding it.

- *Orthonormal basis first.* Once W has an orthonormal or orthogonal basis, the projection is a sum of one-term projections (Definition 6.4.11, Corollary 6.4.10), and in $\mathbb{F}^n$ its matrix is QQ^* (Theorem 6.4.31). This pays when an orthogonal spanning list is visible, or can be made by symmetry (Exercise 6.4.54).
- *Normal equations* (Theorem 6.5.5, Proposition 6.5.23). For any spanning list with Gram matrix G, solve $G\mathbf{c} = \mathbf{d}$. Nothing has to be orthogonalized.
- *The complement.* $\operatorname{Pr}_W = \mathrm{id} - \operatorname{Pr}_{W^\perp}$ (Proposition 6.4.29(d)), which is the better route when $W^\perp$ is the smaller space, as for hyperplanes (Example 6.4.35).
- *Recognize instead of compute* (Technique 6.4.7). To show that $\mathbf{p} = \operatorname{Pr}_W(\mathbf{v})$, check $\mathbf{p} \in W$ and $\mathbf{v} - \mathbf{p} \perp W$. This is also how projections onto related subspaces are compared.
- *Perturb a minimizer* (Technique 6.5.6). When a vector is defined by minimizing a squared norm, perturbing it in each direction produces the orthogonality condition, which is the second proof of Theorem 6.5.5.

Example 6.7.4 (One least-squares error, four ways). Fit a line $y = c_0 + c_1 x$ to the points $(1,1), (2,3), (3,2), (4,5)$. With $\mathbf{1} = (1,1,1,1)$, $\mathbf{x} = (1,2,3,4)$, $\mathbf{y} = (1,3,2,5)$, and $W = \operatorname{span}(\mathbf{1}, \mathbf{x}) \subseteq \mathbb{R}^4$, the squared least-squares error is $\operatorname{dist}(\mathbf{y}, W)^2$. Note $\|\mathbf{y}\|^2 = 39$.

Normal equations. With $A = (\mathbf{1}\ \mathbf{x})$,

$$A^{\mathsf{T}}A = \begin{pmatrix} 4 & 10 \\ 10 & 30 \end{pmatrix}, \quad A^{\mathsf{T}}\mathbf{y} = \begin{pmatrix} 11 \\ 33 \end{pmatrix},$$

so $\mathbf{c} = (0, 11/10)$ and the line is $y = 11x/10$. The residual is $\mathbf{y} - A\mathbf{c} = (-1/10, 4/5, -13/10, 3/5)$, and its squared norm is $(1 + 64 + 169 + 36)/100 = 27/10$.

An orthogonal basis of W. One step of Gram–Schmidt replaces $\mathbf{x}$ by $\mathbf{x} - (10/4)\mathbf{1}$, and doubling gives $\mathbf{w} = (-3, -1, 1, 3) \perp \mathbf{1}$. By Corollary 6.4.10 and Pythagoras (Proposition 6.4.4),

$$\operatorname{dist}(\mathbf{y}, W)^2 = \|\mathbf{y}\|^2 - \frac{\langle \mathbf{y}, \mathbf{1} \rangle^2}{\|\mathbf{1}\|^2} - \frac{\langle \mathbf{y}, \mathbf{w} \rangle^2}{\|\mathbf{w}\|^2} = 39 - \frac{121}{4} - \frac{121}{20} = \frac{27}{10}.$$

The complement. $W^\perp$ has dimension 2 (Corollary 6.4.25). Among vectors of the form (a, b, b, a), the conditions $\perp \mathbf{1}$ and $\perp \mathbf{x}$ leave $\mathbf{g}_1 = (1, -1, -1, 1)$; among vectors of the form $(a, b, -b, -a)$, they leave $\mathbf{g}_2 = (1, -3, 3, -1)$. Vectors of these two forms are always orthogonal, so $\mathbf{g}_1, \mathbf{g}_2$ is an orthogonal basis of $W^\perp$. The residual is $\operatorname{Pr}_{W^\perp}(\mathbf{y}) = (1/4)\mathbf{g}_1 - (7/20)\mathbf{g}_2$ (Proposition 6.4.29(d)), and

$$\operatorname{dist}(\mathbf{y}, W)^2 = \frac{1^2}{4} + \frac{7^2}{20} = \frac{27}{10}.$$

Gram determinants. By Exercise 6.4.59(b), $\operatorname{dist}(\mathbf{y}, W)^2$ is the ratio of the Gram determinants of $\mathbf{1}, \mathbf{x}, \mathbf{y}$ and of $\mathbf{1}, \mathbf{x}$:

$$\det\begin{pmatrix} 4 & 10 & 11 \\ 10 & 30 & 33 \\ 11 & 33 & 39 \end{pmatrix} \Big/ \det\begin{pmatrix} 4 & 10 \\ 10 & 30 \end{pmatrix} = \frac{54}{20} = \frac{27}{10}.$$

With two unknowns, the normal equations are the quickest route, and they also produce the line. The orthogonal basis costs one Gram–Schmidt step, after which each coefficient is a single inner product, and fitting a parabola instead would only add a term: the coefficients already found do not change. The complement computes the residual without the fitted values, and it is the efficient route when $W^\perp$ is smaller than W. Gram determinants need no solving, but they give only the distance, not the closest point.

Practice: Exercise 6.7.5 and Exercise 6.7.13.

6.7.4 Choosing an orthonormal basis

In an orthonormal basis, coordinates are inner products (Proposition 6.3.18), inner products are dot products of coordinates (Theorem 6.3.22), the adjoint is the conjugate transpose (Theorem 6.6.15(b)), self-adjoint operators are Hermitian matrices (Corollary 6.6.28), and an orthogonal projection is $\operatorname{diag}(1, \ldots, 1, 0, \ldots, 0)$ when the first basis vectors span its image (Corollary 6.4.25). So when a statement is basis-free but easier in coordinates, choose an orthonormal basis adapted to the problem: one whose first vectors span a given subspace (Theorem 6.4.20(b)), or one of the span of the vectors at hand (Technique 6.7.2). None of these formulas survives in a basis that is not orthonormal. There the Gram matrix G of the basis enters, as in $\langle \mathbf{v}, \mathbf{w} \rangle = [\mathbf{w}]^* G [\mathbf{v}]$ and $[T^*] = G^{-1}[T]^* G$ (Exercise 6.6.46, Example 6.6.16).

Coordinates are not always the shorter route. Statements about kernels, images, and complements usually have one-line proofs without a basis, as $\ker T^* = (\operatorname{im} T)^\perp$ does (Theorem 6.6.21), and a coordinate proof of them hides the reason. And in an infinite-dimensional space only finite-dimensional subspaces are guaranteed an orthonormal basis, so an argument that picks an orthonormal basis of V has assumed $\dim V < \infty$. A useful check after a coordinate proof is to ask whether the quantity computed depends on the basis; if the statement was basis-free, it cannot, and showing that directly sometimes gives a better proof (Exercise 6.7.10).

Practice: Exercise 6.7.10 and Exercise 6.7.11.

6.7.5 Lengths determine inner products

By polarization (Proposition 6.1.32, Technique 6.1.33), $\langle \mathbf{x}, \mathbf{y} \rangle$ is a combination of the four lengths $\|\mathbf{x} + i^k \mathbf{y}\|$, or of two over $\mathbb{R}$. So a hypothesis about lengths alone is a hypothesis about inner products: a linear map that preserves lengths preserves inner products (Exercise 6.1.51, Exercise 6.6.40), and two inner products with the same norm are equal (Corollary 6.1.34). For operators, the corresponding statement is about the numbers $\langle T\mathbf{v}, \mathbf{v} \rangle$, and here real and complex scalars part ways: over $\mathbb{C}$ these numbers determine T (Proposition 6.1.41), and they are all real exactly when T is self-adjoint (Proposition 6.6.30); over $\mathbb{R}$ they see only the self-adjoint part $(T + T^*)/2$ (Exercise 6.1.52). The general move behind all of this is to apply a hypothesis to $\mathbf{x} + c\mathbf{y}$ for a few scalars c and solve for the cross term (Technique 6.1.40).

A useful habit is to write every proof over $\mathbb{F}$, with Re wherever a cross term appears, and to specialize to $\mathbb{R}$ by erasing the bars. The differences between the two cases are concentrated in a few places: the converse of Pythagoras (Theorem 6.3.3(b), Non-example 6.3.4), the polarization identities, rotating the phase, and tests on the diagonal. Practice: Exercise 6.7.15 and Exercise 6.7.8.

6.7.6 Reading the chapter's proofs

Uniqueness first, then existence. The projection was characterized by two conditions before anything was computed (Theorem 6.4.6), and uniqueness then gave independence of the basis for free (Corollary 6.4.8). Adjoints went the same way: uniqueness (Proposition 6.6.9) needs only that inner products distinguish vectors, while existence (Theorem 6.6.15) needs a finite-dimensional space and either the Riesz representation theorem or a matrix computation. Recognizing an object by a property that determines it (Technique 6.4.7, Technique 6.6.11) is the inner-product version of checking that a candidate is an inverse (Technique 2.5.16); compare Section 5.6.5.

Where finite dimension enters. Every existence statement of the chapter needs an orthonormal basis of something, and that is the only place where finite dimension is used. For Pr_W and $V = W \oplus W^\perp$, only W has to be finite-dimensional (Theorem 6.4.24). The identity $\ker T^* = (\operatorname{im} T)^\perp$ needs no dimension hypothesis, while $\operatorname{im} T^* = (\ker T)^\perp$ does (Theorem 6.6.21). When a hypothesis of this kind is dropped, the conclusion can fail (Exercise 6.4.63, Non-example 6.6.7).

Orthogonality turns sums into sums of squares. Pythagoras (Corollary 6.3.6), Parseval (Theorem 6.3.22), Bessel (Theorem 6.3.24), and the defect formula (6.2.2) all say that the squared length of a sum of orthogonal pieces is the sum of the squared lengths. That is what makes coefficients in an orthonormal basis independent of each other (Technique 6.3.12), and why projections, unlike arbitrary idempotents, shrink vectors (Exercise 6.4.57).

The scalars are $\mathbb{R}$ or $\mathbb{C}$ for a reason. Positivity and definiteness use the order on $\mathbb{R}$. Over $\mathbb{F}_p$ or with a symmetric bilinear form over $\mathbb{C}$, there are nonzero vectors orthogonal to themselves (Exercise 6.1.58, Proposition 6.1.6), and then projections, Gram–Schmidt, and the normal equations can all fail (Exercise 6.5.44). Section 12.4 studies what survives.

6.7.7 Common errors

Most of these appear in the chapter as find-the-error exercises.

- *A conjugate in the wrong place.* The inner product is conjugate-linear in the second slot: $\langle \mathbf{v}, a\mathbf{w}\rangle = \bar{a}\langle \mathbf{v}, \mathbf{w}\rangle$ (Proposition 6.1.4). Coordinates need the vector in the first slot (Remark 6.3.19), and Gram–Schmidt with the slots exchanged produces vectors that are not orthogonal (Exercise 6.4.21).
- *The transpose instead of the conjugate transpose.* Over $\mathbb{C}$, $A^{\mathsf{T}}A$ can be singular when the columns of A are independent, and $\sum_k z_k w_k$ is not an inner product (Remark 6.5.10, Exercise 6.2.30).
- *Real facts used over $\mathbb{C}$, and complex facts used over $\mathbb{R}$.* The converse of Pythagoras and the two-term polarization identity hold only over $\mathbb{R}$, and a discriminant argument with a complex parameter proves nothing (Exercise 6.2.35). In the other direction, $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$ forces $T = 0$ only over $\mathbb{C}$ (Example 6.1.39, Exercise 6.1.59, Problem 6.6).
- *Projecting onto a spanning list that is not orthogonal*, one vector at a time (Exercise 6.4.42), and its relative $\mathrm{Pr}_{U+W} = \mathrm{Pr}_U + \mathrm{Pr}_W$ (Exercise 6.4.50).
- *A one-sided inverse used as a two-sided one.* $A(A^*A)^{-1}A^*$ is not I_m (Exercise 6.5.36), $T^*T = \mathrm{id}$ does not give $TT^* = \mathrm{id}$ (Exercise 6.6.41), and orthogonal columns do not give orthogonal rows (Exercise 6.3.55).
- *The conjugate transpose in a basis that is not orthonormal* (Example 6.6.16, Exercise 6.6.46).
- *Assuming the orthogonality to be proved.* Pythagoras needs orthogonal pieces, and using it for $\mathbf{v} = P\mathbf{v} + (\mathbf{v} - P\mathbf{v})$ assumes that P is an orthogonal projection (Exercise 6.7.13). Swapping TT^* for T^*T assumes normality (Exercise 6.7.14).
- *A hypothesis that is never used.* In both of the previous errors, the argument never touches one of the hypotheses. That is worth checking in every proof, and it is a warning sign whenever it happens.
- *Dropping finite dimension* (Exercise 6.4.63, Non-example 6.6.7), or definiteness (Exercise 6.1.60).

Exercises

Exercise 6.7.5. ROUTINE For each problem, choose a method, say why it fits, and compute.

(a) The distance from $\mathbf{v} = (3, 1, 4, 1)$ to $W = \operatorname{span}((1, 1, 1, 1), (1, -1, 1, -1))$ in $\mathbb{R}^4$.

(b) The distance from $\mathbf{v} = (1, 2, 3, 4)$ to the hyperplane $x_1 - x_2 + x_3 - x_4 = 0$ in $\mathbb{R}^4$.

(c) The least-squares solution of $x_1 + x_2 = 1$, $x_1 + 2x_2 = 2$, $x_1 + 3x_2 = 2$.

Solution on page 1533

Exercise 6.7.6. STANDARD Let $\mathbf{x}, \mathbf{y}$ be vectors in an inner product space.

(a) Show that $\|\mathbf{x} + t\mathbf{y}\| \geq \|\mathbf{x}\|$ for every $t \in \mathbb{F}$ if and only if $\langle \mathbf{x}, \mathbf{y} \rangle = 0$.

(b) Over $\mathbb{C}$, show that it is not enough to require the inequality in (a) for real t only.

Solution on page 1534

Exercise 6.7.7. STANDARD Let V be a finite-dimensional inner product space and $T \in \mathrm{L}(V)$, and suppose that $\langle T\mathbf{u}, \mathbf{v} \rangle = 0$ whenever $\mathbf{u} \perp \mathbf{v}$. Show that $T = c\mathrm{id}_V$ for some $c \in \mathbb{F}$.

Solution on page 1534

Exercise 6.7.8. STANDARD Let V be a finite-dimensional inner product space and $T \in \mathrm{L}(V)$. Show that $T^*T = TT^*$ if and only if $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$ for every $\mathbf{v} \in V$. (Such T are called *normal*; see Section 8.1.) Over $\mathbb{R}$, where does your proof use that $T^*T - TT^*$ is self-adjoint?

Solution on page 1535

Exercise 6.7.9. STANDARD Let V be a finite-dimensional inner product space, and let $T \in \mathrm{L}(V)$ be self-adjoint with $T^3 = T^2$.

(a) Show that $T^2 = T$, so that T is an orthogonal projection.

(b) Show by an example that (a) fails without the hypothesis $T^* = T$.

Solution on page 1535

Exercise 6.7.10. STANDARD Let V, W be finite-dimensional inner product spaces and $T \in \mathrm{L}(V, W)$. Let $\mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis of V and $\mathbf{f}_1, \ldots, \mathbf{f}_m$ one of W.

(a) Show that

$$\sum_{j=1}^{n} \|T\mathbf{e}_j\|^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} |\langle T\mathbf{e}_j, \mathbf{f}_i \rangle|^2 = \sum_{i=1}^{m} \|T^*\mathbf{f}_i\|^2.$$

(b) Deduce that $\sum_j \|T\mathbf{e}_j\|^2$ does not depend on the choice of the orthonormal basis of V, and that it equals $\operatorname{tr}(A^*A)$ for the matrix A of T with respect to any orthonormal bases of V and W.

Solution on page 1536

Exercise 6.7.11. STANDARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_k$ be vectors in an inner product space V, with Gram matrix G (Definition 6.3.28). Show that $\det G$ is a nonnegative real number, and that $\det G = 0$ if and only if the list is linearly dependent. Use an orthonormal basis of $\operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$, not Gram–Schmidt residuals as in Exercise 6.4.59.

Solution on page 1536

Exercise 6.7.12. HARD Let $n \geq 2$ and $x \in \mathbb{R}$. Show that there are unit vectors $\mathbf{v}_1, \ldots, \mathbf{v}_n$ in some real inner product space with $\langle \mathbf{v}_i, \mathbf{v}_j \rangle = x$ for all $i \neq j$ if and only if

$$-\frac{1}{n-1} \leq x \leq 1.$$

Describe the configurations at the two endpoints.

Solution on page 1537

Exercise 6.7.13. STANDARD Find the error in the following argument, and then prove the claim correctly. (The claim is true; it is part of Exercise 6.4.57.)

Claim. Let V be a finite-dimensional inner product space, and let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$ and $\|P\mathbf{v}\| \leq \|\mathbf{v}\|$ for every $\mathbf{v} \in V$. Then $P = \mathrm{Pr}_{\mathrm{im}\, P}$.

Proof. Let $\mathbf{v} \in V$. Since $P(\mathbf{v} - P\mathbf{v}) = P\mathbf{v} - P^2\mathbf{v} = \mathbf{0}$, we have $\mathbf{v} = P\mathbf{v} + (\mathbf{v} - P\mathbf{v})$ with $P\mathbf{v} \in \mathrm{im}\, P$ and $\mathbf{v} - P\mathbf{v} \in \ker P$. By the Pythagorean theorem, $\|\mathbf{v}\|^2 = \|P\mathbf{v}\|^2 + \|\mathbf{v} - P\mathbf{v}\|^2$, so the two pieces are orthogonal. Hence $\mathbf{v} - P\mathbf{v} \perp \mathrm{im}\, P$, and $P\mathbf{v} = \mathrm{Pr}_{\mathrm{im}\, P}(\mathbf{v})$ by Theorem 6.4.6.

Solution on page 1537

Exercise 6.7.14. STANDARD Find the error in the following argument, give an operator for which its first displayed equation fails, and prove the claim correctly.

Claim. Let V be a finite-dimensional inner product space and $T \in \mathrm{L}(V)$ with $\|T\mathbf{v}\| \leq \|\mathbf{v}\|$ for all $\mathbf{v}$. Then $\|T^*\mathbf{v}\| \leq \|\mathbf{v}\|$ for all $\mathbf{v}$.

Proof. For every $\mathbf{v} \in V$,

$$\|T^*\mathbf{v}\|^2 = \langle TT^*\mathbf{v}, \mathbf{v} \rangle = \langle T^*T\mathbf{v}, \mathbf{v} \rangle = \|T\mathbf{v}\|^2,$$

and $\|T\mathbf{v}\|^2 \leq \|\mathbf{v}\|^2$.

Solution on page 1538

Exercise 6.7.15. ROUTINE For each statement, decide whether it holds in every real inner product space, and whether it holds in every complex one. Here $\mathbf{x}, \mathbf{y}, \mathbf{v} \in V$ and $T \in \mathrm{L}(V)$, with V finite-dimensional.

(a) If $\langle T\mathbf{v}, \mathbf{v} \rangle = 0$ for every $\mathbf{v}$, then $T = 0$.

(b) If $\|\mathbf{x} + \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2$, then $\mathbf{x} \perp \mathbf{y}$.

(c) $\langle \mathbf{x}, \mathbf{y} \rangle = \frac{1}{4}\big(\|\mathbf{x} + \mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2\big)$.

(d) If $\langle T\mathbf{v}, \mathbf{v} \rangle \in \mathbb{R}$ for every $\mathbf{v}$, then T is self-adjoint.

Solution on page 1538

Problems for Chapter 6

These problems combine the sections of Chapter 6 with each other and with earlier chapters: linear systems, dimension, affine subspaces, determinants, and traces. The first three are review prompts: state a main result, prove it without looking, and then answer a question that the text did not ask. The rest are ordered roughly by difficulty. Problems of kind "competition" are harder than anything the course expects, and two problems that go beyond the course are marked. Section 6.7 compares the techniques these problems call for.

Review: state and prove

Problem 6.1. STANDARD

(a) State the Cauchy–Schwarz inequality, including its equality case.

(b) Prove it, by any of the three methods of Section 6.2.1, without looking.

(c) Let $\mathbf{x}, \mathbf{y}$ be nonzero vectors in an inner product space. Show that

$$\left\| \frac{\mathbf{x}}{\|\mathbf{x}\|} - \frac{\mathbf{y}}{\|\mathbf{y}\|} \right\| \le \frac{2\|\mathbf{x}-\mathbf{y}\|}{\|\mathbf{x}\| + \|\mathbf{y}\|},$$

and that equality holds if and only if $\|\mathbf{x}\| = \|\mathbf{y}\|$ or $\mathbf{y}$ is a negative real multiple of $\mathbf{x}$.

Solution on page 1539

Problem 6.2. STANDARD Let W be a finite-dimensional subspace of an inner product space V.

(a) State the orthogonal decomposition theorem and the best-approximation theorem for W.

(b) Prove both, using only that W has an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_k$ (Theorem 6.4.20) and the formula $\operatorname{Pr}_W(\mathbf{v}) = \sum_j \langle \mathbf{v}, \mathbf{u}_j \rangle \mathbf{u}_j$.

(c) On $\mathbb{R}^2$, let $\|\mathbf{x}\|_\infty = \max(|x_1|, |x_2|)$. Find all points of $W = \operatorname{span}(\mathbf{e}_1)$ closest to $\mathbf{e}_2$ for this norm. Which step of your proof in (b) has no analogue for $\|\cdot\|_\infty$?

Solution on page 1540

Problem 6.3. STANDARD

(a) State the theorem on the kernels and images of T and T^* (Section 6.6.4).

(b) Let $T \in \mathrm{L}(V, W)$ have an adjoint. Prove that $\ker T^* = (\operatorname{im} T)^\perp$, and, if V is finite-dimensional, that $\operatorname{im} T^* = (\ker T)^\perp$.

(c) (*Fredholm alternative.*) Let $A \in \mathbb{F}^{m \times n}$ and $\mathbf{b} \in \mathbb{F}^m$. Show that exactly one of the following holds: $A\mathbf{x} = \mathbf{b}$ has a solution $\mathbf{x} \in \mathbb{F}^n$; or there is $\mathbf{y} \in \mathbb{F}^m$ with $A^*\mathbf{y} = \mathbf{0}$ and $\mathbf{y}^*\mathbf{b} \neq 0$. Use this to decide whether the system

$$x_1 + x_2 = 1, \quad x_2 + x_3 = 1, \quad x_1 - x_3 = 1$$

has a solution, and likewise with right-hand side $(1, 1, 0)$.

Solution on page 1540

Synthesis problems

Problem 6.4. STANDARD Let $\mathbf{p}_0, \dots, \mathbf{p}_k \in \mathbb{R}^n$ be such that $\mathbf{v}_i = \mathbf{p}_i - \mathbf{p}_0$ $(1 \le i \le k)$ are linearly independent, and let $A = \mathbf{p}_0 + \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$, the smallest affine subspace containing the points (Section 4.7).

(a) Show that exactly one point $\mathbf{c} \in A$ is equidistant from $\mathbf{p}_0, \dots, \mathbf{p}_k$. (It is the *circumcenter* of the points.)

(b) Show that $\mathbf{q} \in \mathbb{R}^n$ is equidistant from $\mathbf{p}_0, \dots, \mathbf{p}_k$ if and only if $\mathbf{q} - \mathbf{c} \perp \mathbf{v}_i$ for every i. Deduce that $\mathbf{c}$ is the point of A closest to every such $\mathbf{q}$, and that for $k = n$ the circumcenter is the only point of $\mathbb{R}^n$ equidistant from the $n+1$ points.

(c) Find the circumcenter and the common distance for $\mathbf{p}_0 = \mathbf{0}$, $\mathbf{p}_1 = (2, 0, 0)$, and $\mathbf{p}_2 = (1, 2, 2)$.

Solution on page 1541

Problem 6.5. STANDARD Let $x_0, \dots, x_n \in \mathbb{R}$ be distinct, let $V = \mathbb{R}[x]_{\le n}$, and let

$$\langle p, q\rangle = \sum_{k=0}^{n} p(x_k)q(x_k).$$

(a) Show that this is an inner product on V, and that the Lagrange polynomials $L_0, \dots, L_n$ of the nodes (Definition 3.4.26) form an orthonormal basis, in which the coordinates of p are $p(x_0), \dots, p(x_n)$.

(b) Deduce that the matrix with (i, j) entry $\sum_k x_k^{i+j}$ $(0 \le i, j \le n)$ is invertible. (Compare Problem 5.9.)

(c) Let $y_0, \dots, y_n \in \mathbb{R}$, let $p \in V$ satisfy $p(x_k) = y_k$ for all k (Theorem 3.4.24), and let $d < n$. Show that $\mathrm{Pr}_{\mathbb{R}[x]_{\le d}}(p)$ is the least-squares polynomial of degree at most d for the data (x_k, y_k), in the sense of Proposition 6.5.21.

(d) For the nodes $-1, 0, 1$ and the values $0, 1, 3$, find p and the least-squares line by (c).

Solution on page 1542

Problem 6.6. STANDARD Find the error in the following argument, and show that the claim is false.

Claim. Let V be a finite-dimensional real inner product space and $T \in \mathrm{L}(V)$ with $\langle T\mathbf{v}, \mathbf{v}\rangle \ge 0$ for every $\mathbf{v} \in V$. Then T is self-adjoint.

Proof. Let $S = T - T^*$. For every $\mathbf{v}$,

$$\langle T^*\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = \langle T\mathbf{v}, \mathbf{v}\rangle,$$

the last step because $\langle T\mathbf{v}, \mathbf{v}\rangle \ge 0$ is real. So $\langle S\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$, and $S = 0$ by Proposition 6.1.41.

(a) Then show that the same argument is correct for complex inner product spaces.

(b) Over $\mathbb{R}$, show that $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle H\mathbf{v}, \mathbf{v}\rangle$ for every $\mathbf{v}$, where $H = (T + T^*)/2$.

Solution on page 1543

Problem 6.7. STANDARD Prove or disprove each statement.

(a) If $A \in \mathbb{R}^{m\times n}$ has orthonormal columns, then $AA^{\mathsf{T}} = I_m$.

(b) For every $A \in \mathbb{C}^{n\times n}$, $\det(A^*A)$ is a nonnegative real number.

(c) If $P \in \mathbb{R}^{n\times n}$ satisfies $P^2 = P$ and $P^{\mathsf{T}}P = PP^{\mathsf{T}}$, then P is the matrix of an orthogonal projection.

(d) If U, W are subspaces of a finite-dimensional inner product space V, then $\dim\big(U \cap W^{\perp}\big) \ge \dim U - \dim W$.

(e) For $A \in \mathbb{R}^{n\times n}$: $\|A\mathbf{x}\| \le \|\mathbf{x}\|$ for every $\mathbf{x} \in \mathbb{R}^n$ if and only if $|\det A| \le 1$.

Solution on page 1544

Problem 6.8. HARD Let V be a real inner product space and $f : V \to V$ a function (not assumed linear) with $f(\mathbf{0}) = \mathbf{0}$ and

$$\|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\| \quad \text{for all } \mathbf{x}, \mathbf{y} \in V.$$

(a) Show that $\|f(\mathbf{x})\| = \|\mathbf{x}\|$ and $\langle f(\mathbf{x}), f(\mathbf{y})\rangle = \langle \mathbf{x}, \mathbf{y}\rangle$ for all $\mathbf{x}, \mathbf{y}$.

(b) Show that f is linear. Give a proof that works for every V, and, if V is finite-dimensional, a second proof with an orthonormal basis.

(c) Deduce that every distance-preserving $g : \mathbb{R}^n \to \mathbb{R}^n$ has the form $g(\mathbf{x}) = Q\mathbf{x} + \mathbf{b}$ with $Q^{\mathsf{T}}Q = I_n$.

(d) Now let V be a complex inner product space and $f : V \to V$ satisfy the same two conditions. Show that $f(\mathbf{x} + \mathbf{y}) = f(\mathbf{x}) + f(\mathbf{y})$ and $f(t\mathbf{x}) = tf(\mathbf{x})$ for real t, but that f need not be linear over $\mathbb{C}$.

Solution on page 1544

Problem 6.9. HARD Let V, W be inner product spaces over $\mathbb{F}$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$ and $\mathbf{w}_1, \ldots, \mathbf{w}_k \in W$ have the same Gram matrix: $\langle \mathbf{v}_j, \mathbf{v}_i \rangle = \langle \mathbf{w}_j, \mathbf{w}_i \rangle$ for all i, j.

(a) Show that $\|c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k\| = \|c_1\mathbf{w}_1 + \cdots + c_k\mathbf{w}_k\|$ for all $c_1, \ldots, c_k \in \mathbb{F}$. Deduce that $\sum_i c_i\mathbf{v}_i = \mathbf{0}$ if and only if $\sum_i c_i\mathbf{w}_i = \mathbf{0}$.

(b) Show that there is exactly one linear map $S : \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k) \to \operatorname{span}(\mathbf{w}_1, \ldots, \mathbf{w}_k)$ with $S\mathbf{v}_i = \mathbf{w}_i$ for all i, and that S is bijective with $\langle S\mathbf{x}, S\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$ for all $\mathbf{x}, \mathbf{y}$.

(c) Let $A, B \in \mathbb{F}^{m\times n}$. Show that $A^*A = B^*B$ if and only if $B = UA$ for some unitary $U \in \mathbb{F}^{m\times m}$.

Solution on page 1545

Problem 6.10. HARD Let V be a finite-dimensional inner product space, and let U, W be subspaces with $\dim U = \dim W$. Give U and W the restricted inner products, and define $A : U \to W$ and $B : W \to U$ by $A\mathbf{u} = \operatorname{Pr}_W(\mathbf{u})$ and $B\mathbf{w} = \operatorname{Pr}_U(\mathbf{w})$.

(a) Show that $\langle A\mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{u}, B\mathbf{w} \rangle$ for all $\mathbf{u} \in U$ and $\mathbf{w} \in W$. Conclude that $B = A^*$.

(b) Show that the following are equivalent:
- (i) $U \cap W^\perp = \{\mathbf{0}\}$;
- (ii) $W \cap U^\perp = \{\mathbf{0}\}$;
- (iii) A is bijective;
- (iv) B is bijective.

(c) Show by an example that (i) and (ii) need not be equivalent when $\dim U \neq \dim W$.

Solution on page 1546

Problem 6.11. HARD Give $\mathbb{F}^{n\times n}$ the Frobenius inner product $\langle X, Y \rangle = \operatorname{tr}(Y^*X)$ (Proposition 6.1.16). Let C be the span of all commutators $XY - YX$ with $X, Y \in \mathbb{F}^{n\times n}$, and let $Z = \{A \in \mathbb{F}^{n\times n} \mid \operatorname{tr} A = 0\}$.

(a) Show that $C \subseteq Z$ and that $Z = \operatorname{span}(I_n)^\perp$.

(b) Show that $\langle XY - YX, M \rangle = \langle Y, X^*M - MX^* \rangle$ for all X, Y, M. Deduce that every $M \in C^\perp$ commutes with every matrix.

(c) Deduce that $C = Z$: every matrix of trace 0 is a sum of commutators.

(d) Give a second proof of $C = Z$, valid over every field F, by writing each matrix in the spanning list of Z found in Example 2.6.28 as a commutator of matrix units.

Solution on page 1547

Problem 6.12. HARD Let $A \in \mathbb{F}^{m\times n}$.

(a) Show that $I_n + A^*A$ is the Gram matrix of the columns $\mathbf{c}_1, \ldots, \mathbf{c}_n$ of the matrix $C \in \mathbb{F}^{(n+m)\times n}$ that has I_n on top of A.

(b) Show that $\det(I_n + A^*A) \geq 1$, with equality if and only if $A = 0$.

Solution on page 1547

Solution on page 1548

Problem 6.13. HARD Let V be a real inner product space of dimension $n \geq 1$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_m \in V$ be nonzero vectors with $\langle \mathbf{v}_i, \mathbf{v}_j \rangle \leq 0$ for all $i \neq j$. Show that $m \leq 2n$, and give an example with $m = 2n$.

Solution on page 1548

Problem 6.14. HARD BEYOND 21-242 (*The kernel trick.*) Let $\Phi \in \mathbb{R}^{m\times N}$ have rows $\boldsymbol{\varphi}_1^{\mathsf{T}}, \dots, \boldsymbol{\varphi}_m^{\mathsf{T}}$ (the *feature vectors* of m data points), let $\mathbf{y} \in \mathbb{R}^m$, and let $K = \Phi\Phi^{\mathsf{T}}$, the matrix with entries $\boldsymbol{\varphi}_i \cdot \boldsymbol{\varphi}_j$.

(a) Show that the least-squares solution of minimal norm $\mathbf{w}^+$ of $\Phi\mathbf{w} = \mathbf{y}$ (Proposition 6.5.27) lies in $\operatorname{im}\Phi^{\mathsf{T}}$.

(b) Show that for $\boldsymbol{\alpha} \in \mathbb{R}^m$, $\Phi^{\mathsf{T}}\boldsymbol{\alpha}$ is a least-squares solution of $\Phi\mathbf{w} = \mathbf{y}$ if and only if $\boldsymbol{\alpha}$ is a least-squares solution of $K\boldsymbol{\alpha} = \mathbf{y}$. Deduce that $\mathbf{w}^+ = \Phi^{\mathsf{T}}\boldsymbol{\alpha}$ for every least-squares solution $\boldsymbol{\alpha}$ of $K\boldsymbol{\alpha} = \mathbf{y}$, and that for any $\boldsymbol{\varphi} \in \mathbb{R}^N$,

$$\boldsymbol{\varphi} \cdot \mathbf{w}^+ = \sum_{i=1}^{m} \alpha_i \, \boldsymbol{\varphi} \cdot \boldsymbol{\varphi}_i.$$

(c) Data points $t = -1, 0, 1$ have values $\mathbf{y} = (0, 1, 3)$, and each point t has the feature vector $\boldsymbol{\varphi}(t) = \left(1, \sqrt{2}t, t^2\right)$. Using only the kernel $k(s,t) = \boldsymbol{\varphi}(s) \cdot \boldsymbol{\varphi}(t)$, compute K, $\boldsymbol{\alpha}$, and the fitted function $t \mapsto \boldsymbol{\varphi}(t) \cdot \mathbf{w}^+$.

Solution on page 1549

Problem 6.15. HARD For a continuous $f : [0,1] \to \mathbb{R}$, let

$$I(f) = \int_0^1 x^2 f(x)\,\mathrm{d}x \quad \text{and} \quad J(f) = \int_0^1 x f(x)^2\,\mathrm{d}x.$$

Find the largest value of $I(f) - J(f)$ over all such f, and the functions attaining it.

Solution on page 1550

Problem 6.16. HARD Let a, b, c be positive real numbers with $abc = 1$. Show that

$$\frac{1}{a^3(b+c)} + \frac{1}{b^3(c+a)} + \frac{1}{c^3(a+b)} \geq \frac{3}{2},$$

and find when equality holds.

Solution on page 1550

Problem 6.17. CHALLENGE BEYOND 21-242 Let $G \in \mathbb{F}^{k\times k}$ satisfy $G^* = G$ and $\mathbf{c}^* G\mathbf{c} \geq 0$ for every $\mathbf{c} \in \mathbb{F}^k$. For $\mathbf{c}, \mathbf{d} \in \mathbb{F}^k$, let $\beta(\mathbf{c}, \mathbf{d}) = \mathbf{d}^* G\mathbf{c}$.

(a) Show that $|\beta(\mathbf{c}, \mathbf{d})|^2 \leq \beta(\mathbf{c}, \mathbf{c})\beta(\mathbf{d}, \mathbf{d})$ for all $\mathbf{c}, \mathbf{d}$. (Decide which proof of Theorem 6.2.1 survives without definiteness.)

(b) Show that $\beta(\mathbf{c}, \mathbf{c}) = 0$ if and only if $G\mathbf{c} = \mathbf{0}$.

(c) On the quotient space $V = \mathbb{F}^k / \ker G$ (Definition 4.6.20), show that $\langle [\mathbf{c}], [\mathbf{d}] \rangle = \mathbf{d}^* G\mathbf{c}$ is well defined and is an inner product, and that G is the Gram matrix of $[\mathbf{e}_1], \dots, [\mathbf{e}_k]$.

(d) Deduce that a matrix G with $G^* = G$ is the Gram matrix of a list in some inner product space if and only if $\mathbf{c}^* G\mathbf{c} \geq 0$ for all $\mathbf{c}$, if and only if $G = B^* B$ for some $B \in \mathbb{F}^{r\times k}$, where one can take $r = \operatorname{rank} G$.

Solution on page 1551

Problem 6.18. CHALLENGE Let $\mathcal{G}$ be a finite set of invertible matrices in $\mathbb{R}^{n\times n}$ that contains I_n and is closed under multiplication and inverses, and let $|\mathcal{G}|$ be the number of its elements.

(a) Show that $\langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}} = \sum_{M \in \mathcal{G}} (M\mathbf{x}) \cdot (M\mathbf{y})$ is an inner product on $\mathbb{R}^n$, and that $\langle N\mathbf{x}, N\mathbf{y} \rangle_{\mathcal{G}} = \langle \mathbf{x}, \mathbf{y} \rangle_{\mathcal{G}}$ for every $N \in \mathcal{G}$.

(b) Let $P = |\mathcal{G}|^{-1} \sum_{M \in \mathcal{G}} M$. Show that $NP = P$ for every $N \in \mathcal{G}$, that $P^2 = P$, and that P is self-adjoint for $\langle \cdot, \cdot \rangle_{\mathcal{G}}$.

(c) Deduce that $\operatorname{tr} P = \operatorname{rank} P$. Conclude that if $\sum_{M \in \mathcal{G}} \operatorname{tr} M = 0$, then $\sum_{M \in \mathcal{G}} M = 0$.

(d) Show that there is an invertible $S \in \mathbb{R}^{n \times n}$ such that $S^{-1}MS$ is orthogonal for every $M \in \mathcal{G}$.

Solution on page 1552

Chapter 7

Eigenvalues and diagonalization

Polynomials, eigenvalues and invariant subspaces, the characteristic polynomial, diagonalization, and Schur's theorem.

7.1 Polynomials

The eigenvalues of a square matrix will turn out to be the roots of a polynomial attached to it, its characteristic polynomial (Section 7.3). So we need to know how many roots a polynomial can have, when it has any at all, and how its roots show up in its factors. All of this rests on multiplying and dividing polynomials. So far (Definition 1.2.13), $F[x]$ has only been a vector space. This section gives it a multiplication and develops the algebra of $F[x]$ that the rest of the book uses. Throughout, F is a field.

7.1.1 Multiplying polynomials

To multiply $a_0 + a_1x + a_2x^2$ by $b_0 + b_1x$, we expand with the distributive law, use $x^ix^j = x^{i+j}$, and collect equal powers of x:

$$\begin{aligned}\left(a_0 + a_1x + a_2x^2\right)(b_0 + b_1x) = a_0b_0 + (a_0b_1 + a_1b_0)x \\ +(a_1b_1 + a_2b_0)x^2 + a_2b_1x^3.\end{aligned}$$

The coefficient of x^k collects the products a_ib_j with $i + j = k$. A polynomial is its sequence of coefficients (Definition 1.2.13), so we take this rule as the definition.

Definition 7.1.1 (Product of polynomials). Let $p = (a_0, a_1, a_2, \ldots)$ and $q = (b_0, b_1, b_2, \ldots)$ be polynomials in $F[x]$. Their **product** is $pq = (c_0, c_1, c_2, \ldots)$, where

$$c_k = \sum_{i=0}^{k} a_ib_{k-i} = a_0b_k + a_1b_{k-1} + \cdots + a_kb_0.$$

We also write $c_k = \sum_{i+j=k} a_ib_j$, a sum over the pairs (i, j) of nonnegative integers with $i + j = k$.

The product is again a polynomial. If $a_i = 0$ for $i > m$ and $b_j = 0$ for $j > n$, then for $k > m + n$ every pair with $i + j = k$ has $i > m$ or $j > n$, so every term of c_k is 0 (Proposition 1.1.15).

Two special cases connect the definition with the notation of Notation 1.2.15. First, $x^jx^k = x^{j+k}$, because the only nonzero term of the product is $1 \cdot 1$, in position $j + k$. In particular x^k is the product of k copies of x, so the notation x^k means what it says. Second, a constant $c = (c, 0, 0, \ldots)$ times q is $(cb_0, cb_1, \ldots)$, which is the scalar multiple cq of Definition 1.2.13. So writing cq is unambiguous.

Example 7.1.2 (Products over three fields).

(a) Over $\mathbb{Q}$, the product $(1+x)\big(1-x+x^2\big)$ has coefficients $c_0 = 1$, $c_1 = 1\cdot(-1)+1\cdot 1 = 0$, $c_2 = 1\cdot 1+1\cdot(-1) = 0$, and $c_3 = 1\cdot 1 = 1$. So $(1+x)\big(1-x+x^2\big) = 1+x^3$.

(b) Over $\mathbb{C}$, $(x-i)(x+i) = x^2+(i-i)x-i^2 = x^2+1$.

(c) Over $\mathbb{F}_2$, $(1+x)^2 = 1+(1+1)x+x^2 = 1+x^2$. So x^2+1 is a square in $\mathbb{F}_2[x]$, while in $\mathbb{R}[x]$ it is not even a product of two polynomials of degree 1 (Corollary 7.1.42).

Proposition 7.1.3 ($F[x]$ is a commutative ring). For all $p, q, r \in F[x]$ and $c \in F$:

(a) $pq = qp$;

(b) $(pq)r = p(qr)$;

(c) $p(q+r) = pq+pr$;

(d) $1p = p$;

(e) $c(pq) = (cp)q = p(cq)$.

In particular, $F[x]$ with its addition and this multiplication is a commutative ring (Definition 1.1.20).

Proof. ROUTINE

Uses. Definition 7.1.1 (Product of polynomials), Proposition 1.2.14 ($F[x]$ is a vector space), Definition 1.1.20 (Commutative ring), Definition 1.1.1 (Field)
Techniques. Compute entry by entry (Technique 2.4.15)
Hint 1. Compare the k-th coefficients of the two sides of each identity, the way one compares entries of matrices.
Hint 2. For (b), write the k-th coefficient of each side as a single sum over the triples (i,j,l) of nonnegative integers with $i+j+l = k$.
Sketch. Each identity holds coefficient by coefficient. The k-th coefficient of pq is $\sum_{i+j=k} a_i b_j$, which is symmetric in p and q. Both sides of (b) have k-th coefficient $\sum_{i+j+l=k} a_i b_j d_l$. Parts (c), (d), and (e) follow from distributivity in F, and the additive ring axioms are those of the vector space $F[x]$.

Write $p = (a_i)$, $q = \big(b_j\big)$, and $r = (d_l)$. All sums below are finite, so they can be reordered and regrouped freely.

(a) The k-th coefficient of pq is $\sum_{i+j=k} a_i b_j$, and that of qp is $\sum_{j+i=k} b_j a_i$. These are sums over the same pairs, and $a_i b_j = b_j a_i$.

(b) By distributivity, the k-th coefficient of $(pq)r$ is

$$\sum_{m+l=k}\left(\sum_{i+j=m} a_i b_j\right) d_l = \sum_{i+j+l=k} a_i b_j d_l,$$

since each triple (i,j,l) with $i+j+l=k$ occurs exactly once on the left, with $m = i+j$. In the same way, the k-th coefficient of $p(qr)$ is $\sum_{i+m=k} a_i\big(\sum_{j+l=m} b_j d_l\big) = \sum_{i+j+l=k} a_i b_j d_l$. By associativity in F, the two agree.

(c) The k-th coefficient of $p(q+r)$ is $\sum_{i+j=k} a_i\big(b_j+d_j\big) = \sum_{i+j=k} a_i b_j + \sum_{i+j=k} a_i d_j$, which is the k-th coefficient of $pq+pr$.

(d) Since $1 = (1,0,0,\ldots)$, the only possibly nonzero term in the k-th coefficient of $1p$ is $1\cdot a_k = a_k$.

(e) $\sum_{i+j=k}(ca_i)b_j = c\sum_{i+j=k} a_i b_j = \sum_{i+j=k} a_i\big(cb_j\big)$.

Finally, the axioms of a commutative ring that involve only addition (commutativity, associativity, a zero element, and negatives) hold because $F[x]$ is a vector space (Proposition 1.2.14). Together with (a)–(d), this makes $F[x]$ a commutative ring. □

By (c), (e), and $x^i x^j = x^{i+j}$, polynomials are multiplied by expanding and collecting terms:

$$\left(\sum_i a_i x^i\right)\left(\sum_j b_j x^j\right) = \sum_{i,j} a_i b_j x^{i+j}.$$

From now on we compute with polynomials as in school. The identities of Section 1.1.2 that do not use multiplicative inverses, such as $\mathbf{0}p = \mathbf{0}$, $(-1)p = -p$, and the sign rules, have the same proofs in every commutative ring, so they hold in $F[x]$.

Intuition. In a product of two polynomials, the highest power of x comes only from the two leading terms, $(ax^m)(bx^n) = abx^{m+n}$. Every other pair of terms lands lower. Over a field $ab \neq 0$ when $a, b \neq 0$, so nothing can cancel the top term. Over $\mathbb{Z}/4\mathbb{Z}$, where $2 \cdot 2 = 0$, the same definition would give $(2x+1)^2 = 4x^2 + 4x + 1 = 1$, and the degree would drop.

Proposition 7.1.4 (Degree of a product). Let $p, q \in F[x]$ be nonzero, with leading coefficients a and b. Then $pq \neq \mathbf{0}$, $\deg(pq) = \deg p + \deg q$, and the leading coefficient of pq is ab. With the conventions $-\infty + n = n + (-\infty) = -\infty + (-\infty) = -\infty$, the formula $\deg(pq) = \deg p + \deg q$ holds for all $p, q \in F[x]$.

Proof. ROUTINE

Uses. Definition 7.1.1 (Product of polynomials), Definition 1.2.16 (Degree), Proposition 1.1.17 (No zero divisors), Proposition 1.1.15 (Multiplying by zero)
Hint 1. Let $m = \deg p$ and $n = \deg q$. Which pairs (i, j) can give a nonzero term $a_i b_j$?
Hint 2. Only pairs with $i \leq m$ and $j \leq n$, so $i + j \leq m + n$. For $k = m + n$ only the pair (m, n) survives.
Sketch. A term $a_i b_j$ is nonzero only if $i \leq m$ and $j \leq n$. So the coefficients of pq vanish beyond position $m + n$, and the coefficient of x^{m+n} is $a_m b_n = ab$, which is nonzero because F has no zero divisors. If p or q is $\mathbf{0}$, every coefficient of pq is 0.

Write $p = (a_i)$ and $q = (b_j)$, and let $m = \deg p$ and $n = \deg q$, so that $a = a_m$ and $b = b_n$. A term $a_i b_j$ can be nonzero only if $a_i \neq 0$ and $b_j \neq 0$, that is, only if $i \leq m$ and $j \leq n$, and then $i + j \leq m + n$. Hence the k-th coefficient of pq is 0 for $k > m + n$, and for $k = m + n$ the only pair that can contribute is (m, n). So the coefficient of x^{m+n} in pq is ab, which is nonzero by Proposition 1.1.17. Therefore $pq \neq \mathbf{0}$, $\deg(pq) = m + n$, and ab is the leading coefficient of pq.

If $p = \mathbf{0}$ or $q = \mathbf{0}$, every term $a_i b_j$ has a factor 0, so $pq = \mathbf{0}$ (Proposition 1.1.15), and both sides of the formula are $-\infty$. □

Definition 7.1.5 (Monic polynomial). A nonzero polynomial is **monic** if its leading coefficient is 1.

For example, $x^2 - 3x + 2$ and every product $(x - c_1)(x - c_2)\cdots(x - c_n)$ are monic, by Proposition 7.1.4, while $2x + 1$ is not. Every nonzero p is a times a monic polynomial for exactly one $a \in F$, namely its leading coefficient a: indeed $p = a(a^{-1}p)$, and cu has leading coefficient c when u is monic.

The proposition gives an argument that recurs throughout the book.

Technique 7.1.6 (Compare degrees and leading coefficients). To show that a polynomial is zero, or that an identity between polynomials cannot hold, compare the degrees of the two sides, and when the degrees agree, their leading coefficients. Over a field the degree of a product is the sum of the degrees (Proposition 7.1.4), and a sum has degree at most the larger of the two degrees, with equality when they differ (Proposition 1.2.18). The typical use: if $sg = h$ with $s \neq \mathbf{0}$ and $\deg h < \deg s$, then $g = \mathbf{0}$, because a nonzero multiple of s has degree at least $\deg s$.

Reach for it in uniqueness statements about polynomials (quotients and remainders, greatest common divisors, and later minimal polynomials), and to show that a polynomial is constant or zero. Leading coefficients settle what degrees alone cannot, for instance that two monic polynomials that divide each other are equal. The canonical example is the uniqueness half of Theorem 7.1.14. Proposition 1.5.24 was an earlier instance.

Used in. Corollary 7.1.7, Theorem 7.1.14, Theorem 7.1.45, Exercise 7.1.55, Exercise 7.1.65, Theorem 7.6.2, Problem 7.12, Exercise 7.1.69.

Corollary 7.1.7 (No zero divisors, cancellation, and units). Let $p, q, r \in F[x]$.

(a) If $pq = \mathbf{0}$, then $p = \mathbf{0}$ or $q = \mathbf{0}$.

(b) If $p \neq \mathbf{0}$ and $pq = pr$, then $q = r$.

(c) p has a multiplicative inverse in $F[x]$ if and only if p is a nonzero constant.

Proof. ROUTINE

Uses. Proposition 7.1.4 (Degree of a product), Proposition 7.1.3 ($F[x]$ is a commutative ring)
Techniques. Compare degrees and leading coefficients (Technique 7.1.6)
Hint 1. (a) is a restatement of part of Proposition 7.1.4. For (b), move everything to one side.
Hint 2. For (c), if $pq = 1$, take degrees of both sides.
Sketch. (a) A product of nonzero polynomials is nonzero. (b) $p(q - r) = \mathbf{0}$ with $p \neq \mathbf{0}$ forces $q - r = \mathbf{0}$. (c) If $pq = 1$, then $\deg p + \deg q = 0$ with both degrees nonnegative, so $\deg p = 0$; nonzero constants c have the inverse c^{-1}.

(a) If p and q are both nonzero, then $pq \neq \mathbf{0}$ by Proposition 7.1.4.

(b) By Proposition 7.1.3, $p(q - r) = pq - pr = \mathbf{0}$. Since $p \neq \mathbf{0}$, (a) gives $q - r = \mathbf{0}$, that is, $q = r$.

(c) A nonzero constant c has the inverse c^{-1}, since $c \cdot c^{-1} = 1$. Conversely, suppose $pq = 1$. Then p and q are nonzero, and $\deg p + \deg q = \deg 1 = 0$ by Proposition 7.1.4. Both degrees are nonnegative integers, so $\deg p = 0$, and p is a nonzero constant. □

So $F[x]$ shares two features with the integers: a product of nonzero elements is nonzero, and few elements are invertible (in $\mathbb{Z}$, only ± 1). In particular x has no inverse, and $F[x]$ is not a field. The analogy with $\mathbb{Z}$ continues in Section 7.1.2 with division with remainder.

Exercise 7.1.8. ROUTINE

(a) Over $\mathbb{Q}$, compute $\left(x^2 - x + 1\right)\left(x^2 + x + 1\right)$ and, for $n \geq 1$, $(1 - x)\left(1 + x + x^2 + \cdots + x^{n-1}\right)$.

(b) Over $\mathbb{F}_2$, compute $\left(1 + x + x^2\right)^2$. Over $\mathbb{F}_3$, compute $(1 + x)^3$.

Solution on page 1553

Evaluation and substitution

Evaluating a polynomial at a scalar (Definition 1.2.17) uses only that scalars can be added, multiplied, and raised to powers. The same formula makes sense with a polynomial in place of the scalar.

Definition 7.1.9 (Substitution). Let $p = \sum_{k=0}^{d} a_k x^k \in F[x]$ and $r \in F[x]$. The polynomial obtained by **substituting** r into p is

$$p(r) = \sum_{k=0}^{d} a_k r^k \in F[x],$$

where $r^0 = 1$ and r^k is the product of k copies of r.

For instance $p(x) = p$, since x^k is the k-th power of x, and if $p = x^2 - 3$, then $p(x + 1) = (x + 1)^2 - 3 = x^2 + 2x - 2$. If $r = c$ is a constant, then $p(c)$ is the constant polynomial whose value is the scalar $p(c)$ of Definition 1.2.17, so the two notations agree.

Proposition 7.1.10 (Evaluation respects sums and products). Let $p, q \in F[x]$ and $c \in F$, and let t be either a scalar in F or a polynomial in $F[x]$. Then

$$(p + q)(t) = p(t) + q(t), \quad (cp)(t) = cp(t),$$

$$(pq)(t) = p(t)q(t).$$

Proof. ROUTINE

Uses. Definition 1.2.17 (Evaluation), Definition 7.1.9 (Substitution), Definition 7.1.1 (Product of polynomials), Proposition 7.1.3 ($F[x]$ is a commutative ring), Proposition 1.2.18 (Degree and evaluation versus the operations)
Hint 1. Write $p = \sum_i a_i x^i$ and $q = \sum_j b_j x^j$, and substitute t into the formula for the coefficients of pq.
Hint 2. Regroup the double sum $\sum_k \sum_{i+j=k}$ as a sum over all pairs (i, j), and use $t^{i+j} = t^i t^j$.
Sketch. The first two identities are the computation of Proposition 1.2.18(c). For the product, $(pq)(t) = \sum_k \bigl(\sum_{i+j=k} a_i b_j\bigr) t^k = \sum_{i,j} (a_i t^i)(b_j t^j) = p(t)q(t)$, by distributivity, $t^{i+j} = t^i t^j$, and commutativity, all of which hold in F and in the commutative ring $F[x]$.

In both cases t lies in a commutative ring, F or $F[x]$ (Proposition 7.1.3), in which scalars multiply as in F (for $F[x]$ this is Proposition 7.1.3(e)) and $t^i t^j = t^{i+j}$. These are the only facts we use.

Choose d with $p = \sum_{i=0}^{d} a_i x^i$ and $q = \sum_{j=0}^{d} b_j x^j$, and put $a_i = b_i = 0$ for $i > d$. Then $p + q = \sum_i (a_i + b_i) x^i$ and $cp = \sum_i (c a_i) x^i$, and distributivity gives $(p + q)(t) = p(t) + q(t)$ and $(cp)(t) = cp(t)$, as in Proposition 1.2.18(c). For the product, $pq = \sum_{k=0}^{2d} \bigl(\sum_{i+j=k} a_i b_j\bigr) x^k$, so

$$\begin{aligned}(pq)(t) &= \sum_{k=0}^{2d} \sum_{i+j=k} a_i b_j t^k = \sum_{i=0}^{d} \sum_{j=0}^{d} (a_i t^i)(b_j t^j) \\ &= \left(\sum_{i=0}^{d} a_i t^i\right)\left(\sum_{j=0}^{d} b_j t^j\right) = p(t)q(t).\end{aligned}$$

The second equality regroups the terms by pairs (i, j) instead of by $k = i + j$ (the pairs with $i > d$ or $j > d$ contribute 0) and uses $t^{i+j} = t^i t^j$ and commutativity. The third is distributivity. □

Remark 7.1.11 (Polynomials in a matrix). For $A \in F^{n \times n}$ and $p = \sum_{k=0}^{d} a_k x^k$, write $p(A) = a_0 I_n + a_1 A + \cdots + a_d A^d$, as in Proposition 4.1.31. The proof above used only that powers of t satisfy $t^i t^j = t^{i+j}$, that products distribute over sums, and that scalars commute with powers of t. It never multiplied t by anything except its own powers and scalars. All of this holds for A (Notation 2.4.16, Proposition 2.4.14), so

$$(p + q)(A) = p(A) + q(A), \quad (cp)(A) = cp(A),$$
$$(pq)(A) = p(A)q(A),$$

even though matrix multiplication is not commutative. In particular $p(A)q(A) = (pq)(A) = (qp)(A) = q(A)p(A)$: any two polynomials in the same matrix commute. Section 7.2 evaluates polynomials at operators in the same way.

Corollary 7.1.12 (Substituting twice). Let $p, r \in F[x]$, and let t be a scalar in F or a polynomial in $F[x]$. Then $(p(r))(t) = p(r(t))$.

Proof. ROUTINE

Uses. Proposition 7.1.10 (Evaluation respects sums and products), Definition 7.1.9 (Substitution), induction on k
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. Both sides respect sums and scalar multiples in p. So it is enough to check the identity for $p = x^k$.
Hint 2. For $p = x^k$ the left side is $\bigl(r^k\bigr)(t)$. Apply the product rule of Proposition 7.1.10 k times.
Sketch. By Proposition 7.1.10, $p \mapsto (p(r))(t)$ and $p \mapsto p(r(t))$ both respect sums and scalar multiples, and every polynomial is a finite combination of the x^k. For $p = x^k$, $\bigl(r^k\bigr)(t) = r(t)^k$ by Proposition 7.1.10 and induction on k, and this is $x^k(r(t))$.

Let $s = r(t)$. By Proposition 7.1.10, applied first with r and then with t, the map $p \mapsto (p(r))(t)$ respects sums and scalar multiples, and so does $p \mapsto p(s)$. Every polynomial is a finite linear combination of $1, x, x^2, \ldots$, so it suffices to prove the identity for $p = x^k$, $k \geq 0$.

For $p = x^k$ we have $x^k(r) = r^k$ and $x^k(s) = s^k$, so we must show $\big(r^k\big)(t) = s^k$. For $k = 0$ both sides are 1. If $\big(r^k\big)(t) = s^k$, then by Proposition 7.1.10, $\big(r^{k+1}\big)(t) = \big(r^k r\big)(t) = \big(r^k\big)(t)\, r(t) = s^k s = s^{k+1}$. □

For example, substituting $x + 1$ into $p(x + 1)$ gives $p((x + 1) + 1) = p(x + 2)$: take $r = t = x + 1$. This is the fact used in Exercise 2.3.48.

7.1.2 Division with remainder

For integers a and $b > 0$ there are integers q and r with $a = bq + r$ and $0 \le r < b$. Polynomials can be divided the same way, with the degree in place of size. Long division, familiar from school, computes the quotient: at each step, subtract a multiple of the divisor that cancels the leading term of what is left.

Example 7.1.13 (Long division). Over $\mathbb{Q}$, divide $p = 2x^4 - x^3 + 3x^2 + x - 1$ by $s = 2x^2 + 1$. The leading term $2x^4$ of p is x^2 times the leading term $2x^2$ of s, so we subtract $x^2 s$. The leading term of what is left is $-x^3 = \left(-\frac{1}{2}x\right) \cdot 2x^2$, so we subtract $-\frac{1}{2}xs$, and so on:

$$\begin{aligned} p - x^2 s &= -x^3 + 2x^2 + x - 1, \\ p - \left(x^2 - \frac{1}{2}x\right)s &= 2x^2 + \frac{3}{2}x - 1, \\ p - \left(x^2 - \frac{1}{2}x + 1\right)s &= \frac{3}{2}x - 2. \end{aligned}$$

The last line has degree $1 < 2 = \deg s$, so we stop. With $q = x^2 - \frac{1}{2}x + 1$ and $r = \frac{3}{2}x - 2$,

$$p = \left(2x^2 + 1\right)\left(x^2 - \frac{1}{2}x + 1\right) + \left(\frac{3}{2}x - 2\right).$$

The coefficient $-\frac{1}{2}$ appeared because we divided by the leading coefficient 2 of s. Over $\mathbb{Z}$ this step would be impossible: dividing by the leading coefficient of the divisor is the one place where long division needs a field. Over $\mathbb{F}_3$, where $2^{-1} = 2$, the same steps give $q = x^2 + x + 1$ and $r = 1$.

Theorem 7.1.14 (Division with remainder). Let $p, s \in F[x]$ with $s \neq \mathbf{0}$. There are unique polynomials $q, r \in F[x]$ such that

$$p = sq + r \quad \text{and} \quad \deg r < \deg s.$$

We call q the **quotient** and r the **remainder** of p on division by s.

The theorem is often called the **division algorithm**, after the procedure that proves it. If $\deg s = 0$, the condition $\deg r < 0$ means $r = \mathbf{0}$: division by a nonzero constant b is exact, with $q = b^{-1}p$.

Intuition. Uniqueness is a degree count. Two divisions $p = sq + r = sq' + r'$ give $s(q - q') = r' - r$. The right side has degree less than $\deg s$, and a nonzero multiple of s cannot, so $q = q'$. For existence, one step of long division replaces p by a polynomial of smaller degree, which suggests strong induction on $\deg p$. A second proof avoids division altogether and counts dimensions instead.

Proof (by induction on the degree). STANDARD

Uses. Proposition 7.1.4 (Degree of a product), Proposition 1.2.18 (Degree and evaluation versus the operations), Proposition 7.1.3 ($F[x]$ is a commutative ring), Definition 1.2.16 (Degree)
Techniques. Compare degrees and leading coefficients (Technique 7.1.6), Uniqueness via two candidates (Technique 1.1.8), Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Prove uniqueness and existence separately. For uniqueness, subtract two divisions $p = sq + r = sq' + r'$ and compare degrees.
Hint 2. For existence, use strong induction on $\deg p$. If $\deg p < \deg s$ there is nothing to do. Otherwise subtract from p a multiple of s that cancels its leading term.

Hint 3. With a and b the leading coefficients of p and s, the polynomial $p - (a/b)x^{n-m}s$ has degree less than $n = \deg p$. Divide it by the induction hypothesis, and add $(a/b)x^{n-m}$ to the quotient.
Sketch. If $sq + r = sq' + r'$, then $s(q - q') = r' - r$ has degree less than $\deg s$, which forces $q = q'$, and then $r = r'$. For existence, induct on $n = \deg p$. If $n < m = \deg s$, take $q = \mathbf{0}$ and $r = p$. Otherwise the leading terms of p and $(a/b)x^{n-m}s$ agree, so $p_1 = p - (a/b)x^{n-m}s$ has degree less than n. If $p_1 = sq_1 + r_1$, then $p = s(q_1 + (a/b)x^{n-m}) + r_1$.

Let $m = \deg s$, which is a nonnegative integer, and let $b \neq 0$ be the leading coefficient of s.

Uniqueness. Suppose $p = sq + r = sq' + r'$ with $\deg r < m$ and $\deg r' < m$. By Proposition 7.1.3, $s(q - q') = r' - r$, and $\deg(r' - r) < m$ by Proposition 1.2.18(a) and (b). If $q \neq q'$, then by Proposition 7.1.4

$$\deg(s(q - q')) = m + \deg(q - q') \geq m,$$

which is impossible. So $q = q'$, and then $r' - r = s \cdot \mathbf{0} = \mathbf{0}$, so $r = r'$.

Existence. If $p = \mathbf{0}$, take $q = r = \mathbf{0}$. For nonzero p we use strong induction on $n = \deg p$: let $n \geq 0$, and assume that every polynomial of degree less than n (including $\mathbf{0}$) has a quotient and remainder on division by s. Let $\deg p = n$, with leading coefficient a.

If $n < m$, take $q = \mathbf{0}$ and $r = p$. Suppose $n \geq m$. By Proposition 7.1.4, the polynomial $(a/b)x^{n-m}s$ has degree $(n - m) + m = n$ and leading coefficient $(a/b)b = a$. So in

$$p_1 = p - (a/b)x^{n-m}s,$$

the coefficient of x^n is $a - a = 0$, and all coefficients beyond x^n are 0. Hence $\deg p_1 < n$, and by the induction hypothesis $p_1 = sq_1 + r_1$ for some q_1, r_1 with $\deg r_1 < m$. Then

$$p = p_1 + (a/b)x^{n-m}s = s(q_1 + (a/b)x^{n-m}) + r_1,$$

as desired. □

Unwound, the induction is long division. The equation $p = sq + r$ is an invariant, and $\deg r$ is a quantity that drops at every step, so this is an instance of Technique 3.3.5.

Algorithm 7.1.15 (Long division)

Input Polynomials $p, s \in F[x]$ with $s \neq \mathbf{0}$. Let $m = \deg s$ and let b be the leading coefficient of s.
Output The quotient q and the remainder r of p on division by s.

1. Set $q = \mathbf{0}$ and $r = p$.
2. If $\deg r < m$, output q and r and stop.
3. Otherwise, let $d = \deg r$ and let c be the leading coefficient of r. Replace q by $q + (c/b)x^{d-m}$ and r by $r - (c/b)x^{d-m}s$, and return to step 2.

At the start $p = sq + r$, and step 3 adds $(c/b)x^{d-m}s$ to sq and subtracts it from r, so $p = sq + r$ remains true. The same step lowers $\deg r$, as in the proof. So the algorithm stops after at most $\deg p - m + 1$ steps, and then $\deg r < m$.

The second proof is the one in LADR. It proves existence without constructing anything.

Proof of Theorem 7.1.14 (by linear algebra). STANDARD

Uses. Proposition 1.5.24 (Distinct degrees), Example 4.1.7 (Dimensions of the standard spaces), Theorem 4.1.10 (Independent lists are short), Proposition 7.1.4 (Degree of a product), Proposition 7.1.3 ($F[x]$ is a commutative ring)
Techniques. Uniqueness gives existence (Technique 3.4.21), Dimension counting (Technique 4.2.24)
Hint 1. Uniqueness is the degree count from the first proof. For existence, let $n = \deg p \geq m = \deg s$ and work in $F[x]_{\leq n}$. Which polynomials have the form $sq + r$ with $\deg q \leq n - m$ and $\deg r < m$?
Hint 2. They are the linear combinations of $1, x, \ldots, x^{m-1}, s, xs, \ldots, x^{n-m}s$. Show that this list is a basis of $F[x]_{\leq n}$.
Hint 3. The list consists of $n + 1$ nonzero polynomials with the distinct degrees $0, 1, \ldots, n$.

Sketch. Let $n = \deg p \geq m$ (otherwise take $q = \mathbf{0}$, $r = p$). The $n+1$ polynomials $1, x, \ldots, x^{m-1}, s, xs, \ldots, x^{n-m}s$ have the distinct degrees $0, \ldots, n$, so they are independent, and since $\dim F[x]_{\leq n} = n+1$, they form a basis. Expanding p in this basis writes it as $r + sq$, with r a combination of $1, \ldots, x^{m-1}$ and q a combination of $1, \ldots, x^{n-m}$. Uniqueness is as in the first proof.

Uniqueness was proved in the first proof without induction, so we prove existence. Let $m = \deg s$. If $p = \mathbf{0}$ or $\deg p < m$, take $q = \mathbf{0}$ and $r = p$. So let $n = \deg p \geq m$, and consider the list

$$\mathcal{B} = 1, x, \ldots, x^{m-1}, s, xs, \ldots, x^{n-m}s$$

in $F[x]_{\leq n}$. By Proposition 7.1.4, $\deg(x^j s) = j + m$, so the $n+1$ polynomials in $\mathcal{B}$ are nonzero with degrees $0, 1, \ldots, m-1, m, m+1, \ldots, n$, which are distinct. By Proposition 1.5.24, $\mathcal{B}$ is linearly independent. Its length $n+1$ equals $\dim F[x]_{\leq n}$ (Example 4.1.7), so $\mathcal{B}$ is a basis of $F[x]_{\leq n}$ by Theorem 4.1.10(b). Hence there are scalars with

$$\begin{aligned} p = {} & a_0 + a_1 x + \cdots + a_{m-1}x^{m-1} \\ & + b_0 s + b_1 xs + \cdots + b_{n-m}x^{n-m}s. \end{aligned}$$

Let $r = \sum_{i=0}^{m-1} a_i x^i$ and $q = \sum_{j=0}^{n-m} b_j x^j$. By Proposition 7.1.3, $p = sq + r$, and $\deg r \leq m - 1 < m$. □

Intuition (Two proofs compared). The first proof constructs q and r and unwinds into long division, so it is the one to use for computing. The second never divides. Independence of the list $\mathcal{B}$ is the uniqueness statement for $p = \mathbf{0}$, and a dimension count upgrades it to spanning, which is existence. This is Technique 3.4.21, which proved polynomial interpolation in Section 3.4.5. In the language of Section 4.2, the map $F^{n+1} \to F[x]_{\leq n}$ sending a list of coefficients to the corresponding combination of $\mathcal{B}$ is an injective linear map between spaces of the same dimension, hence bijective (Corollary 4.2.18). The count works because the conditions $\deg q \leq n - m$ and $\deg r \leq m - 1$ leave exactly $(n - m + 1) + m = n + 1$ unknown coefficients, one for each coefficient of p.

Definition 7.1.16 (Divisibility). Let $p, s \in F[x]$. We say that s **divides** p, and write $s \mid p$, if $p = sq$ for some $q \in F[x]$. Then s is a **factor** (or **divisor**) of p, and p is a **multiple** of s.

If $s \neq \mathbf{0}$, then $s \mid p$ exactly when the remainder of p on division by s is $\mathbf{0}$, by the uniqueness in Theorem 7.1.14. Some consequences of the definition and of Proposition 7.1.4:

- every s divides $\mathbf{0}$, and $\mathbf{0}$ divides only $\mathbf{0}$;
- a nonzero constant c divides every p, since $p = c(c^{-1}p)$;
- if $s \mid p$ and $p \neq \mathbf{0}$, then $\deg s \leq \deg p$;
- if $s \mid p$ and $p \mid s$ with $p, s \neq \mathbf{0}$, then $p = cs$ for a nonzero constant c. (If $p = sg$ and $s = ph$, then $s = sgh$, so $gh = 1$ by Corollary 7.1.7(b), and g is a nonzero constant by Corollary 7.1.7(c).) In particular, two monic polynomials that divide each other are equal.

For example, $x + 1 \mid x^3 + 1$ over every field, since $x^3 + 1 = (x + 1)(x^2 - x + 1)$.

The quotient and remainder do not depend on the field in which we compute them. This is useful when a polynomial with real coefficients is factored over $\mathbb{C}$.

Corollary 7.1.17 (Division does not depend on the field). Let F be a subfield of a field K (Definition 1.1.32), and let $p, s \in F[x]$ with $s \neq \mathbf{0}$. The quotient and remainder of p on division by s in $K[x]$ are the quotient and remainder in $F[x]$. In particular, s divides p in $K[x]$ if and only if s divides p in $F[x]$.

Proof. ROUTINE

Uses. Definition 1.1.32 (Subfield), Theorem 7.1.14 (Division with remainder), Definition 7.1.1 (Product of polynomials)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Divide in $F[x]$ first. Does the result still satisfy the conditions of Theorem 7.1.14 when it is read in $K[x]$?
Hint 2. Use the uniqueness half of Theorem 7.1.14 over K.

Sketch. $F[x] \subseteq K[x]$, and sums, products, and degrees of polynomials with coefficients in F are the same whether computed in F or in K. So the quotient and remainder over F also satisfy $p = sq + r$ and $\deg r < \deg s$ in $K[x]$, and by uniqueness over K they are the quotient and remainder there.

A polynomial with coefficients in F is also one with coefficients in K, so $F[x] \subseteq K[x]$. The operations of F are those of K restricted to F (Definition 1.1.32), and sums and products of polynomials are computed from their coefficients by the formulas of Definition 1.2.13 and Definition 7.1.1. So for $p, s \in F[x]$, the sum and product are the same whether computed in $F[x]$ or in $K[x]$, and so is the degree.

Let $q, r \in F[x]$ be the quotient and remainder of p on division by s in $F[x]$. Then $p = sq + r$ and $\deg r < \deg s$ also hold in $K[x]$. By the uniqueness in Theorem 7.1.14 over K, q and r are the quotient and remainder in $K[x]$. In particular the remainder in $K[x]$ is $\mathbf{0}$ if and only if the remainder in $F[x]$ is $\mathbf{0}$. □

Exercise 7.1.18. ROUTINE Let $p = x^4 + x^3 + x + 2$ and $s = x^2 + 1$. Find the quotient and remainder of p on division by s over $\mathbb{Q}$, over $\mathbb{F}_2$, and over $\mathbb{F}_3$. Over which of these fields does s divide p?

Solution on page 1553

7.1.3 Roots and linear factors

Definition 7.1.19 (Root). Let $p \in F[x]$. A scalar $c \in F$ is a **root** (or **zero**) of p if $p(c) = 0$.

Which roots exist depends on the field. The polynomial $x^2 + 1$ has no root in $\mathbb{R}$, since $t^2 + 1 \geq 1$ for real t; in $\mathbb{C}$ it has the roots i and $-i$; in $\mathbb{F}_2$ it has the root 1; and in $\mathbb{F}_5$ it has the roots 2 and 3, as $2^2 + 1 = 5$ and $3^2 + 1 = 10$. The polynomial $x^2 - 2$ has no root in $\mathbb{Q}$, because $\sqrt{2}$ is irrational, and two roots in $\mathbb{R}$.

The theorem below is the link between roots and factors. It is the case $s = x - c$ of division with remainder.

Theorem 7.1.20 (Factor theorem). Let $p \in F[x]$ and $c \in F$. There is a unique $q \in F[x]$ with

$$p = (x - c)q + p(c),$$

and if $\deg p \geq 1$, then $\deg q = \deg p - 1$. In particular, c is a root of p if and only if $x - c$ divides p.

Proof (by division with remainder). ROUTINE

Uses. Theorem 7.1.14 (Division with remainder), Proposition 7.1.10 (Evaluation respects sums and products), Proposition 7.1.4 (Degree of a product), Definition 7.1.16 (Divisibility)
Hint 1. Divide p by $x - c$. What can the remainder be?
Hint 2. The remainder is a constant. Evaluate both sides of $p = (x - c)q + r$ at c.
Sketch. Division by $x - c$, which has degree 1, leaves a constant remainder r. Evaluating $p = (x - c)q + r$ at c with Proposition 7.1.10 gives $p(c) = 0 \cdot q(c) + r = r$. The quotient is unique by Theorem 7.1.14, and degrees give $\deg q = \deg p - 1$. If $p(c) = 0$, then $p = (x - c)q$; conversely, $p = (x - c)q'$ gives $p(c) = 0$.

By Theorem 7.1.14 with $s = x - c$, which has degree 1, there are unique q, r with $p = (x - c)q + r$ and $\deg r < 1$, so r is a constant. By Proposition 7.1.10, $p(c) = (c - c)q(c) + r = r$. So $p = (x - c)q + p(c)$. If also $p = (x - c)q' + p(c)$, this is a division with remainder $p(c)$, of degree less than 1, so $q' = q$ by uniqueness.

If $\deg p \geq 1$, then $(x - c)q = p - p(c)$ has the same degree as p, because subtracting a constant does not change any coefficient beyond the constant term. So $q \neq \mathbf{0}$ and $1 + \deg q = \deg p$ (Proposition 7.1.4).

Finally, if $p(c) = 0$, then $p = (x - c)q$, so $x - c \mid p$. Conversely, if $p = (x - c)q'$ for some q', then $p(c) = (c - c)q'(c) = 0$ by Proposition 7.1.10. □

The quotient can also be written down directly. This is how Section 3.4.5 split off a root before products were available, and it gives a fast way to compute q by hand.

Proof (explicitly, by Horner's scheme). STANDARD

Uses. Lemma 3.4.23 (Too many roots), Proposition 7.1.3 ($F[x]$ is a commutative ring), Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 7.1.10 (Evaluation respects sums and products)
Hint 1. The identity $x^j - c^j = (x-c)\big(x^{j-1} + cx^{j-2} + \cdots + c^{j-1}\big)$ holds in $F[x]$. Prove it by expanding the right side.
Hint 2. Multiply it by a_j, sum over j, and collect powers of x. The coefficients of q are the numbers b_i from the proof of Lemma 3.4.23.
Sketch. The right side of $x^j - c^j = (x-c)\sum_{i<j} x^i c^{j-1-i}$ telescopes. Multiplying by a_j and summing gives $p - p(c) = (x-c)q$ with $q = \sum_{i<n} b_i x^i$ and $b_i = \sum_{j>i} a_j c^{j-1-i}$, computed from the top by $b_{n-1} = a_n$ and $b_i = a_{i+1} + cb_{i+1}$. Uniqueness of q is cancellation of $x - c$, and $b_{n-1} = a_n \neq 0$ gives the degree.

If p is constant, then $p - p(c) = \mathbf{0} = (x-c)\mathbf{0}$. Otherwise write $p = \sum_{j=0}^{n} a_j x^j$ with $n \geq 1$ and $a_n \neq 0$. For $j \geq 1$, the following sum telescopes in $F[x]$:

$$(x-c)\sum_{i=0}^{j-1} x^i c^{j-1-i} = \sum_{i=0}^{j-1} x^{i+1} c^{j-1-i} - \sum_{i=0}^{j-1} x^i c^{j-i} = x^j - c^j.$$

This is the computation in the proof of Lemma 3.4.23, with the indeterminate x in place of the scalar t. Multiplying by a_j, summing over $j = 1, \ldots, n$, and collecting the terms with the same power of x,

$$p - p(c) = \sum_{j=1}^{n} a_j\big(x^j - c^j\big) = (x-c)q,$$

where

$$q = \sum_{i=0}^{n-1} b_i x^i, \quad b_i = \sum_{j=i+1}^{n} a_j c^{j-1-i}.$$

The leading coefficient of q is $b_{n-1} = a_n \neq 0$, so $\deg q = n - 1$. In both cases, if also $p - p(c) = (x-c)q'$, then $q' = q$ by Corollary 7.1.7(b). The last sentence of the theorem follows as in the first proof. □

As computed in the proof of Lemma 3.4.23, $b_{n-1} = a_n$ and $b_i = a_{i+1} + cb_{i+1}$. Continuing one more step, $a_0 + cb_0 = p(c)$, by expanding the nested form $p(c) = a_0 + c(a_1 + c(a_2 + \cdots + ca_n))$. This recursion is **Horner's scheme**, or **synthetic division**. It computes the quotient by $x - c$ and the value $p(c)$ at once, with n multiplications.

Example 7.1.21 (Synthetic division). Let $p = x^3 - 6x^2 + 11x - 6$ and $c = 1$. Horner's scheme runs through the coefficients $1, -6, 11, -6$ from the top:

$$b_2 = 1, \quad b_1 = -6 + 1 \cdot 1 = -5,$$
$$b_0 = 11 + 1 \cdot (-5) = 6, \quad p(1) = -6 + 1 \cdot 6 = 0.$$

So 1 is a root and $p = (x-1)\big(x^2 - 5x + 6\big)$. Running the scheme again on $x^2 - 5x + 6$ with $c = 2$ gives 1, $-5 + 2 = -3$, and remainder $6 + 2 \cdot (-3) = 0$, so $x^2 - 5x + 6 = (x-2)(x-3)$, and

$$p = (x-1)(x-2)(x-3).$$

In the language of Example 2.6.29, the factor theorem says $\ker \mathrm{ev}_c = \mathrm{im}(M - c\,\mathrm{id})$: the polynomials with root c are exactly the multiples $(x-c)q = (M - c\,\mathrm{id})(q)$.

Intuition. Each root splits off a linear factor. Distinct roots split off distinct factors: after $p = (x-c_1)q$, a second root $c_2 \neq c_1$ of p satisfies $0 = (c_2 - c_1)q(c_2)$, and since $c_2 - c_1 \neq 0$ and F has no zero divisors, c_2 is a root of q. Each factor costs one degree, so there is room for at most $\deg p$ of them.

Proposition 7.1.22 (Counting roots). Let $p \in F[x]$ be nonzero, and let $c_1, \ldots, c_k \in F$ be distinct roots of p. Then

$$(x-c_1)(x-c_2)\cdots(x-c_k) \mid p,$$

and $k \le \deg p$. In particular, a nonzero polynomial p has at most $\deg p$ roots in F.

Proof. STANDARD

Uses. Theorem 7.1.20 (Factor theorem), Proposition 7.1.10 (Evaluation respects sums and products), Proposition 1.1.17 (No zero divisors), Proposition 7.1.4 (Degree of a product)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Induct on k, the length of the list of roots. For the inductive step, assume $p = (x - c_1)\cdots(x - c_{k-1})q$.
Hint 2. Evaluate this factorization at c_k. Why must $q(c_k) = 0$?
Hint 3. For the bound, compare degrees in $p = (x - c_1)\cdots(x - c_k)q'$, noting that $q' \neq \mathbf{0}$.
Sketch. By induction on k, $p = (x - c_1)\cdots(x - c_{k-1})q$. Evaluating at c_k gives $0 = (c_k - c_1)\cdots(c_k - c_{k-1})q(c_k)$, and the differences are nonzero, so $q(c_k) = 0$ and $x - c_k$ divides q by the factor theorem. Then $p = (x - c_1)\cdots(x - c_k)q'$ with $q' \neq \mathbf{0}$, and $\deg p = k + \deg q' \ge k$.

We prove the divisibility by induction on k. For $k = 0$ the product is empty, that is, equal to 1, which divides p. Let $k \ge 1$, and suppose $p = (x - c_1)\cdots(x - c_{k-1})q$ for some $q \in F[x]$. By Proposition 7.1.10,

$$0 = p(c_k) = (c_k - c_1)\cdots(c_k - c_{k-1})\, q(c_k).$$

The roots are distinct, so $c_k - c_i \neq 0$ for each $i < k$, and the product of these differences is nonzero by Proposition 1.1.17. Hence $q(c_k) = 0$, and $q = (x - c_k)q'$ for some q' by Theorem 7.1.20. So $p = (x - c_1)\cdots(x - c_k)q'$, which proves the divisibility.

Since $p \neq \mathbf{0}$, also $q' \neq \mathbf{0}$. Each $x - c_i$ has degree 1, so Proposition 7.1.4 gives $\deg p = k + \deg q' \ge k$. □

The bound $k \le \deg p$ is Lemma 3.4.23 in another form: a polynomial in $F[x]_{\le n}$ with $n + 1$ distinct roots is zero. What is new is the divisibility, which says where the roots sit in p. The proof used that F has no zero divisors, to conclude $q(c_k) = 0$. With coefficients in $\mathbb{Z}/8\mathbb{Z}$, which has zero divisors, $x^2 - 1$ has four roots (Exercise 7.1.52).

Corollary 7.1.23 (Polynomials and their values).

(a) Let $p, q \in F[x]_{\le n}$. If $p(c) = q(c)$ for $n + 1$ distinct $c \in F$, then $p = q$.

(b) A nonzero polynomial has only finitely many roots. If F is infinite, two polynomials with the same polynomial function $F \to F$ are equal.

Proof. ROUTINE

Uses. Proposition 7.1.22 (Counting roots), Proposition 1.2.18 (Degree and evaluation versus the operations)
Techniques. Contrapositive (Technique 1.5.4)
Hint. Apply Proposition 7.1.22 to $p - q$.
Sketch. In (a), $p - q \in F[x]_{\le n}$ has $n + 1$ roots, more than its degree if it were nonzero. In (b), if p and q have the same function, $p - q$ has every element of F as a root, infinitely many.

(a) By Proposition 1.2.18, $p - q \in F[x]_{\le n}$ and $(p - q)(c) = p(c) - q(c) = 0$ for the $n + 1$ given points. If $p - q$ were nonzero, it would have at least $n + 1 > \deg(p - q)$ roots, contradicting Proposition 7.1.22. So $p = q$.

(b) The first claim is Proposition 7.1.22. If $p(c) = q(c)$ for every $c \in F$ and F is infinite, then $p - q$ has infinitely many roots, so $p - q = \mathbf{0}$. □

Part (b) is the fact promised in Aside (Polynomials versus polynomial functions): over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$, a polynomial is determined by its polynomial function. Over a finite field it is not. Section 7.1.4 finds all polynomials with a given function.

Multiplicity

A root can split off more than one linear factor, as in $x^2 - 2x + 1 = (x - 1)^2$. Counting roots with these repetitions gives a sharper version of Proposition 7.1.22, and over $\mathbb{C}$ an exact count.

Definition 7.1.24 (Multiplicity of a root). Let $p \in F[x]$ be nonzero and $c \in F$. The **multiplicity** of c as a root of p is the largest integer $m \geq 0$ such that $(x-c)^m \mid p$. A root of multiplicity 1 is **simple**, and a root of multiplicity at least 2 is **repeated** (or **multiple**).

The largest such m exists, because $(x-c)^0 = 1$ divides p, and $(x-c)^m \mid p$ forces $m \leq \deg p$ (degrees, as $p \neq \mathbf{0}$). By the factor theorem, c is a root of p exactly when its multiplicity is at least 1. We do not define multiplicities for the zero polynomial, which every power of $x-c$ divides.

Lemma 7.1.25 (Reading off a multiplicity). Let $p \in F[x]$ be nonzero, $c \in F$, and $m \geq 0$. Then c has multiplicity exactly m as a root of p if and only if $p = (x-c)^m q$ for some $q \in F[x]$ with $q(c) \neq 0$.

Proof. ROUTINE

Uses. Definition 7.1.24 (Multiplicity of a root), Corollary 7.1.7 (No zero divisors, cancellation, and units), Theorem 7.1.20 (Factor theorem)
Hint 1. For "if", suppose also $(x-c)^{m+1} \mid p$, and cancel $(x-c)^m$.
Hint 2. For "only if", if $q(c) = 0$, the factor theorem splits one more factor $x-c$ off q.
Sketch. If $p = (x-c)^m q$ with $q(c) \neq 0$ and also $p = (x-c)^{m+1} q'$, cancelling $(x-c)^m$ gives $q = (x-c)q'$, so $q(c) = 0$, a contradiction; so m is the largest exponent. Conversely, if m is the multiplicity and $p = (x-c)^m q$ with $q(c) = 0$, then $q = (x-c)q''$ and $(x-c)^{m+1}$ divides p.

Suppose $p = (x-c)^m q$ with $q(c) \neq 0$. Then $(x-c)^m \mid p$. If $(x-c)^{m'} \mid p$ for some $m' > m$, then so does $(x-c)^{m+1}$, say $p = (x-c)^{m+1} q'$. Then $(x-c)^m q = (x-c)^m (x-c) q'$, and cancelling the nonzero factor $(x-c)^m$ (Corollary 7.1.7(b)) gives $q = (x-c)q'$, so $q(c) = 0$, a contradiction. Hence m is the multiplicity.

Conversely, let m be the multiplicity, and write $p = (x-c)^m q$. If $q(c) = 0$, then $q = (x-c)q''$ by Theorem 7.1.20, and $(x-c)^{m+1} \mid p$, contradicting the maximality of m. So $q(c) \neq 0$. □

Example 7.1.26 (Multiplicity depends on the field). Let $p = x^3 - x^2 - x + 1$. Over $\mathbb{Q}$, $p = (x-1)^2(x+1)$, and $q = x+1$ has $q(1) = 2 \neq 0$. So 1 is a root of multiplicity 2, and -1 is a simple root. Over $\mathbb{F}_2$ the same polynomial is $x^3 + x^2 + x + 1$, and since $x + 1 = x - 1$ there, $p = (x-1)^3$: the root 1 has multiplicity 3. In the factorization $(x-1)^2(x+1)$, the cofactor now has $q(1) = 1 + 1 = 0$, so Lemma 7.1.25 does not stop at $m = 2$.

Proposition 7.1.27 (Multiplicities add up to at most the degree). Let $p \in F[x]$ be nonzero, and let $c_1, \ldots, c_k \in F$ be distinct, with multiplicities $m_1, \ldots, m_k$ as roots of p. Then

$$(x-c_1)^{m_1}(x-c_2)^{m_2}\cdots(x-c_k)^{m_k} \mid p,$$

and in particular $m_1 + m_2 + \cdots + m_k \leq \deg p$.

Proof. STANDARD

Uses. Lemma 7.1.25 (Reading off a multiplicity), Proposition 7.1.10 (Evaluation respects sums and products), Proposition 1.1.17 (No zero divisors), Proposition 7.1.4 (Degree of a product)
Techniques. Induction on the length of a list (Technique 1.6.9)
Hint 1. Induct on k, as in the proof of Proposition 7.1.22, now splitting off $(x-c_k)^{m_k}$ at once.
Hint 2. Suppose $p = (x-c_1)^{m_1}\cdots(x-c_{k-1})^{m_{k-1}} q$. Let μ be the multiplicity of c_k as a root of q, and write $q = (x-c_k)^\mu h$ with $h(c_k) \neq 0$.
Hint 3. Then $p = (x-c_k)^\mu g$ for a g with $g(c_k) \neq 0$. Apply Lemma 7.1.25 to p.
Sketch. Induct on k. If $p = \prod_{i<k}(x-c_i)^{m_i} q$ and $q = (x-c_k)^\mu h$ with $h(c_k) \neq 0$, then $p = (x-c_k)^\mu g$ with $g = \prod_{i<k}(x-c_i)^{m_i} h$ and $g(c_k) = \prod_{i<k}(c_k - c_i)^{m_i} h(c_k) \neq 0$. By Lemma 7.1.25 $\mu = m_k$, so $(x-c_k)^{m_k}$ divides q. Degrees give $\sum m_i \leq \deg p$.

We induct on k; for $k = 0$ there is nothing to prove. Let $k \geq 1$ and suppose $p = (x-c_1)^{m_1}\cdots(x-c_{k-1})^{m_{k-1}} q$. Since $p \neq \mathbf{0}, q \neq \mathbf{0}$. Let μ be the multiplicity of c_k as a root of q. By Lemma 7.1.25, $q = (x-c_k)^\mu h$ with $h(c_k) \neq 0$. Reordering the factors,

$$p = (x-c_k)^\mu g, \quad \text{where } g = (x-c_1)^{m_1}\cdots(x-c_{k-1})^{m_{k-1}} h.$$

By Proposition 7.1.10, $g(c_k) = (c_k - c_1)^{m_1} \cdots (c_k - c_{k-1})^{m_{k-1}} h(c_k)$, which is nonzero by Proposition 1.1.17, as every factor is nonzero. By Lemma 7.1.25 applied to p, the multiplicity of c_k as a root of p is μ, so $\mu = m_k$. Hence $p = (x - c_1)^{m_1} \cdots (x - c_k)^{m_k} h$, which proves the divisibility. Comparing degrees with Proposition 7.1.4, $\deg p = m_1 + \cdots + m_k + \deg h \geq m_1 + \cdots + m_k$. □

With all $m_i \geq 1$, this sharpens Proposition 7.1.22: counted with multiplicity, a nonzero polynomial has at most $\deg p$ roots. Over $\mathbb{C}$ the count is exactly $\deg p$ (Corollary 7.1.35).

Repeated roots can be detected without factoring, with the formal derivative p' of Example 2.1.9.

> **Exercise 7.1.28.** STANDARD Let $p \in F[x]$ be nonzero and $c \in F$. Show that c is a repeated root of p if and only if $p(c) = 0$ and $p'(c) = 0$.

Solution on page 1554

7.1.4 Interpolation, revisited

In Section 3.4.5, the existence of interpolating polynomials came from their uniqueness, through a square linear system, and the Lagrange polynomials L_i were *defined* as solutions of that system. Example 3.4.28 previewed a closed form that needed products. We can now prove it.

> **Proposition 7.1.29** (Lagrange polynomials in closed form). Let $c_0, \ldots, c_n \in F$ be distinct. For $i = 0, \ldots, n$,
>
> $$L_i = \prod_{j \neq i} \frac{x - c_j}{c_i - c_j}.$$
>
> Consequently, for $d_0, \ldots, d_n \in F$, the unique $p \in F[x]_{\leq n}$ with $p(c_i) = d_i$ for all i is
>
> $$p = \sum_{i=0}^{n} d_i \prod_{j \neq i} \frac{x - c_j}{c_i - c_j}.$$

Proof. ROUTINE

Uses. Definition 3.4.26 (Lagrange polynomials), Theorem 3.4.24 (Polynomial interpolation), Proposition 3.4.27 (Lagrange's formula), Proposition 7.1.10 (Evaluation respects sums and products), Proposition 7.1.4 (Degree of a product)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Check that the product has degree at most n and takes the values that define L_i.
Hint 2. Evaluate the product at c_k with Proposition 7.1.10. Which factor vanishes when $k \neq i$?
Sketch. The product P_i is a nonzero scalar times a product of n linear factors, so it has degree n. At c_i every factor is 1; at c_k with $k \neq i$, the factor with $j = k$ is 0. So P_i has the defining values of L_i, and $P_i = L_i$ by uniqueness in Theorem 3.4.24. The formula for p is then Proposition 3.4.27.

Let P_i be the product on the right. The scalar $\prod_{j \neq i}(c_i - c_j)$ is nonzero, since the nodes are distinct and F has no zero divisors, so

$$P_i = \left(\prod_{j \neq i} (c_i - c_j) \right)^{-1} \prod_{j \neq i} (x - c_j)$$

is a nonzero scalar times a product of n polynomials of degree 1, and $\deg P_i = n$ by Proposition 7.1.4. By Proposition 7.1.10,

$$P_i(c_k) = \prod_{j \neq i} \frac{c_k - c_j}{c_i - c_j}.$$

For $k = i$ every factor is 1, so $P_i(c_i) = 1$. For $k \neq i$, the factor with $j = k$ is 0, so $P_i(c_k) = 0$. Thus $P_i \in F[x]_{\leq n}$ has the values that define L_i (Definition 3.4.26), and $P_i = L_i$ by the uniqueness in Theorem 3.4.24. The formula for p follows from Proposition 3.4.27. □

Intuition (Two routes to interpolation). With the closed form in hand, Theorem 3.4.24 has a second proof that reverses the roles of existence and uniqueness. Existence is now a construction: the polynomial $\sum_i d_i P_i$ has degree at most n, and the computation above shows that it takes the value d_k at c_k. Uniqueness is Corollary 7.1.23(a), a count of roots. In Section 3.4.5, by contrast, uniqueness was the root count and existence came for free from the square system. The first route needs no formula, which helps when one is hard to guess, as in Exercise 7.1.57. The second gives the answer explicitly and explains the shape of L_i: it is the simplest polynomial vanishing at the other nodes, rescaled to be 1 at c_i.

The node polynomial $\omega = (x - c_0)(x - c_1)\cdots(x - c_n)$, of degree $n + 1$, describes what happens without the degree bound.

Corollary 7.1.30 (All interpolating polynomials). Let $c_0, \ldots, c_n \in F$ be distinct, let $d_0, \ldots, d_n \in F$, let $p_0 \in F[x]_{\leq n}$ be the polynomial with $p_0(c_i) = d_i$ for all i, and let $\omega = (x - c_0)\cdots(x - c_n)$. A polynomial $p \in F[x]$ satisfies $p(c_i) = d_i$ for all i if and only if

$$p = p_0 + \omega h \quad \text{for some } h \in F[x].$$

In particular, p_0 is the remainder of every such p on division by ω.

Proof. ROUTINE

Uses. Proposition 7.1.22 (Counting roots), Proposition 7.1.10 (Evaluation respects sums and products), Theorem 7.1.14 (Division with remainder), Theorem 3.4.24 (Polynomial interpolation)
Techniques. Particular plus homogeneous (Technique 3.1.18)
Hint 1. The conditions are linear in p, and p_0 is one solution. Which p satisfy the homogeneous conditions $p(c_i) = 0$?
Hint 2. Use the divisibility in Proposition 7.1.22.
Sketch. If $p = p_0 + \omega h$, then $p(c_i) = d_i + 0$. Conversely, $p - p_0$ has the $n + 1$ distinct roots c_i, so ω divides it by Proposition 7.1.22 (or $p - p_0 = \mathbf{0}$). Since $\deg p_0 < \deg \omega$, the equation $p = \omega h + p_0$ is a division with remainder.

If $p = p_0 + \omega h$, then $p(c_i) = p_0(c_i) + \omega(c_i)h(c_i) = d_i + 0 = d_i$ by Proposition 7.1.10, since c_i is a root of ω. Conversely, suppose $p(c_i) = d_i$ for all i. Then $p - p_0$ has the $n + 1$ distinct roots $c_0, \ldots, c_n$. If $p - p_0 = \mathbf{0}$, take $h = \mathbf{0}$. Otherwise $\omega \mid p - p_0$ by Proposition 7.1.22, so $p - p_0 = \omega h$ for some h.

Finally, $p = \omega h + p_0$ with $\deg p_0 \leq n < n + 1 = \deg \omega$, so by the uniqueness in Theorem 7.1.14, p_0 is the remainder of p on division by ω. □

This is Technique 3.1.18 once more: p_0 is a particular solution, and the polynomials vanishing at all nodes are the multiples of ω. The quartic q of Figure 3.4.1 is an example. It passes through the same four points as the cubic p, and indeed $q - p = \frac{1}{2}\big(x^4 - 2x^3 - x^2 + 2x\big) = \frac{1}{2}(x + 1)x(x - 1)(x - 2)$ is a multiple of ω.

The figure can be explored with the least-squares component of Section 6.5. With four points and degree 3, the least-squares cubic passes through all four points, so it is the interpolating polynomial.

$$p = 2L_0 + L_1 + 0L_2 + 5L_3 = 1 - 2x + x^3,$$
$$L_3 = \frac{(x + 1)x(x - 1)}{6}$$

With four points at distinct x-values and degree 3, the residuals are 0 and the curve is the interpolating cubic $1 - 2x + x^3$ of Example 3.4.25. Drag one point up or down while the others stay fixed: the cubic changes by a multiple of the Lagrange polynomial of that node, which vanishes at the other three nodes. Add a fifth point and the cubic no longer passes through all of them, unless the new point happens to lie on it. (Interactive in the web version.)

Remark 7.1.31 (Finite fields). Let F be a finite field with q elements, and take all q elements of F as the nodes. Corollary 7.1.30 with all values $d_i = 0$ shows that the polynomials whose polynomial function is zero are exactly the multiples of

$$\omega_F = \prod_{c \in F} (x - c),$$

a monic polynomial of degree q. Two polynomials have the same polynomial function if and only if their difference is a multiple of ω_F, and each function $F \to F$ is the polynomial function of exactly one polynomial of degree less than q (Theorem 3.4.24 with all q elements as nodes; compare Problem 1.18). For $F = \mathbb{F}_p$, $\omega_F = x^p - x$ (Exercise 7.1.55), which explains the example $x^p - x$ of Aside (Polynomials versus polynomial functions).

7.1.5 The Fundamental Theorem of Algebra

Over $\mathbb{R}$, the polynomial $x^2 + 1$ has no root. Correspondingly, the rotation of the plane by a right angle has no eigenvalue (Section 7.2): no line through $\mathbf{0}$ is mapped to itself. The complex numbers were built to give $x^2 + 1$ a root (Section 1.1.4). The surprise is that nothing more needs to be added: every nonconstant polynomial with complex coefficients, even one with nonreal coefficients such as $x^2 - i$ or $x^5 + ix + 1$, already has a root in $\mathbb{C}$.

Theorem 7.1.32 (Fundamental Theorem of Algebra). Every nonconstant polynomial $p \in \mathbb{C}[x]$ has a root in $\mathbb{C}$.

Intuition (Why there must be a root). Let p have degree $n \geq 1$, and watch the values $p(z)$ as z goes once around the circle $|z| = R$. For large R, the leading term dominates, $p(z) \approx a_n z^n$, and since z^n goes around 0 exactly n times when z goes around once, so does the curve traced by $p(z)$. For tiny R, $p(z) \approx p(0)$, and if $p(0) \neq 0$ (otherwise 0 is a root), the curve is a small loop near $p(0)$ that does not go around 0 at all. As R grows from small to large, the curve moves continuously, and the number of times it winds around 0 changes from 0 to n. It can only change when the curve passes through 0, and a point z with $p(z) = 0$ is a root. Figure 7.1.1 shows this for $p = z^3 + z + 1$.

Making "winds around" precise takes topology. The proof below avoids it. It finds a root as the point where $|p|$ is smallest: at a point where $p \neq 0$, a small step in a well-chosen direction always makes $|p|$ smaller.

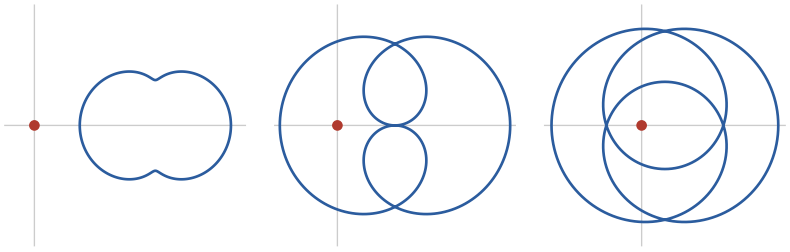

Figure 7.1.1. The images of the circles $|z| = R$ under $p(z) = z^3 + z + 1$, with 0 marked in red. For $R = 1/2$ the curve stays near $p(0) = 1$; for $R = 3/2$ it winds three times around 0. In between it sweeps across 0 three times: at $R \approx 0.68$, the modulus of the real root $-0.68\ldots$, and at $R \approx 1.21$, the common modulus of the two nonreal roots $0.34\ldots \pm 1.16\ldots i$.

Proof of Theorem 7.1.32 (by minimizing $|p|$). CHALLENGE BEYOND 21-242

Uses. Definition B.1.7 (Modulus), Section B.1, the extreme value theorem: a continuous real function on a closed disk attains a minimum, every complex number has a k-th root, for every $k \geq 1$

Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Show first that $|p(z)| > |p(0)|$ outside a large disk. Then $|p|$ has a global minimum at some z_0, by the extreme value theorem.
Hint 2. Suppose $p(z_0) \neq 0$. Write $p(z_0 + w)/p(z_0)$ as $1 + b_k w^k$ plus higher powers of w, with $b_k \neq 0$.
Hint 3. Choose β with $\beta^k = -1/b_k$. For small real $t > 0$, the value at $w = t\beta$ has modulus about $1 - t^k < 1$.
Sketch. For $|z|$ large, $|p(z)| \geq |a_n|\,|z|^n - \sum_{k<n}|a_k|\,|z|^k > |p(0)|$, so the minimum of $|p|$ on a large closed disk is a global minimum, attained at some z_0. If $p(z_0) \neq 0$, then $g(w) = p(z_0 + w)/p(z_0) = 1 + b_k w^k + \cdots$ with $b_k \neq 0$ has $|g| \geq 1$. With $\beta^k = -1/b_k$ and small $t > 0$, $|g(t\beta)| \leq 1 - t^k + Ct^{k+1} < 1$, a contradiction.

Let $p = a_0 + a_1 x + \cdots + a_n x^n$ with $n \geq 1$ and $a_n \neq 0$. We use the modulus $|z|$ (Definition B.1.7), with $|zw| = |z|\,|w|$ and $|z + w| \leq |z| + |w|$, and two facts from outside algebra: the extreme value theorem, and the existence of k-th roots in $\mathbb{C}$ (polar form, Section B.1).

$|p|$ attains a global minimum. Let $A = |a_0| + \cdots + |a_{n-1}|$. For $|z| = \rho \geq 1$, we have $|a_k z^k| \leq |a_k|\,\rho^{n-1}$ for $k < n$, so

$$|p(z)| \geq |a_n|\,\rho^n - A\rho^{n-1} = \rho^{n-1}(|a_n|\,\rho - A).$$

Let $R = \max(1, (A + |a_0| + 1)/|a_n|)$. For $|z| > R$ the right side is at least $|a_0| + 1 > |p(0)|$. The function $z \mapsto |p(z)|$ is continuous, so it attains a minimum on the closed disk $|z| \leq R$, at some z_0. Then $|p(z_0)| \leq |p(0)| < |p(z)|$ for $|z| > R$, so $|p(z_0)| \leq |p(z)|$ for every $z \in \mathbb{C}$.

The minimum is 0. Suppose $p(z_0) \neq 0$. Expanding each $(z_0 + w)^j$ shows that $g(w) = p(z_0 + w)/p(z_0)$ is a polynomial in w of degree n (its coefficient of w^n is $a_n/p(z_0)$), with $g(0) = 1$ and $|g(w)| \geq 1$ for all w. Write

$$g(w) = 1 + b_k w^k + b_{k+1} w^{k+1} + \cdots + b_n w^n,$$

where $1 \leq k \leq n$ and $b_k \neq 0$. Choose $\beta \in \mathbb{C}$ with $\beta^k = -1/b_k$, and let $C = \sum_{j=k+1}^{n} |b_j|\,|\beta|^j$. For real t with $0 < t \leq 1$, we have $b_k(t\beta)^k = -t^k$ and $t^j \leq t^{k+1}$ for $j > k$, so

$$\begin{aligned} |g(t\beta)| &\leq |1 - t^k| + \sum_{j=k+1}^{n} |b_j|\,t^j\,|\beta|^j \\ &\leq 1 - t^k + Ct^{k+1} = 1 - t^k(1 - Ct). \end{aligned}$$

For $0 < t < 1$ with $Ct < 1$, this is less than 1, contradicting $|g| \geq 1$. Hence $p(z_0) = 0$.

The details of both steps, and a second proof by linear algebra due to Derksen, are in Section C.1. □

Some analysis is unavoidable in any proof. The theorem fails for the field $\mathbb{Q}(i) = \{a + bi \mid a, b \in \mathbb{Q}\}$, which satisfies all the field axioms and contains a square root of -1, but in which $x^2 - 2$ has no root. So no argument from the field axioms alone can prove it; every proof uses a property of $\mathbb{R}$ such as completeness.

Splitting into linear factors

Definition 7.1.33 (Splitting). A nonzero polynomial $p \in F[x]$ **splits** over F if

$$p = a(x - \lambda_1)(x - \lambda_2)\cdots(x - \lambda_n)$$

for some $a, \lambda_1, \ldots, \lambda_n \in F$.

Then $n = \deg p$ and a is the leading coefficient, by Proposition 7.1.4. The polynomial $x^2 + 1$ does not split over $\mathbb{R}$, since a factor $x - \lambda$ would give a real root; it splits over $\mathbb{C}$ as $(x - i)(x + i)$. The polynomial $x^2 - 2$ splits over $\mathbb{R}$ but not over $\mathbb{Q}$. When a polynomial splits, its factors record its roots and their multiplicities.

Proposition 7.1.34 (Roots of a split polynomial). Let $p = a(x - \lambda_1)\cdots(x - \lambda_n)$ with $a \in F$ nonzero and $\lambda_1, \ldots, \lambda_n \in F$. The roots of p are exactly $\lambda_1, \ldots, \lambda_n$, and each root of p occurs in the list $\lambda_1, \ldots, \lambda_n$ exactly as many times as its multiplicity. In particular, the list is determined by p up to order, and the multiplicities of the distinct roots of p add up to $\deg p$.

Proof. ROUTINE

Uses. Lemma 7.1.25 (Reading off a multiplicity), Proposition 7.1.10 (Evaluation respects sums and products), Proposition 1.1.17 (No zero divisors), Proposition 7.1.4 (Degree of a product)
Hint 1. Fix $\lambda \in F$ and let m be the number of indices i with $\lambda_i = \lambda$. Collect these factors in front.
Hint 2. What is the value at λ of the product of the remaining factors? Apply Lemma 7.1.25.
Sketch. For $\lambda \in F$ occurring m times in the list, $p = (x-\lambda)^m q$ with $q = a\prod_{\lambda_i \neq \lambda}(x-\lambda_i)$, and $q(\lambda) = a\prod_{\lambda_i \neq \lambda}(\lambda - \lambda_i) \neq 0$. By Lemma 7.1.25, λ has multiplicity m. So the number of occurrences of each scalar is its multiplicity, which depends only on p; summing over the distinct values in the list gives $n = \deg p$.

Fix $\lambda \in F$, and let m be the number of indices i with $\lambda_i = \lambda$ (possibly $m = 0$). Reordering the factors,

$$p = (x-\lambda)^m q, \quad \text{where } q = a\prod_{i:\lambda_i \neq \lambda}(x-\lambda_i).$$

By Proposition 7.1.10, $q(\lambda) = a\prod_{i:\lambda_i \neq \lambda}(\lambda - \lambda_i)$, which is nonzero by Proposition 1.1.17, as each factor is. By Lemma 7.1.25, the multiplicity of λ as a root of p is m. So λ is a root exactly when it occurs in the list, and it occurs as many times as its multiplicity. The number of occurrences of each scalar is therefore determined by p, which means the list is determined up to order. Summing the numbers of occurrences over the distinct values in the list counts every index once, which gives $n = \deg p$ (Proposition 7.1.4). □

Corollary 7.1.35 (Factorization over $\mathbb{C}$). Let $p \in \mathbb{C}[x]$ be nonzero, of degree n and with leading coefficient a. Then

$$p = a(x-\lambda_1)(x-\lambda_2)\cdots(x-\lambda_n),$$

where $\lambda_1, \ldots, \lambda_n$ are the roots of p, each listed as many times as its multiplicity. The factorization is unique up to the order of the factors. In particular, counted with multiplicity, p has exactly $\deg p$ roots in $\mathbb{C}$.

Proof. ROUTINE

Uses. Theorem 7.1.32 (Fundamental Theorem of Algebra), Theorem 7.1.20 (Factor theorem), Proposition 7.1.4 (Degree of a product), Proposition 7.1.34 (Roots of a split polynomial), induction on n
Hint 1. Induct on n. Use Theorem 7.1.32 to find one root, and Theorem 7.1.20 to split it off.
Hint 2. Uniqueness and the statement about multiplicities are Proposition 7.1.34.
Sketch. For $n = 0$, $p = a$. For $n \geq 1$, Theorem 7.1.32 gives a root λ_n, the factor theorem gives $p = (x-\lambda_n)q$ with $\deg q = n-1$ and leading coefficient a, and induction factors q. The rest is Proposition 7.1.34.

We show by induction on n that p splits. For $n = 0$, $p = a$ is the empty product times a. Let $n \geq 1$. By Theorem 7.1.32, p has a root $\lambda_n \in \mathbb{C}$, and by Theorem 7.1.20, $p = (x-\lambda_n)q$ with $\deg q = n-1$. By Proposition 7.1.4, the leading coefficient of q is that of p, namely a. By the induction hypothesis $q = a(x-\lambda_1)\cdots(x-\lambda_{n-1})$, and so $p = a(x-\lambda_1)\cdots(x-\lambda_n)$. By Proposition 7.1.34, the λ_i are the roots of p, each occurring as often as its multiplicity, and the list is determined by p up to order. □

So over $\mathbb{C}$ the bound of Proposition 7.1.27 is an equality. This is the count behind "an $n \times n$ complex matrix has n eigenvalues, counted with multiplicity" in Section 7.4. The coefficients of a split polynomial are also expressed through its roots. We record the two that matter most later.

Proposition 7.1.36 (Sum and product of the roots). Let $n \geq 1$ and $\lambda_1, \ldots, \lambda_n \in F$. In $(x-\lambda_1)\cdots(x-\lambda_n)$, the coefficient of x^{n-1} is $-(\lambda_1 + \cdots + \lambda_n)$ and the constant term is $(-1)^n \lambda_1 \lambda_2 \cdots \lambda_n$. So for $n \geq 2$,

$$\begin{aligned}(x-\lambda_1)\cdots(x-\lambda_n) = x^n - (\lambda_1 + \cdots + \lambda_n)x^{n-1} \\ + \cdots + (-1)^n \lambda_1 \lambda_2 \cdots \lambda_n,\end{aligned}$$

where the omitted terms have degrees from 1 to $n-2$.

Proof. ROUTINE

Uses. Proposition 7.1.10 (Evaluation respects sums and products), Proposition 7.1.3 ($F[x]$ is a commutative ring), induction on n

Hint 1. The constant term of a polynomial is its value at 0.
Hint 2. For the coefficient of x^{n-1}, induct on n and multiply by $x - \lambda_{n+1}$.
Sketch. The constant term is the value at 0, which is $\prod(0-\lambda_i) = (-1)^n \prod \lambda_i$. If $(x-\lambda_1)\cdots(x-\lambda_n) = x^n - ex^{n-1} + r$ with $\deg r \le n-2$, then multiplying by $x - \lambda_{n+1}$ gives $x^{n+1} - (e + \lambda_{n+1})x^n$ plus terms of degree at most $n-1$.

Let $P_n = (x-\lambda_1)\cdots(x-\lambda_n)$. Its constant term is $P_n(0) = (0-\lambda_1)\cdots(0-\lambda_n) = (-1)^n\lambda_1\cdots\lambda_n$ by Proposition 7.1.10.

For the coefficient of x^{n-1} we induct on n. For $n = 1$, $P_1 = x - \lambda_1$. Suppose $P_n = x^n - e_n x^{n-1} + r$ with $e_n = \lambda_1 + \cdots + \lambda_n$ and $\deg r \le n-2$. Then

$$\begin{aligned} P_{n+1} &= (x - \lambda_{n+1})P_n \\ &= x^{n+1} - (e_n + \lambda_{n+1})x^n + \left(\lambda_{n+1}e_n x^{n-1} + xr - \lambda_{n+1}r\right), \end{aligned}$$

and the last group has degree at most $n-1$. So the coefficient of x^n in P_{n+1} is $-(\lambda_1 + \cdots + \lambda_{n+1})$. □

By Corollary 7.1.35, for a monic $p = x^n + c_{n-1}x^{n-1} + \cdots + c_0 \in \mathbb{C}[x]$, the sum of its roots counted with multiplicity is $-c_{n-1}$, and their product is $(-1)^n c_0$. Applied to characteristic polynomials, this says that the trace of a complex matrix is the sum of its eigenvalues and the determinant is their product (compare the coefficients in Proposition 5.3.19; see Section 7.5). Exercise 7.1.59 computes the remaining coefficient of a cubic.

7.1.6 Factorization over $\mathbb{R}$

A polynomial with real coefficients is also a polynomial with complex coefficients, so Corollary 7.1.35 factors it over $\mathbb{C}$. The factors need not be real, but they come in conjugate pairs, and each pair multiplies to a real quadratic.

For $f = \sum_k c_k x^k \in \mathbb{C}[x]$, write $\overline{f} = \sum_k \overline{c_k} x^k$ for the polynomial with conjugated coefficients (Definition B.1.1).

Lemma 7.1.37 (Conjugating polynomials). For $f, g \in \mathbb{C}[x]$ and $\lambda \in \mathbb{C}$:

(a) $\overline{f+g} = \overline{f} + \overline{g}$ and $\overline{fg} = \overline{f}\,\overline{g}$;

(b) $\overline{f}\left(\overline{\lambda}\right) = \overline{f(\lambda)}$;

(c) $\overline{f} = f$ if and only if $f \in \mathbb{R}[x]$.

Proof. ROUTINE

Uses. Notation 6.1.1 (Real and complex scalars), Definition 7.1.1 (Product of polynomials), Definition 1.2.17 (Evaluation)
Hint. Conjugation of complex numbers respects sums and products (Notation 6.1.1). Apply it to the formulas for the coefficients of $f+g$ and fg, and to the formula for $f(\lambda)$.
Sketch. The k-th coefficient of $\overline{fg}$ is $\overline{\sum_{i+j=k} a_i b_j} = \sum_{i+j=k} \overline{a_i}\,\overline{b_j}$, that of $\overline{f}\,\overline{g}$; sums are similar. Likewise $\overline{f(\lambda)} = \sum \overline{c_k}\,\overline{\lambda}^k$. A complex number equals its conjugate exactly when it is real.

Write $f = \sum_k a_k x^k$ and $g = \sum_k b_k x^k$. We use $\overline{z+w} = \overline{z} + \overline{w}$, $\overline{zw} = \overline{z}\,\overline{w}$, and $\overline{z} = z$ if and only if $z \in \mathbb{R}$ (Notation 6.1.1).

(a) The k-th coefficient of $\overline{f+g}$ is $\overline{a_k + b_k} = \overline{a_k} + \overline{b_k}$, that of $\overline{f} + \overline{g}$. The k-th coefficient of $\overline{fg}$ is $\overline{\sum_{i+j=k} a_i b_j} = \sum_{i+j=k} \overline{a_i}\,\overline{b_j}$, that of $\overline{f}\,\overline{g}$.
(b) $\overline{f(\lambda)} = \overline{\sum_k a_k \lambda^k} = \sum_k \overline{a_k}\,\overline{\lambda}^k = \overline{f}\left(\overline{\lambda}\right)$.
(c) $\overline{f} = f$ means $\overline{a_k} = a_k$ for every k, that is, $a_k \in \mathbb{R}$ for every k. □

Intuition. Conjugation is a symmetry of $\mathbb{C}$: it respects sums and products and fixes every real number. So it carries any equation with real coefficients to another true equation. Applied to $p(\lambda) = 0$ for a real polynomial p, it gives $p\left(\overline{\lambda}\right) = 0$, and applied to a factorization, it shows that λ and $\overline{\lambda}$ occur equally often.

Proposition 7.1.38 (Conjugate roots). Let $p \in \mathbb{R}[x]$ be nonzero, regarded as an element of $\mathbb{C}[x]$, and let $\lambda \in \mathbb{C}$. Then λ and $\overline{\lambda}$ have the same multiplicity as roots of p. In particular, the nonreal roots of p come in pairs $\lambda \neq \overline{\lambda}$.

Proof. STANDARD

Uses. Lemma 7.1.37 (Conjugating polynomials), Lemma 7.1.25 (Reading off a multiplicity), Notation 6.1.1 (Real and complex scalars)
Hint 1. First show that $\overline{\lambda}$ is a root whenever λ is: conjugate the equation $p(\lambda) = 0$.
Hint 2. For multiplicities, conjugate a factorization $p = (x-\lambda)^m q$ with $q(\lambda) \neq 0$, and apply Lemma 7.1.25 at $\overline{\lambda}$.
Sketch. Let m be the multiplicity of λ, so $p = (x-\lambda)^m q$ with $q(\lambda) \neq 0$. Conjugating with Lemma 7.1.37, and using $\overline{p} = p$ and $\overline{x-\lambda} = x - \overline{\lambda}$, gives $p = \big(x-\overline{\lambda}\big)^m \overline{q}$ with $\overline{q}\big(\overline{\lambda}\big) = \overline{q(\lambda)} \neq 0$. So $\overline{\lambda}$ has multiplicity m.

Let m be the multiplicity of λ, and write $p = (x-\lambda)^m q$ with $q(\lambda) \neq 0$ (Lemma 7.1.25). Since p has real coefficients, $\overline{p} = p$, and $\overline{x-\lambda} = x - \overline{\lambda}$. By Lemma 7.1.37(a), applied to each factor,

$$p = \overline{p} = \big(x-\overline{\lambda}\big)^m \overline{q},$$

and by Lemma 7.1.37(b), $\overline{q}\big(\overline{\lambda}\big) = \overline{q(\lambda)} \neq 0$. By Lemma 7.1.25, $\overline{\lambda}$ has multiplicity m as a root of p. If λ is not real, then $\lambda \neq \overline{\lambda}$, so the nonreal roots of p come in pairs $\lambda, \overline{\lambda}$ of equal multiplicity. □

Theorem 7.1.39 (Factorization over $\mathbb{R}$). Every nonzero $p \in \mathbb{R}[x]$ can be written as

$$p = a(x-\lambda_1)\cdots(x-\lambda_k)\big(x^2+b_1x+c_1\big)\cdots\big(x^2+b_lx+c_l\big),$$

where $a, \lambda_i, b_j, c_j \in \mathbb{R}$ and $b_j^2 < 4c_j$ for each j (so $k+2l = \deg p$). Here $\lambda_1, \ldots, \lambda_k$ are the real roots of p, each listed as many times as its multiplicity. The factorization is unique up to the order of the factors.

Proof. STANDARD

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Proposition 7.1.38 (Conjugate roots), Proposition 7.1.34 (Roots of a split polynomial), Notation 6.1.1 (Real and complex scalars), Corollary 7.1.17 (Division does not depend on the field)
Hint 1. Factor p over $\mathbb{C}$. The real roots give real linear factors. What is $(x-\mu)(x-\overline{\mu})$ for a nonreal μ?
Hint 2. $(x-\mu)(x-\overline{\mu}) = x^2 - 2(\operatorname{Re}\mu)x + |\mu|^2$. Use Proposition 7.1.38 to pair up all nonreal factors.
Hint 3. For uniqueness, split each real quadratic factor over $\mathbb{C}$ into a conjugate pair, and compare with the complex factorization, which is unique by Proposition 7.1.34.
Sketch. Over $\mathbb{C}$, $p = a\prod_i (x-\lambda_i)$ with a real. By Proposition 7.1.38, the nonreal roots with negative imaginary part are the conjugates of those with positive imaginary part, with the same multiplicities, so the nonreal factors pair up as $(x-\mu)(x-\overline{\mu}) = x^2 - 2(\operatorname{Re}\mu)x + |\mu|^2$, a real quadratic with discriminant $-4(\operatorname{Im}\mu)^2 < 0$. Conversely, each real quadratic with $b^2 < 4c$ is $(x-\nu)(x-\overline{\nu})$ for a nonreal ν, so any real factorization gives the complex one; the real roots are the λ_i, and the roots with positive imaginary part determine the quadratics.

Existence. By Corollary 7.1.35, $p = a(x-\lambda_1)\cdots(x-\lambda_n)$ in $\mathbb{C}[x]$, where a is the leading coefficient of p, which is real, and the λ_i are the roots of p listed with multiplicity. Reorder them so that $\lambda_1, \ldots, \lambda_k$ are the real ones. Let $\mu_1, \ldots, \mu_l$ be the roots of p with positive imaginary part, each listed as many times as its multiplicity. By Proposition 7.1.38, conjugation maps the roots with positive imaginary part bijectively onto the roots with negative imaginary part, preserving multiplicities. So $\overline{\mu_1}, \ldots, \overline{\mu_l}$ are the roots with negative imaginary part, listed with multiplicity. Hence, reordering factors,

$$p = a(x-\lambda_1)\cdots(x-\lambda_k)\prod_{j=1}^{l}\big(x-\mu_j\big)\big(x-\overline{\mu_j}\big).$$

For each j, using $\mu + \overline{\mu} = 2\operatorname{Re}\mu$ and $\mu\overline{\mu} = |\mu|^2$ (Notation 6.1.1),

$$\big(x-\mu_j\big)\big(x-\overline{\mu_j}\big) = x^2 - 2\big(\operatorname{Re}\mu_j\big)x + |\mu_j|^2 = x^2 + b_jx + c_j,$$

with $b_j = -2\operatorname{Re}\mu_j$ and $c_j = |\mu_j|^2$ real, and $b_j^2 - 4c_j = 4\big(\operatorname{Re}\mu_j\big)^2 - 4\Big(\big(\operatorname{Re}\mu_j\big)^2 + \big(\operatorname{Im}\mu_j\big)^2\Big) = -4\big(\operatorname{Im}\mu_j\big)^2 < 0$. All factors now lie in $\mathbb{R}[x]$, and products in $\mathbb{R}[x]$ are computed by the same formula as in $\mathbb{C}[x]$, so this is a

factorization of the required form in $\mathbb{R}[x]$. The λ_i are the real roots listed with their multiplicities in $\mathbb{C}[x]$; for a real root λ this is also its multiplicity in $\mathbb{R}[x]$, because whether $(x-\lambda)^m$ divides p does not depend on the field (Corollary 7.1.17).

Uniqueness. Take any factorization of the stated form, with factors $x-\lambda_i'$ ($i \le k'$) and $x^2+b_j'x+c_j'$ ($j \le l'$) and constant a'. Comparing leading coefficients (Proposition 7.1.4), $a'=a$. For each j, since $4c_j'-b_j'^2 > 0$, the number

$$v_j = \frac{-b_j' + i\sqrt{4c_j' - b_j'^2}}{2}$$

is not real, and $v_j + \overline{v_j} = -b_j'$ and $v_j\overline{v_j} = \left(b_j'^2 + \left(4c_j' - b_j'^2\right)\right)/4 = c_j'$, so $x^2+b_j'x+c_j' = \left(x-v_j\right)\left(x-\overline{v_j}\right)$. Substituting, p splits over $\mathbb{C}$ with the list of roots $\lambda_1', \ldots, \lambda_{k'}', v_1, \overline{v_1}, \ldots, v_{l'}, \overline{v_{l'}}$. By Proposition 7.1.34 this list is, up to order, the list of roots of p with multiplicity. Its real members are the λ_i', so these are the real roots of p listed with multiplicity. Its members with positive imaginary part are the v_j, so these are the roots of p with positive imaginary part, listed with multiplicity. Both lists are determined by p, and each quadratic factor is determined by its v_j, as $\left(x-v_j\right)\left(x-\overline{v_j}\right)$. Hence the factors are determined by p up to order. □

Example 7.1.40 (x^4+4). Since $(1+i)^2 = 2i$, we get $(1+i)^4 = (2i)^2 = -4$, and in the same way $(\pm 1 \pm i)^4 = -4$ for all four choices of signs. These are four distinct roots of x^4+4, so by Corollary 7.1.35

$$x^4+4 = (x-1-i)(x-1+i)(x+1-i)(x+1+i).$$

Pairing conjugates as in the proof, $(x-1-i)(x-1+i) = (x-1)^2+1$ and $(x+1-i)(x+1+i) = (x+1)^2+1$, so

$$x^4+4 = \left(x^2-2x+2\right)\left(x^2+2x+2\right)$$

over $\mathbb{R}$, and even over $\mathbb{Q}$, although x^4+4 has no real root. As Proposition 7.1.36 predicts, the roots add up to 0, the negative of the coefficient of x^3, and their product is $(1+1)(1+1) = 4 = (-1)^4 \cdot 4$.

The real quadratic factors cannot be split further over $\mathbb{R}$. This is the real counterpart of the fact that linear factors cannot be split further over $\mathbb{C}$.

Definition 7.1.41 (Irreducible polynomial). A polynomial $p \in F[x]$ of degree at least 1 is **irreducible** over F if it cannot be written as $p = gh$ with $g, h \in F[x]$ both of degree at least 1. Otherwise, and if $\deg p \ge 1$, it is **reducible**.

Every polynomial of degree 1 is irreducible, since degrees add (Proposition 7.1.4). Irreducibility depends on the field: x^2+1 is irreducible over $\mathbb{R}$ but equals $(x-i)(x+i)$ over $\mathbb{C}$; x^2+x+1 is irreducible over $\mathbb{F}_2$, since it has no root there (Exercise 7.1.61), but equals $(x-1)^2$ over $\mathbb{F}_3$. Irreducible polynomials play the role of prime numbers (Exercise 7.1.68).

Corollary 7.1.42 (Irreducible polynomials over $\mathbb{C}$ and $\mathbb{R}$).

(a) A polynomial in $\mathbb{C}[x]$ is irreducible over $\mathbb{C}$ if and only if it has degree 1.

(b) A polynomial in $\mathbb{R}[x]$ is irreducible over $\mathbb{R}$ if and only if it has degree 1, or it is ax^2+bx+c with $a \ne 0$ and $b^2 < 4ac$.

Proof. ROUTINE

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Theorem 7.1.39 (Factorization over $\mathbb{R}$), Theorem 7.1.20 (Factor theorem), Exercise 1.1.50, Proposition 7.1.4 (Degree of a product)

Hint 1. A polynomial of degree 1 is always irreducible. For larger degrees, read off a factorization from Corollary 7.1.35 or Theorem 7.1.39.

Hint 2. For a real quadratic, a factorization into two linear factors gives a real root. When does $ax^2 + bx + c$ have a real root?
Sketch. Degree 1 is irreducible because degrees add. Over $\mathbb{C}$, degree $n \geq 2$ splits into $n \geq 2$ linear factors. Over $\mathbb{R}$, degree at least 3 gives at least two factors in Theorem 7.1.39, as $k + 2l \geq 3$. A real quadratic is reducible if and only if it has a real root, and by the quadratic formula (Exercise 1.1.50) that happens if and only if $b^2 - 4ac \geq 0$.

Polynomials of degree 1 are irreducible over every field, because in a product gh of two polynomials of degree at least 1, the degree is at least 2.

(a) If $p \in \mathbb{C}[x]$ has degree $n \geq 2$, then by Corollary 7.1.35 $p = (a(x - \lambda_1)) \cdot ((x - \lambda_2) \cdots (x - \lambda_n))$, a product of two polynomials of degrees 1 and $n - 1 \geq 1$.

(b) Let $p \in \mathbb{R}[x]$. If $\deg p \geq 3$, then in Theorem 7.1.39 $k + 2l = \deg p \geq 3$, so there are at least two non-constant factors. Splitting off one of them (and absorbing a into it) writes p as a product of two polynomials of degree at least 1, so p is reducible.

Now let $p = ax^2 + bx + c$ with $a \neq 0$. If p has a real root t, then $p = (x - t)q$ with $\deg q = 1$ (Theorem 7.1.20), so p is reducible. Conversely, if $p = gh$ with $\deg g = \deg h = 1$, say $g = ux + v$ with $u \neq 0$, then $-v/u$ is a root of g, hence of p. So p is irreducible if and only if it has no real root. By Exercise 1.1.50, p has a real root if and only if $b^2 - 4ac = d^2$ for some $d \in \mathbb{R}$, that is, if and only if $b^2 - 4ac \geq 0$. So p is irreducible if and only if $b^2 < 4ac$. □

The last consequence concerns odd degree. It has a proof from the factorization and a proof that avoids $\mathbb{C}$ altogether.

Corollary 7.1.43 (Odd degree gives a real root). Every polynomial $p \in \mathbb{R}[x]$ of odd degree has a real root.

Proof (by conjugate pairs). ROUTINE

Uses. Theorem 7.1.39 (Factorization over $\mathbb{R}$), Proposition 7.1.10 (Evaluation respects sums and products)
Hint. In Theorem 7.1.39, $k + 2l = \deg p$. What does odd degree say about k?
Sketch. $k + 2l = \deg p$ is odd, so $k \geq 1$, and λ_1 is a real root.

In the factorization of Theorem 7.1.39, $k + 2l = \deg p$ is odd, so k is odd and in particular $k \geq 1$. Then λ_1 is a real root of p, by Proposition 7.1.10. □

Proof (by the intermediate value theorem). STANDARD

Uses. the intermediate value theorem
Hint 1. Assume the leading coefficient is positive. Show that $p(t) > 0$ for large positive t and $p(t) < 0$ for large negative t.
Hint 2. For $|t| \geq 1$, bound the lower terms by $A\,|t|^{n-1}$, where A is the sum of the absolute values of the lower coefficients.
Sketch. With $a_n > 0$ and $A = \sum_{k<n} |a_k|$, for $|t| \geq 1$ the lower terms are at most $A\,|t|^{n-1}$ in absolute value. At $T = 1 + A/a_n$ this gives $p(T) > 0 > p(-T)$, because n is odd. The intermediate value theorem gives a root in $(-T, T)$.

Let $p = \sum_{k=0}^{n} a_k x^k$ with n odd and $a_n \neq 0$. Replacing p by $-p$, which has the same roots, we may assume $a_n > 0$. Let $A = |a_0| + \cdots + |a_{n-1}|$. For real t with $|t| \geq 1$, we have $|a_k t^k| \leq |a_k|\,|t|^{n-1}$ for $k < n$, so

$$|p(t) - a_n t^n| \leq A\,|t|^{n-1}.$$

Let $T = 1 + A/a_n \geq 1$, so that $a_n T - A = a_n > 0$. Then $p(T) \geq a_n T^n - A T^{n-1} = T^{n-1} a_n > 0$, and since n is odd, $(-T)^n = -T^n$ and

$$p(-T) \leq -a_n T^n + A T^{n-1} = -T^{n-1} a_n < 0.$$

The function $t \mapsto p(t)$ is continuous on $[-T, T]$, so by the intermediate value theorem it vanishes somewhere in $(-T, T)$. □

The second proof is the more elementary one: it uses the completeness of $\mathbb{R}$ directly, through the intermediate value theorem, while the first relies on the Fundamental Theorem of Algebra, whose proof uses completeness in a much more elaborate way. On the other hand, the first proof gives more: the number of

real roots, counted with multiplicity, has the same parity as $\deg p$. In Section 7.3, this corollary shows that every operator on a real vector space of odd dimension has an eigenvalue.

7.1.7 Greatest common divisors BEYOND 21-242

Greatest common divisors of polynomials are not covered in lecture. They are used in Section 7.6, Section 10.2, and Section 14.4.

The integers have greatest common divisors, computed by the Euclidean algorithm, and $\gcd(a, b)$ is an integer combination $ua + vb$ (Bézout's identity). All of this carries over to $F[x]$, because the only tool it needs is division with remainder. The application to linear algebra is this: if p and s have no common factor, then $up + vs = 1$ for some polynomials u and v, and for a square matrix A, Remark 7.1.11 turns this into $u(A)p(A) + v(A)s(A) = I_n$. Section 7.6 and Section 10.2 use such identities to split a space into the kernels of $p(A)$ and $s(A)$.

Definition 7.1.44 (Greatest common divisor). Let $p, s \in F[x]$, not both $\mathbf{0}$. A **greatest common divisor** of p and s is a monic polynomial d such that $d \mid p$, $d \mid s$, and every common divisor of p and s divides d. If 1 is a greatest common divisor of p and s, they are **coprime**.

"Greatest" refers to divisibility, but it implies the largest degree: every common divisor divides d, so its degree is at most $\deg d$.

Theorem 7.1.45 (Bézout's identity). Let $p, s \in F[x]$, not both $\mathbf{0}$. Then p and s have exactly one greatest common divisor d, written $\gcd(p, s)$, and there are $u, v \in F[x]$ with

$$d = up + vs.$$

Moreover, d is the monic polynomial of smallest degree of the form $up + vs$.

Intuition. Consider all combinations $up + vs$. Every common divisor of p and s divides each of them, so a combination that itself divides p and s is automatically a greatest common divisor. The smallest nonzero combination is the natural candidate: dividing p by it leaves a remainder that is again a combination, and smaller, so it must be $\mathbf{0}$.

Proof (by a combination of smallest degree). HARD

Uses. Theorem 7.1.14 (Division with remainder), Definition 7.1.44 (Greatest common divisor), Definition 7.1.16 (Divisibility), Corollary 7.1.7 (No zero divisors, cancellation, and units)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Uniqueness via two candidates (Technique 1.1.8), Compare degrees and leading coefficients (Technique 7.1.6)
Hint 1. Let $I = \{up + vs \mid u, v \in F[x]\}$. Choose a nonzero element of I of smallest degree, and scale it to be monic.
Hint 2. Divide p by this element d. Show that the remainder lies in I, and conclude from minimality that it is $\mathbf{0}$.
Hint 3. For uniqueness, two greatest common divisors divide each other, and both are monic.
Sketch. The set I of combinations $up + vs$ is closed under sums and under multiplication by polynomials, and contains a nonzero element. Let $d \in I$ be monic of smallest degree. The remainder of p on division by d is $p - qd \in I$ and has degree less than $\deg d$, so it is $\mathbf{0}$; thus $d \mid p$, and likewise $d \mid s$. A common divisor of p and s divides $up + vs = d$. Two greatest common divisors divide each other and are monic, so they are equal.

Let $I = \{up + vs \mid u, v \in F[x]\}$. It contains $p = 1p + \mathbf{0}s$ and s, so it contains a nonzero polynomial. It is closed under sums, since $(up + vs) + (u'p + v's) = (u + u')p + (v + v')s$, and under multiplication by any $w \in F[x]$, since $w(up + vs) = (wu)p + (wv)s$.

Existence. Among the nonzero elements of I, choose one of smallest degree. Multiplying it by the inverse of its leading coefficient keeps it in I and makes it monic; call the result $d = up + vs$. Divide p by d: $p = dq + r$ with $\deg r < \deg d$ (Theorem 7.1.14). Then

$$r = p - qd = (1 - qu)p + (-qv)s \in I.$$

By the choice of d, no nonzero element of I has degree less than $\deg d$, so $r = \mathbf{0}$ and $d \mid p$. In the same way $d \mid s$. If e divides both p and s, say $p = ep'$ and $s = es'$, then $d = up + vs = e(up' + vs')$, so $e \mid d$. Hence d is a greatest common divisor, and it is a combination of p and s.

Uniqueness. If d and d' are both greatest common divisors, then each divides the other, by the definition applied twice. As noted after Definition 7.1.16, two monic polynomials that divide each other are equal.

Smallest degree. We showed that the gcd is a monic element of I of smallest degree. Conversely, any monic $d' \in I$ of smallest degree is, by the existence argument applied to d', a greatest common divisor, so it equals d. □

The second proof computes d, and u and v as well, by repeated division.

Algorithm 7.1.46 (Euclidean algorithm)

Input Polynomials $p, s \in F[x]$ with $s \neq \mathbf{0}$.
Output $\gcd(p, s)$.

1. Set $r_0 = p$ and $r_1 = s$, and $i = 1$.
2. If $r_i = \mathbf{0}$, output r_{i-1} divided by its leading coefficient, and stop.
3. Otherwise let r_{i+1} be the remainder of r_{i-1} on division by r_i, increase i by 1, and return to step 2.

Proof of Theorem 7.1.45 (by the Euclidean algorithm). HARD

> *Uses.* Theorem 7.1.14 (Division with remainder), Definition 7.1.44 (Greatest common divisor), Definition 7.1.16 (Divisibility)
> *Techniques.* Algorithms as proofs: invariants and termination (Technique 3.3.5)
> *Hint 1.* If $s = \mathbf{0}$, the gcd is p made monic. Otherwise run Algorithm 7.1.46. Why does it stop?
> *Hint 2.* Find an invariant: compare the common divisors of r_{i-1} and r_i with those of r_i and r_{i+1}.
> *Hint 3.* Show also by induction that every r_i is a combination $u_i p + v_i s$.
> *Sketch.* The degrees $\deg r_1 > \deg r_2 > \cdots$ strictly decrease, so some $r_{N+1} = \mathbf{0}$. Since $r_{i+1} = r_{i-1} - q_i r_i$ and $r_{i-1} = q_i r_i + r_{i+1}$, the pairs (r_{i-1}, r_i) and (r_i, r_{i+1}) have the same common divisors. So the common divisors of p and s are those of r_N and $\mathbf{0}$, the divisors of r_N. Each r_i is a combination of p and s by induction. Making r_N monic gives d; uniqueness is as in the first proof.

If $s = \mathbf{0}$, then $p \neq \mathbf{0}$, and the common divisors of p and $\mathbf{0}$ are the divisors of p. So p divided by its leading coefficient a is a greatest common divisor, and it equals $a^{-1}p + \mathbf{0}s$. Now let $s \neq \mathbf{0}$ and run Algorithm 7.1.46. Each r_{i+1} is a remainder on division by r_i, so $\deg r_{i+1} < \deg r_i$. A strictly decreasing sequence of nonnegative integers is finite, so some $r_{N+1} = \mathbf{0}$ with $r_N \neq \mathbf{0}$, and the algorithm stops.

Invariant. Write $r_{i-1} = q_i r_i + r_{i+1}$. If e divides r_{i-1} and r_i, it divides $r_{i+1} = r_{i-1} - q_i r_i$; if e divides r_i and r_{i+1}, it divides r_{i-1}. So the pairs (r_{i-1}, r_i) and (r_i, r_{i+1}) have the same common divisors. Following the chain from $(p, s) = (r_0, r_1)$ to $(r_N, r_{N+1}) = (r_N, \mathbf{0})$, the common divisors of p and s are exactly the divisors of r_N. In particular, with a the leading coefficient of r_N, the monic polynomial $d = a^{-1}r_N$ divides p and s, and every common divisor divides d. So d is a greatest common divisor.

Combination. We show by induction on i that $r_i = u_i p + v_i s$ for some u_i, v_i. This holds for $r_0 = 1p + \mathbf{0}s$ and $r_1 = \mathbf{0}p + 1s$, and if it holds for r_{i-1} and r_i, then $r_{i+1} = r_{i-1} - q_i r_i = (u_{i-1} - q_i u_i)p + (v_{i-1} - q_i v_i)s$. So $d = a^{-1}u_N p + a^{-1}v_N s$. Every nonzero combination $up + vs$ is divisible by d, which divides p and s, so it has degree at least $\deg d$; and a monic combination d' of degree $\deg d$ is divisible by d, so $d' = d$ (compare leading coefficients). Uniqueness of the gcd is proved as in the first proof. □

Example 7.1.47 (A greatest common divisor over $\mathbb{Q}$). Let $p = x^4 - 1$ and $s = x^3 + 2x^2 + 2x + 1$. The Euclidean algorithm, with $r_0 = p$ and $r_1 = s$, gives

$$p = (x - 2)s + r_2, \qquad r_2 = 2x^2 + 3x + 1,$$

$$s = \left(\frac{1}{2}x + \frac{1}{4}\right)r_2 + r_3, r_3 = \frac{3}{4}(x+1),$$
$$r_2 = \left(\frac{8}{3}x + \frac{4}{3}\right)r_3.$$

The last nonzero remainder is $r_3 = \frac{3}{4}(x+1)$, so $\gcd(p,s) = x+1$. Running the substitutions backwards, with $r_2 = p - (x-2)s$ and $r_3 = s - \left(\frac{1}{2}x + \frac{1}{4}\right)r_2$,

$$x + 1 = \frac{4}{3}r_3 = -\left(\frac{2}{3}x + \frac{1}{3}\right)p + \left(\frac{2}{3}x^2 - x + \frac{2}{3}\right)s.$$

The factorizations $p = (x-1)(x+1)\left(x^2+1\right)$ and $s = (x+1)\left(x^2+x+1\right)$ confirm the answer.

Corollary 7.1.48 (Coprime polynomials). Let $p, s \in F[x]$, not both $\mathbf{0}$.

(a) p and s are coprime if and only if $up + vs = 1$ for some $u, v \in F[x]$.

(b) If $F = \mathbb{C}$, then p and s are coprime if and only if they have no common root.

Proof. STANDARD

Uses. Theorem 7.1.45 (Bézout's identity), Corollary 7.1.7 (No zero divisors, cancellation, and units), Theorem 7.1.20 (Factor theorem), Theorem 7.1.32 (Fundamental Theorem of Algebra)
Hint 1. For (a), "only if" is Theorem 7.1.45. For "if", what can a common divisor of p and s be, if it divides 1?
Hint 2. For (b), a common root λ gives the common factor $x - \lambda$. Conversely, apply Theorem 7.1.32 to the gcd.
Sketch. (a) If p, s are coprime, Bézout gives $up + vs = 1$. Conversely, every common divisor divides $up + vs = 1$, so it is a nonzero constant, and the monic gcd is 1. (b) A common root λ makes $x - \lambda$ a common divisor of degree 1, so the gcd is not 1. If the gcd d is not 1, it is monic of degree at least 1 and has a root by Theorem 7.1.32, which is a root of p and of s.

(a) If p and s are coprime, Theorem 7.1.45 gives $up + vs = \gcd(p,s) = 1$. Conversely, suppose $up + vs = 1$, and let $d = \gcd(p,s)$. Then d divides $up + vs = 1$, so $\deg d \leq 0$, and d, being monic, is 1.

(b) If λ is a common root, then $x - \lambda$ divides p and s (Theorem 7.1.20), so it divides $\gcd(p,s)$, which therefore has degree at least 1 and is not 1. Conversely, if $d = \gcd(p,s) \neq 1$, then d is monic of degree at least 1, since the only monic constant is 1. By Theorem 7.1.32, d has a root $\lambda \in \mathbb{C}$, and since d divides p and s, λ is a root of both. □

Part (b) fails over $\mathbb{R}$: $x^2 + 1$ and $x^4 - 1$ have no common real root, but their gcd is $x^2 + 1$.

Exercises

Exercise 7.1.49. ROUTINE Let $p = x^4 - 2x^3 + 2x - 1$. Factor p into linear factors over $\mathbb{Q}$, over $\mathbb{F}_3$, and over $\mathbb{F}_2$, and in each case list the roots of p with their multiplicities.

Solution on page 1554

Exercise 7.1.50. STANDARD Over $\mathbb{Q}$, find the remainder of x^{100} on division by (a) $x^2 - 1$; (b) $x^2 + 1$; (c) $(x-1)^2$.

Solution on page 1554

Exercise 7.1.51. STANDARD Let $s \in F[x]$ have degree $m \geq 1$, let $n \geq m$, and for $p \in F[x]_{\leq n}$ let $R(p)$ be the remainder of p on division by s.

(a) Show that $R : F[x]_{\leq n} \to F[x]_{\leq m-1}$ is linear.

(b) Show that R is surjective and that $\ker R = \{sq \mid q \in F[x]_{\leq n-m}\}$.

(c) Verify the rank–nullity formula (Theorem 4.2.11) for R.

Solution on page 1555

Exercise 7.1.52. STANDARD The definitions of this section make sense with coefficients in $\mathbb{Z}/8\mathbb{Z}$, which is a commutative ring but not a field (Lemma 1.1.21).

(a) Show that $x^2 - 1$ has four roots in $\mathbb{Z}/8\mathbb{Z}$, and that $x^2 - 1 = (x-1)(x+1) = (x-3)(x+3)$ in $(\mathbb{Z}/8\mathbb{Z})[x]$.

(b) The proof of Proposition 7.1.22, run over $\mathbb{Z}/8\mathbb{Z}$, would show that $x^2 - 1$ has at most two roots. Find the first step that fails.

Solution on page 1555

Exercise 7.1.53. STANDARD Prove or disprove, for $p, q, r \in F[x]$.

(a) If $p(c) = q(c)$ for every $c \in F$, then $p = q$.

(b) If $p \mid q$ and $q \mid p$, then $p = q$.

(c) If $p \mid qr$, then $p \mid q$ or $p \mid r$.

(d) If $p \in \mathbb{R}[x]$ has no real root, then $\deg p$ is even.

(e) If $p \in \mathbb{R}[x]$ is nonzero, then the number of real roots of p, counted with multiplicity, has the same parity as $\deg p$.

Solution on page 1556

Exercise 7.1.54. STANDARD

(a) Let $n \geq 1$. Show that $x^n - 1$ has n distinct roots in $\mathbb{C}$.

(b) Let p be a prime. Show that $x^p - 1 = (x-1)^p$ in $\mathbb{F}_p[x]$, so that 1 is the only root of $x^p - 1$ in $\mathbb{F}_p$, with multiplicity p.

Solution on page 1556

Exercise 7.1.55. HARD Let p be a prime.

(a) Show that $x^p - x = \prod_{a \in \mathbb{F}_p} (x - a)$ in $\mathbb{F}_p[x]$.

(b) Deduce Wilson's theorem: $(p-1)! \equiv -1 \pmod{p}$.

Solution on page 1557

Exercise 7.1.56. STANDARD Consider $f \in F[x]$ with $f(x+1) = f$.

(a) Show that if F has characteristic 0 (Definition 1.1.28), then f is constant.

(b) Let p be a prime. Find a nonconstant $f \in \mathbb{F}_p[x]$ with $f(x+1) = f$.

Solution on page 1557

Exercise 7.1.57. STANDARD Let $a, b, c, d \in F$.

(a) Show that there is exactly one $f \in F[x]_{\leq 3}$ with $f(0) = a$, $f'(0) = b$, $f(1) = c$, and $f'(1) = d$, where f' is the formal derivative.

(b) Find f over $\mathbb{Q}$ for $(a, b, c, d) = (1, 0, 0, 0)$.

Solution on page 1558

Exercise 7.1.58. STANDARD Let $n \geq 1$, let $c_0, \ldots, c_n \in F$ be distinct, let $L_0, \ldots, L_n$ be the Lagrange polynomials (Definition 3.4.26), and let $\omega = (x - c_0) \cdots (x - c_n)$.

(a) Show that $L_0 + L_1 + \cdots + L_n = 1$ and $c_0 L_0 + c_1 L_1 + \cdots + c_n L_n = x$.

(b) Show that $\omega'(c_i) = \prod_{j \neq i} (c_i - c_j)$, and deduce that $L_i = \omega_i / \omega'(c_i)$, where $\omega_i = \prod_{j \neq i} (x - c_j)$.

Solution on page 1558

Exercise 7.1.59. ROUTINE Let $\lambda_1, \lambda_2, \lambda_3$ be the roots of $x^3 - 2x + 5$ in $\mathbb{C}$, listed with multiplicity.

(a) Expand $(x - \lambda_1)(x - \lambda_2)(x - \lambda_3)$.

(b) Compute $\lambda_1 + \lambda_2 + \lambda_3$, $\lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3$, $\lambda_1\lambda_2\lambda_3$, and $\lambda_1^2 + \lambda_2^2 + \lambda_3^2$.

Solution on page 1558

Exercise 7.1.60. STANDARD Factor $x^4 + 1$ and $x^6 - 1$ into irreducible polynomials over $\mathbb{C}$ and over $\mathbb{R}$.

Solution on page 1559

Exercise 7.1.61. ROUTINE

(a) Let $p \in F[x]$ have degree 2 or 3. Show that p is irreducible over F if and only if p has no root in F.

(b) Show that (a) fails in degree 4: find a polynomial of degree 4 over $\mathbb{Q}$, and one over $\mathbb{F}_2$, that has no root but is reducible.

(c) Which of $x^2 + x + 1$, $x^3 + x + 1$, and $x^3 + 1$ are irreducible over $\mathbb{F}_2$?

Solution on page 1559

Exercise 7.1.62. STANDARD Let p be a prime. Show that there are exactly $p(p-1)/2$ monic irreducible polynomials of degree 2 in $\mathbb{F}_p[x]$, and list them for $p = 3$.

Solution on page 1560

Exercise 7.1.63. STANDARD Let $f \in \mathbb{C}[x]_{\leq n}$, and suppose that $f(t_k) \in \mathbb{R}$ for $n+1$ distinct real numbers $t_0, \ldots, t_n$. Show that f has real coefficients. Show by an example that the hypothesis $\deg f \leq n$ cannot be dropped.

Solution on page 1560

Exercise 7.1.64. HARD Let $p \in \mathbb{R}[x]$ satisfy $p(t) \geq 0$ for every $t \in \mathbb{R}$. Show that $p = f^2 + g^2$ for some $f, g \in \mathbb{R}[x]$.

Solution on page 1560

Exercise 7.1.65. HARD

(a) Let F be a field with $1 + 1 \neq 0$. Find all $p \in F[x]$ with $p(x^2) = p^2$.

(b) Show that every $p \in \mathbb{F}_2[x]$ satisfies $p(x^2) = p^2$.

Solution on page 1561

Exercise 7.1.66. CHALLENGE BEYOND 21-242 (Gauss–Lucas) Let $p \in \mathbb{C}[x]$ have degree $n \geq 2$ and roots $\lambda_1, \ldots, \lambda_n$, listed with multiplicity. Show that every root w of p' is a convex combination of the roots of p: $w = t_1\lambda_1 + \cdots + t_n\lambda_n$ for some real $t_i \geq 0$ with $t_1 + \cdots + t_n = 1$.

Solution on page 1562

Exercise 7.1.67. STANDARD BEYOND 21-242 Let $p = x^4 + x^3 + 2x^2 + x + 1$ and $s = x^3 - 1$.

(a) Over $\mathbb{Q}$, compute $\gcd(p, s)$ with the Euclidean algorithm, and find $u, v \in \mathbb{Q}[x]$ with $up + vs = \gcd(p, s)$.

(b) Compute $\gcd(p, s)$ over $\mathbb{F}_2$. Why is the answer different?

Solution on page 1562

Exercise 7.1.68. HARD BEYOND 21-242

(a) (Euclid's lemma) Let $p \in F[x]$ be irreducible and $g, h \in F[x]$. Show that if $p \mid gh$, then $p \mid g$ or $p \mid h$.

(b) Show that every polynomial of degree at least 1 is a product of irreducible polynomials, and that the factorization is unique in the following sense: if $ap_1 \cdots p_k = bq_1 \cdots q_l$ with $a, b \in F$ nonzero and all p_i, q_j monic irreducible, then $a = b$, $k = l$, and the q_j are the p_i in some order.

Solution on page 1563

Exercise 7.1.69. HARD BEYOND 21-242 (Chinese remainder theorem) Let $m_1, m_2 \in F[x]$ be coprime, of degrees $d_1, d_2 \geq 1$, and let $r_1, r_2 \in F[x]$.

(a) Show that there is exactly one $p \in F[x]$ with $\deg p < d_1 + d_2$ such that $m_1 \mid p - r_1$ and $m_2 \mid p - r_2$.

(b) Explain why polynomial interpolation at two nodes (Theorem 3.4.24 with $n = 1$) is the special case $m_i = x - c_i$.

Solution on page 1563

7.2 Eigenvalues, eigenvectors, and invariant subspaces

A diagonal matrix $D = \operatorname{diag}(d_1, \ldots, d_n)$ is the simplest kind of operator: it multiplies the i-th coordinate by d_i, so it sends each standard basis vector $\mathbf{e}_i$ to the multiple $d_i\mathbf{e}_i$ of itself. A general operator mixes directions, but it may still have some directions that it only stretches, that is, nonzero vectors $\mathbf{v}$ with $T\mathbf{v} = \lambda\mathbf{v}$. If V has a basis of such vectors, the matrix of T in that basis is diagonal, and questions about T (its powers, its kernel, its long-run behavior) become questions about the scalars λ. This section introduces these vectors, the eigenvectors, together with the more general subspaces that an operator maps into themselves. Computing eigenvalues is the subject of Section 7.3, and the question of when a basis of eigenvectors exists is the subject of Section 7.4.

Throughout, V is a vector space over a field F, possibly infinite-dimensional unless we say otherwise, and $T \in \mathrm{L}(V)$ is an operator on V (Notation 2.1.2). We write $T\mathbf{v}$ for $T(\mathbf{v})$ when no confusion can arise.

7.2.1 Invariant subspaces

To understand an operator, we would like to cut V into pieces that T does not mix. The minimal requirement on a piece U is that T does not move vectors of U out of U. Then T restricts to an operator on U, which we can study on its own.

Definition 7.2.1 (Invariant subspace). Let $T \in \mathrm{L}(V)$. A subspace U of V is **invariant under** T (or T-**invariant**) if $T\mathbf{u} \in U$ for every $\mathbf{u} \in U$, that is, if $\operatorname{im}(T|_U) \subseteq U$. In that case we regard $T|_U$ as an operator on U, $T|_U \in \mathrm{L}(U)$.

Example 7.2.2 (Invariant subspaces).

(a) The subspaces $\{\mathbf{0}\}$ and V are invariant under every operator on V.

(b) $\ker T$ and $\operatorname{im} T$ are T-invariant. If $\mathbf{u} \in \ker T$, then $T\mathbf{u} = \mathbf{0} \in \ker T$; and $T\mathbf{u} \in \operatorname{im} T$ for every $\mathbf{u} \in V$, in particular for every $\mathbf{u} \in \operatorname{im} T$.

(c) Every subspace is invariant under a scaling map $\lambda \mathrm{id}_V$, since $\lambda\mathbf{u} \in U$ whenever $\mathbf{u} \in U$.

(d) Differentiation D on $F[x]$ (Example 2.1.9) lowers degrees, so for each $n \geq 0$ the subspace $F[x]_{\leq n}$ is D-invariant. Multiplication by x, $M(p) = xp$, raises degrees, and $F[x]_{\leq n}$ is not M-invariant, as $M(x^n) = x^{n+1}$. The subspace $\{p \mid p(0) = 0\}$ is M-invariant, since $(xp)(0) = 0$ for every p.

(e) The cyclic permutation $Z(x, y, z) = (z, x, y)$ of Example 4.5.37 leaves the line spanned by $(1, 1, 1)$ and the plane $x + y + z = 0$ invariant.

Non-example 7.2.3 (A line that moves). Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, the shear $(x, y) \mapsto (x + y, y)$ of F^2. Then $A\mathbf{e}_1 = \mathbf{e}_1$, so the line $\operatorname{span}(\mathbf{e}_1)$ is invariant. But $A\mathbf{e}_2 = (1, 1) \notin \operatorname{span}(\mathbf{e}_2)$, so the line $\operatorname{span}(\mathbf{e}_2)$ is not, although it is a complement of an invariant line. Invariance is a property of a subspace relative to T, and complements of invariant subspaces need not inherit it.

In the last two examples we checked invariance only on spanning vectors. That is always enough.

Proposition 7.2.4 (Invariance is checked on a spanning list). Let $T \in \mathrm{L}(V)$ and $U = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_k)$. Then U is T-invariant if and only if $T\mathbf{u}_i \in U$ for $i = 1, \ldots, k$.

Proof. ROUTINE

Uses. Definition 7.2.1 (Invariant subspace), Definition 1.3.10 (Span), Definition 2.1.1 (Linear map), Proposition 1.4.14 (The span is the smallest subspace containing a list)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. One direction is immediate. For the other, write an arbitrary $\mathbf{u} \in U$ as a combination of the $\mathbf{u}_i$.
Hint 2. Apply T to the combination and use that U is closed under linear combinations.
Sketch. If U is invariant, then in particular $T\mathbf{u}_i \in U$. Conversely, $T(\sum a_i\mathbf{u}_i) = \sum a_i T\mathbf{u}_i$ is a linear combination of vectors of the subspace U, so it lies in U.

If U is T-invariant, then $T\mathbf{u}_i \in U$ because $\mathbf{u}_i \in U$. Conversely, suppose $T\mathbf{u}_i \in U$ for each i, and let $\mathbf{u} \in U$. By Definition 1.3.10, $\mathbf{u} = a_1\mathbf{u}_1 + \cdots + a_k\mathbf{u}_k$ for some $a_i \in F$, and by linearity

$$T\mathbf{u} = a_1 T\mathbf{u}_1 + \cdots + a_k T\mathbf{u}_k.$$

This is a linear combination of vectors of the subspace U, so it lies in U (Proposition 1.4.14). □

Remark 7.2.5 (Invariant subspaces and block matrices). Suppose V is finite-dimensional. By Proposition 4.5.35, a subspace U is T-invariant exactly when, in a basis of V that starts with a basis of U, the matrix of T has the block form

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix},$$

and then A is the matrix of $T|_U$. If $V = U \oplus W$ with both U and W invariant, then $B = 0$ as well, and T splits into the two operators $T|_U$ and $T|_W$ (Technique 4.5.36). So invariant subspaces are what make matrices block triangular, and invariant complements are what make them block diagonal. The smallest nonzero blocks have size 1×1, and they come from invariant lines.

7.2.2 Eigenvalues and eigenvectors

Intuition (Invariant lines). A line $\operatorname{span}(\mathbf{v})$, with $\mathbf{v} \neq \mathbf{0}$, is T-invariant exactly when $T\mathbf{v} \in \operatorname{span}(\mathbf{v})$ (Proposition 7.2.4), that is, when $T\mathbf{v} = \lambda\mathbf{v}$ for some scalar λ. On such a line T acts as multiplication by λ:

$T(c\mathbf{v}) = c\lambda\mathbf{v} = \lambda(c\mathbf{v})$. So the one-dimensional invariant subspaces are the directions that T stretches (by λ, possibly 0 or negative) without turning.

Definition 7.2.6 (Eigenvalue, eigenvector). Let $T \in \mathrm{L}(V)$. A scalar $\lambda \in F$ is an **eigenvalue** of T if there is a vector $\mathbf{v} \in V$ with

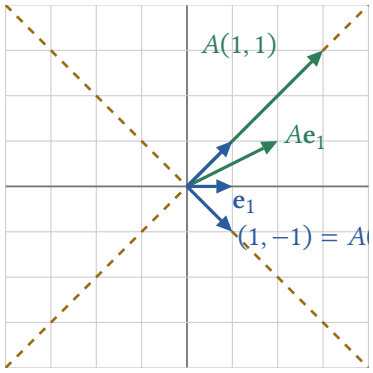
$$\mathbf{v} \neq \mathbf{0} \quad \text{and} \quad T\mathbf{v} = \lambda\mathbf{v}.$$

Such a vector $\mathbf{v}$ is an **eigenvector** of T with eigenvalue λ (or an eigenvector for λ). For $A \in F^{n\times n}$, the eigenvalues and eigenvectors of A are those of T_A: nonzero $\mathbf{v} \in F^n$ with $A\mathbf{v} = \lambda\mathbf{v}$.

Three remarks on the definition. First, eigenvectors are nonzero by definition: $T\mathbf{0} = \lambda\mathbf{0}$ holds for every λ, so allowing $\mathbf{0}$ would make every scalar an eigenvalue. The eigenvalue 0 is allowed, and it occurs exactly when $\ker T \neq \{\mathbf{0}\}$. Second, an eigenvector determines its eigenvalue: if $\lambda\mathbf{v} = \mu\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $(\lambda - \mu)\mathbf{v} = \mathbf{0}$, so $\lambda = \mu$ by Proposition 1.2.35. Third, eigenvalues are elements of F. The same matrix can have eigenvalues over $\mathbb{C}$ and none over $\mathbb{R}$ (Example 7.2.18), so the field is part of the question.

Proposition 7.2.7 (Invariant lines are spanned by eigenvectors). Let $T \in \mathrm{L}(V)$ and $\mathbf{v} \in V$ with $\mathbf{v} \neq \mathbf{0}$. Then $\operatorname{span}(\mathbf{v})$ is T-invariant if and only if $\mathbf{v}$ is an eigenvector of T. In that case every nonzero vector of $\operatorname{span}(\mathbf{v})$ is an eigenvector of T with the same eigenvalue.

Proof. ROUTINE



Uses. Proposition 7.2.4 (Invariance is checked on a spanning list), Definition 7.2.6 (Eigenvalue, eigenvector), Definition 1.3.10 (Span)
Hint 1. Apply Proposition 7.2.4 to the list consisting of $\mathbf{v}$ alone.
Hint 2. For the last claim, compute $T(c\mathbf{v})$.
Sketch. By Proposition 7.2.4, $\operatorname{span}(\mathbf{v})$ is invariant iff $T\mathbf{v} \in \operatorname{span}(\mathbf{v}) = \{c\mathbf{v} \mid c \in F\}$, which says $T\mathbf{v} = \lambda\mathbf{v}$ for some λ. Then $T(c\mathbf{v}) = \lambda(c\mathbf{v})$.

By Proposition 7.2.4, $\operatorname{span}(\mathbf{v})$ is T-invariant if and only if $T\mathbf{v} \in \operatorname{span}(\mathbf{v}) = \{c\mathbf{v} \mid c \in F\}$, that is, if and only if $T\mathbf{v} = \lambda\mathbf{v}$ for some $\lambda \in F$. Since $\mathbf{v} \neq \mathbf{0}$, this says that $\mathbf{v}$ is an eigenvector. If $T\mathbf{v} = \lambda\mathbf{v}$ and $c \neq 0$, then $c\mathbf{v} \neq \mathbf{0}$ and $T(c\mathbf{v}) = c\lambda\mathbf{v} = \lambda(c\mathbf{v})$. □

Example 7.2.8 (Eigenvectors of a symmetric 2×2 matrix). Let $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} \in \mathbb{R}^{2\times 2}$. Then

$$A\begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 3 \\ 3 \end{pmatrix} = 3\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad A\begin{pmatrix} 1 \\ -1 \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}, \quad A\begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix}.$$

So $(1, 1)$ is an eigenvector with eigenvalue 3, $(1, -1)$ is an eigenvector with eigenvalue 1, and $\mathbf{e}_1$ is not an eigenvector, since $(2, 1)$ is not a multiple of $(1, 0)$. The lines $y = x$ and $y = -x$ are invariant. In the basis $(1, 1), (1, -1)$ the matrix of T_A is $\operatorname{diag}(3, 1)$: A stretches the first diagonal by 3 and fixes the second pointwise. We will see in Corollary 7.2.22 that A has no other eigenvalues.

The map of $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$. The dashed lines $y = x$ and $y = -x$ are invariant: $A(1,1) = (3,3)$, while $(1,-1)$ is fixed. The vector $\mathbf{e}_1$ is turned toward the diagonal. In the interactive version, drag $A\mathbf{e}_1$ and $A\mathbf{e}_2$ and look for lines through $\mathbf{0}$ that are mapped to themselves. The far corner of the image of the unit square is $A(1,1) = A\mathbf{e}_1 + A\mathbf{e}_2$, so the diagonal $y = x$ is invariant exactly when that corner stays on it, that is, when the two rows of A have the same sum. The x-axis is invariant exactly when $A\mathbf{e}_1$ lies on it. Try a rotation by an angle that is not a multiple of π, which leaves no line in place, and a shear, which keeps exactly one. (Interactive in the web version.)

To find all eigenvalues, rewrite $T\mathbf{v} = \lambda\mathbf{v}$ as $(T - \lambda\,\mathrm{id})\mathbf{v} = \mathbf{0}$, which turns the search for eigenvalues into a question about kernels.

Theorem 7.2.9 (Eigenvalues and invertibility). Let $T \in \mathrm{L}(V)$ and $\lambda \in F$, and consider the conditions

(I) λ is an eigenvalue of T;

(II) $\ker(T - \lambda\,\mathrm{id}) \neq \{\mathbf{0}\}$, that is, $T - \lambda\,\mathrm{id}$ is not injective;

(III) $T - \lambda\,\mathrm{id}$ is not surjective;

(IV) $T - \lambda\,\mathrm{id}$ is not invertible.

Then (I) and (II) are equivalent. If V is finite-dimensional, all four are equivalent. In particular, λ is an eigenvalue of $A \in F^{n\times n}$ if and only if $A - \lambda I_n$ is not invertible, if and only if $\operatorname{rank}(A - \lambda I_n) < n$, if and only if $\det(A - \lambda I_n) = 0$.

Proof. ROUTINE

Uses. Definition 7.2.6 (Eigenvalue, eigenvector), Definition 2.1.21 (Pointwise operations), Theorem 2.6.11 (Injectivity is decided at $\mathbf{0}$), Corollary 4.2.18 (Injective if and only if surjective), Proposition 2.7.7 (Bijective linear maps are invertible), Corollary 3.5.25 (The invertible matrix theorem), Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 5.4.7 (Invertibility and the determinant)
Hint 1. Rewrite $T\mathbf{v} = \lambda\mathbf{v}$ using the operator $T - \lambda\,\mathrm{id}$.
Hint 2. For (I) $\Leftrightarrow$ (II), use Theorem 2.6.11. In finite dimensions, Corollary 4.2.18 compares (II), (III), and (IV).
Hint 3. For matrices, $T_{A-\lambda I_n} = T_A - \lambda\,\mathrm{id}$. Translate "not injective" with Corollary 3.5.25 and Theorem 5.4.7.
Sketch. $(T - \lambda\,\mathrm{id})\mathbf{v} = T\mathbf{v} - \lambda\mathbf{v}$, so the eigenvectors for λ are exactly the nonzero vectors of $\ker(T - \lambda\,\mathrm{id})$, and such vectors exist iff $T - \lambda\,\mathrm{id}$ is not injective. If V is finite-dimensional, an operator on V is injective iff surjective iff bijective iff invertible. For A, apply this to $T_A - \lambda\,\mathrm{id} = T_{A-\lambda I_n}$ and use the invertible matrix theorem and det.

By Definition 2.1.21, $(T - \lambda\,\mathrm{id})\mathbf{v} = T\mathbf{v} - \lambda\mathbf{v}$, so $T\mathbf{v} = \lambda\mathbf{v}$ if and only if $\mathbf{v} \in \ker(T - \lambda\,\mathrm{id})$. Hence λ is an eigenvalue if and only if $\ker(T - \lambda\,\mathrm{id})$ contains a nonzero vector, which proves (I) $\Leftrightarrow$ (II). The two forms of (II) are equivalent by Theorem 2.6.11, applied to the linear map $T - \lambda\,\mathrm{id}$.

Now let V be finite-dimensional. By Corollary 4.2.18, the operator $T - \lambda\,\mathrm{id}$ on V is injective if and only if it is surjective, if and only if it is bijective, and by Proposition 2.7.7 a bijective linear map is invertible (conversely, an invertible map is bijective). Negating, (II), (III), and (IV) are equivalent.

For $A \in F^{n\times n}$, $(A - \lambda I_n)\mathbf{x} = A\mathbf{x} - \lambda\mathbf{x}$ for every $\mathbf{x}$, so $T_{A-\lambda I_n} = T_A - \lambda\,\mathrm{id}$. Thus λ is an eigenvalue of A if and only if $T_{A-\lambda I_n}$ is not injective. By Theorem 3.5.12 and Corollary 3.5.25, this happens if and only if $\operatorname{rank}(A - \lambda I_n) < n$, if and only if $A - \lambda I_n$ is not invertible, and by Theorem 5.4.7 if and only if $\det(A - \lambda I_n) = 0$. □

The determinant condition is the practical one: $\det(xI_n - A)$ is a polynomial in x whose roots are the eigenvalues (Section 7.3). Until then we find eigenvalues by solving $A\mathbf{v} = \lambda\mathbf{v}$ directly, as in the examples below.

Remark 7.2.10 (Infinite dimensions). Without finite dimension, (III) and (IV) are not equivalent to (I). Multiplication by x on $F[x]$, $M(p) = xp$, is injective but not surjective (the constant 1 is not of the form xp). So $M - 0\,\mathrm{id} = M$ is not invertible, yet 0 is not an eigenvalue of M, since $xp = \mathbf{0}$ forces $p = \mathbf{0}$. In fact M has no eigenvalues at all (Example 7.2.20).

Exercise 7.2.11. ROUTINE Let $A = \begin{pmatrix} 1 & 2 & 0 \\ 2 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix} \in \mathbb{R}^{3\times 3}$. Decide which of the vectors

$$(1,1,0), \quad (1,-1,0), \quad (0,0,1), \quad (1,0,0), \quad (1,-1,1), \quad (1,1,1)$$

are eigenvectors of A, and give the eigenvalue of each one that is.

Solution on page 1564

Exercise 7.2.12. ROUTINE Let $T \in \mathrm{L}(V)$ be invertible. Show that 0 is not an eigenvalue of T, and that for $\lambda \neq 0$, a vector $\mathbf{v}$ is an eigenvector of T with eigenvalue λ if and only if it is an eigenvector of T^{-1} with eigenvalue λ^{-1}.

Solution on page 1564

The eigenvectors for a fixed λ, together with $\mathbf{0}$, form the kernel in Theorem 7.2.9(II). That kernel gets a name.

Definition 7.2.13 (Eigenspace). Let $T \in \mathrm{L}(V)$ and $\lambda \in F$. The **eigenspace** of T for λ is

$$E_\lambda = E_\lambda(T) = \ker(T - \lambda\,\mathrm{id}) = \{\mathbf{v} \in V \mid T\mathbf{v} = \lambda\mathbf{v}\}.$$

For $A \in F^{n\times n}$, $E_\lambda(A) = \ker(A - \lambda I_n)$ is the null space of $A - \lambda I_n$.

The eigenspace is defined for every $\lambda \in F$, and it is a subspace, being a kernel (Proposition 2.6.8). By Theorem 7.2.9, $E_\lambda \neq \{\mathbf{0}\}$ exactly when λ is an eigenvalue, and then E_λ consists of $\mathbf{0}$ and the eigenvectors for λ. Each eigenspace is T-invariant, since T acts on it as the scaling $\lambda\,\mathrm{id}$. The eigenvectors of T for all eigenvalues together, with $\mathbf{0}$ added, do not form a subspace in general, as Exercise 7.2.11 showed. Its dimension, $\dim E_\lambda$, is the geometric multiplicity of λ (Section 7.4).

Example 7.2.14 (Computing eigenspaces). Let $J \in \mathbb{R}^{3\times 3}$ be the matrix whose entries are all 1, and let

$$A = 2I_3 + J = \begin{pmatrix} 3 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 3 \end{pmatrix}.$$

Since $J(x,y,z) = (s,s,s)$ with $s = x + y + z$, we have $A\mathbf{v} = 2\mathbf{v} + s(1,1,1)$. So

$$E_2 = \ker J = \{(x,y,z) \mid x + y + z = 0\} = \operatorname{span}((1,-1,0),(0,1,-1)),$$

a plane, and $A(1,1,1) = (5,5,5)$, so 5 is an eigenvalue. To find all of E_5, row reduce $A - 5I_3$:

$$\begin{pmatrix} -2 & 1 & 1 \\ 1 & -2 & 1 \\ 1 & 1 & -2 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{pmatrix},$$

so $E_5 = \{(x,y,z) \mid x = z, y = z\} = \operatorname{span}((1,1,1))$. We will see right after Theorem 7.2.21 that 2 and 5 are the only eigenvalues of A.

7.2.3 A gallery of examples

The following operators will serve as examples and counterexamples for the rest of the chapter. In each case we solve $T\mathbf{v} = \lambda\mathbf{v}$ by hand.

Example 7.2.15 (Diagonal matrices). Let $D = \operatorname{diag}(d_1, \ldots, d_n)$. Then $D\mathbf{e}_i = d_i\mathbf{e}_i$, so each d_i is an eigenvalue, with eigenvector $\mathbf{e}_i$. There are no others: if $\lambda \neq d_i$ for every i, then $D - \lambda I_n = \operatorname{diag}(d_1 - \lambda, \ldots, d_n - \lambda)$ has inverse $\operatorname{diag}\big((d_1-\lambda)^{-1}, \ldots, (d_n-\lambda)^{-1}\big)$, so λ is not an eigenvalue by Theorem 7.2.9. The eigenspace E_λ is spanned by the $\mathbf{e}_i$ with $d_i = \lambda$, because $(D - \lambda I_n)\mathbf{x}$ has coordinates $(d_i - \lambda)x_i$, which all vanish exactly when $x_i = 0$ for every i with $d_i \neq \lambda$.

Example 7.2.16 (Projections). Let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$, for instance the projection Pr_ℓ of $\mathbb{R}^2$ onto a line ℓ (Example 2.1.11). If $P\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then

$$\lambda\mathbf{v} = P\mathbf{v} = P(P\mathbf{v}) = P(\lambda\mathbf{v}) = \lambda^2\mathbf{v},$$

so $\big(\lambda^2 - \lambda\big)\mathbf{v} = \mathbf{0}$ and $\lambda(\lambda - 1) = 0$. So the only possible eigenvalues are 0 and 1. Their eigenspaces are

$$E_1 = \operatorname{im} P, \quad E_0 = \ker P.$$

The second is the definition. For the first, if $\mathbf{v} = P\mathbf{w}$, then $P\mathbf{v} = P^2\mathbf{w} = P\mathbf{w} = \mathbf{v}$, and conversely $P\mathbf{v} = \mathbf{v}$ exhibits $\mathbf{v}$ as a value of P. For Pr_ℓ, $E_1 = \ell$ and E_0 is the line through $\mathbf{0}$ perpendicular to ℓ. Every vector is the sum of its components in these two eigenspaces, $\mathbf{v} = P\mathbf{v} + (\mathbf{v} - P\mathbf{v})$.

Example 7.2.17 (Reflections, and the field $\mathbb{F}_2$). Let $S \in \mathrm{L}(V)$ satisfy $S^2 = \mathrm{id}$, for instance the reflection S_ℓ of $\mathbb{R}^2$ across a line ℓ. If $S\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{v} = S^2\mathbf{v} = \lambda^2\mathbf{v}$, so $\lambda^2 = 1$, that is, $(\lambda - 1)(\lambda + 1) = 0$, and $\lambda = \pm 1$. For S_ℓ, $E_1 = \ell$ and E_{-1} is the perpendicular line.

Now take the swap $\sigma(x,y) = (y,x)$ on F^2, the reflection across the diagonal. Then $\sigma(1,1) = (1,1)$ and $\sigma(1,-1) = (-1,1) = -(1,-1)$. If $1 + 1 \neq 0$ in F, then $1 \neq -1$, and $(1,1)$, $(1,-1)$ are eigenvectors for the two different eigenvalues 1 and -1; they form a basis, in which σ has matrix $\operatorname{diag}(1,-1)$. Over $\mathbb{F}_2$, however, $-1 = 1$, and 1 is the only possible eigenvalue. Its eigenspace is $\ker(\sigma - \mathrm{id})$, and $(\sigma - \mathrm{id})(x,y) = (y - x, x - y)$, so $E_1 = \operatorname{span}((1,1))$ is a line. Over $\mathbb{F}_2$ the swap has no basis of eigenvectors, although it still satisfies $\sigma^2 = \mathrm{id}$.

Example 7.2.18 (Rotations). Let $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, so that $A(x,y) = (-y,x)$; over $\mathbb{R}$ this is the rotation $R_{\pi/2}$ by a right angle. Suppose $A(x,y) = \lambda(x,y)$, that is, $-y = \lambda x$ and $x = \lambda y$. Substituting each equation into the other gives

$$x = \lambda y = -\lambda^2 x, \quad y = -\lambda x = -\lambda^2 y, \quad \text{so} \quad \big(1 + \lambda^2\big)x = \big(1 + \lambda^2\big)y = 0.$$

So if $\lambda^2 \neq -1$, then $(x,y) = \mathbf{0}$, and λ is not an eigenvalue. If $\lambda^2 = -1$, then $(1,-\lambda)$ is an eigenvector: $A(1,-\lambda) = (\lambda,1) = \lambda(1,-\lambda)$, since $-\lambda^2 = 1$. So the eigenvalues of A are exactly the square roots of -1 in F:

- Over $\mathbb{R}$: none, since $\lambda^2 \geq 0 > -1$. A rotation by a right angle turns every line, so its only invariant subspaces are $\{\mathbf{0}\}$ and $\mathbb{R}^2$ (by Proposition 7.2.7 and Proposition 4.1.21, an invariant subspace other than these would be an invariant line).
- Over $\mathbb{C}$: $\lambda = i$ with eigenvector $(1,-i)$, and $\lambda = -i$ with eigenvector $(1,i)$.
- Over $\mathbb{F}_5$: $2^2 = 4 = -1$ and $3^2 = 9 = -1$, so the eigenvalues are 2 and 3, with eigenvectors $(1,-2) = (1,3)$ and $(1,-3) = (1,2)$.
- Over $\mathbb{F}_3$: the squares are $0, 1, 1$, and $-1 = 2$ is not among them, so there are no eigenvalues.
- Over $\mathbb{F}_2$: $-1 = 1$, so $\lambda = 1$, and A is the swap of Example 7.2.17, with the single eigenvector line $\operatorname{span}((1,1))$.

This is the polynomial x^2+1 of Section 7.1.5 in disguise: it has no real root, and accordingly the rotation has no eigenvalue.

Example 7.2.19 (Differentiation). Let D be differentiation on $F[x]$, over any field. We claim that 0 is its only eigenvalue. Suppose $Dp = \lambda p$ with $p \neq \mathbf{0}$. If p is a nonzero constant, then $Dp = \mathbf{0}$, so $\lambda p = \mathbf{0}$ and $\lambda = 0$. If $\deg p \geq 1$, then Dp is either $\mathbf{0}$ or of degree less than $\deg p$ (Example 2.1.9), while λp has degree $\deg p$ unless $\lambda = 0$; so again $\lambda = 0$. And 0 is an eigenvalue, as $D1 = \mathbf{0}$. Its eigenspace $E_0 = \ker D$ is the constants over $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$; over $\mathbb{F}_p$ it is larger, since $D(x^p) = px^{p-1} = \mathbf{0}$ (Example 4.1.28).

Contrast this with differentiation on the real vector space of infinitely differentiable functions $\mathbb{R} \to \mathbb{R}$. There, for every $\lambda \in \mathbb{R}$, the function $f_\lambda(t) = e^{\lambda t}$ satisfies $f_\lambda{}' = \lambda f_\lambda$, so every real number is an eigenvalue. For $\lambda \neq 0$ these eigenvectors are not polynomials.

Example 7.2.20 (Shifts). Write $p \in F[x]$ by its coefficient sequence $(a_0, a_1, a_2, \ldots)$ (Definition 1.2.13). Multiplication by x, M, shifts the sequence to the right, and the map L of Exercise 2.5.41,

$$L(a_0, a_1, a_2, \ldots) = (a_1, a_2, a_3, \ldots),$$

shifts it to the left. M has no eigenvalues: if $xp = \lambda p$ with $p \neq \mathbf{0}$, the left side has degree $\deg p + 1$ and the right side has degree at most $\deg p$. L lowers degrees like D, and the argument of Example 7.2.19 shows that 0 is its only eigenvalue, with $E_0 = \ker L$ the constants.

On the space F^X of all sequences $(x_0, x_1, \ldots)$, where $X = \{0, 1, 2, \ldots\}$ (Remark 1.2.11), the left shift L given by the same formula behaves differently. $L\mathbf{x} = \lambda\mathbf{x}$ says $x_{n+1} = \lambda x_n$ for all n, that is, $x_n = \lambda^n x_0$. So every $\lambda \in F$ is an eigenvalue, with

$$E_\lambda = \operatorname{span}\big((1, \lambda, \lambda^2, \lambda^3, \ldots)\big),$$

a line of geometric sequences. Only for $\lambda = 0$ is the eigenvector a polynomial.

Finally, on F^n the shift $N(x_1, \ldots, x_n) = (x_2, \ldots, x_n, 0)$ of Section 4.1.7 satisfies $N^n = 0$. If $N\mathbf{v} = \lambda\mathbf{v}$, then applying N repeatedly gives $\mathbf{0} = N^n\mathbf{v} = \lambda^n\mathbf{v}$, so $\lambda = 0$; and $E_0 = \ker N = \operatorname{span}(\mathbf{e}_1)$.

So an operator may have no eigenvalues (a rotation of $\mathbb{R}^2$, multiplication by x), a few, or every scalar (the left shift on sequences). In finite dimensions there are at most $\dim V$ eigenvalues, as we now show; over an infinite field, this rules out the last behavior.

7.2.4 Eigenvectors for distinct eigenvalues

In every example so far, eigenvectors for different eigenvalues pointed in different directions. They are in fact always linearly independent. The reason is that T treats them differently, and that difference can be used to separate them.

Intuition (Separating eigenvectors). Let $T\mathbf{v}_l = \lambda_l\mathbf{v}_l$. The operator $T - \mu\,\mathrm{id}$ multiplies each $\mathbf{v}_l$ by $\lambda_l - \mu$:

$$(T - \mu\,\mathrm{id})\mathbf{v}_l = T\mathbf{v}_l - \mu\mathbf{v}_l = (\lambda_l - \mu)\mathbf{v}_l.$$

Choosing $\mu = \lambda_j$ kills $\mathbf{v}_j$ and only rescales the others, by nonzero factors when the eigenvalues are distinct. So, given a linear relation among eigenvectors, we can apply such operators to destroy chosen terms of the relation while keeping control of the rest. There are two ways to organize this. We can kill all terms but one at once, using a product of such operators, or we can kill one term at a time and argue that a shortest relation cannot exist.

Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent). Let $T \in \mathrm{L}(V)$, and let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be eigenvectors of T with eigenvalues $\lambda_1, \ldots, \lambda_m$, which are pairwise distinct. Then $\mathbf{v}_1, \ldots, \mathbf{v}_m$ is linearly independent.

Proof (kill all terms but one). STANDARD

> *Uses.* Definition 7.2.6 (Eigenvalue, eigenvector), Definition 2.1.21 (Pointwise operations), Proposition 1.1.17 (No zero divisors), Proposition 1.2.35 (Zero products), Theorem 1.5.5 (Independence is decided at zero)
> *Techniques.* Apply an operator to a relation to kill terms (Technique 4.1.25)
> *Hint 1.* Take a relation $a_1\mathbf{v}_1 + \cdots + a_m\mathbf{v}_m = \mathbf{0}$ and fix an index i. Find an operator that sends $\mathbf{v}_l$ to $\mathbf{0}$ for every $l \neq i$, but not $\mathbf{v}_i$.
> *Hint 2.* Try the composite P_i of the operators $T - \lambda_j \operatorname{id}$ for all $j \neq i$. Each factor multiplies $\mathbf{v}_l$ by $\lambda_l - \lambda_j$.
> *Hint 3.* So $P_i\mathbf{v}_l = \prod_{j\neq i}(\lambda_l - \lambda_j)\mathbf{v}_l$. For $l \neq i$ the product contains the factor $\lambda_l - \lambda_l = 0$; for $l = i$ every factor is nonzero.
> *Sketch.* Let P_i be the composite of the $T - \lambda_j \operatorname{id}$, $j \neq i$. Since $(T - \lambda_j \operatorname{id})\mathbf{v}_l = (\lambda_l - \lambda_j)\mathbf{v}_l$, applying the factors one at a time gives $P_i\mathbf{v}_l = \prod_{j\neq i}(\lambda_l - \lambda_j)\mathbf{v}_l$, which is $\mathbf{0}$ for $l \neq i$ and a nonzero multiple of $\mathbf{v}_i$ for $l = i$. Applying P_i to a relation $\sum a_l\mathbf{v}_l = \mathbf{0}$ leaves $a_ic_i\mathbf{v}_i = \mathbf{0}$ with $c_i \neq 0$, so $a_i = 0$.

First, for every l and every $\mu \in F$,

$$(T - \mu \operatorname{id})\mathbf{v}_l = T\mathbf{v}_l - \mu\mathbf{v}_l = (\lambda_l - \mu)\mathbf{v}_l. \tag{7.2.1}$$

Suppose $a_1\mathbf{v}_1 + \cdots + a_m\mathbf{v}_m = \mathbf{0}$, and fix $i \in \{1, \ldots, m\}$. Let P_i be the composite, in increasing order of j, of the operators $T - \lambda_j \operatorname{id}$ with $j \neq i$. It is linear, as a composite of linear maps. Applying its factors to $\mathbf{v}_l$ one at a time, (7.2.1) shows that each factor multiplies $\mathbf{v}_l$ by a scalar, so

$$P_i\mathbf{v}_l = c_{il}\mathbf{v}_l, \quad \text{where} \quad c_{il} = \prod_{j\neq i}(\lambda_l - \lambda_j).$$

If $l \neq i$, the product c_{il} contains the factor $\lambda_l - \lambda_l = 0$ (the factor with $j = l$), so $c_{il} = 0$. If $l = i$, every factor $\lambda_i - \lambda_j$ is nonzero because the eigenvalues are distinct, so $c_{ii} \neq 0$ by Proposition 1.1.17. Applying P_i to the relation therefore gives

$$\mathbf{0} = P_i\left(\sum_{l=1}^{m} a_l\mathbf{v}_l\right) = \sum_{l=1}^{m} a_lc_{il}\mathbf{v}_l = a_ic_{ii}\mathbf{v}_i.$$

Since $\mathbf{v}_i \neq \mathbf{0}$, Proposition 1.2.35 gives $a_ic_{ii} = 0$, and since $c_{ii} \neq 0$, $a_i = 0$. This holds for every i, so the list is independent by Theorem 1.5.5. □

Proof (a shortest relation). STANDARD

> *Uses.* Definition 7.2.6 (Eigenvalue, eigenvector), Definition 1.5.3 (Linear relation), Proposition 1.2.35 (Zero products), Theorem 1.5.5 (Independence is decided at zero)
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9)
> *Hint 1.* Argue by contradiction. Among all nontrivial relations $\sum a_l\mathbf{v}_l = \mathbf{0}$, choose one with as few nonzero coefficients as possible.
> *Hint 2.* Pick k with $a_k \neq 0$ and apply $T - \lambda_k \operatorname{id}$ to the relation. Which coefficients of the new relation are nonzero?
> *Hint 3.* The new relation has coefficients $a_l(\lambda_l - \lambda_k)$: zero at $l = k$, and nonzero exactly where $a_l \neq 0$ for $l \neq k$. It is shorter, so it must be trivial.
> *Sketch.* Take a nontrivial relation with the fewest nonzero coefficients, and k with $a_k \neq 0$. Applying $T - \lambda_k \operatorname{id}$ gives the relation $\sum a_l(\lambda_l - \lambda_k)\mathbf{v}_l = \mathbf{0}$, which has strictly fewer nonzero coefficients, hence is trivial. So $a_l = 0$ for all $l \neq k$, and the original relation reads $a_k\mathbf{v}_k = \mathbf{0}$ with $a_k \neq 0$, contradicting $\mathbf{v}_k \neq \mathbf{0}$.

Suppose, for contradiction, that the list is linearly dependent. Then it has nontrivial linear relations (Theorem 1.5.5). Choose one, $a_1\mathbf{v}_1 + \cdots + a_m\mathbf{v}_m = \mathbf{0}$, in which the number of nonzero coefficients is as small as possible, and choose k with $a_k \neq 0$. Applying $T - \lambda_k \operatorname{id}$ and using (7.2.1),

$$\sum_{l=1}^{m} a_l(\lambda_l - \lambda_k)\mathbf{v}_l = \mathbf{0}.$$

In this relation the coefficient of $\mathbf{v}_k$ is 0, and for $l \neq k$ the coefficient $a_l(\lambda_l - \lambda_k)$ is nonzero exactly when $a_l \neq 0$, since $\lambda_l \neq \lambda_k$. So it has exactly one nonzero coefficient fewer than the chosen relation. By minimality it is not nontrivial: all its coefficients are 0, so $a_l = 0$ for every $l \neq k$. The chosen relation then reads $a_k\mathbf{v}_k = \mathbf{0}$ with $a_k \neq 0$, so $\mathbf{v}_k = \mathbf{0}$ by Proposition 1.2.35. This contradicts that $\mathbf{v}_k$ is an eigenvector. □

The first proof is constructive: the operator P_i isolates the i-th term of any combination of the $\mathbf{v}_l$, and after dividing by c_{ii} it extracts the coefficient a_i. In the language of Section 7.2.5 below, $c_{ii}^{-1}P_i$ is $L_i(T)$, where L_i is the Lagrange polynomial (Definition 3.4.26) for the nodes $\lambda_1, \dots, \lambda_m$ with $L_i(\lambda_l) = 0$ for $l \neq i$ and $L_i(\lambda_i) = 1$. The second proof needs only one operator at a time, and it is the argument the lecture gives as an induction on m: assuming the result for $m-1$ eigenvectors, apply $T - \lambda_m \mathrm{id}$. Choosing a shortest relation does that induction in one step.

Corollary 7.2.22 (At most $\dim V$ eigenvalues). If V is finite-dimensional, an operator $T \in \mathrm{L}(V)$ has at most $\dim V$ distinct eigenvalues. In particular, $A \in F^{n\times n}$ has at most n eigenvalues.

Proof. ROUTINE

Uses. Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Theorem 4.1.10 (Independent lists are short)
Hint 1. Choose one eigenvector for each of m distinct eigenvalues.
Hint 2. Compare the length of that list with $\dim V$.
Sketch. Eigenvectors $\mathbf{v}_1, \dots, \mathbf{v}_m$ for m distinct eigenvalues form an independent list by Theorem 7.2.21, so $m \leq \dim V$.

Let $\lambda_1, \dots, \lambda_m$ be distinct eigenvalues of T, and choose an eigenvector $\mathbf{v}_i$ for each λ_i. By Theorem 7.2.21 the list $\mathbf{v}_1, \dots, \mathbf{v}_m$ is independent, so $m \leq \dim V$ by Theorem 4.1.10(a). The statement for A is the case $T = T_A$, $V = F^n$. □

So the symmetric matrix of Example 7.2.8 has no eigenvalues besides 3 and 1. The theorem also says something about whole eigenspaces.

Corollary 7.2.23 (Eigenspaces are independent). Let $\lambda_1, \dots, \lambda_m \in F$ be distinct. Then the sum $E_{\lambda_1} + \cdots + E_{\lambda_m}$ of the eigenspaces of T is direct. If V is finite-dimensional, then

$$\dim E_{\lambda_1} + \cdots + \dim E_{\lambda_m} \leq \dim V.$$

Proof. STANDARD

Uses. Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Theorem 4.4.7 (Criteria for direct sums), Definition 4.4.4 (Direct sum), Theorem 4.1.10 (Independent lists are short), Theorem 1.5.5 (Independence is decided at zero)
Hint 1. By Theorem 4.4.7, it suffices to show: if $\mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{0}$ with $\mathbf{u}_i \in E_{\lambda_i}$, then every $\mathbf{u}_i = \mathbf{0}$. Which of the $\mathbf{u}_i$ are eigenvectors?
Hint 2. For the dimension bound, concatenate bases of the eigenspaces and show that the long list is independent.
Sketch. The nonzero $\mathbf{u}_i$ in $\mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{0}$ are eigenvectors for distinct eigenvalues, and the equation is a relation among them with all coefficients 1, so by Theorem 7.2.21 there are none. For the bound, a relation among the concatenated bases groups into $\mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{0}$ with $\mathbf{u}_i \in E_{\lambda_i}$, so each $\mathbf{u}_i = \mathbf{0}$, and independence of each basis kills the coefficients.

Suppose $\mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{0}$ with $\mathbf{u}_i \in E_{\lambda_i}$, and let $I = \{i \mid \mathbf{u}_i \neq \mathbf{0}\}$. For $i \in I$, $\mathbf{u}_i$ is an eigenvector with eigenvalue λ_i, and these eigenvalues are distinct. If I were nonempty, $\sum_{i\in I} 1 \cdot \mathbf{u}_i = \mathbf{0}$ would be a nontrivial relation among them, contradicting Theorem 7.2.21. So I is empty, every $\mathbf{u}_i$ is $\mathbf{0}$, and the sum is direct by the implication (II) ⇒ (I) of Theorem 4.4.7.

Now let V be finite-dimensional, let $d_i = \dim E_{\lambda_i}$, and choose a basis $\mathbf{b}_{i1}, \dots, \mathbf{b}_{id_i}$ of each E_{λ_i}. Suppose $\sum_{i=1}^{m}\sum_{j=1}^{d_i} a_{ij}\mathbf{b}_{ij} = \mathbf{0}$. With $\mathbf{u}_i = \sum_j a_{ij}\mathbf{b}_{ij} \in E_{\lambda_i}$ this reads $\mathbf{u}_1 + \cdots + \mathbf{u}_m = \mathbf{0}$, so every $\mathbf{u}_i = \mathbf{0}$ by the first part, and then every $a_{ij} = 0$ because the $\mathbf{b}_{ij}$ with fixed i are independent. So the concatenated list, of length $d_1 + \cdots + d_m$, is independent, and $d_1 + \cdots + d_m \leq \dim V$ by Theorem 4.1.10(a). □

For the matrix $A = 2I_3 + J$ of Example 7.2.14, $\dim E_2 + \dim E_5 = 2 + 1 = 3$. If A had a third eigenvalue λ, its eigenspace would add at least 1 to this sum, which would then exceed $\dim \mathbb{R}^3 = 3$. So 2 and 5 are the only eigenvalues. When the dimensions of the eigenspaces add up to $\dim V$, concatenating their bases gives a basis of eigenvectors; this is the starting point of Section 7.4.

Example 7.2.24 (Independence for free). Two independence results from earlier chapters are instances of the theorem.

(a) The geometric sequences $\left(1, \lambda_i, \lambda_i^2, \ldots\right)$ for distinct $\lambda_1, \ldots, \lambda_k \in F$ are eigenvectors of the left shift on F^X with the distinct eigenvalues λ_i (Example 7.2.20). So they are independent, which is Exercise 1.5.44.

(b) The functions $t \mapsto e^{\lambda_i t}$ for distinct real λ_i are eigenvectors of differentiation with distinct eigenvalues (Example 7.2.19), so they are independent, which is Example 1.5.27 and its generalization.

Exercise 7.2.25. ROUTINE Let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be eigenvectors of T with distinct eigenvalues $\lambda_1, \ldots, \lambda_m$, where $m \geq 2$. Show that $\mathbf{v}_1 + \cdots + \mathbf{v}_m$ is not an eigenvector of T.

Solution on page 1565

7.2.5 Polynomials in an operator

The proofs above composed operators of the form $T - \lambda\,\mathrm{id}$. Such composites are polynomials in T, and polynomials in T are the natural source of operators that interact well with T.

Definition 7.2.26 (Polynomials in an operator). Let $T \in \mathrm{L}(V)$ and $p = a_0 + a_1 x + \cdots + a_d x^d \in F[x]$. Then

$$p(T) = a_0 \mathrm{id}_V + a_1 T + a_2 T^2 + \cdots + a_d T^d \in \mathrm{L}(V),$$

where T^k is the k-fold composite (Notation 2.1.18) and $T^0 = \mathrm{id}_V$. For a matrix $A \in F^{n\times n}$, $p(A) = a_0 I_n + a_1 A + \cdots + a_d A^d$, as in Remark 7.1.11.

For example, if $p = x^2 - 3x + 2 = (x-1)(x-2)$, then $p(T) = T^2 - 3T + 2\,\mathrm{id}$, and the next proposition shows that this equals $(T - \mathrm{id})(T - 2\,\mathrm{id})$, and also $(T - 2\,\mathrm{id})(T - \mathrm{id})$.

Proposition 7.2.27 (Evaluating polynomials at an operator). Let $T \in \mathrm{L}(V)$, $p, q \in F[x]$, and $c \in F$.

(a) $(p+q)(T) = p(T) + q(T)$, $(cp)(T) = cp(T)$, and $(pq)(T) = p(T)q(T)$, where the product of operators is composition.

(b) In particular $p(T)q(T) = q(T)p(T)$, and $p(T)$ commutes with T.

(c) If V is finite-dimensional and $\mathcal{B}$ is a basis of V, then $[p(T)]_{\mathcal{B}\mathcal{B}} = p([T]_{\mathcal{B}\mathcal{B}})$.

(d) Every T-invariant subspace is $p(T)$-invariant.

Proof. ROUTINE

Uses. Proposition 7.1.10 (Evaluation respects sums and products), Remark 7.1.11 (Polynomials in a matrix), Proposition 2.1.24 (Algebra of composition), Notation 2.1.18, Theorem 2.4.2 (The matrix of a composite), Proposition 7.2.4 (Invariance is checked on a spanning list)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. For (a), copy the proof of Proposition 7.1.10. Which facts about multiplication did it use, and do they hold for composition of operators?
Hint 2. It used $t^i t^j = t^{i+j}$, distributivity, and that scalars commute with powers of t. For operators these are Notation 2.1.18 and Proposition 2.1.24. Then (b) is (a) with $pq = qp$.
Hint 3. For (d), show by induction that $T^k \mathbf{u} \in U$ for $\mathbf{u} \in U$, then take a combination.
Sketch. The proof of Proposition 7.1.10 used only $t^i t^j = t^{i+j}$, that multiplication distributes over sums, and that scalars commute with powers of t; all three hold for composition of operators (Proposition 2.1.24), so (a) follows, as for matrices in Remark 7.1.11. (b) is $p(T)q(T) = (pq)(T) = (qp)(T) = q(T)p(T)$ with $q = x$. (c): $T \mapsto [T]_{\mathcal{B}\mathcal{B}}$ respects sums, scalar multiples, and composites. (d): T^k maps U into U by induction, and $p(T)\mathbf{u}$ is a combination of the $T^k\mathbf{u}$.

(a) The proof of Proposition 7.1.10, with $t = T$, used only three facts: $t^i t^j = t^{i+j}$; multiplication distributes over sums on both sides; and scalars can be moved past powers of t, $\left(at^i\right)\left(bt^j\right) = (ab)t^{i+j}$. For composition of operators, the first is Notation 2.1.18 and the other two are Proposition 2.1.24. Commutativity of t with

itself was never needed beyond $t^i t^j = t^{i+j}$. So the same computation proves (a), exactly as for matrices in Remark 7.1.11.

(b) Since $F[x]$ is commutative, $pq = qp$, so by (a), $p(T)q(T) = (pq)(T) = (qp)(T) = q(T)p(T)$. Taking $q = x$, for which $q(T) = T$, shows that $p(T)T = Tp(T)$.

(c) Write $A = [T]_{\mathcal{BB}}$. By Theorem 2.4.2 and induction on k, $\left[T^k\right]_{\mathcal{BB}} = A^k$, and $[\mathrm{id}_V]_{\mathcal{BB}} = I_n$ with $n = \dim V$. The map $S \mapsto [S]_{\mathcal{BB}}$ respects sums and scalar multiples, so $\left[\sum_k a_k T^k\right]_{\mathcal{BB}} = \sum_k a_k A^k = p(A)$.

(d) Let U be T-invariant and $\mathbf{u} \in U$. Then $T^0\mathbf{u} = \mathbf{u} \in U$, and if $T^k\mathbf{u} \in U$, then $T^{k+1}\mathbf{u} = T\left(T^k\mathbf{u}\right) \in U$. So every $T^k\mathbf{u}$ lies in U, and so does the linear combination $p(T)\mathbf{u} = \sum_k a_k T^k\mathbf{u}$. □

Proposition 7.2.28 (Polynomials act on eigenvectors by their values). Let $T \in \mathrm{L}(V)$, and let $\mathbf{v}$ be an eigenvector of T with eigenvalue λ. Then for every $p \in F[x]$,

$$p(T)\mathbf{v} = p(\lambda)\mathbf{v}.$$

Consequently, if $p(T) = 0$, then every eigenvalue of T is a root of p.

Proof. ROUTINE

Uses. Definition 7.2.26 (Polynomials in an operator), Definition 1.2.17 (Evaluation), Proposition 1.2.35 (Zero products)
Hint 1. First show $T^k\mathbf{v} = \lambda^k\mathbf{v}$ by induction on k.
Hint 2. For the consequence, apply $p(T) = 0$ to an eigenvector.
Sketch. By induction, $T^k\mathbf{v} = \lambda^k\mathbf{v}$, so $p(T)\mathbf{v} = \sum a_k\lambda^k\mathbf{v} = p(\lambda)\mathbf{v}$. If $p(T) = 0$ and $\mathbf{v}$ is an eigenvector for λ, then $p(\lambda)\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$, so $p(\lambda) = 0$.

We have $T^0\mathbf{v} = \mathbf{v} = \lambda^0\mathbf{v}$, and if $T^k\mathbf{v} = \lambda^k\mathbf{v}$, then $T^{k+1}\mathbf{v} = T\left(\lambda^k\mathbf{v}\right) = \lambda^k T\mathbf{v} = \lambda^{k+1}\mathbf{v}$. So for $p = \sum_k a_k x^k$,

$$p(T)\mathbf{v} = \sum_k a_k T^k\mathbf{v} = \sum_k a_k\lambda^k\mathbf{v} = p(\lambda)\mathbf{v}.$$

If $p(T) = 0$ and λ is an eigenvalue with eigenvector $\mathbf{v}$, then $\mathbf{0} = p(T)\mathbf{v} = p(\lambda)\mathbf{v}$, so $p(\lambda) = 0$ by Proposition 1.2.35. □

This explains the computations in Example 7.2.16, Example 7.2.17, and Example 7.2.20 at once. A projection satisfies $p(P) = 0$ for $p = x^2 - x$, so its eigenvalues lie among the roots $0, 1$. An involution satisfies $x^2 - 1$, with roots ± 1. A nilpotent operator satisfies x^m, whose only root is 0. The cyclic permutation Z of Example 7.2.2 satisfies $Z^3 = \mathrm{id}$, so its eigenvalues are cube roots of 1: over $\mathbb{R}$ the only candidate is 1, and over $\mathbb{C}$ the candidates are $1, \omega, \omega^2$, where $\omega = e^{2\pi i/3}$. The converse fails: the identity satisfies $x^2 - x$, but 0 is not one of its eigenvalues. A polynomial with $p(T) = 0$ only bounds the eigenvalues; Section 7.6 finds the polynomial that pins them down exactly.

Exercise 7.2.29. ROUTINE Let $T \in \mathrm{L}(V)$ satisfy $T^2 = 5T - 6\,\mathrm{id}$.

(a) Show that every eigenvalue of T is 2 or 3.

(b) Assume $1 + 1 \neq 0$ in F. Show that $T - 4\,\mathrm{id}$ is invertible, and write its inverse as a polynomial in T.

Solution on page 1565

The commutativity in Proposition 7.2.27(b) has a geometric consequence, which is the main source of invariant subspaces in this book.

Proposition 7.2.30 (Kernels and images of commuting operators are invariant). Let $S, T \in \mathrm{L}(V)$ with $ST = TS$. Then $\ker S$ and $\operatorname{im} S$ are T-invariant. In particular:

(a) for every $p \in F[x]$, $\ker p(T)$ and $\operatorname{im} p(T)$ are T-invariant;

(b) every eigenspace $E_\lambda(S)$ of S is T-invariant.

Proof. ROUTINE

Uses. Definition 2.6.5 (Kernel), Definition 2.6.6 (Image), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 7.2.13 (Eigenspace), Proposition 2.1.24 (Algebra of composition)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Take $\mathbf{v} \in \ker S$ and compute $S(T\mathbf{v})$, moving T to the left with $ST = TS$.
Hint 2. For $\operatorname{im} S$, write the vector as $S\mathbf{w}$ and rewrite $TS\mathbf{w}$ as a value of S.
Hint 3. For (a) and (b), find an operator that commutes with T and has the given kernel or image.
Sketch. If $S\mathbf{v} = \mathbf{0}$, then $ST\mathbf{v} = TS\mathbf{v} = \mathbf{0}$. And $T(S\mathbf{w}) = S(T\mathbf{w}) \in \operatorname{im} S$. Then (a) is the case $S = p(T)$, which commutes with T by Proposition 7.2.27(b), and (b) is the case $S - \lambda \operatorname{id}$, which commutes with T because S and id do.

Let $\mathbf{v} \in \ker S$. Then $S(T\mathbf{v}) = T(S\mathbf{v}) = T\mathbf{0} = \mathbf{0}$, so $T\mathbf{v} \in \ker S$. Let $\mathbf{u} \in \operatorname{im} S$, say $\mathbf{u} = S\mathbf{w}$. Then $T\mathbf{u} = TS\mathbf{w} = S(T\mathbf{w}) \in \operatorname{im} S$. (This is part (a) of Exercise 2.6.52.)

(a) $p(T)$ commutes with T by Proposition 7.2.27(b), so the first part applies with $S = p(T)$.

(b) By Proposition 2.1.24, $(S - \lambda \operatorname{id})T = ST - \lambda T = TS - \lambda T = T(S - \lambda \operatorname{id})$. Apply the first part to $S - \lambda \operatorname{id}$, whose kernel is $E_\lambda(S)$. □

Technique 7.2.31 (Look for invariant subspaces among kernels and images of commuting operators). To find subspaces that T maps into themselves, look for operators S with $ST = TS$: the kernel and the image of each such S, and each eigenspace of S, are T-invariant. Polynomials in T always commute with T (Proposition 7.2.27), so $\ker(T - \lambda \operatorname{id})^k$, $\operatorname{im}(T - \lambda \operatorname{id})^k$, and $\ker p(T)$ are always available. Conversely, if the operators at hand commute, an eigenspace of one is a space on which the others act, and the problem can often be reduced to that smaller space.

Reach for it when a problem involves two operators that commute, or when you need an invariant subspace of T and have a polynomial identity for T. The canonical example is Proposition 7.2.30. Generalized eigenspaces $\ker(T - \lambda \operatorname{id})^k$ (Section 10.1) and common eigenvectors of commuting operators (Section 7.6) rest on the same observation.
Used in. Exercise 7.2.47, Exercise 7.2.48, Exercise 7.2.55, Exercise 7.4.50, Exercise 7.4.51, Proposition 7.6.12, Theorem 7.6.28, Theorem 7.6.31, Theorem 7.6.34, Exercise 7.7.6, Exercise 7.7.12, Exercise 7.7.13, Problem 7.4, Exercise 8.2.36, Exercise 7.4.36.

Example 7.2.32 (What commutes with a diagonal matrix). Let $D = \operatorname{diag}(d_1, \ldots, d_n)$ with distinct d_i, and suppose $SD = DS$ for some $S \in F^{n \times n}$. Each eigenspace $E_{d_i}(D) = \operatorname{span}(\mathbf{e}_i)$ (Example 7.2.15) is S-invariant by Proposition 7.2.30(b), so $\mathbf{e}_i$ is an eigenvector of S by Proposition 7.2.7: $S\mathbf{e}_i = s_i\mathbf{e}_i$. That is, the i-th column of S is $s_i\mathbf{e}_i$, and S is diagonal. This recovers Exercise 2.4.42 without computing a single entry of $SD - DS$. If two of the d_i coincide, the eigenspace is a plane, and S only has to preserve the plane, so non-diagonal S appear.

7.2.6 Krylov subspaces and chains

Given a single vector $\mathbf{v}$, what is the smallest T-invariant subspace containing it? It must contain $T\mathbf{v}$, then $T^2\mathbf{v}$, and so on, and all their linear combinations. These combinations are exactly the vectors $p(T)\mathbf{v}$.

Definition 7.2.33 (Krylov subspace). Let $T \in \mathrm{L}(V)$ and $\mathbf{v} \in V$. The **Krylov subspace** (or **cyclic subspace**) of $\mathbf{v}$ under T is

$$K_T(\mathbf{v}) = \{p(T)\mathbf{v} \mid p \in F[x]\},$$

the set of all finite linear combinations of $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$.

Proposition 7.2.34 (The smallest invariant subspace containing a vector). Let $T \in \mathrm{L}(V)$ and $\mathbf{v} \in V$. Then $K_T(\mathbf{v})$ is a T-invariant subspace containing $\mathbf{v}$, and it is contained in every T-invariant subspace that contains $\mathbf{v}$.

Proof. ROUTINE

Uses. Definition 7.2.33 (Krylov subspace), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 1.4.1 (Subspace), Definition 7.2.1 (Invariant subspace)
Hint 1. Use Proposition 7.2.27(a): $p(T)\mathbf{v} + cq(T)\mathbf{v} = (p+cq)(T)\mathbf{v}$ and $Tp(T)\mathbf{v} = (xp)(T)\mathbf{v}$.
Hint 2. For minimality, take an invariant U containing $\mathbf{v}$, and use Proposition 7.2.27(d).
Sketch. $K_T(\mathbf{v})$ contains $\mathbf{0} = \mathbf{0}(T)\mathbf{v}$ and $\mathbf{v} = 1(T)\mathbf{v}$, is closed under combinations by $(p+cq)(T) = p(T) + cq(T)$, and is invariant because $Tp(T)\mathbf{v} = (xp)(T)\mathbf{v}$. If U is invariant and $\mathbf{v} \in U$, then $p(T)\mathbf{v} \in U$ by Proposition 7.2.27(d).

The constant polynomials $\mathbf{0}$ and 1 give $\mathbf{0} = \mathbf{0}(T)\mathbf{v}$ and $\mathbf{v} = \mathrm{id}\,\mathbf{v} = 1(T)\mathbf{v}$, so $\mathbf{0}, \mathbf{v} \in K_T(\mathbf{v})$. For $p, q \in F[x]$ and $c \in F$, Proposition 7.2.27(a) gives

$$p(T)\mathbf{v} + cq(T)\mathbf{v} = (p+cq)(T)\mathbf{v} \in K_T(\mathbf{v}), \quad T(p(T)\mathbf{v}) = (xp)(T)\mathbf{v} \in K_T(\mathbf{v}).$$

So $K_T(\mathbf{v})$ is a subspace (Definition 1.4.1), and it is T-invariant. If U is a T-invariant subspace with $\mathbf{v} \in U$, then U is $p(T)$-invariant for every p by Proposition 7.2.27(d), so $p(T)\mathbf{v} \in U$, and $K_T(\mathbf{v}) \subseteq U$. □

In particular, $K_T(\mathbf{v})$ is a line exactly when $\mathbf{v}$ is an eigenvector, and $\{\mathbf{0}\}$ exactly when $\mathbf{v} = \mathbf{0}$. In finite dimensions the sequence $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ must eventually become dependent, and the first dependence tells us everything about $K_T(\mathbf{v})$.

Proposition 7.2.35 (A basis of a Krylov subspace). Let $T \in \mathrm{L}(V)$ and $\mathbf{v} \in V$ with $\mathbf{v} \neq \mathbf{0}$, and suppose $K_T(\mathbf{v})$ is finite-dimensional (for instance, V is). Then there is a smallest integer $d \geq 1$ with

$$T^d\mathbf{v} \in \operatorname{span}\left(\mathbf{v}, T\mathbf{v}, \ldots, T^{d-1}\mathbf{v}\right),$$

and for this d:

(a) $\mathbf{v}, T\mathbf{v}, \ldots, T^{d-1}\mathbf{v}$ is a basis of $K_T(\mathbf{v})$, so $\dim K_T(\mathbf{v}) = d$;

(b) writing $T^d\mathbf{v} = -\left(c_0\mathbf{v} + c_1T\mathbf{v} + \cdots + c_{d-1}T^{d-1}\mathbf{v}\right)$, the monic polynomial $p = x^d + c_{d-1}x^{d-1} + \cdots + c_0$ satisfies $p(T)\mathbf{v} = \mathbf{0}$, and no nonzero polynomial of degree less than d sends $\mathbf{v}$ to $\mathbf{0}$.

Proof. STANDARD

Uses. Lemma 1.5.10 (Linear dependence lemma), Theorem 4.1.10 (Independent lists are short), Proposition 7.2.4 (Invariance is checked on a spanning list), Proposition 7.2.34 (The smallest invariant subspace containing a vector), Theorem 1.5.5 (Independence is decided at zero)
Techniques. Too many vectors force a dependence (Technique 4.1.30), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. For existence of d: if $\dim K_T(\mathbf{v}) = m$, the $m+1$ vectors $\mathbf{v}, \ldots, T^m\mathbf{v}$ lie in $K_T(\mathbf{v})$. Apply the linear dependence lemma.
Hint 2. Independence of $\mathbf{v}, \ldots, T^{d-1}\mathbf{v}$: if they were dependent, the linear dependence lemma would produce a smaller d.
Hint 3. Spanning: show that $W = \operatorname{span}\left(\mathbf{v}, \ldots, T^{d-1}\mathbf{v}\right)$ is T-invariant by checking the spanning vectors, then use Proposition 7.2.34.
Sketch. The $m+1$ vectors $\mathbf{v}, \ldots, T^m\mathbf{v}$ in the m-dimensional $K_T(\mathbf{v})$ are dependent, and the linear dependence lemma gives some $T^j\mathbf{v}$ in the span of the earlier ones, with $j \geq 1$ as $\mathbf{v} \neq \mathbf{0}$; so d exists. The same lemma shows that $\mathbf{v}, \ldots, T^{d-1}\mathbf{v}$ is independent, by minimality of d. Their span W is invariant, since T sends each $T^i\mathbf{v}$ to the next one and $T^d\mathbf{v} \in W$; so $K_T(\mathbf{v}) \subseteq W \subseteq K_T(\mathbf{v})$. In (b), a polynomial of degree less than d killing $\mathbf{v}$ is a relation among the basis vectors.

Let $m = \dim K_T(\mathbf{v})$. The vectors $\mathbf{v}, T\mathbf{v}, \ldots, T^m\mathbf{v}$ lie in $K_T(\mathbf{v})$, and there are $m+1$ of them, so they are dependent (Theorem 4.1.10(a)). By Lemma 1.5.10 some $T^j\mathbf{v}$, $0 \leq j \leq m$, lies in the span of $\mathbf{v}, \ldots, T^{j-1}\mathbf{v}$. Here $j \neq 0$, because the span of the empty list is $\{\mathbf{0}\}$ and $\mathbf{v} \neq \mathbf{0}$. So the set of integers $d \geq 1$ with $T^d\mathbf{v} \in \operatorname{span}\left(\mathbf{v}, \ldots, T^{d-1}\mathbf{v}\right)$ is nonempty, and it has a smallest element d.

(a) If $\mathbf{v}, \ldots, T^{d-1}\mathbf{v}$ were dependent, Lemma 1.5.10 would give $j \leq d-1$ with $T^j\mathbf{v} \in \operatorname{span}\left(\mathbf{v}, \ldots, T^{j-1}\mathbf{v}\right)$, and as before $j \geq 1$; this contradicts the minimality of d. So the list is independent. Let W be its span. For $i < d-1$, $T\left(T^i\mathbf{v}\right) = T^{i+1}\mathbf{v} \in W$, and $T\left(T^{d-1}\mathbf{v}\right) = T^d\mathbf{v} \in W$ by the choice of d. So W is T-invariant by Proposition 7.2.4, and it contains $\mathbf{v}$, so $K_T(\mathbf{v}) \subseteq W$ by Proposition 7.2.34. Conversely, each $T^i\mathbf{v}$ lies in $K_T(\mathbf{v})$, so $W \subseteq K_T(\mathbf{v})$. Hence $W = K_T(\mathbf{v})$, and the list is a basis.

(b) By the choice of $c_0, \dots, c_{d-1}$,

$$p(T)\mathbf{v} = T^d\mathbf{v} + c_{d-1}T^{d-1}\mathbf{v} + \cdots + c_0\mathbf{v} = \mathbf{0}.$$

If $q = b_0 + b_1x + \cdots + b_{d-1}x^{d-1}$ satisfies $q(T)\mathbf{v} = \mathbf{0}$, then $b_0\mathbf{v} + \cdots + b_{d-1}T^{d-1}\mathbf{v} = \mathbf{0}$ is a linear relation among the basis vectors of (a), so every $b_i = 0$ and $q = \mathbf{0}$ (Theorem 1.5.5). □

In the basis of (a), T shifts each basis vector to the next, except that the last one goes to $T^d\mathbf{v} = -\sum c_iT^i\mathbf{v}$. So the matrix of $T\restriction_{K_T(\mathbf{v})}$ has 1's just below the diagonal, the numbers $-c_0, \dots, -c_{d-1}$ in its last column, and 0's elsewhere. This is the companion matrix of p, which reappears in Section 7.3.

Example 7.2.36 (Krylov subspaces of the cyclic permutation). Let $Z(x, y, z) = (z, x, y)$ on F^3.

(a) For $\mathbf{v} = (1, 1, 1)$, $Z\mathbf{v} = \mathbf{v}$, so $d = 1$, $p = x - 1$, and $K_Z(\mathbf{v})$ is the line $\operatorname{span}(\mathbf{v})$.

(b) For $\mathbf{v} = (1, -1, 0)$, $Z\mathbf{v} = (0, 1, -1)$, which is not a multiple of $\mathbf{v}$, and $Z^2\mathbf{v} = (-1, 0, 1) = -\mathbf{v} - Z\mathbf{v}$. So $d = 2$, $p = x^2 + x + 1$, and $K_Z(\mathbf{v}) = \operatorname{span}((1, -1, 0), (0, 1, -1))$ is the plane $x + y + z = 0$.

(c) For $\mathbf{v} = \mathbf{e}_1$, the vectors $\mathbf{e}_1, Z\mathbf{e}_1 = \mathbf{e}_2, Z^2\mathbf{e}_1 = \mathbf{e}_3$ are independent and $Z^3\mathbf{e}_1 = \mathbf{e}_1$. So $d = 3$, $p = x^3 - 1$, and $K_Z(\mathbf{e}_1) = F^3$.

The polynomials fit together: $x^3 - 1 = (x - 1)\big(x^2 + x + 1\big)$, the line in (a) and the plane in (b) are the two invariant subspaces of Example 7.2.2, and $\mathbf{e}_1 = \frac{1}{3}(1, 1, 1) + \frac{1}{3}(2, -1, -1)$ splits along them (when $3 \neq 0$ in F).

Chains

The Krylov sequence of $\mathbf{v}$ can also end by reaching $\mathbf{0}$. In Section 4.1.7 we proved that if $T^k\mathbf{v} \neq \mathbf{0}$ and $T^{k+1}\mathbf{v} = \mathbf{0}$, then $\mathbf{v}, T\mathbf{v}, \dots, T^k\mathbf{v}$ is independent (Proposition 4.1.26). The same holds with T replaced by $T - \lambda\,\mathrm{id}$, and in that form the chain carries information about eigenvalues: its last nonzero vector is an eigenvector.

Proposition 7.2.37 (Chains are independent). Let $T \in \mathrm{L}(V)$, $\lambda \in F$, and $N = T - \lambda\,\mathrm{id}$. Let $\mathbf{v} \in V$ and $k \geq 0$ satisfy

$$N^k\mathbf{v} \neq \mathbf{0} \quad \text{and} \quad N^{k+1}\mathbf{v} = \mathbf{0}.$$

Then $\mathbf{v}, N\mathbf{v}, N^2\mathbf{v}, \dots, N^k\mathbf{v}$ is linearly independent.

For $\lambda = 0$ this is Proposition 4.1.26. Every power N^j with $j \geq k + 1$ kills $\mathbf{v}$, since $N^j\mathbf{v} = N^{j-k-1}\big(N^{k+1}\mathbf{v}\big) = \mathbf{0}$. So applying a power of N to a combination of the chain pushes every term toward the end of the chain, and terms that are pushed past $N^k\mathbf{v}$ disappear. The two proofs below use this in different ways.

Proof (peel off the coefficients). STANDARD

Uses. Theorem 1.5.5 (Independence is decided at zero), Notation 2.1.18, Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Proposition 1.2.35 (Zero products)
Techniques. Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Take a relation $a_0\mathbf{v} + a_1N\mathbf{v} + \cdots + a_kN^k\mathbf{v} = \mathbf{0}$ and apply N^k. Which terms survive?
Hint 2. Only $a_0N^k\mathbf{v}$ survives, so $a_0 = 0$. Now apply N^{k-1} to what is left.
Hint 3. Prove $a_i = 0$ by induction on i: if $a_0 = \cdots = a_{i-1} = 0$, apply N^{k-i}.
Sketch. Let $\sum_{j=0}^{k} a_jN^j\mathbf{v} = \mathbf{0}$. Assume $a_j = 0$ for $j < i$ and apply N^{k-i}: the term $j = i$ becomes $a_iN^k\mathbf{v}$, and every term with $j > i$ becomes $N^{k+(j-i)}\mathbf{v} = \mathbf{0}$. So $a_iN^k\mathbf{v} = \mathbf{0}$, and $a_i = 0$ because $N^k\mathbf{v} \neq \mathbf{0}$. By induction all $a_i = 0$.

Suppose that

$$a_0\mathbf{v} + a_1N\mathbf{v} + \cdots + a_kN^k\mathbf{v} = \mathbf{0}. \tag{7.2.2}$$

We show $a_i = 0$ by induction on $i \in \{0, \dots, k\}$. Let i be given and assume $a_j = 0$ for all $j < i$ (no assumption when $i = 0$). Then (7.2.2) reads $\sum_{j=i}^{k} a_jN^j\mathbf{v} = \mathbf{0}$. Applying the linear map N^{k-i},

$$\mathbf{0} = \sum_{j=i}^{k} a_j N^{k-i+j}\mathbf{v} = a_i N^k \mathbf{v} + \sum_{j=i+1}^{k} a_j N^{k+(j-i)}\mathbf{v} = a_i N^k \mathbf{v},$$

because each exponent $k + (j - i)$ in the last sum is at least $k + 1$. As $N^k\mathbf{v} \neq \mathbf{0}$, Proposition 1.2.35 gives $a_i = 0$. So all $a_i = 0$, and the list is independent by Theorem 1.5.5. □

Proof (lowest nonzero coefficient). STANDARD

Uses. Theorem 1.5.5 (Independence is decided at zero), Notation 2.1.18, Proposition 2.1.4 (Linear maps preserve $\mathbf{0}$ and negatives), Proposition 1.2.35 (Zero products)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Apply an operator to a relation to kill terms (Technique 4.1.25)
Hint 1. Suppose there is a nontrivial relation, and let m be the smallest index with $a_m \neq 0$.
Hint 2. Apply a single power of N that moves $N^m\mathbf{v}$ exactly to the end of the chain. Where do the terms with $j > m$ go?
Hint 3. Applying N^{k-m} leaves only $a_m N^k\mathbf{v}$.
Sketch. If $\sum_{j=0}^{k} a_j N^j\mathbf{v} = \mathbf{0}$ is nontrivial, let m be the least index with $a_m \neq 0$. Applying N^{k-m} to $\sum_{j\geq m} a_j N^j\mathbf{v} = \mathbf{0}$ sends the term $j = m$ to $a_m N^k\mathbf{v}$ and every term with $j > m$ past the end of the chain, to $\mathbf{0}$. So $a_m N^k\mathbf{v} = \mathbf{0}$, forcing $a_m = 0$, a contradiction.

Suppose, for contradiction, that (7.2.2) holds with not all a_j zero, and let m be the smallest index with $a_m \neq 0$. Then $\sum_{j=m}^{k} a_j N^j\mathbf{v} = \mathbf{0}$. Applying N^{k-m},

$$\mathbf{0} = a_m N^k\mathbf{v} + \sum_{j=m+1}^{k} a_j N^{k+(j-m)}\mathbf{v} = a_m N^k\mathbf{v},$$

since $k + (j - m) \geq k + 1$ for $j > m$. As $N^k\mathbf{v} \neq \mathbf{0}$, this forces $a_m = 0$ (Proposition 1.2.35), contradicting the choice of m. So the relation is trivial, and the list is independent by Theorem 1.5.5. □

Intuition (Why the lowest index). The first proof peels off the coefficients from the front of the chain, one application at a time, and needs an induction to organize the peeling. The second proof asks which single term of a relation is hardest to kill, and kills everything else. Applying N^s shifts every term s places toward the end, and the term that reaches the end last is the one with the smallest index. So the lowest index with a nonzero coefficient is the right extremal choice, and one application of N^{k-m} isolates it. Choosing the highest index instead does not work: applying $N^{k-m'}$ for the highest index m' sends every lower term somewhere strictly inside the chain, so nothing is isolated.

The pattern "choose the extremal term, then apply the operator that kills everything except that term" is exactly the shortest-relation proof of Theorem 7.2.21, with "smallest index" in place of "fewest terms". It solves Exercise 7.2.51, where several chains are mixed together.

Corollary 7.2.38 (The span of a chain). Under the hypotheses of Proposition 7.2.37:

(a) $N^k\mathbf{v}$ is an eigenvector of T with eigenvalue λ;

(b) $\operatorname{span}\big(\mathbf{v}, N\mathbf{v}, \ldots, N^k\mathbf{v}\big) = K_T(\mathbf{v})$, so $\dim K_T(\mathbf{v}) = k + 1$;

(c) in the basis $N^k\mathbf{v}, N^{k-1}\mathbf{v}, \ldots, N\mathbf{v}, \mathbf{v}$ of $K_T(\mathbf{v})$, the matrix of $T\restriction_{K_T(\mathbf{v})}$ has every diagonal entry equal to λ, every entry just above the diagonal equal to 1, and all other entries 0.

Proof. ROUTINE

Uses. Proposition 7.2.37 (Chains are independent), Proposition 7.2.34 (The smallest invariant subspace containing a vector), Proposition 7.2.4 (Invariance is checked on a spanning list), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 2.3.1 (Matrix of a linear map)
Hint 1. For (a), compute $(T - \lambda\,\mathrm{id})\big(N^k\mathbf{v}\big)$.
Hint 2. For (b), each $N^j\mathbf{v} = (x - \lambda)^j(T)\mathbf{v}$ lies in $K_T(\mathbf{v})$. For the other inclusion, show the span of the chain is T-invariant, using $T = N + \lambda\,\mathrm{id}$.
Hint 3. For (c), compute T on each basis vector: $T\big(N^j\mathbf{v}\big) = N^{j+1}\mathbf{v} + \lambda N^j\mathbf{v}$.

Sketch. (a) $N\big(N^k\mathbf{v}\big) = N^{k+1}\mathbf{v} = \mathbf{0}$ and $N^k\mathbf{v} \neq \mathbf{0}$. (b) $N^j\mathbf{v} = \big((x-\lambda)^j\big)(T)\mathbf{v} \in K_T(\mathbf{v})$, and $T\big(N^j\mathbf{v}\big) = N^{j+1}\mathbf{v} + \lambda N^j\mathbf{v}$ lies in the span W of the chain, so W is invariant and contains $K_T(\mathbf{v})$. The chain is independent, so $\dim = k+1$. (c) Read off the coordinates of $T\big(N^j\mathbf{v}\big)$.

(a) $(T-\lambda\,\mathrm{id})\big(N^k\mathbf{v}\big) = N^{k+1}\mathbf{v} = \mathbf{0}$, so $T\big(N^k\mathbf{v}\big) = \lambda N^k\mathbf{v}$, and $N^k\mathbf{v} \neq \mathbf{0}$ by hypothesis.

(b) Let $W = \operatorname{span}\big(\mathbf{v}, N\mathbf{v}, \ldots, N^k\mathbf{v}\big)$. Each $N^j = (T-\lambda\,\mathrm{id})^j$ equals $q_j(T)$ for $q_j = (x-\lambda)^j$ (Proposition 7.2.27(a)), so $N^j\mathbf{v} \in K_T(\mathbf{v})$ and $W \subseteq K_T(\mathbf{v})$. Since $T = N + \lambda\,\mathrm{id}$,

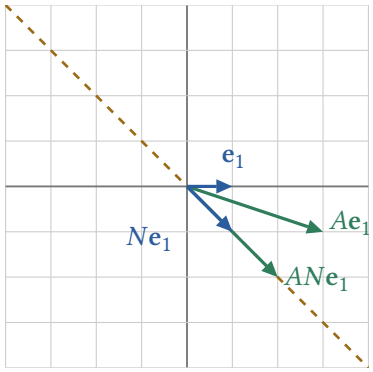
$$T\big(N^j\mathbf{v}\big) = N^{j+1}\mathbf{v} + \lambda N^j\mathbf{v}, \tag{7.2.3}$$

which lies in W for $j < k$, and equals $\lambda N^k\mathbf{v} \in W$ for $j = k$. So W is T-invariant (Proposition 7.2.4) and contains $\mathbf{v}$, hence $K_T(\mathbf{v}) \subseteq W$ (Proposition 7.2.34). Thus $W = K_T(\mathbf{v})$, and by Proposition 7.2.37 the chain is a basis of it, of length $k+1$.

(c) Number the basis as $\mathbf{b}_1 = N^k\mathbf{v}, \mathbf{b}_2 = N^{k-1}\mathbf{v}, \ldots, \mathbf{b}_{k+1} = \mathbf{v}$, so $\mathbf{b}_i = N^{k+1-i}\mathbf{v}$. By (7.2.3), $T\mathbf{b}_1 = \lambda\mathbf{b}_1$ and $T\mathbf{b}_i = \mathbf{b}_{i-1} + \lambda\mathbf{b}_i$ for $i \geq 2$. So the i-th column of the matrix has λ in row i, 1 in row $i-1$ when $i \geq 2$, and 0 elsewhere (Definition 2.3.1). □

For $k = 2$ the matrix in (c) is

$$\begin{pmatrix} \lambda & 1 & 0 \\ 0 & \lambda & 1 \\ 0 & 0 & \lambda \end{pmatrix}.$$



Matrices of this shape are Jordan blocks, and Section 10.3 shows that every operator on a finite-dimensional complex vector space is built out of chains like these. Here is the smallest example that is not diagonal in any basis.

Example 7.2.39 (A matrix with a single invariant line). Let $A = \begin{pmatrix} 3 & 1 \\ -1 & 1 \end{pmatrix} \in \mathbb{R}^{2\times 2}$, $\lambda = 2$, and

$$N = A - 2I_2 = \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}, \quad N^2 = \begin{pmatrix} 1-1 & 1-1 \\ -1+1 & -1+1 \end{pmatrix} = 0.$$

Take $\mathbf{v} = \mathbf{e}_1$: $N\mathbf{e}_1 = (1,-1) \neq \mathbf{0}$ and $N^2\mathbf{e}_1 = \mathbf{0}$, so Proposition 7.2.37 applies with $k = 1$. By Corollary 7.2.38, $(1,-1)$ is an eigenvector with eigenvalue 2 (indeed $A(1,-1) = (2,-2)$), and in the basis $(1,-1), \mathbf{e}_1$ the matrix of T_A is $\begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$.

The only eigenvalue is 2: if $A\mathbf{w} = \mu\mathbf{w}$, then $N\mathbf{w} = (\mu-2)\mathbf{w}$ and $\mathbf{0} = N^2\mathbf{w} = (\mu-2)^2\mathbf{w}$, so $\mu = 2$ when $\mathbf{w} \neq \mathbf{0}$. Its eigenspace $E_2 = \ker N = \operatorname{span}((1,-1))$ is a line, since $N(x,y) = (x+y)(1,-1)$. So A has exactly one invariant line, and there is no basis of $\mathbb{R}^2$ consisting of eigenvectors of A.

The map of $A = \begin{pmatrix} 3 & 1 \\ -1 & 1 \end{pmatrix}$ from Example 7.2.39. The dashed line $y = -x$ is stretched by 2 and is the only invariant line. The vector $\mathbf{e}_1$ goes to $A\mathbf{e}_1 = 2\mathbf{e}_1 + N\mathbf{e}_1$: twice itself plus a vector on the invariant line. In the interactive version, change the entries slightly and the single invariant line either splits into two or disappears. For $\begin{pmatrix} 3 & b \\ c & 1 \end{pmatrix}$ there are two invariant lines when $bc > -1$, one when $bc = -1$, and none when $bc < -1$. (Interactive in the web version.)

Exercise 7.2.40. ROUTINE Let $A = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix} \in F^{3\times 3}$ and $N = A - I_3$.

(a) Compute $N\mathbf{e}_3$, $N^2\mathbf{e}_3$, and $N^3\mathbf{e}_3$, and deduce that $\mathbf{e}_3, N\mathbf{e}_3, N^2\mathbf{e}_3$ is a basis of F^3.

(b) Show that 1 is the only eigenvalue of A and that $E_1(A) = \operatorname{span}(\mathbf{e}_1)$.

Solution on page 1565

Exercises

Exercise 7.2.41. ROUTINE Let $B = \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$. Find all eigenvalues of B, with an eigenvector for each, over $\mathbb{R}$, $\mathbb{F}_2$, $\mathbb{F}_3$, $\mathbb{F}_5$, and $\mathbb{F}_7$.

Solution on page 1566

Exercise 7.2.42. STANDARD For $\theta \in \mathbb{R}$, let $R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$, the rotation by θ (Example 2.1.11).

(a) For which θ does R_θ have a real eigenvalue? Find the eigenspaces in those cases.

(b) Regard R_θ as a matrix in $\mathbb{C}^{2\times 2}$. Show that $(1, -i)$ and $(1, i)$ are eigenvectors, with eigenvalues $\cos\theta + i\sin\theta$ and $\cos\theta - i\sin\theta$.

Solution on page 1566

Exercise 7.2.43. STANDARD Let $S, T \in \mathrm{L}(V)$. Prove or disprove:

(a) If λ is an eigenvalue of S and μ is an eigenvalue of T, then $\lambda + \mu$ is an eigenvalue of $S + T$.

(b) If λ is an eigenvalue of S and μ is an eigenvalue of T, then $\lambda\mu$ is an eigenvalue of ST.

(c) If $\mathbf{v}$ is an eigenvector of both S and T, then it is an eigenvector of $S + T$ and of ST.

(d) If $\mathbf{v}$ is an eigenvector of ST, then it is an eigenvector of TS.

(e) If $ST = TS$, then every eigenvector of S is an eigenvector of T.

Solution on page 1566

Exercise 7.2.44. STANDARD Let $A \in F^{n\times n}$.

(a) Suppose every row of A has the same sum s. Show that s is an eigenvalue of A.

(b) Show that A and A^{T} have the same eigenvalues.

(c) Suppose every column of A has the same sum s. Show that s is an eigenvalue of A. Must $(1, \ldots, 1)$ be an eigenvector?

Solution on page 1567

Exercise 7.2.45. STANDARD

(a) Show that an operator $T \in \mathrm{L}(\mathbb{R}^2)$ has 0, 1, 2, or infinitely many invariant lines, and give an example of each.

(b) Over $\mathbb{F}_2$, show that every $T \in \mathrm{L}(\mathbb{F}_2^2)$ has 0, 1, 2, or 3 invariant lines, and give an example of each.

Solution on page 1567

Exercise 7.2.46. STANDARD Let D be differentiation on $\mathbb{R}[x]$.

(a) Show that the D-invariant subspaces of $\mathbb{R}[x]$ are exactly $\{\mathbf{0}\}$, the spaces $\mathbb{R}[x]_{\leq n}$ for $n \geq 0$, and $\mathbb{R}[x]$ itself.

(b) Over $\mathbb{F}_p$, find a D-invariant subspace of $\mathbb{F}_p[x]$ that is not of this form.

Solution on page 1568

Exercise 7.2.47. STANDARD Let $\dim V = n$, and let $T \in \mathrm{L}(V)$ have n distinct eigenvalues $\lambda_1, \ldots, \lambda_n$, with eigenvectors $\mathbf{v}_1, \ldots, \mathbf{v}_n$. Let $S \in \mathrm{L}(V)$ commute with T.

(a) Show that each $\mathbf{v}_i$ is an eigenvector of S.

(b) Show that $S = p(T)$ for some $p \in F[x]$ of degree less than n.

Solution on page 1568

Exercise 7.2.48. HARD Let $\dim V = n$, and let $T \in \mathrm{L}(V)$ have n distinct eigenvalues. Show that T has exactly 2^n invariant subspaces.

Solution on page 1569

Exercise 7.2.49. STANDARD Let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be eigenvectors of $T \in \mathrm{L}(V)$ with distinct eigenvalues $\lambda_1, \ldots, \lambda_n$, and let $\mathbf{w} = \mathbf{v}_1 + \cdots + \mathbf{v}_n$. Show that $\mathbf{w}, T\mathbf{w}, \ldots, T^{n-1}\mathbf{w}$ is linearly independent, and deduce that $K_T(\mathbf{w}) = \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_n)$.

Solution on page 1569

Exercise 7.2.50. HARD Let $\dim V = n \geq 1$, and let $N \in \mathrm{L}(V)$ satisfy $N^n = 0$ and $N^{n-1} \neq 0$.

(a) Show that $\dim \ker N^j = j$ for $j = 0, 1, \ldots, n$.

(b) Show that the N-invariant subspaces of V are exactly $\ker N^0, \ker N^1, \ldots, \ker N^n$. In particular there are exactly $n + 1$ of them.

Solution on page 1570

Exercise 7.2.51. HARD Let $N \in \mathrm{L}(V)$, let $\mathbf{u}_1, \ldots, \mathbf{u}_r \in V$, and let $k_1, \ldots, k_r \geq 0$ satisfy $N^{k_i+1}\mathbf{u}_i = \mathbf{0}$ for each i. Suppose the "tops" $N^{k_1}\mathbf{u}_1, \ldots, N^{k_r}\mathbf{u}_r$ are linearly independent. Show that the list of all vectors

$$N^j \mathbf{u}_i \quad (1 \le i \le r, 0 \le j \le k_i)$$

is linearly independent.

Solution on page 1570

Exercise 7.2.52. STANDARD Let $n \ge 1$ and define $T : F[x]_{\le n} \to F[x]_{\le n}$ by $T(p) = xp'$, where p' is the formal derivative.

(a) Over $\mathbb{R}$, find the eigenvalues and eigenspaces of T.

(b) Over $\mathbb{F}_3$ with $n = 5$, find the eigenvalues and eigenspaces of T.

Solution on page 1571

Exercise 7.2.53. STANDARD Find the error in the following argument, and decide whether the claim is true.

Claim. Let $T \in \mathrm{L}(V)$ with V a complex vector space. Every eigenvector of T^2 is an eigenvector of T.

"Proof." Let $T^2\mathbf{v} = \mu\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, and choose $\lambda \in \mathbb{C}$ with $\lambda^2 = \mu$. Then

$$(T - \lambda \,\mathrm{id})(T + \lambda \,\mathrm{id})\mathbf{v} = \big(T^2 - \lambda^2 \,\mathrm{id}\big)\mathbf{v} = \mathbf{0}.$$

So either $(T + \lambda \,\mathrm{id})\mathbf{v} = \mathbf{0}$ or $(T - \lambda \,\mathrm{id})\mathbf{v} = \mathbf{0}$. In the first case $\mathbf{v}$ is an eigenvector of T for $-\lambda$, and in the second for λ.

Solution on page 1571

Exercise 7.2.54. STANDARD Let $T \in \mathrm{L}(V)$, and let U, W be subspaces of V. Prove or disprove:

(a) If U and W are T-invariant, then so are $U + W$ and $U \cap W$.

(b) If U is T^2-invariant, then U is T-invariant.

(c) If V is finite-dimensional, T is invertible, and U is T-invariant, then U is T^{-1}-invariant.

(d) Statement (c) holds without assuming that V is finite-dimensional.

Solution on page 1572

Exercise 7.2.55. HARD BEYOND 21-242 Let $T \in \mathrm{L}(V)$ and let $p, q \in F[x]$ be coprime, with $p(T)q(T) = 0$. Show that

$$V = \ker p(T) \oplus \ker q(T),$$

and that both summands are T-invariant. Deduce that if $1 + 1 \neq 0$ in F and $T^2 = \mathrm{id}$, then $V = E_1 \oplus E_{-1}$.

Solution on page 1572

Exercise 7.2.56. STANDARD Let $Z(x, y, z) = (z, x, y)$ be the cyclic permutation of coordinates on F^3. Find all eigenvalues of Z, and an eigenvector for each, over $\mathbb{C}$, over $\mathbb{R}$, over $\mathbb{F}_7$, and over $\mathbb{F}_3$.

Solution on page 1573

Exercise 7.2.57. HARD Let $\dim V = n$ and $1 \le k < n$. Suppose $T \in \mathrm{L}(V)$ leaves every k-dimensional subspace of V invariant. Show that $T = \lambda \,\mathrm{id}$ for some $\lambda \in F$.

Solution on page 1573

Exercise 7.2.58. ROUTINE Find $A \in \mathbb{Q}^{2\times 2}$ with $A(1, 2) = 3(1, 2)$ and $A(1, 1) = -(1, 1)$. Is A unique?

Solution on page 1574

7.3 The characteristic polynomial

In Section 7.2 we found eigenvalues by solving $T\mathbf{v} = \lambda\mathbf{v}$ by hand, with a separate argument for each operator. Theorem 7.2.9 points to a systematic method: λ is an eigenvalue of $A \in F^{n\times n}$ exactly when $\det(A - \lambda I_n) = 0$. If we leave λ unknown and call it x, the Leibniz formula turns $\det(xI_n - A)$ into a polynomial of degree n in x, and the eigenvalues of A are its roots. This section makes that precise, reads the trace and the determinant of A off the coefficients, and shows that every monic polynomial occurs. It also settles the existence question raised by the rotation in Example 7.2.18. Over $\mathbb{C}$ every operator on a nonzero finite-dimensional space has an eigenvalue, and we prove this twice, once with the characteristic polynomial and once without determinants.

7.3.1 Determinants with polynomial entries

The matrix $xI_n - A$ has entries in $F[x]$, and $F[x]$ is not a field: x has no multiplicative inverse in $F[x]$ (Corollary 7.1.7). Chapter 5 defined the determinant only for matrices with entries in a field. So before we can write $\det(xI_n - A)$, we have to say what it means and which rules it obeys.

Intuition (What the Leibniz formula needs). The Leibniz formula (Theorem 5.3.3) builds $\det A$ out of the entries of A with additions, subtractions, and multiplications, and never divides. So it makes sense for entries from any commutative ring (Definition 1.1.20), and for $F[x]$ in particular (Proposition 7.1.3). The real question is which theorems of Chapter 5 survive. Most facts there were proved twice: once by row reduction, which divides by pivots, and once from the Leibniz formula or from the uniqueness of multilinear alternating functions, which do not divide. The second kind of proof works over a commutative ring word for word. The one statement that changes is the invertibility criterion, because in a ring a nonzero element need not be invertible.

Definition 7.3.1 (Determinant over a commutative ring). Let R be a commutative ring and $n \geq 1$. We write $R^{n\times n}$ for the set of $n \times n$ arrays $M = (m_{ij})$ with entries in R, and add, multiply, and transpose such arrays by the same formulas as matrices over a field. The **determinant** of $M \in R^{n\times n}$ is

$$\det M = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) m_{\sigma(1)1} m_{\sigma(2)2} \cdots m_{\sigma(n)n} \in R,$$

where $\operatorname{sgn}(\sigma) \in \{1, -1\}$ is read in R. When $R = F$ is a field, this is the determinant of Definition 5.3.6, by Theorem 5.3.3.

For example, with $R = F[x]$,

$$\det\begin{pmatrix} x-a & -b \\ -c & x-d \end{pmatrix} = (x-a)(x-d) - (-b)(-c) = x^2 - (a+d)x + (ad - bc).$$

Proposition 7.3.2 (Determinants over a commutative ring). Let R and R' be commutative rings, $n \geq 1$, and $M, N \in R^{n\times n}$.

(a) Multiplication in $R^{n\times n}$ is associative and distributes over addition, $(rM)N = r(MN) = M(rN)$ for $r \in R$, and the array I_n with 1 on the diagonal and 0 elsewhere is a two-sided identity. In particular the scalar arrays rI_n commute with every array.

(b) det is linear in each column (with coefficients in R), it vanishes when two columns are equal, and $\det I_n = 1$. Every function $D : R^{n\times n} \to R$ with these first two properties satisfies $D(M) = D(I_n)\det M$.

(c) $\det(MN) = \det M \det N$.

(d) $\det M^{\mathsf{T}} = \det M$. So (b) holds for rows as well as columns.

(e) If $M = \begin{pmatrix} P & Q \\ 0 & S \end{pmatrix}$ with square blocks P and S, then $\det M = \det P \det S$. In particular, if M is upper or lower triangular, then $\det M = m_{11}m_{22}\cdots m_{nn}$.

(f) For $n \geq 2$, cofactor expansion along any row or column computes $\det M$, and $M\,\mathrm{adj}(M) = \mathrm{adj}(M)M = (\det M)I_n$.

(g) Let $\varphi : R \to R'$ satisfy $\varphi(a+b) = \varphi(a) + \varphi(b)$, $\varphi(ab) = \varphi(a)\varphi(b)$, and $\varphi(1) = 1$ for all $a, b \in R$, and write $\varphi(M) = \big(\varphi(m_{ij})\big)$. Then $\det \varphi(M) = \varphi(\det M)$.

Proof. STANDARD

Uses. Definition 7.3.1 (Determinant over a commutative ring), Proposition 2.4.14 (Algebra of matrices), Theorem 5.3.4 (Existence and uniqueness of the determinant), Theorem 5.3.3 (The Leibniz formula), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Theorem 5.4.26 (Block-triangular matrices), Proposition 5.3.15 (Triangular matrices), Theorem 5.5.3 (Cofactor expansion), Theorem 5.5.9 (The adjugate and the inverse), Definition 1.1.20 (Commutative ring)
Techniques. Cancel terms in pairs (Technique 5.3.5), Recognize the determinant by its axioms (Technique 5.4.11)
Hint 1. For (a)–(f), go back to Chapter 5 and, for each fact, find a proof that never divides. Which proofs used row reduction, and which used only the Leibniz formula or the uniqueness of multilinear alternating functions?
Hint 2. Alternation is the delicate point: the shortcut "$L(A) = -L(A)$" divides by $1+1$. The proof of Theorem 5.3.4 cancelled terms in pairs instead.
Hint 3. For (g), apply φ to the Leibniz sum term by term. You need $\varphi(0) = 0$ and $\varphi(-a) = -\varphi(a)$; derive them from additivity.
Sketch. Each of (a)–(f) has a proof in Chapter 5 that uses only the commutative ring axioms: entrywise computation for (a); the Leibniz formula, pairing σ with $\sigma\tau$, for (b); uniqueness for (c), since $\mathbf{b} \mapsto \det(M\mathbf{b})$ is multilinear and alternating; reindexing by σ^{-1} for (d); the Leibniz formula for (e) and (f). For (g), $\varphi(0) = 0$ and $\varphi(-a) = -\varphi(a)$ follow from additivity, so φ maps each Leibniz term of M to the corresponding term of $\varphi(M)$.

We go through Chapter 5 and point, for each statement, to an argument that uses only the commutative ring axioms, that is, never divides and never uses $1 + 1 \neq 0$.

(a) The entrywise proof of Proposition 2.4.14 compares the entries of both sides, each of which is a sum of products of entries, using associativity, commutativity, and distributivity in the scalars. These hold in R.

(b) The proof of Theorem 5.3.4 (parts 2 and 3) shows that the Leibniz formula is normalized, linear in each column, and alternating. Normalization and multilinearity are checked term by term, since each term contains exactly one entry from each column. Alternation is proved by pairing each even σ with $\sigma\tau$, where τ swaps the two equal columns, and the two terms cancel (Technique 5.3.5). None of this divides. The last statement is Theorem 5.3.3. Its proof expands $D(M)$ by multilinearity into a sum over functions $[n] \to [n]$, discards the non-injective ones because D vanishes on arrays with two equal columns, and evaluates D on permuted identity columns with Theorem 5.2.31; these steps use multilinearity, alternation, and the ring axioms only.

(c) We use the second proof of Theorem 5.4.10 (Technique 5.4.11). Fix M and let $D(N) = \det(MN)$. Column j of MN is M times column j of N, so D is linear in each column of N by (a) and (b), and two equal columns of N give two equal columns of MN, where det vanishes. By (b), $D(N) = D(I_n)\det N = \det M \det N$.

(d) The second proof of Theorem 5.4.14 reindexes the Leibniz sum by $\sigma \mapsto \sigma^{-1}$ and uses $\mathrm{sgn}(\sigma^{-1}) = \mathrm{sgn}(\sigma)$; this is ring arithmetic.

(e) In the Leibniz formula for $\begin{pmatrix} P & Q \\ 0 & S \end{pmatrix}$, with P of size $k \times k$, a term can be nonzero only if σ maps $\{1, \ldots, k\}$ into itself, and then the term is a product of a Leibniz term of P and one of S. This is the proof of Theorem 5.4.26 via the Leibniz formula, and the triangular case is the Leibniz proof of Proposition 5.3.15. Lower block-triangular arrays follow by (d).

(f) The second proof of Theorem 5.5.3 derives the expansion from the Leibniz formula by regrouping its terms, using the signs of cycles and the multiplicativity of sgn, and gets the row version from (d). The identity $M \operatorname{adj}(M) = (\det M) I_n$ is proved in Theorem 5.5.9 by expanding along a row and noting that expansion along the "wrong" row computes the determinant of an array with two equal rows, which is 0 by (b) and (d). Neither step divides.

(g) First, $\varphi(0) = \varphi(0+0) = \varphi(0) + \varphi(0)$, so $\varphi(0) = 0$; and $\varphi(a) + \varphi(-a) = \varphi(0) = 0$, so $\varphi(-a) = -\varphi(a)$. Hence $\varphi(\operatorname{sgn}(\sigma)) = \operatorname{sgn}(\sigma)$, and since φ respects sums and products of any finite length,

$$\varphi(\det M) = \sum_{\sigma \in S_n} \varphi(\operatorname{sgn}(\sigma)) \varphi\left(m_{\sigma(1)1}\right) \cdots \varphi\left(m_{\sigma(n)n}\right) = \det \varphi(M).$$

□

The most important instance of (g) is evaluation. For $M \in F[x]^{n \times n}$ and $\lambda \in F$, let $M(\lambda) \in F^{n \times n}$ be the matrix obtained by evaluating every entry at λ. Evaluation respects sums, products, and 1 (Proposition 7.1.10), so

$$(\det M)(\lambda) = \det M(\lambda). \tag{7.3.1}$$

In words, it does not matter whether we first compute the determinant as a polynomial and then plug in λ, or first plug in λ and then compute a determinant of scalars. The same holds for substituting a polynomial $r \in F[x]$ for x in every entry (also Proposition 7.1.10), and for complex conjugation of the coefficients of polynomials in $\mathbb{C}[x]$ (Lemma 7.1.37).

Remark 7.3.3 (What does not carry over). Over a field, M is invertible if and only if $\det M \neq 0$ (Theorem 5.4.7). Over $F[x]$ this fails: $\det(xI_n) = x^n \neq \mathbf{0}$, but xI_n has no inverse in $F[x]^{n \times n}$: if $(xI_n)N = I_n$, then $xn_{11} = 1$, which is impossible by Corollary 7.1.7(c). The proof of Theorem 5.4.7 used row reduction, which divides by pivots. What survives is (f): if $\det M$ has an inverse in R, then $(\det M)^{-1} \operatorname{adj}(M)$ is an inverse of M. The converse also holds, by (c): $MN = I_n$ gives $\det M \det N = 1$. So M is invertible in $R^{n \times n}$ exactly when $\det M$ is invertible in R, which for $R = F[x]$ means that $\det M$ is a nonzero constant. We will not need this, but it explains why nothing like "$\det(xI_n - A) \neq \mathbf{0}$, so $xI_n - A$ is invertible" can be used.

ASIDE: *Rational functions*

There is a second way to make sense of $\det(xI_n - A)$. Fractions p/q of polynomials with $q \neq \mathbf{0}$, with the usual rules for fractions, form a field $F(x)$ that contains $F[x]$, in the same way that $\mathbb{Q}$ contains $\mathbb{Z}$. All of Chapter 5 applies to matrices over $F(x)$, and the Leibniz formula shows that a matrix with polynomial entries has a polynomial determinant. This route gives everything in Proposition 7.3.2 for $R = F[x]$ at once, at the cost of constructing $F(x)$. We stay with commutative rings, which we need anyway for (g).

7.3.2 The characteristic polynomial

Definition 7.3.4 (Characteristic polynomial). Let $n \geq 1$ and $A \in F^{n \times n}$. The **characteristic polynomial** of A is

$$p_A = \det(xI_n - A) \in F[x],$$

the determinant (Definition 7.3.1) of the matrix $xI_n - A \in F[x]^{n \times n}$, whose diagonal entries are $x - a_{ii}$ and whose off-diagonal entries are the constants $-a_{ij}$. When the polynomial is evaluated, we write $p_A(\lambda)$ for its value at $\lambda \in F$.

Some texts, including the lecture notes, use $\det(A - xI_n)$ instead. Multiplying each of the n columns by -1 shows $\det(A - xI_n) = (-1)^n p_A$ (Proposition 7.3.2(b)), so the two conventions differ by a sign and have the same roots. With our sign, p_A is monic (Proposition 7.3.18).

Example 7.3.5 (Small cases).

(a) For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, the computation after Definition 7.3.1 gives

$$p_A = x^2 - (a+d)x + (ad - bc) = x^2 - (\operatorname{tr} A)x + \det A.$$

(b) For $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$ of Example 7.2.8, $p_A = x^2 - 4x + 3 = (x-1)(x-3)$, and its roots 1 and 3 are the eigenvalues found there.

(c) For the rotation $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ of Example 7.2.18, $p_A = x^2 + 1$. It has no root in $\mathbb{R}$ or $\mathbb{F}_3$, the roots $\pm i$ in $\mathbb{C}$, and the roots $2, 3$ in $\mathbb{F}_5$, matching the eigenvalues found there field by field.

(d) If A is upper triangular, so is $xI_n - A$, with diagonal entries $x - a_{ii}$. By Proposition 7.3.2(e),

$$p_A = (x - a_{11})(x - a_{22}) \cdots (x - a_{nn}).$$

For instance, $p_A = (x-2)^2$ for $A = \begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$, the matrix of Example 7.2.39 in its chain basis.

Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial). Let $A \in F^{n \times n}$ and $\lambda \in F$. Then λ is an eigenvalue of A if and only if $p_A(\lambda) = 0$.

Proof. ROUTINE

Uses. Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 7.3.2 (Determinants over a commutative ring), Proposition 7.1.10 (Evaluation respects sums and products), Definition 7.3.4 (Characteristic polynomial)
Hint 1. Theorem 7.2.9 already says that λ is an eigenvalue if and only if $\det(A - \lambda I_n) = 0$. How is that number related to the polynomial p_A?
Hint 2. Evaluate $xI_n - A$ entry by entry at λ and use (7.3.1).
Sketch. By (7.3.1), $p_A(\lambda) = \det(\lambda I_n - A) = (-1)^n \det(A - \lambda I_n)$, which vanishes exactly when λ is an eigenvalue, by Theorem 7.2.9.

Evaluating every entry of $xI_n - A$ at λ gives $\lambda I_n - A$, so by (7.3.1), $p_A(\lambda) = \det(\lambda I_n - A)$. Multiplying each column by -1 gives $\det(\lambda I_n - A) = (-1)^n \det(A - \lambda I_n)$. So $p_A(\lambda) = 0$ if and only if $\det(A - \lambda I_n) = 0$, which by Theorem 7.2.9 holds if and only if λ is an eigenvalue of A. □

The theorem turns the search for eigenvalues into a search for roots of one polynomial of degree n. It reproves Corollary 7.2.22 for matrices: a nonzero polynomial of degree n has at most n roots (Proposition 7.1.22).

Algorithm 7.3.7 (Eigenvalues by the characteristic polynomial)

Input A matrix $A \in F^{n \times n}$.
Output The eigenvalues of A in F, and a basis of each eigenspace.

1. Compute $p_A = \det(xI_n - A)$, by cofactor expansion along a sparse row or column, or by the Leibniz formula for small n.
2. Find the roots $\lambda_1, \ldots, \lambda_k$ of p_A in F. These are the eigenvalues.
3. For each λ_j, row reduce $A - \lambda_j I_n$ and read off a basis of its null space E_{λ_j} from the free columns.

The algorithm is correct by Theorem 7.3.6 and Definition 7.2.13. In step 3 the matrix $A - \lambda_j I_n$ must have rank less than n; if row reduction finds n pivots, then λ_j was not a root, and the arithmetic in step 1 or step 2 should be checked. The hard step is step 2: for $n \geq 5$ there is no formula in radicals for the roots in

general, and in practice eigenvalues are computed by other methods. For hand computations in this book, the roots will be findable.

Example 7.3.8 (A 3×3 computation). Let $A = \begin{pmatrix} 4 & 0 & 1 \\ -2 & 1 & 0 \\ -2 & 0 & 1 \end{pmatrix} \in \mathbb{R}^{3\times 3}$. Then

$$xI_3 - A = \begin{pmatrix} x-4 & 0 & -1 \\ 2 & x-1 & 0 \\ 2 & 0 & x-1 \end{pmatrix}.$$

The middle column has a single nonzero entry, so expanding along it (Proposition 7.3.2(f)),

$$p_A = (x-1)\det\begin{pmatrix} x-4 & -1 \\ 2 & x-1 \end{pmatrix} = (x-1)((x-4)(x-1)+2) = (x-1)\left(x^2-5x+6\right) = (x-1)(x-2)(x-3).$$

So the eigenvalues are 1, 2, 3. For $\lambda = 2$, row reduction gives

$$A - 2I_3 = \begin{pmatrix} 2 & 0 & 1 \\ -2 & -1 & 0 \\ -2 & 0 & -1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & 1/2 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{pmatrix},$$

so $E_2 = \operatorname{span}((1,-2,-2))$; check: $A(1,-2,-2) = (2,-4,-4)$. In the same way, $E_1 = \operatorname{span}((0,1,0))$ and $E_3 = \operatorname{span}((1,-1,-1))$. Realize that $\operatorname{tr} A = 6 = 1+2+3$ and $\det A = 6 = 1\cdot 2\cdot 3$; Remark 7.3.19 explains this.

$$\begin{pmatrix} 2 & 0 & 1 \\ -2 & -1 & 0 \\ -2 & 0 & -1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & 1/2 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{pmatrix}$$

Row reduction of $A - 2I_3$ from Example 7.3.8. The third column is free, so E_2 is a line. Use "Edit" to try $A - \lambda I_3$ for other values of λ: you get three pivots, and only the zero vector in the null space, unless λ is 1, 2, or 3. (Interactive in the web version.)

Exercise 7.3.9. ROUTINE Let $A = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$. Find p_A, and find the eigenvalues of A together with an eigenvector for each, over $\mathbb{R}$, over $\mathbb{F}_2$, over $\mathbb{F}_5$, and over $\mathbb{F}_{11}$.

Solution on page 1574

Remark 7.3.10 (A polynomial, not a function). Over a finite field, the function $\lambda \mapsto \det(\lambda I_n - A)$ on F carries less information than the polynomial p_A. Over $\mathbb{F}_2$, take $A = 0_{3\times 3}$ and $B = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 1 \end{pmatrix}$. Then $p_A = x^3$, and by Proposition 7.3.2(e) and Example 7.3.5(a), $p_B = x\left(x^2+x+1\right) = x^3+x^2+x$. Both polynomials take the value 0 at 0 and 1 at 1, so they define the same function on $\mathbb{F}_2$. But they differ, and so do $\operatorname{tr} A = 0$ and $\operatorname{tr} B = 1$, which Proposition 7.3.18 reads off the coefficients. This is why we defined p_A through determinants over $F[x]$, instead of as the function $\lambda \mapsto \det(\lambda I_n - A)$.

7.3.3 Similarity and operators

The characteristic polynomial of a matrix should depend only on the operator the matrix represents, as the trace and the determinant do (Definition 4.5.30, Definition 5.4.18).

Proposition 7.3.11 (Similar matrices have the same characteristic polynomial). If $A, B \in F^{n\times n}$ are similar, then $p_A = p_B$.

Proof (by multiplicativity over $F[x]$). ROUTINE

Uses. Definition 4.5.23 (Similar matrices), Proposition 7.3.2 (Determinants over a commutative ring), Definition 7.3.4 (Characteristic polynomial)
Hint 1. Write $B = S^{-1}AS$. Can you write $xI_n - B$ as a product of three matrices with entries in $F[x]$?
Hint 2. $xI_n = S^{-1}(xI_n)S$. Then take determinants in $F[x]$, using Proposition 7.3.2(c).
Sketch. $xI_n - S^{-1}AS = S^{-1}(xI_n - A)S$ in $F[x]^{n\times n}$. Taking determinants with Proposition 7.3.2(c) gives $p_B = \det S^{-1}\, p_A \det S = p_A$, since $\det S^{-1} \det S = \det I_n = 1$.

Let $B = S^{-1}AS$ with $S \in F^{n\times n}$ invertible. In $F[x]^{n\times n}$, by Proposition 7.3.2(a),

$$S^{-1}(xI_n - A)S = xS^{-1}S - S^{-1}AS = xI_n - B.$$

Taking determinants and using Proposition 7.3.2(c) twice,

$$p_B = \det\bigl(S^{-1}\bigr)\det(xI_n - A)\det(S) = \det\bigl(S^{-1}\bigr)\det(S)p_A = \det\bigl(S^{-1}S\bigr)p_A = p_A,$$

where we used that $F[x]$ is commutative and $\det I_n = 1$. □

Proof (pointwise, when F is infinite). ROUTINE

Uses. Theorem 5.4.10 (Multiplicativity), Corollary 7.1.23 (Polynomials and their values), (7.3.1)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. Compare the values $p_A(\lambda)$ and $p_B(\lambda)$ for a scalar λ. Only determinants over F are involved.
Hint 2. Two polynomials that agree at infinitely many points are equal.
Sketch. For $\lambda \in F$, $p_B(\lambda) = \det\bigl(S^{-1}(\lambda I_n - A)S\bigr) = p_A(\lambda)$ by multiplicativity over F. If F is infinite, polynomials that agree at every point are equal.

Let $B = S^{-1}AS$ and $\lambda \in F$. By (7.3.1) and multiplicativity over the field F (Theorem 5.4.10),

$$p_B(\lambda) = \det\bigl(S^{-1}(\lambda I_n - A)S\bigr) = \det\bigl(S^{-1}\bigr)\det(\lambda I_n - A)\det(S) = p_A(\lambda).$$

So p_A and p_B agree at every point of F. If F is infinite, Corollary 7.1.23 gives $p_A = p_B$. □

The second proof avoids determinants over $F[x]$ but only proves equality of functions, which is weaker than equality of polynomials over a finite field (Remark 7.3.10). Over an infinite field this is no loss. The idea of proving a polynomial identity by checking it at many points returns in Proposition 7.3.22.

Definition 7.3.12 (Characteristic polynomial of an operator). Let V be finite-dimensional with $\dim V \geq 1$, and $T \in \mathrm{L}(V)$. The **characteristic polynomial** of T is

$$p_T = p_{[T]_{\mathcal{B}\mathcal{B}}},$$

where $\mathcal{B}$ is any basis of V. Matrices of T in two bases are similar (Theorem 4.5.25), so by Proposition 7.3.11 this does not depend on $\mathcal{B}$.

Corollary 7.3.13 (Eigenvalues of an operator). Let V be finite-dimensional with $\dim V \geq 1$, $T \in \mathrm{L}(V)$, and $\lambda \in F$. Then λ is an eigenvalue of T if and only if $p_T(\lambda) = 0$.

Proof. ROUTINE

Uses. Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Definition 7.3.12 (Characteristic polynomial of an operator), Definition 2.3.1 (Matrix of a linear map), Proposition 1.6.20 (Coordinates translate questions about V into F^n)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Fix a basis $\mathcal{B}$ and let $A = [T]_{\mathcal{B}\mathcal{B}}$. Compare the eigenvectors of T with those of A.
Hint 2. $[T\mathbf{v}]_{\mathcal{B}} = A[\mathbf{v}]_{\mathcal{B}}$, and the coordinate map is a linear bijection.
Sketch. With $A = [T]_{\mathcal{B}\mathcal{B}}$, $T\mathbf{v} = \lambda\mathbf{v}$ if and only if $A[\mathbf{v}]_{\mathcal{B}} = \lambda[\mathbf{v}]_{\mathcal{B}}$, and $\mathbf{v} \neq \mathbf{0}$ if and only if $[\mathbf{v}]_{\mathcal{B}} \neq \mathbf{0}$. So T and A have the same eigenvalues, which are the roots of $p_A = p_T$.

Let $\mathcal{B}$ be a basis of V and $A = [T]_{\mathcal{B}\mathcal{B}}$, so $p_T = p_A$. For $\mathbf{v} \in V$, $[T\mathbf{v}]_{\mathcal{B}} = A[\mathbf{v}]_{\mathcal{B}}$ (Definition 2.3.1), and the coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{B}}$ is a linear bijection (Proposition 1.6.20). So $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$ if and only if $A\mathbf{w} = \lambda\mathbf{w}$ with $\mathbf{w} = [\mathbf{v}]_{\mathcal{B}} \neq \mathbf{0}$. Hence T and A have the same eigenvalues, and Theorem 7.3.6 finishes the proof. □

Example 7.3.14 (Characteristic polynomials of operators).

(a) Differentiation D on $F[x]_{\leq n}$ has, in the basis $1, x, \ldots, x^n$, a strictly upper triangular matrix (it lowers degrees). So $p_D = x^{n+1}$ by Example 7.3.5(d), and 0 is its only eigenvalue, as found in Example 7.2.19.

(b) On the real vector space $W = \operatorname{span}(\cos, \sin)$ of functions $\mathbb{R} \to \mathbb{R}$, differentiation maps $\cos \mapsto -\sin$ and $\sin \mapsto \cos$. Its matrix in the basis cos, sin is $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$, with characteristic polynomial $x^2 + 1$. So it has no real eigenvalue: no nonzero $a\cos + b\sin$ is proportional to its own derivative.

(c) The cyclic permutation $Z(x, y, z) = (z, x, y)$ of Example 7.2.36 has matrix $\begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$ in the standard basis. Expanding along the first row,

$$p_Z = \det\begin{pmatrix} x & 0 & -1 \\ -1 & x & 0 \\ 0 & -1 & x \end{pmatrix} = x \cdot x^2 + (-1) \cdot (-1)^{1+3} \cdot ((-1)(-1) - x \cdot 0) = x^3 - 1.$$

The converse of Proposition 7.3.11 is false. The matrices I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ both have characteristic polynomial $(x-1)^2$, but the only matrix similar to I_2 is $S^{-1} I_2 S = I_2$ itself. So the characteristic polynomial is one more similarity invariant to try (Technique 4.5.29), stronger than trace and determinant together, but not a complete one. Chapter 10 finds the complete invariant over $\mathbb{C}$ (Section 10.3).

Block-triangular matrices and invariant subspaces

Proposition 7.3.15 (Block-triangular matrices). Let $M = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix} \in F^{n \times n}$, where $A \in F^{k \times k}$ and $D \in F^{(n-k)\times(n-k)}$ with $1 \leq k < n$. Then $p_M = p_A p_D$. The same holds for $\begin{pmatrix} A & 0 \\ C & D \end{pmatrix}$.

Proof. ROUTINE

Uses. Proposition 7.3.2 (Determinants over a commutative ring), Definition 7.3.4 (Characteristic polynomial)
Hint 1. Write $xI_n - M$ in block form. Is it still block triangular?
Hint 2. Apply Proposition 7.3.2(e) over the ring $F[x]$.
Sketch. $xI_n - M = \begin{pmatrix} xI_k - A & -B \\ 0 & xI_{n-k} - D \end{pmatrix}$ is block upper triangular in $F[x]^{n\times n}$, so its determinant is $p_A p_D$ by Proposition 7.3.2(e). The lower case is the same, or follows by transposing.

In $F[x]^{n\times n}$,

$$xI_n - M = \begin{pmatrix} xI_k - A & -B \\ 0 & xI_{n-k} - D \end{pmatrix},$$

which is block upper triangular with diagonal blocks $xI_k - A$ and $xI_{n-k} - D$. By Proposition 7.3.2(e), $p_M = \det(xI_k - A)\det(xI_{n-k} - D) = p_A p_D$. For $\begin{pmatrix} A & 0 \\ C & D \end{pmatrix}$, the matrix $xI_n - M$ is block lower triangular, and Proposition 7.3.2(e) applies again. □

Combined with the block form of an operator with an invariant subspace (Remark 7.2.5), this says that an invariant subspace splits off a factor of the characteristic polynomial.

Corollary 7.3.16 (Invariant subspaces give factors). Let V be finite-dimensional, $T \in \mathrm{L}(V)$, and U a T-invariant subspace with $\dim U \geq 1$. Then $p_{T|_U}$ divides p_T.

Proof. ROUTINE

Uses. Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Proposition 7.3.15 (Block-triangular matrices), Theorem 4.1.16 (Extending to a basis), Definition 7.3.12 (Characteristic polynomial of an operator)
Techniques. Choose a basis adapted to a preserved subspace (Technique 4.5.36)
Hint 1. Choose a basis of V that starts with a basis of U. What does the matrix of T look like?
Hint 2. Proposition 4.5.35 gives $\begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$ with $A = [T|_U]$. Now use Proposition 7.3.15.

Sketch. If $U = V$ there is nothing to prove. Otherwise extend a basis of U to a basis $\mathcal{B}$ of V; then $[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix}$ with A the matrix of $T{\restriction_U}$ (Proposition 4.5.35), and $p_T = p_A p_D = p_{T{\restriction_U}} p_D$.

If $U = V$, then $T{\restriction_U} = T$ and there is nothing to prove. Otherwise let $k = \dim U$ and $n = \dim V$, so $1 \le k < n$. Extend a basis $\mathbf{b}_1, \ldots, \mathbf{b}_k$ of U to a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of V (Theorem 4.1.16). By Proposition 4.5.35,

$$[T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix} \quad \text{with } A = [T{\restriction_U}]_{\mathcal{B}_U \mathcal{B}_U}.$$

By Proposition 7.3.15, $p_T = p_A p_D = p_{T{\restriction_U}} p_D$. □

Exercise 7.3.17. ROUTINE Let $A \in F^{n\times n}$.

(a) Show that $p_{A^{\mathsf{T}}} = p_A$.

(b) For $F = \mathbb{C}$, let $\overline{A}$ be the entrywise conjugate of A, and $\overline{f}$ the polynomial whose coefficients are the conjugates of those of $f \in \mathbb{C}[x]$. Show that $p_{\overline{A}} = \overline{p_A}$, and deduce that the eigenvalues of A^{H} are the conjugates of the eigenvalues of A.

Solution on page 1574

7.3.4 The coefficients: trace and determinant

Proposition 7.3.18 (The first and last coefficients). Let $A \in F^{n\times n}$. Then p_A is monic of degree n, the coefficient of x^{n-1} in p_A is $-\operatorname{tr} A$, and its constant term is $(-1)^n \det A$. That is, for $n \ge 3$,

$$p_A = x^n - (\operatorname{tr} A)x^{n-1} + c_{n-2}x^{n-2} + \cdots + c_1 x + (-1)^n \det A$$

for some $c_1, \ldots, c_{n-2} \in F$, while $p_A = x^2 - (\operatorname{tr} A)x + \det A$ for $n = 2$ and $p_A = x - a_{11}$ for $n = 1$.

Proof. STANDARD

Uses. Definition 7.3.1 (Determinant over a commutative ring), Proposition 7.3.2 (Determinants over a commutative ring), Definition 2.4.26 (Trace), Proposition 7.1.4 (Degree of a product), Proposition 5.3.19 ($\det(A + tI_n)$ as a function of t)

Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)

Hint 1. Each entry of $xI_n - A$ has degree at most 1, and only the diagonal entries involve x. In the Leibniz term of σ, which factors have degree 1?

Hint 2. Only the factors $x - a_{jj}$ with $\sigma(j) = j$. A permutation $\sigma \neq \mathrm{id}$ moves at least two points. What does that say about the degree of its term?

Hint 3. So x^n and x^{n-1} come only from $(x - a_{11})\cdots(x - a_{nn})$. For the constant term, evaluate at 0 with (7.3.1).

Sketch. The Leibniz term of σ is a product of n factors of degree at most 1, of which only those with $\sigma(j) = j$ have degree 1. A permutation other than id fixes at most $n - 2$ points, so its term has degree at most $n - 2$. Thus the coefficients of x^n and x^{n-1} are those of $\prod_j (x - a_{jj}) = x^n - \left(\sum_j a_{jj}\right)x^{n-1} + \cdots$. The constant term is $p_A(0) = \det(-A) = (-1)^n \det A$.

Let $M = xI_n - A$, so $m_{jj} = x - a_{jj}$ and $m_{ij} = -a_{ij}$ for $i \neq j$. The Leibniz term of $\sigma \in S_n$ is

$$t_\sigma = \operatorname{sgn}(\sigma) \prod_{j=1}^{n} m_{\sigma(j)j}.$$

Each factor has degree at most 1, with degree 1 exactly when $\sigma(j) = j$. So t_σ is $\mathbf{0}$ or has degree at most the number of fixed points of σ (Proposition 7.1.4). If $\sigma \neq \mathrm{id}$, pick j with $\sigma(j) \neq j$; then $i = \sigma(j)$ is also moved, since $\sigma(i) = i = \sigma(j)$ would contradict injectivity. So σ fixes at most $n - 2$ points, and t_σ contributes nothing to the coefficients of x^n and x^{n-1}.

These two coefficients therefore come from

$$t_{\mathrm{id}} = (x - a_{11})(x - a_{22})\cdots(x - a_{nn}).$$

Expanding by distributivity, a product of n factors $x - a_{jj}$ is a sum over the ways to choose x or $-a_{jj}$ from each factor. The only way to get x^n is to choose x every time, and the ways to get x^{n-1} are to choose $-a_{jj}$ from exactly one factor j. So the coefficient of x^n is 1 and that of x^{n-1} is $-(a_{11} + \cdots + a_{nn}) = -\operatorname{tr} A$. In particular p_A is monic of degree n.

The constant term of a polynomial is its value at 0. By (7.3.1), $p_A(0) = \det(-A)$, and multiplying each of the n columns of A by -1 multiplies det by $(-1)^n$ (Proposition 7.3.2(b)). So the constant term is $(-1)^n \det A$. □

This is the computation in the proof of Proposition 5.3.19, done in $F[x]$ instead of for each scalar t. The coefficients in between are sums of minors (Exercise 7.3.53).

Remark 7.3.19 (Trace and determinant from the roots). Suppose p_A splits over F, say $p_A = (x - \lambda_1)\cdots(x - \lambda_n)$ with $\lambda_i \in F$. By Proposition 7.1.36, the coefficient of x^{n-1} in this product is $-(\lambda_1 + \cdots + \lambda_n)$ and its constant term is $(-1)^n \lambda_1 \cdots \lambda_n$. Comparing with Proposition 7.3.18 gives

$$\operatorname{tr} A = \lambda_1 + \cdots + \lambda_n, \quad \det A = \lambda_1 \lambda_2 \cdots \lambda_n.$$

The λ_i are the eigenvalues of A (Theorem 7.3.6), each repeated as often as its multiplicity as a root of p_A, its algebraic multiplicity (Definition 7.4.11). Repetitions matter: $\left(\begin{smallmatrix} 2 & 1 \\ 0 & 2 \end{smallmatrix}\right)$ has the single eigenvalue 2 but trace $4 = 2 + 2$. Over $\mathbb{C}$, p_A always splits (Corollary 7.1.35), and Theorem 7.5.22 proves the same statement a second way, by triangularizing A.

For 2×2 matrices the trace and determinant determine $p_A = x^2 - (\operatorname{tr} A)x + \det A$, and with it the eigenvalues. Over $\mathbb{R}$, the quadratic formula says that the number of real eigenvalues is governed by the discriminant

$$\Delta = (\operatorname{tr} A)^2 - 4 \det A :$$

two real eigenvalues if $\Delta > 0$, one repeated real eigenvalue if $\Delta = 0$, and a pair of conjugate nonreal eigenvalues if $\Delta < 0$ (Theorem B.1.30).

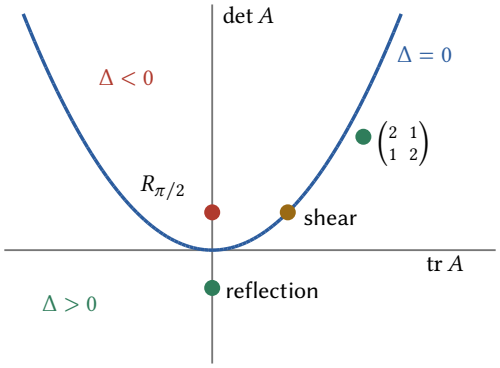


Figure 7.3.1. Real 2×2 matrices placed by $(\operatorname{tr} A, \det A)$, with $\Delta = (\operatorname{tr} A)^2 - 4 \det A$. Below the parabola $\det A = (\operatorname{tr} A)^2/4$ there are two real eigenvalues, and above it none. The rotation $R_{\pi/2}$ sits at $(0, 1)$, above the parabola. The matrix $\left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ of Example 7.2.8 sits at $(4, 3)$ and the reflection $\operatorname{diag}(1, -1)$ at $(0, -1)$, both below. The shear $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ sits on the parabola at $(2, 1)$, as do I_2 and the matrix of Example 7.2.39 (at $(4, 4)$). A point on the parabola can be a multiple of I_2 or not: the plane cannot tell them apart.

Exercise 7.3.20. ROUTINE Let $A \in \mathbb{R}^{3\times 3}$ have $\operatorname{tr} A = 2$ and $\det A = -2$, and suppose $A - I_3$ is not invertible and p_A splits over $\mathbb{R}$. Find p_A and the eigenvalues of A.

Solution on page 1575

Products in either order

For square matrices, AB and BA are usually different, and they need not be similar. But their characteristic polynomials always agree.

Technique 7.3.21 (Compare AB and BA). The products AB and BA are close relatives. If A is invertible, they are similar: $BA = A^{-1}(AB)A$. In general they are not necessarily similar, but they still share the characteristic polynomial (when square) and the nonzero eigenvalues (always). Three ways to transfer information between them are useful. Conjugate by A when A is invertible, and reduce the general case to it by a polynomial identity in a perturbation parameter. Or embed both products in block matrices of twice the size that are similar. Or transport eigenvectors directly: if $AB\mathbf{v} = \lambda\mathbf{v}$ with $\lambda \neq 0$, then $B\mathbf{v} \neq \mathbf{0}$ and $BA(B\mathbf{v}) = \lambda B\mathbf{v}$.

Reach for it whenever a question involves a product in both orders, such as $A^{\mathsf{T}}A$ and AA^{T}, or $\mathbf{u}\mathbf{v}^{\mathsf{T}}$ and $\mathbf{v}^{\mathsf{T}}\mathbf{u}$. The canonical example is Proposition 7.3.22.

Used in. Proposition 7.3.22, Exercise 7.3.40, Exercise 7.3.41, Exercise 7.7.10, Proposition 8.3.20.

Proposition 7.3.22 (AB and BA). For $A, B \in F^{n\times n}$, $p_{AB} = p_{BA}$. In particular AB and BA have the same eigenvalues.

Intuition. If A is invertible, then $BA = A^{-1}(AB)A$ is similar to AB, and we are done by Proposition 7.3.11. If A is not invertible, AB and BA need not be similar: for $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $AB = B \neq 0$ while $BA = 0$. Two ideas get around this. The first replaces A by the invertible matrices $A + tI_n$, which differ from A by a parameter t that we then set to 0; this needs the identity to be polynomial in t, and enough values of t to conclude. The second finds a pair of larger matrices, built from AB and BA, that are similar for every A.

Proof (by block matrices). STANDARD

Uses. Proposition 7.3.11 (Similar matrices have the same characteristic polynomial), Proposition 7.3.15 (Block-triangular matrices), Theorem 2.4.34 (Block multiplication), Corollary 7.1.7 (No zero divisors, cancellation, and units)
Techniques. Compare AB and BA (Technique 7.3.21), Block decomposition (Technique 2.4.35)
Hint 1. Look for a $2n \times 2n$ matrix S with $\begin{pmatrix} AB & 0 \\ B & 0 \end{pmatrix} S = S \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix}$. Try S block upper triangular with identity blocks on the diagonal.
Hint 2. $S = \begin{pmatrix} I_n & A \\ 0 & I_n \end{pmatrix}$ works. Both block matrices are block triangular; compute their characteristic polynomials.
Hint 3. You get $x^n p_{AB} = x^n p_{BA}$. Cancel x^n in $F[x]$.
Sketch. With $X = \begin{pmatrix} AB & 0 \\ B & 0 \end{pmatrix}$, $Y = \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix}$, and $S = \begin{pmatrix} I_n & A \\ 0 & I_n \end{pmatrix}$, block multiplication gives $XS = \begin{pmatrix} AB & ABA \\ B & BA \end{pmatrix} = SY$, and S is invertible, so X and Y are similar. By Proposition 7.3.15, $p_X = p_{AB}x^n$ and $p_Y = x^n p_{BA}$. Cancel x^n (Corollary 7.1.7).

Consider the $2n \times 2n$ matrices

$$X = \begin{pmatrix} AB & 0 \\ B & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix}, \quad S = \begin{pmatrix} I_n & A \\ 0 & I_n \end{pmatrix}.$$

By block multiplication (Theorem 2.4.34),

$$XS = \begin{pmatrix} AB & ABA \\ B & BA \end{pmatrix} = SY.$$

The matrix S is invertible, with inverse $\begin{pmatrix} I_n & -A \\ 0 & I_n \end{pmatrix}$ (multiply out). So $Y = S^{-1}XS$, and $p_X = p_Y$ by Proposition 7.3.11. Both matrices are block triangular, so by Proposition 7.3.15,

$$p_X = p_{AB}p_{0_{n\times n}} = p_{AB}x^n, \quad p_Y = p_{0_{n\times n}}p_{BA} = x^n p_{BA}.$$

So $x^n p_{AB} = x^n p_{BA}$, and since $x^n \neq \mathbf{0}$, cancellation in $F[x]$ (Corollary 7.1.7(b)) gives $p_{AB} = p_{BA}$. The statement about eigenvalues follows from Theorem 7.3.6. □

Proof (by perturbation, when F is infinite). HARD

> *Uses.* Proposition 7.3.11 (Similar matrices have the same characteristic polynomial), Proposition 5.3.19 ($\det(A+tI_n)$ as a function of t), Proposition 7.3.2 (Determinants over a commutative ring), Proposition 7.1.22 (Counting roots), Corollary 7.1.23 (Polynomials and their values), Theorem 5.4.7 (Invertibility and the determinant)
> *Techniques.* Compare AB and BA (Technique 7.3.21), Polynomial identity arguments (Technique 5.5.24), det is a polynomial in the entries (Technique 5.3.18)
> *Hint 1.* Fix $\lambda \in F$. For a scalar s with $A+sI_n$ invertible, compare $\det(\lambda I_n - (A+sI_n)B)$ with $\det(\lambda I_n - B(A+sI_n))$.
> *Hint 2.* They are equal, by similarity. Now regard s as an indeterminate t: both sides are values of polynomials in t, and their difference has infinitely many roots.
> *Hint 3.* Set $t=0$ to get $p_{AB}(\lambda) = p_{BA}(\lambda)$ for every λ, and use that F is infinite once more.
> *Sketch.* Fix λ. In $F[t]$ let $g = \det(\lambda I_n - (A+tI_n)B) - \det(\lambda I_n - B(A+tI_n))$. For each $s \in F$ with $A+sI_n$ invertible, $g(s) = 0$ by similarity; this excludes at most n values of s. So g has infinitely many roots and $g = \mathbf{0}$. Then $g(0) = p_{AB}(\lambda) - p_{BA}(\lambda) = 0$ for every $\lambda \in F$, and Corollary 7.1.23 finishes.

Assume F is infinite, and fix $\lambda \in F$. Work in $F[t]$, polynomials in a new indeterminate t, and let

$$g = \det(\lambda I_n - (A+tI_n)B) - \det(\lambda I_n - B(A+tI_n)) \in F[t].$$

For $s \in F$, evaluating every entry at $t = s$ (Proposition 7.3.2(g)) gives

$$g(s) = \det(\lambda I_n - (A+sI_n)B) - \det(\lambda I_n - B(A+sI_n)).$$

If $A+sI_n$ is invertible, then $B(A+sI_n) = (A+sI_n)^{-1}((A+sI_n)B)(A+sI_n)$, so the two matrices $(A+sI_n)B$ and $B(A+sI_n)$ are similar, and their characteristic polynomials agree at λ (Proposition 7.3.11). So $g(s) = 0$.

By Proposition 5.3.19 and Theorem 5.4.7, $A+sI_n$ fails to be invertible only for roots s of a monic polynomial of degree n, that is, for at most n values of s (Proposition 7.1.22). Since F is infinite, g has infinitely many roots, so $g = \mathbf{0}$, again by Proposition 7.1.22. In particular $g(0) = 0$, which says $p_{AB}(\lambda) = p_{BA}(\lambda)$ by (7.3.1). This holds for every $\lambda \in F$, so $p_{AB} = p_{BA}$ by Corollary 7.1.23. □

The first proof is shorter and works over every field. The second shows a pattern that recurs: prove an identity for invertible matrices, where it is easy, and extend it to all matrices because both sides are polynomials. Over a finite field there are too few values of t, and this pattern alone does not suffice.

7.3.5 Companion matrices

Which polynomials occur as characteristic polynomials? Every characteristic polynomial of an $n \times n$ matrix is monic of degree n. Conversely, every such polynomial occurs, and the matrix realizing it already appeared twice: in Proposition 5.5.20 as a determinant computation, and after Proposition 7.2.35 as the matrix of an operator on a Krylov subspace.

Definition 7.3.23 (Companion matrix). Let $p = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \in F[x]$ be monic of degree $n \geq 1$. The **companion matrix** of p is

$$C_p = \begin{pmatrix} 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & \cdots & 0 & -a_1 \\ 0 & 1 & \cdots & 0 & -a_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & -a_{n-1} \end{pmatrix} \in F^{n\times n},$$

whose column k is $\mathbf{e}_{k+1}$ for $k < n$ and whose last column is $-(a_0, a_1, \ldots, a_{n-1})$.

For example, $C_{x-c} = (c)$, the companion matrix of x^2+1 is the rotation $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, and the companion matrix of $x^3 - 1$ is the matrix of the cyclic permutation Z in Example 7.3.14. In general $C_p\mathbf{e}_k = \mathbf{e}_{k+1}$ for $k < n$: C_p shifts the standard basis forward, and the last basis vector goes to $C_p\mathbf{e}_n = -(a_0\mathbf{e}_1 + \cdots + a_{n-1}\mathbf{e}_n)$. Some books use the transpose C_p^{T} instead; it has the same characteristic polynomial (Exercise 7.3.17).

Theorem 7.3.24 (Every monic polynomial is a characteristic polynomial). Let $p \in F[x]$ be monic of degree $n \geq 1$. Then $p_{C_p} = p$.

Proof (by rerunning Proposition 5.5.20). STANDARD

Uses. Proposition 5.5.20 (Companion matrices), Proposition 7.3.2 (Determinants over a commutative ring)
Hint 1. Proposition 5.5.20 proves $\det(tI_n - C) = p(t)$ for every scalar $t \in F$. Over a finite field this is weaker than an identity in $F[x]$. Which tools did its first proof use?
Hint 2. It used cofactor expansion along the first row, a triangular determinant, and induction on n. All of these are available over $F[x]$ by Proposition 7.3.2.
Sketch. The first proof of Proposition 5.5.20 expands $\det\big(tI_n - C_p\big)$ along the first row, recognizes one minor as the same kind of matrix for $q = (p - a_0)/x$ and the other as triangular with -1's on the diagonal, and inducts. Each step is valid with t replaced by the indeterminate x, by Proposition 7.3.2(e) and (f). So $\det\big(xI_n - C_p\big) = xq + a_0 = p$ in $F[x]$.

The first proof of Proposition 5.5.20 computes $\det\big(tI_n - C_p\big)$ by induction on n. It expands along the first row, identifies the minor at position $(1,1)$ as $tI_{n-1} - C_q$ for $q = a_1 + a_2x + \cdots + a_{n-1}x^{n-2} + x^{n-1}$, and the minor at position $(1,n)$ as an upper triangular matrix with diagonal entries -1. It then concludes $\det\big(tI_n - C_p\big) = tq(t) + a_0 = p(t)$. Every step uses only cofactor expansion, the determinant of a triangular matrix, and ring arithmetic. By Proposition 7.3.2(e) and (f) these hold in $F[x]^{n\times n}$, so the same induction, with the indeterminate x in place of the scalar t, proves $\det\big(xI_n - C_p\big) = xq + a_0 = p$ in $F[x]$. □

Proof (by expanding along the last column). STANDARD

Uses. Proposition 7.3.2 (Determinants over a commutative ring), Definition 7.3.23 (Companion matrix)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12)
Hint 1. The last column of $xI_n - C_p$ is $(a_0, a_1, \ldots, a_{n-2}, x + a_{n-1})$. Expand along it.
Hint 2. Deleting row k and column n leaves a block-diagonal matrix: a lower triangular block of size $k-1$ with x on the diagonal, and an upper triangular block of size $n-k$ with -1 on the diagonal.
Hint 3. So the minor is $x^{k-1}(-1)^{n-k}$, and the sign $(-1)^{k+n}$ cancels the $(-1)^{n-k}$.
Sketch. Let $M = xI_n - C_p$. The minor $M_{\widehat{kn}}$ is block diagonal, with a lower triangular $(k-1)\times(k-1)$ block with diagonal x and an upper triangular $(n-k)\times(n-k)$ block with diagonal -1, so $\det M_{\widehat{kn}} = x^{k-1}(-1)^{n-k}$. Expanding along column n: $\det M = \sum_k (-1)^{k+n} m_{kn} x^{k-1}(-1)^{n-k} = \sum_k m_{kn}x^{k-1} = a_0 + a_1x + \cdots + a_{n-2}x^{n-2} + (x + a_{n-1})x^{n-1} = p$.

For $n = 1$, $C_p = (-a_0)$ and $\det\big(xI_1 - C_p\big) = x + a_0 = p$. Let $n \geq 2$ and $M = xI_n - C_p$. Row k of M has -1 in column $k-1$ (if $k \geq 2$), x in column k (if $k \leq n-1$), and $m_{kn} = a_{k-1}$ in column n, except that $m_{nn} = x + a_{n-1}$; all other entries are 0. Fix k and delete row k and column n.

- Rows $1, \ldots, k-1$ have their nonzero entries (outside column n) in columns $1, \ldots, k-1$. They form a $(k-1)\times(k-1)$ lower triangular block L with diagonal entries x.
- Rows $k+1, \ldots, n$ have their nonzero entries (outside column n) in columns $k, \ldots, n-1$: row i has -1 in column $i-1$ and x in column i (if $i \leq n-1$). They form an $(n-k)\times(n-k)$ upper triangular block U with diagonal entries -1.

So $M_{\widehat{kn}} = \begin{pmatrix} L & 0 \\ 0 & U \end{pmatrix}$, and by Proposition 7.3.2(e), $\det M_{\widehat{kn}} = x^{k-1}(-1)^{n-k}$. (For $k = 1$ there is no block L, and for $k = n$ no block U; the formula still holds.) Expanding along column n (Proposition 7.3.2(f)),

$$\begin{aligned} \det M &= \sum_{k=1}^{n} (-1)^{k+n} m_{kn} x^{k-1}(-1)^{n-k} = \sum_{k=1}^{n} m_{kn}x^{k-1} \\ &= a_0 + a_1x + \cdots + a_{n-2}x^{n-2} + (x + a_{n-1})x^{n-1} = p, \end{aligned}$$

since $(-1)^{k+n}(-1)^{n-k} = (-1)^{2n} = 1$. □

The first proof builds p from the inside out, as in Horner's scheme. The second reads all coefficients off at once: the cofactor of the entry in row k of the last column is exactly x^{k-1}, so the last column of $xI_n - C_p$ is the list of coefficients of p and the expansion reassembles p.

Example 7.3.25 (Matrices with prescribed eigenvalues).

(a) The polynomial $p = x^3 - 2$ has no root in $\mathbb{Q}$ (a rational root would be an integer dividing 2, by the argument of Exercise 7.3.42, and none of $\pm 1, \pm 2$ works). So $C_p = \begin{pmatrix} 0 & 0 & 2 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$ has no eigenvalues in $\mathbb{Q}$, although over $\mathbb{R}$ it has the eigenvalue $\sqrt[3]{2}$.

(b) To get a real 2×2 matrix with eigenvalues 3 and -1 that is neither diagonal nor triangular, take $p = (x-3)(x+1) = x^2 - 2x - 3$ and $C_p = \begin{pmatrix} 0 & 3 \\ 1 & 2 \end{pmatrix}$.

The connection with Krylov subspaces gives the companion matrix its meaning. By Proposition 7.2.35, if $\mathbf{v} \neq \mathbf{0}$ and $K_T(\mathbf{v})$ is finite-dimensional, then $\mathbf{v}, T\mathbf{v}, \ldots, T^{d-1}\mathbf{v}$ is a basis of $K_T(\mathbf{v})$, and

$$T^d\mathbf{v} = -\big(c_0\mathbf{v} + c_1 T\mathbf{v} + \cdots + c_{d-1}T^{d-1}\mathbf{v}\big).$$

In this basis, $T\restriction_{K_T(\mathbf{v})}$ moves each basis vector to the next and sends the last one to the vector with coordinates $-(c_0, \ldots, c_{d-1})$. That is the description of C_p for $p = x^d + c_{d-1}x^{d-1} + \cdots + c_0$.

Proposition 7.3.26 (Krylov subspaces and the characteristic polynomial). Let V be finite-dimensional, $T \in \mathrm{L}(V)$, and $\mathbf{v} \in V$ with $\mathbf{v} \neq \mathbf{0}$. Let d and the monic polynomial p of degree d be as in Proposition 7.2.35, so that $p(T)\mathbf{v} = \mathbf{0}$. Then

(a) the matrix of $T\restriction_{K_T(\mathbf{v})}$ in the basis $\mathbf{v}, T\mathbf{v}, \ldots, T^{d-1}\mathbf{v}$ is C_p;

(b) $p_{T\restriction_{K_T(\mathbf{v})}} = p$;

(c) p divides p_T.

Proof. ROUTINE

Uses. Proposition 7.2.35 (A basis of a Krylov subspace), Proposition 7.2.34 (The smallest invariant subspace containing a vector), Definition 2.3.1 (Matrix of a linear map), Theorem 7.3.24 (Every monic polynomial is a characteristic polynomial), Corollary 7.3.16 (Invariant subspaces give factors)
Hint 1. Compute T on each basis vector $T^i\mathbf{v}$ and write the result in the basis.
Hint 2. For (b) use Theorem 7.3.24, and for (c) use that $K_T(\mathbf{v})$ is T-invariant.
Sketch. $T\big(T^i\mathbf{v}\big) = T^{i+1}\mathbf{v}$ for $i < d-1$, and $T\big(T^{d-1}\mathbf{v}\big) = -\sum_i c_i T^i\mathbf{v}$, so the columns are $\mathbf{e}_2, \ldots, \mathbf{e}_d$ and $-(c_0, \ldots, c_{d-1})$, which is C_p. Then the characteristic polynomial is $p_{C_p} = p$, and p divides p_T because $K_T(\mathbf{v})$ is invariant (Corollary 7.3.16).

Write $p = x^d + c_{d-1}x^{d-1} + \cdots + c_0$ and $\mathbf{b}_{i+1} = T^i\mathbf{v}$ for $0 \leq i \leq d-1$. For $i < d-1$, $T\mathbf{b}_{i+1} = T^{i+1}\mathbf{v} = \mathbf{b}_{i+2}$, and $T\mathbf{b}_d = T^d\mathbf{v} = -(c_0\mathbf{b}_1 + \cdots + c_{d-1}\mathbf{b}_d)$ because $p(T)\mathbf{v} = \mathbf{0}$. So column k of the matrix of $T\restriction_{K_T(\mathbf{v})}$ is $\mathbf{e}_{k+1}$ for $k < d$, and the last column is $-(c_0, \ldots, c_{d-1})$ (Definition 2.3.1). This is C_p, proving (a). Then (b) follows from (a), Definition 7.3.12, and Theorem 7.3.24. Since $K_T(\mathbf{v})$ is T-invariant (Proposition 7.2.34) and has dimension $d \geq 1$, (c) follows from (b) and Corollary 7.3.16. □

So every nonzero vector produces a factor of p_T, namely the polynomial that records the first dependence among $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$. In Example 7.2.36, the vectors $(1,1,1)$, $(1,-1,0)$, and $\mathbf{e}_1$ produced $x-1$, x^2+x+1, and x^3-1, and each divides $p_Z = x^3 - 1$. When $K_T(\mathbf{v}) = V$, part (b) says $p_T = p$ (Exercise 7.3.50).

7.3.6 Eigenvalues exist over $\mathbb{C}$

Example 7.2.18 showed that a real operator need not have an eigenvalue, and Example 7.2.20 that an operator on an infinite-dimensional space need not either. Neither obstruction survives over $\mathbb{C}$ in finite dimensions.

Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$). Let V be a finite-dimensional complex vector space with $V \neq \{\mathbf{0}\}$, and let $T \in \mathrm{L}(V)$. Then T has an eigenvalue. In particular, every $A \in \mathbb{C}^{n\times n}$ with $n \geq 1$ has an eigenvalue.

The two proofs below locate the eigenvalue in two different polynomials. The first uses p_T, which collects all eigenvalues at once and needs determinants. The second uses the polynomial of a single Krylov sequence, which only needs linear dependence.

Proof (via the characteristic polynomial). ROUTINE

> *Uses.* Proposition 7.3.18 (The first and last coefficients), Theorem 7.1.32 (Fundamental Theorem of Algebra), Corollary 7.3.13 (Eigenvalues of an operator)
> *Hint 1.* What is the degree of p_T?
> *Hint 2.* A polynomial of degree at least 1 over $\mathbb{C}$ has a root (Theorem 7.1.32).
> *Sketch.* p_T has degree $\dim V \geq 1$, so it has a root $\lambda \in \mathbb{C}$ by the FTA, and λ is an eigenvalue by Corollary 7.3.13.

Let $n = \dim V \geq 1$. By Proposition 7.3.18, p_T is monic of degree n, in particular nonconstant. By Theorem 7.1.32 it has a root $\lambda \in \mathbb{C}$, and λ is an eigenvalue of T by Corollary 7.3.13. □

> *Intuition (A proof without determinants).* Take any $\mathbf{v} \neq \mathbf{0}$ and look at $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$. In a space of dimension n, the $n+1$ vectors $\mathbf{v}, \ldots, T^n\mathbf{v}$ are dependent, so some nonzero polynomial q has $q(T)\mathbf{v} = \mathbf{0}$. Over $\mathbb{C}$ we can factor $q = c(x-\lambda_1)\cdots(x-\lambda_m)$, so
>
> $$c(T - \lambda_1 \operatorname{id})(T - \lambda_2 \operatorname{id})\cdots(T - \lambda_m \operatorname{id})\mathbf{v} = \mathbf{0}$$
>
> with $\mathbf{v} \neq \mathbf{0}$. A composite of injective maps is injective, so some factor $T - \lambda_j \operatorname{id}$ is not injective, and λ_j is an eigenvalue. If we use the *first* dependence, the polynomial p of Proposition 7.2.35, we can even say which vector is the eigenvector: split off one linear factor, $p = (x-\lambda)q$, and apply $q(T)$ to $\mathbf{v}$. The result is nonzero because q has smaller degree than p, and $T - \lambda \operatorname{id}$ kills it.

> **Technique 7.3.28** (Krylov sequences must become dependent). In a finite-dimensional space, the sequence $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ eventually becomes dependent, and the first dependence is a monic polynomial p with $p(T)\mathbf{v} = \mathbf{0}$ and no nonzero polynomial of smaller degree killing $\mathbf{v}$ (Proposition 7.2.35). This converts a question about T into a question about one polynomial: factor p, and use the factors to build vectors. If $p = fq$ with $\deg f \geq 1$, then $\mathbf{w} = q(T)\mathbf{v}$ is nonzero and $f(T)\mathbf{w} = \mathbf{0}$, so a factor $f = x - \lambda$ produces an eigenvector, and a quadratic factor produces a two-dimensional invariant subspace (Theorem 7.3.31).
>
> Reach for it when you need an eigenvector or a small invariant subspace and want to avoid determinants, or when V is infinite-dimensional but some Krylov subspace is not. The canonical example is the second proof of Theorem 7.3.27.
> *Used in.* Theorem 7.3.27, Theorem 7.3.31, Exercise 7.3.45, Exercise 7.3.46, Exercise 7.3.51, Lemma 7.6.21, Exercise 7.6.47, Problem 7.9, Problem 7.15, Theorem 8.1.3.

Proof (via a Krylov sequence, without determinants). STANDARD

> *Uses.* Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.1.32 (Fundamental Theorem of Algebra), Theorem 7.1.20 (Factor theorem), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 7.2.6 (Eigenvalue, eigenvector)
> *Techniques.* Krylov sequences must become dependent (Technique 7.3.28), Too many vectors force a dependence (Technique 4.1.30)
> *Hint 1.* Fix $\mathbf{v} \neq \mathbf{0}$. The sequence $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ cannot stay independent. Use the first dependence, from Proposition 7.2.35.
> *Hint 2.* This gives a monic p of degree $d \geq 1$ with $p(T)\mathbf{v} = \mathbf{0}$, and no nonzero polynomial of degree less than d kills $\mathbf{v}$. Use the FTA to split off a linear factor $x - \lambda$.
> *Hint 3.* Write $p = (x-\lambda)q$. Then $q(T)\mathbf{v} \neq \mathbf{0}$ (why?) and $(T - \lambda \operatorname{id})q(T)\mathbf{v} = p(T)\mathbf{v}$.
> *Sketch.* Let $\mathbf{v} \neq \mathbf{0}$ and let p, of degree $d \geq 1$, record the first dependence among $\mathbf{v}, T\mathbf{v}, \ldots$ (Proposition 7.2.35). By the FTA and the factor theorem, $p = (x-\lambda)q$ with q monic of degree $d-1$. Then $\mathbf{w} = q(T)\mathbf{v} \neq \mathbf{0}$ by the minimality of d, and $(T - \lambda \operatorname{id})\mathbf{w} = p(T)\mathbf{v} = \mathbf{0}$. So $\mathbf{w}$ is an eigenvector for λ.

Choose $\mathbf{v} \in V$ with $\mathbf{v} \neq \mathbf{0}$. Since V is finite-dimensional, so is $K_T(\mathbf{v})$, and Proposition 7.2.35 gives $d \geq 1$ and a monic polynomial $p \in \mathbb{C}[x]$ of degree d with $p(T)\mathbf{v} = \mathbf{0}$, such that no nonzero polynomial of degree less than d sends $\mathbf{v}$ to $\mathbf{0}$.

As $\deg p = d \geq 1$, the FTA (Theorem 7.1.32) gives a root $\lambda \in \mathbb{C}$ of p, and the factor theorem (Theorem 7.1.20) gives $p = (x - \lambda)q$ for some $q \in \mathbb{C}[x]$. Comparing leading coefficients and degrees, q is monic of degree $d - 1$; in particular $q \neq \mathbf{0}$. Let $\mathbf{w} = q(T)\mathbf{v}$. Since q is nonzero of degree less than d, $\mathbf{w} \neq \mathbf{0}$. By Proposition 7.2.27(a),

$$(T - \lambda\,\mathrm{id})\mathbf{w} = ((x - \lambda)q)(T)\mathbf{v} = p(T)\mathbf{v} = \mathbf{0}.$$

So $T\mathbf{w} = \lambda\mathbf{w}$ with $\mathbf{w} \neq \mathbf{0}$, and λ is an eigenvalue of T (Definition 7.2.6). □

Example 7.3.29 (Finding an eigenvector from a Krylov sequence). Let $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \in \mathbb{C}^{2\times 2}$ and $\mathbf{v} = \mathbf{e}_1$. Then $A\mathbf{v} = \mathbf{e}_2$, which is not a multiple of $\mathbf{e}_1$, and $A^2\mathbf{v} = -\mathbf{e}_1 = -\mathbf{v}$. So the first dependence is $A^2\mathbf{v} + \mathbf{v} = \mathbf{0}$, and $p = x^2 + 1 = (x - i)(x + i)$. Splitting off $x - i$ leaves $q = x + i$, and

$$\mathbf{w} = (A + iI_2)\mathbf{e}_1 = (i, 1), \quad A\mathbf{w} = (-1, i) = i(i, 1).$$

Splitting off $x + i$ instead gives $(A - iI_2)\mathbf{e}_1 = (-i, 1)$, an eigenvector for $-i$. For the cyclic permutation Z and $\mathbf{v} = \mathbf{e}_1$, the first dependence is $x^3 - 1 = (x - 1)\big(x^2 + x + 1\big)$ (Example 7.2.36), and $\big(Z^2 + Z + \mathrm{id}\big)\mathbf{e}_1 = (1, 1, 1)$ is the eigenvector for 1.

Intuition (Comparing the two proofs). The first proof is shorter, but it rests on determinants over $F[x]$, and it finds an eigenvalue without an eigenvector. The second proof needs only linear dependence and polynomial arithmetic. It also uses less: it never needs all of V, only the finite-dimensional subspace $K_T(\mathbf{v})$. So it shows, for instance, that an operator on an infinite-dimensional complex space has an eigenvalue as soon as some nonzero vector has a finite-dimensional Krylov subspace. On the other hand, the first proof locates every eigenvalue at once, with multiplicities, which the second does not.

Both proofs use exactly one property of $\mathbb{C}$: every nonconstant polynomial over $\mathbb{C}$ has a root. So both prove the theorem over any field with this property, and over $\mathbb{R}$ both fail at the same step, with the rotation as the witness: its characteristic polynomial is $x^2 + 1$, and so is the Krylov polynomial of every $\mathbf{v} \neq \mathbf{0}$. Over a finite field the theorem always fails (Exercise 7.3.44).

7.3.7 Real operators BEYOND 21-242

Real operators and complexification are covered in LADR and LADW (5.8), but not in 21-242 lecture.

Over $\mathbb{R}$ an operator may have no eigenvalue, but it cannot avoid small invariant subspaces altogether.

Proposition 7.3.30 (Odd dimension). Let V be a real vector space of odd dimension. Then every $T \in \mathrm{L}(V)$ has an eigenvalue.

Proof. ROUTINE

Uses. Proposition 7.3.18 (The first and last coefficients), Corollary 7.1.43 (Odd degree gives a real root), Corollary 7.3.13 (Eigenvalues of an operator)
Hint. What is the degree of p_T, and what do you know about real polynomials of that degree?
Sketch. $p_T \in \mathbb{R}[x]$ has odd degree $\dim V$, so it has a real root (Corollary 7.1.43), which is an eigenvalue.

By Proposition 7.3.18, $p_T \in \mathbb{R}[x]$ has degree $\dim V$, which is odd. By Corollary 7.1.43 it has a real root λ, and λ is an eigenvalue of T by Corollary 7.3.13. □

For example, every operator on $\mathbb{R}^3$ maps some line to itself; for a rotation this is its axis. In even dimension there may be no eigenvalue: the operator on $\mathbb{R}^4$ with matrix $\begin{pmatrix} R_{\pi/2} & 0 \\ 0 & R_{\pi/2} \end{pmatrix}$ has characteristic polynomial $\big(x^2 + 1\big)^2$ by Proposition 7.3.15. It still has invariant planes, such as $\mathrm{span}(\mathbf{e}_1, \mathbf{e}_2)$.

Theorem 7.3.31 (Small invariant subspaces). Let V be a finite-dimensional real vector space with $V \neq \{\mathbf{0}\}$, and let $T \in \mathrm{L}(V)$. Then T has an invariant subspace of dimension 1 or 2.

Proof (via a Krylov sequence). STANDARD

Uses. Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.1.39 (Factorization over $\mathbb{R}$), Proposition 7.2.27 (Evaluating polynomials at an operator), Proposition 7.2.4 (Invariance is checked on a spanning list), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors)
Techniques. Krylov sequences must become dependent (Technique 7.3.28)
Hint 1. Imitate the second proof of Theorem 7.3.27. What replaces the FTA over $\mathbb{R}$?
Hint 2. By Theorem 7.1.39, the polynomial p of the first dependence has a monic factor f of degree 1 or 2. Write $p = fq$ and set $\mathbf{w} = q(T)\mathbf{v}$.
Hint 3. If $f = x^2 + bx + c$, then $T^2\mathbf{w} = -bT\mathbf{w} - c\mathbf{w}$. Which subspace is invariant?
Sketch. Let p record the first dependence of a Krylov sequence. Over $\mathbb{R}$, p has a monic factor f of degree 1 or 2 (Theorem 7.1.39); write $p = fq$. Then $\mathbf{w} = q(T)\mathbf{v} \neq \mathbf{0}$ and $f(T)\mathbf{w} = \mathbf{0}$. If $f = x - \lambda$, $\mathbf{w}$ spans an invariant line. If $f = x^2 + bx + c$, then $T(T\mathbf{w}) = -bT\mathbf{w} - c\mathbf{w}$, so $\operatorname{span}(\mathbf{w}, T\mathbf{w})$ is invariant, of dimension 1 or 2.

Choose $\mathbf{v} \neq \mathbf{0}$ and let p, monic of degree $d \geq 1$, be as in Proposition 7.2.35. By Theorem 7.1.39, p is a product of monic factors of degree 1 and 2 (times its leading coefficient 1), so $p = fq$ with f monic of degree 1 or 2 and q monic of degree less than d. Let $\mathbf{w} = q(T)\mathbf{v}$. Then $\mathbf{w} \neq \mathbf{0}$ by the minimality in Proposition 7.2.35, and $f(T)\mathbf{w} = p(T)\mathbf{v} = \mathbf{0}$ by Proposition 7.2.27(a).

If $f = x - \lambda$, then $T\mathbf{w} = \lambda\mathbf{w}$, so $\operatorname{span}(\mathbf{w})$ is an invariant line (Proposition 7.2.7). If $f = x^2 + bx + c$, then $T^2\mathbf{w} + bT\mathbf{w} + c\mathbf{w} = \mathbf{0}$. Let $U = \operatorname{span}(\mathbf{w}, T\mathbf{w})$. Then $T\mathbf{w} \in U$ and $T(T\mathbf{w}) = -bT\mathbf{w} - c\mathbf{w} \in U$, so U is T-invariant by Proposition 7.2.4. It has dimension 1 or 2, since $\mathbf{w} \neq \mathbf{0}$ and it is spanned by two vectors. □

A second proof, through complex eigenvectors, follows in the next subsection.

7.3.8 Complexification BEYOND 21-242

To use complex eigenvalues for a real operator, we need a complex vector space for it to act on. For $\mathbb{R}^n$ the answer is $\mathbb{C}^n$: a real matrix is also a complex matrix. For an abstract real vector space V, we build the complex space by adjoining "imaginary parts", just as $\mathbb{C}$ is built from $\mathbb{R}$ (Definition 1.1.29).

Definition 7.3.32 (Complexification). Let V be a real vector space. Its **complexification** $V_{\mathbb{C}}$ is the set $V \times V$, whose element $(\mathbf{u}, \mathbf{v})$ we write $\mathbf{u} + i\mathbf{v}$, with addition $(\mathbf{u} + i\mathbf{v}) + (\mathbf{u}' + i\mathbf{v}') = (\mathbf{u} + \mathbf{u}') + i(\mathbf{v} + \mathbf{v}')$ and scalar multiplication by $a + bi \in \mathbb{C}$ $(a, b \in \mathbb{R})$ given by

$$(a + bi)(\mathbf{u} + i\mathbf{v}) = (a\mathbf{u} - b\mathbf{v}) + i(b\mathbf{u} + a\mathbf{v}).$$

We identify $\mathbf{u} \in V$ with $\mathbf{u} + i\mathbf{0} \in V_{\mathbb{C}}$. For $T \in \mathrm{L}(V)$, its **complexification** is $T_{\mathbb{C}} : V_{\mathbb{C}} \to V_{\mathbb{C}}$, $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = T\mathbf{u} + iT\mathbf{v}$.

The formula for scalar multiplication is what we get by expanding $(a + bi)(\mathbf{u} + i\mathbf{v})$ formally with $i^2 = -1$. For $V = \mathbb{R}^n$, the map $\mathbf{u} + i\mathbf{v} \mapsto \mathbf{u} + i\mathbf{v} \in \mathbb{C}^n$ (with the right side computed coordinatewise) identifies $V_{\mathbb{C}}$ with $\mathbb{C}^n$, and $T_{\mathbb{C}}$ with the complex matrix of T.

Proposition 7.3.33 (Basic properties). Let V be a real vector space and $T \in \mathrm{L}(V)$.

(a) $V_{\mathbb{C}}$ is a complex vector space.

(b) If $\mathbf{b}_1, \ldots, \mathbf{b}_n$ is a basis of V over $\mathbb{R}$, it is a basis of $V_{\mathbb{C}}$ over $\mathbb{C}$. In particular $\dim_{\mathbb{C}} V_{\mathbb{C}} = \dim_{\mathbb{R}} V$.

(c) $T_{\mathbb{C}}$ is $\mathbb{C}$-linear, and $[T_{\mathbb{C}}]_{\mathcal{B}\mathcal{B}} = [T]_{\mathcal{B}\mathcal{B}}$ for every basis $\mathcal{B}$ of V. In particular $p_{T_{\mathbb{C}}} = p_T$ when V is finite-dimensional and nonzero.

Proof. STANDARD

Uses. Definition 7.3.32 (Complexification), Definition 1.2.1 (Vector space), Definition 1.6.1 (Basis), Definition 2.3.1 (Matrix of a linear map), Definition 7.3.12 (Characteristic polynomial of an operator)
Hint 1. For (a), most axioms hold coordinatewise. The interesting one is $(\alpha\beta)\mathbf{z} = \alpha(\beta\mathbf{z})$; expand both sides with $\alpha = a + bi$, $\beta = c + di$.
Hint 2. For (b), write $\mathbf{u} + i\mathbf{v}$ with $\mathbf{u} = \sum \alpha_k \mathbf{b}_k$ and $\mathbf{v} = \sum \beta_k \mathbf{b}_k$, and compute $\sum(\alpha_k + i\beta_k)\mathbf{b}_k$.
Hint 3. For (c), check $T_{\mathbb{C}}((a + bi)\mathbf{z}) = (a + bi)T_{\mathbb{C}}(\mathbf{z})$ directly, and compute $T_{\mathbb{C}}\mathbf{b}_j$.

Sketch. (a) Addition is that of $V \times V$; scalar multiplication satisfies $1\mathbf{z} = \mathbf{z}$, both distributive laws (by linearity of the formula in (a, b) and in $(\mathbf{u}, \mathbf{v})$), and associativity, which reduces to the multiplication rule of $\mathbb{C}$. (b) $\sum(\alpha_k + i\beta_k)\mathbf{b}_k = \sum \alpha_k \mathbf{b}_k + i\sum \beta_k \mathbf{b}_k$, so spanning and independence over $\mathbb{C}$ reduce to the same statements over $\mathbb{R}$ for the real and imaginary parts. (c) Expanding gives linearity; $T_{\mathbb{C}}\mathbf{b}_j = T\mathbf{b}_j$ has the same real coordinates.

(a) $V \times V$ is a real vector space under coordinatewise operations, so addition in $V_{\mathbb{C}}$ satisfies the additive axioms. For scalar multiplication, $1(\mathbf{u} + i\mathbf{v}) = \mathbf{u} + i\mathbf{v}$ is the case $a = 1$, $b = 0$. The formula is additive in $a + bi$ and in $\mathbf{u} + i\mathbf{v}$ separately, which gives the two distributive laws. For associativity, let $\alpha = a + bi$ and $\beta = c + di$. Then

$$\begin{aligned}\alpha(\beta(\mathbf{u} + i\mathbf{v})) &= \alpha((c\mathbf{u} - d\mathbf{v}) + i(d\mathbf{u} + c\mathbf{v})) \\ &= (a(c\mathbf{u} - d\mathbf{v}) - b(d\mathbf{u} + c\mathbf{v})) + i(b(c\mathbf{u} - d\mathbf{v}) + a(d\mathbf{u} + c\mathbf{v})) \\ &= ((ac - bd)\mathbf{u} - (ad + bc)\mathbf{v}) + i((ad + bc)\mathbf{u} + (ac - bd)\mathbf{v}),\end{aligned}$$

which is $(\alpha\beta)(\mathbf{u} + i\mathbf{v})$ since $\alpha\beta = (ac - bd) + (ad + bc)i$.

(b) For $\alpha_k, \beta_k \in \mathbb{R}$, $(\alpha_k + i\beta_k)\mathbf{b}_k = (\alpha_k + i\beta_k)(\mathbf{b}_k + i\mathbf{0}) = \alpha_k\mathbf{b}_k + i\beta_k\mathbf{b}_k$, so

$$\sum_k (\alpha_k + i\beta_k)\mathbf{b}_k = \sum_k \alpha_k \mathbf{b}_k + i\sum_k \beta_k \mathbf{b}_k. \tag{7.3.2}$$

Every $\mathbf{u} + i\mathbf{v} \in V_{\mathbb{C}}$ is of this form, by expanding $\mathbf{u}$ and $\mathbf{v}$ in the basis, so the $\mathbf{b}_k$ span $V_{\mathbb{C}}$. If the left side of (7.3.2) is $\mathbf{0}$, then $\sum \alpha_k \mathbf{b}_k = \mathbf{0}$ and $\sum \beta_k \mathbf{b}_k = \mathbf{0}$, so all α_k and β_k vanish. Hence the $\mathbf{b}_k$ are independent over $\mathbb{C}$.

(c) $T_{\mathbb{C}}$ is additive because T is. For $a + bi \in \mathbb{C}$,

$$T_{\mathbb{C}}((a + bi)(\mathbf{u} + i\mathbf{v})) = T(a\mathbf{u} - b\mathbf{v}) + iT(b\mathbf{u} + a\mathbf{v}) = (aT\mathbf{u} - bT\mathbf{v}) + i(bT\mathbf{u} + aT\mathbf{v}),$$

which is $(a + bi)(T\mathbf{u} + iT\mathbf{v})$. Finally, $T_{\mathbb{C}}\mathbf{b}_j = T\mathbf{b}_j + i\mathbf{0} = \sum_k t_{kj}\mathbf{b}_k$, where $[T]_{\mathcal{B}\mathcal{B}} = (t_{kj})$, so $T_{\mathbb{C}}$ has the same matrix (Definition 2.3.1) and the same characteristic polynomial. □

Conjugation $\overline{\mathbf{u} + i\mathbf{v}} = \mathbf{u} - i\mathbf{v}$ on $V_{\mathbb{C}}$ commutes with $T_{\mathbb{C}}$, and this pairs up the eigenvectors of $T_{\mathbb{C}}$.

Proposition 7.3.34 (Eigenvalues of a complexification). Let $V \neq \{\mathbf{0}\}$ be a finite-dimensional real vector space and $T \in \mathrm{L}(V)$.

(a) A real number λ is an eigenvalue of T if and only if it is an eigenvalue of $T_{\mathbb{C}}$.

(b) If $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = \lambda(\mathbf{u} + i\mathbf{v})$, then $T_{\mathbb{C}}(\mathbf{u} - i\mathbf{v}) = \overline{\lambda}(\mathbf{u} - i\mathbf{v})$. So the nonreal eigenvalues of $T_{\mathbb{C}}$ come in conjugate pairs.

(c) If $\lambda = a + bi$ with $b \neq 0$ and $\mathbf{u} + i\mathbf{v}$ is an eigenvector of $T_{\mathbb{C}}$ for λ, then $\mathbf{u}, \mathbf{v}$ is linearly independent, $U = \mathrm{span}(\mathbf{u}, \mathbf{v})$ is T-invariant, and the matrix of $T|_U$ in the basis $\mathbf{u}, \mathbf{v}$ is $\begin{pmatrix} a & b \\ -b & a \end{pmatrix}$.

Proof. STANDARD

Uses. Proposition 7.3.33 (Basic properties), Corollary 7.3.13 (Eigenvalues of an operator), Proposition 7.2.4 (Invariance is checked on a spanning list), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Proposition 1.2.35 (Zero products)
Techniques. Complexify, then take real and imaginary parts (Technique 7.3.35)
Hint 1. For (a), compare characteristic polynomials.
Hint 2. For (b) and (c), write out $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = (a + bi)(\mathbf{u} + i\mathbf{v})$ and compare the parts in front of i and outside it.
Hint 3. You should get $T\mathbf{u} = a\mathbf{u} - b\mathbf{v}$ and $T\mathbf{v} = b\mathbf{u} + a\mathbf{v}$. If $\mathbf{u}, \mathbf{v}$ were dependent, they would lie on a T-invariant line.
Sketch. (a) $p_{T_{\mathbb{C}}} = p_T$. (b), (c) Comparing real and imaginary parts, $T\mathbf{u} = a\mathbf{u} - b\mathbf{v}$ and $T\mathbf{v} = b\mathbf{u} + a\mathbf{v}$, which gives both the conjugate eigenvector and the invariant plane with matrix $\begin{pmatrix} a & b \\ -b & a \end{pmatrix}$. If $\mathbf{u}, \mathbf{v}$ were dependent, they would lie on an invariant line on which T acts by a real μ, forcing $\lambda = \mu$.

(a) By Proposition 7.3.33(c), $p_{T_{\mathbb{C}}} = p_T$. For real λ, both statements say $p_T(\lambda) = 0$, by Corollary 7.3.13 applied to T and to $T_{\mathbb{C}}$.

(b) Let $\lambda = a + bi$. The equation $T\mathbf{u} + iT\mathbf{v} = (a\mathbf{u} - b\mathbf{v}) + i(b\mathbf{u} + a\mathbf{v})$ is an equation in $V \times V$, so

$$T\mathbf{u} = a\mathbf{u} - b\mathbf{v}, \quad T\mathbf{v} = b\mathbf{u} + a\mathbf{v}. \tag{7.3.3}$$

Then $T_{\mathbb{C}}(\mathbf{u} - i\mathbf{v}) = (a\mathbf{u} - b\mathbf{v}) - i(b\mathbf{u} + a\mathbf{v})$, and the definition of scalar multiplication gives the same vector for $(a - bi)(\mathbf{u} + i(-\mathbf{v}))$. Since $\mathbf{u} + i\mathbf{v} \neq \mathbf{0}$, also $\mathbf{u} - i\mathbf{v} \neq \mathbf{0}$, so $\overline{\lambda}$ is an eigenvalue whenever λ is.

(c) By (7.3.3) and Proposition 7.2.4, U is T-invariant, and the coordinates of $T\mathbf{u}$ and $T\mathbf{v}$ in $\mathbf{u}, \mathbf{v}$ are $(a, -b)$ and (b, a), giving the matrix $\begin{pmatrix} a & b \\ -b & a \end{pmatrix}$, once we know that $\mathbf{u}, \mathbf{v}$ is independent. Suppose it is not. Since $\mathbf{u}$ and $\mathbf{v}$ are not both $\mathbf{0}$, U is then a line $\operatorname{span}(\mathbf{z})$, and it is T-invariant, so $T\mathbf{z} = \mu\mathbf{z}$ for some $\mu \in \mathbb{R}$ (Proposition 7.2.7). Writing $\mathbf{u} = \alpha\mathbf{z}$ and $\mathbf{v} = \beta\mathbf{z}$ with $\alpha, \beta \in \mathbb{R}$, we get $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = \mu(\mathbf{u} + i\mathbf{v})$. Comparing with $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = \lambda(\mathbf{u} + i\mathbf{v})$ gives $(\lambda - \mu)(\mathbf{u} + i\mathbf{v}) = \mathbf{0}$, so $\lambda = \mu \in \mathbb{R}$ by Proposition 1.2.35, contradicting $b \neq 0$. □

Technique 7.3.35 (Complexify, then take real and imaginary parts). To prove something about an operator T on a real vector space, pass to $T_{\mathbb{C}}$ on $V_{\mathbb{C}}$, where the FTA is available, use a complex result (an eigenvector, later a triangular form), and then split the conclusion into real and imaginary parts. A complex eigenvector $\mathbf{u} + i\mathbf{v}$ for $a + bi$ becomes the pair of real equations (7.3.3), and conjugation exchanges λ with $\overline{\lambda}$.

Reach for it when a statement about real operators is easy over $\mathbb{C}$, and the obstruction over $\mathbb{R}$ is only that p_T may have nonreal roots. The canonical example is the second proof of Theorem 7.3.31.
Used in. Proposition 7.3.34, Theorem 7.3.31, Exercise 7.7.12, Problem 7.17, Exercise 8.2.48, Theorem 8.4.27.

Proof of Theorem 7.3.31 (via complexification). STANDARD

Uses. Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 7.3.33 (Basic properties), Proposition 7.3.34 (Eigenvalues of a complexification), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors)
Techniques. Complexify, then take real and imaginary parts (Technique 7.3.35)
Hint 1. $T_{\mathbb{C}}$ acts on a nonzero finite-dimensional complex space. What does Theorem 7.3.27 give?
Hint 2. Split into the cases $\lambda \in \mathbb{R}$ and $\lambda \notin \mathbb{R}$, and use Proposition 7.3.34.
Sketch. $T_{\mathbb{C}}$ has an eigenvalue λ. If λ is real, it is an eigenvalue of T, and an eigenvector spans an invariant line. Otherwise an eigenvector $\mathbf{u} + i\mathbf{v}$ gives the invariant plane $\operatorname{span}(\mathbf{u}, \mathbf{v})$ of Proposition 7.3.34(c).

By Proposition 7.3.33(b), $V_{\mathbb{C}}$ is a nonzero finite-dimensional complex vector space, so $T_{\mathbb{C}}$ has an eigenvalue λ by Theorem 7.3.27. If $\lambda \in \mathbb{R}$, it is an eigenvalue of T by Proposition 7.3.34(a), and any eigenvector spans a T-invariant line (Proposition 7.2.7). If $\lambda \notin \mathbb{R}$, an eigenvector $\mathbf{u} + i\mathbf{v}$ of $T_{\mathbb{C}}$ gives the two-dimensional T-invariant subspace $\operatorname{span}(\mathbf{u}, \mathbf{v})$ of Proposition 7.3.34(c). □

The Krylov proof stays inside V and uses the real factorization of polynomials. The complexification proof uses only the complex theorem, but has to leave V and come back, and it is the version that generalizes, to the block triangular form of real operators (Section 7.5) and to real normal operators in Chapter 8.

Example 7.3.36 (Decomplexification). The opposite construction forgets structure. A complex vector space is also a real vector space, by restricting scalars to $\mathbb{R}$, and $\mathbb{C}^n$ becomes $\mathbb{R}^{2n}$ with real basis $\mathbf{e}_1, \ldots, \mathbf{e}_n, i\mathbf{e}_1, \ldots, i\mathbf{e}_n$. A complex matrix $A = P + iQ$, with $P, Q \in \mathbb{R}^{n \times n}$, acts by

$$(P + iQ)(\mathbf{x} + i\mathbf{y}) = (P\mathbf{x} - Q\mathbf{y}) + i(Q\mathbf{x} + P\mathbf{y}) \quad (\mathbf{x}, \mathbf{y} \in \mathbb{R}^n),$$

so as a real linear map of $\mathbb{R}^{2n}$ its matrix is $\begin{pmatrix} P & -Q \\ Q & P \end{pmatrix}$. For $n = 1$, multiplication by $a + bi$ on $\mathbb{C} = \mathbb{R}^2$ becomes $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$, as in Proposition B.1.18. Conversely, decomplexifying $V_{\mathbb{C}}$ gives $V \times V$, on which $T_{\mathbb{C}}$ acts as $\begin{pmatrix} T & 0 \\ 0 & T \end{pmatrix}$.

Exercises

Exercise 7.3.37. ROUTINE For each matrix, find p_A, the eigenvalues, and a basis of each eigenspace.

(a) $A = \begin{pmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{pmatrix} \in \mathbb{R}^{3\times 3}$.

(b) $A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & -5 & 4 \end{pmatrix} \in \mathbb{R}^{3\times 3}$.

(c) $A = \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix}$, over $\mathbb{R}$ and over $\mathbb{C}$.

Solution on page 1575

Exercise 7.3.38. STANDARD Let $A, B \in F^{n\times n}$. Prove or disprove:

(a) If $p_A = p_B$, then A and B are similar.

(b) If $p_A = p_B$, then $\operatorname{rank} A = \operatorname{rank} B$.

(c) For every $c \in F$, p_{A+cI_n} is obtained from p_A by substituting $x - c$ for x, that is, $p_{A+cI_n} = p_A(x - c)$.

(d) If $p_A = p_B$ and p_A has n distinct roots in F, then A and B are similar.

Solution on page 1576

Exercise 7.3.39. STANDARD

(a) Let $\tau : F^{n\times n} \to F^{n\times n}$ be transposition, $\tau(X) = X^{\mathsf{T}}$. Show that

$$p_\tau = (x-1)^{n(n+1)/2}(x+1)^{n(n-1)/2}.$$

(b) Let W be the real vector space of functions $\mathbb{R} \to \mathbb{R}$ with basis $\sin t, \cos t, t\sin t, t\cos t$. Find the characteristic polynomial of differentiation $D : W \to W$, and conclude that no nonzero function in W satisfies $f' = \lambda f$ with $\lambda \in \mathbb{R}$.

Solution on page 1576

Exercise 7.3.40. STANDARD Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$, where $m, n \geq 1$.

(a) Show that $x^n p_{AB} = x^m p_{BA}$.

(b) Deduce that AB and BA have the same nonzero eigenvalues.

(c) Prove (b) again without characteristic polynomials: if $AB\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$ and $\lambda \neq 0$, show that $B\mathbf{v}$ is an eigenvector of BA.

(d) Give an example in which 0 is an eigenvalue of BA but not of AB.

Solution on page 1577

Exercise 7.3.41. STANDARD Let $n \geq 2$ and $\mathbf{u}, \mathbf{v} \in F^n$.

(a) Show that $p_{\mathbf{u}\mathbf{v}^{\mathsf{T}}} = x^{n-1}\left(x - \mathbf{v}^{\mathsf{T}}\mathbf{u}\right)$.

(b) Let $J \in F^{n\times n}$ be the matrix whose entries are all 1. Find p_J and the eigenvalues of J over $\mathbb{Q}$, and over $\mathbb{F}_p$ for a prime p dividing n.

Solution on page 1577

Exercise 7.3.42. STANDARD Let $A \in \mathbb{Q}^{n\times n}$ have integer entries.

(a) Show that all coefficients of p_A are integers.

(b) Show that every rational eigenvalue of A is an integer that divides $\det A$.

(c) Show that $\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$ has no rational eigenvalue.

Solution on page 1578

Exercise 7.3.43. STANDARD Let $A \in \mathbb{R}^{n\times n}$ satisfy $A^2 = -I_n$.

(a) Show that n is even, using determinants.

(b) Give a second proof using p_A and the eigenvalues of A regarded as a complex matrix.

(c) Show that, conversely, $A^2 = -I_n$ has a solution in $\mathbb{R}^{n\times n}$ for every even n, and in $\mathbb{C}^{n\times n}$ for every n.

Solution on page 1578

Exercise 7.3.44. STANDARD Let F be a finite field with elements $c_1, \ldots, c_q$.

(a) Show that $p = (x - c_1)(x - c_2)\cdots\left(x - c_q\right) + 1$ has no root in F.

(b) Deduce that some operator on F^q has no eigenvalue. So Theorem 7.3.27 fails over every finite field.

(c) Write down this operator for $F = \mathbb{F}_2$ and check directly that it has no eigenvalue.

Solution on page 1579

Exercise 7.3.45. STANDARD Let $p = x^n + a_{n-1}x^{n-1} + \cdots + a_0 \in F[x]$ with $n \geq 2$, and let $C = C_p$.

(a) Show that $\operatorname{rank}(C - \lambda I_n) \geq n - 1$ for every $\lambda \in F$. So every eigenspace of C is a line.

(b) Let λ be a root of p and write $p = (x - \lambda)q$ with $q = x^{n-1} + b_{n-2}x^{n-2} + \cdots + b_0$. Show that $(b_0, b_1, \ldots, b_{n-2}, 1)$ is an eigenvector of C for λ.

(c) Show that F^n has a basis of eigenvectors of C if and only if p has n distinct roots in F.

Solution on page 1579

Exercise 7.3.46. STANDARD Let $A = \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix} \in \mathbb{C}^{3\times 3}$.

(a) For $\mathbf{v} = \mathbf{e}_1 + \mathbf{e}_3$, compute $\mathbf{v}, A\mathbf{v}, A^2\mathbf{v}, A^3\mathbf{v}$, and find the polynomial p of Proposition 7.2.35.

(b) Factor p over $\mathbb{C}$, and use the second proof of Theorem 7.3.27 to produce an eigenvector for each root.

(c) Repeat (a) for $\mathbf{v} = \mathbf{e}_1$. Which eigenvalue does this Krylov sequence miss, and why is that consistent with Proposition 7.3.26?

Solution on page 1579

Exercise 7.3.47. STANDARD Find the error in the following argument.

Claim. For every $A \in F^{n\times n}$, $p_A(A) = 0$.

"Proof." By definition, $p_A(x) = \det(xI_n - A)$. Substituting $x = A$ gives $p_A(A) = \det(AI_n - A) = \det(A - A) = \det 0 = 0$.

Solution on page 1580

Exercise 7.3.48. HARD Let $A \in F^{n\times n}$ with $A^k = 0$ for some $k \geq 1$.

(a) Show that in $F[x]^{n\times n}$,
$$(xI_n - A)\left(x^{k-1}I_n + x^{k-2}A + \cdots + xA^{k-2} + A^{k-1}\right) = x^k I_n.$$
(b) Deduce that $p_A = x^n$. In particular $\operatorname{tr} A = 0$, and 0 is the only eigenvalue of A.
(c) For $F = \mathbb{C}$, give a shorter proof of (b) using eigenvalues. Why does it not work over every field?

Solution on page 1581

Exercise 7.3.49. HARD Let $A \in F^{n\times n}$. For $f \in F[x]$, write $f(x^2)$ and $f(-x)$ for the polynomials obtained by substituting x^2 and $-x$ for x (Definition 7.1.9).
(a) Show that $p_{A^2}(x^2) = (-1)^n p_A(x)p_A(-x)$.
(b) Suppose $p_A = (x-\lambda_1)\cdots(x-\lambda_n)$. Show that $p_{A^2} = \left(x-\lambda_1^2\right)\cdots\left(x-\lambda_n^2\right)$.
(c) Deduce that if $A \in \mathbb{R}^{n\times n}$, p_A splits over $\mathbb{R}$, and $\operatorname{tr}\left(A^2\right) = 0$, then $p_A = x^n$.

Solution on page 1581

Exercise 7.3.50. HARD Let $\dim V = n \geq 1$ and $T \in \mathrm{L}(V)$. A vector $\mathbf{v}$ is a **cyclic vector** for T if $K_T(\mathbf{v}) = V$.
(a) Show that if T has a cyclic vector, then the matrix of T in some basis is C_{p_T}.
(b) Suppose $A, B \in F^{n\times n}$ both have cyclic vectors (for T_A and T_B). Show that A and B are similar if and only if $p_A = p_B$.
(c) Show that I_2 has no cyclic vector, and that C_p and C_p^{T} are similar for every monic p.

Solution on page 1582

Exercise 7.3.51. HARD BEYOND 21-242 Let V be finite-dimensional with $\dim V \geq 1$, and $T \in \mathrm{L}(V)$.
(a) Use Proposition 7.3.26 to show that $p_T(T) = 0$. This is the Cayley–Hamilton theorem (Theorem 7.6.20).
(b) Deduce that every $A \in F^{n\times n}$ satisfies a monic polynomial of degree n, improving the degree n^2 of Proposition 4.1.31.

Solution on page 1582

Exercise 7.3.52. HARD Let q be a prime and $f = x^2 - tx + d \in \mathbb{F}_q[x]$.
(a) Show that the number of matrices $A \in \mathbb{F}_q^{2\times 2}$ with $p_A = f$ is $q^2 + q$ if f has two distinct roots in $\mathbb{F}_q$, q^2 if it has one repeated root, and $q^2 - q$ if it has no root.
(b) Deduce that exactly $\left(q^2 - q\right)^2/2$ matrices in $\mathbb{F}_q^{2\times 2}$ have no eigenvalue in $\mathbb{F}_q$, and check that the counts in (a) add up to q^4.

Solution on page 1582

Exercise 7.3.53. HARD BEYOND 21-242 For $A \in F^{n\times n}$ and $S \subseteq \{1, \ldots, n\}$, let A_S be the principal submatrix of A with rows and columns in S, and let $e_k(A) = \sum_{|S|=k} \det A_S$ for $1 \leq k \leq n$, and $e_0(A) = 1$. Show that
$$p_A = \sum_{k=0}^{n} (-1)^k e_k(A) x^{n-k},$$
and check that this agrees with Proposition 7.3.18. For $n = 3$, write out the coefficient of x.

Solution on page 1583

Exercise 7.3.54. STANDARD BEYOND 21-242 Let V be a finite-dimensional real vector space, and let $T \in \mathrm{L}(V)$ have no eigenvalue.

(a) Show that every T-invariant subspace of V has even dimension.

(b) Give such a T on $\mathbb{R}^4$, and find three different T-invariant planes.

Solution on page 1584

Exercise 7.3.55. CHALLENGE Let $A, B \in \mathbb{C}^{n\times n}$ satisfy $AB - BA = A$.

(a) Show that $A^k B - BA^k = kA^k$ for every $k \geq 1$.

(b) Show that $A^k = 0$ for some k.

(c) Deduce that $p_A = x^n$.

Solution on page 1584

7.4 Diagonalization

Let $A = \begin{pmatrix} 4 & -2 \\ 1 & 1 \end{pmatrix}$, and suppose we want A^{100}. Multiplying out 100 copies of A is hopeless by hand, and the entries of the partial products show no obvious pattern. But A has two eigenvectors,

$$A\begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 2 \\ 2 \end{pmatrix} = 2\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad A\begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 6 \\ 3 \end{pmatrix} = 3\begin{pmatrix} 2 \\ 1 \end{pmatrix},$$

and they form a basis of $\mathbb{R}^2$. In this basis A only scales: it doubles the first coordinate and triples the second, so A^{100} multiplies them by 2^{100} and 3^{100}. All that remains is to convert coordinates back. This section finds which operators admit such a basis, by a test in terms of two kinds of multiplicity, and then uses such bases for matrix powers, linear recurrences, and the long-run behavior of linear dynamical systems.

Throughout, V is a finite-dimensional vector space over a field F with $\dim V = n \geq 1$, and $T \in \mathrm{L}(V)$.

7.4.1 Diagonalizable operators

Definition 7.4.1 (Diagonalizable). An operator $T \in \mathrm{L}(V)$ is **diagonalizable** if there is a basis $\mathcal{B}$ of V for which $[T]_{\mathcal{B}\mathcal{B}}$ is a diagonal matrix. A matrix $A \in F^{n\times n}$ is **diagonalizable** if it is similar to a diagonal matrix, that is, if

$$A = SDS^{-1}$$

for some invertible $S \in F^{n\times n}$ and some diagonal $D \in F^{n\times n}$. Such a factorization is a **diagonalization** of A.

The lecture defines a diagonalizable operator as one with a basis of eigenvectors. The next theorem shows that this is the same notion, and that the matrix and operator versions agree. A basis of V consisting of eigenvectors of T is called an **eigenbasis** for T.

Theorem 7.4.2 (Diagonalizable means an eigenbasis). Let $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V and $\lambda_1, \ldots, \lambda_n \in F$. Then

$$[T]_{\mathcal{B}\mathcal{B}} = \mathrm{diag}(\lambda_1, \ldots, \lambda_n) \iff T\mathbf{b}_j = \lambda_j \mathbf{b}_j \text{ for } j = 1, \ldots, n.$$

In particular, T is diagonalizable if and only if V has an eigenbasis for T, and then the diagonal entries of $[T]_{\mathcal{B}\mathcal{B}}$ are the eigenvalues of the vectors of the eigenbasis, in order.

For $A \in F^{n\times n}$ the following are equivalent:

(I) A is diagonalizable;

(II) the operator T_A on F^n is diagonalizable;

(III) F^n has a basis of eigenvectors of A.

More precisely, if S is invertible with columns $\mathbf{s}_1, \ldots, \mathbf{s}_n$ and $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$, then $A = SDS^{-1}$ if and only if $A\mathbf{s}_j = \lambda_j \mathbf{s}_j$ for every j.

Proof. ROUTINE

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.14 (Coordinates), Definition 7.2.6 (Eigenvalue, eigenvector), Example 2.4.10 (Diagonal matrices), Corollary 3.5.25 (The invertible matrix theorem), Proposition 2.3.16 (The matrix of T_A)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. What is the j-th column of $[T]_{\mathcal{BB}}$? When is it $\lambda_j \mathbf{e}_j$?
Hint 2. For matrices, rewrite $A = SDS^{-1}$ as $AS = SD$ and compare the two sides column by column. Right multiplication by a diagonal matrix scales columns.
Hint 3. Columns of an invertible matrix form a basis of F^n, and conversely (Corollary 3.5.25).
Sketch. The j-th column of $[T]_{\mathcal{BB}}$ is $\left[T\mathbf{b}_j\right]_{\mathcal{B}}$, and it equals $\lambda_j \mathbf{e}_j$ exactly when $T\mathbf{b}_j = \lambda_j \mathbf{b}_j$; basis vectors are nonzero, so these are eigenvectors. For matrices, $A = SDS^{-1}$ iff $AS = SD$, whose j-th columns are $A\mathbf{s}_j$ and $\lambda_j \mathbf{s}_j$. An invertible S is the same as a basis of columns, which gives (I) $\Leftrightarrow$ (III), and (II) $\Leftrightarrow$ (III) is the first part for T_A.

By Definition 2.3.1, the j-th column of $[T]_{\mathcal{BB}}$ is the coordinate vector $\left[T\mathbf{b}_j\right]_{\mathcal{B}}$. Since coordinates are unique (Definition 1.6.14), $\left[T\mathbf{b}_j\right]_{\mathcal{B}} = \lambda_j \mathbf{e}_j$ if and only if $T\mathbf{b}_j = \lambda_j \mathbf{b}_j$. So $[T]_{\mathcal{BB}} = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ exactly when $T\mathbf{b}_j = \lambda_j \mathbf{b}_j$ for all j. The vectors of a basis are nonzero, so in that case each $\mathbf{b}_j$ is an eigenvector with eigenvalue λ_j (Definition 7.2.6), and $\mathcal{B}$ is an eigenbasis. Conversely, if $\mathcal{B}$ is an eigenbasis with $T\mathbf{b}_j = \lambda_j \mathbf{b}_j$, then $[T]_{\mathcal{BB}} = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$. This proves the first two claims.

For matrices, let S be invertible with columns $\mathbf{s}_j$ and $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$. Multiplying on the right by S or by S^{-1} shows that $A = SDS^{-1}$ if and only if $AS = SD$. The j-th column of AS is $A\mathbf{s}_j$, and the j-th column of SD is $\lambda_j \mathbf{s}_j$, since right multiplication by a diagonal matrix scales the columns (Example 2.4.10). So $A = SDS^{-1}$ if and only if $A\mathbf{s}_j = \lambda_j \mathbf{s}_j$ for every j.

(I) $\Leftrightarrow$ (III). If $A = SDS^{-1}$, the columns of S form a basis of F^n by Corollary 3.5.25, and by the previous paragraph they are eigenvectors of A. Conversely, if $\mathbf{s}_1, \ldots, \mathbf{s}_n$ is a basis of F^n with $A\mathbf{s}_j = \lambda_j \mathbf{s}_j$, the matrix S with these columns is invertible (Corollary 3.5.25), and $A = SDS^{-1}$ with $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$.

(II) $\Leftrightarrow$ (III). The eigenvectors of A are by definition those of T_A, so this is the first part of the theorem applied to $T = T_A$. □

Remark 7.4.3 (Two readings of $A = SDS^{-1}$). The proof read $A = SDS^{-1}$ column by column: A scales the columns of S. There is also the reading of Section 4.5. If $\mathring{\mathcal{B}}$ is the list of columns of S, then $S = [\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}}$, and Theorem 4.5.17 gives

$$D = S^{-1}AS = [\mathrm{id}]_{\mathring{\mathcal{B}}\mathcal{E}}[T_A]_{\mathcal{EE}}[\mathrm{id}]_{\mathcal{E}\mathring{\mathcal{B}}} = [T_A]_{\mathring{\mathcal{B}}\mathring{\mathcal{B}}}.$$

Read from right to left, $A = SDS^{-1}$ says: convert standard coordinates into eigenbasis coordinates (S^{-1}), scale each coordinate by its eigenvalue (D), and convert back (S). Diagonalization is the strongest instance of Technique 4.5.33: the operator is as simple as an operator can be, and the basis that achieves this is made of the operator's own eigenvectors.

Example 7.4.4 (Diagonalizing a 2×2 matrix). Let $A = \begin{pmatrix} 4 & -2 \\ 1 & 1 \end{pmatrix} \in \mathbb{R}^{2\times 2}$, the matrix of the introduction. By Theorem 7.2.9, λ is an eigenvalue exactly when

$$\det(A - \lambda I_2) = (4 - \lambda)(1 - \lambda) + 2 = \lambda^2 - 5\lambda + 6 = (\lambda - 2)(\lambda - 3)$$

vanishes, so the eigenvalues are 2 and 3. Row reducing,

$$A - 2I_2 = \begin{pmatrix} 2 & -2 \\ 1 & -1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & -1 \\ 0 & 0 \end{pmatrix}, \quad A - 3I_2 = \begin{pmatrix} 1 & -2 \\ 1 & -2 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & -2 \\ 0 & 0 \end{pmatrix},$$

so $E_2 = \operatorname{span}((1,1))$ and $E_3 = \operatorname{span}((2,1))$. The vectors $(1,1)$ and $(2,1)$ are not parallel, so they form an eigenbasis, and by Theorem 7.4.2

$$A = SDS^{-1}, \quad S = \begin{pmatrix} 1 & 2 \\ 1 & 1 \end{pmatrix}, \quad D = \begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}, \quad S^{-1} = \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix}.$$

To check the work it is enough to verify $AS = SD$: both sides equal $\begin{pmatrix} 2 & 6 \\ 2 & 3 \end{pmatrix}$. The order of the columns is our choice. Swapping them swaps the diagonal entries of D, and rescaling a column of S by $c \neq 0$ changes nothing in D. So a diagonalization is far from unique, but D is unique up to the order of its entries (Theorem 7.4.16 will show why).

$$[\mathbf{e}_1]_{\mathcal{B}} = \begin{pmatrix} -1 \\ 1 \end{pmatrix}, \quad [A\mathbf{e}_1]_{\mathcal{B}} = \left[\begin{pmatrix} 4 \\ 1 \end{pmatrix}\right]_{\mathcal{B}} = \begin{pmatrix} -2 \\ 3 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}\begin{pmatrix} -1 \\ 1 \end{pmatrix}.$$

The standard grid and the grid of the eigenbasis $\mathcal{B} = (1,1),(2,1)$ of $A = \begin{pmatrix} 4 & -2 \\ 1 & 1 \end{pmatrix}$. In $\mathcal{B}$-coordinates A only scales, $[A\mathbf{v}]_{\mathcal{B}} = D[\mathbf{v}]_{\mathcal{B}}$ with $D = \operatorname{diag}(2,3)$. The vector $\mathbf{v} = \mathbf{e}_1$ starts with $[\mathbf{v}]_{\mathcal{B}} = (-1,1)$, so $A\mathbf{e}_1 = -2(1,1) + 3(2,1) = (4,1)$, which is the first column of A. In the interactive version, type $\mathbf{v} = (4,1)$ and confirm that its $\mathcal{B}$-coordinates are $(-2,3)$. Moving $\mathbf{v}$ along a line of the $\mathcal{B}$-grid changes only one coordinate, and A moves the point along the corresponding line of the stretched grid. (Interactive in the web version.)

In Example 7.4.4 the two eigenvalues were different, and that alone guaranteed the eigenbasis.

Corollary 7.4.5 (Distinct eigenvalues give a diagonalization). If T has $n = \dim V$ distinct eigenvalues $\lambda_1, \ldots, \lambda_n$, then T is diagonalizable: any choice of eigenvectors $\mathbf{v}_1, \ldots, \mathbf{v}_n$ for $\lambda_1, \ldots, \lambda_n$ is an eigenbasis, and in it T has matrix $\operatorname{diag}(\lambda_1, \ldots, \lambda_n)$. In particular, $A \in F^{n \times n}$ with n distinct eigenvalues is diagonalizable.

Proof. ROUTINE

Uses. Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Theorem 4.1.10 (Independent lists are short), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
Hint 1. Pick one eigenvector for each eigenvalue. What do you know about this list?
Hint 2. It is independent and has length $\dim V$.
Sketch. Eigenvectors for distinct eigenvalues are independent (Theorem 7.2.21), and n independent vectors in an n-dimensional space form a basis (Theorem 4.1.10(b)). Apply Theorem 7.4.2.

The list $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is independent by Theorem 7.2.21, and it has length $n = \dim V$, so it is a basis by Theorem 4.1.10(b). It consists of eigenvectors, so Theorem 7.4.2 gives $[T]_{\mathcal{B}\mathcal{B}} = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ for $\mathcal{B} = \mathbf{v}_1, \ldots, \mathbf{v}_n$. □

The converse fails: for $n \geq 2$, I_n is diagonal, with the single eigenvalue 1. Repeated eigenvalues are allowed as long as each one comes with enough eigenvectors.

Example 7.4.6 (A repeated eigenvalue with enough eigenvectors). The matrix $A = 2I_3 + J = \begin{pmatrix} 3 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 3 \end{pmatrix}$ of Example 7.2.14 has only the eigenvalues 2 and 5, with

$$E_2 = \operatorname{span}((1,-1,0),(0,1,-1)), \quad E_5 = \operatorname{span}((1,1,1)).$$

These three vectors form a basis of $\mathbb{R}^3$: the sum $E_2 + E_5$ is direct (Corollary 7.2.23), so concatenating bases gives an independent list (Theorem 4.4.13), of length 3. Hence

$$A = S\begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 5 \end{pmatrix}S^{-1}, \quad S = \begin{pmatrix} 1 & 0 & 1 \\ -1 & 1 & 1 \\ 0 & -1 & 1 \end{pmatrix}.$$

Obstructions to diagonalizability

There are two ways an operator can fail to be diagonalizable: it may have too few eigenvalues in F, or an eigenvalue may have too few eigenvectors. The simplest instance of the second failure is an operator with one eigenvalue.

Proposition 7.4.7 (One eigenvalue). Suppose T is diagonalizable and λ is its only eigenvalue. Then $T = \lambda \mathrm{id}_V$. In particular, if $A \in F^{n\times n}$ is diagonalizable with only eigenvalue λ, then $A = \lambda I_n$.

Proof. ROUTINE

Uses. Theorem 7.4.2 (Diagonalizable means an eigenbasis), Definition 7.2.6 (Eigenvalue, eigenvector)
Techniques. Check it on a basis (Technique 2.2.7)
Hint 1. Take an eigenbasis. What is the eigenvalue of each of its vectors?
Hint 2. Two linear maps that agree on a basis are equal.
Sketch. Every vector of an eigenbasis is an eigenvector, so its eigenvalue is λ. Then T and λ id agree on a basis, so they are equal.

Let $\mathbf{b}_1, \ldots, \mathbf{b}_n$ be an eigenbasis for T. The eigenvalue of each $\mathbf{b}_j$ is an eigenvalue of T, hence equals λ, so $T\mathbf{b}_j = \lambda\mathbf{b}_j = (\lambda \mathrm{id}_V)\mathbf{b}_j$ for every j. Two linear maps that agree on a basis are equal (Technique 2.2.7), so $T = \lambda\mathrm{id}_V$. For A, apply this to T_A: then $T_A = \lambda$ id, and its matrix in the standard basis is $A = \lambda I_n$. □

Example 7.4.8 (Shears and nilpotent matrices). Let $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, a shear, over any field. Then $J - \mu I_2 = \begin{pmatrix} 1-\mu & 1 \\ 0 & 1-\mu \end{pmatrix}$ has determinant $(1-\mu)^2$, so 1 is the only eigenvalue (Theorem 7.2.9). Since $J \neq I_2$, Proposition 7.4.7 shows that J is not diagonalizable. Directly: $E_1 = \ker\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} = \mathrm{span}(\mathbf{e}_1)$ is a line, so there is no basis of eigenvectors.

More generally, let $N \in F^{n\times n}$ be nilpotent and nonzero, say $N^k = 0$. If $N\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{0} = N^k\mathbf{v} = \lambda^k\mathbf{v}$, so $\lambda = 0$; and 0 is an eigenvalue, because N is not injective (otherwise N^k would be injective too, while $N^k = 0$ on $F^n \neq \{\mathbf{0}\}$). So 0 is the only eigenvalue, and $N \neq 0 = 0 \cdot I_n$ is not diagonalizable. The same argument works for an upper triangular matrix with all diagonal entries equal to λ: its only eigenvalue is λ, because $A - \mu I_n$ is triangular with diagonal entries $\lambda - \mu$, hence invertible for $\mu \neq \lambda$ (Proposition 5.3.15, Theorem 5.4.7). So it is diagonalizable only if it equals λI_n.

These are the minimal counterexamples of Technique 1.4.18 for diagonalizability. In particular, being invertible (J) and being diagonalizable are unrelated: J is invertible but not diagonalizable, and $\mathrm{diag}(1, 0)$ is diagonal but not invertible.

Example 7.4.9 (Rotations: the field matters). Let $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, the rotation by a right angle. By Example 7.2.18 its eigenvalues are the square roots of -1 in F.

- Over $\mathbb{R}$ there are none, so there are no eigenvectors at all, and A is not diagonalizable over $\mathbb{R}$.
- Over $\mathbb{C}$ the eigenvalues i and $-i$ are distinct, with eigenvectors $(1, -i)$ and $(1, i)$, so by Corollary 7.4.5

$$A = \begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}\begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}^{-1}.$$

- Over $\mathbb{F}_5$, where $2^2 = 3^2 = -1$, it is diagonalizable with eigenvalues 2 and 3; over $\mathbb{F}_3$ there are no eigenvalues.
- Over $\mathbb{F}_2$, A is the swap $(x, y) \mapsto (y, x)$, whose only eigenvalue is 1 (Example 7.2.17). Since $A \neq I_2$, it is not diagonalizable over $\mathbb{F}_2$, by Proposition 7.4.7. Over every field with $1 + 1 \neq 0$ the swap is diagonalizable, with eigenbasis $(1, 1), (1, -1)$.

So "diagonalizable" is a property of a matrix together with a field. The real matrix A fails for lack of eigenvalues, while over $\mathbb{F}_2$ the matrix fails for lack of eigenvectors.

Exercise 7.4.10. ROUTINE Without computing any eigenvectors, decide which of the following real matrices are diagonalizable over $\mathbb{R}$, and which over $\mathbb{C}$.

$$A_1 = \begin{pmatrix} 1 & 5 \\ 0 & 2 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 2 & 5 \\ 0 & 2 \end{pmatrix}, \quad A_3 = \begin{pmatrix} 1 & -2 \\ 1 & -1 \end{pmatrix}, \quad A_4 = \begin{pmatrix} 7 & 0 & 0 \\ 0 & 7 & 0 \\ 0 & 0 & 7 \end{pmatrix}.$$

Solution on page 1584

7.4.2 Algebraic and geometric multiplicity

The obstructions above suggest counting, for each eigenvalue, how many times it "should" occur on the diagonal and how many independent eigenvectors it actually has. The first count comes from the characteristic polynomial, the second from the eigenspace.

Recall from Section 7.3 that the characteristic polynomial of $A \in F^{n\times n}$ is the monic polynomial $p_A = \det(xI_n - A) \in F[x]$ of degree n (Definition 7.3.4), and that its roots in F are exactly the eigenvalues of A (Theorem 7.3.6). Similar matrices have the same characteristic polynomial, so the **characteristic polynomial of** T, $p_T = p_A$ for $A = [T]_{\mathcal{B}\mathcal{B}}$, does not depend on the basis $\mathcal{B}$. Determinants of matrices with entries in $F[x]$ obey the same rules as over F (triangular and block triangular matrices, products), as explained in Section 7.3; we use these rules freely.

Definition 7.4.11 (Algebraic multiplicity). Let $\lambda \in F$. The **algebraic multiplicity** of λ for T, written $\operatorname{am}_T(\lambda)$, is the multiplicity of λ as a root of p_T (Definition 7.1.24): the largest $m \geq 0$ with $(x-\lambda)^m$ dividing p_T. For a matrix A, $\operatorname{am}_A(\lambda)$ is the multiplicity of λ as a root of p_A.

Definition 7.4.12 (Geometric multiplicity). Let $\lambda \in F$. The **geometric multiplicity** of λ for T is

$$\operatorname{gm}_T(\lambda) = \dim E_\lambda(T) = \dim \ker(T - \lambda \mathrm{id}_V),$$

and for a matrix A, $\operatorname{gm}_A(\lambda) = \dim \ker(A - \lambda I_n)$.

We drop the subscript when the operator is clear. Both multiplicities are defined for every $\lambda \in F$, and by Theorem 7.3.6 and Theorem 7.2.9 each is positive exactly when λ is an eigenvalue. The geometric multiplicity is computed by row reduction, through a rank.

Lemma 7.4.13 (Geometric multiplicity through a rank). For every basis $\mathcal{B}$ of V and every $\lambda \in F$,

$$\operatorname{gm}_T(\lambda) = n - \operatorname{rank}([T]_{\mathcal{B}\mathcal{B}} - \lambda I_n).$$

In particular, $\operatorname{gm}_T(\lambda) = \operatorname{gm}_A(\lambda)$ for every matrix A of T, and similar matrices have the same geometric multiplicities.

Proof. ROUTINE

Uses. Theorem 4.2.11 (Rank–nullity), Proposition 4.2.15 (Rank through any matrix), Definition 2.3.1 (Matrix of a linear map), Theorem 4.5.25 (Similar matrices are one operator in two bases)
Hint 1. $\operatorname{gm}_T(\lambda)$ is the nullity of $T - \lambda$ id. What does rank–nullity say?
Hint 2. What is the matrix of $T - \lambda$ id in the basis $\mathcal{B}$?
Sketch. By rank–nullity, $\dim \ker(T - \lambda \mathrm{id}) = n - \operatorname{rank}(T - \lambda \mathrm{id})$. The matrix of $T - \lambda$ id in $\mathcal{B}$ is $[T]_{\mathcal{B}\mathcal{B}} - \lambda I_n$, and a map has the rank of any of its matrices. For a matrix A this is the same formula with $T = T_A$; similar matrices are matrices of one operator.

By Theorem 4.2.11, $\operatorname{gm}_T(\lambda) = \dim \ker(T - \lambda \mathrm{id}) = n - \operatorname{rank}(T - \lambda \mathrm{id})$. The matrix of a sum and of a scalar multiple of maps is the sum and the scalar multiple of the matrices, and $[\mathrm{id}]_{\mathcal{B}\mathcal{B}} = I_n$, so $[T - \lambda \mathrm{id}]_{\mathcal{B}\mathcal{B}} =$

$[T]_{\mathcal{BB}} - \lambda I_n$. A linear map has the same rank as each of its matrices (Proposition 4.2.15), which gives the formula. For $A \in F^{n\times n}$, $\mathrm{gm}_A(\lambda) = n - \mathrm{rank}(A - \lambda I_n)$ by the same computation with $T = T_A$ and the standard basis. Finally, two similar matrices are matrices of one operator in two bases (Theorem 4.5.25), so they have the same geometric multiplicities, namely those of that operator. □

Example 7.4.14 (The multiplicities of a diagonal matrix). Let $D = \mathrm{diag}(d_1, \ldots, d_n)$ and $\lambda \in F$, and let m be the number of indices i with $d_i = \lambda$. Then $xI_n - D = \mathrm{diag}(x - d_1, \ldots, x - d_n)$ is diagonal, so

$$p_D = (x - d_1)(x - d_2)\cdots(x - d_n),$$

and by Proposition 7.1.34, $\mathrm{am}_D(\lambda) = m$. On the other hand $D - \lambda I_n = \mathrm{diag}(d_1 - \lambda, \ldots, d_n - \lambda)$ has exactly $n - m$ nonzero columns, which are multiples of distinct standard basis vectors, so its rank is $n - m$, and $\mathrm{gm}_D(\lambda) = m$ by Lemma 7.4.13. So for a diagonal matrix the two multiplicities agree: both count how often λ occurs on the diagonal. Consequently, if T is diagonalizable, the number of times λ occurs on the diagonal of a diagonal matrix of T does not depend on the eigenbasis: it is $\mathrm{gm}_T(\lambda)$. This is why D in a diagonalization $A = SDS^{-1}$ is unique up to order.

For the shear $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, $p_J = (x-1)^2$, so $\mathrm{am}_J(1) = 2$, while $\mathrm{gm}_J(1) = 2 - \mathrm{rank}\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} = 1$.

Intuition (Why the geometric multiplicity cannot exceed the algebraic one). Suppose λ has g independent eigenvectors. Put them first in a basis. Then the first g columns of the matrix of T are $\lambda\mathbf{e}_1, \ldots, \lambda\mathbf{e}_g$, so the matrix is block upper triangular with top left block λI_g, and its characteristic polynomial picks up the factor $(x - \lambda)^g$ from that block. The bottom right block may contribute further factors $x - \lambda$, which are not visible as eigenvectors. For the shear, the bottom right block is the 1×1 matrix (1), and it contributes the second factor $x - 1$ without contributing a second eigenvector.

Theorem 7.4.15 (Geometric multiplicity is at most algebraic multiplicity). For every $\lambda \in F$,

$$\mathrm{gm}_T(\lambda) \le \mathrm{am}_T(\lambda).$$

If λ is an eigenvalue of T, then $1 \le \mathrm{gm}_T(\lambda) \le \mathrm{am}_T(\lambda)$.

Proof. STANDARD

Uses. Theorem 4.1.16 (Extending to a basis), Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Definition 7.2.13 (Eigenspace), Theorem 5.4.26 (Block-triangular matrices), Definition 7.3.4 (Characteristic polynomial), Definition 7.1.24 (Multiplicity of a root), Proposition 4.1.21 (Dimensions of subspaces)
Techniques. Choose a basis adapted to a preserved subspace (Technique 4.5.36)
Hint 1. Let $g = \mathrm{gm}_T(\lambda)$. Choose a basis of E_λ and extend it to a basis of V. What does the matrix of T look like?
Hint 2. E_λ is T-invariant and T acts on it as λ id, so by Proposition 4.5.35 the matrix is $\begin{pmatrix} \lambda I_g & B \\ 0 & C \end{pmatrix}$.
Hint 3. Compute $\det(xI_n - [T]_{\mathcal{BB}})$ with the block triangular rule. Which power of $x - \lambda$ divides it?
Sketch. Extend a basis of E_λ, of length g, to a basis $\mathcal{B}$ of V. Since T acts on E_λ as λ id, $[T]_{\mathcal{BB}} = \begin{pmatrix} \lambda I_g & B \\ 0 & C \end{pmatrix}$, so $p_T = \det\big((x - \lambda)I_g\big)\det\big(xI_{n-g} - C\big) = (x - \lambda)^g p_C$. Hence $(x - \lambda)^g$ divides p_T, and $g \le \mathrm{am}_T(\lambda)$. If λ is an eigenvalue, $E_\lambda \ne \{\mathbf{0}\}$, so $g \ge 1$.

Let $g = \mathrm{gm}_T(\lambda) = \dim E_\lambda$. If $g = 0$ there is nothing to prove. If $g = n$, then $E_\lambda = V$ (Proposition 4.1.21), so $T = \lambda \mathrm{id}_V$, $[T]_{\mathcal{BB}} = \lambda I_n$ in every basis, and $p_T = (x - \lambda)^n$; so $\mathrm{am}_T(\lambda) = n = g$.

Let $1 \le g < n$. Choose a basis $\mathbf{u}_1, \ldots, \mathbf{u}_g$ of E_λ and extend it to a basis $\mathcal{B} = \mathbf{u}_1, \ldots, \mathbf{u}_g, \mathbf{w}_1, \ldots, \mathbf{w}_{n-g}$ of V (Theorem 4.1.16). For $\mathbf{u} \in E_\lambda$ we have $T\mathbf{u} = \lambda\mathbf{u} \in E_\lambda$, so E_λ is mapped into itself, and the restriction of T to E_λ is $\lambda \mathrm{id}_{E_\lambda}$, whose matrix in $\mathbf{u}_1, \ldots, \mathbf{u}_g$ is λI_g. By Proposition 4.5.35,

$$[T]_{\mathcal{BB}} = \begin{pmatrix} \lambda I_g & B \\ 0 & C \end{pmatrix}$$

for some $B \in F^{g\times(n-g)}$ and $C \in F^{(n-g)\times(n-g)}$. Then

$$xI_n - [T]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} (x-\lambda)I_g & -B \\ 0 & xI_{n-g} - C \end{pmatrix}$$

is block upper triangular with entries in $F[x]$, and by Theorem 5.4.26

$$p_T = \det\Big((x-\lambda)I_g\Big) \cdot \det\Big(xI_{n-g} - C\Big) = (x-\lambda)^g p_C.$$

So $(x-\lambda)^g$ divides p_T, and $g \leq \mathrm{am}_T(\lambda)$ by Definition 7.1.24.

If λ is an eigenvalue, then E_λ contains a nonzero vector, so $g \geq 1$. □

The lecture calls Theorem 7.4.15 the "AM–GM inequality", as a joke: the inequality between the arithmetic and geometric means has the same letters in the same order. The proof is Technique 4.5.36 applied to the most obvious invariant subspace of T, an eigenspace.

We can now say exactly when T is diagonalizable. Let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T. Every eigenvector lies in some E_{λ_i}, the sum of these eigenspaces is direct (Corollary 7.2.23), and p_T has degree n. So

$$\mathrm{gm}(\lambda_1) + \cdots + \mathrm{gm}(\lambda_m) \leq \mathrm{am}(\lambda_1) + \cdots + \mathrm{am}(\lambda_m) \leq \deg p_T = n, \tag{7.4.1}$$

where the first inequality is Theorem 7.4.15 term by term, and the second is Proposition 7.1.27, since the λ_i are distinct roots of p_T. Diagonalizability turns out to mean that the left end equals the right end, which forces both inequalities to be equalities.

Theorem 7.4.16 (Criteria for diagonalizability). Let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T ($m \geq 0$). The following are equivalent.

(I) T is diagonalizable.

(II) $V = E_{\lambda_1} \oplus E_{\lambda_2} \oplus \cdots \oplus E_{\lambda_m}$.

(III) $\mathrm{gm}(\lambda_1) + \mathrm{gm}(\lambda_2) + \cdots + \mathrm{gm}(\lambda_m) = n$.

(IV) p_T splits over F, and $\mathrm{gm}(\lambda_i) = \mathrm{am}(\lambda_i)$ for $i = 1, \ldots, m$.

In that case, for every eigenbasis $\mathcal{B}$ the matrix $[T]_{\mathcal{B}\mathcal{B}}$ has λ_i on its diagonal exactly $\mathrm{gm}(\lambda_i) = \mathrm{am}(\lambda_i)$ times.

Proof, part 1 of 2: (I) ⇒ (II) ⇒ (III) ⇒ (I). STANDARD

Uses. Theorem 7.4.2 (Diagonalizable means an eigenbasis), Corollary 7.2.23 (Eigenspaces are independent), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 4.1.21 (Dimensions of subspaces), Proposition 4.4.2 (Sums are the smallest containing subspaces)
Techniques. Proving TFAE (Technique 2.7.1), Dimension counting (Technique 4.2.24), Glue bases of the summands (Technique 4.4.14)
Hint 1. For (I) ⇒ (II): where does each vector of an eigenbasis live? The sum is direct by Corollary 7.2.23.
Hint 2. For (II) ⇒ (III) and (III) ⇒ (I), use Theorem 4.4.13: the dimension of a direct sum, and bases of a direct sum by concatenation.
Hint 3. In (III) ⇒ (I), the concatenated list is independent of length n. Why is it a basis of V?
Sketch. (I) ⇒ (II): each vector of an eigenbasis lies in some E_{λ_i}, so the sum of the eigenspaces contains a basis and equals V; it is direct by Corollary 7.2.23. (II) ⇒ (III): the dimension of a direct sum is the sum of the dimensions. (III) ⇒ (I): the sum of the eigenspaces is direct, so concatenating their bases gives a basis of the sum, of length n; the sum is then all of V, and the concatenation is an eigenbasis.

Write $U = E_{\lambda_1} + \cdots + E_{\lambda_m}$. By Corollary 7.2.23 the sum is direct, whatever T is.

(I) ⇒ (II). Let $\mathcal{B}$ be an eigenbasis. Each vector of $\mathcal{B}$ is an eigenvector, whose eigenvalue is one of the λ_i, so it lies in $E_{\lambda_i} \subseteq U$. So U, which is a subspace (Proposition 4.4.2), contains a basis of V, hence contains its span V. Thus $V = U$, and the sum is direct.

(II) ⇒ (III). By Theorem 4.4.13(c), $n = \dim V = \dim E_{\lambda_1} + \cdots + \dim E_{\lambda_m}$.

(III) ⇒ (I). Choose a basis of each E_{λ_i} and concatenate them. Since U is a direct sum, the concatenation is a basis of U by Theorem 4.4.13(b), so $\dim U = \sum_i \operatorname{gm}(\lambda_i) = n$, and $U = V$ by Proposition 4.1.21(b). So the concatenation is a basis of V consisting of eigenvectors, and T is diagonalizable by Theorem 7.4.2.

So far nothing used the characteristic polynomial: (I), (II), and (III) are statements about eigenvectors only. Condition (IV) brings in the polynomial, through the squeeze (7.4.1).

Proof, part 2 of 2: (III) ⇔ (IV). STANDARD

> *Uses.* Theorem 7.4.15 (Geometric multiplicity is at most algebraic multiplicity), Proposition 7.1.27 (Multiplicities add up to at most the degree), Proposition 7.1.34 (Roots of a split polynomial), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Proposition 7.1.4 (Degree of a product), Example 7.4.14 (The multiplicities of a diagonal matrix)
> *Hint 1.* Look at the chain (7.4.1). Condition (III) says that its two ends are equal.
> *Hint 2.* A chain $a \le b \le c$ with $a = c$ forces $a = b$ and $b = c$. The first equality is a sum of termwise inequalities.
> *Hint 3.* For $\sum_i \operatorname{am}(\lambda_i) = n$ ⇔ "p_T splits": Proposition 7.1.27 gives a monic divisor of p_T of degree $\sum_i \operatorname{am}(\lambda_i)$; compare degrees.
> *Sketch.* In $\sum \operatorname{gm}(\lambda_i) \le \sum \operatorname{am}(\lambda_i) \le n$, (III) says the ends are equal. That holds iff $\operatorname{gm}(\lambda_i) = \operatorname{am}(\lambda_i)$ for each i (the terms satisfy gm ≤ am) and $\sum \operatorname{am}(\lambda_i) = n$. The latter means that $\prod (x - \lambda_i)^{\operatorname{am}(\lambda_i)}$, a monic divisor of p_T, has degree n, so equals p_T, i.e. p_T splits; conversely, if p_T splits, its roots are the λ_i and their multiplicities add up to n.

Write $g_i = \operatorname{gm}(\lambda_i)$ and $a_i = \operatorname{am}(\lambda_i)$. By Theorem 7.4.15, $g_i \le a_i$ for each i, so $\sum_i g_i \le \sum_i a_i$, with equality if and only if $g_i = a_i$ for every i. By Theorem 7.3.6 the λ_i are distinct roots of p_T, so by Proposition 7.1.27,

$$q = (x - \lambda_1)^{a_1} \cdots (x - \lambda_m)^{a_m} \text{ divides } p_T, \quad \text{and} \quad \sum_i a_i \le n.$$

We claim that $\sum_i a_i = n$ if and only if p_T splits. If $\sum_i a_i = n$, write $p_T = qh$. Comparing degrees (Proposition 7.1.4), $\deg h = 0$, and comparing leading coefficients, which are 1 for p_T and q, gives $h = 1$. So $p_T = q$ splits. Conversely, if p_T splits, then by Proposition 7.1.34 the multiplicities of its distinct roots add up to $\deg p_T = n$, and its roots are exactly the eigenvalues $\lambda_1, \ldots, \lambda_m$ (Theorem 7.3.6). So $\sum_i a_i = n$.

Now (III) says $\sum_i g_i = n$. Since $\sum_i g_i \le \sum_i a_i \le n$, this holds if and only if $\sum_i g_i = \sum_i a_i$ and $\sum_i a_i = n$, that is, if and only if $g_i = a_i$ for every i and p_T splits. This is (IV).

For the last claim, if $\mathcal{B}$ is an eigenbasis, $[T]_{\mathcal{B}\mathcal{B}}$ is a diagonal matrix of T, and by Example 7.4.14 and Lemma 7.4.13, λ_i occurs on its diagonal $\operatorname{gm}(\lambda_i)$ times. □

Remark 7.4.17 (Over $\mathbb{C}$, and over other fields). Over $\mathbb{C}$ every polynomial splits (Corollary 7.1.35), so a complex operator is diagonalizable if and only if $\operatorname{gm}(\lambda) = \operatorname{am}(\lambda)$ for every eigenvalue. Over $\mathbb{R}$, or over $\mathbb{Q}$ or $\mathbb{F}_p$, splitting is a genuine condition: the real rotation by a right angle has $p = x^2 + 1$, both sums in (7.4.1) are 0, and $n = 2$. Condition (III) handles both failures at once, which makes it the practical test: add up the dimensions of the eigenspaces and compare with n. Splitting alone is not enough, as the shear shows.

Algorithm 7.4.18 (Diagonalizing a matrix)

Input $A \in F^{n \times n}$.
Output An invertible S and a diagonal D with $A = SDS^{-1}$, or the conclusion that A is not diagonalizable over F.

1. Compute $p_A = \det(xI_n - A)$ and find its distinct roots $\lambda_1, \ldots, \lambda_m$ in F.
2. For each λ_i, row reduce $A - \lambda_i I_n$ and read off a basis of $E_{\lambda_i} = \ker(A - \lambda_i I_n)$, of length $g_i = n - \operatorname{rank}(A - \lambda_i I_n)$.
3. If $g_1 + \cdots + g_m < n$, stop: A is not diagonalizable over F.
4. Otherwise let S be the matrix whose columns are the basis vectors found in step 2, and D the diagonal matrix whose j-th entry is the eigenvalue of the j-th column of S. Check $AS = SD$.

The algorithm is correct by Theorem 7.4.16, (I) ⇔ (III), and the proof of (III) ⇒ (I) shows that the columns found in step 2 form a basis. In step 1 one can stop early if p_A does not split, and in step 2 as soon as some g_i is less than the multiplicity of λ_i as a root.

Example 7.4.19 (Two matrices that differ in one entry). Let

$$A = \begin{pmatrix} 3 & 1 & 1 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix}, \quad A' = \begin{pmatrix} 3 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 2 \end{pmatrix}.$$

Both are upper triangular with diagonal $3, 2, 2$, so $p_A = p_{A'} = (x-3)(x-2)^2$: the eigenvalue 3 is simple, and $\operatorname{am}(2) = 2$ for both. For A,

$$A - 2I_3 = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

has rank 1, so $\operatorname{gm}_A(2) = 2$, with $E_2 = \{(x, y, z) \mid x + y + z = 0\} = \operatorname{span}((1, -1, 0), (1, 0, -1))$. Since 3 is simple, $\operatorname{gm}_A(3) = 1$, by Theorem 7.4.15, and $E_3 = \operatorname{span}(\mathbf{e}_1)$. The dimensions add up to 3, and

$$A = S\begin{pmatrix} 3 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix}S^{-1}, \quad S = \begin{pmatrix} 1 & 1 & 1 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

For A',

$$A' - 2I_3 = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$$

has rank 2, so $\operatorname{gm}_{A'}(2) = 1 < 2 = \operatorname{am}_{A'}(2)$, and A' is not diagonalizable. The single entry $a'_{23} = 1$ destroys one eigenvector for 2. In particular A and A' are not similar, although they have the same characteristic polynomial (Lemma 7.4.13).

Example 7.4.20 (The Fibonacci matrix over several fields). Let $Q = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, so that $p_Q = \det\left(\begin{smallmatrix} x-1 & -1 \\ -1 & x \end{smallmatrix}\right) = x^2 - x - 1$. Each failure mode of Theorem 7.4.16 occurs over some field.

- Over $\mathbb{F}_2$, $p_Q = x^2 + x + 1$ has no roots ($p_Q(0) = p_Q(1) = 1$). So Q has no eigenvalues and is not diagonalizable: p_Q does not split.
- Over $\mathbb{F}_5$, $(x+2)^2 = x^2 + 4x + 4 = x^2 - x - 1$, so p_Q splits with the single root $-2 = 3$, of algebraic multiplicity 2. But $Q - 3I_2 = \left(\begin{smallmatrix} -2 & 1 \\ 1 & -3 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 3 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ has rank 1 (its second row is 2 times its first in $\mathbb{F}_5$), so $\operatorname{gm}(3) = 1 < 2$. Not diagonalizable: the multiplicities differ.
- Over $\mathbb{F}_{11}$, $(x-4)(x+3) = x^2 - x - 12 = x^2 - x - 1$, so Q has the distinct eigenvalues 4 and $-3 = 8$, and is diagonalizable by Corollary 7.4.5.
- Over $\mathbb{R}$, the roots $\varphi = \left(1 + \sqrt{5}\right)/2$ and $\psi = \left(1 - \sqrt{5}\right)/2$ are distinct, and Q is diagonalizable; Section 7.4.4 uses this to find the Fibonacci numbers.

The discriminant 5 of $x^2 - x - 1$ explains the pattern: the roots are $\left(1 \pm \sqrt{5}\right)/2$ whenever $1 + 1 \neq 0$, they coincide when $5 = 0$, and they lie in $\mathbb{F}_p$ when 5 is a square there, as $4^2 = 16 = 5$ is in $\mathbb{F}_{11}$.

Exercise 7.4.21. ROUTINE Let

$$A = \begin{pmatrix} 2 & 1 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix} \in \mathbb{Q}^{4\times 4}.$$

Find $\mathrm{am}_A(\lambda)$ and $\mathrm{gm}_A(\lambda)$ for every eigenvalue λ, and decide whether A is diagonalizable. Which single entry of A above the diagonal can you change to make A diagonalizable?

Solution on page 1585

7.4.3 Computing with a diagonalization

A diagonalization turns questions about A into questions about the scalars on the diagonal of D, because conjugating by S respects products.

Technique 7.4.22 (Diagonalize, solve, conjugate back). If $A = SDS^{-1}$ with D diagonal, then $A^k = SD^kS^{-1}$, and more generally every expression built from A by sums, products, and scalar multiples is $S(\cdots)S^{-1}$ with D in place of A. Diagonal matrices are computed entry by entry, so a problem about A splits into n problems about scalars. The recipe: diagonalize; solve the problem for D, one diagonal entry at a time; conjugate back by S. In operator language, pass to eigenbasis coordinates, where T is n independent scalings, solve there, and translate back.

Reach for it when a problem involves powers or polynomials of a matrix (closed forms for A^k, square roots, $p(A)$), a linear recurrence $\mathbf{x}_{k+1} = A\mathbf{x}_k$, or a linear differential equation $\mathbf{x}' = A\mathbf{x}$. If A is not diagonalizable, the same recipe works with a triangular or Jordan form in place of D (Section 7.5, Section 10.3), at the price of harder computations with that form. The canonical example is Proposition 7.4.23.

Used in. Proposition 7.4.23, Theorem 7.4.30, Proposition 7.4.33, Proposition 7.4.34, Exercise 7.4.36, Exercise 7.4.44, Exercise 7.4.46, Exercise 7.7.11, Problem 7.8, Problem 7.13, Problem 7.16, Exercise 8.2.16, Exercise 8.2.32, Exercise 7.4.27, Exercise 7.4.52.

Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix). Let $A = SDS^{-1}$ with $D = \mathrm{diag}(\lambda_1, \ldots, \lambda_n)$. Then for every integer $k \geq 0$ and every $p \in F[x]$,

$$A^k = S\begin{pmatrix} \lambda_1^k & & \\ & \ddots & \\ & & \lambda_n^k \end{pmatrix}S^{-1}, \quad p(A) = S\begin{pmatrix} p(\lambda_1) & & \\ & \ddots & \\ & & p(\lambda_n) \end{pmatrix}S^{-1}.$$

If every λ_i is nonzero, then A is invertible, $A^{-1} = S\,\mathrm{diag}\left(\lambda_1^{-1}, \ldots, \lambda_n^{-1}\right)S^{-1}$, and the formula for A^k holds for all $k \in \mathbb{Z}$.

Proof. ROUTINE

Uses. Proposition 2.4.14 (Algebra of matrices), Example 2.4.10 (Diagonal matrices), Definition 7.2.26 (Polynomials in an operator), Proposition 2.5.17 (Algebra of inverses)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. Multiply out $(SDS^{-1})(SDS^{-1})$. What happens in the middle?
Hint 2. Induct on k, then use linearity for $p(A) = \sum_k a_k A^k$. Diagonal matrices multiply entry by entry.
Sketch. The inner factors cancel: $(SDS^{-1})\left(SD^kS^{-1}\right) = SD^{k+1}S^{-1}$, so by induction $A^k = SD^kS^{-1}$, and $D^k = \mathrm{diag}\left(\lambda_i^k\right)$ since diagonal matrices multiply entrywise. Summing, $p(A) = Sp(D)S^{-1}$ with $p(D) = \mathrm{diag}(p(\lambda_i))$. For the inverse, check that $S\,\mathrm{diag}\left(\lambda_i^{-1}\right)S^{-1}$ multiplies A to I_n on both sides.

We show $A^k = SD^kS^{-1}$ by induction on k. For $k = 0$ both sides are I_n. If it holds for k, then by associativity (Proposition 2.4.14)

$$A^{k+1} = AA^k = \left(SDS^{-1}\right)\left(SD^kS^{-1}\right) = SD\left(S^{-1}S\right)D^kS^{-1} = SD^{k+1}S^{-1}.$$

Diagonal matrices multiply entry by entry (Example 2.4.10), so $D^k = \operatorname{diag}\left(\lambda_1^k, \ldots, \lambda_n^k\right)$. For $p = \sum_k a_k x^k$, distributivity gives

$$p(A) = \sum_k a_k S D^k S^{-1} = S\left(\sum_k a_k D^k\right) S^{-1} = S \operatorname{diag}(p(\lambda_1), \ldots, p(\lambda_n)) S^{-1}.$$

If every $\lambda_i \neq 0$, let $D' = \operatorname{diag}\left(\lambda_1^{-1}, \ldots, \lambda_n^{-1}\right)$, so that $DD' = D'D = I_n$. Then $A\left(SD'S^{-1}\right) = SDD'S^{-1} = I_n$ and likewise $\left(SD'S^{-1}\right)A = I_n$, so A is invertible with $A^{-1} = SD'S^{-1}$. Applying the first part to $A^{-1} = SD'S^{-1}$ gives $A^{-k} = SD'^k S^{-1} = S \operatorname{diag}\left(\lambda_i^{-k}\right) S^{-1}$ for $k \geq 0$. □

Example 7.4.24 (A closed form for A^k). For $A = \begin{pmatrix} 4 & -2 \\ 1 & 1 \end{pmatrix} = S \operatorname{diag}(2,3) S^{-1}$ from Example 7.4.4,

$$A^k = \begin{pmatrix} 1 & 2 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 2^k & 0 \\ 0 & 3^k \end{pmatrix} \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix} = \begin{pmatrix} 2 \cdot 3^k - 2^k & 2^{k+1} - 2 \cdot 3^k \\ 3^k - 2^k & 2^{k+1} - 3^k \end{pmatrix}$$

for every $k \in \mathbb{Z}$. At $k = 1$ this returns A, and at $k = 0$ it returns I_2. Every entry of A^k is a combination $\alpha 2^k + \beta 3^k$, and for large k the term 3^k dominates.

Often only $A^k \mathbf{v}$ is needed, and then S^{-1} is unnecessary. Expand $\mathbf{v}$ in the eigenbasis, $\mathbf{v} = c_1 \mathbf{s}_1 + c_2 \mathbf{s}_2$; then $A^k \mathbf{v} = c_1 2^k \mathbf{s}_1 + c_2 3^k \mathbf{s}_2$, because $A^k \mathbf{s}_j = \lambda_j^k \mathbf{s}_j$ (Proposition 7.2.28). For instance $(0,1) = 2(1,1) - (2,1)$, so $A^k(0,1) = \left(2^{k+1} - 2 \cdot 3^k, 2^{k+1} - 3^k\right)$, the second column above.

The second paragraph of Example 7.4.24 proved a matrix identity by checking it on eigenvectors. For diagonalizable operators this is a general method.

Technique 7.4.25 (Test an identity on eigenvectors). To show that two operators built from a diagonalizable T are equal, such as $p(T) = 0$ or $S = q(T)$, it is enough to show that they agree on each vector of an eigenbasis. On an eigenvector $\mathbf{v}$ with eigenvalue λ, every polynomial in T acts as the scalar $p(\lambda)$ (Proposition 7.2.28), so the check becomes an identity between scalars, one eigenvalue at a time. This is Technique 2.2.7 with the most convenient basis.

Reach for it when the hypothesis says "diagonalizable" and the claim is an identity between polynomials in T, or between T and another operator with the same eigenvectors. The canonical example is Proposition 7.4.26. Without diagonalizability the method fails: the shear J satisfies $p(J)\mathbf{v} = p(1)\mathbf{v}$ on its only eigenvector line, but $(J - I)$ kills that line without being 0.

Used in. Proposition 7.4.26, Exercise 7.4.49, Exercise 7.4.52, Exercise 7.7.7, Proposition 8.2.20, Proposition 8.2.24, Notation 8.3.10, Exercise 8.3.40, Exercise 8.3.43, Exercise 8.2.33.

Proposition 7.4.26 (Polynomials that kill a diagonalizable operator). Let T be diagonalizable with distinct eigenvalues $\lambda_1, \ldots, \lambda_m$, and let $p \in F[x]$. Then $p(T) = 0$ if and only if $p(\lambda_i) = 0$ for $i = 1, \ldots, m$. In particular,

$$(T - \lambda_1 \operatorname{id})(T - \lambda_2 \operatorname{id}) \cdots (T - \lambda_m \operatorname{id}) = 0.$$

Proof. ROUTINE

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Proposition 7.2.27 (Evaluating polynomials at an operator)
Techniques. Test an identity on eigenvectors (Technique 7.4.25), Check it on a basis (Technique 2.2.7)
Hint 1. One direction is the last sentence of Proposition 7.2.28.
Hint 2. For the other, evaluate $p(T)$ on each vector of an eigenbasis.
Sketch. If $p(T) = 0$, every eigenvalue is a root of p (Proposition 7.2.28). Conversely, on an eigenbasis vector $\mathbf{b}$ with eigenvalue λ_i, $p(T)\mathbf{b} = p(\lambda_i)\mathbf{b} = \mathbf{0}$; a linear map that vanishes on a basis is 0. The product is $p(T)$ for $p = \prod(x - \lambda_i)$ (Proposition 7.2.27).

If $p(T) = 0$, then every eigenvalue of T is a root of p, by Proposition 7.2.28. Conversely, suppose $p(\lambda_i) = 0$ for every i, and let $\mathcal{B}$ be an eigenbasis. Each $\mathbf{b} \in \mathcal{B}$ has some eigenvalue λ_i, so $p(T)\mathbf{b} = p(\lambda_i)\mathbf{b} = \mathbf{0}$ by Proposition 7.2.28. The linear map $p(T)$ vanishes on a basis, so $p(T) = 0$. For the last claim, take $p = (x - \lambda_1)\cdots(x - \lambda_m)$; by Proposition 7.2.27(a), $p(T)$ is the product of the operators $T - \lambda_i \operatorname{id}$. □

For instance, a diagonalizable T whose eigenvalues lie in $\{0, 1\}$ satisfies $T^2 - T = T(T - \operatorname{id}) = 0$, so it is a projection; one with eigenvalues in $\{1, -1\}$ satisfies $T^2 = \operatorname{id}$. The converse of the last statement, that an operator killed by a product of distinct linear factors is diagonalizable, is also true. Exercise 7.4.49 proves it, and Section 7.6 builds the minimal polynomial on it.

> **Exercise 7.4.27.** ROUTINE Let $A \in F^{n\times n}$ be diagonalizable. Show that A^{T} and $p(A)$, for every $p \in F[x]$, are diagonalizable, and that A^{-1} is diagonalizable if A is invertible. How are the eigenvalues of $p(A)$ related to those of A?

Solution on page 1585

7.4.4 Linear recurrences

The Fibonacci numbers $f_0 = 0$, $f_1 = 1$, $f_{k+2} = f_{k+1} + f_k$ are generated by a matrix: with $\mathbf{u}_k = (f_{k+1}, f_k)$,

$$\mathbf{u}_{k+1} = \begin{pmatrix} f_{k+1} + f_k \\ f_{k+1} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \mathbf{u}_k = Q\mathbf{u}_k,$$

so $\mathbf{u}_k = Q^k\mathbf{u}_0$ with $\mathbf{u}_0 = (1, 0)$, as in Exercise 2.4.47. Diagonalizing Q gives a closed formula.

Example 7.4.28 (Binet's formula). By Example 7.4.20, Q has the distinct real eigenvalues $\varphi = \left(1 + \sqrt{5}\right)/2$ and $\psi = \left(1 - \sqrt{5}\right)/2$, the roots of $x^2 = x + 1$. Eigenvectors are $(\varphi, 1)$ and $(\psi, 1)$: for instance $Q(\varphi, 1) = (\varphi + 1, \varphi) = (\varphi^2, \varphi) = \varphi(\varphi, 1)$. Since $\varphi - \psi = \sqrt{5}$,

$$\mathbf{u}_0 = \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \frac{1}{\sqrt{5}}\left(\begin{pmatrix} \varphi \\ 1 \end{pmatrix} - \begin{pmatrix} \psi \\ 1 \end{pmatrix}\right), \quad \text{so} \quad \mathbf{u}_k = Q^k\mathbf{u}_0 = \frac{1}{\sqrt{5}}\left(\varphi^k\begin{pmatrix} \varphi \\ 1 \end{pmatrix} - \psi^k\begin{pmatrix} \psi \\ 1 \end{pmatrix}\right).$$

The second coordinate is **Binet's formula**

$$f_k = \frac{\varphi^k - \psi^k}{\sqrt{5}} \quad \text{for all } k \geq 0.$$

Since $|\psi| < 1$, the term $\psi^k/\sqrt{5}$ has absolute value at most $1/\sqrt{5} < 1/2$, so f_k is the integer nearest to $\varphi^k/\sqrt{5}$. For instance $\varphi^{10}/\sqrt{5} \approx 55.004$, and $f_{10} = 55$. The eigenvalue $\varphi \approx 1.618$ of larger absolute value controls the growth.

The same formula appeared in Exercise 1.6.39 without any matrices, by finding a basis of geometric sequences of the space of all solutions. The two arguments are the same argument seen from two sides: the map $\mathbf{s} \mapsto (s_1, s_0)$ identifies the solution space with $\mathbb{R}^2$, and under it, shifting a sequence one step to the left becomes multiplication by Q. The eigenvectors $(\varphi, 1)$ and $(\psi, 1)$ correspond to the geometric sequences $\left(\varphi^k\right)$ and $\left(\psi^k\right)$, which the left shift multiplies by φ and ψ (Example 7.2.20). We now do this for every recurrence of finite order.

Fix $k \geq 1$ and $c_0, \ldots, c_{k-1} \in F$, and consider sequences $\mathbf{s} = (s_0, s_1, s_2, \ldots)$ in F with

$$s_{j+k} = c_{k-1}s_{j+k-1} + \cdots + c_1 s_{j+1} + c_0 s_j \quad \text{for all } j \geq 0. \tag{7.4.2}$$

The **characteristic polynomial of the recurrence** is $q = x^k - c_{k-1}x^{k-1} - \cdots - c_1 x - c_0$; a geometric sequence $\left(r^j\right)_{j\geq 0}$ satisfies (7.4.2) exactly when $r^j q(r) = 0$ for all j, that is, when $q(r) = 0$. Let W be the set of solutions of (7.4.2), a subspace of the sequence space F^X, $X = \{0, 1, 2, \ldots\}$ (the recurrence is linear in $\mathbf{s}$). Let $C \in F^{k\times k}$ be the matrix with

$$C\begin{pmatrix} x_1 \\ \vdots \\ x_{k-1} \\ x_k \end{pmatrix} = \begin{pmatrix} x_2 \\ \vdots \\ x_k \\ c_0x_1 + c_1x_2 + \cdots + c_{k-1}x_k \end{pmatrix}, \quad \text{that is,} \quad C = \begin{pmatrix} 0 & 1 & & \\ & \ddots & \ddots & \\ & & 0 & 1 \\ c_0 & c_1 & \cdots & c_{k-1} \end{pmatrix},$$

a companion matrix of q (compare Definition 7.3.23; conventions differ by a transpose and the order of the basis). For $k = 2$, $c_0 = c_1 = 1$, it is Q with the basis reversed.

Proposition 7.4.29 (The matrix of a recurrence). With the notation above:

(a) if $\mathbf{s} \in W$ and $\mathbf{u}_j = (s_j, s_{j+1}, \ldots, s_{j+k-1})$, then $\mathbf{u}_{j+1} = C\mathbf{u}_j$, so $\mathbf{u}_j = C^j\mathbf{u}_0$;

(b) the eigenvalues of C are the roots of q in F, and for each root r, $E_r(C) = \operatorname{span}\left(\left(1, r, r^2, \ldots, r^{k-1}\right)\right)$;

(c) C is diagonalizable if and only if q has k distinct roots in F.

Proof. STANDARD

Uses. Definition 7.2.6 (Eigenvalue, eigenvector), Definition 7.2.13 (Eigenspace), Theorem 7.4.16 (Criteria for diagonalizability)
Hint 1. (a) is the definition of C and the recurrence at index j.
Hint 2. For (b), write out $C\mathbf{v} = \lambda\mathbf{v}$ coordinate by coordinate. The first $k-1$ equations determine $\mathbf{v}$ from v_1.
Hint 3. For (c), every eigenspace is a line. Use criterion (III) of Theorem 7.4.16.
Sketch. $C\mathbf{v} = \lambda\mathbf{v}$ says $v_{i+1} = \lambda v_i$ for $i < k$, so $\mathbf{v} = v_1\left(1, \lambda, \ldots, \lambda^{k-1}\right)$, and the last coordinate then says $v_1 q(\lambda) = 0$. So eigenvalues are roots of q, each with a one-dimensional eigenspace. Then $\sum \operatorname{gm}$ = the number of distinct roots of q in F, which is k exactly when q has k distinct roots.

(a) The first $k-1$ coordinates of $C\mathbf{u}_j$ are $s_{j+1}, \ldots, s_{j+k-1}$, and the last is $c_0s_j + \cdots + c_{k-1}s_{j+k-1} = s_{j+k}$ by (7.4.2). So $C\mathbf{u}_j = \mathbf{u}_{j+1}$, and $\mathbf{u}_j = C^j\mathbf{u}_0$ by induction.

(b) Let $\lambda \in F$ and $\mathbf{v} = (v_1, \ldots, v_k) \in F^k$. Comparing coordinates, $C\mathbf{v} = \lambda\mathbf{v}$ says

$$v_2 = \lambda v_1, \quad v_3 = \lambda v_2, \quad \ldots, \quad v_k = \lambda v_{k-1}, \quad c_0v_1 + c_1v_2 + \cdots + c_{k-1}v_k = \lambda v_k.$$

The first $k-1$ equations hold if and only if $v_i = \lambda^{i-1}v_1$ for all i, that is, $\mathbf{v} = v_1\mathbf{w}_\lambda$ with $\mathbf{w}_\lambda = \left(1, \lambda, \ldots, \lambda^{k-1}\right)$. Substituting into the last equation gives $v_1\left(c_0 + c_1\lambda + \cdots + c_{k-1}\lambda^{k-1}\right) = v_1\lambda^k$, that is, $v_1 q(\lambda) = 0$. So if $q(\lambda) \neq 0$, then $v_1 = 0$ and $\mathbf{v} = \mathbf{0}$: λ is not an eigenvalue. If $q(\lambda) = 0$, the solutions are exactly the multiples of $\mathbf{w}_\lambda \neq \mathbf{0}$, so λ is an eigenvalue with $E_\lambda(C) = \operatorname{span}(\mathbf{w}_\lambda)$.

(c) By (b), $\operatorname{gm}_C(r) = 1$ for each root r of q in F, so the sum of the geometric multiplicities is the number of distinct roots of q in F. By Theorem 7.4.16, (I) $\Leftrightarrow$ (III), C is diagonalizable if and only if this number is k. □

So C never has two independent eigenvectors for the same eigenvalue: a repeated root of q always destroys diagonalizability. When the roots are distinct, the solutions are combinations of geometric sequences.

Theorem 7.4.30 (Recurrences with distinct characteristic roots). Suppose q has k distinct roots $r_1, \ldots, r_k \in F$. Then the geometric sequences $\left(r_i^j\right)_{j\geq 0}$, $i = 1, \ldots, k$, form a basis of W. That is, every solution of (7.4.2) is

$$s_j = a_1r_1^j + a_2r_2^j + \cdots + a_kr_k^j \quad (j \geq 0)$$

for unique $a_1, \ldots, a_k \in F$, which are determined by $s_0, \ldots, s_{k-1}$.

Proof (diagonalize the matrix of the recurrence). STANDARD

Uses. Proposition 7.4.29 (The matrix of a recurrence), Theorem 7.2.21 (Eigenvectors for distinct eigenvalues are independent), Corollary 7.4.5 (Distinct eigenvalues give a diagonalization), Proposition 7.2.28 (Polynomials act on eigenvectors by their values)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. By Proposition 7.4.29, $\mathbf{u}_j = C^j\mathbf{u}_0$ and C has the eigenbasis $\mathbf{w}_{r_1}, \ldots, \mathbf{w}_{r_k}$. Expand $\mathbf{u}_0$ in it.

Hint 2. Then $C^j\mathbf{u}_0 = \sum_i a_i r_i^j \mathbf{w}_{r_i}$. Read off the first coordinate, and note that each $\mathbf{w}_{r_i}$ has first coordinate 1.
Hint 3. For uniqueness, $s_0, \dots, s_{k-1}$ are the coordinates of $\mathbf{u}_0$, and coordinates in a basis are unique.
Sketch. The vectors $\mathbf{w}_{r_i} = \left(1, r_i, \dots, r_i^{k-1}\right)$ are eigenvectors for distinct eigenvalues, so an eigenbasis. Write $\mathbf{u}_0 = \sum a_i \mathbf{w}_{r_i}$; then $\mathbf{u}_j = C^j\mathbf{u}_0 = \sum a_i r_i^j \mathbf{w}_{r_i}$, whose first coordinate is $s_j = \sum a_i r_i^j$. So the geometric sequences span W; they lie in W since $q(r_i) = 0$. If $\sum a_i r_i^j = 0$ for all j, then $\sum a_i \mathbf{w}_{r_i} = \mathbf{0}$ (the cases $j < k$), so all $a_i = 0$.

Write $\mathbf{w}_i = \left(1, r_i, r_i^2, \dots, r_i^{k-1}\right)$. By Proposition 7.4.29(b), $\mathbf{w}_i$ is an eigenvector of C with eigenvalue r_i, and since the r_i are distinct, $\mathbf{w}_1, \dots, \mathbf{w}_k$ is a basis of F^k (Corollary 7.4.5). Each geometric sequence $\left(r_i^j\right)_j$ lies in W, because $q(r_i) = 0$.

Let $\mathbf{s} \in W$, and write $\mathbf{u}_0 = (s_0, \dots, s_{k-1}) = a_1\mathbf{w}_1 + \cdots + a_k\mathbf{w}_k$. By Proposition 7.4.29(a) and Proposition 7.2.28,

$$\mathbf{u}_j = C^j\mathbf{u}_0 = \sum_{i=1}^{k} a_i C^j \mathbf{w}_i = \sum_{i=1}^{k} a_i r_i^j \mathbf{w}_i.$$

The first coordinate of $\mathbf{u}_j$ is s_j, and the first coordinate of each $\mathbf{w}_i$ is 1, so $s_j = \sum_i a_i r_i^j$ for all j. Thus the geometric sequences span W.

They are independent: if $\sum_i a_i r_i^j = 0$ for all $j \geq 0$, then the cases $j = 0, \dots, k-1$ say $\sum_i a_i \mathbf{w}_i = \mathbf{0}$, so all $a_i = 0$. Hence they form a basis of W, the a_i are unique, and they are the coordinates of $\mathbf{u}_0 = (s_0, \dots, s_{k-1})$ in the basis $\mathbf{w}_1, \dots, \mathbf{w}_k$. □

Proof (count dimensions in the solution space). STANDARD

Uses. Theorem 4.1.10 (Independent lists are short), Example 7.2.24 (Independence for free), Definition 4.5.1 (Isomorphism)
Techniques. Dimension counting (Technique 4.2.24)
Hint 1. Show that $\mathbf{s} \mapsto (s_0, \dots, s_{k-1})$ is an isomorphism $W \to F^k$. So $\dim W = k$.
Hint 2. The k geometric sequences lie in W. Why are they independent? Think of the left shift.
Hint 3. k independent vectors in a k-dimensional space form a basis.
Sketch. A solution is determined by its first k terms, and any first k terms extend (define s_{j+k} by (7.4.2)), so $\mathbf{s} \mapsto (s_0, \dots, s_{k-1})$ is a linear bijection and $\dim W = k$. The geometric sequences lie in W and are eigenvectors of the left shift with distinct eigenvalues r_i, hence independent; k of them form a basis.

Let $\Phi : W \to F^k, \Phi(\mathbf{s}) = (s_0, \dots, s_{k-1})$. It is linear. It is injective: if $s_0 = \cdots = s_{k-1} = 0$, then (7.4.2) and induction on j give $s_j = 0$ for all j. It is surjective: given $(t_0, \dots, t_{k-1})$, set $s_j = t_j$ for $j < k$ and define s_{j+k} for $j = 0, 1, 2, \dots$ by (7.4.2); the resulting sequence lies in W. So Φ is an isomorphism (Definition 4.5.1) and $\dim W = k$.

Since $q(r_i) = 0$, each geometric sequence $\left(r_i^j\right)_j$ lies in W. These k sequences are eigenvectors of the left shift on F^X with the distinct eigenvalues $r_1, \dots, r_k$, so they are independent (Example 7.2.24(a)). By Theorem 4.1.10(b) they form a basis of the k-dimensional space W, and the coefficients a_i of a solution are its coordinates in this basis, which are unique. Applying Φ, they are determined by $s_0, \dots, s_{k-1}$. □

The first proof computes: it finds the a_i by solving one linear system, $\mathbf{u}_0 = \sum a_i \mathbf{w}_i$, whose matrix has rows $(1, \dots, 1), (r_1, \dots, r_k), \dots$ (a Vandermonde matrix, Theorem 5.5.21). The second proof needs no matrix at all, only the dimension of W; it is Technique 4.2.24, and it is the proof that generalizes to linear differential equations (Section 15.2).

Remark 7.4.31 (Repeated roots). If q has a repeated root, C is not diagonalizable (Proposition 7.4.29(c)), and the geometric sequences no longer span W. For $s_{j+2} = 2s_{j+1} - s_j$ we have $q = (x-1)^2$, the only geometric solution is the constant sequence, and W consists of the arithmetic sequences $s_j = a + bj$. In general, a root r of multiplicity m with $r \neq 0$ contributes the solutions $\left(j^i r^j\right)_j$ for $i < m$ (when F has characteristic 0); the source of these is the Jordan form of C (Section 10.3), and Section 15.2 develops them.

7.4.5 Discrete dynamical systems

A **discrete linear dynamical system** is a sequence of states $\mathbf{x}_0, \mathbf{x}_1, \mathbf{x}_2, \ldots$ in F^n with $\mathbf{x}_{k+1} = A\mathbf{x}_k$ for a fixed $A \in F^{n\times n}$, so $\mathbf{x}_k = A^k\mathbf{x}_0$. If A has an eigenbasis $\mathbf{s}_1, \ldots, \mathbf{s}_n$ with eigenvalues $\lambda_1, \ldots, \lambda_n$, and $\mathbf{x}_0 = c_1\mathbf{s}_1 + \cdots + c_n\mathbf{s}_n$, then

$$\mathbf{x}_k = c_1\lambda_1^k\mathbf{s}_1 + c_2\lambda_2^k\mathbf{s}_2 + \cdots + c_n\lambda_n^k\mathbf{s}_n. \tag{7.4.3}$$

Each eigen-component evolves on its own, by repeated multiplication by its eigenvalue. Over $\mathbb{R}$ or $\mathbb{C}$, a component with $|\lambda_i| < 1$ dies out, one with $|\lambda_i| > 1$ grows, and the components with the largest $|\lambda_i|$ eventually dominate.

Example 7.4.32 (Migration between two cities). Each year, 20% of the population of city 1 moves to city 2, and 30% of the population of city 2 moves to city 1; nobody else moves, and the total population is constant. With $\mathbf{x}_k = (a_k, b_k)$ the populations in year k,

$$\mathbf{x}_{k+1} = A\mathbf{x}_k, \quad A = \begin{pmatrix} 0.8 & 0.3 \\ 0.2 & 0.7 \end{pmatrix}.$$

Here $\det(A - \lambda I_2) = \lambda^2 - 1.5\lambda + 0.5 = (\lambda - 1)(\lambda - 0.5)$, with eigenvectors $(3, 2)$ for 1 and $(1, -1)$ for 0.5. Writing $\mathbf{x}_0 = (a, b) = c_1(3, 2) + c_2(1, -1)$ gives $c_1 = (a + b)/5$ and $c_2 = (2a - 3b)/5$, so by (7.4.3)

$$\mathbf{x}_k = \frac{a+b}{5}\begin{pmatrix}3\\2\end{pmatrix} + \frac{2a-3b}{5}\cdot 2^{-k}\begin{pmatrix}1\\-1\end{pmatrix} \quad\to\quad \frac{a+b}{5}\begin{pmatrix}3\\2\end{pmatrix} \quad (k \to \infty).$$

Whatever the initial distribution, the populations approach a $60 : 40$ split of the total $a + b$. The limit is the component of $\mathbf{x}_0$ in E_1, and the deviation from it halves every year. The columns of A add up to 1, which is why 1 is an eigenvalue (the rows of $A - I_2$ add up to zero) and why the total is preserved. Such matrices are the subject of Section 11.1.

Proposition 7.4.33 (Long-run behavior). Let $A \in \mathbb{C}^{n\times n}$ be diagonalizable, with an eigenbasis $\mathbf{s}_1, \ldots, \mathbf{s}_n$ and corresponding eigenvalues $\lambda_1, \ldots, \lambda_n$. Let $\mathbf{x}_0 = c_1\mathbf{s}_1 + \cdots + c_n\mathbf{s}_n$ and $\mathbf{x}_k = A^k\mathbf{x}_0$. Limits of vectors are taken coordinate by coordinate.

(a) If $|\lambda_i| < 1$ for every i, then $\mathbf{x}_k \to \mathbf{0}$ for every $\mathbf{x}_0$, and $A^k \to 0$ entry by entry.

(b) Suppose $\mu \neq 0$ is an eigenvalue with $|\lambda_i| < |\mu|$ for every $\lambda_i \neq \mu$. Then

$$\mu^{-k}\mathbf{x}_k \to \sum_{i:\lambda_i=\mu} c_i\mathbf{s}_i,$$

the component of $\mathbf{x}_0$ in E_μ. In particular, if $\mu = 1$, then $\mathbf{x}_k$ converges to the component of $\mathbf{x}_0$ in E_1.

Proof. STANDARD

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.4.16 (Criteria for diagonalizability)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. Start from (7.4.3). Each coordinate of $\mathbf{x}_k$ is a fixed linear combination of the λ_i^k.
Hint 2. For complex z with $|z| < 1$, $|z^k| = |z|^k \to 0$.
Hint 3. For (b), divide (7.4.3) by μ^k and split the sum according to whether $\lambda_i = \mu$.
Sketch. By (7.4.3), $\mathbf{x}_k = \sum c_i\lambda_i^k\mathbf{s}_i$, a combination with fixed vectors and coefficients λ_i^k. If all $|\lambda_i| < 1$, each $\lambda_i^k \to 0$. For (b), $\mu^{-k}\mathbf{x}_k = \sum_{\lambda_i=\mu} c_i\mathbf{s}_i + \sum_{\lambda_i\neq\mu} c_i(\lambda_i/\mu)^k\mathbf{s}_i$, and the second sum tends to $\mathbf{0}$. Apply (a) to the columns $A^k\mathbf{e}_j$ to get $A^k \to 0$.

Since $A^k\mathbf{s}_i = \lambda_i^k\mathbf{s}_i$ (Proposition 7.2.28), (7.4.3) holds: $\mathbf{x}_k = \sum_i c_i\lambda_i^k\mathbf{s}_i$. Each coordinate of $\mathbf{x}_k$ is therefore $\sum_i c_i\lambda_i^k s_{i,l}$, where $s_{i,l}$ is the l-th coordinate of $\mathbf{s}_i$, a sum of n fixed complex numbers times k-th powers.

(a) If $|\lambda_i| < 1$, then $|\lambda_i^k| = |\lambda_i|^k \to 0$, so $\lambda_i^k \to 0$, and each coordinate of $\mathbf{x}_k$ tends to 0. The j-th column of A^k is $A^k\mathbf{e}_j$, which is the case $\mathbf{x}_0 = \mathbf{e}_j$, so every entry of A^k tends to 0.

(b) Dividing by μ^k,

$$\mu^{-k}\mathbf{x}_k = \sum_{i:\lambda_i=\mu} c_i\mathbf{s}_i + \sum_{i:\lambda_i\neq\mu} c_i\left(\frac{\lambda_i}{\mu}\right)^k \mathbf{s}_i.$$

The first sum does not depend on k, and in the second $|\lambda_i/\mu| < 1$, so each term tends to $\mathbf{0}$ as in (a). The first sum lies in E_μ, and the second in the sum of the other eigenspaces; since $\mathbb{C}^n$ is the direct sum of the eigenspaces (Theorem 7.4.16), the first sum is the component of $\mathbf{x}_0$ in E_μ. □

In Example 7.4.32, $\mu = 1$ and the other eigenvalue is 0.5. In Example 7.4.28, $\mu = \varphi$ dominates ψ, so $\varphi^{-k}\mathbf{u}_k \to (\varphi, 1)/\sqrt{5}$: the ratio f_{k+1}/f_k of consecutive Fibonacci numbers tends to φ. When A is not diagonalizable, (7.4.3) is replaced by terms $k^i\lambda^k$ coming from the Jordan form, and (a) still holds, but the proof needs Section 10.3.

7.4.6 Systems of linear differential equations BEYOND 21-242

Differential equations are not part of 21-242.

The continuous analog of $\mathbf{x}_{k+1} = A\mathbf{x}_k$ is the system $\mathbf{x}' = A\mathbf{x}$, where $\mathbf{x} : \mathbb{R} \to \mathbb{R}^n$ is differentiable and the derivative is taken coordinate by coordinate. For $n = 1$ this is $x' = \lambda x$, whose solutions are $x(t) = x(0)e^{\lambda t}$: if $x' = \lambda x$, then $\left(e^{-\lambda t}x(t)\right)' = e^{-\lambda t}(x' - \lambda x) = 0$, so $e^{-\lambda t}x(t)$ is constant. A diagonalization decouples a system into n such equations.

Proposition 7.4.34 (Solving $\mathbf{x}' = A\mathbf{x}$). Let $A = SDS^{-1} \in \mathbb{R}^{n\times n}$ with $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ real, and let $\mathbf{s}_1, \ldots, \mathbf{s}_n$ be the columns of S. A differentiable $\mathbf{x} : \mathbb{R} \to \mathbb{R}^n$ satisfies $\mathbf{x}' = A\mathbf{x}$ if and only if

$$\mathbf{x}(t) = c_1e^{\lambda_1 t}\mathbf{s}_1 + c_2e^{\lambda_2 t}\mathbf{s}_2 + \cdots + c_ne^{\lambda_n t}\mathbf{s}_n$$

for some $c_1, \ldots, c_n \in \mathbb{R}$, namely $(c_1, \ldots, c_n) = S^{-1}\mathbf{x}(0)$.

Proof. STANDARD

Uses. Theorem 7.4.2 (Diagonalizable means an eigenbasis)
Techniques. Diagonalize, solve, conjugate back (Technique 7.4.22)
Hint 1. Change variables: let $\mathbf{y}(t) = S^{-1}\mathbf{x}(t)$. Differentiation commutes with multiplication by a constant matrix.
Hint 2. Then $\mathbf{y}' = D\mathbf{y}$, which is n separate equations $y_{i'} = \lambda_i y_i$.
Sketch. With $\mathbf{y} = S^{-1}\mathbf{x}$, $\mathbf{y}' = S^{-1}\mathbf{x}'$ (each coordinate is a fixed linear combination), so $\mathbf{x}' = A\mathbf{x}$ iff $\mathbf{y}' = D\mathbf{y}$, iff $y_{i'} = \lambda_i y_i$ for all i, iff $y_i(t) = c_ie^{\lambda_i t}$. Then $\mathbf{x} = S\mathbf{y} = \sum c_ie^{\lambda_i t}\mathbf{s}_i$.

Let $\mathbf{y}(t) = S^{-1}\mathbf{x}(t)$. Each coordinate of $\mathbf{y}$ is a fixed linear combination of the coordinates of $\mathbf{x}$, so $\mathbf{y}$ is differentiable with $\mathbf{y}' = S^{-1}\mathbf{x}'$, and similarly $\mathbf{x}' = S\mathbf{y}'$. Hence

$$\mathbf{x}' = A\mathbf{x} \iff S\mathbf{y}' = SDS^{-1}S\mathbf{y} \iff \mathbf{y}' = D\mathbf{y},$$

multiplying by S^{-1} or S. The system $\mathbf{y}' = D\mathbf{y}$ consists of the n separate equations $y_{i'} = \lambda_i y_i$, whose solutions are exactly $y_i(t) = c_ie^{\lambda_i t}$ with $c_i = y_i(0)$, by the case $n = 1$ above. So $\mathbf{x}' = A\mathbf{x}$ if and only if $\mathbf{x} = S\mathbf{y} = \sum_i c_ie^{\lambda_i t}\mathbf{s}_i$, and then $(c_1, \ldots, c_n) = \mathbf{y}(0) = S^{-1}\mathbf{x}(0)$. □

For $A = \begin{pmatrix} 4 & -2 \\ 1 & 1 \end{pmatrix}$ and $\mathbf{x}(0) = (1, 0)$, Example 7.4.4 gives $S^{-1}\mathbf{x}(0) = (-1, 1)$, so

$$\mathbf{x}(t) = -e^{2t}\begin{pmatrix} 1 \\ 1 \end{pmatrix} + e^{3t}\begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 2e^{3t} - e^{2t} \\ e^{3t} - e^{2t} \end{pmatrix}.$$

In matrix form, the solution is $\mathbf{x}(t) = S\operatorname{diag}\left(e^{\lambda_1 t}, \ldots, e^{\lambda_n t}\right)S^{-1}\mathbf{x}(0)$, and the matrix in front of $\mathbf{x}(0)$ is the **matrix exponential** e^{tA}, which Technique 7.4.22 computes from e^{tD}. Complex eigenvalues produce oscillations: for the rotation generator $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, diagonalizable over $\mathbb{C}$ with eigenvalues $\pm i$, the solutions are $\mathbf{x}(t) = (\alpha\cos t - \beta\sin t, \alpha\sin t + \beta\cos t)$, circles traversed at unit angular speed. A non-diagonalizable A produces terms $t^je^{\lambda t}$, which come from the Jordan form (Section 10.3).

Exercises

Exercise 7.4.35. ROUTINE For each matrix over $\mathbb{Q}$, find an invertible S and a diagonal D with $A = SDS^{-1}$, or show that none exist.

(a) $A = \begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$.

(b) $A = \begin{pmatrix} 3 & 1 \\ -1 & 1 \end{pmatrix}$.

(c) $A = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}$.

Solution on page 1586

Exercise 7.4.36. STANDARD Let $A = \begin{pmatrix} 7 & -10 \\ 3 & -4 \end{pmatrix} \in \mathbb{R}^{2\times 2}$.

(a) Find a formula for A^k valid for every $k \in \mathbb{Z}$.

(b) Find all $B \in \mathbb{R}^{2\times 2}$ with $B^2 = A$.

Solution on page 1586

Exercise 7.4.37. STANDARD For which $a, b, c \in F$ is the matrix

$$A = \begin{pmatrix} 1 & a & b \\ 0 & 1 & c \\ 0 & 0 & 2 \end{pmatrix}$$

diagonalizable?

Solution on page 1587

Exercise 7.4.38. STANDARD Let $n \geq 2$ and $A, B \in F^{n\times n}$. Prove or disprove:

(a) If A is diagonalizable, then A is invertible.

(b) If A is invertible, then A is diagonalizable.

(c) If A^2 is diagonalizable, then A is diagonalizable.

(d) If A and B are diagonalizable, then so is $A + B$.

(e) If A is diagonalizable and B is similar to A, then B is diagonalizable.

Solution on page 1587

Exercise 7.4.39. ROUTINE Find the error in the following argument.

"Every $A \in \mathbb{C}^{n\times n}$ is diagonalizable. By the Fundamental Theorem of Algebra, $p_A = (x - \lambda_1)\cdots(x - \lambda_n)$ for some $\lambda_1, \ldots, \lambda_n \in \mathbb{C}$. Each λ_i is a root of p_A, hence an eigenvalue; choose an eigenvector $\mathbf{v}_i$ for λ_i. Eigenvectors for different eigenvalues are independent, so $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is an independent list of length n, hence a basis of $\mathbb{C}^n$, and it is an eigenbasis."

Solution on page 1588

Exercise 7.4.40. STANDARD Let $A \in F^{n\times n}$ have rank 1. Show that A is diagonalizable if and only if $\operatorname{tr} A \neq 0$, and that in this case A is similar to $\operatorname{diag}(\operatorname{tr} A, 0, \ldots, 0)$.

Solution on page 1588

Exercise 7.4.41. STANDARD Let $n \geq 2$, and let $\tau \in \mathrm{L}(F^{n\times n})$ be the transpose map, $\tau(X) = X^{\mathsf{T}}$. Show that τ is diagonalizable if and only if $1 + 1 \neq 0$ in F. In that case, find $\mathrm{gm}(1)$ and $\mathrm{gm}(-1)$.

Solution on page 1589

Exercise 7.4.42. STANDARD

(a) Show that if $T \in \mathrm{L}(V)$ is diagonalizable, then $V = \ker T \oplus \operatorname{im} T$.

(b) Give an example of a non-diagonalizable T with $V = \ker T \oplus \operatorname{im} T$, and one with $\ker T \cap \operatorname{im} T \neq \{\mathbf{0}\}$.

Solution on page 1589

Exercise 7.4.43. STANDARD

(a) Let $A, B \in F^{n\times n}$ be diagonalizable. Show that A and B are similar if and only if $p_A = p_B$.

(b) Show that (a) fails if only one of A, B is assumed diagonalizable.

Solution on page 1589

Exercise 7.4.44. STANDARD Let f_k be the Fibonacci numbers, and work in $\mathbb{F}_{11}$.

(a) Using Example 7.4.20, show that $f_k = 3\left(8^k - 4^k\right)$ in $\mathbb{F}_{11}$ for all $k \geq 0$.

(b) Deduce that $f_{k+10} = f_k$ in $\mathbb{F}_{11}$ for all k, that is, the Fibonacci numbers modulo 11 repeat with period dividing 10.

Solution on page 1590

Exercise 7.4.45. ROUTINE Find a closed formula for the sequence of real numbers with $s_0 = 3, s_1 = 2, s_2 = 6$, and

$$s_{j+3} = 2s_{j+2} + s_{j+1} - 2s_j \quad (j \geq 0).$$

Solution on page 1590

Exercise 7.4.46. STANDARD Two quantities evolve by

$$x_{k+1} = 0.7x_k + 0.4y_k, \quad y_{k+1} = 0.2x_k + 0.9y_k.$$

(a) Find (x_k, y_k) in closed form in terms of (x_0, y_0).

(b) Show that if $x_0, y_0 \geq 0$ are not both 0, then $x_k/y_k \to 1$ and both quantities eventually grow by about 10% per step.

(c) For which $(x_0, y_0) \in \mathbb{R}^2$ does $(x_k, y_k) \to (0, 0)$?

Solution on page 1590

Exercise 7.4.47. STANDARD Let $A \in \mathbb{R}^{n\times n}$ be diagonalizable over $\mathbb{C}$, and suppose all its complex eigenvalues are real. Show that A is diagonalizable over $\mathbb{R}$.

Solution on page 1591

Exercise 7.4.48. STANDARD Find all $A \in \mathbb{R}^{2\times 2}$ with $A^2 = I_2$. Describe them in terms of their entries, and geometrically.

Solution on page 1591

Exercise 7.4.49. HARD Let $q = (x - r_1)(x - r_2)\cdots(x - r_k) \in F[x]$ with $r_1, \ldots, r_k \in F$ distinct, and suppose $q(T) = 0$.

(a) Show that T is diagonalizable. (Use the Lagrange polynomials $L_1, \ldots, L_k$ for the nodes $r_1, \ldots, r_k$: show that $L_1 + \cdots + L_k = 1$ and that $\operatorname{im} L_j(T) \subseteq E_{r_j}$.)

(b) Deduce that every $A \in \mathbb{C}^{n\times n}$ with $A^m = I_n$ for some $m \geq 1$ is diagonalizable over $\mathbb{C}$.

(c) Let p be prime. Deduce that every $A \in \mathbb{F}_p^{n\times n}$ with $A^p = A$ is diagonalizable over $\mathbb{F}_p$.

Solution on page 1592

Exercise 7.4.50. HARD Let $T \in \mathrm{L}(V)$ be diagonalizable with distinct eigenvalues $\lambda_1, \ldots, \lambda_m$, and let $U \subseteq V$ be a T-invariant subspace. Show that

$$U = \big(U \cap E_{\lambda_1}\big) \oplus \cdots \oplus \big(U \cap E_{\lambda_m}\big),$$

and deduce that the restriction of T to U is diagonalizable.

Solution on page 1592

Exercise 7.4.51. HARD BEYOND 21-242 Let $S, T \in \mathrm{L}(V)$ be diagonalizable with $ST = TS$. Show that S and T are **simultaneously diagonalizable**: there is a basis of V consisting of vectors that are eigenvectors of both S and T. Show by example that the hypothesis $ST = TS$ cannot be dropped.

Solution on page 1593

Exercise 7.4.52. HARD Let $A \in \mathbb{C}^{n\times n}$ satisfy $A^3 = A$. Show that $\operatorname{rank} A = \operatorname{tr}\big(A^2\big)$.

Solution on page 1593

Exercise 7.4.53. CHALLENGE Let V be a finite-dimensional complex vector space and $T \in \mathrm{L}(V)$. Show that T is diagonalizable if and only if

$$\ker(T - \lambda\,\mathrm{id}) \cap \operatorname{im}(T - \lambda\,\mathrm{id}) = \{\mathbf{0}\} \quad \text{for every } \lambda \in \mathbb{C}.$$

Solution on page 1594

7.5 Upper-triangular form and Schur's theorem

Not every operator can be diagonalized, even over $\mathbb{C}$. The shift $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has the single eigenvalue 0 and $\ker N = \operatorname{span}(\mathbf{e}_1)$, so $\mathbb{C}^2$ has no basis of eigenvectors of N (Section 7.4). But N is already upper triangular, and an upper-triangular matrix shows most of what a diagonal one does: its eigenvalues, its determinant, and its trace can all be read off the diagonal. This section shows that over $\mathbb{C}$ every operator has an upper-triangular matrix (Theorem 7.5.13), and that on an inner product space the basis can be taken orthonormal (Schur's theorem, Theorem 7.5.18). The cost of settling for triangular is the entries above the diagonal; in exchange, the result holds for every operator.

Throughout, V is a finite-dimensional vector space over a field F with $\dim V = n \geq 1$, and $T \in \mathrm{L}(V)$. We abbreviate $[T]_{\mathcal{B}\mathcal{B}}$ to $[T]_{\mathcal{B}}$.

7.5.1 Upper-triangular matrices and invariant flags

Recall (Definition 3.3.31) that $A \in F^{n\times n}$ is upper triangular if $a_{ij} = 0$ whenever $i > j$. For the matrix of an operator this condition has a clean meaning. Column j of $[T]_{\mathcal{B}}$ holds the coordinates of $T\mathbf{b}_j$, so the zeros

below the diagonal in column j say exactly that $T\mathbf{b}_j$ is a combination of $\mathbf{b}_1, \ldots, \mathbf{b}_j$ alone: each basis vector is sent into the span of itself and the vectors before it.

Definition 7.5.1 (Triangularizable). Let $\mathcal{B}$ be a basis of V. The operator T is **upper triangular with respect to $\mathcal{B}$** if $[T]_{\mathcal{B}}$ is upper triangular, and T is **triangularizable** if it is upper triangular with respect to some basis of V. A matrix $A \in F^{n\times n}$ is **triangularizable** if it is similar to an upper-triangular matrix, that is (Theorem 4.5.25), if T_A is triangularizable.

Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces). Let $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V, and let $V_j = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$ for $0 \le j \le n$, so that $V_0 = \{\mathbf{0}\}$. The following are equivalent.

(I) $[T]_{\mathcal{B}}$ is upper triangular.

(II) $T\mathbf{b}_j \in V_j$ for each $j = 1, \ldots, n$.

(III) V_j is T-invariant for each $j = 1, \ldots, n$.

Proof. ROUTINE

Uses. Definition 2.3.1 (Matrix of a linear map), Definition 1.6.14 (Coordinates), Proposition 7.2.4 (Invariance is checked on a spanning list), Definition 7.2.1 (Invariant subspace)
Techniques. Proving TFAE (Technique 2.7.1), Check it on a basis (Technique 2.2.7)
Hint 1. Column j of $[T]_{\mathcal{B}}$ is $[T\mathbf{b}_j]_{\mathcal{B}}$. When does a vector lie in V_j, in terms of its coordinates?
Hint 2. For (II) $\Rightarrow$ (III), V_j is spanned by $\mathbf{b}_1, \ldots, \mathbf{b}_j$, and $T\mathbf{b}_i \in V_i \subseteq V_j$ for $i \le j$. Use Proposition 7.2.4.
Sketch. A vector lies in V_j exactly when its coordinates after position j vanish, so (I) $\Leftrightarrow$ (II) column by column. Since $V_i \subseteq V_j$ for $i \le j$, (II) gives $T\mathbf{b}_i \in V_j$ for all $i \le j$, and invariance follows from Proposition 7.2.4. Conversely, $\mathbf{b}_j \in V_j$, so invariance of V_j gives (II).

We prove (I) $\Leftrightarrow$ (II) and (II) $\Leftrightarrow$ (III).

(I) $\Leftrightarrow$ (II). A vector of V lies in V_j if and only if its $\mathcal{B}$-coordinates in positions $j+1, \ldots, n$ are 0, by uniqueness of coordinates (Definition 1.6.14). Column j of $[T]_{\mathcal{B}}$ is $[T\mathbf{b}_j]_{\mathcal{B}}$ (Definition 2.3.1), so $T\mathbf{b}_j \in V_j$ if and only if column j has zeros in rows $j+1, \ldots, n$. These conditions for $j = 1, \ldots, n$ together say that $a_{ij} = 0$ whenever $i > j$.

(II) $\Rightarrow$ (III). Fix j. For $i \le j$ we have $T\mathbf{b}_i \in V_i \subseteq V_j$. So T maps each vector of the spanning list $\mathbf{b}_1, \ldots, \mathbf{b}_j$ of V_j into V_j, and V_j is T-invariant by Proposition 7.2.4.

(III) $\Rightarrow$ (II). $\mathbf{b}_j \in V_j$, and V_j is T-invariant, so $T\mathbf{b}_j \in V_j$. □

The subspaces $V_0 \subsetneq V_1 \subsetneq \cdots \subsetneq V_n$ in the proposition are nested and grow by one dimension at a time. Such chains deserve a name.

Definition 7.5.3 (Flag). A **flag** in V is a list of subspaces $V_0 \subseteq V_1 \subseteq \cdots \subseteq V_n$ with $\dim V_j = j$ for each j (so $V_0 = \{\mathbf{0}\}$ and $V_n = V$). The **flag of a basis** $\mathbf{b}_1, \ldots, \mathbf{b}_n$ is given by $V_j = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$. A flag is **$T$-invariant** if every V_j is T-invariant.

Every flag is the flag of some basis: choose $\mathbf{b}_j \in V_j$ with $\mathbf{b}_j \notin V_{j-1}$ for each j. By induction on j, the list $\mathbf{b}_1, \ldots, \mathbf{b}_j$ is linearly independent (Proposition 1.5.14) and lies in V_j, so it is a basis of V_j (Theorem 4.1.10). In $\mathbb{R}^3$, a flag is a line through $\mathbf{0}$ lying in a plane through $\mathbf{0}$. So Proposition 7.5.2 says that T is triangularizable if and only if V has a T-invariant flag, and that then every basis of that flag triangularizes T. Only the flag matters, not the particular vectors. In particular, the first vector $\mathbf{b}_1$ of a triangularizing basis spans an invariant line, so it is an eigenvector of T, with eigenvalue the $(1,1)$ entry (Proposition 7.2.7). A triangularizable operator has at least one eigenvalue.

Technique 7.5.4 (Build a flag of invariant subspaces). To find a basis in which T is upper triangular, look for nested invariant subspaces of every dimension instead of for matrix entries (Proposition 7.5.2). The flag can be built from the bottom (first an eigenvector, then a vector sent into the span of it and

itself, and so on) or from the top (a large invariant subspace, then invariant subspaces inside it). Any basis adapted to the flag will do, so the vectors can afterwards be changed freely within the flag, for instance orthonormalized.

Reach for it whenever a statement is about triangular matrices of an operator, both to produce them and to use them: "$[T]_{\mathcal{B}}$ is upper triangular" is the statement "T maps $\operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$ into itself for every j", which survives any operation that preserves these spans. The canonical example is the second proof of Theorem 7.5.13. Later uses: Schur's theorem (Theorem 7.5.18), where Gram–Schmidt keeps the flag, and simultaneous triangularization of commuting operators (Section 7.6).

Used in. Theorem 7.5.13, Theorem 7.5.18, Lemma 7.6.21, Theorem 7.6.32, Theorem 8.2.12, Exercise 7.5.30, Exercise 7.5.34.

Example 7.5.5 (Differentiation and shifts).

(a) Let $D \in \mathrm{L}\big(F[x]_{\le 3}\big)$ be differentiation, and use the basis $1, x, x^2, x^3$. Differentiation lowers degrees, so D maps $F[x]_{\le k}$ into $F[x]_{\le k-1} \subseteq F[x]_{\le k}$. The flag $F[x]_{\le 0} \subseteq F[x]_{\le 1} \subseteq F[x]_{\le 2} \subseteq F[x]_{\le 3}$ (plus $\{\mathbf{0}\}$ at the bottom) is D-invariant, and indeed

$$[D]_{1,x,x^2,x^3} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

(b) The shift $N \in \mathrm{L}(F^n)$ with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$ for $j \ge 2$ (Example 7.2.20) is upper triangular in the standard basis: the flag of coordinate subspaces $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_j)$ is invariant.

(c) Every upper-triangular $A \in F^{n\times n}$ preserves the coordinate subspaces $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_j)$, the vectors whose last $n - j$ coordinates vanish.

Non-example 7.5.6 (A rotation). Let $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \in \mathbb{R}^{2\times 2}$, the rotation by a right angle. If T_R were upper triangular with respect to a basis $\mathbf{b}_1, \mathbf{b}_2$ of $\mathbb{R}^2$, then $\mathbf{b}_1$ would be an eigenvector. But R has no real eigenvalues (Example 7.2.18): it moves every line through $\mathbf{0}$. So R is not triangularizable over $\mathbb{R}$. Over $\mathbb{C}$ it is, and even diagonalizable: $R(1, -i) = (i, 1) = i(1, -i)$ and $R(1, i) = -i(1, i)$, and these two vectors form a basis of $\mathbb{C}^2$.

$$A = \begin{pmatrix} 2 & 1 \\ 0 & 1 \end{pmatrix}, \quad A\mathbf{e}_1 = 2\mathbf{e}_1, \quad A\mathbf{e}_2 = \mathbf{e}_1 + \mathbf{e}_2$$

The upper-triangular matrix $A = \left(\begin{smallmatrix} 2 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. The x-axis is invariant, since $A\mathbf{e}_1 = 2\mathbf{e}_1$, and $\{\mathbf{0}\} \subseteq \operatorname{span}(\mathbf{e}_1) \subseteq \mathbb{R}^2$ is an invariant flag. In the interactive version, drag $A\mathbf{e}_1$ off the axis: the matrix is no longer upper triangular in the standard basis, but it is still triangularizable over $\mathbb{R}$ as long as some line through $\mathbf{0}$ is mapped into itself. A rotation by an angle that is not a multiple of π leaves no line in place. (Interactive in the web version.)

Exercise 7.5.7. ROUTINE Let $\mathcal{B} = \mathbf{b}_1, \dots, \mathbf{b}_n$ be a basis of V and $\mathcal{B}' = \mathbf{b}_n, \dots, \mathbf{b}_1$ the same basis in reverse order. Show that $[T]_{\mathcal{B}}$ is upper triangular if and only if $[T]_{\mathcal{B}'}$ is lower triangular. Write down $[D]_{\mathcal{B}'}$ for the differentiation operator of Example 7.5.5(a) and $\mathcal{B}' = x^3, x^2, x, 1$.

Solution on page 1594

Reading the diagonal

The diagonal of a triangular matrix carries the eigenvalues. We give two proofs: one computes a determinant, the other sees where a zero on the diagonal loses a dimension.

Proposition 7.5.8 (The diagonal of a triangular matrix). Suppose $[T]_{\mathcal{B}}$ is upper triangular with diagonal entries $\lambda_1, \dots, \lambda_n$.

(a) T is invertible if and only if $\lambda_j \neq 0$ for every j.

(b) The eigenvalues of T are exactly $\lambda_1, \dots, \lambda_n$.

Proof (via determinants). ROUTINE

Uses. Definition 5.4.18 (Determinant of an operator), Proposition 5.3.15 (Triangular matrices), Proposition 5.4.20 (Properties of the determinant of an operator), Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 2.4.12 (Matrices of sums and scalar multiples)
Hint 1. What is $\det T$, computed from $[T]_{\mathcal{B}}$?
Hint 2. For (b), $[T - \lambda \mathrm{id}_V]_{\mathcal{B}} = [T]_{\mathcal{B}} - \lambda I_n$ is again upper triangular. Apply (a) to $T - \lambda \mathrm{id}_V$.
Sketch. $\det T = \det [T]_{\mathcal{B}} = \lambda_1 \cdots \lambda_n$, which is nonzero exactly when every λ_j is. For (b), $T - \lambda \mathrm{id}_V$ has the upper-triangular matrix $[T]_{\mathcal{B}} - \lambda I_n$ with diagonal $\lambda_j - \lambda$, and λ is an eigenvalue exactly when $T - \lambda \mathrm{id}_V$ is not invertible.

(a) By Definition 5.4.18 and Proposition 5.3.15, $\det T = \det [T]_{\mathcal{B}} = \lambda_1 \lambda_2 \cdots \lambda_n$. By Proposition 5.4.20(c), T is invertible if and only if this product is nonzero, that is, if and only if every λ_j is nonzero.

(b) Let $\lambda \in F$. By Proposition 2.4.12, $[T - \lambda \mathrm{id}_V]_{\mathcal{B}} = [T]_{\mathcal{B}} - \lambda I_n$, which is upper triangular with diagonal entries $\lambda_1 - \lambda, \dots, \lambda_n - \lambda$. By Theorem 7.2.9, λ is an eigenvalue of T if and only if $T - \lambda \mathrm{id}_V$ is not invertible, which by (a) happens if and only if $\lambda_j - \lambda = 0$ for some j. □

Intuition (Where the dimension goes). Suppose $\lambda_j = 0$. Then $T\mathbf{b}_j$ has no $\mathbf{b}_j$-component, so T maps $V_j = \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$ into the smaller space V_{j-1}. A map from a j-dimensional space into a $(j-1)$-dimensional one cannot be injective. Conversely, if every $\lambda_j \neq 0$, we can solve for $\mathbf{b}_j$ in $T\mathbf{b}_j = \lambda_j \mathbf{b}_j + (\cdots)$ and see, one index at a time, that every basis vector lies in the image. This argument uses no determinants, and it is the version that survives where determinants are unavailable.

Proof (without determinants). STANDARD

Uses. Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Theorem 4.2.11 (Rank–nullity), Corollary 4.2.18 (Injective if and only if surjective), Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 2.4.12 (Matrices of sums and scalar multiples)
Techniques. Dimension counting (Technique 4.2.24), Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Let $V_j = \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$. If $\lambda_j = 0$, where does T send V_j?
Hint 2. If $\lambda_j = 0$, then T maps the j-dimensional V_j into V_{j-1}, so $T|_{V_j}$ has a nonzero kernel by rank–nullity.
Hint 3. If all $\lambda_j \neq 0$, show $\mathbf{b}_j \in \operatorname{im} T$ by strong induction on j, solving $T\mathbf{b}_j = \lambda_j \mathbf{b}_j + \sum_{i<j} a_{ij}\mathbf{b}_i$ for $\mathbf{b}_j$.
Sketch. If $\lambda_j = 0$, then $T\mathbf{b}_i \in V_i \subseteq V_{j-1}$ for $i < j$ and $T\mathbf{b}_j = \sum_{i<j} a_{ij}\mathbf{b}_i \in V_{j-1}$, so $T|_{V_j} : V_j \to V_{j-1}$ is not injective. If all $\lambda_j \neq 0$, then $\mathbf{b}_j = \lambda_j^{-1}\big(T\mathbf{b}_j - \sum_{i<j} a_{ij}\mathbf{b}_i\big) \in \operatorname{im} T$ by induction, so T is surjective, hence invertible. (b) follows from (a) applied to $T - \lambda \mathrm{id}_V$.

Write $[T]_{\mathcal{B}} = (a_{ij})$, so $a_{jj} = \lambda_j$, and $V_j = \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$. By Proposition 7.5.2, $T\mathbf{b}_j = \lambda_j \mathbf{b}_j + \sum_{i<j} a_{ij}\mathbf{b}_i$ for each j.

(a) Suppose $\lambda_j = 0$ for some j. For $i < j$, $T\mathbf{b}_i \in V_i \subseteq V_{j-1}$, and $T\mathbf{b}_j = \sum_{i<j} a_{ij}\mathbf{b}_i \in V_{j-1}$. So T maps the spanning list $\mathbf{b}_1, \dots, \mathbf{b}_j$ of V_j into the subspace V_{j-1}, and $\operatorname{im}\big(T|_{V_j}\big) \subseteq V_{j-1}$. By rank–nullity (Theorem 4.2.11) applied to $T|_{V_j} : V_j \to V$,

$$\dim \ker\big(T|_{V_j}\big) = j - \dim \operatorname{im}\big(T|_{V_j}\big) \geq j - (j-1) = 1.$$

So some nonzero vector of V_j is sent to $\mathbf{0}$, and T is not invertible.

Conversely, suppose every $\lambda_j \neq 0$. We show $\mathbf{b}_j \in \operatorname{im} T$ by strong induction on j. Assume $\mathbf{b}_i \in \operatorname{im} T$ for all $i < j$ (for $j = 1$ there is nothing to assume). Then

$$\mathbf{b}_j = \lambda_j^{-1}\left(T\mathbf{b}_j - \sum_{i<j} a_{ij}\mathbf{b}_i\right)$$

is a linear combination of $T\mathbf{b}_j$ and the $\mathbf{b}_i$ with $i < j$, all of which lie in the subspace $\operatorname{im} T$. So $\mathbf{b}_j \in \operatorname{im} T$. Hence $\operatorname{im} T$ contains a basis of V, and T is surjective, so it is invertible by Corollary 4.2.18.

(b) As in the first proof, $[T-\lambda \mathrm{id}_V]_{\mathcal{B}}$ is upper triangular with diagonal entries $\lambda_j - \lambda$, and λ is an eigenvalue if and only if $T-\lambda\mathrm{id}_V$ is not invertible (Theorem 7.2.9), that is, by (a), if and only if $\lambda = \lambda_j$ for some j. □

The diagonal also records how often each eigenvalue occurs. Write p_T for the characteristic polynomial of T (Definition 7.3.4), so that $p_T = \det(xI_n - A)$ for every matrix A of T. Here the determinant of a matrix with entries in $F[x]$ is defined by the Leibniz formula, and Section 7.3 shows that the results of Chapter 5 proved by expanding that formula, such as Proposition 5.3.15 and Theorem 5.4.26, hold for such matrices.

Proposition 7.5.9 (Multiplicities on the diagonal). Suppose $[T]_{\mathcal{B}}$ is upper triangular with diagonal entries $\lambda_1, \ldots, \lambda_n$. Then

$$p_T = (x-\lambda_1)(x-\lambda_2)\cdots(x-\lambda_n).$$

Consequently each eigenvalue λ of T occurs among $\lambda_1, \ldots, \lambda_n$ exactly as many times as its algebraic multiplicity (Definition 7.4.11). In particular, this number is the same for every basis in which T is upper triangular.

Proof. ROUTINE

Uses. Definition 7.3.4 (Characteristic polynomial), Proposition 5.3.15 (Triangular matrices), Proposition 7.1.34 (Roots of a split polynomial), Definition 7.4.11 (Algebraic multiplicity)
Hint 1. $xI_n - [T]_{\mathcal{B}}$ is upper triangular. What is its determinant?
Hint 2. The algebraic multiplicity of λ is its multiplicity as a root of p_T. Use Proposition 7.1.34.
Sketch. $xI_n - [T]_{\mathcal{B}}$ is upper triangular with diagonal entries $x-\lambda_j$, so its determinant is their product. A root of a split polynomial occurs in its list of linear factors exactly as often as its multiplicity.

The matrix $xI_n - [T]_{\mathcal{B}}$ has entries in $F[x]$; it is upper triangular, with diagonal entries $x-\lambda_1, \ldots, x-\lambda_n$. By Proposition 5.3.15 (whose proof only uses the Leibniz formula), $p_T = \det(xI_n - [T]_{\mathcal{B}}) = (x-\lambda_1)\cdots(x-\lambda_n)$. By Proposition 7.1.34, each root of p_T occurs in the list $\lambda_1, \ldots, \lambda_n$ exactly as many times as its multiplicity as a root of p_T, which is its algebraic multiplicity as an eigenvalue (Definition 7.4.11). The polynomial p_T does not depend on the basis, so neither do these counts. □

When p_T splits over F, say $p_T = (x-\lambda_1)\cdots(x-\lambda_n)$ (Definition 7.1.33), we call $\lambda_1, \ldots, \lambda_n$ the eigenvalues of T **counted with multiplicity**. Each eigenvalue occurs in this list as often as its algebraic multiplicity, and the list is determined by T up to order (Proposition 7.1.34). Over $\mathbb{C}$, p_T always splits (Corollary 7.1.35).

Exercise 7.5.10. ROUTINE Let $\mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3$ be a basis of a complex vector space V, and let $T \in \mathrm{L}(V)$ satisfy

$$T\mathbf{b}_1 = 3\mathbf{b}_1, \quad T\mathbf{b}_2 = \mathbf{b}_1 - \mathbf{b}_2, \quad T\mathbf{b}_3 = \mathbf{b}_1 + \mathbf{b}_2 + 3\mathbf{b}_3.$$

Find the eigenvalues of T with their algebraic multiplicities, decide whether T is invertible, and find an eigenvector for each eigenvalue. Is T diagonalizable?

Solution on page 1595

7.5.2 Triangularization over $\mathbb{C}$

Intuition (How to find an invariant flag). By Proposition 7.5.2 we need an invariant flag, and its bottom V_1 is an invariant line, spanned by an eigenvector. So we need an eigenvalue, and over $\mathbb{C}$ there always is one (Theorem 7.3.27). Over $\mathbb{R}$ the rotation of Non-example 7.5.6 shows that the theorem can fail at this very first step.

Having found an eigenvector $\mathbf{b}_1$, we would like to finish by induction on $\dim V$. The obvious move is to restrict T to a complement W of $\mathrm{span}(\mathbf{b}_1)$ and use the induction hypothesis there. It fails: T need not map W into W, so $T{\restriction_W}$ is a map $W \to V$, not an operator on W, and the induction hypothesis says nothing about it. (Exercise A.2.13 makes exactly this mistake.) The fix is to throw away the part of $T\mathbf{w}$ that lies in $\mathrm{span}(\mathbf{b}_1)$, by projecting $T\mathbf{w}$ back into W along $\mathrm{span}(\mathbf{b}_1)$. That produces an honest operator on W. The

part thrown away is harmless, because $\operatorname{span}(\mathbf{b}_1)$ sits at the bottom of the flag, and every V_j will contain it anyway.

Lemma 7.5.11 (Compressing an operator to a complement). Let U be a T-invariant subspace of V, and let $V = U \oplus W$. The **compression** of T to W is the operator

$$S = \operatorname{Pr}_{W,U} \circ T\restriction_W \in \mathrm{L}(W),$$

where $\operatorname{Pr}_{W,U}$ is the projection onto W along U (Definition 4.4.24).

(a) $T\mathbf{w} - S\mathbf{w} \in U$ for every $\mathbf{w} \in W$.

(b) Let $\mathcal{C}$ be a basis of U and $\mathcal{D}$ a basis of W, both nonempty. Then $\mathcal{B} = \mathcal{C}, \mathcal{D}$ is a basis of V, and

$$[T]_{\mathcal{B}} = \begin{pmatrix} [T\restriction_U]_{\mathcal{C}} & X \\ 0 & [S]_{\mathcal{D}} \end{pmatrix}$$

for some matrix X, where $T\restriction_U$ is regarded as an operator on U.

Proof. ROUTINE

Uses. Definition 4.4.24 (Projection along a complement), Proposition 4.4.26 (Properties of projections), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 4.5.35 (Preserved subspaces give block triangular matrices), Definition 2.3.1 (Matrix of a linear map)
Techniques. Choose a basis adapted to a preserved subspace (Technique 4.5.36)
Hint 1. For (a), $\operatorname{Pr}_{U,W} + \operatorname{Pr}_{W,U} = \mathrm{id}_V$. Apply both sides to $T\mathbf{w}$.
Hint 2. For (b), Proposition 4.5.35 gives the zero block and the top left block. For a column belonging to $\mathbf{d}_j \in \mathcal{D}$, write $T\mathbf{d}_j = (T\mathbf{d}_j - S\mathbf{d}_j) + S\mathbf{d}_j$ and read off the $\mathcal{D}$-coordinates.
Sketch. $T\mathbf{w} = \operatorname{Pr}_{U,W}(T\mathbf{w}) + \operatorname{Pr}_{W,U}(T\mathbf{w})$, and the first term lies in U; this is (a). In (b), $\mathcal{B}$ is a basis because the sum is direct, Proposition 4.5.35 gives the block form with $[T\restriction_U]_{\mathcal{C}}$ in the corner, and by (a) the $\mathcal{D}$-coordinates of $T\mathbf{d}_j$ are those of $S\mathbf{d}_j$, which form column j of $[S]_{\mathcal{D}}$.

(a) By Proposition 4.4.26, $\operatorname{Pr}_{U,W} + \operatorname{Pr}_{W,U} = \mathrm{id}_V$ and $\operatorname{im} \operatorname{Pr}_{U,W} = U$. So for $\mathbf{w} \in W$,

$$T\mathbf{w} - S\mathbf{w} = T\mathbf{w} - \operatorname{Pr}_{W,U}(T\mathbf{w}) = \operatorname{Pr}_{U,W}(T\mathbf{w}) \in U.$$

(b) Since $V = U \oplus W$, the list $\mathcal{B} = \mathcal{C}, \mathcal{D}$ is a basis of V (Theorem 4.4.13). Let k be the length of $\mathcal{C}$. Since $U = \operatorname{span}(\mathcal{C})$ is T-invariant, Proposition 4.5.35 shows that $[T]_{\mathcal{B}}$ has a zero block below the first k columns and that its top left block is $[T\restriction_U]_{\mathcal{C}}$. Let $\mathcal{D} = \mathbf{d}_1, \ldots, \mathbf{d}_m$ and $[S]_{\mathcal{D}} = (s_{ij})$, so $S\mathbf{d}_j = \sum_i s_{ij}\mathbf{d}_i$ (Definition 2.3.1). By (a), $T\mathbf{d}_j = \mathbf{u} + \sum_i s_{ij}\mathbf{d}_i$ for some $\mathbf{u} \in U = \operatorname{span}(\mathcal{C})$. So the last m coordinates of $T\mathbf{d}_j$ in $\mathcal{B}$ are $s_{1j}, \ldots, s_{mj}$, and the bottom right block of $[T]_{\mathcal{B}}$ is $[S]_{\mathcal{D}}$. □

The compression depends on the choice of W, but its matrix is always the bottom right block of $[T]_{\mathcal{B}}$. This is the move the triangularization theorem needs, and it is an instance of a general technique.

Technique 7.5.12 (Induction on dimension via an invariant subspace). To prove that every operator on every finite-dimensional space (of some kind) has a property, induct on $\dim V$. In the inductive step, find a T-invariant subspace U with $\{\mathbf{0}\} \neq U \neq V$, apply the induction hypothesis to an operator on a smaller space built from U, and glue the pieces with the block triangular form of Proposition 4.5.35. The smaller operator can be

- the restriction $T\restriction_U$, an operator on U because U is invariant;
- the compression of T to a complement W of U (Lemma 7.5.11), or to $U^\perp$ when there is an inner product;
- the quotient operator T/U on V/U (Proposition 4.6.32), if quotients are available.

The hypothesis applies only to operators, so whatever is passed down must map the smaller space into itself; a restriction to a subspace that is not invariant does not qualify (Exercise A.2.13). The invariant subspace usually comes from an eigenvector, which is why such inductions tend to need $\mathbb{C}$, or from a kernel or image of a polynomial in T (Technique 7.2.31).

Reach for it for existence statements about bases adapted to an operator: triangular, block triangular, orthonormal and triangular, diagonal. The canonical example is Theorem 7.5.13. Later uses: Schur's theorem (Theorem 7.5.18), the spectral theorems (Section 8.2), and the structure of nilpotent operators (Section 10.3).

Used in. Theorem 7.5.13, Theorem 7.5.17, Theorem 7.5.18, Theorem 7.5.27, Exercise 7.5.38, Exercise 7.5.42, Theorem 7.6.32, Exercise 7.7.13, Problem 7.14, Theorem 8.2.5, Theorem 8.2.12, Exercise 8.2.35, Exercise 8.2.48, Theorem 8.4.15, Theorem 8.4.25, Exercise 8.4.44.

Theorem 7.5.13 (Upper-triangular form). Let V be a finite-dimensional complex vector space with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$. Then there is a basis $\mathcal{B}$ of V such that $[T]_{\mathcal{B}}$ is upper triangular. Its diagonal entries are the eigenvalues of T, each occurring as many times as its algebraic multiplicity.

Proof (compress to a complement). STANDARD

Uses. Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Proposition 4.4.16 (Complements exist), Lemma 7.5.11 (Compressing an operator to a complement), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Theorem 4.4.13 (Bases and dimension of a sum), Proposition 7.5.9 (Multiplicities on the diagonal)

Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12), Build a flag of invariant subspaces (Technique 7.5.4)

Hint 1. Induct on $n = \dim V$. Over $\mathbb{C}$, T has an eigenvector $\mathbf{b}_1$, and $\operatorname{span}(\mathbf{b}_1)$ is invariant. It should be the bottom of the flag.

Hint 2. Choose a complement W of $\operatorname{span}(\mathbf{b}_1)$. The restriction of T to W is not an operator on W; what is?

Hint 3. Apply the induction hypothesis to the compression S of T to W, getting $\mathbf{b}_2, \dots, \mathbf{b}_n$. Then use $T\mathbf{w} - S\mathbf{w} \in \operatorname{span}(\mathbf{b}_1)$ to check that $T\mathbf{b}_j \in \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$.

Sketch. Induct on n; $n = 1$ is trivial. Take an eigenvector $\mathbf{b}_1$ (Theorem 7.3.27), a complement W of $U = \operatorname{span}(\mathbf{b}_1)$, and the compression $S \in \mathrm{L}(W)$. By induction, W has a basis $\mathbf{b}_2, \dots, \mathbf{b}_n$ with $S\mathbf{b}_j \in \operatorname{span}(\mathbf{b}_2, \dots, \mathbf{b}_j)$. Then $T\mathbf{b}_1 = \lambda_1 \mathbf{b}_1$ and $T\mathbf{b}_j = (T\mathbf{b}_j - S\mathbf{b}_j) + S\mathbf{b}_j \in \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$, so $\mathbf{b}_1, \dots, \mathbf{b}_n$ triangularizes T. The diagonal is described by Proposition 7.5.9.

The statement about the diagonal is Proposition 7.5.9, so we prove existence, by induction on $n = \dim V$. If $n = 1$, every 1×1 matrix is upper triangular, and any basis works.

Let $n \geq 2$, and assume the theorem for complex vector spaces of dimension $n - 1$. By Theorem 7.3.27, T has an eigenvalue λ_1; let $\mathbf{b}_1$ be an eigenvector for it. Then $U = \operatorname{span}(\mathbf{b}_1)$ is T-invariant (Proposition 7.2.7). By Proposition 4.4.16, U has a complement W, and $\dim W = n - 1$. Let $S \in \mathrm{L}(W)$ be the compression of T to W (Lemma 7.5.11). By the induction hypothesis and Proposition 7.5.2, W has a basis $\mathbf{b}_2, \dots, \mathbf{b}_n$ with

$$S\mathbf{b}_j \in \operatorname{span}(\mathbf{b}_2, \dots, \mathbf{b}_j) \quad \text{for } j = 2, \dots, n.$$

The list $\mathcal{B} = \mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_n$ is a basis of $V = U \oplus W$ (Theorem 4.4.13). We check condition (II) of Proposition 7.5.2. First, $T\mathbf{b}_1 = \lambda_1 \mathbf{b}_1 \in \operatorname{span}(\mathbf{b}_1)$. For $j \geq 2$, by Lemma 7.5.11(a),

$$T\mathbf{b}_j = \underbrace{(T\mathbf{b}_j - S\mathbf{b}_j)}_{\in \operatorname{span}(\mathbf{b}_1)} + \underbrace{S\mathbf{b}_j}_{\in \operatorname{span}(\mathbf{b}_2, \dots, \mathbf{b}_j)} \in \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j).$$

So $[T]_{\mathcal{B}}$ is upper triangular. In block form (Lemma 7.5.11(b)), $[T]_{\mathcal{B}} = \begin{pmatrix} \lambda_1 & X \\ 0 & [S]_{\mathbf{b}_2, \dots, \mathbf{b}_n} \end{pmatrix}$. □

Intuition (A second route, from the top). The first proof builds the flag from the bottom: an invariant line first, then whatever the smaller problem returns. The second proof (LADR's) works from the top. Fix an eigenvalue λ, and consider $U = \operatorname{im}(T - \lambda \mathrm{id}_V)$. Since $T\mathbf{v} = \lambda\mathbf{v} + (T - \lambda \mathrm{id}_V)\mathbf{v}$, every subspace that contains U is T-invariant: T moves each vector only within its own span plus U. And $U \neq V$, because $T - \lambda \mathrm{id}_V$ is not injective. So above U the flag can be chosen arbitrarily, and the only real work happens inside U, where the restriction of T is an honest operator on a smaller space. This route needs no complement and no projection, only restriction.

Proof (via the invariant subspace $\operatorname{im}(T - \lambda \mathrm{id}_V)$). STANDARD

Uses. Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Theorem 7.2.9 (Eigenvalues and invertibility), Corollary 4.2.18 (Injective if and only if surjective), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Theorem 4.1.16 (Extending to a basis), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12), Build a flag of invariant subspaces (Technique 7.5.4), Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Let λ be an eigenvalue and $U = \operatorname{im}(T - \lambda \mathrm{id}_V)$. Show that U is T-invariant and $\dim U < n$.
Hint 2. Apply the induction hypothesis to $T|_U$ (strong induction, since $\dim U$ can be anything below n), and extend the resulting basis of U to a basis of V.
Hint 3. For an added vector $\mathbf{v}$, write $T\mathbf{v} = \lambda\mathbf{v} + (T - \lambda \mathrm{id}_V)\mathbf{v}$.
Sketch. By strong induction on n. Let λ be an eigenvalue and $U = \operatorname{im}(T - \lambda \mathrm{id}_V)$; it is T-invariant because T commutes with $T - \lambda \mathrm{id}_V$, and $U \neq V$ because $T - \lambda \mathrm{id}_V$ is not injective, hence not surjective. Triangularize $T|_U$ by $\mathbf{u}_1, \ldots, \mathbf{u}_m$ and extend by $\mathbf{v}_1, \ldots, \mathbf{v}_k$. Then $T\mathbf{v}_j = \lambda\mathbf{v}_j + (T - \lambda \mathrm{id}_V)\mathbf{v}_j \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_m, \mathbf{v}_j)$.

We use strong induction on $n = \dim V$. For $n = 1$ there is nothing to prove. Let $n \geq 2$, and assume the theorem for all complex spaces of dimension less than n.

By Theorem 7.3.27, T has an eigenvalue λ. Let $U = \operatorname{im}(T - \lambda \mathrm{id}_V)$. Since T commutes with $T - \lambda \mathrm{id}_V$, the image U is T-invariant (Proposition 7.2.30). Since λ is an eigenvalue, $T - \lambda \mathrm{id}_V$ is not injective (Theorem 7.2.9), hence not surjective (Corollary 4.2.18), so $m = \dim U < n$.

If $m = 0$, then $T = \lambda \mathrm{id}_V$, and every basis triangularizes T. Otherwise $T|_U$ is an operator on U, and by the induction hypothesis and Proposition 7.5.2, U has a basis $\mathbf{u}_1, \ldots, \mathbf{u}_m$ with $T\mathbf{u}_j \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j)$ for each j. Extend it to a basis $\mathbf{u}_1, \ldots, \mathbf{u}_m, \mathbf{v}_1, \ldots, \mathbf{v}_k$ of V (Theorem 4.1.16). For each $j \leq k$,

$$T\mathbf{v}_j = \lambda\mathbf{v}_j + \underbrace{(T - \lambda \mathrm{id}_V)\mathbf{v}_j}_{\in U} \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_m, \mathbf{v}_1, \ldots, \mathbf{v}_j).$$

So every vector of the basis is sent into the span of itself and the vectors before it, and T is upper triangular with respect to this basis by Proposition 7.5.2. □

The two proofs pass different objects down the induction. The first passes a compression to a space of dimension exactly $n - 1$, and so needs a complement and a projection; the second passes a restriction to a space of unknown smaller dimension, and so needs strong induction. The second proof also says something about the diagonal: the last k basis vectors have diagonal entry λ, and $k = n - \dim \operatorname{im}(T - \lambda \mathrm{id}_V) = \dim \ker(T - \lambda \mathrm{id}_V)$ by rank–nullity. With Proposition 7.5.9, the algebraic multiplicity of λ is at least $\dim E_\lambda$, its geometric multiplicity. So this argument recovers Theorem 7.4.15 for complex operators.

Corollary 7.5.14 (Triangularizing a matrix). Every $A \in \mathbb{C}^{n \times n}$ is similar to an upper-triangular matrix: $A = SRS^{-1}$ with $S \in \mathbb{C}^{n \times n}$ invertible and R upper triangular. The columns of S form a basis of $\mathbb{C}^n$ whose flag is T_A-invariant, and the diagonal of R lists the eigenvalues of A counted with multiplicity.

Proof. ROUTINE

Uses. Theorem 7.5.13 (Upper-triangular form), Theorem 4.5.17 (Change of basis)
Hint. Apply Theorem 7.5.13 to T_A and translate the change of basis into matrices.
Sketch. If $\mathcal{B}$ triangularizes T_A and S has the vectors of $\mathcal{B}$ as columns, then $S = [\mathrm{id}]_{\mathcal{E}\mathcal{B}}$ and $[T_A]_{\mathcal{B}} = S^{-1}AS$ by Theorem 4.5.17.

By Theorem 7.5.13 there is a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of $\mathbb{C}^n$ with $R = [T_A]_{\mathcal{B}}$ upper triangular. Let S be the matrix with columns $\mathbf{b}_1, \ldots, \mathbf{b}_n$, that is, $S = [\mathrm{id}]_{\mathcal{E}\mathcal{B}}$ for the standard basis $\mathcal{E}$. It is invertible, and Theorem 4.5.17 gives $R = S^{-1}[T_A]_{\mathcal{E}}S = S^{-1}AS$, so $A = SRS^{-1}$. The rest is Theorem 7.5.13. □

Example 7.5.15 (Triangularizing a 3×3 matrix). Let

$$A = \begin{pmatrix} 2 & 0 & -1 \\ 0 & 2 & -2 \\ -1 & 1 & 0 \end{pmatrix} \in \mathbb{C}^{3 \times 3}.$$

We follow the first proof of Theorem 7.5.13. Its characteristic polynomial is $(x-2)(x-1)^2$, and $\mathbf{b}_1 = (1,1,0)$ is an eigenvector: $A\mathbf{b}_1 = (2,2,0) = 2\mathbf{b}_1$. A convenient complement of $\operatorname{span}(\mathbf{b}_1)$ is $W = \operatorname{span}(\mathbf{e}_2, \mathbf{e}_3)$, since $\mathbf{b}_1$ has a nonzero first coordinate. Every vector decomposes as

$$(x_1, x_2, x_3) = x_1\mathbf{b}_1 + (0, x_2 - x_1, x_3),$$

so the projection onto W along $\operatorname{span}(\mathbf{b}_1)$ is $(x_1, x_2, x_3) \mapsto (0, x_2 - x_1, x_3)$. The compression S sends

$$\mathbf{e}_2 \mapsto \Pr(A\mathbf{e}_2) = \Pr(0,2,1) = 2\mathbf{e}_2 + \mathbf{e}_3, \quad \mathbf{e}_3 \mapsto \Pr(A\mathbf{e}_3) = \Pr(-1,-2,0) = -\mathbf{e}_2,$$

so $[S]_{\mathbf{e}_2,\mathbf{e}_3} = \begin{pmatrix} 2 & -1 \\ 1 & 0 \end{pmatrix}$. This 2×2 problem has the eigenvalue 1 with eigenvector $(1,1)$ in these coordinates, that is, $\mathbf{b}_2 = \mathbf{e}_2 + \mathbf{e}_3$, and we complete it with $\mathbf{b}_3 = \mathbf{e}_3$. Now

$$A\mathbf{b}_1 = 2\mathbf{b}_1, \quad A\mathbf{b}_2 = (-1,0,1) = -\mathbf{b}_1 + \mathbf{b}_2, \quad A\mathbf{b}_3 = (-1,-2,0) = -\mathbf{b}_1 - \mathbf{b}_2 + \mathbf{b}_3,$$

so with $P = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}$, whose columns are $\mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3$,

$$P^{-1}AP = \begin{pmatrix} 2 & -1 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}.$$

The diagonal $2, 1, 1$ matches $p_A = (x-2)(x-1)^2$. The matrix A is not diagonalizable: $A - I_3$ has rank 2, so E_1 is a line, while 1 has algebraic multiplicity 2. The entries above the diagonal cannot all be removed.

Remark 7.5.16 (The quotient version). BEYOND 21-242 With quotient spaces (Section 4.6), the first proof needs no choice of complement. Let $U = \operatorname{span}(\mathbf{b}_1)$. The operator T/U on V/U (Proposition 4.6.32) is triangularized by some $\mathbf{b}_2 + U, \ldots, \mathbf{b}_n + U$, by induction, since $\dim V/U = n-1$. Then $\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_n$ is a basis of V (Proposition 4.6.28), and Proposition 4.6.32(b) gives $[T] = \begin{pmatrix} \lambda_1 & X \\ 0 & [T/U] \end{pmatrix}$, which is upper triangular. The compression is T/U in disguise: the isomorphism $W \to V/U$, $\mathbf{w} \mapsto \mathbf{w} + U$ (Proposition 4.6.29), carries S to T/U, because $S\mathbf{w} + U = T\mathbf{w} + U$ by Lemma 7.5.11(a). So different complements give different compressions, but they are all similar to one operator.

Only one step of the first proof used $\mathbb{C}$: the existence of an eigenvalue, for T and then for each compression. Over a general field we can ask for exactly that, and the characteristic polynomial tells us when it holds.

Theorem 7.5.17 (Triangularizable means the characteristic polynomial splits). BEYOND 21-242 Let V be a finite-dimensional vector space over any field F, with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$. Then T is triangularizable if and only if p_T splits over F.

Proof. HARD

Uses. Proposition 7.5.9 (Multiplicities on the diagonal), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Lemma 7.5.11 (Compressing an operator to a complement), Theorem 5.4.26 (Block-triangular matrices), Proposition 7.1.34 (Roots of a split polynomial), Corollary 7.1.7 (No zero divisors, cancellation, and units), Proposition 4.4.16 (Complements exist)

Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)

Hint 1. One direction is Proposition 7.5.9. For the other, run the first proof of Theorem 7.5.13. What has to be checked at each step?

Hint 2. The eigenvalue for the first step is a root of p_T. For the induction, show that $p_T = (x - \lambda_1)p_S$ for the compression S, using Lemma 7.5.11(b) and block triangular determinants.

Hint 3. If $(x-\lambda_1)q = (x-\mu_1)\cdots(x-\mu_n)$, then λ_1 is one of the μ_i, and cancelling shows that q splits.

Sketch. If T is upper triangular, $p_T = \prod(x - \lambda_j)$ splits. Conversely, by induction on n: a root λ_1 of p_T is an eigenvalue; take an eigenvector, a complement W and the compression S. The block form of Lemma 7.5.11(b) gives $p_T = (x - \lambda_1)p_S$, so p_S splits after cancelling the factor $x - \lambda_1$. Triangularize S by induction and finish as in the first proof of Theorem 7.5.13.

If $[T]_{\mathcal{B}}$ is upper triangular, then p_T splits by Proposition 7.5.9.

Conversely, suppose p_T splits. We induct on $n = \dim V$; for $n = 1$ every basis works. Let $n \geq 2$ and $p_T = (x-\mu_1)\cdots(x-\mu_n)$. Then $\lambda_1 = \mu_1$ is a root of p_T, hence an eigenvalue of T (Theorem 7.3.6); let $\mathbf{b}_1$ be an eigenvector, $U = \operatorname{span}(\mathbf{b}_1)$, W a complement of U (Proposition 4.4.16), and S the compression of T to W. For any basis $\mathcal{D}$ of W and $\mathcal{B} = \mathbf{b}_1, \mathcal{D}$, Lemma 7.5.11(b) gives

$$xI_n - [T]_{\mathcal{B}} = \begin{pmatrix} x-\lambda_1 & -X \\ 0 & xI_{n-1} - [S]_{\mathcal{D}} \end{pmatrix},$$

so by Theorem 5.4.26 (over $F[x]$), $p_T = (x-\lambda_1)p_S$. Hence $(x-\mu_1)p_S = (x-\mu_1)(x-\mu_2)\cdots(x-\mu_n)$, and cancelling the nonzero factor $x-\mu_1$ (Corollary 7.1.7) gives $p_S = (x-\mu_2)\cdots(x-\mu_n)$, which splits. By the induction hypothesis, W has a basis $\mathbf{b}_2, \ldots, \mathbf{b}_n$ in which S is upper triangular, and the computation in the first proof of Theorem 7.5.13, which used only Lemma 7.5.11(a), shows that T is upper triangular with respect to $\mathbf{b}_1, \ldots, \mathbf{b}_n$. □

For example, a real matrix is triangularizable over $\mathbb{R}$ exactly when all its complex eigenvalues are real, and $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right) \in \mathbb{Q}^{2\times 2}$ is triangularizable over $\mathbb{R}$ but not over $\mathbb{Q}$, since $x^2 - 2$ splits over $\mathbb{R}$ but not over $\mathbb{Q}$.

7.5.3 Schur's theorem

Now let V be a finite-dimensional inner product space over $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$ (Definition 6.1.2). Orthonormal bases are the best bases to compute in: coordinates are inner products (Proposition 6.3.18), the (i,j) entry of $[T]_{\mathcal{O}}$ is $\langle T\mathbf{u}_j, \mathbf{u}_i\rangle$, and the change-of-basis matrix to an orthonormal basis of $\mathbb{F}^n$ is unitary, so its inverse is its conjugate transpose (Definition 6.3.33). Can a triangularizing basis be chosen orthonormal?

By Proposition 7.5.2, being upper triangular depends only on the flag of the basis. And Gram–Schmidt replaces a basis by an orthonormal one with the same flag: $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j) = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$ for every j (Theorem 6.4.15(d)). So the answer is yes, at no extra cost.

Theorem 7.5.18 (Schur's theorem). Let V be a finite-dimensional complex inner product space with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$.

(a) There is an orthonormal basis $\mathcal{O}$ of V such that $[T]_{\mathcal{O}}$ is upper triangular.

(b) Every $A \in \mathbb{C}^{n\times n}$ can be written as $A = URU^*$ with U unitary and R upper triangular. The diagonal entries of R are the eigenvalues of A, counted with multiplicity.

Proof (Gram–Schmidt on a triangularizing basis). ROUTINE

Uses. Theorem 7.5.13 (Upper-triangular form), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Theorem 6.4.15 (Gram–Schmidt is correct), Theorem 4.5.17 (Change of basis), Definition 6.3.33 (Unitary and orthogonal matrices), Theorem 6.3.29 (Orthonormal columns)
Techniques. Build a flag of invariant subspaces (Technique 7.5.4)
Hint 1. Start from a basis $\mathcal{B}$ with $[T]_{\mathcal{B}}$ upper triangular. What does Proposition 7.5.2 say about the subspaces $\operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$?
Hint 2. Gram–Schmidt does not change these subspaces (Theorem 6.4.15(d)).
Sketch. Triangularize T in some basis $\mathcal{B}$ (Theorem 7.5.13), so the flag of $\mathcal{B}$ is invariant. Gram–Schmidt turns $\mathcal{B}$ into an orthonormal basis $\mathcal{O}$ with the same flag, so T is upper triangular with respect to $\mathcal{O}$. For (b), apply (a) to T_A on $\mathbb{C}^n$ with the dot product; the matrix U whose columns are the vectors of $\mathcal{O}$ is unitary.

(a) By Theorem 7.5.13, there is a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of V with $[T]_{\mathcal{B}}$ upper triangular, and by Proposition 7.5.2 every $V_j = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$ is T-invariant. Apply Gram–Schmidt to $\mathcal{B}$. Since $\mathcal{B}$ is linearly independent, Theorem 6.4.15(c),(d) gives an orthonormal basis $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ of V with $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j) = V_j$ for every j. These subspaces are T-invariant, so $[T]_{\mathcal{O}}$ is upper triangular by Proposition 7.5.2.

(b) Apply (a) to T_A on $\mathbb{C}^n$ with the dot product, and let U be the matrix whose columns are the vectors of $\mathcal{O}$. Its columns are orthonormal, so U is unitary (Theorem 6.3.29, Definition 6.3.33) and $U^{-1} = U^*$. By

Theorem 4.5.17, $R = [T_A]_{\mathcal{O}} = U^{-1}AU = U^*AU$ is upper triangular, and $A = URU^*$. The diagonal of R is described by Theorem 7.5.13. □

Intuition (The lecture's proof). The second proof does the algebra and the geometry at once, without quoting Theorem 7.5.13. It is the first proof of Theorem 7.5.13 with the complement chosen orthogonal: take a unit eigenvector $\mathbf{u}_1$, use $W = \operatorname{span}(\mathbf{u}_1)^\perp$ as the complement, and compress T to W with the orthogonal projection. The compression is the operator on a smaller space to which the induction hypothesis applies (Technique 7.5.12). This is the template for the spectral theorem in Section 8.2: for a self-adjoint T, the complement W turns out to be invariant itself, the compression is just the restriction, and the entries above the diagonal vanish too.

Proof (induction with an orthogonal complement). STANDARD

Uses. Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Theorem 6.4.24 (Orthogonal decomposition), Corollary 6.4.25 (Dimension of the orthogonal complement), Theorem 4.4.13 (Bases and dimension of a sum), Definition 6.3.15 (Orthonormal list, orthonormal basis), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Definition 6.1.2 (Inner product)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Induct on $n = \dim V$. Take a unit eigenvector $\mathbf{u}_1$ and $W = \operatorname{span}(\mathbf{u}_1)^\perp$. Which operator on W should the induction hypothesis be applied to?
Hint 2. Define $S\mathbf{w} = T\mathbf{w} - \langle T\mathbf{w}, \mathbf{u}_1\rangle \mathbf{u}_1$. Check that $S\mathbf{w} \in W$.
Hint 3. With an orthonormal basis $\mathbf{u}_2, \dots, \mathbf{u}_n$ of W triangularizing S, write $T\mathbf{u}_j = \langle T\mathbf{u}_j, \mathbf{u}_1\rangle \mathbf{u}_1 + S\mathbf{u}_j$.
Sketch. Induct on n. Take a unit eigenvector $\mathbf{u}_1$ and $W = \operatorname{span}(\mathbf{u}_1)^\perp$, of dimension $n-1$. The map $S\mathbf{w} = T\mathbf{w} - \langle T\mathbf{w}, \mathbf{u}_1\rangle \mathbf{u}_1$ is an operator on W (the compression of T). By induction, W has an orthonormal basis $\mathbf{u}_2, \dots, \mathbf{u}_n$ triangularizing S. Then $\mathbf{u}_1, \dots, \mathbf{u}_n$ is orthonormal, and $T\mathbf{u}_j = \langle T\mathbf{u}_j, \mathbf{u}_1\rangle \mathbf{u}_1 + S\mathbf{u}_j \in \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_j)$.

We prove (a) by induction on $n = \dim V$; part (b) follows from (a) as in the first proof. If $n = 1$, any unit vector forms an orthonormal basis, and 1×1 matrices are upper triangular.

Let $n \geq 2$, and assume (a) for complex inner product spaces of dimension $n-1$. By Theorem 7.3.27, T has an eigenvector; dividing it by its norm gives an eigenvector $\mathbf{u}_1$ with $\|\mathbf{u}_1\| = 1$ and $T\mathbf{u}_1 = \lambda_1 \mathbf{u}_1$. Let $W = \operatorname{span}(\mathbf{u}_1)^\perp$, the set of vectors orthogonal to $\mathbf{u}_1$. By Theorem 6.4.24 and Corollary 6.4.25, $V = \operatorname{span}(\mathbf{u}_1) \oplus W$ and $\dim W = n - 1$; with the inner product of V restricted to it, W is a complex inner product space. Define

$$S : W \to W, \quad S\mathbf{w} = T\mathbf{w} - \langle T\mathbf{w}, \mathbf{u}_1\rangle \mathbf{u}_1.$$

This lands in W, since $\langle S\mathbf{w}, \mathbf{u}_1\rangle = \langle T\mathbf{w}, \mathbf{u}_1\rangle - \langle T\mathbf{w}, \mathbf{u}_1\rangle\langle \mathbf{u}_1, \mathbf{u}_1\rangle = 0$, and it is linear because T is linear and the inner product is linear in its first slot (Definition 6.1.2). ($S\mathbf{w}$ is the orthogonal projection of $T\mathbf{w}$ onto W, so S is the compression of T to W.)

By the induction hypothesis and Proposition 7.5.2, W has an orthonormal basis $\mathbf{u}_2, \dots, \mathbf{u}_n$ with $S\mathbf{u}_j \in \operatorname{span}(\mathbf{u}_2, \dots, \mathbf{u}_j)$ for $2 \leq j \leq n$. Each $\mathbf{u}_j$ with $j \geq 2$ lies in W, so it is orthogonal to $\mathbf{u}_1$, and $\mathcal{O} = \mathbf{u}_1, \dots, \mathbf{u}_n$ is orthonormal (Definition 6.3.15); it is a basis of $V = \operatorname{span}(\mathbf{u}_1) \oplus W$ by Theorem 4.4.13. Finally, $T\mathbf{u}_1 = \lambda_1 \mathbf{u}_1$, and for $j \geq 2$,

$$T\mathbf{u}_j = \langle T\mathbf{u}_j, \mathbf{u}_1\rangle \mathbf{u}_1 + S\mathbf{u}_j \in \operatorname{span}(\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_j).$$

By Proposition 7.5.2, $[T]_{\mathcal{O}}$ is upper triangular. □

The first proof separates the two ingredients: the algebra (an invariant flag exists over $\mathbb{C}$) and the geometry (Gram–Schmidt keeps flags). It shows that any triangularizing basis can be orthonormalized, so for instance the basis of Example 7.5.15 turns into a Schur basis of that matrix. The second proof is self-contained and computes the entries as it goes: $[T]_{\mathcal{O}}$ has (i, j) entry $\langle T\mathbf{u}_j, \mathbf{u}_i\rangle = \langle S\mathbf{u}_j, \mathbf{u}_i\rangle$ for $i, j \geq 2$.

Example 7.5.19 (A Schur form). Let $A = \begin{pmatrix} 1 & 2 \\ -2 & 5 \end{pmatrix} \in \mathbb{C}^{2\times 2}$. Then $\det(A - \lambda I_2) = (1-\lambda)(5-\lambda) + 4 = (\lambda - 3)^2$, so 3 is the only eigenvalue, and $A - 3I_2 = \begin{pmatrix} -2 & 2 \\ -2 & 2 \end{pmatrix}$ gives the unit eigenvector $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1,1)$. Complete it to the orthonormal basis $\mathbf{u}_1, \mathbf{u}_2$ with $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(-1,1)$. Since $A\mathbf{u}_2 = \frac{1}{\sqrt{2}}(1,7)$,

$$\langle A\mathbf{u}_2, \mathbf{u}_1 \rangle = \frac{1}{2}(1+7) = 4, \quad \langle A\mathbf{u}_2, \mathbf{u}_2 \rangle = \frac{1}{2}(-1+7) = 3,$$

and so

$$A = URU^*, \quad U = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \quad R = \begin{pmatrix} 3 & 4 \\ 0 & 3 \end{pmatrix}.$$

Here E_3 is a line, so A is not diagonalizable, and no unitary change of basis can remove the entry 4. In fact no change of basis at all can make it 0, although a non-orthonormal one can make it 1.

Remark 7.5.20 (What is unique). A Schur form is far from unique. The eigenvalues can be made to appear on the diagonal in any order (Exercise 7.5.38), and even for a fixed order, replacing U by UD with $D = \operatorname{diag}\left(e^{i\theta_1}, \ldots, e^{i\theta_n}\right)$ replaces R by D^*RD, which multiplies r_{ij} by $e^{i(\theta_j - \theta_i)}$. What does not change is the list of diagonal entries, up to order (Proposition 7.5.9), and the total size $\sum_{i,j} |r_{ij}|^2 = \operatorname{tr}(A^*A)$ (Exercise 7.5.41).

For a real matrix with nonreal eigenvalues, U and R cannot both be real, since a real upper-triangular R has real eigenvalues. If all eigenvalues of $A \in \mathbb{R}^{n\times n}$ are real, then $A = QRQ^{\mathsf{T}}$ with Q orthogonal and R real (Exercise 7.5.42). For general real matrices, see Section 7.5.5.

Exercise 7.5.21. ROUTINE Find a unitary U and an upper-triangular R with $\begin{pmatrix} 3 & -1 \\ 1 & 1 \end{pmatrix} = URU^*$.

Solution on page 1595

7.5.4 Trace and determinant from eigenvalues

Every operator on a complex space has a triangular matrix whose diagonal lists its eigenvalues. Trace and determinant are both read off the diagonal of a triangular matrix, and both are independent of the basis. Putting these facts together gives formulas for them that mention no basis at all.

Theorem 7.5.22 (Trace and determinant from eigenvalues). Let V be a finite-dimensional vector space over F with $\dim V = n \geq 1$, let $T \in \mathrm{L}(V)$, and suppose that p_T splits over F, as it always does when $F = \mathbb{C}$. Let $\lambda_1, \ldots, \lambda_n$ be the eigenvalues of T counted with multiplicity. Then

$$\operatorname{tr} T = \lambda_1 + \lambda_2 + \cdots + \lambda_n \quad \text{and} \quad \det T = \lambda_1\lambda_2\cdots\lambda_n.$$

In particular, for $A \in \mathbb{C}^{n\times n}$, and so for every real matrix regarded as a complex one, $\operatorname{tr} A$ is the sum and $\det A$ the product of the complex eigenvalues of A, counted with multiplicity.

Proof (triangularize). ROUTINE

Uses. Theorem 7.5.13 (Upper-triangular form), Theorem 7.5.17 (Triangularizable means the characteristic polynomial splits), Definition 4.5.30 (Trace of an operator), Definition 5.4.18 (Determinant of an operator), Definition 2.4.26 (Trace), Proposition 5.3.15 (Triangular matrices), Proposition 7.5.9 (Multiplicities on the diagonal)
Techniques. Prove it for triangular matrices first (Technique 7.5.23), Choose a convenient basis (Technique 4.5.33)
Hint 1. Both sides do not depend on the basis. Which basis makes the left sides easy to compute?
Hint 2. In a triangularizing basis $\mathcal{B}$, what are $\operatorname{tr}[T]_{\mathcal{B}}$ and $\det[T]_{\mathcal{B}}$, and what is the diagonal?
Sketch. Choose $\mathcal{B}$ with $R = [T]_{\mathcal{B}}$ upper triangular (Theorem 7.5.13 over $\mathbb{C}$, Theorem 7.5.17 in general). Then $\operatorname{tr} T = \operatorname{tr} R$ and $\det T = \det R$ are the sum and the product of the diagonal entries, and the diagonal entries are the eigenvalues counted with multiplicity (Proposition 7.5.9).

By Theorem 7.5.13 when $F = \mathbb{C}$, and by Theorem 7.5.17 in general, there is a basis $\mathcal{B}$ with $R = [T]_{\mathcal{B}}$ upper triangular. By Definition 4.5.30 and Definition 5.4.18, $\operatorname{tr} T = \operatorname{tr} R$ and $\det T = \det R$. By Definition 2.4.26 and Proposition 5.3.15,

$$\operatorname{tr} R = r_{11} + \cdots + r_{nn}, \quad \det R = r_{11} r_{22} \cdots r_{nn}.$$

By Proposition 7.5.9, $p_T = (x - r_{11}) \cdots (x - r_{nn})$, so $r_{11}, \ldots, r_{nn}$ are the eigenvalues of T counted with multiplicity, in some order. Sums and products do not depend on the order. □

Technique 7.5.23 (Prove it for triangular matrices first). If a statement about an operator T (or a square matrix A) does not change under change of basis (or similarity), it is enough to prove it for an upper-triangular matrix of T, which exists over $\mathbb{C}$ (Theorem 7.5.13), or over any field once the characteristic polynomial splits. Triangular matrices are easy to compute with: products, powers, inverses, and polynomials of upper-triangular matrices are upper triangular, and their diagonals are computed entry by entry (Proposition 2.4.36, Exercise 7.5.34), while the diagonal itself is the list of eigenvalues.

Reach for it for identities that involve eigenvalues together with similarity invariants: trace, determinant, the characteristic polynomial, $\operatorname{tr}\left(A^k\right)$, invertibility, nilpotence. It is a special case of Technique 4.5.33. Over $\mathbb{R}$, either check that the characteristic polynomial splits, or regard the real matrix as a complex one first. The canonical example is Theorem 7.5.22. Later it proves the Cayley–Hamilton theorem (Section 7.6).

Used in. Theorem 7.5.22, Exercise 7.5.34, Exercise 7.5.36, Exercise 7.5.45, Lemma 7.6.21, Theorem 7.6.28, Problem 7.5, Problem 7.10, Theorem 8.2.5, Theorem 8.2.12, Theorem 8.4.25, Exercise 7.6.51.

The second proof avoids triangularization. It compares two descriptions of the coefficients of the characteristic polynomial.

Proof (read off the characteristic polynomial). STANDARD

Uses. Definition 7.3.4 (Characteristic polynomial), Proposition 7.1.36 (Sum and product of the roots)
Techniques. Read structure off the Leibniz expansion (Technique 5.3.12), Polynomial identity arguments (Technique 5.5.24)
Hint 1. Section 7.3 computes two coefficients of $p_A = \det(xI_n - A)$ directly from the entries of A. Which ones?
Hint 2. Compare them with the coefficients of $(x - \lambda_1) \cdots (x - \lambda_n)$ from Proposition 7.1.36.
Sketch. For any matrix A of T, Section 7.3 shows $p_T = x^n - (\operatorname{tr} A)x^{n-1} + \cdots + (-1)^n \det A$: the constant term is $\det(-A)$, and in the Leibniz expansion only the identity permutation reaches degree $n - 1$. On the other hand $p_T = \prod(x - \lambda_i)$ has these coefficients equal to $-\sum \lambda_i$ and $(-1)^n \prod \lambda_i$.

Let $A = [T]_{\mathcal{B}}$ for some basis $\mathcal{B}$, so $p_T = \det(xI_n - A)$, $\operatorname{tr} T = \operatorname{tr} A$, and $\det T = \det A$. By Section 7.3, the coefficient of x^{n-1} in p_T is $-\operatorname{tr} A$ and its constant term is $(-1)^n \det A$. (The constant term is $\det(-A)$, by setting $x = 0$; for the other coefficient, a permutation other than the identity moves at least two indices, so its term in the Leibniz expansion has at most $n - 2$ factors containing x, and only $(x - a_{11}) \cdots (x - a_{nn})$ contributes.) On the other hand $p_T = (x - \lambda_1) \cdots (x - \lambda_n)$, whose coefficient of x^{n-1} is $-(\lambda_1 + \cdots + \lambda_n)$ and whose constant term is $(-1)^n \lambda_1 \cdots \lambda_n$ (Proposition 7.1.36). Comparing coefficients, $\operatorname{tr} A = \lambda_1 + \cdots + \lambda_n$ and $\det A = \lambda_1 \cdots \lambda_n$. □

The first proof is the more flexible one: the same reduction gives the eigenvalues of A^k and of A^{-1} (Exercise 7.5.34). The second proof needs no triangular form, only two coefficients of the characteristic polynomial, which are $-\operatorname{tr} T$ and $(-1)^n \det T$ over every field, whether or not p_T splits.

Example 7.5.24 (Rotations and a 3×3 check). The rotation $R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \in \mathbb{R}^{2\times 2}$ has the complex eigenvalues $\cos\theta \pm i \sin\theta$ (Exercise 7.2.42). Their sum is $2\cos\theta = \operatorname{tr} R_\theta$ and their product is $\cos^2\theta + \sin^2\theta = 1 = \det R_\theta$. For a real matrix the nonreal eigenvalues come in conjugate pairs (Proposition 7.1.38), and each pair $\lambda, \overline{\lambda}$ contributes $2 \operatorname{Re} \lambda$ to the trace and $|\lambda|^2 > 0$ to the determinant.

For the matrix A of Example 7.5.15, with eigenvalues $2, 1, 1$, the theorem predicts $\operatorname{tr} A = 4$ and $\det A = 2$. Directly: $\operatorname{tr} A = 2 + 2 + 0 = 4$, and expanding along the first row, $\det A = 2(0 + 2) - 0 + (-1)(0 + 2) = 2$.

The trace of an operator

The trace of an operator was defined through a matrix (Definition 4.5.30). Over $\mathbb{C}$, Theorem 7.5.22 gives it a meaning without any basis: it is the sum of the eigenvalues. The matrix identities of Section 2.4.7 also have versions for maps, and for those, maps between different spaces are allowed.

Proposition 7.5.25 (Cyclicity of the trace for linear maps). Let V and W be finite-dimensional, both of dimension at least 1, and let $S \in \mathrm{L}(V, W)$ and $T \in \mathrm{L}(W, V)$. Then

$$\operatorname{tr}(TS) = \operatorname{tr}(ST),$$

where $TS \in \mathrm{L}(V)$ and $ST \in \mathrm{L}(W)$. In particular $\operatorname{tr}(ST) = \operatorname{tr}(TS)$ for all $S, T \in \mathrm{L}(V)$.

Proof. ROUTINE

Uses. Definition 4.5.30 (Trace of an operator), Theorem 2.4.2 (The matrix of a composite), Proposition 2.4.28 (Cyclicity of the trace)
Techniques. Translate between maps and matrices (Technique 2.3.27), Cyclicity of trace (Technique 2.4.29)
Hint 1. Choose bases $\mathcal{B}$ of V and $\mathcal{C}$ of W, and write the matrices of TS and ST as products.
Hint 2. Proposition 2.4.28 holds for rectangular matrices.
Sketch. With $X = [S]_{\mathcal{C}\mathcal{B}}$ and $Y = [T]_{\mathcal{B}\mathcal{C}}$, we have $[TS]_{\mathcal{B}} = YX$ and $[ST]_{\mathcal{C}} = XY$, and $\operatorname{tr}(YX) = \operatorname{tr}(XY)$.

Let $\mathcal{B}$ and $\mathcal{C}$ be bases of V and W, with $\dim V = n$ and $\dim W = m$, and let $X = [S]_{\mathcal{C}\mathcal{B}} \in F^{m \times n}$ and $Y = [T]_{\mathcal{B}\mathcal{C}} \in F^{n \times m}$. By Theorem 2.4.2, $[TS]_{\mathcal{B}} = YX$ and $[ST]_{\mathcal{C}} = XY$. So by Definition 4.5.30 and Proposition 2.4.28,

$$\operatorname{tr}(TS) = \operatorname{tr}(YX) = \operatorname{tr}(XY) = \operatorname{tr}(ST). \qquad \square$$

Corollary 7.5.26 ($ST - TS \neq \mathrm{id}_V$). Let V be finite-dimensional with $n = \dim V \geq 1$, and suppose that $n * 1 \neq 0$ in F (for instance, $F = \mathbb{R}$ or $\mathbb{C}$). Then $ST - TS \neq \mathrm{id}_V$ for all $S, T \in \mathrm{L}(V)$.

Proof. ROUTINE

Uses. Proposition 7.5.25 (Cyclicity of the trace for linear maps), Definition 4.5.30 (Trace of an operator), Proposition 2.4.12 (Matrices of sums and scalar multiples), Proposition 2.4.27 (The trace is linear)
Techniques. Cyclicity of trace (Technique 2.4.29)
Hint. Take the trace of both sides.
Sketch. $\operatorname{tr}(ST - TS) = \operatorname{tr}(ST) - \operatorname{tr}(TS) = 0$, while $\operatorname{tr} \mathrm{id}_V = \operatorname{tr} I_n = n * 1 \neq 0$.

The trace of operators is linear, by Definition 4.5.30, Proposition 2.4.12, and Proposition 2.4.27. So by Proposition 7.5.25, $\operatorname{tr}(ST - TS) = \operatorname{tr}(ST) - \operatorname{tr}(TS) = 0$. But $\operatorname{tr} \mathrm{id}_V = \operatorname{tr} I_n = n * 1 \neq 0$. Hence $ST - TS \neq \mathrm{id}_V$. $\square$

This is Proposition 2.4.30 restated for maps, and the hypotheses matter in the same ways. On the infinite-dimensional space $F[x]$, differentiation and multiplication by x satisfy $DM - MD = \mathrm{id}$ (Exercise 2.4.51), and over $\mathbb{F}_p$ there are $p \times p$ matrices with $AB - BA = I_p$ (Exercise 2.4.52). The trace argument shows more than the corollary states: $ST - TS$ always has trace 0. Over $\mathbb{C}$ the converse also holds, a theorem of Shoda: every matrix of trace 0 is of the form $AB - BA$. The practice bank has a proof.

7.5.5 Real operators: block upper-triangular form BEYOND 21-242

The real block form and the real Schur form are not covered in lecture.

Over $\mathbb{R}$ an operator need not have any eigenvalue, so it need not be triangularizable. But it always comes close: the bottom of an invariant flag may have to be a plane instead of a line, and the matrix becomes upper triangular with some 2×2 blocks on the diagonal. The key fact, proved in Section 7.3, is that small invariant subspaces always exist: every operator on a nonzero finite-dimensional real vector space has an invariant subspace of dimension 1 or 2. One proof complexifies a matrix A of T: a complex eigenvector

$\mathbf{x} + i\mathbf{y}$ ($\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$) for an eigenvalue $a + bi$ gives $A\mathbf{x} = a\mathbf{x} - b\mathbf{y}$ and $A\mathbf{y} = b\mathbf{x} + a\mathbf{y}$, by comparing real and imaginary parts, so the vectors with coordinates $\mathbf{x}$ and $\mathbf{y}$ span an invariant subspace. The induction of Theorem 7.5.13 then goes through with this subspace in place of an eigenvector.

Theorem 7.5.27 (Real block upper-triangular form). Let V be a real vector space with $1 \le \dim V < \infty$, and let $T \in \mathrm{L}(V)$.

(a) There is a basis $\mathcal{B}$ of V such that $[T]_{\mathcal{B}}$ is block upper triangular, with every diagonal block of size 1×1 or 2×2, and with no 2×2 diagonal block having a real eigenvalue.

(b) If V is a real inner product space, $\mathcal{B}$ can be chosen orthonormal. In particular, every $A \in \mathbb{R}^{n \times n}$ can be written as $A = QRQ^{\mathsf{T}}$ with Q orthogonal and R block upper triangular as in (a) (the **real Schur form**).

Proof. HARD

Uses. an invariant subspace of dimension 1 or 2 exists (Section 7.3), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Proposition 4.4.16 (Complements exist), Lemma 7.5.11 (Compressing an operator to a complement), Theorem 6.4.24 (Orthogonal decomposition), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 4.5.17 (Change of basis)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Strong induction on $\dim V$. Choose an invariant subspace U of dimension 1 if T has a real eigenvalue, and of dimension 2 otherwise.
Hint 2. Compress T to a complement W of U, apply the induction hypothesis to the compression, and read off the block form from Lemma 7.5.11(b).
Hint 3. For (b), use the orthogonal complement and orthonormal bases throughout.
Sketch. If T has a real eigenvalue, let U be an eigenvector's span; otherwise an invariant subspace of dimension 1 or 2 (Section 7.3) must be a plane U, and $T|_U$ has no real eigenvalue. If $U = V$ we are done. Otherwise compress T to a complement W (for (b), to $U^\perp$), use the induction hypothesis on the compression, and assemble with Lemma 7.5.11(b): the first diagonal block is $[T|_U]$, the rest are the blocks of the compression.

(a) We use strong induction on $n = \dim V$. Choose a T-invariant subspace U as follows. If T has a real eigenvalue, let U be the span of an eigenvector, of dimension 1 (Proposition 7.2.7). Otherwise, by Section 7.3 there is an invariant subspace U of dimension 1 or 2, and dimension 1 is impossible since it would be spanned by an eigenvector; so $\dim U = 2$. In that case $T|_U$ has no real eigenvalue, since an eigenvector of $T|_U$ would be an eigenvector of T.

If $U = V$, any basis of V works: $[T]_{\mathcal{B}}$ is a single block of size 1, or of size 2 with no real eigenvalue. Otherwise let W be a complement of U (Proposition 4.4.16), so $1 \le \dim W < n$, and let $S \in \mathrm{L}(W)$ be the compression of T to W. By the induction hypothesis, W has a basis $\mathcal{D}$ with $[S]_{\mathcal{D}}$ block upper triangular as in (a). Let $\mathcal{C}$ be any basis of U, and $\mathcal{B} = \mathcal{C}, \mathcal{D}$. By Lemma 7.5.11(b),

$$[T]_{\mathcal{B}} = \begin{pmatrix} [T|_U]_{\mathcal{C}} & X \\ 0 & [S]_{\mathcal{D}} \end{pmatrix},$$

which is block upper triangular, with first diagonal block $[T|_U]_{\mathcal{C}}$ and the remaining diagonal blocks those of $[S]_{\mathcal{D}}$. All of them have the required form.

(b) Run the same induction with $W = U^\perp$, which is a complement of U by Theorem 6.4.24, and with an orthonormal basis $\mathcal{C}$ of U and, by the induction hypothesis applied to the real inner product space W, an orthonormal basis $\mathcal{D}$ of W. Then $\mathcal{C}, \mathcal{D}$ is orthonormal, since vectors of U and of $U^\perp$ are orthogonal. For $A \in \mathbb{R}^{n \times n}$, apply this to T_A on $\mathbb{R}^n$ with the dot product, and let Q have the resulting orthonormal basis as columns. Then Q is orthogonal, and $R = Q^{\mathsf{T}}AQ = [T_A]_{\mathcal{B}}$ by Theorem 4.5.17. □

Example 7.5.28 (An invariant plane). Let

$$A = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ -2 & 2 & -1 \end{pmatrix} \in \mathbb{R}^{3\times 3}.$$

Its characteristic polynomial is $(x-1)\big(x^2+1\big)$, so 1 is its only real eigenvalue, with eigenvector $\mathbf{v} = (1,1,0)$. Over $\mathbb{C}$, $\mathbf{z} = (1,0,-1+i)$ is an eigenvector for i, as one checks: $A\mathbf{z} = (i,0,-1-i) = i\mathbf{z}$. As above, split $\mathbf{z} = \mathbf{x} + i\mathbf{y}$ with $\mathbf{x} = (1,0,-1)$ and $\mathbf{y} = (0,0,1)$. Then

$$A\mathbf{x} = (0,0,-1) = -\mathbf{y}, \quad A\mathbf{y} = (1,0,-1) = \mathbf{x},$$

so $\operatorname{span}(\mathbf{x},\mathbf{y})$ is an invariant plane on which A acts by $\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, a rotation by a right angle, with eigenvalues $\pm i$. In the basis $\mathbf{x}, \mathbf{y}, \mathbf{v}$,

$$[T_A] = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Here the plane happens to have an invariant complement, $\operatorname{span}(\mathbf{v})$, so the matrix is even block diagonal. As a check, $\operatorname{tr} A = 1 = i + (-i) + 1$ and $\det A = 1 = i \cdot (-i) \cdot 1$.

Exercises

Exercise 7.5.29. ROUTINE Find an invertible S and an upper-triangular R with diagonal $1, 1, 2$ such that $A = SRS^{-1}$, where

$$A = \begin{pmatrix} 2 & -2 & 0 \\ 2 & -1 & -2 \\ -1 & 0 & 3 \end{pmatrix} \in \mathbb{C}^{3\times 3}.$$

Solution on page 1596

Exercise 7.5.30. STANDARD

(a) Let V be a complex vector space with $\dim V = n \geq 1$, and $T \in \mathrm{L}(V)$. Show that for each $k = 0, 1, \ldots, n$, there is a T-invariant subspace of V of dimension k.

(b) Let $T \in \mathrm{L}\big(\mathbb{R}^4\big)$ be $T(x_1,x_2,x_3,x_4) = (-x_2, x_1, -x_4, x_3)$. Show that T has no invariant subspace of dimension 1 or 3.

Solution on page 1596

Exercise 7.5.31. STANDARD How many of the 16 matrices in $\mathbb{F}_2^{2\times 2}$ are triangularizable over $\mathbb{F}_2$? List the ones that are not.

Solution on page 1597

Exercise 7.5.32. ROUTINE

(a) Find $A \in \mathbb{Q}^{2\times 2}$ that is triangularizable over $\mathbb{R}$ but not over $\mathbb{Q}$.

(b) Find $A \in \mathbb{R}^{3\times 3}$ that has a real eigenvalue but is not triangularizable over $\mathbb{R}$.

Solution on page 1597

Exercise 7.5.33. STANDARD Prove or disprove.

(a) If $A \in F^{n\times n}$ is triangularizable, then so is A^{T}.

(b) If $A, B \in \mathbb{R}^{2\times 2}$ are triangularizable over $\mathbb{R}$, then so is $A + B$.

(c) If T is upper triangular with respect to both $\mathbf{b}_1, \ldots, \mathbf{b}_n$ and $\mathbf{c}_1, \ldots, \mathbf{c}_n$, then $\mathbf{c}_1$ is a multiple of $\mathbf{b}_1$.

(d) Two upper-triangular matrices with the same diagonal are similar.

Solution on page 1598

Exercise 7.5.34. STANDARD Let $A \in \mathbb{C}^{n\times n}$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, counted with multiplicity.

(a) Show that for every $k \geq 1$, the eigenvalues of A^k counted with multiplicity are $\lambda_1^k, \ldots, \lambda_n^k$. Deduce that $\operatorname{tr}\left(A^k\right) = \lambda_1^k + \cdots + \lambda_n^k$.

(b) Suppose A is invertible. Show that the eigenvalues of A^{-1} counted with multiplicity are $\lambda_1^{-1}, \ldots, \lambda_n^{-1}$, and that $\operatorname{tr}\left(A^{-1}\right) = \lambda_1^{-1} + \cdots + \lambda_n^{-1}$.

Solution on page 1598

Exercise 7.5.35. STANDARD A matrix $A \in \mathbb{C}^{3\times 3}$ satisfies $\operatorname{tr} A = 2$, $\operatorname{tr}\left(A^2\right) = 6$, and $\det A = -2$. Find the eigenvalues of A, and decide whether A is diagonalizable.

Solution on page 1598

Exercise 7.5.36. STANDARD

(a) Let $A \in \mathbb{C}^{n\times n}$. Show that 0 is the only eigenvalue of A if and only if $A^n = 0$.

(b) Find $A \in \mathbb{R}^{3\times 3}$ whose only real eigenvalue is 0 but with $A^k \neq 0$ for every $k \geq 1$.

Solution on page 1599

Exercise 7.5.37. STANDARD Find the error in the following argument.

Claim. If $A, B \in \mathbb{C}^{n\times n}$ have eigenvalues $\lambda_1, \ldots, \lambda_n$ and $\mu_1, \ldots, \mu_n$ (counted with multiplicity), then the eigenvalues of AB are $\lambda_1\mu_1, \ldots, \lambda_n\mu_n$, in some order.

Proof. By Schur's theorem, $A = URU^*$ and $B = UR'U^*$ with U unitary and R, R' upper triangular, with diagonals $\lambda_1, \ldots, \lambda_n$ and $\mu_1, \ldots, \mu_n$. Then $AB = URR'U^*$, and RR' is upper triangular with diagonal $\lambda_1\mu_1, \ldots, \lambda_n\mu_n$.

Solution on page 1599

Exercise 7.5.38. HARD Let V be a complex vector space with $\dim V = n \geq 1$, and let $T \in \mathrm{L}(V)$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, counted with multiplicity and listed in any order chosen in advance. Show that there is a basis $\mathcal{B}$ of V such that $[T]_{\mathcal{B}}$ is upper triangular with diagonal entries $\lambda_1, \lambda_2, \ldots, \lambda_n$ in this order. If V is an inner product space, show that $\mathcal{B}$ can be taken orthonormal.

Solution on page 1600

Exercise 7.5.39. STANDARD BEYOND 21-242 Let $A \in \mathbb{C}^{n\times n}$, and write $A = SRS^{-1}$ as in Corollary 7.5.14. Let $S = QR'$ be the QR factorization of S (Theorem 6.4.38). Show that $A = QR''Q^*$ with $R'' = R'RR'^{-1}$ upper triangular with the same diagonal as R. Explain why this is the first proof of Theorem 7.5.18 in matrix form.

Solution on page 1600

Exercise 7.5.40. STANDARD

(a) Show that an upper-triangular unitary matrix $R \in \mathbb{C}^{n\times n}$ is diagonal, with $|r_{jj}| = 1$ for every j.

(b) Deduce that every unitary $A \in \mathbb{C}^{n\times n}$ can be written as $A = UDU^*$ with U unitary and D diagonal.

Solution on page 1601

Exercise 7.5.41. HARD Let $A \in \mathbb{C}^{n\times n}$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, counted with multiplicity. Prove **Schur's inequality**

$$\sum_{j=1}^{n} |\lambda_j|^2 \le \sum_{i,j=1}^{n} |a_{ij}|^2,$$

with equality if and only if $A = UDU^*$ for some unitary U and diagonal D.

Solution on page 1601

Exercise 7.5.42. HARD Let $A \in \mathbb{R}^{n\times n}$, and suppose that p_A splits over $\mathbb{R}$, that is, all eigenvalues of A are real. Show that $A = QRQ^{\mathsf{T}}$ with $Q \in \mathbb{R}^{n\times n}$ orthogonal and $R \in \mathbb{R}^{n\times n}$ upper triangular.

Solution on page 1601

Exercise 7.5.43. HARD Let $A \in \mathbb{C}^{n\times n}$ with $\operatorname{tr}\left(A^k\right) = 0$ for $k = 1, 2, \ldots, n$. Show that $A^n = 0$. Then show that the statement fails over $\mathbb{F}_p$.

Solution on page 1602

Exercise 7.5.44. HARD Let $A, B \in \mathbb{C}^{n\times n}$ satisfy $AB - BA = A$. Show that $A^n = 0$.

Solution on page 1603

Solution on page 1603

Exercise 7.5.45. HARD Let $A \in \mathbb{C}^{n\times n}$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, counted with multiplicity, and let $L_A \in \mathrm{L}(\mathbb{C}^{n\times n})$ be $L_A(X) = AX - XA$. Use the matrix units $U_{ij} = \mathbf{e}_i\mathbf{e}_j^{\mathsf{T}}$ (Lemma 2.4.24).

(a) Suppose A is upper triangular. List the matrix units row by row, and within each row from right to left: $U_{1n}, U_{1,n-1}, \ldots, U_{11}, U_{2n}, \ldots, U_{21}, \ldots, U_{n1}$. Show that L_A is upper triangular with respect to this basis, with diagonal entry $a_{ii} - a_{jj}$ at U_{ij}.

(b) Deduce that for every A, the eigenvalues of L_A counted with multiplicity are the n^2 numbers $\lambda_i - \lambda_j$ $(1 \le i, j \le n)$.

(c) Deduce again that $\operatorname{tr} L_A = 0$, and that L_A is not invertible.

Solution on page 1603

Exercise 7.5.46. STANDARD BEYOND 21-242 Let $A = \begin{pmatrix} 0 & 2 & -1 \\ 0 & 1 & 0 \\ 1 & -1 & 0 \end{pmatrix} \in \mathbb{R}^{3\times 3}$.

(a) Check that $(1, 0, -i)$ is an eigenvector of A over $\mathbb{C}$, and use it to find a two-dimensional T_A-invariant subspace of $\mathbb{R}^3$.

(b) Find a basis of $\mathbb{R}^3$ in which T_A has the form of Theorem 7.5.27(a).

(c) Find an orthogonal Q such that $Q^{\mathsf{T}}AQ$ is a real Schur form.

Solution on page 1604

7.6 Minimal polynomials, Cayley–Hamilton, and commuting operators BEYOND 21-242

By Proposition 4.1.31, every operator on an n-dimensional space is a root of some nonzero polynomial of degree at most n^2. Polynomial identities of this kind have already done a lot of work. A polynomial that kills T confines the eigenvalues of T to its roots (Proposition 7.2.28), and a diagonalizable operator is killed by the product of the factors $x-\lambda$ over its eigenvalues (Proposition 7.4.26). This section studies the best such polynomial, the one of least degree. Its roots are exactly the eigenvalues, and whether it has a repeated root decides whether T is diagonalizable, a test that needs no eigenvectors at all. The Cayley–Hamilton theorem says that the characteristic polynomial is always among the polynomials that kill T, which brings the degree bound down from n^2 to n; we prove it four ways. The last two topics also run on polynomials in an operator: commuting operators, which over $\mathbb{C}$ can be triangularized by a single basis (and, if each is diagonalizable, diagonalized by one over any field), and Gershgorin's theorem, which locates eigenvalues without computing them.

Throughout, V is a finite-dimensional vector space over a field F with $\dim V = n \geq 1$, and $T \in \mathrm{L}(V)$.

7.6.1 Annihilating polynomials and the minimal polynomial

Definition 7.6.1 (Annihilating polynomial). A polynomial $p \in F[x]$ **annihilates** T if $p(T) = 0$. Similarly, p annihilates $A \in F^{n\times n}$ if $p(A) = 0$.

The zero polynomial annihilates every operator, so the question is which nonzero polynomials do. We have met several. A projection ($P^2 = P$) is annihilated by $x^2 - x$, an operator with $N^k = 0$ by x^k, the cyclic permutation Z of Example 7.2.36 by $x^3 - 1$, and a diagonalizable operator with distinct eigenvalues $\lambda_1, \ldots, \lambda_m$ by $(x-\lambda_1)\cdots(x-\lambda_m)$. Annihilating polynomials never come alone: if $p(T) = 0$, then $(qp)(T) = q(T)p(T) = 0$ for every $q \in F[x]$ (Proposition 7.2.27(a)). So the natural candidate for "the" polynomial of T is one of least degree.

Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial). There is exactly one monic polynomial $m \in F[x]$ such that $m(T) = 0$ and $\deg m \leq \deg p$ for every nonzero $p \in F[x]$ with $p(T) = 0$. Moreover, for every $p \in F[x]$,

$$p(T) = 0 \quad \Longleftrightarrow \quad m \mid p.$$

Proof. STANDARD

Uses. Proposition 4.1.31 (Every square matrix satisfies a polynomial), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 7.1.14 (Division with remainder), Definition 7.1.5 (Monic polynomial), Definition 7.1.16 (Divisibility)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Uniqueness via two candidates (Technique 1.1.8), Compare degrees and leading coefficients (Technique 7.1.6)
Hint 1. Among the nonzero annihilating polynomials, take one of smallest degree. Why is there one, and how do you make it monic?
Hint 2. For the divisibility statement, divide p by m with remainder and evaluate the identity at T. The remainder annihilates T too. What does the choice of m say about it?
Hint 3. For uniqueness, if m and m' both qualify, they have the same degree. Look at $m - m'$.
Sketch. Nonzero annihilating polynomials exist by Proposition 4.1.31(b); take one of least degree d and divide it by its leading coefficient. If $p(T) = 0$, write $p = qm + r$ with $r = \mathbf{0}$ or $\deg r < d$; then $r(T) = p(T) - q(T)m(T) = 0$, so $r = \mathbf{0}$ by minimality. Multiples of m annihilate T. A second candidate m' also has degree d, and $m - m'$ annihilates T with degree less than d (the leading terms cancel), so $m = m'$.

Existence. By Proposition 4.1.31(b), some nonzero polynomial annihilates T. So the degrees of the nonzero annihilating polynomials form a nonempty set of nonnegative integers, which has a least element d. Let p_0 be a nonzero annihilating polynomial of degree d, with leading coefficient $a \neq 0$, and put $m = a^{-1}p_0$.

Then m is monic of degree d, and $m(T) = a^{-1}p_0(T) = 0$ by Proposition 7.2.27(a). By the choice of d, $\deg m \leq \deg p$ for every nonzero p with $p(T) = 0$.

Divisibility. If $m \mid p$, say $p = qm$, then $p(T) = q(T)m(T) = 0$ by Proposition 7.2.27(a). Conversely, suppose $p(T) = 0$. By Theorem 7.1.14 there are $q, r \in F[x]$ with $p = qm + r$, where $r = \mathbf{0}$ or $\deg r < d$. Then

$$r(T) = p(T) - q(T)m(T) = 0 - 0 = 0.$$

If r were nonzero, it would be a nonzero annihilating polynomial of degree less than d, contradicting the choice of d. So $r = \mathbf{0}$, and $m \mid p$.

Uniqueness. Suppose m' is also monic, $m'(T) = 0$, and $\deg m' \leq \deg p$ for every nonzero annihilating p. Applying this to $p = m$, and the same property of m to $p = m'$, gives $\deg m' = \deg m = d$. Both are monic of degree d, so the coefficients of x^d cancel in $m - m'$, which is therefore $\mathbf{0}$ or of degree less than d. It annihilates T, so $m - m' = \mathbf{0}$ by the minimality of d. □

Definition 7.6.3 (Minimal polynomial). The polynomial m of Theorem 7.6.2 is the **minimal polynomial** of T, written m_T. For $A \in F^{n\times n}$, the **minimal polynomial** m_A of A is the minimal polynomial of $T_A \in \mathrm{L}(F^n)$. Since $p(T_A) = T_{p(A)}$ (Proposition 7.2.27(c)), m_A is the monic polynomial of least degree with $m_A(A) = 0$.

So m_T is minimal in two senses: no nonzero annihilating polynomial has smaller degree, and every annihilating polynomial is a multiple of it. Since $V \neq \{\mathbf{0}\}$, a nonzero constant c gives $c\mathrm{id}_V \neq 0$, so $\deg m_T \geq 1$. Moreover $\deg m_T = 1$ exactly when $T - \lambda\mathrm{id}_V = 0$ for some $\lambda \in F$, that is, when $T = \lambda\mathrm{id}_V$ is a scalar multiple of the identity; then $m_T = x - \lambda$.

ASIDE: *Ideals*

The set $I_T = \{p \in F[x] \mid p(T) = 0\}$ is closed under addition and under multiplication by arbitrary polynomials. Such a subset of a commutative ring is called an **ideal**. The proof of Theorem 7.6.2 used nothing about I_T except these two closure properties and $I_T \neq \{\mathbf{0}\}$, so it shows that every nonzero ideal of $F[x]$ consists of the multiples of one monic polynomial. This makes $F[x]$ a *principal ideal domain*, the setting of Section 14.4. The greatest common divisor (Theorem 7.1.45) is the same phenomenon for the ideal $\{up + vs \mid u, v \in F[x]\}$.

The least degree can be found by looking for the first linear dependence among the powers of T, exactly as the Krylov polynomial of a vector was found among $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ in Proposition 7.2.35.

Proposition 7.6.4 (The minimal polynomial is the first dependence among the powers). Let $d = \deg m_T$. Then $\mathrm{id}_V, T, \ldots, T^{d-1}$ are linearly independent in $\mathrm{L}(V)$, and d is the smallest integer $k \geq 1$ with $T^k \in \mathrm{span}\big(\mathrm{id}_V, T, \ldots, T^{k-1}\big)$. If

$$T^d = -\big(c_0\mathrm{id}_V + c_1T + \cdots + c_{d-1}T^{d-1}\big),$$

then $m_T = x^d + c_{d-1}x^{d-1} + \cdots + c_1x + c_0$. Moreover, $\mathrm{id}_V, T, \ldots, T^{d-1}$ is a basis of the subspace $F[T] = \{p(T) \mid p \in F[x]\}$ of $\mathrm{L}(V)$, so $\dim F[T] = \deg m_T$.

Proof. ROUTINE

Uses. Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Theorem 7.1.14 (Division with remainder), Theorem 1.5.5 (Independence is decided at zero), Definition 7.2.26 (Polynomials in an operator)
Techniques. Too many vectors force a dependence (Technique 4.1.30)
Hint 1. A linear relation $b_0\mathrm{id}_V + b_1T + \cdots + b_{k-1}T^{k-1} = 0$ says that the polynomial $b_0 + b_1x + \cdots + b_{k-1}x^{k-1}$ annihilates T.
Hint 2. For the basis of $F[T]$, divide an arbitrary p by m_T with remainder.
Sketch. A nontrivial relation among $\mathrm{id}_V, \ldots, T^{d-1}$ would be a nonzero annihilating polynomial of degree less than d. The relation $m_T(T) = 0$ expresses T^d through lower powers, and since those are independent, the coefficients are unique,

so they are those of m_T. If T^k were a combination of lower powers for some $k < d$, there would be a monic annihilating polynomial of degree $k < d$. Finally, $p = qm_T + r$ gives $p(T) = r(T) \in \operatorname{span}\left(\mathrm{id}_V, \ldots, T^{d-1}\right)$.

For scalars $b_0, \ldots, b_{k-1}$, the relation $\sum_{i<k} b_i T^i = 0$ says exactly that $q = \sum_{i<k} b_i x^i$ annihilates T (Definition 7.2.26). If $\mathrm{id}_V, T, \ldots, T^{d-1}$ satisfied a nontrivial relation, q would be a nonzero annihilating polynomial of degree less than d, which Theorem 7.6.2 rules out. So the list is independent.

Writing $m_T = x^d + a_{d-1}x^{d-1} + \cdots + a_0$, the equation $m_T(T) = 0$ says $T^d = -\left(a_0\mathrm{id}_V + \cdots + a_{d-1}T^{d-1}\right)$. So T^d lies in the span of the lower powers, and since these are independent, its coefficients are unique (Theorem 1.5.5). Hence $c_i = a_i$ for every i. If $T^k = \sum_{i<k} b_i T^i$ for some $1 \le k < d$, then $x^k - \sum_{i<k} b_i x^i$ would be a monic annihilating polynomial of degree $k < d$, which is impossible. So d is the smallest such k.

Finally, let $p \in F[x]$. By Theorem 7.1.14, $p = qm_T + r$ with $r = \mathbf{0}$ or $\deg r < d$, so $p(T) = q(T)m_T(T) + r(T) = r(T)$, a combination of $\mathrm{id}_V, \ldots, T^{d-1}$. Thus this independent list spans $F[T]$, and it is a basis. □

In the language of Proposition 7.2.35: the Krylov sequence of the "vector" $\mathrm{id}_V \in \mathrm{L}(V)$ under the operator $S \mapsto TS$ on $\mathrm{L}(V)$ is $\mathrm{id}_V, T, T^2, \ldots$, and its Krylov polynomial is m_T.

Example 7.6.5 (First minimal polynomials).

(a) *Projections.* Let $P \in \mathrm{L}(V)$ with $P^2 = P$ and $P \neq 0, \mathrm{id}_V$. Then $x^2 - x$ annihilates P. If $P = c\mathrm{id}_V$, then $c^2 = c$, so $c \in \{0, 1\}$; this is excluded, so no polynomial of degree 1 annihilates P, and $m_P = x^2 - x = x(x-1)$.

(b) *The shift.* Let $N \in \mathrm{L}(F^n)$ with $N\mathbf{e}_1 = \mathbf{0}$ and $N\mathbf{e}_j = \mathbf{e}_{j-1}$ for $j \ge 2$ (Example 7.2.20). Then $N^n = 0$. For scalars $b_0, \ldots, b_{n-1}$,

$$\left(b_0\,\mathrm{id} + b_1N + \cdots + b_{n-1}N^{n-1}\right)\mathbf{e}_n = b_0\mathbf{e}_n + b_1\mathbf{e}_{n-1} + \cdots + b_{n-1}\mathbf{e}_1,$$

which is $\mathbf{0}$ only if every $b_i = 0$. So $\mathrm{id}, N, \ldots, N^{n-1}$ are independent, and Proposition 7.6.4 gives $\deg m_N \ge n$. Since x^n annihilates N, $m_N \mid x^n$, so $\deg m_N = n$, and a monic divisor of x^n of degree n is x^n itself. Hence $m_N = x^n$.

(c) *A rotation.* Let $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Then $R^2 = -I_2$, so $x^2 + 1$ annihilates R, and R is not a scalar matrix, so $m_R = x^2 + 1$, over $\mathbb{R}$ and over $\mathbb{C}$ alike. Over $\mathbb{R}$ this has no roots, and R has no eigenvalues; over $\mathbb{C}$ its roots are $\pm i$, which are the eigenvalues of R (Non-example 7.5.6).

(d) *The cyclic permutation.* Let $Z(x, y, z) = (z, x, y)$ on F^3, so $Z^3 = \mathrm{id}$. The matrices of id, Z, Z^2 have their 1's in disjoint positions,

$$I_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad [Z] = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad [Z]^2 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},$$

so they are independent, and $m_Z = x^3 - 1$ over every field.

Exercise 7.6.6. ROUTINE Let $A \in F^{n\times n}$ and $c \in F$.

(a) Show that $m_{A^{\mathsf{T}}} = m_A$.

(b) Show that $m_{A+cI_n}(x) = m_A(x - c)$. Deduce the minimal polynomial of $\lambda I_n + N$, where N is the shift of Example 7.6.5(b).

Solution on page 1605

7.6.2 Roots of the minimal polynomial

In each part of Example 7.6.5, the roots of m_T in F were exactly the eigenvalues of T: 0 and 1 for a projection, 0 for the shift, none for the real rotation, $\pm i$ for the complex one, and the cube roots of 1 in F for Z. This always happens.

Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues). Let $\lambda \in F$. Then λ is an eigenvalue of T if and only if $m_T(\lambda) = 0$.

One direction is Proposition 7.2.28. For the other, peel the factor $x - \lambda$ off m_T. What is left has smaller degree, so it does not annihilate T; it produces some nonzero vector, and $T - \lambda\,\mathrm{id}$ kills that vector.

Proof. ROUTINE

Uses. Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 7.1.20 (Factor theorem), Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 7.2.6 (Eigenvalue, eigenvector)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. The direction "eigenvalue ⇒ root" was proved in Section 7.2. Where?
Hint 2. If $m_T(\lambda) = 0$, write $m_T = (x - \lambda)q$. Why is $q(T) \neq 0$?
Hint 3. Choose $\mathbf{v}$ with $q(T)\mathbf{v} \neq \mathbf{0}$, and apply $T - \lambda\mathrm{id}_V$ to $q(T)\mathbf{v}$.
Sketch. If λ is an eigenvalue, then $m_T(\lambda) = 0$ by Proposition 7.2.28, as $m_T(T) = 0$. Conversely, if $m_T(\lambda) = 0$, the factor theorem gives $m_T = (x - \lambda)q$ with q monic of degree $\deg m_T - 1$, so $q(T) \neq 0$ by minimality. For $\mathbf{v}$ with $\mathbf{w} = q(T)\mathbf{v} \neq \mathbf{0}$, we get $(T - \lambda\mathrm{id}_V)\mathbf{w} = m_T(T)\mathbf{v} = \mathbf{0}$, so $\mathbf{w}$ is an eigenvector for λ.

If λ is an eigenvalue of T, then $m_T(\lambda) = 0$ by Proposition 7.2.28, because $m_T(T) = 0$.

Conversely, suppose $m_T(\lambda) = 0$. By the factor theorem (Theorem 7.1.20), $m_T = (x - \lambda)q$ for some $q \in F[x]$ of degree $\deg m_T - 1$, and q is monic because m_T is. Since $q \neq \mathbf{0}$ has smaller degree than m_T, Theorem 7.6.2 gives $q(T) \neq 0$. Choose $\mathbf{v} \in V$ with $\mathbf{w} = q(T)\mathbf{v} \neq \mathbf{0}$. By Proposition 7.2.27(a),

$$(T - \lambda\mathrm{id}_V)\mathbf{w} = (T - \lambda\mathrm{id}_V)q(T)\mathbf{v} = m_T(T)\mathbf{v} = \mathbf{0}.$$

So $T\mathbf{w} = \lambda\mathbf{w}$ with $\mathbf{w} \neq \mathbf{0}$, and λ is an eigenvalue of T (Definition 7.2.6). □

So m_T and the characteristic polynomial p_T have the same roots in F, namely the eigenvalues (Corollary 7.3.13). They can differ in the multiplicities of those roots: $m_{\mathrm{id}_V} = x - 1$, while $p_{\mathrm{id}_V} = (x - 1)^n$.

Corollary 7.6.8 (The shape of the minimal polynomial over $\mathbb{C}$). Suppose $F = \mathbb{C}$, and let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T. Then

$$m_T = (x - \lambda_1)^{k_1}(x - \lambda_2)^{k_2}\cdots(x - \lambda_m)^{k_m}$$

for some integers $k_1, \ldots, k_m \geq 1$.

Proof. ROUTINE

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues)
Hint. Factor the monic polynomial m_T completely over $\mathbb{C}$. Which numbers can appear in the factors, and which must?
Sketch. By Corollary 7.1.35, m_T is a product of factors $x - \mu$ over its roots μ. By Theorem 7.6.7, the roots are exactly $\lambda_1, \ldots, \lambda_m$, so each occurs at least once; group equal factors.

Since m_T is monic of degree at least 1, Corollary 7.1.35 writes it as $(x - \mu_1)\cdots(x - \mu_d)$, where $\mu_1, \ldots, \mu_d$ are its roots listed with multiplicity. By Theorem 7.6.7, the set of roots is $\{\lambda_1, \ldots, \lambda_m\}$. Grouping equal factors gives the stated form, with $k_i \geq 1$ the number of j with $\mu_j = \lambda_i$. □

Two quick consequences show what the minimal polynomial is good for.

Corollary 7.6.9 (Inverses are polynomials). T is invertible if and only if $m_T(0) \neq 0$. In that case, write $m_T = xs + c_0$ with $c_0 = m_T(0)$ and $s \in F[x]$. Then

$$T^{-1} = -c_0^{-1}s(T),$$

a polynomial in T of degree $\deg m_T - 1$.

Proof. ROUTINE

Uses. Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues), Theorem 7.1.20 (Factor theorem), Proposition 7.2.27 (Evaluating polynomials at an operator)
Hint 1. T is invertible if and only if 0 is not an eigenvalue. Use Theorem 7.6.7.
Hint 2. Evaluate $m_T = xs + c_0$ at T and solve for id_V.
Sketch. Since V is finite-dimensional, T is invertible exactly when 0 is not an eigenvalue, that is, when $m_T(0) \neq 0$. Then $0 = m_T(T) = Ts(T) + c_0\mathrm{id}_V$ gives $T\big(-c_0^{-1}s(T)\big) = \mathrm{id}_V$, and $s(T)$ commutes with T.

By Theorem 7.2.9 (with $\lambda = 0$, using $\dim V < \infty$), T is invertible if and only if 0 is not an eigenvalue of T, which by Theorem 7.6.7 happens if and only if $m_T(0) \neq 0$.

Suppose $c_0 = m_T(0) \neq 0$. By Theorem 7.1.20 with $c = 0$, $m_T = xs + c_0$ with $\deg s = \deg m_T - 1$. Evaluating at T (Proposition 7.2.27(a)),

$$0 = m_T(T) = Ts(T) + c_0\mathrm{id}_V, \quad \text{so} \quad T\big(-c_0^{-1}s(T)\big) = \mathrm{id}_V.$$

By Proposition 7.2.27(b), $s(T)$ commutes with T, so also $\big(-c_0^{-1}s(T)\big)T = \mathrm{id}_V$, and $-c_0^{-1}s(T)$ is the inverse of T. □

For example, $A = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$ has $A^2 = \begin{pmatrix} 5 & 3 \\ 3 & 2 \end{pmatrix} = 3A - I_2$, and A is not a scalar matrix, so $m_A = x^2 - 3x + 1$. Here $m_A(0) = 1$ and $m_A = x(x-3) + 1$, so $A^{-1} = -(A - 3I_2) = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$, as one checks by multiplying.

Proposition 7.6.10 (Invariant subspaces and similarity).

(a) If $U \neq \{\mathbf{0}\}$ is a T-invariant subspace of V, then $m_{T|_U}$ divides m_T, where $T|_U$ is regarded as an operator on U.

(b) If $V = U \oplus W$ with U and W both T-invariant and nonzero, then for every $p \in F[x]$,

$$p(T) = 0 \iff p(T|_U) = 0 \text{ and } p(T|_W) = 0.$$

(c) For every basis $\mathcal{B}$ of V, $m_{[T]_{\mathcal{B}\mathcal{B}}} = m_T$. In particular, similar matrices have the same minimal polynomial.

Proof. ROUTINE

Uses. Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 4.2.1 (Restriction), Proposition 2.4.12 (Matrices of sums and scalar multiples), Theorem 4.5.25 (Similar matrices are one operator in two bases)
Techniques. Restrict to a subspace (Technique 4.2.5)
Hint 1. First show that $p(T)$ restricted to an invariant U is $p(T|_U)$. Start with powers.
Hint 2. For (c), use $[p(T)]_{\mathcal{B}\mathcal{B}} = p([T]_{\mathcal{B}\mathcal{B}})$ and the injectivity of $S \mapsto [S]_{\mathcal{B}\mathcal{B}}$.
Sketch. For invariant U, $T^k|_U = (T|_U)^k$ by induction, so $p(T)|_U = p(T|_U)$. Then (a): $m_T(T|_U) = m_T(T)|_U = 0$, so $m_{T|_U} \mid m_T$. (b): write $\mathbf{v} = \mathbf{u} + \mathbf{w}$. (c): $p(T) = 0$ if and only if $p([T]_{\mathcal{B}\mathcal{B}}) = [p(T)]_{\mathcal{B}\mathcal{B}} = 0$, so T and $[T]_{\mathcal{B}\mathcal{B}}$ have the same annihilating polynomials; similar matrices are matrices of one operator.

Let U be T-invariant. For $\mathbf{u} \in U$, induction on k gives $T^k\mathbf{u} = (T|_U)^k\mathbf{u}$: both sides are $\mathbf{u}$ for $k = 0$, and $T^{k+1}\mathbf{u} = T(T|_U)^k\mathbf{u} = (T|_U)^{k+1}\mathbf{u}$ because $(T|_U)^k\mathbf{u} \in U$. Taking linear combinations, $p(T)\mathbf{u} = p(T|_U)\mathbf{u}$ for every $p \in F[x]$ and $\mathbf{u} \in U$.

(a) By the above, $m_T(T|_U)\mathbf{u} = m_T(T)\mathbf{u} = \mathbf{0}$ for every $\mathbf{u} \in U$. So m_T annihilates $T|_U$, and $m_{T|_U} \mid m_T$ by Theorem 7.6.2.

(b) If $p(T) = 0$, then $p(T|_U)\mathbf{u} = p(T)\mathbf{u} = \mathbf{0}$ for all $\mathbf{u} \in U$, and likewise on W. Conversely, if both restrictions are annihilated, write $\mathbf{v} \in V$ as $\mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in U$, $\mathbf{w} \in W$. Then $p(T)\mathbf{v} = p(T|_U)\mathbf{u} + p(T|_W)\mathbf{w} = \mathbf{0}$.

(c) By Proposition 7.2.27(c), $[p(T)]_{\mathcal{B}\mathcal{B}} = p([T]_{\mathcal{B}\mathcal{B}})$, and $S \mapsto [S]_{\mathcal{B}\mathcal{B}}$ is injective (Proposition 2.4.12). So $p(T) = 0$ if and only if $p([T]_{\mathcal{B}\mathcal{B}}) = 0$. Thus T and $[T]_{\mathcal{B}\mathcal{B}}$ have the same annihilating polynomials, hence the same minimal polynomial by the uniqueness in Theorem 7.6.2. If $A \sim B$, then A and B are matrices of a single operator T (Theorem 4.5.25), so $m_A = m_T = m_B$. □

Remark 7.6.11 (Neither polynomial determines the other). The matrices I_2 and $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ have the same characteristic polynomial $(x-1)^2$. But $m_{I_2} = x - 1$, while $J - I_2 \neq 0$ and $(J - I_2)^2 = 0$, so $m_J = (x-1)^2$. In the other direction, $\operatorname{diag}(2,2,3)$ and $\operatorname{diag}(2,3,3)$ have the same minimal polynomial $(x-2)(x-3)$ but different characteristic polynomials. Even the two together do not determine a matrix up to similarity (Exercise 7.6.43); the Jordan form of Section 10.3 does.

7.6.3 Diagonalizability

Proposition 7.4.26 shows that a diagonalizable operator is killed by a product of distinct linear factors. The converse is the most useful property of the minimal polynomial: to show that T is diagonalizable, it is enough to find one polynomial identity of the right shape, without looking for a single eigenvector.

Intuition (Why distinct factors should split the space). If $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_m}$, each summand is killed by its own factor $T - \lambda_i \operatorname{id}$, so the product of all the factors kills V. Running this backwards: if $(T - c_1 \operatorname{id}) \cdots (T - c_k \operatorname{id}) = 0$ with distinct c_i, we want to write each $\mathbf{v}$ as a sum of vectors $\mathbf{v}_i$ with $(T - c_i \operatorname{id})\mathbf{v}_i = \mathbf{0}$. Polynomials in T are the only operators we have, so we look for polynomials L_i with $L_1 + \cdots + L_k = 1$ and $(x - c_i)L_i$ divisible by the product $q = (x - c_1) \cdots (x - c_k)$. Then $\mathbf{v} = \sum L_i(T)\mathbf{v}$, and $L_i(T)\mathbf{v}$ is killed by $T - c_i \operatorname{id}$. The Lagrange polynomials of the nodes $c_1, \ldots, c_k$ (Section 7.1.4) are exactly such polynomials. If a factor is repeated, as in $(x - c)^2$, no such decomposition can work, and the shift shows it does not.

Proposition 7.6.12 (Distinct linear factors force a diagonalization). Let $c_1, \ldots, c_k \in F$ be distinct, and suppose $q = (x - c_1)(x - c_2) \cdots (x - c_k)$ annihilates T. Then

$$V = E_{c_1} \oplus E_{c_2} \oplus \cdots \oplus E_{c_k},$$

where $E_c = \ker(T - c\mathrm{id}_V)$ (some of these may be $\{\mathbf{0}\}$). In particular, T is diagonalizable, and its eigenvalues are among $c_1, \ldots, c_k$.

Proof (Lagrange interpolation in T). STANDARD

Uses. Proposition 7.1.29 (Lagrange polynomials in closed form), Corollary 7.1.23 (Polynomials and their values), Proposition 7.2.27 (Evaluating polynomials at an operator), Corollary 7.2.23 (Eigenspaces are independent), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
Techniques. Lagrange interpolation in T (Technique 7.6.13), Use an annihilating polynomial (Technique 7.6.17)
Hint 1. Let $L_1, \ldots, L_k$ be the Lagrange polynomials for the nodes $c_1, \ldots, c_k$. What is $L_1 + \cdots + L_k$?
Hint 2. $(x - c_i)L_i$ is a constant multiple of q. What does that say about $\operatorname{im} L_i(T)$?
Hint 3. Write $\mathbf{v} = \sum_i L_i(T)\mathbf{v}$. Why is the resulting sum of eigenspaces direct?
Sketch. Let $L_i = \prod_{j \neq i} (x - c_j)/(c_i - c_j)$. Then $\sum_i L_i = 1$, since both sides have degree less than k and agree at the k nodes. Also $(x - c_i)L_i = a_i q$ for a constant a_i, so $(T - c_i \operatorname{id})L_i(T) = 0$ and $\operatorname{im} L_i(T) \subseteq E_{c_i}$. So $\mathbf{v} = \sum L_i(T)\mathbf{v} \in E_{c_1} + \cdots + E_{c_k}$, and the sum is direct by Corollary 7.2.23. Concatenating bases of the summands gives an eigenbasis.

If $k = 1$, then $T - c_1 \mathrm{id}_V = 0$, so $V = E_{c_1}$ and every basis is an eigenbasis. Let $k \geq 2$, and let

$$L_i = \prod_{j \neq i} \frac{x - c_j}{c_i - c_j} \quad (i = 1, \ldots, k)$$

be the Lagrange polynomials of the nodes $c_1, \ldots, c_k$ (Proposition 7.1.29), so $L_i(c_j) = 1$ if $i = j$ and 0 otherwise.

First, $L_1 + \cdots + L_k = 1$. Both sides have degree at most $k - 1$, and at each node c_j the left side takes the value $\sum_i L_i(c_j) = 1$. By Corollary 7.1.23(a), they are equal.

Second, $(x - c_i)L_i = a_i q$ with $a_i = \prod_{j \neq i} (c_i - c_j)^{-1}$, since multiplying L_i by $x - c_i$ supplies the one missing factor of q.

Let $P_i = L_i(T)$. Evaluating the two identities at T (Proposition 7.2.27(a)) gives

$$P_1 + \cdots + P_k = \mathrm{id}_V, \quad (T - c_i \mathrm{id}_V)P_i = a_i q(T) = 0.$$

The second says $\operatorname{im} P_i \subseteq E_{c_i}$. So every $\mathbf{v} \in V$ satisfies

$$\mathbf{v} = P_1\mathbf{v} + \cdots + P_k\mathbf{v} \in E_{c_1} + \cdots + E_{c_k},$$

and $V = E_{c_1} + \cdots + E_{c_k}$. The c_i are distinct, so this sum is direct (Corollary 7.2.23). Concatenating bases of the nonzero E_{c_i} gives a basis of V (Theorem 4.4.13) consisting of eigenvectors of T, so T is diagonalizable (Theorem 7.4.2). Every eigenvalue is a root of q by Proposition 7.2.28, so it is one of the c_i. □

The operators $P_i = L_i(T)$ in this proof are worth keeping. P_i maps V into E_{c_i}, and on each E_{c_j} it acts as the scalar $L_i(c_j)$ (Proposition 7.2.28), which is 1 for $j = i$ and 0 otherwise. So P_i is the projection of V onto E_{c_i} along the sum of the other eigenspaces, and it is a polynomial in T. The same argument, without the Lagrange formula, is Exercise 7.4.49.

> **Technique 7.6.13** (Lagrange interpolation in T). If $q(T) = 0$ for $q = (x - c_1)\cdots(x - c_k)$ with distinct c_i, evaluate the Lagrange polynomials L_i of the nodes c_i at T. The operators $P_i = L_i(T)$ satisfy $\sum P_i = \mathrm{id}$, $P_iP_j = 0$ for $i \neq j$ (as $q \mid L_iL_j$), and $P_i^2 = P_i$, and P_i is the projection onto E_{c_i} along the other eigenspaces. More generally, for any values $d_1, \ldots, d_k$, the interpolating polynomial $p = \sum d_iL_i$ gives an operator $p(T)$ that acts as d_i on E_{c_i}.
>
> Reach for it to write spectral projections as polynomials in T, to build operators with a prescribed action on each eigenspace (square roots, inverses, operators commuting with T), or to decompose a vector along the eigenspaces without finding an eigenbasis. The canonical example is the first proof of Proposition 7.6.12. Later: the spectral decomposition (Section 8.2).
>
> *Used in.* Proposition 7.6.12, Exercise 7.6.45.

The second proof avoids interpolation. It peels off one eigenspace at a time, like the second proof of Theorem 7.5.13, and the only polynomial fact it uses is that $q(c_k) \neq 0$ after the factor $x - c_k$ is removed.

Proof (induction on the number of factors). STANDARD

> *Uses.* Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Theorem 4.2.11 (Rank–nullity), Theorem 4.4.7 (Criteria for direct sums), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 7.4.2 (Diagonalizable means an eigenbasis)
> *Techniques.* Dimension counting (Technique 4.2.24), Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Restrict to a subspace (Technique 4.2.5)
> *Hint 1.* Induct on k. Let $N = T - c_k\mathrm{id}_V$ and $U = \operatorname{im} N$. Which polynomial annihilates $T|_U$?
> *Hint 2.* Show $E_{c_k} \cap U = \{\mathbf{0}\}$: for $\mathbf{v} = N\mathbf{w}$ in E_{c_k}, compute $q'(T)\mathbf{v}$ in two ways, where $q' = (x - c_1)\cdots(x - c_{k-1})$.
> *Hint 3.* Rank–nullity gives $\dim E_{c_k} + \dim U = n$, so $V = E_{c_k} \oplus U$.
> *Sketch.* By induction on k; $k = 1$ means $T = c_1\mathrm{id}_V$. Let $N = T - c_k\mathrm{id}_V$, $U = \operatorname{im} N$ (which is T-invariant), and $q' = q/(x - c_k)$. Then $q'(T|_U) = 0$, since $q'(T)N\mathbf{w} = q(T)\mathbf{w}$, so by induction U is the direct sum of the eigenspaces of $T|_U$. If $\mathbf{v} = N\mathbf{w} \in E_{c_k}$, then $q'(c_k)\mathbf{v} = q'(T)\mathbf{v} = q(T)\mathbf{w} = \mathbf{0}$ with $q'(c_k) \neq 0$, so $E_{c_k} \cap U = \{\mathbf{0}\}$; with rank–nullity, $V = E_{c_k} \oplus U$.

We prove the statement for all finite-dimensional spaces, by induction on k. If $k = 1$, then $T = c_1\mathrm{id}_V$ and $V = E_{c_1}$.

Let $k \geq 2$, and assume the statement for $k - 1$ distinct factors. Let $N = T - c_k\mathrm{id}_V$, $U = \operatorname{im} N$, and $q' = (x - c_1)\cdots(x - c_{k-1})$, so $q = q'(x - c_k)$. The subspace U is T-invariant by Proposition 7.2.30(a). For $\mathbf{u} = N\mathbf{w} \in U$,

$$q'(T)\mathbf{u} = q'(T)(T - c_k\mathrm{id}_V)\mathbf{w} = q(T)\mathbf{w} = \mathbf{0},$$

so q' annihilates $T|_U$. If $U \neq \{\mathbf{0}\}$, the induction hypothesis applied to $T|_U \in \mathrm{L}(U)$ shows that U is the direct sum of the eigenspaces of $T|_U$, so U has a basis of eigenvectors of $T|_U$, which are eigenvectors of T. If $U = \{\mathbf{0}\}$, then $T = c_k\mathrm{id}_V$ and there is nothing to prove.

Next, $E_{c_k} \cap U = \{\mathbf{0}\}$. Let $\mathbf{v} \in E_{c_k} \cap U$, say $\mathbf{v} = N\mathbf{w}$. As above, $q'(T)\mathbf{v} = q(T)\mathbf{w} = \mathbf{0}$. On the other hand, if $\mathbf{v} \neq \mathbf{0}$, it is an eigenvector for c_k, and Proposition 7.2.28 gives $q'(T)\mathbf{v} = q'(c_k)\mathbf{v}$, where $q'(c_k) = \prod_{j<k}(c_k - c_j) \neq 0$. Then $q'(c_k)\mathbf{v} = \mathbf{0}$ forces $\mathbf{v} = \mathbf{0}$, a contradiction.

By rank–nullity (Theorem 4.2.11) applied to N, $\dim E_{c_k} + \dim U = \dim \ker N + \dim \operatorname{im} N = n$. So the sum $E_{c_k} + U$ is direct (Theorem 4.4.7) of dimension n (Theorem 4.4.13(c)), hence equal to V (Proposition 4.1.21), and $V = E_{c_k} \oplus U$. Concatenating a basis of E_{c_k} with an eigenbasis of U gives an eigenbasis of V, so T is diagonalizable (Theorem 7.4.2). The eigenspace decomposition follows: the eigenvalues of T are roots of q (Proposition 7.2.28), so the eigenbasis lies in $E_{c_1} \cup \cdots \cup E_{c_k}$, which gives $V = E_{c_1} + \cdots + E_{c_k}$, and this sum is direct by Corollary 7.2.23. □

Remark 7.6.14 (Coprime factors). The identity $\sum L_i = 1$ in the first proof is a special case of Bézout's identity: if p and s are coprime, then $up + vs = 1$ for some $u, v \in F[x]$ (Corollary 7.1.48). The same argument then shows that if $(ps)(T) = 0$, then $V = \ker p(T) \oplus \ker s(T)$, with both summands T-invariant (Exercise 7.2.55). Applied to the factorization $m_T = (x - \lambda_1)^{k_1} \cdots (x - \lambda_m)^{k_m}$ over $\mathbb{C}$, whose factors are pairwise coprime, it splits V into the subspaces $\ker(T - \lambda_i \operatorname{id})^{k_i}$ even when T is not diagonalizable. That is the generalized eigenspace decomposition of Section 10.2.

Theorem 7.6.15 (Diagonalizability and the minimal polynomial). The following are equivalent.

(I) T is diagonalizable.

(II) $m_T = (x - \lambda_1)(x - \lambda_2) \cdots (x - \lambda_m)$ for some distinct $\lambda_1, \ldots, \lambda_m \in F$.

(III) Some product $(x - c_1) \cdots (x - c_k)$ of distinct linear factors, with $c_1, \ldots, c_k \in F$, annihilates T.

In that case, the λ_i in (II) are exactly the distinct eigenvalues of T.

Proof. STANDARD

Uses. Proposition 7.4.26 (Polynomials that kill a diagonalizable operator), Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Theorem 7.6.7 (The roots of the minimal polynomial are the eigenvalues), Proposition 7.1.22 (Counting roots), Proposition 7.6.12 (Distinct linear factors force a diagonalization)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. For (I) ⇒ (II), Proposition 7.4.26 gives an annihilating polynomial. How does it compare with m_T?
Hint 2. Both m_T and that polynomial have every eigenvalue as a root. Show that each divides the other.
Sketch. (I) ⇒ (II): $q = \prod(x - \lambda_i)$ over the distinct eigenvalues annihilates T, so $m_T \mid q$. Each λ_i is a root of m_T, so $q \mid m_T$ by Proposition 7.1.22. Both are monic, so $m_T = q$. (II) ⇒ (III) is immediate, and (III) ⇒ (I) is Proposition 7.6.12.

We prove (I) ⇒ (II) ⇒ (III) ⇒ (I).

(I) ⇒ (II). Let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T and $q = (x - \lambda_1) \cdots (x - \lambda_m)$. By Proposition 7.4.26, $q(T) = 0$, so $m_T \mid q$ (Theorem 7.6.2). By Theorem 7.6.7, each λ_i is a root of m_T, so $q \mid m_T$ by Proposition 7.1.22. Two monic polynomials that divide each other are equal (their quotient is a constant, which is 1 by comparing leading coefficients). So $m_T = q$.

(II) ⇒ (III). Take $c_i = \lambda_i$; m_T annihilates T.

(III) ⇒ (I). This is Proposition 7.6.12.

Finally, by Theorem 7.6.7 the roots of m_T are the eigenvalues, so in (II) the λ_i are exactly the distinct eigenvalues. □

Corollary 7.6.16 (Restrictions of diagonalizable operators). If T is diagonalizable and $U \neq \{\mathbf{0}\}$ is T-invariant, then $T{\restriction_U} \in \mathrm{L}(U)$ is diagonalizable.

Proof. ROUTINE

Uses. Theorem 7.6.15 (Diagonalizability and the minimal polynomial), Proposition 7.6.10 (Invariant subspaces and similarity)
Hint. Which polynomial annihilates $T{\restriction_U}$?
Sketch. m_T is a product of distinct linear factors and annihilates $T{\restriction_U}$ (Proposition 7.6.10(a)), so (III) of Theorem 7.6.15 holds for $T{\restriction_U}$.

By Theorem 7.6.15, m_T is a product of distinct linear factors. By the proof of Proposition 7.6.10(a), $m_T(T\restriction_U) = 0$. So $T\restriction_U$ satisfies condition (III) of Theorem 7.6.15, and it is diagonalizable. (Compare Exercise 7.4.50, whose first solution argues directly with Lagrange polynomials.) □

Technique 7.6.17 (Use an annihilating polynomial). When an operator satisfies a polynomial identity $q(T) = 0$, factor q and read off:

- every eigenvalue of T is a root of q (Proposition 7.2.28), and the minimal polynomial divides q;
- if q is a product of distinct linear factors, T is diagonalizable (Theorem 7.6.15);
- if $q(0) \neq 0$, then T is invertible and T^{-1} is a polynomial in T (Corollary 7.6.9);
- powers T^k reduce to polynomials of degree less than $\deg q$, by dividing x^k by q.

Reach for it whenever the hypothesis is an identity such as $A^2 = A$, $A^3 = A$, $A^k = I$, or $T^2 = 3T - 2\,\mathrm{id}$, and whenever the characteristic polynomial is available, since it always annihilates T (Theorem 7.6.20). Watch the field: $x^2 - 1 = (x-1)(x+1)$ has distinct roots only if $1 + 1 \neq 0$, and $x^2 + 1$ splits over $\mathbb{C}$ and over $\mathbb{F}_5$ but not over $\mathbb{R}$ or $\mathbb{F}_3$. The canonical example is Theorem 7.6.15.

Used in. Proposition 7.6.12, Exercise 7.6.19, Exercise 7.6.27, Exercise 7.6.42, Exercise 7.6.50, Exercise 7.7.4, Exercise 7.7.7, Exercise 7.7.8, Exercise 7.7.10, Problem 7.14, Problem 7.16, Problem 7.17, Exercise 7.6.41, Exercise 7.6.43, Exercise 7.6.45, Exercise 7.6.46.

Example 7.6.18 (Diagonalizability from an identity).

(a) *Projections.* If $P^2 = P$, then $x(x-1)$ annihilates P, and $0 \neq 1$ in every field. So every projection is diagonalizable, with eigenvalues in $\{0, 1\}$, over every field.

(b) *Involutions.* If $T^2 = \mathrm{id}_V$, then $(x-1)(x+1)$ annihilates T. When $1 + 1 \neq 0$, the roots 1 and -1 are distinct, and T is diagonalizable with $V = E_1 \oplus E_{-1}$. Over $\mathbb{F}_2$ this fails: $J = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \mathbb{F}_2^{2\times 2}$ satisfies $J^2 = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = I_2$, but $J \neq I_2$, so $m_J = x^2 - 1 = (x-1)^2$ in $\mathbb{F}_2[x]$, and J is not diagonalizable.

(c) *Nilpotent and diagonalizable.* If $T^k = 0$ and T is diagonalizable, then every eigenvalue is a root of x^k, so 0 is the only eigenvalue, and (II) of Theorem 7.6.15 gives $m_T = x$. So $T = 0$.

(d) *Roots of unity.* The cyclic permutation Z of Example 7.6.5(d) has $m_Z = x^3 - 1$. Over $\mathbb{C}$ the three cube roots of 1 are distinct (Theorem B.1.26), so Z is diagonalizable over $\mathbb{C}$. Over $\mathbb{F}_7$, $x^3 - 1 = (x-1)(x-2)(x-4)$ (as $2^3 = 8$ and $4^3 = 64$ are 1 in $\mathbb{F}_7$), so Z is diagonalizable over $\mathbb{F}_7$. Over $\mathbb{F}_3$, $(x-1)^3 = x^3 - 3x^2 + 3x - 1 = x^3 - 1$, so $m_Z = (x-1)^3$ and Z is not diagonalizable. Over $\mathbb{R}$, $x^3 - 1 = (x-1)\big(x^2 + x + 1\big)$ does not split, and Z is not diagonalizable.

Exercise 7.6.19. ROUTINE For each matrix in $\mathbb{Q}^{n\times n}$, find a polynomial of degree at most 2 that annihilates it, find its minimal polynomial, and decide whether it is diagonalizable.

$$A = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix}, \quad C = \begin{pmatrix} 3 & -2 \\ 4 & -3 \end{pmatrix}.$$

Solution on page 1605

7.6.4 The Cayley–Hamilton theorem

In every example so far, m_T divided the characteristic polynomial p_T: for the shift both are x^n, for a projection $x(x-1)$ divides $x^r(x-1)^{n-r}$, and for $\mathrm{diag}(2, 2, 3)$, $(x-2)(x-3)$ divides $(x-2)^2(x-3)$. By Theorem 7.6.2, this is the statement that p_T annihilates T.

Theorem 7.6.20 (Cayley–Hamilton). $p_T(T) = 0$. Equivalently, m_T divides p_T. In particular, $p_A(A) = 0$ for every $A \in F^{n\times n}$, and $\deg m_T \leq n$.

Intuition (Four ways in). For a diagonal matrix $D = \operatorname{diag}(d_1, \dots, d_n)$ the theorem is clear: $p_D = (x - d_1)\cdots(x - d_n)$, and $p_D(D) = \operatorname{diag}(p_D(d_1), \dots, p_D(d_n)) = 0$ because each d_i is a root. The four proofs below get from this case to the general one in different ways.

- *Triangular form.* Over $\mathbb{C}$, T is upper triangular in a basis whose flag is $V_0 \subseteq V_1 \subseteq \cdots \subseteq V_n$, and $p_T = (x - \lambda_1)\cdots(x - \lambda_n)$ with the λ_j on the diagonal. Each factor $T - \lambda_j\,\mathrm{id}$ pushes V_j down into V_{j-1}, so applying all n factors pushes V down to $\{\mathbf{0}\}$.
- *One Krylov subspace at a time.* To show that $p_T(T)$ kills $\mathbf{v}$, only the Krylov subspace of $\mathbf{v}$ matters. There T acts by a companion matrix, which visibly satisfies its own characteristic polynomial, and that polynomial divides p_T.
- *The adjugate.* The tempting one-liner "$p_A(A) = \det(AI - A) = \det 0 = 0$" is wrong (Exercise 7.3.47). Its idea can be rescued: substitute A not into a determinant, but into the matrix identity $(xI - A)\operatorname{adj}(xI - A) = p_A I$.
- *Perturbation.* Diagonalizable matrices are "most" matrices. Nudge A to a diagonalizable matrix, where the theorem is easy, and let the nudge go to zero. Because everything is polynomial, "go to zero" can be done with algebra instead of limits.

The first proof rests on a lemma that is worth having on its own.

Lemma 7.6.21 (A triangular operator is killed by its diagonal). Let $\mathcal{B} = \mathbf{b}_1, \dots, \mathbf{b}_n$ be a basis with $[T]_{\mathcal{B}}$ upper triangular, with diagonal entries $\lambda_1, \dots, \lambda_n$, and let $V_j = \operatorname{span}(\mathbf{b}_1, \dots, \mathbf{b}_j)$. Then $(T - \lambda_j \mathrm{id}_V)(V_j) \subseteq V_{j-1}$ for each j, and

$$(T - \lambda_1 \mathrm{id}_V)(T - \lambda_2 \mathrm{id}_V)\cdots(T - \lambda_n \mathrm{id}_V) = 0.$$

Proof. ROUTINE

Uses. Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Definition 2.3.1 (Matrix of a linear map), Proposition 7.2.4 (Invariance is checked on a spanning list)
Techniques. Build a flag of invariant subspaces (Technique 7.5.4)
Hint 1. Check $(T - \lambda_j \mathrm{id}_V)\mathbf{b}_i \in V_{j-1}$ for $i < j$ and for $i = j$ separately.
Hint 2. For the product, show by downward induction on j that $(T - \lambda_j \mathrm{id}_V)\cdots(T - \lambda_n \mathrm{id}_V)$ maps V into V_{j-1}.
Sketch. For $i < j$, $(T - \lambda_j\,\mathrm{id})\mathbf{b}_i \in V_i \subseteq V_{j-1}$ since V_i is invariant; and $(T - \lambda_j\,\mathrm{id})\mathbf{b}_j = \sum_{i<j} a_{ij}\mathbf{b}_i \in V_{j-1}$. So $T - \lambda_j\,\mathrm{id}$ maps V_j into V_{j-1}. Applying $T - \lambda_n\,\mathrm{id}, T - \lambda_{n-1}\,\mathrm{id}, \dots, T - \lambda_1\,\mathrm{id}$ in turn moves $V = V_n$ into V_{n-1}, then V_{n-2}, and finally into $V_0 = \{\mathbf{0}\}$.

Write $[T]_{\mathcal{B}} = (a_{ij})$, so $a_{jj} = \lambda_j$ and, by Proposition 7.5.2, $T\mathbf{b}_j = \lambda_j \mathbf{b}_j + \sum_{i<j} a_{ij}\mathbf{b}_i$. Fix j. For $i < j$, $\mathbf{b}_i \in V_i$ and V_i is T-invariant (Proposition 7.5.2), so $(T - \lambda_j \mathrm{id}_V)\mathbf{b}_i \in V_i \subseteq V_{j-1}$. For $i = j$,

$$(T - \lambda_j \mathrm{id}_V)\mathbf{b}_j = \sum_{i<j} a_{ij}\mathbf{b}_i \in V_{j-1}.$$

So $T - \lambda_j \mathrm{id}_V$ maps the spanning list $\mathbf{b}_1, \dots, \mathbf{b}_j$ of V_j into the subspace V_{j-1}, hence maps V_j into V_{j-1}.

Now let $Q_j = (T - \lambda_j \mathrm{id}_V)\cdots(T - \lambda_n \mathrm{id}_V)$. We show $Q_j(V) \subseteq V_{j-1}$ by downward induction on j. For $j = n$, $Q_n(V) = (T - \lambda_n \mathrm{id}_V)(V_n) \subseteq V_{n-1}$. If $Q_{j+1}(V) \subseteq V_j$, then $Q_j(V) = (T - \lambda_j \mathrm{id}_V)\big(Q_{j+1}(V)\big) \subseteq (T - \lambda_j \mathrm{id}_V)(V_j) \subseteq V_{j-1}$. For $j = 1$ this says $Q_1(V) \subseteq V_0 = \{\mathbf{0}\}$, so $Q_1 = 0$. □

Proof (via triangular form). STANDARD

Uses. Theorem 7.5.13 (Upper-triangular form), Theorem 7.5.17 (Triangularizable means the characteristic polynomial splits), Proposition 7.5.9 (Multiplicities on the diagonal), Lemma 7.6.21 (A triangular operator is killed by its diagonal), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 7.3.1 (Determinant over a commutative ring)
Techniques. Prove it for triangular matrices first (Technique 7.5.23), Build a flag of invariant subspaces (Technique 7.5.4)
Hint 1. Over $\mathbb{C}$, choose a basis in which T is upper triangular. What is p_T in terms of the diagonal?
Hint 2. Write $p_T(T)$ as a product of the factors $T - \lambda_j \mathrm{id}_V$ in the order of Lemma 7.6.21.
Hint 3. For a real matrix A, regard it as a complex matrix. Do p_A and $p_A(A)$ change?

Sketch. If p_T splits (always over $\mathbb{C}$), T is upper triangular in some basis with diagonal $\lambda_1, \dots, \lambda_n$, and $p_T = (x-\lambda_1)\cdots(x-\lambda_n)$. Then $p_T(T) = (T-\lambda_1\,\mathrm{id})\cdots(T-\lambda_n\,\mathrm{id}) = 0$ by Lemma 7.6.21. A real matrix has the same characteristic polynomial and the same $p_A(A)$ when regarded as a complex matrix, so the complex case covers it.

Suppose first that p_T splits over F, as it always does when $F = \mathbb{C}$. By Theorem 7.5.17 (or Theorem 7.5.13 when $F = \mathbb{C}$), V has a basis $\mathcal{B}$ in which $[T]_{\mathcal{B}}$ is upper triangular, with diagonal entries $\lambda_1, \dots, \lambda_n$, and then $p_T = (x-\lambda_1)\cdots(x-\lambda_n)$ by Proposition 7.5.9. By Proposition 7.2.27(a) and Lemma 7.6.21,

$$p_T(T) = (T-\lambda_1 \mathrm{id}_V)(T-\lambda_2 \mathrm{id}_V)\cdots(T-\lambda_n \mathrm{id}_V) = 0.$$

Now let $A \in \mathbb{R}^{n\times n}$, and regard it as an element of $\mathbb{C}^{n\times n}$. Its characteristic polynomial is the same polynomial in both views, because $\det(xI_n - A)$ is computed by the Leibniz formula from the entries of A alone (Definition 7.3.1). The matrix $p_A(A)$ is also the same, since it is computed from the entries of A and the coefficients of p_A by sums and products. By the complex case, $p_A(A) = 0$. For a real operator T, apply this to $A = [T]_{\mathcal{B}\mathcal{B}}$ and use $[p_T(T)]_{\mathcal{B}\mathcal{B}} = p_T(A)$ (Proposition 7.2.27(c), Definition 7.3.12).

The same argument works over any subfield of $\mathbb{C}$, such as $\mathbb{Q}$. Over a general field it needs a larger field in which p_T splits; such a field always exists (Section 14.2), but the next two proofs avoid the question. □

The second proof works over every field. All of its work was done in Section 7.3, where Proposition 7.3.26 identified the action of T on a Krylov subspace with a companion matrix; Exercise 7.3.51 already carried it out.

Proof (one Krylov subspace at a time). ROUTINE

Uses. Proposition 7.2.35 (A basis of a Krylov subspace), Proposition 7.3.26 (Krylov subspaces and the characteristic polynomial), Proposition 7.2.27 (Evaluating polynomials at an operator)
Techniques. Krylov sequences must become dependent (Technique 7.3.28)
Hint 1. It suffices to show $p_T(T)\mathbf{v} = \mathbf{0}$ for every $\mathbf{v} \neq \mathbf{0}$. Which polynomial kills $\mathbf{v}$?
Hint 2. The Krylov polynomial p of $\mathbf{v}$ kills $\mathbf{v}$, and by Proposition 7.3.26 it divides p_T.
Sketch. For $\mathbf{v} \neq \mathbf{0}$, let p be the Krylov polynomial of $\mathbf{v}$ (Proposition 7.2.35), so $p(T)\mathbf{v} = \mathbf{0}$. By Proposition 7.3.26, $p_T = gp$ for some g, so $p_T(T)\mathbf{v} = g(T)p(T)\mathbf{v} = \mathbf{0}$.

Let $\mathbf{v} \in V$. If $\mathbf{v} = \mathbf{0}$, then $p_T(T)\mathbf{v} = \mathbf{0}$. Otherwise let p be the monic polynomial of Proposition 7.2.35 for $\mathbf{v}$, so $p(T)\mathbf{v} = \mathbf{0}$. By Proposition 7.3.26(c), $p_T = gp$ for some $g \in F[x]$. By Proposition 7.2.27(a),

$$p_T(T)\mathbf{v} = g(T)(p(T)\mathbf{v}) = g(T)\mathbf{0} = \mathbf{0}.$$

So $p_T(T)$ sends every vector to $\mathbf{0}$, and $p_T(T) = 0$. □

The third proof is pure algebra: it uses only that $F[x]$ is a commutative ring, so it works verbatim for matrices with entries in any commutative ring, such as $\mathbb{Z}$. It turns the naive substitution into a correct argument.

Proof (via the adjugate). HARD

Uses. Definition 7.3.4 (Characteristic polynomial), Proposition 7.3.2 (Determinants over a commutative ring), Definition 5.5.6 (Cofactors, cofactor matrix, adjugate), Proposition 7.1.4 (Degree of a product), Remark 7.1.11 (Polynomials in a matrix)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. In $F[x]^{n\times n}$, $(xI_n - A)\,\mathrm{adj}(xI_n - A) = p_A I_n$ by Proposition 7.3.2(f). The entries of $\mathrm{adj}(xI_n - A)$ have degree at most $n-1$; collect powers of x to write $\mathrm{adj}(xI_n - A) = \sum_{k=0}^{n-1} x^k B_k$ with $B_k \in F^{n\times n}$.
Hint 2. Expand the left side and compare the coefficients of each x^k with those of $p_A I_n = \sum_k c_k x^k I_n$. You get $n+1$ matrix equations.
Hint 3. Multiply the equation for x^k on the left by A^k and add them all up. The left sides telescope.
Sketch. Write $\mathrm{adj}(xI_n - A) = \sum_{k=0}^{n-1} x^k B_k$ and $p_A = \sum_{k=0}^{n} c_k x^k$. Comparing coefficients in $(xI_n - A)\sum_k x^k B_k = p_A I_n$ gives $B_{n-1} = I_n$, $B_{k-1} - AB_k = c_k I_n$ for $1 \le k \le n-1$, and $-AB_0 = c_0 I_n$. Multiplying the x^k equation by A^k and summing, the left sides telescope to 0 and the right sides add up to $p_A(A)$.

It suffices to treat a matrix $A \in F^{n\times n}$; for an operator, take $A = [T]_{\mathcal{B}\mathcal{B}}$ as in the first proof. Write $p_A = c_n x^n + c_{n-1}x^{n-1} + \cdots + c_0$, with $c_n = 1$, and let $M = xI_n - A \in F[x]^{n\times n}$. By Proposition 7.3.2(f) (for $n \geq 2$; for $n = 1$, $\operatorname{adj} M = (1)$ and the identity is clear),

$$M \operatorname{adj}(M) = (\det M) I_n = p_A I_n. \tag{7.6.1}$$

Each entry of $\operatorname{adj}(M)$ is, up to sign, the determinant of an $(n-1)\times(n-1)$ submatrix of M (Definition 5.5.6). Each Leibniz term of such a determinant is a product of $n-1$ entries of degree at most 1, so every entry of $\operatorname{adj}(M)$ is $\mathbf{0}$ or has degree at most $n-1$ (Proposition 7.1.4). Collecting, in each entry, the coefficient of x^k, we get matrices $B_0, \ldots, B_{n-1} \in F^{n\times n}$ with

$$\operatorname{adj}(M) = B_0 + xB_1 + \cdots + x^{n-1}B_{n-1},$$

an identity in $F[x]^{n\times n}$, in which $x^k B_k$ means the matrix with entries $x^k (B_k)_{ij}$. Since x commutes with everything in $F[x]$, the left side of (7.6.1) is

$$(xI_n - A)\sum_{k=0}^{n-1} x^k B_k = \sum_{k=0}^{n-1} x^{k+1} B_k - \sum_{k=0}^{n-1} x^k A B_k.$$

Two matrices with entries in $F[x]$ are equal exactly when, for every k, the matrices of coefficients of x^k are equal. Comparing with the right side $\sum_{k=0}^{n} c_k x^k I_n$:

$$\begin{aligned} x^n: &\quad B_{n-1} = I_n, \\ x^k \text{ for } 1 \leq k \leq n-1: &\quad B_{k-1} - AB_k = c_k I_n, \\ x^0: &\quad -AB_0 = c_0 I_n. \end{aligned}$$

Multiply the equation for x^k on the left by A^k, for $k = 0, 1, \ldots, n$, and add. The right sides add up to $\sum_k c_k A^k = p_A(A)$. The left sides add up to

$$\sum_{k=1}^{n} A^k B_{k-1} - \sum_{k=0}^{n-1} A^{k+1} B_k = \sum_{k=1}^{n} A^k B_{k-1} - \sum_{j=1}^{n} A^j B_{j-1} = 0,$$

where the first sum collects the terms $A^k B_{k-1}$ (from x^k with $1 \leq k \leq n$) and the second the terms $-A^{k+1}B_k$ (from x^k with $0 \leq k \leq n-1$), reindexed by $j = k+1$. So $p_A(A) = 0$. □

Remark 7.6.22 (Where the naive substitution goes wrong). The bogus argument of Exercise 7.3.47 substitutes A for x inside a determinant, which turns scalars a_{ij} into nothing in particular. The adjugate proof substitutes only into identities between polynomials with matrix coefficients, and only after multiplying each coefficient by A^k on the left. That step is safe here because the coefficients I_n and $-A$ of the left factor $xI_n - A$ commute with A. For a factor whose coefficients did not commute with A, "evaluate the product at A" and "multiply the evaluations" could give different answers.

The fourth proof introduces a technique that recurs whenever a statement is easy for "generic" matrices.

> **Technique 7.6.23** (Perturbation and density). To prove an identity for every matrix, first prove it for matrices in general position (diagonalizable, invertible, with distinct eigenvalues), where it is easy. Then move an arbitrary matrix A into general position along a path A_t that depends polynomially on a parameter t, with $A_0 = A$ and A_t in general position for all but finitely many t. If both sides of the identity are polynomials in the entries, the difference is a polynomial in t that vanishes at infinitely many points, hence identically, and in particular at $t = 0$. With analysis available, the same idea reads: the general-position matrices are dense, and both sides are continuous.
>
> Reach for it when a statement is clear for diagonalizable or invertible matrices and both sides are polynomial in the entries, over $\mathbb{C}$ or another infinite field. It fails over finite fields, where there is no

room to perturb. The canonical example is the fourth proof of Theorem 7.6.20. Compare Technique 5.3.18, which is the same move with $A + tI_n$ to reach invertible matrices.
Used in. Lemma 7.6.21, Exercise 7.7.14.

Proof (by perturbation, over $\mathbb{C}$). HARD

Uses. Proposition 7.4.23 (Powers and polynomials of a diagonalizable matrix), Proposition 7.3.11 (Similar matrices have the same characteristic polynomial), Corollary 7.5.14 (Triangularizing a matrix), Proposition 7.5.8 (The diagonal of a triangular matrix), Corollary 7.4.5 (Distinct eigenvalues give a diagonalization), Theorem 5.3.3 (The Leibniz formula), Corollary 7.1.23 (Polynomials and their values)
Techniques. Perturbation and density (Technique 7.6.23), det is a polynomial in the entries (Technique 5.3.18)
Hint 1. Prove $p_A(A) = 0$ first for diagonalizable $A = SDS^{-1}$.
Hint 2. Triangularize $A = SRS^{-1}$ and add $t\,\mathrm{diag}(1, 2, \ldots, n)$ to R. For which t are the new diagonal entries distinct?
Hint 3. Each entry of $p_{A_t}(A_t)$ is a polynomial in t. How many roots does it have?
Sketch. For $A = SDS^{-1}$ with D diagonal, $p_A = p_D$ and $p_A(A) = S\,\mathrm{diag}(p_D(d_i))S^{-1} = 0$. In general write $A = SRS^{-1}$ with R triangular and let $A_t = S(R + t\,\mathrm{diag}(1, \ldots, n))S^{-1}$. Except for finitely many t, A_t has n distinct eigenvalues, so $p_{A_t}(A_t) = 0$. Each entry of $p_{A_t}(A_t)$ is a polynomial in t with infinitely many roots, hence $\mathbf{0}$; evaluate at $t = 0$.

Diagonalizable matrices. Let $A = SDS^{-1}$ with $D = \mathrm{diag}(d_1, \ldots, d_n)$. By Proposition 7.3.11, $p_A = p_D = (x - d_1)\cdots(x - d_n)$, and by Proposition 7.4.23,

$$p_A(A) = S\,\mathrm{diag}(p_A(d_1), \ldots, p_A(d_n))S^{-1} = S0S^{-1} = 0.$$

Perturbing. Let $A \in \mathbb{C}^{n\times n}$ be arbitrary. By Corollary 7.5.14, $A = SRS^{-1}$ with S invertible and R upper triangular with diagonal entries $r_{11}, \ldots, r_{nn}$. For $t \in \mathbb{C}$ let $E = S\,\mathrm{diag}(1, 2, \ldots, n)S^{-1}$ and

$$A_t = S(R + t\,\mathrm{diag}(1, 2, \ldots, n))S^{-1} = A + tE.$$

The matrix $R + t\,\mathrm{diag}(1, \ldots, n)$ is upper triangular with diagonal entries $r_{jj} + jt$. For $i < j$, $r_{ii} + it = r_{jj} + jt$ holds for exactly one t, namely $t = (r_{ii} - r_{jj})/(j - i)$. So outside a finite set of values of t, these diagonal entries are distinct, A_t has n distinct eigenvalues (Proposition 7.5.8(b), as A_t is similar to a triangular matrix), A_t is diagonalizable (Corollary 7.4.5), and $p_{A_t}(A_t) = 0$ by the first step.

Passing to $t = 0$. Each entry of $A_t = A + tE$ is a polynomial in t of degree at most 1. By the Leibniz formula (Theorem 5.3.3), each coefficient of $p_{A_t} = \det(xI_n - A_t)$ is a sum of products of entries of A_t and constants, hence a polynomial in t; so is each entry of every power A_t^k. Therefore each entry of the matrix $p_{A_t}(A_t)$ is a polynomial $f_{ij}(t) \in \mathbb{C}[t]$. We showed that f_{ij} vanishes at all but finitely many $t \in \mathbb{C}$, that is, at infinitely many points, so $f_{ij} = \mathbf{0}$ (Corollary 7.1.23(b)). In particular $f_{ij}(0) = 0$ for all i, j, and $A_0 = A$, so $p_A(A) = 0$. □

Each proof shows something the others do not. The triangular proof is the geometric one: it shows each factor $T - \lambda_j\,\mathrm{id}$ doing its share of the work, but it needs the eigenvalues to lie in F. The Krylov proof reduces everything to companion matrices and works over every field. The adjugate proof never mentions eigenvalues or vectors, and holds over every commutative ring. The perturbation proof shows that the diagonalizable case, which is nearly trivial, already implies the general one.

Corollary 7.6.24 (The minimal polynomial divides the characteristic polynomial).

(a) $m_T \mid p_T$. Hence $\deg m_T \le n$, the operators $\mathrm{id}_V, T, \ldots, T^n$ are linearly dependent, and $\dim F[T] \le n$.

(b) m_T and p_T have the same roots in F, namely the eigenvalues of T.

(c) If $p_T = (x - \lambda_1)^{a_1}\cdots(x - \lambda_m)^{a_m}$ with distinct $\lambda_i \in F$ (as always happens over $\mathbb{C}$), then

$$m_T = (x - \lambda_1)^{k_1}\cdots(x - \lambda_m)^{k_m} \quad \text{with } 1 \le k_i \le a_i.$$

Proof. STANDARD

Uses. Theorem 7.6.20 (Cayley–Hamilton), Theorem 7.6.2 (Existence and uniqueness of the minimal polynomial), Proposition 7.6.4 (The minimal polynomial is the first dependence among the powers), Theorem 7.6.7 (The roots of

the minimal polynomial are the eigenvalues), Corollary 7.3.13 (Eigenvalues of an operator), Theorem 7.1.20 (Factor theorem), Corollary 7.1.7 (No zero divisors, cancellation, and units)
Hint 1. (a) and (b) are direct. For (c), show that a monic divisor of a product of linear factors is a product of some of those factors.
Hint 2. Induct on the number of linear factors. If $q = st$ and μ is a root of q, then μ is a root of s or of t; cancel $x - \mu$.
Sketch. (a) By Cayley–Hamilton and Theorem 7.6.2, $m_T \mid p_T$; then Proposition 7.6.4 gives the rest. (b) Both root sets are the set of eigenvalues. (c) A monic divisor s of a product q of N linear factors is a subproduct: some root μ of q is a root of s or of the cofactor; cancel $x - \mu$ and induct on N. So $m_T = \prod (x - \lambda_i)^{k_i}$ with $k_i \le a_i$, and $k_i \ge 1$ by (b).

(a) By Theorem 7.6.20, p_T annihilates T, so $m_T \mid p_T$ by Theorem 7.6.2, and $\deg m_T \le \deg p_T = n$. By Proposition 7.6.4, $T^{\deg m_T}$ is a combination of lower powers, so $\mathrm{id}_V, \dots, T^n$ are dependent, and $\dim F[T] = \deg m_T \le n$.

(b) By Theorem 7.6.7 and Corollary 7.3.13, the roots of m_T and of p_T in F are both exactly the eigenvalues of T.

(c) We first show: if $q = (x - \mu_1)\cdots(x - \mu_N)$ with $\mu_j \in F$ (repetitions allowed) and s is a monic divisor of q, then s is the product of some of the factors $x - \mu_j$. We induct on N. If $N = 0$, then $q = 1 = st$, so s is a nonzero constant, and $s = 1$ since it is monic. Let $N \ge 1$ and write $q = st$. Since $q(\mu_N) = 0$, we get $s(\mu_N) = 0$ or $t(\mu_N) = 0$, because F has no zero divisors. In the first case, $s = (x - \mu_N)s'$ by Theorem 7.1.20, and cancelling $x - \mu_N$ (Corollary 7.1.7) in $(x - \mu_N)(x - \mu_1)\cdots(x - \mu_{N-1}) = (x - \mu_N)s't$ shows that the monic polynomial s' divides $(x - \mu_1)\cdots(x - \mu_{N-1})$; by induction s' is a product of some of these factors, and so is s. In the second case, $t = (x - \mu_N)t'$, and cancelling shows that s divides $(x - \mu_1)\cdots(x - \mu_{N-1})$; again the induction hypothesis applies.

Apply this with $q = p_T$ and $s = m_T$, which divides p_T by (a). So $m_T = \prod_i (x - \lambda_i)^{k_i}$ with $0 \le k_i \le a_i$, and $k_i \ge 1$ because each λ_i is a root of m_T by (b). □

Example 7.6.25 (Finding a minimal polynomial from the characteristic polynomial). Let

$$D = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}, \quad J = \begin{pmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}.$$

Both have $p = (x - 2)^2(x - 3)$. By Corollary 7.6.24(c), each minimal polynomial is $(x - 2)(x - 3)$ or $(x - 2)^2(x - 3)$, so it suffices to test the smaller candidate. For D, $(D - 2I)(D - 3I) = \mathrm{diag}(0, 0, 1)\,\mathrm{diag}(-1, -1, 0) = 0$, so $m_D = (x - 2)(x - 3)$. For J,

$$(J - 2I)(J - 3I) = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} -1 & 1 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & -1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \neq 0,$$

so $m_J = (x - 2)^2(x - 3)$, and J is not diagonalizable (Theorem 7.6.15).

Example 7.6.26 (Powers without a diagonalization). Let $A = \begin{pmatrix} 3 & 1 \\ -1 & 1 \end{pmatrix}$. Then $\mathrm{tr}\, A = 4$ and $\det A = 4$, so $p_A = x^2 - 4x + 4 = (x - 2)^2$, and $A \neq 2I_2$, so $m_A = (x - 2)^2$ and A is not diagonalizable. The method of Section 7.4.3 is not available, but Cayley–Hamilton is. By the binomial theorem in the commutative ring $F[x]$,

$$x^k = (2 + (x - 2))^k = 2^k + k2^{k-1}(x - 2) + (x - 2)^2 g_k$$

for some $g_k \in F[x]$. Evaluating at A and using $(A - 2I_2)^2 = 0$,

$$A^k = 2^k I_2 + k2^{k-1}(A - 2I_2) = 2^{k-1}\begin{pmatrix} 2 + k & k \\ -k & 2 - k \end{pmatrix}.$$

In general, $A^k = r(A)$, where r is the remainder of x^k on division by p_A (or by m_A), so A^k is always a combination of $I, A, \dots, A^{n-1}$.

Exercise 7.6.27. ROUTINE Let $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$. Use the Cayley–Hamilton theorem to write A^{-1} and A^3 in the form $aI_2 + bA$, and compute both.

Solution on page 1605

7.6.5 Spectral mapping

On an eigenvector, $p(T)$ acts as the scalar $p(\lambda)$ (Proposition 7.2.28). So every $p(\lambda)$, for λ an eigenvalue of T, is an eigenvalue of $p(T)$. Over $\mathbb{C}$ there are no others, and even the multiplicities match.

Theorem 7.6.28 (Spectral mapping theorem). Let V be a finite-dimensional complex vector space with $\dim V = n \geq 1$, let $T \in \mathrm{L}(V)$ and $p \in \mathbb{C}[x]$, and let $\lambda_1, \dots, \lambda_n$ be the eigenvalues of T counted with multiplicity.

(a) The eigenvalues of $p(T)$ are exactly the numbers $p(\lambda)$ with λ an eigenvalue of T.

(b) $p_{p(T)} = (x - p(\lambda_1)) \cdots (x - p(\lambda_n))$. That is, the eigenvalues of $p(T)$ counted with multiplicity are $p(\lambda_1), \dots, p(\lambda_n)$.

Proof (via triangular form). STANDARD

Uses. Theorem 7.5.13 (Upper-triangular form), Proposition 7.5.9 (Multiplicities on the diagonal), Proposition 7.2.27 (Evaluating polynomials at an operator), Definition 2.4.1 (Matrix product), Corollary 7.3.13 (Eigenvalues of an operator)
Techniques. Prove it for triangular matrices first (Technique 7.5.23), Compute entry by entry (Technique 2.4.15)
Hint 1. Triangularize T. What does p do to an upper-triangular matrix?
Hint 2. Show that a product of upper-triangular matrices is upper triangular, with diagonal entries the products of the diagonal entries.
Sketch. In a basis with $R = [T]_{\mathcal{B}}$ upper triangular with diagonal $\lambda_1, \dots, \lambda_n$, products and sums of upper-triangular matrices are upper triangular with the diagonal computed entrywise, so $[p(T)]_{\mathcal{B}} = p(R)$ is upper triangular with diagonal $p(\lambda_1), \dots, p(\lambda_n)$. Then Proposition 7.5.9 gives (b), and (a) follows by taking roots.

By Theorem 7.5.13, there is a basis $\mathcal{B}$ with $R = [T]_{\mathcal{B}}$ upper triangular, and its diagonal entries are $\lambda_1, \dots, \lambda_n$ (Proposition 7.5.9).

If $X, Y \in \mathbb{C}^{n \times n}$ are upper triangular, then $(XY)_{ij} = \sum_l x_{il} y_{lj}$, and $x_{il} y_{lj} \neq 0$ requires $i \leq l \leq j$ (Definition 2.4.1). For $i > j$ there is no such l, and for $i = j$ only $l = i$, so XY is upper triangular with $(XY)_{ii} = x_{ii} y_{ii}$. Sums and scalar multiples of upper-triangular matrices are upper triangular, with diagonals added and scaled. By induction on k, R^k is upper triangular with diagonal entries λ_j^k, and so $p(R)$ is upper triangular with diagonal entries $p(\lambda_1), \dots, p(\lambda_n)$.

Since $[p(T)]_{\mathcal{B}} = p(R)$ (Proposition 7.2.27(c)), Proposition 7.5.9 applied to $p(T)$ gives (b). By Corollary 7.3.13, the eigenvalues of $p(T)$ are the roots of $p_{p(T)}$, which by (b) are $p(\lambda_1), \dots, p(\lambda_n)$; this is (a). □

The second proof gives only (a), but it uses no triangularization, only the factorization of one polynomial and the fact that polynomials in T commute.

Proof (factor $p - \mu$). STANDARD

Uses. Corollary 7.1.35 (Factorization over $\mathbb{C}$), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$)
Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
Hint 1. Fix $\mu \in \mathbb{C}$. When is $p(T) - \mu \mathrm{id}_V$ not injective? Factor $p - \mu$ over $\mathbb{C}$.
Hint 2. A product of commuting operators is injective if and only if each factor is. Why does commuting matter?
Sketch. If p is constant the claim is clear, since T has an eigenvalue. Otherwise $p - \mu = a(x - r_1) \cdots (x - r_d)$, so $p(T) - \mu \,\mathrm{id} = a(T - r_1 \,\mathrm{id}) \cdots (T - r_d \,\mathrm{id})$. These factors commute, so the product fails to be injective exactly when some factor does, that is, when some root r_i of $p - \mu$ is an eigenvalue of T, that is, when $\mu = p(\lambda)$ for some eigenvalue λ.

We prove (a). Let $\mu \in \mathbb{C}$. If $p = c$ is constant, then $p(T) = c\mathrm{id}_V$, whose only eigenvalue is c, and $p(\lambda) = c$ for every eigenvalue λ of T, of which there is at least one (Theorem 7.3.27). So assume $\deg p = d \geq 1$. Then $p - \mu$ has degree d and some leading coefficient $a \neq 0$, and by Corollary 7.1.35,

$$p - \mu = a(x - r_1)(x - r_2)\cdots(x - r_d),$$

where $r_1, \ldots, r_d$ are the roots of $p - \mu$, that is, the solutions of $p(r) = \mu$. By Proposition 7.2.27(a), $p(T) - \mu\mathrm{id}_V = aS_1S_2\cdots S_d$ with $S_i = T - r_i\mathrm{id}_V$, and these factors commute with each other (Proposition 7.2.27(b)).

We claim that $S_1\cdots S_d$ is injective if and only if every S_i is. If every S_i is injective, so is their composite. Conversely, suppose some S_i is not injective, say $S_i\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$. Since the factors commute, $S_1\cdots S_d = \left(\prod_{j\neq i} S_j\right)S_i$, which sends $\mathbf{v}$ to $\mathbf{0}$, so the composite is not injective.

Hence, by Theorem 7.2.9, μ is an eigenvalue of $p(T)$ if and only if $p(T) - \mu\mathrm{id}_V$ is not injective, if and only if some $T - r_i\mathrm{id}_V$ is not injective, if and only if some r_i is an eigenvalue of T. Since the r_i are exactly the solutions of $p(r) = \mu$, this says that $\mu = p(\lambda)$ for some eigenvalue λ of T. □

The second proof never used $\dim V < \infty$ except to know that T has an eigenvalue when p is constant, so part (a) holds for operators on any complex vector space, with nonconstant p.

Non-example 7.6.29 (Spectral mapping over $\mathbb{R}$). Over any field, every $p(\lambda)$ is an eigenvalue of $p(T)$, by Proposition 7.2.28. The converse needs $\mathbb{C}$. The rotation $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \in \mathbb{R}^{2\times 2}$ has no real eigenvalues, but $R^2 = -I_2$ has the eigenvalue -1. In the second proof, the polynomial $x^2 - (-1) = x^2 + 1$ cannot be factored over $\mathbb{R}$.

Corollary 7.6.30 (Trace, determinant, and invertibility of $p(T)$). In the setting of Theorem 7.6.28,

$$\operatorname{tr} p(T) = p(\lambda_1) + \cdots + p(\lambda_n), \quad \det p(T) = p(\lambda_1)\cdots p(\lambda_n),$$

and $p(T)$ is invertible if and only if $p(\lambda) \neq 0$ for every eigenvalue λ of T.

Proof. ROUTINE

Uses. Theorem 7.6.28 (Spectral mapping theorem), Theorem 7.5.22 (Trace and determinant from eigenvalues), Theorem 7.2.9 (Eigenvalues and invertibility)
Hint. Apply Theorem 7.5.22 to the operator $p(T)$.
Sketch. By Theorem 7.6.28(b), the eigenvalues of $p(T)$ with multiplicity are the $p(\lambda_j)$, so Theorem 7.5.22 gives the trace and determinant. $p(T)$ is invertible exactly when 0 is not among its eigenvalues.

By Theorem 7.6.28(b), $p(\lambda_1), \ldots, p(\lambda_n)$ are the eigenvalues of $p(T)$ counted with multiplicity, and Theorem 7.5.22 applied to $p(T)$ gives the two formulas. By Theorem 7.2.9, $p(T)$ is invertible if and only if 0 is not an eigenvalue of $p(T)$, which by Theorem 7.6.28(a) means $p(\lambda) \neq 0$ for every eigenvalue λ of T. □

For example, $A = \begin{pmatrix} 0 & 1 \\ -2 & 3 \end{pmatrix}$ has $p_A = x^2 - 3x + 2 = (x - 1)(x - 2)$, so its eigenvalues are 1 and 2. For $p = x^2 + x + 1$, the matrix $p(A)$ has eigenvalues $p(1) = 3$ and $p(2) = 7$, so $\operatorname{tr} p(A) = 10$ and $\det p(A) = 21$. Directly, $p(A) = A^2 + A + I_2 = \begin{pmatrix} -1 & 4 \\ -8 & 11 \end{pmatrix}$, with trace 10 and determinant $-11 + 32 = 21$.

7.6.6 Commuting operators

If $ST = TS$, then each eigenspace of T is mapped into itself by S (Proposition 7.2.30(b)). Inside an eigenspace of T, every nonzero vector is an eigenvector of T, so an eigenvector of S found there serves both operators. Over $\mathbb{C}$, this is enough to find common eigenvectors, and then common triangular and diagonal forms.

Theorem 7.6.31 (Commuting operators have a common eigenvector). Let V be a finite-dimensional complex vector space with $V \neq \{\mathbf{0}\}$, and let $T_1, \ldots, T_k \in \mathrm{L}(V)$ commute pairwise, that is, $T_iT_j = T_jT_i$ for all i, j. Then some nonzero $\mathbf{v} \in V$ is an eigenvector of every T_i. More generally, every nonzero subspace W that is invariant under all of the T_i contains such a $\mathbf{v}$.

Proof (one operator at a time). STANDARD

> *Uses.* Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Definition 7.2.1 (Invariant subspace), Definition 7.2.13 (Eigenspace)
> *Techniques.* Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Restrict to a subspace (Technique 4.2.5)
> *Hint 1.* Prove the "more generally" statement by induction on k. For $k = 1$, restrict T_1 to W.
> *Hint 2.* Let λ be an eigenvalue of $T_k|_W$. Which subspace of W consists of eigenvectors of T_k (and $\mathbf{0}$), and why is it invariant under $T_1, \dots, T_{k-1}$?
> *Sketch.* Induct on k. For $k = 1$, $T_1|_W$ is an operator on a nonzero complex space and has an eigenvector. For $k \geq 2$, let λ be an eigenvalue of $T_k|_W$ and $W' = W \cap E_\lambda(T_k) \neq \{\mathbf{0}\}$. Each T_i preserves W, and preserves $E_\lambda(T_k)$ because it commutes with T_k, so it preserves W'. By induction, W' contains a common eigenvector of $T_1, \dots, T_{k-1}$, and every nonzero vector of W' is an eigenvector of T_k.

We prove the second statement by induction on k; the first is the case $W = V$. Let $W \neq \{\mathbf{0}\}$ be invariant under every T_i.

If $k = 1$, then $T_1|_W$ is an operator on the nonzero finite-dimensional complex space W, so it has an eigenvector $\mathbf{v} \in W$ (Theorem 7.3.27), and $T_1\mathbf{v} = T_1|_W\mathbf{v}$ is a multiple of $\mathbf{v}$.

Let $k \geq 2$, and assume the statement for $k - 1$ operators. Let λ be an eigenvalue of $T_k|_W$ and

$$W' = W \cap E_\lambda(T_k) = \{\mathbf{w} \in W \mid T_k\mathbf{w} = \lambda\mathbf{w}\},$$

which contains an eigenvector of $T_k|_W$, so $W' \neq \{\mathbf{0}\}$. For $i < k$, T_i commutes with T_k, so $E_\lambda(T_k)$ is T_i-invariant (Proposition 7.2.30(b)); W is T_i-invariant by hypothesis; so W' is T_i-invariant. By the induction hypothesis applied to $T_1, \dots, T_{k-1}$ and W', some nonzero $\mathbf{v} \in W'$ is an eigenvector of $T_1, \dots, T_{k-1}$. Since $\mathbf{v} \in E_\lambda(T_k)$, it is also an eigenvector of T_k. □

> *Intuition (A smallest invariant subspace).* The first proof shrinks W once for each operator. The second goes straight to the end: take a nonzero subspace that is invariant under all the operators and as small as possible. Each operator must act on it as a scalar, since otherwise one of its eigenspaces inside would be a smaller invariant subspace. This extremal argument never counts the operators, so it works for any set of commuting operators, finite or not.

Proof (a minimal common invariant subspace). STANDARD

> *Uses.* Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Proposition 4.1.21 (Dimensions of subspaces)
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9), Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31)
> *Hint 1.* Among the nonzero subspaces of W invariant under every T_i, choose one, W_0, of smallest dimension.
> *Hint 2.* Let λ be an eigenvalue of $T_i|_{W_0}$. Show that $W_0 \cap E_\lambda(T_i)$ is again invariant under every T_j. What does minimality force?
> *Sketch.* Pick a nonzero subspace $W_0 \subseteq W$, invariant under all T_i, of least dimension. For each i, take an eigenvalue λ of $T_i|_{W_0}$; then $W_0 \cap E_\lambda(T_i)$ is nonzero, invariant under all T_j, and contained in W_0, so it equals W_0. Thus every T_i acts on W_0 as a scalar, and every nonzero vector of W_0 is a common eigenvector.

Consider the nonzero subspaces of W that are invariant under every T_i. There is at least one, W itself, so we may choose one, W_0, of smallest dimension. Fix i. By Theorem 7.3.27, $T_i|_{W_0}$ has an eigenvalue λ, so $W_1 = W_0 \cap E_\lambda(T_i)$ is nonzero. For each j, $E_\lambda(T_i)$ is T_j-invariant (Proposition 7.2.30(b)), so W_1 is T_j-invariant. By the choice of W_0, $\dim W_1 \geq \dim W_0$, and as $W_1 \subseteq W_0$, we get $W_1 = W_0$ (Proposition 4.1.21). That is, $T_i\mathbf{w} = \lambda\mathbf{w}$ for every $\mathbf{w} \in W_0$.

So each T_i acts on W_0 as a scalar, and every nonzero $\mathbf{v} \in W_0$ is an eigenvector of every T_i. The argument used neither the number of operators nor their order, so it applies to any set of pairwise commuting operators on V. □

Both hypotheses are needed. Over $\mathbb{R}$ even a single operator, a rotation, may have no eigenvector. And for non-commuting operators the conclusion fails: the eigenvectors of $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ are the nonzero multiples of $\mathbf{e}_1$, and those of N^{T} the nonzero multiples of $\mathbf{e}_2$.

Theorem 7.6.32 (Simultaneous triangularization). Let V be a finite-dimensional complex vector space with $\dim V \geq 1$, and let $T_1, \dots, T_k \in \mathrm{L}(V)$ commute pairwise. Then there is a basis $\mathcal{B}$ of V such that $[T_i]_{\mathcal{B}}$ is upper triangular for every i.

Proof. STANDARD

Uses. Theorem 7.6.31 (Commuting operators have a common eigenvector), Proposition 7.2.7 (Invariant lines are spanned by eigenvectors), Proposition 4.6.32 (Operators on a quotient), Theorem 4.6.27 (Dimension of a quotient), Proposition 4.6.28 (Lifting a basis of a quotient), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12), Build a flag of invariant subspaces (Technique 7.5.4), Pass to a quotient (Technique 4.6.31)
Hint 1. Induct on $n = \dim V$, as in the proof of Theorem 7.5.13. The bottom of the flag should be a common eigenvector.
Hint 2. Pass to V/U with $U = \operatorname{span}(\mathbf{b}_1)$. Do the quotient operators T_i/U still commute?
Hint 3. Lift a basis that triangularizes all T_i/U, and put $\mathbf{b}_1$ in front.
Sketch. Induct on n. Take a common eigenvector $\mathbf{b}_1$ (Theorem 7.6.31); $U = \operatorname{span}(\mathbf{b}_1)$ is invariant under every T_i. The quotient operators commute, since $(T_i/U)\big(T_j/U\big)(\mathbf{v}+U) = T_iT_j\mathbf{v}+U$. By induction, V/U has a basis $\mathbf{b}_2+U, \dots, \mathbf{b}_n+U$ triangularizing all of them. Then $\mathbf{b}_1, \dots, \mathbf{b}_n$ is a basis of V, and $T_i\mathbf{b}_j \in \operatorname{span}\big(\mathbf{b}_1, \dots, \mathbf{b}_j\big)$ because this holds modulo $U = \operatorname{span}(\mathbf{b}_1)$.

We induct on $n = \dim V$. For $n = 1$ every basis works.

Let $n \geq 2$ and assume the theorem in dimension $n-1$. By Theorem 7.6.31 there is a common eigenvector $\mathbf{b}_1$ of $T_1, \dots, T_k$, and $U = \operatorname{span}(\mathbf{b}_1)$ is invariant under every T_i (Proposition 7.2.7). Let $\overline{T}_i = T_i/U \in \mathrm{L}(V/U)$ be the quotient operators (Proposition 4.6.32(a)). They commute: for $\mathbf{v} \in V$,

$$\overline{T}_i\overline{T}_j(\mathbf{v}+U) = \overline{T}_i\big(T_j\mathbf{v}+U\big) = T_iT_j\mathbf{v}+U = T_jT_i\mathbf{v}+U = \overline{T}_j\overline{T}_i(\mathbf{v}+U).$$

Since $\dim V/U = n-1$ (Theorem 4.6.27), the induction hypothesis and Proposition 7.5.2 give $\mathbf{b}_2, \dots, \mathbf{b}_n \in V$ such that $\mathbf{b}_2+U, \dots, \mathbf{b}_n+U$ is a basis of V/U and, for all i and all $j \geq 2$,

$$\overline{T}_i\big(\mathbf{b}_j+U\big) \in \operatorname{span}\big(\mathbf{b}_2+U, \dots, \mathbf{b}_j+U\big).$$

By Proposition 4.6.28, $\mathcal{B} = \mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_n$ is a basis of V. Fix i and $j \geq 2$, and write $\overline{T}_i\big(\mathbf{b}_j+U\big) = \sum_{l=2}^{j} c_l(\mathbf{b}_l + U) = \Big(\sum_{l=2}^{j} c_l\mathbf{b}_l\Big) + U$. Since also $\overline{T}_i\big(\mathbf{b}_j+U\big) = T_i\mathbf{b}_j+U$, the difference $T_i\mathbf{b}_j - \sum_{l=2}^{j} c_l\mathbf{b}_l$ lies in $U = \operatorname{span}(\mathbf{b}_1)$, so $T_i\mathbf{b}_j \in \operatorname{span}\big(\mathbf{b}_1, \dots, \mathbf{b}_j\big)$. Also $T_i\mathbf{b}_1 \in \operatorname{span}(\mathbf{b}_1)$. By Proposition 7.5.2, $[T_i]_{\mathcal{B}}$ is upper triangular for every i. □

With an inner product, the basis can be taken orthonormal: all the T_i preserve the flag of $\mathcal{B}$, and Gram–Schmidt produces an orthonormal basis with the same flag, exactly as in the proof of Theorem 7.5.18 (Technique 7.5.4). So commuting complex matrices $A_1, \dots, A_k$ can be written $A_i = UR_iU^*$ with one unitary U and upper-triangular R_i. The converse fails: upper-triangular matrices need not commute (Exercise 7.6.51).

Corollary 7.6.33 (Eigenvalues of sums and products of commuting operators). Let V be a finite-dimensional complex vector space with $\dim V = n \geq 1$, and let $S, T \in \mathrm{L}(V)$ commute. Then the eigenvalues of S and of T, counted with multiplicity, can be listed as $\lambda_1, \dots, \lambda_n$ and $\mu_1, \dots, \mu_n$ so that the eigenvalues of $S+T$ and of ST, counted with multiplicity, are $\lambda_1+\mu_1, \dots, \lambda_n+\mu_n$ and $\lambda_1\mu_1, \dots, \lambda_n\mu_n$. In particular, every eigenvalue of $S+T$ is $\lambda+\mu$ for some eigenvalue λ of S and some eigenvalue μ of T.

Proof. ROUTINE

Uses. Theorem 7.6.32 (Simultaneous triangularization), Proposition 7.5.9 (Multiplicities on the diagonal), Theorem 2.4.2 (The matrix of a composite), Proposition 2.4.12 (Matrices of sums and scalar multiples)
Hint. Triangularize S and T in one basis. What are the diagonals of $[S+T]$ and $[ST]$?

Sketch. In a common triangularizing basis, $[S+T] = [S] + [T]$ and $[ST] = [S][T]$ are upper triangular, with diagonal entries $\lambda_j + \mu_j$ and $\lambda_j \mu_j$ (as in the proof of Theorem 7.6.28). Read the eigenvalues off the diagonals with Proposition 7.5.9.

By Theorem 7.6.32, there is a basis $\mathcal{B}$ in which $[S]_{\mathcal{B}}$ and $[T]_{\mathcal{B}}$ are both upper triangular; let their diagonal entries be $\lambda_1, \ldots, \lambda_n$ and $\mu_1, \ldots, \mu_n$. By Proposition 7.5.9, these are the eigenvalues of S and of T counted with multiplicity. Now $[S+T]_{\mathcal{B}} = [S]_{\mathcal{B}} + [T]_{\mathcal{B}}$ (Proposition 2.4.12) and $[ST]_{\mathcal{B}} = [S]_{\mathcal{B}}[T]_{\mathcal{B}}$ (Theorem 2.4.2) are upper triangular, with diagonal entries $\lambda_j + \mu_j$ and $\lambda_j \mu_j$ respectively (see the proof of Theorem 7.6.28). Applying Proposition 7.5.9 to $S+T$ and to ST gives the claim. □

Without commuting, nothing of the kind holds: $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and N^{T} both have 0 as their only eigenvalue, while $N + N^{\mathsf{T}} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has eigenvalues ± 1 and $NN^{\mathsf{T}} = \operatorname{diag}(1, 0)$ has the eigenvalue 1.

For diagonalization, commuting is also necessary, since diagonal matrices commute.

Theorem 7.6.34 (Simultaneous diagonalization). Let V be a finite-dimensional vector space over any field F, with $\dim V \geq 1$, and let $T_1, \ldots, T_k \in \mathrm{L}(V)$ be diagonalizable. Then V has a basis consisting of vectors that are eigenvectors of every T_i (equivalently, a basis $\mathcal{B}$ in which every $[T_i]_{\mathcal{B}}$ is diagonal) if and only if $T_i T_j = T_j T_i$ for all i, j.

Proof. STANDARD

Uses. Theorem 7.4.2 (Diagonalizable means an eigenbasis), Theorem 2.4.2 (The matrix of a composite), Proposition 2.4.12 (Matrices of sums and scalar multiples), Corollary 7.6.16 (Restrictions of diagonalizable operators), Proposition 7.2.30 (Kernels and images of commuting operators are invariant), Corollary 7.2.23 (Eigenspaces are independent), Theorem 4.4.13 (Bases and dimension of a sum)

Techniques. Look for invariant subspaces among kernels and images of commuting operators (Technique 7.2.31), Glue bases of the summands (Technique 4.4.14)

Hint 1. For "only if", compute $\left[T_i T_j\right]_{\mathcal{B}}$ and $\left[T_j T_i\right]_{\mathcal{B}}$.

Hint 2. For "if", induct on k, proving: every nonzero subspace W invariant under all T_i has a basis of common eigenvectors.

Hint 3. Split W into the eigenspaces of $T_k|_W$. Why is each piece invariant under $T_1, \ldots, T_{k-1}$, and why is $T_k|_W$ diagonalizable?

Sketch. If every $[T_i]_{\mathcal{B}}$ is diagonal, the matrices commute, hence so do the operators. Conversely, induct on k with the stronger statement for invariant subspaces W. $T_k|_W$ is diagonalizable (Corollary 7.6.16), so W is the direct sum of the pieces $W \cap E_\mu(T_k)$. Each piece is invariant under $T_1, \ldots, T_{k-1}$ because they commute with T_k, so by induction it has a basis of common eigenvectors of $T_1, \ldots, T_{k-1}$, which are also eigenvectors of T_k. Concatenate.

Only if. Let $\mathcal{B}$ be a basis with every $[T_i]_{\mathcal{B}}$ diagonal (Theorem 7.4.2). Diagonal matrices commute, so by Theorem 2.4.2, $\left[T_i T_j\right]_{\mathcal{B}} = [T_i]_{\mathcal{B}}\left[T_j\right]_{\mathcal{B}} = \left[T_j\right]_{\mathcal{B}}[T_i]_{\mathcal{B}} = \left[T_j T_i\right]_{\mathcal{B}}$. Since $S \mapsto [S]_{\mathcal{B}}$ is injective (Proposition 2.4.12), $T_i T_j = T_j T_i$.

If. We show by induction on k: every nonzero subspace W that is invariant under all of $T_1, \ldots, T_k$ has a basis of common eigenvectors of $T_1, \ldots, T_k$. The theorem is the case $W = V$.

For $k = 1$, $T_1|_W$ is diagonalizable by Corollary 7.6.16, and its eigenvectors are eigenvectors of T_1.

Let $k \geq 2$. By Corollary 7.6.16, $T_k|_W$ is diagonalizable. Let $\mu_1, \ldots, \mu_r$ be its distinct eigenvalues and $W_l = W \cap E_{\mu_l}(T_k)$, the eigenspaces of $T_k|_W$. Grouping an eigenbasis of $T_k|_W$ by eigenvalue shows $W = W_1 + \cdots + W_r$, and the sum is direct by Corollary 7.2.23. For $i < k$, T_i commutes with T_k, so $E_{\mu_l}(T_k)$ is T_i-invariant (Proposition 7.2.30(b)), and so is W; hence each W_l is invariant under $T_1, \ldots, T_{k-1}$. Each W_l is nonzero, so by the induction hypothesis it has a basis of common eigenvectors of $T_1, \ldots, T_{k-1}$, and these lie in $E_{\mu_l}(T_k)$, so they are eigenvectors of T_k as well. Concatenating these bases gives a basis of W (Theorem 4.4.13) of common eigenvectors of $T_1, \ldots, T_k$. □

This is the statement of Exercise 7.4.51; the minimal polynomial supplies the one step that needed work there, that a diagonalizable operator stays diagonalizable on an invariant subspace. The theorem extends to an arbitrary set Ω of commuting diagonalizable operators: $\operatorname{span}(\Omega)$ is a subspace of the finite-dimensional space $\mathrm{L}(V)$, so it is spanned by finitely many elements $T_1, \ldots, T_k$ of Ω (keep adding elements of Ω outside

the span of those chosen; the list stays independent, so this stops). A basis that diagonalizes $T_1, \dots, T_k$ diagonalizes every linear combination of them, hence all of Ω.

Example 7.6.35 (A common eigenbasis). Let

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 5 \end{pmatrix} \quad \text{in } \mathbb{Q}^{3\times 3}.$$

Both are block diagonal with blocks of sizes 2 and 1, and A is a scalar on each block, so $AB = BA$. Both are diagonalizable: A is diagonal, and B has the distinct eigenvalues $1, -1, 5$. The eigenspaces of A are $E_1(A) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ and $E_2(A) = \operatorname{span}(\mathbf{e}_3)$, and B preserves both. On $E_1(A)$, B swaps $\mathbf{e}_1$ and $\mathbf{e}_2$, with eigenvectors $\mathbf{e}_1 + \mathbf{e}_2$ (eigenvalue 1) and $\mathbf{e}_1 - \mathbf{e}_2$ (eigenvalue -1). So in the basis $(1,1,0), (1,-1,0), (0,0,1)$,

$$A \mapsto \operatorname{diag}(1,1,2), \quad B \mapsto \operatorname{diag}(1,-1,5).$$

Not every eigenbasis of A works: $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ is one, but $\mathbf{e}_1$ is not an eigenvector of B. The common basis has to be chosen inside the eigenspaces of A, using B, which is how the proof proceeds.

7.6.7 Gershgorin's disk theorem

The eigenvalues of $A \in \mathbb{C}^{n\times n}$ are the roots of a polynomial of degree n, and for $n \geq 5$ there is in general no formula for them. Often a location is enough: is 0 an eigenvalue, that is, is A singular? Do all eigenvalues have negative real part, so that the solutions of $\mathbf{x}' = A\mathbf{x}$ decay (Proposition 7.4.34)? If the off-diagonal entries of A were 0, the eigenvalues would be the diagonal entries. Gershgorin's theorem says that off-diagonal entries can move the eigenvalues away from the diagonal entries, but only as far as the size of the off-diagonal entries in a row allows.

Theorem 7.6.36 (Gershgorin's disk theorem). Let $A = (a_{ij}) \in \mathbb{C}^{n\times n}$. For $i = 1, \dots, n$, let $R_i = \sum_{j\neq i} |a_{ij}|$ and

$$D_i = \{z \in \mathbb{C} \mid |z - a_{ii}| \leq R_i\},$$

the closed disk with center a_{ii} and radius R_i. Then every eigenvalue of A lies in $D_1 \cup D_2 \cup \cdots \cup D_n$. More precisely, if $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, and i is an index with $|v_i| = \max_j |v_j|$, then $\lambda \in D_i$.

Technique 7.6.37 (Look at the largest coordinate). To bound an eigenvalue λ with $A\mathbf{v} = \lambda\mathbf{v}$, look at the row of this equation belonging to a coordinate v_i of largest absolute value. After dividing by v_i, every other coordinate enters only through the ratio $|v_j/v_i| \leq 1$, so the row becomes an inequality involving the entries of A alone.

Reach for it when you need a bound on eigenvalues in terms of entries, or to show that a matrix with a dominant diagonal, or with nonnegative rows summing to 1, is invertible or has its eigenvalues in a given region. The canonical example is Theorem 7.6.36. Later: $|\lambda| \leq 1$ for stochastic matrices (Section 11.1) and the Perron–Frobenius theorem (Section 11.2).

Used in. Theorem 7.6.36, Exercise 7.6.54, Exercise 7.6.55.

Proof. STANDARD

Uses. Definition 2.3.8 (Matrix–vector product), Theorem B.1.11 (Triangle inequality in $\mathbb{C}$), Proposition B.1.8 (Properties of the modulus)
Techniques. Look at the largest coordinate (Technique 7.6.37)
Hint 1. Write out row i of $A\mathbf{v} = \lambda\mathbf{v}$ and move the diagonal term to the right.
Hint 2. Take absolute values, use the triangle inequality, and bound each $|v_j|$ by $|v_i|$.
Sketch. Row i of $A\mathbf{v} = \lambda\mathbf{v}$ gives $(\lambda - a_{ii})v_i = \sum_{j\neq i} a_{ij}v_j$. Taking absolute values and using $|v_j| \leq |v_i|$ gives $|\lambda - a_{ii}||v_i| \leq R_i|v_i|$, and $|v_i| > 0$ since $\mathbf{v} \neq \mathbf{0}$.

Let $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, and choose i with $|v_i| = \max_j |v_j|$; then $|v_i| > 0$. Row i of $A\mathbf{v} = \lambda\mathbf{v}$ reads $\sum_j a_{ij}v_j = \lambda v_i$ (Definition 2.3.8), that is,

$$(\lambda - a_{ii})v_i = \sum_{j \neq i} a_{ij}v_j.$$

By Proposition B.1.8(d) and the triangle inequality (Theorem B.1.11),

$$|\lambda - a_{ii}||v_i| \leq \sum_{j \neq i} |a_{ij}||v_j| \leq \sum_{j \neq i} |a_{ij}||v_i| = R_i|v_i|.$$

Dividing by $|v_i| > 0$ gives $|\lambda - a_{ii}| \leq R_i$, that is, $\lambda \in D_i$. □

Example 7.6.38 (Three disks). Let

$$A = \begin{pmatrix} 3 & -2 & 0 \\ 2 & 0 & 0 \\ 0 & 1 & -4 \end{pmatrix}.$$

The disks are D_1 with center 3 and radius 2, D_2 with center 0 and radius 2, and D_3 with center -4 and radius 1. Expanding $\det(xI_3 - A)$ along the third column gives $p_A = (x+4)\big(x^2 - 3x + 4\big)$, so the eigenvalues are -4 and $\big(3 \pm i\sqrt{7}\big)/2$. The complex pair satisfies $|\lambda|^2 = (9+7)/4 = 4$ and $|\lambda - 3|^2 = 9/4 + 7/4 = 4$: each lies on the boundary of both D_1 and D_2, at the two points where the circles cross. So the disks cannot be shrunk in general. Here Gershgorin cannot decide whether A is invertible, because $0 \in D_2$; in fact $\det A = -16$.

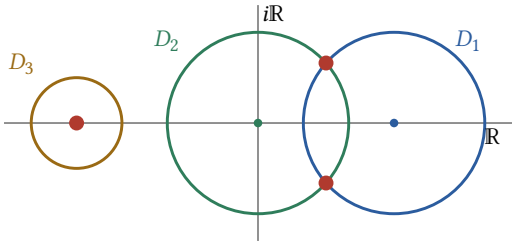

Figure 7.6.1. The Gershgorin disks of the matrix in Example 7.6.38 and its three eigenvalues (red). The eigenvalue -4 is the center of D_3; the other two sit where the circles bounding D_1 and D_2 meet.

Corollary 7.6.39 (Diagonally dominant matrices are invertible). Let $A \in \mathbb{C}^{n\times n}$ be **strictly diagonally dominant**: $|a_{ii}| > \sum_{j\neq i} |a_{ij}|$ for every i. Then A is invertible. The same holds for real or rational matrices.

Proof. ROUTINE

Uses. Theorem 7.6.36 (Gershgorin's disk theorem), Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 5.4.7 (Invertibility and the determinant)
Hint. Is 0 in any Gershgorin disk?
Sketch. $|0 - a_{ii}| > R_i$, so $0 \notin D_i$ for every i, and 0 is not an eigenvalue. A real matrix that is invertible over $\mathbb{C}$ has nonzero determinant, so it is invertible over $\mathbb{R}$.

For every i, $|0 - a_{ii}| = |a_{ii}| > R_i$, so $0 \notin D_i$. By Theorem 7.6.36, 0 is not an eigenvalue of A, so A is invertible (Theorem 7.2.9). If A has real (or rational) entries, then $\det A \neq 0$ by Theorem 5.4.7, and the determinant does not depend on whether A is regarded as real or complex, so A is invertible over $\mathbb{R}$ (or $\mathbb{Q}$) as well. □

Since A^{T} has the same characteristic polynomial as A (Exercise 7.3.17), the theorem also holds with columns in place of rows, and every eigenvalue lies in the intersection of the union of the row disks with the union of the column disks.

ASIDE: *Counting eigenvalues in the disks*

A sharper form of the theorem says: if the union of some k of the disks is disjoint from the union of the other $n-k$, then it contains exactly k eigenvalues, counted with multiplicity. The proof follows the eigenvalues of $A_t = \operatorname{diag}(a_{11},\dots,a_{nn}) + t(A - \operatorname{diag}(a_{11},\dots,a_{nn}))$ as t runs from 0 to 1. The disks of A_t have radii tR_i, so they only grow, and the eigenvalues, being roots of a polynomial whose coefficients depend continuously on t, move continuously and cannot jump from one group of disks to the other. Making "the roots move continuously" precise takes some analysis, which we do not do here. For Example 7.6.38 it says that D_3 contains exactly one eigenvalue. For a real matrix, an isolated disk containing exactly one eigenvalue λ also contains $\overline{\lambda}$ (the disk is symmetric about $\mathbb{R}$, and $\overline{\lambda}$ is an eigenvalue by Proposition 7.1.38), so λ is real.

Exercises

Exercise 7.6.40. ROUTINE Find the characteristic and minimal polynomials of each matrix in $\mathbb{Q}^{3\times 3}$, and decide whether it is diagonalizable.

$$A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}.$$

Solution on page 1606

Exercise 7.6.41. STANDARD

(a) Let $n \geq 2$ and let $J \in F^{n\times n}$ be the matrix with every entry 1. Show that $J^2 = nJ$, where n means $1 + \cdots + 1$ (n terms) in F. Find m_J, and decide when J is diagonalizable. (Distinguish whether $n = 0$ in F.)

(b) Let $R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Find m_R over $\mathbb{F}_2$, $\mathbb{F}_3$, and $\mathbb{F}_5$, and decide in each case whether R is diagonalizable over that field. When it is, find an eigenbasis.

Solution on page 1606

Exercise 7.6.42. STANDARD Let $A = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$.

(a) Find p_A and m_A.

(b) Show that $A^k = (k-1)A^2 + (2-k)A$ for every $k \geq 1$.

(c) Let $B = A + I_3$. Use (a) and Exercise 7.6.6 to find m_B, and write B^{-1} as a polynomial in B. Compute B^{-1}.

Solution on page 1607

Exercise 7.6.43. STANDARD Let $A, B \in F^{n\times n}$. Prove or disprove each statement.

(a) If $p_A = p_B$, then $m_A = m_B$.

(b) If $p_A = p_B$ and $m_A = m_B$, then A and B are similar.

(c) If A^2 is diagonalizable, then A is diagonalizable.

(d) If $F = \mathbb{C}$, A is invertible, and A^2 is diagonalizable, then A is diagonalizable.

Solution on page 1607

Exercise 7.6.44. STANDARD Find the error in the following argument.

Claim. For every $A \in \mathbb{C}^{n\times n}$, $p_A(A) = 0$.

"Proof." Let λ be an eigenvalue of A and $\mathbf{v}$ an eigenvector for λ. By Proposition 7.2.28, $p_A(A)\mathbf{v} = p_A(\lambda)\mathbf{v} = \mathbf{0}$, since λ is a root of p_A. So $p_A(A)$ sends every eigenvector of A to $\mathbf{0}$. A linear map that sends every vector of a spanning set to $\mathbf{0}$ is zero, so $p_A(A) = 0$.

Which matrices does the argument handle correctly? Explain why the fourth proof of Theorem 7.6.20 can be read as a repair of it.

Solution on page 1608

Exercise 7.6.45. STANDARD Let $T \in \mathrm{L}(V)$ satisfy $T^2 = T + 2\mathrm{id}_V$.

(a) Suppose $1 + 1 + 1 \neq 0$ in F. Show that T is diagonalizable with eigenvalues in $\{2, -1\}$, so that $V = E_2 \oplus E_{-1}$, and write the projection of V onto E_2 along E_{-1} as a polynomial in T.

(b) Find $A \in \mathbb{F}_3^{2\times 2}$ with $A^2 = A + 2I_2$ that is not diagonalizable.

Solution on page 1608

Exercise 7.6.46. STANDARD

(a) Find all $A \in \mathbb{F}_2^{2\times 2}$ with $A^2 + A + I_2 = 0$.

(b) For one such A, show that the four matrices $0, I_2, A, A + I_2$ are closed under addition and multiplication, and that each nonzero one has an inverse among them.

Solution on page 1609

Exercise 7.6.47. HARD A vector $\mathbf{v}$ is **cyclic** for T if $K_T(\mathbf{v}) = V$ (Definition 7.2.33).

(a) Show that if T has a cyclic vector, then $m_T = p_T$.

(b) Suppose T is diagonalizable. Show that T has a cyclic vector if and only if T has n distinct eigenvalues.

Solution on page 1609

Exercise 7.6.48. STANDARD Let $\mathbf{v}$ be a cyclic vector for T (as in Exercise 7.6.47). Show that $S \in \mathrm{L}(V)$ commutes with T if and only if $S = q(T)$ for some $q \in F[x]$. Deduce that the operators commuting with T form a subspace of $\mathrm{L}(V)$ of dimension n.

Solution on page 1609

Exercise 7.6.49. HARD Let V be a finite-dimensional complex vector space and $T \in \mathrm{L}(V)$. Show that T is diagonalizable if and only if every T-invariant subspace U of V has a T-invariant complement, that is, a T-invariant W with $V = U \oplus W$. Does "$\Longleftarrow$" hold over $\mathbb{R}$?

Solution on page 1610

Exercise 7.6.50. HARD Let $A \in \mathbb{R}^{n\times n}$ satisfy $A^3 = A + I_n$. Show that $\det A > 0$.

Solution on page 1610

Exercise 7.6.51. STANDARD Let $A, B \in \mathbb{C}^{n\times n}$.

(a) Suppose $AB = BA$ and $A^k = B^k = 0$ for some k. Show that $A + B$ and AB are nilpotent.

(b) Show by example that (a) fails without $AB = BA$.

(c) Suppose A and B are both upper triangular. Show that $AB - BA$ is nilpotent. Deduce that $AB - BA$ is nilpotent whenever A and B can be triangularized by the same basis, and give two upper-triangular matrices that do not commute.

Solution on page 1611

Exercise 7.6.52. STANDARD Let $A, B \in \mathbb{R}^{n\times n}$ with $AB = BA$. Show that $\det(A^2 + B^2) \geq 0$. Find $A, B \in \mathbb{R}^{2\times 2}$ with $\det(A^2 + B^2) < 0$.

Solution on page 1611

Exercise 7.6.53. STANDARD Let

$$A = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

(a) Check that $AB = BA$ and that A and B are diagonalizable over $\mathbb{R}$.

(b) Find a basis of $\mathbb{R}^3$ consisting of common eigenvectors of A and B.

(c) Is there such a basis of $\mathbb{Q}^3$?

Solution on page 1612

Exercise 7.6.54. STANDARD Let $G = \begin{pmatrix} 6 & 1 & -1 \\ 1 & 5 & 2 \\ 0 & -1 & 4 \end{pmatrix} \in \mathbb{R}^{3\times 3}$.

(a) Show that every complex eigenvalue λ of G satisfies $\operatorname{Re}\lambda \geq 2$. Deduce that G is invertible.

(b) Show that $\det G > 0$ without computing it.

(c) Show that $|\lambda| \leq 7$ for every eigenvalue, and explain why the row disks alone give only $|\lambda| \leq 8$.

Solution on page 1612

Exercise 7.6.55. HARD Let $A \in \mathbb{R}^{n\times n}$ have nonnegative entries, with every row summing to 1.

(a) Show that every complex eigenvalue λ of A satisfies $|\lambda| \leq 1$, and that 1 is an eigenvalue.

(b) Suppose moreover that $a_{ii} > 0$ for every i. Show that 1 is the only eigenvalue with $|\lambda| = 1$.

(c) Show that (b) fails without the assumption $a_{ii} > 0$.

Solution on page 1613

Exercise 7.6.56. CHALLENGE Let $A, B \in \mathbb{C}^{n\times n}$, and suppose $C = AB - BA$ commutes with A. Show that C is nilpotent. Show that the statement fails over $\mathbb{F}_p$.

Solution on page 1613

7.7 Proof patterns

The chapter asked one question about an operator T on a finite-dimensional space: in which basis is its matrix as simple as possible, and how simple can it be made? Diagonal when there is an eigenbasis, triangular when the characteristic polynomial splits, and in every case the answer is controlled by polyno-

mials in T. Most of the chapter's proofs use a few moves to turn a hypothesis about T into information about vectors: apply a polynomial in T to kill terms, follow a vector along its chain $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$, look for invariant subspaces among kernels of operators that commute with T, test an identity on eigenvectors, or triangularize and read off the diagonal. This section sorts the chapter's arguments by the question they answer, solves three problems in several ways to compare the moves, and lists the errors that the chapter's exercises warn against. The exercises at the end practice one move at a time, and the problem set (Problems for Chapter 7) mixes them with earlier chapters.

7.7.1 Polynomials in T kill terms

On an eigenvector, every polynomial in T acts as a scalar: $p(T)\mathbf{v} = p(\lambda)\mathbf{v}$ (Proposition 7.2.28). So a polynomial that vanishes at some eigenvalues and not at others removes exactly the terms it vanishes on, and this is the most common move of the chapter.

- *Kill all terms but one* (Technique 4.1.25). To show that eigenvectors $\mathbf{v}_1, \ldots, \mathbf{v}_m$ for distinct eigenvalues are independent, apply $\prod_{j \neq i}(T - \lambda_j \operatorname{id})$ to a relation; only the ith term survives, multiplied by the nonzero scalar $\prod_{j \neq i}(\lambda_i - \lambda_j)$ (Theorem 7.2.21). With the normalized product, the Lagrange polynomial L_i, the surviving term comes out with coefficient 1, and $L_i(T)$ is the projection onto E_{λ_i} (Technique 7.6.13).
- *Read eigenvalues off an annihilating polynomial* (Technique 7.6.17). If $p(T) = 0$, every eigenvalue is a root of p (Proposition 7.2.28). If p is a product of distinct linear factors, T is diagonalizable (Proposition 7.6.12). If $p(0) \neq 0$, then T is invertible and T^{-1} is a polynomial in T, read off from p (Corollary 7.6.9). Note the direction: a root of p need not be an eigenvalue, since $T = 0$ on $V \neq \{\mathbf{0}\}$ is killed by $x(x-1)$ and 1 is not an eigenvalue of it.
- *Bézout in T.* If $up + vq = 1$ in $F[x]$, then $u(T)p(T) + v(T)q(T) = \mathrm{id}_V$, so a vector killed by both $p(T)$ and $q(T)$ is $\mathbf{0}$, and when $p(T)q(T) = 0$ the space splits as $\ker p(T) \oplus \ker q(T)$ (Corollary 7.1.48, Exercise 7.2.55). Lagrange interpolation is the case of linear factors.

Behind all three is the fact that polynomials in T commute with each other and with T (Proposition 7.2.27), so they can be applied to a relation in any order.

7.7.2 Chains

The chain move of Section 4.8.1 returns with T replaced by $N = T - \lambda \operatorname{id}$. If $N^k\mathbf{v} \neq \mathbf{0}$ and $N^{k+1}\mathbf{v} = \mathbf{0}$, then $\mathbf{v}, N\mathbf{v}, \ldots, N^k\mathbf{v}$ is independent (Proposition 7.2.37), its span is the Krylov subspace $K_T(\mathbf{v})$, the smallest T-invariant subspace containing $\mathbf{v}$, and the last nonzero vector $N^k\mathbf{v}$ is an eigenvector with eigenvalue λ (Corollary 7.2.38). Three things make this the most useful single fact of the chapter.

- *It turns "killed by a power" into "an eigenvector exists."* Whenever some $(T - \lambda \operatorname{id})^k$ kills a nonzero $\mathbf{v}$, walk along the chain until the next step gives $\mathbf{0}$; the last vector is an eigenvector. This is how Technique 7.3.28 produces eigenvectors: the first dependence among $\mathbf{v}, T\mathbf{v}, T^2\mathbf{v}, \ldots$ is a polynomial p with $p(T)\mathbf{v} = \mathbf{0}$ (Proposition 7.2.35), and peeling off one factor $x - \lambda$ of p leaves a nonzero vector killed by $T - \lambda \operatorname{id}$. Over $\mathbb{C}$, p always has such a factor, which is the determinant-free proof that eigenvalues exist (Theorem 7.3.27).
- *It counts.* A chain is independent, so it has at most $\dim V$ vectors, and a chain of length $\dim V$ is a basis in which T is λ on the diagonal and 1 just above it (Corollary 7.2.38(c)). Combined with the kernel count $\dim \ker N^{j+1} \leq \dim \ker N^j + \dim \ker N$, it decides when one chain fills the space (Problem 7.3).
- *It works one vector at a time*, with no hypothesis on T beyond the two conditions on $\mathbf{v}$, and in any dimension and over any field. That is why it decides problems where nothing is known about T globally, such as whether a matrix has a square root (Exercise 7.7.9).

Example 7.7.1 (Two eigenvalues cannot share a generalized eigenvector, three ways). Let $T \in \mathrm{L}(V)$, let $\lambda \neq \mu$ in F, let $k, m \geq 1$, and let $\mathbf{v} \in V$ satisfy

$$(T-\lambda\,\mathrm{id})^k\mathbf{v}=\mathbf{0}\quad\text{and}\quad(T-\mu\,\mathrm{id})^m\mathbf{v}=\mathbf{0}.$$

We show $\mathbf{v}=\mathbf{0}$. Here V is any vector space over any field. Write $A=T-\lambda\,\mathrm{id}$ and $B=T-\mu\,\mathrm{id}$; these commute, and $B-A=(\lambda-\mu)\,\mathrm{id}$.

Kill every term. By the binomial theorem for commuting operators (Exercise A.2.8), with $r=k+m-1$,

$$(\lambda-\mu)^r\mathbf{v}=(B-A)^r\mathbf{v}=\sum_{j=0}^{r}\binom{r}{j}(-1)^{r-j}A^{r-j}B^j\mathbf{v}.$$

In each term, either $j\geq m$, and then $B^j\mathbf{v}=\mathbf{0}$, or $j\leq m-1$, and then $r-j\geq k$ and $A^{r-j}B^j\mathbf{v}=B^jA^{r-j}\mathbf{v}=\mathbf{0}$. So $(\lambda-\mu)^r\mathbf{v}=\mathbf{0}$, and since $\lambda-\mu\neq 0$, $\mathbf{v}=\mathbf{0}$.

A chain. Suppose $\mathbf{v}\neq\mathbf{0}$. Since $A^k\mathbf{v}=\mathbf{0}$, there is a largest j with $0\leq j<k$ and $A^j\mathbf{v}\neq\mathbf{0}$. Then $\mathbf{w}=A^j\mathbf{v}$ satisfies $A\mathbf{w}=\mathbf{0}$, so it is an eigenvector of T with eigenvalue λ (Corollary 7.2.38(a)). By Proposition 7.2.28, $B^m\mathbf{w}=(\lambda-\mu)^m\mathbf{w}\neq\mathbf{0}$. But $B^m\mathbf{w}=A^jB^m\mathbf{v}=\mathbf{0}$, a contradiction.

Restrict, then invert. Let $U=\ker A^k\cap\ker B^m$. Both kernels are T-invariant (Proposition 7.2.30(a)), so U is, and on U the restriction $N=A|_U$ satisfies $N^k=0$. Now $B|_U=N+(\lambda-\mu)\mathrm{id}_U=(\lambda-\mu)(\mathrm{id}_U+cN)$ with $c=(\lambda-\mu)^{-1}$, and id_U+cN is invertible, with inverse $\mathrm{id}_U-cN+c^2N^2-\cdots+(-c)^{k-1}N^{k-1}$ (the computation of Exercise 4.1.44). So $B|_U$ is invertible, and so is its mth power. But ${B|_U}^m=0$. An invertible zero operator lives only on $\{\mathbf{0}\}$, so $U=\{\mathbf{0}\}$ and $\mathbf{v}=\mathbf{0}$.

The first proof is Bézout's identity for $(x-\lambda)^k$ and $(x-\mu)^m$, written out by hand, and it is the one that generalizes: for any coprime p,q, a vector killed by $p(T)$ and $q(T)$ is $\mathbf{0}$. The chain proof reduces the question to eigenvectors, where polynomials act as scalars, and it is the shortest once the chain is in your hands. The third proof sees the hypothesis as a statement about the operator on U: there T is "λ plus nilpotent," and a nilpotent perturbation of the nonzero scalar $\lambda-\mu$ cannot be 0. All three are the key step in splitting V into generalized eigenspaces (Section 10.2).

Practice: Exercise 7.7.9, Problem 7.3, Problem 7.12, and Problem 7.9.

7.7.3 Invariant subspaces from commuting operators

To find subspaces that T maps into themselves, look at kernels, images, and eigenspaces of operators that commute with T (Technique 7.2.31, Proposition 7.2.30). Polynomials in T always qualify, so $\ker(T-\lambda\,\mathrm{id})^k$ and $\mathrm{im}\,p(T)$ are always available, and Problem 7.4 finds every invariant subspace of a 3×3 matrix this way. When two given operators S,T commute, each eigenspace of S is a smaller space on which T still acts, and the problem can be continued there. This is the whole proof that commuting operators have a common eigenvector (Theorem 7.6.31): T has an eigenvalue on $E_\lambda(S)$ when the field is $\mathbb{C}$. Two cautions. The restriction of T to $E_\lambda(S)$ inherits diagonalizability (Corollary 7.6.16), but nothing forces it to be diagonalizable when T is not, and the eigenspaces of S need not fill V; so commuting alone gives a common eigenvector and a common triangular form (Theorem 7.6.32), and a common eigenbasis only for diagonalizable operators (Theorem 7.6.34, Exercise 7.7.6). The kernel move does not need eigenvalues at all, which makes it work over any field: two commuting nilpotent operators have a common kernel vector, because $\ker S$ is T-invariant and T is still nilpotent there (Exercise 7.7.13).

Practice: Exercise 7.7.6, Exercise 7.7.13, Exercise 7.7.12, and Problem 7.4.

7.7.4 Proving and refuting diagonalizability

There are four standard ways to show that T is diagonalizable, in roughly increasing order of generality:

- n distinct eigenvalues (Corollary 7.4.5);
- an annihilating polynomial that is a product of distinct linear factors (Theorem 7.6.15), which is the route for any identity such as $T^2=T$, $T^3=T$, or $T^k=\mathrm{id}$ over $\mathbb{C}$;

- a direct sum decomposition of V into eigenspaces, often produced by idempotents (Technique 4.4.28) or by Lagrange polynomials in T;
- counting: p_T splits and $\operatorname{gm}(\lambda) = \operatorname{am}(\lambda)$ for each eigenvalue (Theorem 7.4.16), with $\operatorname{gm}(\lambda) = n - \operatorname{rank}(A - \lambda I_n)$ computed as a rank (Lemma 7.4.13).

To refute it, find one of the obstructions of Obstructions to diagonalizability: p_T does not split over F (the rotation, Example 7.4.9), or some eigenvalue has gm < am (the shear, Example 7.4.8). Two shortcuts catch most examples. A diagonalizable operator with a single eigenvalue λ is λ id (Proposition 7.4.7), so a nonzero nilpotent operator, or $I + N$ with $N \neq 0$ nilpotent, is never diagonalizable. And over a field where the roots of the relevant polynomial collide, the polynomial route fails: $x^2 - 1 = (x-1)^2$ over $\mathbb{F}_2$, and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ satisfies $A^2 = I_2$ there without being diagonalizable.

Example 7.7.2 (An idempotent is diagonalizable, three ways). Let $\dim V = n$ and let $P \in \mathrm{L}(V)$ satisfy $P^2 = P$. We show that P is diagonalizable, with P similar to $\operatorname{diag}(1, \ldots, 1, 0, \ldots, 0)$, where the number of ones is $\operatorname{rank} P$.

An annihilating polynomial. The polynomial $x^2 - x = x(x-1)$ kills P, and its factors are distinct because $0 \neq 1$ in every field. By Proposition 7.6.12, $V = E_0 \oplus E_1$ and P is diagonalizable.

Image and kernel. By Theorem 4.4.27, $V = \operatorname{im} P \oplus \ker P$ and $\operatorname{im} P = \{\mathbf{v} \mid P\mathbf{v} = \mathbf{v}\}$. So $\operatorname{im} P = E_1$ and $\ker P = E_0$, and a basis of $\operatorname{im} P$ followed by a basis of $\ker P$ is a basis of V (Theorem 4.4.13) consisting of eigenvectors. There are $\operatorname{rank} P$ vectors with eigenvalue 1.

Eigenvalues and rank. Every eigenvalue is a root of $x^2 - x$ (Proposition 7.2.28), so it is 0 or 1. By Lemma 7.4.13, $\operatorname{gm}(0) = n - \operatorname{rank} P$ and $\operatorname{gm}(1) = n - \operatorname{rank}(P - \mathrm{id})$. Since $P + (\mathrm{id} - P) = \mathrm{id}$, subadditivity gives $\operatorname{rank} P + \operatorname{rank}(\mathrm{id} - P) \geq n$ (Proposition 4.3.20); since $P(\mathrm{id} - P) = 0$, Sylvester's inequality gives $0 \geq \operatorname{rank} P + \operatorname{rank}(\mathrm{id} - P) - n$ (Exercise 4.3.30). So $\operatorname{gm}(0) + \operatorname{gm}(1) = 2n - (\operatorname{rank} P + \operatorname{rank}(\mathrm{id} - P)) = n$, and Theorem 7.4.16(III) applies.

The polynomial proof is the shortest and generalizes at once: if $(T - a\,\mathrm{id})(T - b\,\mathrm{id}) = 0$ with $a \neq b$, then T is diagonalizable. It is also the one that breaks first when the field changes, as the involution over $\mathbb{F}_2$ above shows. The image-and-kernel proof produces the eigenspaces themselves, and it explains the polynomial proof: for $(T - a\,\mathrm{id})(T - b\,\mathrm{id}) = 0$, the Lagrange polynomial $(T - b\,\mathrm{id})/(a - b)$ is an idempotent with image E_a. The rank proof is the computational one, and run backwards it shows that $\operatorname{rank} P + \operatorname{rank}(\mathrm{id} - P) = n$ characterizes idempotents (Exercise 4.3.42).

Practice: Exercise 7.7.4, Exercise 7.7.11, Problem 7.2, and Problem 7.6.

7.7.5 Proving an identity for every operator

To prove an identity such as $\operatorname{tr} T = \sum \lambda_i$, $\det p(T) = \prod p(\lambda_i)$, or $p_T(T) = 0$, there are four routes, and they apply to fewer operators the more concrete they are.

- *Test on eigenvectors* (Technique 7.4.25). For diagonalizable T, two polynomials in T agree as soon as they agree on an eigenbasis, which reduces the identity to scalars. For other operators the eigenvectors do not span, and the test proves nothing (Exercise 7.7.7).
- *Diagonalize, solve, conjugate back* (Technique 7.4.22). For computations with a diagonalizable matrix: powers, square roots, recurrences, matrix equations. The equation $AX = XB$ becomes $DY = YE$ with diagonal D, E, which is solved entry by entry (Exercise 7.7.11).
- *Triangularize, then read the diagonal* (Technique 7.5.23). Over $\mathbb{C}$ every operator is triangular in some basis (Theorem 7.5.13), and products and polynomials of triangular matrices have the expected diagonals. This proves anything that depends only on the diagonal: characteristic polynomials, traces, determinants, eigenvalues with multiplicity (Theorem 7.5.22, Theorem 7.6.28).

- *A polynomial identity, or perturbation* (Technique 5.5.24, Technique 7.6.23). If both sides are polynomials in the entries, it is enough to prove the identity for $A - tI_n$ (or another path through A) at infinitely many values of t, for instance at those t for which it is invertible or has distinct eigenvalues; both sides are then polynomials in t that agree infinitely often. This route works over every infinite field and needs no eigenvalues of the original matrix.

Example 7.7.3 (A unipotent matrix has determinant 1, four ways). Let $N \in F^{n\times n}$ satisfy $N^k = 0$ for some $k \geq 1$. We show $\det(I_n + N) = 1$.

Triangularize (over $\mathbb{C}$). The only eigenvalue of N is 0, since every eigenvalue is a root of x^k (Proposition 7.2.28). By Corollary 7.5.14, $N = SRS^{-1}$ with R upper triangular, and the diagonal entries of R are eigenvalues of N (Proposition 7.5.8), so they are 0. Then $I_n + N = S(I_n + R)S^{-1}$, and $I_n + R$ is upper triangular with ones on the diagonal, so $\det(I_n + N) = \det(I_n + R) = 1$ (Proposition 5.4.17).

The characteristic polynomial (any field). By Exercise 7.3.48, $p_N = x^n$. Evaluating $p_N = \det(xI_n - N)$ at $x = -1$ is allowed, since evaluation respects sums and products (Proposition 7.1.10, Proposition 7.3.2(g)), and gives $\det(-I_n - N) = (-1)^n$. So $\det(I_n + N) = (-1)^n \det(-I_n - N) = 1$.

A flag of kernels (any field). The kernels $\ker N \subseteq \ker N^2 \subseteq \cdots \subseteq \ker N^k = F^n$ are nested. Choose a basis of $\ker N$, extend it to a basis of $\ker N^2$, and so on up to F^n. If a basis vector $\mathbf{b}$ was added at stage $j+1$, then $N\mathbf{b} \in \ker N^j$, which is spanned by basis vectors added strictly before $\mathbf{b}$. So in this basis N is strictly upper triangular, and $I_n + N$ is similar to an upper triangular matrix with ones on the diagonal (Technique 7.5.4).

A polynomial identity in t (any field). In $F[t]^{n\times n}$, the matrices $I_n + tN$ and $G = \sum_{j=0}^{k-1} (-t)^j N^j$ satisfy $(I_n + tN)G = I_n - (-tN)^k = I_n$, by telescoping. Let $f(t) = \det(I_n + tN) \in F[t]$. By multiplicativity over $F[t]$ (Proposition 7.3.2(c)), $f(t) \det G = 1$, so f is a unit of $F[t]$, hence a nonzero constant (Corollary 7.1.7(c)). Its value at $t = 0$ is $\det I_n = 1$, so $f = 1$, and at $t = 1$ this is $\det(I_n + N) = 1$.

The triangular proof is the quickest, but it needs the eigenvalues of N in the field, which is why it is stated over $\mathbb{C}$; the characteristic polynomial proof removes that need but uses Exercise 7.3.48. The flag proof is the most informative: it shows that over any field a nilpotent matrix is similar to a strictly upper triangular one, so $I_n + N$ has trace n as well. The last proof is the strangest and the most portable. At $t = 1$ alone, $(I_n + N)G = I_n$ shows only that $\det(I_n + N) \neq 0$; the parameter t is what pins the value down, because a polynomial with a polynomial inverse cannot vary. That is the shape of every perturbation argument in Technique 7.6.23.

Practice: Exercise 7.7.7, Exercise 7.7.14, Problem 7.10, and Problem 7.13.

7.7.6 Induction on dimension

The existence theorems of Section 7.5 and Section 7.6.6 all have the same shape (Technique 7.5.12): find an invariant subspace U with $\{\mathbf{0}\} \neq U \neq V$, apply the induction hypothesis to a smaller operator, and glue with a block triangular matrix. The smaller operator can be the restriction to U, the compression to a complement W (Lemma 7.5.11), or the quotient operator on V/U (Section 4.6). The point to check in every such proof is that the smaller operator satisfies the hypotheses again. A restriction of a complex operator is a complex operator, so triangularization goes through; the compressions of two commuting operators to a complement of a common invariant subspace commute, so simultaneous triangularization goes through (Exercise 7.7.13). A compression is not a restriction, and treating it as one is a real error (Problem 7.14). For Schur's theorem one compresses to $U^\perp$, which keeps orthonormality (Theorem 7.5.18), and the same move proves the spectral theorems in Section 8.2.

7.7.7 Real matrices BEYOND 21-242

Complexification is not covered in lecture.

A real matrix need not have a real eigenvalue, and the arguments of the chapter that start from an eigenvector then have nothing to start from. Three moves get around this. In odd dimension there is always a real eigenvalue, by the intermediate value theorem applied to p_A (Proposition 7.3.30). Otherwise, regard A as a complex matrix, use complex eigenvalues and eigenvectors, and come back by taking real and imaginary parts (Technique 7.3.35): a complex eigenvector $\mathbf{u} + i\mathbf{w}$ gives the real invariant plane $\operatorname{span}(\mathbf{u}, \mathbf{w})$ (Proposition 7.3.34), and the nonreal eigenvalues come in conjugate pairs with equal multiplicities (Proposition 7.1.38), so $\det A$ is a product of real eigenvalues and factors $|\lambda|^2 > 0$. That last fact settles sign questions such as $\det\left(A^2 + B^2\right) \geq 0$ for commuting A, B (Exercise 7.6.52). Finally, a real identity can sometimes be factored over $\mathbb{C}$ as $Z\overline{Z}$, whose determinant is $|\det Z|^2 \geq 0$ (Problem 7.18).

Practice: Exercise 7.7.8, Exercise 7.7.12, Problem 7.11, and Problem 7.17.

7.7.8 Reading the chapter's proofs

Which field? Each statement of the chapter depends on the field in one of three ways. Some hold over every field: eigenvectors for distinct eigenvalues are independent, chains are independent, $\operatorname{gm} \leq \operatorname{am}$, and the characteristic polynomial has tr and det as coefficients. Some hold whenever the relevant polynomial splits: triangularization (Theorem 7.5.17), and tr and det as sum and product of eigenvalues. Over $\mathbb{C}$ that is automatic by the Fundamental Theorem of Algebra, and over a finite field it can fail for every size $n \geq 2$ (Exercise 7.3.44). And some depend on the characteristic: "an involution is diagonalizable" needs $1 + 1 \neq 0$, and "$\operatorname{tr} A^k = 0$ for all k forces A nilpotent" needs characteristic 0. When a proof divides by an integer, or uses that roots such as ± 1 are distinct, that is where the field enters.

Where finite dimension enters. Eigenvectors for distinct eigenvalues are independent in any vector space, and so are chains. Existence of eigenvalues is where finite dimension is needed: multiplication by x on $F[x]$ has none (Remark 7.2.10), because the Krylov sequence $\mathbf{v}, T\mathbf{v}, \ldots$ never becomes dependent.

Two polynomials. The characteristic polynomial records multiplicities: am, trace, determinant. The minimal polynomial records structure: the eigenvalues again, and whether T is diagonalizable. Neither determines the other (Remark 7.6.11), and by Cayley–Hamilton the minimal polynomial divides the characteristic one (Theorem 7.6.20). For a vector $\mathbf{v}$, the first dependence in its Krylov sequence is a third polynomial, and the minimal polynomial is assembled from these one basis vector at a time (Problem 7.9).

Similarity invariants. Characteristic polynomial, minimal polynomial, geometric multiplicities, and the ranks of $(A - \lambda I_n)^k$ are all invariant under similarity, and each of the first three fails to determine the similarity class on its own (Exercise 7.3.38, Exercise 7.6.43). When p_A splits, as over $\mathbb{C}$, the ranks of the powers do determine it; that is the Jordan form (Section 10.3).

7.7.9 Common errors

Most of these appear in the chapter as find-the-error exercises.

- *Assuming the eigenvectors span.* An argument that checks an identity on eigenvectors and concludes it everywhere has assumed that T is diagonalizable (Exercise 7.7.7, Exercise 7.6.44). The same gap hides in "choose an eigenbasis" and in "the eigenspaces of A add up to V" (Exercise 7.7.6).
- *Algebraic and geometric multiplicity confused.* $\dim \ker A = \operatorname{gm}(0)$, while "the eigenvalue 0 counted with multiplicity" means $\operatorname{am}(0)$, which can be larger (Exercise 7.7.5). The Fundamental Theorem of Algebra gives am's that add up to n, not gm's (Exercise 7.4.39).
- *Assuming eigenvalues exist.* A real matrix need not have a real eigenvalue, and a matrix over a finite field need not have any (Example 7.4.9, Exercise 7.3.44). "The only real eigenvalue is 1" does not make 1 the only eigenvalue over $\mathbb{C}$ (Exercise 7.7.8).
- *A one-way implication used both ways.* "$\det A = 0$ if and only if 0 is an eigenvalue" is correct (Theorem 7.2.9). But $p(T) = 0$ makes every eigenvalue a root of p, not every root an eigenvalue;

A diagonalizable makes A^2 diagonalizable, not conversely (Exercise 7.4.38); and equal characteristic polynomials follow from similarity without implying it (Exercise 7.3.38).

- *Eigenvalues of sums and products.* For noncommuting A, B the eigenvalues of $A+B$ and AB have nothing to do with sums and products of eigenvalues of A and B (Exercise 7.2.43, Exercise 7.5.37); commuting is what makes them pair up (Corollary 7.6.33).
- *Substituting a matrix for x inside a determinant*, as in the false proof of Cayley–Hamilton (Exercise 7.3.47). The entries of $xI_n - A$ are polynomials; $AI_n - A$ is a matrix with matrix entries, and its "determinant" is not $p_A(A)$.
- *Eigenvectors are not closed under addition*, and an eigenvector of T^2 need not be one of T (Exercise 7.2.25, Exercise 7.2.53).
- *Restriction and compression confused.* Only an invariant subspace carries a restriction of T; a complement usually is not invariant (Problem 7.14).

Exercises

Exercise 7.7.4. ROUTINE For each statement, decide whether it is true, and name the fact that decides it.

(a) Every $A \in \mathbb{Q}^{3\times 3}$ with $A^3 = A$ is diagonalizable over $\mathbb{Q}$. Does the same hold over $\mathbb{F}_2$?

(b) Every $A \in \mathbb{C}^{4\times 4}$ with $p_A = x^2(x-1)^2$, $\operatorname{rank} A = 2$, and $\operatorname{rank}(A - I_4) = 3$ is diagonalizable.

(c) Every $A \in \mathbb{R}^{5\times 5}$ has a real eigenvalue.

(d) If $A \in \mathbb{C}^{3\times 3}$ has eigenvalues $1, 2, 3$, then $\operatorname{rank}\left(A^2 - 3A + 2I_3\right) = 1$.

(e) Every $A \in \mathbb{R}^{2\times 2}$ with $\operatorname{tr} A = 0$ and $\det A < 0$ is diagonalizable over $\mathbb{R}$.

Solution on page 1614

Exercise 7.7.5. ROUTINE Find the error in the following argument, decide whether the claim is true, and prove a correct version.

Claim. If $A \in \mathbb{C}^{n\times n}$ has rank r, then exactly r of the eigenvalues of A, counted with multiplicity, are nonzero.

"Proof." By rank–nullity, $\dim\ker A = n - r$. Since $\ker A = E_0$, the eigenvalue 0 has multiplicity $n - r$. There are n eigenvalues counted with multiplicity, so the other r are nonzero.

Solution on page 1615

Exercise 7.7.6. ROUTINE Find the errors in the following argument, and give a pair of matrices showing that the claim is false.

Claim. If $A, B \in \mathbb{C}^{n\times n}$ commute, then $\mathbb{C}^n$ has a basis of common eigenvectors of A and B.

"Proof." Let λ be an eigenvalue of A. For $\mathbf{v} \in E_\lambda(A)$, $A(B\mathbf{v}) = BA\mathbf{v} = \lambda B\mathbf{v}$, so $E_\lambda(A)$ is B-invariant. Choose a basis of $E_\lambda(A)$ consisting of eigenvectors of B. Doing this for each eigenvalue of A and putting the bases together gives a basis of $\mathbb{C}^n$ consisting of common eigenvectors.

Solution on page 1615

Exercise 7.7.7. STANDARD Find the error in the following argument, show that the claim is false, and then prove the two correct statements below.

Claim. If $A \in \mathbb{C}^{n\times n}$ satisfies $A^3 = A^2$, then $A^2 = A$.

"Proof." Let $A\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. Then $\lambda^3\mathbf{v} = A^3\mathbf{v} = A^2\mathbf{v} = \lambda^2\mathbf{v}$, so $\lambda^2(\lambda - 1) = 0$ and $\lambda \in \{0, 1\}$. Hence $\lambda^2 = \lambda$, and $A^2\mathbf{v} = \lambda^2\mathbf{v} = \lambda\mathbf{v} = A\mathbf{v}$. So A^2 and A agree on every eigenvector of A, and therefore $A^2 = A$.

(a) If $A^3 = A^2$, then A^2 is idempotent.

(b) If $A^3 = A^2$, then $A^2 = A$ if and only if A is diagonalizable.

Solution on page 1615

Exercise 7.7.8. STANDARD Find the error in the following argument, give a counterexample with integer entries, and prove the correct statements below.

Claim. If $A \in \mathbb{R}^{3\times 3}$ satisfies $A^3 = I_3$, then $A = I_3$.

"Proof." If λ is an eigenvalue of A, then $\lambda^3 = 1$ by Proposition 7.2.28, and the only real cube root of 1 is 1. So 1 is the only eigenvalue of A. The minimal polynomial divides $x^3 - 1$ and its roots are the eigenvalues of A, so $m_A = x - 1$, that is, $A = I_3$.

(a) 1 is an eigenvalue of A.

(b) $A = I_3$ if and only if A is diagonalizable over $\mathbb{R}$.

Solution on page 1616

Exercise 7.7.9. STANDARD Let $n \geq 2$, and let $N \in F^{n\times n}$ satisfy $N^n = 0$ and $N^{n-1} \neq 0$. Show that there is no $B \in F^{n\times n}$ with $B^k = N$ for some $k \geq 2$. Give two proofs: one using powers of B, and one using kernels.

Solution on page 1616

Exercise 7.7.10. STANDARD BEYOND 21-242 Let $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $m, n \geq 1$.

(a) Show that $Bf(AB)A = (xf)(BA)$ for every $f \in F[x]$, and deduce that m_{BA} divides xm_{AB}.

(b) Deduce that AB and BA have the same nonzero eigenvalues, and give an example with $m_{AB} \neq m_{BA}$.

(c) Show that $\operatorname{gm}_{AB}(\lambda) = \operatorname{gm}_{BA}(\lambda)$ for every $\lambda \neq 0$.

(d) Suppose AB is diagonalizable and invertible. Show that BA is diagonalizable, and show that "invertible" cannot be dropped.

Solution on page 1617

Exercise 7.7.11. STANDARD Let $A \in F^{m\times m}$ and $B \in F^{n\times n}$ be diagonalizable, and let $W = \{X \in F^{m\times n} \mid AX = XB\}$.

(a) Show that $\dim W = \sum_\lambda \operatorname{gm}_A(\lambda)\operatorname{gm}_B(\lambda)$, the sum over the common eigenvalues of A and B.

(b) Deduce that $AX = XB$ has only the solution $X = 0$ if and only if A and B have no common eigenvalue.

(c) Deduce that the matrices commuting with A form a subspace of dimension at least m, with equality if and only if A has m distinct eigenvalues.

Solution on page 1617

Exercise 7.7.12. STANDARD BEYOND 21-242 Let $A, B \in \mathbb{R}^{n\times n}$ with $n \geq 1$ and $AB = BA$.

(a) Show that there is a subspace $U \subseteq \mathbb{R}^n$ of dimension 1 or 2 with $AU \subseteq U$ and $BU \subseteq U$.

(b) Show by an example that dimension 1 cannot always be achieved.

Solution on page 1618

Exercise 7.7.13. HARD Let $A, B \in F^{n\times n}$, $n \geq 1$, be nilpotent with $AB = BA$, over any field F.

(a) Show that there is a nonzero $\mathbf{v}$ with $A\mathbf{v} = B\mathbf{v} = \mathbf{0}$.

(b) Show that there is an invertible S such that $S^{-1}AS$ and $S^{-1}BS$ are both strictly upper triangular.

(c) Deduce that $A + B$ and AB are nilpotent.

Solution on page 1619

Exercise 7.7.14. HARD BEYOND 21-242 Let $A \in F^{n\times n}$ with $n \geq 2$, and write $p_A = x^n + c_{n-1}x^{n-1} + \cdots + c_1 x + c_0$. Show that

$$\operatorname{adj}(A) = (-1)^{n+1}\bigl(A^{n-1} + c_{n-1}A^{n-2} + \cdots + c_2 A + c_1 I_n\bigr),$$

first for invertible A, and then for all A when F is infinite. Check the formula for $n = 2$.

Solution on page 1619

Problems for Chapter 7

These problems combine the sections of Chapter 7 with each other and with earlier chapters: rank inequalities, direct sums, determinants, transposes, and inner products. The first three are review prompts: state a main result, prove it without looking, and then answer a question that the text did not ask. The rest are ordered roughly by difficulty. Problems that use the minimal polynomial or complexification go beyond the course and are marked, and problems of kind "competition" are harder than anything the course expects. Section 7.7 compares the techniques these problems call for.

Review: state and prove

Problem 7.1. STANDARD

(a) State the theorem on eigenvectors for distinct eigenvalues.

(b) Prove it twice: by applying products of the operators $T - \lambda_j \operatorname{id}$ to a relation, and by a relation of minimal length.

(c) Let V be the real vector space of infinitely differentiable functions $\mathbb{R} \to \mathbb{R}$, and $D^2 \in \mathrm{L}(V)$ the second derivative. Show that $1, \cos x, \cos 2x, \ldots, \cos nx$ are linearly independent. Then show that the $2n + 1$ functions $1, \cos x, \sin x, \ldots, \cos nx, \sin nx$ are linearly independent, although $\cos kx$ and $\sin kx$ are eigenvectors of D^2 for the same eigenvalue.

Solution on page 1620

Problem 7.2. STANDARD

(a) State the criteria for diagonalizability in terms of eigenspaces and of multiplicities.

(b) Prove that T is diagonalizable if and only if $\operatorname{gm}(\lambda_1) + \cdots + \operatorname{gm}(\lambda_m) = \dim V$, and that this holds if and only if p_T splits and $\operatorname{gm}(\lambda_i) = \operatorname{am}(\lambda_i)$ for every i.

(c) Let $B \in F^{k\times k}$ and $D \in F^{l\times l}$ be diagonalizable with no common eigenvalue, and let $C \in F^{k\times l}$. Show that $M = \begin{pmatrix} B & C \\ 0 & D \end{pmatrix}$ is diagonalizable. Show that the hypothesis on eigenvalues cannot be dropped.

Solution on page 1621

Problem 7.3. STANDARD

(a) State the proposition on chains $\mathbf{v}, N\mathbf{v}, \ldots, N^k\mathbf{v}$ with $N = T - \lambda\,\mathrm{id}$, and what it says about the last vector and the span of the chain.

(b) Prove that the chain is independent and that $N^k\mathbf{v}$ is an eigenvector.

(c) Let V be a complex vector space with $\dim V = n \geq 1$, and let $T \in \mathrm{L}(V)$ satisfy $p_T = (x-\lambda)^n$ and $\mathrm{gm}_T(\lambda) = 1$. Show that $(T - \lambda\,\mathrm{id})^{n-1} \neq 0$, and that V has a basis in which the matrix of T has every diagonal entry λ, every entry just above the diagonal 1, and all other entries 0.

Solution on page 1622

Synthesis problems

Problem 7.4. STANDARD Let $A = \begin{pmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$. Find all T_A-invariant subspaces of $\mathbb{Q}^3$. Begin by showing that every invariant subspace U satisfies $U = (U \cap G) \oplus (U \cap E)$, where $G = \ker(A - 2I_3)^2$ and $E = \ker(A - 3I_3)$.

Solution on page 1622

Problem 7.5. STANDARD Let $A, B, N \in \mathbb{C}^{n\times n}$ with $n \geq 1$. Prove or disprove:

(a) If A^2 is similar to A, then every eigenvalue of A is 0 or a root of unity.

(b) If A^2 is similar to B^2, then A is similar to B.

(c) If A is invertible and $A + A^{-1}$ is diagonalizable, then A is diagonalizable.

(d) If N is nilpotent and $I_n + N$ is diagonalizable, then $N = 0$.

Solution on page 1623

Problem 7.6. STANDARD Let $A \in F^{n\times n}$ and $M = \begin{pmatrix} A & A \\ A & A \end{pmatrix} \in F^{2n\times 2n}$.

(a) Show that $p_M = x^n p_{2A}$ over every field.

(b) Suppose $1 + 1 \neq 0$ in F. Show that M is similar to $\begin{pmatrix} 2A & 0 \\ 0 & 0 \end{pmatrix}$, and that M is diagonalizable if and only if A is.

(c) Over $\mathbb{F}_2$, show that $M^2 = 0$, and that M is diagonalizable if and only if $A = 0$.

Solution on page 1623

Problem 7.7. STANDARD Let $A \in F^{n\times n}$.

(a) Suppose $A\mathbf{v} = \lambda\mathbf{v}$ and $A^{\mathsf{T}}\mathbf{w} = \mu\mathbf{w}$ with $\lambda \neq \mu$. Show that $\mathbf{w}^{\mathsf{T}}\mathbf{v} = 0$. (Over $\mathbb{R}$, this says $\mathbf{v} \perp \mathbf{w}$ for the dot product.)

(b) Suppose $A = SDS^{-1}$ with $D = \mathrm{diag}(\lambda_1, \ldots, \lambda_n)$, let $\mathbf{v}_1, \ldots, \mathbf{v}_n$ be the columns of S, and let $\mathbf{w}_1^{\mathsf{T}}, \ldots, \mathbf{w}_n^{\mathsf{T}}$ be the rows of S^{-1}. Show that $A^{\mathsf{T}}\mathbf{w}_i = \lambda_i\mathbf{w}_i$, that $\mathbf{w}_i^{\mathsf{T}}\mathbf{v}_j$ is 1 if $i = j$ and 0 otherwise, and that

$$A = \sum_{i=1}^{n} \lambda_i \mathbf{v}_i \mathbf{w}_i^{\mathsf{T}}.$$

(c) With $P_i = \mathbf{v}_i\mathbf{w}_i^{\mathsf{T}}$, show that $P_iP_j = 0$ for $i \neq j$, $P_i^2 = P_i$, $P_1 + \cdots + P_n = I_n$, and $A^k = \sum_i \lambda_i^k P_i$ for $k \geq 0$.

Solution on page 1624

Problem 7.8. STANDARD For $n \geq 1$, let $A_n \in \mathbb{R}^{n\times n}$ have entries 1 just above and just below the diagonal and 0 elsewhere.

(a) For $\theta \in \mathbb{R}$, let $\mathbf{v} = (\sin\theta, \sin 2\theta, \ldots, \sin n\theta)$. Show that $A_n\mathbf{v} = 2\cos\theta \cdot \mathbf{v} - \sin((n+1)\theta)\mathbf{e}_n$.

(b) Deduce that the eigenvalues of A_n are $2\cos(k\pi/(n+1))$ for $k = 1, \ldots, n$, and that A_n is diagonalizable.

(c) Compute $\det A_n$ from the tridiagonal recurrence, and deduce the value of $\prod_{k=1}^{n} 2\cos(k\pi/(n+1))$.

Solution on page 1625

Problem 7.9. STANDARD BEYOND 21-242 Let V be finite-dimensional and $T \in \mathrm{L}(V)$. For $\mathbf{v} \in V$, let $p_\mathbf{v}$ be the monic polynomial of least degree with $p_\mathbf{v}(T)\mathbf{v} = \mathbf{0}$ (for $\mathbf{v} \neq \mathbf{0}$ it is the polynomial of Proposition 7.2.35, and $p_\mathbf{0} = 1$).

(a) Show that $f(T)\mathbf{v} = \mathbf{0}$ if and only if $p_\mathbf{v}$ divides f.

(b) Let $\mathbf{b}_1, \ldots, \mathbf{b}_n$ be a basis of V. Show that $f(T) = 0$ if and only if every $p_{\mathbf{b}_i}$ divides f. Deduce that m_T is the monic polynomial of least degree divisible by $p_{\mathbf{b}_1}, \ldots, p_{\mathbf{b}_n}$.

(c) Use (b) with the standard basis to find m_A for $A = \begin{pmatrix} 3 & 1 & -1 \\ 0 & 2 & 0 \\ 1 & 1 & 1 \end{pmatrix} \in \mathbb{Q}^{3\times 3}$, and decide whether A is diagonalizable.

Solution on page 1625

Problem 7.10. STANDARD

(a) Show that every $A \in \mathbb{C}^{n\times n}$ is the sum of two diagonalizable matrices.

(b) Write $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ explicitly as such a sum.

(c) Show that every $A \in \mathbb{C}^{n\times n}$ is the sum of two invertible matrices.

Solution on page 1626

Problem 7.11. HARD Let $A \in \mathbb{R}^{n\times n}$ satisfy $A^2 = -I_n$.

(a) Show that n is even, say $n = 2m$, and that $\mathbb{R}^n$ has a basis $\mathbf{v}_1, \ldots, \mathbf{v}_m, A\mathbf{v}_1, \ldots, A\mathbf{v}_m$.

(b) Deduce that A is similar to $J = \begin{pmatrix} 0 & -I_m \\ I_m & 0 \end{pmatrix}$, so that any two real matrices of the same size with square $-I$ are similar.

Solution on page 1626

Problem 7.12. HARD Let $n \geq 1$, $V = F[x]_{\leq n}$, and $T \in \mathrm{L}(V)$, $T(f) = f(x+1)$ (Definition 7.1.9). Let $\Delta = T - \mathrm{id}_V$.

(a) Let $F = \mathbb{Q}$. Show that $\deg \Delta f = \deg f - 1$ for every nonconstant f, that $x^n, \Delta x^n, \ldots, \Delta^n x^n$ is a basis of V, and that T has 1 as its only eigenvalue, with $\mathrm{gm}(1) = 1$. Is T diagonalizable?

(b) Let $F = \mathbb{F}_p$ with p prime and $n \geq p$. Show that $T^p = \mathrm{id}_V$ and $\Delta^p = 0$, and that $\mathrm{gm}(1) \geq 2$.

Solution on page 1627

Problem 7.13. HARD For $A, B \in F^{n\times n}$, let $L \in \mathrm{L}(F^{n\times n})$ be $L(X) = AXB$.

(a) Show that if $A\mathbf{v} = \lambda\mathbf{v}$ and $B^{\mathsf{T}}\mathbf{w} = \mu\mathbf{w}$ with $\mathbf{v}, \mathbf{w} \neq \mathbf{0}$, then $\mathbf{v}\mathbf{w}^{\mathsf{T}}$ is an eigenvector of L with eigenvalue $\lambda\mu$.

(b) Suppose A and B are diagonalizable, with eigenvalues $\lambda_1, \ldots, \lambda_n$ and $\mu_1, \ldots, \mu_n$ counted with multiplicity. Show that L is diagonalizable with eigenvalues $\lambda_i\mu_j$ $(1 \leq i, j \leq n)$, and deduce $\operatorname{tr} L = \operatorname{tr} A \operatorname{tr} B$ and $\det L = (\det A)^n (\det B)^n$.

(c) Show that $\det L = (\det A)^n (\det B)^n$ for all A, B, over every field.

Solution on page 1628

Problem 7.14. HARD BEYOND 21-242 Find the error in the following argument, and then prove the claim correctly.

Claim. Let V be finite-dimensional, let $T \in \mathrm{L}(V)$ be diagonalizable, let U be a T-invariant subspace, and let W be any complement of U. Then the compression $S = \mathrm{Pr}_{W,U} \circ T\restriction_W \in \mathrm{L}(W)$ (Lemma 7.5.11) is diagonalizable, and its eigenvalues are eigenvalues of T.

"Proof." S is the restriction of T to W, and the restriction of a diagonalizable operator is diagonalizable (Corollary 7.6.16). Every eigenvector of S is an eigenvector of T with the same eigenvalue.

Solution on page 1628

Problem 7.15. HARD BEYOND 21-242 Let $V \neq \{\mathbf{0}\}$ be a finite-dimensional complex vector space and $T \in \mathrm{L}(V)$, with $m_T = (x - \lambda_1)^{k_1} \cdots (x - \lambda_r)^{k_r}$ for distinct λ_i. With $p_{\mathbf{v}}$ as in Problem 7.9, show that there is $\mathbf{v} \in V$ with $p_{\mathbf{v}} = m_T$. Deduce that $\dim K_T(\mathbf{v}) = \deg m_T$, and that V has a cyclic vector (a $\mathbf{v}$ with $K_T(\mathbf{v}) = V$) if and only if $m_T = p_T$.

Solution on page 1629

Problem 7.16. HARD Does there exist $A \in \mathbb{R}^{3\times 3}$ with $\operatorname{tr} A = 0$ and $A^2 + A^{\mathsf{T}} = I_3$?

Solution on page 1630

Problem 7.17. HARD BEYOND 21-242 Let $n \geq 2$, and let $A, B \in \mathbb{R}^{n\times n}$ be invertible with $A + B$ invertible and

$$A^{-1} + B^{-1} = (A + B)^{-1}.$$

Show that $\det A = \det B$. Does the same conclusion hold for complex matrices?

Solution on page 1630

Problem 7.18. CHALLENGE Let $A, B \in \mathbb{R}^{n\times n}$ satisfy $A^2 + B^2 = AB$, and suppose $AB - BA$ is invertible. Show that n is divisible by 3.

Solution on page 1631

Chapter 8

The spectral theorems

Self-adjoint and normal operators, the real and complex spectral theorems, positive operators, and isometries.

8.1 Self-adjoint and normal operators

An operator with an orthonormal basis of eigenvectors is the best kind of operator to have on an inner product space. In that basis it is a diagonal matrix, coordinates are inner products (Proposition 6.3.18), and lengths are computed by Pythagoras. This chapter determines which operators have such a basis. The answer, proved in Section 8.2, depends on the field: over $\mathbb{R}$ they are the self-adjoint operators, and over $\mathbb{C}$ they are the *normal* operators, the ones that commute with their adjoint. This section studies the two classes before that theorem is available. Self-adjoint operators have real eigenvalues and mutually orthogonal eigenspaces, and on a nonzero finite-dimensional real space they always have an eigenvalue. Normal operators are exactly the operators T for which T and T^* stretch every vector by the same amount, and this one fact gives them orthogonal eigenspaces as well.

Throughout, V is an inner product space over $\mathbb{F}$, where $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$, and we write $T\mathbf{v}$ for $T(\mathbf{v})$. Whenever T^* appears, T is assumed to have an adjoint; by Theorem 6.6.15 this is automatic when V is finite-dimensional. Results that need finite dimension say so.

8.1.1 Self-adjoint operators and their eigenvalues

Recall that $T \in \mathrm{L}(V)$ is self-adjoint if $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w} \in V$ (Definition 6.6.26), and that in an orthonormal basis this says that the matrix of T is Hermitian (Corollary 6.6.28). Section 6.6.5 collected examples: orthogonal projections, the operators T^*T, and the maps $\mathbf{x} \mapsto A\mathbf{x}$ for real symmetric and complex Hermitian matrices A. Over $\mathbb{C}$, the self-adjoint operators are the ones whose values $\langle T\mathbf{v}, \mathbf{v}\rangle$ are all real (Proposition 6.6.30). Their eigenvalues are real as well, and this is the first thing the defining identity gives when we feed it eigenvectors.

Intuition. If $T\mathbf{v} = \lambda\mathbf{v}$, then T acts on $\mathbf{v}$ as the scalar λ, and the defining identity $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle$ moves this scalar from the first slot to the second. Pulled out of the first slot it is λ; pulled out of the second it is $\overline{\lambda}$ (Proposition 6.1.4). So $\lambda = \overline{\lambda}$. With eigenvectors $\mathbf{v}$ and $\mathbf{w}$ for two different eigenvalues, the same identity, applied to the pair, gives $\lambda\langle \mathbf{v}, \mathbf{w}\rangle = \mu\langle \mathbf{v}, \mathbf{w}\rangle$, and that forces $\langle \mathbf{v}, \mathbf{w}\rangle = 0$.

Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators). Let $T \in \mathrm{L}(V)$ be self-adjoint.

(a) Every eigenvalue of T is real.

(b) If $T\mathbf{v} = \lambda\mathbf{v}$ and $T\mathbf{w} = \mu\mathbf{w}$ with $\lambda \neq \mu$, then $\langle \mathbf{v}, \mathbf{w}\rangle = 0$. That is, eigenspaces of T for distinct eigenvalues are orthogonal: every vector of one is orthogonal to every vector of the other.

Proof (by moving T across the inner product). ROUTINE

Uses. Definition 6.6.26 (Self-adjoint operator), Definition 7.2.6 (Eigenvalue, eigenvector), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm), Notation 6.1.1 (Real and complex scalars)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. Let $\mathbf{v}$ be an eigenvector for λ. Compute $\langle T\mathbf{v}, \mathbf{v}\rangle$ and $\langle \mathbf{v}, T\mathbf{v}\rangle$ separately.
Hint 2. The first is $\lambda\|\mathbf{v}\|^2$ and the second is $\overline{\lambda}\|\mathbf{v}\|^2$, and $\|\mathbf{v}\| \neq 0$.
Hint 3. For (b), compute both sides of $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle$, and use (a) to drop the conjugate on μ.
Sketch. (a) $\lambda\|\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\lambda}\|\mathbf{v}\|^2$, and $\mathbf{v} \neq \mathbf{0}$, so $\lambda = \overline{\lambda}$. (b) $\lambda\langle \mathbf{v}, \mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle = \overline{\mu}\langle \mathbf{v}, \mathbf{w}\rangle = \mu\langle \mathbf{v}, \mathbf{w}\rangle$, and $\lambda \neq \mu$.

(a) Let λ be an eigenvalue of T and $\mathbf{v}$ an eigenvector for it. Then

$$\lambda\|\mathbf{v}\|^2 = \langle \lambda\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \langle \mathbf{v}, \lambda\mathbf{v}\rangle = \overline{\lambda}\|\mathbf{v}\|^2,$$

where the middle equality is self-adjointness and the last uses Proposition 6.1.4. Since $\mathbf{v} \neq \mathbf{0}$, $\|\mathbf{v}\|^2 \neq 0$ (Proposition 6.1.27), so $\lambda = \overline{\lambda}$, which says that $\lambda \in \mathbb{R}$ (Notation 6.1.1). Over $\mathbb{R}$ there was nothing to prove.

(b) By (a), μ is real, so

$$\lambda\langle \mathbf{v}, \mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T\mathbf{w}\rangle = \overline{\mu}\langle \mathbf{v}, \mathbf{w}\rangle = \mu\langle \mathbf{v}, \mathbf{w}\rangle.$$

Hence $(\lambda - \mu)\langle \mathbf{v}, \mathbf{w}\rangle = 0$, and $\lambda \neq \mu$ gives $\langle \mathbf{v}, \mathbf{w}\rangle = 0$. If $\mathbf{v} \in E_\lambda$ and $\mathbf{w} \in E_\mu$ are arbitrary, then either one of them is $\mathbf{0}$, and $\langle \mathbf{v}, \mathbf{w}\rangle = 0$ trivially, or both are eigenvectors and the computation applies. So E_λ and E_μ are orthogonal. □

Proof (for (a), through the values $\langle T\mathbf{v}, \mathbf{v}\rangle$). ROUTINE

Uses. Definition 6.6.26 (Self-adjoint operator), Proposition 6.6.30 (Self-adjoint means real values), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. For self-adjoint T, every number $\langle T\mathbf{v}, \mathbf{v}\rangle$ is real. Express an eigenvalue through such a number.
Hint 2. If $T\mathbf{v} = \lambda\mathbf{v}$, then $\langle T\mathbf{v}, \mathbf{v}\rangle = \lambda\|\mathbf{v}\|^2$.
Sketch. $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v}, \mathbf{v}\rangle}$ is real for every $\mathbf{v}$. For an eigenvector, $\lambda = \langle T\mathbf{v}, \mathbf{v}\rangle/\|\mathbf{v}\|^2$ is a real number divided by a positive one.

For every $\mathbf{v} \in V$, self-adjointness and conjugate symmetry give $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v}, \mathbf{v}\rangle}$, so $\langle T\mathbf{v}, \mathbf{v}\rangle \in \mathbb{R}$. (This is the easy direction of Proposition 6.6.30; it needs neither $\mathbb{C}$ nor finite dimension.) If $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\langle T\mathbf{v}, \mathbf{v}\rangle = \lambda\|\mathbf{v}\|^2$, so

$$\lambda = \frac{\langle T\mathbf{v}, \mathbf{v}\rangle}{\|\mathbf{v}\|^2}$$

is a real number divided by a positive real number (Proposition 6.1.27), hence real. □

The second proof shows where eigenvalues live. The function $\mathbf{v} \mapsto \langle T\mathbf{v}, \mathbf{v}\rangle/\|\mathbf{v}\|^2$ on nonzero vectors, the *Rayleigh quotient* of T, takes only real values, and at an eigenvector it equals the eigenvalue. So every eigenvalue of T lies between the infimum and the supremum of the Rayleigh quotient. Section 12.3 shows that in finite dimensions the smallest and largest eigenvalues are exactly the minimum and maximum of the Rayleigh quotient.

Example 8.1.2 (A Hermitian 2×2 matrix). Let $A = \begin{pmatrix} 2 & 1-i \\ 1+i & 3 \end{pmatrix}$, which is Hermitian (Example 6.6.27). Its characteristic polynomial is

$$p_A = (x-2)(x-3) - (1-i)(1+i) = x^2 - 5x + 4 = (x-1)(x-4),$$

so its eigenvalues are 1 and 4, real although the entries of A are not. For $\lambda = 1$, the first row of $A - I_2 = \begin{pmatrix} 1 & 1-i \\ 1+i & 2 \end{pmatrix}$ gives $x_1 + (1-i)x_2 = 0$, and the second row is $1+i$ times the first, so $E_1 = \operatorname{span}((-1+i, 1))$. For $\lambda = 4$, the first row of $A - 4I_2 = \begin{pmatrix} -2 & 1-i \\ 1+i & -1 \end{pmatrix}$ gives $E_4 = \operatorname{span}((1-i, 2))$. As predicted,

$$(-1+i, 1) \cdot (1-i, 2) = (-1+i)\overline{(1-i)} + 2 = (-1+i)(1+i) + 2 = -2 + 2 = 0.$$

The squared norms are 3 and 6, so $\mathbf{u}_1 = \frac{1}{\sqrt{3}}(-1+i, 1)$, $\mathbf{u}_2 = \frac{1}{\sqrt{6}}(1-i, 2)$ is an orthonormal basis of $\mathbb{C}^2$ consisting of eigenvectors, and with the unitary matrix U whose columns are $\mathbf{u}_1$ and $\mathbf{u}_2$, we get $U^* A U = \operatorname{diag}(1, 4)$.

Part (b) says nothing about two eigenvectors for the *same* eigenvalue: for the identity, every nonzero vector is an eigenvector. An orthonormal list of eigenvectors is obtained by choosing an orthonormal basis inside each eigenspace, with Gram–Schmidt (Algorithm 6.4.14), and Exercise 8.1.23 does this in an example.

Real self-adjoint operators have eigenvalues

Over $\mathbb{R}$, part (a) of Proposition 8.1.1 has no content, since the eigenvalues of an operator on a real space are real by definition. The real question is whether there are any; the rotation by $\pi/2$ has none (Example 7.2.18). Self-adjoint operators always do. The idea is to let a real symmetric matrix act on $\mathbb{C}^n$, where eigenvalues exist, and to apply part (a) there.

Theorem 8.1.3 (Self-adjoint operators have eigenvalues). Let V be a finite-dimensional inner product space with $V \neq \{\mathbf{0}\}$, and let $T \in \mathrm{L}(V)$ be self-adjoint. Then T has an eigenvalue, and it is real. In particular, every real symmetric matrix $A \in \mathbb{R}^{n \times n}$ with $n \geq 1$ has a real eigenvalue.

Proof (by letting the matrix act on $\mathbb{C}^n$). STANDARD

Uses. Theorem 6.4.20 (Orthonormal bases exist), Corollary 6.6.28 (Self-adjointness in an orthonormal basis), Example 6.6.10 (The adjoint of a matrix), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Definition 7.3.12 (Characteristic polynomial of an operator), Corollary 7.3.13 (Eigenvalues of an operator)
Techniques. Pass to orthonormal coordinates (Technique 6.7.2)
Hint 1. Over $\mathbb{C}$ this is Theorem 7.3.27 together with Proposition 8.1.1(a). For $\mathbb{R}$, pass to the matrix A of T in an orthonormal basis.
Hint 2. A is real and symmetric. Regard it as a complex matrix acting on $\mathbb{C}^n$ with the dot product. What kind of operator is $\mathbf{x} \mapsto A\mathbf{x}$ there?
Hint 3. That operator is self-adjoint on $\mathbb{C}^n$, so it has an eigenvalue λ, which is real. Now λ is a real root of $p_A = p_T$.
Sketch. Choose an orthonormal basis $\mathcal{O}$; then $A = [T]_{\mathcal{O}}$ is Hermitian. On $\mathbb{C}^n$ with the dot product, T_A is self-adjoint since $A^* = A$, so it has an eigenvalue λ (Theorem 7.3.27), which is real by Proposition 8.1.1(a). Hence λ is a root of p_A, which is the same polynomial whether A is read as real or complex, and $p_A = p_T$. So $\lambda \in \mathbb{F}$ is a root of p_T, hence an eigenvalue of T.

Let $n = \dim V \geq 1$. By Theorem 6.4.20, V has an orthonormal basis $\mathcal{O}$, and $A = [T]_{\mathcal{O}} \in \mathbb{F}^{n \times n}$ satisfies $A^* = A$ by Corollary 6.6.28. Regard A as an element of $\mathbb{C}^{n \times n}$; when $\mathbb{F} = \mathbb{R}$ its entries are real and still $A^* = A^{\mathsf{T}} = A$. By Example 6.6.10, the operator $T_A : \mathbf{x} \mapsto A\mathbf{x}$ on $\mathbb{C}^n$ with the dot product has adjoint $T_{A^*} = T_A$, so it is self-adjoint. By Theorem 7.3.27, T_A has an eigenvalue $\lambda \in \mathbb{C}$, and $\lambda \in \mathbb{R}$ by Proposition 8.1.1(a). By Theorem 7.3.6, $p_A(\lambda) = 0$.

The polynomial $p_A = \det(xI_n - A)$ is computed from the entries of A alone, so it is the same polynomial whether A is regarded as a real or a complex matrix, and it equals p_T (Definition 7.3.12). So λ is a root of p_T lying in $\mathbb{R} \subseteq \mathbb{F}$, and by Corollary 7.3.13 it is an eigenvalue of T. It is real by Proposition 8.1.1(a). The last sentence of the theorem is the case $V = \mathbb{R}^n$ with the dot product and $T = T_A$, which is self-adjoint by Example 6.6.10. □

The proof shows more. Every complex root of p_A is an eigenvalue of the self-adjoint operator T_A on $\mathbb{C}^n$, hence real, so by Corollary 7.1.35

$$p_A = (x-\lambda_1)(x-\lambda_2)\cdots(x-\lambda_n) \quad \text{with all } \lambda_j \in \mathbb{R}.$$

The characteristic polynomial of a Hermitian matrix, and in particular of a real symmetric matrix, splits over $\mathbb{R}$. This is what the real spectral theorem in Section 8.2 needs.

The first proof leans on determinants and lets a real matrix act on $\mathbb{C}^n$. The second avoids determinants and never complexifies the operator, although the factorization over $\mathbb{R}$ that it uses still rests on the Fundamental Theorem of Algebra. Following the determinant-free proof of Theorem 7.3.27, it factors a polynomial that kills a vector. Over $\mathbb{R}$ some factors may be quadratics without real roots, and these are exactly where a real operator can fail to have eigenvalues; for a self-adjoint operator they turn out to be injective, hence harmless.

Proof (without determinants). HARD BEYOND 21-242

> *Uses.* Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.1.39 (Factorization over $\mathbb{R}$), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 6.2.1 (Cauchy–Schwarz inequality), Theorem 7.2.9 (Eigenvalues and invertibility)
> *Techniques.* Krylov sequences must become dependent (Technique 7.3.28), A sum of nonnegative terms (Technique 6.1.9)
> *Hint 1.* Over $\mathbb{C}$, combine Theorem 7.3.27 with (a) of Proposition 8.1.1. Over $\mathbb{R}$, imitate the second proof of Theorem 7.3.27. What goes wrong over $\mathbb{R}$, and how could self-adjointness repair it?
> *Hint 2.* Over $\mathbb{R}$, the polynomial p with $p(T)\mathbf{v} = \mathbf{0}$ factors into linear factors and quadratics $x^2 + bx + c$ with $b^2 < 4c$ (Theorem 7.1.39). Show that each such quadratic gives an injective operator $T^2 + bT + c\,\mathrm{id}$.
> *Hint 3.* Compute $\langle (T^2 + bT + c\,\mathrm{id})\mathbf{v}, \mathbf{v}\rangle = \|T\mathbf{v}\|^2 + b\langle T\mathbf{v}, \mathbf{v}\rangle + c\|\mathbf{v}\|^2$, bound the middle term with Cauchy–Schwarz, and complete the square.
> *Sketch.* For $b^2 < 4c$ and $\mathbf{v} \neq \mathbf{0}$, $\langle (T^2 + bT + c\,\mathrm{id})\mathbf{v}, \mathbf{v}\rangle \geq (\|T\mathbf{v}\| - |b|\|\mathbf{v}\|/2)^2 + (c - b^2/4)\|\mathbf{v}\|^2 > 0$, so the quadratic factors are injective at T. Take $\mathbf{v} \neq \mathbf{0}$ and a monic p of positive degree with $p(T)\mathbf{v} = \mathbf{0}$ (Proposition 7.2.35). Factor p over $\mathbb{R}$. Then $p(T)$ is the composite of its factors evaluated at T, and it is not injective, so some linear factor $T - \lambda\,\mathrm{id}$ is not injective.

If $\mathbb{F} = \mathbb{C}$, then T has an eigenvalue by Theorem 7.3.27, and it is real by Proposition 8.1.1(a). So let $\mathbb{F} = \mathbb{R}$.

Quadratics without real roots are injective at T. Let $b, c \in \mathbb{R}$ with $b^2 < 4c$, and let $Q = T^2 + bT + c\,\mathrm{id}$. For $\mathbf{v} \in V$, self-adjointness gives $\langle T^2\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, T\mathbf{v}\rangle = \|T\mathbf{v}\|^2$, and Cauchy–Schwarz (Theorem 6.2.1) gives $b\langle T\mathbf{v}, \mathbf{v}\rangle \geq -|b|\|T\mathbf{v}\|\|\mathbf{v}\|$. Hence

$$\begin{aligned}\langle Q\mathbf{v}, \mathbf{v}\rangle &\geq \|T\mathbf{v}\|^2 - |b|\|T\mathbf{v}\|\|\mathbf{v}\| + c\|\mathbf{v}\|^2 \\ &= \left(\|T\mathbf{v}\| - \frac{|b|}{2}\|\mathbf{v}\|\right)^2 + \left(c - \frac{b^2}{4}\right)\|\mathbf{v}\|^2.\end{aligned}$$

If $\mathbf{v} \neq \mathbf{0}$, the last term is positive, so $\langle Q\mathbf{v}, \mathbf{v}\rangle > 0$ and $Q\mathbf{v} \neq \mathbf{0}$. So Q is injective.

Some linear factor is not injective. Fix $\mathbf{v} \in V$ with $\mathbf{v} \neq \mathbf{0}$. By Proposition 7.2.35 there is a monic $p \in \mathbb{R}[x]$ of degree $d \geq 1$ with $p(T)\mathbf{v} = \mathbf{0}$. By Theorem 7.1.39, and since p is monic,

$$p = (x-\lambda_1)\cdots(x-\lambda_k)\left(x^2 + b_1x + c_1\right)\cdots\left(x^2 + b_lx + c_l\right)$$

with $b_j^2 < 4c_j$ for each j. By Proposition 7.2.27(a),

$$p(T) = (T - \lambda_1\,\mathrm{id})\cdots(T - \lambda_k\,\mathrm{id})Q_1\cdots Q_l, \quad Q_j = T^2 + b_jT + c_j\,\mathrm{id}.$$

Each Q_j is injective by the first part. If every $T - \lambda_i\,\mathrm{id}$ were injective too (this includes the case $k = 0$), then $p(T)$ would be a composite of injective maps, hence injective, contradicting $p(T)\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$. So some $T - \lambda_i\,\mathrm{id}$ is not injective, and λ_i is an eigenvalue of T by Theorem 7.2.9. □

For the rotation $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ the Krylov polynomial of $\mathbf{e}_1$ is $x^2 + 1$, and $J^2 + \mathrm{id} = 0$ is as far from injective as possible. The positivity estimate is exactly what a rotation violates: $\langle J^2\mathbf{v}, \mathbf{v}\rangle = -\|\mathbf{v}\|^2$, whereas for self-adjoint T the term $\langle T^2\mathbf{v}, \mathbf{v}\rangle = \|T\mathbf{v}\|^2$ is never negative.

8.1.2 Testing self-adjoint operators on the diagonal

By Proposition 6.1.41, an operator T on a complex inner product space with $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$ is 0, and over $\mathbb{R}$ this fails for the rotation J (Example 6.1.39). The rotation is far from self-adjoint, and for self-adjoint operators the real case behaves like the complex one. We will need this to characterize normal operators over both fields at once.

> *Intuition.* Put $\mathbf{v} = \mathbf{x} + \mathbf{y}$ into $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$. Over either field the result is $\langle T\mathbf{x}, \mathbf{y}\rangle + \langle T\mathbf{y}, \mathbf{x}\rangle = 0$ (Proposition 6.1.41, first proof), and for J the two terms cancel without being 0. If T is self-adjoint, then $\langle T\mathbf{y}, \mathbf{x}\rangle = \langle \mathbf{y}, T\mathbf{x}\rangle$ is the conjugate of $\langle T\mathbf{x}, \mathbf{y}\rangle$, so the sum is $2\operatorname{Re}\langle T\mathbf{x}, \mathbf{y}\rangle$. Then $\operatorname{Re}\langle T\mathbf{x}, \mathbf{y}\rangle = 0$ for all $\mathbf{y}$, and the choice $\mathbf{y} = T\mathbf{x}$ gives $\|T\mathbf{x}\|^2 = 0$.

Proposition 8.1.4 (Self-adjoint operators are determined by their diagonal values). Let $T \in \mathrm{L}(V)$ be self-adjoint, where $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$. If $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v} \in V$, then $T = 0$. Consequently, if $S, T \in \mathrm{L}(V)$ are self-adjoint and $\langle S\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, \mathbf{v}\rangle$ for every $\mathbf{v} \in V$, then $S = T$.

Proof (by polarization). STANDARD

> *Uses.* Definition 6.6.26 (Self-adjoint operator), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm), Proposition 6.6.18 (Properties of the adjoint)
> *Techniques.* Polarization (Technique 6.1.33), Show a vector is zero via its norm (Technique 6.1.36)
> *Hint 1.* Expand $\langle T(\mathbf{x}+\mathbf{y}), \mathbf{x}+\mathbf{y}\rangle - \langle T(\mathbf{x}-\mathbf{y}), \mathbf{x}-\mathbf{y}\rangle$.
> *Hint 2.* With self-adjointness, the result is $4\operatorname{Re}\langle T\mathbf{x}, \mathbf{y}\rangle$. So $\operatorname{Re}\langle T\mathbf{x}, \mathbf{y}\rangle = 0$ for all $\mathbf{x}, \mathbf{y}$.
> *Hint 3.* Choose $\mathbf{y} = T\mathbf{x}$.
> *Sketch.* Expanding, and using $\langle T\mathbf{y}, \mathbf{x}\rangle = \langle \mathbf{y}, T\mathbf{x}\rangle = \overline{\langle T\mathbf{x}, \mathbf{y}\rangle}$, we get $0 = \langle T(\mathbf{x}+\mathbf{y}), \mathbf{x}+\mathbf{y}\rangle - \langle T(\mathbf{x}-\mathbf{y}), \mathbf{x}-\mathbf{y}\rangle = 4\operatorname{Re}\langle T\mathbf{x}, \mathbf{y}\rangle$. With $\mathbf{y} = T\mathbf{x}$ this is $4\|T\mathbf{x}\|^2$. For the last claim, apply this to $S - T$, which is self-adjoint.

Let $\mathbf{x}, \mathbf{y} \in V$. Expanding by linearity of T and sesquilinearity, the terms $\langle T\mathbf{x}, \mathbf{x}\rangle$ and $\langle T\mathbf{y}, \mathbf{y}\rangle$ cancel, and

$$\langle T(\mathbf{x}+\mathbf{y}), \mathbf{x}+\mathbf{y}\rangle - \langle T(\mathbf{x}-\mathbf{y}), \mathbf{x}-\mathbf{y}\rangle = 2\langle T\mathbf{x}, \mathbf{y}\rangle + 2\langle T\mathbf{y}, \mathbf{x}\rangle.$$

Since T is self-adjoint, $\langle T\mathbf{y}, \mathbf{x}\rangle = \langle \mathbf{y}, T\mathbf{x}\rangle = \overline{z}$, where $z = \langle T\mathbf{x}, \mathbf{y}\rangle$. So the right side is $2(z + \overline{z}) = 4\operatorname{Re} z$, and the left side is 0 by hypothesis. Hence $\operatorname{Re}\langle T\mathbf{x}, \mathbf{y}\rangle = 0$ for all $\mathbf{x}, \mathbf{y} \in V$. Taking $\mathbf{y} = T\mathbf{x}$ gives $\|T\mathbf{x}\|^2 = \operatorname{Re}\langle T\mathbf{x}, T\mathbf{x}\rangle = 0$, so $T\mathbf{x} = \mathbf{0}$ (Proposition 6.1.27). As $\mathbf{x}$ was arbitrary, $T = 0$.

For the last statement, $S - T$ is self-adjoint, since $(S-T)^* = S^* - T^* = S - T$ by (a) and (b) of Proposition 6.6.18, and $\langle (S-T)\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, \mathbf{v}\rangle - \langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$. So $S - T = 0$. □

Proof (with the test vector $\mathbf{v} + T\mathbf{v}$). STANDARD

> *Uses.* Definition 6.6.26 (Self-adjoint operator), Proposition 6.1.4 (Sesquilinearity), Proposition 6.1.27 (Basic properties of the norm)
> *Techniques.* Plug in clever test vectors (Technique 6.1.40), Show a vector is zero via its norm (Technique 6.1.36)
> *Hint 1.* We want $\|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = \langle T^2\mathbf{v}, \mathbf{v}\rangle$ to vanish. Feed the hypothesis a vector built from $\mathbf{v}$ and $T\mathbf{v}$.
> *Hint 2.* Try $\mathbf{v} + T\mathbf{v}$. Two of the four terms in the expansion vanish by the hypothesis, applied at $\mathbf{v}$ and at $T\mathbf{v}$.
> *Sketch.* $\langle T(\mathbf{v}+T\mathbf{v}), \mathbf{v}+T\mathbf{v}\rangle = \langle T\mathbf{v}, \mathbf{v}\rangle + \langle T\mathbf{v}, T\mathbf{v}\rangle + \langle T^2\mathbf{v}, \mathbf{v}\rangle + \langle T(T\mathbf{v}), T\mathbf{v}\rangle$. The first and last terms vanish by hypothesis, and $\langle T^2\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, T\mathbf{v}\rangle$ by self-adjointness, so $0 = 2\|T\mathbf{v}\|^2$.

Let $\mathbf{v} \in V$ and put $\mathbf{w} = T\mathbf{v}$. Applying the hypothesis to $\mathbf{v} + \mathbf{w}$ and expanding,

$$0 = \langle T\mathbf{v}, \mathbf{v}\rangle + \langle T\mathbf{v}, \mathbf{w}\rangle + \langle T\mathbf{w}, \mathbf{v}\rangle + \langle T\mathbf{w}, \mathbf{w}\rangle.$$

The first and last terms are 0 by hypothesis, applied at $\mathbf{v}$ and at $\mathbf{w}$. The second is $\langle T\mathbf{v}, T\mathbf{v}\rangle = \|T\mathbf{v}\|^2$, and the third is $\langle T(T\mathbf{v}), \mathbf{v}\rangle = \langle T\mathbf{v}, T\mathbf{v}\rangle = \|T\mathbf{v}\|^2$ because T is self-adjoint. So $2\|T\mathbf{v}\|^2 = 0$, and $T\mathbf{v} = \mathbf{0}$ (Proposition 6.1.27). The last statement follows as in the first proof. □

The first proof is the polarization argument of Proposition 6.1.41, with self-adjointness supplying the second equation that the scalar i supplied there. The second proof chooses its test vector by looking at the goal. We want $\|T\mathbf{v}\|^2$, which by self-adjointness is $\langle T^2\mathbf{v}, \mathbf{v}\rangle$, and $\mathbf{v} + T\mathbf{v}$ is the simplest vector whose expansion contains that term.

Without self-adjointness, the real case is described by Exercise 6.1.52(b): an operator T on a real inner product space satisfies $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$ exactly when $\langle T\mathbf{v}, \mathbf{w}\rangle = -\langle \mathbf{v}, T\mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w}$, that is, when $T^* = -T$. The rotation J is of this kind, and such operators have a name.

Definition 8.1.5 (Skew-adjoint operators, skew-Hermitian matrices). An operator $T \in \mathrm{L}(V)$ is **skew-adjoint** if it has an adjoint and $T^* = -T$. A matrix $A \in \mathbb{F}^{n\times n}$ is **skew-Hermitian** if $A^* = -A$. A real skew-Hermitian matrix, one with $A^{\mathsf{T}} = -A$, is **skew-symmetric**.

The matrices $\begin{pmatrix} 0 & -b \\ b & 0 \end{pmatrix}$ with $b \in \mathbb{R}$, among them J, are skew-symmetric, and every skew-symmetric matrix has zeros on its diagonal. A skew-Hermitian matrix has purely imaginary diagonal entries, as in $\begin{pmatrix} i & 1+i \\ -1+i & 0 \end{pmatrix}$. Differentiation on trigonometric polynomials is skew-adjoint (Exercise 6.6.39). Over $\mathbb{C}$, T is skew-adjoint if and only if iT is self-adjoint, because $(iT)^* = -iT^*$ (Proposition 6.6.18(b)). For every T, the operator $T - T^*$ is skew-adjoint.

Over $\mathbb{R}$, every operator T splits as $T = S + K$ with $S = (T + T^*)/2$ self-adjoint and $K = (T - T^*)/2$ skew-adjoint, and $\langle K\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$. So $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, \mathbf{v}\rangle$, and by Proposition 8.1.4 these values determine S and nothing more. The values $\langle T\mathbf{v}, \mathbf{v}\rangle$ see exactly the self-adjoint part of a real operator.

Exercise 8.1.6. ROUTINE Let $K \in \mathrm{L}(V)$ be skew-adjoint and $c \in \mathbb{R}$. Show that

$$\|(K - c\,\mathrm{id})\mathbf{v}\|^2 = \|K\mathbf{v}\|^2 + c^2\|\mathbf{v}\|^2 \quad \text{for every } \mathbf{v} \in V.$$

Deduce that K has no nonzero real eigenvalue, and that $\mathrm{id} + K$ is injective.

Solution on page 1631

8.1.3 Normal operators

Suppose V is finite-dimensional and has an orthonormal basis $\mathcal{O}$ of eigenvectors of T. What does this force on T? In the basis $\mathcal{O}$, T is a diagonal matrix D, and T^* is D^*, which is diagonal too. Diagonal matrices commute, so T and T^* commute. Over $\mathbb{R}$, moreover, $D^* = D$.

Proposition 8.1.7 (What an orthonormal eigenbasis forces). Let V be finite-dimensional and $T \in \mathrm{L}(V)$. Suppose that V has an orthonormal basis consisting of eigenvectors of T. Then $T^*T = TT^*$. If moreover every eigenvalue of T is real, which is automatic when $\mathbb{F} = \mathbb{R}$, then T is self-adjoint.

Proof. ROUTINE

Uses. Theorem 6.6.15 (Existence of adjoints), Definition 6.3.26 (Conjugate transpose), Theorem 2.4.2 (The matrix of a composite), Theorem 2.3.20 (Linear maps correspond to matrices)
Techniques. Pass to orthonormal coordinates (Technique 6.7.2), Translate between maps and matrices (Technique 2.3.27)
Hint 1. Write down the matrix D of T in the given basis, and use Theorem 6.6.15(b) for the matrix of T^*.
Hint 2. D^* is diagonal with entries $\overline{\lambda_j}$, and diagonal matrices commute.
Sketch. $[T]_{\mathcal{O}} = D = \mathrm{diag}(\lambda_1, \ldots, \lambda_n)$, so $[T^*]_{\mathcal{O}} = D^* = \mathrm{diag}\big(\overline{\lambda_1}, \ldots, \overline{\lambda_n}\big)$. Then $[T^*T]_{\mathcal{O}} = D^*D = DD^* = [TT^*]_{\mathcal{O}}$, so $T^*T = TT^*$. If all λ_j are real, $D^* = D$ and $T^* = T$.

Let $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ be the orthonormal basis, with $T\mathbf{u}_j = \lambda_j\mathbf{u}_j$. Then $[T]_{\mathcal{O}} = D = \mathrm{diag}(\lambda_1, \ldots, \lambda_n)$, and by Theorem 6.6.15(b) and Definition 6.3.26, $[T^*]_{\mathcal{O}} = D^* = \mathrm{diag}\big(\overline{\lambda_1}, \ldots, \overline{\lambda_n}\big)$. By Theorem 2.4.2, $[T^*T]_{\mathcal{O}} = D^*D$ and $[TT^*]_{\mathcal{O}} = DD^*$, and both equal $\mathrm{diag}\big(|\lambda_1|^2, \ldots, |\lambda_n|^2\big)$. So $T^*T = TT^*$ by Theorem 2.3.20. If every λ_j is real, then $D^* = D$, so $[T^*]_{\mathcal{O}} = [T]_{\mathcal{O}}$ and $T^* = T$. □

So orthonormal eigenbases occur only for operators that commute with their adjoints, and over $\mathbb{R}$ only for self-adjoint ones. The spectral theorems of Section 8.2 prove the converses in finite dimensions: over $\mathbb{C}$ the first condition suffices, and over $\mathbb{R}$ the second. Over $\mathbb{C}$, self-adjointness would be too much to ask, since a diagonal matrix such as $\mathrm{diag}(1, i)$ has an orthonormal eigenbasis without being Hermitian. The weaker condition gets a name.

Definition 8.1.8 (Normal operator, normal matrix). An operator $T \in \mathrm{L}(V)$ is **normal** if it has an adjoint and

$$T^*T = TT^*.$$

A matrix $A \in \mathbb{F}^{n\times n}$ is **normal** if $A^*A = AA^*$.

For $A \in \mathbb{F}^{n\times n}$, the operator T_A on $\mathbb{F}^n$ with the dot product is normal exactly when A is, because $(T_A)^* = T_{A^*}$ (Example 6.6.10) and the matrix of a composite is the product of the matrices.

Example 8.1.9 (Normal operators).

(a) Self-adjoint and skew-adjoint operators are normal: if $T^* = T$, then $T^*T = T^2 = TT^*$, and if $T^* = -T$, then $T^*T = -T^2 = TT^*$.

(b) Unitary matrices are normal, since $U^*U = I_n = UU^*$ by Proposition 6.3.34; in particular orthogonal matrices are normal. More generally, every operator with $T^*T = TT^* = \mathrm{id}$ is normal. These are the unitary operators (Definition 8.4.9) of Section 8.4.

(c) For $a, b \in \mathbb{R}$, the matrix $A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix} = aI_2 + bJ$ satisfies

$$A^{\mathsf{T}}A = \begin{pmatrix} a & b \\ -b & a \end{pmatrix}\begin{pmatrix} a & -b \\ b & a \end{pmatrix} = (a^2+b^2)I_2 = AA^{\mathsf{T}}.$$

When $a \neq 0$, $b \neq 0$, and $a^2 + b^2 \neq 1$, it is neither symmetric, skew-symmetric, nor orthogonal. Identifying $\mathbb{R}^2$ with $\mathbb{C}$ by $(x, y) \leftrightarrow x + iy$, the map $\mathbf{x} \mapsto A\mathbf{x}$ is multiplication by $a + bi$: it rotates by the argument of $a + bi$ and scales by $|a + bi|$.

(d) Every diagonal matrix D is normal, as $D^*D = DD^*$ is diagonal with entries $|d_{jj}|^2$. For instance $\mathrm{diag}(1, 2i)$ is normal but not Hermitian, not skew-Hermitian, and not unitary.

Non-example 8.1.10 (Operators that are not normal).

- The nilpotent $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$: here $N^*N = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ while $NN^* = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$.
- The shear $S = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ (Example 7.4.8), which is invertible: $S^{\mathsf{T}}S = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$ while $SS^{\mathsf{T}} = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$.
- $B = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$, which is diagonalizable, with eigenvectors $(1, 0)$ for 1 and $(1, 1)$ for 2: $B^{\mathsf{T}}B = \begin{pmatrix} 1 & 1 \\ 1 & 5 \end{pmatrix}$ while $BB^{\mathsf{T}} = \begin{pmatrix} 2 & 2 \\ 2 & 4 \end{pmatrix}$.
- The complex symmetric matrix $C = \begin{pmatrix} 1 & i \\ i & -1 \end{pmatrix}$ of Exercise 6.6.34: $C^*C = \begin{pmatrix} 2 & 2i \\ -2i & 2 \end{pmatrix}$ while $CC^* = \begin{pmatrix} 2 & -2i \\ 2i & 2 \end{pmatrix}$.

None of these has an orthonormal eigenbasis, by Proposition 8.1.7. For N, S, and C there is no eigenbasis at all: each has a single eigenvalue ($C^2 = 0$, so 0 is the only eigenvalue of C) and is not a multiple of the identity. The matrix B does have an eigenbasis, but its eigenspaces are two lines that are not perpendicular, so no choice of eigenvectors is orthogonal.

Sums of normal operators need not be normal: $N = (N + N^*)/2 + (N - N^*)/2$ is a sum of a self-adjoint and a skew-adjoint operator (Exercise 8.1.24). So the normal operators do not form a subspace of $\mathrm{L}(V)$, unlike the self-adjoint operators over $\mathbb{R}$.

Corollary 8.1.11 (Normality in an orthonormal basis). Let V be finite-dimensional, let $\mathcal{O}$ be an orthonormal basis of V, let $T \in \mathrm{L}(V)$, and let $A = [T]_{\mathcal{O}}$. Then T is normal, self-adjoint, skew-adjoint, or satisfies $T^*T = TT^* = \mathrm{id}$ if and only if A is normal, Hermitian, skew-Hermitian, or unitary, respectively.

Proof. ROUTINE

Uses. Theorem 6.6.15 (Existence of adjoints), Theorem 2.4.2 (The matrix of a composite), Theorem 2.3.20 (Linear maps correspond to matrices), Proposition 6.3.34 (Characterizations of unitary matrices), Example 2.3.6 (The zero map and the identity map)

Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Translate each operator identity into a matrix identity with $[T^*]_{\mathcal{O}} = A^*$ (Theorem 6.6.15(b)).
Hint 2. Two operators are equal if and only if their matrices in $\mathcal{O}$ are equal.
Sketch. $[T^*]_{\mathcal{O}} = A^*$, $[T^*T]_{\mathcal{O}} = A^*A$, $[TT^*]_{\mathcal{O}} = AA^*$, $[-T]_{\mathcal{O}} = -A$, and $[\mathrm{id}_V]_{\mathcal{O}} = I_n$. Since $T \mapsto [T]_{\mathcal{O}}$ is injective, each identity among operators holds iff the same identity holds among the matrices.

By Theorem 6.6.15(b), $[T^*]_{\mathcal{O}} = A^*$. By Theorem 2.4.2, $[T^*T]_{\mathcal{O}} = A^*A$ and $[TT^*]_{\mathcal{O}} = AA^*$; also $[-T]_{\mathcal{O}} = -A$, since every entry of the matrix of $-T$ is the negative of the corresponding entry of A, and $[\mathrm{id}_V]_{\mathcal{O}} = I_n$ (Example 2.3.6). By Theorem 2.3.20, two operators are equal if and only if their matrices in $\mathcal{O}$ are equal. So $T^*T = TT^*$ iff $A^*A = AA^*$, $T^* = T$ iff $A^* = A$, $T^* = -T$ iff $A^* = -A$, and $T^*T = TT^* = \mathrm{id}_V$ iff $A^*A = AA^* = I_n$, which by Proposition 6.3.34 says that A is unitary. □

Orthonormality matters here, as it did for Corollary 6.6.28. The matrix B of Non-example 8.1.10 is diagonal in the basis $(1,0), (1,1)$, so its matrix in that basis is normal, but T_B is not normal for the dot product.

Condition	Operator	Matrix	Eigenvalues
$T^* = T$	self-adjoint	Hermitian (symmetric)	real
$T^* = -T$	skew-adjoint	skew-Hermitian (skew-symmetric)	in $i\mathbb{R}$
$T^*T = TT^* = \mathrm{id}$	unitary	unitary (orthogonal)	$\lvert\lambda\rvert = 1$
$T^*T = TT^*$	normal	normal	any

Table 8.1.1. Four classes of normal operators. The third column names the matrix of the operator in an orthonormal basis (Corollary 8.1.11), with the name used for real matrices in parentheses. The last column is Corollary 8.1.20. Under the analogy between $T \mapsto T^*$ and $z \mapsto \overline{z}$ (Section 6.6.5), the rows correspond to the real numbers ($\overline{z} = z$), the imaginary numbers ($\overline{z} = -z$), the unit circle ($\overline{z}z = 1$), and all of $\mathbb{C}$, where $\overline{z}z = z\overline{z}$ always holds.

Exercise 8.1.12. ROUTINE Let $T \in \mathrm{L}(V)$ be normal and $c \in \mathbb{F}$. Show that T^*, cT, and T^k for $k \geq 1$ are normal. Show also that if T is invertible and T^{-1} has an adjoint, then T^{-1} is normal.

Solution on page 1632

8.1.4 Normal operators and their adjoints

The definition compares the operators T^*T and TT^*. Feeding both the same vector and taking an inner product with that vector turns this into a comparison of lengths.

Proposition 8.1.13 (Normal means $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$). Let $T \in \mathrm{L}(V)$ have an adjoint. Then T is normal if and only if

$$\|T\mathbf{v}\| = \|T^*\mathbf{v}\| \quad \text{for every } \mathbf{v} \in V.$$

Proof (through the diagonal values of $T^*T - TT^*$). STANDARD

Uses. Definition 6.6.8 (Adjoint), Proposition 6.6.18 (Properties of the adjoint), Proposition 8.1.4 (Self-adjoint operators are determined by their diagonal values), Definition 8.1.8 (Normal operator, normal matrix)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. Write $\|T\mathbf{v}\|^2$ and $\|T^*\mathbf{v}\|^2$ in the form $\langle X\mathbf{v}, \mathbf{v}\rangle$ for suitable operators X.
Hint 2. $\|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2 = \langle (T^*T - TT^*)\mathbf{v}, \mathbf{v}\rangle$. Which proposition turns "this vanishes for every $\mathbf{v}$" into "$T^*T - TT^* = 0$"? Check its hypothesis.
Sketch. Moving operators across, $\|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2 = \langle S\mathbf{v}, \mathbf{v}\rangle$ with $S = T^*T - TT^*$. The operator S is self-adjoint, so by Proposition 8.1.4, $S = 0$ if and only if $\langle S\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$.

For $\mathbf{v} \in V$, the defining identities of T^* and of $(T^*)^* = T$ (Proposition 6.6.18(c)) give

$$\|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = \langle T^*T\mathbf{v}, \mathbf{v}\rangle, \quad \|T^*\mathbf{v}\|^2 = \langle T^*\mathbf{v}, T^*\mathbf{v}\rangle = \langle TT^*\mathbf{v}, \mathbf{v}\rangle.$$

So $\|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2 = \langle S\mathbf{v}, \mathbf{v}\rangle$, where $S = T^*T - TT^*$. If T is normal, then $S = 0$ and the norms agree. Conversely, S is self-adjoint: by (a)–(d) of Proposition 6.6.18,

$$S^* = (T^*T)^* - (TT^*)^* = T^*(T^*)^* - (T^*)^*T^* = T^*T - TT^* = S.$$

If $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$ for every $\mathbf{v}$, then $\langle S\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$, and Proposition 8.1.4 gives $S = 0$. □

Proof (by polarization). STANDARD

Uses. Proposition 6.1.32 (Polarization identities), Corollary 6.1.38 (Linear maps are determined by inner products), Definition 6.6.8 (Adjoint), Proposition 6.6.18 (Properties of the adjoint)
Techniques. Polarization (Technique 6.1.33)
Hint 1. Equal norms for all vectors should give equal inner products. Which identity recovers $\langle \mathbf{x}, \mathbf{y}\rangle$ from norms?
Hint 2. Apply Proposition 6.1.32 to $\langle T\mathbf{v}, T\mathbf{w}\rangle$ and to $\langle T^*\mathbf{v}, T^*\mathbf{w}\rangle$, using $T(\mathbf{v} + c\mathbf{w}) = T\mathbf{v} + cT\mathbf{w}$.
Sketch. By polarization, $\langle T\mathbf{v}, T\mathbf{w}\rangle$ is a fixed combination of the numbers $\|T(\mathbf{v} + c\mathbf{w})\|^2$ with $c \in \{\pm 1\}$ (over $\mathbb{R}$) or $c \in \{\pm 1, \pm i\}$ (over $\mathbb{C}$), and the same combination of the numbers $\|T^*(\mathbf{v} + c\mathbf{w})\|^2$ gives $\langle T^*\mathbf{v}, T^*\mathbf{w}\rangle$. So $\langle T^*T\mathbf{v}, \mathbf{w}\rangle = \langle TT^*\mathbf{v}, \mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w}$, and $T^*T = TT^*$.

If T is normal, then $\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \langle TT^*\mathbf{v}, \mathbf{v}\rangle = \|T^*\mathbf{v}\|^2$ for every $\mathbf{v}$.

Conversely, suppose $\|T\mathbf{x}\| = \|T^*\mathbf{x}\|$ for every $\mathbf{x} \in V$, and let $\mathbf{v}, \mathbf{w} \in V$. Over $\mathbb{C}$, Proposition 6.1.32(b) and linearity of T and T^* give

$$\langle T\mathbf{v}, T\mathbf{w}\rangle = \frac{1}{4}\sum_{k=0}^{3} i^k \left\|T\left(\mathbf{v} + i^k\mathbf{w}\right)\right\|^2 = \frac{1}{4}\sum_{k=0}^{3} i^k \left\|T^*\left(\mathbf{v} + i^k\mathbf{w}\right)\right\|^2 = \langle T^*\mathbf{v}, T^*\mathbf{w}\rangle,$$

and over $\mathbb{R}$ the same holds with Proposition 6.1.32(a), which uses only $\mathbf{v} \pm \mathbf{w}$. Moving the operators across, the two ends of this chain are $\langle T^*T\mathbf{v}, \mathbf{w}\rangle$ and $\langle TT^*\mathbf{v}, \mathbf{w}\rangle$. They agree for all $\mathbf{v}, \mathbf{w} \in V$, so $T^*T = TT^*$ by Corollary 6.1.38. □

The first proof locates normality in a single self-adjoint operator, $T^*T - TT^*$, whose diagonal values are the differences $\|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2$. The second proof produces something visibly stronger along the way: T and T^* give the same inner products, $\langle T\mathbf{v}, T\mathbf{w}\rangle = \langle T^*\mathbf{v}, T^*\mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w}$.

Intuition. T and T^* need not be equal, but for a normal operator they stretch every vector by the same factor; they may send it in different directions. For $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ this fails as badly as possible: $N\mathbf{e}_2 = \mathbf{e}_1$ has length 1, while $N^*\mathbf{e}_2 = \mathbf{0}$. Everything else in this section follows from the equality of lengths. The first consequence is about kernels: a vector killed by T is killed by T^*.

Proposition 8.1.14 (Kernels and images of normal operators). Let $T \in \mathrm{L}(V)$ be normal.

(a) $\ker T = \ker T^*$.

(b) For every $\lambda \in \mathbb{F}$, the operator $T - \lambda\,\mathrm{id}$ is normal, and $(T - \lambda\,\mathrm{id})^* = T^* - \overline{\lambda}\,\mathrm{id}$.

(c) If V is finite-dimensional, then $\operatorname{im} T = \operatorname{im} T^* = (\ker T)^\perp$. So $V = \ker T \oplus \operatorname{im} T$, and $\ker T$ and $\operatorname{im} T$ are orthogonal.

Proof. ROUTINE

Uses. Proposition 8.1.13 (Normal means $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$), Proposition 6.1.27 (Basic properties of the norm), Proposition 6.6.18 (Properties of the adjoint), Theorem 6.6.21 (Kernels and images of adjoints), Theorem 6.4.24 (Orthogonal decomposition)
Techniques. Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. For (a), $T\mathbf{v} = \mathbf{0}$ if and only if $\|T\mathbf{v}\| = 0$.
Hint 2. For (b), compute both $(T - \lambda\,\mathrm{id})^*(T - \lambda\,\mathrm{id})$ and $(T - \lambda\,\mathrm{id})(T - \lambda\,\mathrm{id})^*$, using $(T - \lambda\,\mathrm{id})^* = T^* - \overline{\lambda}\,\mathrm{id}$.
Hint 3. For (c), combine (a) with (c) and (d) of Theorem 6.6.21.

Sketch. (a) $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$, so one is 0 iff the other is. (b) Both products equal $T^*T - \lambda T^* - \overline{\lambda}T + |\lambda|^2 \operatorname{id}$. (c) $\operatorname{im} T = (\ker T^*)^\perp = (\ker T)^\perp = \operatorname{im} T^*$, and $V = \ker T \oplus (\ker T)^\perp$.

(a) By Proposition 8.1.13, $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$ for every $\mathbf{v}$, and a vector is $\mathbf{0}$ if and only if its norm is 0 (Proposition 6.1.27). So $T\mathbf{v} = \mathbf{0}$ if and only if $T^*\mathbf{v} = \mathbf{0}$.

(b) By (a), (b), and (e) of Proposition 6.6.18, $T - \lambda \operatorname{id}$ has the adjoint $T^* - \overline{\lambda} \operatorname{id}$. Expanding,

$$\big(T^* - \overline{\lambda} \operatorname{id}\big)(T - \lambda \operatorname{id}) = T^*T - \lambda T^* - \overline{\lambda}T + |\lambda|^2 \operatorname{id},$$
$$(T - \lambda \operatorname{id})\big(T^* - \overline{\lambda} \operatorname{id}\big) = TT^* - \overline{\lambda}T - \lambda T^* + |\lambda|^2 \operatorname{id},$$

and these are equal because $T^*T = TT^*$.

(c) By (d) and (c) of Theorem 6.6.21, together with (a),

$$\operatorname{im} T = (\ker T^*)^\perp = (\ker T)^\perp = \operatorname{im} T^*.$$

By Theorem 6.4.24, applied to the finite-dimensional subspace $\ker T$, we get $V = \ker T \oplus (\ker T)^\perp = \ker T \oplus \operatorname{im} T$, and the two summands are orthogonal by the definition of $(\ker T)^\perp$. □

Part (a) has a second proof that never mentions norms: by Proposition 6.6.23(a), applied to T and to T^* (whose adjoint is T), $\ker T = \ker(T^*T) = \ker(TT^*) = \ker T^*$.

Part (c) says that a normal operator splits a finite-dimensional V into two perpendicular pieces. It kills $\ker T$, and it maps $\operatorname{im} T$ into itself injectively, since $\operatorname{im} T \cap \ker T = \{\mathbf{0}\}$; so on $\operatorname{im} T$ it is a bijection. The nilpotent N shows what normality rules out: $\ker N = \operatorname{im} N = \operatorname{span}(\mathbf{e}_1)$, so the image of N falls into its kernel. For a normal T with $T^2 = 0$ this would put $\operatorname{im} T$ inside $\ker T \cap \operatorname{im} T = \{\mathbf{0}\}$, so $T = 0$, which is one of the three proofs in Example 6.7.3.

Part (b) is what lets us pass from kernels to eigenvectors. The move is common enough to name.

Technique 8.1.15 (Shift by a scalar). A statement about the kernel of an operator becomes a statement about eigenvectors once it is applied to $T - \lambda \operatorname{id}$, because $E_\lambda(T) = \ker(T - \lambda \operatorname{id})$ (Definition 7.2.13). So prove the statement for kernels, check that the hypotheses survive the shift $T \mapsto T - \lambda \operatorname{id}$, and apply it to the shifted operator. Hypotheses that survive include being normal, being self-adjoint when λ is real, commuting with a fixed operator, and being upper triangular in a fixed basis.

Reach for it when you want a fact about every eigenvalue and the case $\lambda = 0$ is easier to see. The canonical example is Theorem 8.1.16, which is $\ker T = \ker T^*$ applied to $T - \lambda \operatorname{id}$.

Used in. Theorem 8.1.16, Theorem 8.1.18, Exercise 8.1.28.

Theorem 8.1.16 (Eigenvectors of a normal operator and of its adjoint). Let $T \in \mathrm{L}(V)$ be normal, $\mathbf{v} \in V$, and $\lambda \in \mathbb{F}$. Then

$$T\mathbf{v} = \lambda\mathbf{v} \quad \Longleftrightarrow \quad T^*\mathbf{v} = \overline{\lambda}\mathbf{v}.$$

In particular $E_\lambda(T) = E_{\overline{\lambda}}(T^*)$, and λ is an eigenvalue of T if and only if $\overline{\lambda}$ is an eigenvalue of T^*, with the same eigenvectors.

Proof. ROUTINE

Uses. Proposition 8.1.14 (Kernels and images of normal operators), Definition 7.2.13 (Eigenspace)
Techniques. Shift by a scalar (Technique 8.1.15)
Hint 1. Rewrite $T\mathbf{v} = \lambda\mathbf{v}$ as a statement about a kernel.
Hint 2. Apply Proposition 8.1.14(a) to the normal operator $T - \lambda \operatorname{id}$, whose adjoint is $T^* - \overline{\lambda} \operatorname{id}$.
Sketch. $T\mathbf{v} = \lambda\mathbf{v}$ iff $\mathbf{v} \in \ker(T - \lambda \operatorname{id}) = \ker\big((T - \lambda \operatorname{id})^*\big) = \ker\big(T^* - \overline{\lambda} \operatorname{id}\big)$ iff $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$, using (b) and then (a) of Proposition 8.1.14.

By Proposition 8.1.14(b), $T - \lambda \operatorname{id}$ is normal with adjoint $T^* - \overline{\lambda} \operatorname{id}$. Applying Proposition 8.1.14(a) to it,

$$\ker(T - \lambda\,\mathrm{id}) = \ker\left(T^* - \overline{\lambda}\,\mathrm{id}\right).$$

The left side is $E_\lambda(T)$ and the right side is $E_{\overline{\lambda}}(T^*)$ (Definition 7.2.13), which is the claim. □

Without normality, T and T^* usually have different eigenvectors. For $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $N\mathbf{e}_1 = \mathbf{0}$, but $N^*\mathbf{e}_1 = \mathbf{e}_2$, and $E_0(N^*) = \operatorname{span}(\mathbf{e}_2)$. What survives in general is an orthogonality between the eigenvectors of T and those of T^*.

Lemma 8.1.17 (Eigenvectors of T and of T^*). Let $T \in \mathrm{L}(V)$ have an adjoint. If $T\mathbf{v} = \lambda\mathbf{v}$ and $T^*\mathbf{w} = \nu\mathbf{w}$ with $\lambda \neq \overline{\nu}$, then $\langle \mathbf{v}, \mathbf{w}\rangle = 0$.

Proof. ROUTINE

Uses. Definition 6.6.8 (Adjoint), Proposition 6.1.4 (Sesquilinearity)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint. Compute $\langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T^*\mathbf{w}\rangle$ in two ways.
Sketch. $\lambda\langle \mathbf{v}, \mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T^*\mathbf{w}\rangle = \overline{\nu}\langle \mathbf{v}, \mathbf{w}\rangle$, and $\lambda \neq \overline{\nu}$.

By the defining identity of T^* and Proposition 6.1.4,

$$\lambda\langle \mathbf{v}, \mathbf{w}\rangle = \langle T\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, T^*\mathbf{w}\rangle = \langle \mathbf{v}, \nu\mathbf{w}\rangle = \overline{\nu}\langle \mathbf{v}, \mathbf{w}\rangle.$$

So $(\lambda - \overline{\nu})\langle \mathbf{v}, \mathbf{w}\rangle = 0$, and since $\lambda \neq \overline{\nu}$, $\langle \mathbf{v}, \mathbf{w}\rangle = 0$. □

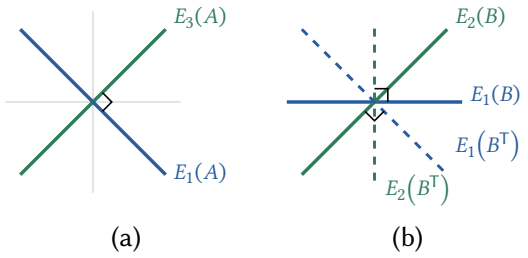

Figure 8.1.1. (a) The symmetric matrix $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$ has the eigenspaces $E_1(A) = \operatorname{span}((1,-1))$ and $E_3(A) = \operatorname{span}((1,1))$, which are perpendicular. (b) $B = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$ has the eigenspaces $E_1(B) = \operatorname{span}(\mathbf{e}_1)$ and $E_2(B) = \operatorname{span}((1,1))$ (solid), at an angle of $\pi/4$. The eigenspaces of B^{T} (dashed) are $E_1\left(B^{\mathsf{T}}\right) = \operatorname{span}((1,-1))$ and $E_2\left(B^{\mathsf{T}}\right) = \operatorname{span}(\mathbf{e}_2)$. Each eigenspace of B is perpendicular to the eigenspace of B^{T} for the other eigenvalue (Lemma 8.1.17). For a normal matrix the solid and dashed lines coincide (Theorem 8.1.16), and the eigenspaces themselves become perpendicular.

Theorem 8.1.18 (Eigenspaces of a normal operator are orthogonal). Let $T \in \mathrm{L}(V)$ be normal. If $T\mathbf{v} = \lambda\mathbf{v}$ and $T\mathbf{w} = \mu\mathbf{w}$ with $\lambda \neq \mu$, then $\langle \mathbf{v}, \mathbf{w}\rangle = 0$. So eigenspaces of T for distinct eigenvalues are orthogonal.

Proof (through the eigenvectors of T^*). ROUTINE

Uses. Theorem 8.1.16 (Eigenvectors of a normal operator and of its adjoint), Lemma 8.1.17 (Eigenvectors of T and of T^*)
Hint 1. What does T^* do to $\mathbf{w}$?
Hint 2. $T^*\mathbf{w} = \overline{\mu}\mathbf{w}$. Apply Lemma 8.1.17 with $\nu = \overline{\mu}$.
Sketch. By Theorem 8.1.16, $T^*\mathbf{w} = \overline{\mu}\mathbf{w}$, and $\lambda \neq \mu = \overline{\overline{\mu}}$, so Lemma 8.1.17 applies.

By Theorem 8.1.16, $T^*\mathbf{w} = \overline{\mu}\mathbf{w}$. Since $\lambda \neq \mu = \overline{\overline{\mu}}$, Lemma 8.1.17 with $\nu = \overline{\mu}$ gives $\langle \mathbf{v}, \mathbf{w}\rangle = 0$. For arbitrary $\mathbf{v} \in E_\lambda(T)$ and $\mathbf{w} \in E_\mu(T)$, either one of them is $\mathbf{0}$ or both are eigenvectors, so the eigenspaces are orthogonal. □

Proof (through kernels and images). STANDARD

Uses. Proposition 8.1.14 (Kernels and images of normal operators), Theorem 6.6.21 (Kernels and images of adjoints), Definition 6.4.22 (Orthogonal complement)
Techniques. Shift by a scalar (Technique 8.1.15)
Hint 1. Let $R = T - \mu\,\mathrm{id}$. Then $\mathbf{w} \in \ker R$. Show that $\mathbf{v} \in \operatorname{im} R$.

Hint 2. $R\mathbf{v} = (\lambda - \mu)\mathbf{v}$ with $\lambda - \mu \neq 0$. Now relate $\ker R$ to $\operatorname{im} R$ using that R is normal.
Sketch. With $R = T - \mu\,\mathrm{id}$, $\mathbf{v} = R(\mathbf{v}/(\lambda - \mu)) \in \operatorname{im} R$ and $\mathbf{w} \in \ker R = \ker R^* = (\operatorname{im} R)^\perp$, by Proposition 8.1.14 and Theorem 6.6.21(a).

Let $R = T - \mu\,\mathrm{id}$, which is normal by Proposition 8.1.14(b). Since $R\mathbf{v} = (\lambda - \mu)\mathbf{v}$ and $\lambda - \mu \neq 0$, we have $\mathbf{v} = R\big((\lambda - \mu)^{-1}\mathbf{v}\big) \in \operatorname{im} R$. On the other hand $\mathbf{w} \in \ker R$, and by Proposition 8.1.14(a) and Theorem 6.6.21(a),

$$\ker R = \ker R^* = (\operatorname{im} R)^\perp.$$

So $\mathbf{w}$ is orthogonal to every vector of $\operatorname{im} R$, in particular to $\mathbf{v}$. The statement about eigenspaces follows as in the first proof. □

The first proof reduces the theorem to a fact about single eigenvectors: T^* has the same eigenvectors as T, so the orthogonality of Lemma 8.1.17 applies to eigenvectors of T alone. The second proof is about subspaces and proves more. Every eigenvector $\mathbf{w}$ for μ is orthogonal to all of $\operatorname{im}(T - \mu\,\mathrm{id})$, which contains the eigenvectors for every other eigenvalue but in general much more. Part (b) of Proposition 8.1.1 is the special case of self-adjoint T.

Exercise 8.1.19. ROUTINE Let V be a complex inner product space, let $T \in \mathrm{L}(V)$ be normal, and let $\mathbf{v}, \mathbf{w} \in V$ satisfy $T\mathbf{v} = 2\mathbf{v}$, $T\mathbf{w} = i\mathbf{w}$, $\|\mathbf{v}\| = 1$, and $\|\mathbf{w}\| = 3$. Compute $\|T(\mathbf{v} + \mathbf{w})\|$, $\|T^*(\mathbf{v} - \mathbf{w})\|$, and $\langle T(\mathbf{v} + \mathbf{w}), \mathbf{v} - \mathbf{w}\rangle$.

Solution on page 1632

Applied to the special classes of Example 8.1.9, Theorem 8.1.16 says what their eigenvalues can be.

Corollary 8.1.20 (Eigenvalues of self-adjoint, skew-adjoint, and unitary operators). Let $T \in \mathrm{L}(V)$ have an adjoint, and let λ be an eigenvalue of T.

(a) If $T^* = T$, then $\lambda \in \mathbb{R}$.

(b) If $T^* = -T$, then $\overline{\lambda} = -\lambda$, that is, $\lambda \in i\mathbb{R}$.

(c) If $T^*T = TT^* = \mathrm{id}$, then $|\lambda| = 1$.

Proof. ROUTINE
Uses. Example 8.1.9 (Normal operators), Theorem 8.1.16 (Eigenvectors of a normal operator and of its adjoint), Proposition 1.2.35 (Zero products)
Hint 1. Each such T is normal. Let $\mathbf{v}$ be an eigenvector for λ. What is $T^*\mathbf{v}$?
Hint 2. $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$. Compare with what the hypothesis says about $T^*\mathbf{v}$, or for (c) compute $T^*T\mathbf{v}$.
Sketch. Each T is normal, so $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$. (a) $\overline{\lambda}\mathbf{v} = T\mathbf{v} = \lambda\mathbf{v}$. (b) $\overline{\lambda}\mathbf{v} = -\lambda\mathbf{v}$. (c) $\mathbf{v} = T^*T\mathbf{v} = \lambda\overline{\lambda}\mathbf{v}$.

In each case T is normal (Example 8.1.9). Let $\mathbf{v}$ be an eigenvector for λ; by Theorem 8.1.16, $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$.

(a) $\overline{\lambda}\mathbf{v} = T^*\mathbf{v} = T\mathbf{v} = \lambda\mathbf{v}$, so $\big(\overline{\lambda} - \lambda\big)\mathbf{v} = \mathbf{0}$, and $\overline{\lambda} = \lambda$ since $\mathbf{v} \neq \mathbf{0}$ (Proposition 1.2.35).

(b) $\overline{\lambda}\mathbf{v} = T^*\mathbf{v} = -T\mathbf{v} = -\lambda\mathbf{v}$, so $\overline{\lambda} = -\lambda$ in the same way.

(c) $\mathbf{v} = T^*T\mathbf{v} = T^*(\lambda\mathbf{v}) = \lambda\overline{\lambda}\mathbf{v} = |\lambda|^2\mathbf{v}$, so $|\lambda|^2 = 1$. □

Part (a) is a third proof of Proposition 8.1.1(a), and part (c) returns in Section 8.4. The converses fail without normality: $B = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$ has real eigenvalues and is not symmetric, and the shear $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ has only the eigenvalue 1 and is not orthogonal. For normal operators on finite-dimensional complex spaces the converses hold, because by Section 8.2 such an operator is determined by its eigenvalues on an orthonormal eigenbasis.

8.1.5 The Cartesian decomposition BEYOND 21-242

The Cartesian decomposition is in LADR 7A but not in the lecture.

Every complex number is $z = x + iy$ with x, y real, and then $|z|^2 = x^2 + y^2$. Operators split the same way: $T = S + K$ with $S = (T + T^*)/2$ self-adjoint and $K = (T - T^*)/2$ skew-adjoint, and this is the only such

splitting (over $\mathbb{C}$ this is Exercise 6.6.37, with $K = iB$). For numbers the two parts commute automatically. For operators they need not, and their commuting is exactly normality.

Proposition 8.1.21 (Normal means commuting parts). Let $T \in \mathrm{L}(V)$ have an adjoint, and let $S = (T + T^*)/2$ and $K = (T - T^*)/2$. Then S is self-adjoint, K is skew-adjoint, $T = S + K$, and

$$T^*T - TT^* = 2(SK - KS).$$

Hence T is normal if and only if $SK = KS$. When $\mathbb{F} = \mathbb{C}$, writing $K = iB$ with $B = (T - T^*)/(2i)$ self-adjoint, T is normal if and only if $SB = BS$.

Proof. ROUTINE

Uses. Proposition 6.6.18 (Properties of the adjoint), Definition 8.1.5 (Skew-adjoint operators, skew-Hermitian matrices)
Hint 1. $T^* = S^* + K^* = S - K$.
Hint 2. Expand $(S - K)(S + K) - (S + K)(S - K)$.
Sketch. $S^* = S$ and $K^* = -K$ by Proposition 6.6.18, so $T^* = S - K$. Then $T^*T - TT^* = (S - K)(S + K) - (S + K)(S - K) = 2(SK - KS)$. Over $\mathbb{C}$, $SK - KS = i(SB - BS)$.

By (a)–(c) of Proposition 6.6.18, $S^* = (T^* + T)/2 = S$ and $K^* = (T^* - T)/2 = -K$, and clearly $S + K = T$. So $T^* = S - K$, and

$$\begin{aligned} T^*T - TT^* &= (S - K)(S + K) - (S + K)(S - K) \\ &= \left(S^2 + SK - KS - K^2\right) - \left(S^2 - SK + KS - K^2\right) = 2(SK - KS). \end{aligned}$$

So $T^*T = TT^*$ if and only if $SK = KS$. When $\mathbb{F} = \mathbb{C}$, $B = -iK$ satisfies $B^* = \overline{-i}K^* = i(-K) = B$, so B is self-adjoint, $K = iB$, and $SK - KS = i(SB - BS)$, which vanishes if and only if $SB = BS$. □

For $B = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$, the parts are $S = \begin{pmatrix} 1 & 1/2 \\ 1/2 & 2 \end{pmatrix}$ and $K = \begin{pmatrix} 0 & 1/2 \\ -1/2 & 0 \end{pmatrix}$, and

$$2(SK - KS) = 2\left(\begin{pmatrix} -1/4 & 1/2 \\ -1 & 1/4 \end{pmatrix} - \begin{pmatrix} 1/4 & 1 \\ -1/2 & -1/4 \end{pmatrix}\right) = \begin{pmatrix} -1 & -1 \\ -1 & 1 \end{pmatrix} = B^{\mathsf{T}}B - BB^{\mathsf{T}},$$

as the proposition predicts, so the parts of B do not commute.

Intuition. For a normal operator, $T^*T = (S - K)(S + K) = S^2 - K^2$, and for every $\mathbf{v}$,

$$\|T\mathbf{v}\|^2 = \langle S^2\mathbf{v}, \mathbf{v}\rangle - \langle K^2\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2 + \|K\mathbf{v}\|^2,$$

since $-\langle K^2\mathbf{v}, \mathbf{v}\rangle = -\langle K\mathbf{v}, K^*\mathbf{v}\rangle = \|K\mathbf{v}\|^2$. This is $|z|^2 = x^2 + y^2$ for operators, and Exercise 8.1.29 shows that it characterizes normal operators.

Exercises

Exercise 8.1.22. ROUTINE For each matrix, decide whether it is Hermitian, skew-Hermitian, unitary, or normal (any number of these may hold).

(a) $\begin{pmatrix} 1 & 2 \\ -2 & 1 \end{pmatrix} \in \mathbb{R}^{2\times 2}$.

(b) $\begin{pmatrix} i & 1 \\ -1 & 2i \end{pmatrix}$.

(c) $\begin{pmatrix} 2 & i \\ i & 2 \end{pmatrix}$.

(d) $\begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \in \mathbb{R}^{3\times 3}$.

(e) $\begin{pmatrix} 1 & i \\ 0 & 1 \end{pmatrix}$.

Solution on page 1632

Exercise 8.1.23. ROUTINE Let $A = \begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 2 \end{pmatrix} \in \mathbb{R}^{3\times 3}$.

(a) Find the eigenvalues and eigenspaces of A. (Write $A = I_3 + \mathbf{1}\mathbf{1}^{\mathsf{T}}$ with $\mathbf{1} = (1,1,1)$.)

(b) Check that the eigenspaces are orthogonal, and find two eigenvectors for the same eigenvalue that are not orthogonal.

(c) Find an orthonormal basis of $\mathbb{R}^3$ consisting of eigenvectors of A.

Solution on page 1633

Exercise 8.1.24. STANDARD Let V be a finite-dimensional inner product space and $S, T \in \mathrm{L}(V)$. Prove or disprove each statement.

(a) If S and T are normal, then $S + T$ is normal.

(b) If T^2 is normal, then T is normal.

(c) If $\ker T = \ker T^*$, then T is normal.

(d) If T is normal, then $T + cT^*$ is normal for every $c \in \mathbb{F}$.

(e) If $\mathbb{F} = \mathbb{R}$, T is normal, and $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v} \in V$, then $T = 0$.

Solution on page 1633

Exercise 8.1.25. STANDARD Show that $A \in \mathbb{R}^{2\times 2}$ is normal if and only if either A is symmetric or $A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ for some $a, b \in \mathbb{R}$. Describe the second family geometrically, and show that for $b \neq 0$ it has no real eigenvalues.

Solution on page 1634

Exercise 8.1.26. STANDARD Let $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$ be nonzero, and let $A = \mathbf{x}\mathbf{y}^* \in \mathbb{C}^{n\times n}$. Show that A is normal if and only if $\mathbf{y} = c\mathbf{x}$ for some $c \in \mathbb{C}$, and that in this case A is Hermitian if and only if $c \in \mathbb{R}$.

Solution on page 1634

Exercise 8.1.27. STANDARD Find the error in the following argument, and give an operator for which its conclusion fails. Then name a hypothesis on T under which the conclusion is true.

Claim. Let $T \in \mathrm{L}(V)$ have an adjoint. If $T\mathbf{v} = \lambda\mathbf{v}$, then $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$.

Proof. We have $\langle T^*\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \langle \mathbf{v}, \lambda\mathbf{v}\rangle = \overline{\lambda}\langle \mathbf{v}, \mathbf{v}\rangle = \langle \overline{\lambda}\mathbf{v}, \mathbf{v}\rangle$. Since $T^*\mathbf{v}$ and $\overline{\lambda}\mathbf{v}$ have the same inner product with $\mathbf{v}$, they are equal.

Solution on page 1635

Exercise 8.1.28. STANDARD Let V be a complex inner product space, $T \in \mathrm{L}(V)$ self-adjoint, and $\lambda = a + bi$ with $a, b \in \mathbb{R}$.

(a) Show that $\|(T - \lambda\,\mathrm{id})\mathbf{v}\|^2 = \|(T - a\,\mathrm{id})\mathbf{v}\|^2 + b^2\|\mathbf{v}\|^2$ for every $\mathbf{v} \in V$.

(b) Deduce once more that the eigenvalues of T are real.

(c) Suppose V is finite-dimensional and $b \neq 0$. Show that $T - \lambda\,\mathrm{id}$ is invertible and that $\left\|(T - \lambda\,\mathrm{id})^{-1}\mathbf{w}\right\| \leq \|\mathbf{w}\|/|b|$ for every $\mathbf{w} \in V$.

Solution on page 1635

Exercise 8.1.29. STANDARD BEYOND 21-242 Let $T \in \mathrm{L}(V)$ have an adjoint, and let $S = (T + T^*)/2$ and $K = (T - T^*)/2$ be its self-adjoint and skew-adjoint parts.

(a) Show that $\|T\mathbf{v}\|^2 = \|S\mathbf{v}\|^2 + \|K\mathbf{v}\|^2 + \langle (SK - KS)\mathbf{v}, \mathbf{v}\rangle$ for every $\mathbf{v} \in V$.

(b) Deduce that T is normal if and only if $\|T\mathbf{v}\|^2 = \|S\mathbf{v}\|^2 + \|K\mathbf{v}\|^2$ for every $\mathbf{v} \in V$.

Solution on page 1636

Exercise 8.1.30. STANDARD Let $U \in \mathbb{F}^{n\times n}$ be both Hermitian and unitary.

(a) Show that $U^2 = I_n$.

(b) Show that $P = (I_n + U)/2$ satisfies $P^2 = P = P^*$, so that $\mathbf{x} \mapsto P\mathbf{x}$ is an orthogonal projection of $\mathbb{F}^n$, and that $U = 2P - I_n$. Describe $\mathbf{x} \mapsto U\mathbf{x}$ geometrically.

(c) Conversely, show that $2P - I_n$ is Hermitian and unitary whenever $P^2 = P = P^*$.

(d) Find U when P is the matrix of the orthogonal projection of $\mathbb{R}^2$ onto $\operatorname{span}((1, 1))$.

Solution on page 1636

Exercise 8.1.31. STANDARD Theorem 8.1.3 says that every real symmetric matrix has a real eigenvalue. Prove or disprove the analogues over other fields.

(a) Every symmetric $A \in \mathbb{Q}^{2\times 2}$ has an eigenvalue in $\mathbb{Q}$.

(b) Every symmetric $A \in \mathbb{F}_2^{2\times 2}$ has an eigenvalue in $\mathbb{F}_2$.

(c) Which steps of the first proof of Theorem 8.1.3 fail over $\mathbb{Q}$ and over $\mathbb{F}_2$?

Solution on page 1637

Exercise 8.1.32. HARD Let V be finite-dimensional and let $T \in \mathrm{L}(V)$ be normal with $T^3 = T^2$. Show that T is an orthogonal projection, that is, $T = \mathrm{Pr}_W$ for some subspace W of V.

Solution on page 1637

Exercise 8.1.33. HARD Let $A \in \mathbb{F}^{n\times n}$ satisfy $\|A^*\mathbf{x}\| \le \|A\mathbf{x}\|$ for every $\mathbf{x} \in \mathbb{F}^n$ (dot product). Show that A is normal.

Solution on page 1637

Exercise 8.1.34. HARD Let $A \in \mathbb{R}^{n\times n}$ satisfy $A^{\mathsf{T}} = A^2$.

(a) Show that $A^4 = A$ and that A is normal.

(b) Show that A^3 is the matrix of an orthogonal projection.

(c) Find all such A when $n = 2$.

Solution on page 1638

Exercise 8.1.35. HARD Let $K \in \mathbb{F}^{n\times n}$ be skew-Hermitian.

(a) Show that $I_n + K$ and $I_n - K$ are invertible.

(b) Show that $Q = (I_n - K)(I_n + K)^{-1}$ is unitary and that -1 is not an eigenvalue of Q.

(c) Compute Q for $K = \begin{pmatrix} 0 & -t \\ t & 0 \end{pmatrix}$ with $t \in \mathbb{R}$, and identify it as a rotation.

Solution on page 1639

Exercise 8.1.36. STANDARD Let V be finite-dimensional and let $T \in \mathrm{L}(V)$ be normal and diagonalizable. Show that V has an orthonormal basis consisting of eigenvectors of T. Deduce that a diagonalizable operator has an orthonormal eigenbasis if and only if it is normal.

Solution on page 1639

Exercise 8.1.37. HARD Let $A \in \mathbb{C}^{n\times n}$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, listed with algebraic multiplicity.

(a) Prove *Schur's inequality*

$$\sum_{j=1}^{n} |\lambda_j|^2 \leq \operatorname{tr}(A^*A) = \sum_{i,j} |a_{ij}|^2.$$

(b) Show that if equality holds, then A is normal.

Solution on page 1640

Exercise 8.1.38. CHALLENGE Let $A \in \mathbb{C}^{n\times n}$ be normal and let $W \subseteq \mathbb{C}^n$ be a subspace with $AW \subseteq W$. Show that $A^*W \subseteq W$, and deduce that $AW^\perp \subseteq W^\perp$. (Let P be the matrix of Pr_W, so that $AW \subseteq W$ says $PAP = AP$, and consider $X = PA(I_n - P)$.)

Solution on page 1640

8.2 The spectral theorems

An operator is easiest to understand when it is diagonal in some basis. On an inner product space we want more: a basis that is diagonal for T *and* orthonormal, so that T stretches V by scalar factors along mutually perpendicular axes, and coordinates are computed by inner products instead of linear systems. This section answers the question of which operators have such a basis. Over $\mathbb{C}$ the answer is the normal operators (Definition 8.1.8), and over $\mathbb{R}$ it is the self-adjoint ones. Both answers come from the same short computation, which shows that these conditions are necessary; the work is in showing that they suffice.

Throughout, V is a finite-dimensional inner product space over $\mathbb{F}$, with $\dim V \geq 1$, and $T \in \mathrm{L}(V)$. As in Section 6.6, inner products are linear in the first slot. For an orthonormal basis $\mathcal{O}$ we write $[T]_{\mathcal{O}}$ for $[T]_{\mathcal{O}\mathcal{O}}$, and we use freely that $[T^*]_{\mathcal{O}} = \big([T]_{\mathcal{O}}\big)^*$ (Theorem 6.6.15) and $[ST]_{\mathcal{O}} = [S]_{\mathcal{O}}[T]_{\mathcal{O}}$ (Theorem 2.4.2).

8.2.1 Orthonormal eigenbases

An **orthonormal eigenbasis** for T is an orthonormal basis of V consisting of eigenvectors of T. By Theorem 7.4.2, an orthonormal basis $\mathcal{O}$ is an eigenbasis exactly when $[T]_{\mathcal{O}}$ is diagonal. For matrices, the change-of-basis matrix is then unitary.

Definition 8.2.1 (Unitarily and orthogonally diagonalizable). A matrix $A \in \mathbb{F}^{n\times n}$ is **unitarily diagonalizable** if

$$A = UDU^*$$

for some unitary $U \in \mathbb{F}^{n\times n}$ and some diagonal $D \in \mathbb{F}^{n\times n}$. When $\mathbb{F} = \mathbb{R}$, U is then an orthogonal matrix Q and $A = QDQ^{\mathsf{T}}$; we say A is **orthogonally diagonalizable**.

Since $U^* = U^{-1}$ for unitary U (Definition 6.3.33), $A = UDU^*$ is a diagonalization $A = SDS^{-1}$ with $S = U$. By the last part of Theorem 7.4.2, it says that the columns of U are eigenvectors of A with eigenvalues the diagonal entries of D; and by Theorem 6.3.29, U is unitary exactly when its columns are orthonormal. So A is unitarily diagonalizable if and only if $\mathbb{F}^n$, with the dot product, has an orthonormal eigenbasis for A.

We start with the easy direction of both spectral theorems, because its proof shows where the conditions "normal" and "self-adjoint" come from.

Proposition 8.2.2 (Necessary conditions). Suppose V has an orthonormal eigenbasis for T.

(a) T is normal: $T^*T = TT^*$.

(b) If every eigenvalue of T is real (in particular, if $\mathbb{F} = \mathbb{R}$), then T is self-adjoint.

Proof. ROUTINE

Uses. Theorem 7.4.2 (Diagonalizable means an eigenbasis), Theorem 6.6.15 (Existence of adjoints), Theorem 2.4.2 (The matrix of a composite), Theorem 2.3.20 (Linear maps correspond to matrices), Definition 8.1.8 (Normal operator, normal matrix), Definition 6.6.26 (Self-adjoint operator)
Techniques. Choose a convenient basis (Technique 4.5.33)
Hint 1. Write down $[T]_{\mathcal{O}}$ for the orthonormal eigenbasis $\mathcal{O}$. What is $[T^*]_{\mathcal{O}}$?
Hint 2. Diagonal matrices commute with each other, and $D^* = D$ for a real diagonal D.
Sketch. In the eigenbasis $\mathcal{O}$, $[T]_{\mathcal{O}} = D$ is diagonal, so $[T^*]_{\mathcal{O}} = D^*$ is diagonal too. Diagonal matrices commute, so $[T^*T]_{\mathcal{O}} = D^*D = DD^* = [TT^*]_{\mathcal{O}}$. If the eigenvalues are real, $D^* = D$, so $T^* = T$.

Let $\mathcal{O}$ be an orthonormal eigenbasis, with $T\mathbf{u}_j = \lambda_j \mathbf{u}_j$. By Theorem 7.4.2, $[T]_{\mathcal{O}} = D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$, and by Theorem 6.6.15, $[T^*]_{\mathcal{O}} = D^* = \operatorname{diag}\left(\overline{\lambda_1}, \ldots, \overline{\lambda_n}\right)$.

(a) Products of diagonal matrices are computed entry by entry, so $D^*D = \operatorname{diag}\left(|\lambda_1|^2, \ldots, |\lambda_n|^2\right) = DD^*$. By Theorem 2.4.2, $[T^*T]_{\mathcal{O}} = D^*D = DD^* = [TT^*]_{\mathcal{O}}$, and maps with the same matrix are equal (Theorem 2.3.20). So $T^*T = TT^*$.

(b) If every λ_j is real, then $D^* = D$, so $[T^*]_{\mathcal{O}} = [T]_{\mathcal{O}}$ and $T^* = T$ by Theorem 2.3.20. □

So normality is what remains of "diagonal in an orthonormal basis" once the basis is forgotten: a diagonal matrix commutes with its conjugate transpose. The spectral theorems say that nothing else is needed. Before proving them, here are the examples that show which hypothesis goes with which field.

Example 8.2.3 (Which matrices have orthonormal eigenbases).

(a) $A = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix} \in \mathbb{R}^{2\times 2}$ has the distinct eigenvalues 1 and 2, so it is diagonalizable (Corollary 7.4.5), with eigenvectors $(1, 0)$ and $(1, 1)$. These are not orthogonal, and each eigenspace is a line, so no choice of eigenvectors is orthogonal. Correspondingly A is not normal: $(A^*A)_{11} = 1$ while $(AA^*)_{11} = 2$. Diagonalizable and unitarily diagonalizable are different conditions.

(b) The rotation $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ satisfies $J^{\mathsf{T}}J = I_2 = JJ^{\mathsf{T}}$, so T_J is normal on $\mathbb{R}^2$ and on $\mathbb{C}^2$. Over $\mathbb{R}$ it has no eigenvector at all (Example 7.2.18). Over $\mathbb{C}$,

$$J\begin{pmatrix} 1 \\ -i \end{pmatrix} = \begin{pmatrix} i \\ 1 \end{pmatrix} = i\begin{pmatrix} 1 \\ -i \end{pmatrix}, \quad J\begin{pmatrix} 1 \\ i \end{pmatrix} = \begin{pmatrix} -i \\ 1 \end{pmatrix} = -i\begin{pmatrix} 1 \\ i \end{pmatrix},$$

and $\frac{1}{\sqrt{2}}(1, -i)$, $\frac{1}{\sqrt{2}}(1, i)$ is an orthonormal eigenbasis of $\mathbb{C}^2$, since $(1, -i) \cdot (1, i) = 1 + (-i)\bar{i} = 1 - 1 = 0$. So over $\mathbb{C}$ normality is the right condition, while over $\mathbb{R}$ we will need the stronger condition $T^* = T$.

Intuition (Two ways to build the basis). Suppose we want an orthonormal eigenbasis for a normal T on a complex space. There are two natural plans, and both work.

The first plan starts from something we already have. Schur's theorem (Theorem 7.5.18) gives an orthonormal basis in which T is upper triangular, so it remains to show that normality kills everything above the diagonal. For an upper-triangular R, the first column has only one nonzero entry, r_{11}, while the first row is $r_{11}, r_{12}, \ldots, r_{1n}$. The diagonal entries of R^*R and RR^* are the squared norms of the columns and of the rows, so $R^*R = RR^*$ forces the first row to have no more mass than the first column. Then the same comparison works for the second row, and so on down the diagonal.

The second plan builds the basis one vector at a time (Technique 7.5.12). Take a unit eigenvector $\mathbf{u}$ and try to recurse on $W = \operatorname{span}(\mathbf{u})^{\perp}$. In the second proof of Schur's theorem this required compressing T to W, because W need not be T-invariant, and the compression produced the entries above the diagonal. For a normal T, $\mathbf{u}$ is also an eigenvector of T^*, and this is exactly what makes W invariant (Exercise 6.6.38). The compression is then a restriction, and nothing appears above the diagonal.

8.2.2 The complex spectral theorem

We start with the matrix fact behind the first plan.

Lemma 8.2.4 (Triangular and normal means diagonal). Let $R \in \mathbb{F}^{n\times n}$ be upper triangular with $R^*R = RR^*$. Then R is diagonal.

Proof. STANDARD

Uses. Definition 2.4.1 (Matrix product), Definition 6.3.26 (Conjugate transpose)
Techniques. A sum of nonnegative terms (Technique 6.1.9), Strong induction and well-ordering (Technique 5.2.12)
Hint 1. Compute the diagonal entries $(R^*R)_{kk}$ and $(RR^*)_{kk}$ as sums of $|r_{ij}|^2$. Which entries of R appear in each?
Hint 2. $(R^*R)_{kk}$ is the squared norm of column k and $(RR^*)_{kk}$ that of row k. Start with $k = 1$, where the column has a single possibly nonzero entry.
Hint 3. Prove by strong induction on k that row k has no nonzero entries to the right of the diagonal. When you reach row k, the entries of column k above the diagonal lie in earlier rows.
Sketch. $(R^*R)_{kk} = \sum_i |r_{ik}|^2$ is the squared norm of column k, and $(RR^*)_{kk} = \sum_j |r_{kj}|^2$ that of row k. By strong induction on k: if rows $1, \dots, k-1$ vanish off the diagonal, then column k has only the entry r_{kk}, so equating the two norms gives $\sum_{j>k} |r_{kj}|^2 = 0$, and row k vanishes off the diagonal too.

For each k, the definitions of the product and of R^* give

$$(R^*R)_{kk} = \sum_{i=1}^{n} \overline{r_{ik}} r_{ik} = \sum_{i=1}^{n} |r_{ik}|^2, \quad (RR^*)_{kk} = \sum_{j=1}^{n} r_{kj}\overline{r_{kj}} = \sum_{j=1}^{n} |r_{kj}|^2,$$

the squared norms of column k and of row k. We prove by strong induction on k that $r_{kj} = 0$ for all $j > k$. Let $1 \le k \le n$ and suppose this holds for every row $i < k$. Then $r_{ik} = 0$ for $i < k$ by the hypothesis (as $k > i$), and $r_{ik} = 0$ for $i > k$ because R is upper triangular. So column k has the single entry r_{kk}, and $(R^*R)_{kk} = (RR^*)_{kk}$ reads

$$|r_{kk}|^2 = |r_{kk}|^2 + \sum_{j>k} |r_{kj}|^2.$$

Hence $\sum_{j>k} |r_{kj}|^2 = 0$. A sum of nonnegative reals vanishes only if every term does, so $r_{kj} = 0$ for all $j > k$. (For $k = 1$ the hypothesis is empty and the same argument applies.) So every entry above the diagonal is 0, and R is diagonal. □

Theorem 8.2.5 (Complex spectral theorem). Let V be a finite-dimensional complex inner product space with $\dim V \ge 1$, and let $T \in \mathrm{L}(V)$. The following are equivalent:

(I) T is normal;

(II) V has an orthonormal basis consisting of eigenvectors of T;

(III) $[T]_{\mathcal{O}}$ is diagonal for some orthonormal basis $\mathcal{O}$ of V.

In matrix form: $A \in \mathbb{C}^{n\times n}$ satisfies $A^*A = AA^*$ if and only if A is unitarily diagonalizable.

(II) and (III) say the same thing by Theorem 7.4.2, and (II) ⇒ (I) is Proposition 8.2.2(a). The content is (I) ⇒ (III). We give three proofs. The first two carry out the two plans of Intuition (Two ways to build the basis); the third avoids induction altogether.

Proof (Schur, then normality). ROUTINE

Uses. Theorem 7.5.18 (Schur's theorem), Lemma 8.2.4 (Triangular and normal means diagonal), Theorem 6.6.15 (Existence of adjoints), Theorem 2.4.2 (The matrix of a composite), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Proposition 8.2.2 (Necessary conditions), Theorem 4.5.17 (Change of basis), Definition 6.3.33 (Unitary and orthogonal matrices)
Techniques. Proving TFAE (Technique 2.7.1), Prove it for triangular matrices first (Technique 7.5.23)
Hint 1. Start from a Schur basis: an orthonormal $\mathcal{O}$ with $R = [T]_{\mathcal{O}}$ upper triangular. What does normality of T say about R?
Hint 2. Since $\mathcal{O}$ is orthonormal, $[T^*]_{\mathcal{O}} = R^*$. Apply Lemma 8.2.4.
Sketch. (II) $\Leftrightarrow$ (III) is Theorem 7.4.2, and (II) $\Rightarrow$ (I) is Proposition 8.2.2. For (I) $\Rightarrow$ (III), Schur gives an orthonormal $\mathcal{O}$ with $R = [T]_{\mathcal{O}}$ upper triangular, and $R^*R = [T^*T]_{\mathcal{O}} = [TT^*]_{\mathcal{O}} = RR^*$. By Lemma 8.2.4, R is diagonal. For matrices, apply this to T_A on $\mathbb{C}^n$ and use that the columns of an orthonormal basis form a unitary matrix.

(II) and (III) are equivalent by Theorem 7.4.2, and (II) $\Rightarrow$ (I) is Proposition 8.2.2(a). Suppose T is normal. By Theorem 7.5.18 there is an orthonormal basis $\mathcal{O}$ with $R = [T]_{\mathcal{O}}$ upper triangular. By Theorem 6.6.15 and Theorem 2.4.2,

$$R^*R = [T^*]_{\mathcal{O}}[T]_{\mathcal{O}} = [T^*T]_{\mathcal{O}} = [TT^*]_{\mathcal{O}} = RR^*.$$

By Lemma 8.2.4, R is diagonal, which is (III).

For the matrix form, if $A = UDU^*$ with U unitary and D diagonal, then $A^*A = UD^*DU^* = UDD^*U^* = AA^*$. Conversely, if $A^*A = AA^*$, then T_A is normal on $\mathbb{C}^n$ with the dot product (Example 6.6.10), so by (II) there is an orthonormal eigenbasis $\mathbf{u}_1, \dots, \mathbf{u}_n$ of $\mathbb{C}^n$. The matrix U with these columns is unitary (Definition 6.3.33), and by Theorem 4.5.17, $U^*AU = U^{-1}AU = [T_A]_{\mathcal{O}} = D$ is diagonal. Hence $A = UDU^*$. □

Intuition (What the second proof needs from normality). The induction runs on $W = \operatorname{span}(\mathbf{u})^{\perp}$, and two facts about normal operators make it work. Both have one-line proofs, given inside the proof below; Section 8.1 treats them properly.

- *T and T^* stretch every vector equally:* $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$ for every $\mathbf{v}$. Applied to the normal operator $T - \lambda\,\mathrm{id}$, this says that $T\mathbf{u} = \lambda\mathbf{u}$ implies $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$.
- *Restrictions stay normal:* if W is invariant under both T and T^*, then the adjoint of $T|_W$ is $T^*|_W$.

Proof (induction with invariant complements). STANDARD

Uses. Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Definition 8.1.8 (Normal operator, normal matrix), Definition 6.6.8 (Adjoint), Proposition 6.6.18 (Properties of the adjoint), Proposition 6.6.9 (Adjoints are unique and linear), Exercise 6.6.38, Theorem 6.4.24 (Orthogonal decomposition), Corollary 6.4.25 (Dimension of the orthogonal complement), Theorem 4.4.13 (Bases and dimension of a sum), Definition 6.3.15 (Orthonormal list, orthonormal basis)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12), Move an operator across the inner product (Technique 6.6.20), Show a vector is zero via its norm (Technique 6.1.36)
Hint 1. Induct on $n = \dim V$. Take a unit eigenvector $\mathbf{u}$ with $T\mathbf{u} = \lambda\mathbf{u}$, and let $W = \operatorname{span}(\mathbf{u})^{\perp}$. You want W to be T-invariant. By Exercise 6.6.38, what would suffice?
Hint 2. It suffices that $\operatorname{span}(\mathbf{u})$ is T^*-invariant, that is, that $\mathbf{u}$ is an eigenvector of T^*. Show $\|T\mathbf{v}\| = \|T^*\mathbf{v}\|$ for normal T, and apply it to $T - \lambda\,\mathrm{id}$.
Hint 3. To apply the induction hypothesis to $S = T|_W$, check that W is also T^*-invariant and that $S^* = T^*|_W$. Then S is normal.
Sketch. For normal T, $\|T\mathbf{v}\|^2 = \langle T^*T\mathbf{v}, \mathbf{v}\rangle = \langle TT^*\mathbf{v}, \mathbf{v}\rangle = \|T^*\mathbf{v}\|^2$; since $T - \lambda\,\mathrm{id}$ is normal, $T\mathbf{u} = \lambda\mathbf{u}$ gives $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$. Take a unit eigenvector $\mathbf{u}$ (it exists over $\mathbb{C}$). Then $\operatorname{span}(\mathbf{u})$ is invariant under T and T^*, so $W = \operatorname{span}(\mathbf{u})^{\perp}$ is too (Exercise 6.6.38). On W, $T|_W$ has adjoint $T^*|_W$, so it is normal, and by induction W has an orthonormal eigenbasis. Add $\mathbf{u}$.

We prove (I) $\Rightarrow$ (II) by induction on $n = \dim V$; the rest is as in the first proof. First, two facts about a normal operator N on an inner product space.

- For every $\mathbf{v}$, $\|N\mathbf{v}\| = \|N^*\mathbf{v}\|$, because

$$\|N\mathbf{v}\|^2 = \langle N\mathbf{v}, N\mathbf{v}\rangle = \langle N^*N\mathbf{v}, \mathbf{v}\rangle = \langle NN^*\mathbf{v}, \mathbf{v}\rangle = \langle N^*\mathbf{v}, N^*\mathbf{v}\rangle = \|N^*\mathbf{v}\|^2.$$

- For every $\lambda \in \mathbb{C}$, $N - \lambda\,\mathrm{id}$ is normal. Indeed $(N - \lambda\,\mathrm{id})^* = N^* - \overline{\lambda}\,\mathrm{id}$ by Proposition 6.6.18, and expanding,

$$(N - \lambda\,\mathrm{id})\big(N^* - \overline{\lambda}\,\mathrm{id}\big) = NN^* - \overline{\lambda}N - \lambda N^* + |\lambda|^2\,\mathrm{id} = \big(N^* - \overline{\lambda}\,\mathrm{id}\big)(N - \lambda\,\mathrm{id}),$$

using $NN^* = N^*N$. So if $N\mathbf{u} = \lambda\mathbf{u}$, the first fact applied to $N - \lambda\,\mathrm{id}$ gives $\big\|\big(N^* - \overline{\lambda}\,\mathrm{id}\big)\mathbf{u}\big\| = \|(N - \lambda\,\mathrm{id})\mathbf{u}\| = 0$, that is, $N^*\mathbf{u} = \overline{\lambda}\mathbf{u}$.

Now let T be normal. If $n = 1$, any unit vector $\mathbf{u}$ spans V, so $T\mathbf{u} \in \operatorname{span}(\mathbf{u})$, and $\mathbf{u}$ alone is an orthonormal eigenbasis. Let $n \geq 2$, and assume (I) $\Rightarrow$ (II) for complex inner product spaces of dimension $n - 1$. By Theorem 7.3.27, T has an eigenvector; dividing by its norm, we get $\mathbf{u}$ with $\|\mathbf{u}\| = 1$ and $T\mathbf{u} = \lambda\mathbf{u}$. By the facts above, $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$. Let $U = \operatorname{span}(\mathbf{u})$ and $W = U^\perp$. Then U is invariant under T and under T^*. Applying Exercise 6.6.38 to T shows that T^* maps W into W, and applying it to T^* (whose adjoint is T, by Proposition 6.6.18(c)) shows that T maps W into W.

Let $S = T{\restriction}_W \in \mathrm{L}(W)$, where W carries the inner product of V. For $\mathbf{w}, \mathbf{w}' \in W$ we have $T^*{\restriction}_W\mathbf{w}' = T^*\mathbf{w}' \in W$ and

$$\langle S\mathbf{w}, \mathbf{w}'\rangle = \langle T\mathbf{w}, \mathbf{w}'\rangle = \langle \mathbf{w}, T^*\mathbf{w}'\rangle,$$

so $T^*{\restriction}_W$ is the adjoint of S (Definition 6.6.8, Proposition 6.6.9). Hence $S^*S = (T^*T){\restriction}_W = (TT^*){\restriction}_W = SS^*$, and S is normal. By Theorem 6.4.24 and Corollary 6.4.25, $V = U \oplus W$ and $\dim W = n - 1$. By the induction hypothesis, W has an orthonormal basis $\mathbf{u}_2, \ldots, \mathbf{u}_n$ of eigenvectors of S, which are eigenvectors of T. Each $\mathbf{u}_j$ lies in $W = U^\perp$, so $\mathbf{u}, \mathbf{u}_2, \ldots, \mathbf{u}_n$ is orthonormal (Definition 6.3.15), and it is a basis of $V = U \oplus W$ by Theorem 4.4.13. It consists of eigenvectors of T. □

The third proof looks at all eigenvectors at once. Let E be the sum of all the eigenspaces of T. If $E \neq V$, we look for an eigenvector of T in $E^\perp$, which is impossible since every eigenvector lies in E. Finding one needs $E^\perp$ to be T-invariant, and once again that comes from T^* preserving eigenspaces.

Proof (the sum of the eigenspaces is everything). STANDARD

> *Uses.* Definition 7.2.13 (Eigenspace), Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Exercise 6.6.38, Corollary 6.4.27 (Testing whether a subspace is everything), Theorem 6.4.20 (Orthonormal bases exist), Definition 6.3.15 (Orthonormal list, orthonormal basis), Proposition 6.3.13 (Orthogonal lists are independent)
> *Techniques.* Extremal choice and minimal counterexamples (Technique 1.5.9), Move an operator across the inner product (Technique 6.6.20)
> *Hint 1.* Let $E = E_{\lambda_1} + \cdots + E_{\lambda_k}$ be the sum of the eigenspaces. Use, as in the second proof, that $T\mathbf{u} = \lambda\mathbf{u}$ implies $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$. Which subspaces does T^* preserve?
> *Hint 2.* T^* maps each E_λ into itself, so E is T^*-invariant, and $E^\perp$ is T-invariant. What would an eigenvector of $T{\restriction}_{E^\perp}$ be?
> *Hint 3.* For orthogonality, compute $\langle T\mathbf{u}, \mathbf{v}\rangle$ in two ways for $\mathbf{u} \in E_\lambda$ and $\mathbf{v} \in E_\mu$.
> *Sketch.* Every eigenvector of T is one of T^* (second proof), so T^* preserves each eigenspace and hence $E = \sum_j E_{\lambda_j}$; by Exercise 6.6.38, T preserves $E^\perp$. If $E^\perp \neq \{\mathbf{0}\}$, then $T{\restriction}_{E^\perp}$ has an eigenvector, which lies in $E \cap E^\perp = \{\mathbf{0}\}$, a contradiction. So $E = V$. Eigenspaces for $\lambda \neq \mu$ are orthogonal since $\lambda\langle\mathbf{u}, \mathbf{v}\rangle = \langle T\mathbf{u}, \mathbf{v}\rangle = \langle \mathbf{u}, T^*\mathbf{v}\rangle = \mu\langle\mathbf{u}, \mathbf{v}\rangle$. Concatenate orthonormal bases of the eigenspaces.

Let T be normal, let $\lambda_1, \ldots, \lambda_k$ be its distinct eigenvalues (there is at least one, by Theorem 7.3.27), and let $E = E_{\lambda_1} + \cdots + E_{\lambda_k}$. As shown in the second proof, $T\mathbf{u} = \lambda\mathbf{u}$ implies $T^*\mathbf{u} = \overline{\lambda}\mathbf{u}$. So T^* maps each E_{λ_j} into itself, and therefore maps E into E. By Exercise 6.6.38 applied to T^*, the operator $T = (T^*)^*$ maps $E^\perp$ into $E^\perp$.

Suppose $E^\perp \neq \{\mathbf{0}\}$. Then $T{\restriction}_{E^\perp}$ is an operator on a nonzero finite-dimensional complex space, so it has an eigenvector $\mathbf{w}$ (Theorem 7.3.27). This $\mathbf{w}$ is an eigenvector of T, so $\mathbf{w} \in E$. Then $\mathbf{w} \in E \cap E^\perp$, so $\langle \mathbf{w}, \mathbf{w}\rangle = 0$ and $\mathbf{w} = \mathbf{0}$, a contradiction. Hence $E^\perp = \{\mathbf{0}\}$, and $E = V$ by Corollary 6.4.27.

Next, eigenspaces for different eigenvalues are orthogonal. Let $\mathbf{u} \in E_\lambda$ and $\mathbf{v} \in E_\mu$ with $\lambda \neq \mu$. Then $T^*\mathbf{v} = \overline{\mu}\mathbf{v}$, and

$$\lambda\langle\mathbf{u}, \mathbf{v}\rangle = \langle T\mathbf{u}, \mathbf{v}\rangle = \langle \mathbf{u}, T^*\mathbf{v}\rangle = \langle \mathbf{u}, \overline{\mu}\mathbf{v}\rangle = \mu\langle\mathbf{u}, \mathbf{v}\rangle.$$

Since $\lambda \neq \mu$, $\langle\mathbf{u}, \mathbf{v}\rangle = 0$.

Finally, choose an orthonormal basis $\mathcal{O}_j$ of each E_{λ_j} (Theorem 6.4.20), and let $\mathcal{O}$ be the concatenation $\mathcal{O}_1, \ldots, \mathcal{O}_k$. Vectors within one $\mathcal{O}_j$ are orthonormal, and vectors from different $\mathcal{O}_j$ are orthogonal by the previous paragraph, so $\mathcal{O}$ is orthonormal (Definition 6.3.15), hence linearly independent (Proposition 6.3.13). It spans $E_{\lambda_1} + \cdots + E_{\lambda_k} = V$. So $\mathcal{O}$ is an orthonormal eigenbasis. □

Remark 8.2.6 (Comparing the three proofs). The first proof is the shortest, because Schur's theorem has already done the work of finding a basis, and it isolates the role of normality in a single matrix lemma. The second is self-contained apart from the existence of one eigenvalue, and it is the template for the real theorem below, where Schur's theorem is not available in the same form. The third proves more than it states: it shows directly that V is the orthogonal direct sum of the eigenspaces, which is the spectral decomposition of Section 8.2.4. It also shows a pattern worth remembering: to prove that some subspace E is everything, show that $E^{\perp}$ is invariant and that any eigenvector in it would have to lie in E.

The lecture states the spectral theorem for self-adjoint operators on complex spaces. It is a special case, and Schur's theorem proves it without the lemma.

Corollary 8.2.7 (Hermitian matrices). Let V be a finite-dimensional complex inner product space with $\dim V \geq 1$, and $T \in \mathrm{L}(V)$. Then T is self-adjoint if and only if V has an orthonormal eigenbasis for T and every eigenvalue of T is real. In matrix form: $A \in \mathbb{C}^{n\times n}$ is Hermitian if and only if $A = UDU^*$ with U unitary and D diagonal with real entries.

Proof (from the complex spectral theorem). ROUTINE

> *Uses.* Theorem 8.2.5 (Complex spectral theorem), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Proposition 8.2.2 (Necessary conditions)
> *Hint 1.* A self-adjoint operator is normal.
> *Hint 2.* Which result says the eigenvalues of a self-adjoint operator are real?
> *Sketch.* If $T^* = T$ then $T^*T = T^2 = TT^*$, so Theorem 8.2.5 gives an orthonormal eigenbasis, and the eigenvalues are real by Proposition 8.1.1. The converse is Proposition 8.2.2(b).

If T is self-adjoint, then $T^*T = TT = TT^*$, so T is normal and has an orthonormal eigenbasis by Theorem 8.2.5; its eigenvalues are real by Proposition 8.1.1. The converse is Proposition 8.2.2(b). The matrix form follows as in the first proof of Theorem 8.2.5: A is Hermitian if and only if T_A is self-adjoint (Example 6.6.10), and $U^*AU = D$ is real diagonal exactly when the columns of U form an orthonormal eigenbasis with real eigenvalues. □

Proof (directly from Schur, as in lecture). ROUTINE

> *Uses.* Theorem 7.5.18 (Schur's theorem), Corollary 6.6.28 (Self-adjointness in an orthonormal basis), Proposition 8.2.2 (Necessary conditions)
> *Hint 1.* Take a Schur basis $\mathcal{O}$. If T is self-adjoint, what is the relation between $[T]_{\mathcal{O}}$ and its conjugate transpose?
> *Hint 2.* A matrix that equals its conjugate transpose and is upper triangular is also lower triangular.
> *Sketch.* For a Schur basis, $R = [T]_{\mathcal{O}}$ is upper triangular and $R^* = R$ (Corollary 6.6.28). So R is also lower triangular, hence diagonal, and $r_{jj} = \overline{r_{jj}}$ is real.

Let T be self-adjoint, and let $\mathcal{O}$ be an orthonormal basis with $R = [T]_{\mathcal{O}}$ upper triangular (Theorem 7.5.18). By Corollary 6.6.28, $R^* = R$, that is, $r_{ij} = \overline{r_{ji}}$ for all i, j. For $i > j$ we have $r_{ij} = 0$, so $r_{ji} = \overline{r_{ij}} = 0$: the entries above the diagonal vanish too, and R is diagonal. Its diagonal entries satisfy $r_{jj} = \overline{r_{jj}}$, so they are real, and they are the eigenvalues of the vectors of $\mathcal{O}$. The converse is Proposition 8.2.2(b). □

Example 8.2.8 (Two unitary diagonalizations).

(a) The real matrix $N = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} = I_2 + J$ is normal, since J commutes with $J^{\mathsf{T}} = -J$. It is not symmetric, so it is not orthogonally diagonalizable over $\mathbb{R}$ (and indeed $p_N = (x-1)^2 + 1$ has no real root). Over $\mathbb{C}$ its eigenvectors are those of J from Example 8.2.3, with eigenvalues $1+i$ and $1-i$:

$$N = U\begin{pmatrix} 1+i & 0 \\ 0 & 1-i \end{pmatrix}U^*, \quad U = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}.$$

(b) The Hermitian matrix $H = \begin{pmatrix} 2 & 1-i \\ 1+i & 3 \end{pmatrix}$ of Example 6.6.27 has $p_H = (x-2)(x-3) - (1-i)(1+i) = x^2 - 5x + 4 = (x-1)(x-4)$. Row reducing $H - I_2$ and $H - 4I_2$ gives the eigenvectors $(-1+i, 1)$ for 1 and $(1, 1+i)$ for 4. Each has squared norm 3, and they are orthogonal, as Corollary 8.2.7 predicts: $(-1+i)\cdot\overline{1} + 1\cdot\overline{1+i} = -1+i+1-i = 0$. So

$$H = U\begin{pmatrix} 1 & 0 \\ 0 & 4 \end{pmatrix}U^*, \quad U = \frac{1}{\sqrt{3}}\begin{pmatrix} -1+i & 1 \\ 1 & 1+i \end{pmatrix}.$$

Exercise 8.2.9. ROUTINE For each matrix, decide whether it is unitarily diagonalizable (over $\mathbb{C}$), and for the real ones also whether it is orthogonally diagonalizable (over $\mathbb{R}$).

(a) $\begin{pmatrix} 1 & 2 \\ 0 & 3 \end{pmatrix}$
(b) $\begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix}$
(c) $\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix}$
(d) $\begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}$
(e) $\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix}$

Solution on page 1641

8.2.3 The real spectral theorem

Over $\mathbb{R}$, Example 8.2.3(b) shows that normality is not enough, and Proposition 8.2.2(b) shows that self-adjointness is necessary. To prove it is sufficient, we want to run the second proof of Theorem 8.2.5 again. Self-adjointness takes care of the invariance of W for free (Exercise 6.6.38), so the only step that used $\mathbb{C}$ is the existence of an eigenvector. That is the content of the next lemma.

Lemma 8.2.10 (Self-adjoint operators have eigenvalues). Let V be a finite-dimensional real inner product space with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$ be self-adjoint. Then T has an eigenvalue. In fact every complex root of p_T is real, so p_T splits over $\mathbb{R}$.

The first proof borrows the eigenvalue from $\mathbb{C}$. It turns T into a real symmetric matrix, regards that matrix as a complex Hermitian matrix, and uses that Hermitian matrices have only real eigenvalues.

Proof (via a Hermitian matrix). STANDARD

Uses. Theorem 6.4.20 (Orthonormal bases exist), Corollary 6.6.28 (Self-adjointness in an orthonormal basis), Example 6.6.10 (The adjoint of a matrix), Corollary 7.1.35 (Factorization over $\mathbb{C}$), Theorem 7.3.6 (Eigenvalues are the roots of the characteristic polynomial), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Definition 7.3.12 (Characteristic polynomial of an operator), Corollary 7.3.13 (Eigenvalues of an operator)
Hint 1. Choose an orthonormal basis and let $A = [T]_{\mathcal{O}} \in \mathbb{R}^{n\times n}$. What do you know about A?
Hint 2. A is symmetric, so as a complex matrix it is Hermitian. Where are the complex roots of p_A?
Sketch. $A = [T]_{\mathcal{O}}$ is real symmetric, hence Hermitian as a complex matrix. Over $\mathbb{C}$, p_A factors into linear factors, and each root is an eigenvalue of the self-adjoint T_A on $\mathbb{C}^n$, hence real. So $p_T = p_A$ splits over $\mathbb{R}$, and any of its roots is an eigenvalue of T.

Let $\mathcal{O}$ be an orthonormal basis of V (Theorem 6.4.20) and $A = [T]_{\mathcal{O}} \in \mathbb{R}^{n\times n}$, $n = \dim V$. By Corollary 6.6.28, $A^{\mathsf{T}} = A$. Regard A as a matrix in $\mathbb{C}^{n\times n}$. Its entries are real, so $A^* = \overline{A}^{\mathsf{T}} = A^{\mathsf{T}} = A$, and T_A is a self-adjoint operator on $\mathbb{C}^n$ with the dot product (Example 6.6.10). By Corollary 7.1.35, $p_A = (x-\lambda_1)\cdots(x-\lambda_n)$ for some $\lambda_i \in \mathbb{C}$. Each λ_i is an eigenvalue of $A \in \mathbb{C}^{n\times n}$ (Theorem 7.3.6), that is, of T_A, so $\lambda_i \in \mathbb{R}$ by Proposition 8.1.1. Hence p_A splits over $\mathbb{R}$. (The determinant $\det(xI_n - A)$ is the same polynomial whether A is viewed as real or complex.) Since $p_T = p_A$ (Definition 7.3.12), the real number λ_1 is a root of p_T, hence an eigenvalue of T by Corollary 7.3.13. □

The second proof stays inside V. The idea comes from factoring polynomials over $\mathbb{R}$: some nonzero polynomial p satisfies $p(T)\mathbf{v} = \mathbf{0}$, and p factors into linear factors and irreducible quadratics (Theorem 7.1.39). The rotation by $\pi/2$ shows that a quadratic factor such as x^2+1 can be what kills $\mathbf{v}$. Self-adjointness rules this out: for self-adjoint T, an irreducible quadratic q gives an invertible $q(T)$, because $\langle q(T)\mathbf{v}, \mathbf{v}\rangle$ is bounded below by a quadratic in $\|T\mathbf{v}\|$ with negative discriminant.

Proof (without complex numbers). HARD

> *Uses.* Proposition 7.2.35 (A basis of a Krylov subspace), Theorem 7.1.39 (Factorization over $\mathbb{R}$), Proposition 7.2.27 (Evaluating polynomials at an operator), Theorem 6.2.1 (Cauchy–Schwarz inequality), Definition 6.6.26 (Self-adjoint operator), Theorem 7.2.9 (Eigenvalues and invertibility)
> *Techniques.* A nonnegative quadratic has nonpositive discriminant (Technique 6.2.7), Move an operator across the inner product (Technique 6.6.20)
> *Hint 1.* Take $\mathbf{v} \neq \mathbf{0}$. Some monic p of degree $d \geq 1$ has $p(T)\mathbf{v} = \mathbf{0}$ (Proposition 7.2.35). Factor p over $\mathbb{R}$.
> *Hint 2.* Show that $q(T) = T^2 + bT + c\,\mathrm{id}$ is injective when $b^2 < 4c$: for $\mathbf{v} \neq \mathbf{0}$, show $\langle q(T)\mathbf{v}, \mathbf{v}\rangle > 0$. Use $\langle T^2\mathbf{v}, \mathbf{v}\rangle = \|T\mathbf{v}\|^2$ and Cauchy–Schwarz on $\langle T\mathbf{v}, \mathbf{v}\rangle$.
> *Hint 3.* Complete the square: $\|T\mathbf{v}\|^2 - |b|\|T\mathbf{v}\|\|\mathbf{v}\| + c\|\mathbf{v}\|^2 = \left(\|T\mathbf{v}\| - \frac{|b|}{2}\|\mathbf{v}\|\right)^2 + \left(c - \frac{b^2}{4}\right)\|\mathbf{v}\|^2$. Then $p(T)$ is a product of injective quadratic factors and factors $T - \lambda_i\,\mathrm{id}$, and it is not injective.
> *Sketch.* For $b^2 < 4c$ and $\mathbf{v} \neq \mathbf{0}$, self-adjointness and Cauchy–Schwarz give $\left\langle (T^2 + bT + c\,\mathrm{id})\mathbf{v}, \mathbf{v}\right\rangle \geq \left(\|T\mathbf{v}\| - \frac{|b|}{2}\|\mathbf{v}\|\right)^2 + \left(c - \frac{b^2}{4}\right)\|\mathbf{v}\|^2 > 0$, so $T^2 + bT + c\,\mathrm{id}$ is injective. Pick a monic p of degree ≥ 1 with $p(T)\mathbf{v} = \mathbf{0}$ for some $\mathbf{v} \neq \mathbf{0}$ and factor it over $\mathbb{R}$. The product $p(T)$ of the factors is not injective, so some factor is not; it cannot be a quadratic one, so it is some $T - \lambda\,\mathrm{id}$, and λ is an eigenvalue.

We prove that T has an eigenvalue. First let $b, c \in \mathbb{R}$ with $b^2 < 4c$; we show that $q(T) = T^2 + bT + c\,\mathrm{id}$ is injective. Let $\mathbf{v} \neq \mathbf{0}$. Since T is self-adjoint, $\langle T^2\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, T\mathbf{v}\rangle = \|T\mathbf{v}\|^2$, and by Cauchy–Schwarz, $b\langle T\mathbf{v}, \mathbf{v}\rangle \geq -|b|\|T\mathbf{v}\|\|\mathbf{v}\|$. Hence

$$\begin{aligned}\langle q(T)\mathbf{v}, \mathbf{v}\rangle &= \|T\mathbf{v}\|^2 + b\langle T\mathbf{v}, \mathbf{v}\rangle + c\|\mathbf{v}\|^2 \\ &\geq \|T\mathbf{v}\|^2 - |b|\|T\mathbf{v}\|\|\mathbf{v}\| + c\|\mathbf{v}\|^2 \\ &= \left(\|T\mathbf{v}\| - \frac{|b|}{2}\|\mathbf{v}\|\right)^2 + \left(c - \frac{b^2}{4}\right)\|\mathbf{v}\|^2 > 0,\end{aligned}$$

because $c - b^2/4 > 0$ and $\|\mathbf{v}\| > 0$. So $q(T)\mathbf{v} \neq \mathbf{0}$.

Now fix $\mathbf{v} \neq \mathbf{0}$. By Proposition 7.2.35 there is a monic $p \in \mathbb{R}[x]$ of degree $d \geq 1$ with $p(T)\mathbf{v} = \mathbf{0}$. By Theorem 7.1.39,

$$p = (x-\lambda_1)\cdots(x-\lambda_k)q_1\cdots q_l, \quad q_j = x^2 + b_j x + c_j, \quad b_j^2 < 4c_j,$$

and by Proposition 7.2.27,

$$p(T) = (T - \lambda_1\,\mathrm{id})\cdots(T - \lambda_k\,\mathrm{id})q_1(T)\cdots q_l(T).$$

A composition of injective maps is injective, and $p(T)$ is not injective since it kills $\mathbf{v}$. So at least one factor is not injective. The factors $q_j(T)$ are injective by the first paragraph, so some $T - \lambda_i\,\mathrm{id}$ is not injective (in particular $k \geq 1$), and λ_i is an eigenvalue of T by Theorem 7.2.9.

The second statement of the lemma (all complex roots of p_T are real) follows from the first proof of Theorem 8.2.12 below, which uses only the first statement: in an orthonormal eigenbasis, $[T]_{\mathcal{O}} = \operatorname{diag}(\mu_1, \ldots, \mu_n)$ with real μ_j, so $p_T = (x - \mu_1)\cdots(x - \mu_n)$. □

Remark 8.2.11 (A third proof, by maximizing). There is a third proof, which finds the eigenvector as the solution of an optimization problem. On the unit sphere $S = \{\mathbf{v} \in V \mid \|\mathbf{v}\| = 1\}$, the function $\mathbf{v} \mapsto \langle T\mathbf{v}, \mathbf{v}\rangle$ is continuous, and S is closed and bounded, so the function attains a maximum at some $\mathbf{u} \in S$. Perturbing a maximizer (Technique 6.5.6) along any direction $\mathbf{w} \perp \mathbf{u}$ shows that $\langle T\mathbf{u}, \mathbf{w}\rangle = 0$ (the derivative of the perturbed value is $2\langle T\mathbf{u}, \mathbf{w}\rangle$ because $\langle T\mathbf{w}, \mathbf{u}\rangle = \langle \mathbf{w}, T\mathbf{u}\rangle$, which is where self-adjointness enters), that is, $T\mathbf{u} \in \operatorname{span}(\mathbf{u})$, so $\mathbf{u}$ is an eigenvector, and its eigenvalue is the maximum value. The existence of the maximum is a fact from analysis, which is why this book postpones the argument to Section 12.3. That section also explains what the other eigenvalues maximize (the Courant–Fischer theorem).

Theorem 8.2.12 (Real spectral theorem). Let V be a finite-dimensional real inner product space with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$. The following are equivalent:

(I) T is self-adjoint;

(II) V has an orthonormal basis consisting of eigenvectors of T;

(III) $[T]_{\mathcal{O}}$ is diagonal for some orthonormal basis $\mathcal{O}$ of V.

In matrix form: $A \in \mathbb{R}^{n\times n}$ is symmetric if and only if $A = QDQ^{\mathsf{T}}$ for some orthogonal $Q \in \mathbb{R}^{n\times n}$ and some diagonal $D \in \mathbb{R}^{n\times n}$, that is, if and only if A is orthogonally diagonalizable.

Again (II) ⇔ (III) is Theorem 7.4.2 and (II) ⇒ (I) is Proposition 8.2.2(b), so we prove (I) ⇒ (II).

Proof (induction with invariant complements). STANDARD

Uses. Lemma 8.2.10 (Self-adjoint operators have eigenvalues), Exercise 6.6.38, Definition 6.6.26 (Self-adjoint operator), Theorem 6.4.24 (Orthogonal decomposition), Corollary 6.4.25 (Dimension of the orthogonal complement), Theorem 4.4.13 (Bases and dimension of a sum), Definition 6.3.15 (Orthonormal list, orthonormal basis), Proposition 8.2.2 (Necessary conditions), Theorem 4.5.17 (Change of basis), Definition 6.3.33 (Unitary and orthogonal matrices)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12), Proving TFAE (Technique 2.7.1)
Hint 1. Follow the second proof of Theorem 8.2.5. Which step used $\mathbb{C}$, and what replaces it?
Hint 2. Lemma 8.2.10 provides a unit eigenvector $\mathbf{u}$. Why is $W = \operatorname{span}(\mathbf{u})^{\perp}$ invariant this time, and why is $T{\restriction_W}$ self-adjoint?
Sketch. Induct on $\dim V$. By Lemma 8.2.10, T has a unit eigenvector $\mathbf{u}$. Since $T^* = T$ maps $\operatorname{span}(\mathbf{u})$ into itself, T maps $W = \operatorname{span}(\mathbf{u})^{\perp}$ into itself (Exercise 6.6.38), and $T{\restriction_W}$ is self-adjoint because $\langle T\mathbf{w}, \mathbf{w}'\rangle = \langle \mathbf{w}, T\mathbf{w}'\rangle$ for $\mathbf{w}, \mathbf{w}' \in W$. By induction W has an orthonormal eigenbasis; add $\mathbf{u}$. For matrices, put the eigenbasis of T_A into the columns of Q.

We prove (I) ⇒ (II) by induction on $n = \dim V$. If $n = 1$, any unit vector is an orthonormal eigenbasis, as in the complex case. Let $n \geq 2$, assume the claim in dimension $n - 1$, and let T be self-adjoint. By Lemma 8.2.10, T has an eigenvector, and dividing by its norm gives $\mathbf{u}$ with $\|\mathbf{u}\| = 1$ and $T\mathbf{u} = \lambda\mathbf{u}$. Let $U = \operatorname{span}(\mathbf{u})$ and $W = U^{\perp}$. Since $T^* = T$ maps U into U, Exercise 6.6.38 (applied to T^*, whose adjoint is T) shows that T maps W into W. The operator $S = T{\restriction_W} \in \mathrm{L}(W)$ is self-adjoint for the inner product of V restricted to W, since $\langle S\mathbf{w}, \mathbf{w}'\rangle = \langle T\mathbf{w}, \mathbf{w}'\rangle = \langle \mathbf{w}, T\mathbf{w}'\rangle = \langle \mathbf{w}, S\mathbf{w}'\rangle$ for $\mathbf{w}, \mathbf{w}' \in W$ (Definition 6.6.26). By Theorem 6.4.24 and Corollary 6.4.25, $V = U \oplus W$ with $\dim W = n - 1 \geq 1$. By the induction hypothesis, W has an orthonormal basis $\mathbf{u}_2, \ldots, \mathbf{u}_n$ of eigenvectors of S, hence of T. As in the complex case, $\mathbf{u}, \mathbf{u}_2, \ldots, \mathbf{u}_n$ is an orthonormal basis of V (Definition 6.3.15, Theorem 4.4.13) consisting of eigenvectors of T.

For the matrix form, $\left(QDQ^{\mathsf{T}}\right)^{\mathsf{T}} = QD^{\mathsf{T}}Q^{\mathsf{T}} = QDQ^{\mathsf{T}}$, so orthogonally diagonalizable matrices are symmetric. Conversely, if A is symmetric, T_A is self-adjoint on $\mathbb{R}^n$ with the dot product, so $\mathbb{R}^n$ has an orthonormal eigenbasis $\mathbf{q}_1, \ldots, \mathbf{q}_n$. The matrix Q with these columns is orthogonal (Definition 6.3.33), and $Q^{\mathsf{T}}AQ = Q^{-1}AQ = D$ is diagonal by Theorem 4.5.17. Hence $A = QDQ^{\mathsf{T}}$. □

The second proof follows the first proof of the complex theorem instead, with a real Schur basis.

Proof (triangularize, then use symmetry). STANDARD

> *Uses.* Lemma 8.2.10 (Self-adjoint operators have eigenvalues), Theorem 7.5.17 (Triangularizable means the characteristic polynomial splits), Proposition 7.5.2 (Upper-triangular matrices and invariant subspaces), Theorem 6.4.15 (Gram–Schmidt is correct), Corollary 6.6.28 (Self-adjointness in an orthonormal basis)
> *Techniques.* Build a flag of invariant subspaces (Technique 7.5.4), Prove it for triangular matrices first (Technique 7.5.23)
> *Hint 1.* By Lemma 8.2.10, p_T splits over $\mathbb{R}$. What does Theorem 7.5.17 give?
> *Hint 2.* Gram–Schmidt preserves the flag of a triangularizing basis, exactly as in the first proof of Theorem 7.5.18. Then compare $[T]_{\mathcal{O}}$ with its transpose.
> *Sketch.* p_T splits over $\mathbb{R}$ (Lemma 8.2.10), so some basis $\mathcal{B}$ triangularizes T; Gram–Schmidt turns it into an orthonormal $\mathcal{O}$ with the same invariant flag, so $R = [T]_{\mathcal{O}}$ is upper triangular. It is also symmetric (Corollary 6.6.28), hence diagonal.

By Lemma 8.2.10, p_T splits over $\mathbb{R}$, so by Theorem 7.5.17 there is a basis $\mathcal{B} = \mathbf{b}_1, \ldots, \mathbf{b}_n$ of V with $[T]_{\mathcal{B}}$ upper triangular; by Proposition 7.5.2, every $V_j = \operatorname{span}(\mathbf{b}_1, \ldots, \mathbf{b}_j)$ is T-invariant. Gram–Schmidt applied to $\mathcal{B}$ gives an orthonormal basis $\mathcal{O} = \mathbf{u}_1, \ldots, \mathbf{u}_n$ with $\operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_j) = V_j$ for every j (Theorem 6.4.15(d)), so $R = [T]_{\mathcal{O}}$ is upper triangular by Proposition 7.5.2. (This is the first proof of Theorem 7.5.18, which used nothing about $\mathbb{C}$ beyond the triangularizing basis.) By Corollary 6.6.28, $R^{\mathsf{T}} = R$. For $i < j$, $r_{ij} = r_{ji} = 0$, so R is diagonal, and $\mathcal{O}$ is an orthonormal eigenbasis. □

Non-example 8.2.13 (Symmetric matrices over other fields). The real spectral theorem is about *real* symmetric matrices, and the inner product on $\mathbb{R}^n$ is what makes it work. Over other fields the transpose still exists, but symmetric matrices need not be diagonalizable.

(a) $A = \begin{pmatrix} 1 & i \\ i & -1 \end{pmatrix} \in \mathbb{C}^{2\times 2}$ satisfies $A^{\mathsf{T}} = A$, and $A^2 = \begin{pmatrix} 1+i^2 & i-i \\ i-i & i^2+1 \end{pmatrix} = 0$. So A is nilpotent and nonzero, and is not diagonalizable (its only eigenvalue is 0, and $A \neq 0$). Over $\mathbb{C}$, the right condition is $A^* = A$, not $A^{\mathsf{T}} = A$.

(b) $A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \in \mathbb{F}_2^{2\times 2}$ is symmetric with $A^2 = \begin{pmatrix} 2 & 2 \\ 2 & 2 \end{pmatrix} = 0$ in $\mathbb{F}_2$. Again a nonzero nilpotent matrix, so not diagonalizable.

In both cases the proofs above fail at the same point: the "inner product" $\mathbf{x}^{\mathsf{T}}\mathbf{y}$ has nonzero vectors with $\mathbf{x}^{\mathsf{T}}\mathbf{x} = 0$, such as $(1, i)$ and $(1, 1)$, and every argument above that divided by $\|\mathbf{u}\|$ or used $\|\mathbf{w}\| = 0 \Rightarrow \mathbf{w} = \mathbf{0}$ breaks. Section 12.4 studies what survives.

Computing an orthogonal diagonalization

The proofs suggest the computation. Eigenspaces for different eigenvalues are automatically orthogonal (third proof of Theorem 8.2.5, which applies verbatim to self-adjoint operators on real spaces), so orthogonality only has to be arranged inside each eigenspace.

Algorithm 8.2.14 (Orthogonal diagonalization)

Input A symmetric $A \in \mathbb{R}^{n\times n}$.
Output An orthogonal Q and a diagonal D with $A = QDQ^{\mathsf{T}}$.

1. Compute p_A and its roots $\lambda_1, \ldots, \lambda_k$ (all real, by Lemma 8.2.10).
2. For each λ_j, find a basis of $E_{\lambda_j} = \ker(A - \lambda_j I_n)$ by row reduction.
3. Apply Gram–Schmidt to each of these bases separately, to get an orthonormal basis of each E_{λ_j}.
4. Let Q have these orthonormal bases as its columns, and let D be diagonal with the eigenvalue of each column in the matching position.

The columns found in step 3 are orthonormal within each eigenspace, and orthogonal across eigenspaces by the computation in the third proof of Theorem 8.2.5. There are n of them, since A is diagonalizable and so the eigenspace dimensions add up to n (Theorem 7.4.16). Only step 3 is new compared with Algorithm 7.4.18. For a simple eigenvalue it just normalizes the eigenvector; Gram–Schmidt does real work only for repeated eigenvalues.

Example 8.2.15 (A repeated eigenvalue). Let $A = \begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 2 \end{pmatrix} = I_3 + J_3$, where J_3 is the all-ones matrix. Since $J_3\mathbf{x} = (x_1 + x_2 + x_3)(1, 1, 1)$, the eigenvalues of J_3 are 3 (on $\operatorname{span}((1, 1, 1))$) and 0 (on the plane $x_1 + x_2 + x_3 = 0$), so A has eigenvalues 4 and 1, with

$$E_4 = \operatorname{span}((1, 1, 1)), \quad E_1 = \{\mathbf{x} \mid x_1 + x_2 + x_3 = 0\} = \operatorname{span}((1, -1, 0), (1, 0, -1)).$$

The basis of E_1 from row reduction is not orthogonal. Gram–Schmidt replaces $(1, 0, -1)$ by $(1, 0, -1) - \frac{1}{2}(1, -1, 0) = \frac{1}{2}(1, 1, -2)$. Normalizing,

$$Q = \begin{pmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & 0 & -\frac{2}{\sqrt{6}} \end{pmatrix}, \quad D = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad A = QDQ^{\mathsf{T}}.$$

Any orthonormal basis of the plane E_1 would do in the last two columns; step 3 only picks one. The first column is orthogonal to the plane E_1 automatically.

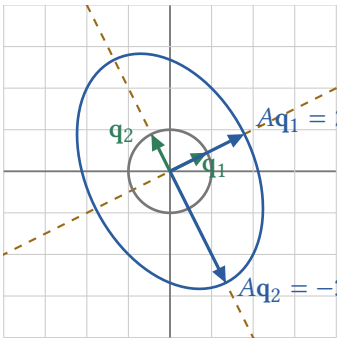
Exercise 8.2.16. ROUTINE Find an orthogonal Q and a diagonal D with $\begin{pmatrix} 7 & -2 \\ -2 & 4 \end{pmatrix} = QDQ^{\mathsf{T}}$.

Solution on page 1641

Symmetric matrices and ellipses

Geometrically, the real spectral theorem says that a real symmetric matrix stretches $\mathbb{R}^n$ by the factors $\lambda_1, \ldots, \lambda_n$ along n perpendicular axes, with a flip when $\lambda_j < 0$. In the plane, this is visible on the unit circle.

Example 8.2.17 (The image of the unit circle). Let $A \in \mathbb{R}^{2\times 2}$ be symmetric and invertible, and write $A = QDQ^{\mathsf{T}}$ with $Q = (\mathbf{q}_1 \mid \mathbf{q}_2)$ orthogonal and $D = \operatorname{diag}(\lambda_1, \lambda_2)$. A unit vector is $\mathbf{x} = y_1\mathbf{q}_1 + y_2\mathbf{q}_2$ with $y_1^2 + y_2^2 = 1$ (Proposition 6.3.18, Theorem 6.3.22), and $A\mathbf{x} = \lambda_1 y_1\mathbf{q}_1 + \lambda_2 y_2\mathbf{q}_2$. So the image of the unit circle is



$$\left\{ z_1\mathbf{q}_1 + z_2\mathbf{q}_2 \;\middle|\; \frac{z_1^2}{\lambda_1^2} + \frac{z_2^2}{\lambda_2^2} = 1 \right\},$$

an ellipse whose axes point along the eigenvectors, with semi-axes $|\lambda_1|$ and $|\lambda_2|$.

For instance, $A = \begin{pmatrix} 1 & 2 \\ 2 & -2 \end{pmatrix}$ has $p_A = x^2 + x - 6 = (x - 2)(x + 3)$, with $E_2 = \operatorname{span}((2, 1))$ and $E_{-3} = \operatorname{span}((-1, 2))$. So $A = QDQ^{\mathsf{T}}$ with

$$Q = \frac{1}{\sqrt{5}}\begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix}, \quad D = \begin{pmatrix} 2 & 0 \\ 0 & -3 \end{pmatrix},$$

and the image of the unit circle is an ellipse with semi-axis 2 along $(2, 1)$ and 3 along $(-1, 2)$. A non-symmetric matrix also maps the circle to an ellipse, but its axes are generally not along its eigenvectors; that is the subject of Section 9.1.

The unit circle and its image under the symmetric matrix $A = \begin{pmatrix} 1 & 2 \\ 2 & -2 \end{pmatrix}$. The eigenvectors $\mathbf{q}_1, \mathbf{q}_2$ are perpendicular, and A scales them by 2 and -3; the images lie along the axes of the ellipse. In the interactive version the two off-diagonal entries move together, so A stays symmetric. Move the point $\mathbf{x}$ around the circle: $A\mathbf{x}$ is farthest from $\mathbf{0}$ when $\mathbf{x} = \pm\mathbf{q}$ for the eigenvalue of largest absolute value. Make an eigenvalue 0 to flatten the ellipse to a segment, and make A a multiple of I, where every direction is an eigenvector. (Interactive in the web version.)

8.2.4 The spectral decomposition

An orthonormal eigenbasis is not unique: in Example 8.2.15 any orthonormal basis of the plane E_1 would do. What is unique is the splitting of V into eigenspaces, and the orthogonal projections onto them. Writing T in terms of these projections gives a basis-free form of the spectral theorems.

For the rest of the section, we say that T satisfies the **spectral hypothesis** if T is normal and $\mathbb{F} = \mathbb{C}$, or T is self-adjoint and $\mathbb{F} = \mathbb{R}$. By Theorem 8.2.5 and Theorem 8.2.12, these are exactly the cases in which V has an orthonormal eigenbasis. (Self-adjoint operators on complex spaces are included, being normal.)

Theorem 8.2.18 (Spectral decomposition). Let T satisfy the spectral hypothesis, let $\lambda_1, \dots, \lambda_k$ be the distinct eigenvalues of T, and let $P_j = \mathrm{Pr}_{E_{\lambda_j}}$ be the orthogonal projection onto E_{λ_j}.

(a) The eigenspaces are pairwise orthogonal, and $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_k}$.

(b) $P_i P_j = 0$ for $i \neq j$, and $P_1 + \cdots + P_k = \mathrm{id}_V$.

(c) $T = \lambda_1 P_1 + \cdots + \lambda_k P_k$.

In matrix form: if $A = UDU^*$ with U unitary (orthogonal, if $\mathbb{F} = \mathbb{R}$) with columns $\mathbf{u}_1, \dots, \mathbf{u}_n$ and $D = \mathrm{diag}(\mu_1, \dots, \mu_n)$, then

$$A = \mu_1 \mathbf{u}_1 \mathbf{u}_1^* + \cdots + \mu_n \mathbf{u}_n \mathbf{u}_n^*,$$

and grouping the terms with equal μ_i gives $A = \sum_j \lambda_j P_j$, where P_j is the matrix of $\mathrm{Pr}_{E_{\lambda_j}}$.

Proof. STANDARD

Uses. Theorem 8.2.5 (Complex spectral theorem), Theorem 8.2.12 (Real spectral theorem), Proposition 6.3.18 (Coordinates in an orthonormal basis), Definition 6.4.11 (Orthogonal projection), Proposition 6.4.29 (The orthogonal projection as a linear map), Theorem 4.4.13 (Bases and dimension of a sum), Theorem 6.4.31 (The matrix of an orthogonal projection), Proposition 2.4.8 (Four views of the product)
Techniques. Pass to orthonormal coordinates (Technique 6.7.2)
Hint 1. Take an orthonormal eigenbasis $\mathbf{u}_1, \dots, \mathbf{u}_n$ and group its vectors by eigenvalue. Show that the group belonging to λ_j spans E_{λ_j}.
Hint 2. If $\mathbf{v} = \sum c_i \mathbf{u}_i$ is in E_{λ_j}, compare the coordinates of $T\mathbf{v}$ and $\lambda_j \mathbf{v}$.
Hint 3. With an orthonormal basis of E_{λ_j} in hand, $P_j \mathbf{v}$ is the part of the expansion $\mathbf{v} = \sum \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i$ coming from that group.

Sketch. Let $\mathbf{u}_1, \dots, \mathbf{u}_n$ be an orthonormal eigenbasis with $T\mathbf{u}_i = \mu_i \mathbf{u}_i$, and let $\mathcal{O}_j$ consist of the $\mathbf{u}_i$ with $\mu_i = \lambda_j$. Comparing coordinates shows $E_{\lambda_j} = \operatorname{span}(\mathcal{O}_j)$. So the eigenspaces are spanned by disjoint pieces of one orthonormal basis, which gives (a), and $P_j\mathbf{v} = \sum_{\mathbf{u}_i \in \mathcal{O}_j} \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i$. Summing over j gives $\mathbf{v}$, and applying T to the expansion of $\mathbf{v}$ gives $\sum_j \lambda_j P_j \mathbf{v}$.

By Theorem 8.2.5 or Theorem 8.2.12, V has an orthonormal basis $\mathbf{u}_1, \dots, \mathbf{u}_n$ with $T\mathbf{u}_i = \mu_i \mathbf{u}_i$, and every μ_i is one of $\lambda_1, \dots, \lambda_k$. For each j, let $\mathcal{O}_j$ be the list of those $\mathbf{u}_i$ with $\mu_i = \lambda_j$.

We claim $E_{\lambda_j} = \operatorname{span}(\mathcal{O}_j)$. Each vector of $\mathcal{O}_j$ lies in E_{λ_j}, which gives $\supseteq$. Conversely, let $\mathbf{v} \in E_{\lambda_j}$ and write $\mathbf{v} = \sum_i c_i \mathbf{u}_i$. Then

$$\sum_i c_i \mu_i \mathbf{u}_i = T\mathbf{v} = \lambda_j \mathbf{v} = \sum_i c_i \lambda_j \mathbf{u}_i,$$

so $c_i(\mu_i - \lambda_j) = 0$ for every i, by uniqueness of coordinates. Hence $c_i = 0$ unless $\mu_i = \lambda_j$, and $\mathbf{v} \in \operatorname{span}(\mathcal{O}_j)$.

(a) For $i \neq j$, $\mathcal{O}_i$ and $\mathcal{O}_j$ have no vector in common, so every vector of $\mathcal{O}_i$ is orthogonal to every vector of $\mathcal{O}_j$, and hence every vector of $\operatorname{span}(\mathcal{O}_i) = E_{\lambda_i}$ is orthogonal to every vector of E_{λ_j}. The lists $\mathcal{O}_1, \dots, \mathcal{O}_k$ together are a reordering of a basis of V, so $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_k}$ by Theorem 4.4.13.

(b) Since $\mathcal{O}_j$ is an orthonormal basis of E_{λ_j}, Definition 6.4.11 gives

$$P_j\mathbf{v} = \sum_{\mathbf{u}_i \in \mathcal{O}_j} \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i. \tag{8.2.1}$$

Summing over j gives $\sum_j P_j\mathbf{v} = \sum_{i=1}^n \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i = \mathbf{v}$ by Proposition 6.3.18, so $\sum_j P_j = \mathrm{id}_V$. For $i \neq j$, $P_j\mathbf{v} \in E_{\lambda_j} \subseteq E_{\lambda_i}^{\perp} = \ker P_i$ by (a) and Proposition 6.4.29(a), so $P_iP_j = 0$.

(c) By Proposition 6.3.18 and linearity,

$$T\mathbf{v} = \sum_{i=1}^n \langle \mathbf{v}, \mathbf{u}_i \rangle T\mathbf{u}_i = \sum_{i=1}^n \mu_i \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i = \sum_{j=1}^k \lambda_j \sum_{\mathbf{u}_i \in \mathcal{O}_j} \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i = \sum_{j=1}^k \lambda_j P_j \mathbf{v},$$

by (8.2.1).

For the matrix form, $A = UDU^* = (UD)U^*$, and the column–row expansion of a product (Proposition 2.4.8) gives $\sum_i (\mu_i \mathbf{u}_i)\mathbf{u}_i^*$. By Theorem 6.4.31, $\sum_{\mathbf{u}_i \in \mathcal{O}_j} \mathbf{u}_i \mathbf{u}_i^*$ is the matrix of $\mathrm{Pr}_{E_{\lambda_j}}$, where E_{λ_j} is now the eigenspace of A in $\mathbb{F}^n$. □

So a normal operator is a linear combination of orthogonal projections onto mutually perpendicular subspaces that fill V. The converse also holds, and the decomposition is unique, which is what makes it useful for defining things.

Proposition 8.2.19 (Uniqueness of the spectral decomposition). Let $\mu_1, \dots, \mu_m \in \mathbb{F}$ be distinct, and let $Q_1, \dots, Q_m \in \mathrm{L}(V)$ be nonzero orthogonal projections with $Q_iQ_j = 0$ for $i \neq j$ and $Q_1 + \cdots + Q_m = \mathrm{id}_V$. Let $T = \mu_1 Q_1 + \cdots + \mu_m Q_m$. Then:

(a) T is normal, and self-adjoint if every μ_j is real;

(b) the eigenvalues of T are exactly $\mu_1, \dots, \mu_m$, and $Q_j = \mathrm{Pr}_{E_{\mu_j}}$ for every j.

Proof. STANDARD

Uses. Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.6.18 (Properties of the adjoint), Definition 7.2.13 (Eigenspace), Proposition 6.4.29 (The orthogonal projection as a linear map)
Hint 1. Each Q_j is self-adjoint (Corollary 6.6.29). Compute T^*.
Hint 2. For (b), first show that T acts as μ_j on $\operatorname{im} Q_j$. Then take an eigenvector $\mathbf{v}$ with eigenvalue λ, apply Q_i to $T\mathbf{v} = \lambda\mathbf{v}$, and use $Q_iQ_j = 0$.

Sketch. (a) $T^* = \sum \overline{\mu_j} Q_j$, and $TT^* = \sum_j |\mu_j|^2 Q_j = T^*T$ because $Q_iQ_j = 0$ for $i \neq j$ and $Q_j^2 = Q_j$. (b) If $\mathbf{v} \in \operatorname{im} Q_j$ then $Q_i\mathbf{v} = Q_iQ_j\mathbf{v} = 0$ for $i \neq j$, so $T\mathbf{v} = \mu_j\mathbf{v}$: $\operatorname{im} Q_j \subseteq E_{\mu_j}$. If $T\mathbf{v} = \lambda\mathbf{v}$, applying Q_i gives $\mu_i Q_i\mathbf{v} = \lambda Q_i\mathbf{v}$, so $Q_i\mathbf{v} = \mathbf{0}$ unless $\mu_i = \lambda$; as $\mathbf{v} = \sum Q_i\mathbf{v} \neq \mathbf{0}$, λ is some μ_j and $\mathbf{v} = Q_j\mathbf{v} \in \operatorname{im} Q_j$.

Each Q_j is an orthogonal projection, so $Q_j^2 = Q_j = Q_j^*$ (Corollary 6.6.29).

(a) By Proposition 6.6.18, $T^* = \sum_j \overline{\mu_j} Q_j$. Expanding the products and using $Q_iQ_j = 0$ for $i \neq j$ and $Q_j^2 = Q_j$,

$$TT^* = \sum_{i,j} \mu_i \overline{\mu_j} Q_iQ_j = \sum_j |\mu_j|^2 Q_j = \sum_{i,j} \overline{\mu_j} \mu_i Q_jQ_i = T^*T.$$

If every μ_j is real, then $T^* = T$.

(b) Let $\mathbf{v} \in \operatorname{im} Q_j$, say $\mathbf{v} = Q_j\mathbf{x}$. Then $Q_j\mathbf{v} = Q_j^2\mathbf{x} = \mathbf{v}$ and $Q_i\mathbf{v} = Q_iQ_j\mathbf{x} = \mathbf{0}$ for $i \neq j$, so $T\mathbf{v} = \mu_j\mathbf{v}$. Hence $\operatorname{im} Q_j \subseteq E_{\mu_j}$, and since $Q_j \neq 0$, μ_j is an eigenvalue.

Conversely, let $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. For each i, $Q_iT = \sum_j \mu_j Q_iQ_j = \mu_i Q_i$, so applying Q_i to $T\mathbf{v} = \lambda\mathbf{v}$ gives $\mu_i Q_i\mathbf{v} = \lambda Q_i\mathbf{v}$, that is, $(\mu_i - \lambda)Q_i\mathbf{v} = \mathbf{0}$. Since $\mathbf{v} = \sum_i Q_i\mathbf{v} \neq \mathbf{0}$, some $Q_j\mathbf{v} \neq \mathbf{0}$, and then $\lambda = \mu_j$. Moreover $Q_i\mathbf{v} = \mathbf{0}$ for all $i \neq j$ (as $\mu_i \neq \mu_j = \lambda$), so $\mathbf{v} = Q_j\mathbf{v} \in \operatorname{im} Q_j$. This shows that the eigenvalues are exactly the μ_j and that $E_{\mu_j} = \operatorname{im} Q_j$. Finally, an orthogonal projection is the orthogonal projection onto its image (Corollary 6.6.29), so $Q_j = \operatorname{Pr}_{\operatorname{im} Q_j} = \operatorname{Pr}_{E_{\mu_j}}$. □

The projections P_j can be computed without finding any eigenvectors. On E_{λ_i}, a polynomial $p(T)$ acts as the scalar $p(\lambda_i)$ (Proposition 7.2.28), so a polynomial that is 1 at λ_j and 0 at the other eigenvalues acts as P_j. These are the Lagrange polynomials.

Proposition 8.2.20 (Spectral projections are polynomials in T). Let T satisfy the spectral hypothesis, with distinct eigenvalues $\lambda_1, \ldots, \lambda_k$ and $P_j = \operatorname{Pr}_{E_{\lambda_j}}$. Then

$$P_j = L_j(T), \quad \text{where} \quad L_j = \prod_{i \neq j} \frac{x - \lambda_i}{\lambda_j - \lambda_i}.$$

Consequently:

(a) every operator $S \in \mathrm{L}(V)$ with $ST = TS$ commutes with every P_j and maps every eigenspace E_{λ_j} into itself;

(b) if $\mathbb{F} = \mathbb{C}$, then $T^* = p(T)$ for the polynomial $p = \sum_j \overline{\lambda_j} L_j$.

Proof. STANDARD

Uses. Theorem 8.2.18 (Spectral decomposition), Proposition 7.1.29 (Lagrange polynomials in closed form), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Proposition 7.2.27 (Evaluating polynomials at an operator), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.6.18 (Properties of the adjoint)
Techniques. Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. Both P_j and $L_j(T)$ are linear, and V is the sum of the eigenspaces. Compare them on a vector of E_{λ_i}.
Hint 2. For (a), S commutes with T, hence with every polynomial in T.
Hint 3. For (b), take adjoints in $T = \sum_j \lambda_j P_j$.
Sketch. On $\mathbf{u} \in E_{\lambda_i}$, $L_j(T)\mathbf{u} = L_j(\lambda_i)\mathbf{u}$, which is $\mathbf{u}$ if $i = j$ and $\mathbf{0}$ otherwise, and P_j does the same. Since $V = \oplus_i E_{\lambda_i}$, $P_j = L_j(T)$. Then (a): S commutes with T^m for all m, hence with $L_j(T) = P_j$, and $SP_j\mathbf{v} = P_jS\mathbf{v} \in \operatorname{im} P_j$. (b) $T^* = \sum \overline{\lambda_j} P_j^* = \sum \overline{\lambda_j} L_j(T)$.

The formula for L_j is the Lagrange polynomial for the points $\lambda_1, \ldots, \lambda_k$ (Proposition 7.1.29), so $L_j(\lambda_j) = 1$ and $L_j(\lambda_i) = 0$ for $i \neq j$. (If $k = 1$, $L_1 = 1$ and the claim is $P_1 = \mathrm{id}_V$.) Let $\mathbf{u} \in E_{\lambda_i}$. By Proposition 7.2.28, $L_j(T)\mathbf{u} = L_j(\lambda_i)\mathbf{u}$. On the other hand, $P_j\mathbf{u} = \mathbf{u}$ if $i = j$, and $P_j\mathbf{u} = \mathbf{0}$ if $i \neq j$, since then $\mathbf{u} \in E_{\lambda_j}^{\perp} = \ker P_j$ by Theorem 8.2.18(a). So P_j and $L_j(T)$ agree on every eigenspace. Every $\mathbf{v} \in V$ is a sum of vectors from the eigenspaces (Theorem 8.2.18(a)), so $P_j = L_j(T)$ by linearity.

(a) If $ST = TS$, then $ST^m = T^m S$ for every $m \geq 0$ by induction on m, and so $Sq(T) = q(T)S$ for every polynomial q. In particular $SP_j = P_j S$, and for $\mathbf{v} \in E_{\lambda_j} = \operatorname{im} P_j$ we get $S\mathbf{v} = SP_j\mathbf{v} = P_j S\mathbf{v} \in \operatorname{im} P_j = E_{\lambda_j}$.

(b) By Theorem 8.2.18(c), Proposition 6.6.18, and $P_j^* = P_j$ (Corollary 6.6.29), $T^* = \sum_j \overline{\lambda_j} P_j = \sum_j \overline{\lambda_j} L_j(T) = p(T)$ by Proposition 7.2.27. □

Part (b) gives another description of normality: on a finite-dimensional complex space, T is normal if and only if T^* is a polynomial in T. (The converse holds because polynomials in T commute with T.)

Example 8.2.21 (A spectral decomposition). For $A = I_3 + J_3$ of Example 8.2.15, the eigenvalues are 4 and 1, so

$$P_4 = L_4(A) = \frac{A - I_3}{4 - 1} = \frac{1}{3}J_3, \quad P_1 = L_1(A) = \frac{A - 4I_3}{1 - 4} = I_3 - \frac{1}{3}J_3.$$

Indeed $\frac{1}{3}J_3 = \mathbf{q}_1\mathbf{q}_1^{\mathsf{T}}$ for $\mathbf{q}_1 = \frac{1}{\sqrt{3}}(1,1,1)$, as Theorem 6.4.31 predicts, and P_1 is the projection onto the plane $x_1 + x_2 + x_3 = 0$. The decomposition reads

$$A = 4 \cdot \frac{1}{3}J_3 + 1 \cdot \left(I_3 - \frac{1}{3}J_3\right).$$

We found P_1 without choosing a basis of the plane, which is exactly the choice that was not unique.

Exercise 8.2.22. ROUTINE Let $H = \begin{pmatrix} 3 & i \\ -i & 3 \end{pmatrix}$. Find the spectral decomposition $H = \lambda_1 P_1 + \lambda_2 P_2$, once with Lagrange polynomials and once from unit eigenvectors, and check that $P_1 P_2 = 0$.

Solution on page 1641

8.2.5 Functions of an operator

On an eigenspace E_λ, the operator T is just multiplication by λ, so T^2 is multiplication by λ^2, T^{-1} by λ^{-1}, and so on. The spectral decomposition lets us do this with any function of λ, not only with powers.

Definition 8.2.23 (Functions of an operator). Let T satisfy the spectral hypothesis, with distinct eigenvalues $\lambda_1, \ldots, \lambda_k$ and $P_j = \operatorname{Pr}_{E_{\lambda_j}}$. For a function $f : \{\lambda_1, \ldots, \lambda_k\} \to \mathbb{F}$, define

$$f(T) = f(\lambda_1)P_1 + \cdots + f(\lambda_k)P_k.$$

For a matrix $A = UDU^*$ as in Theorem 8.2.18, with $D = \operatorname{diag}(\mu_1, \ldots, \mu_n)$, this is

$$f(A) = U \operatorname{diag}(f(\mu_1), \ldots, f(\mu_n))U^*.$$

The two formulas agree by the matrix form of Theorem 8.2.18, grouping equal μ_i. In particular, $f(A)$ does not depend on the choice of U, because the projections P_j do not. Note also that f only needs to be defined on the eigenvalues. When $\mathbb{F} = \mathbb{R}$, f is real-valued and $f(T)$ is an operator on the real space V.

Proposition 8.2.24 (Properties of $f(T)$). Let T satisfy the spectral hypothesis, with distinct eigenvalues $\lambda_1, \ldots, \lambda_k$, and let f, g be functions from $\{\lambda_1, \ldots, \lambda_k\}$ to $\mathbb{F}$, and $c \in \mathbb{F}$.

(a) $f(T)\mathbf{v} = f(\lambda_j)\mathbf{v}$ for every $\mathbf{v} \in E_{\lambda_j}$.

(b) If $p \in \mathbb{F}[x]$ and $f(\lambda_j) = p(\lambda_j)$ for every j, then $f(T) = p(T)$. In particular, $f(T) = p(T)$ for the interpolating polynomial $p = \sum_j f(\lambda_j) L_j$ of Proposition 8.2.20, and $f(T)$ commutes with every operator that commutes with T.

(c) $(f+g)(T) = f(T) + g(T)$, $(cf)(T) = cf(T)$, and $(fg)(T) = f(T)g(T)$.

(d) $f(T)^* = \overline{f}(T)$, where $\overline{f}(\lambda) = \overline{f(\lambda)}$. So $f(T)$ is normal, and it is self-adjoint if and only if every $f(\lambda_j)$ is real.

(e) The eigenvalues of $f(T)$ are the values $f(\lambda_1), \ldots, f(\lambda_k)$.

Proof. STANDARD

Uses. Definition 8.2.23 (Functions of an operator), Theorem 8.2.18 (Spectral decomposition), Proposition 7.2.28 (Polynomials act on eigenvectors by their values), Proposition 8.2.20 (Spectral projections are polynomials in T), Proposition 6.6.18 (Properties of the adjoint), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 8.2.19 (Uniqueness of the spectral decomposition)
Techniques. Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. Prove (a) first, from $P_i\mathbf{v} = \mathbf{0}$ for $i \neq j$ and $P_j\mathbf{v} = \mathbf{v}$.
Hint 2. Then every identity between operators built from T can be tested on each eigenspace, where everything is a scalar. V is the sum of the eigenspaces.
Hint 3. For (d), take adjoints term by term. For (e), use Proposition 8.2.19, after grouping equal values of f.
Sketch. (a) is immediate from $P_iP_j = 0$ and $P_j\mathbf{v} = \mathbf{v}$ on E_{λ_j}. Since $V = \oplus E_{\lambda_j}$, two operators agree as soon as they agree on each E_{λ_j}; on E_{λ_j}, $p(T)$, $f(T) + g(T)$, and $f(T)g(T)$ act as $p(\lambda_j)$, $f(\lambda_j) + g(\lambda_j)$, and $f(\lambda_j)g(\lambda_j)$, which gives (b) and (c). (d) $f(T)^* = \sum \overline{f(\lambda_j)} P_j$, and $f(T)$ commutes with $\overline{f}(T)$ by (c). (e) Group the P_j by the value of f and apply Proposition 8.2.19.

By Theorem 8.2.18(a), $V = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_k}$, so two linear maps on V are equal as soon as they agree on each E_{λ_j}.

(a) Let $\mathbf{v} \in E_{\lambda_j}$. Then $P_j\mathbf{v} = \mathbf{v}$, and $P_i\mathbf{v} = \mathbf{0}$ for $i \neq j$ since $\mathbf{v} \in E_{\lambda_i}^{\perp}$. So $f(T)\mathbf{v} = f(\lambda_j)\mathbf{v}$.

(b) On E_{λ_j}, $p(T)$ acts as $p(\lambda_j)$ (Proposition 7.2.28) and $f(T)$ as $f(\lambda_j)$ by (a). These agree, so $f(T) = p(T)$. The interpolating polynomial satisfies $p(\lambda_i) = \sum_j f(\lambda_j) L_j(\lambda_i) = f(\lambda_i)$. If $ST = TS$, then S commutes with $p(T) = f(T)$, as in the proof of Proposition 8.2.20(a).

(c) On E_{λ_j}, $f(T) + g(T)$ and $cf(T)$ act as $f(\lambda_j) + g(\lambda_j)$ and $cf(\lambda_j)$. For $\mathbf{v} \in E_{\lambda_j}$, $g(T)\mathbf{v} = g(\lambda_j)\mathbf{v} \in E_{\lambda_j}$, so $f(T)g(T)\mathbf{v} = g(\lambda_j)f(T)\mathbf{v} = f(\lambda_j)g(\lambda_j)\mathbf{v} = (fg)(T)\mathbf{v}$.

(d) By Proposition 6.6.18 and $P_j^* = P_j$ (Corollary 6.6.29), $f(T)^* = \sum_j \overline{f(\lambda_j)} P_j = \overline{f}(T)$. By (c), $f(T)f(T)^* = (f\overline{f})(T) = (\overline{f}f)(T) = f(T)^* f(T)$. If every $f(\lambda_j)$ is real, $\overline{f} = f$ and $f(T)^* = f(T)$. Conversely, if $f(T)^* = f(T)$, then applying both sides to a nonzero $\mathbf{v} \in E_{\lambda_j}$ and using (a) gives $\overline{f(\lambda_j)} = f(\lambda_j)$.

(e) Let $\nu_1, \ldots, \nu_m$ be the distinct values among $f(\lambda_1), \ldots, f(\lambda_k)$, and let Q_i be the sum of the P_j with $f(\lambda_j) = \nu_i$. Then $f(T) = \sum_i \nu_i Q_i$. Each Q_i is nonzero, and by Theorem 8.2.18(b), $Q_i^2 = Q_i = Q_i^*$, $Q_iQ_{i'} = 0$ for $i \neq i'$, and $\sum_i Q_i = \mathrm{id}_V$. So by Corollary 6.6.29 the Q_i are orthogonal projections, and Proposition 8.2.19 says that the eigenvalues of $f(T)$ are $\nu_1, \ldots, \nu_m$. □

Technique 8.2.25 (Apply a function to the eigenvalues). To build an operator that does to T what a scalar function does to a number (a square root, an inverse, an exponential, the sign, a cutoff that keeps only large eigenvalues), keep the eigenspaces of T and apply the function to the eigenvalues: $f(T) = \sum_j f(\lambda_j) \operatorname{Pr}_{E_{\lambda_j}}$, or $f(A) = Uf(D)U^*$. Identities between such operators reduce to identities between numbers, one eigenvalue at a time (Proposition 8.2.24), which is Technique 7.4.25 in its strongest form.

Reach for it when the hypothesis says normal or self-adjoint and the problem asks for an operator with prescribed algebraic behavior: "find S with $S^2 = T$", "show that T has a self-adjoint inverse square root", "solve $\mathbf{x}' = A\mathbf{x}$". For a diagonalizable but not normal operator the same recipe works with SDS^{-1} in place

of UDU^* (Technique 7.4.22), but the result is not normal in general. The canonical example is the square root (Example 8.2.26); Section 8.3 shows that this square root is the only self-adjoint square root with nonnegative eigenvalues.

Used in. Exercise 8.2.39, Exercise 8.2.40, Exercise 8.2.47, Notation 8.3.10, Exercise 8.3.12, Exercise 8.3.37, Exercise 8.4.38, Exercise 8.2.33, Exercise 8.2.34, Exercise 8.2.38.

Example 8.2.26 (A square root). Let T be self-adjoint with every eigenvalue $\lambda_j \geq 0$, and let $f(\lambda) = \sqrt{\lambda}$. By Proposition 8.2.24, $\sqrt{T} = \sum_j \sqrt{\lambda_j} P_j$ is self-adjoint, its eigenvalues $\sqrt{\lambda_j}$ are nonnegative, and $\left(\sqrt{T}\right)^2 = \left(f^2\right)(T) = T$, since $f^2(\lambda) = \lambda$ on the eigenvalues.

For $A = \begin{pmatrix} 5 & 4 \\ 4 & 5 \end{pmatrix}$, the eigenvalues are 9 and 1, with $E_9 = \operatorname{span}((1,1))$ and $E_1 = \operatorname{span}((1,-1))$, so

$$P_9 = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, \quad P_1 = \frac{1}{2}\begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}, \quad \sqrt{A} = 3P_9 + 1P_1 = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}.$$

Check: $\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}^2 = \begin{pmatrix} 5 & 4 \\ 4 & 5 \end{pmatrix}$. The choice of $3 = \sqrt{9}$ and $1 = \sqrt{1}$ was ours; $3P_9 - P_1 = \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}$ is another symmetric square root of A, with eigenvalues 3 and -1.

Similarly, if no eigenvalue is 0, then $f(\lambda) = 1/\lambda$ gives $f(T) = \sum_j \lambda_j^{-1} P_j$ with $Tf(T) = (\lambda \cdot 1/\lambda)(T) = \mathrm{id}_V$, so $T^{-1} = \sum_j \lambda_j^{-1} P_j$.

BEYOND 21-242: The matrix exponential is not covered in 21-242.

Example 8.2.27 (The exponential). For a real symmetric A with $A = \sum_j \lambda_j P_j$, define $e^{tA} = \sum_j e^{t\lambda_j} P_j$ for $t \in \mathbb{R}$. By Proposition 8.2.24, $e^{sA}e^{tA} = e^{(s+t)A}$, and $e^{0A} = \mathrm{id}$. For $\mathbf{x}_0 \in \mathbb{R}^n$, the function

$$\mathbf{x}(t) = e^{tA}\mathbf{x}_0 = \sum_j e^{t\lambda_j} P_j \mathbf{x}_0$$

satisfies $\mathbf{x}'(t) = \sum_j \lambda_j e^{t\lambda_j} P_j \mathbf{x}_0 = A\mathbf{x}(t)$, using $AP_j = \lambda_j P_j$, and $\mathbf{x}(0) = \mathbf{x}_0$. This is the solution of Proposition 7.4.34 written with orthogonal projections: the component of $\mathbf{x}_0$ in each eigenspace grows or decays at its own rate $e^{t\lambda_j}$, independently of the others. One can show that $e^{tA} = \sum_{m \geq 0} t^m A^m / m!$, the series that defines e^{tA} for every square matrix, but we do not need this.

8.2.6 Quadratic forms and principal axes

The historical origin of the spectral theorem is the problem of finding the axes of an ellipse or ellipsoid given by an equation such as $5x^2 - 4xy + 8y^2 = 36$. A homogeneous quadratic polynomial in $x_1, \ldots, x_n$ can always be written as $\mathbf{x}^{\mathsf{T}} A \mathbf{x}$ with A symmetric: put the coefficient of x_i^2 at a_{ii}, and split the coefficient of $x_i x_j$ $(i \neq j)$ evenly between a_{ij} and a_{ji}. Section 12.2 develops quadratic forms systematically; here is the one fact the spectral theorem gives immediately.

Corollary 8.2.28 (Principal axes). Let $A \in \mathbb{R}^{n \times n}$ be symmetric, and write $A = QDQ^{\mathsf{T}}$ with Q orthogonal with columns $\mathbf{q}_1, \ldots, \mathbf{q}_n$ and $D = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ (Theorem 8.2.12). For $\mathbf{x} \in \mathbb{R}^n$, let $\mathbf{y} = Q^{\mathsf{T}}\mathbf{x}$, so that $y_i = \langle \mathbf{x}, \mathbf{q}_i \rangle$. Then

$$\mathbf{x}^{\mathsf{T}} A \mathbf{x} = \lambda_1 y_1^2 + \cdots + \lambda_n y_n^2 \quad \text{and} \quad \|\mathbf{y}\| = \|\mathbf{x}\|.$$

Proof. ROUTINE

Uses. Theorem 8.2.12 (Real spectral theorem), Proposition 2.4.23 (Transpose of a product), Definition 6.3.33 (Unitary and orthogonal matrices), Theorem 6.3.22 (Parseval's identity)
Techniques. Choose a convenient basis (Technique 4.5.33)
Hint. Substitute $A = QDQ^{\mathsf{T}}$ and regroup.
Sketch. $\mathbf{x}^{\mathsf{T}} QDQ^{\mathsf{T}} \mathbf{x} = \left(Q^{\mathsf{T}}\mathbf{x}\right)^{\mathsf{T}} D \left(Q^{\mathsf{T}}\mathbf{x}\right) = \mathbf{y}^{\mathsf{T}} D \mathbf{y} = \sum \lambda_i y_i^2$. And $\|\mathbf{y}\|^2 = \mathbf{x}^{\mathsf{T}} QQ^{\mathsf{T}} \mathbf{x} = \|\mathbf{x}\|^2$.

By Proposition 2.4.23, $\mathbf{x}^{\mathsf{T}}Q = \left(Q^{\mathsf{T}}\mathbf{x}\right)^{\mathsf{T}} = \mathbf{y}^{\mathsf{T}}$, so

$$\mathbf{x}^{\mathsf{T}}A\mathbf{x} = \left(\mathbf{x}^{\mathsf{T}}Q\right)D\left(Q^{\mathsf{T}}\mathbf{x}\right) = \mathbf{y}^{\mathsf{T}}D\mathbf{y} = \sum_{i=1}^{n}\lambda_i y_i^2.$$

The i-th entry of $Q^{\mathsf{T}}\mathbf{x}$ is $\mathbf{q}_i^{\mathsf{T}}\mathbf{x} = \langle \mathbf{x}, \mathbf{q}_i\rangle$. Since Q is orthogonal, $QQ^{\mathsf{T}} = I_n$, so $\|\mathbf{y}\|^2 = \mathbf{x}^{\mathsf{T}}QQ^{\mathsf{T}}\mathbf{x} = \|\mathbf{x}\|^2$ (alternatively, this is Theorem 6.3.22 in the basis $\mathbf{q}_1, \ldots, \mathbf{q}_n$). □

In the coordinates y_i along the eigenvectors, the cross terms disappear. The lines $\operatorname{span}(\mathbf{q}_i)$ are the **principal axes** of the quadratic form.

Example 8.2.29 (An ellipse). The equation $5x^2 - 4xy + 8y^2 = 36$ is $\mathbf{x}^{\mathsf{T}}A\mathbf{x} = 36$ with $A = \begin{pmatrix} 5 & -2 \\ -2 & 8 \end{pmatrix}$; the cross term $-4xy$ is split as $-2xy - 2yx$. Here $p_A = x^2 - 13x + 36 = (x-4)(x-9)$, with $E_4 = \operatorname{span}((2,1))$ and $E_9 = \operatorname{span}((-1,2))$, so $\mathbf{q}_1 = \frac{1}{\sqrt{5}}(2,1)$ and $\mathbf{q}_2 = \frac{1}{\sqrt{5}}(-1,2)$. In the coordinates $y_1 = (2x+y)/\sqrt{5}$, $y_2 = (-x+2y)/\sqrt{5}$, Corollary 8.2.28 turns the equation into

$$4y_1^2 + 9y_2^2 = 36, \quad \text{that is,} \quad \frac{y_1^2}{9} + \frac{y_2^2}{4} = 1.$$

This is an ellipse with semi-axis 3 along $\mathbf{q}_1$ and semi-axis 2 along $\mathbf{q}_2$. Its vertices are $\pm 3\mathbf{q}_1 = \pm\frac{3}{\sqrt{5}}(2,1)$ and $\pm 2\mathbf{q}_2 = \pm\frac{2}{\sqrt{5}}(-1,2)$; for instance $\mathbf{x} = \frac{3}{\sqrt{5}}(2,1)$ gives $\frac{1}{5}(5\cdot 36 - 4\cdot 18 + 8\cdot 9) = 36$.

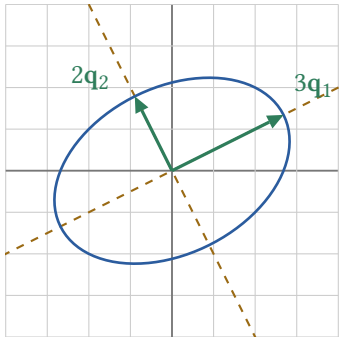


Figure 8.2.1. The ellipse $5x^2 - 4xy + 8y^2 = 36$ and its principal axes (dashed), along the eigenvectors $\mathbf{q}_1 = \frac{1}{\sqrt{5}}(2,1)$ and $\mathbf{q}_2 = \frac{1}{\sqrt{5}}(-1,2)$ of $A = \begin{pmatrix} 5 & -2 \\ -2 & 8 \end{pmatrix}$. The semi-axes are $\sqrt{36/4} = 3$ and $\sqrt{36/9} = 2$.

Remark 8.2.30 (Classifying conics). The same computation classifies every curve $ax^2 + 2bxy + cy^2 = 1$. Let $\lambda_1 \geq \lambda_2$ be the eigenvalues of $A = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$, so the curve is $\lambda_1 y_1^2 + \lambda_2 y_2^2 = 1$ in the rotated coordinates of Corollary 8.2.28.

- If $\lambda_1 \geq \lambda_2 > 0$, it is an ellipse with semi-axes $1/\sqrt{\lambda_1}$ and $1/\sqrt{\lambda_2}$ along $\mathbf{q}_1$ and $\mathbf{q}_2$ (a circle if $\lambda_1 = \lambda_2$).
- If $\lambda_1 > 0 > \lambda_2$, it is a hyperbola whose vertices $\pm\mathbf{q}_1/\sqrt{\lambda_1}$ lie on the axis of the positive eigenvalue.
- If $\lambda_1 > 0 = \lambda_2$, it is the pair of parallel lines $y_1 = \pm 1/\sqrt{\lambda_1}$.
- If $\lambda_1 \leq 0$, the left side is never positive and the curve is empty.

Since $\lambda_1\lambda_2 = \det A = ac - b^2$ and $\lambda_1 + \lambda_2 = \operatorname{tr} A = a + c$, the type can be read off without computing eigenvalues: an ellipse when $ac - b^2 > 0$ and $a > 0$, a hyperbola when $ac - b^2 < 0$. This is the discriminant test from analytic geometry, now with a proof.

BEYOND 21-242: Infinite-dimensional spaces are not covered in 21-242.

Remark 8.2.31 (Infinite dimensions). The spectral theorems need V to be finite-dimensional. On $C([0,1],\mathbb{C})$ with $\langle f, g\rangle = \int_0^1 f\overline{g}$, the multiplication operator $(Mf)(t) = tf(t)$ is self-adjoint (Example 6.6.14), but it has no eigenvalues at all: if $tf(t) = \lambda f(t)$ for all t, then $f(t) = 0$ for every $t \neq \lambda$, and by

continuity $f = 0$. So no eigenvector exists, let alone an orthonormal eigenbasis. The infinite-dimensional theory replaces the sum $\sum \lambda_j P_j$ by an integral over a "continuous spectrum"; Section 15.3 gives a first look.

Exercises

Exercise 8.2.32. STANDARD Find an orthogonal Q and a diagonal D with

$$\begin{pmatrix} 3 & -2 & 4 \\ -2 & 6 & 2 \\ 4 & 2 & 3 \end{pmatrix} = QDQ^{\mathsf{T}}.$$

Solution on page 1642

Exercise 8.2.33. STANDARD Let V be a finite-dimensional complex inner product space and $T \in \mathrm{L}(V)$ normal. Show:

(a) T is self-adjoint if and only if every eigenvalue of T is real;
(b) $T^* = -T$ if and only if every eigenvalue of T is purely imaginary (in $i\mathbb{R}$);
(c) T is an orthogonal projection if and only if every eigenvalue of T is 0 or 1;
(d) $T^*T = \mathrm{id}_V$ if and only if every eigenvalue of T has absolute value 1.

Then show by an example that (a) fails for operators that are not normal.

Solution on page 1643

Exercise 8.2.34. STANDARD Prove or disprove each statement. Throughout, V is a finite-dimensional inner product space.

(a) If V is complex, $T \in \mathrm{L}(V)$ is normal, and $T^m = 0$ for some $m \geq 1$, then $T = 0$.
(b) If V is real, $T \in \mathrm{L}(V)$ is self-adjoint, and $T^3 + T = 2\mathrm{id}_V$, then $T = \mathrm{id}_V$.
(c) The statement in (b) remains true without the hypothesis that T is self-adjoint.
(d) If $A \in \mathbb{R}^{n\times n}$ is symmetric, then every basis of $\mathbb{R}^n$ consisting of eigenvectors of A is orthogonal.
(e) If $A \in \mathbb{R}^{n\times n}$ is diagonalizable over $\mathbb{R}$ and its eigenspaces are pairwise orthogonal, then A is symmetric.

Solution on page 1643

Exercise 8.2.35. STANDARD Find the error in the following "proof" that every normal operator T on a finite-dimensional real inner product space V with $\dim V \geq 1$ has an orthonormal eigenbasis. Then give a counterexample to the claim, and name a hypothesis on T that repairs the proof.

"Proof." Induct on $n = \dim V$; the case $n = 1$ is clear. Let $n \geq 2$, and let $\mathbf{u}$ be a unit eigenvector of T, with $T\mathbf{u} = \lambda\mathbf{u}$. Since T is normal, $\|(T^* - \lambda\,\mathrm{id})\mathbf{u}\| = \|(T - \lambda\,\mathrm{id})\mathbf{u}\| = 0$, so $\mathbf{u}$ is an eigenvector of T^* as well. Hence $W = \mathrm{span}(\mathbf{u})^{\perp}$ is invariant under T and T^*, and $T{\restriction}_W$ is normal. By the induction hypothesis, W has an orthonormal eigenbasis for $T{\restriction}_W$, and adding $\mathbf{u}$ gives one for T.

Solution on page 1643

Exercise 8.2.36. STANDARD Let V be a finite-dimensional inner product space over $\mathbb{F}$ and let $S, T \in \mathrm{L}(V)$ be self-adjoint. Show that $ST = TS$ if and only if V has an orthonormal basis consisting of vectors that are eigenvectors of both S and T.

Solution on page 1644

Exercise 8.2.37. STANDARD Let V be a finite-dimensional complex inner product space, $T \in \mathrm{L}(V)$ normal, and $S \in \mathrm{L}(V)$ with $ST = TS$.

(a) Show that $ST^* = T^*S$.
(b) Show by an example that (a) can fail if T is not normal.
(c) Suppose that S is normal as well. Show that S, S^*, T, T^* pairwise commute, and deduce that ST and $S + T$ are normal.

Solution on page 1644

Exercise 8.2.38. STANDARD

(a) Find the symmetric $A \in \mathbb{R}^{2\times 2}$ with eigenvalues 1 and 3 such that $(1, 2)$ is an eigenvector for 3, and show that it is unique.
(b) Find a matrix $B \in \mathbb{R}^{2\times 2}$, not symmetric, with eigenvalues 1 and 3 such that $(1, 2)$ is an eigenvector for 3.

Solution on page 1645

Exercise 8.2.39. STANDARD Let $A = \begin{pmatrix} 10 & 6 \\ 6 & 10 \end{pmatrix}$.

(a) Find the symmetric B with nonnegative eigenvalues such that $B^2 = A$.
(b) Find all $B \in \mathbb{R}^{2\times 2}$ with $B^2 = A$.
(c) Explain why I_2, in contrast, has infinitely many square roots in $\mathbb{R}^{2\times 2}$.

Solution on page 1645

Exercise 8.2.40. STANDARD BEYOND 21-242 Using Example 8.2.27 (and its analogue $e^{tN} = \sum_j e^{t\lambda_j} P_j$ for normal $N \in \mathbb{C}^{n\times n}$), compute e^{tA} for $A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and e^{tJ} for $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, where $t \in \mathbb{R}$. Interpret e^{tJ} geometrically.

Solution on page 1646

Exercise 8.2.41. STANDARD Identify each curve in $\mathbb{R}^2$ (ellipse, hyperbola, pair of lines, or empty), and find its principal axes.

(a) $x^2 + 4xy + y^2 = 1$
(b) $3x^2 + 2xy + 3y^2 = 8$
(c) $2x^2 + 4xy + 2y^2 = 1$

Solution on page 1646

Exercise 8.2.42. STANDARD Let $T \in \mathrm{L}(V)$ be self-adjoint, and let $\lambda_{\min}$ and $\lambda_{\max}$ be its smallest and largest eigenvalues.

(a) Show that $\lambda_{\min}\|\mathbf{v}\|^2 \le \langle T\mathbf{v}, \mathbf{v}\rangle \le \lambda_{\max}\|\mathbf{v}\|^2$ for every $\mathbf{v} \in V$, with equality on the right if and only if $\mathbf{v} \in E_{\lambda_{\max}}$.
(b) Deduce that for a real symmetric $A \in \mathbb{R}^{n\times n}$, $\lambda_{\min} \le a_{ii} \le \lambda_{\max}$ for every i.
(c) Show that $\begin{pmatrix} 1 & 2 & 0 \\ 2 & 1 & 2 \\ 0 & 2 & 1 \end{pmatrix}$ has an eigenvalue greater than 3.

Solution on page 1647

Exercise 8.2.43. HARD Let $A \in \mathbb{R}^{n\times n}$ be symmetric and nonzero. Show that

$$\operatorname{rank} A \geq \frac{(\operatorname{tr} A)^2}{\operatorname{tr}(A^2)},$$

and determine when equality holds.

Solution on page 1647

Exercise 8.2.44. HARD Let V be a finite-dimensional complex inner product space and $T \in \mathrm{L}(V)$. Show that T is normal if and only if every eigenvector of T is also an eigenvector of T^*.

Solution on page 1648

Exercise 8.2.45. STANDARD

(a) Show that $A \in \mathbb{R}^{2\times 2}$ satisfies $A^{\mathsf{T}}A = AA^{\mathsf{T}}$ if and only if A is symmetric or $A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ for some $a, b \in \mathbb{R}$.

(b) Deduce that a real normal 2×2 matrix that is not symmetric has no real eigenvalue, and interpret $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ geometrically.

Solution on page 1648

Exercise 8.2.46. STANDARD Adapt the third proof of Theorem 8.2.5 (the sum of the eigenspaces is everything) to give another proof of (I) ⇒ (II) in Theorem 8.2.12. Point out exactly where self-adjointness is used.

Solution on page 1649

Exercise 8.2.47. HARD Let $H \in \mathbb{C}^{n\times n}$ be Hermitian.

(a) Show that $I_n + iH$ is invertible.

(b) Show that $C = (I_n - iH)(I_n + iH)^{-1}$ is unitary, and that -1 is not an eigenvalue of C.

(c) Conversely, show that every unitary C without the eigenvalue -1 arises in this way from a unique Hermitian H.

Solution on page 1649

Exercise 8.2.48. CHALLENGE BEYOND 21-242 Let $A \in \mathbb{R}^{n\times n}$ be normal ($A^{\mathsf{T}}A = AA^{\mathsf{T}}$). Show that there is an orthogonal Q such that $Q^{\mathsf{T}}AQ$ is block diagonal, with each block either 1×1 or of the form $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ with $b > 0$.

Solution on page 1650

8.3 Positive operators

Among complex numbers, the nonnegative reals stand out: they are the numbers of the form $\overline{w}w$, and also the real numbers that are squares of real numbers. In the analogy between operators and complex numbers (Section 6.6.5), the adjoint plays the role of complex conjugation and self-adjoint operators play the role of real numbers. This section finds the operators that play the role of nonnegative numbers. We have already met several: orthogonal projections, the matrices A^*A of the normal equations (Theorem 6.5.5), and Gram matrices (Definition 6.3.28). Positive operators have nonnegative eigenvalues and a unique positive square root, and the positive definite ones are exactly the matrices of inner products. In Section 9.1 the positive operator T^*T produces the singular value decomposition.

Throughout, V is a finite-dimensional inner product space over $\mathbb{F}$ with $\dim V \geq 1$, and $T \in \mathrm{L}(V)$; only the definitions make sense more generally. Matrices in $\mathbb{F}^{n\times n}$ act on $\mathbb{F}^n$ with the dot product, so that $\langle A\mathbf{x}, \mathbf{x}\rangle = \mathbf{x}^* A\mathbf{x}$. For an orthonormal basis $\mathcal{O}$ we write $[T]_{\mathcal{O}}$ for $[T]_{\mathcal{O}\mathcal{O}}$, as in Section 8.2.

8.3.1 Positive operators

Definition 8.3.1 (Positive operator). Let V be an inner product space. An operator $T \in \mathrm{L}(V)$ is **positive** if T is self-adjoint and

$$\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0 \quad \text{for every } \mathbf{v} \in V.$$

A matrix $A \in \mathbb{F}^{n\times n}$ is **positive** if T_A is positive on $\mathbb{F}^n$ with the dot product, that is, if $A^* = A$ and $\mathbf{x}^* A\mathbf{x} \geq 0$ for every $\mathbf{x} \in \mathbb{F}^n$.

The name is traditional but a little misleading: "positive" here means "nonnegative", in the sense in which $0 \geq 0$. For matrices the same notion is often called **positive semidefinite**. The strict version, $\langle T\mathbf{v}, \mathbf{v}\rangle > 0$ for $\mathbf{v} \neq \mathbf{0}$, is positive definiteness (Definition 8.3.14).

Intuition (What the condition says). In a real space, $\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ says that $T\mathbf{v}$ never makes an obtuse angle with $\mathbf{v}$: T may stretch, shrink, and turn a vector, but never by more than a right angle. For a self-adjoint T the spectral theorem says more: T stretches V along perpendicular axes, and the stretch factors are its eigenvalues. On the axis of a unit eigenvector $\mathbf{u}$ with $T\mathbf{u} = \lambda\mathbf{u}$ we have $\langle T\mathbf{u}, \mathbf{u}\rangle = \lambda$, so positivity says at least that no axis is flipped. Theorem 8.3.5 shows that this is all it says.

Example 8.3.2 (Positive operators).

(a) Every orthogonal projection $P = \mathrm{Pr}_U$ is positive. It is self-adjoint and $P^2 = P$ (Corollary 6.6.29), so

$$\langle P\mathbf{v}, \mathbf{v}\rangle = \langle P^2\mathbf{v}, \mathbf{v}\rangle = \langle P\mathbf{v}, P\mathbf{v}\rangle = \|P\mathbf{v}\|^2 \geq 0.$$

(b) Let W be an inner product space and let $S \in \mathrm{L}(V, W)$ have an adjoint. Then $S^*S \in \mathrm{L}(V)$ is positive: $(S^*S)^* = S^*(S^*)^* = S^*S$ by Proposition 6.6.18, and $\langle S^*S\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, S\mathbf{v}\rangle = \|S\mathbf{v}\|^2 \geq 0$. In particular A^*A is positive for every $A \in \mathbb{F}^{m\times n}$; it is the coefficient matrix of the normal equations (Theorem 6.5.5).

(c) The Gram matrix G of a list $\mathbf{v}_1, \ldots, \mathbf{v}_k$ in V (Definition 6.3.28) is positive. Its entries satisfy $g_{ji} = \langle \mathbf{v}_i, \mathbf{v}_j\rangle = \overline{\langle \mathbf{v}_j, \mathbf{v}_i\rangle} = \overline{g_{ij}}$, so $G^* = G$, and $\mathbf{c}^* G\mathbf{c} = \|c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k\|^2 \geq 0$ by Proposition 6.3.30. For matrices, (b) is the special case of the columns of A, whose Gram matrix is A^*A.

(d) $A = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}$ is positive. It is Hermitian, and for $\mathbf{x} \in \mathbb{C}^2$,

$$\mathbf{x}^* A\mathbf{x} = 2|x_1|^2 - 2\,\mathrm{Re}(\overline{x_1}x_2) + 2|x_2|^2 = |x_1 - x_2|^2 + |x_1|^2 + |x_2|^2 \geq 0.$$

Non-example 8.3.3 (Matrices that are not positive).

(a) $A = \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}$ is symmetric with positive entries, but for $\mathbf{x} = (1, -1)$ we get $\mathbf{x}^{\mathsf{T}} A\mathbf{x} = 1 - 2 - 2 + 1 = -2 < 0$. Together with Example 8.3.2(d), this shows that the signs of the entries say little about positivity.

(b) On $\mathbb{R}^2$, let $B = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$. Then $\mathbf{x}^{\mathsf{T}} B\mathbf{x} = x_1^2 - x_1x_2 + x_2x_1 + x_2^2 = \|\mathbf{x}\|^2 \geq 0$ for every $\mathbf{x} \in \mathbb{R}^2$, but B is not symmetric, so it is not positive. Geometrically, B is $\sqrt{2}$ times the rotation by $\pi/4$: it turns every vector by an angle of $\pi/4$, less than a right angle, and its characteristic polynomial $(x-1)^2 + 1$ has no real roots.

Remark 8.3.4 (Why self-adjointness is part of the definition). Over $\mathbb{C}$ the self-adjointness in Definition 8.3.1 comes for free. If $\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ for every $\mathbf{v}$, then in particular every value $\langle T\mathbf{v}, \mathbf{v}\rangle$ is real, and T is self-adjoint by Proposition 6.6.30. So on a complex space, T is positive if and only if $\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ for every $\mathbf{v} \in V$.

Over $\mathbb{R}$ it does not come for free, and Non-example 8.3.3(b) shows why we must ask for it. On a real space $\langle T^*\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \langle T\mathbf{v}, \mathbf{v}\rangle$, so

$$\langle T\mathbf{v}, \mathbf{v}\rangle = \left\langle \frac{1}{2}(T + T^*)\mathbf{v}, \mathbf{v}\right\rangle \quad \text{for every } \mathbf{v} \in V.$$

The values $\langle T\mathbf{v}, \mathbf{v}\rangle$ only see the self-adjoint part $(T + T^*)/2$ of T (Exercise 6.1.52), and the condition $\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ says nothing about the rest. For B, the self-adjoint part is I_2 and the rest is the rotation $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Without the self-adjointness requirement, B would count as positive although it has no real eigenvalues, it is not of the form S^*S (such operators are self-adjoint), and it has no self-adjoint square root (the square of a self-adjoint operator is self-adjoint). With the requirement, the real and complex notions agree: a real matrix is positive in $\mathbb{R}^{n\times n}$ if and only if it is positive in $\mathbb{C}^{n\times n}$ (Exercise 8.3.30), and the characterizations below hold over both fields with the same proofs.

Intuition (Positive operators as nonnegative numbers). A complex number z is a nonnegative real number exactly when it can be written in any one of the forms $z = \overline{w}w$ with $w \in \mathbb{C}$, $z = r^2$ with $r \in \mathbb{R}$, or $z = r^2$ with $r \geq 0$. Each form has an operator analogue: $T = S^*S$, $T = R^2$ with R self-adjoint, and $T = R^2$ with R positive. One more description makes sense only for operators. By the spectral theorem, a self-adjoint operator is described by real numbers, its eigenvalues, attached to perpendicular axes, and we can ask that these numbers be nonnegative. The next theorem says that all of these descriptions agree with the definition.

8.3.2 Characterizations

Theorem 8.3.5 (Characterizations of positive operators). Let V be a finite-dimensional inner product space with $\dim V \geq 1$, and let $T \in \mathrm{L}(V)$. The following are equivalent:

(I) T is positive;

(II) T is self-adjoint and every eigenvalue of T is nonnegative;

(III) $[T]_{\mathcal{O}}$ is diagonal with nonnegative diagonal entries for some orthonormal basis $\mathcal{O}$ of V;

(IV) $T = R^2$ for some positive $R \in \mathrm{L}(V)$;

(V) $T = R^2$ for some self-adjoint $R \in \mathrm{L}(V)$;

(VI) $T = S^*S$ for some $S \in \mathrm{L}(V, W)$, where W is a finite-dimensional inner product space;

(VII) for some orthonormal basis $\mathcal{O}$ of V, $[T]_{\mathcal{O}}$ is the Gram matrix of a list of vectors in some inner product space.

In matrix form: $A \in \mathbb{F}^{n\times n}$ is positive if and only if $A = UDU^*$ with U unitary and D diagonal with nonnegative entries, if and only if $A = B^*B$ for some $B \in \mathbb{F}^{m\times n}$, if and only if A is a Gram matrix.

Over $\mathbb{C}$, condition (I) may be replaced by "$\langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ for every $\mathbf{v}$" (Remark 8.3.4).

Intuition (How the cycle is arranged). Seven conditions need seven implications if we arrange them in a cycle (Technique 2.7.1). Most of the cycle runs downhill, each condition handing the next one a witness: (II) $\Rightarrow$ (III) is the spectral theorem, (III) $\Rightarrow$ (IV) takes square roots of the diagonal entries, and (IV) $\Rightarrow$ (V) $\Rightarrow$ (VI) forget information. The cycle closes with one computation. Once $T = S^*S$, we have $\langle T\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2$, and the Gram condition (VII) is the same computation written in coordinates. The only deep step is the spectral theorem.

Proof. STANDARD

Uses. Definition 8.3.1 (Positive operator), Theorem 8.2.12 (Real spectral theorem), Corollary 8.2.7 (Hermitian matrices), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Theorem 2.2.1 (Linear maps are determined by a basis),

Corollary 6.6.28 (Self-adjointness in an orthonormal basis), Proposition 6.3.18 (Coordinates in an orthonormal basis), Definition 6.3.28 (Gram matrix), Proposition 6.3.30 (Gram matrices detect independence), Theorem 6.6.15 (Existence of adjoints), Definition 8.2.1 (Unitarily and orthogonally diagonalizable)
Techniques. Proving TFAE (Technique 2.7.1), Gram matrices (Technique 6.3.31), Pass to orthonormal coordinates (Technique 6.7.2)
Hint 1. Use the cycle (I) ⇒ (II) ⇒ ⋯ ⇒ (VII) ⇒ (I). For (I) ⇒ (II), put an eigenvector into $\langle T\mathbf{v}, \mathbf{v}\rangle$.
Hint 2. (II) ⇒ (III) is a spectral theorem. For (III) ⇒ (IV), define R on the orthonormal eigenbasis by taking square roots of the eigenvalues.
Hint 3. For (VI) ⇒ (VII), compute the entries $\langle T\mathbf{e}_j, \mathbf{e}_i\rangle$ of $[T]_{\mathcal{O}}$ when $T = S^*S$. For (VII) ⇒ (I), expand $\langle T\mathbf{v}, \mathbf{v}\rangle$ in the coordinates $\mathbf{c} = [\mathbf{v}]_{\mathcal{O}}$ and use Proposition 6.3.30.
Sketch. (I) ⇒ (II): $\lambda\|\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$ for an eigenvector. (II) ⇒ (III): spectral theorem. (III) ⇒ (IV): $R\mathbf{e}_i = \sqrt{d_i}\mathbf{e}_i$ on the eigenbasis. (IV) ⇒ (V) ⇒ (VI): R is self-adjoint, so $T = R^*R$. (VI) ⇒ (VII): $\langle T\mathbf{e}_j, \mathbf{e}_i\rangle = \langle S\mathbf{e}_j, S\mathbf{e}_i\rangle$, so $[T]_{\mathcal{O}}$ is the Gram matrix of $S\mathbf{e}_1, \ldots, S\mathbf{e}_n$. (VII) ⇒ (I): a Gram matrix is Hermitian, and $\langle T\mathbf{v}, \mathbf{v}\rangle = \mathbf{c}^*G\mathbf{c} = \left\|\sum_j c_j\mathbf{w}_j\right\|^2$.

We prove (I) ⇒ (II) ⇒ (III) ⇒ (IV) ⇒ (V) ⇒ (VI) ⇒ (VII) ⇒ (I).

(I) ⇒ (II). T is self-adjoint by definition. Let λ be an eigenvalue of T, with eigenvector $\mathbf{v} \neq \mathbf{0}$. Then

$$\lambda\|\mathbf{v}\|^2 = \langle \lambda\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, \mathbf{v}\rangle \geq 0,$$

and since $\|\mathbf{v}\|^2 > 0$, $\lambda = \langle T\mathbf{v}, \mathbf{v}\rangle / \|\mathbf{v}\|^2$ is a nonnegative real number.

(II) ⇒ (III). By Theorem 8.2.12 if $\mathbb{F} = \mathbb{R}$, or Corollary 8.2.7 if $\mathbb{F} = \mathbb{C}$, V has an orthonormal basis $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ of eigenvectors of T, say $T\mathbf{e}_i = d_i\mathbf{e}_i$. Then $[T]_{\mathcal{O}} = \operatorname{diag}(d_1, \ldots, d_n)$ (Theorem 7.4.2), and each d_i is an eigenvalue of T, so $d_i \geq 0$.

(III) ⇒ (IV). Let $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis with $[T]_{\mathcal{O}} = \operatorname{diag}(d_1, \ldots, d_n)$ and every $d_i \geq 0$, so that $T\mathbf{e}_i = d_i\mathbf{e}_i$. By Theorem 2.2.1 there is $R \in \mathrm{L}(V)$ with $R\mathbf{e}_i = \sqrt{d_i}\mathbf{e}_i$ for every i. Its matrix $[R]_{\mathcal{O}} = \operatorname{diag}\left(\sqrt{d_1}, \ldots, \sqrt{d_n}\right)$ is real and diagonal, hence Hermitian, so R is self-adjoint (Corollary 6.6.28). For $\mathbf{v} = c_1\mathbf{e}_1 + \cdots + c_n\mathbf{e}_n$, orthonormality gives

$$\langle R\mathbf{v}, \mathbf{v}\rangle = \left\langle \sum_i \sqrt{d_i}c_i\mathbf{e}_i, \sum_j c_j\mathbf{e}_j \right\rangle = \sum_i \sqrt{d_i}|c_i|^2 \geq 0,$$

so R is positive. Finally $R^2\mathbf{e}_i = \sqrt{d_i}\sqrt{d_i}\mathbf{e}_i = d_i\mathbf{e}_i = T\mathbf{e}_i$ for every i, so $R^2 = T$ by the uniqueness part of Theorem 2.2.1.

(IV) ⇒ (V). A positive operator is self-adjoint.

(V) ⇒ (VI). Take $W = V$ and $S = R$. Then $S^*S = RR = T$.

(VI) ⇒ (VII). Let $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ be *any* orthonormal basis of V. By Proposition 6.3.18, the i-th coordinate of $T\mathbf{e}_j$ is $\langle T\mathbf{e}_j, \mathbf{e}_i\rangle$, so the (i, j) entry of $[T]_{\mathcal{O}}$ is

$$\langle T\mathbf{e}_j, \mathbf{e}_i\rangle = \langle S^*S\mathbf{e}_j, \mathbf{e}_i\rangle = \langle S\mathbf{e}_j, S\mathbf{e}_i\rangle.$$

This is the (i, j) entry of the Gram matrix of the list $S\mathbf{e}_1, \ldots, S\mathbf{e}_n$ in W (Definition 6.3.28).

(VII) ⇒ (I). Let $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis such that $G = [T]_{\mathcal{O}}$ is the Gram matrix of a list $\mathbf{w}_1, \ldots, \mathbf{w}_n$ in an inner product space W. As in Example 8.3.2(c), $G^* = G$, so $[T^*]_{\mathcal{O}} = G^* = [T]_{\mathcal{O}}$ by Theorem 6.6.15, and $T^* = T$. Let $\mathbf{v} = c_1\mathbf{e}_1 + \cdots + c_n\mathbf{e}_n$ and $\mathbf{c} = (c_1, \ldots, c_n)$. Since $g_{ij} = \langle T\mathbf{e}_j, \mathbf{e}_i\rangle$,

$$\langle T\mathbf{v}, \mathbf{v}\rangle = \sum_{i,j} c_j\overline{c_i}\langle T\mathbf{e}_j, \mathbf{e}_i\rangle = \sum_{i,j} \overline{c_i}g_{ij}c_j = \mathbf{c}^*G\mathbf{c} = \|c_1\mathbf{w}_1 + \cdots + c_n\mathbf{w}_n\|^2 \geq 0$$

by Proposition 6.3.30. So T is positive.

For the matrix form, apply the theorem to T_A on $\mathbb{F}^n$; its matrix in the standard basis $\mathcal{E}$ is A. Condition (III) for T_A says that $\mathbb{F}^n$ has an orthonormal eigenbasis for A with nonnegative eigenvalues, which means $A = UDU^*$ with U unitary (its columns are the eigenbasis) and D diagonal with nonnegative entries, as

explained after Definition 8.2.1. If $A = B^*B$ with $B \in \mathbb{F}^{m\times n}$, then $T_A = (T_B)^* T_B$, because the adjoint of T_B is T_{B^*} (Theorem 6.6.15); this is (VI). Conversely, (V) gives $A = B^*B$ with $B = [R]_{\mathcal{E}}$. Finally, if A is a Gram matrix, then (VII) holds with $\mathcal{O} = \mathcal{E}$, so A is positive; and if A is positive, the proof of (VI) $\Rightarrow$ (VII), which worked for every orthonormal basis, shows that $A = [T_A]_{\mathcal{E}}$ is a Gram matrix. □

The proof of (VI) $\Rightarrow$ (VII) did not depend on the orthonormal basis. So for a positive T the matrix in *every* orthonormal basis is a Gram matrix, and in particular its diagonal entries $\langle T\mathbf{e}_i, \mathbf{e}_i\rangle$ are nonnegative. For bases that are not orthonormal this fails (Exercise 8.3.29). Note also that conditions (V) and (VI) look weaker than (IV). A self-adjoint square root may have negative eigenvalues, and S need not be self-adjoint or even map V to itself, yet each of them forces T to be positive.

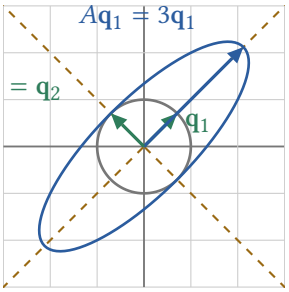
Example 8.3.6 (Three certificates of positivity). Let

$$A = \begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix}.$$

Each of three conditions of Theorem 8.3.5 can be checked directly.

Eigenvalues (II). A is symmetric, and expanding $\det(xI_3 - A)$ along the first row gives $p_A = (x-2)^3 - 2(x-2) = (x-2)\big(x^2 - 4x + 2\big)$. The eigenvalues 2 and $2 \pm \sqrt{2}$ are all positive.

The form (I). For $\mathbf{x} \in \mathbb{R}^3$,



$$\mathbf{x}^{\mathsf{T}} A\mathbf{x} = 2x_1^2 + 2x_2^2 + 2x_3^2 - 2x_1x_2 - 2x_2x_3 = x_1^2 + (x_1 - x_2)^2 + (x_2 - x_3)^2 + x_3^2 \geq 0.$$

A factorization (VI). $A = B^{\mathsf{T}}B$ for the 4×3 difference matrix

$$B = \begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \end{pmatrix}, \qquad B\mathbf{x} = (x_1,\, x_2 - x_1,\, x_3 - x_2,\, -x_3),$$

so A is the Gram matrix of the columns of B.

The last two certificates are the same computation, since $\mathbf{x}^{\mathsf{T}}B^{\mathsf{T}}B\mathbf{x} = \|B\mathbf{x}\|^2$ is exactly the sum of squares. The factorization is the most useful in practice: a sum of squares or a product B^*B certifies positivity without computing any eigenvalue. (The matrix A is the second-difference matrix, a close relative of the graph Laplacians of Section 16.5.)

A symmetric 2×2 matrix A maps the unit circle to an ellipse with axes along the orthonormal eigenvectors $\mathbf{q}_1, \mathbf{q}_2$. A is positive exactly when neither $\lambda_1\mathbf{q}_1$ nor $\lambda_2\mathbf{q}_2$ is reversed, which is the same as saying that $A\mathbf{x}$ never points more than a right angle away from $\mathbf{x}$. Drag $A\mathbf{e}_1$ and $A\mathbf{e}_2$, or type entries, until an eigenvalue turns negative, then move $\mathbf{x}$ to that eigenvector. (Interactive in the web version.)

Exercise 8.3.7. ROUTINE Decide which of the following matrices are positive, and justify each answer by a condition of Theorem 8.3.5 or by a vector $\mathbf{x}$ with $\mathbf{x}^* A\mathbf{x} < 0$.

(a) $\begin{pmatrix} 3 & 1 \\ 1 & 3 \end{pmatrix} \in \mathbb{R}^{2\times 2}$.

(b) $\begin{pmatrix} 1 & 3 \\ 3 & 1 \end{pmatrix} \in \mathbb{R}^{2\times 2}$.

(c) $\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix} \in \mathbb{C}^{2\times 2}$.

(d) $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \in \mathbb{R}^{2\times 2}$.

(e) $\begin{pmatrix} 2 & 1 \\ -1 & 2 \end{pmatrix} \in \mathbb{R}^{2\times 2}$.

Solution on page 1651

The last characterization we need concerns vectors on which the form $\langle T\mathbf{v}, \mathbf{v}\rangle$ vanishes. For a positive number t, $tx^2 = 0$ forces $x = 0$; for a positive operator, the analogue is that $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ forces $T\mathbf{v} = \mathbf{0}$.

Lemma 8.3.8 (Where the form vanishes). Let $T \in \mathrm{L}(V)$ be positive and $\mathbf{v} \in V$. Then $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$ if and only if $T\mathbf{v} = \mathbf{0}$. Consequently

$$\ker T = \{\mathbf{v} \in V \mid \langle T\mathbf{v}, \mathbf{v}\rangle = 0\}.$$

Proof (in an eigenbasis). ROUTINE

Uses. Theorem 8.3.5 (Characterizations of positive operators), Proposition 6.3.18 (Coordinates in an orthonormal basis)
Techniques. A sum of nonnegative terms (Technique 6.1.9), Pass to orthonormal coordinates (Technique 6.7.2)
Hint 1. Only one direction needs proof. Take an orthonormal basis as in Theorem 8.3.5(III) and expand $\langle T\mathbf{v}, \mathbf{v}\rangle$ in it.
Hint 2. You get $\sum_i d_i |c_i|^2$ with every $d_i \geq 0$. When is such a sum 0?
Sketch. In an orthonormal eigenbasis with $T\mathbf{e}_i = d_i\mathbf{e}_i$, $d_i \geq 0$, and $\mathbf{v} = \sum c_i\mathbf{e}_i$: $\langle T\mathbf{v}, \mathbf{v}\rangle = \sum_i d_i |c_i|^2$. If this is 0, every term is 0, so $d_i c_i = 0$ for every i, and $T\mathbf{v} = \sum_i d_i c_i \mathbf{e}_i = \mathbf{0}$.

If $T\mathbf{v} = \mathbf{0}$, then $\langle T\mathbf{v}, \mathbf{v}\rangle = 0$. Conversely, by Theorem 8.3.5(III) there is an orthonormal basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$ with $T\mathbf{e}_i = d_i\mathbf{e}_i$ and every $d_i \geq 0$. Write $\mathbf{v} = \sum_i c_i\mathbf{e}_i$. Then

$$\langle T\mathbf{v}, \mathbf{v}\rangle = \left\langle \sum_i d_i c_i \mathbf{e}_i, \sum_j c_j \mathbf{e}_j \right\rangle = \sum_i d_i |c_i|^2.$$

If this is 0, then, being a sum of nonnegative terms, each term $d_i|c_i|^2$ is 0. So for each i, either $d_i = 0$ or $c_i = 0$, and in both cases $d_i c_i = 0$. Hence $T\mathbf{v} = \sum_i d_i c_i \mathbf{e}_i = \mathbf{0}$. □

Proof (with a square root). ROUTINE

Uses. Theorem 8.3.5 (Characterizations of positive operators), Definition 6.1.26 (Norm)
Techniques. Show a vector is zero via its norm (Technique 6.1.36), Move an operator across the inner product (Technique 6.6.20)
Hint. Write $T = R^2$ with R positive (Theorem 8.3.5(IV)) and move one factor R across the inner product.
Sketch. With $T = R^2$ and R self-adjoint, $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle R\mathbf{v}, R\mathbf{v}\rangle = \|R\mathbf{v}\|^2$. If this is 0, then $R\mathbf{v} = \mathbf{0}$ and $T\mathbf{v} = R(R\mathbf{v}) = \mathbf{0}$.

By Theorem 8.3.5(IV), $T = R^2$ for some positive, hence self-adjoint, R. Then

$$\langle T\mathbf{v}, \mathbf{v}\rangle = \langle R(R\mathbf{v}), \mathbf{v}\rangle = \langle R\mathbf{v}, R\mathbf{v}\rangle = \|R\mathbf{v}\|^2.$$

If this is 0, then $R\mathbf{v} = \mathbf{0}$, and $T\mathbf{v} = R(R\mathbf{v}) = R\mathbf{0} = \mathbf{0}$. □

The second proof is the general pattern: once the form $\langle T\mathbf{v}, \mathbf{v}\rangle$ is a squared norm $\|R\mathbf{v}\|^2$, its vanishing kills $R\mathbf{v}$ and therefore $T\mathbf{v}$. Without positivity the lemma fails. On $\mathbb{R}^2$ the rotation $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ has $\langle J\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$ (Example 6.1.39), but $\ker J = \{\mathbf{0}\}$; and the symmetric matrix $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ gives 0 at $\mathbf{v} = (1, 1)$, which is not in its kernel.

8.3.3 The positive square root

Every nonnegative real number has exactly one nonnegative square root, although a positive number has two real square roots. Operators have many more square roots. Every reflection squares to the identity (Exercise 8.2.39), so when $\dim V \geq 2$ the identity has infinitely many self-adjoint square roots. Asking for a *positive* square root restores uniqueness.

Theorem 8.3.9 (The positive square root). Let $T \in \mathrm{L}(V)$ be positive, with spectral decomposition $T = \lambda_1 P_1 + \cdots + \lambda_k P_k$ (Theorem 8.2.18). Then

$$R = \sqrt{\lambda_1} P_1 + \cdots + \sqrt{\lambda_k} P_k$$

is the only positive operator $R \in \mathrm{L}(V)$ with $R^2 = T$. Moreover $R = p(T)$ for some polynomial $p \in \mathbb{R}[x]$, so R commutes with every operator that commutes with T.

Notation 8.3.10. For a positive T, the operator of Theorem 8.3.9 is the **positive square root** of T, written $\sqrt{T}$. In the notation of Definition 8.2.23, $\sqrt{T} = f(T)$ for $f(\lambda) = \sqrt{\lambda}$. For a positive matrix A, $\sqrt{A}$ is the positive matrix whose square is A; it is the matrix of $\sqrt{T_A}$.

A positive operator is self-adjoint, so it satisfies the spectral hypothesis of Section 8.2.4 (over $\mathbb{C}$ because self-adjoint operators are normal), and its eigenvalues λ_j are nonnegative by Theorem 8.3.5. So the formula for R makes sense.

Proof, part 1 of 2: existence. ROUTINE

> *Uses.* Definition 8.2.23 (Functions of an operator), Proposition 8.2.24 (Properties of $f(T)$), Theorem 8.2.18 (Spectral decomposition), Theorem 8.3.5 (Characterizations of positive operators)
> *Techniques.* Apply a function to the eigenvalues (Technique 8.2.25)
> *Hint 1.* This is Example 8.2.26. Apply Proposition 8.2.24 to $f(\lambda) = \sqrt{\lambda}$ on the eigenvalues.
> *Hint 2.* Which parts of Proposition 8.2.24 give self-adjointness, the eigenvalues of $f(T)$, the identity $f(T)^2 = T$, and the polynomial?
> *Sketch.* $R = f(T)$ for $f = \sqrt{\cdot}$ on $\{\lambda_1, \ldots, \lambda_k\}$. It is self-adjoint because f is real, its eigenvalues $\sqrt{\lambda_j}$ are nonnegative, so it is positive, and $R^2 = (f^2)(T) = T$ because $f^2(\lambda_j) = \lambda_j$. It equals $p(T)$ for the real interpolating polynomial of Proposition 8.2.24(b).

Let $f(\lambda) = \sqrt{\lambda}$ on $\{\lambda_1, \ldots, \lambda_k\}$, so that $R = f(T)$ (Definition 8.2.23). By Proposition 8.2.24(d), R is self-adjoint, since every value $f(\lambda_j)$ is real, and by Proposition 8.2.24(e), its eigenvalues $\sqrt{\lambda_j}$ are nonnegative. So R is positive by Theorem 8.3.5. By Proposition 8.2.24(c),

$$R^2 = (f^2)(T) = \lambda_1 P_1 + \cdots + \lambda_k P_k = T,$$

because $f^2(\lambda_j) = \lambda_j$ and $T = \sum_j \lambda_j P_j$ (Theorem 8.2.18(c)). Finally, by Proposition 8.2.24(b), $R = p(T)$ for $p = \sum_j \sqrt{\lambda_j} L_j$, where the Lagrange polynomials L_j have real coefficients because the λ_j are real; and R commutes with every operator that commutes with T.

> *Intuition (Three ways to see uniqueness).* Let R be any positive operator with $R^2 = T$. We must show that R acts on each eigenspace E_λ of T as $\sqrt{\lambda}$. The three proofs below look at different objects. The first looks at the eigenspaces of T: R commutes with T, so it preserves them, and on each one it is a positive operator whose square is a scalar. The second looks at the eigenspaces of R: squaring the spectral decomposition of R gives a spectral decomposition of T, and such decompositions are unique. The third compares two square roots R and R' directly and shows that their difference has no nonzero eigenvalue. In the first two proofs the nonnegativity of the eigenvalues of R is used exactly once, to rule out $-\sqrt{\lambda}$; in the third, positivity enters through the signs of $\langle R\mathbf{v}, \mathbf{v}\rangle$ and $\langle R'\mathbf{v}, \mathbf{v}\rangle$.

Proof (via the eigenspaces of T), part 2 of 2: uniqueness. STANDARD

Uses. Proposition 8.2.20 (Spectral projections are polynomials in T), Theorem 8.3.5 (Characterizations of positive operators), Theorem 8.2.18 (Spectral decomposition), Definition 6.6.26 (Self-adjoint operator)
Techniques. Restrict to a subspace (Technique 4.2.5), Test an identity on eigenvectors (Technique 7.4.25)
Hint 1. R commutes with $R^2 = T$. What does Proposition 8.2.20(a) say about R and the eigenspaces of T?
Hint 2. Let R_λ be the restriction of R to E_λ. Check that R_λ is a positive operator on E_λ and that $R_\lambda^2 = \lambda \mathrm{id}_{E_\lambda}$.
Hint 3. Apply Theorem 8.3.5 to R_λ: its eigenvalues μ satisfy $\mu^2 = \lambda$ and $\mu \geq 0$.
Sketch. $RT = R^3 = TR$, so R maps each E_λ into itself. The restriction R_λ is self-adjoint with $\langle R_\lambda \mathbf{v}, \mathbf{v}\rangle \geq 0$, so E_λ has an orthonormal basis of eigenvectors of R_λ with eigenvalues $\mu \geq 0$, and $\mu^2 \mathbf{u} = R^2\mathbf{u} = T\mathbf{u} = \lambda\mathbf{u}$ gives $\mu = \sqrt{\lambda}$. So $R = \sqrt{\lambda}\,\mathrm{id}$ on every E_λ, and $V = \oplus E_\lambda$ gives $R = \sum \sqrt{\lambda_j} P_j$.

Let $R \in \mathrm{L}(V)$ be positive with $R^2 = T$. Then $RT = R^3 = TR$, so by Proposition 8.2.20(a), R maps each eigenspace E_{λ_j} of T into itself. Fix j, write $\lambda = \lambda_j$, and let $R_\lambda \in \mathrm{L}(E_\lambda)$ be the restriction of R to E_λ, which is an inner product space with the inner product of V. For $\mathbf{v}, \mathbf{w} \in E_\lambda$,

$$\langle R_\lambda \mathbf{v}, \mathbf{w}\rangle = \langle R\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, R\mathbf{w}\rangle = \langle \mathbf{v}, R_\lambda \mathbf{w}\rangle \quad \text{and} \quad \langle R_\lambda \mathbf{v}, \mathbf{v}\rangle = \langle R\mathbf{v}, \mathbf{v}\rangle \geq 0,$$

so R_λ is positive. By Theorem 8.3.5(III), applied on E_λ, there is an orthonormal basis $\mathbf{u}_1, \ldots, \mathbf{u}_m$ of E_λ with $R\mathbf{u}_i = \mu_i \mathbf{u}_i$ and $\mu_i \geq 0$. Then

$$\lambda \mathbf{u}_i = T\mathbf{u}_i = R^2 \mathbf{u}_i = \mu_i^2 \mathbf{u}_i,$$

so $\mu_i^2 = \lambda$, and since $\mu_i \geq 0$, $\mu_i = \sqrt{\lambda}$. Thus R and $\sqrt{\lambda}\,\mathrm{id}$ agree on a basis of E_λ, so $R\mathbf{v} = \sqrt{\lambda_j}\mathbf{v}$ for every $\mathbf{v} \in E_{\lambda_j}$, for every j. Finally, every $\mathbf{v} \in V$ is $\mathbf{v} = \sum_j P_j \mathbf{v}$ with $P_j \mathbf{v} \in E_{\lambda_j}$ (Theorem 8.2.18), so

$$R\mathbf{v} = \sum_j R P_j \mathbf{v} = \sum_j \sqrt{\lambda_j} P_j \mathbf{v},$$

that is, $R = \sum_j \sqrt{\lambda_j} P_j$. □

The step $\mu_i^2 = \lambda \Rightarrow \mu_i = \sqrt{\lambda}$ is where positivity of R entered. A self-adjoint R with $R^2 = T$ also preserves each E_λ, but on E_λ it only has to satisfy $R_\lambda^2 = \lambda\,\mathrm{id}$, and when $\lambda > 0$ and $\dim E_\lambda \geq 2$ there are infinitely many such R_λ (Exercise 8.3.38).

Proof (via the spectral decomposition of R), part 2 of 2: uniqueness. STANDARD

Uses. Theorem 8.2.18 (Spectral decomposition), Proposition 8.2.19 (Uniqueness of the spectral decomposition), Theorem 8.3.5 (Characterizations of positive operators)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Write $R = \mu_1 Q_1 + \cdots + \mu_m Q_m$, its own spectral decomposition, and square it.
Hint 2. $R^2 = \sum_i \mu_i^2 Q_i$. Why are the numbers μ_i^2 distinct? Now use Proposition 8.2.19.
Sketch. $R = \sum_i \mu_i Q_i$ with distinct $\mu_i \geq 0$, so $T = R^2 = \sum_i \mu_i^2 Q_i$, and the μ_i^2 are distinct because squaring is injective on $[0, \infty)$. By Proposition 8.2.19, the μ_i^2 are the eigenvalues of T and $Q_i = \mathrm{Pr}_{E_{\mu_i^2}}$. So $R = \sum \sqrt{\lambda_j} P_j$.

Let $R \in \mathrm{L}(V)$ be positive with $R^2 = T$. By Theorem 8.2.18, $R = \mu_1 Q_1 + \cdots + \mu_m Q_m$, where $\mu_1, \ldots, \mu_m$ are the distinct eigenvalues of R, all nonnegative by Theorem 8.3.5, and Q_i is the orthogonal projection onto the eigenspace of R for μ_i. The Q_i are nonzero, $Q_i Q_l = 0$ for $i \neq l$, $Q_i^2 = Q_i$, and $\sum_i Q_i = \mathrm{id}_V$. Expanding,

$$T = R^2 = \sum_{i,l} \mu_i \mu_l Q_i Q_l = \mu_1^2 Q_1 + \cdots + \mu_m^2 Q_m.$$

The numbers μ_i^2 are distinct, because $\mu_i \geq 0$ and $t \mapsto t^2$ is injective on $[0, \infty)$. So Proposition 8.2.19 applies to this expression of T: the eigenvalues of T are exactly $\mu_1^2, \ldots, \mu_m^2$, and Q_i is the orthogonal projection onto $E_{\mu_i^2}$, the eigenspace of T. Relabelling so that $\lambda_i = \mu_i^2$ (and $k = m$), we get $\mu_i = \sqrt{\lambda_i}$ and $Q_i = P_i$, so $R = \sum_i \sqrt{\lambda_i} P_i$. □

Proof (by comparing two square roots), part 2 of 2: uniqueness. STANDARD

Uses. Lemma 8.3.8 (Where the form vanishes), Proposition 8.1.1 (Eigenvalues and eigenvectors of self-adjoint operators), Theorem 8.2.12 (Real spectral theorem), Corollary 8.2.7 (Hermitian matrices), Proposition 6.6.18 (Properties of the adjoint)

Techniques. A sum of nonnegative terms (Technique 6.1.9), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Let R and R' be positive square roots of T and $D = R - R'$. D is self-adjoint, so it suffices to show that every eigenvalue of D is 0.
Hint 2. Check the identity $R^2 - R'^2 = RD + DR'$. Apply it to an eigenvector $\mathbf{v}$ of D, $D\mathbf{v} = \mu\mathbf{v}$, and take the inner product with $\mathbf{v}$.
Hint 3. You get $0 = \mu(\langle R\mathbf{v}, \mathbf{v}\rangle + \langle R'\mathbf{v}, \mathbf{v}\rangle)$. If $\mu \neq 0$, use Lemma 8.3.8.
Sketch. Let $D = R - R'$, self-adjoint, with $D\mathbf{v} = \mu\mathbf{v}$, $\mathbf{v} \neq \mathbf{0}$, $\mu \in \mathbb{R}$. Since $0 = R^2 - R'^2 = RD + DR'$, we get $0 = \langle (RD + DR')\mathbf{v}, \mathbf{v}\rangle = \mu(\langle R\mathbf{v}, \mathbf{v}\rangle + \langle R'\mathbf{v}, \mathbf{v}\rangle)$. If $\mu \neq 0$, both nonnegative terms vanish, so $R\mathbf{v} = R'\mathbf{v} = \mathbf{0}$ by Lemma 8.3.8, and $\mu\mathbf{v} = D\mathbf{v} = \mathbf{0}$, a contradiction. So all eigenvalues of D are 0, and a self-adjoint operator with only the eigenvalue 0 is 0.

Let $R, R' \in \mathrm{L}(V)$ be positive with $R^2 = R'^2 = T$, and let $D = R - R'$. Then D is self-adjoint (Proposition 6.6.18), and

$$RD + DR' = R^2 - RR' + RR' - R'^2 = R^2 - R'^2 = 0.$$

Let μ be an eigenvalue of D with eigenvector $\mathbf{v} \neq \mathbf{0}$; μ is real by Proposition 8.1.1. Using $D^* = D$,

$$0 = \langle (RD + DR')\mathbf{v}, \mathbf{v}\rangle = \langle R(\mu\mathbf{v}), \mathbf{v}\rangle + \langle R'\mathbf{v}, D\mathbf{v}\rangle = \mu\langle R\mathbf{v}, \mathbf{v}\rangle + \overline{\mu}\langle R'\mathbf{v}, \mathbf{v}\rangle,$$

and since μ is real, $0 = \mu(\langle R\mathbf{v}, \mathbf{v}\rangle + \langle R'\mathbf{v}, \mathbf{v}\rangle)$. Suppose $\mu \neq 0$. Then the two nonnegative numbers $\langle R\mathbf{v}, \mathbf{v}\rangle$ and $\langle R'\mathbf{v}, \mathbf{v}\rangle$ add up to 0, so both are 0, and by Lemma 8.3.8, $R\mathbf{v} = R'\mathbf{v} = \mathbf{0}$. Then $\mu\mathbf{v} = D\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$, so $\mu = 0$, a contradiction. Hence every eigenvalue of D is 0. By Theorem 8.2.12 or Corollary 8.2.7, D has an orthonormal eigenbasis, in which its matrix is diagonal with the eigenvalues on the diagonal, that is, zero. So $D = 0$ and $R = R'$. Since $\sqrt{T}$ is a positive square root of T, every positive square root of T equals $\sqrt{T}$. □

The third proof never mentions the eigenspaces of T and uses only Lemma 8.3.8 and the identity $R^2 - R'^2 = RD + DR'$. That makes it the one that adapts to inequalities: the same computation shows that $A \mapsto \sqrt{A}$ preserves the order between positive operators (Exercise 8.3.40).

Example 8.3.11 (A square root as a polynomial). For $A = I_3 + J_3 = \begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 2 \end{pmatrix}$ of Example 8.2.21, the eigenvalues are 4 and 1, with $P_4 = (A - I_3)/3$ and $P_1 = (A - 4I_3)/(-3)$. So

$$\sqrt{A} = 2P_4 + 1P_1 = \frac{2(A - I_3) - (A - 4I_3)}{3} = \frac{A + 2I_3}{3} = \begin{pmatrix} 4/3 & 1/3 & 1/3 \\ 1/3 & 4/3 & 1/3 \\ 1/3 & 1/3 & 4/3 \end{pmatrix}.$$

The polynomial is $p(x) = (x + 2)/3$, the line through $(1, 1)$ and $(4, 2)$: it agrees with $\sqrt{x}$ at the two eigenvalues, which is all that matters. Check: $(I_3 + J_3/3)^2 = I_3 + 2J_3/3 + J_3^2/9 = I_3 + J_3$, since $J_3^2 = 3J_3$.

Exercise 8.3.12. ROUTINE Let $A = \begin{pmatrix} 5 & -4 \\ -4 & 5 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & -2 \\ -2 & 1 \end{pmatrix}$.

(a) Compute $\sqrt{A}$, and check that $B^2 = A$.

(b) Compute $\sqrt{A^2}$ and $\sqrt{B^2}$. Which of $\sqrt{A^2} = A$ and $\sqrt{B^2} = B$ holds, and why?

Solution on page 1651

Remark 8.3.13 (The absolute value of an operator). Let W be a finite-dimensional inner product space and $S \in \mathrm{L}(V, W)$. Then S^*S is positive (Example 8.3.2(b)), so it has a positive square root

$$|S| = \sqrt{S^*S} \in \mathrm{L}(V).$$

It satisfies $\||S|\mathbf{v}\|^2 = \langle |S|^2\mathbf{v}, \mathbf{v}\rangle = \langle S^*S\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2$, so $|S|$ moves every vector exactly as far as S does. For a complex number, $|z| = \sqrt{\overline{z}z}$ is the size of z with its direction forgotten, and $|S|$ plays the same role. In Section 9.1 the eigenvalues of $|S|$ become the singular values of S.

8.3.4 Positive definite operators

Definition 8.3.14 (Positive definite). An operator $T \in \mathrm{L}(V)$ is **positive definite** if T is self-adjoint and

$$\langle T\mathbf{v}, \mathbf{v}\rangle > 0 \quad \text{for every nonzero } \mathbf{v} \in V.$$

A matrix $A \in \mathbb{F}^{n\times n}$ is **positive definite** if $A^* = A$ and $\mathbf{x}^* A\mathbf{x} > 0$ for every nonzero $\mathbf{x} \in \mathbb{F}^n$.

The lecture notes define a positive definite matrix as a matrix whose eigenvalues are all positive. For Hermitian matrices this is the same notion, by (II) of the next proposition. Every positive definite operator is positive, and by Lemma 8.3.8 a positive operator is positive definite exactly when its kernel is $\{\mathbf{0}\}$. So positive definite operators are to positive operators what positive numbers are to nonnegative ones.

Proposition 8.3.15 (Characterizations of positive definite operators). Let $T \in \mathrm{L}(V)$. The following are equivalent:

(I) T is positive definite;

(II) T is self-adjoint and every eigenvalue of T is positive;

(III) T is positive and invertible;

(IV) $T = S^*S$ for some injective $S \in \mathrm{L}(V, W)$, where W is a finite-dimensional inner product space;

(V) for some orthonormal basis $\mathcal{O}$ of V, $[T]_{\mathcal{O}}$ is the Gram matrix of a linearly independent list.

In matrix form: $A \in \mathbb{F}^{n\times n}$ is positive definite if and only if $A = B^*B$ for some $B \in \mathbb{F}^{m\times n}$ with $\operatorname{rank} B = n$, if and only if A is the Gram matrix of a linearly independent list, if and only if A is positive and $\det A \neq 0$.

Proof. STANDARD

Uses. Theorem 8.3.5 (Characterizations of positive operators), Theorem 8.3.9 (The positive square root), Theorem 7.2.9 (Eigenvalues and invertibility), Proposition 6.3.30 (Gram matrices detect independence), Theorem 3.5.12 (First Fundamental Theorem, completed), Theorem 5.4.7 (Invertibility and the determinant), Corollary 4.2.18 (Injective if and only if surjective)
Techniques. Proving TFAE (Technique 2.7.1), Gram matrices (Technique 6.3.31)
Hint 1. Follow the proof of Theorem 8.3.5 with strict inequalities: (I) ⇒ (II) ⇒ (III) ⇒ (IV) ⇒ (V) ⇒ (I).
Hint 2. For (III) ⇒ (IV), take $S = \sqrt{T}$; why is it injective? For (IV) ⇒ (V), injective maps send independent lists to independent lists.
Hint 3. For (V) ⇒ (I), the computation $\langle T\mathbf{v}, \mathbf{v}\rangle = \left\|\sum_j c_j \mathbf{w}_j\right\|^2$ from Theorem 8.3.5 is still available. When is $\sum_j c_j \mathbf{w}_j = \mathbf{0}$?
Sketch. (I) ⇒ (II): $\lambda\|\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle > 0$. (II) ⇒ (III): positive by Theorem 8.3.5, and 0 is not an eigenvalue. (III) ⇒ (IV): $S = \sqrt{T}$; $S\mathbf{v} = \mathbf{0}$ gives $T\mathbf{v} = \mathbf{0}$, so $\mathbf{v} = \mathbf{0}$. (IV) ⇒ (V): $[T]_{\mathcal{O}}$ is the Gram matrix of $S\mathbf{e}_1, \ldots, S\mathbf{e}_n$, which is independent as S is injective. (V) ⇒ (I): T is positive, and $\langle T\mathbf{v}, \mathbf{v}\rangle = \left\|\sum c_j \mathbf{w}_j\right\|^2 > 0$ for $\mathbf{c} \neq \mathbf{0}$ by independence.

We prove (I) ⇒ (II) ⇒ (III) ⇒ (IV) ⇒ (V) ⇒ (I).

(I) ⇒ (II). If $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\lambda\|\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle > 0$, so $\lambda > 0$.

(II) ⇒ (III). T is positive by Theorem 8.3.5. Since 0 is not an eigenvalue of T, T is invertible by Theorem 7.2.9.

(III) ⇒ (IV). Let $W = V$ and $S = \sqrt{T}$ (Theorem 8.3.9). Then $S^*S = S^2 = T$. If $S\mathbf{v} = \mathbf{0}$, then $T\mathbf{v} = S(S\mathbf{v}) = \mathbf{0}$, so $\mathbf{v} = \mathbf{0}$ since T is invertible. Hence S is injective.

(IV) ⇒ (V). Let $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis. By the proof of Theorem 8.3.5 ((VI) ⇒ (VII)), $[T]_{\mathcal{O}}$ is the Gram matrix of $S\mathbf{e}_1, \ldots, S\mathbf{e}_n$. This list is independent: if $\sum_i c_i S\mathbf{e}_i = \mathbf{0}$, then $S\left(\sum_i c_i \mathbf{e}_i\right) = \mathbf{0}$, so $\sum_i c_i \mathbf{e}_i = \mathbf{0}$ because S is injective, and every $c_i = 0$.

(V) ⇒ (I). T is positive by Theorem 8.3.5 ((VII) ⇒ (I)), in particular self-adjoint. Let $[T]_{\mathcal{O}}$ be the Gram matrix of the independent list $\mathbf{w}_1, \ldots, \mathbf{w}_n$, and let $\mathbf{v} \neq \mathbf{0}$ have coordinates $\mathbf{c} = [\mathbf{v}]_{\mathcal{O}} \neq \mathbf{0}$. As in the proof of Theorem 8.3.5, $\langle T\mathbf{v}, \mathbf{v}\rangle = \|c_1\mathbf{w}_1 + \cdots + c_n\mathbf{w}_n\|^2$, and the vector inside the norm is nonzero because the list is independent. So $\langle T\mathbf{v}, \mathbf{v}\rangle > 0$.

For the matrix form, apply this to T_A as in Theorem 8.3.5: T_B is injective if and only if $\operatorname{rank} B = n$ (Theorem 3.5.12), and the Gram matrix statement is (V) with the standard basis. Finally, if A is positive then A is invertible exactly when $\det A \neq 0$ (Theorem 5.4.7), which is (III). □

Corollary 8.3.16 (Inner products on $\mathbb{F}^n$). The inner products on $\mathbb{F}^n$ are exactly the functions

$$\langle \mathbf{x}, \mathbf{y} \rangle_A = \mathbf{y}^* A \mathbf{x}$$

with $A \in \mathbb{F}^{n\times n}$ positive definite. For such an inner product, A is the Gram matrix of the standard basis: $a_{ij} = \langle \mathbf{e}_j, \mathbf{e}_i \rangle_A$.

Proof. ROUTINE

Uses. Proposition 6.1.22 (Inner products on $\mathbb{F}^n$), Definition 8.3.14 (Positive definite)
Hint. Compare Definition 8.3.14 with the condition in Proposition 6.1.22(b).
Sketch. Proposition 6.1.22(b) says that $\mathbf{y}^* M \mathbf{x}$ is an inner product if and only if $M^* = M$ and $\mathbf{x}^* M \mathbf{x} > 0$ for $\mathbf{x} \neq \mathbf{0}$, that is, M is positive definite. Part (a) says every inner product has this form with $m_{ij} = \langle \mathbf{e}_j, \mathbf{e}_i \rangle$.

By Proposition 6.1.22(b), the formula $\langle \mathbf{x}, \mathbf{y} \rangle_M = \mathbf{y}^* M \mathbf{x}$ defines an inner product if and only if $M^* = M$ and $\mathbf{x}^* M \mathbf{x} > 0$ for every nonzero $\mathbf{x}$, that is, if and only if M is positive definite. By Proposition 6.1.22(a), every inner product on $\mathbb{F}^n$ is of this form, with $m_{ij} = \langle \mathbf{e}_j, \mathbf{e}_i \rangle$. □

So positive definite matrices and inner products on $\mathbb{F}^n$ are the same objects, and Example 6.1.23 was a positive definite matrix in disguise. Questions about one inner product compared with another become questions about a positive definite matrix compared with I_n.

Example 8.3.17 (Positive, and positive definite). The matrix A of Example 8.3.6 is positive definite: its eigenvalues are positive, and equivalently the difference matrix B has independent columns (it has rank 3). The matrix $C = \begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix}$ of Exercise 8.3.7 is positive but not positive definite: $C = B^* B$ only for matrices B with dependent columns, such as $B = \begin{pmatrix} 1 & i \end{pmatrix}$, whose columns $1, i$ are dependent in $\mathbb{C}^1$. Accordingly $\det C = 0$ and $C(-i, 1) = \mathbf{0}$, where $\mathbf{x} = (-i, 1)$ has $\mathbf{x}^* C \mathbf{x} = |-i + i|^2 = 0$.

If T is positive definite, so are $\sqrt{T}$ and T^{-1}: their eigenvalues $\sqrt{\lambda_j}$ and $1/\lambda_j$ are positive (Proposition 8.2.24(e), with $T^{-1} = \sum_j \lambda_j^{-1} P_j$ as in Section 8.2.5). Applying Proposition 8.2.24(c) to $f(\lambda) = 1/\sqrt{\lambda}$ shows that $f(T)\sqrt{T} = \mathrm{id}_V$ and $f(T)^2 = T^{-1}$; since $f(T)$ is positive, uniqueness of square roots gives $\left(\sqrt{T}\right)^{-1} = f(T) = \sqrt{T^{-1}}$. We write $T^{-1/2}$ for this operator.

Exercise 8.3.18. ROUTINE For which real numbers t is $A_t = \begin{pmatrix} 1 & t \\ t & 4 \end{pmatrix}$ positive? For which is it positive definite?

Solution on page 1651

Quadratic forms

For a real symmetric matrix A, the function $q(\mathbf{x}) = \mathbf{x}^{\mathsf{T}} A \mathbf{x}$ on $\mathbb{R}^n$ is the **quadratic form** of A (Section 8.2.6). By definition, A is positive definite exactly when $q(\mathbf{x}) > 0$ for every nonzero $\mathbf{x}$, and this is how positive definite matrices usually enter: through quadratic forms. By Corollary 8.2.28, in the coordinates $\mathbf{y} = Q^{\mathsf{T}} \mathbf{x}$ along an orthonormal eigenbasis $\mathbf{q}_1, \ldots, \mathbf{q}_n$,

$$q(\mathbf{x}) = \lambda_1 y_1^2 + \cdots + \lambda_n y_n^2.$$

If A is positive definite, the level set $q(\mathbf{x}) = 1$ is therefore an ellipsoid with semi-axes $1/\sqrt{\lambda_i}$ along the $\mathbf{q}_i$ (in $\mathbb{R}^2$, the ellipses of Remark 8.2.30). If $A \neq 0$ is positive but some $\lambda_i = 0$, the level set is unbounded in the direction of $\mathbf{q}_i$, and if some $\lambda_i < 0$, then q takes negative values. For example, the form $q(\mathbf{x}) = 2x_1^2 + 2x_2^2 + 2x_3^2 - 2x_1x_2 - 2x_2x_3$ of Example 8.3.6 is positive definite, and $q(\mathbf{x}) = 1$ is an ellipsoid with semi-axes $1/\sqrt{2+\sqrt{2}}$, $1/\sqrt{2}$, and $1/\sqrt{2-\sqrt{2}}$.

This is the linear algebra behind the second-derivative test. At a critical point $\mathbf{x}_0$ of a smooth $f:\mathbb{R}^n\to\mathbb{R}$, $f(\mathbf{x}_0+\mathbf{h})=f(\mathbf{x}_0)+\frac{1}{2}\mathbf{h}^{\mathsf{T}}H\mathbf{h}+(\cdots)$, where H is the symmetric matrix of second partial derivatives and the omitted terms are small compared with $\|\mathbf{h}\|^2$; a positive definite H makes $\mathbf{x}_0$ a strict local minimum. Section 12.2 studies quadratic forms in general, and Section 12.3 gives further tests for positive definiteness, among them Sylvester's criterion on the leading minors, together with the min–max description of eigenvalues.

8.3.5 Products of positive operators

The product of two nonnegative numbers is nonnegative. The product of two positive operators need not even be self-adjoint: for $A=\begin{pmatrix}2&1\\1&1\end{pmatrix}$ and the projection $B=\begin{pmatrix}1&0\\0&0\end{pmatrix}$, the product $AB=\begin{pmatrix}2&0\\1&0\end{pmatrix}$ is not symmetric. The obstruction is that A and B need not commute. What survives is a statement about eigenvalues, and the proof introduces a move that we will use repeatedly.

Technique 8.3.19 (Sandwich between square roots). Two positive operators A and B do not commute in general, so AB need not be positive. Split $A=\sqrt{A}\sqrt{A}$ and move one factor to the other side: the operator $\sqrt{A}B\sqrt{A}$ is always positive, since $\langle\sqrt{A}B\sqrt{A}\mathbf{v},\mathbf{v}\rangle=\langle B\sqrt{A}\mathbf{v},\sqrt{A}\mathbf{v}\rangle\geq 0$, and it is close to AB. It has the same characteristic polynomial (by Proposition 7.3.22, applied to $\sqrt{A}$ and $\sqrt{A}B$), and if A is invertible it is similar to AB. In the same way, when B is positive definite, the congruence $X\mapsto B^{-1/2}XB^{-1/2}$ turns the pair (A,B) into (C,id) with $C=B^{-1/2}AB^{-1/2}$ positive, and a question about two operators becomes a question about the eigenvalues of one.

Reach for it when a statement involves two positive operators (a product, a comparison $A\preceq B$, $\det(A+B)$, $\operatorname{tr}(AB)$) and the case of a single operator is easy by Technique 8.2.25. The canonical example is Proposition 8.3.20.

Used in. Proposition 8.3.20, Exercise 8.3.34, Exercise 8.3.39, Exercise 8.3.42.

Proposition 8.3.20 (Products of positive operators). Let $A,B\in\mathrm{L}(V)$ be positive.

(a) AB is positive if and only if $AB=BA$.

(b) Every root of p_{AB} in $\mathbb{C}$ is real and nonnegative. In particular every eigenvalue of AB is nonnegative.

(c) If A is invertible, then AB is diagonalizable.

Proof. STANDARD

Uses. Theorem 8.3.9 (The positive square root), Proposition 6.6.18 (Properties of the adjoint), Proposition 7.3.22 (AB and BA), Definition 7.3.12 (Characteristic polynomial of an operator), Theorem 2.4.2 (The matrix of a composite), Theorem 8.3.5 (Characterizations of positive operators), Theorem 7.2.9 (Eigenvalues and invertibility), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Corollary 7.3.13 (Eigenvalues of an operator)
Techniques. Sandwich between square roots (Technique 8.3.19), Compare AB and BA (Technique 7.3.21)
Hint 1. For (a), a positive operator is self-adjoint, and $(AB)^*=BA$. For the converse, B commutes with $\sqrt{A}$ (Theorem 8.3.9).
Hint 2. For (b), write $AB=XY$ with $X=\sqrt{A}$ and $Y=\sqrt{A}B$. What is YX? Use Proposition 7.3.22 on the matrices of X and Y.
Hint 3. For (c), $AB=\sqrt{A}\big(\sqrt{A}B\sqrt{A}\big)\big(\sqrt{A}\big)^{-1}$. Push an eigenbasis of the positive operator $\sqrt{A}B\sqrt{A}$ forward by $\sqrt{A}$.
Sketch. (a) If AB is positive it is self-adjoint, so $AB=(AB)^*=BA$. If $AB=BA$, then B commutes with $\sqrt{A}$, so $AB=\sqrt{A}B\sqrt{A}$, which is positive. (b) AB and $\sqrt{A}B\sqrt{A}$ are XY and YX for $X=\sqrt{A}$, $Y=\sqrt{A}B$, so they have the same characteristic polynomial, which for the positive operator $\sqrt{A}B\sqrt{A}$ is $\prod(x-d_i)$ with $d_i\geq 0$. (c) If $\sqrt{A}B\sqrt{A}\mathbf{u}_i=d_i\mathbf{u}_i$ for an eigenbasis $\mathbf{u}_i$, then $AB\big(\sqrt{A}\mathbf{u}_i\big)=d_i\sqrt{A}\mathbf{u}_i$, and $\sqrt{A}\mathbf{u}_1,\dots,\sqrt{A}\mathbf{u}_n$ is a basis because $\sqrt{A}$ is invertible.

First, $C=\sqrt{A}B\sqrt{A}$ is positive: it is self-adjoint by Proposition 6.6.18, and $\langle C\mathbf{v},\mathbf{v}\rangle=\langle B\sqrt{A}\mathbf{v},\sqrt{A}\mathbf{v}\rangle\geq 0$.

(a) If AB is positive, it is self-adjoint, so $AB=(AB)^*=B^*A^*=BA$. Conversely, if $AB=BA$, then B commutes with $\sqrt{A}$ by Theorem 8.3.9, and $AB=\sqrt{A}\sqrt{A}B=\sqrt{A}B\sqrt{A}=C$, which is positive.

(b) Fix an orthonormal basis $\mathcal{O}$ and let $X = \left[\sqrt{A}\right]_{\mathcal{O}}$ and $Y = \left[\sqrt{AB}\right]_{\mathcal{O}}$. By Theorem 2.4.2, $XY = \left[\sqrt{A}\sqrt{AB}\right]_{\mathcal{O}} = [AB]_{\mathcal{O}}$ and $YX = \left[\sqrt{AB}\sqrt{A}\right]_{\mathcal{O}} = [C]_{\mathcal{O}}$. So by Definition 7.3.12 and Proposition 7.3.22, $p_{AB} = p_{XY} = p_{YX} = p_C$. Since C is positive, Theorem 8.3.5(III) gives an orthonormal basis in which C is $\operatorname{diag}(d_1, \ldots, d_n)$ with every $d_i \geq 0$, so $p_C = (x - d_1)\cdots(x - d_n)$. Hence every root of p_{AB} is one of the d_i, and every eigenvalue of AB, being a root of p_{AB} (Corollary 7.3.13), is nonnegative.

(c) If A is invertible, then 0 is not an eigenvalue of A, so the eigenvalues $\sqrt{\lambda_j}$ of $\sqrt{A}$ are positive and $\sqrt{A}$ is invertible (Theorem 7.2.9). Let $\mathbf{u}_1, \ldots, \mathbf{u}_n$ be an eigenbasis of the positive operator C, with $C\mathbf{u}_i = d_i\mathbf{u}_i$ (Theorem 8.3.5(III)). Then

$$AB\left(\sqrt{A}\mathbf{u}_i\right) = \sqrt{A}\left(\sqrt{A}B\sqrt{A}\right)\mathbf{u}_i = \sqrt{A}C\mathbf{u}_i = d_i\sqrt{A}\mathbf{u}_i,$$

and $\sqrt{A}\mathbf{u}_1, \ldots, \sqrt{A}\mathbf{u}_n$ is a basis of V, being the image of a basis under an invertible map. So V has a basis of eigenvectors of AB, and AB is diagonalizable (Theorem 7.4.2). □

For the example above, $AB = \begin{pmatrix} 2 & 0 \\ 1 & 0 \end{pmatrix}$ has eigenvalues 2 and 0, and it is diagonalizable, as (c) predicts since $\det A = 1$. Its eigenvectors $(2, 1)$ and $(0, 1)$ are not orthogonal, so AB is diagonalizable but not unitarily diagonalizable. When A is invertible, AB is similar to a positive operator, $AB = \sqrt{A}C\left(\sqrt{A}\right)^{-1}$, but similarity does not preserve orthogonality.

8.3.6 The Löwner order

BEYOND 21-242

The Löwner order is not covered in 21-242.

For real numbers, $x \leq y$ means that $y - x \geq 0$. Positivity gives the same kind of comparison between self-adjoint operators.

Definition 8.3.21 (Löwner order). For self-adjoint $S, T \in \mathrm{L}(V)$, write $S \preceq T$ if $T - S$ is positive, that is, if $\langle S\mathbf{v}, \mathbf{v}\rangle \leq \langle T\mathbf{v}, \mathbf{v}\rangle$ for every $\mathbf{v} \in V$. In particular $0 \preceq T$ means that T is positive.

The two descriptions agree because $T - S$ is automatically self-adjoint. For matrices, $A \preceq B$ is defined in the same way for Hermitian A and B.

Proposition 8.3.22 (Properties of the Löwner order). Let $S, T, U \in \mathrm{L}(V)$ be self-adjoint.

(a) $\preceq$ is a partial order: $T \preceq T$; if $S \preceq T$ and $T \preceq S$, then $S = T$; and if $S \preceq T$ and $T \preceq U$, then $S \preceq U$.

(b) If $S \preceq T$, then $S + U \preceq T + U$, and $cS \preceq cT$ for every real $c \geq 0$.

(c) If $S \preceq T$, V' is a finite-dimensional inner product space, and $X \in \mathrm{L}(V', V)$, then $X^*SX \preceq X^*TX$.

(d) For $c \in \mathbb{R}$, $T \preceq c\mathrm{id}_V$ if and only if every eigenvalue of T is at most c, and $c\mathrm{id}_V \preceq T$ if and only if every eigenvalue of T is at least c.

Proof. ROUTINE

Uses. Definition 8.3.21 (Löwner order), Lemma 8.3.8 (Where the form vanishes), Proposition 6.6.18 (Properties of the adjoint), Theorem 8.3.5 (Characterizations of positive operators)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. Each part is a statement about one positive operator, such as $T - S$. For antisymmetry, $P = T - S$ and $-P$ are both positive; use Lemma 8.3.8.
Hint 2. For (c), move X across the inner product. For (d), compare the eigenvalues of $c\mathrm{id}_V - T$ with those of T.
Sketch. (a) $T - T = 0$. If $P = T - S$ and $-P$ are positive, then $\langle P\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$, so $P = 0$ by Lemma 8.3.8. $U - S = (U - T) + (T - S)$ is a sum of positive operators. (b) The differences are $T - S$ and $c(T - S)$. (c) $\langle X^*(T - S)X\mathbf{u}, \mathbf{u}\rangle = \langle (T - S)X\mathbf{u}, X\mathbf{u}\rangle \geq 0$. (d) $c\mathrm{id}_V - T$ is self-adjoint with eigenvalues $c - \lambda$; apply Theorem 8.3.5(II).

(a) $T - T = 0$ is positive. If $P = T - S$ and $-P = S - T$ are both positive, then $\langle P\mathbf{v}, \mathbf{v}\rangle \geq 0$ and $-\langle P\mathbf{v}, \mathbf{v}\rangle \geq 0$, so $\langle P\mathbf{v}, \mathbf{v}\rangle = 0$ for every $\mathbf{v}$, and $P\mathbf{v} = \mathbf{0}$ for every $\mathbf{v}$ by Lemma 8.3.8. So $S = T$. If $S \preceq T \preceq U$, then $U - S = (U - T) + (T - S)$ is self-adjoint and $\langle (U - S)\mathbf{v}, \mathbf{v}\rangle = \langle (U - T)\mathbf{v}, \mathbf{v}\rangle + \langle (T - S)\mathbf{v}, \mathbf{v}\rangle \geq 0$.

(b) $(T+U)-(S+U)=T-S$ is positive, and $cT-cS=c(T-S)$ is self-adjoint (c is real) with $\langle c(T-S)\mathbf{v},\mathbf{v}\rangle = c\langle (T-S)\mathbf{v},\mathbf{v}\rangle \geq 0$.

(c) $X^*TX - X^*SX = X^*(T-S)X$ is self-adjoint by Proposition 6.6.18, and for $\mathbf{u}\in V'$, $\langle X^*(T-S)X\mathbf{u},\mathbf{u}\rangle = \langle (T-S)X\mathbf{u}, X\mathbf{u}\rangle \geq 0$.

(d) $T\mathbf{v}=\lambda\mathbf{v}$ if and only if $(c\mathrm{id}_V - T)\mathbf{v} = (c-\lambda)\mathbf{v}$, so the eigenvalues of the self-adjoint operator $c\mathrm{id}_V - T$ are the numbers $c-\lambda$ with λ an eigenvalue of T. By Theorem 8.3.5(II), $c\mathrm{id}_V - T$ is positive if and only if $c-\lambda\geq 0$ for all of them. The second statement is the same argument for $T - c\mathrm{id}_V$. □

For example, every orthogonal projection satisfies $0 \preceq \mathrm{Pr}_U \preceq \mathrm{id}_V$, by (d), because its eigenvalues are 0 and 1. Unlike the order on $\mathbb{R}$, the Löwner order is not total: neither of $\mathrm{diag}(1,0)$ and $\mathrm{diag}(0,1)$ is $\preceq$ the other, since their difference has eigenvalues 1 and -1. Some familiar inequalities survive and some do not. Inverses reverse the order and square roots preserve it, while squares need not preserve it (Exercise 8.3.39, Exercise 8.3.40). The inverse inequality is proved with Technique 8.3.19, which compares an operator with id_V, where (d) applies; the square-root inequality uses the eigenvector trick of the third uniqueness proof in Theorem 8.3.9.

8.3.7 Cholesky factorization BEYOND 21-242

Cholesky factorization is standard in numerical linear algebra (LADR 7D), but it is not part of the course.

By Theorem 8.3.5 a positive matrix can be written as B^*B in many ways, for example with $B=\sqrt{A}$. One of these factorizations is triangular, and it can be computed by a short algorithm that needs no eigenvalues. It is the standard way to solve $A\mathbf{x}=\mathbf{b}$ when A is positive definite, and it is also the cheapest test of positive definiteness.

Theorem 8.3.23 (Cholesky factorization). Let $A\in\mathbb{F}^{n\times n}$ be positive definite. Then there is exactly one upper triangular $R\in\mathbb{F}^{n\times n}$ with positive real diagonal entries such that

$$A = R^*R.$$

Proof (via QR), part 1 of 2: existence. ROUTINE

Uses. Proposition 8.3.15 (Characterizations of positive definite operators), Theorem 6.4.38 (QR factorization), Theorem 6.3.29 (Orthonormal columns)
Hint 1. Write $A=B^*B$ with B invertible, and factor B.
Hint 2. Apply QR factorization (Theorem 6.4.38) to B. What is Q^*Q?
Sketch. $A=B^*B$ with B invertible (for instance $B=\sqrt{A}$). QR gives $B=QR$ with orthonormal columns in Q, so $A = R^*Q^*QR = R^*R$.

By Proposition 8.3.15, $A=B^*B$ for some $B\in\mathbb{F}^{n\times n}$ with $\mathrm{rank}\, B = n$ (for instance $B=\sqrt{A}$). The columns of B are independent, so Theorem 6.4.38 gives $B=QR$ with $Q\in\mathbb{F}^{n\times n}$ having orthonormal columns and R upper triangular with positive diagonal entries. Since $Q^*Q=I_n$ (Theorem 6.3.29),

$$A = B^*B = R^*Q^*QR = R^*R.$$

The first proof hides the work inside QR. The second builds R one row at a time, and it is the proof behind the algorithm below.

Proof (by induction on n), part 1 of 2: existence. STANDARD

Uses. Definition 2.4.33 (Block matrix), Definition 8.3.14 (Positive definite)
Techniques. Induction on matrix size (Technique 5.5.17), Block decomposition (Technique 2.4.35), Plug in clever test vectors (Technique 6.1.40)
Hint 1. Write $A=\begin{pmatrix} a & \mathbf{w}^* \\ \mathbf{w} & A'\end{pmatrix}$ with $a\in\mathbb{R}$. Why is $a>0$? Guess the first row of R from the $(1,1)$ and $(1,2)$ blocks of R^*R.
Hint 2. The first row must be $(\sqrt{a}, \mathbf{w}^*/\sqrt{a})$. The rest of R must then be a Cholesky factor of $A'' = A' - \mathbf{w}\mathbf{w}^*/a$.
Hint 3. To see that A'' is positive definite, evaluate $\mathbf{x}^*A\mathbf{x}$ at $\mathbf{x}=(t,\mathbf{y})$ with $t=-\mathbf{w}^*\mathbf{y}/a$.

Sketch. Write $A = \begin{pmatrix} a & \mathbf{w}^* \\ \mathbf{w} & A' \end{pmatrix}$ with $a = \mathbf{e}_1^* A \mathbf{e}_1 > 0$, and let $A'' = A' - \mathbf{w}\mathbf{w}^*/a$. For $\mathbf{y} \neq \mathbf{0}$ and $t = -\mathbf{w}^*\mathbf{y}/a$, $\mathbf{y}^* A'' \mathbf{y} = (t, \mathbf{y})^* A (t, \mathbf{y}) > 0$, so A'' is positive definite and $A'' = R''^* R''$ by induction. Then $R = \begin{pmatrix} \sqrt{a} & \mathbf{w}^*/\sqrt{a} \\ \mathbf{0} & R'' \end{pmatrix}$ works, by block multiplication.

We induct on n. If $n = 1$, then $A = (a)$ with $a = \mathbf{e}_1^* A \mathbf{e}_1 > 0$, and $R = \left(\sqrt{a}\right)$. Let $n \geq 2$, and write in block form (Definition 2.4.33)

$$A = \begin{pmatrix} a & \mathbf{w}^* \\ \mathbf{w} & A' \end{pmatrix}, \quad a \in \mathbb{R}, \quad \mathbf{w} \in \mathbb{F}^{n-1}, \quad A' \in \mathbb{F}^{(n-1)\times(n-1)},$$

where a is real and $A'^* = A'$ because $A^* = A$, and $a = \mathbf{e}_1^* A \mathbf{e}_1 > 0$. Let $A'' = A' - \mathbf{w}\mathbf{w}^*/a$, which is Hermitian. For $t \in \mathbb{F}$ and $\mathbf{y} \in \mathbb{F}^{n-1}$, block multiplication gives

$$\begin{pmatrix} t \\ \mathbf{y} \end{pmatrix}^* A \begin{pmatrix} t \\ \mathbf{y} \end{pmatrix} = a|t|^2 + \bar{t}\mathbf{w}^*\mathbf{y} + t\mathbf{y}^*\mathbf{w} + \mathbf{y}^* A' \mathbf{y}.$$

Take $\mathbf{y} \neq \mathbf{0}$ and $t = -\mathbf{w}^*\mathbf{y}/a$. Since $\mathbf{y}^*\mathbf{w} = \overline{\mathbf{w}^*\mathbf{y}}$, the first three terms are $|\mathbf{w}^*\mathbf{y}|^2/a - 2|\mathbf{w}^*\mathbf{y}|^2/a = -|\mathbf{w}^*\mathbf{y}|^2/a = -\mathbf{y}^*\mathbf{w}\mathbf{w}^*\mathbf{y}/a$, so the whole expression equals $\mathbf{y}^* A'' \mathbf{y}$. The vector $(t, \mathbf{y})$ is nonzero, so $\mathbf{y}^* A'' \mathbf{y} > 0$, and A'' is positive definite. By the induction hypothesis, $A'' = R''^* R''$ with R'' upper triangular with positive diagonal entries. Let

$$R = \begin{pmatrix} \sqrt{a} & \mathbf{w}^*/\sqrt{a} \\ \mathbf{0} & R'' \end{pmatrix}.$$

It is upper triangular with positive diagonal entries, and

$$R^* R = \begin{pmatrix} \sqrt{a} & \mathbf{0}^* \\ \mathbf{w}/\sqrt{a} & R''^* \end{pmatrix} \begin{pmatrix} \sqrt{a} & \mathbf{w}^*/\sqrt{a} \\ \mathbf{0} & R'' \end{pmatrix} = \begin{pmatrix} a & \mathbf{w}^* \\ \mathbf{w} & \mathbf{w}\mathbf{w}^*/a + R''^* R'' \end{pmatrix} = \begin{pmatrix} a & \mathbf{w}^* \\ \mathbf{w} & A' \end{pmatrix} = A.$$

Proof, part 2 of 2: uniqueness. STANDARD

Uses. Lemma 3.3.32 (Products and inverses of triangular matrices), Definition 3.3.31 (Triangular matrices), Proposition 5.3.15 (Triangular matrices), Theorem 5.4.7 (Invertibility and the determinant)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Suppose $R^* R = S^* S$, with R, S as in the theorem. Rearrange to $SR^{-1} = (S^*)^{-1} R^*$.
Hint 2. The left side is upper triangular and the right side lower triangular, so both are diagonal. Compare their diagonal entries.
Sketch. R and S are invertible, and $SR^{-1} = (S^*)^{-1} R^* = \left(RS^{-1}\right)^*$ is both upper and lower triangular, hence diagonal, with diagonal entries s_{ii}/r_{ii} and r_{ii}/s_{ii}. These agree, so $s_{ii}^2 = r_{ii}^2$ and $s_{ii} = r_{ii}$. Thus $SR^{-1} = I_n$.

Suppose $A = R^* R = S^* S$ with R and S upper triangular with positive diagonal entries. Both are invertible, since their determinants are the products of the diagonal entries (Proposition 5.3.15, Theorem 5.4.7). An invertible upper triangular matrix R has an upper triangular inverse whose diagonal entries are $1/r_{ii}$: write $R = DU$ with $D = \operatorname{diag}(r_{11}, \ldots, r_{nn})$ and $U = D^{-1}R$ unit upper triangular, so that $R^{-1} = U^{-1}D^{-1}$, and apply Lemma 3.3.32. Multiplying $S^* S = R^* R$ on the left by $(S^*)^{-1}$ and on the right by R^{-1} gives

$$SR^{-1} = (S^*)^{-1} R^* = \left(RS^{-1}\right)^*.$$

By Lemma 3.3.32, SR^{-1} and RS^{-1} are upper triangular, with diagonal entries s_{ii}/r_{ii} and r_{ii}/s_{ii}. So the matrix $M = SR^{-1}$ is upper triangular, and also lower triangular, being the conjugate transpose of an upper triangular matrix. Hence M is diagonal, and comparing diagonal entries, $s_{ii}/r_{ii} = \overline{r_{ii}/s_{ii}} = r_{ii}/s_{ii}$. So $s_{ii}^2 = r_{ii}^2$, and since both are positive, $s_{ii} = r_{ii}$. Therefore $M = I_n$ and $S = R$. □

The equations behind the algorithm come from reading $A = R^* R$ entry by entry. Since $r_{ik} = 0$ for $i > k$, for $k \leq j$ the (k, j) entry is

$$a_{kj} = \sum_{i \le k} \overline{r_{ik}} r_{ij} = \sum_{i<k} \overline{r_{ik}} r_{ij} + r_{kk} r_{kj}.$$

The last term is the only one that involves row k of R. So if rows $1, \dots, k-1$ are known, the equation with $j = k$ determines r_{kk}, and then the equations with $j > k$ determine the rest of row k.

Algorithm 8.3.24 (Cholesky factorization)

Input A Hermitian matrix $A \in \mathbb{F}^{n \times n}$.
Output The Cholesky factor R of A, or the conclusion that A is not positive definite.

1. Set $k = 1$.
2. Compute $d = a_{kk} - \sum_{i<k} |r_{ik}|^2$. If $d \le 0$, stop: A is not positive definite. Otherwise set $r_{kk} = \sqrt{d}$.
3. For $j = k+1, \dots, n$, set $r_{kj} = \left(a_{kj} - \sum_{i<k} \overline{r_{ik}} r_{ij}\right) / r_{kk}$.
4. If $k < n$, increase k by 1 and return to step 2. Otherwise output $R = \left(r_{ij}\right)$, with $r_{ij} = 0$ for $i > j$.

Proposition 8.3.25 (Correctness of the Cholesky algorithm). Let $A \in \mathbb{F}^{n \times n}$ be Hermitian. If A is positive definite, Algorithm 8.3.24 outputs the matrix R of Theorem 8.3.23. If A is not positive definite, Algorithm 8.3.24 stops in step 2.

Proof. STANDARD

Uses. Theorem 8.3.23 (Cholesky factorization), Proposition 8.3.15 (Characterizations of positive definite operators), Proposition 5.3.15 (Triangular matrices)
Techniques. Algorithms as proofs: invariants and termination (Technique 3.3.5), Compute entry by entry (Technique 2.4.15)
Hint 1. If A is positive definite, the Cholesky factor exists. Show that its entries satisfy exactly the equations that the algorithm solves, in the same order.
Hint 2. If the algorithm runs to the end, it has produced an upper triangular R with positive diagonal and $a_{kj} = (R^* R)_{kj}$ for $k \le j$. Why does this give $A = R^* R$, and why is A then positive definite?
Sketch. The entries of the Cholesky factor satisfy $r_{kk}^2 = a_{kk} - \sum_{i<k} |r_{ik}|^2$ and $r_{kk} r_{kj} = a_{kj} - \sum_{i<k} \overline{r_{ik}} r_{ij}$, so by induction on the order of computation the algorithm reproduces them, with $d = r_{kk}^2 > 0$. Conversely, if the algorithm finishes, A and $R^* R$ agree on and above the diagonal, hence everywhere, and $A = R^* R$ with R invertible is positive definite. So for A not positive definite it cannot finish.

Suppose A is positive definite, and let R be its Cholesky factor (Theorem 8.3.23). By the entry formula above, for each k,

$$r_{kk}^2 = a_{kk} - \sum_{i<k} |r_{ik}|^2, \quad r_{kk} r_{kj} = a_{kj} - \sum_{i<k} \overline{r_{ik}} r_{ij} \quad (j > k).$$

We show by induction on k that the algorithm computes row k of R. If it has computed rows $1, \dots, k-1$ correctly, then the number d of step 2 is $r_{kk}^2 > 0$, so the algorithm does not stop and sets $r_{kk} = \sqrt{d}$, the correct (positive) value; and step 3 solves the second equation for r_{kj}. So the output is R.

Conversely, suppose the algorithm runs to the end and outputs R. Then R is upper triangular with positive diagonal entries, and the equations it solved say that $a_{kj} = (R^* R)_{kj}$ for all $k \le j$. Both A and $R^* R$ are Hermitian, so they also agree below the diagonal, and $A = R^* R$. Since $\det R$ is the product of its diagonal entries (Proposition 5.3.15), R has rank n, and A is positive definite by Proposition 8.3.15. So if A is not positive definite, the algorithm cannot run to the end, and it stops in step 2. □

Example 8.3.26 (A Cholesky factorization). Let

$$A = \begin{pmatrix} 4 & 2 & -2 \\ 2 & 10 & 2 \\ -2 & 2 & 6 \end{pmatrix}.$$

For $k=1$: $r_{11}=\sqrt{4}=2$, $r_{12}=2/2=1$, $r_{13}=-2/2=-1$. For $k=2$: $d=10-1^2=9$, so $r_{22}=3$, and $r_{23}=(2-1\cdot(-1))/3=1$. For $k=3$: $d=6-(-1)^2-1^2=4$, so $r_{33}=2$. Hence

$$A=R^{\mathsf{T}}R,\quad R=\begin{pmatrix}2&1&-1\\0&3&1\\0&0&2\end{pmatrix},$$

and A is positive definite. If the corner entry 6 is replaced by 2, the last step gives $d=2-1-1=0$, and the algorithm stops: the new matrix A' is not positive definite. Indeed $A'(2,-1,3)=\mathbf{0}$, so $(2,-1,3)^{\mathsf{T}}A'(2,-1,3)=0$.

Remark 8.3.27 (What Cholesky adds). For a real positive definite $A=R^{\mathsf{T}}R$, the matrices $L=R^{\mathsf{T}}\operatorname{diag}(1/r_{11},\dots,1/r_{nn})$, which is unit lower triangular, and $D=\operatorname{diag}\bigl(r_{11}^2,\dots,r_{nn}^2\bigr)$ satisfy $LDL^{\mathsf{T}}=R^{\mathsf{T}}R=A$. This is the factorization of Theorem 3.3.37, and $R=\sqrt{D}L^{\mathsf{T}}$: Cholesky is LDL^{T} with the pivots split evenly between the two factors. Because of the symmetry it needs about $n^3/6$ multiplications, half as many as LU.

The induction proof never used eigenvalues. It shows directly that a positive definite matrix has the form B^*B, which is the hard implication of Theorem 8.3.5, by elimination alone. It also shows that a Hermitian matrix is positive definite if and only if the pivots r_{kk}^2 produced along the way are all positive, a criterion that Section 12.3 rephrases in terms of determinants (Sylvester's criterion).

Exercises

Exercise 8.3.28. ROUTINE Let $S,T\in\mathrm{L}(V)$ be positive, let $c\geq 0$ be real, and let $X\in\mathrm{L}(U,V)$, where U is a finite-dimensional inner product space. Show that:

(a) $S+T$ and cT are positive;

(b) $X^*TX\in\mathrm{L}(U)$ is positive;

(c) T^m is positive for every integer $m\geq 0$;

(d) if T is invertible, then T^{-1} is positive.

Solution on page 1652

Exercise 8.3.29. STANDARD Prove or disprove each statement. Throughout, V is a finite-dimensional inner product space.

(a) If $T\in\mathrm{L}(V)$ is positive, then for every basis $\mathcal{B}$ of V, the diagonal entries of $[T]_{\mathcal{B}\mathcal{B}}$ are nonnegative.

(b) If $T\in\mathrm{L}(V)$ is self-adjoint and T^3 is positive, then T is positive.

(c) If $T\in\mathrm{L}(V)$ is self-adjoint and T^2 is positive, then T is positive.

(d) If $S,T\in\mathrm{L}(V)$ are positive, then $ST+TS$ is positive.

(e) If $A\in\mathbb{C}^{n\times n}$ and $\mathbf{x}^*A\mathbf{x}\geq 0$ for every $\mathbf{x}\in\mathbb{R}^n$, then A is positive.

Solution on page 1652

Exercise 8.3.30. STANDARD Let $A\in\mathbb{R}^{n\times n}$. Show that the following are equivalent:

(i) A is positive as an element of $\mathbb{R}^{n\times n}$: $A^{\mathsf{T}}=A$ and $\mathbf{x}^{\mathsf{T}}A\mathbf{x}\geq 0$ for every $\mathbf{x}\in\mathbb{R}^n$;

(ii) $\mathbf{x}^*A\mathbf{x}\geq 0$ for every $\mathbf{x}\in\mathbb{C}^n$.

Then show that (ii) does not follow from "$\mathbf{x}^{\mathsf{T}}A\mathbf{x}\geq 0$ for every $\mathbf{x}\in\mathbb{R}^n$" alone. This is why Definition 8.3.1 requires self-adjointness over $\mathbb{R}$ (Remark 8.3.4).

Solution on page 1653

Exercise 8.3.31. STANDARD Let $A = \begin{pmatrix} a & b \\ \overline{b} & c \end{pmatrix} \in \mathbb{F}^{2\times 2}$ with $a, c \in \mathbb{R}$.

(a) Show that A is positive if and only if $a \geq 0$, $c \geq 0$, and $ac - |b|^2 \geq 0$.

(b) Show that A is positive definite if and only if $a > 0$ and $ac - |b|^2 > 0$.

(c) Show by an example that $a \geq 0$ and $\det A \geq 0$ do not imply that A is positive.

Solution on page 1653

Solution on page 1654

Exercise 8.3.32. STANDARD Let $T \in \mathrm{L}(V)$ be positive, let $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis of V, and let $A = [T]_{\mathcal{O}}$.

(a) Show that $|a_{ij}|^2 \leq a_{ii}a_{jj}$ for all i, j.

(b) Deduce that if $a_{ii} = 0$, then row i and column i of A are zero.

(c) Deduce that the largest of the numbers $|a_{ij}|$ occurs on the diagonal.

Solution on page 1654

Solution on page 1655

Exercise 8.3.33. STANDARD Let $T \in \mathrm{L}(V)$ be positive.

(a) Show that $|\langle T\mathbf{v}, \mathbf{w}\rangle|^2 \leq \langle T\mathbf{v}, \mathbf{v}\rangle\langle T\mathbf{w}, \mathbf{w}\rangle$ for all $\mathbf{v}, \mathbf{w} \in V$.

(b) Use (a) to give a third proof of Lemma 8.3.8.

(c) Show that $\ker\sqrt{T} = \ker T$ and $\operatorname{im}\sqrt{T} = \operatorname{im} T$.

Solution on page 1655

Exercise 8.3.34. STANDARD Let $S, T \in \mathrm{L}(V)$ be positive.

(a) Show that $\operatorname{tr} T \geq 0$ and $\det T \geq 0$, and that $\operatorname{tr} T = 0$ only if $T = 0$.

(b) Show that $\operatorname{tr}(ST) \geq 0$.

(c) Show that $\operatorname{tr}(ST) = 0$ if and only if $ST = 0$.

Solution on page 1656

Exercise 8.3.35. STANDARD

(a) Show that the $n \times n$ **Hilbert matrix** H_n, with entries $h_{ij} = 1/(i + j - 1)$, is positive definite. Deduce that $\det H_n > 0$.

(b) Show that the $n \times n$ matrix K_n with entries $k_{ij} = 1/(i + j)$ is positive definite.

Solution on page 1656

Exercise 8.3.36. STANDARD Let $A \in \mathbb{F}^{2\times 2}$ be positive and nonzero, and let $\delta = \sqrt{\det A}$.

(a) Show that

$$\sqrt{A} = \frac{A + \delta I_2}{\sqrt{\operatorname{tr} A + 2\delta}}.$$

(b) Use (a) to compute $\sqrt{A}$ for $A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$ and for $A = \begin{pmatrix} 5 & 4i \\ -4i & 5 \end{pmatrix}$.

Solution on page 1656

Exercise 8.3.37. STANDARD Let $T \in \mathrm{L}(V)$ be self-adjoint, with spectral decomposition $T = \sum_j \lambda_j P_j$. Define $|T| = \sqrt{T^2}$, which makes sense because $T^2 = T^*T$ is positive (Remark 8.3.13).

(a) Show that $|T| = \sum_j |\lambda_j| P_j$.

(b) Show that $|T| = T$ if and only if T is positive.

(c) Let $T_+ = (|T| + T)/2$ and $T_- = (|T| - T)/2$. Show that T_+ and T_- are positive, $T = T_+ - T_-$, and $T_+ T_- = 0$.

Solution on page 1657

Exercise 8.3.38. STANDARD Consider the following argument.

"*Claim.* A positive operator T has exactly one self-adjoint square root. *Proof.* Let R be self-adjoint with $R^2 = T$. Then R commutes with T, so by Proposition 8.2.20(a) it maps each eigenspace E_λ of T into itself. On E_λ we have $R^2 = T = \lambda\,\mathrm{id}$, so $R = \sqrt{\lambda}\,\mathrm{id}$ on E_λ. Hence $R = \sum_j \sqrt{\lambda_j} P_j = \sqrt{T}$."

(a) Find the error, and show that the claim is false.

(b) Suppose $\dim V = n$ and T is positive with n distinct eigenvalues, k of which are nonzero. How many self-adjoint square roots does T have?

Solution on page 1658

Exercise 8.3.39. HARD BEYOND 21-242 Let $A, B \in \mathbb{F}^{n\times n}$ be positive definite with $A \preceq B$ (Definition 8.3.21).

(a) Show that $B^{-1} \preceq A^{-1}$.

(b) Show that $\det A \le \det B$.

(c) Show that for positive matrices, $A \preceq B$ does not imply $A^2 \preceq B^2$: take $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$.

Solution on page 1658

Exercise 8.3.40. HARD BEYOND 21-242 Let $A, B \in \mathrm{L}(V)$ with $0 \preceq A \preceq B$. Show that $\sqrt{A} \preceq \sqrt{B}$. Then show that the converse fails: $\sqrt{A} \preceq \sqrt{B}$ does not imply $A \preceq B$.

Solution on page 1659

Exercise 8.3.41. STANDARD BEYOND 21-242

(a) Find the Cholesky factorization of $A = \begin{pmatrix} 1 & 2 & 1 \\ 2 & 13 & 8 \\ 1 & 8 & 14 \end{pmatrix}$ with Algorithm 8.3.24.

(b) Use Algorithm 8.3.24 to decide whether $B = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 5 & 4 \\ 3 & 4 & 6 \end{pmatrix}$ is positive definite.

(c) From the computation in (b), find a vector $\mathbf{x}$ with $\mathbf{x}^{\mathsf{T}} B \mathbf{x} < 0$.

Solution on page 1659

Exercise 8.3.42. HARD BEYOND 21-242

(a) (Hadamard's inequality.) Show that every positive $A \in \mathbb{F}^{n\times n}$ satisfies $\det A \le a_{11} a_{22} \cdots a_{nn}$.

(b) Deduce that every $B \in \mathbb{F}^{n\times n}$ with columns $\mathbf{b}_1, \ldots, \mathbf{b}_n$ satisfies $|\det B| \le \|\mathbf{b}_1\| \|\mathbf{b}_2\| \cdots \|\mathbf{b}_n\|$. If B is invertible, show that equality holds if and only if the columns of B are orthogonal.

Solution on page 1660

Solution on page 1660

Exercise 8.3.43. CHALLENGE BEYOND 21-242 Let $A \in \mathbb{F}^{n\times n}$ be positive definite. For $C \in \mathbb{F}^{n\times n}$ consider the equation

$$AX + XA = C \quad (X \in \mathbb{F}^{n\times n}).$$

(a) Show that the equation has exactly one solution X.

(b) Show that if C is Hermitian, then so is X.

(c) Show that if C is positive, then so is X.

(d) Deduce that for real numbers $a_1, \ldots, a_n > 0$, the matrix with entries $1/(a_i + a_j)$ is positive.

Solution on page 1661

8.4 Isometries and unitary operators

A rotation of the plane moves almost every vector but changes no length and no angle. Section 6.3 met the matrices that behave like this, the unitary matrices, through a condition on their columns, $U^*U = I_n$. This section starts from the other end, from linear maps that preserve lengths, and shows that preserving lengths forces the rest: inner products are preserved, $S^*S = \mathrm{id}$, and the columns of every matrix in orthonormal bases are orthonormal. For operators on a finite-dimensional space these maps are the unitary operators of Table 8.1.1, the analogues of the complex numbers on the unit circle, and over $\mathbb{C}$ the spectral theorem describes them completely. Over $\mathbb{R}$ the description is the classical one, by rotations in perpendicular planes and reflections. We derive it in the second half of the section, together with the distance-preserving maps of $\mathbb{R}^n$ that are not linear.

Throughout, V and W are inner product spaces over $\mathbb{F}$, and inner products are linear in the first slot.

8.4.1 Isometries

Definition 8.4.1 (Isometry). Let V and W be inner product spaces over $\mathbb{F}$. A linear map $S \in \mathrm{L}(V, W)$ is an **isometry** if

$$\|S\mathbf{v}\| = \|\mathbf{v}\| \quad \text{for every } \mathbf{v} \in V.$$

Since S is linear, $\|S\mathbf{u} - S\mathbf{v}\| = \|S(\mathbf{u} - \mathbf{v})\| = \|\mathbf{u} - \mathbf{v}\|$, so an isometry preserves distances as well as lengths. In metric geometry "isometry" means any distance-preserving map, linear or not, and translations are the basic nonlinear examples. Our isometries are always linear; Section 8.4.6 shows that, in a real inner product space, the general distance-preserving maps differ from them only by a translation.

Example 8.4.2 (Isometries).

(a) Every unitary matrix $U \in \mathbb{F}^{n\times n}$ gives an isometry $\mathbf{x} \mapsto U\mathbf{x}$ of $\mathbb{F}^n$ (Exercise 6.3.37). In particular, the rotations R_θ and the reflections S_θ of Example 6.3.35 are isometries of $\mathbb{R}^2$.

(b) More generally, let $A \in \mathbb{F}^{m\times n}$ have orthonormal columns. Then $A^*A = I_n$ (Theorem 6.3.29), so for every $\mathbf{x} \in \mathbb{F}^n$,

$$\|A\mathbf{x}\|^2 = (A\mathbf{x})^*(A\mathbf{x}) = \mathbf{x}^*A^*A\mathbf{x} = \mathbf{x}^*\mathbf{x} = \|\mathbf{x}\|^2.$$

For instance, $A = \frac{1}{3}\begin{pmatrix} 1 & 2 \\ 2 & 1 \\ 2 & -2 \end{pmatrix}$ maps $\mathbb{R}^2$ isometrically onto a plane in $\mathbb{R}^3$; it sends $(1,1)$ to $(1,1,0)$, and both have length $\sqrt{2}$.

(c) If U is a subspace of V, the inclusion $U \to V$, $\mathbf{u} \mapsto \mathbf{u}$, is an isometry.

(d) Let $\mathcal{O} = \mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis of V. By Theorem 6.3.22(b), the coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_\mathcal{O}$ is an isometry from V to $\mathbb{F}^n$ with the dot product, and so is its inverse $(a_1, \ldots, a_n) \mapsto a_1\mathbf{e}_1 + \cdots + a_n\mathbf{e}_n$.

Non-example 8.4.3 (Maps that are not isometries).

- The shear $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ sends $\mathbf{e}_2$ to $(1,1)$, which has length $\sqrt{2}$.
- An orthogonal projection Pr_U with $U \neq V$ is not an isometry. For $\mathbf{v} \notin U$, the vector $\mathbf{v} - \mathrm{Pr}_U \mathbf{v}$ is nonzero and orthogonal to $\mathrm{Pr}_U \mathbf{v}$, so $\|\mathrm{Pr}_U \mathbf{v}\| < \|\mathbf{v}\|$ by Theorem 6.3.3.
- The columns of $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ are orthogonal but have length $\sqrt{2}$. The matrix is $\sqrt{2}$ times an orthogonal matrix, so it multiplies every length by $\sqrt{2}$. It preserves right angles without being an isometry (compare Exercise 8.4.34).

Intuition (Why lengths control angles). Over $\mathbb{R}$, the law of cosines

$$\|\mathbf{u} - \mathbf{v}\|^2 = \|\mathbf{u}\|^2 - 2\langle \mathbf{u}, \mathbf{v}\rangle + \|\mathbf{v}\|^2$$

computes the inner product of $\mathbf{u}$ and $\mathbf{v}$ from the three side lengths of the triangle with vertices $\mathbf{0}$, $\mathbf{u}$, $\mathbf{v}$. A linear map S sends this triangle to the triangle with vertices $\mathbf{0}$, $S\mathbf{u}$, $S\mathbf{v}$, whose third side is $S\mathbf{u} - S\mathbf{v} = S(\mathbf{u} - \mathbf{v})$. If S preserves lengths, the two triangles have the same side lengths, hence the same angle at $\mathbf{0}$. Over $\mathbb{C}$ the polarization identity (Proposition 6.1.32) plays the role of the law of cosines. Linearity is used once, to know that the third side of the image is the image of the third side.

The main theorem lists the equivalent forms of the definition. Parts of it appeared as exercises in Section 6.6 (Exercise 6.1.51 and Exercise 6.6.40).

Theorem 8.4.4 (Characterizations of isometries). Let V and W be finite-dimensional inner product spaces with $n = \dim V$, and let $S \in \mathrm{L}(V, W)$. The following are equivalent.

(I) S is an isometry.

(II) S preserves inner products: $\langle S\mathbf{u}, S\mathbf{v}\rangle = \langle \mathbf{u}, \mathbf{v}\rangle$ for all $\mathbf{u}, \mathbf{v} \in V$.

(III) $S^*S = \mathrm{id}_V$.

(IV) S maps every orthonormal list in V to an orthonormal list in W.

(V) S maps some orthonormal basis of V to an orthonormal list in W.

(VI) For some orthonormal bases $\mathcal{B}$ of V and $\mathcal{C}$ of W, the columns of $A = [S]_{\mathcal{C}\mathcal{B}}$ are orthonormal, that is, $A^*A = I_n$.

(VII) For all orthonormal bases $\mathcal{B}$ of V and $\mathcal{C}$ of W, the columns of $[S]_{\mathcal{C}\mathcal{B}}$ are orthonormal.

Proof (by polarization). STANDARD

Uses. Proposition 6.1.32 (Polarization identities), Definition 6.6.8 (Adjoint), Proposition 6.1.37 (Inner products distinguish vectors), Theorem 6.4.20 (Orthonormal bases exist), Proposition 6.3.18 (Coordinates in an orthonormal basis), Corollary 6.3.6 (Pythagoras for orthogonal lists), Theorem 6.6.15 (Existence of adjoints), Theorem 2.4.2 (The matrix of a composite), Theorem 2.3.20 (Linear maps correspond to matrices), Theorem 6.3.29 (Orthonormal columns)
Techniques. Proving TFAE (Technique 2.7.1), Polarization (Technique 6.1.33), Move an operator across the inner product (Technique 6.6.20), Translate between maps and matrices (Technique 2.3.27)
Hint 1. For (I) ⇒ (II), express $\langle S\mathbf{u}, S\mathbf{v}\rangle$ through lengths of the vectors $S\mathbf{u} + cS\mathbf{v}$, and use linearity to pull S out.
Hint 2. For (II) ⇒ (III), rewrite $\langle S\mathbf{u}, S\mathbf{v}\rangle$ with the adjoint as $\langle \mathbf{u}, S^*S\mathbf{v}\rangle$. For (V) ⇒ (I), expand $\mathbf{v}$ in the orthonormal basis and apply Pythagoras to $\mathbf{v}$ and to $S\mathbf{v}$.
Hint 3. For the matrix conditions, $[S^*]_{\mathcal{BC}} = A^*$ in orthonormal bases, so $[S^*S]_{\mathcal{BB}} = A^*A$.
Sketch. Polarization writes $\langle S\mathbf{u}, S\mathbf{v}\rangle$ as a combination of $\|S(\mathbf{u} + c\mathbf{v})\|^2 = \|\mathbf{u} + c\mathbf{v}\|^2$, which gives (II). Then $\langle \mathbf{u}, S^*S\mathbf{v}\rangle = \langle \mathbf{u}, \mathbf{v}\rangle$ for all $\mathbf{u}$ forces $S^*S\mathbf{v} = \mathbf{v}$. From (III), $\langle S\mathbf{e}_j, S\mathbf{e}_i\rangle = \langle \mathbf{e}_j, S^*S\mathbf{e}_i\rangle = \delta_{ij}$. If $S\mathbf{e}_1, \dots, S\mathbf{e}_n$ is orthonormal, Pythagoras gives $\|S\mathbf{v}\|^2 = \sum |a_j|^2 = \|\mathbf{v}\|^2$. In orthonormal bases S^*S has matrix A^*A, so (III) holds iff $A^*A = I_n$ in one, or in all, such pairs of bases.

We prove (I) ⇒ (II) ⇒ (III) ⇒ (IV) ⇒ (V) ⇒ (I), and then (III) ⇒ (VII) ⇒ (VI) ⇒ (III).

(I) ⇒ (II). Let $\mathbf{u}, \mathbf{v} \in V$. For every scalar c, linearity gives $S\mathbf{u} + cS\mathbf{v} = S(\mathbf{u} + c\mathbf{v})$, so by (I)

$$\|S\mathbf{u} + cS\mathbf{v}\| = \|\mathbf{u} + c\mathbf{v}\|.$$

If $\mathbb{F} = \mathbb{R}$, Proposition 6.1.32(a) with $c = \pm 1$ gives

$$\langle S\mathbf{u}, S\mathbf{v}\rangle = \frac{1}{4}\Big(\|S\mathbf{u} + S\mathbf{v}\|^2 - \|S\mathbf{u} - S\mathbf{v}\|^2\Big) = \frac{1}{4}\Big(\|\mathbf{u} + \mathbf{v}\|^2 - \|\mathbf{u} - \mathbf{v}\|^2\Big) = \langle \mathbf{u}, \mathbf{v}\rangle.$$

If $\mathbb{F} = \mathbb{C}$, the same computation with the four values $c = i^k$ in Proposition 6.1.32(b) gives $\langle S\mathbf{u}, S\mathbf{v}\rangle = \langle \mathbf{u}, \mathbf{v}\rangle$.

(II) ⇒ (III). Let $\mathbf{v} \in V$. By the definition of the adjoint (Definition 6.6.8) and (II), for every $\mathbf{u} \in V$

$$\langle \mathbf{u}, S^*S\mathbf{v}\rangle = \langle S\mathbf{u}, S\mathbf{v}\rangle = \langle \mathbf{u}, \mathbf{v}\rangle.$$

Conjugating both sides, $\langle S^*S\mathbf{v}, \mathbf{u}\rangle = \langle \mathbf{v}, \mathbf{u}\rangle$ for all $\mathbf{u}$, so $S^*S\mathbf{v} = \mathbf{v}$ by Proposition 6.1.37. Hence $S^*S = \mathrm{id}_V$.

(III) ⇒ (IV). Let $\mathbf{e}_1, \dots, \mathbf{e}_k$ be orthonormal in V. Then

$$\langle S\mathbf{e}_j, S\mathbf{e}_i\rangle = \langle \mathbf{e}_j, S^*S\mathbf{e}_i\rangle = \langle \mathbf{e}_j, \mathbf{e}_i\rangle = \delta_{ij},$$

so $S\mathbf{e}_1, \dots, S\mathbf{e}_k$ is orthonormal.

(IV) ⇒ (V). V has an orthonormal basis (Theorem 6.4.20(a)), and by (IV) its image is orthonormal.

(V) ⇒ (I). Let $\mathbf{e}_1, \dots, \mathbf{e}_n$ be an orthonormal basis of V with $S\mathbf{e}_1, \dots, S\mathbf{e}_n$ orthonormal, and let $\mathbf{v} \in V$. By Proposition 6.3.18, $\mathbf{v} = \sum_j a_j \mathbf{e}_j$ with $a_j = \langle \mathbf{v}, \mathbf{e}_j\rangle$, so $S\mathbf{v} = \sum_j a_j S\mathbf{e}_j$. Applying Corollary 6.3.6 to both orthonormal lists,

$$\|S\mathbf{v}\|^2 = \sum_{j=1}^{n} |a_j|^2 \|S\mathbf{e}_j\|^2 = \sum_{j=1}^{n} |a_j|^2 = \sum_{j=1}^{n} |a_j|^2 \|\mathbf{e}_j\|^2 = \|\mathbf{v}\|^2.$$

(III) ⇒ (VII). Let $\mathcal{B}, \mathcal{C}$ be orthonormal bases of V and W, and $A = [S]_{\mathcal{CB}}$. By Theorem 6.6.15(b), $[S^*]_{\mathcal{BC}} = A^*$, and by Theorem 2.4.2,

$$A^*A = [S^*]_{\mathcal{BC}}[S]_{\mathcal{CB}} = [S^*S]_{\mathcal{BB}} = [\mathrm{id}_V]_{\mathcal{BB}} = I_n.$$

By Theorem 6.3.29, $A^*A = I_n$ says exactly that the columns of A are orthonormal.

(VII) ⇒ (VI). Orthonormal bases of V and W exist (Theorem 6.4.20(a)).

(VI) ⇒ (III). The computation in (III) ⇒ (VII), read backwards, gives $[S^*S]_{\mathcal{BB}} = A^*A = I_n = [\mathrm{id}_V]_{\mathcal{BB}}$, and a linear map is determined by its matrix (Theorem 2.3.20). So $S^*S = \mathrm{id}_V$. □

The polarization step is the only place where an identity for single vectors becomes one for pairs. There is a second route from lengths to S^*S that hides the pairs inside a result about self-adjoint operators.

Proof (through the quadratic form of $S^*S - \mathrm{id}_V$). STANDARD

> *Uses.* Proposition 6.6.18 (Properties of the adjoint), Definition 6.6.8 (Adjoint), Proposition 8.1.4 (Self-adjoint operators are determined by their diagonal values)
> *Techniques.* Move an operator across the inner product (Technique 6.6.20)
> *Hint 1.* Let $P = S^*S - \mathrm{id}_V$. Is P self-adjoint? Compute $\langle P\mathbf{v}, \mathbf{v}\rangle$.
> *Hint 2.* $\langle P\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2 - \|\mathbf{v}\|^2$. Which result says that a self-adjoint operator with $\langle P\mathbf{v}, \mathbf{v}\rangle = 0$ for all $\mathbf{v}$ is zero?
> *Sketch.* $P = S^*S - \mathrm{id}_V$ is self-adjoint, and $\langle P\mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2 - \|\mathbf{v}\|^2$. So (I) says that the quadratic form of P vanishes, and Proposition 8.1.4 gives $P = 0$. Then (III) ⇒ (II) is one line, and the rest is as in the first proof.

We prove the cycle (I) ⇒ (III) ⇒ (II) ⇒ (I); the remaining implications are as in the first proof.

Let $P = S^*S - \mathrm{id}_V$. By Proposition 6.6.18, $(S^*S)^* = S^*(S^*)^* = S^*S$, so P is self-adjoint. For $\mathbf{v} \in V$, the definition of the adjoint gives $\langle S^*S\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, S\mathbf{v}\rangle$ (apply Definition 6.6.8 to S^*, whose adjoint is S), so

$$\langle P\mathbf{v}, \mathbf{v}\rangle = \langle S\mathbf{v}, S\mathbf{v}\rangle - \langle \mathbf{v}, \mathbf{v}\rangle = \|S\mathbf{v}\|^2 - \|\mathbf{v}\|^2.$$

If (I) holds, this vanishes for every $\mathbf{v}$, and $P = 0$ by Proposition 8.1.4; that is (III). Conversely, if (III) holds, then for all $\mathbf{u}, \mathbf{v}$,

$$\langle S\mathbf{u}, S\mathbf{v}\rangle = \langle \mathbf{u}, S^*S\mathbf{v}\rangle = \langle \mathbf{u}, \mathbf{v}\rangle,$$

which is (II), and taking $\mathbf{u} = \mathbf{v}$ in (II) gives (I). □

The first proof recovers inner products from lengths; the second recovers the operator $S^*S - \mathrm{id}_V$ from its values $\langle P\mathbf{v}, \mathbf{v}\rangle$. They rest on the same fact (the proof of Proposition 8.1.4 is a polarization argument), but the second shows the shape of the condition. An isometry is a map whose "defect" $S^*S - \mathrm{id}_V$ has zero quadratic form, and Section 8.3 studies maps whose S^*S is merely compared with id_V.

Remark 8.4.5 (Without finite dimension). The implications (I) ⇒ (II) ⇒ (I) use neither bases nor adjoints, and neither does (II) ⇒ (IV), since $\langle S\mathbf{e}_j, S\mathbf{e}_i\rangle = \langle \mathbf{e}_j, \mathbf{e}_i\rangle = \delta_{ij}$ for an orthonormal list; so they hold for a linear map between any two inner product spaces. So does (II) ⇒ (III), whenever S has an adjoint. In particular, every isometry preserves inner products, orthogonality, and angles (Definition 6.2.16).

Corollary 8.4.6 (Properties of isometries). Let $S \in \mathrm{L}(V, W)$ be an isometry.

(a) S is injective, and it preserves inner products, distances, and orthogonality.

(b) If $R \in \mathrm{L}(W, X)$ is also an isometry, so is RS.

(c) If V and W are finite-dimensional, then $\dim V \le \dim W$, and SS^* is the orthogonal projection $\mathrm{Pr}_{\mathrm{im}\, S}$.

(d) If $\dim V = \dim W < \infty$, then S is bijective, $S^{-1} = S^*$, and S^{-1} is an isometry.

Proof. ROUTINE

> *Uses.* Remark 8.4.5 (Without finite dimension), Theorem 8.4.4 (Characterizations of isometries), Proposition 4.2.6 (Injective maps preserve dimension), Corollary 6.6.29 (Orthogonal projections are the self-adjoint idempotents), Proposition 6.6.18 (Properties of the adjoint), Theorem 4.2.11 (Rank–nullity)
> *Techniques.* Test injectivity at $\mathbf{0}$ (Technique 2.6.12)
> *Hint 1.* For injectivity, test at $\mathbf{0}$: what is $\|\mathbf{v}\|$ if $S\mathbf{v} = \mathbf{0}$?
> *Hint 2.* For (c), check that $P = SS^*$ satisfies $P^2 = P = P^*$, and compare $\mathrm{im}\, P$ with $\mathrm{im}\, S$ using $S = S(S^*S)$.
> *Hint 3.* For (d), S is injective between spaces of equal finite dimension, and S^* is a left inverse.
> *Sketch.* If $S\mathbf{v} = \mathbf{0}$ then $\|\mathbf{v}\| = \|S\mathbf{v}\| = 0$. Composites: $\|RS\mathbf{v}\| = \|S\mathbf{v}\| = \|\mathbf{v}\|$. Injectivity gives $\dim V = \dim \mathrm{im}\, S \le \dim W$. $P = SS^*$ has $P^2 = S(S^*S)S^* = P$ and $P^* = P$, and $\mathrm{im}\, P = \mathrm{im}\, S$ because $S = PS$. If $\dim V = \dim W$, S is bijective, and $S^* = S^*\left(SS^{-1}\right) = S^{-1}$.

(a) If $S\mathbf{v} = \mathbf{0}$, then $\|\mathbf{v}\| = \|S\mathbf{v}\| = 0$, so $\mathbf{v} = \mathbf{0}$; hence S is injective. Inner products are preserved by Remark 8.4.5, distances because $S\mathbf{u} - S\mathbf{v} = S(\mathbf{u} - \mathbf{v})$, and orthogonality because it is a statement about inner products.

(b) $\|RS\mathbf{v}\| = \|S\mathbf{v}\| = \|\mathbf{v}\|$ for every $\mathbf{v}$.

(c) Since S is injective, $\dim V = \dim \operatorname{im} S \le \dim W$ (Proposition 4.2.6). Let $P = SS^*$. By (III) of Theorem 8.4.4 and Proposition 6.6.18,

$$P^2 = S(S^*S)S^* = SS^* = P, \quad P^* = (S^*)^*S^* = SS^* = P,$$

so P is the orthogonal projection onto $\operatorname{im} P$ (Corollary 6.6.29). Clearly $\operatorname{im} P \subseteq \operatorname{im} S$, and $S = S(S^*S) = PS$ gives $\operatorname{im} S \subseteq \operatorname{im} P$. So $P = \operatorname{Pr}_{\operatorname{im} S}$.

(d) By (a) and rank–nullity (Theorem 4.2.11), $\dim \operatorname{im} S = \dim V = \dim W$, so S is also surjective. Then $S^* = S^*\big(SS^{-1}\big) = (S^*S)S^{-1} = S^{-1}$, and for $\mathbf{w} \in W$, $\big\|S^{-1}\mathbf{w}\big\| = \big\|S\big(S^{-1}\mathbf{w}\big)\big\| = \|\mathbf{w}\|$. □

For example, the matrix $A = \frac{1}{3}\begin{pmatrix} 1 & 2 \\ 2 & 1 \\ 2 & -2 \end{pmatrix}$ of Example 8.4.2(b) has

$$A^{\mathsf{T}}A = I_2, \quad AA^{\mathsf{T}} = \frac{1}{9}\begin{pmatrix} 5 & 4 & -2 \\ 4 & 5 & 2 \\ -2 & 2 & 8 \end{pmatrix},$$

and AA^{T} is the projection onto the plane $\operatorname{im} A$, whose unit normal is $\frac{1}{3}(2,-2,1)$. Indeed $AA^{\mathsf{T}} = I_3 - \mathbf{n}\mathbf{n}^{\mathsf{T}}$ with $\mathbf{n} = \frac{1}{3}(2,-2,1)$. So A^{T} is a left inverse of A but not a right inverse (compare Exercise 6.6.41).

The next corollary makes precise the remark in Section 6.3 that an n-dimensional inner product space "looks like" $\mathbb{F}^n$ with the dot product.

Corollary 8.4.7 (Inner product spaces are classified by dimension). Let V and W be finite-dimensional inner product spaces over $\mathbb{F}$. There is a bijective isometry $V \to W$ if and only if $\dim V = \dim W$. In particular, for every orthonormal basis $\mathcal{O}$ of an n-dimensional V, the coordinate map $\mathbf{v} \mapsto [\mathbf{v}]_{\mathcal{O}}$ is a bijective isometry $V \to \mathbb{F}^n$.

Proof. ROUTINE

Uses. Theorem 6.4.20 (Orthonormal bases exist), Theorem 2.2.1 (Linear maps are determined by a basis), Theorem 8.4.4 (Characterizations of isometries), Corollary 8.4.6 (Properties of isometries), Example 8.4.2 (Isometries)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4)
Hint 1. A bijective linear map preserves dimension. For the converse, which map should send what where?
Hint 2. Choose orthonormal bases of V and W, and define S on the first basis by sending it to the second.
Sketch. A bijective linear map sends a basis to a basis, so the dimensions agree. Conversely, pick orthonormal bases $\mathbf{e}_1, \dots, \mathbf{e}_n$ and $\mathbf{f}_1, \dots, \mathbf{f}_n$, and let $S\mathbf{e}_j = \mathbf{f}_j$; by (V) of Theorem 8.4.4 S is an isometry, and it is bijective by Corollary 8.4.6(d).

If $S : V \to W$ is a bijective isometry, it is a bijective linear map, so it sends a basis of V to a basis of W and $\dim V = \dim W$. Conversely, suppose $\dim V = \dim W = n$. By Theorem 6.4.20(a) there are orthonormal bases $\mathbf{e}_1, \dots, \mathbf{e}_n$ of V and $\mathbf{f}_1, \dots, \mathbf{f}_n$ of W, and by Theorem 2.2.1 there is a linear $S : V \to W$ with $S\mathbf{e}_j = \mathbf{f}_j$ for each j. It maps an orthonormal basis to an orthonormal list, so it is an isometry by (V) ⇒ (I) of Theorem 8.4.4, and it is bijective by Corollary 8.4.6(d). The last sentence is Example 8.4.2(d): the coordinate map sends $\mathbf{e}_j$ to the standard basis vector $\mathbf{e}_j$ of $\mathbb{F}^n$. □

So everything about lengths and angles in an n-dimensional inner product space can be computed in $\mathbb{F}^n$ with the dot product, once an orthonormal basis is fixed. What does depend on the space is how particular operators sit inside it.

Exercise 8.4.8. ROUTINE Let V, W be finite-dimensional and $S \in \mathrm{L}(V, W)$.

(a) Prove or disprove: if $\|S\mathbf{e}_j\| = 1$ for every vector of some orthonormal basis $\mathbf{e}_1, \dots, \mathbf{e}_n$ of V, then S is an isometry.

(b) Prove or disprove: if $\|S\mathbf{v}\| = 1$ for every unit vector $\mathbf{v} \in V$, then S is an isometry.

Solution on page 1661

8.4.2 Unitary operators

An isometry $V \to V$ is injective. In finite dimensions it is therefore invertible, and its inverse is again an isometry; in infinite dimensions it need not be (Example 8.4.12). The invertible ones get a name.

Definition 8.4.9 (Unitary operator). Let V be an inner product space. An operator $S \in \mathrm{L}(V)$ is **unitary** if it is an isometry and invertible. When $\mathbb{F} = \mathbb{R}$, unitary operators are also called **orthogonal operators**.

In Table 8.1.1 the unitary row was described by $T^*T = TT^* = \mathrm{id}$. The two descriptions agree in every dimension.

Proposition 8.4.10 (Unitary means $S^* = S^{-1}$). Let V be an inner product space and $S \in \mathrm{L}(V)$. Then S is unitary if and only if S has an adjoint and

$$S^*S = SS^* = \mathrm{id}_V.$$

In that case $S^* = S^{-1}$, and S^* is unitary as well.

Proof. ROUTINE

Uses. Remark 8.4.5 (Without finite dimension), Definition 6.6.8 (Adjoint), Proposition 6.6.9 (Adjoints are unique and linear), Definition 2.5.12 (Invertible)
Techniques. Find the adjoint by isolating the input (Technique 6.6.11)
Hint 1. To show that S^* exists, guess it: which map could satisfy $\langle S\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, S^*\mathbf{w}\rangle$?
Hint 2. Write $\mathbf{w} = S\big(S^{-1}\mathbf{w}\big)$ and use that S preserves inner products.
Sketch. If S is unitary, $\langle S\mathbf{v}, \mathbf{w}\rangle = \big\langle S\mathbf{v}, SS^{-1}\mathbf{w}\big\rangle = \big\langle \mathbf{v}, S^{-1}\mathbf{w}\big\rangle$, so S^{-1} is the adjoint. Conversely $S^*S = SS^* = \mathrm{id}$ says that S is invertible with inverse S^*, and $\|S\mathbf{v}\|^2 = \langle \mathbf{v}, S^*S\mathbf{v}\rangle = \|\mathbf{v}\|^2$.

Suppose S is unitary. By Remark 8.4.5, S preserves inner products, so for all $\mathbf{v}, \mathbf{w} \in V$,

$$\langle S\mathbf{v}, \mathbf{w}\rangle = \big\langle S\mathbf{v}, S\big(S^{-1}\mathbf{w}\big)\big\rangle = \big\langle \mathbf{v}, S^{-1}\mathbf{w}\big\rangle.$$

So S^{-1} is an adjoint of S (Definition 6.6.8), and by Proposition 6.6.9, $S^* = S^{-1}$. Hence $S^*S = SS^* = \mathrm{id}_V$.

Conversely, suppose $S^*S = SS^* = \mathrm{id}_V$. Then S is invertible with $S^{-1} = S^*$ (Definition 2.5.12), and for every $\mathbf{v}$,

$$\|S\mathbf{v}\|^2 = \langle S\mathbf{v}, S\mathbf{v}\rangle = \langle \mathbf{v}, S^*S\mathbf{v}\rangle = \|\mathbf{v}\|^2.$$

So S is unitary. Finally, $S^* = S^{-1}$ is invertible, and $\big\|S^{-1}\mathbf{v}\big\| = \big\|S\big(S^{-1}\mathbf{v}\big)\big\| = \|\mathbf{v}\|$, so S^* is unitary. □

Theorem 8.4.11 (Characterizations of unitary operators). Let V be a finite-dimensional inner product space and $S \in \mathrm{L}(V)$. The following are equivalent.

(I) S is an isometry.
(II) S is unitary.
(III) $S^*S = \mathrm{id}_V$.
(IV) $SS^* = \mathrm{id}_V$.
(V) S^* is an isometry.
(VI) S maps some orthonormal basis of V to an orthonormal basis of V.
(VII) S maps every orthonormal basis of V to an orthonormal basis of V.
(VIII) $[S]_{\mathcal{O}}$ is a unitary matrix for some orthonormal basis $\mathcal{O}$ of V, or equivalently for every one.

Proof. ROUTINE

Uses. Theorem 8.4.4 (Characterizations of isometries), Corollary 8.4.6 (Properties of isometries), Proposition 8.4.10 (Unitary means $S^* = S^{-1}$), Remark 4.2.20 (One-sided inverses of operators), Proposition 6.6.18 (Properties of the adjoint), Corollary 6.3.14 (Counting orthogonal vectors), Definition 6.3.33 (Unitary and orthogonal matrices)

Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Most of the work is in Theorem 8.4.4 with $W = V$. What does finite dimension add?
Hint 2. An injective operator on a finite-dimensional space is invertible, and a one-sided inverse of such an operator is two-sided.
Hint 3. For (V), apply Theorem 8.4.4 to S^*, whose adjoint is S. For (VI) and (VII), an orthonormal list of length $\dim V$ is a basis.
Sketch. (I) ⇔ (III) is Theorem 8.4.4, and an isometry of a finite-dimensional space is invertible (Corollary 8.4.6(d)), which gives (II). Unitary operators satisfy (IV) by Proposition 8.4.10, and (IV) ⇒ (III) because one-sided inverses of operators are two-sided. (V) is (IV) by Theorem 8.4.4 applied to S^*. An orthonormal list of length n is an orthonormal basis, so (VI) and (VII) are (V) and (IV) of Theorem 8.4.4; and (VIII) is its (VI)–(VII) with $\mathcal{B} = \mathcal{C} = \mathcal{O}$.

We prove (I) ⇒ (II) ⇒ (IV) ⇒ (III) ⇒ (I), then (IV) ⇔ (V), and finally (I) ⇔ (VI) ⇔ (VII) and (III) ⇔ (VIII).

(I) ⇒ (II). By Corollary 8.4.6(d) with $W = V$, S is bijective, with $S^{-1} = S^*$; so S is an invertible isometry.

(II) ⇒ (IV). Proposition 8.4.10.

(IV) ⇒ (III). S^* is a right inverse of the operator S on the finite-dimensional space V, hence also a left inverse (Remark 4.2.20).

(III) ⇒ (I). (III) ⇒ (I) of Theorem 8.4.4.

(IV) ⇔ (V). By Proposition 6.6.18, $(S^*)^* = S$. So by (I) ⇔ (III) of Theorem 8.4.4 applied to $S^* \in \mathrm{L}(V)$, S^* is an isometry if and only if $SS^* = \mathrm{id}_V$.

(I) ⇔ (VI) ⇔ (VII). Let $n = \dim V$. An orthonormal list of length n in V is a basis (Corollary 6.3.14). So (VI) says the same as (V) of Theorem 8.4.4, and (VII) says the same as its (IV) restricted to lists of length n. Thus (I) ⇒ (VII) by (I) ⇒ (IV) there, (VII) ⇒ (VI) is clear, and (VI) ⇒ (I) is (V) ⇒ (I) there.

(III) ⇔ (VIII). With $\mathcal{B} = \mathcal{C} = \mathcal{O}$, (VI) and (VII) of Theorem 8.4.4 say that $[S]_{\mathcal{O}}^* [S]_{\mathcal{O}} = I_n$ for some, respectively every, orthonormal basis $\mathcal{O}$, which is the definition of a unitary matrix (Definition 6.3.33). Both are equivalent to (III). □

So for operators on finite-dimensional spaces "isometry", "unitary", and "unitary matrix in an orthonormal basis" mean the same thing, and we use them interchangeably. For a real matrix Q, the operator $\mathbf{x} \mapsto Q\mathbf{x}$ on $\mathbb{R}^n$ with the dot product is orthogonal exactly when Q is an orthogonal matrix.

BEYOND 21-242: Infinite-dimensional spaces are not covered in 21-242.

Example 8.4.12 (The shift). On $\mathbb{F}[x]$, define

$$\left\langle a_0 + a_1 x + \cdots + a_d x^d, b_0 + b_1 x + \cdots + b_d x^d \right\rangle = \sum_{k=0}^{d} a_k \overline{b_k},$$

padding the shorter polynomial with zero coefficients. This is the dot product of coefficient vectors, so it is an inner product, and $1, x, x^2, \ldots$ is an orthonormal list. Let $M \in \mathrm{L}(\mathbb{F}[x])$ be multiplication by x, which shifts the coefficients one step to the right. Then $\|xp\| = \|p\|$ for every p, so M is an isometry, but it is not surjective: every xp has constant term 0, so $1 \notin \operatorname{im} M$. So M is an isometry of an inner product space into itself that is not unitary, and (I) ⇒ (II) of Theorem 8.4.11 fails without finite dimension. Exercise 8.4.40 computes its adjoint, which is a left inverse but not a right inverse.

Isometries have two more invariants that we can read off right away.

Corollary 8.4.13 (Eigenvalues and determinant).

(a) If $S \in \mathrm{L}(V)$ is an isometry and λ is an eigenvalue of S, then $|\lambda| = 1$.

(b) If V is finite-dimensional and $S \in \mathrm{L}(V)$ is unitary, then $|\det S| = 1$. In particular $\det S = \pm 1$ when $\mathbb{F} = \mathbb{R}$.

Proof (by norms and by $\det(U^*) = \overline{\det U}$). ROUTINE

> *Uses.* Definition 7.2.6 (Eigenvalue, eigenvector), Definition 5.4.18 (Determinant of an operator), Theorem 8.4.11 (Characterizations of unitary operators), Theorem 5.4.14 (The transpose), Theorem 5.4.10 (Multiplicativity), Definition 5.3.6 (Determinant)
> *Hint 1.* For (a), take norms in $S\mathbf{v} = \lambda\mathbf{v}$.
> *Hint 2.* For (b), pass to the unitary matrix $U = [S]_{\mathcal{O}}$ and take the determinant of $U^*U = I_n$. You need $\det(U^*) = \overline{\det U}$.
> *Sketch.* (a) $\|\mathbf{v}\| = \|S\mathbf{v}\| = |\lambda|\|\mathbf{v}\|$ with $\mathbf{v} \neq \mathbf{0}$. (b) $\det S = \det U$ for the unitary matrix $U = [S]_{\mathcal{O}}$, and $1 = \det(U^*U) = \overline{\det U}\det U = |\det U|^2$, since conjugation commutes with the polynomial det and det is unchanged by transposing.

(a) Let $S\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. Then $\|\mathbf{v}\| = \|S\mathbf{v}\| = \|\lambda\mathbf{v}\| = |\lambda|\|\mathbf{v}\|$, and dividing by $\|\mathbf{v}\| \neq 0$ gives $|\lambda| = 1$.

(b) Let $\mathcal{O}$ be an orthonormal basis of V and $U = [S]_{\mathcal{O}}$, which is a unitary matrix by Theorem 8.4.11; $\det S = \det U$ by Definition 5.4.18. The determinant is a polynomial in the entries with integer coefficients (Definition 5.3.6), and complex conjugation respects sums and products, so $\det(\overline{U}) = \overline{\det U}$, where $\overline{U}$ conjugates every entry. With Theorem 5.4.14, $\det(U^*) = \det\left(\overline{U}^{\mathsf{T}}\right) = \det(\overline{U}) = \overline{\det U}$. Now by Theorem 5.4.10,

$$1 = \det I_n = \det(U^*U) = \det(U^*)\det U = \overline{\det U}\det U = |\det U|^2.$$

So $|\det S| = 1$. Over $\mathbb{R}$, $\det S$ is a real number of absolute value 1. □

Proof (through the eigenvalues, over $\mathbb{C}$). ROUTINE

> *Uses.* Theorem 7.5.22 (Trace and determinant from eigenvalues), Theorem 8.4.11 (Characterizations of unitary operators), Definition 5.4.18 (Determinant of an operator)
> *Hint 1.* Over $\mathbb{C}$, the determinant is the product of the eigenvalues counted with multiplicity.
> *Hint 2.* For a real orthogonal operator, regard its matrix as a complex unitary matrix.
> *Sketch.* For (b): $\det U = \lambda_1 \cdots \lambda_n$, and each $|\lambda_j| = 1$ by (a). A real orthogonal matrix is also a complex unitary matrix, with the same determinant.

Part (a) is as in the first proof. For (b), let $U = [S]_{\mathcal{O}}$ for an orthonormal basis $\mathcal{O}$. Over $\mathbb{R}$, U has real entries, and $U^*U = I_n$ also holds in $\mathbb{C}^{n\times n}$, so in either case we may regard U as a complex unitary matrix with the same determinant. By Theorem 7.5.22, $\det U = \lambda_1 \cdots \lambda_n$, where $\lambda_1, \ldots, \lambda_n$ are the complex eigenvalues of U counted with multiplicity. Each is an eigenvalue of the isometry $\mathbf{x} \mapsto U\mathbf{x}$ of $\mathbb{C}^n$, so $|\lambda_j| = 1$ by (a), and $|\det U| = \prod_j |\lambda_j| = 1$. □

For unitary operators, (a) is also Corollary 8.1.20(c), which was proved through normality. The norm argument here needs neither normality nor an adjoint, so it applies to every isometry, including the shift of Example 8.4.12 (which turns out to have no eigenvalues at all). Neither condition is sufficient for unitarity: the shear $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ has determinant 1 and the single eigenvalue 1, and it is not an isometry.

Invariant subspaces and the spectral form

For a normal operator, the orthogonal complement of an invariant subspace spanned by eigenvectors is invariant; this is what made the induction in the second proof of Theorem 8.2.5 work. For a unitary operator the same conclusion holds for every invariant subspace, with a proof that needs no eigenvectors. (By the spectral theorem it holds for normal operators on complex spaces too, but that is a consequence of the theorem, not a step towards it.)

> **Lemma 8.4.14** (Invariant complements). Let V be finite-dimensional, let $S \in \mathrm{L}(V)$ be unitary, and let U be an S-invariant subspace. Then $S(U) = U$, the complement $U^\perp$ is S-invariant, and $S|_U$ and $S|_{U^\perp}$ are unitary operators on U and on $U^\perp$.

Proof (directly). ROUTINE

> *Uses.* Corollary 4.2.18 (Injective if and only if surjective), Corollary 8.4.6 (Properties of isometries), Theorem 8.4.11 (Characterizations of unitary operators), Definition 4.2.1 (Restriction)
> *Hint 1.* $S|_U$ is an injective operator on the finite-dimensional space U. So every $\mathbf{u} \in U$ is $S\mathbf{u}'$ for some $\mathbf{u}' \in U$.
> *Hint 2.* For $\mathbf{w} \in U^\perp$, compute $\langle S\mathbf{w}, S\mathbf{u}'\rangle$.

Sketch. $S\restriction_U$ is injective, hence onto U. For $\mathbf{w} \in U^\perp$ and $\mathbf{u} = S\mathbf{u}' \in U$, $\langle S\mathbf{w}, \mathbf{u}\rangle = \langle S\mathbf{w}, S\mathbf{u}'\rangle = \langle \mathbf{w}, \mathbf{u}'\rangle = 0$. Both restrictions are isometries of finite-dimensional spaces into themselves, hence unitary.

Since S is injective, so is $S\restriction_U : U \to U$, and U is finite-dimensional, so $S\restriction_U$ is surjective (Corollary 4.2.18). That is, $S(U) = U$. Now let $\mathbf{w} \in U^\perp$ and $\mathbf{u} \in U$. Write $\mathbf{u} = S\mathbf{u}'$ with $\mathbf{u}' \in U$; since S preserves inner products (Corollary 8.4.6(a)),

$$\langle S\mathbf{w}, \mathbf{u}\rangle = \langle S\mathbf{w}, S\mathbf{u}'\rangle = \langle \mathbf{w}, \mathbf{u}'\rangle = 0.$$

So $S\mathbf{w} \in U^\perp$, and $U^\perp$ is S-invariant. The restrictions of S to U and to $U^\perp$ preserve norms, so they are isometries of finite-dimensional spaces into themselves, hence unitary by Theorem 8.4.11. □

Proof (through the adjoint). ROUTINE

Uses. Proposition 8.4.10 (Unitary means $S^* = S^{-1}$), Exercise 6.6.38, Corollary 4.2.18 (Injective if and only if surjective), Theorem 8.4.11 (Characterizations of unitary operators)
Techniques. Move an operator across the inner product (Technique 6.6.20)
Hint 1. T maps U into U if and only if T^* maps $U^\perp$ into $U^\perp$ (Exercise 6.6.38). Apply this with $T = S^*$.
Hint 2. Why does $S^* = S^{-1}$ map U into U?
Sketch. $S(U) = U$ as before, so $S^{-1}(U) = U$, that is, U is invariant under $S^* = S^{-1}$. By Exercise 6.6.38 applied to $T = S^*$, $U^\perp$ is invariant under $(S^*)^* = S$.

As in the first proof, $S(U) = U$, so S^{-1} maps U onto U. By Proposition 8.4.10, $S^* = S^{-1}$, so U is S^*-invariant. By Exercise 6.6.38 applied to $T = S^*$, whose adjoint is S, the complement $U^\perp$ is S-invariant. The restrictions are unitary as in the first proof. □

The first proof uses only that S preserves inner products and maps U onto itself. The second places the lemma in the pattern of Section 6.6: invariance passes from T on U to T^* on $U^\perp$, and for unitary S the adjoint is the inverse, which has the same invariant subspaces. The lemma fails for isometries that are not onto: the shift M of Example 8.4.12 maps $U = \operatorname{span}(x, x^2, \ldots)$ (the polynomials with constant term 0) into itself, but $U^\perp = \operatorname{span}(1)$ is not M-invariant.

Over $\mathbb{C}$ every operator has an eigenvector, so the lemma splits off one eigenline at a time. Alternatively, unitary operators are normal, and the complex spectral theorem applies. Either way:

Theorem 8.4.15 (Spectral form of unitary operators). Let V be a finite-dimensional complex inner product space and $S \in \mathrm{L}(V)$. The following are equivalent.

(I) S is unitary.

(II) S is normal and every eigenvalue of S has absolute value 1.

(III) V has an orthonormal basis consisting of eigenvectors of S, and every eigenvalue of S has absolute value 1.

In matrix form: $U \in \mathbb{C}^{n\times n}$ is unitary if and only if $U = WDW^*$ for some unitary W and some $D = \operatorname{diag}\left(e^{i\theta_1}, \ldots, e^{i\theta_n}\right)$ with $\theta_1, \ldots, \theta_n \in \mathbb{R}$.

Proof (from the complex spectral theorem). ROUTINE

Uses. Proposition 8.4.10 (Unitary means $S^* = S^{-1}$), Corollary 8.4.13 (Eigenvalues and determinant), Theorem 8.2.5 (Complex spectral theorem), Theorem 8.4.11 (Characterizations of unitary operators), Theorem 7.4.2 (Diagonalizable means an eigenbasis), Exercise 6.3.37, Example 6.3.35 (Unitary and orthogonal matrices)
Techniques. Proving TFAE (Technique 2.7.1)
Hint 1. Unitary operators satisfy $S^*S = SS^* = \mathrm{id}$, so they are normal. Which theorem gives orthonormal eigenbases of normal operators?
Hint 2. For (III) ⇒ (I), show that S maps the orthonormal eigenbasis to an orthonormal basis.
Sketch. (I) ⇒ (II): $S^*S = SS^* = \mathrm{id}$, and eigenvalues of isometries have absolute value 1. (II) ⇒ (III) is Theorem 8.2.5. (III) ⇒ (I): $\langle S\mathbf{e}_j, S\mathbf{e}_k\rangle = \lambda_j\overline{\lambda_k}\delta_{jk} = \delta_{jk}$, so S maps an orthonormal basis to one. For matrices, apply this to $\mathbf{x} \mapsto U\mathbf{x}$ and put the eigenbasis into the columns of W.

(I) ⇒ (II). By Proposition 8.4.10, $S^*S = \mathrm{id}_V = SS^*$, so S is normal, and its eigenvalues have absolute value 1 by Corollary 8.4.13(a).

(II) ⇒ (III). Theorem 8.2.5 gives an orthonormal eigenbasis, and the eigenvalues have absolute value 1 by hypothesis.

(III) ⇒ (I). Let $\mathbf{e}_1, \ldots, \mathbf{e}_n$ be an orthonormal basis with $S\mathbf{e}_j = \lambda_j \mathbf{e}_j$ and $|\lambda_j| = 1$. Then

$$\langle S\mathbf{e}_j, S\mathbf{e}_k \rangle = \lambda_j \overline{\lambda_k} \langle \mathbf{e}_j, \mathbf{e}_k \rangle = \lambda_j \overline{\lambda_k} \delta_{jk} = |\lambda_j|^2 \delta_{jk} = \delta_{jk},$$

so S maps an orthonormal basis to an orthonormal basis, and S is unitary by (VI) ⇒ (II) of Theorem 8.4.11.

Matrices. If U is unitary, apply (I) ⇒ (III) to $\mathbf{x} \mapsto U\mathbf{x}$ on $\mathbb{C}^n$ with the dot product. Let W have the orthonormal eigenvectors as columns; it is unitary, and by Theorem 7.4.2, $U = WDW^{-1} = WDW^*$ with D diagonal, whose entries have absolute value 1, so they are $e^{i\theta_j}$ for some real θ_j. Conversely, D is unitary (Example 6.3.35(c)), and products of unitary matrices are unitary (Exercise 6.3.37), so WDW^* is unitary. □

Proof ((I) ⇒ (III) by induction, without the spectral theorem). STANDARD

> *Uses.* Theorem 7.3.27 (Existence of eigenvalues over $\mathbb{C}$), Corollary 8.4.13 (Eigenvalues and determinant), Lemma 8.4.14 (Invariant complements), Corollary 6.4.25 (Dimension of the orthogonal complement), Theorem 6.4.24 (Orthogonal decomposition)
> *Techniques.* Induction on dimension via an invariant subspace (Technique 7.5.12)
> *Hint 1.* Over $\mathbb{C}$, S has an eigenvector. Normalize it.
> *Hint 2.* The eigenline is S-invariant. Apply Lemma 8.4.14 and induct on $\dim V$.
> *Sketch.* Take a unit eigenvector $\mathbf{e}$; $\mathrm{span}(\mathbf{e})$ is invariant, so its complement is invariant and S restricted to it is unitary (Lemma 8.4.14). By induction the complement has an orthonormal eigenbasis; add $\mathbf{e}$. Eigenvalues have absolute value 1 by Corollary 8.4.13(a).

We prove (I) ⇒ (III) by induction on $n = \dim V$; the other implications are as in the first proof. Every eigenvalue has absolute value 1 by Corollary 8.4.13(a), so we only need the orthonormal eigenbasis. If $n = 0$ the empty list works. Let $n \geq 1$. By Theorem 7.3.27, S has an eigenvector, and we scale it to a unit vector $\mathbf{e}$. The line $L = \mathrm{span}(\mathbf{e})$ is S-invariant, so by Lemma 8.4.14 $L^\perp$ is S-invariant and $S{\restriction}_{L^\perp}$ is unitary. Since $\dim L^\perp = n - 1$ (Corollary 6.4.25), the induction hypothesis gives an orthonormal basis $\mathbf{e}_2, \ldots, \mathbf{e}_n$ of $L^\perp$ consisting of eigenvectors of $S{\restriction}_{L^\perp}$, hence of S. Since $V = L \oplus L^\perp$ (Theorem 6.4.24), the list $\mathbf{e}, \mathbf{e}_2, \ldots, \mathbf{e}_n$ is an orthonormal basis of V consisting of eigenvectors of S. □

The first proof inherits everything from normal operators. The second shows why the unitary case is easier to prove than the normal one: the invariance of the complement comes from Lemma 8.4.14, which needs neither eigenvectors nor adjoint identities. Over $\mathbb{R}$ the second proof breaks at the first step, because a rotation of $\mathbb{R}^2$ has no eigenvector. Repairing it with two-dimensional invariant subspaces gives the normal form of Section 8.4.4.

Example 8.4.16 (Two unitary diagonalizations).

(a) The rotation $R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$ with $\theta \notin \pi\mathbb{Z}$ has no real eigenvalue, but as a complex matrix

$$R_\theta \begin{pmatrix} 1 \\ -i \end{pmatrix} = \begin{pmatrix} \cos\theta + i\sin\theta \\ \sin\theta - i\cos\theta \end{pmatrix} = e^{i\theta}\begin{pmatrix} 1 \\ -i \end{pmatrix}, \quad R_\theta \begin{pmatrix} 1 \\ i \end{pmatrix} = e^{-i\theta}\begin{pmatrix} 1 \\ i \end{pmatrix}.$$

With $W = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}$, which is unitary, $R_\theta = W \operatorname{diag}\left(e^{i\theta}, e^{-i\theta}\right) W^*$. The same W works for every θ, which reflects the fact that rotations of the plane commute with each other.

(b) Let $C \in \mathbb{R}^{n\times n}$ be the cyclic shift, $C\mathbf{e}_k = \mathbf{e}_{k+1}$, with indices $0, \ldots, n-1$ read modulo n as in Definition 6.3.40. It is a permutation matrix, hence orthogonal, and $(C\mathbf{x})_j = x_{j-1}$. For the Fourier vector $\mathbf{f}_k = \left(\omega^{jk}\right)_{j=0}^{n-1}$,

$$(C\mathbf{f}_k)_j = \omega^{(j-1)k} = \omega^{-k}(\mathbf{f}_k)_j,$$

so $C\mathbf{f}_k = \omega^{-k}\mathbf{f}_k$. Since $\Phi_n/\sqrt{n}$ is unitary (Proposition 6.3.41), $C = WDW^*$ with $W = \Phi_n/\sqrt{n}$ and $D = \operatorname{diag}\left(1, \omega^{-1}, \ldots, \omega^{-(n-1)}\right)$. The eigenvalues of C are all the nth roots of unity. For $n = 3$, C is the rotation of $\mathbb{R}^3$ by $2\pi/3$ about the line through $(1,1,1)$ (Example 8.4.28).

Exercise 8.4.17. ROUTINE Find the matrix $U \in \mathbb{C}^{2\times 2}$ with $U\begin{pmatrix} 1 \\ 1 \end{pmatrix} = i\begin{pmatrix} 1 \\ 1 \end{pmatrix}$ and $U\begin{pmatrix} 1 \\ -1 \end{pmatrix} = -\begin{pmatrix} 1 \\ -1 \end{pmatrix}$. Show that U is unitary, and compute U^4 and U^*.

Solution on page 1662

Remark 8.4.18 (The unitary group). The identity is unitary, and composites and inverses of unitary operators are unitary, by Corollary 8.4.6(b) and Proposition 8.4.10. So the unitary operators on V form a group under composition. For matrices, the **unitary group** $\mathrm{U}(n)$ consists of the unitary $n \times n$ matrices, the **orthogonal group** $\mathrm{O}(n)$ of the real orthogonal ones, and the **special orthogonal group** $\mathrm{SO}(n)$ of the orthogonal matrices with determinant 1; $\mathrm{U}(1)$ is the unit circle in $\mathbb{C}$. Groups of matrices are the subject of Section 14.1. Under the analogy of Table 8.1.1, $\mathrm{U}(1)$ is the set of z with $\bar{z}z = 1$, and just as every complex number is $z = e^{i\theta}|z|$, every operator on a finite-dimensional space is a unitary operator times a positive one (Definition 8.3.1), the **polar decomposition** of Section 9.2.

Unitary operators can move any orthonormal list to any other of the same length. This is the precise form of the statement that an inner product space "looks the same" in all directions.

Proposition 8.4.19 (Moving orthonormal lists). Let V be finite-dimensional.

(a) If $\mathbf{e}_1, \ldots, \mathbf{e}_k$ and $\mathbf{f}_1, \ldots, \mathbf{f}_k$ are orthonormal lists in V, there is a unitary $S \in \mathrm{L}(V)$ with $S\mathbf{e}_j = \mathbf{f}_j$ for $j = 1, \ldots, k$.

(b) If U is a subspace of V and $S_0 \in \mathrm{L}(U, V)$ is an isometry, there is a unitary $S \in \mathrm{L}(V)$ with $S|_U = S_0$.

Proof. ROUTINE

Uses. Theorem 6.4.20 (Orthonormal bases exist), Theorem 2.2.1 (Linear maps are determined by a basis), Theorem 8.4.11 (Characterizations of unitary operators), Theorem 8.4.4 (Characterizations of isometries)
Techniques. Construct a map by choosing it on a basis (Technique 2.2.4), Extend a basis of a subspace (Technique 4.1.18)
Hint 1. Extend both lists to orthonormal bases of V. How long are the extensions?
Hint 2. Define S on the first basis. For (b), apply (a) to an orthonormal basis of U and its image.
Sketch. Both lists extend to orthonormal bases of length $n = \dim V$; the linear map sending the first basis to the second, term by term, maps an orthonormal basis to one and is unitary. For (b), S_0 maps an orthonormal basis of U to an orthonormal list; extend as in (a), and two linear maps agreeing on a basis of U agree on U.

(a) By Theorem 6.4.20(b), the lists extend to orthonormal bases $\mathbf{e}_1, \ldots, \mathbf{e}_n$ and $\mathbf{f}_1, \ldots, \mathbf{f}_n$ of V, both of length $n = \dim V$. By Theorem 2.2.1 there is $S \in \mathrm{L}(V)$ with $S\mathbf{e}_j = \mathbf{f}_j$ for all $j \le n$. It maps an orthonormal basis to an orthonormal basis, so it is unitary by Theorem 8.4.11.

(b) Let $\mathbf{e}_1, \dots, \mathbf{e}_k$ be an orthonormal basis of U. By (IV) of Theorem 8.4.4, $S_0\mathbf{e}_1, \dots, S_0\mathbf{e}_k$ is orthonormal in V, so (a) gives a unitary S with $S\mathbf{e}_j = S_0\mathbf{e}_j$ for all j. The linear maps $S|_U$ and S_0 agree on a basis of U, so they are equal by the uniqueness in Theorem 2.2.1. □

In particular, any unit vector can be moved to any other by a unitary operator. When a problem is unchanged by unitary operators (it involves only lengths and inner products), we may therefore assume that a given unit vector is $\mathbf{e}_1$. Section 8.4.3 writes down an explicit operator that does this.

8.4.3 Householder reflections

The simplest unitary operators other than scalars are reflections across hyperplanes.

Example 8.4.20 (Householder reflections). Let $\mathbf{u} \in \mathbb{F}^n$ be a unit vector, and let

$$H_{\mathbf{u}} = I_n - 2\mathbf{u}\mathbf{u}^*.$$

Then $H_{\mathbf{u}}\mathbf{x} = \mathbf{x} - 2(\mathbf{u}^*\mathbf{x})\mathbf{u} = \mathbf{x} - 2(\mathbf{x}\cdot\mathbf{u})\mathbf{u}$. So $H_{\mathbf{u}}\mathbf{u} = \mathbf{u} - 2\mathbf{u} = -\mathbf{u}$, and $H_{\mathbf{u}}\mathbf{x} = \mathbf{x}$ for every $\mathbf{x} \perp \mathbf{u}$. In words, $H_{\mathbf{u}}$ fixes the hyperplane $\mathbf{u}^\perp$ and reverses the normal direction: it is the reflection across $\mathbf{u}^\perp$. By Theorem 6.4.31, $P = \mathbf{u}\mathbf{u}^*$ is the orthogonal projection onto $\operatorname{span}(\mathbf{u})$, and

$$H_{\mathbf{u}} = (I_n - P) - P,$$

which keeps the component of $\mathbf{x}$ in $\mathbf{u}^\perp$ and negates the component along $\mathbf{u}$. This is the operator $-(2P - I_n)$ of Exercise 8.1.30, so $H_{\mathbf{u}}$ is Hermitian and unitary, and $H_{\mathbf{u}}^2 = I_n$. Directly: $H_{\mathbf{u}}^* = I_n - 2(\mathbf{u}\mathbf{u}^*)^* = H_{\mathbf{u}}$, and

$$H_{\mathbf{u}}^2 = I_n - 4\mathbf{u}\mathbf{u}^* + 4\mathbf{u}(\mathbf{u}^*\mathbf{u})\mathbf{u}^* = I_n.$$

Extending $\mathbf{u}$ to an orthonormal basis $\mathbf{u}, \mathbf{u}_2, \dots, \mathbf{u}_n$ of eigenvectors, with eigenvalues $-1, 1, \dots, 1$, gives $\det H_{\mathbf{u}} = -1$ (Theorem 7.5.22).

For instance, for $\mathbf{u} = \frac{1}{\sqrt{3}}(1,-1,-1)$,

$$H_{\mathbf{u}} = I_3 - \frac{2}{3}\begin{pmatrix} 1 & -1 & -1 \\ -1 & 1 & 1 \\ -1 & 1 & 1 \end{pmatrix} = \frac{1}{3}\begin{pmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ 2 & -2 & 1 \end{pmatrix},$$

the orthogonal matrix of Example 6.3.35(d). So that matrix is a reflection, across the plane $x_1 - x_2 - x_3 = 0$.

The point of Householder reflections is that they can move a given vector to any other vector of the same length.

> **Proposition 8.4.21** (A reflection exchanging two vectors). Let $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$ with $\mathbf{x} \neq \mathbf{y}$, $\|\mathbf{x}\| = \|\mathbf{y}\|$, and $\mathbf{x}\cdot\mathbf{y} \in \mathbb{R}$. Let $\mathbf{u} = (\mathbf{x}-\mathbf{y})/\|\mathbf{x}-\mathbf{y}\|$. Then
>
> $$H_{\mathbf{u}}\mathbf{x} = \mathbf{y} \quad \text{and} \quad H_{\mathbf{u}}\mathbf{y} = \mathbf{x}.$$

Proof (by computation). ROUTINE

> *Uses.* Example 8.4.20 (Householder reflections), Proposition 6.1.29 (Expanding a norm), Proposition 6.1.4 (Sesquilinearity)
> *Hint 1.* $H_{\mathbf{u}}\mathbf{x} = \mathbf{x} - 2(\mathbf{x}\cdot\mathbf{u})\mathbf{u}$. Write everything in terms of $\mathbf{d} = \mathbf{x} - \mathbf{y}$.
> *Hint 2.* You need $2(\mathbf{x}\cdot\mathbf{d}) = \|\mathbf{d}\|^2$. Expand both sides using $\|\mathbf{x}\| = \|\mathbf{y}\|$ and $\mathbf{x}\cdot\mathbf{y} = \mathbf{y}\cdot\mathbf{x}$.
> *Sketch.* With $\mathbf{d} = \mathbf{x} - \mathbf{y}$: $H_{\mathbf{u}}\mathbf{x} = \mathbf{x} - \big(2(\mathbf{x}\cdot\mathbf{d})/\|\mathbf{d}\|^2\big)\mathbf{d}$. Both $2(\mathbf{x}\cdot\mathbf{d})$ and $\|\mathbf{d}\|^2$ equal $2\|\mathbf{x}\|^2 - 2(\mathbf{x}\cdot\mathbf{y})$, so the coefficient is 1 and $H_{\mathbf{u}}\mathbf{x} = \mathbf{y}$. Then $H_{\mathbf{u}}\mathbf{y} = H_{\mathbf{u}}^2\mathbf{x} = \mathbf{x}$.

Let $\mathbf{d} = \mathbf{x} - \mathbf{y} \neq \mathbf{0}$, so $\mathbf{u} = \mathbf{d}/\|\mathbf{d}\|$ and

$$H_{\mathbf{u}}\mathbf{x} = \mathbf{x} - 2(\mathbf{x}\cdot\mathbf{u})\mathbf{u} = \mathbf{x} - \frac{2(\mathbf{x}\cdot\mathbf{d})}{\|\mathbf{d}\|^2}\mathbf{d}.$$

Since $\mathbf{x}\cdot\mathbf{y}$ is real, $\mathbf{y}\cdot\mathbf{x} = \overline{\mathbf{x}\cdot\mathbf{y}} = \mathbf{x}\cdot\mathbf{y}$. Using $\|\mathbf{y}\| = \|\mathbf{x}\|$,

$$\mathbf{x}\cdot\mathbf{d} = \|\mathbf{x}\|^2 - \mathbf{x}\cdot\mathbf{y},$$
$$\|\mathbf{d}\|^2 = \|\mathbf{x}\|^2 - \mathbf{x}\cdot\mathbf{y} - \mathbf{y}\cdot\mathbf{x} + \|\mathbf{y}\|^2 = 2\Big(\|\mathbf{x}\|^2 - \mathbf{x}\cdot\mathbf{y}\Big).$$

So $2(\mathbf{x}\cdot\mathbf{d}) = \|\mathbf{d}\|^2$, and $H_{\mathbf{u}}\mathbf{x} = \mathbf{x} - \mathbf{d} = \mathbf{y}$. Since $H_{\mathbf{u}}^2 = I_n$ (Example 8.4.20), $H_{\mathbf{u}}\mathbf{y} = H_{\mathbf{u}}^2\mathbf{x} = \mathbf{x}$. □

Proof (by decomposing along the mirror). ROUTINE

> *Uses.* Example 8.4.20 (Householder reflections), Proposition 6.1.4 (Sesquilinearity)
> *Techniques.* Orthogonal decomposition (Technique 6.2.4)
> *Hint 1.* Write $\mathbf{x} = \frac{1}{2}(\mathbf{x}+\mathbf{y}) + \frac{1}{2}(\mathbf{x}-\mathbf{y})$. Where does each piece lie relative to the mirror $\mathbf{u}^\perp$?
> *Hint 2.* Show that $\mathbf{x}+\mathbf{y} \perp \mathbf{x}-\mathbf{y}$; this is where both hypotheses are used.
> *Sketch.* $(\mathbf{x}+\mathbf{y})\cdot(\mathbf{x}-\mathbf{y}) = \|\mathbf{x}\|^2 - \|\mathbf{y}\|^2 + (\mathbf{y}\cdot\mathbf{x} - \mathbf{x}\cdot\mathbf{y}) = 0$, so $\mathbf{x}+\mathbf{y}$ lies in the mirror and is fixed, while $\mathbf{x}-\mathbf{y}$ is a multiple of $\mathbf{u}$ and is negated. Hence $H_{\mathbf{u}}\mathbf{x} = \frac{1}{2}(\mathbf{x}+\mathbf{y}) - \frac{1}{2}(\mathbf{x}-\mathbf{y}) = \mathbf{y}$.

First,

$$(\mathbf{x}+\mathbf{y})\cdot(\mathbf{x}-\mathbf{y}) = \|\mathbf{x}\|^2 - \mathbf{x}\cdot\mathbf{y} + \mathbf{y}\cdot\mathbf{x} - \|\mathbf{y}\|^2 = 0,$$

since $\|\mathbf{x}\| = \|\mathbf{y}\|$ and $\mathbf{y}\cdot\mathbf{x} = \overline{\mathbf{x}\cdot\mathbf{y}} = \mathbf{x}\cdot\mathbf{y}$. So $\mathbf{x}+\mathbf{y} \in \mathbf{u}^\perp$, and $H_{\mathbf{u}}$ fixes it, while $\mathbf{x}-\mathbf{y} = \|\mathbf{x}-\mathbf{y}\|\mathbf{u}$ is negated (Example 8.4.20). Hence

$$H_{\mathbf{u}}\mathbf{x} = H_{\mathbf{u}}\left(\frac{1}{2}(\mathbf{x}+\mathbf{y}) + \frac{1}{2}(\mathbf{x}-\mathbf{y})\right) = \frac{1}{2}(\mathbf{x}+\mathbf{y}) - \frac{1}{2}(\mathbf{x}-\mathbf{y}) = \mathbf{y},$$

and in the same way $H_{\mathbf{u}}\mathbf{y} = \frac{1}{2}(\mathbf{x}+\mathbf{y}) + \frac{1}{2}(\mathbf{x}-\mathbf{y}) = \mathbf{x}$. □

The second proof is the picture in Figure 8.4.1: the mirror is the perpendicular bisector of the segment from $\mathbf{x}$ to $\mathbf{y}$, which passes through $\mathbf{0}$ because $\mathbf{x}$ and $\mathbf{y}$ are equally long. The condition $\mathbf{x}\cdot\mathbf{y} \in \mathbb{R}$ cannot be dropped over $\mathbb{C}$: since $H_{\mathbf{u}}$ is Hermitian, $(H_{\mathbf{u}}\mathbf{x})\cdot\mathbf{x}$ is always real (Proposition 6.6.30), so no Householder reflection maps $\mathbf{x}$ to a $\mathbf{y}$ with $\mathbf{y}\cdot\mathbf{x} \notin \mathbb{R}$. Multiplying $\mathbf{y}$ by a suitable scalar of absolute value 1 first repairs this (??).

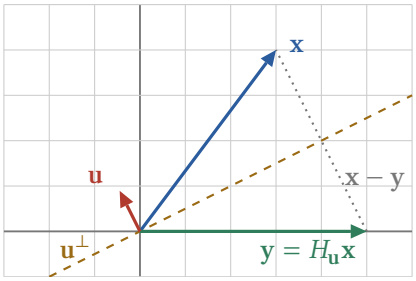


Figure 8.4.1. The Householder reflection with $\mathbf{x} = (3,4)$ and $\mathbf{y} = (5,0)$, both of length 5. The unit normal is $\mathbf{u} = (\mathbf{x}-\mathbf{y})/\|\mathbf{x}-\mathbf{y}\| = \frac{1}{\sqrt{5}}(-1,2)$, and the mirror $\mathbf{u}^\perp$ (dashed) is the line through $\mathbf{0}$ and $\mathbf{x}+\mathbf{y} = (8,4)$, the perpendicular bisector of the dotted segment.

Take $\mathbf{y} = -c\|\mathbf{x}\|\mathbf{e}_1$, where $c = x_1/|x_1|$ (and $c = 1$ if $x_1 = 0$). Then $\mathbf{x}\cdot\mathbf{y} = -\bar{c}x_1\|\mathbf{x}\| = -|x_1|\|\mathbf{x}\|$ is real, so unless $\mathbf{x} = \mathbf{y}$ already, one reflection turns $\mathbf{x}$ into $\mathbf{y}$, whose entries after the first are 0. Applied to the first column of a matrix $A \in \mathbb{F}^{m\times n}$, and then to the first column of the lower right block, and so on (skipping a step when the column is already in the required form), this produces a unitary $Q \in \mathbb{F}^{m\times m}$, a product of reflections, with $R_0 = Q^*A$ upper triangular. This is a full QR factorization $A = QR_0$; when the columns of A are independent, keeping the first n columns of Q and the top $n\times n$ block of R_0, and rescaling by scalars of absolute value 1 to make the diagonal positive, gives the factorization of Theorem 6.4.38. This is how QR factorizations are computed in practice; ?? carries it out for a 3×2 matrix.

Exercise 8.4.22. ROUTINE Find a Householder reflection H with $H(2,1,2) = (3,0,0)$, and one with $H(2,1,2) = (-3,0,0)$. Check that the first is symmetric and orthogonal.

Solution on page 1662

8.4.4 Real orthogonal operators BEYOND 21-242

The normal form of real orthogonal operators, orientation, and rigid motions are not covered in lecture; see LADW Chapters 5 and 6 and LADR 7D.

Over $\mathbb{R}$ an orthogonal operator need not have an eigenvector: a rotation of the plane has none. So the spectral form of Theorem 8.4.15 has no direct real analogue. Instead, we will show that every orthogonal operator is assembled from rotations of perpendicular planes and from ± 1 on perpendicular lines. We first list the orthogonal operators of the plane.

Lemma 8.4.23 (Orthogonal 2×2 matrices). Let $Q \in \mathbb{R}^{2\times 2}$ be orthogonal. Then there is exactly one $\theta \in [0, 2\pi)$ such that Q is one of

$$R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \quad \text{or} \quad S_\theta = \begin{pmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{pmatrix},$$

and $\det R_\theta = 1$, $\det S_\theta = -1$. The matrix S_θ is the reflection across the line spanned by $\mathbf{c} = (\cos(\theta/2), \sin(\theta/2))$: it fixes $\mathbf{c}$ and negates $\mathbf{c}' = (-\sin(\theta/2), \cos(\theta/2))$, so it has the eigenvalues 1 and -1.

Proof. ROUTINE

Uses. Definition 6.3.33 (Unitary and orthogonal matrices), Corollary 6.3.14 (Counting orthogonal vectors), Proposition 6.3.18 (Coordinates in an orthonormal basis), Definition 5.1.14 (The 2×2 determinant)
Techniques. Take an inner product to isolate a coefficient (Technique 6.3.12)
Hint 1. The first column is a unit vector, so it is $(\cos\theta, \sin\theta)$ for exactly one $\theta \in [0, 2\pi)$.
Hint 2. The second column is a unit vector orthogonal to the first. Expand it in the orthonormal basis $(\cos\theta, \sin\theta), (-\sin\theta, \cos\theta)$.
Sketch. The first column is $(\cos\theta, \sin\theta)$. The second column is orthogonal to it, so its coordinates in the orthonormal basis $(\cos\theta, \sin\theta), (-\sin\theta, \cos\theta)$ are $(0, t)$, and being a unit vector forces $t = \pm 1$. The sign is the determinant. For S_θ, the angle-subtraction formulas give $S_\theta \mathbf{c} = \mathbf{c}$ and $S_\theta \mathbf{c}' = -\mathbf{c}'$.

The columns (a, b) and (c, d) of Q are orthonormal (Definition 6.3.33). Since $a^2 + b^2 = 1$, there is exactly one $\theta \in [0, 2\pi)$ with $(a, b) = (\cos\theta, \sin\theta)$. The vectors $(\cos\theta, \sin\theta)$ and $(-\sin\theta, \cos\theta)$ are orthonormal, hence an orthonormal basis of $\mathbb{R}^2$ (Corollary 6.3.14), so by Proposition 6.3.18

$$(c, d) = (c\cos\theta + d\sin\theta)(\cos\theta, \sin\theta) + t(-\sin\theta, \cos\theta), \quad t = -c\sin\theta + d\cos\theta.$$

The first coefficient is $(c, d) \cdot (a, b) = 0$, and $1 = \|(c, d)\| = |t|$, so $t = \pm 1$. For $t = 1$ we get $Q = R_\theta$ and for $t = -1$ we get $Q = S_\theta$; the determinants are $\cos^2\theta + \sin^2\theta = 1$ and $-\cos^2\theta - \sin^2\theta = -1$. Since θ is determined by the first column and the sign by the determinant, the description is unique.

Write $\varphi = \theta/2$. By the angle-subtraction formulas,

$$S_\theta \mathbf{c} = (\cos\theta\cos\varphi + \sin\theta\sin\varphi, \sin\theta\cos\varphi - \cos\theta\sin\varphi) = (\cos\varphi, \sin\varphi) = \mathbf{c},$$
$$S_\theta \mathbf{c}' = (-\cos\theta\sin\varphi + \sin\theta\cos\varphi, -\sin\theta\sin\varphi - \cos\theta\cos\varphi) = (\sin\varphi, -\cos\varphi) = -\mathbf{c}'. \qquad \square$$

So an orthogonal operator of the plane is a rotation if its determinant is 1 and a reflection across a line if it is -1. Rotations by 0 and π are $\pm I_2$, the only orthogonal 2×2 matrices that are scalars. In higher dimensions we need one more lemma, the block version of "a triangular unitary matrix is diagonal" (Exercise 6.3.57(c)).

Lemma 8.4.24 (Block-triangular unitary matrices). Let $R \in \mathbb{F}^{n\times n}$ be unitary and block upper triangular, with square diagonal blocks $B_1, \dots, B_m$. Then all blocks above the diagonal are 0, and each B_i is unitary.

Proof. STANDARD

Uses. Proposition 6.3.34 (Characterizations of unitary matrices), Definition 6.3.33 (Unitary and orthogonal matrices), Definition 2.4.33 (Block matrix)
Techniques. A sum of nonnegative terms (Technique 6.1.9), Induction on matrix size (Technique 5.5.17)
Hint 1. Count the sum of $|r_{ij}|^2$ over the first block of columns, and then over the first block of rows.
Hint 2. Both the columns and the rows of a unitary matrix are orthonormal (Proposition 6.3.34). The first k columns are zero outside B_1.
Sketch. Let B_1 be $k \times k$. The first k columns are orthonormal and vanish below B_1, so the squared entries of B_1 add up to k. The first k rows are orthonormal, so the squared entries in those rows also add up to k. Hence every entry to the right of B_1 is 0. Then $R = \left(\begin{smallmatrix} B_1 & 0 \\ 0 & R' \end{smallmatrix}\right)$ with B_1 and R' unitary, and induction on m finishes.

We induct on m. If $m = 1$, then $R = B_1$. Let $m \geq 2$, let B_1 be $k \times k$, and write

$$R = \begin{pmatrix} B_1 & X \\ 0 & R' \end{pmatrix}$$

with $X \in \mathbb{F}^{k\times(n-k)}$ and R' block upper triangular with diagonal blocks $B_2, \dots, B_m$. The first k columns of R are orthonormal and have zero entries below B_1, so adding their squared lengths gives $\sum |b|^2 = k$, the sum over all entries b of B_1. By Proposition 6.3.34, the first k rows of R are orthonormal too, so the sum of $|r|^2$ over all entries r of these rows is also k. These rows consist of the entries of B_1 and of X, so

$$k = \sum_{b \text{ in } B_1} |b|^2 + \sum_{x \text{ in } X} |x|^2 = k + \sum_{x \text{ in } X} |x|^2.$$

A sum of nonnegative terms vanishes only if each term does, so $X = 0$. Now $R = \left(\begin{smallmatrix} B_1 & 0 \\ 0 & R' \end{smallmatrix}\right)$ and

$$I_n = R^* R = \begin{pmatrix} B_1^* B_1 & 0 \\ 0 & R'^* R' \end{pmatrix},$$

so B_1 and R' are unitary. By the induction hypothesis applied to R', its blocks above the diagonal vanish and $B_2, \dots, B_m$ are unitary. □

Theorem 8.4.25 (Normal form of orthogonal operators). Let V be a real inner product space with $1 \leq \dim V < \infty$, and let $S \in \mathrm{L}(V)$ be orthogonal. Then V has an orthonormal basis $\mathcal{O}$ in which $[S]_{\mathcal{O}}$ is block diagonal with diagonal blocks

$$R_{\theta_1}, \dots, R_{\theta_k}, I_p, -I_q,$$

where $k, p, q \geq 0$, $2k + p + q = \dim V$, and $0 < \theta_1 \leq \cdots \leq \theta_k < \pi$. Equivalently, every $Q \in \mathrm{O}(n)$ can be written as $Q = PBP^{\mathsf{T}}$ with P orthogonal and B block diagonal of this form.

Intuition. Read geometrically, the theorem says that V splits into perpendicular planes, each rotated by its own angle, and perpendicular lines, each fixed or reversed. Over $\mathbb{C}$ we could diagonalize; over $\mathbb{R}$ the planes are what is left of pairs of conjugate eigenvalues $e^{\pm i\theta_j}$. The two proofs below are the two routes to real block forms we have seen: triangularize first and then use orthogonality to clear the upper part, or split off one small invariant subspace at a time.

Proof (from the real Schur form). HARD

Uses. Theorem 7.5.27 (Real block upper-triangular form), Theorem 8.4.11 (Characterizations of unitary operators), Lemma 8.4.24 (Block-triangular unitary matrices), Lemma 8.4.23 (Orthogonal 2×2 matrices), Theorem 4.5.17 (Change of basis)

Techniques. Prove it for triangular matrices first (Technique 7.5.23)
Hint 1. Theorem 7.5.27(b) gives an orthonormal basis in which $[S]_{\mathcal{O}}$ is block upper triangular with blocks of size 1 and 2. What does orthogonality of this matrix force?
Hint 2. By Lemma 8.4.24 the matrix is block diagonal with orthogonal blocks. Identify the 1×1 and 2×2 orthogonal blocks; recall that the 2×2 blocks have no real eigenvalue.
Hint 3. To move $\theta\in(\pi,2\pi)$ into $(0,\pi)$, replace one vector of the pair by its negative.
Sketch. The real Schur form gives an orthonormal $\mathcal{O}$ with $R=[S]_{\mathcal{O}}$ block upper triangular, diagonal blocks of size 1 or 2, the latter without real eigenvalues. R is orthogonal, so it is block diagonal with orthogonal blocks. A 1×1 block is ± 1; a 2×2 block without real eigenvalues is a rotation R_θ with $\theta\notin\{0,\pi\}$, since reflections have eigenvalues ± 1. Flipping one basis vector replaces R_θ by $R_{-\theta}$, and reordering the basis puts the blocks in order.

By Theorem 7.5.27(b), V has an orthonormal basis $\mathcal{O}$ such that $R=[S]_{\mathcal{O}}$ is block upper triangular with diagonal blocks of size 1×1 or 2×2, where no 2×2 diagonal block has a real eigenvalue. By Theorem 8.4.11, R is orthogonal, so by Lemma 8.4.24 it is block diagonal and each diagonal block is orthogonal.

A 1×1 orthogonal matrix (a) has $a^2=1$, so it is (1) or (-1). A 2×2 diagonal block B is orthogonal without real eigenvalues. By Lemma 8.4.23, it is R_θ or S_θ for some $\theta\in[0,2\pi)$; the reflection S_θ has the eigenvalue 1, and $R_0=I_2$, $R_\pi=-I_2$ have real eigenvalues, so $B=R_\theta$ with $\theta\in(0,\pi)\cup(\pi,2\pi)$. If $\theta\in(\pi,2\pi)$, let $\mathbf{a},\mathbf{b}$ be the two vectors of $\mathcal{O}$ belonging to this block, and replace $\mathbf{b}$ by $-\mathbf{b}$. The new list is still orthonormal, and by Theorem 4.5.17 the block becomes

$$\begin{pmatrix}1&0\\0&-1\end{pmatrix}R_\theta\begin{pmatrix}1&0\\0&-1\end{pmatrix}=\begin{pmatrix}\cos\theta&\sin\theta\\-\sin\theta&\cos\theta\end{pmatrix}=R_{2\pi-\theta},$$

with $2\pi-\theta\in(0,\pi)$. Finally, reordering $\mathcal{O}$ (keeping the two vectors of each rotation block together) permutes the diagonal blocks, so we can list the rotation blocks first, in increasing order of angle, then the blocks (1), then the blocks (-1).

For the matrix form, apply this to $\mathbf{x}\mapsto Q\mathbf{x}$ on $\mathbb{R}^n$ with the dot product, and let P have the vectors of $\mathcal{O}$ as columns. Then P is orthogonal and $Q=PBP^{-1}=PBP^{\mathsf{T}}$ with $B=[S]_{\mathcal{O}}$. □

Proof (by induction on dimension). HARD

Uses. Theorem 7.3.31 (Small invariant subspaces), Lemma 8.4.14 (Invariant complements), Lemma 8.4.23 (Orthogonal 2×2 matrices), Corollary 8.4.13 (Eigenvalues and determinant), Theorem 6.4.24 (Orthogonal decomposition), Remark 7.2.5 (Invariant subspaces and block matrices)
Techniques. Induction on dimension via an invariant subspace (Technique 7.5.12)
Hint 1. Theorem 7.3.31 gives an S-invariant subspace U of dimension 1 or 2. What does Lemma 8.4.14 say about $U^\perp$?
Hint 2. On U, S is orthogonal of dimension 1 or 2. Use Lemma 8.4.23, and note that a reflection of a plane splits it into two eigenlines.
Sketch. Pick an invariant U with $\dim U\in\{1,2\}$. Then $U^\perp$ is invariant and both restrictions are orthogonal. On a line, $S=\pm\,\mathrm{id}$. On a plane, S is a rotation R_θ in an orthonormal basis (normalize θ as in the first proof; $\theta\in\{0,\pi\}$ gives $\pm I_2$) or a reflection, which is $\mathrm{diag}(1,-1)$ in the basis of its eigenvectors. Apply induction to $U^\perp$, concatenate, and reorder.

We induct on $n=\dim V$, proving the statement without the ordering of the blocks; reordering the basis as in the first proof then arranges them. By Theorem 7.3.31, S has an invariant subspace U with $\dim U\in\{1,2\}$. By Lemma 8.4.14, $U^\perp$ is S-invariant and $S{\restriction}_U$, $S{\restriction}_{U^\perp}$ are orthogonal.

The piece U. If $\dim U=1$, then U is spanned by an eigenvector, whose eigenvalue is real of absolute value 1 (Corollary 8.4.13(a)), so $S{\restriction}_U=\pm\mathrm{id}_U$, a block (1) or (-1) in a unit basis vector of U. If $\dim U=2$, let $\mathbf{a},\mathbf{b}$ be an orthonormal basis of U; the matrix of $S{\restriction}_U$ in it is orthogonal, so by Lemma 8.4.23 it is R_θ or S_θ. If it is S_θ, the unit eigenvectors $\mathbf{c},\mathbf{c}'$ of the lemma (taken as combinations of $\mathbf{a},\mathbf{b}$) form an orthonormal basis of U in which the matrix is $\mathrm{diag}(1,-1)$. If it is R_θ with $\theta\in\{0,\pi\}$, it is $\pm I_2$. Otherwise it is a rotation block, and replacing $\mathbf{b}$ by $-\mathbf{b}$ if necessary makes $\theta\in(0,\pi)$, as in the first proof.

The piece $U^\perp$. If $U=V$ we are done. Otherwise $1\le\dim U^\perp<n$, and the induction hypothesis gives an orthonormal basis of $U^\perp$ in which $S{\restriction}_{U^\perp}$ has the required block form.

By Theorem 6.4.24, $V = U \oplus U^\perp$, so the two bases together form an orthonormal basis of V. Both summands are invariant, so in this basis $[S]$ is block diagonal, with the blocks of $S|_U$ followed by those of $S|_{U^\perp}$ (Remark 7.2.5). □

The first proof spends its effort in the real Schur form and needs only bookkeeping afterwards; the second needs only a small invariant subspace and does the splitting by hand, using that invariant complements come for free for orthogonal operators. A third proof complexifies and pairs conjugate eigenvectors, as in Proposition 7.3.34; ?? carries it out.

The numbers in the normal form are determined by S. The complex eigenvalues of $[S]_{\mathcal{O}}$, counted with multiplicity, are $e^{\pm i\theta_1}, \dots, e^{\pm i\theta_k}$ together with 1 (p times) and -1 (q times), by Proposition 7.3.15, since R_θ has characteristic polynomial $x^2 - 2\cos\theta x + 1 = \big(x - e^{i\theta}\big)\big(x - e^{-i\theta}\big)$. In particular $\det S = (-1)^q$ (Proposition 5.3.17).

8.4.5 Orientation and rotations of $\mathbb{R}^3$ BEYOND 21-242

By Corollary 8.4.13(b), every orthogonal operator has determinant 1 or -1. The sign records whether S preserves orientation: whether it maps a right-handed orthonormal basis to a right-handed one, or reverses the handedness as a mirror does. In the plane, Lemma 8.4.23 says the two kinds are the rotations and the reflections, and the "F" in the picture below shows the difference.

Definition 8.4.26 (Rotation). Let V be a finite-dimensional real inner product space. An orthogonal operator $S \in \mathrm{L}(V)$ is a **rotation** (or **proper**) if $\det S = 1$, and **improper** if $\det S = -1$. The rotations of $\mathbb{R}^n$ form the group $\mathrm{SO}(n)$.

$$S = \begin{pmatrix} 0.6 & 0.8 \\ 0.8 & -0.6 \end{pmatrix}, \quad \det S = -1, \quad S\begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix}, \quad S\begin{pmatrix} -1 \\ 2 \end{pmatrix} = \begin{pmatrix} 1 \\ -2 \end{pmatrix}.$$

The reflection $S = \begin{pmatrix} 0.6 & 0.8 \\ 0.8 & -0.6 \end{pmatrix} = S_\theta$ with $\cos\theta = 0.6$, $\sin\theta = 0.8$. It fixes the line through $(2, 1)$ and reverses $(-1, 2)$, and $\det S = -1$: the "F" comes out mirrored. In the interactive version, drag $S\mathbf{e}_2$ to $(-0.8, 0.6)$ to get the rotation R_θ, with determinant 1 and an unmirrored "F". Every other position of $S\mathbf{e}_2$ leaves the orthogonal matrices. (Interactive in the web version.)

The determinant is a continuous function of the entries that takes only the values ± 1 on $\mathrm{O}(n)$, so no path of orthogonal matrices leads from a rotation to a reflection. Conversely, by Theorem 8.4.25 every rotation is PBP^{T} with an even number of blocks -1, which pair up into blocks $-I_2 = R_\pi$; letting all the angles shrink to 0 moves B continuously to I_n inside $\mathrm{SO}(n)$. This is the precise sense in which the rotations are the orthogonal operators that can be "performed physically".

In three dimensions a rotation has more structure than the word suggests: it always turns about a fixed axis.

Theorem 8.4.27 (Euler's rotation theorem). Let V be a real inner product space with $\dim V = 3$, and let $S \in \mathrm{L}(V)$ be a rotation. Then S has an **axis**: a unit vector $\mathbf{a}$ with $S\mathbf{a} = \mathbf{a}$. Moreover, for every orthonormal basis $\mathcal{O} = \mathbf{a}, \mathbf{b}, \mathbf{c}$ of V starting with $\mathbf{a}$,

$$[S]_{\mathcal{O}} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{pmatrix}$$

for some $\theta \in [0, 2\pi)$, and $\operatorname{tr} S = 1 + 2\cos\theta$.

Intuition. We need 1 to be an eigenvalue. Three different reasons are available: a determinant identity that says $\det(S - \mathrm{id})$ equals its own negative, a count of complex eigenvalues on the unit circle with product 1, and the normal form, in which an odd dimension leaves at least one 1×1 block. Once an axis exists, the plane perpendicular to it is invariant, and Lemma 8.4.23 identifies what happens there.

Proof (by a determinant identity). STANDARD

Uses. Theorem 8.4.11 (Characterizations of unitary operators), Theorem 5.4.10 (Multiplicativity), Theorem 5.4.14 (The transpose), Definition 5.1.1 (Determinant function), Theorem 7.2.9 (Eigenvalues and invertibility), Lemma 8.4.14 (Invariant complements), Lemma 8.4.23 (Orthogonal 2×2 matrices), Proposition 5.3.17 (Block-diagonal matrices)
Hint 1. Let A be the matrix of S in an orthonormal basis. Write $A - I_3 = A - AA^{\mathsf{T}}$ and factor out A.
Hint 2. $\det(A - I_3) = \det A \cdot \det\left(I_3 - A^{\mathsf{T}}\right) = \det(I_3 - A)$. Compare $\det(I_3 - A)$ with $\det(A - I_3)$ in dimension 3.
Hint 3. For the matrix, the plane $\mathbf{a}^{\perp}$ is invariant. What is the determinant of S on it?
Sketch. $\det(A - I) = \det\left(A\left(I - A^{\mathsf{T}}\right)\right) = \det A \det\left((I - A)^{\mathsf{T}}\right) = \det(I - A) = (-1)^3 \det(A - I)$, so $\det(A - I) = 0$ and 1 is an eigenvalue. With a unit fixed vector $\mathbf{a}$, $\mathbf{a}^{\perp}$ is invariant and S is orthogonal on it with determinant $\det S/1 = 1$, so it is a rotation R_θ of that plane. The trace is $1 + 2\cos\theta$.

An axis. Let $A = [S]_{\mathcal{B}}$ for some orthonormal basis $\mathcal{B}$; it is orthogonal with $\det A = \det S = 1$. Using $AA^{\mathsf{T}} = I_3$, Theorem 5.4.10, and Theorem 5.4.14,

$$\det(A - I_3) = \det\left(A - AA^{\mathsf{T}}\right) = \det(A)\det\left(I_3 - A^{\mathsf{T}}\right) = \det\left((I_3 - A)^{\mathsf{T}}\right) = \det(I_3 - A).$$

Since $I_3 - A = (-1)(A - I_3)$ and the determinant is multilinear in the three columns (Definition 5.1.1), $\det(I_3 - A) = (-1)^3 \det(A - I_3)$. So $\det(A - I_3) = -\det(A - I_3)$, that is, $\det(A - I_3) = 0$. Hence 1 is an eigenvalue of A, and so of S (Theorem 7.2.9); a unit eigenvector $\mathbf{a}$ is an axis.

The matrix. Let $\mathbf{a}, \mathbf{b}, \mathbf{c}$ be an orthonormal basis. The line $\operatorname{span}(\mathbf{a})$ is S-invariant, so by Lemma 8.4.14 the plane $P = \operatorname{span}(\mathbf{b}, \mathbf{c}) = \mathbf{a}^{\perp}$ is invariant and $S{\restriction}_P$ is orthogonal. So $[S]_{\mathcal{O}}$ is block diagonal with blocks (1) and the orthogonal matrix B of $S{\restriction}_P$ in $\mathbf{b}, \mathbf{c}$, and $1 = \det S = 1 \cdot \det B$ (Proposition 5.3.17). By Lemma 8.4.23, $B = R_\theta$ for some $\theta \in [0, 2\pi)$. Finally $\operatorname{tr} S = 1 + 2\cos\theta$. □

Proof (by counting eigenvalues). STANDARD

Uses. Theorem 7.1.32 (Fundamental Theorem of Algebra), Proposition B.1.4 (Roots of real polynomials come in conjugate pairs), Corollary 7.1.43 (Odd degree gives a real root), Theorem 7.5.22 (Trace and determinant from eigenvalues), Corollary 8.4.13 (Eigenvalues and determinant), Corollary 7.3.13 (Eigenvalues of an operator)
Techniques. Complexify, then take real and imaginary parts (Technique 7.3.35)
Hint 1. Regard the matrix A of S as a complex unitary matrix. Its three eigenvalues lie on the unit circle and multiply to $\det A = 1$.
Hint 2. The characteristic polynomial is real of degree 3: its nonreal roots come in conjugate pairs, and it has a real root.
Sketch. The eigenvalues $\lambda_1, \lambda_2, \lambda_3 \in \mathbb{C}$ of A have absolute value 1 and product 1. If two are a conjugate pair, their product is $|\lambda|^2 = 1$, so the third is 1. If all are real, they are ± 1 with product 1, so they are not all -1. Either way 1 is a root of p_S, hence an eigenvalue of S.

We show that 1 is an eigenvalue; the rest is as in the first proof. Let A be the matrix of S in an orthonormal basis, regarded as a complex unitary matrix, and let $\lambda_1, \lambda_2, \lambda_3$ be its eigenvalues counted with multiplicity, the roots of p_A (Theorem 7.1.32). Each satisfies $|\lambda_j| = 1$ (Corollary 8.4.13(a)), and $\lambda_1\lambda_2\lambda_3 = \det A = 1$ (Theorem 7.5.22). Since p_A is a real polynomial of odd degree, it has a real root (Corollary 7.1.43), say $\lambda_3 \in \{1, -1\}$, and its nonreal roots come in conjugate pairs (Proposition B.1.4).

If $\lambda_1 \notin \mathbb{R}$, then $\lambda_2 = \overline{\lambda_1}$, so $\lambda_1\lambda_2 = |\lambda_1|^2 = 1$ and $\lambda_3 = 1$. If all three are real, each is ± 1, and their product is 1, so they are not all -1. In both cases 1 is a root of $p_A = p_S$, hence an eigenvalue of S (Corollary 7.3.13).□

Proof (from the normal form). ROUTINE

Uses. Theorem 8.4.25 (Normal form of orthogonal operators), Proposition 5.3.17 (Block-diagonal matrices)
Hint 1. In the normal form, $2k + p + q = 3$ and $\det S = (-1)^q$.
Hint 2. The number q of blocks -1 is even. Can p be 0?

Sketch. $\det S = (-1)^q = 1$ forces q even. If $k = 1$, then $p + q = 1$, so $q = 0$ and $p = 1$. If $k = 0$, then $p + q = 3$ with $q \in \{0, 2\}$, so $p \geq 1$. A block (1) is a fixed unit vector.

By Theorem 8.4.25, $[S]_{\mathcal{O}}$ is block diagonal with k rotation blocks, p blocks (1), and q blocks (-1), where $2k + p + q = 3$. By Proposition 5.3.17, $\det S = (-1)^q$ (each R_θ has determinant 1), so q is even. If $k = 1$, then $p + q = 1$ forces $q = 0$ and $p = 1$. If $k = 0$, then $p + q = 3$ with $q \in \{0, 2\}$, so $p \geq 1$. Either way some vector of $\mathcal{O}$ is fixed by S. The matrix and trace follow as in the first proof. □

The first proof is the shortest and shows what matters: in any odd dimension n, $\det(I_n - A) = (-1)^n \det(A - I_n)$, so every rotation of $\mathbb{R}^n$ with n odd has a fixed vector (Exercise 8.4.42). In even dimensions this fails: $R_\theta \in \mathrm{SO}(2)$ with $\theta \neq 0$, and $\begin{pmatrix} R_\theta & 0 \\ 0 & R_\varphi \end{pmatrix} \in \mathrm{SO}(4)$ with $\theta, \varphi \neq 0$, fix only $\mathbf{0}$. The second proof is a computation with the spectrum, and the third reads the answer off the classification.

The trace formula identifies a rotation of $\mathbb{R}^3$ quickly. Its axis is a kernel vector of $S - \mathrm{id}$, and the angle θ satisfies $\cos\theta = (\operatorname{tr} S - 1)/2$. The cosine determines θ only up to sign; replacing $\mathbf{b}, \mathbf{c}$ by $\mathbf{c}, \mathbf{b}$ replaces θ by $2\pi - \theta$, so the sense of the rotation depends on an orientation of the plane $\mathbf{a}^\perp$.

Example 8.4.28 (Axis and angle). Let

$$Q = \frac{1}{3}\begin{pmatrix} 2 & -1 & 2 \\ 2 & 2 & -1 \\ -1 & 2 & 2 \end{pmatrix}.$$

Its columns have squared lengths $(4 + 4 + 1)/9 = 1$ and pairwise dot products $(-2 + 4 - 2)/9$, $(4 - 2 - 2)/9$, $(-2 - 2 + 4)/9$, all 0, so Q is orthogonal. Expanding along the first row, $\det(3Q) = 2(4 + 2) + (4 - 1) + 2(4 + 2) = 27$, so $\det Q = 1$ and Q is a rotation. Each row of Q sums to 1, so $Q(1, 1, 1) = (1, 1, 1)$, and the axis is $\mathbf{a} = \frac{1}{\sqrt{3}}(1, 1, 1)$. Since $\operatorname{tr} Q = 2 = 1 + 2\cos\theta$, we get $\cos\theta = 1/2$: Q turns the plane $x_1 + x_2 + x_3 = 0$ through $\pi/3$. For instance $Q(1, -1, 0) = (1, 0, -1)$, and these two vectors of length $\sqrt{2}$ have dot product $1 = \sqrt{2} \cdot \sqrt{2} \cdot \cos(\pi/3)$.

Squaring, $Q^2 = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$, the cyclic shift C of Example 8.4.16(b) for $n = 3$: it turns about the same axis through $2\pi/3$, and its trace is $0 = 1 + 2\cos(2\pi/3)$.

Since $\mathrm{SO}(3)$ is a group, the composite of two rotations of $\mathbb{R}^3$, about any two axes, is again a rotation about some axis, which is not obvious from the pictures (??).

8.4.6 Rigid motions BEYOND 21-242

We now drop linearity and ask for maps that preserve distances.

Definition 8.4.29 (Rigid motion). Let V be a real inner product space. A function $f : V \to V$, not assumed linear, is a **rigid motion** if

$$\|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\| \quad \text{for all } \mathbf{x}, \mathbf{y} \in V.$$

Translations $\mathbf{x} \mapsto \mathbf{x} + \mathbf{b}$ and orthogonal operators are rigid motions, and so are their composites $\mathbf{x} \mapsto S\mathbf{x} + \mathbf{b}$. These are affine maps (Definition 4.7.35) with orthogonal linear part. The theorem of this subsection is that there are no others. In Problem 6.8 the linearity of $f - f(\mathbf{0})$ was proved by polarization; here we give a different proof that uses distances only, through the observation that in an inner product space a point is determined by its distances to the two ends of a segment that it lies on.

Lemma 8.4.30 (Points between two points). Let V be an inner product space, let $\mathbf{a}, \mathbf{b}, \mathbf{z} \in V$, and let $t \in [0, 1]$. If

$$\|\mathbf{z}-\mathbf{a}\| = t\|\mathbf{b}-\mathbf{a}\| \quad \text{and} \quad \|\mathbf{b}-\mathbf{z}\| = (1-t)\|\mathbf{b}-\mathbf{a}\|,$$

then $\mathbf{z} = (1-t)\mathbf{a} + t\mathbf{b}$.

Proof. STANDARD

Uses. Theorem 6.2.11 (Triangle inequality), Proposition 6.1.27 (Basic properties of the norm)
Hint 1. Let $\mathbf{x} = \mathbf{z}-\mathbf{a}$ and $\mathbf{y} = \mathbf{b}-\mathbf{z}$. Then $\mathbf{x}+\mathbf{y} = \mathbf{b}-\mathbf{a}$. What do the hypotheses say about $\|\mathbf{x}\| + \|\mathbf{y}\|$?
Hint 2. Equality holds in the triangle inequality, so one of $\mathbf{x}, \mathbf{y}$ is a nonnegative multiple of the other (Theorem 6.2.11(b)). Deduce that $\mathbf{x}$ is a nonnegative multiple of $\mathbf{b}-\mathbf{a}$, and find the factor from $\|\mathbf{x}\|$.
Sketch. With $\mathbf{x} = \mathbf{z}-\mathbf{a}$, $\mathbf{y} = \mathbf{b}-\mathbf{z}$: $\|\mathbf{x}\| + \|\mathbf{y}\| = \|\mathbf{x}+\mathbf{y}\|$, so $\mathbf{x}$ and $\mathbf{y}$ point the same way, and then $\mathbf{x} = s(\mathbf{b}-\mathbf{a})$ with $s \geq 0$. Taking norms, $s = t$ (if $\mathbf{b} \neq \mathbf{a}$; if $\mathbf{b} = \mathbf{a}$, then $\mathbf{z} = \mathbf{a}$ directly).

If $\mathbf{b} = \mathbf{a}$, the first hypothesis gives $\|\mathbf{z}-\mathbf{a}\| = 0$, so $\mathbf{z} = \mathbf{a} = (1-t)\mathbf{a} + t\mathbf{b}$. Suppose $\mathbf{b} \neq \mathbf{a}$, and let $\mathbf{x} = \mathbf{z}-\mathbf{a}$, $\mathbf{y} = \mathbf{b}-\mathbf{z}$, so that $\mathbf{x}+\mathbf{y} = \mathbf{b}-\mathbf{a}$ and

$$\|\mathbf{x}\| + \|\mathbf{y}\| = t\|\mathbf{b}-\mathbf{a}\| + (1-t)\|\mathbf{b}-\mathbf{a}\| = \|\mathbf{x}+\mathbf{y}\|.$$

By Theorem 6.2.11(b), one of $\mathbf{x}, \mathbf{y}$ is a nonnegative real multiple of the other. If $\mathbf{x} = c\mathbf{y}$ with $c \geq 0$, then $\mathbf{b}-\mathbf{a} = (c+1)\mathbf{y}$, so $\mathbf{x} = c/(c+1)(\mathbf{b}-\mathbf{a})$. If $\mathbf{y} = c\mathbf{x}$ with $c \geq 0$, then $\mathbf{b}-\mathbf{a} = (1+c)\mathbf{x}$, so $\mathbf{x} = 1/(1+c)(\mathbf{b}-\mathbf{a})$. Either way $\mathbf{x} = s(\mathbf{b}-\mathbf{a})$ for some real $s \geq 0$, and taking norms gives $s\|\mathbf{b}-\mathbf{a}\| = \|\mathbf{x}\| = t\|\mathbf{b}-\mathbf{a}\|$, so $s = t$. Hence $\mathbf{z} = \mathbf{a} + t(\mathbf{b}-\mathbf{a}) = (1-t)\mathbf{a} + t\mathbf{b}$. □

Theorem 8.4.31 (Distance-preserving maps are affine). Let V and W be real inner product spaces, and let $f : V \to W$ satisfy $\|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x}-\mathbf{y}\|$ for all $\mathbf{x}, \mathbf{y} \in V$. Then $S(\mathbf{x}) = f(\mathbf{x}) - f(\mathbf{0})$ defines an isometry $S \in \mathrm{L}(V, W)$, so $f = S + f(\mathbf{0})$ is affine.

In particular, if V is finite-dimensional, every rigid motion of V has the form $\mathbf{x} \mapsto S\mathbf{x} + \mathbf{b}$ with S orthogonal, and is bijective. The rigid motions of $\mathbb{R}^n$ are the maps $\mathbf{x} \mapsto Q\mathbf{x} + \mathbf{b}$ with $Q \in \mathrm{O}(n)$ and $\mathbf{b} \in \mathbb{R}^n$.

Proof (by betweenness). HARD

Uses. Lemma 8.4.30 (Points between two points), Theorem 2.1.3 (Checking linearity), Definition 4.7.35 (Affine map), Theorem 8.4.11 (Characterizations of unitary operators), Proposition 2.3.17 (Every linear map $F^n \to F^m$ is some T_A)
Techniques. Choose a base point (Technique 4.7.4)
Hint 1. Use Lemma 8.4.30 to show that $f((1-t)\mathbf{a} + t\mathbf{b}) = (1-t)f(\mathbf{a}) + tf(\mathbf{b})$ for $t \in [0,1]$: the point on the left has the right distances to $f(\mathbf{a})$ and $f(\mathbf{b})$.
Hint 2. Extend to all real t: for $t > 1$, the point $\mathbf{b}$ lies between $\mathbf{a}$ and $(1-t)\mathbf{a} + t\mathbf{b}$.
Hint 3. Now $S(t\mathbf{x}) = f((1-t)\mathbf{0} + t\mathbf{x}) - f(\mathbf{0})$, and $\mathbf{x}+\mathbf{y}$ is twice the midpoint of $\mathbf{x}$ and $\mathbf{y}$.
Sketch. Distances from $f(\mathbf{z})$ to $f(\mathbf{a})$ and $f(\mathbf{b})$ equal those from $\mathbf{z} = (1-t)\mathbf{a} + t\mathbf{b}$ to $\mathbf{a}$ and $\mathbf{b}$, so Lemma 8.4.30 forces $f(\mathbf{z}) = (1-t)f(\mathbf{a}) + tf(\mathbf{b})$ for $t \in [0,1]$, and a relabelling gives all $t \in \mathbb{R}$. Then $S = f - f(\mathbf{0})$ satisfies $S(t\mathbf{x}) = tS(\mathbf{x})$ and $S(\mathbf{x}+\mathbf{y}) = 2S((\mathbf{x}+\mathbf{y})/2) = S(\mathbf{x}) + S(\mathbf{y})$, and $\|S\mathbf{x}\| = \|\mathbf{x}\|$. In finite dimension S is orthogonal, hence bijective.

Step 1: segments go to segments. Let $\mathbf{a}, \mathbf{b} \in V$, $t \in [0,1]$, and $\mathbf{z} = (1-t)\mathbf{a} + t\mathbf{b}$. Then $\mathbf{z}-\mathbf{a} = t(\mathbf{b}-\mathbf{a})$ and $\mathbf{b}-\mathbf{z} = (1-t)(\mathbf{b}-\mathbf{a})$, so, as f preserves distances,

$$\|f(\mathbf{z}) - f(\mathbf{a})\| = t\|f(\mathbf{b}) - f(\mathbf{a})\|, \quad \|f(\mathbf{b}) - f(\mathbf{z})\| = (1-t)\|f(\mathbf{b}) - f(\mathbf{a})\|.$$

By Lemma 8.4.30 in W, $f(\mathbf{z}) = (1-t)f(\mathbf{a}) + tf(\mathbf{b})$.

Step 2: lines go to lines. We show that $f((1-t)\mathbf{a} + t\mathbf{b}) = (1-t)f(\mathbf{a}) + tf(\mathbf{b})$ for every $t \in \mathbb{R}$. Let $t > 1$ and $\mathbf{c} = (1-t)\mathbf{a} + t\mathbf{b}$. With $s = 1/t \in (0,1)$, a direct check gives $\mathbf{b} = (1-s)\mathbf{a} + s\mathbf{c}$, so Step 1 gives $f(\mathbf{b}) = (1-s)f(\mathbf{a}) + sf(\mathbf{c})$. Solving for $f(\mathbf{c})$,

$$f(\mathbf{c}) = tf(\mathbf{b}) - (t-1)f(\mathbf{a}) = (1-t)f(\mathbf{a}) + tf(\mathbf{b}).$$

For $t < 0$, write $(1-t)\mathbf{a} + t\mathbf{b} = (1-t')\mathbf{b} + t'\mathbf{a}$ with $t' = 1-t > 1$, and apply the case just proved with $\mathbf{a}$ and $\mathbf{b}$ exchanged.

Step 3: S is linear. Let $S(\mathbf{x}) = f(\mathbf{x}) - f(\mathbf{0})$. For $t \in \mathbb{R}$, Step 2 with $\mathbf{a} = \mathbf{0}$, $\mathbf{b} = \mathbf{x}$ gives

$$S(t\mathbf{x}) = f((1-t)\mathbf{0} + t\mathbf{x}) - f(\mathbf{0}) = (1-t)f(\mathbf{0}) + tf(\mathbf{x}) - f(\mathbf{0}) = tS(\mathbf{x}).$$

For $\mathbf{x}, \mathbf{y} \in V$, Step 1 with $t = 1/2$ gives $f\left(\frac{1}{2}\mathbf{x} + \frac{1}{2}\mathbf{y}\right) = \frac{1}{2}f(\mathbf{x}) + \frac{1}{2}f(\mathbf{y})$, so, using homogeneity,

$$S(\mathbf{x}+\mathbf{y}) = 2S\left(\frac{1}{2}(\mathbf{x}+\mathbf{y})\right) = 2\left(\frac{1}{2}f(\mathbf{x}) + \frac{1}{2}f(\mathbf{y}) - f(\mathbf{0})\right) = S(\mathbf{x}) + S(\mathbf{y}).$$

So S is linear (Theorem 2.1.3), and $\|S\mathbf{x}\| = \|f(\mathbf{x}) - f(\mathbf{0})\| = \|\mathbf{x} - \mathbf{0}\| = \|\mathbf{x}\|$, so S is an isometry. Thus $f = S + f(\mathbf{0})$ is affine (Definition 4.7.35).

Finite dimension. If $W = V$ is finite-dimensional, S is orthogonal by (I) $\Rightarrow$ (II) of Theorem 8.4.11, so it is bijective, and so is $f = S + \mathbf{b}$, with inverse $\mathbf{y} \mapsto S^{-1}(\mathbf{y} - \mathbf{b})$. For $V = \mathbb{R}^n$, S is $\mathbf{x} \mapsto Q\mathbf{x}$ for a matrix Q (Proposition 2.3.17), which is orthogonal by Theorem 8.4.11. □

The proof used the inner product only through Lemma 8.4.30, that is, through the equality case of the triangle inequality: the "midpoint" of $\mathbf{a}$ and $\mathbf{b}$, defined by distances alone, is unique. This is the idea behind the Mazur–Ulam theorem, which says that every surjective distance-preserving map between real normed spaces is affine. In a normed space such as $\mathbb{R}^2$ with $\|\mathbf{x}\|_\infty = \max(|x_1|, |x_2|)$ there are many points at distance 1 from both $(0,0)$ and $(2,0)$, and Exercise 8.4.45 shows that the conclusion of Theorem 8.4.31 then fails for maps that are not onto. Over $\mathbb{C}$, Lemma 8.4.30 still holds and Steps 1–3 go through with real t, so a distance-preserving map of complex spaces is additive and real-homogeneous after subtracting $f(\mathbf{0})$; complex conjugation on $\mathbb{C}^n$ shows that it need not be complex-linear (Problem 6.8(d)).

In homogeneous coordinates (Section 4.7.6), the rigid motion $f(\mathbf{x}) = Q\mathbf{x} + \mathbf{b}$ of $\mathbb{R}^n$ is the matrix

$$M_f = \begin{pmatrix} Q & \mathbf{b} \\ 0 & 1 \end{pmatrix} \in \mathbb{R}^{(n+1)\times(n+1)},$$

and by Theorem 4.7.42 composites and inverses correspond to products and inverses:

$$\begin{pmatrix} Q_1 & \mathbf{b}_1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} Q_2 & \mathbf{b}_2 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} Q_1Q_2 & Q_1\mathbf{b}_2 + \mathbf{b}_1 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} Q & \mathbf{b} \\ 0 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} Q^{\mathsf{T}} & -Q^{\mathsf{T}}\mathbf{b} \\ 0 & 1 \end{pmatrix}.$$

So the rigid motions of $\mathbb{R}^n$ form a group, the **Euclidean group**. A rigid motion is **proper** if $\det Q = 1$; these are the motions of a solid body in space, and in the plane they are the translations and the rotations about a point (Exercise 4.7.62).

Exercises

Exercise 8.4.32. ROUTINE Decide which of the following linear maps are isometries, and which of the isometries are unitary.

(a) $T : \mathbb{R}^2 \to \mathbb{R}^3$, $T(x,y) = \frac{1}{3}(x + 2y, 2x + y, 2x - 2y)$.

(b) $T : \mathbb{C}^2 \to \mathbb{C}^2$, $T(z,w) = \frac{1}{\sqrt{2}}(z + iw, iz + w)$.

(c) $T : V \to V$, $(Tp)(x) = p(1-x)$, where $V = \mathbb{R}[x]_{\le 1}$ with $\langle p, q\rangle = p(0)q(0) + p(1)q(1)$.

(d) $T : V \to V$, $(Tp)(x) = p(x/2)$, with V as in (c).

(e) $T : \mathbb{C}^{2\times 2} \to \mathbb{C}^{2\times 2}$, $T(A) = A^{\mathsf{T}}$, with the Frobenius inner product.

Solution on page 1663

Exercise 8.4.33. STANDARD Prove or disprove each statement. Here V and W are finite-dimensional.

(a) If $S \in \mathrm{L}(V, W)$ is an isometry, then so is S^*.

(b) If V is complex and every eigenvalue of $T \in \mathrm{L}(V)$ has absolute value 1, then T is unitary.

(c) If V is complex, $T \in \mathrm{L}(V)$ is normal, and $\|T\mathbf{v}\| = \|\mathbf{v}\|$ for every eigenvector $\mathbf{v}$ of T, then T is unitary.

(d) Statement (c) with "complex" replaced by "real".

Solution on page 1663

Exercise 8.4.34. STANDARD Let V and W be finite-dimensional, and let $T \in \mathrm{L}(V, W)$ preserve orthogonality: $\langle T\mathbf{u}, T\mathbf{v}\rangle = 0$ whenever $\langle \mathbf{u}, \mathbf{v}\rangle = 0$. Show that either $T = 0$ or $T = cS$ for a real number $c > 0$ and an isometry S. (So the maps that preserve right angles are exactly the scalar multiples of isometries.)

Solution on page 1664

Exercise 8.4.35. STANDARD

(a) Show that an orthogonal matrix $Q \in \mathbb{R}^{n\times n}$ with integer entries is a **signed permutation matrix**: each row and each column has exactly one nonzero entry, which is 1 or -1.

(b) Count the orthogonal $n \times n$ matrices with integer entries, and count those with determinant 1 (for $n \geq 1$).

Solution on page 1664

Exercise 8.4.36. STANDARD Let $Q = \left(q_{ij}\right) \in \mathbb{R}^{n\times n}$ be orthogonal.

(a) Show that $\left|\sum_{i,j} q_{ij}\right| \leq n$, and that the sum equals n if and only if every row of Q sums to 1.

(b) Show that $\sum_{i,j}|q_{ij}| \leq n\sqrt{n}$, with equality if and only if every $|q_{ij}| = 1/\sqrt{n}$. Give an example of equality for $n = 2$.

Solution on page 1664

Exercise 8.4.37. STANDARD Let $U \in \mathbb{C}^{n\times n}$ be unitary. Show that $|\mathrm{tr}\, U| \leq n$, with equality if and only if $U = cI_n$ for some $c \in \mathbb{C}$ with $|c| = 1$. Deduce that a real orthogonal Q with $\mathrm{tr}\, Q = n$ is I_n.

Solution on page 1665

Exercise 8.4.38. HARD Let V be a finite-dimensional complex inner product space and $S \in \mathrm{L}(V)$ unitary.

(a) Show that there is a self-adjoint $A \in \mathrm{L}(V)$, with all eigenvalues in $[0, 2\pi)$, such that $S = f(A)$ for $f(t) = e^{it}$ (Definition 8.2.23).

(b) Show that S has a unitary square root: a unitary R with $R^2 = S$.

(c) Suppose $\dim V = n$ and S has n distinct eigenvalues. Show that S has exactly 2^n square roots $R \in \mathrm{L}(V)$, and that all of them are unitary.

Solution on page 1665

Exercise 8.4.39. STANDARD A student argues: "Let S be an orthogonal operator on a finite-dimensional real inner product space. Then $S^*S = SS^* = \mathrm{id}$, so S is normal, and by the spectral theorem V has an orthonormal basis of eigenvectors of S."

(a) Find the error, and give a counterexample to the conclusion.

(b) Show that an orthogonal S has an orthonormal eigenbasis if and only if $S^2 = \mathrm{id}$, and describe such operators geometrically.

Solution on page 1666

Exercise 8.4.40. STANDARD BEYOND 21-242 Let M be multiplication by x on $\mathbb{F}[x]$, with the inner product of Example 8.4.12, and define $L \in \mathrm{L}(\mathbb{F}[x])$ by

$$L\left(a_0 + a_1 x + \cdots + a_d x^d\right) = a_1 + a_2 x + \cdots + a_d x^{d-1}.$$

(a) Show that L is the adjoint of M.

(b) Show that $LM = \mathrm{id}$ and $ML = \mathrm{id} - \mathrm{Pr}_{\mathrm{span}(1)}$.

(c) Show that M has no eigenvalues, and that the only eigenvalue of L is 0.

Solution on page 1666

Exercise 8.4.41. ROUTINE BEYOND 21-242 Show that

$$Q = \frac{1}{9}\begin{pmatrix} 1 & -4 & 8 \\ 8 & 4 & 1 \\ -4 & 7 & 4 \end{pmatrix}$$

is a rotation of $\mathbb{R}^3$, and find its axis and its angle.

Solution on page 1667

Exercise 8.4.42. STANDARD BEYOND 21-242 Let $Q \in \mathrm{O}(n)$.

(a) Show that if $\det Q = -1$, then -1 is an eigenvalue of Q.

(b) Show that if $\det Q = 1$ and n is odd, then 1 is an eigenvalue of Q.

(c) Give a $Q \in \mathrm{SO}(4)$ with no real eigenvalue, and a $Q \in \mathrm{O}(2)$ with $\det Q = -1$ that does not have the eigenvalue 1, or show that none exists.

Solution on page 1667

Exercise 8.4.43. STANDARD For $\alpha \in \mathbb{R}$, let $S_\alpha = \begin{pmatrix} \cos\alpha & \sin\alpha \\ \sin\alpha & -\cos\alpha \end{pmatrix}$, the reflection across the line at angle $\alpha/2$ (Example 6.3.35).

(a) Show that $S_\alpha S_\beta = R_{\alpha-\beta}$. In words: reflecting across a line ℓ_2 and then across a line ℓ_1 through $\mathbf{0}$ rotates the plane by twice the angle from ℓ_2 to ℓ_1.

(b) Deduce that every rotation R_θ is a product of two reflections, and that the first of them (the one applied first) can be any reflection.

Solution on page 1667

Exercise 8.4.44. CHALLENGE BEYOND 21-242 Let $Q \in \mathrm{O}(n)$ and $r = \mathrm{rank}(Q - I_n)$. A **reflection** of $\mathbb{R}^n$ means a Householder matrix $H_{\mathbf{u}}$.

(a) Show that if $Q = H_{\mathbf{u}_1} \cdots H_{\mathbf{u}_k}$, then $k \geq r$ and $\det Q = (-1)^k$.

(b) Show that Q is a product of exactly r reflections. (This is the Cartan–Dieudonné theorem for $\mathbb{R}^n$, in its sharp form.)

(c) Deduce that every rotation of $\mathbb{R}^3$ other than I_3 is a product of two reflections, and never of an odd number of reflections.

Solution on page 1668

Exercise 8.4.45. STANDARD BEYOND 21-242 On $\mathbb{R}^2$, let $\|\mathbf{x}\|_\infty = \max(|x_1|, |x_2|)$, and let $f : \mathbb{R} \to \mathbb{R}^2$, $f(t) = (t, |t|)$.

(a) Show that $\|f(s) - f(t)\|_\infty = |s - t|$ for all $s, t \in \mathbb{R}$, but that f is not affine.

(b) Which step of the proof of Theorem 8.4.31 fails for $\|\cdot\|_\infty$? Find all points $\mathbf{z} \in \mathbb{R}^2$ with $\|\mathbf{z} - f(-1)\|_\infty = \|\mathbf{z} - f(1)\|_\infty = 1$.

Solution on page 1668

Exercise 8.4.46. STANDARD BEYOND 21-242 Let f, g be rigid motions of $\mathbb{R}^n$, and let $\mathbf{p}_0, \ldots, \mathbf{p}_n$ be affinely independent (Definition 4.7.18) with $f(\mathbf{p}_i) = g(\mathbf{p}_i)$ for all i. Show that $f = g$. Deduce that a rigid motion of $\mathbb{R}^2$ fixing three non-collinear points is the identity.

Appendix A

Sets, functions, and proofs

Functions and inverses, induction, equivalence relations, Zorn's lemma, and an index of proof techniques.

A.1 Sets and functions

This appendix collects the set-theoretic language that the book uses without comment: functions and their inverses, finite sets, induction, equivalence relations, and Zorn's lemma. The main text cites the results here where they are needed. Several of them have linear counterparts in the main text (one-sided inverses of linear maps in Section 2.5, injectivity and surjectivity in Section 2.6, quotient spaces in Section 4.6), and comparing the two versions shows which parts of a linear-algebra argument are really about linearity.

A.1.1 Sets

Notation A.1.1 (Sets). We write $x \in X$ when x is an element of the set X, and $A \subseteq X$ when every element of A is an element of X. Two sets are equal when they have the same elements, so $A = B$ means $A \subseteq B$ and $B \subseteq A$ (Technique 1.3.14). For subsets $A, B \subseteq X$,

$$A \cup B = \{x \in X \mid x \in A \text{ or } x \in B\}, \quad A \cap B = \{x \in X \mid x \in A \text{ and } x \in B\}, \quad X \setminus A = \{x \in X \mid x \notin A\}.$$

The empty set is $\emptyset$, and A and B are **disjoint** if $A \cap B = \emptyset$. The **power set** $P(X)$ is the set of all subsets of X. The **Cartesian product** $X \times Y$ is the set of ordered pairs (x, y) with $x \in X$ and $y \in Y$, and X^n is the set of n-tuples of elements of X. For an integer $n \geq 0$, we write $[n] = \{1, 2, \ldots, n\}$, so that $[0] = \emptyset$. Finally, $\mathbb{N} = \{0, 1, 2, \ldots\}$ includes 0.

A.1.2 Functions, images, and preimages

Definition A.1.2 (Function). A **function** (or **map**) $f : X \to Y$ assigns to each element $x \in X$ exactly one element $f(x) \in Y$. The set X is the **domain** of f and Y is its **codomain**. Two functions $f, g : X \to Y$ are **equal** if $f(x) = g(x)$ for every $x \in X$. The **identity** of X is $\mathrm{id}_X : X \to X$, $\mathrm{id}_X(x) = x$.

Formally, f is its graph $\{(x, f(x)) \mid x \in X\} \subseteq X \times Y$, a subset that contains exactly one pair (x, y) for each $x \in X$. The codomain is part of the data: $x \mapsto x^2$ from $\mathbb{R}$ to $\mathbb{R}$ and from $\mathbb{R}$ to $[0, \infty)$ are different functions, since the second is surjective and the first is not. For every set Y there is exactly one function $\emptyset \to Y$, the empty function, and there is no function $X \to \emptyset$ when $X \neq \emptyset$.

Definition A.1.3 (Image and preimage). Let $f : X \to Y$. For $A \subseteq X$, the **image** of A under f is

$$\mathrm{im}(f|_A) = \{f(a) \mid a \in A\} \subseteq Y,$$

and the image of f is $\operatorname{im} f = \operatorname{im}(f{\restriction_X})$. For $B \subseteq Y$, the **preimage** of B under f is

$$f^{-1}(B) = \{x \in X \mid f(x) \in B\} \subseteq X.$$

For $y \in Y$ we write $f^{-1}(y)$ for $f^{-1}(\{y\})$, the set of preimages of y, and call it the **fiber** of f over y.

The notation $\operatorname{im}(f{\restriction_A})$ reads "the image of f restricted to A", which is what it is. The notation $f^{-1}(B)$ does not presuppose that f has an inverse: every function has preimages, and a fiber $f^{-1}(y)$ can be empty or have many elements. In this language, Definition 2.6.1, Definition 2.6.2 and Definition 2.6.3 say that f is injective, surjective, or bijective when every fiber has at most one, at least one, or exactly one element. For a linear map T, the kernel is the fiber $T^{-1}(\mathbf{0})$, and the solution set of $T(\mathbf{v}) = \mathbf{w}$ is the fiber $T^{-1}(\mathbf{w})$.

Example A.1.4 (Images and preimages of $x \mapsto x^2$). Let $f : \mathbb{R} \to \mathbb{R}$, $f(x) = x^2$. Then $\operatorname{im}\big(f{\restriction_{[-1,2]}}\big) = [0, 4]$ and $\operatorname{im} f = [0, \infty)$. Preimages: $f^{-1}([1, 4]) = [-2, -1] \cup [1, 2]$, $f^{-1}(4) = \{-2, 2\}$, and $f^{-1}(-1) = \emptyset$. Taking the image and then the preimage can enlarge a set: $f^{-1}\big(\operatorname{im}\big(f{\restriction_{[0,1]}}\big)\big) = f^{-1}([0, 1]) = [-1, 1]$. Taking the preimage and then the image can shrink one: $\operatorname{im}\big(f{\restriction_{f^{-1}([-1,1])}}\big) = [0, 1]$.

The example shows the general pattern. Preimages respect all the set operations, images respect unions but not intersections, and the two operations undo each other exactly when f is injective (in one order) or surjective (in the other).

Proposition A.1.5 (Images and preimages). Let $f : X \to Y$, let $A, A' \subseteq X$, and let $B, B' \subseteq Y$.

(a) $f^{-1}(B \cup B') = f^{-1}(B) \cup f^{-1}(B')$, $f^{-1}(B \cap B') = f^{-1}(B) \cap f^{-1}(B')$, and $f^{-1}(Y \setminus B) = X \setminus f^{-1}(B)$.

(b) $\operatorname{im}(f{\restriction_{A \cup A'}}) = \operatorname{im}(f{\restriction_A}) \cup \operatorname{im}(f{\restriction_{A'}})$ and $\operatorname{im}(f{\restriction_{A \cap A'}}) \subseteq \operatorname{im}(f{\restriction_A}) \cap \operatorname{im}(f{\restriction_{A'}})$, with equality if f is injective.

(c) $A \subseteq f^{-1}(\operatorname{im}(f{\restriction_A}))$, with equality if f is injective.

(d) $\operatorname{im}\big(f{\restriction_{f^{-1}(B)}}\big) = B \cap \operatorname{im} f$. In particular $\operatorname{im}\big(f{\restriction_{f^{-1}(B)}}\big) \subseteq B$, with equality if f is surjective.

Proof. ROUTINE

Uses. Definition A.1.3 (Image and preimage), Definition 2.6.1 (Injective), Definition 2.6.2 (Surjective)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Each claim is an equality or containment of sets. Take a generic element of one side and unwind the definitions until it is visibly in the other side.
Hint 2. For preimages, $x \in f^{-1}(B)$ is the statement $f(x) \in B$, so (a) is the logic of "or", "and", and "not" applied to $f(x)$. For images, $y \in \operatorname{im}(f{\restriction_A})$ means $y = f(a)$ for some $a \in A$.
Hint 3. Injectivity enters when an element is written as a value in two ways: if $y = f(a) = f(a')$ with $a \in A$ and $a' \in A'$, then $a = a' \in A \cap A'$.
Sketch. (a) unwinds to $f(x) \in B \cup B'$ iff $f(x) \in B$ or $f(x) \in B'$, and similarly for $\cap$ and complements. In (b), $f(a)$ with $a \in A \cup A'$ lies in one of the two images; for the intersection, a common value $f(a) = f(a')$ forces $a = a'$ when f is injective. (c): $a \in A$ has $f(a) \in \operatorname{im}(f{\restriction_A})$; if $f(x) = f(a)$ and f is injective, then $x = a$. (d): the values $f(x)$ with $f(x) \in B$ are exactly the elements of B that are values.

(a) For $x \in X$, $x \in f^{-1}(B \cup B')$ means $f(x) \in B \cup B'$, that is, $f(x) \in B$ or $f(x) \in B'$, that is, $x \in f^{-1}(B)$ or $x \in f^{-1}(B')$. The same unwinding with "and" proves the second equality. For the third, $x \in f^{-1}(Y \setminus B)$ means $f(x) \notin B$, that is, $x \notin f^{-1}(B)$.

(b) An element of $\operatorname{im}(f{\restriction_{A \cup A'}})$ is $f(a)$ with $a \in A$ or $a \in A'$, so it lies in $\operatorname{im}(f{\restriction_A})$ or in $\operatorname{im}(f{\restriction_{A'}})$; conversely, $\operatorname{im}(f{\restriction_A})$ and $\operatorname{im}(f{\restriction_{A'}})$ are both contained in $\operatorname{im}(f{\restriction_{A \cup A'}})$. If $a \in A \cap A'$, then $f(a)$ lies in both images, which proves the containment. Now suppose f is injective and $y \in \operatorname{im}(f{\restriction_A}) \cap \operatorname{im}(f{\restriction_{A'}})$, say $y = f(a) = f(a')$ with $a \in A$ and $a' \in A'$. Then $a = a'$, so $a \in A \cap A'$ and $y \in \operatorname{im}(f{\restriction_{A \cap A'}})$.

(c) If $a \in A$, then $f(a) \in \operatorname{im}(f{\restriction_A})$, so $a \in f^{-1}(\operatorname{im}(f{\restriction_A}))$. Suppose f is injective and $x \in f^{-1}(\operatorname{im}(f{\restriction_A}))$. Then $f(x) = f(a)$ for some $a \in A$, so $x = a \in A$.

(d) An element of $\operatorname{im}\big(f\restriction_{f^{-1}(B)}\big)$ is $f(x)$ with $f(x) \in B$, so it lies in $B \cap \operatorname{im} f$. Conversely, if $y \in B \cap \operatorname{im} f$, write $y = f(x)$; then $x \in f^{-1}(B)$ and $y \in \operatorname{im}\big(f\restriction_{f^{-1}(B)}\big)$. If f is surjective, then $\operatorname{im} f = Y$ and $B \cap \operatorname{im} f = B$.□

The hypotheses in (b), (c), and (d) cannot be dropped. For $f(x) = x^2$, the sets $A = \{-1\}$ and $A' = \{1\}$ are disjoint, so $\operatorname{im}(f\restriction_{A\cap A'}) = \varnothing$, while $\operatorname{im}(f\restriction_A) \cap \operatorname{im}(f\restriction_{A'}) = \{1\}$; Example A.1.4 does the same for (c) and (d). Exercise A.1.24 shows that injectivity is also necessary for equality in (b).

A.1.3 Composition and inverses

Definition A.1.6 (Composition). For $f : X \to Y$ and $g : Y \to Z$, the **composition** $g \circ f : X \to Z$ is the function $(g \circ f)(x) = g(f(x))$.

Composition is defined only when the codomain of f is the domain of g, and it is read right to left: $g \circ f$ applies f first. Even when both $g \circ f$ and $f \circ g$ are defined, they are usually different (Example 2.1.19 shows this for linear maps).

Proposition A.1.7 (Associativity and identities). Let $f : X \to Y$, $g : Y \to Z$, and $h : Z \to W$. Then $h \circ (g \circ f) = (h \circ g) \circ f$, and $f \circ \mathrm{id}_X = f = \mathrm{id}_Y \circ f$.

Proof. ROUTINE

Uses. Definition A.1.6 (Composition), Definition A.1.2 (Function)
Hint 1. Two functions $X \to W$ are equal when they agree at every $x \in X$.
Hint 2. Evaluate both sides at x and apply the definition of composition twice on each side.
Sketch. Both sides of the first identity send x to $h(g(f(x)))$. Both $f \circ \mathrm{id}_X$ and $\mathrm{id}_Y \circ f$ send x to $f(x)$.

Both sides are functions $X \to W$. For $x \in X$,

$$(h \circ (g \circ f))(x) = h((g \circ f)(x)) = h(g(f(x))) = (h \circ g)(f(x)) = ((h \circ g) \circ f)(x).$$

Similarly $(f \circ \mathrm{id}_X)(x) = f(x) = \mathrm{id}_Y(f(x)) = (\mathrm{id}_Y \circ f)(x)$. □

So we may write $h \circ g \circ f$ without parentheses. The next proposition is used constantly, and its last two parts are easy to get backwards. If $g \circ f$ is injective, the function applied *first* must be injective, since a collision $f(x) = f(x')$ would survive into $g(f(x)) = g(f(x'))$. If $g \circ f$ is surjective, the function applied *last* must be surjective, since every value of $g \circ f$ is a value of g.

Proposition A.1.8 (Composites, injectivity, and surjectivity). Let $f : X \to Y$ and $g : Y \to Z$.

(a) If f and g are injective, so is $g \circ f$. If f and g are surjective, so is $g \circ f$.

(b) If $g \circ f$ is injective, then f is injective.

(c) If $g \circ f$ is surjective, then g is surjective.

Proof. ROUTINE

Uses. Definition 2.6.1 (Injective), Definition 2.6.2 (Surjective), Definition A.1.6 (Composition)
Hint 1. For injectivity, start from $(g \circ f)(x) = (g \circ f)(x')$, or from $f(x) = f(x')$, and see what follows.
Hint 2. For (b), apply g to both sides of $f(x) = f(x')$. For (c), every value of $g \circ f$ is g of something.
Sketch. (a) Peel off g, then f: $g(f(x)) = g(f(x'))$ gives $f(x) = f(x')$, then $x = x'$. For surjectivity, lift z through g, then through f. (b) $f(x) = f(x')$ gives $g(f(x)) = g(f(x'))$, so $x = x'$. (c) $z = g(f(x))$ is a value of g.

(a) Suppose f and g are injective, and $g(f(x)) = g(f(x'))$. Injectivity of g gives $f(x) = f(x')$, and injectivity of f gives $x = x'$. Suppose f and g are surjective, and let $z \in Z$. Then $z = g(y)$ for some $y \in Y$, and $y = f(x)$ for some $x \in X$, so $z = (g \circ f)(x)$.

(b) If $f(x) = f(x')$, then $(g \circ f)(x) = g(f(x)) = g(f(x')) = (g \circ f)(x')$, so $x = x'$ because $g \circ f$ is injective.

(c) Let $z \in Z$. Since $g \circ f$ is surjective, $z = g(f(x))$ for some $x \in X$, so z is a value of g. □

Definition A.1.9 (One-sided inverses of a function). Let $f : X \to Y$. A function $g : Y \to X$ is a **left inverse** of f if $g \circ f = \mathrm{id}_X$, and a **right inverse** of f if $f \circ g = \mathrm{id}_Y$.

Definition A.1.10 (Inverse function). A function $g : Y \to X$ is an **inverse** of $f : X \to Y$ if it is both a left and a right inverse of f, that is, $g \circ f = \mathrm{id}_X$ and $f \circ g = \mathrm{id}_Y$. If f has an inverse, f is **invertible**.

These are Definition 2.5.1, Definition 2.5.2 and Definition 2.5.12 without linearity. The definitions in Section 2.5 ask for more: there, a left inverse of a linear map must itself be linear. Remark 2.5.8 explains why that matters for one-sided inverses, and Proposition 2.7.7 shows that it does not matter for two-sided ones.

Example A.1.11 (The successor function). Let $s : \mathbb{N} \to \mathbb{N}$, $s(n) = n + 1$. For any $c \in \mathbb{N}$, the function

$$g_c(n) = \begin{cases} n - 1 & \text{if } n \geq 1 \\ c & \text{if } n = 0 \end{cases}$$

satisfies $g_c(s(n)) = n$ for all n, so every g_c is a left inverse of s. The value at 0 is free because 0 is not a value of s. On the other hand, s has no right inverse: $s(g(0)) = 0$ is impossible for every function g, since $0 \notin \operatorname{im} s$. Multiplication by x on $F[x]$ (Example 2.6.4(e)) is the linear version of s: it shifts coefficients up by one place.

Theorem A.1.12 (One-sided inverses of functions). Let $f : X \to Y$.

(a) If f has a left inverse, then f is injective. Conversely, if f is injective and $X \neq \emptyset$, then f has a left inverse.

(b) f has a right inverse if and only if f is surjective.

Intuition. A left inverse g must send each value $f(x)$ back to x. This is possible exactly when no value comes from two different inputs, and then g is forced on $\operatorname{im} f$ and free elsewhere, which is where $X \neq \emptyset$ is needed: g needs somewhere to send the points outside $\operatorname{im} f$. A right inverse must choose, for each $y \in Y$, some preimage of y. This is possible exactly when every y has one, but there may be many, and g chooses one in each fiber.

Proof. ROUTINE

Uses. Definition A.1.9 (One-sided inverses of a function), Definition 2.6.1 (Injective), Definition 2.6.2 (Surjective), Remark A.1.13 (The axiom of choice)
Techniques. Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. The two "if" directions are one line each: apply g to $f(x) = f(x')$, or apply f to $g(y)$.
Hint 2. For the converse in (a), define g on $\operatorname{im} f$ by sending $f(x)$ to x. Why is this a function there? What should g do off $\operatorname{im} f$?
Hint 3. For the converse in (b), each fiber $f^{-1}(y)$ is nonempty. Let $g(y)$ be an element of it.
Sketch. If $g \circ f = \mathrm{id}_X$, then $f(x) = f(x')$ gives $x = g(f(x)) = g(f(x')) = x'$. If f is injective, each $y \in \operatorname{im} f$ has a unique preimage; send it there, and send every $y \notin \operatorname{im} f$ to a fixed $x_0 \in X$. If $f \circ g = \mathrm{id}_Y$, then $y = f(g(y))$ is a value. If f is surjective, choose $g(y) \in f^{-1}(y)$ for each y; then $f(g(y)) = y$.

(a) Suppose $g \circ f = \mathrm{id}_X$, and $f(x) = f(x')$. Then $x = g(f(x)) = g(f(x')) = x'$, so f is injective.

Conversely, suppose f is injective, and fix some $x_0 \in X$. Each $y \in \operatorname{im} f$ has exactly one preimage, which we call x_y. Define $g : Y \to X$ by $g(y) = x_y$ if $y \in \operatorname{im} f$ and $g(y) = x_0$ otherwise. For every $x \in X$, x is the preimage of $f(x) \in \operatorname{im} f$, so $g(f(x)) = x$. Hence $g \circ f = \mathrm{id}_X$.

(b) If $f \circ g = \mathrm{id}_Y$, then every $y \in Y$ equals $f(g(y))$, so f is surjective. Conversely, suppose f is surjective. Then every fiber $f^{-1}(y)$ is nonempty, and we let $g(y)$ be an element of $f^{-1}(y)$ for each $y \in Y$ (Remark A.1.13). Then $f(g(y)) = y$ for all y, so $f \circ g = \mathrm{id}_Y$. □

Remark A.1.13 (The axiom of choice). The last step of the proof chooses an element of every fiber at once. When Y is finite, these are finitely many choices, and induction on $|Y|$ makes the construction precise. In general, the step is an instance of the **axiom of choice**: for every family of nonempty sets $(S_i)_{i \in I}$ there is a

function c on I with $c(i) \in S_i$ for every i. Conversely, the axiom of choice follows from (b): given nonempty sets S_i, the map $(i, s) \mapsto i$ from the set of pairs $\{(i, s) \mid i \in I, s \in S_i\}$ to I is surjective, and if g is a right inverse of it, then $c(i) =$ the second coordinate of $g(i)$ is a choice function. So "every surjection has a right inverse" is the axiom of choice in another form. The left inverses in (a) need no choice, because g is forced on $\operatorname{im} f$ and constant elsewhere.

The axiom is part of the standard foundations (ZFC), and we use it freely. Its most useful form for linear algebra is Zorn's lemma (Section A.4), which shows that every vector space has a basis (Section 15.1).

When f is a bijection, neither half of the construction involves a choice, and the one-sided inverses merge.

Theorem A.1.14 (Bijections and inverses). Let $f : X \to Y$.

(a) If f has a left inverse g and a right inverse h, then $g = h$. In particular, an inverse of f, if it exists, is unique. We denote it f^{-1}.

(b) f is invertible if and only if f is bijective. In that case $f^{-1}(y)$ is the unique preimage of y, and f^{-1} is bijective with $\left(f^{-1}\right)^{-1} = f$.

(c) If $f : X \to Y$ and $g : Y \to Z$ are bijective, then so is $g \circ f$, and $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$.

Proof. ROUTINE

Uses. Proposition A.1.7 (Associativity and identities), Theorem A.1.12 (One-sided inverses of functions), Proposition A.1.8 (Composites, injectivity, and surjectivity), Definition A.1.10 (Inverse function)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. For (a), evaluate $g \circ f \circ h$ in two ways, using associativity.
Hint 2. For (b), "$\Rightarrow$" is Theorem A.1.12. For "$\Leftarrow$", send each y to its unique preimage; no choice and no x_0 is needed.
Hint 3. For (c), guess the inverse and check both composites.
Sketch. $g = g \circ (f \circ h) = (g \circ f) \circ h = h$. An invertible f has one-sided inverses on both sides, so it is injective and surjective; a bijective f is inverted by "the unique preimage". The equations $f^{-1} \circ f = \mathrm{id}$, $f \circ f^{-1} = \mathrm{id}$ say that f is an inverse of f^{-1}. For (c), $f^{-1} \circ g^{-1}$ is an inverse of $g \circ f$ by associativity.

(a) By Proposition A.1.7,

$$g = g \circ \mathrm{id}_Y = g \circ (f \circ h) = (g \circ f) \circ h = \mathrm{id}_X \circ h = h.$$

If g and h are both inverses of f, then g is a left inverse and h is a right inverse, so $g = h$.

(b) If f is invertible, it has a left and a right inverse, so it is injective and surjective by Theorem A.1.12. Conversely, if f is bijective, every $y \in Y$ has exactly one preimage x_y. Let $g(y) = x_y$. Then $f(g(y)) = y$, and $g(f(x)) = x$ because x is the preimage of $f(x)$. So g is an inverse of f, and by (a) it is the only one. Finally, the equations $f^{-1} \circ f = \mathrm{id}_X$ and $f \circ f^{-1} = \mathrm{id}_Y$ say that f is an inverse of f^{-1}. So f^{-1} is invertible, hence bijective, and $\left(f^{-1}\right)^{-1} = f$ by (a).

(c) By Proposition A.1.7,

$$\left(f^{-1} \circ g^{-1}\right) \circ (g \circ f) = f^{-1} \circ \left(g^{-1} \circ g\right) \circ f = f^{-1} \circ f = \mathrm{id}_X,$$

and similarly $(g \circ f) \circ \left(f^{-1} \circ g^{-1}\right) = \mathrm{id}_Z$. So $g \circ f$ is invertible with the stated inverse, and bijective by (b).□

For a bijection f and $B \subseteq Y$, the preimage $f^{-1}(B)$ of Definition A.1.3 equals the image $\operatorname{im}\left(f^{-1}\restriction_B\right)$ of B under the inverse function, so the two meanings of $f^{-1}(B)$ agree whenever both make sense.

Exercise A.1.15. ROUTINE Prove or disprove: if $f : X \to Y$ has exactly one left inverse, then f is bijective.

Solution on page 1669

A.1.4 Finite sets and counting

A finite set is one whose elements can be listed as $x_1, \dots, x_n$ without repetition, which is a bijection $[n] \to X$. That the number n does not depend on the listing is a theorem, and the same theorem is behind every counting argument in the book.

Definition A.1.16 (Finite set and cardinality). A set X is **finite** with n **elements** if there is a bijection $[n] \to X$ for some integer $n \geq 0$. We then write $|X| = n$, the **cardinality** of X. A set that is not finite is **infinite**.

Theorem A.1.17 (Pigeonhole principle). If $m > n \geq 0$, there is no injective function $[m] \to [n]$.

Intuition. We induct on the number n of boxes. Given an injection $[m] \to [n]$, we want an injection $[m-1] \to [n-1]$, so we delete the last box and one object. The object to delete is the one in box n, if any; after swapping it into position m, the rest of the objects avoid box n.

Proof. STANDARD

Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering), Proposition A.1.8 (Composites, injectivity, and surjectivity)
Hint 1. Induct on n. For $n = 0$, is there any function $[m] \to \emptyset$ with $m \geq 1$?
Hint 2. Given an injection $f : [m] \to [n]$, you want an injection $[m-1] \to [n-1]$. If $n \notin \operatorname{im} f$, restrict f to $[m-1]$.
Hint 3. If $f(k) = n$, first compose f with the bijection of $[m]$ that swaps k and m. The new function sends m to n and, being injective, sends nothing else there.
Sketch. Induction on n. For $n = 0$ there is no function $[m] \to \emptyset$. For the step, let $f : [m] \to [n]$ be injective. Compose with the swap of k and m, where $f(k) = n$ (if $n \in \operatorname{im} f$), so that only m can map to n. Then f restricted to $[m-1]$ is an injection into $[n-1]$ with $m - 1 > n - 1$, which contradicts the induction hypothesis.

We use induction on n (Theorem A.2.1). For $n = 0$ and $m \geq 1$ there is no function $[m] \to [0] = \emptyset$ at all, since $1 \in [m]$ would need a value.

Let $n \geq 1$, suppose that there is no injection $[m'] \to [n-1]$ whenever $m' > n - 1$, and suppose for contradiction that $f : [m] \to [n]$ is injective with $m > n$. We first arrange that only m can map to n. If $n = f(k)$ for some $k \in [m]$, let $\tau : [m] \to [m]$ swap k and m and fix everything else. Then τ is a bijection, so $f' = f \circ \tau$ is injective (Proposition A.1.8), and $f'(m) = f(k) = n$. If $n \notin \operatorname{im} f$, let $f' = f$. In either case, f' is injective and no $i \in [m-1]$ has $f'(i) = n$: in the first case because $f'(i) = n = f'(m)$ would force $i = m$, and in the second because n is not a value at all. So the restriction of f' to $[m-1]$ is an injective function $[m-1] \to [n-1]$. Since $m - 1 > n - 1$, this contradicts the induction hypothesis. □

Corollary A.1.18 (Cardinality is well defined). Let X and Y be finite.

(a) If there are bijections $[m] \to X$ and $[n] \to X$, then $m = n$. So $|X|$ is well defined.

(b) If there is an injection $X \to Y$, then $|X| \leq |Y|$. There is a bijection $X \to Y$ if and only if $|X| = |Y|$.

Proof. ROUTINE

Uses. Theorem A.1.17 (Pigeonhole principle), Theorem A.1.14 (Bijections and inverses), Proposition A.1.8 (Composites, injectivity, and surjectivity)
Hint 1. Transport the question to $[m]$ and $[n]$ by composing with the given bijections and their inverses.
Hint 2. In (a), $\psi^{-1} \circ \varphi : [m] \to [n]$ is a bijection; apply Theorem A.1.17 in both directions.
Sketch. With bijections $\varphi : [m] \to X$ and $\psi : [n] \to Y$, an injection $f : X \to Y$ gives the injection $\psi^{-1} \circ f \circ \varphi : [m] \to [n]$, so $m \leq n$ by pigeonhole. Part (a) is the case $Y = X$, $f = \mathrm{id}_X$, applied in both directions. A bijection $X \to Y$ exists when $m = n$ by composing $\psi \circ \varphi^{-1}$.

Let $\varphi : [m] \to X$ and $\psi : [n] \to Y$ be bijections. If $f : X \to Y$ is injective, then $\psi^{-1} \circ f \circ \varphi : [m] \to [n]$ is injective by Proposition A.1.8, since bijections are injective (Theorem A.1.14). By Theorem A.1.17, $m \leq n$.

(a) Take $Y = X$ and $f = \mathrm{id}_X$: with two bijections $\varphi : [m] \to X$ and $\psi : [n] \to X$, the argument above gives $m \leq n$, and exchanging their roles gives $n \leq m$.

(b) The first claim is the argument above. If $f : X \to Y$ is a bijection, it is injective, and so is f^{-1}, which gives $|X| \le |Y| \le |X|$. Conversely, if $m = n$, then $\psi \circ \varphi^{-1} : X \to Y$ is a bijection by Theorem A.1.14(c). □

Proposition A.1.19 (Subsets of finite sets). Let X be finite and $A \subseteq X$. Then A is finite and $|A| \le |X|$, with equality if and only if $A = X$.

Proof. STANDARD

Uses. Corollary A.1.18 (Cardinality is well defined), Theorem A.2.1 (Induction, strong induction, and well-ordering), Definition A.1.16 (Finite set and cardinality)
Hint 1. A bijection $[n] \to X$ carries subsets of $[n]$ to subsets of X of the same size, so it suffices to treat $X = [n]$.
Hint 2. Induct on n. For $A \subseteq [n]$, apply the hypothesis to $A \cap [n-1]$ and then ask whether $n \in A$.
Sketch. Reduce to $X = [n]$ via a bijection $\varphi : [n] \to X$, replacing A by its preimage. Induct on n. Write $A' = A \cap [n-1]$, with $|A'| = k \le n-1$ and equality only for $A' = [n-1]$. If $n \notin A$, then $A = A'$ and $|A| < n$. If $n \in A$, extend a bijection $[k] \to A'$ by $k+1 \mapsto n$ to get $|A| = k+1 \le n$, with equality only if $A' = [n-1]$, that is, $A = [n]$.

Let $\varphi : [n] \to X$ be a bijection and $A_0 = \varphi^{-1}(A) \subseteq [n]$. Then φ restricts to a bijection $A_0 \to A$, so A is finite with $|A| = |A_0|$ once A_0 is, and $A = X$ if and only if $A_0 = [n]$. So we may assume $X = [n]$, and we induct on n. If $n = 0$, then $A = \varnothing = [0]$.

Let $n \ge 1$ and $A \subseteq [n]$. By the induction hypothesis, $A' = A \cap [n-1]$ is finite with $k = |A'| \le n-1$, and $k = n-1$ only if $A' = [n-1]$. If $n \notin A$, then $A = A'$, so A is finite with $|A| \le n-1 < n$. If $n \in A$, then $A = A' \cup \{n\}$ with $n \notin A'$. A bijection $[k] \to A'$, extended by $k+1 \mapsto n$, is a bijection $[k+1] \to A$, so $|A| = k+1 \le n$. Equality holds if and only if $k = n-1$, that is, $A' = [n-1]$, and since $n \in A$ this means $A = [n]$. □

For finite sets of the same size, half of bijectivity is free. This is the set-theoretic model for Corollary 4.2.18, where an operator on a finite-dimensional space is injective if and only if it is surjective; there, dimension plays the role of cardinality.

Theorem A.1.20 (Injective, surjective, and bijective for finite sets). Let X and Y be finite with $|X| = |Y|$, and let $f : X \to Y$. Then f is injective if and only if f is surjective, and hence if and only if f is bijective.

Proof. STANDARD

Uses. Proposition A.1.19 (Subsets of finite sets), Corollary A.1.18 (Cardinality is well defined), Theorem A.1.12 (One-sided inverses of functions), Theorem A.1.14 (Bijections and inverses)
Hint 1. If f is injective, then f is a bijection from X onto $\operatorname{im} f$. What does that say about $|\operatorname{im} f|$?
Hint 2. Use Proposition A.1.19 to compare $\operatorname{im} f$ with Y.
Hint 3. For the converse, a surjection has a right inverse $g : Y \to X$, which is injective. Apply the first half to g.
Sketch. If f is injective, $f : X \to \operatorname{im} f$ is a bijection, so $|\operatorname{im} f| = |X| = |Y|$, and $\operatorname{im} f = Y$ by Proposition A.1.19. If f is surjective, it has a right inverse g, which is injective (it has the left inverse f), hence bijective by the first half; then $f = f \circ g \circ g^{-1} = g^{-1}$ is bijective.

Suppose f is injective. Then f, viewed as a function $X \to \operatorname{im} f$, is a bijection, so $|\operatorname{im} f| = |X| = |Y|$ by Corollary A.1.18. Since $\operatorname{im} f \subseteq Y$, Proposition A.1.19 gives $\operatorname{im} f = Y$, and f is surjective.

Suppose f is surjective. By Theorem A.1.12(b) it has a right inverse $g : Y \to X$. Since $f \circ g = \mathrm{id}_Y$, f is a left inverse of g, so g is injective by Theorem A.1.12(a). As $|Y| = |X|$, the first half applied to g shows that g is bijective. Then

$$f = f \circ \left(g \circ g^{-1}\right) = (f \circ g) \circ g^{-1} = g^{-1},$$

so f is bijective by Theorem A.1.14(b). (Here Y is finite, so the choice of g needs no axiom of choice.) □

The successor function $s(n) = n + 1$ on $\mathbb{N}$ (Example A.1.11) is injective and not surjective, so Theorem A.1.20 fails for infinite sets. It is one way of saying that $\mathbb{N}$ is infinite.

Technique A.1.21 (Pigeonhole). If a function goes from a finite set to a smaller one, two inputs share a value (Theorem A.1.17). In practice: more than n objects in n boxes put two objects in one box. The skill

is in choosing the boxes, which are often the values of some quantity that can take only n values, such as a remainder mod n or an element of a finite field or of a finite set of matrices.

Reach for it when a statement claims that some coincidence or repetition must occur, but gives no way to find it. A typical consequence is that a sequence in a finite set repeats, so an invertible operation applied repeatedly eventually returns to the start. The canonical example is Example A.1.22; the cycle decomposition of permutations (Section 5.2) uses the same idea.
Used in. Exercise A.1.29.

Example A.1.22 (Powers of a matrix over a finite field). Let F be a finite field with q elements and $A \in F^{n\times n}$ invertible. We show that $A^k = I_n$ for some k with $1 \le k \le q^{n^2}$.

The set $F^{n\times n}$ has $N = q^{n^2}$ elements (Exercise A.1.28). The function $i \mapsto A^i$ from $\{0, 1, \dots, N\}$, a set of $N+1$ elements, to $F^{n\times n}$ is not injective by Theorem A.1.17 (composed with bijections to $[N+1]$ and $[N]$). So $A^i = A^j$ for some $0 \le i < j \le N$. Multiplying by $\left(A^{-1}\right)^i$ gives $I_n = A^{j-i}$, and $k = j - i$ satisfies $1 \le k \le N$.

For example, over $\mathbb{F}_2$ the matrix $A = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$ has $A^2 = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$ and $A^3 = I_2$, much sooner than the bound $2^4 = 16$. Over $\mathbb{R}$ the conclusion fails: $\begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}^k \neq I_2$ for every $k \ge 1$.

Exercises

Exercise A.1.23. ROUTINE Let $f : \mathbb{R} \to \mathbb{R}$, $f(x) = x^2 - 2x$. Compute $\operatorname{im}\left(f\restriction_{[0,3]}\right)$, $f^{-1}([-1, 0])$, and $f^{-1}\left(\operatorname{im}\left(f\restriction_{[0,1]}\right)\right)$. Which part of Proposition A.1.5 does the last answer illustrate?

Solution on page 1670

Exercise A.1.24. STANDARD Let $f : X \to Y$. Show that f is injective if and only if $\operatorname{im}(f\restriction_{A\cap A'}) = \operatorname{im}(f\restriction_A) \cap \operatorname{im}(f\restriction_{A'})$ for all subsets $A, A' \subseteq X$.

Solution on page 1670

Exercise A.1.25. ROUTINE Let $f : X \to Y$ and $g : Y \to Z$. Prove or disprove each claim.

(a) If $g \circ f$ is injective, then g is injective.

(b) If $g \circ f$ is bijective, then f is injective and g is surjective.

(c) If $g \circ f$ is bijective, then f and g are bijective.

Solution on page 1670

Exercise A.1.26. STANDARD Let $f : X \to Y$. Show that f is injective if and only if it can be cancelled on the left: for every set W and all functions $g, h : W \to X$, $f \circ g = f \circ h$ implies $g = h$. State and prove the analogous characterization of surjectivity, with cancellation on the right.

Solution on page 1670

Exercise A.1.27. STANDARD

(a) Let X and Y be finite with $|X| = m \ge 1$ and $|Y| = n$, and let $f : X \to Y$ be injective. How many left inverses does f have?

(b) Let $f : X \to Y$ be surjective with $Y = \{y_1, \dots, y_k\}$ finite and every fiber finite. Show that f has exactly $\left|f^{-1}(y_1)\right| \cdots \left|f^{-1}(y_k)\right|$ right inverses.

(c) Find the number of left inverses of $f : [2] \to [4]$, $f(i) = i$, and the number of right inverses of $p : [4] \to [2]$, $p(i) = 1$ for i odd and $p(i) = 2$ for i even.

Solution on page 1671

Exercise A.1.28. STANDARD For sets X and Y, let Y^X be the set of all functions $X \to Y$.

(a) Show by induction on $|X|$ that if X and Y are finite, then $\left|Y^X\right| = |Y|^{|X|}$ (with $0^0 = 1$).

(b) Construct a bijection $P(X) \to \{0,1\}^X$, and deduce that $|P(X)| = 2^{|X|}$.

(c) Deduce that $|F^n| = q^n$ and $|F^{m\times n}| = q^{mn}$ for a field F with q elements.

Solution on page 1671

Exercise A.1.29. STANDARD Let $a_1, \ldots, a_n$ be integers, where $n \geq 1$. Show that some nonempty block of consecutive terms $a_{i+1} + a_{i+2} + \cdots + a_j$, with $0 \leq i < j \leq n$, is divisible by n.

Solution on page 1672

Exercise A.1.30. HARD BEYOND 21-242 Let X be any set. Show that there is no surjective function $X \to P(X)$. In particular, there is no bijection $\mathbb{N} \to P(\mathbb{N})$.

Solution on page 1672

A.2 Induction and well-ordering

Most proofs about "all n" in this book are inductions, and the measure n is rarely the obvious one: it is the length of a list, the size of a matrix, the degree of a polynomial, the number of points a permutation moves, or the dimension of a space. This section states the three equivalent forms of induction and proves that they are equivalent, then discusses how induction is set up in linear algebra, where the induction hypothesis is usually applied to a different space from the one we started with.

A.2.1 Three forms of induction

Theorem A.2.1 (Induction, strong induction, and well-ordering). For each integer $n \geq 0$ let $P(n)$ be a statement. The following three principles are equivalent.

(I) (*Induction.*) If $P(0)$ holds, and $P(n)$ implies $P(n+1)$ for every $n \geq 0$, then $P(n)$ holds for every $n \geq 0$.

(II) (*Strong induction.*) If, for every $n \geq 0$, the truth of $P(k)$ for all $0 \leq k < n$ implies $P(n)$, then $P(n)$ holds for every $n \geq 0$.

(III) (*Well-ordering.*) Every nonempty subset of $\mathbb{N}$ has a least element.

"Equivalent" means that each principle can be derived from each other one, using only the arithmetic and order of the integers (every $n \geq 1$ is $k+1$ for some $k \geq 0$, and $k < n+1$ if and only if $k \leq n$). One of them has to be taken as an axiom about $\mathbb{N}$; the usual choice is (I), one of Peano's axioms for the natural numbers. So all three are true, and we use whichever is convenient. Technique 5.2.12 describes when strong induction and well-ordering are the convenient forms. Here we prove that they are no stronger than ordinary induction.

Intuition. Strong induction looks stronger than induction, because its hypothesis assumes more. The trick in (I) $\Rightarrow$ (II) is to induct on the statement "$P(0), \ldots, P(n)$ all hold", whose single predecessor is the whole history. Well-ordering is strong induction in contrapositive form: a set with no least element cannot contain 0, then cannot contain 1, and so on, and strong induction makes "and so on" precise.

Proof. STANDARD

Uses. the order of the integers

Techniques. Proving TFAE (Technique 2.7.1), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Prove (I) ⇒ (II) ⇒ (III) ⇒ (I). For the first, apply (I) to a different statement $Q(n)$ that packages $P(0), \dots, P(n)$ together.
Hint 2. For (II) ⇒ (III), take $S \subseteq \mathbb{N}$ with no least element and prove "$n \notin S$" for all n by strong induction.
Hint 3. For (III) ⇒ (I), look at the set of n for which $P(n)$ fails, and at its least element m. Why is $m \neq 0$, and what about $m-1$?
Sketch. (I) ⇒ (II): apply induction to $Q(n)$: "$P(k)$ for all $k \leq n$". (II) ⇒ (III): if S has no least element, then $n \notin S$ whenever no $k < n$ is in S (else n would be least), so $S = \emptyset$ by strong induction. (III) ⇒ (I): a least counterexample m is not 0, and $P(m-1)$ holds by minimality, so $P(m)$ holds, a contradiction.

We prove (I) ⇒ (II) ⇒ (III) ⇒ (I).

(I) ⇒ (II). Assume the hypothesis of (II), and let $Q(n)$ be the statement "$P(k)$ holds for all $0 \leq k \leq n$". The hypothesis of (II) for $n = 0$ has an empty premise, since there is no k with $0 \leq k < 0$; so $P(0)$ holds, which is $Q(0)$. If $Q(n)$ holds, then $P(k)$ holds for all $k < n+1$, so the hypothesis of (II) gives $P(n+1)$, and $Q(n+1)$ follows. By (I), $Q(n)$ holds for all n, and in particular so does $P(n)$.

(II) ⇒ (III). Let $S \subseteq \mathbb{N}$ have no least element. We show by strong induction that $P(n)$: "$n \notin S$" holds for every n, so that $S = \emptyset$. Suppose $k \notin S$ for all $k < n$. If n were in S, then every element $s \in S$ would satisfy $s \geq n$ (as $s < n$ would give $s \notin S$), so n would be the least element of S. Hence $n \notin S$. By (II), $S = \emptyset$, which is the contrapositive of (III).

(III) ⇒ (I). Assume the hypotheses of (I), and suppose for contradiction that $S = \{n \in \mathbb{N} \mid P(n) \text{ fails}\}$ is nonempty. By (III) it has a least element m. Since $P(0)$ holds, $m \geq 1$, so $m - 1 \in \mathbb{N}$, and $m - 1 \notin S$ because $m - 1 < m$. So $P(m-1)$ holds, and the hypothesis of (I) gives $P(m)$, contradicting $m \in S$. □

Induction can start at any integer n_0: to prove $P(n)$ for all $n \geq n_0$, apply Theorem A.2.1 to the statements $P(n_0 + n)$, $n \geq 0$. Likewise, every nonempty set of integers that are all $\geq n_0$ has a least element.

Example A.2.2 (A geometric sum of matrices). For $A \in F^{n\times n}$ and every $k \geq 1$,

$$(I - A)\left(I + A + A^2 + \cdots + A^{k-1}\right) = I - A^k.$$

For $k = 1$ both sides are $I - A$. If the identity holds for k, then by distributivity

$$\begin{aligned}(I - A)\left(I + A + \cdots + A^{k}\right) &= (I - A)\left(I + A + \cdots + A^{k-1}\right) + (I - A)A^k \\ &= I - A^k + A^k - A^{k+1} = I - A^{k+1},\end{aligned}$$

so it holds for $k + 1$. In particular, if $A^k = 0$ for some k, then $I - A$ is invertible, with inverse $I + A + \cdots + A^{k-1}$ (the other product equals I by the same computation, or by Theorem 3.5.23).

Example A.2.3 (Factorization into primes). Every integer $n \geq 2$ is a product of primes (a prime counts as a product of one prime). We use strong induction, starting at 2. Let $n \geq 2$ and suppose every k with $2 \leq k < n$ is a product of primes. If n is prime, we are done. Otherwise $n = ab$ with $2 \leq a, b < n$, and a and b are products of primes by hypothesis, hence so is n.

Ordinary induction would be awkward here: the factors a and b are smaller than n, but we cannot say by how much, so knowing $P(n-1)$ alone does not help.

The well-ordering principle is the form to use when an argument begins "take the least n such that …". The book needs it once in an essential way, already in Definition 1.1.19: dividing integers with remainder.

Proposition A.2.4 (Division with remainder). Let $n \geq 1$ and $x \in \mathbb{Z}$. There are unique integers q and r with $x = qn + r$ and $0 \leq r < n$.

Proof. ROUTINE
Uses. Theorem A.2.1 (Induction, strong induction, and well-ordering)

Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9), Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Among the numbers $x - qn$ with $q \in \mathbb{Z}$, look at the nonnegative ones, and take the least.
Hint 2. Why is the set of nonnegative values of $x - qn$ nonempty? Try $q = -|x|$.
Hint 3. If the least one, $r = x - qn$, satisfied $r \geq n$, then $x - (q+1)n$ would be smaller. For uniqueness, if $qn + r = q'n + r'$, then n divides $r - r'$, and $|r - r'| < n$.
Sketch. Let $S = \{x - qn \mid q \in \mathbb{Z}\} \cap \mathbb{N}$. It contains $x + |x|n \geq 0$, so it has a least element $r = x - qn$. If $r \geq n$, then $r - n \in S$ is smaller, so $0 \leq r < n$. If $qn + r = q'n + r'$ with $0 \leq r, r' < n$, then $(q - q')n = r' - r$ has absolute value less than n, so it is 0.

Existence. Let $S = \{x - qn \mid q \in \mathbb{Z} \text{ and } x - qn \geq 0\} \subseteq \mathbb{N}$. Taking $q = -|x|$ gives $x + |x|n \geq x + |x| \geq 0$, so S is nonempty, and by well-ordering (Theorem A.2.1(III)) it has a least element $r = x - qn$. Then $r \geq 0$. If $r \geq n$, then $x - (q+1)n = r - n \geq 0$ is an element of S smaller than r, which is impossible. So $0 \leq r < n$.

Uniqueness. If $x = qn + r = q'n + r'$ with $0 \leq r, r' < n$, then $(q - q')n = r' - r$, and $-n < r' - r < n$. A multiple of n strictly between $-n$ and n is 0, so $q = q'$ and $r = r'$. □

The remainder r is the number $x \bmod n$ of Definition 1.1.19. The polynomial version, Theorem 7.1.14, has the same shape: there the size of a remainder is its degree, and the proof uses strong induction on the degree.

A.2.2 Induction in linear algebra

An induction proof has three parts, and in linear algebra each of them needs a decision.

The first is the **measure**: the quantity n that the induction runs on. In this book it is the length of a list (Technique 1.6.9, as in Theorem 1.6.10 and Lemma 4.1.2), the number of summands in a direct sum (Technique 4.4.10), the size of a matrix (Technique 5.5.17, as in cofactor expansion), the number of points a permutation moves or the degree of a polynomial (Technique 5.2.12), and the dimension of a space (in Section 7.5 and Section 8.2). The right measure is one that a natural reduction step makes smaller.

The second is the **statement** $P(n)$, and here linear algebra has a characteristic feature. In an induction on dimension, the reduction step replaces V by a smaller space: an invariant subspace, a complement, or a quotient. So the induction hypothesis must apply to every space of smaller dimension, not just to subspaces of the original one, and $P(n)$ has to be quantified accordingly: "for every vector space V with $\dim V = n$ and every $T \in \mathrm{L}(V)$ with the stated properties, the conclusion holds". The hypothesis is then applied to some $T' \in \mathrm{L}(V')$ built from T, for instance the restriction of T to an invariant subspace (Definition 7.2.1). This T' must again be an operator on V', which is the point that Exercise A.2.13 gets wrong. Similarly, an induction on the length of a list proves a statement about every list of length n in every space, so that it can be applied to a shorter list after a vector has been removed or replaced.

The third is the **base case**, which is often $n = 0$ (the empty list, the zero space) or $n = 1$. The base case has to be checked (Exercise A.2.12), and the step from n to $n + 1$ must be valid for every n at or above the base case, including the smallest one. The classic false proof that any n objects are equal breaks exactly there: its step works for $n \geq 2$ but not from $n = 1$ to $n = 2$.

Sometimes the statement we want is too weak to prove by induction directly: the hypothesis $P(n)$ does not give enough to prove $P(n + 1)$. Then the fix is often to prove more.

Technique A.2.5 (Strengthen the induction hypothesis). If the induction step fails because $P(n)$ is too weak to imply $P(n + 1)$, replace $P(n)$ by a stronger statement $P'(n)$ that implies it and that does carry from n to $n + 1$. The stronger statement is harder to prove, but the hypothesis you get to use is stronger too, and often the step becomes easy.

Reach for it when an induction step needs information about the smaller case that $P(n)$ does not record. Typical strengthenings: replace a bound by a sharper one that depends on n; carry along an extra property

of the object being built, as Gram–Schmidt carries the equality of the spans of the first k inputs and outputs (Section 6.4); or prove a statement for all objects of size n rather than for one. The canonical example is Example A.2.6.
Used in. Exercise A.2.11.

Example A.2.6 (A bound that has to be sharpened). We show that $\sum_{k=1}^{n} 1/k^2 < 2$ for all $n \geq 1$. Induction on "$S_n = \sum_{k=1}^{n} 1/k^2 < 2$" fails: from $S_n < 2$ we only get $S_{n+1} < 2 + 1/(n+1)^2$. The trouble is that the hypothesis leaves no room for the next term. So we prove the stronger statement

$$S_n \leq 2 - \frac{1}{n} \quad \text{for all } n \geq 1.$$

For $n = 1$, $S_1 = 1 = 2 - 1$. If $S_n \leq 2 - 1/n$, then

$$S_{n+1} \leq 2 - \frac{1}{n} + \frac{1}{(n+1)^2} \leq 2 - \frac{1}{n} + \frac{1}{n(n+1)} = 2 - \frac{1}{n+1},$$

using $1/n - 1/(n+1) = 1/(n(n+1))$. Hence $S_n \leq 2 - 1/n < 2$ for every n.

Exercises

Exercise A.2.7. ROUTINE Let $\lambda \in F$ and $J = \begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix}$. Show that $J^n = \begin{pmatrix} \lambda^n & n\lambda^{n-1} \\ 0 & \lambda^n \end{pmatrix}$ for every $n \geq 1$, where $n\lambda^{n-1}$ means λ^{n-1} added to itself n times.

Solution on page 1672

Exercise A.2.8. STANDARD Let $A, B \in F^{n \times n}$ with $AB = BA$.

(a) Show that $A^k B = BA^k$ for all $k \geq 0$.

(b) Show that $(A+B)^m = \sum_{k=0}^{m} \binom{m}{k} A^k B^{m-k}$ for all $m \geq 0$.

(c) Show that (b) can fail for $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.

Solution on page 1673

Exercise A.2.9. STANDARD Show that every integer $n \geq 1$ can be written as a sum of distinct powers of 2, and that this representation is unique up to the order of the terms.

Solution on page 1673

Exercise A.2.10. STANDARD Let $S \subseteq \mathbb{Z}$ be a set with $S \neq \{0\}$ and $S \neq \emptyset$ that is closed under subtraction: $a - b \in S$ whenever $a, b \in S$. Show that S has a least positive element d, and that $S = d\mathbb{Z} = \{dk \mid k \in \mathbb{Z}\}$.

Solution on page 1673

Exercise A.2.11. HARD Show that for every $n \geq 1$,

$$\frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \leq \frac{1}{\sqrt{3n}}.$$

(Induction on this inequality as stated does not work.)

Solution on page 1674

Exercise A.2.12. ROUTINE Find the error in the following argument.

Claim: $n^2 + n + 1$ is even for every integer $n \geq 0$. *Proof:* Suppose $n^2 + n + 1$ is even. Then $(n+1)^2 + (n+1) + 1 = \left(n^2 + n + 1\right) + 2(n+1)$ is a sum of two even numbers, hence even. By induction, the claim holds for every n.

Solution on page 1674

Exercise A.2.13. STANDARD Find the error in the following argument.

Claim: Every operator on a nonzero finite-dimensional real vector space has an eigenvector. *Proof:* By induction on $n = \dim V \geq 1$. If $n = 1$, then $V = \operatorname{span}(\mathbf{v})$ for any $\mathbf{v} \neq \mathbf{0}$, and $T(\mathbf{v}) = \lambda \mathbf{v}$ for some $\lambda \in \mathbb{R}$, so $\mathbf{v}$ is an eigenvector. Suppose the claim holds in dimension n, and let $\dim V = n+1$ and $T \in \mathrm{L}(V)$. Pick a subspace W of V with $\dim W = n$. By the induction hypothesis, the restriction of T to W has an eigenvector $\mathbf{w} \in W$, so $T(\mathbf{w}) = \lambda \mathbf{w}$ and $\mathbf{w}$ is an eigenvector of T.

Solution on page 1674

A.3 Equivalence relations

Much of the book classifies objects up to some notion of sameness: matrices up to row operations (Section 3.2.4), vector spaces up to isomorphism and square matrices up to change of basis (Section 4.5), vectors up to an element of a subspace (Section 4.6). Each notion is an equivalence relation, and each one cuts its set into classes. This section sets up the general language: equivalence classes, quotient sets, functions on quotient sets, and invariants.

A.3.1 Equivalence relations

Definition A.3.1 (Equivalence relation). A **relation** on a set X is a subset $R \subseteq X \times X$; we write $x \sim y$ for $(x, y) \in R$. A relation $\sim$ is an **equivalence relation** if it is

- *reflexive*: $x \sim x$ for every $x \in X$;
- *symmetric*: if $x \sim y$, then $y \sim x$;
- *transitive*: if $x \sim y$ and $y \sim z$, then $x \sim z$.

Example A.3.2 (Equivalence relations).

(a) Equality on any set.

(b) Let $n \geq 1$. **Congruence modulo** n on $\mathbb{Z}$: $x \equiv y \pmod{n}$ if n divides $x - y$. It is reflexive since $n \mid 0$, symmetric since $n \mid x - y$ implies $n \mid y - x$, and transitive since $x - z = (x - y) + (y - z)$.

(c) Any function $f : X \to Y$ defines the relation $x \underset{f}{\sim} x'$ if $f(x) = f(x')$. It inherits the three properties from equality in Y. For instance, "$A \sim B$ if $\operatorname{rank} A = \operatorname{rank} B$" is an equivalence relation on $F^{m \times n}$.

(d) Row equivalence of matrices (Proposition 3.2.22), similarity of square matrices (Proposition 4.5.24), isomorphism of vector spaces (Proposition 4.5.4), and congruence modulo a subspace U, $\mathbf{v} - \mathbf{w} \in U$ (Remark 4.6.16).

Each axiom can fail on its own, and the failures of transitivity are the instructive ones.

Non-example A.3.3 (Relations that are not equivalence relations).

(a) $\leq$ on $\mathbb{R}$ is reflexive and transitive but not symmetric.

(b) On a vector space V, let $\mathbf{v} \sim \mathbf{w}$ if one of $\mathbf{v}, \mathbf{w}$ is a scalar multiple of the other. This is reflexive and symmetric, but not transitive when $\dim V \geq 2$: for independent $\mathbf{v}, \mathbf{w}$ we have $\mathbf{v} \sim \mathbf{0}$ and $\mathbf{0} \sim \mathbf{w}$, since $\mathbf{0} = 0\mathbf{v} = 0\mathbf{w}$, but not $\mathbf{v} \sim \mathbf{w}$. On $V \setminus \{\mathbf{0}\}$, the relation becomes "$\mathbf{w} = c\mathbf{v}$ for some $c \neq 0$", which is an equivalence relation (Exercise A.3.16).

(c) On $F^{n\times n}$, let $A \sim B$ if $AB = BA$. This is reflexive and symmetric, but every A commutes with I, so transitivity would make all matrices commute, which fails for $n \geq 2$ (Example 2.1.19).

(d) On $\mathbb{R}$, let $x \sim y$ if $|x - y| \leq 1$. Then $0 \sim 1 \sim 2$ but not $0 \sim 2$. "Close to" is rarely transitive.

A.3.2 Classes and partitions

Definition A.3.4 (Equivalence class). Let $\sim$ be an equivalence relation on X. The **equivalence class** of $x \in X$ is

$$[x] = \{y \in X \mid x \sim y\}.$$

Any element of $[x]$ is called a **representative** of the class.

For congruence modulo n, the class of x is $x + n\mathbb{Z} = \{x + nk \mid k \in \mathbb{Z}\}$. For congruence modulo a subspace U, it is the coset $\mathbf{v} + U$ (Lemma 4.6.14). For $\underset{f}{\sim}$, it is the fiber $f^{-1}(f(x))$ (Definition A.1.3). The next lemma says that classes behave like cosets: two classes are equal or disjoint, and any element of a class can name it.

Lemma A.3.5 (Equal classes). Let $\sim$ be an equivalence relation on X and $x, y \in X$. The following are equivalent:

(i) $x \sim y$;
(ii) $[x] = [y]$;
(iii) $[x] \cap [y] \neq \emptyset$.

Proof. ROUTINE

Uses. Definition A.3.1 (Equivalence relation), Definition A.3.4 (Equivalence class)
Techniques. Proving TFAE (Technique 2.7.1), Double containment (Technique 1.3.14)
Hint 1. Prove (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (i). Which axiom does each step use?
Hint 2. For (i) $\Rightarrow$ (ii), take $z \in [y]$ and chain $x \sim y \sim z$. For (iii) $\Rightarrow$ (i), take z in both classes and chain $x \sim z$ with $z \sim y$.
Sketch. (i) $\Rightarrow$ (ii): if $x \sim y$ and $y \sim z$, then $x \sim z$, so $[y] \subseteq [x]$; by symmetry $[x] \subseteq [y]$. (ii) $\Rightarrow$ (iii): $x \in [x]$ by reflexivity. (iii) $\Rightarrow$ (i): if $x \sim z$ and $y \sim z$, then $x \sim z \sim y$.

(i) $\Rightarrow$ (ii). Suppose $x \sim y$. If $z \in [y]$, then $y \sim z$, so $x \sim z$ by transitivity, and $z \in [x]$. Thus $[y] \subseteq [x]$. By symmetry $y \sim x$, and the same argument gives $[x] \subseteq [y]$.

(ii) $\Rightarrow$ (iii). By reflexivity $x \in [x] = [y]$, so $x \in [x] \cap [y]$.

(iii) $\Rightarrow$ (i). Let $z \in [x] \cap [y]$, so $x \sim z$ and $y \sim z$. By symmetry $z \sim y$, and by transitivity $x \sim y$. □

Definition A.3.6 (Partition). A **partition** of a set X is a set Π of nonempty subsets of X, called **blocks**, such that every element of X lies in exactly one block.

Theorem A.3.7 (Equivalence relations are partitions). Let X be a set.

(a) If $\sim$ is an equivalence relation on X, its equivalence classes form a partition of X.

(b) If Π is a partition of X, the relation "$x \sim y$ if x and y lie in the same block" is an equivalence relation, and its classes are the blocks of Π.

(c) These two constructions are inverse to each other. So equivalence relations on X correspond bijectively to partitions of X.

Proof. ROUTINE

> *Uses.* Lemma A.3.5 (Equal classes), Definition A.3.6 (Partition), Definition A.3.1 (Equivalence relation)
> *Hint 1.* For (a), every class is nonempty and $x \in [x]$. Two classes that share an element are equal by Lemma A.3.5.
> *Hint 2.* For (b), each axiom follows from "exactly one block". For the classes, the class of x is the block containing x.
> *Hint 3.* For (c), start from $\sim$, pass to its classes, and then to "same class"; by Lemma A.3.5, x and y are in the same class iff $x \sim y$.
> *Sketch.* (a) $x \in [x]$, and if $x \in [y] \cap [z]$, then $[y] = [x] = [z]$. (b) Same block is reflexive, symmetric and transitive because each element is in exactly one block, and the class of x is its block. (c) Partition then relation: x, y in the same class iff $x \sim y$, which recovers $\sim$. Relation then partition: by (b) the classes are the blocks.

(a) Each class $[x]$ is nonempty, since $x \in [x]$ by reflexivity, so every element lies in at least one class. If $x \in [y]$ and $x \in [z]$, then $[y] \cap [z] \neq \emptyset$, so $[y] = [z]$ by Lemma A.3.5. So x lies in exactly one class.

(b) Let $B(x)$ denote the block containing x. Then $x \sim y$ means $B(x) = B(y)$, and this is an equivalence relation by Example A.3.2(c), applied to the function $x \mapsto B(x)$. The class of x is $\{y \mid B(y) = B(x)\} = B(x)$, since $y \in B(x)$ if and only if $B(y) = B(x)$.

(c) Start with $\sim$, form the partition into classes, and let $\approx$ be "in the same class". Then $x \approx y$ means that the class containing x, which is $[x]$, is the class containing y, which is $[y]$. By Lemma A.3.5 this happens if and only if $x \sim y$, so $\approx$ is $\sim$. In the other order, starting with a partition, (b) says that the classes of the relation are the blocks, so we recover the partition. □

For congruence modulo a subspace, (a) is Corollary 4.6.15. In practice, the theorem is used to define a partition by giving a relation, which is easier to check: three axioms instead of "exactly one block".

A.3.3 Quotient sets and well-defined functions

Definition A.3.8 (Quotient set). Let $\sim$ be an equivalence relation on X. The **quotient set** $X/\sim$ is the set of equivalence classes, and the **quotient map** is

$$q : X \to X/\sim, \quad q(x) = [x].$$

The quotient map is surjective, and $q(x) = q(y)$ if and only if $x \sim y$ (Lemma A.3.5), so passing to the quotient set turns $\sim$ into equality. That is the purpose of the construction: in $X/\sim$, equivalent elements have become equal. The quotient space V/U of Definition 4.6.20 is the quotient set for congruence modulo U, with a vector space structure added.

Example A.3.9 ($\mathbb{Z}/n\mathbb{Z}$ as a quotient set). Let $n \geq 2$, and let $\sim$ be congruence modulo n. By Proposition A.2.4, each $x \in \mathbb{Z}$ is congruent to exactly one $r \in \{0, 1, \ldots, n-1\}$, namely $r = x \bmod n$. So each class contains exactly one of $0, 1, \ldots, n-1$, and

$$\mathbb{Z}/\sim = \{[0], [1], \ldots, [n-1]\},$$

with these n classes distinct. In Definition 1.1.19, $\mathbb{Z}/n\mathbb{Z}$ was defined as the set $\{0, 1, \ldots, n-1\}$ of remainders; we identify the remainder r with its class $[r]$. Under this identification, Lemma 1.1.21(a) says that $[a] + [b] = [a+b]$ and $[a][b] = [ab]$. These formulas define operations on classes, because the right side does not depend on the representatives: if $a \sim a'$ and $b \sim b'$, then n divides $(a+b) - (a'+b')$ and $ab - a'b' = a(b - b') + (a - a')b'$.

The last sentence is the general issue with quotient sets. A function on $X/\sim$ is usually given by a formula in a representative, and the formula must not depend on which representative is used (Technique 4.6.18). The theorem below says exactly when such a formula defines a function, and what properties the function then has.

Theorem A.3.10 (Functions on a quotient set). Let $\sim$ be an equivalence relation on X with quotient map $q : X \to X/\sim$, and let $g : X \to Y$.

(a) There is a function $\overline{g} : X/{\sim} \to Y$ with $\overline{g} \circ q = g$ if and only if g is constant on classes: $x \sim x'$ implies $g(x) = g(x')$. In that case $\overline{g}$ is unique, and $\overline{g}([x]) = g(x)$.

(b) Such a $\overline{g}$ is injective if and only if $g(x) = g(x')$ implies $x \sim x'$.

(c) Such a $\overline{g}$ is surjective if and only if g is surjective.

Proof. ROUTINE

Uses. Definition A.3.8 (Quotient set), Lemma A.3.5 (Equal classes), Definition A.1.2 (Function)
Techniques. Check that a definition does not depend on the representative (Technique 4.6.18), Uniqueness via two candidates (Technique 1.1.8)
Hint 1. If $\overline{g} \circ q = g$, then $\overline{g}([x]) = g(x)$ for every x, which settles uniqueness and the formula.
Hint 2. For existence, define $\overline{g}(C)$ for a class C as $g(x)$ for any $x \in C$. What has to be checked for this to be a function?
Hint 3. For (b), translate: $\overline{g}([x]) = \overline{g}([x'])$ means $g(x) = g(x')$, and $[x] = [x']$ means $x \sim x'$. For (c), $\operatorname{im}\overline{g} = \operatorname{im} g$ because q is surjective.
Sketch. If $\overline{g} \circ q = g$, then $g(x) = \overline{g}([x]) = \overline{g}([x']) = g(x')$ when $x \sim x'$, and $\overline{g}$ is forced to be $[x] \mapsto g(x)$. Conversely, if g is constant on classes, this formula is independent of the representative, so it defines $\overline{g}$. Injectivity of $\overline{g}$ reads "$g(x) = g(x') \Rightarrow [x] = [x']$". Since q is surjective, $\overline{g}$ and g have the same image.

(a) Suppose $\overline{g} \circ q = g$. Then $\overline{g}([x]) = g(x)$ for every x, which determines $\overline{g}$, since every class is $[x]$ for some x. And if $x \sim x'$, then $[x] = [x']$ by Lemma A.3.5, so $g(x) = \overline{g}([x]) = \overline{g}([x']) = g(x')$.

Conversely, suppose g is constant on classes. For a class $C \in X/{\sim}$, all $x \in C$ satisfy $x \sim x_0$ for a fixed $x_0 \in C$, so g takes the single value $g(x_0)$ on C. Setting $\overline{g}(C)$ equal to this value defines a function $X/{\sim} \to Y$, and $\overline{g}([x]) = g(x)$ because $x \in [x]$.

(b) $\overline{g}$ is injective if and only if $\overline{g}([x]) = \overline{g}([x'])$ implies $[x] = [x']$ for all $x, x' \in X$, that is, if and only if $g(x) = g(x')$ implies $x \sim x'$.

(c) Since q is surjective, the values of $\overline{g}$ are exactly the values $\overline{g}(q(x)) = g(x)$, so $\operatorname{im}\overline{g} = \operatorname{im} g$. □

Taking $\sim$ to be $\underset{f}{\sim}$ gives a factorization of every function.

Corollary A.3.11 (Factoring a function). Let $f : X \to Y$, and let $\underset{f}{\sim}$ be the relation $f(x) = f(x')$. Then $\overline{f}([x]) = f(x)$ is a well-defined bijection $X/{\sim_f} \to \operatorname{im} f$. So f is the composite

$$X \xrightarrow{q} X/{\sim_f} \xrightarrow{\overline{f}} \operatorname{im} f \xrightarrow{\iota} Y$$

of a surjection, a bijection, and the injective inclusion $\iota(y) = y$.

Proof. ROUTINE

Uses. Theorem A.3.10 (Functions on a quotient set)
Hint 1. Apply Theorem A.3.10 to f, viewed as a function $X \to \operatorname{im} f$.
Hint 2. Both conditions, in (a) and in (b) of the theorem, are the definition of $\underset{f}{\sim}$.
Sketch. For $g = f : X \to \operatorname{im} f$, "$x \underset{f}{\sim} x' \Rightarrow g(x) = g(x')$" and its converse both hold by definition of $\underset{f}{\sim}$, and g is surjective. So $\overline{f}$ exists and is injective and surjective. Composing with q and ι recovers f.

View f as a surjective function $g : X \to \operatorname{im} f$. By definition of $\underset{f}{\sim}$, $x \underset{f}{\sim} x'$ if and only if $g(x) = g(x')$. So g is constant on classes, and $\overline{f}$ exists by Theorem A.3.10(a); it is injective by (b) and surjective by (c). For every x, $\iota\big(\overline{f}(q(x))\big) = f(x)$. □

For a linear map $T : V \to W$, $T(\mathbf{v}) = T(\mathbf{v}')$ if and only if $\mathbf{v} - \mathbf{v}' \in \ker T$, so $\underset{T}{\sim}$ is congruence modulo $\ker T$ and $V/{\sim_T}$ is the quotient space $V/\ker T$. The corollary then says that $\overline{T}$ is a bijection $V/\ker T \to \operatorname{im} T$, and the first isomorphism theorem (Theorem 4.6.34) adds that it is linear.

A.3.4 Invariants and normal forms

To classify objects up to $\sim$ is to describe the quotient set $X/\sim$: decide when two given objects are equivalent, and list one object from each class.

Definition A.3.12 (Invariant, normal form). Let $\sim$ be an equivalence relation on X.

- An **invariant** of $\sim$ is a function $g : X \to Y$ that is constant on classes: $x \sim x'$ implies $g(x) = g(x')$.
- An invariant is **complete** if moreover $g(x) = g(x')$ implies $x \sim x'$.
- A set of **normal forms** for $\sim$ is a subset $N \subseteq X$ that contains exactly one element of each class.

By Theorem A.3.10, an invariant is a function on $X/\sim$, and a complete invariant is an injective one, so it identifies $X/\sim$ with the set of its values. A set of normal forms N is mapped bijectively onto $X/\sim$ by q, and "the normal form of x" is a complete invariant with values in N. The classification results of the book all have this shape:

- For row equivalence on $F^{m\times n}$, the RREF is a complete invariant, and the matrices in RREF are normal forms (Corollary 3.3.18). So is the kernel (Corollary 3.3.20).
- For isomorphism of finite-dimensional vector spaces, the dimension is a complete invariant (Theorem 4.5.6), and $F^0, F^1, F^2, \ldots$ are normal forms.
- For the relation $B = PAQ$ with P, Q invertible, the rank is a complete invariant, with normal forms $\begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$ (Theorem 3.5.27).
- For similarity, rank, trace, and determinant are invariants (Proposition 4.5.27, Proposition 5.4.17), but even all of them together are not complete: I_2 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ share them and are not similar. Over $\mathbb{C}$, the Jordan form, with a fixed ordering of the blocks, provides normal forms (Section 10.3).
- For congruence modulo n, the remainder $x \bmod n$ is a complete invariant, with normal forms $0, 1, \ldots, n-1$ (Example A.3.9).

Technique A.3.13 (Classify by a complete invariant). To decide when two objects are equivalent, find a quantity that equivalent objects share (an invariant), and then prove that it is complete. To prove that x and x' are *not* equivalent, one invariant on which they differ is enough (Technique 4.5.29). To prove that they *are* equivalent, completeness is needed, and it is usually proved by reducing every object to a normal form that depends only on the invariant: if both x and x' are equivalent to the same normal form, they are equivalent to each other by symmetry and transitivity.

Reach for it whenever a question asks "when are these the same up to ...?" or "how many essentially different ... are there?". The canonical example is Theorem 3.5.27, where row and column operations reduce every matrix to $\begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix}$ with r the rank.

Exercises

Exercise A.3.14. ROUTINE Decide which of the following are equivalence relations. For those that are, describe the classes.

(a) On $\mathbb{R}$: $x \sim y$ if $x - y \in \mathbb{Z}$.

(b) On $\mathbb{Z}$: $x \sim y$ if $xy > 0$.

(c) On $F^{m\times n}$: $A \sim B$ if $\operatorname{rank} A = \operatorname{rank} B$.

(d) On $V \setminus \{\mathbf{0}\}$, for a vector space V: $\mathbf{v} \sim \mathbf{w}$ if $\operatorname{span}(\mathbf{v}) = \operatorname{span}(\mathbf{w})$.

(e) On $P(X)$, for a set X with at least two elements: $A \sim B$ if $A \cap B \neq \emptyset$.

Solution on page 1675

Exercise A.3.15. STANDARD Count the equivalence relations on $[3]$ and on $[4]$.

Solution on page 1675

Exercise A.3.16. STANDARD Let F be a field and $n \geq 0$. On $F^{n+1} \setminus \{\mathbf{0}\}$, let $\mathbf{v} \sim \mathbf{w}$ if $\mathbf{w} = c\mathbf{v}$ for some nonzero $c \in F$.

(a) Show that $\sim$ is an equivalence relation, and describe its classes in terms of one-dimensional subspaces of F^{n+1}.

(b) If F has q elements, show that the quotient set has $\left(q^{n+1}-1\right)/(q-1) = 1 + q + \cdots + q^n$ elements.

Solution on page 1676

Exercise A.3.17. STANDARD Let R and S be equivalence relations on X, viewed as subsets of $X \times X$. Prove or disprove: (a) $R \cap S$ is an equivalence relation; (b) $R \cup S$ is an equivalence relation.

Solution on page 1676

Exercise A.3.18. ROUTINE Find the error in the following argument.

Claim: A relation that is symmetric and transitive is reflexive. *Proof:* Let $x \in X$ and pick y with $x \sim y$. By symmetry $y \sim x$, and by transitivity, $x \sim y$ and $y \sim x$ give $x \sim x$.

Solution on page 1676

Exercise A.3.19. STANDARD Let $m, n \geq 2$, and write $[a]_n$ for the class of $a \in \mathbb{Z}$ under congruence modulo n. Show that the formula $f\left([a]_n\right) = [a]_m$ defines a function $\mathbb{Z}/n\mathbb{Z} \to \mathbb{Z}/m\mathbb{Z}$ if and only if m divides n. When it does, show that f is surjective, and bijective only if $m = n$.

Solution on page 1676

Exercise A.3.20. HARD Let R be any relation on X. Define $x \approx y$ if there is a finite sequence $x = x_0, x_1, \ldots, x_k = y$, with $k \geq 0$, such that for each i, $(x_{i-1}, x_i) \in R$ or $(x_i, x_{i-1}) \in R$.

(a) Show that $\approx$ is an equivalence relation containing R, and that it is contained in every equivalence relation that contains R. It is the equivalence relation **generated** by R.

(b) Let R be the relation on $F^{m \times n}$ given by "B is obtained from A by one elementary row operation". Show that the equivalence relation generated by R is row equivalence (Definition 3.2.21).

Solution on page 1677

A.4 Zorn's lemma BEYOND 21-242

In a finite-dimensional space, a basis is built by adding vectors one at a time until the list spans; the process stops because an independent list has at most $\dim V$ vectors (Theorem 4.1.16). In a space such as $F^{\mathbb{N}}$ or $\mathbb{R}$ over $\mathbb{Q}$, the process need not stop after finitely many steps, or after countably many, and there is no last step to point to. Zorn's lemma replaces the process by a single statement: if every partial result can be extended to an upper bound, then a maximal one exists. It is the standard way to prove that objects of linear algebra exist in infinite dimensions, and Section 15.1 uses it to show that every vector space has a basis.

A.4.1 Partial orders and chains

Definition A.4.1 (Partial order). A **partial order** on a set P is a relation $\leq$ that is

- *reflexive*: $p \leq p$;
- *antisymmetric*: if $p \leq p'$ and $p' \leq p$, then $p = p'$;
- *transitive*: if $p \leq p'$ and $p' \leq p''$, then $p \leq p''$.

The pair $(P, \leq)$ is a **partially ordered set**. We write $p < p'$ if $p \leq p'$ and $p \neq p'$. Two elements p, p' are **comparable** if $p \leq p'$ or $p' \leq p$. A **chain** is a subset $C \subseteq P$ in which any two elements are comparable.

Definition A.4.2 (Upper bound, maximal element). Let $(P, \leq)$ be a partially ordered set. An **upper bound** of a subset $S \subseteq P$ is an element $u \in P$ with $s \leq u$ for every $s \in S$; it need not lie in S. An element $m \in P$ is **maximal** if no element of P is strictly larger: $m \leq p$ implies $p = m$.

In linear algebra, P is almost always a collection of sets, such as subspaces or independent sets, ordered by inclusion $\subseteq$. A chain is then a family of sets that is *nested*: of any two, one contains the other. A maximal element is one that cannot be enlarged within the collection. It need not be the largest element: there may be many maximal elements, none containing the others.

Example A.4.3 (Chains and maximal elements).

(a) In $P(X)$, ordered by $\subseteq$, every chain has the upper bound X, and X is the only maximal element.

(b) Let P be the set of subspaces of $\mathbb{R}^3$ of dimension at most 2, ordered by $\subseteq$. The maximal elements are the planes through $\mathbf{0}$, and there are infinitely many of them. Every chain has an upper bound: a nonempty chain has at most three distinct members, of dimensions 0, 1, 2, and its largest member is an upper bound, while the empty chain is bounded by $\{\mathbf{0}\}$.

(c) Let P be the set of proper subspaces of $F[x]$, ordered by $\subseteq$. The subspaces $F[x]_{\leq n}$ of polynomials of degree at most n form a chain, and it has no upper bound in P: a subspace containing every $F[x]_{\leq n}$ contains every polynomial, so it is $F[x]$, which is not proper.

(d) $\mathbb{N}$ with $\leq$ is a chain with no upper bound, and it has no maximal element.

In (b), an upper bound of a chain was its largest member. In (c) and (d) the chains are infinite with no largest member, and nothing in P lies above all of their members; in (c), the natural candidate, the union, is $F[x]$, which is not in P. Zorn's lemma says that this failure is the only obstruction to a maximal element.

A.4.2 Zorn's lemma

Theorem A.4.4 (Zorn's lemma). Let $(P, \leq)$ be a partially ordered set in which every chain has an upper bound. Then P has a maximal element.

The empty set is a chain, and an upper bound of it is any element of P. So the hypothesis includes $P \neq \emptyset$, and in practice one checks that P is nonempty and that every nonempty chain has an upper bound.

Zorn's lemma is equivalent to the axiom of choice (Remark A.1.13): Exercise A.4.11 derives the axiom of choice from it, and the proof below derives it from the axiom of choice. The proof is not needed anywhere in the book, and it uses a transfinite construction that the rest of the book does not, so it is marked beyond and the reader can skip it.

Intuition (Why Zorn's lemma should be true). Suppose P has no maximal element. Then every chain C has a *strict* upper bound: it has an upper bound u, and u is not maximal, so something is larger than u. Start from any element p_0, take a strict upper bound p_1 of $\{p_0\}$, then p_2 of $\{p_0, p_1\}$, and so on. After all finite stages, the chain $\{p_0, p_1, \ldots\}$ again has a strict upper bound p_ω, and we continue. The process never gets stuck, and it never repeats an element, so it should eventually use up more elements than P has. The proof makes "continue forever, through all stages" precise without ordinals, by looking at all chains that are built by this rule at once.

Proof. CHALLENGE

Uses. Remark A.1.13 (The axiom of choice), Definition A.4.1 (Partial order), Definition A.4.2 (Upper bound, maximal element)
Techniques. Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Suppose there is no maximal element. Show that every chain C then has a strict upper bound, and use the axiom of choice to fix one, $s(C)$, for every chain.
Hint 2. Call $W \subseteq P$ a tower if every nonempty subset of W has a least element, and every $w \in W$ equals $s(W_{<w})$, where $W_{<w} = \{x \in W \mid x < w\}$. Show that of any two towers, one is an initial segment of the other.
Hint 3. For the comparison, take the union I of all sets that are downward closed in both towers W and V. If $I \neq W$ and $I \neq V$, the least elements of $W \setminus I$ and of $V \setminus I$ are both $s(I)$.
Hint 4. Then the union U of all towers is a tower, and $U \cup \{s(U)\}$ is a strictly larger tower, a contradiction.
Sketch. Assume no maximal element; then every chain has a strict upper bound, and choice gives a function s picking one. A tower is a well-ordered W with $w = s(W_{<w})$ for all $w \in W$. Any two towers are comparable, one an initial segment of the other: the largest common downward closed set I is all of one of them, since otherwise $s(I)$ would extend it. So the union U of all towers is a tower, and so is $U \cup \{s(U)\}$, which contradicts $s(U) \notin U$.

Suppose that P has no maximal element. Let C be a chain, and let u be an upper bound of C. Since u is not maximal, there is $p \in P$ with $u < p$. Then $c < p$ for every $c \in C$: we have $c \leq u \leq p$, and $c = p$ would give $p \leq u \leq p$, so $u = p$. So the set of *strict* upper bounds of C is nonempty, and by the axiom of choice there is a function s that assigns to every chain C a strict upper bound $s(C)$.

A subset $W \subseteq P$ is **well ordered** if every nonempty subset of W has a least element; then W is a chain, since every pair $\{x, y\} \subseteq W$ has a least element. For $w \in W$ write $W_{<w} = \{x \in W \mid x < w\}$. Call W a **tower** if it is well ordered and $w = s(W_{<w})$ for every $w \in W$. (For instance $\emptyset$, $\{s(\emptyset)\}$, and $\{s(\emptyset), s(\{s(\emptyset)\})\}$ are towers.) A subset $A \subseteq W$ is **downward closed** in W if $x \in A$, $y \in W$, and $y < x$ imply $y \in A$.

Step 1. If A is downward closed in a well-ordered W and $A \neq W$, then $A = W_{<m}$, where m is the least element of $W \setminus A$. If $y \in W$ and $y < m$, then $y \in A$ by minimality of m. If $y \in A$, then $m \leq y$ is impossible, since it would put m in A (either $m = y$ or $m < y$ and A is downward closed); as W is a chain, $y < m$.

Step 2. If W and V are towers, then one of them is downward closed in the other. Let I be the union of all subsets of $W \cap V$ that are downward closed in both W and V. A union of downward closed sets is downward closed, so I is downward closed in both, and it is the largest such set. Suppose $I \neq W$ and $I \neq V$. By Step 1, $I = W_{<m}$ and $I = V_{<n}$, where m and n are the least elements of $W \setminus I$ and $V \setminus I$. Since W and V are towers,

$$m = s(W_{<m}) = s(I) = s(V_{<n}) = n.$$

Then $I \cup \{m\}$ is downward closed in W (an element of W below m lies in $W_{<m} = I$), and likewise in V. By maximality of I, $m \in I$, which is false. So $I = W$ or $I = V$; that is, W is downward closed in V, or V in W.

Step 3. The union U of all towers is a tower. Let W be a tower and $w \in W$. We claim $U_{<w} = W_{<w}$. Clearly $W_{<w} \subseteq U_{<w}$. If $u \in U$ and $u < w$, then $u \in V$ for some tower V. By Step 2, either V is downward closed in W, so $V \subseteq W$ and $u \in W$; or W is downward closed in V, and then $u \in V$, $u < w \in W$ give $u \in W$. Either way $u \in W_{<w}$.

Now U is a chain: for $x, y \in U$, say $x \in W$ and $y \in V$, Step 2 puts both in W or both in V, which are chains. It is well ordered: let $A \subseteq U$ be nonempty, pick $a \in A$ in some tower W, and let m be the least element of $A \cap W$. If $b \in A$ had $b < m$, then $b \in U_{<m} = W_{<m}$, so $b \in A \cap W$ and $b < m$, which is impossible. As U is a chain, $m \leq b$ for all $b \in A$. Finally, for $u \in U$, say $u \in W$, we have $s(U_{<u}) = s(W_{<u}) = u$. So U is a tower.

Step 4. Contradiction. Let $p = s(U)$, a strict upper bound of the chain U, so $p \notin U$. Then $U' = U \cup \{p\}$ is a tower: a nonempty subset of U' has as least element its least element in U if it meets U, and p otherwise; $U'_{<p} = U$ and $s(U) = p$; and for $u \in U$, $U'_{<u} = U_{<u}$ since $p > u$, so $s(U'_{<u}) = u$. Hence $U' \subseteq U$ by definition of U, and $p \in U$, a contradiction. So P has a maximal element. □

A.4.3 Using Zorn's lemma

Every application in linear algebra has the same three steps, and the second step rests on one small fact: a union of a chain of sets is "finitary", in that any finitely many of its elements already lie in one member of the chain. Spans and linear relations only ever involve finitely many vectors, so this is what lets linear properties pass to the union.

Technique A.4.5 (Apply Zorn's lemma). To prove that an object with some property exists in a possibly infinite-dimensional setting:

1. Let P be the set of *partial* objects (independent sets, subspaces meeting U only in $\mathbf{0}$, maps defined on part of the space, ...), ordered by inclusion or by extension. Check that $P \neq \emptyset$.
2. Show that every nonempty chain in P has an upper bound in P. The candidate is almost always the union. The work is to show that the union is still in P, and Lemma A.4.6 does most of it.
3. Let m be a maximal element. Show that m is a complete object, by contradiction: if it were not, enlarge it by one vector (or one point), and check that the enlargement is still in P.

Reach for it whenever a finite-dimensional proof proceeds by "add one more until done". The canonical example is Theorem A.4.7; Section 15.1 applies it to linearly independent sets.
Used in. Theorem A.4.7, Exercise A.4.11.

Lemma A.4.6 (Finitely many elements of a union of a chain). Let Γ be a nonempty set of sets that is a chain under $\subseteq$, and let $x_1, ..., x_k$, with $k \geq 0$, be elements of the union $\bigcup \Gamma$. Then some single member of Γ contains all of $x_1, ..., x_k$.

Proof. ROUTINE

Uses. Definition A.4.1 (Partial order), Theorem A.2.1 (Induction, strong induction, and well-ordering)
Hint 1. Each x_i lies in some member C_i. Among finitely many members of a chain, one contains all the others.
Hint 2. Prove the last statement by induction on the number of members.
Sketch. Pick $C_i \in \Gamma$ with $x_i \in C_i$. Finitely many members of a chain have a largest one, by induction: the larger of C_k and the largest of $C_1, ..., C_{k-1}$. It contains every x_i. For $k = 0$, any member works.

For $k = 0$ any member of Γ works, since $\Gamma \neq \emptyset$. For $k \geq 1$, pick $C_i \in \Gamma$ with $x_i \in C_i$ for each i. We show by induction on k that one of $C_1, ..., C_k$ contains all the others. For $k = 1$ this is clear. If C_j contains $C_1, ..., C_{k-1}$, then C_j and C_k are comparable since Γ is a chain, and the larger of the two contains all of $C_1, ..., C_k$. That member contains $x_1, ..., x_k$. □

In Section 4.4, every subspace of a finite-dimensional space was shown to have a complement by extending a basis of the subspace (Proposition 4.4.16). The same statement holds in every vector space, and the proof is a direct application of Zorn's lemma, without bases.

Theorem A.4.7 (Complements exist). Let V be any vector space over F, and U a subspace of V. Then there is a subspace W of V with $V = U \oplus W$.

Intuition. We want W as large as possible subject to $W \cap U = \{\mathbf{0}\}$, because then $U + W$ should be all of V: if some $\mathbf{v}$ were missing, we could add it to W without creating an intersection with U. In finite dimensions "as large as possible" can be achieved by adding one vector at a time. Here Zorn's lemma provides it, once we check that the union of a nested family of such subspaces is again one.

Proof. HARD

Uses. Theorem A.4.4 (Zorn's lemma), Lemma A.4.6 (Finitely many elements of a union of a chain), Theorem 1.4.3 (Subspace criterion), Theorem 4.4.7 (Criteria for direct sums)
Techniques. Apply Zorn's lemma (Technique A.4.5), Extremal choice and minimal counterexamples (Technique 1.5.9)
Hint 1. Let P be the set of subspaces W with $W \cap U = \{\mathbf{0}\}$, ordered by $\subseteq$. Why is P nonempty?

Hint 2. For a nonempty chain in P, show that the union is a subspace and still meets U only in $\mathbf{0}$. Two vectors of the union lie in one member of the chain.
Hint 3. If W is maximal and $\mathbf{v} \notin U + W$, show that $W + \operatorname{span}(\mathbf{v})$ is in P. If $\mathbf{w} + c\mathbf{v} \in U$, why must $c = 0$?
Sketch. Let $P = \{W \text{ subspace} \mid W \cap U = \{\mathbf{0}\}\}$, which contains $\{\mathbf{0}\}$. The union of a nonempty chain is a subspace, since any two of its vectors lie in a common member, and it meets U only in $\mathbf{0}$; so it is an upper bound. Zorn gives a maximal W. If $\mathbf{v} \notin U + W$, then $W + \operatorname{span}(\mathbf{v})$ still meets U trivially: $\mathbf{w} + c\mathbf{v} \in U$ with $c \neq 0$ would put $\mathbf{v}$ in $U + W$. This contradicts maximality, so $U + W = V$, and the sum is direct.

Let P be the set of subspaces W of V with $W \cap U = \{\mathbf{0}\}$, ordered by inclusion. It contains $\{\mathbf{0}\}$, so it is nonempty.

Let Γ be a nonempty chain in P, and $W^* = \bigcup \Gamma$. We show that $W^* \in P$; it is then an upper bound of Γ. It contains $\mathbf{0}$. If $\mathbf{w}, \mathbf{w'} \in W^*$ and $a \in F$, then by Lemma A.4.6 both lie in one $C \in \Gamma$, which is a subspace, so $\mathbf{w} + \mathbf{w'} \in C \subseteq W^*$ and $a\mathbf{w} \in C \subseteq W^*$. So W^* is a subspace (Theorem 1.4.3). If $\mathbf{w} \in W^* \cap U$, then $\mathbf{w} \in C$ for some $C \in \Gamma$, so $\mathbf{w} \in C \cap U = \{\mathbf{0}\}$. Hence $W^* \in P$.

By Zorn's lemma (Theorem A.4.4), P has a maximal element W. Suppose for contradiction that $U + W \neq V$, and pick $\mathbf{v} \in V \setminus (U + W)$. Let $W' = W + \operatorname{span}(\mathbf{v})$, a subspace containing W, with $W' \neq W$ since $\mathbf{v} \notin W$. We claim $W' \in P$. Let $\mathbf{w} + c\mathbf{v} \in U$ with $\mathbf{w} \in W$ and $c \in F$, say $\mathbf{w} + c\mathbf{v} = \mathbf{u}$. If $c \neq 0$, then $\mathbf{v} = c^{-1}(\mathbf{u} - \mathbf{w}) \in U + W$, which is false. So $c = 0$, and $\mathbf{w} = \mathbf{u} \in W \cap U = \{\mathbf{0}\}$. Hence $W' \cap U = \{\mathbf{0}\}$, so $W' \in P$ and $W \subsetneq W'$, contradicting maximality.

Therefore $U + W = V$ and $U \cap W = \{\mathbf{0}\}$, so $V = U \oplus W$ by Theorem 4.4.7. □

The proof gives no way to write W down. For $V = \mathbb{R}$ over $\mathbb{Q}$ and $U = \mathbb{Q}$, the theorem produces a $\mathbb{Q}$-subspace W of $\mathbb{R}$ with $\mathbb{R} = \mathbb{Q} \oplus W$, so that every real number is uniquely a rational plus an element of W, but nobody can describe such a W explicitly. Such sets are the price of the axiom of choice. In Section 4.6, this is one reason to prefer the quotient V/U to a complement: the quotient is constructed, not chosen.

Exercises

Exercise A.4.8. ROUTINE Without using Zorn's lemma, show that every finite nonempty partially ordered set has a maximal element.

Solution on page 1677

Exercise A.4.9. STANDARD Find the error in the following argument.

Claim: Every nonzero vector space V has a maximal proper subspace. *Proof:* Let P be the set of proper subspaces of V, ordered by $\subseteq$. It contains $\{\mathbf{0}\}$. If Γ is a nonempty chain in P, its union is a subspace by the argument in the proof of Theorem A.4.7, and it contains every member of Γ, so it is an upper bound. By Zorn's lemma, P has a maximal element.

Solution on page 1678

Exercise A.4.10. STANDARD Let V be any vector space, U a subspace, and $\mathbf{v} \in V \setminus U$. Show that there is a linear map $\varphi : V \to F$ with $\varphi(\mathbf{u}) = 0$ for all $\mathbf{u} \in U$ and $\varphi(\mathbf{v}) = 1$. Deduce that every nonzero vector space has a maximal proper subspace.

Solution on page 1678

Exercise A.4.11. HARD Use Zorn's lemma to prove that every surjective function $f : X \to Y$ has a right inverse, without using the axiom of choice directly. (So Zorn's lemma implies the axiom of choice, by Remark A.1.13.)

Solution on page 1678

Appendix B

Complex numbers

Arithmetic, conjugation, modulus, polar form, and roots of unity.

B.1 Complex numbers

Section 1.1.4 built $\mathbb{C}$ as $\mathbb{R}^2$ with a new multiplication and proved that it is a field. This appendix collects what else the book uses about complex numbers. Conjugation and the modulus are the raw material of inner products over $\mathbb{C}$ (Chapter 6). Polar form explains what multiplying by a complex number does to the plane. Roots of unity give the discrete Fourier basis (Section 6.3.4), and square roots give the first cases of the Fundamental Theorem of Algebra (Theorem 7.1.32).

Throughout, when we write $z = a + bi$ or $w = c + di$, the letters a, b, c, d denote real numbers.

B.1.1 Conjugation

The multiplication of $\mathbb{C}$ is forced by the single rule $i^2 = -1$ (Section 1.1.4). But $(-i)^2 = -1$ as well, and nothing in that rule, or in the arithmetic of $\mathbb{R}$, prefers i to $-i$. Exchanging the two is conjugation.

Definition B.1.1 (Complex conjugate). Let $z = a + bi \in \mathbb{C}$. The **complex conjugate** of z is $\overline{z} = a - bi$. We write $\operatorname{Re} z = a$ and $\operatorname{Im} z = b$ for the real and imaginary parts of z (Definition 1.1.29); both are real numbers, and $z = \operatorname{Re} z + i \operatorname{Im} z$. We call z **purely imaginary** if $\operatorname{Re} z = 0$.

For example, $\overline{3 + 2i} = 3 - 2i$, $\overline{i} = -i$, and $\overline{5} = 5$. In the plane, $\overline{z}$ is the mirror image of z in the real axis (Figure B.1.1). As a map $\mathbb{C} \to \mathbb{C}$, conjugation is $\mathbb{R}$-linear but not $\mathbb{C}$-linear (Non-example 2.1.14).

For $z \neq 0$ and an integer $n > 0$ we write $z^{-n} = \left(z^{-1}\right)^n$. The laws $z^m z^n = z^{m+n}$, $(z^m)^n = z^{mn}$, and $(zw)^n = z^n w^n$ then hold for all integers m, n (with $z, w \neq 0$ when an exponent is negative), by the same inductions as for real numbers, and we use them freely.

Proposition B.1.2 (Conjugation respects the field operations). Let $z, w \in \mathbb{C}$.

(a) $\overline{z + w} = \overline{z} + \overline{w}$ and $\overline{zw} = \overline{z}\,\overline{w}$.

(b) $\overline{\overline{z}} = z$. In particular, conjugation is a bijection $\mathbb{C} \to \mathbb{C}$ and is its own inverse.

(c) $\overline{z} = z$ if and only if $z \in \mathbb{R}$, and $\overline{z} = -z$ if and only if z is purely imaginary.

(d) $\operatorname{Re} z = (z + \overline{z})/2$ and $\operatorname{Im} z = (z - \overline{z})/(2i)$.

(e) $\overline{-z} = -\overline{z}$. If $z \neq 0$, then $\overline{z} \neq 0$ and $\overline{z^{-1}} = \overline{z}^{-1}$. Consequently $\overline{z^n} = \overline{z}^n$ for every integer n (with $z \neq 0$ if $n < 0$).

Proof. ROUTINE

> *Uses.* Definition B.1.1 (Complex conjugate), Definition 1.1.29 (Complex numbers), Theorem 1.1.9 (Uniqueness of identities and inverses), induction on n
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* Write $z = a + bi$ and $w = c + di$, and compute both sides of (a)–(d) from Definition 1.1.29.
> *Hint 2.* For (e), avoid coordinates. Apply (a) to $z + (-z) = 0$ and to $zz^{-1} = 1$, and use the uniqueness of inverses. Then induct on n.
> *Sketch.* Parts (a)–(d) are coordinate computations; for the product, both sides equal $(ac - bd) - (ad + bc)i$. For (e), conjugating $z + (-z) = 0$ and $zz^{-1} = 1$ with (a) shows that $\overline{-z}$ and $\overline{z^{-1}}$ are the additive and multiplicative inverses of $\overline{z}$. Powers follow from (a) by induction.

Let $z = a + bi$ and $w = c + di$.

(a) $\overline{z + w} = (a + c) - (b + d)i = (a - bi) + (c - di) = \overline{z} + \overline{w}$. Since $zw = (ac - bd) + (ad + bc)i$,

$$\overline{zw} = (ac - bd) - (ad + bc)i = (a - bi)(c - di) = \overline{z}\,\overline{w},$$

where the middle equality is the multiplication rule of Definition 1.1.29 applied to $a + (-b)i$ and $c + (-d)i$: the real part of the product is $ac - (-b)(-d) = ac - bd$, and its imaginary part is $a(-d) + (-b)c = -(ad + bc)$.

(b) $\overline{\overline{z}} = \overline{a - bi} = a + bi = z$. A map that is its own inverse is a bijection.

(c) $\overline{z} = z$ means $-b = b$, that is, $b = 0$, which says that $z = a \in \mathbb{R}$. Likewise $\overline{z} = -z$ means $a = -a$, that is, $\operatorname{Re} z = 0$.

(d) $z + \overline{z} = 2a$ and $z - \overline{z} = 2bi$.

(e) Since $z + (-z) = 0$ and $\overline{0} = 0$, part (a) gives $\overline{z} + \overline{-z} = 0$, so $\overline{-z} = -\overline{z}$ by Theorem 1.1.9. If $z \neq 0$, then $zz^{-1} = 1$ and $\overline{1} = 1$, so (a) gives $\overline{z}\,\overline{z^{-1}} = 1$. Hence $\overline{z} \neq 0$, and $\overline{z^{-1}} = \overline{z}^{-1}$ by Theorem 1.1.9.

For $n \geq 0$ we show $\overline{z^n} = \overline{z}^n$ by induction on n. The case $n = 0$ is $\overline{1} = 1$, and if it holds for n, then by (a)

$$\overline{z^{n+1}} = \overline{z^n z} = \overline{z^n}\,\overline{z} = \overline{z}^n \overline{z} = \overline{z}^{n+1}.$$

For $n < 0$ and $z \neq 0$, the case $-n > 0$ applied to z^{-1} gives $\overline{z^n} = \overline{\left(z^{-1}\right)^{-n}} = \overline{z^{-1}}^{-n} = \left(\overline{z}^{-1}\right)^{-n} = \overline{z}^n$. □

A bijection $\sigma : F \to F$ of a field with $\sigma(a + b) = \sigma(a) + \sigma(b)$ and $\sigma(ab) = \sigma(a)\sigma(b)$ for all $a, b \in F$ is an **automorphism** of F. By (a) and (b), conjugation is an automorphism of $\mathbb{C}$, and by (c) the numbers it fixes are exactly the real ones. Exercise B.1.43 shows that it is the only automorphism of $\mathbb{C}$ other than the identity that fixes every real number.

> *Intuition (Conjugation as a symmetry).* Read Proposition B.1.2 as a symmetry of $\mathbb{C}$. Take any true equation built from complex numbers with sums, products, and inverses. Conjugate both sides and push the bars inward with (a) and (e): every complex number in it is replaced by its conjugate, and every real number stays as it is. So the new equation is also true. This is the precise sense in which i and $-i$ cannot be told apart.

Technique B.1.3 (Conjugate the equation). Conjugation respects sums, products, and inverses, and it fixes real numbers (Proposition B.1.2). So conjugating both sides of a true equation gives another true equation, in which each complex number is replaced by its conjugate and each real number is unchanged. Two uses come up again and again.

- To get a second solution of an equation with real coefficients from a first one, conjugate the first. The canonical example is Proposition B.1.4: the nonreal roots of a real polynomial come in pairs $z, \overline{z}$.
- To show that a complex quantity q is real, show that $\overline{q} = q$; to show that it is purely imaginary, show that $\overline{q} = -q$ (Proposition B.1.2(c)).

Reach for it when real coefficients meet complex unknowns, as when a real matrix acts on $\mathbb{C}^n$, or when a quantity built symmetrically from z and $\overline{z}$ ought to be real. The second use shows that the eigenvalues of a self-adjoint operator are real (Proposition 8.1.1).
Used in. Problem 7.18, Proposition B.1.4, Exercise B.1.40.

Proposition B.1.4 (Roots of real polynomials come in conjugate pairs). Let $p = a_0 + a_1 x + \cdots + a_d x^d$ with $a_0, \ldots, a_d \in \mathbb{R}$, and evaluate p at complex numbers (Definition 1.2.17, with $F = \mathbb{C}$). Then $p(\overline{z}) = \overline{p(z)}$ for every $z \in \mathbb{C}$. In particular, if $p(z) = 0$, then $p(\overline{z}) = 0$.

Proof. ROUTINE

Uses. Proposition B.1.2 (Conjugation respects the field operations), Definition 1.2.17 (Evaluation)
Techniques. Conjugate the equation (Technique B.1.3)
Hint 1. Conjugate the number $p(z) = \sum_k a_k z^k$ and push the bar inward.
Hint 2. The bar passes through sums and products by Proposition B.1.2(a), and $\overline{a_k} = a_k$ because a_k is real.
Sketch. $\overline{p(z)} = \sum_k \overline{a_k}\,\overline{z}^k = \sum_k a_k \overline{z}^k = p(\overline{z})$. If $p(z) = 0$, then $p(\overline{z}) = \overline{0} = 0$.

By Proposition B.1.2(a) and (e), and since $\overline{a_k} = a_k$ for real a_k (Proposition B.1.2(c)),

$$\overline{p(z)} = \overline{\sum_{k=0}^{d} a_k z^k} = \sum_{k=0}^{d} \overline{a_k}\,\overline{z}^k = \sum_{k=0}^{d} a_k \overline{z}^k = p(\overline{z}).$$

If $p(z) = 0$, then $p(\overline{z}) = \overline{0} = 0$. □

Example B.1.5 ($x^4 + 4$). Let $p = x^4 + 4$. Since $(1+i)^2 = 2i$, we get $(1+i)^4 = (2i)^2 = -4$, so $p(1+i) = 0$. By Proposition B.1.4, $p(1-i) = 0$ too. As $p(-z) = p(z)$ for every z, also $p(-1-i) = p(-1+i) = 0$. So p has the four roots $\pm 1 \pm i$, and by Proposition 7.1.22 it has no others. (Example B.1.27 finds them again as the fourth roots of -4.)

The real coefficients matter: $x - i$ has the root i but not $-i$.

Exercise B.1.6. ROUTINE Find all $z \in \mathbb{C}$ with $z^2 = \overline{z}^2$.

Solution on page 1679

B.1.2 The modulus

Definition B.1.7 (Modulus). The **modulus** (or **absolute value**) of $z = a + bi \in \mathbb{C}$ is the real number $|z| = \sqrt{a^2 + b^2}$.

So $|z|$ is the length of the vector (a, b), and $|z - w| = \sqrt{(a-c)^2 + (b-d)^2}$ is the distance between the points z and w of the plane. For a real number $a = a + 0i$, $|a| = \sqrt{a^2}$ is its usual absolute value, so the notation is consistent. For example, $|3 - 4i| = 5$, $|i| = 1$, and $|\cos\theta + i\sin\theta| = 1$ for every $\theta \in \mathbb{R}$.

Proposition B.1.8 (Properties of the modulus). Let $z, w \in \mathbb{C}$.

(a) $|z| \geq 0$, with equality if and only if $z = 0$.

(b) $|z|^2 = z\overline{z}$, and $|\overline{z}| = |-z| = |z|$.

(c) If $z \neq 0$, then $z^{-1} = \overline{z}/|z|^2$.

(d) $|zw| = |z||w|$, and if $w \neq 0$, then $|z/w| = |z|/|w|$.

(e) $|\operatorname{Re} z| \leq |z|$ and $|\operatorname{Im} z| \leq |z|$. Moreover $\operatorname{Re} z \leq |z|$, with equality if and only if z is a nonnegative real number.

(f) $|z + w|^2 = |z|^2 + 2\operatorname{Re}(z\overline{w}) + |w|^2$.

Most of these are one-line computations in coordinates. Parts (d) and (f) are better done without coordinates, by a move worth naming.

> **Technique B.1.9** (Square the modulus). The modulus is a square root, and square roots do not expand. Its square does: $|z|^2 = z\overline{z}$ is a product, which can be multiplied out with the field axioms and conjugated term by term with Proposition B.1.2. Nothing is lost by squaring, since moduli are nonnegative: for real $s, t \geq 0$, $s = t$ if and only if $s^2 = t^2$, and $s \leq t$ if and only if $s^2 \leq t^2$. So to prove an identity or an inequality between moduli, square both sides, write each $|u|^2$ as $u\overline{u}$, and expand.
>
> Reach for it whenever moduli of sums or products appear. The canonical example is $|zw| = |z||w|$ in Proposition B.1.8, where $|zw|^2 = zw\,\overline{z}\,\overline{w} = |z|^2|w|^2$. With $\|\mathbf{v}\|^2 = \langle \mathbf{v}, \mathbf{v}\rangle$ in place of $|z|^2 = z\overline{z}$, the same move expands norms in inner product spaces (Proposition 6.1.29).
>
> *Used in.* Proposition B.1.8, Theorem B.1.11, Exercise B.1.35, Exercise B.1.36, Exercise B.1.37, Exercise B.1.44.

Proof. ROUTINE

> *Uses.* Definition B.1.7 (Modulus), Proposition B.1.2 (Conjugation respects the field operations), Theorem 1.1.9 (Uniqueness of identities and inverses)
> *Techniques.* Square the modulus (Technique B.1.9)
> *Hint 1.* Parts (a), (b), and (e) are statements about $a^2 + b^2$ for $z = a + bi$. Compute in coordinates.
> *Hint 2.* For (c), multiply z by the proposed inverse and use (b). For (d), compare $|zw|^2$ with $|z|^2|w|^2$, writing each as a number times its conjugate.
> *Hint 3.* For (f), expand $(z + w)(\overline{z} + \overline{w})$ and recognize the two cross terms as a number and its conjugate.
> *Sketch.* Parts (a), (b), and (e) are coordinate facts about $a^2 + b^2$. Then $z \cdot \overline{z}/|z|^2 = 1$ gives (c), and $|zw|^2 = (zw)(\overline{z}\,\overline{w}) = |z|^2|w|^2$ gives (d). For (f), $(z + w)(\overline{z} + \overline{w}) = |z|^2 + (u + \overline{u}) + |w|^2$ with $u = z\overline{w}$, and $u + \overline{u} = 2\operatorname{Re} u$.

Let $z = a + bi$.

(a) $a^2 + b^2 \geq 0$, so the square root is defined and nonnegative. It is 0 if and only if $a^2 + b^2 = 0$, that is, $a = b = 0$.

(b) $z\overline{z} = (a + bi)(a - bi) = \left(a^2 + b^2\right) + (-ab + ba)i = a^2 + b^2 = |z|^2$. Also $|\overline{z}| = \sqrt{a^2 + (-b)^2} = |z|$ and $|-z| = \sqrt{(-a)^2 + (-b)^2} = |z|$.

(c) By (a), $|z|^2$ is a nonzero real number, and by (b), $z \cdot \overline{z}/|z|^2 = |z|^2/|z|^2 = 1$. So $\overline{z}/|z|^2$ is the inverse of z (Theorem 1.1.9).

(d) By (b) and Proposition B.1.2(a),

$$|zw|^2 = (zw)\overline{zw} = (z\overline{z})(w\overline{w}) = |z|^2|w|^2 = (|z||w|)^2.$$

Both $|zw|$ and $|z||w|$ are nonnegative, so they are equal. If $w \neq 0$, then $|z/w||w| = |z|$ by what we just proved, and dividing by $|w| > 0$ gives $|z/w| = |z|/|w|$.

(e) $|a| = \sqrt{a^2} \leq \sqrt{a^2 + b^2} = |z|$, and likewise $|b| \leq |z|$. Next, $\operatorname{Re} z = a \leq |a| \leq |z|$. The first inequality is an equality if and only if $a \geq 0$, and the second if and only if $b = 0$. So $\operatorname{Re} z = |z|$ if and only if $b = 0$ and $a \geq 0$, that is, z is a nonnegative real number.

(f) By (b) and Proposition B.1.2(a),

$$|z + w|^2 = (z + w)(\overline{z} + \overline{w}) = z\overline{z} + (z\overline{w} + \overline{z}w) + w\overline{w}.$$

By Proposition B.1.2(a) and (b), $\overline{z}w = \overline{z\overline{w}}$, so the middle term is $u + \overline{u} = 2\operatorname{Re} u$ with $u = z\overline{w}$ (Proposition B.1.2(d)). □

In coordinates, (d) says that $\left(a^2 + b^2\right)\left(c^2 + d^2\right) = (ac - bd)^2 + (ad + bc)^2$: a product of two sums of two squares is again a sum of two squares. Exercise B.1.48 puts this to use. Similarly, $\operatorname{Re}(z\overline{w}) = ac + bd$ is the dot product of (a, b) and (c, d), so (f) is the law of cosines in the plane.

Exercise B.1.10. ROUTINE Let $z = (1+2i)/(2-i)$. Find $|z|$ without computing z. Then compute z, and check your answer.

Solution on page 1679

The triangle inequality

The modulus is a length, so it should satisfy the triangle inequality. In the triangle with vertices 0, z, and $z+w$, the sides have lengths $|z|$, $|w|$, and $|z+w|$ (Figure B.1.1(b)). With more terms, the broken path $0, z_1, z_1+z_2, \ldots$ is at least as long as the straight segment from 0 to its endpoint, and the two are equally long only if the path never turns.

Theorem B.1.11 (Triangle inequality in $\mathbb{C}$). Let $n \geq 1$ and $z_1, \ldots, z_n \in \mathbb{C}$.

(a) $|z_1 + \cdots + z_n| \leq |z_1| + \cdots + |z_n|$.

(b) Equality holds in (a) if and only if there is a $u \in \mathbb{C}$ with $|u| = 1$ such that $z_k = |z_k|u$ for every k. That is, all the z_k point in the same direction u.

Intuition (Two ways in). For two terms, Technique B.1.9 applies. By Proposition B.1.8(f), $|z+w|^2 = |z|^2 + 2\operatorname{Re}(z\overline{w}) + |w|^2$, while $(|z|+|w|)^2 = |z|^2 + 2|z\overline{w}| + |w|^2$. So the inequality says $\operatorname{Re}(z\overline{w}) \leq |z\overline{w}|$, which is Proposition B.1.8(e), and induction handles n terms.

Alternatively, rotate the whole picture so that the sum s points along the positive real axis (Technique 6.2.8). Then $|s|$ is the real part of the rotated sum. The real part of a sum is the sum of the real parts, and each real part is at most the modulus of its term. The first argument is the one that generalizes to inner product spaces (Theorem 6.2.11). The second handles all n terms at once and makes the equality case transparent.

Proof (by squaring). STANDARD

Uses. Proposition B.1.8 (Properties of the modulus), induction on n
Techniques. Square the modulus (Technique B.1.9)
Hint 1. Prove the case $n = 2$ first. Both sides are nonnegative, so compare squares, and expand $|z+w|^2$ with Proposition B.1.8(f).
Hint 2. The case $n = 2$ reduces to $\operatorname{Re}(z\overline{w}) \leq |z\overline{w}|$, with equality exactly when $z\overline{w}$ is a nonnegative real number. For n terms, induct, splitting off z_n.
Hint 3. For the equality case with n terms, equality forces equality in both steps of $|s+z_n| \leq |s| + |z_n| \leq \sum_k |z_k|$, where $s = z_1 + \cdots + z_{n-1}$. Treat $s = 0$ separately.
Sketch. For two terms, $|z+w|^2 = |z|^2 + 2\operatorname{Re}(z\overline{w}) + |w|^2 \leq (|z|+|w|)^2$, with equality if and only if $z\overline{w}$ is real and nonnegative. Induction on n gives (a). For (b), "if" is a computation. For "only if", equality for n terms forces equality for $z_1, \ldots, z_{n-1}$, so they point along some u, and for the two terms $s = z_1 + \cdots + z_{n-1} = |s|u$ and z_n. If $s \neq 0$, then $u\overline{z_n} \geq 0$, which gives $z_n = |z_n|u$; if $s = 0$, then $z_1 = \cdots = z_{n-1} = 0$, and the direction of z_n works for all terms.

Two terms. Let $z, w \in \mathbb{C}$. By parts (f), (e), (d), and (b) of Proposition B.1.8,

$$\begin{aligned} |z+w|^2 &= |z|^2 + 2\operatorname{Re}(z\overline{w}) + |w|^2 \\ &\leq |z|^2 + 2|z\overline{w}| + |w|^2 = (|z|+|w|)^2, \end{aligned}$$

with equality if and only if $\operatorname{Re}(z\overline{w}) = |z\overline{w}|$, that is (by Proposition B.1.8(e)), if and only if $z\overline{w}$ is a nonnegative real number. Both $|z+w|$ and $|z|+|w|$ are nonnegative, so

$$|z+w| \leq |z| + |w|, \quad \text{with equality if and only if } z\overline{w} \in \mathbb{R} \text{ and } z\overline{w} \geq 0. \tag{B.1.1}$$

(a) We induct on n. For $n = 1$ there is nothing to prove. For $n \geq 2$, let $s = z_1 + \cdots + z_{n-1}$. By (B.1.1) and the induction hypothesis,

$$|s + z_n| \leq |s| + |z_n| \leq |z_1| + \cdots + |z_{n-1}| + |z_n|. \tag{B.1.2}$$

(b) Suppose $z_k = |z_k|u$ for every k, with $|u| = 1$. Then $\sum_k z_k = \big(\sum_k |z_k|\big)u$, and by Proposition B.1.8(d) its modulus is $\sum_k |z_k|$.

Conversely, suppose equality holds in (a). We find u by induction on n. For $n = 1$, take $u = z_1/|z_1|$ if $z_1 \neq 0$ and $u = 1$ if $z_1 = 0$. Let $n \geq 2$. Equality between the two ends of (B.1.2) forces equality in both of its steps:

$$|s + z_n| = |s| + |z_n| \quad \text{and} \quad |s| = |z_1| + \cdots + |z_{n-1}|.$$

By the induction hypothesis there is u with $|u| = 1$ and $z_k = |z_k|u$ for $k < n$, and then $s = |s|u$ by the computation in the previous paragraph.

- If $s = 0$, then $|z_1| + \cdots + |z_{n-1}| = 0$, so $z_1 = \cdots = z_{n-1} = 0$. Choose u' for the single number z_n as in the case $n = 1$; then $z_k = |z_k|u'$ for every k.
- If $s \neq 0$, then by the first equality and (B.1.1), $s\overline{z_n} = |s|u\overline{z_n}$ is a nonnegative real number. Dividing by $|s| > 0$, so is $u\overline{z_n}$, and hence $u\overline{z_n} = |u\overline{z_n}| = |z_n|$. Conjugating gives $\overline{u}z_n = |z_n|$, and multiplying by u, with $u\overline{u} = |u|^2 = 1$, gives $z_n = |z_n|u$. □

Proof (by rotating the phase). STANDARD

Uses. Proposition B.1.8 (Properties of the modulus), Definition 1.1.29 (Complex numbers)
Techniques. Rotate the phase (Technique 6.2.8)
Hint 1. Let $s = z_1 + \cdots + z_n$. If $s \neq 0$, multiply s by $\overline{u}$, where $u = s/|s|$. What is $\overline{u}s$?
Hint 2. $|s| = \overline{u}s = \mathrm{Re}(\overline{u}s) = \sum_k \mathrm{Re}(\overline{u}z_k)$. Bound each term with Proposition B.1.8(e).
Hint 3. Equality holds if and only if $\mathrm{Re}(\overline{u}z_k) = |\overline{u}z_k|$ for every k. When does that happen?
Sketch. If $s = 0$, (a) is clear, and equality forces every $z_k = 0$. Otherwise let $u = s/|s|$. Then $|s| = \mathrm{Re}(\overline{u}s) = \sum_k \mathrm{Re}(\overline{u}z_k) \leq \sum_k |\overline{u}z_k| = \sum_k |z_k|$, with equality if and only if each $\overline{u}z_k$ is a nonnegative real number. As $|\overline{u}z_k| = |z_k|$, that means $\overline{u}z_k = |z_k|$, that is, $z_k = |z_k|u$.

If $z_k = |z_k|u$ for all k with $|u| = 1$, then $\sum_k z_k = \big(\sum_k |z_k|\big)u$ has modulus $\sum_k |z_k|$ by Proposition B.1.8(d). This is the "if" part of (b).

Let $s = z_1 + \cdots + z_n$. If $s = 0$, then (a) holds because its right side is nonnegative, and equality means $|z_1| + \cdots + |z_n| = 0$. Then every z_k is 0, and $u = 1$ works.

Suppose $s \neq 0$, and let $u = s/|s|$. Then $|u| = 1$, and $\overline{u}s = \overline{s}s/|s| = |s|$ by Proposition B.1.8(b). The real part of a sum is the sum of the real parts, since addition in $\mathbb{C}$ is coordinatewise (Definition 1.1.29). With parts (e) and (d) of Proposition B.1.8,

$$|s| = \mathrm{Re}(\overline{u}s) = \sum_{k=1}^{n} \mathrm{Re}(\overline{u}z_k) \leq \sum_{k=1}^{n} |\overline{u}z_k| = \sum_{k=1}^{n} |z_k|.$$

This is (a). If equality holds, then $\mathrm{Re}(\overline{u}z_k) = |\overline{u}z_k|$ for every k, because a sum of nonnegative gaps vanishes only if each gap does. By Proposition B.1.8(e), each $\overline{u}z_k$ is then a nonnegative real number, and since $|\overline{u}z_k| = |z_k|$, this says $\overline{u}z_k = |z_k|$. Multiplying by u gives $z_k = |z_k|u$ for every k. □

The first proof found the direction u one term at a time; the second named it at the start, as the direction of the sum, and then checked each term against it.

Corollary B.1.12 (Two terms, and the reverse triangle inequality). Let $z, w \in \mathbb{C}$.

(a) $|z + w| = |z| + |w|$ if and only if one of z, w is a nonnegative real multiple of the other, if and only if $z\overline{w}$ is a nonnegative real number.

(b) $\big||z| - |w|\big| \leq |z - w|$.

Proof. ROUTINE

Uses. Theorem B.1.11 (Triangle inequality in $\mathbb{C}$), Proposition B.1.8 (Properties of the modulus)
Hint 1. For (a), take $n = 2$ in Theorem B.1.11(b), and translate "$z = |z|u$ and $w = |w|u$" into the other two conditions.
Hint 2. For (b), write $z = (z - w) + w$ and apply the triangle inequality; then exchange the roles of z and w.

Sketch. (a) If $z = |z|u$ and $w = |w|u$, then $z\overline{w} = |z||w| \geq 0$. If $z\overline{w} = t \geq 0$ and $w \neq 0$, then $z = \left(t/|w|^2\right)w$. If $z = tw$ with $t \geq 0$ and $w \neq 0$, then $u = w/|w|$ works. (b) $|z| \leq |z - w| + |w|$ and $|w| \leq |w - z| + |z|$.

(a) By Theorem B.1.11(b) with $n = 2$, the equality holds if and only if (i) $z = |z|u$ and $w = |w|u$ for some u with $|u| = 1$. Let (ii) say that $z\overline{w}$ is a nonnegative real number, and (iii) that one of z, w is a nonnegative real multiple of the other. We prove (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (i).

If (i) holds, then $z\overline{w} = |z||w|u\overline{u} = |z||w| \geq 0$.

Suppose $z\overline{w} = t$ with t real and $t \geq 0$. If $w = 0$, then $w = 0 \cdot z$. If $w \neq 0$, multiplying by w gives $z|w|^2 = tw$, so $z = \left(t/|w|^2\right)w$ with $t/|w|^2 \geq 0$.

Suppose finally that $z = tw$ with $t \geq 0$; the case $w = tz$ is the same with z and w exchanged, and (i) is symmetric in z and w. If $w = 0$, then $z = 0$ as well, and $u = 1$ works. If $w \neq 0$, let $u = w/|w|$. Then $w = |w|u$ and $z = t|w|u$, where $t|w| = |tw| = |z|$ by Proposition B.1.8(d).

(b) By Theorem B.1.11, $|z| = |(z - w) + w| \leq |z - w| + |w|$, so $|z| - |w| \leq |z - w|$. Exchanging z and w, and using $|w - z| = |-(z - w)| = |z - w|$ (Proposition B.1.8(b)), gives $|w| - |z| \leq |z - w|$. Together these say $||z| - |w|| \leq |z - w|$. □

With the dot product $z\overline{w}$ on $\mathbb{C} = \mathbb{C}^1$ (Definition 6.1.8), $|z|$ is the norm, and Corollary B.1.12(a) is the case $V = \mathbb{C}$ of Theorem 6.2.11(b). The proofs above use only Proposition B.1.8, so Chapter 6 can rely on them.

B.1.3 The plane and polar form

As a real vector space, $\mathbb{C}$ is $\mathbb{R}^2$ with the basis $1, i$ (Example 1.6.5). So adding complex numbers is adding vectors, by the parallelogram rule, and multiplying by a real number scales (Figure B.1.1). What is new is multiplication by a nonreal number, and to describe it we need polar coordinates.

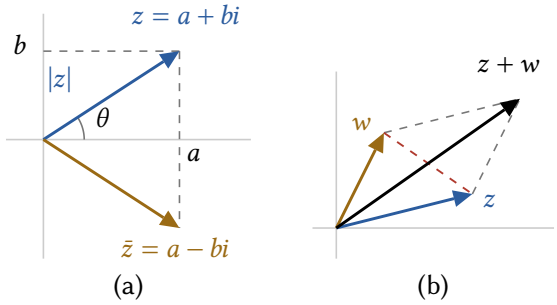

Figure B.1.1. (a) The number $z = a + bi$ as the point (a, b), with its modulus $|z|$ and an argument θ, and its conjugate $\overline{z}$, the mirror image in the real axis. (b) Addition is vector addition. The triangle $0, z, z + w$ has sides of lengths $|z|$, $|w|$, and $|z + w|$, and the red diagonal of the parallelogram has length $|z - w|$.

Remark B.1.13 (Facts about cos *and* sin*).* We use the following facts about the real functions cos and sin, from calculus.

(T1) $\cos^2\theta + \sin^2\theta = 1$, $\cos(-\theta) = \cos\theta$, $\sin(-\theta) = -\sin\theta$, and the angle addition formulas

$$\cos(\alpha + \beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta, \quad \sin(\alpha + \beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta.$$

(T2) $\cos\theta = \cos\theta'$ and $\sin\theta = \sin\theta'$ if and only if $\theta - \theta' \in 2\pi\mathbb{Z} = \{2\pi k \mid k \in \mathbb{Z}\}$.

(T3) For every $(x, y) \in \mathbb{R}^2$ with $x^2 + y^2 = 1$ there is a $\theta \in \mathbb{R}$ with $(x, y) = (\cos\theta, \sin\theta)$.

We used (T1) to show that rotations are linear (Example 2.1.11).

Definition B.1.14 (Polar form and argument). Let $z \in \mathbb{C}$ be nonzero. An **argument** of z is a real number θ with

$$z = |z|(\cos\theta + i\sin\theta).$$

Writing $z = r(\cos\theta + i\sin\theta)$ with $r > 0$ and $\theta \in \mathbb{R}$ is writing z in **polar form**.

Proposition B.1.15 (Existence and uniqueness of polar form). Let $z \in \mathbb{C}$ be nonzero.

(a) z has an argument.

(b) If $z = r(\cos\theta + i\sin\theta)$ with $r > 0$ and $\theta \in \mathbb{R}$, then $r = |z|$, so θ is an argument of z.

(c) If θ is an argument of z, then the arguments of z are exactly the numbers $\theta + 2\pi k$ with $k \in \mathbb{Z}$.

Proof. ROUTINE

Uses. Definition B.1.14 (Polar form and argument), Proposition B.1.8 (Properties of the modulus), Remark B.1.13 (Facts about cos and sin)
Hint 1. For (a), the number $z/|z|$ has modulus 1, so its coordinates (x, y) satisfy $x^2 + y^2 = 1$. Apply (T3).
Hint 2. For (b), take moduli of both sides. For (c), divide by $|z|$ and compare coordinates using (T2).
Sketch. (a) $z/|z| = x + yi$ with $x^2 + y^2 = 1$, and (T3) writes $(x, y) = (\cos\theta, \sin\theta)$. (b) Taking moduli, $|z| = r|\cos\theta + i\sin\theta| = r$. (c) θ' is an argument if and only if $\cos\theta' + i\sin\theta' = z/|z| = \cos\theta + i\sin\theta$, if and only if $\theta' - \theta \in 2\pi\mathbb{Z}$ by (T2).

(a) Let $z/|z| = x + yi$. By Proposition B.1.8(d), $x^2 + y^2 = |z/|z||^2 = 1$, so by (T3) there is a θ with $x = \cos\theta$ and $y = \sin\theta$. Then $z = |z|(\cos\theta + i\sin\theta)$.

(b) By Proposition B.1.8(d) and (T1), $|z| = r|\cos\theta + i\sin\theta| = r\sqrt{\cos^2\theta + \sin^2\theta} = r$.

(c) Dividing by $|z|$, a real number θ' is an argument of z if and only if $\cos\theta' + i\sin\theta' = z/|z| = \cos\theta + i\sin\theta$. Comparing real and imaginary parts, this holds if and only if $\cos\theta' = \cos\theta$ and $\sin\theta' = \sin\theta$, which by (T2) holds if and only if $\theta' - \theta \in 2\pi\mathbb{Z}$. □

So two nonzero complex numbers are equal if and only if they have the same modulus and their arguments differ by a multiple of 2π. The number 0 has no argument.

Example B.1.16 (Polar forms). $1 + i = \sqrt{2}\left(\cos\frac{\pi}{4} + i\sin\frac{\pi}{4}\right)$, $-2 = 2(\cos\pi + i\sin\pi)$, $-3i = 3\left(\cos\left(-\frac{\pi}{2}\right) + i\sin\left(-\frac{\pi}{2}\right)\right)$, and $\sqrt{3} - i = 2\left(\cos\left(-\frac{\pi}{6}\right) + i\sin\left(-\frac{\pi}{6}\right)\right)$. Any argument may be changed by a multiple of 2π: also $-3i = 3\left(\cos\frac{3\pi}{2} + i\sin\frac{3\pi}{2}\right)$.

Proposition B.1.17 (Multiplication in polar form). For all $\alpha, \beta \in \mathbb{R}$,

$$(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta) = \cos(\alpha + \beta) + i\sin(\alpha + \beta).$$

Consequently, if $z = r(\cos\alpha + i\sin\alpha)$ and $w = s(\cos\beta + i\sin\beta)$ with $r, s > 0$, then

$$zw = rs(\cos(\alpha + \beta) + i\sin(\alpha + \beta)),$$
$$z^{-1} = r^{-1}(\cos(-\alpha) + i\sin(-\alpha)),$$
$$\overline{z} = r(\cos(-\alpha) + i\sin(-\alpha)).$$

That is, moduli multiply and arguments add, and inverting or conjugating negates the argument.

Proof. ROUTINE

Uses. Definition 1.1.29 (Complex numbers), Remark B.1.13 (Facts about cos and sin)
Hint 1. Multiply out the left side with $i^2 = -1$ and compare with the angle addition formulas (T1).
Hint 2. For z^{-1}, multiply z by the proposed inverse, using the first part with $\beta = -\alpha$.
Sketch. Expanding gives $(\cos\alpha\cos\beta - \sin\alpha\sin\beta) + (\sin\alpha\cos\beta + \cos\alpha\sin\beta)i$, which is the right side by (T1). The formula for zw follows by regrouping. The proposed inverse times z is $\cos 0 + i\sin 0 = 1$, and $\overline{z} = r(\cos\alpha - i\sin\alpha)$ is the stated number by (T1).

Expanding with $i^2 = -1$,

$$(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta) = (\cos\alpha\cos\beta - \sin\alpha\sin\beta) + (\sin\alpha\cos\beta + \cos\alpha\sin\beta)i,$$

which is $\cos(\alpha+\beta)+i\sin(\alpha+\beta)$ by (T1). For z and w as stated, $zw = rs(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta)$ by commutativity and associativity, which gives the formula for zw. With $\beta = -\alpha$, the first part gives

$$z \cdot r^{-1}(\cos(-\alpha) + i\sin(-\alpha)) = \cos 0 + i\sin 0 = 1,$$

which is the formula for z^{-1}. Finally $\overline{z} = r(\cos\alpha - i\sin\alpha) = r(\cos(-\alpha) + i\sin(-\alpha))$ by (T1). □

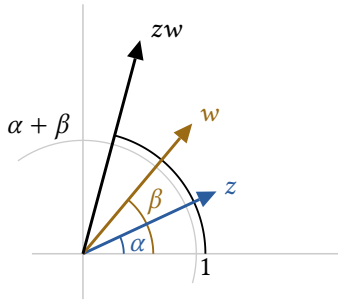

Figure B.1.2. Multiplying $z = |z|(\cos\alpha + i\sin\alpha)$ by $w = |w|(\cos\beta + i\sin\beta)$. The product zw has modulus $|z||w|$ and argument $\alpha+\beta$. The faint arc is part of the unit circle.

The computation in the proof is the one that shows that rotating by β and then by α is rotating by $\alpha+\beta$ (Exercise 2.1.43). The next proposition explains why.

B.1.4 Multiplication as rotation and scaling

Proposition B.1.18 (Multiplication by w as a map of the plane). Let $w = c + di \in \mathbb{C}$, and let $M_w : \mathbb{C} \to \mathbb{C}$, $M_w(z) = wz$. Regard $\mathbb{C}$ as a vector space over $\mathbb{R}$ with the basis $\mathcal{B} = 1, i$.

(a) M_w is $\mathbb{R}$-linear, and

$$[M_w]_{\mathcal{B}\mathcal{B}} = \begin{pmatrix} c & -d \\ d & c \end{pmatrix}, \quad \text{where} \quad c^2 + d^2 = |w|^2.$$

(b) If $w \neq 0$ and θ is an argument of w, then

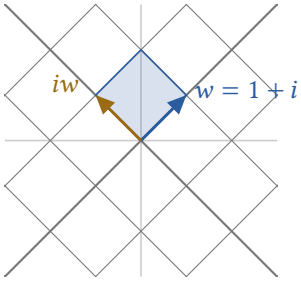
$$[M_w]_{\mathcal{B}\mathcal{B}} = |w|\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} = |w|[R_\theta]_{\mathcal{E}\mathcal{E}},$$

where R_θ is the rotation of $\mathbb{R}^2$ by θ (Example 2.1.11). So, identifying $a+bi$ with (a,b), multiplication by w is the rotation by θ followed by scaling by $|w|$.

Proof. ROUTINE

Uses. Exercise 2.1.5, Definition 2.3.1 (Matrix of a linear map), Example 2.3.3 (Matrices with respect to standard bases), Definition B.1.14 (Polar form and argument)
Techniques. Translate between maps and matrices (Technique 2.3.27)
Hint 1. Linearity comes from distributivity and commutativity in $\mathbb{C}$. The columns of $[M_w]_{\mathcal{B}\mathcal{B}}$ are the coordinates of $M_w(1)$ and $M_w(i)$.
Hint 2. For (b), substitute $c = |w|\cos\theta$ and $d = |w|\sin\theta$, and recall the matrix of R_θ from Example 2.3.3.
Sketch. M_w is even $\mathbb{C}$-linear (Exercise 2.1.5), hence $\mathbb{R}$-linear. $M_w(1) = c + di$ and $M_w(i) = -d + ci$ give the columns (c,d) and $(-d,c)$. In polar form $c = |w|\cos\theta$ and $d = |w|\sin\theta$, and the matrix becomes $|w|$ times the rotation matrix.

(a) By Exercise 2.1.5 with $F = \mathbb{C}$, M_w is $\mathbb{C}$-linear: $w(z+z') = wz + wz'$ and $w(\lambda z) = \lambda(wz)$ for $\lambda \in \mathbb{C}$. In particular this holds for real λ, so M_w is $\mathbb{R}$-linear. Its values on $\mathcal{B}$ are



$$M_w(1) = c + di = c\cdot 1 + d\cdot i, \quad M_w(i) = ci + di^2 = (-d)\cdot 1 + c\cdot i,$$

so by Definition 2.3.1 the columns of $[M_w]_{\mathcal{B}\mathcal{B}}$ are (c,d) and $(-d,c)$.

(b) By Definition B.1.14, $c + di = |w|(\cos\theta + i\sin\theta)$, so $c = |w|\cos\theta$ and $d = |w|\sin\theta$. Substituting into (a) gives the first equality, and the second is the matrix of R_θ from Example 2.3.3. The coordinate map $a + bi \mapsto (a, b)$ sends the basis $\mathcal{B}$ to the standard basis $\mathcal{E}$ of $\mathbb{R}^2$, so under it M_w becomes the linear map of $\mathbb{R}^2$ with standard matrix $|w|[R_\theta]_{\mathcal{E}\mathcal{E}}$, namely $|w|R_\theta$. □

Part (a) is also part (a) of Exercise 2.3.35. The determinant of the matrix is $c^2 + d^2 = |w|^2$ (Definition 5.1.14): multiplication by w scales areas by $|w|^2$, as a rotation followed by scaling every direction by $|w|$ should. The shape of the matrix records $M_w(i) = iM_w(1)$: its second column is its first, turned a quarter turn counterclockwise. An $\mathbb{R}$-linear map of the plane has this property exactly when it is $\mathbb{C}$-linear, that is, multiplication by a complex number (Exercise 2.1.47), and exactly when it commutes with the quarter turn $R_{\pi/2}$ (Exercise 2.2.30).

In the plane transformer below, $A = [M_w]_{\mathcal{B}\mathcal{B}}$ for $w = 1 + i$. So $A\mathbf{e}_1 = (1, 1)$ is w and $A\mathbf{e}_2 = (-1, 1)$ is iw. The grid turns by $\pi/4$ and stretches by $|w| = \sqrt{2}$, and $\det A = 2 = |w|^2$. Drag $A\mathbf{e}_1$ to another w, and then $A\mathbf{e}_2$ to its quarter turn iw: the grid stays square, and the determinant is $|w|^2$. In any other position of $A\mathbf{e}_2$ the map is still $\mathbb{R}$-linear, but it is not multiplication by a complex number. Squares become non-square parallelograms, except at $A\mathbf{e}_2 = -iw$, where the map is $z \mapsto w\bar{z}$: it keeps squares square but reverses orientation, and $\det A = -|w|^2$.

Multiplication by $w = 1 + i$ as a map of $\mathbb{C} = \mathbb{R}^2$. The unit square turns by $\pi/4$ and grows by the factor $|w| = \sqrt{2}$ in each direction, so its area becomes $|w|^2 = \det A = 2$. (Interactive in the web version.)

The notation $e^{i\theta}$

Notation B.1.19 ($e^{i\theta}$). For $\theta \in \mathbb{R}$ we write

$$e^{i\theta} = \cos\theta + i\sin\theta.$$

In this notation a nonzero z with argument θ is $z = |z|e^{i\theta}$, and Proposition B.1.17, Proposition B.1.8, and (T2) say that

$$e^{i\alpha}e^{i\beta} = e^{i(\alpha+\beta)}, \quad \overline{e^{i\theta}} = e^{-i\theta} = \left(e^{i\theta}\right)^{-1}, \quad \left|e^{i\theta}\right| = 1,$$

$$e^{i\theta} = 1 \quad \text{if and only if} \quad \theta \in 2\pi\mathbb{Z}.$$

For example, $e^{i\pi/2} = i$, $e^{i\pi} = -1$, and $e^{2\pi i} = 1$. For us $e^{i\theta}$ is an abbreviation, chosen because the first identity is a law of exponents. It is also the value of a genuine exponential function, but we never need that.

ASIDE: *Why an exponential* BEYOND 21-242

The power series $\exp(z) = \sum_{n\geq 0} z^n/n!$ converges for every $z \in \mathbb{C}$, and multiplying two such series, with the binomial theorem, gives $\exp(z + w) = \exp(z)\exp(w)$. Splitting $\exp(i\theta)$ into its even and odd terms and using $i^{2k} = (-1)^k$ gives the Taylor series of $\cos\theta$ and $i\sin\theta$. So $\exp(i\theta) = \cos\theta + i\sin\theta$ (Euler's formula), and $\exp(a + ib) = e^a e^{ib}$ for real a, b. All of this needs convergence of series, which belongs to analysis.

Powers

Theorem B.1.20 (De Moivre's formula). For every $\theta \in \mathbb{R}$ and every integer n,

$$(\cos\theta + i\sin\theta)^n = \cos n\theta + i\sin n\theta, \quad \text{that is,} \quad \left(e^{i\theta}\right)^n = e^{in\theta}.$$

Consequently $\left(re^{i\theta}\right)^n = r^n e^{in\theta}$ for $r > 0$.

Proof. ROUTINE

Uses. Proposition B.1.17 (Multiplication in polar form), Notation B.1.19 ($e^{i\theta}$), induction on n
Hint 1. For $n \geq 0$, induct on n, using $e^{i(n+1)\theta} = e^{in\theta}e^{i\theta}$.
Hint 2. For $n < 0$, write $\left(e^{i\theta}\right)^n = \left(\left(e^{i\theta}\right)^{-1}\right)^{-n}$ and use $\left(e^{i\theta}\right)^{-1} = e^{i(-\theta)}$.
Sketch. The case $n = 0$ is $1 = 1$, and $e^{in\theta}e^{i\theta} = e^{i(n+1)\theta}$ is the induction step. For negative n, apply the nonnegative case to $-\theta$ and $-n$, since $\left(e^{i\theta}\right)^{-1} = e^{-i\theta}$.

For $n = 0$ both sides are 1. If the formula holds for some $n \geq 0$, then by Proposition B.1.17

$$\left(e^{i\theta}\right)^{n+1} = \left(e^{i\theta}\right)^n e^{i\theta} = e^{in\theta}e^{i\theta} = e^{i(n+1)\theta}.$$

So it holds for every $n \geq 0$. If $n < 0$, then $-n > 0$, and since $\left(e^{i\theta}\right)^{-1} = e^{i(-\theta)}$ (Notation B.1.19), the case already proved, applied to $-\theta$ and $-n$, gives

$$\left(e^{i\theta}\right)^n = \left(\left(e^{i\theta}\right)^{-1}\right)^{-n} = \left(e^{i(-\theta)}\right)^{-n} = e^{i(-\theta)(-n)} = e^{in\theta}.$$

Finally, $\left(re^{i\theta}\right)^n = r^n\left(e^{i\theta}\right)^n = r^n e^{in\theta}$. □

Technique B.1.21 (Use polar form for products, powers, and roots). Addition is easy in the form $a + bi$. Multiplication is easy in polar form, where moduli multiply and arguments add (Proposition B.1.17). So when a problem is about products, quotients, powers, or roots of complex numbers, or about rotations of the plane, write the numbers as $re^{i\theta}$. The problem then splits into a question about positive real numbers (the moduli) and a question about angles modulo 2π (the arguments), and each is usually easy. Converting back to the form $a + bi$ costs a cosine and a sine.

Reach for it to compute a high power, to solve $z^n = w$, or to see what a product does geometrically. The canonical example is the solution of $z^n = w$ in Theorem B.1.26.
Used in. Exercise B.1.23, Theorem B.1.25, Theorem B.1.26, Proposition B.1.29, Exercise B.1.33, Exercise B.1.34.

Example B.1.22 (Powers and multiple angles).

(a) $1 + i = \sqrt{2}e^{i\pi/4}$, so by Theorem B.1.20, $(1+i)^8 = \left(\sqrt{2}\right)^8 e^{2\pi i} = 16$. Compare the repeated squaring in Exercise 1.1.36(d).

(b) $\sqrt{3} - i = 2e^{-i\pi/6}$, so $\left(\sqrt{3} - i\right)^{-6} = 2^{-6}e^{i\pi} = -1/64$.

(c) Expand the left side of $(\cos\theta + i\sin\theta)^3 = \cos 3\theta + i\sin 3\theta$ with the binomial theorem and compare real parts:

$$\cos 3\theta = \cos^3\theta - 3\cos\theta\sin^2\theta = 4\cos^3\theta - 3\cos\theta,$$

using $\sin^2\theta = 1 - \cos^2\theta$. The imaginary parts give $\sin 3\theta = 3\cos^2\theta\sin\theta - \sin^3\theta = 3\sin\theta - 4\sin^3\theta$.

Exercise B.1.23. ROUTINE Write $-2 + 2i$ and $-1 - \sqrt{3}i$ in polar form, and compute $(-2+2i)^5/\left(-1-\sqrt{3}i\right)^3$.

Solution on page 1679

B.1.5 Roots of unity

Definition B.1.24 (Roots of unity). Let $n \geq 1$. An **nth root of unity** is a complex number ζ with $\zeta^n = 1$. When n is fixed we write

$$\omega = e^{2\pi i/n} = \cos\frac{2\pi}{n} + i\sin\frac{2\pi}{n},$$

and ω_n when several values of n are in play.

For $n = 4$, $\omega = i$, and the 4th roots of unity are $1, i, -1, -i$. For $n = 3$, $\omega = -1/2 + \left(\sqrt{3}/2\right)i$, and $\omega^2 = \overline{\omega}$. Every nth root of unity is nonzero, and -1 is an nth root of unity exactly when n is even.

Theorem B.1.25 (The nth roots of unity). Let $n \geq 1$ and $\omega = e^{2\pi i/n}$.

(a) For every integer m, $\omega^m = e^{2\pi i m/n}$, and $\omega^m = 1$ if and only if $n \mid m$. Consequently $\omega^m = \omega^{m'}$ if and only if $n \mid m - m'$.

(b) The nth roots of unity are exactly $1, \omega, \omega^2, \ldots, \omega^{n-1}$, and these n numbers are distinct.

(c) Every nth root of unity ζ satisfies $|\zeta| = 1$ and $\overline{\zeta} = \zeta^{-1}$. Products and inverses of nth roots of unity are nth roots of unity.

(d) If n is even, then $\omega^{n/2} = -1$.

Proof. STANDARD

Uses. Theorem B.1.20 (De Moivre's formula), Notation B.1.19 ($e^{i\theta}$), Proposition B.1.15 (Existence and uniqueness of polar form), Proposition B.1.8 (Properties of the modulus)
Techniques. Use polar form for products, powers, and roots (Technique B.1.21)
Hint 1. For (a), apply de Moivre's formula, then ask when $e^{i\varphi} = 1$.
Hint 2. For the hard half of (b), let $\zeta^n = 1$. First show $|\zeta| = 1$, then write $\zeta = e^{i\theta}$ and use the criterion for $e^{in\theta} = 1$.
Hint 3. For (c), $|\zeta|^n = |\zeta^n| = 1$, and $\overline{\zeta}\zeta = |\zeta|^2$.
Sketch. (a) $\omega^m = e^{2\pi i m/n}$ by de Moivre, and $e^{i\varphi} = 1$ exactly when $\varphi \in 2\pi\mathbb{Z}$, which here means $m/n \in \mathbb{Z}$. (b) Each ω^k is a root, since $\left(\omega^k\right)^n = (\omega^n)^k = 1$, and they are distinct by (a). If $\zeta^n = 1$, then $|\zeta| = 1$, so $\zeta = e^{i\theta}$, and $e^{in\theta} = 1$ gives $n\theta = 2\pi k$, so $\zeta = \omega^k$; reduce k modulo n. (c) $|\zeta|^n = 1$ forces $|\zeta| = 1$, so $\overline{\zeta} = \zeta^{-1}$. (d) $\omega^{n/2} = e^{i\pi} = -1$.

(a) By Theorem B.1.20, $\omega^m = e^{i(2\pi m/n)} = e^{2\pi i m/n}$. By Notation B.1.19 this is 1 if and only if $2\pi m/n \in 2\pi\mathbb{Z}$, that is, $m/n \in \mathbb{Z}$, that is, $n \mid m$. Multiplying by $\omega^{-m'}$, $\omega^m = \omega^{m'}$ if and only if $\omega^{m-m'} = 1$, if and only if $n \mid m - m'$.

(b) For $0 \leq k \leq n-1$, $\left(\omega^k\right)^n = (\omega^n)^k = 1$ by (a), so each ω^k is an nth root of unity. If $0 \leq j < k \leq n-1$, then $0 < k - j < n$, so $n \nmid k - j$, and $\omega^j \neq \omega^k$ by (a).

Conversely, let $\zeta^n = 1$. Then $\zeta \neq 0$, and $|\zeta|^n = |\zeta^n| = 1$ by Proposition B.1.8(d). A positive real number r with $r^n = 1$ equals 1, since $r < 1$ gives $r^n < 1$ and $r > 1$ gives $r^n > 1$. So $|\zeta| = 1$, and $\zeta = e^{i\theta}$ for an argument θ of ζ (Proposition B.1.15). By Theorem B.1.20, $e^{in\theta} = \zeta^n = 1$, so $n\theta = 2\pi k$ for some $k \in \mathbb{Z}$, and $\zeta = e^{2\pi ik/n} = \omega^k$. Dividing k by n with remainder, $k = qn + r$ with $0 \leq r \leq n-1$, and $\omega^k = \omega^r$ by (a). So ζ is one of $1, \omega, \ldots, \omega^{n-1}$.

(c) As in (b), $|\zeta| = 1$, so $\overline{\zeta} = \zeta^{-1}$ by Proposition B.1.8(c). If $\zeta^n = \eta^n = 1$, then $(\zeta\eta)^n = \zeta^n\eta^n = 1$ and $\left(\zeta^{-1}\right)^n = (\zeta^n)^{-1} = 1$.

(d) By (a), $\omega^{n/2} = e^{2\pi i(n/2)/n} = e^{i\pi} = -1$. □

The roots $\omega^k = e^{2\pi ik/n}$ lie on the unit circle at the angles $2\pi k/n$, equally spaced. So for $n \geq 3$ they are the vertices of a regular n-gon inscribed in the unit circle, with one vertex at 1 (Figure B.1.3(a)). Multiplying by ω rotates the plane by $2\pi/n$ (Proposition B.1.18), which carries each vertex ω^k to the next one, ω^{k+1}, and ω^{n-1} back to $\omega^n = 1$. Parts (a)–(d) are the facts about ω behind the discrete Fourier basis (Section 6.3.4).

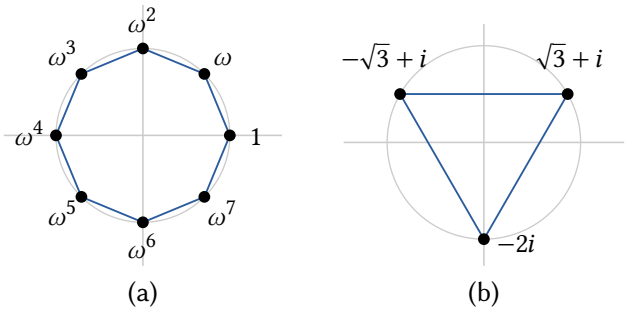


Figure B.1.3. (a) The 8th roots of unity ω^k, $\omega = e^{2\pi i/8}$, are the vertices of a regular octagon; multiplication by ω turns each vertex into the next. (b) The cube roots of $8i$ (Example B.1.27) form an equilateral triangle inscribed in the circle of radius 2.

Every nonzero number has n nth roots, by the same method.

Theorem B.1.26 (nth roots). Let $n \geq 1$, and let $w = re^{i\varphi}$ with $r > 0$ and $\varphi \in \mathbb{R}$. The equation $z^n = w$ has exactly n solutions in $\mathbb{C}$, namely

$$z_k = r^{1/n} e^{i(\varphi+2\pi k)/n}, \quad k = 0, 1, \ldots, n-1,$$

where $r^{1/n}$ is the positive real nth root of r. If z_* is any one solution, the solutions are exactly the numbers $z_*\zeta$ with ζ an nth root of unity. For $n \geq 3$ they are the vertices of a regular n-gon inscribed in the circle of radius $r^{1/n}$ about 0.

Proof. STANDARD

Uses. Theorem B.1.20 (De Moivre's formula), Theorem B.1.25 (The nth roots of unity), Corollary 1.1.14 (Cancellation), Proposition B.1.17 (Multiplication in polar form)
Techniques. Use polar form for products, powers, and roots (Technique B.1.21)
Hint 1. Check with de Moivre's formula that z_0 is a solution.
Hint 2. If z_* and z are both solutions, what equation does z/z_* satisfy?
Sketch. By de Moivre, $z_0^n = re^{i\varphi} = w$. If z_* is one solution, then $z^n = w$ if and only if $(z/z_*)^n = 1$, that is, $z = z_*\zeta$ for an n th root of unity ζ, and there are exactly n of these by Theorem B.1.25. With $z_* = z_0$ this is the list $z_k = z_0\omega^k$.

By Theorem B.1.20, $z_0^n = \left(r^{1/n}\right)^n e^{i\varphi} = w$, so solutions exist. Let z_* be any solution. Since $w \neq 0$, also $z_* \neq 0$. For $z \in \mathbb{C}$, $z^n = w$ if and only if $(z/z_*)^n = z^n/w = 1$, that is, z/z_* is an nth root of unity. So the solutions are the numbers $z_*\zeta$ with $\zeta^n = 1$. By Theorem B.1.25(b) there are exactly n such ζ, namely $1, \omega, \ldots, \omega^{n-1}$ with $\omega = e^{2\pi i/n}$, and the numbers $z_*\omega^k$ are distinct because $z_* \neq 0$ (Corollary 1.1.14). Taking $z_* = z_0$ and using Proposition B.1.17,

$$z_0\omega^k = r^{1/n}e^{i\varphi/n}e^{2\pi ik/n} = r^{1/n}e^{i(\varphi+2\pi k)/n} = z_k.$$

All the z_k have modulus $r^{1/n}$, and their arguments $(\varphi + 2\pi k)/n$ are spaced $2\pi/n$ apart, so for $n \geq 3$ they are the vertices of a regular n-gon. □

For $w = 0$, the only solution of $z^n = 0$ is $z = 0$, by Proposition 1.1.17.

Example B.1.27 (Cube roots of $8i$, fourth roots of -4).

(a) $8i = 8e^{i\pi/2}$, so the cube roots of $8i$ are $2e^{i(\pi/2+2\pi k)/3}$ for $k = 0, 1, 2$, with arguments $\pi/6, 5\pi/6$, and $3\pi/2$:

$$2e^{i\pi/6} = \sqrt{3} + i, \quad 2e^{5\pi i/6} = -\sqrt{3} + i, \quad 2e^{3\pi i/2} = -2i.$$

For instance, $(-2i)^3 = -8i^3 = 8i$. They form an equilateral triangle (Figure B.1.3(b)).

(b) $-4 = 4e^{i\pi}$, so the fourth roots of -4 are $\sqrt{2}e^{i(\pi+2\pi k)/4}$ for $k = 0, 1, 2, 3$. That is, they are $\sqrt{2}e^{i\pi/4} = 1 + i$ times the fourth roots of unity $1, i, -1, -i$: the numbers $\pm 1 \pm i$ of Example B.1.5.

The sum of the roots of unity

The nth roots of unity are the vertices of a regular polygon centred at 0, so their average, the centre of mass of the vertices, should be 0. Rotating by $2\pi/n$ permutes the vertices, so their sum S satisfies $\omega S = S$, and as $\omega \neq 1$, this forces $S = 0$. Here are two proofs, together with the product of the roots.

Proposition B.1.28 (Sum and product of the roots of unity). Let $n \geq 2$ and $\omega = e^{2\pi i/n}$. The nth roots of unity add up to 0, and their product is $(-1)^{n-1}$:

$$\sum_{k=0}^{n-1} \omega^k = 0, \quad \prod_{k=0}^{n-1} \omega^k = (-1)^{n-1}.$$

Proof (factor and cancel). ROUTINE

Uses. Theorem B.1.25 (The nth roots of unity), Proposition 1.1.17 (No zero divisors)
Hint 1. Multiply the sum $S = 1 + \omega + \cdots + \omega^{n-1}$ by $\omega - 1$. The products telescope.
Hint 2. For the product, add the exponents: $0 + 1 + \cdots + (n-1) = n(n-1)/2$. Treat odd and even n separately, using Theorem B.1.25(a) and (d).
Sketch. $(\omega - 1)S = \omega^n - 1 = 0$, and $\omega \neq 1$ since $n \geq 2$, so $S = 0$. The product is $\omega^{n(n-1)/2}$. For odd n, n divides $n(n-1)/2$, so the product is 1; for even n, it is $\left(\omega^{n/2}\right)^{n-1} = (-1)^{n-1}$.

Let $S = 1 + \omega + \cdots + \omega^{n-1}$. Then

$$(\omega - 1)S = \left(\omega + \omega^2 + \cdots + \omega^n\right) - \left(1 + \omega + \cdots + \omega^{n-1}\right) = \omega^n - 1 = 0.$$

Since $n \geq 2$, $n \nmid 1$, so $\omega \neq 1$ by Theorem B.1.25(a), and Proposition 1.1.17 gives $S = 0$.

The product is $\omega^{0+1+\cdots+(n-1)} = \omega^{n(n-1)/2}$. If n is odd, then $(n-1)/2$ is an integer, so n divides $n(n-1)/2$, and the product is $1 = (-1)^{n-1}$ by Theorem B.1.25(a). If n is even, then $n(n-1)/2 = (n/2)(n-1)$, and by Theorem B.1.25(d) the product is $\left(\omega^{n/2}\right)^{n-1} = (-1)^{n-1}$. □

Proof (compare coefficients). STANDARD

Uses. Theorem B.1.25 (The nth roots of unity), the factor theorem: a polynomial of degree n with leading coefficient 1 and n distinct roots $c_1, \ldots, c_n$ equals $(x - c_1)\cdots(x - c_n)$ (Section 7.1)
Techniques. Polynomial identity arguments (Technique 5.5.24)
Hint 1. The nth roots of unity are exactly the roots of the polynomial $x^n - 1$, and there are n of them. Factor $x^n - 1$.
Hint 2. In $(x - c_1)\cdots(x - c_n)$, the coefficient of x^{n-1} is $-(c_1 + \cdots + c_n)$ and the constant term is $(-1)^n c_1 \cdots c_n$.
Sketch. By Theorem B.1.25, $x^n - 1$ has the n distinct roots ω^k, so $x^n - 1 = \prod_k \left(x - \omega^k\right)$. Comparing the coefficients of x^{n-1} (which is 0 on the left, as $n \geq 2$) and the constant terms gives $-\sum_k \omega^k = 0$ and $(-1)^n \prod_k \omega^k = -1$.

The polynomial $x^n - 1 \in \mathbb{C}[x]$ has degree n and leading coefficient 1, and by Theorem B.1.25(b) it has the n distinct roots $1, \omega, \ldots, \omega^{n-1}$. By the factor theorem (Section 7.1),

$$x^n - 1 = (x - 1)(x - \omega)\cdots\left(x - \omega^{n-1}\right).$$

Multiplying out the right side, each term picks x or $-\omega^k$ from each factor. The terms of degree $n - 1$ pick $-\omega^k$ from exactly one factor, so the coefficient of x^{n-1} is $-\left(1 + \omega + \cdots + \omega^{n-1}\right)$. The constant term picks $-\omega^k$ from every factor, so it is $(-1)^n \omega^0 \omega^1 \cdots \omega^{n-1}$. On the left, the coefficient of x^{n-1} is 0, since $n - 1 \geq 1$, and the constant term is -1. Comparing,

$$\sum_{k=0}^{n-1} \omega^k = 0, \quad \prod_{k=0}^{n-1} \omega^k = (-1)^{n+1} = (-1)^{n-1}.$$

□

The first proof needs nothing about polynomials. The second reads both identities off one factorization, the way Vieta's formulas relate the coefficients of a polynomial to its roots, and the other coefficients of $x^n - 1$ give more identities of the same kind (Exercise B.1.45 uses the factorization again).

The first proof applies to any nth root of unity $\zeta \neq 1$: since $(\zeta - 1)\big(1 + \zeta + \cdots + \zeta^{n-1}\big) = \zeta^n - 1 = 0$, we get $1 + \zeta + \cdots + \zeta^{n-1} = 0$. With $\zeta = \omega^m$ this is Lemma 6.3.39, the computation behind the orthogonality of the discrete Fourier basis.

B.1.6 Square roots and quadratic equations

$\mathbb{R}$ was enlarged to $\mathbb{C}$ to give -1 a square root. Every complex number then has a square root without any further enlargement, and so every quadratic equation over $\mathbb{C}$ can be solved.

Proposition B.1.29 (Square roots in $\mathbb{C}$). Every $w \in \mathbb{C}$ has a square root in $\mathbb{C}$. If $w \neq 0$, it has exactly two square roots, z_* and $-z_*$, where z_* is any one of them. The only square root of 0 is 0.

Proof (by polar form). ROUTINE

Uses. Theorem B.1.26 (nth roots), Theorem B.1.25 (The nth roots of unity), Proposition 1.1.17 (No zero divisors)
Techniques. Use polar form for products, powers, and roots (Technique B.1.21)
Hint 1. Apply Theorem B.1.26 with $n = 2$.
Hint 2. The square roots of unity are 1 and $e^{i\pi} = -1$.
Sketch. For $w \neq 0$, Theorem B.1.26 with $n = 2$ gives exactly the two solutions $z_*\zeta$ with $\zeta \in \{1, -1\}$. For $w = 0$, $z^2 = 0$ forces $z = 0$.

If $w = 0$, then $z^2 = 0$ forces $z = 0$ (Proposition 1.1.17). If $w \neq 0$, Theorem B.1.26 with $n = 2$ gives exactly two solutions of $z^2 = w$, namely $z_*\zeta$ for the two square roots of unity ζ. By Theorem B.1.25 with $n = 2$, these are 1 and $\omega^{2/2} = -1$, so the solutions are z_* and $-z_*$. Explicitly, if $w = re^{i\varphi}$, then $z_* = \sqrt{r}e^{i\varphi/2}$ is one of them. □

Proof (by solving for the real and imaginary parts). STANDARD

Uses. Proposition B.1.8 (Properties of the modulus), Proposition 1.1.17 (No zero divisors), Definition 1.1.29 (Complex numbers)
Hint 1. Write $w = a + bi$ and look for $z = x + yi$. Then $z^2 = w$ says $x^2 - y^2 = a$ and $2xy = b$.
Hint 2. Taking moduli, $x^2 + y^2 = |w|$. Combine this with $x^2 - y^2 = a$ to find x^2 and y^2, then fix the signs with $2xy = b$.
Hint 3. For the count, factor $z^2 - z_*^2$.
Sketch. A solution must satisfy $x^2 - y^2 = a$ and $x^2 + y^2 = |w|$, so $x^2 = (|w| + a)/2$ and $y^2 = (|w| - a)/2$, both nonnegative because $|a| \leq |w|$. Taking the nonnegative root for x and giving y the sign of b (either sign if $b = 0$), one checks that $x^2 - y^2 = a$ and $2xy = b$. Finally, $z^2 = z_*^2$ if and only if $(z - z_*)(z + z_*) = 0$.

Let $w = a + bi$. We first find a candidate. If $z = x + yi$ satisfies $z^2 = w$, then $x^2 - y^2 = a$ and $2xy = b$, and taking moduli, $x^2 + y^2 = |z|^2 = |z^2| = |w|$ (Proposition B.1.8(d)). Hence

$$x^2 = \frac{|w| + a}{2}, \quad y^2 = \frac{|w| - a}{2}.$$

Both right sides are nonnegative, since $|a| \leq |w|$ (Proposition B.1.8(e)). So let $\sigma = 1$ if $b \geq 0$ and $\sigma = -1$ if $b < 0$, and put

$$z_* = \sqrt{\frac{|w| + a}{2}} + \sigma\sqrt{\frac{|w| - a}{2}}\, i. \tag{B.1.3}$$

We check that $z_*^2 = w$. The real part of z_*^2 is $(|w| + a)/2 - (|w| - a)/2 = a$, and its imaginary part is

$$2\sigma\sqrt{\frac{|w| + a}{2}}\sqrt{\frac{|w| - a}{2}} = \sigma\sqrt{|w|^2 - a^2} = \sigma\sqrt{b^2} = \sigma|b| = b.$$

So every w has a square root. Now if $z_*^2 = w$, then $z^2 = w$ if and only if $(z - z_*)(z + z_*) = z^2 - z_*^2 = 0$, which by Proposition 1.1.17 holds if and only if $z = z_*$ or $z = -z_*$. These differ unless $2z_* = 0$, that is, unless $z_* = 0$, which happens exactly when $w = 0$. □

The second proof needs no trigonometry: (B.1.3) computes a square root from two real square roots. For $w = 3 + 4i$ we have $|w| = 5$, so $z_* = \sqrt{4} + \sqrt{1}\,i = 2 + i$, and indeed $(2+i)^2 = 3 + 4i$. For $w = i$ it gives $z_* = (1+i)/\sqrt{2}$, as in Exercise 1.1.44(b).

Theorem B.1.30 (Quadratic equations over $\mathbb{C}$). Let $a, b, c \in \mathbb{C}$ with $a \neq 0$, let $\Delta = b^2 - 4ac$, and let s be a square root of Δ (Proposition B.1.29). Then the solutions of $az^2 + bz + c = 0$ are

$$z_1 = \frac{-b+s}{2a}, \quad z_2 = \frac{-b-s}{2a},$$

which are distinct if $\Delta \neq 0$ and equal if $\Delta = 0$. Moreover, $az^2 + bz + c = a(z - z_1)(z - z_2)$ for every $z \in \mathbb{C}$.

Proof. ROUTINE

Uses. Proposition B.1.29 (Square roots in $\mathbb{C}$), Exercise 1.1.50
Hint 1. Complete the square: multiply the equation by $4a$.
Hint 2. $4a\big(az^2 + bz + c\big) = (2az + b)^2 - \Delta$. Now use that the square roots of Δ are $\pm s$.
Hint 3. For the factorization, compute $z_1 + z_2$ and $z_1 z_2$.
Sketch. Since $4a\big(az^2 + bz + c\big) = (2az + b)^2 - \Delta$ and $4a \neq 0$, z is a solution if and only if $2az + b$ is a square root of Δ, that is, $2az + b = \pm s$. The roots coincide exactly when $s = 0$. Finally $z_1 + z_2 = -b/a$ and $z_1 z_2 = \big(b^2 - s^2\big)/\big(4a^2\big) = c/a$.

Expanding, $(2az + b)^2 - \Delta = 4a^2z^2 + 4abz + 4ac = 4a\big(az^2 + bz + c\big)$. Since $4a \neq 0$, z is a solution if and only if $(2az + b)^2 = \Delta$, that is, $2az + b$ is a square root of Δ. By Proposition B.1.29 the square roots of Δ are s and $-s$, so z is a solution if and only if $2az + b = \pm s$, that is, $z = z_1$ or $z = z_2$. These coincide if and only if $s = -s$, that is, $s = 0$, that is, $\Delta = 0$. Finally $z_1 + z_2 = -b/a$ and

$$z_1 z_2 = \frac{(-b)^2 - s^2}{4a^2} = \frac{4ac}{4a^2} = \frac{c}{a},$$

so $a(z - z_1)(z - z_2) = az^2 - a(z_1 + z_2)z + az_1z_2 = az^2 + bz + c$. □

This is Exercise 1.1.50(a) for the field $\mathbb{C}$, where the hypothesis that $b^2 - 4ac$ is a square always holds.

Example B.1.31 (A quadratic with complex coefficients). To solve $z^2 - 3z + (3 - i) = 0$, compute $\Delta = 9 - 4(3 - i) = -3 + 4i$. Here $|\Delta| = 5$, and (B.1.3) gives the square root $s = \sqrt{1} + \sqrt{4}\,i = 1 + 2i$. So the solutions are

$$z = \frac{3 \pm (1 + 2i)}{2}, \quad \text{that is,} \quad z = 2 + i \quad \text{and} \quad z = 1 - i.$$

Check: their sum is 3 and their product is $(2 + i)(1 - i) = 3 - i$. The roots are not conjugate to each other, which is allowed because the coefficients are not real (compare Proposition B.1.4).

Remark B.1.32 (The Fundamental Theorem of Algebra). Theorem B.1.26 and Theorem B.1.30 solve two kinds of polynomial equations over $\mathbb{C}$. The Fundamental Theorem of Algebra (Theorem 7.1.32) says that every nonconstant polynomial with complex coefficients has a root in $\mathbb{C}$. Over $\mathbb{R}$ this fails already for $x^2 + 1$, and $\mathbb{C}$ was built by adjoining a root of that single polynomial; the theorem says that no polynomial ever forces a further enlargement. Together with the factor theorem, it factors every polynomial in $\mathbb{C}[x]$ into linear factors, and together with Proposition B.1.4, it factors every polynomial in $\mathbb{R}[x]$ into real factors of degree at most 2 (Section 7.1). For degree 5 and higher there is no formula in radicals like Theorem B.1.30, and the proofs in Section C.1 show that a root exists without producing it. In linear algebra, the theorem is what guarantees that every operator on a nonzero finite-dimensional complex vector space has an eigenvalue (Theorem 7.3.27).

Exercises

Exercise B.1.33. ROUTINE Write each of the following in the form $a + bi$: (a) $(1 - i)^{10}$; (b) $\left(1 + \sqrt{3}i\right)^{-4}$; (c) $(\cos(\pi/9) + i\sin(\pi/9))^{12}$; (d) $((1 + i)/(1 - i))^{2027}$.

Solution on page 1680

Exercise B.1.34. ROUTINE Find all $z \in \mathbb{C}$ with $z^6 = -64$, in the form $a + bi$, and draw them. Which of them satisfy $z^2 = -4$?

Solution on page 1680

Exercise B.1.35. ROUTINE Let $z, w \in \mathbb{C}$.

(a) Show that $|z+w|^2 + |z-w|^2 = 2|z|^2 + 2|w|^2$, and interpret this in the parallelogram with vertices $0, z, w, z+w$.

(b) Show that $|z+w|^2 - |z-w|^2 = 4\,\mathrm{Re}(z\overline{w})$. Deduce that the two diagonals of the parallelogram have the same length if and only if $\mathrm{Re}(z\overline{w}) = 0$, and interpret this condition geometrically.

Solution on page 1680

Exercise B.1.36. STANDARD Let $z, w \in \mathbb{C}$.

(a) Show that $|1 - \overline{z}w|^2 - |z-w|^2 = \left(1 - |z|^2\right)\left(1 - |w|^2\right)$.

(b) Deduce that if $|z| < 1$ and $|w| < 1$, then $1 - \overline{z}w \neq 0$ and

$$\left|\frac{z-w}{1-\overline{z}w}\right| < 1.$$

(c) Show that if $|w| = 1$ and $\overline{z}w \neq 1$, then $|(z-w)/(1-\overline{z}w)| = 1$.

Solution on page 1681

Exercise B.1.37. STANDARD Describe each of the following sets geometrically.

(a) $\{z \in \mathbb{C} \mid |z-1| = |z+i|\}$.

(b) $\{z \in \mathbb{C} \mid |z-1| = 2|z+1|\}$.

(c) $\{z \in \mathbb{C} \mid z \neq -1, \mathrm{Re}((z-1)/(z+1)) = 0\}$.

Solution on page 1681

Exercise B.1.38. ROUTINE Prove or disprove each statement, for all $z, w \in \mathbb{C}$.

(a) $\mathrm{Re}(zw) = \mathrm{Re}\, z\, \mathrm{Re}\, w$.

(b) $|z^2| = |z|^2$.

(c) If z^2 is real, then z is real.

(d) If $|z| = |w|$, then $z = w$ or $z = -w$.

(e) If $|z+w| = |z-w|$, then $\mathrm{Re}(z\overline{w}) = 0$.

(f) If $z \neq 0$, then $\overline{1/z} = 1/\overline{z}$.

Solution on page 1682

Exercise B.1.39. ROUTINE Find the error in the following argument.

Claim. $1 = -1$.

Proof. By de Moivre's formula with $n = 1/2$, $(\cos\theta + i\sin\theta)^{1/2} = \cos(\theta/2) + i\sin(\theta/2)$ for every $\theta \in \mathbb{R}$. Now $1 = \cos 0 + i\sin 0 = \cos 2\pi + i\sin 2\pi$. Taking $\theta = 0$ gives $1^{1/2} = \cos 0 + i\sin 0 = 1$, and taking $\theta = 2\pi$ gives $1^{1/2} = \cos\pi + i\sin\pi = -1$. So $1 = -1$.

Solution on page 1682

Exercise B.1.40. STANDARD For $\mathbf{z} = (z_1, \ldots, z_n) \in \mathbb{C}^n$, write $\overline{\mathbf{z}} = (\overline{z_1}, \ldots, \overline{z_n})$. Let $A \in \mathbb{R}^{m \times n}$.

(a) Show that $A\overline{\mathbf{z}} = \overline{A\mathbf{z}}$ for every $\mathbf{z} \in \mathbb{C}^n$.

(b) Let $m = n$, $\lambda \in \mathbb{C}$, and $\mathbf{v} \in \mathbb{C}^n$ with $A\mathbf{v} = \lambda\mathbf{v}$. Show that $A\overline{\mathbf{v}} = \overline{\lambda}\,\overline{\mathbf{v}}$.

(c) Let $\mathbf{b} \in \mathbb{R}^m$. Show that the set of solutions $\mathbf{z} \in \mathbb{C}^n$ of $A\mathbf{z} = \mathbf{b}$ is closed under conjugation, and that if it is nonempty, it contains a vector in $\mathbb{R}^n$.

Solution on page 1682

Exercise B.1.41. STANDARD

(a) Find $A \in \mathbb{R}^{2\times 2}$ with $A^3 = -I_2$ but $A \neq -I_2$.

(b) For each $n \geq 2$, find $A \in \mathbb{R}^{2\times 2}$ with $A^n = I_2$ but $A^k \neq I_2$ for $1 \leq k < n$.

Solution on page 1683

Exercise B.1.42. STANDARD For $z = a + bi \in \mathbb{C}$, let $\varphi(z) = \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \in \mathbb{R}^{2\times 2}$, and let $K = \{\varphi(z) \mid z \in \mathbb{C}\}$.

(a) Show that $\varphi(z + w) = \varphi(z) + \varphi(w)$, $\varphi(zw) = \varphi(z)\varphi(w)$, and $\varphi(1) = I_2$, and that φ is injective.

(b) Show that $\varphi(\overline{z}) = \varphi(z)^{\mathsf{T}}$ and $\det \varphi(z) = |z|^2$.

(c) Show that K, with matrix addition and multiplication, is a field, and that $\varphi(z)^{-1} = \varphi\big(z^{-1}\big)$ for $z \neq 0$.

Solution on page 1683

Exercise B.1.43. STANDARD Let $\sigma : \mathbb{C} \to \mathbb{C}$ be an automorphism of $\mathbb{C}$ (Section B.1.1) with $\sigma(t) = t$ for every $t \in \mathbb{R}$. Show that σ is either the identity or conjugation.

Solution on page 1684

Exercise B.1.44. STANDARD Let $z_1, z_2, z_3 \in \mathbb{C}$ with $|z_1| = |z_2| = |z_3| = 1$ and $z_1 + z_2 + z_3 = 0$. Show that $\{z_1, z_2, z_3\} = \{u, u\omega, u\omega^2\}$ for some u with $|u| = 1$, where $\omega = e^{2\pi i/3}$. Conclude that z_1, z_2, z_3 are the vertices of an equilateral triangle.

Solution on page 1684

Exercise B.1.45. HARD Let $n \geq 2$ and $\omega = e^{2\pi i/n}$.

(a) Show that $1 + x + \cdots + x^{n-1} = (x - \omega)\big(x - \omega^2\big)\cdots\big(x - \omega^{n-1}\big)$ in $\mathbb{C}[x]$.

(b) Deduce that $(1 - \omega)\big(1 - \omega^2\big)\cdots\big(1 - \omega^{n-1}\big) = n$.

(c) Show that the product of the distances from one vertex of a regular n-gon inscribed in the unit circle to the other $n - 1$ vertices is n. Deduce that

$$\prod_{k=1}^{n-1} \sin\frac{k\pi}{n} = \frac{n}{2^{n-1}}.$$

Solution on page 1684

Exercise B.1.46. STANDARD An nth root of unity ζ is **primitive** if $\zeta^m \neq 1$ for $1 \leq m < n$. Let $\omega = e^{2\pi i/n}$.

(a) Show that for $0 \le k \le n-1$, ω^k is primitive if and only if $\gcd(k,n) = 1$.

(b) Show that if ζ is primitive, then $1, \zeta, \zeta^2, \ldots, \zeta^{n-1}$ are all the nth roots of unity.

(c) List the primitive 12th roots of unity in the form $a + bi$.

Solution on page 1685

Exercise B.1.47. HARD Let $n \ge 1$. Show that $x^2 + x + 1$ divides $x^{2n} + x^n + 1$ in $\mathbb{R}[x]$ if and only if $3 \nmid n$.

Solution on page 1685

Exercise B.1.48. STANDARD BEYOND 21-242 The **Gaussian integers** are $\mathbb{Z}[i] = \{a + bi \mid a, b \in \mathbb{Z}\}$, and the **norm** of $z \in \mathbb{Z}[i]$ is $N(z) = |z|^2$.

(a) Show that $\mathbb{Z}[i]$ is closed under addition, negation, and multiplication, that $N(z)$ is a nonnegative integer, and that $N(zw) = N(z)N(w)$.

(b) A **unit** of $\mathbb{Z}[i]$ is a $z \in \mathbb{Z}[i]$ with $zw = 1$ for some $w \in \mathbb{Z}[i]$. Show that the units are $1, -1, i, -i$.

(c) Starting from $5 = N(2+i)$ and $13 = N(3+2i)$, write 65 as a sum of two squares of integers in two different ways.

Solution on page 1686

Exercise B.1.49. CHALLENGE Let $z_1, \ldots, z_n \in \mathbb{C}$. Show that there is a set $S \subseteq \{1, \ldots, n\}$ with

$$\left| \sum_{k \in S} z_k \right| \ge \frac{1}{\pi} \sum_{k=1}^{n} |z_k|.$$

Solutions

Section 1.1

Solution to Exercise 1.1.11

Uses. Theorem 1.1.9 (Uniqueness of identities and inverses), Definition 1.1.1 (Field)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. By Theorem 1.1.9, to show that $y = -x$ it suffices to show that $x + y = 0$.
Hint 2. For the second claim, add $(a+b)+((-a)+(-b))$ and regroup so that a meets $-a$ and b meets $-b$.
Sketch. $0 + 0 = 0$, so 0 is an additive inverse of 0. Regrouping gives $(a+b)+((-a)+(-b)) = (a+(-a))+(b+(-b)) = 0$. Both claims follow from uniqueness of additive inverses.

Since $0 + 0 = 0$ by the additive identity axiom, 0 is an additive inverse of 0, so $-0 = 0$ by Theorem 1.1.9.

For the second claim,

$$\begin{aligned}
(a+b)+((-a)+(-b)) &= a+(b+((-a)+(-b))) && \text{(associativity)}\\
&= a+((b+(-a))+(-b)) && \text{(associativity)}\\
&= a+(((-a)+b)+(-b)) && \text{(commutativity)}\\
&= a+((-a)+(b+(-b))) && \text{(associativity)}\\
&= (a+(-a))+(b+(-b)) && \text{(associativity)}\\
&= 0+0=0 && \text{(additive inverses, additive identity).}
\end{aligned}$$

So $(-a)+(-b)$ is an additive inverse of $a+b$, and by Theorem 1.1.9 it equals $-(a+b)$.

Solution to Exercise 1.1.18

Uses. Proposition 1.1.17 (No zero divisors), Proposition 1.1.16 (Sign rules), Proposition 1.1.13 (Solving $a+x=b$ and $ax=b$)
Hint 1. Move everything to one side and factor.
Hint 2. $x^2 - x = x(x-1)$. Now use Proposition 1.1.17.
Sketch. $x^2 = x$ if and only if $x(x-1) = 0$, which by Proposition 1.1.17 happens exactly when $x = 0$ or $x = 1$.

By distributivity and Proposition 1.1.16, $x(x-1) = x^2 + x(-1) = x^2 - x$. By Proposition 1.1.13, $x^2 = x$ holds if and only if $x^2 - x = 0$, that is, if and only if $x(x-1) = 0$. By Proposition 1.1.17 this happens if and only if $x = 0$ or $x - 1 = 0$, and $x - 1 = 0$ means $x = 1$ (again by Proposition 1.1.13). So the solutions are exactly $x = 0$ and $x = 1$, which are distinct since $0 \neq 1$.

Solution to Exercise 1.1.27

Uses. Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Proposition 1.1.13 (Solving $a+x=b$ and $ax=b$)
Hint 1. Multiply pairs of nonzero elements and reduce modulo 7; you want products that leave remainder 1.
Hint 2. For the equation, follow Proposition 1.1.13: subtract 5, then multiply by 3^{-1}.
Sketch. $2 \cdot 4 = 8$, $3 \cdot 5 = 15$, and $6 \cdot 6 = 36$ all leave remainder 1. Then $3x = 2 - 5 = 4$, so $x = 5 \cdot 4 = 6$.

Since $2 \cdot 4 = 8 = 7 + 1$, $3 \cdot 5 = 15 = 14 + 1$, and $6 \cdot 6 = 36 = 35 + 1$, the inverses are

$$1^{-1} = 1, \quad 2^{-1} = 4, \quad 3^{-1} = 5, \quad 4^{-1} = 2, \quad 5^{-1} = 3, \quad 6^{-1} = 6.$$

For the equation, $3x + 5 = 2$ holds if and only if $3x = 2 - 5 = -3 = 4$, which holds if and only if $x = 3^{-1} \cdot 4 = 5 \cdot 4 = 20 \bmod 7 = 6$ (Proposition 1.1.13). Check: $3 \cdot 6 + 5 = 23 = 21 + 2$, so $3 \cdot 6 + 5 = 2$ in $\mathbb{F}_7$.

Solution to Exercise 1.1.35

Uses. Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$)
Hint 1. Eliminate x as you would over $\mathbb{R}$, by subtracting 3 times the first equation from the second. Every step is field arithmetic, so it is valid over $\mathbb{F}_7$.
Hint 2. In $\mathbb{F}_7$, $2^{-1} = 4$. Over $\mathbb{F}_2$, first rewrite the coefficients: $2 = 4 = 0$ and $3 = 1$.
Sketch. Over $\mathbb{F}_7$, elimination gives $-2y = -1$, so $y = 4$ and $x = 2$; this pair checks. Over $\mathbb{F}_2$ the system collapses to $x = 1$ twice, so y is free and there are two solutions.

(a) We work in $\mathbb{F}_7$, where $2^{-1} = 4$ since $2 \cdot 4 = 8 = 7 + 1$. Suppose (x, y) is a solution. Subtracting 3 times the first equation from the second gives

$$(3x + 4y) - 3(x + 2y) = 1 - 3 \cdot 3, \quad \text{that is,} \quad -2y = -8.$$

In $\mathbb{F}_7$, $-8 = -1$, so $2y = 1$ by Proposition 1.1.16, and $y = 2^{-1} = 4$. The first equation then gives $x = 3 - 2 \cdot 4 = -5 = 2$. So $(2, 4)$ is the only possible solution, and it is one: in $\mathbb{F}_7$, $2 + 2 \cdot 4 = 10 = 3$ and $3 \cdot 2 + 4 \cdot 4 = 22 = 1$.

(b) In $\mathbb{F}_2$ we have $2 = 4 = 0$ and $3 = 1$, so the system reads $x = 1$, $x = 1$. Its solutions are $(x, y) = (1, 0)$ and $(1, 1)$. The elimination in (a) is unavailable here, because it divided by 2, which is 0 in $\mathbb{F}_2$.

Solution to Exercise 1.1.36

Uses. Proposition 1.1.30 ($\mathbb{C}$ is a field)
Hint 1. Expand products with distributivity and use $i^2 = -1$.
Hint 2. For (b) and (c), use the inverse formula of Proposition 1.1.30, or multiply by $a - bi$ where $a + bi$ is the number being inverted. For (d), square repeatedly.
Sketch. (a) $3 + 12i - 2i + 8 = 11 + 10i$. (b) $(2 - i)/5$. (c) $(1 + i)^2/2 = i$. (d) $(1 + i)^2 = 2i$, so $(1 + i)^8 = (2i)^4 = 16$.

(a) $(3 - 2i)(1 + 4i) = 3 + 12i - 2i - 8i^2 = 11 + 10i$.

(b) By Proposition 1.1.30 with $a = 2$, $b = 1$, and $a^2 + b^2 = 5$, $(2 + i)^{-1} = \frac{2}{5} - \frac{1}{5}i$. Check: $(2 + i)(2 - i) = 4 + 1 = 5$.

(c) $(1 - i)^{-1} = (1 + i)/2$, so $(1 + i)/(1 - i) = (1 + i)^2/2 = \left(1 + 2i + i^2\right)/2 = i$.

(d) $(1 + i)^2 = 2i$, so $(1 + i)^4 = (2i)^2 = -4$ and $(1 + i)^8 = (-4)^2 = 16$.

Solution to Exercise 1.1.37

Uses. Theorem 1.1.9 (Uniqueness of identities and inverses), Proposition 1.1.15 (Multiplying by zero), Proposition 1.1.17 (No zero divisors)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Before writing $\left(a^{-1}\right)^{-1}$ you must know that $a^{-1} \neq 0$, because the inverse axiom only applies to nonzero elements. What would $a^{-1} = 0$ give?
Hint 2. To identify an inverse, exhibit a candidate and invoke uniqueness: check that a is an inverse of a^{-1}, and that $a^{-1}b^{-1}$ is an inverse of ab.
Sketch. If $a^{-1} = 0$, then $1 = aa^{-1} = 0$. Since $a^{-1}a = 1$, a is the inverse of a^{-1}. By Proposition 1.1.17, $ab \neq 0$, and $(ab)\left(a^{-1}b^{-1}\right) = \left(aa^{-1}\right)\left(bb^{-1}\right) = 1$.

If $a^{-1} = 0$, then $1 = aa^{-1} = a0 = 0$ by Proposition 1.1.15, contradicting $1 \neq 0$. So $a^{-1} \neq 0$, and a^{-1} has a multiplicative inverse. Since $a^{-1}a = aa^{-1} = 1$, the element a is a multiplicative inverse of a^{-1}, so $\left(a^{-1}\right)^{-1} = a$ by Theorem 1.1.9.

By Proposition 1.1.17, $ab \neq 0$. Reordering the product,

$$(ab)\left(a^{-1}b^{-1}\right) = \left(aa^{-1}\right)\left(bb^{-1}\right) = 1 \cdot 1 = 1,$$

so $a^{-1}b^{-1}$ is a multiplicative inverse of ab, and $(ab)^{-1} = a^{-1}b^{-1}$ by Theorem 1.1.9.

Solution to Exercise 1.1.38

Uses. Notation 1.1.10, Exercise 1.1.37, Definition 1.1.1 (Field)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Rewrite every fraction x/y as xy^{-1}, and note that $bd \neq 0$ with $(bd)^{-1} = b^{-1}d^{-1}$ (Exercise 1.1.37).
Hint 2. Then expand with distributivity and reorder products freely. The factors bb^{-1} and dd^{-1} collapse to 1.
Sketch. With $(bd)^{-1} = b^{-1}d^{-1}$, the right-hand sides expand to $ab^{-1}(dd^{-1}) + cd^{-1}(bb^{-1})$ and $(ab^{-1})(cd^{-1})$. For the last claim, multiply $a/b = c/d$ by bd, and $ad = bc$ by $b^{-1}d^{-1}$.

By Exercise 1.1.37, $bd \neq 0$ and $(bd)^{-1} = b^{-1}d^{-1}$. Using distributivity and reordering products,

$$\frac{ad+bc}{bd} = (ad+bc)b^{-1}d^{-1} = ab^{-1}\big(dd^{-1}\big) + cd^{-1}\big(bb^{-1}\big) = ab^{-1} + cd^{-1} = \frac{a}{b} + \frac{c}{d}.$$

Similarly,

$$\frac{a}{b} \cdot \frac{c}{d} = ab^{-1}cd^{-1} = (ac)\big(b^{-1}d^{-1}\big) = (ac)(bd)^{-1} = \frac{ac}{bd}.$$

For the last claim, suppose $ab^{-1} = cd^{-1}$. Multiplying both sides by bd gives $ad\big(bb^{-1}\big) = bc\big(dd^{-1}\big)$, that is, $ad = bc$. Conversely, if $ad = bc$, multiplying both sides by $b^{-1}d^{-1}$ gives $ab^{-1}\big(dd^{-1}\big) = cd^{-1}\big(bb^{-1}\big)$, that is, $a/b = c/d$.

Solution to Exercise 1.1.39

Uses. Proposition 1.1.15 (Multiplying by zero)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Compute $a \cdot 1$ for an arbitrary $a \in F$, in two ways.
Hint 2. You will want $a0 = 0$. Check that the proof of Proposition 1.1.15 never used $1 \neq 0$.
Sketch. $a = a \cdot 1 = a \cdot 0 = 0$ for every a, where $a0 = 0$ holds because the proof of Proposition 1.1.15 used only distributivity, the additive axioms, and cancellation.

The set F is nonempty because it contains 0. The proof of Proposition 1.1.15 used distributivity, the additive identity axiom, and additive cancellation, which in turn rests only on the additive axioms; none of these involve $1 \neq 0$. So $a0 = 0$ for every $a \in F$. Now for every $a \in F$,

$$a = a \cdot 1 = a \cdot 0 = 0,$$

using the multiplicative identity axiom and $1 = 0$. Hence $F = \{0\}$.

Solution to Exercise 1.1.40

Uses. Proposition 1.1.16 (Sign rules), Proposition 1.1.17 (No zero divisors)
Hint 1. Move everything to one side and try to factor $a^2 - b^2$.
Hint 2. $(a-b)(a+b) = a^2 - b^2$ in every field. Now use Proposition 1.1.17.
Sketch. True: $(a-b)(a+b) = a^2 - b^2 = 0$, so $a - b = 0$ or $a + b = 0$.

The claim is true. Expanding with distributivity and Proposition 1.1.16,

$$(a-b)(a+b) = a^2 + ab - ba - b^2 = a^2 - b^2,$$

since $ab - ba = ab - ab = 0$. If $a^2 = b^2$, then $a^2 - b^2 = 0$, so $(a-b)(a+b) = 0$. By Proposition 1.1.17, $a - b = 0$ or $a + b = 0$, that is, $a = b$ or $a = -b$.

In $\mathbb{F}_2$ we have $-b = b$, so the conclusion just says $a = b$. That is consistent: $0^2 = 0$ and $1^2 = 1$ are different.

Solution to Exercise 1.1.41

Uses. Definition 1.1.19 (Integers modulo n)
Hint 1. Try small primes one at a time. Each $\mathbb{F}_p$ has only p elements to test.
Hint 2. $p = 2$ and $p = 5$ work. Try $p = 3$.
Sketch. False: in $\mathbb{F}_3$, $x^2 + 1$ takes the values $1, 2, 2$ at $x = 0, 1, 2$.

The claim is false. In $\mathbb{F}_3$,

$$0^2 + 1 = 1, \quad 1^2 + 1 = 2, \quad 2^2 + 1 = 5 \bmod 3 = 2,$$

so $x^2 + 1 = 0$ has no solution. (It does for some primes: $x = 1$ in $\mathbb{F}_2$, and $x = 2$ or $x = 3$ in $\mathbb{F}_5$.)

Solution to Exercise 1.1.42

> *Uses.* Proposition 1.1.17 (No zero divisors), Example 1.1.4 (The field with two elements)
> *Hint 1.* The factorization and the use of Proposition 1.1.17 are correct. Test the conclusion in the smallest field.
> *Hint 2.* In $\mathbb{F}_2$, what is -1?
> *Sketch.* The argument shows that the solutions are exactly 1 and -1, but these coincide when $1 + 1 = 0$. In $\mathbb{F}_2$ there is only one solution.

The argument correctly shows that the solutions of $x^2 = 1$ are exactly $x = 1$ and $x = -1$. The error is the last sentence: 1 and -1 need not be different. In $\mathbb{F}_2$, $1 + 1 = 0$, so $-1 = 1$, and $x^2 = 1$ has exactly one solution. In general $1 = -1$ if and only if $1 + 1 = 0$, so the correct statement is that $x^2 = 1$ has exactly two solutions when $1 + 1 \neq 0$, and exactly one when $1 + 1 = 0$.

Solution to Exercise 1.1.43

> *Uses.* Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$), Proposition 1.1.15 (Multiplying by zero)
> *Hint 1.* f is a bijection if and only if, for every $y \in F$, the equation $ax + b = y$ has exactly one solution x.
> *Hint 2.* For $a \neq 0$, use Proposition 1.1.13 twice. For $a = 0$, f is constant. Why is a constant function on F not injective?
> *Sketch.* If $a \neq 0$, then $ax + b = y$ if and only if $x = a^{-1}(y - b)$, so f is bijective with $f^{-1}(y) = a^{-1}(y - b)$. If $a = 0$, then $f(0) = f(1) = b$ with $0 \neq 1$.

Suppose $a \neq 0$, and let $y \in F$. By part (a) of Proposition 1.1.13, applied with unknown ax, the equation $ax + b = y$ holds if and only if $ax = y - b$, and by part (b) this holds if and only if $x = a^{-1}(y - b)$. So every y has exactly one preimage, that is, f is a bijection, and $f^{-1}(y) = a^{-1}(y - b)$.

Suppose $a = 0$. Then $f(x) = 0x + b = b$ for every x, by Proposition 1.1.15. In particular $f(0) = f(1)$, and $0 \neq 1$, so f is not injective.

Solution to Exercise 1.1.44

> *Uses.* Proposition 1.1.17 (No zero divisors), Proposition 1.1.30 ($\mathbb{C}$ is a field), Exercise 1.1.40
> *Hint 1.* For (a), factor $z^2 + 1$ using $i^2 = -1$, then use that a field has no zero divisors.
> *Hint 2.* For (b), write $z = a + bi$ with $a, b \in \mathbb{R}$ and compare the real and imaginary parts of $z^2 = i$.
> *Hint 3.* You get $a^2 = b^2$ and $2ab = 1$. So $b = \pm a$, and one sign is impossible.
> *Sketch.* (a) $z^2 + 1 = (z - i)(z + i)$. (b) $z^2 = \left(a^2 - b^2\right) + 2abi$, so $a^2 = b^2$ and $2ab = 1$; this forces $b = a$ and $a = \pm 1/\sqrt{2}$, so $z = \pm(1 + i)/\sqrt{2}$.

(a) Since $i^2 = -1$, we have $(z - i)(z + i) = z^2 - i^2 = z^2 + 1$. So $z^2 = -1$ if and only if $(z - i)(z + i) = 0$, which by Proposition 1.1.17 holds if and only if $z = i$ or $z = -i$. These are different, since $i - (-i) = 2i \neq 0$.

(b) Write $z = a + bi$ with $a, b \in \mathbb{R}$. Then $z^2 = \left(a^2 - b^2\right) + 2abi$, so $z^2 = i$ if and only if $a^2 - b^2 = 0$ and $2ab = 1$. The first equation gives $b = a$ or $b = -a$ (Exercise 1.1.40, in $\mathbb{R}$). If $b = -a$, then $2ab = -2a^2 \leq 0$, which is not 1. So $b = a$ and $2a^2 = 1$, giving $a = \pm 1/\sqrt{2}$. Hence

$$z = \frac{1 + i}{\sqrt{2}} \quad \text{or} \quad z = -\frac{1 + i}{\sqrt{2}},$$

and both work: $\left((1 + i)/\sqrt{2}\right)^2 = \left(1 + 2i + i^2\right)/2 = i$.

Once one square root w of i is known, (a)'s method finds all of them: $z^2 = w^2$ means $(z - w)(z + w) = 0$, so $z = \pm w$.

Solution to Exercise 1.1.45

> *Uses.* Corollary 1.1.14 (Cancellation), Non-example 1.1.23 ($\mathbb{Z}/6\mathbb{Z}$), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
> *Hint 1.* Every step but one is valid for all n. Check what each cited result assumes.
> *Hint 2.* Where did Corollary 1.1.14 come from, and does $\mathbb{Z}/6\mathbb{Z}$ satisfy it? Try $a = 2$.
> *Sketch.* Multiplicative cancellation was proved for fields, using a^{-1}. Applying it to $\mathbb{Z}/n\mathbb{Z}$ assumes the inverse we are trying to produce. It fails in $\mathbb{Z}/6\mathbb{Z}$: $2 \cdot 0 = 2 \cdot 3$.

The error is the appeal to Corollary 1.1.14. That result was proved for fields, and its multiplicative part multiplies by a^{-1}, which is exactly what the argument is trying to show exists. So the argument is circular. Cancellation genuinely fails in $\mathbb{Z}/6\mathbb{Z}$: $2 \cdot 0 = 0 = 2 \cdot 3$ but $0 \neq 3$, so m is not injective there (Nonexample 1.1.23). The rest of the argument is fine, and the counting proof of Proposition 1.1.24 repairs it by proving injectivity from Euclid's lemma, which is where primality of n enters.

Solution to Exercise 1.1.46

> *Uses.* Corollary 1.1.14 (Cancellation), Theorem 1.1.9 (Uniqueness of identities and inverses), Proposition 1.1.15 (Multiplying by zero), Proposition 1.1.17 (No zero divisors), Exercise 1.1.40
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* In (a), determine $1 + 1$ first. Rule out $1 + 1 = 1$ with cancellation, and $1 + 1 = 0$ by asking what $1 + c$ could then be.
> *Hint 2.* The other entries are forced the same way. Products involving 0 or 1 are already known from the axioms and Proposition 1.1.15.
> *Hint 3.* In (b), factor $x^3 - x = x(x-1)(x+1)$ and use Proposition 1.1.17 to show $F \subseteq \{0, 1, -1\}$.
> *Sketch.* (a) Each sum is pinned down by cancellation or by uniqueness of inverses; $c^2 = 1$ because $c^2 = 0$ and $c^2 = c$ are impossible. (b) $x^3 = x$ forces $x \in \{0, 1, -1\}$, so F has two or three elements, and it is $\mathbb{F}_2$ or $\mathbb{F}_3$ up to renaming; both satisfy $x^3 = x$.

(a) Sums involving 0, and products involving 0 or 1, are determined by the identity axioms and Proposition 1.1.15, so we need $1 + 1$, $1 + c$, $c + c$, and $c \cdot c$. Throughout, 0, 1, c are distinct.

$1 + 1$. If $1 + 1 = 1 = 1 + 0$, then $1 = 0$ by cancellation, which is false. Suppose $1 + 1 = 0$. If $1 + c = 1 = 1 + 0$, then $c = 0$; if $1 + c = c = 0 + c$, then $1 = 0$; both are false, so $1 + c = 0$. But then 1 and c are both additive inverses of 1, so $c = 1$ by Theorem 1.1.9, which is false. Hence $1 + 1 = c$.

$1 + c$. As above, $1 + c = 1$ forces $c = 0$ and $1 + c = c$ forces $1 = 0$. So $1 + c = 0$, and in particular $-c = 1$.

$c + c$. If $c + c = c = c + 0$, then $c = 0$. If $c + c = 0$, then $-c = c$, but $-c = 1$, so $c = 1$. Both are false, so $c + c = 1$.

$c \cdot c$. If $c^2 = 0$, then $c = 0$ by Proposition 1.1.17. If $c^2 = c = c \cdot 1$, then $c = 1$ by cancellation (as $c \neq 0$). So $c^2 = 1$.

In $\mathbb{F}_3$, $1 + 1 = 2$, $1 + 2 = 3 \bmod 3 = 0$, $2 + 2 = 4 \bmod 3 = 1$, and $2 \cdot 2 = 4 \bmod 3 = 1$. So the tables of F are those of $\mathbb{F}_3$ with c in place of 2.

(b) Suppose $x^3 = x$ for all $x \in F$. As in Exercise 1.1.40, $(x-1)(x+1) = x^2 - 1$, so $x(x-1)(x+1) = x^3 - x = 0$ for every x. By Proposition 1.1.17 (applied twice), every x equals 0, 1, or -1. So $F \subseteq \{0, 1, -1\}$.

If $1 + 1 = 0$, then $-1 = 1$ and $F = \{0, 1\}$. In a field with two elements every sum and product is forced as above, with $1 + 1 = 0$ because $1 + 1 = 1$ would give $1 = 0$; so F has the tables of $\mathbb{F}_2$. If $1 + 1 \neq 0$, then $-1 \neq 1$, and $-1 \neq 0$, so $F = \{0, 1, -1\}$ has exactly three elements, and by (a) F has the tables of $\mathbb{F}_3$ (with -1 in place of 2).

Conversely, $x^3 = x$ holds in $\mathbb{F}_2$ ($0^3 = 0$, $1^3 = 1$) and in $\mathbb{F}_3$ ($2^3 = 8 \bmod 3 = 2$). So the fields with $x^3 = x$ for all x are exactly $\mathbb{F}_2$ and $\mathbb{F}_3$, up to renaming the elements.

Solution to Exercise 1.1.47

> *Uses.* Proposition 1.1.15 (Multiplying by zero), Proposition 1.1.16 (Sign rules), Theorem 1.1.9 (Uniqueness of identities and inverses), Exercise 1.1.40
> *Techniques.* Uniqueness via two candidates (Technique 1.1.8)
> *Hint 1.* Prove the cycle (i) ⇒ (ii) ⇒ (iii) ⇒ (i).
> *Hint 2.* (i) ⇒ (ii): $a + a = (1 + 1)a$. (ii) ⇒ (iii): use Exercise 1.1.40. (iii) ⇒ (i): compare the squares of 1 and -1.
> *Sketch.* If $1 + 1 = 0$, then $a + a = (1 + 1)a = 0$, so $a = -a$. If $a = -a$ always, then $x^2 = y^2$ gives $x = \pm y = y$. If squaring is injective, then $1^2 = (-1)^2$ gives $1 = -1$, so $1 + 1 = 0$.

We prove (i) ⇒ (ii) ⇒ (iii) ⇒ (i).

(i) ⇒ (ii). Let $a \in F$. By distributivity and Proposition 1.1.15, $a + a = 1a + 1a = (1 + 1)a = 0a = 0$. So a is an additive inverse of a, and $a = -a$ by Theorem 1.1.9.

(ii) ⇒ (iii). Suppose $x^2 = y^2$. By Exercise 1.1.40, $x = y$ or $x = -y$, and $-y = y$ by (ii). So $x = y$.

(iii) ⇒ (i). By Proposition 1.1.16, $(-1)^2 = 1 \cdot 1 = 1^2$. Injectivity gives $-1 = 1$, so $1 + 1 = 1 + (-1) = 0$.

Solution to Exercise 1.1.48

Uses. Definition 1.1.28 (Characteristic), Proposition 1.1.17 (No zero divisors)
Hint 1. Suppose $\operatorname{char} F = m > 0$ and $m = rs$ with $1 < r, s < m$. What can you say about $(r \cdot 1)(s \cdot 1)$?
Hint 2. Show that $(r \cdot 1)(s \cdot 1) = (rs) \cdot 1$ using distributivity, then use Proposition 1.1.17 and the minimality of m.
Sketch. $(r \cdot 1)(s \cdot 1) = (rs) \cdot 1$ by distributivity. If the characteristic m factored as rs with $1 < r, s < m$, then $(r \cdot 1)(s \cdot 1) = m \cdot 1 = 0$ would force $r \cdot 1 = 0$ or $s \cdot 1 = 0$, contradicting the minimality of m.

First, for positive integers r and s, distributivity gives

$$(r \cdot 1)(s \cdot 1) = (r \cdot 1)(1 + \cdots + 1) = (r \cdot 1) + \cdots + (r \cdot 1) = (rs) \cdot 1,$$

where there are s terms in the middle expressions, and the last sum consists of rs ones.

Suppose $\operatorname{char} F = m > 0$. Then $m \neq 1$, since $1 \cdot 1 = 1 \neq 0$. Suppose for contradiction that m is not prime, so $m = rs$ with $1 < r, s < m$. Then $(r \cdot 1)(s \cdot 1) = m \cdot 1 = 0$, so by Proposition 1.1.17, $r \cdot 1 = 0$ or $s \cdot 1 = 0$. Either way some positive integer smaller than m kills 1, contradicting the choice of m as the least such integer. Hence m is prime.

Solution to Exercise 1.1.49

Uses. Definition 1.1.32 (Subfield), $\sqrt{2}$ is irrational
Hint 1. Check the conditions of Definition 1.1.32 one at a time. All but one are immediate.
Hint 2. For the inverse of $a + b\sqrt{2} \neq 0$, imitate the complex case: multiply by $a - b\sqrt{2}$.
Hint 3. Why is $a^2 - 2b^2 \neq 0$? Use that $\sqrt{2}$ is irrational.
Sketch. Closure under $+$, $\cdot$, and negation is a direct computation. For $a + b\sqrt{2} \neq 0$, $\left(a + b\sqrt{2}\right)\left(a - b\sqrt{2}\right) = a^2 - 2b^2$, which is a nonzero rational because $\sqrt{2} \notin \mathbb{Q}$; dividing $a - b\sqrt{2}$ by it gives the inverse.

Write $K = \mathbb{Q}(\sqrt{2})$. Clearly $0 = 0 + 0\sqrt{2}$ and $1 = 1 + 0\sqrt{2}$ lie in K. For $a, b, c, d \in \mathbb{Q}$,

$$\begin{aligned}
\left(a + b\sqrt{2}\right) + \left(c + d\sqrt{2}\right) &= (a + c) + (b + d)\sqrt{2}, \\
\left(a + b\sqrt{2}\right)\left(c + d\sqrt{2}\right) &= (ac + 2bd) + (ad + bc)\sqrt{2}, \\
-\left(a + b\sqrt{2}\right) &= (-a) + (-b)\sqrt{2},
\end{aligned}$$

and these lie in K because $\mathbb{Q}$ is closed under its operations.

Now let $z = a + b\sqrt{2} \neq 0$. We claim $a^2 - 2b^2 \neq 0$. If $b = 0$, then $a = z \neq 0$, so $a^2 - 2b^2 = a^2 \neq 0$. If $b \neq 0$ and $a^2 = 2b^2$, then $(a/b)^2 = 2$, so $\sqrt{2} = |a/b|$ would be rational, which is false. Hence $q = a^2 - 2b^2$ is a nonzero rational, and

$$\left(a + b\sqrt{2}\right)\left(\frac{a}{q} - \frac{b}{q}\sqrt{2}\right) = \frac{a^2 - 2b^2}{q} = 1.$$

So $z^{-1} = a/q - (b/q)\sqrt{2} \in K$. Thus K is a subfield of $\mathbb{R}$, and by Proposition 1.1.33 it is a field.

Solution to Exercise 1.1.50

Uses. Proposition 1.1.17 (No zero divisors), Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$), Exercise 1.1.40
Hint 1. Complete the square. Multiplying the equation by $4a$ is allowed and reversible, because $4a \neq 0$.
Hint 2. Check that $4a\left(ax^2 + bx + c\right) = (2ax + b)^2 - \left(b^2 - 4ac\right)$.
Hint 3. For (b), note that $4 = 0$ in $\mathbb{F}_2$, so $b^2 - 4ac = b^2$ is always a square. Try $x^2 + x + 1$.
Sketch. Since $4a \neq 0$, the equation is equivalent to $(2ax + b)^2 = b^2 - 4ac$. A solution x gives $d = 2ax + b$; conversely d gives $x = (d - b)/(2a)$, and Exercise 1.1.40 shows every solution has this form for d or $-d$. In $\mathbb{F}_2$, $x^2 + x + 1$ has discriminant $1 = 1^2$ but no root.

(a) Since $2 \neq 0$ and $a \neq 0$, Proposition 1.1.17 gives $2a \neq 0$ and $4a = 2 \cdot 2 \cdot a \neq 0$. Expanding,

$$(2ax + b)^2 - \big(b^2 - 4ac\big) = 4a^2x^2 + 4abx + 4ac = 4a\big(ax^2 + bx + c\big).$$

Because $4a \neq 0$, a product $4ay$ is 0 exactly when $y = 0$. So x is a solution if and only if $(2ax + b)^2 = b^2 - 4ac$.

If x is a solution, then $d = 2ax + b$ satisfies $d^2 = b^2 - 4ac$. Conversely, suppose $d^2 = b^2 - 4ac$. If x is a solution, then $(2ax + b)^2 = d^2$, so $2ax + b = d$ or $2ax + b = -d$ (Exercise 1.1.40), and solving for x (Proposition 1.1.13) gives $x = (-b + d)/(2a)$ or $x = (-b - d)/(2a)$. Both of these are solutions, since for them $(2ax + b)^2 = (\pm d)^2 = d^2 = b^2 - 4ac$. So the solutions are exactly $x = (-b \pm d)/(2a)$.

(b) Take $a = b = c = 1$. In $\mathbb{F}_2$, $4 = 0$, so $b^2 - 4ac = 1 = 1^2$ is a square. But $0^2 + 0 + 1 = 1$ and $1^2 + 1 + 1 = 1$, so $x^2 + x + 1$ has no root in $\mathbb{F}_2$. The proof of (a) breaks at the first step, which multiplies by $4a = 0$.

Solution to Exercise 1.1.51

> *Uses.* Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Proposition 1.1.17 (No zero divisors), Corollary 1.1.14 (Cancellation)
> *Hint 1.* For (a), show that the $p - 1$ products are nonzero and pairwise distinct. You may now use that $\mathbb{F}_p$ is a field.
> *Hint 2.* For (b), multiply all $p - 1$ products together, in two ways.
> *Hint 3.* The product $P = 1 \cdot 2 \cdots (p - 1)$ is nonzero, so it can be cancelled.
> *Sketch.* The products ax for $x \neq 0$ are nonzero and distinct, so they list the $p - 1$ nonzero elements. Multiplying them all gives $a^{p-1}P = P$ with $P = 1 \cdot 2 \cdots (p - 1) \neq 0$; cancel P.

By Proposition 1.1.24, $\mathbb{F}_p$ is a field.

(a) Each product ax with $x \in \{1, \ldots, p - 1\}$ is nonzero by Proposition 1.1.17. If $ax = ay$, then $x = y$ by Corollary 1.1.14, which applies because $a \neq 0$ in a field. So the products are $p - 1$ distinct elements of the $(p - 1)$-element set $\{1, \ldots, p - 1\}$, hence all of it.

(b) Let $P = 1 \cdot 2 \cdots (p - 1)$, which is nonzero by Proposition 1.1.17. By (a), the product of $a \cdot 1, \ldots, a \cdot (p - 1)$ is the product of $1, \ldots, p - 1$ in another order, which is P. Reordering factors, the same product is $a^{p-1}P$. So $a^{p-1}P = P = 1 \cdot P$, and cancelling P (Corollary 1.1.14) gives $a^{p-1} = 1$.

Contrast this use of cancellation with Exercise 1.1.45: here we already know that $\mathbb{F}_p$ is a field.

Solution to Exercise 1.1.52

> *Uses.* Exercise 1.1.40, Proposition 1.1.17 (No zero divisors), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime)
> *Hint 1.* 0 is a square. For the nonzero squares, ask when two nonzero elements have the same square.
> *Hint 2.* By Exercise 1.1.40, $x^2 = y^2$ if and only if $y = \pm x$. When p is odd, $x \neq -x$ for $x \neq 0$.
> *Hint 3.* So squaring is two-to-one on the $p - 1$ nonzero elements.
> *Sketch.* The nonzero elements split into $(p - 1)/2$ pairs $\{x, -x\}$ with $x \neq -x$. Elements of a pair have the same square, different pairs have different squares, and squares of nonzero elements are nonzero. With 0, that makes $(p + 1)/2$ squares.

There are $(p + 1)/2$ squares.

First, $x \neq -x$ for $x \neq 0$: otherwise $(1 + 1)x = x + x = 0$, so $1 + 1 = 0$ by Proposition 1.1.17, but $1 + 1 = 2 \neq 0$ in $\mathbb{F}_p$ because p is odd. So the $p - 1$ nonzero elements split into $(p - 1)/2$ disjoint pairs $\{x, -x\}$.

By Exercise 1.1.40, two nonzero elements have the same square if and only if they lie in the same pair. Also $x^2 \neq 0$ for $x \neq 0$ by Proposition 1.1.17. So the nonzero squares are in bijection with the pairs, and there are $(p - 1)/2$ of them. Adding the square $0 = 0^2$ gives $(p + 1)/2$.

For example, the squares in $\mathbb{F}_7$ are 0, 1, $2 = 3^2$, and $4 = 2^2$, which is $(7 + 1)/2 = 4$ elements.

Solution to Exercise 1.1.53

> *Uses.* Definition 1.1.32 (Subfield), $\sqrt[3]{2}$ is irrational
> *Hint 1.* K contains 0 and 1 and is closed under addition and negation. Try products.
> *Hint 2.* Is $\left(\sqrt[3]{2}\right)^2 = \sqrt[3]{4}$ in K? Suppose $\sqrt[3]{4} = a + b\sqrt[3]{2}$ and multiply both sides by $\sqrt[3]{2}$.
> *Hint 3.* You get $2 = ab + \left(a + b^2\right)\sqrt[3]{2}$. Use the irrationality of $\sqrt[3]{2}$, twice.

Sketch. False: K is not closed under multiplication, because $\sqrt[3]{4} \notin K$. Writing $\sqrt[3]{4} = a + b\sqrt[3]{2}$ and multiplying by $\sqrt[3]{2}$ gives $2 = ab + \left(a + b^2\right)\sqrt[3]{2}$; irrationality of $\sqrt[3]{2}$ forces $a = -b^2$ and then $b^3 = -2$, which is impossible for rational b.

The claim is false: K is not closed under multiplication. Write $t = \sqrt[3]{2}$, so $t \in K$ and $t^3 = 2$. We will show that $t^2 \notin K$.

First, t is irrational. If $t = r/s$ with integers r, s, $s > 0$, and $\gcd(r, s) = 1$, then $r^3 = 2s^3$, so r is even. Writing $r = 2k$ gives $8k^3 = 2s^3$, so $s^3 = 4k^3$ and s is even too, a contradiction.

Suppose $t^2 = a + bt$ with $a, b \in \mathbb{Q}$. Multiplying by t,

$$2 = t^3 = at + bt^2 = at + b(a + bt) = ab + \left(a + b^2\right)t.$$

If $a + b^2 \neq 0$, then $t = (2 - ab)/\left(a + b^2\right)$ is rational, which is false. So $a = -b^2$, and then $2 = ab = -b^3$, so $(-b)^3 = 2$ with $-b \in \mathbb{Q}$, again contradicting the irrationality of t. Hence $t^2 \notin K$, although $t \in K$, so K is not a subfield of $\mathbb{R}$.

Solution to Exercise 1.1.54

Uses. Proposition 1.1.30 ($\mathbb{C}$ is a field), Proposition 1.1.17 (No zero divisors), Definition 1.1.20 (Commutative ring)
Hint 1. Show that every axiom except multiplicative inverses holds for every c; for associativity, expand both sides. So the question is when nonzero elements are invertible.
Hint 2. For $c < 0$ imitate $\mathbb{C}$: multiply (a, b) by $(a, -b)$.
Hint 3. For $c \geq 0$, write $c = t^2$ with $t \geq 0$, and look for zero divisors among $(t, 1)$ and $(-t, 1)$.
Sketch. For every c the structure is a commutative ring with identity $(1, 0)$. If $c < 0$, then $(a, b)(a, -b) = \left(a^2 - cb^2, 0\right)$ with $a^2 - cb^2 > 0$ for $(a, b) \neq (0, 0)$, which gives inverses. If $c = t^2 \geq 0$, then $(t, 1)(-t, 1) = (0, 0)$, so there are zero divisors. Answer: exactly when $c < 0$.

The answer is: exactly when $c < 0$.

The other axioms hold for every c. Addition is componentwise, so its axioms hold as in $\mathbb{R}^2$. The multiplication is commutative, because the formula is symmetric under swapping (a, b) and (a', b'). The element $(1, 0)$ is an identity, $(a, b)(1, 0) = (a, b)$, and $(1, 0) \neq (0, 0)$. Distributivity holds because each coordinate of the product is a sum of terms each involving exactly one coordinate of the second factor, so it is additive in the second factor. For associativity, with $(a, b), (a', b'), (a'', b'')$,

$$((a, b)(a', b'))(a'', b'') = ((aa' + cbb')a'' + c(ab' + ba')b'', (aa' + cbb')b'' + (ab' + ba')a''),$$
$$(a, b)((a', b')(a'', b'')) = (a(a'a'' + cb'b'') + cb(a'b'' + b'a''), a(a'b'' + b'a'') + b(a'a'' + cb'b'')),$$

and both first coordinates equal $aa'a'' + c(ab'b'' + ba'b'' + bb'a'')$, while both second coordinates equal $aa'b'' + ab'a'' + ba'a'' + cbb'b''$. So for every c we have a commutative ring, and it is a field exactly when every nonzero element has a multiplicative inverse.

If $c < 0$. For $(a, b) \neq (0, 0)$, $q = a^2 - cb^2 = a^2 + |c|b^2 > 0$. Since $(a, b)(a, -b) = \left(a^2 - cb^2, -ab + ba\right) = (q, 0)$, the element $(a/q, -b/q)$ is an inverse of (a, b). So the structure is a field.

If $c \geq 0$. Let $t = \sqrt{c}$. Then

$$(t, 1)(-t, 1) = \left(-t^2 + c, t - t\right) = (0, 0),$$

while $(t, 1)$ and $(-t, 1)$ are nonzero. By Proposition 1.1.17 the structure is not a field.

Solution to Exercise 1.1.55

Uses. Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Proposition 1.1.15 (Multiplying by zero), the division algorithm: $x \bmod n = y \bmod n$ if and only if $n \mid x - y$
Hint 1. Without distributivity, $+$ and $\cdot$ are unrelated. Keep the addition of $\mathbb{Z}/3\mathbb{Z}$ and look for a separate multiplication on $\{0, 1, 2\}$.
Hint 2. The axioms about multiplication alone ask for a commutative, associative operation with identity 1 in which every nonzero element has an inverse. The addition of $\mathbb{Z}/3\mathbb{Z}$ has all these properties, but its identity is 0. Shift it so that the identity becomes 1.

Hint 3. Try $a * b = (a + b - 1) \bmod 3$.
Sketch. On $\{0, 1, 2\}$ take the addition of $\mathbb{Z}/3\mathbb{Z}$ and the multiplication $a * b = (a + b - 1) \bmod 3$. This multiplication is commutative and associative with identity 1, and every element has an inverse, but $0 * 0 = 2$.

Let $F = \{0, 1, 2\}$ with the addition $+_3$ of $\mathbb{Z}/3\mathbb{Z}$, and define

$$a * b = (a + b - 1) \bmod 3.$$

The additive axioms hold by Lemma 1.1.21. For the multiplication we use that $x \bmod 3 = y \bmod 3$ whenever $3 \mid x - y$. The operation $*$ is commutative since $a + b - 1 = b + a - 1$. It is associative: $(a + b - 1) \bmod 3$ differs from $a + b - 1$ by a multiple of 3, so

$$(a * b) * c = ((a + b - 1) \bmod 3 + c - 1) \bmod 3 = (a + b + c - 2) \bmod 3,$$

and in the same way $a * (b * c) = (a + b + c - 2) \bmod 3$. The element 1 is an identity, since $a * 1 = a \bmod 3 = a$, and $1 \neq 0$. Every element has an inverse: $(2 - a) \bmod 3$ differs from $2 - a$ by a multiple of 3, so $a * ((2 - a) \bmod 3) = (a + 2 - a - 1) \bmod 3 = 1$. So every field axiom except distributivity holds. However,

$$0 * 0 = (-1) \bmod 3 = 2 \neq 0.$$

By Proposition 1.1.15, distributivity must therefore fail. Indeed $0 * (0 + 0) = 2$, while $0 * 0 + 0 * 0 = 2 +_3 2 = 1$.

Solution to Exercise 1.1.56

Uses. Definition 1.1.1 (Field), Lemma 1.1.21 (Arithmetic in $\mathbb{Z}/n\mathbb{Z}$), Proposition 1.1.24 ($\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime), Definition 1.1.28 (Characteristic)
Hint 1. Do not check all 64 triples. Identify the elements with pairs of elements of $\mathbb{F}_2$: $0 = (0, 0)$, $1 = (1, 0)$, $\alpha = (0, 1)$, $\beta = (1, 1)$. What does addition become?
Hint 2. The nonzero elements are 1, α, $\alpha^2 = \beta$, and $\alpha^3 = 1$. How does multiplication of nonzero elements act on exponents?
Hint 3. For distributivity, write multiplication by α as a map on pairs and check that it respects addition. Multiplication by β is that map applied twice.
Sketch. As pairs over $\mathbb{F}_2$, addition is coordinatewise, which gives the additive axioms. Nonzero elements are $\alpha^0, \alpha^1, \alpha^2$ with $\alpha^i \alpha^j = \alpha^{i +_3 j}$, so multiplication of nonzero elements is addition in $\mathbb{Z}/3\mathbb{Z}$, which gives the multiplicative axioms. Multiplication by α is $(u, v) \mapsto (v, u + v)$, which respects addition, and multiplication by β is its square, which gives distributivity. Since $1 + 1 = 0$, the characteristic is 2, whereas $\mathbb{Z}/4\mathbb{Z}$ is not even a field.

(a) We check the axioms in groups.

Addition. Identify $0, 1, \alpha, \beta$ with the pairs $(0, 0), (1, 0), (0, 1), (1, 1)$ of elements of $\mathbb{F}_2$. Under this identification the given addition is coordinatewise addition in $\mathbb{F}_2$: each pair added to itself gives $(0, 0)$, and the sum of two different nonzero pairs is the third, for example $(1, 0) + (0, 1) = (1, 1)$. Coordinatewise addition is commutative and associative with identity $(0, 0)$, because addition in $\mathbb{F}_2$ is, and every element is its own additive inverse.

Multiplication. If some factor is 0, both sides of the commutative and associative laws are 0. The nonzero elements are $\alpha^0 = 1$, $\alpha^1 = \alpha$, and $\alpha^2 = \beta$, and $\alpha^3 = \alpha\beta = 1$. Checking the table, $\alpha^i \alpha^j = \alpha^{i +_3 j}$ for all $i, j \in \{0, 1, 2\}$; for example $\beta\beta = \alpha^{2 +_3 2} = \alpha^1 = \alpha$. So multiplying nonzero elements amounts to adding exponents in $\mathbb{Z}/3\mathbb{Z}$, and multiplication of nonzero elements is commutative and associative because addition in $\mathbb{Z}/3\mathbb{Z}$ is (Lemma 1.1.21). The identity is $\alpha^0 = 1 \neq 0$, and α^i has inverse α^{3-i} for $i = 1, 2$.

Distributivity. We show $x(y + z) = xy + xz$. For $x = 0$ and $x = 1$ this is clear. Multiplication by α sends $0 \mapsto 0$, $1 \mapsto \alpha$, $\alpha \mapsto \beta$, $\beta \mapsto 1$, which in pairs is

$$(u, v) \mapsto (v, u + v).$$

This map respects addition: $(u + u', v + v')$ goes to $(v + v', u + u' + v + v') = (v, u + v) + (v', u' + v')$. So $\alpha(y + z) = \alpha y + \alpha z$. Since $\beta = \alpha\alpha$, associativity gives $\beta y = \alpha(\alpha y)$, and therefore

$$\beta(y+z) = \alpha(\alpha y + \alpha z) = \alpha(\alpha y) + \alpha(\alpha z) = \beta y + \beta z.$$

So $\mathbb{F}_4$ is a field.

(b) $1 + 1 = 0$ and $1 \neq 0$, so $\operatorname{char} \mathbb{F}_4 = 2$. Renaming the elements of $\mathbb{Z}/4\mathbb{Z}$ cannot change whether it satisfies the field axioms, and $\mathbb{Z}/4\mathbb{Z}$ is not a field by Proposition 1.1.24 (in it $2 \cdot 2 = 0$). So $\mathbb{F}_4$ is not a renamed $\mathbb{Z}/4\mathbb{Z}$. Another way to see it: $x + x = 0$ for every $x \in \mathbb{F}_4$, while $1 + 1 = 2 \neq 0$ in $\mathbb{Z}/4\mathbb{Z}$.

Solution to Exercise 1.1.57

> *Uses.* Proposition 1.1.13 (Solving $a + x = b$ and $ax = b$), Proposition 1.1.17 (No zero divisors)
> *Hint 1.* Call the sum S. Multiplying every element of F by a fixed nonzero c permutes F. What does that say about cS?
> *Hint 2.* You get $cS = S$. To conclude $S = 0$ you need such a c with $c \neq 1$. When does one exist?
> *Sketch.* If $|F| > 2$, pick $c \notin \{0, 1\}$. Since $x \mapsto cx$ is a bijection of F, $cS = S$, so $(c-1)S = 0$ with $c - 1 \neq 0$, and $S = 0$. If $F = \{0, 1\}$, then $S = 1$.

Let S be the sum of all elements of F. If F has exactly two elements, then $F = \{0, 1\}$ and $S = 1 \neq 0$, which is the exception.

Suppose F has more than two elements, and pick $c \in F$ with $c \neq 0$ and $c \neq 1$. By part (b) of Proposition 1.1.13, for each $y \in F$ the equation $cx = y$ has exactly one solution, so $x \mapsto cx$ is a bijection $F \to F$. Hence the elements cx, for $x \in F$, are the elements of F in another order, and their sum is S. By distributivity their sum is also cS. So $cS = S$, that is, $(c-1)S = 0$. Since $c - 1 \neq 0$, Proposition 1.1.17 gives $S = 0$.

Solution to Exercise 1.1.58

> *Uses.* Definition 1.1.1 (Field)
> *Techniques.* Proving from axioms (Technique 1.1.7)
> *Hint 1.* Expand $(1 + 1)(a + b)$ in two different ways using distributivity.
> *Hint 2.* You get $a + a + b + b = a + b + a + b$. To finish you want to cancel a on the left and b on the right, but our proof of cancellation used commutativity of addition.
> *Hint 3.* Re-prove what you need from the remaining axioms. First show that if $a + b = 0$ then $b + a = 0$, and that $0 + a = a$. Then both cancellation laws follow.
> *Sketch.* Without commutativity of $+$, the right inverse b of a is also a left inverse, and 0 is also a left identity; this gives cancellation on both sides. Distributivity on each side (multiplication is still commutative) expands $(1 + 1)(a + b)$ as both $a + a + b + b$ and $a + b + a + b$. Cancelling a on the left and b on the right gives $a + b = b + a$.

We may still use commutativity of multiplication, so both distributive laws hold and $1x = x1 = x$. Associativity of $+$ lets us drop parentheses in sums (the remark in Section 1.1.2 does not need commutativity for this).

Inverses work on both sides. Let $a + b = 0$, and choose c with $b + c = 0$. Then

$$b + a = (b + a) + 0 = (b + a) + (b + c) = b + (a + b) + c = b + 0 + c = b + c = 0.$$

0 *is a left identity.* With $a + b = 0$ as before, $0 + a = (a + b) + a = a + (b + a) = a + 0 = a$.

Cancellation on both sides. Suppose $x + y = x + z$, and let $x + w = 0$, so $w + x = 0$ as well. Adding w on the left, $y = 0 + y = (w + x) + y = w + (x + y) = w + (x + z) = (w + x) + z = 0 + z = z$. Similarly, if $y + x = z + x$, adding w on the right gives $y = y + (x + w) = (y + x) + w = (z + x) + w = z$.

The main computation. By distributivity, applied in two different ways,

$$(1 + 1)(a + b) = (1 + 1)a + (1 + 1)b = a + a + b + b,$$
$$(1 + 1)(a + b) = 1(a + b) + 1(a + b) = a + b + a + b.$$

So $a + (a + b) + b = a + (b + a) + b$. Cancelling a on the left and b on the right gives $a + b = b + a$, as desired.

Section 1.2

Solution to Exercise 1.2.8

Uses. Definition 1.2.4 (The space F^n), Definition 1.2.7 (Matrices), Proposition 1.1.13 (Solving $a+x=b$ and $ax=b$), Proposition 1.1.30 ($\mathbb{C}$ is a field)
Hint 1. The operations are coordinatewise, so each equation is a separate equation in F for each coordinate or entry.
Hint 2. Solve each one with Proposition 1.1.13: subtract, then multiply by the inverse of the coefficient. In $\mathbb{F}_3$, $2^{-1}=2$; in $\mathbb{F}_5$, $3^{-1}=2$; in $\mathbb{C}$, $(1+i)^{-1}=(1-i)/2$.
Sketch. (a) $2\mathbf{x}=(1,1,1)$, so $\mathbf{x}=(2,2,2)$. (b) $3X=B-A=\begin{pmatrix}4&4\\3&1\end{pmatrix}$, so $X=\begin{pmatrix}3&3\\1&2\end{pmatrix}$. (c) $(1+i)\mathbf{v}=(-1,2i)$, so $\mathbf{v}=((-1+i)/2,1+i)$.

In each part, both sides are equal exactly when they agree in every coordinate (or entry), so we solve one equation in F per coordinate, using Proposition 1.1.13.

(a) In $\mathbb{F}_3$, the coordinates of $(2,0,1)$ minus those of $(1,2,0)$ are $2-1=1$, $0-2=-2=1$, and $1-0=1$, so $2\mathbf{x}=(1,1,1)$. Since $2\cdot 2=4=1$ in $\mathbb{F}_3$, $2^{-1}=2$, and $\mathbf{x}=(2,2,2)$. Check: $2(2,2,2)+(1,2,0)=(1,1,1)+(1,2,0)=(2,0,1)$ in $\mathbb{F}_3$.

(b) Entrywise in $\mathbb{F}_5$,

$$3X=\begin{pmatrix}0-1&1-2\\1-3&0-4\end{pmatrix}=\begin{pmatrix}4&4\\3&1\end{pmatrix}.$$

Since $3\cdot 2=6=1$ in $\mathbb{F}_5$, $3^{-1}=2$, so

$$X=2\begin{pmatrix}4&4\\3&1\end{pmatrix}=\begin{pmatrix}8&8\\6&2\end{pmatrix}=\begin{pmatrix}3&3\\1&2\end{pmatrix}.$$

Check: $3X=\begin{pmatrix}9&9\\3&6\end{pmatrix}=\begin{pmatrix}4&4\\3&1\end{pmatrix}$, and adding A gives $\begin{pmatrix}5&6\\6&5\end{pmatrix}=\begin{pmatrix}0&1\\1&0\end{pmatrix}=B$ in $\mathbb{F}_5$.

(c) We need $(1+i)v_1=-1$ and $(1+i)v_2=2i$. By Proposition 1.1.30, $(1+i)^{-1}=(1-i)/2$, so

$$v_1=\frac{-(1-i)}{2}=\frac{-1+i}{2},\quad v_2=\frac{2i(1-i)}{2}=i-i^2=1+i.$$

Check: $(1+i)(-1+i)/2=\left(-1+i-i+i^2\right)/2=-1$, and $(1+i)(1+i)=2i$.

Solution to Exercise 1.2.24

Uses. Proposition 1.2.22 (Transport of structure), Example 1.2.23 (Repairing the line)
Hint 1. The zero vector is defined by (A3) relative to the addition. Which addition is the argument assuming?
Hint 2. To refute the claim, transport the structure of $\mathbb{R}$ along a bijection $\mathbb{R}\to(1,2)$. The function $g(t)=t/(1+|t|)$ is a bijection $\mathbb{R}\to(-1,1)$.
Sketch. The zero vector depends on the operations; 0 is the zero of $\mathbb{R}$ for its usual addition, which is not an operation on $(1,2)$ anyway. Transporting along the bijection $\varphi(t)=(3+g(t))/2$, $g(t)=t/(1+|t|)$, makes $(1,2)$ a real vector space with zero vector $\varphi(0)=3/2$.

The error is the assertion that the zero vector must be 0. The zero vector is whatever element satisfies (A3) for the addition in question, and 0 plays that role only for the usual addition of $\mathbb{R}$, which is not even an operation on $(1,2)$. A different addition on $(1,2)$ can have a different zero vector.

The conclusion is false. Let $g(t)=t/(1+|t|)$. For $t\geq 0$, $g(t)=t/(1+t)\in[0,1)$, and for $s\in[0,1)$ the equation $s=t/(1+t)$ has the unique solution $t=s/(1-s)\geq 0$. For $t<0$, $g(t)=t/(1-t)\in(-1,0)$, and for $s\in(-1,0)$ the equation $s=t/(1-t)$ has the unique solution $t=s/(1+s)<0$. So g is a bijection $\mathbb{R}\to(-1,1)$ with inverse $s\mapsto s/(1-|s|)$. Then $\varphi(t)=(3+g(t))/2$ is a bijection $\mathbb{R}\to(1,2)$, and by Proposition 1.2.22, transporting the structure of $\mathbb{R}$ along φ makes $(1,2)$ a real vector space. Its zero vector is $\varphi(0)=3/2$.

Solution to Exercise 1.2.37

Uses. Proposition 1.2.30 (Additive arithmetic), Corollary 1.2.36 (Cancelling scalars and vectors), Proposition 1.2.32 (The scalar zero), Definition 1.2.1 (Vector space)
Hint 1. First isolate $a\mathbf{x}$ with Proposition 1.2.30(a), as you would isolate ax in a field.
Hint 2. For existence, try $\mathbf{x}=a^{-1}(\mathbf{w}-\mathbf{u})$. For uniqueness, two solutions $\mathbf{x},\mathbf{x}'$ have $a\mathbf{x}=a\mathbf{x}'$.

Sketch. The equation holds if and only if $a\mathbf{x} = \mathbf{w} - \mathbf{u}$. If $a \neq 0$, then $\mathbf{x} = a^{-1}(\mathbf{w} - \mathbf{u})$ works, and it is the only solution by Corollary 1.2.36(a). If $a = 0$, then $a\mathbf{x} = \mathbf{0}$, so there is a solution exactly when $\mathbf{u} = \mathbf{w}$, and then every $\mathbf{x}$ is one.

By Proposition 1.2.30(a), applied with the vector $a\mathbf{x}$ as the unknown, $a\mathbf{x} + \mathbf{u} = \mathbf{w}$ holds if and only if $a\mathbf{x} = \mathbf{w} - \mathbf{u}$ (using (A1) to write $a\mathbf{x} + \mathbf{u} = \mathbf{u} + a\mathbf{x}$).

(a) Let $\mathbf{x} = a^{-1}(\mathbf{w} - \mathbf{u})$. By (A6), $a\mathbf{x} = \left(aa^{-1}\right)(\mathbf{w} - \mathbf{u}) = 1(\mathbf{w} - \mathbf{u}) = \mathbf{w} - \mathbf{u}$, so $\mathbf{x}$ is a solution. If $\mathbf{x}'$ is another, then $a\mathbf{x}' = \mathbf{w} - \mathbf{u} = a\mathbf{x}$, and $\mathbf{x}' = \mathbf{x}$ by Corollary 1.2.36(a). So $a^{-1}(\mathbf{w} - \mathbf{u})$ is the only solution.

(b) If $a = 0$, then $a\mathbf{x} = \mathbf{0}$ for every $\mathbf{x}$ by Proposition 1.2.32, so the equation reads $\mathbf{0} + \mathbf{u} = \mathbf{w}$, that is, $\mathbf{u} = \mathbf{w}$. So if $\mathbf{u} = \mathbf{w}$, every $\mathbf{x} \in V$ is a solution, and otherwise there is none.

Solution to Exercise 1.2.41

Uses. Proposition 1.2.18 (Degree and evaluation versus the operations), Definition 1.2.16 (Degree)
Hint 1. For (a), find two polynomials whose leading terms cancel.
Hint 2. (b) is the contrapositive of part of Proposition 1.2.18(a), plus a look at one coefficient. For (c), check closure.
Sketch. (a) False: $\left(x^2 + 1\right) + \left(-x^2\right) = 1$. (b) True: if $\deg p \neq \deg q$, then $\deg(p + q) = \max(\deg p, \deg q) \geq \deg p$; so $\deg p = \deg q = n$, and the n-th coefficient $a_n + b_n$ of $p + q$ must be 0. (c) False: $x^2 + \left(x - x^2\right) = x$ has degree 1.

(a) False. Take $p = x^2 + 1$ and $q = -x^2$, both of degree 2. Then $p + q = 1$ has degree $0 < 2$.

(b) True. If $\deg p \neq \deg q$, then $\deg(p + q) = \max(\deg p, \deg q) \geq \deg p$ by Proposition 1.2.18(a). So $\deg(p + q) < \deg p$ forces $\deg p = \deg q$; call it n. Write $p = (a_k)$ and $q = (b_k)$. If $a_n + b_n \neq 0$, then the n-th coefficient of $p + q$ is nonzero and $\deg(p + q) \geq n = \deg p$. So $a_n + b_n = 0$.

(c) False. The polynomials x^2 and $x - x^2$ both have degree exactly 2, but their sum x has degree 1. So addition is not an operation on this set. (The zero polynomial, of degree $-\infty$, is not in the set either.)

Solution to Exercise 1.2.42

Uses. Corollary 1.2.36 (Cancelling scalars and vectors)
Hint 1. Pick a nonzero vector $\mathbf{v}$ and look at all of its multiples.
Hint 2. By Corollary 1.2.36(b), the map $F \to V$, $a \mapsto a\mathbf{v}$, is injective.
Sketch. For $\mathbf{v} \neq \mathbf{0}$, $a \mapsto a\mathbf{v}$ is an injective map $F \to V$, so V has at least $|F|$ elements.

Since $V \neq \{\mathbf{0}\}$, there is some $\mathbf{v} \in V$ with $\mathbf{v} \neq \mathbf{0}$. Define $m : F \to V$ by $m(a) = a\mathbf{v}$. If $m(a) = m(b)$, then $a\mathbf{v} = b\mathbf{v}$, so $a = b$ by Corollary 1.2.36(b). So m is injective, and its image is a subset of V with as many elements as F. Hence V has at least as many elements as F. If F is infinite, so is V; and if V is finite, then F, which injects into V, is finite.

Solution to Exercise 1.2.43

Uses. Proposition 1.2.27 (Uniqueness of the zero vector), Proposition 1.2.30 (Additive arithmetic), Remark 1.2.2 (Reading the axioms)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. Read Proposition 1.2.27 with its quantifiers. What property does it say only $\mathbf{0}$ has?
Hint 2. For (b), compare $\mathbf{u} + \mathbf{v} = \mathbf{u}$ with $\mathbf{u} + \mathbf{0} = \mathbf{u}$. For (c), the argument in (b) must use (A4), so drop it. Try max on $[0, \infty)$.
Sketch. (a) Proposition 1.2.27 is about vectors $\mathbf{z}$ with $\mathbf{w} + \mathbf{z} = \mathbf{w}$ for *every* $\mathbf{w}$; the hypothesis gives this for one $\mathbf{u}$. (b) $\mathbf{u} + \mathbf{v} = \mathbf{u} + \mathbf{0}$, so $\mathbf{v} = \mathbf{0}$ by cancellation. (c) On $[0, \infty)$ with $s + t = \max(s, t)$, the identity is 0, and $\max(5, 3) = 5$.

(a) Proposition 1.2.27 says that only one vector $\mathbf{z}$ satisfies $\mathbf{w} + \mathbf{z} = \mathbf{w}$ *for every* $\mathbf{w} \in V$. It says nothing about vectors $\mathbf{z}$ that satisfy $\mathbf{u} + \mathbf{z} = \mathbf{u}$ for one particular $\mathbf{u}$, and that is all the hypothesis gives for $\mathbf{v}$. This is the quantifier distinction of Remark 1.2.2. The claim is true, but this argument does not prove it.

(b) By (A3), $\mathbf{u} + \mathbf{v} = \mathbf{u} = \mathbf{u} + \mathbf{0}$. Cancelling $\mathbf{u}$ (Proposition 1.2.30(b)) gives $\mathbf{v} = \mathbf{0}$.

(c) Let $S = [0, \infty)$ with $s + t = \max(s, t)$. This is commutative and associative, and 0 satisfies (A3), since $\max(s, 0) = s$ for $s \geq 0$. But $\max(5, 3) = 5$, so $5 + 3 = 5$ although $3 \neq 0$. The proof in (b) breaks down because cancellation relied on (A4), which fails here: $\max(5, t) \geq 5 > 0$ for every t.

Solution to Exercise 1.2.44

Uses. Corollary 1.2.36 (Cancelling scalars and vectors), Proposition 1.2.30 (Additive arithmetic), Proposition 1.2.28 (Uniqueness of additive inverses), Proposition 1.2.34 (Negatives and the scalar -1), Example 1.2.6 (Small fields)
Hint 1. For (a), a two-element space is $\{\mathbf{0}, \mathbf{v}\}$ with $\mathbf{v} \neq \mathbf{0}$. How many multiples does $\mathbf{v}$ have?
Hint 2. For (b), take a vector space V of the given size, and a vector outside the multiples of some nonzero $\mathbf{v}$. Where can its sum with $\mathbf{v}$ lie?
Hint 3. Over $\mathbb{F}_2$, $-\mathbf{v} = (-1)\mathbf{v} = \mathbf{v}$; over $\mathbb{F}_3$, $-\mathbf{v} = 2\mathbf{v}$. Rule out each possible value of the sum with cancellation.
Sketch. (a) If $V = \{\mathbf{0}, \mathbf{v}\}$, then $a \mapsto a\mathbf{v}$ injects F into V, so F has exactly two elements; conversely such an F is a two-element vector space over itself. (b) In a three-element $\mathbb{F}_2$-space $\{\mathbf{0}, \mathbf{u}, \mathbf{w}\}$, the sum $\mathbf{u} + \mathbf{w}$ can be none of $\mathbf{0}$, $\mathbf{u}$, $\mathbf{w}$. In a four-element $\mathbb{F}_3$-space, $\mathbf{0}, \mathbf{v}, 2\mathbf{v}$ are distinct; for the fourth element $\mathbf{w}$, the sum $\mathbf{w} + \mathbf{v}$ can be none of the four.

(a) Exactly the fields with two elements. Suppose V is a vector space over F with exactly two elements, so $V = \{\mathbf{0}, \mathbf{v}\}$ with $\mathbf{v} \neq \mathbf{0}$. By Corollary 1.2.36(b), $a \mapsto a\mathbf{v}$ is an injective map $F \to V$, so F has at most two elements. A field has at least two elements, $0 \neq 1$, so F has exactly two. Conversely, if F has exactly two elements, then $F = F^1$ is a vector space over itself (Example 1.2.6) with two elements.

(b) *Over* $\mathbb{F}_2$. Suppose $V = \{\mathbf{0}, \mathbf{u}, \mathbf{w}\}$ with three distinct elements. Consider $\mathbf{u} + \mathbf{w} \in V$. If $\mathbf{u} + \mathbf{w} = \mathbf{u} = \mathbf{u} + \mathbf{0}$, then $\mathbf{w} = \mathbf{0}$ by cancellation (Proposition 1.2.30(b)). If $\mathbf{u} + \mathbf{w} = \mathbf{w}$, then likewise $\mathbf{u} = \mathbf{0}$. If $\mathbf{u} + \mathbf{w} = \mathbf{0}$, then $\mathbf{w} = -\mathbf{u} = (-1)\mathbf{u}$ by Proposition 1.2.28 and Proposition 1.2.34, and $-1 = 1$ in $\mathbb{F}_2$, so $\mathbf{w} = 1\mathbf{u} = \mathbf{u}$. Each case contradicts distinctness.

Over $\mathbb{F}_3$. Suppose V has exactly four elements, and pick $\mathbf{v} \neq \mathbf{0}$ in V. By Corollary 1.2.36(b), the vectors $0\mathbf{v} = \mathbf{0}$, $\mathbf{v}$, and $2\mathbf{v}$ are distinct; let $\mathbf{w}$ be the fourth element of V. Consider $\mathbf{w} + \mathbf{v}$. If it equals $\mathbf{w} = \mathbf{w} + \mathbf{0}$, then $\mathbf{v} = \mathbf{0}$. If it equals $\mathbf{0}$, then $\mathbf{w} = -\mathbf{v} = (-1)\mathbf{v} = 2\mathbf{v}$, as $-1 = 2$ in $\mathbb{F}_3$. If it equals $\mathbf{v} = \mathbf{0} + \mathbf{v}$, then $\mathbf{w} = \mathbf{0}$. If it equals $2\mathbf{v} = \mathbf{v} + \mathbf{v}$, then $\mathbf{w} = \mathbf{v}$. Each case is a contradiction.

Solution to Exercise 1.2.45

Uses. Definition 1.2.1 (Vector space), Proposition 1.2.32 (The scalar zero), Proposition 1.2.35 (Zero products), Definition 1.1.28 (Characteristic)
Hint 1. First show $n * \mathbf{v} = (n * 1)\mathbf{v}$ by induction on n, using (A5) and (A8).
Hint 2. Then (i) $\Rightarrow$ (ii) is Proposition 1.2.32, (ii) $\Rightarrow$ (iii) uses $V \neq \{\mathbf{0}\}$, and (iii) $\Rightarrow$ (i) is Proposition 1.2.35.
Sketch. By (A5), (A8), and induction, $n * \mathbf{v} = (n * 1)\mathbf{v}$. If $n * 1 = 0$ this is $\mathbf{0}$ for all $\mathbf{v}$; some nonzero $\mathbf{v}$ exists; and $(n * 1)\mathbf{v} = \mathbf{0}$ with $\mathbf{v} \neq \mathbf{0}$ forces $n * 1 = 0$. So the n killing all of V are exactly those with $n * 1 = 0$.

First, $n * \mathbf{v} = (n * 1)\mathbf{v}$ for every $n \geq 1$, by induction on n. For $n = 1$ this is (A5). If it holds for n, then

$$(n + 1) * \mathbf{v} = n * \mathbf{v} + \mathbf{v} = (n * 1)\mathbf{v} + 1\mathbf{v} = (n * 1 + 1)\mathbf{v} = ((n + 1) * 1)\mathbf{v},$$

by the inductive hypothesis, (A5), and (A8).

(i) $\Rightarrow$ (ii). If $n * 1 = 0$, then $n * \mathbf{v} = 0\mathbf{v} = \mathbf{0}$ for every $\mathbf{v}$, by Proposition 1.2.32.

(ii) $\Rightarrow$ (iii). Since $V \neq \{\mathbf{0}\}$, some $\mathbf{v} \neq \mathbf{0}$ exists, and $n * \mathbf{v} = \mathbf{0}$ by (ii).

(iii) $\Rightarrow$ (i). If $\mathbf{v} \neq \mathbf{0}$ and $(n * 1)\mathbf{v} = n * \mathbf{v} = \mathbf{0}$, then $n * 1 = 0$ by Proposition 1.2.35.

By the equivalence of (i) and (ii), the positive integers n with $n * \mathbf{v} = \mathbf{0}$ for all $\mathbf{v}$ are exactly those with $n * 1 = 0$. So the least such n is $\operatorname{char} F$, and there is none exactly when $\operatorname{char} F = 0$.

Solution to Exercise 1.2.46

Uses. Exercise 1.2.45, Example 1.2.39 (When does $\mathbf{v} = -\mathbf{v}$ force $\mathbf{v} = \mathbf{0}$?), Proposition 1.2.27 (Uniqueness of the zero vector)
Hint 1. Whatever the scalar multiplication is, Exercise 1.2.45 constrains the addition. What does it say about $p \cdot \mathbf{v}$ over $\mathbb{F}_p$?
Hint 2. For (b), split into the cases $1 + 1 = 0$ and $1 + 1 \neq 0$ in F, and look at the elements 1 and 2 of $\mathbb{Z}/4\mathbb{Z}$.
Sketch. (a) No: over $\mathbb{F}_p$, $p * \mathbf{v} = \mathbf{0}$ for every $\mathbf{v}$, but $p * 1 = p \neq 0$ in $\mathbb{Z}$. (b) No: if $1 + 1 = 0$ in F, then $\mathbf{v} + \mathbf{v} = \mathbf{0}$ for all $\mathbf{v}$, but $1 + 1 = 2 \neq 0$ in $\mathbb{Z}/4\mathbb{Z}$; if $1 + 1 \neq 0$, then $\mathbf{v} + \mathbf{v} = \mathbf{0}$ forces $\mathbf{v} = \mathbf{0}$, but $2 + 2 = 0$ with $2 \neq 0$.

(a) No. Suppose some scalar multiplication made $\mathbb{Z}$ a vector space over $\mathbb{F}_p$. Its zero vector is the identity element 0 of the addition, by Proposition 1.2.27. In $\mathbb{F}_p$ we have $p * 1 = 0$, so by Exercise 1.2.45, adding any vector to itself p times gives the zero vector. But adding $1 \in \mathbb{Z}$ to itself p times gives $p \neq 0$.

(b) No. Suppose F and a scalar multiplication make $\mathbb{Z}/4\mathbb{Z}$ an F-vector space; again its zero vector is 0. If $1+1=0$ in F, then $\mathbf{v}+\mathbf{v}=\mathbf{0}$ for every $\mathbf{v}$ (Example 1.2.39), but $1+1=2\neq 0$ in $\mathbb{Z}/4\mathbb{Z}$. If $1+1\neq 0$ in F, then $\mathbf{v}+\mathbf{v}=\mathbf{0}$ forces $\mathbf{v}=\mathbf{0}$ (Example 1.2.39), but $2+2=0$ in $\mathbb{Z}/4\mathbb{Z}$ although $2\neq 0$. Both cases are impossible.

Solution to Exercise 1.2.47

Uses. Definition 1.2.1 (Vector space)
Hint 1. Suppose such a $\odot$ exists, and let $r=i\odot 1\in\mathbb{R}$. Compute $i\odot(i\odot 1)$ in two ways.
Hint 2. One way uses (A6): $i\odot(i\odot 1)=(i^2)\odot 1$. For the other, write $r=r\odot 1$ and use (A6) and commutativity in $\mathbb{C}$ to move i past r.
Sketch. No. With $r=i\odot 1$, (A6) gives $i\odot r=i\odot(r\odot 1)=(ri)\odot 1=r\odot(i\odot 1)=r^2$, and also $i\odot r=i\odot(i\odot 1)=(-1)\odot 1=-1$. So $r^2=-1$ with $r\in\mathbb{R}$, which is impossible.

No. Suppose such a $\odot$ exists, and let $r=i\odot 1$, a real number. Since r is real, $r=r\cdot 1=r\odot 1$. By (A6) and commutativity of multiplication in $\mathbb{C}$,

$$i\odot r=i\odot(r\odot 1)=(ir)\odot 1=(ri)\odot 1=r\odot(i\odot 1)=r\odot r=r^2.$$

On the other hand, by (A6),

$$i\odot r=i\odot(i\odot 1)=(ii)\odot 1=(-1)\odot 1=-1.$$

So $r^2=-1$, which no real number satisfies.

The requirement that real scalars act as usual is essential. Without it, there is a complex vector space structure on $(\mathbb{R},+)$, but its construction uses the axiom of choice (Section 15.1).

Solution to Exercise 1.2.48

Uses. Proposition 1.2.5 (F^n is a vector space), Definition 1.1.29 (Complex numbers)
Hint 1. Addition is unchanged, so only (A5)–(A8) need checking, and each reduces to a property of the function $a\mapsto\overline{a}$, $|a|$, or $\operatorname{Re}a$.
Hint 2. (A6) needs the function to be multiplicative, and (A8) needs it to be additive. Check $\overline{a+b}=\overline{a}+\overline{b}$ and $\overline{ab}=\overline{a}\,\overline{b}$ by writing a and b in coordinates.
Sketch. (a) Yes: conjugation fixes 1, and is additive and multiplicative. (b) No: (A8) fails for $a=1$, $b=-1$, since $|0|\mathbf{v}=\mathbf{0}$ but $|1|\mathbf{v}+|-1|\mathbf{v}=2\mathbf{v}$. (c) No: (A6) fails for $a=b=i$, since $\operatorname{Re}(i^2)=-1$ but $\operatorname{Re}(i)\operatorname{Re}(i)=0$.

Since the addition is that of $\mathbb{C}^2$, (A1)–(A4) hold in all three cases. For $g:\mathbb{C}\to\mathbb{C}$ and $a\odot\mathbf{v}=g(a)\mathbf{v}$, (A7) also holds, as $g(a)(\mathbf{v}+\mathbf{w})=g(a)\mathbf{v}+g(a)\mathbf{w}$ in $\mathbb{C}^2$. The remaining axioms read $g(1)\mathbf{v}=\mathbf{v}$, $g(ab)\mathbf{v}=g(a)g(b)\mathbf{v}$, and $g(a+b)\mathbf{v}=g(a)\mathbf{v}+g(b)\mathbf{v}$.

(a) Yes. First, $\overline{1}=1$, which gives (A5). Write $a=x+yi$ and $b=u+wi$. Then $\overline{a+b}=(x+u)-(y+w)i=\overline{a}+\overline{b}$, which gives (A8). Also $ab=(xu-yw)+(xw+yu)i$, so $\overline{ab}=(xu-yw)-(xw+yu)i$, while

$$\overline{a}\,\overline{b}=(x-yi)(u-wi)=(xu-yw)+(-xw-yu)i.$$

These agree, so $\overline{ab}\mathbf{v}=\overline{a}\big(\overline{b}\mathbf{v}\big)$, which gives (A6).

(b) No. Take $a=1$, $b=-1$, and $\mathbf{v}=(1,0)$. Then $(a+b)\odot\mathbf{v}=|0|\mathbf{v}=\mathbf{0}$, while $a\odot\mathbf{v}+b\odot\mathbf{v}=|1|\mathbf{v}+|-1|\mathbf{v}=(2,0)$. So (A8) fails.

(c) No. Take $a=b=i$ and $\mathbf{v}=(1,0)$. Then $(ab)\odot\mathbf{v}=\operatorname{Re}(-1)\mathbf{v}=(-1,0)$, while $a\odot(b\odot\mathbf{v})=\operatorname{Re}(i)(\operatorname{Re}(i)\mathbf{v})=\mathbf{0}$. So (A6) fails. (Here (A5) and (A8) do hold, since $\operatorname{Re}1=1$ and Re is additive.)

Solution to Exercise 1.2.49

Uses. Proposition 1.2.5 (F^n is a vector space)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. Test small cases first: try $a=b=1$ in (A8) over $\mathbb{R}$, and then over $\mathbb{F}_2$.
Hint 2. All axioms except (A8) hold for every F. (A8) holds if and only if $(a+b)^2=a^2+b^2$ for all $a,b\in F$.
Sketch. (A1)–(A7) always hold: $1^2=1$ and $(ab)^2=a^2b^2$. (A8) in the second coordinate needs $(a+b)^2=a^2+b^2$, that is, $(1+1)ab=0$ for all a,b. This holds for all a,b exactly when $1+1=0$. So the answer is: the fields with $1+1=0$.

Exactly the fields with $1+1=0$.

Over $\mathbb{R}$, (A8) fails: $(1+1)\odot(0,1)=(0,4)$, while $1\odot(0,1)+1\odot(0,1)=(0,2)$. Over $\mathbb{F}_2$, $a^2=a$ for both elements, so $\odot$ is the usual scalar multiplication and all axioms hold. These two small cases suggest that $1+1$ is what matters.

In general, (A1)–(A4) hold because the addition is that of F^2. (A5) holds since $1^2=1$. (A6) holds since $(ab)\odot(x,y)=\big(abx,a^2b^2y\big)=a\odot\big(bx,b^2y\big)$. (A7) holds since $a\odot(x+x',y+y')=\big(ax+ax',a^2y+a^2y'\big)$. For (A8), the first coordinates of $(a+b)\odot(x,y)$ and $a\odot(x,y)+b\odot(x,y)$ agree, and the second coordinates are $(a+b)^2y$ and $\big(a^2+b^2\big)y$. Since $(a+b)^2=a^2+(1+1)ab+b^2$, (A8) holds for all a,b,x,y if and only if $(1+1)aby=0$ for all $a,b,y\in F$. If $1+1=0$, this holds. If $1+1\neq 0$, it fails for $a=b=y=1$. So F^2 with $\odot$ is a vector space exactly when $1+1=0$ in F.

Over $\mathbb{F}_2$ the new structure is the usual one. Over a larger field with $1+1=0$, such as the four-element field of Exercise 1.1.56, $a\mapsto a^2$ is not the identity, so $\odot$ is a different scalar multiplication from the usual one.

Solution to Exercise 1.2.50

Uses. Proposition 1.2.22 (Transport of structure)
Hint 1. The parabola is in bijection with $\mathbb{R}$. Transport the structure of $\mathbb{R}$ (Proposition 1.2.22).
Hint 2. Use $\varphi(t)=\big(t,t^2\big)$, whose inverse is $(x,y)\mapsto x$.
Sketch. Transport along $\varphi(t)=\big(t,t^2\big)$: $\big(s,s^2\big)\oplus\big(t,t^2\big)=\big(s+t,(s+t)^2\big)$ and $a\odot\big(t,t^2\big)=\big(at,a^2t^2\big)$. Then $(1,1)\oplus(2,4)=\varphi(3)=(3,9)$, the zero vector is $(0,0)$, $-(2,4)=(-2,4)$, and $3\odot(-1,1)=(-3,9)$.

Define $\varphi:\mathbb{R}\to P$ by $\varphi(t)=\big(t,t^2\big)$. It is a bijection: each point of P is $\big(x,x^2\big)=\varphi(x)$, and $\varphi(s)=\varphi(t)$ forces $s=t$ by comparing first coordinates. So $\varphi^{-1}(x,y)=x$. By Proposition 1.2.22, P is a real vector space with

$$\big(s,s^2\big)\oplus\big(t,t^2\big)=\varphi(s+t)=\big(s+t,(s+t)^2\big),\quad a\odot\big(t,t^2\big)=\varphi(at)=\big(at,a^2t^2\big).$$

In particular $(1,1)\oplus(2,4)=\varphi(1+2)=(3,9)$. The zero vector is $\varphi(0)=(0,0)$. The inverse of $(2,4)=\varphi(2)$ is $\varphi(-2)=(-2,4)$, since $\varphi(2)\oplus\varphi(-2)=\varphi(0)$. Finally $3\odot(-1,1)=\varphi(3\cdot(-1))=(-3,9)$.

The set P is curved, but that is no obstacle: the structure lives in the operations, and only the operations of $\mathbb{R}^2$ fail to preserve P.

Solution to Exercise 1.2.51

Uses. Definition 1.2.17 (Evaluation), Proposition 1.2.18 (Degree and evaluation versus the operations), Exercise 1.1.51
Hint 1. Write $f=a_0+a_1x+a_2x^2+a_3x^3$ and compute $f(0)$ and $f(1)$ in terms of the coefficients.
Hint 2. Two polynomials have the same function exactly when their difference has the zero function, by Proposition 1.2.18(c). For (b), use Fermat's little theorem (Exercise 1.1.51).
Sketch. (a) $f(0)=a_0$ and $f(1)=a_0+a_1+a_2+a_3$, so the zero function needs $a_0=0$ and an even number of a_1,a_2,a_3 equal to 1: $f\in\{\mathbf{0},x+x^2,x+x^3,x^2+x^3\}$. There are 16 polynomials and 4 functions; f and g agree as functions iff $f-g$ is one of these four. (b) Coefficient 1 in position p, so nonzero; $c^p=c$ for all $c\in\mathbb{F}_p$.

(a) Write $f=a_0+a_1x+a_2x^2+a_3x^3$ with $a_k\in\mathbb{F}_2$. Then $f(0)=a_0$ and $f(1)=a_0+a_1+a_2+a_3$. So the polynomial function of f is zero exactly when $a_0=0$ and $a_1+a_2+a_3=0$ in $\mathbb{F}_2$, that is, when an even number of a_1,a_2,a_3 equal 1. This gives

$$f\in\{\mathbf{0},x+x^2,x+x^3,x^2+x^3\}.$$

$\mathbb{F}_2[x]_{\leq 3}$ has $2^4=16$ elements, one for each choice of (a_0,a_1,a_2,a_3), while there are $2^2=4$ functions $\mathbb{F}_2\to\mathbb{F}_2$. By Proposition 1.2.18(c), f and g have the same polynomial function if and only if $(f-g)(c)=f(c)-g(c)=0$ for all c, that is, if and only if $f-g$ is one of the four polynomials above.

(b) The coefficient of x^p-x in position $p\geq 2$ is 1, so $x^p-x\neq\mathbf{0}$; in fact $\deg(x^p-x)=p$. Its value at $c\in\mathbb{F}_p$ is c^p-c. For $c=0$ this is 0. For $c\neq 0$, Fermat's little theorem (Exercise 1.1.51) gives $c^{p-1}=1$, so $c^p=c$ and $c^p-c=0$.

Solution to Exercise 1.2.52

Uses. Definition 1.2.1 (Vector space), Corollary 1.2.36 (Cancelling scalars and vectors), Proposition 1.2.34 (Negatives and the scalar -1), Proposition 1.2.28 (Uniqueness of additive inverses), Proposition 1.2.27 (Uniqueness of the zero vector), Proposition 1.2.32 (The scalar zero)
Techniques. Uniqueness via two candidates (Technique 1.1.8)
Hint 1. (a) is induction with (A5) and (A8). For (b), check that $q\mathbf{v}$ works using (A6), and get uniqueness from Corollary 1.2.36(a).
Hint 2. For (c), show first that $m \odot \mathbf{v}$, for every integer m, is expressible using only $+$ and negatives. Then use (b) for both structures.
Sketch. (a) $(n+1)\mathbf{w} = n\mathbf{w} + 1\mathbf{w}$. (b) $n(q\mathbf{v}) = (nq)\mathbf{v} = m\mathbf{v}$, and $n\mathbf{w} = n\mathbf{w}'$ with $n \neq 0$ forces $\mathbf{w} = \mathbf{w}'$. (c) By (a), $m \odot \mathbf{v}$ is an m-fold sum for $m \geq 1$, it is $\mathbf{0}$ for $m = 0$, and $-((-m) \odot \mathbf{v})$ for $m < 0$; so it agrees with $m \odot' \mathbf{v}$. Then $q \odot \mathbf{v}$ and $q \odot' \mathbf{v}$ both solve "$\mathbf{w} + \cdots + \mathbf{w} = m \odot \mathbf{v}$" ($n$ terms), which has at most one solution.

(a) By induction on n. For $n = 1$, $1\mathbf{w} = \mathbf{w}$ by (A5). If $n\mathbf{w}$ is the n-fold sum, then $(n+1)\mathbf{w} = n\mathbf{w} + 1\mathbf{w} = n\mathbf{w} + \mathbf{w}$ by (A8) and (A5), which is the $(n+1)$-fold sum.

(b) By (A6), $n(q\mathbf{v}) = (nq)\mathbf{v} = m\mathbf{v}$, so $q\mathbf{v}$ is such a vector. If $n\mathbf{w} = m\mathbf{v} = n\mathbf{w}'$, then $\mathbf{w} = \mathbf{w}'$ by Corollary 1.2.36(a), since $n \neq 0$ in $\mathbb{Q}$.

(c) Let $\odot$ and $\odot'$ be as stated; both have the same addition, hence the same zero vector and the same negatives (Proposition 1.2.27 and Proposition 1.2.28). First let $m \in \mathbb{Z}$. If $m \geq 1$, then by (a) both $m \odot \mathbf{v}$ and $m \odot' \mathbf{v}$ equal the m-fold sum $\mathbf{v} + \cdots + \mathbf{v}$. If $m = 0$, both are $\mathbf{0}$ by Proposition 1.2.32. If $m < 0$, then by Proposition 1.2.34(b), applied to both structures,

$$m \odot \mathbf{v} = -((-m) \odot \mathbf{v}) = -((-m) \odot' \mathbf{v}) = m \odot' \mathbf{v}.$$

So $m \odot \mathbf{v} = m \odot' \mathbf{v}$ for every integer m.

Now let $q = m/n$ with $n \geq 1$, and write $n * \mathbf{w}$ for the n-fold sum $\mathbf{w} + \cdots + \mathbf{w}$, which by (a) equals both $n \odot \mathbf{w}$ and $n \odot' \mathbf{w}$. By (b) for $\odot$, the vector $q \odot \mathbf{v}$ satisfies $n * (q \odot \mathbf{v}) = m \odot \mathbf{v}$, and it is the only vector $\mathbf{w}$ with $n * \mathbf{w} = m \odot \mathbf{v}$. By (b) for $\odot'$, $n * (q \odot' \mathbf{v}) = m \odot' \mathbf{v} = m \odot \mathbf{v}$. So $q \odot' \mathbf{v}$ is also such a vector, and $q \odot' \mathbf{v} = q \odot \mathbf{v}$.

For instance, the usual product is the only scalar multiplication that makes $(\mathbb{R}, +)$ a vector space over $\mathbb{Q}$. Compare Exercise 1.2.47, where the scalars were $\mathbb{C}$.

Solution to Exercise 1.2.53

Uses. Proposition 1.2.22 (Transport of structure), $\tanh : \mathbb{R} \to (-1, 1)$ is a bijection, the addition formula for tanh
Hint 1. For (a), compare $1 + uv$ with $u + v$ and $-(u + v)$; both differences factor.
Hint 2. For (b), look for a bijection $\varphi : \mathbb{R} \to (-1, 1)$ with $\varphi(s + t) = \varphi(s) \oplus \varphi(t)$. Which function has an addition formula of this shape?
Hint 3. Use the addition formula for tanh, and transport the structure of $\mathbb{R}$ along tanh.
Sketch. (a) $1 + uv > 0$, and $(1 + uv) \mp (u + v) = (1 \mp u)(1 \mp v) > 0$. (b) tanh is a bijection $\mathbb{R} \to (-1, 1)$ carrying $+$ to $\oplus$, so transporting along it gives $a \odot v = \tanh(a \operatorname{artanh} v)$, which can be written with powers of $1 \pm v$. Then $2 \odot v = 2v/(1 + v^2)$, $(1/2) \odot v = \left(1 - \sqrt{1 - v^2}\right)/v$ for $v \neq 0$, the zero vector is 0, and the inverse of v is $-v$.

(a) Let $u, v \in (-1, 1)$. Then $|uv| < 1$, so $1 + uv > 0$. Also

$$(1 + uv) - (u + v) = (1 - u)(1 - v) > 0, \quad (1 + uv) + (u + v) = (1 + u)(1 + v) > 0.$$

So $-(1 + uv) < u + v < 1 + uv$, and dividing by $1 + uv > 0$ gives $-1 < u \oplus v < 1$.

(b) The function $\tanh : \mathbb{R} \to (-1, 1)$ is a bijection: it is continuous and strictly increasing, with limits -1 and 1 at $-\infty$ and ∞. Its inverse is $\operatorname{artanh} v = (1/2)\ln((1 + v)/(1 - v))$. The addition formula

$$\tanh(s + t) = \frac{\tanh s + \tanh t}{1 + \tanh s \tanh t}$$

says exactly that $\tanh(s + t) = \tanh(s) \oplus \tanh(t)$. Hence, with $u = \tanh s$ and $v = \tanh t$, we get $u \oplus v = \tanh(\operatorname{artanh} u + \operatorname{artanh} v)$, which is the addition obtained by transporting the structure of $\mathbb{R}$ along tanh. By Proposition 1.2.22, V becomes a real vector space with this addition and

$$a \odot v = \tanh(a \operatorname{artanh} v).$$

Using $\tanh s = \left(e^{2s}-1\right)/\left(e^{2s}+1\right)$ and $e^{2a \operatorname{artanh} v} = ((1+v)/(1-v))^a$,

$$a \odot v = \frac{(1+v)^a - (1-v)^a}{(1+v)^a + (1-v)^a}.$$

For $a = 2$, this is $(4v)/\left(2+2v^2\right) = 2v/\left(1+v^2\right)$, which equals $v \oplus v$, as (A5) and (A8) require. For $a = 1/2$, multiplying the numerator and denominator by $\sqrt{1+v} - \sqrt{1-v}$ gives, for $v \neq 0$,

$$\frac{1}{2} \odot v = \frac{\sqrt{1+v}-\sqrt{1-v}}{\sqrt{1+v}+\sqrt{1-v}} = \frac{2-2\sqrt{1-v^2}}{2v} = \frac{1-\sqrt{1-v^2}}{v},$$

and $(1/2) \odot 0 = 0$. For example, $(1/2) \odot (4/5) = (1-3/5)/(4/5) = 1/2$, and indeed $(1/2) \oplus (1/2) = 1/(5/4) = 4/5$. The zero vector is $\tanh 0 = 0$, and the inverse of $v = \tanh t$ is $\tanh(-t) = -v$; directly, $v \oplus (-v) = 0/\left(1-v^2\right) = 0$.

Solution to Exercise 1.2.54

Uses. Proposition 1.2.32 (The scalar zero), Proposition 1.2.30 (Additive arithmetic), Definition 1.2.1 (Vector space)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. Trace the proof of Proposition 1.2.32 back to the axioms. Which ones does it use?
Hint 2. For (b), you need an addition with an identity but without inverses. On $\{0,1\}$, try $u+v = \max(u,v)$. Then look for a scalar multiplication satisfying (A5)–(A8); a very lazy one works.
Sketch. (a) Proposition 1.2.32 cancels $0\mathbf{v}$, and cancellation (Proposition 1.2.30) was proved with (A4); the argument is circular. (b) On $\{0,1\}$ let $u+v = \max(u,v)$ and $a \odot v = v$ for all a. (A1)–(A3) hold with identity 0, and (A5)–(A8) hold because $\max(v,v) = v$. But $1+w = 1$ for every w, so 1 has no inverse.

(a) The argument uses Proposition 1.2.32, whose proof cancelled $0\mathbf{v}$ from $0\mathbf{v} + 0\mathbf{v} = 0\mathbf{v} + \mathbf{0}$. That cancellation is Proposition 1.2.30(b), which was proved by adding $-\mathbf{u}$, an inverse supplied by (A4). So the argument assumes (A4) in order to prove it. The computation does show something true: in a vector space, $(-1)\mathbf{v}$ *is* the inverse of $\mathbf{v}$ (Proposition 1.2.34).

(b) Let $V = \{0,1\}$, let F be any field, and define

$$u + v = \max(u,v), \quad a \odot v = v \quad (a \in F,\ u,v \in V).$$

(A1) and (A2) hold because max is commutative and associative. (A3) holds with zero vector 0, as $\max(v,0) = v$. (A5): $1 \odot v = v$. (A6): $(ab) \odot v = v = a \odot (b \odot v)$. (A7): $a \odot (u+v) = u+v = (a \odot u) + (a \odot v)$. (A8): $(a+b) \odot v = v = \max(v,v) = (a \odot v) + (b \odot v)$. But (A4) fails for $v = 1$: $1 + w = \max(1,w) = 1 \neq 0$ for both $w \in V$.

Consistently with (a), the conclusion of Proposition 1.2.32 fails here: $0 \odot 1 = 1$, which is not the zero vector.

Solution to Exercise 1.2.55

Uses. Proposition 1.2.27 (Uniqueness of the zero vector), Proposition 1.2.30 (Additive arithmetic), Proposition 1.2.32 (The scalar zero), Proposition 1.2.33 (The zero vector), Proposition 1.2.28 (Uniqueness of additive inverses)
Techniques. Proving from axioms (Technique 1.1.7)
Hint 1. First list the consequences of the axioms that remain available: everything in Proposition 1.2.27, Proposition 1.2.28, Proposition 1.2.30, Proposition 1.2.32, and Proposition 1.2.33, since none of their proofs used (A5). Check that $a(-\mathbf{u}) = -(a\mathbf{u})$ still holds.
Hint 2. For existence in (a), try $\mathbf{w} = 1\mathbf{v}$ and $\mathbf{n} = \mathbf{v} - 1\mathbf{v}$. Use (A6) to compute $1(1\mathbf{v})$ and $a(1\mathbf{v})$.
Hint 3. For uniqueness, apply the scalar 1 to $\mathbf{v} = \mathbf{w} + \mathbf{n}$.
Sketch. Without (A5), the results through Proposition 1.2.33 still hold, and $a(-\mathbf{u}) = -(a\mathbf{u})$ follows from (A7). Then $1(1\mathbf{v}) = 1\mathbf{v}$ and $a(\mathbf{v} - 1\mathbf{v}) = a\mathbf{v} - (a1)\mathbf{v} = \mathbf{0}$, so $\mathbf{v} = 1\mathbf{v} + (\mathbf{v} - 1\mathbf{v})$ is a decomposition, and applying 1 to any decomposition recovers $\mathbf{w} = 1\mathbf{v}$. W contains $\mathbf{0}$ and is closed under the operations and negatives. If (A5) holds, $\mathbf{n} = 1\mathbf{n} = \mathbf{0}$; if $N = \{\mathbf{0}\}$, every $\mathbf{v} = 1\mathbf{v}$.

What is still available. The proofs of Proposition 1.2.27, Proposition 1.2.28, and Proposition 1.2.30 used only (A1)–(A4). The proofs of Proposition 1.2.32 and Proposition 1.2.33 (first approach) used in addition only (A8) and (A7). So all of these hold in V. We also need $a(-\mathbf{u}) = -(a\mathbf{u})$, whose earlier proof used (A5). Instead, by (A7) and Proposition 1.2.33, $a\mathbf{u} + a(-\mathbf{u}) = a(\mathbf{u} + (-\mathbf{u})) = a\mathbf{0} = \mathbf{0}$, so $a(-\mathbf{u}) = -(a\mathbf{u})$ by Proposition 1.2.28.

(a) *Existence.* Let $\mathbf{w} = 1\mathbf{v}$ and $\mathbf{n} = \mathbf{v} - 1\mathbf{v}$. By (A6), $1\mathbf{w} = 1(1\mathbf{v}) = (1 \cdot 1)\mathbf{v} = 1\mathbf{v} = \mathbf{w}$, so $\mathbf{w} \in W$. For $a \in F$, by (A7), the rule above, and (A6),

$$a\mathbf{n} = a\mathbf{v} + a(-(1\mathbf{v})) = a\mathbf{v} - a(1\mathbf{v}) = a\mathbf{v} - (a \cdot 1)\mathbf{v} = a\mathbf{v} - a\mathbf{v} = \mathbf{0},$$

so $\mathbf{n} \in N$. And $\mathbf{w} + \mathbf{n} = 1\mathbf{v} + (\mathbf{v} - 1\mathbf{v}) = \mathbf{v}$ by Proposition 1.2.30(a).

Uniqueness. Suppose $\mathbf{v} = \mathbf{w} + \mathbf{n}$ with $\mathbf{w} \in W$ and $\mathbf{n} \in N$. By (A7), $1\mathbf{v} = 1\mathbf{w} + 1\mathbf{n} = \mathbf{w} + \mathbf{0} = \mathbf{w}$. So $\mathbf{w} = 1\mathbf{v}$ is determined by $\mathbf{v}$, and then $\mathbf{n} = \mathbf{v} - \mathbf{w}$ is determined by Proposition 1.2.30(a).

(b) We have $\mathbf{0} \in W$, since $1\mathbf{0} = \mathbf{0}$ by Proposition 1.2.33. For $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$: $1(\mathbf{w} + \mathbf{w}') = 1\mathbf{w} + 1\mathbf{w}' = \mathbf{w} + \mathbf{w}'$ by (A7); $1(a\mathbf{w}) = (1a)\mathbf{w} = a\mathbf{w}$ by (A6); and $1(-\mathbf{w}) = -(1\mathbf{w}) = -\mathbf{w}$ by the rule above. So W is closed under addition, scalar multiplication, and negatives, and the operations of V restrict to operations on W. The equations in (A1), (A2), and (A6)–(A8) hold in W because they hold in V; (A3) and (A4) hold because $\mathbf{0} \in W$ and $-\mathbf{w} \in W$; and (A5) holds in W by the definition of W.

(c) If (A5) holds and $\mathbf{n} \in N$, then $\mathbf{n} = 1\mathbf{n} = \mathbf{0}$, so $N = \{\mathbf{0}\}$ (and $\mathbf{0} \in N$ by Proposition 1.2.33). Conversely, if $N = \{\mathbf{0}\}$, then in the decomposition of (a), $\mathbf{v} = 1\mathbf{v} + \mathbf{0} = 1\mathbf{v}$ for every $\mathbf{v}$, which is (A5).

So without (A5), V splits into a genuine vector space W and a part N that every scalar sends to $\mathbf{0}$; (A5) is exactly what removes N. Example (a) of Example 1.2.25 is an instance, with W the x-axis and N the y-axis.

Solution to Exercise 1.2.56

> *Uses.* Definition 1.2.1 (Vector space), Exercise 1.1.58
> *Techniques.* Proving from axioms (Technique 1.1.7)
> *Hint 1.* Expand $(1 + 1)(\mathbf{u} + \mathbf{v})$ in two ways, once with (A8) first and once with (A7) first.
> *Hint 2.* You get $\mathbf{u} + \mathbf{v} + \mathbf{u} + \mathbf{v} = \mathbf{u} + \mathbf{u} + \mathbf{v} + \mathbf{v}$. To cancel $\mathbf{u}$ on the left and $\mathbf{v}$ on the right, you need two-sided inverses and a two-sided zero, which (A3) and (A4) do not provide directly.
> *Hint 3.* Use scalars. Show $0\mathbf{v} = \mathbf{0}$ using only right-hand inverses, then check that $(-1)\mathbf{v}$ is an inverse on both sides and that $\mathbf{0} + \mathbf{v} = 0\mathbf{v} + 1\mathbf{v} = \mathbf{v}$.
> *Sketch.* Adding a right inverse of $0\mathbf{v}$ to $0\mathbf{v} = 0\mathbf{v} + 0\mathbf{v}$ gives $0\mathbf{v} = \mathbf{0}$. Then (A8) gives $\mathbf{v} + (-1)\mathbf{v} = (-1)\mathbf{v} + \mathbf{v} = 0\mathbf{v} = \mathbf{0}$ and $\mathbf{0} + \mathbf{v} = (0 + 1)\mathbf{v} = \mathbf{v}$, so cancellation works on both sides. Expanding $(1 + 1)(\mathbf{u} + \mathbf{v})$ two ways gives $\mathbf{u} + (\mathbf{v} + \mathbf{u}) + \mathbf{v} = \mathbf{u} + (\mathbf{u} + \mathbf{v}) + \mathbf{v}$; cancel.

By (A2) we may drop parentheses in sums. We cannot reorder terms.

Step 1: $0\mathbf{v} = \mathbf{0}$. By (A8), $0\mathbf{v} = (0 + 0)\mathbf{v} = 0\mathbf{v} + 0\mathbf{v}$. By (A4) choose $\mathbf{y}$ with $0\mathbf{v} + \mathbf{y} = \mathbf{0}$, and add it on the right:

$$\mathbf{0} = 0\mathbf{v} + \mathbf{y} = 0\mathbf{v} + 0\mathbf{v} + \mathbf{y} = 0\mathbf{v} + \mathbf{0} = 0\mathbf{v}.$$

Step 2: two-sided inverses and zero. By (A5), (A8), and Step 1,

$$\mathbf{v} + (-1)\mathbf{v} = (1 + (-1))\mathbf{v} = 0\mathbf{v} = \mathbf{0}, \quad (-1)\mathbf{v} + \mathbf{v} = ((-1) + 1)\mathbf{v} = \mathbf{0},$$

and $\mathbf{0} + \mathbf{v} = 0\mathbf{v} + 1\mathbf{v} = (0 + 1)\mathbf{v} = \mathbf{v}$.

Step 3: cancellation on both sides. If $\mathbf{x} + \mathbf{y} = \mathbf{x} + \mathbf{z}$, adding $(-1)\mathbf{x}$ on the left and using Step 2 gives $\mathbf{0} + \mathbf{y} = \mathbf{0} + \mathbf{z}$, so $\mathbf{y} = \mathbf{z}$. If $\mathbf{y} + \mathbf{x} = \mathbf{z} + \mathbf{x}$, adding $(-1)\mathbf{x}$ on the right and using Step 2 and (A3) gives $\mathbf{y} = \mathbf{z}$.

Step 4. By (A8) and (A5),

$$(1 + 1)(\mathbf{u} + \mathbf{v}) = (\mathbf{u} + \mathbf{v}) + (\mathbf{u} + \mathbf{v}) = \mathbf{u} + (\mathbf{v} + \mathbf{u}) + \mathbf{v},$$

and by (A7), then (A8) and (A5),

$$(1 + 1)(\mathbf{u} + \mathbf{v}) = (1 + 1)\mathbf{u} + (1 + 1)\mathbf{v} = \mathbf{u} + \mathbf{u} + \mathbf{v} + \mathbf{v} = \mathbf{u} + (\mathbf{u} + \mathbf{v}) + \mathbf{v}.$$

Cancelling $\mathbf{u}$ on the left and $\mathbf{v}$ on the right (Step 3) gives $\mathbf{v}+\mathbf{u}=\mathbf{u}+\mathbf{v}$, as desired.

Compare Exercise 1.1.58, the same statement for fields. There the two-sided inverses had to be built from the additive axioms alone; here the scalar -1 supplies them.

Solution to Exercise 1.2.57

Uses. Definition 1.2.1 (Vector space), between any two distinct real numbers there is a rational number
Hint 1. For (a), (A7) always holds, and each of (A5), (A6), (A8) is equivalent to one of the three conditions; for the forward direction, take $x=1$.
Hint 2. For (b), first find f on $\mathbb{Z}$ and then on $\mathbb{Q}$ using additivity and $f(1)=1$.
Hint 3. Multiplicativity gives $f(a^2)=f(a)^2\geq 0$, so f sends nonnegative numbers to nonnegative numbers. With additivity, f is nondecreasing. Now squeeze $f(a)$ between rationals.
Sketch. (a) (A5), (A6), (A8) at $x=1$ are the three conditions, and conversely the conditions give the axioms for all x. (b) Additivity and $f(1)=1$ give $f(q)=q$ for rational q. Since $f(b)=f\left(\sqrt{b}\right)^2\geq 0$ for $b\geq 0$, f is nondecreasing. If $f(a)<a$, a rational q with $f(a)<q<a$ gives $q=f(q)\leq f(a)$, a contradiction; similarly $f(a)>a$ is impossible.

(a) Since the addition is that of $\mathbb{R}$, (A1)–(A4) hold, and (A7) holds because $f(a)(x+y)=f(a)x+f(a)y$. The other axioms read, for all $a,b,x\in\mathbb{R}$,

$$\text{(A5)}\ \ f(1)x=x,\quad \text{(A6)}\ \ f(ab)x=f(a)f(b)x,\quad \text{(A8)}\ \ f(a+b)x=f(a)x+f(b)x.$$

Taking $x=1$ shows that they imply $f(1)=1$, $f(ab)=f(a)f(b)$, and $f(a+b)=f(a)+f(b)$. Conversely, multiplying these three equations by x gives the three axioms.

(b) Let f satisfy the three conditions.

f fixes $\mathbb{Q}$. From $f(0)=f(0+0)=f(0)+f(0)$ we get $f(0)=0$, and then $f(a)+f(-a)=f(0)=0$ gives $f(-a)=-f(a)$. For an integer $n\geq 1$, additivity and $f(1)=1$ give $f(n)=f(1)+\cdots+f(1)=n$ by induction, and so $f(n)=n$ for all $n\in\mathbb{Z}$. For $q=m/n$ with $n\geq 1$, $nf(q)=f(nq)=f(m)=m$ (again by additivity), so $f(q)=q$.

f is nondecreasing. If $b\geq 0$, then $f(b)=f\left(\sqrt{b}\sqrt{b}\right)=f\left(\sqrt{b}\right)^2\geq 0$. So if $a\leq b$, then $f(b)-f(a)=f(b-a)\geq 0$.

$f(a)=a$. Let $a\in\mathbb{R}$, and suppose $f(a)<a$. Choose a rational q with $f(a)<q<a$. Since $q<a$ and f is nondecreasing, $q=f(q)\leq f(a)$, contradicting $f(a)<q$. If $f(a)>a$, choose a rational q with $a<q<f(a)$; then $f(a)\leq f(q)=q$, again a contradiction. So $f(a)=a$.

Over $\mathbb{C}$ the analogous question has at least two answers, the identity and conjugation (Exercise 1.2.48). The proof above used the order of $\mathbb{R}$, which $\mathbb{C}$ lacks.

Section 1.3

Solution to Exercise 1.3.6

Uses. Definition 1.3.4 (Linear combination), Definition 1.2.4 (The space F^n)
Hint 1. Compute the vector represented by an arbitrary linear combination $a_1(0,0)+a_2(1,-1)+a_3(-\pi,\pi)$, one coordinate at a time.
Hint 2. The second coordinate is always the negative of the first, so a single equation constrains a_1,a_2,a_3. Which coefficient does not appear in it?
Sketch. The combination represents $(a_2-\pi a_3,-(a_2-\pi a_3))$. It represents $(1,-1)$ exactly when $a_2=1+\pi a_3$, and $\mathbf{0}$ exactly when $a_2=\pi a_3$, with a_1 and a_3 free in both cases. Adding the coefficients of each representation of $\mathbf{0}$ to those of one representation of $(1,-1)$ gives all representations of $(1,-1)$.

By the coordinatewise operations, the linear combination with coefficients a_1,a_2,a_3 represents

$$a_1(0,0)+a_2(1,-1)+a_3(-\pi,\pi)=(a_2-\pi a_3,-a_2+\pi a_3).$$

The second coordinate is the negative of the first. So the combination represents $(1,-1)$ exactly when $a_2-\pi a_3=1$, and it represents $\mathbf{0}$ exactly when $a_2-\pi a_3=0$; the coefficient a_1 plays no role. Hence the linear combinations representing $(1,-1)$ are those with coefficients

$$a_1, \quad 1+\pi t, \quad t \quad (a_1, t \in \mathbb{R}),$$

and those representing $\mathbf{0}$ are those with coefficients $a_1, \pi t, t$ for $a_1, t \in \mathbb{R}$. The first family is obtained from the single representation with coefficients $0, 1, 0$ by adding the coefficients of each member of the second: $(0+a_1, 1+\pi t, 0+t)$. Exercise 1.3.40 shows that this is a general phenomenon.

Solution to Exercise 1.3.16

Uses. Definition 1.3.10 (Span), Definition 1.2.4 (The space F^n)
Techniques. Double containment (Technique 1.3.14), Fix an arbitrary element and chase it (Technique 1.3.13)
Hint 1. Compute the vector represented by $a(1,0,-1)+b(0,1,-1)$ and add up its coordinates.
Hint 2. For the other containment, a vector (x,y,z) with $x+y+z=0$ has $z=-x-y$. Which coefficients reproduce its first two coordinates?
Sketch. $a(1,0,-1)+b(0,1,-1)=(a,b,-a-b)$ has coordinate sum 0. Conversely, if $x+y+z=0$ then $(x,y,z)=(x,y,-x-y)=x(1,0,-1)+y(0,1,-1)$.

Let $P=\{(x,y,z)\in\mathbb{R}^3 \mid x+y+z=0\}$. We proceed by double containment.

span $\subseteq P$. Every element of the span is represented by some linear combination $a(1,0,-1)+b(0,1,-1)=(a,b,-a-b)$, whose coordinates add up to $a+b-a-b=0$. So it lies in P.

$P \subseteq$ span. Let $(x,y,z)\in P$. Then $z=-x-y$, and

$$x(1,0,-1)+y(0,1,-1)=(x,y,-x-y)=(x,y,z).$$

So (x,y,z) is in the span, as desired.

Solution to Exercise 1.3.24

Uses. Corollary 1.3.19 (Equal spans), Proposition 1.3.17 (A list lies in its span)
Hint 1. By Corollary 1.3.19, it suffices to show $\mathcal{L}\subseteq\operatorname{span}(\mathcal{M})$ and $\mathcal{M}\subseteq\operatorname{span}(\mathcal{L})$.
Hint 2. Each entry of $\mathcal{L}$ is an entry of $\mathcal{M}$. Where do the entries of $\mathcal{M}$ lie?
Sketch. Every entry of $\mathcal{L}$ is an entry of $\mathcal{M}$, hence lies in $\operatorname{span}(\mathcal{M})$ by Proposition 1.3.17, and symmetrically. Apply Corollary 1.3.19.

Let $\mathbf{v}\in\mathcal{L}$. By assumption $\mathbf{v}\in\mathcal{M}$, so $\mathbf{v}\in\operatorname{span}(\mathcal{M})$ by Proposition 1.3.17. Hence $\mathcal{L}\subseteq\operatorname{span}(\mathcal{M})$, and by the same argument with the roles exchanged, $\mathcal{M}\subseteq\operatorname{span}(\mathcal{L})$. By Corollary 1.3.19, $\operatorname{span}(\mathcal{L})=\operatorname{span}(\mathcal{M})$.

Solution to Exercise 1.3.25

Uses. Corollary 1.3.19 (Equal spans)
Hint 1. Use Corollary 1.3.19. Each $\mathbf{w}_j$ is visibly a linear combination of the $\mathbf{v}_i$.
Hint 2. Recover $\mathbf{v}_j$ from two consecutive partial sums.
Sketch. $\mathbf{w}_j$ is the combination of the $\mathbf{v}_i$ with coefficients 1 in positions $1,\dots,j$ and 0 after. Conversely $\mathbf{v}_1=\mathbf{w}_1$ and $\mathbf{v}_j=\mathbf{w}_j-\mathbf{w}_{j-1}$ for $j\geq 2$.

Write $\mathcal{V}=\mathbf{v}_1,\dots,\mathbf{v}_k$ and $\mathcal{W}=\mathbf{w}_1,\dots,\mathbf{w}_k$. Each $\mathbf{w}_j$ is represented by the linear combination of $\mathcal{V}$ with coefficient 1 on $\mathbf{v}_1,\dots,\mathbf{v}_j$ and 0 on the remaining entries, so $\mathcal{W}\subseteq\operatorname{span}(\mathcal{V})$. Conversely, $\mathbf{v}_1=\mathbf{w}_1$, and for $j\geq 2$,

$$\mathbf{w}_j-\mathbf{w}_{j-1}=\left(\mathbf{v}_1+\cdots+\mathbf{v}_{j-1}+\mathbf{v}_j\right)-\left(\mathbf{v}_1+\cdots+\mathbf{v}_{j-1}\right)=\mathbf{v}_j$$

by Proposition 1.2.30(a). So each $\mathbf{v}_j$ is a linear combination of $\mathcal{W}$, with coefficient 1 on $\mathbf{w}_j$, -1 on $\mathbf{w}_{j-1}$, and 0 elsewhere, and $\mathcal{V}\subseteq\operatorname{span}(\mathcal{W})$. By Corollary 1.3.19, the spans are equal.

Solution to Exercise 1.3.26

Uses. Definition 1.3.10 (Span), Definition 1.2.4 (The space F^n)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For (a), compute the vector represented by $a(1,2,0)+b(0,1,1)$ and compare its middle coordinate with the outer ones.
Hint 2. For the other containment in (a), the coefficients can be read off from the first and third coordinates. Then (b) is a matter of checking the equation $y=2x+z$.

Sketch. (a) $a(1,2,0)+b(0,1,1)=(a,2a+b,b)$ satisfies $y=2x+z$; conversely, if $y=2x+z$, then $(x,y,z)=x(1,2,0)+z(0,1,1)$. (b) $(1,1,1)$ fails the equation since $2+1\neq 1$; $(2,5,1)$ satisfies it, and $(2,5,1)=2(1,2,0)+(0,1,1)$.

(a) Let $P=\{(x,y,z)\in\mathbb{R}^3 \mid y=2x+z\}$. We proceed by double containment. An element of $\operatorname{span}(\mathcal{L})$ is represented by some linear combination

$$a(1,2,0)+b(0,1,1)=(a,2a+b,b),$$

and its middle coordinate $2a+b$ is twice the first plus the third. So $\operatorname{span}(\mathcal{L})\subseteq P$. Conversely, let $(x,y,z)\in P$. Then

$$x(1,2,0)+z(0,1,1)=(x,2x+z,z)=(x,y,z),$$

so $(x,y,z)\in\operatorname{span}(\mathcal{L})$. Hence $P\subseteq\operatorname{span}(\mathcal{L})$.

(b) For $(1,1,1)$ we have $2\cdot 1+1=3\neq 1$, so $(1,1,1)\notin\operatorname{span}(\mathcal{L})$ by (a). For $(2,5,1)$ we have $2\cdot 2+1=5$, so $(2,5,1)\in\operatorname{span}(\mathcal{L})$, and the proof of (a) gives the representation $(2,5,1)=2(1,2,0)+1(0,1,1)$.

Solution to Exercise 1.3.27

Uses. Definition 1.3.10 (Span), Corollary 1.3.20 (Operations that preserve the span), Definition 1.3.4 (Linear combination)
Hint 1. The combination $a(1,1,0)+b(0,1,2)$ represents $(a,a+b,2b)$. Run through the nine choices of $a,b\in\mathbb{F}_3$, reducing modulo 3.
Hint 2. For (b), $(1,2,2)$ is the sum of the other two entries. Rewrite an arbitrary combination of $\mathcal{M}$ as a combination of $\mathcal{L}$ and use that the nine vectors in (a) are distinct.
Sketch. (a) The span consists of the vectors $(a,a+b,2b)$: $(0,0,0),(0,1,2),(0,2,1),(1,1,0),(1,2,2),(1,0,1),(2,2,0),(2,0,2),(2,1,1)$. It contains $(1,0,1)$ ($a=1$, $b=2$) but not $(1,1,1)$. (b) $(1,2,2)\in\operatorname{span}(\mathcal{L})$. There are 27 combinations; a,b,c represents $(a+c)(1,1,0)+(b+c)(0,1,2)$, which is $(1,0,1)$ exactly when $a+c=1$ and $b+c=2$, giving 3 combinations, one for each c.

(a) The combination with coefficients a,b represents $a(1,1,0)+b(0,1,2)=(a,a+b,2b)$. Running through $a,b\in\mathbb{F}_3$ and reducing modulo 3:

$$\begin{aligned} a=0:&\quad (0,0,0),(0,1,2),(0,2,1),\\ a=1:&\quad (1,1,0),(1,2,2),(1,0,1),\\ a=2:&\quad (2,2,0),(2,0,2),(2,1,1),\end{aligned}$$

with $b=0,1,2$ in each row. These nine vectors are distinct, because the first coordinate determines a and the third determines b (as $2b=2b'$ forces $b=b'$). The vector $(1,0,1)$ appears, with $a=1$ and $b=2$. The vector $(1,1,1)$ does not: $a=1$ and $2b=1$ force $b=2$, and then $a+b=0\neq 1$.

(b) In $\mathbb{F}_3^3$, $(1,1,0)+(0,1,2)=(1,2,2)$, so the third entry of $\mathcal{M}$ lies in $\operatorname{span}(\mathcal{L})$, and $\operatorname{span}(\mathcal{M})=\operatorname{span}(\mathcal{L})$ by Corollary 1.3.20(c). A linear combination of $\mathcal{M}$ is determined by its three coefficients, so there are $3^3=27$ of them. By Lemma 1.3.9, the one with coefficients a,b,c represents

$$a(1,1,0)+b(0,1,2)+c((1,1,0)+(0,1,2))=(a+c)(1,1,0)+(b+c)(0,1,2).$$

By (a), the combinations of $\mathcal{L}$ represent distinct vectors for distinct coefficients, and $(1,0,1)$ is represented by the coefficients $1,2$. So a,b,c represents $(1,0,1)$ exactly when $a+c=1$ and $b+c=2$. For each $c\in\mathbb{F}_3$ there is exactly one such a and b, so exactly 3 linear combinations of $\mathcal{M}$ represent $(1,0,1)$: those with coefficients $1,2,0$, then $0,1,1$, and $2,0,2$. The same count holds for each of the nine vectors of the span, and $9\cdot 3=27$.

Solution to Exercise 1.3.28

Uses. Proposition 1.3.17 (A list lies in its span), Proposition 1.3.18 (Comparing spans), Corollary 1.3.19 (Equal spans), Definition 1.3.10 (Span), Proposition 1.2.33 (The zero vector)
Hint 1. For (a), if some entry is nonzero, what does Proposition 1.3.17 say? If all entries are $\mathbf{0}$, compare with the empty list.
Hint 2. For (b), the forward direction gives $\mathbf{w}=c\mathbf{v}$ for some c. Rule out $c=0$ separately in the cases $\mathbf{v}=\mathbf{0}$ and $\mathbf{v}\neq\mathbf{0}$.

Sketch. (a) $\operatorname{span}(\mathcal{L}) = \{\mathbf{0}\}$ exactly when every entry is $\mathbf{0}$, the empty list included; these are also exactly the lists that span $\{\mathbf{0}\}$. (b) If $\mathbf{w} = c\mathbf{v}$ with $c \neq 0$, then $\mathbf{v} = c^{-1}\mathbf{w}$, so the spans agree. Conversely $\mathbf{w} \in \operatorname{span}(\mathbf{v})$ gives $\mathbf{w} = c\mathbf{v}$; if $c = 0$ then $\mathbf{w} = \mathbf{0}$, so $\mathbf{v} \in \operatorname{span}(\mathbf{0}) = \{\mathbf{0}\}$ and $\mathbf{w} = 1\mathbf{v}$ anyway.

(a) If some entry $\mathbf{v}_j$ of $\mathcal{L}$ is nonzero, then $\mathbf{v}_j \in \operatorname{span}(\mathcal{L})$ by Proposition 1.3.17, so $\operatorname{span}(\mathcal{L}) \neq \{\mathbf{0}\}$. If every entry of $\mathcal{L}$ is $\mathbf{0}$ (this includes the empty list), then $\mathcal{L} \subseteq \{\mathbf{0}\} = \operatorname{span}(())$, so $\operatorname{span}(\mathcal{L}) \subseteq \{\mathbf{0}\}$ by Proposition 1.3.18, and $\mathbf{0} \in \operatorname{span}(\mathcal{L})$ by Proposition 1.3.17. So $\operatorname{span}(\mathcal{L}) = \{\mathbf{0}\}$ exactly when all entries of $\mathcal{L}$ are $\mathbf{0}$. A list in the zero space has all its entries equal to $\mathbf{0}$, so by what we just showed, every list in $\{\mathbf{0}\}$ spans it: $()$, $\mathbf{0}$, $\mathbf{0}$, $\mathbf{0}$, and so on.

(b) Suppose $\mathbf{w} = c\mathbf{v}$ with $c \neq 0$. Then $\mathbf{w} \in \operatorname{span}(\mathbf{v})$, and $\mathbf{v} = c^{-1}(c\mathbf{v}) = c^{-1}\mathbf{w} \in \operatorname{span}(\mathbf{w})$ by (A6) and (A5). So the spans are equal by Corollary 1.3.19.

Conversely, suppose $\operatorname{span}(\mathbf{v}) = \operatorname{span}(\mathbf{w})$. Then $\mathbf{w} \in \operatorname{span}(\mathbf{v})$ by Proposition 1.3.17, so $\mathbf{w} = c\mathbf{v}$ for some $c \in F$. If $c \neq 0$ we are done. If $c = 0$, then $\mathbf{w} = \mathbf{0}$, so $\operatorname{span}(\mathbf{v}) = \operatorname{span}(\mathbf{0}) = \{\mathbf{0}\}$, and therefore $\mathbf{v} = \mathbf{0}$ by (a). Then $\mathbf{w} = \mathbf{0} = 1\mathbf{v}$, with $1 \neq 0$.

Solution to Exercise 1.3.29

Uses. Definition 1.3.4 (Linear combination), Example 1.3.5 (One vector, many representations)
Hint 1. What does the equation $a_1\mathbf{v}_1 + a_2\mathbf{v}_2 = b_1\mathbf{v}_1 + b_2\mathbf{v}_2$ assert: that two expressions are the same, or that two vectors are equal?
Hint 2. For a counterexample, take $\mathbf{v}_1 = \mathbf{v}_2$.
Sketch. The equation says that the two linear combinations represent the same vector, not that they are the same linear combination. With $\mathbf{v}_1 = \mathbf{v}_2 = \mathbf{v} \neq \mathbf{0}$, $1\mathbf{v}_1 + 0\mathbf{v}_2 = 0\mathbf{v}_1 + 1\mathbf{v}_2$. For $(1,0), (0,1)$, the two sides are (a_1, a_2) and (b_1, b_2).

(a) The hypothesis is an equation between vectors: it says that the two linear combinations *represent* the same vector. The argument reads it as saying that the two linear combinations are the same, which is what the claim asserts. So the argument assumes its conclusion.

(b) Let $\mathbf{v} \neq \mathbf{0}$ (for instance $\mathbf{v} = (1,0)$ in $\mathbb{R}^2$), and take $\mathbf{v}_1 = \mathbf{v}_2 = \mathbf{v}$. Then $1\mathbf{v}_1 + 0\mathbf{v}_2 = \mathbf{v} = 0\mathbf{v}_1 + 1\mathbf{v}_2$, but $1 \neq 0$. For $\mathbf{v}_1 = (1,0)$ and $\mathbf{v}_2 = (0,1)$, the two sides represent (a_1, a_2) and (b_1, b_2), and these columns are equal only if $a_1 = b_1$ and $a_2 = b_2$. The lists for which the claim holds are the linearly independent ones (Section 1.5).

Solution to Exercise 1.3.30

Uses. Definition 1.3.10 (Span), Example 1.3.11 (Small spans)
Techniques. Double containment (Technique 1.3.14), Try small cases and small fields (Technique 1.2.38)
Hint 1. The argument proves a containment. Which one, and is it the one with content?
Hint 2. For (b), solve $a + b = x$ and $a - b = y$ for a and b. Which field element do you divide by?
Sketch. (a) It shows only span $\subseteq \mathbb{R}^2$, which holds for any list in $\mathbb{R}^2$; the containment $\mathbb{R}^2 \subseteq$ span is missing. (b) $(x,y) = \frac{x+y}{2}(1,1) + \frac{x-y}{2}(1,-1)$. (c) Over $\mathbb{F}_2$, $(1,-1) = (1,1)$ and the span is $\{\mathbf{0}, (1,1)\} \neq \mathbb{F}_2^2$. Over $\mathbb{F}_3$, $2^{-1} = 2$, so the formula of (b) works and the span is $\mathbb{F}_3^2$.

(a) The argument proves $\operatorname{span}((1,1),(1,-1)) \subseteq \mathbb{R}^2$, which holds for every list in $\mathbb{R}^2$ because the operations of $\mathbb{R}^2$ produce elements of $\mathbb{R}^2$. The containment $\mathbb{R}^2 \subseteq \operatorname{span}((1,1),(1,-1))$ is never addressed, and it is the one with content.

(b) It remains to show $\mathbb{R}^2 \subseteq \operatorname{span}((1,1),(1,-1))$. Let $(x,y) \in \mathbb{R}^2$, and set $a = (x+y)/2$ and $b = (x-y)/2$. Then

$$a(1,1) + b(1,-1) = (a+b, a-b) = (x,y),$$

so (x,y) lies in the span.

(c) In $\mathbb{F}_2^2$, $-1 = 1$, so the list is $(1,1),(1,1)$, and its span is $\operatorname{span}((1,1)) = \{\mathbf{0}, (1,1)\}$ by Corollary 1.3.20(c) and Example 1.3.11. This is not $\mathbb{F}_2^2$; for instance, $(1,0)$ is missing. The proof of (b) breaks down because it divides by $2 = 0$. In $\mathbb{F}_3$, $2 \neq 0$ and $2^{-1} = 2$, so with $a = 2(x+y)$ and $b = 2(x-y)$,

$$a(1,1) + b(1,-1) = (4x, 4y) = (x,y),$$

since $4 = 1$ in $\mathbb{F}_3$. So the list spans $\mathbb{F}_3^2$.

Solution to Exercise 1.3.31

Uses. Definition 1.3.10 (Span), Definition 1.2.9 (Function spaces)
Hint 1. For (a), use a double-angle formula. For (b), compare $f(t)$ with $f(-t)$ for $f = a + b\cos$.
Hint 2. For (c), write $\sin^2 = 1 - \cos^2$. If $\sin^2 = a + b\cos$, evaluate at three values of t where $\cos t$ is 0, 1, and -1.
Sketch. (a) $\cos^2 t = \frac{1}{2} + \frac{1}{2}\cos 2t$. (b) Every $a + b\cos$ is even, while $\sin(\pi/2) = 1 \neq -1 = \sin(-\pi/2)$. (c) No: $\sin^2 = a + b\cos$ at $t = \pi/2, 0, \pi$ gives $1 = a$, $0 = a + b$, $0 = a - b$, which is inconsistent.

(a) By the double-angle formula $\cos 2t = 2\cos^2 t - 1$, we have $\cos^2 t = \frac{1}{2} \cdot 1 + \frac{1}{2}\cos 2t$ for all t. So $t \mapsto \cos^2 t$ is represented by the linear combination $\frac{1}{2} \cdot 1 + \frac{1}{2}c_2$.

(b) Every element of $\operatorname{span}(1, \cos)$ has the form $f = a + b\cos$ with $a, b \in \mathbb{R}$, and $f(-t) = a + b\cos(-t) = a + b\cos t = f(t)$ for all t. But $\sin(\pi/2) = 1$ and $\sin(-\pi/2) = -1$, so sin is not of this form.

(c) No. Suppose $\sin^2 t = a + b\cos t$ for all $t \in \mathbb{R}$. At $t = \pi/2$ this gives $1 = a$. At $t = 0$ it gives $0 = a + b$, and at $t = \pi$ it gives $0 = a - b$. Adding the last two equations gives $a = 0$, contradicting $a = 1$.

Solution to Exercise 1.3.32

Uses. Definition 1.2.17 (Evaluation), Definition 1.2.16 (Degree), Definition 1.3.10 (Span), Notation 1.2.15
Techniques. Double containment (Technique 1.3.14)
Hint 1. Write $p = a_0 + a_1x + a_2x^2 + a_3x^3$. The condition $p(1) = 0$ expresses a_0 in terms of a_1, a_2, a_3.
Hint 2. Substitute $a_0 = -a_1 - a_2 - a_3$ and group the terms by a_1, a_2, and a_3.
Sketch. The list $x - 1, x^2 - 1, x^3 - 1$. A combination $a_1(x-1) + a_2(x^2-1) + a_3(x^3-1)$ has degree at most 3 and vanishes at 1. Conversely, if $p(1) = a_0 + a_1 + a_2 + a_3 = 0$, then $p = a_1(x-1) + a_2(x^2-1) + a_3(x^3-1)$.

We show that $\operatorname{span}(x - 1, x^2 - 1, x^3 - 1) = W$, by double containment.

$\operatorname{span} \subseteq W$. A linear combination of the list represents

$$a_1(x-1) + a_2(x^2-1) + a_3(x^3-1) = -(a_1 + a_2 + a_3) + a_1x + a_2x^2 + a_3x^3,$$

which has no nonzero coefficients beyond position 3, so it lies in $\mathbb{R}[x]_{\leq 3}$. Its value at 1 is $-(a_1 + a_2 + a_3) + a_1 + a_2 + a_3 = 0$ (Definition 1.2.17). So it lies in W.

$W \subseteq \operatorname{span}$. Let $p = a_0 + a_1x + a_2x^2 + a_3x^3 \in W$. Then $p(1) = a_0 + a_1 + a_2 + a_3 = 0$, so $a_0 = -(a_1 + a_2 + a_3)$, and by the computation above,

$$p = -(a_1 + a_2 + a_3) + a_1x + a_2x^2 + a_3x^3 = a_1(x-1) + a_2(x^2-1) + a_3(x^3-1).$$

So p lies in the span.

Solution to Exercise 1.3.33

Uses. Proposition 1.3.18 (Comparing spans), Example 1.3.11 (Small spans), Definition 1.2.16 (Degree), induction on n
Techniques. Double containment (Technique 1.3.14)
Hint 1. One containment is a degree count, via Proposition 1.3.18 and $F[x]_{\leq n} = \operatorname{span}(1, x, \ldots, x^n)$. For the other, it suffices to show that each x^k with $k \leq n$ lies in $\operatorname{span}(p_0, \ldots, p_n)$.
Hint 2. Induct on n. If p_n has leading coefficient $c \neq 0$, then $p_n - cx^n$ has degree less than n, and $x^n = c^{-1}(p_n - (p_n - cx^n))$.
Sketch. (a) Each p_k lies in $F[x]_{\leq n} = \operatorname{span}(1, \ldots, x^n)$, giving $\subseteq$. For $\supseteq$, induct on n: p_0 is a nonzero constant, so $1 \in \operatorname{span}(p_0)$. If $\operatorname{span}(p_0, \ldots, p_{n-1}) = F[x]_{\leq n-1}$ and $p_n = cx^n + r$ with $c \neq 0$ and $\deg r < n$, then $r \in \operatorname{span}(p_0, \ldots, p_{n-1})$, so $x^n = c^{-1}(p_n - r) \in \operatorname{span}(p_0, \ldots, p_n)$, and the lower powers are there by induction. (b) $x^2 = (x^2 - 2x + 1) + 2(x - 1) + 1$.

(a) Write $\mathcal{P}_n = p_0, \ldots, p_n$. We prove $\operatorname{span}(\mathcal{P}_n) = F[x]_{\leq n}$ by induction on n, and in each case by double containment.

$\operatorname{span}(\mathcal{P}_n) \subseteq F[x]_{\leq n}$. Each p_k has degree $k \leq n$, so $\mathcal{P}_n \subseteq F[x]_{\leq n} = \operatorname{span}(1, x, \ldots, x^n)$ (Example 1.3.11). By Proposition 1.3.18, $\operatorname{span}(\mathcal{P}_n) \subseteq \operatorname{span}(1, x, \ldots, x^n) = F[x]_{\leq n}$.

$F[x]_{\leq n} \subseteq \operatorname{span}(\mathcal{P}_n)$. By Proposition 1.3.18, it suffices to show $x^k \in \operatorname{span}(\mathcal{P}_n)$ for $0 \leq k \leq n$. For $n = 0$, p_0 has degree 0, so $p_0 = c$ is a nonzero constant and $1 = c^{-1}p_0 \in \operatorname{span}(p_0)$. Now let $n \geq 1$, and assume $\operatorname{span}(\mathcal{P}_{n-1}) = F[x]_{\leq n-1}$. Let $c \neq 0$ be the leading coefficient of p_n, and let $r = p_n - cx^n$. The coefficients

of r in positions $k > n$ are 0, and so is its coefficient in position n, so $r \in F[x]_{\le n-1} = \operatorname{span}(\mathcal{P}_{n-1})$, say $r = \sum_{k=0}^{n-1} d_k p_k$. Then

$$x^n = c^{-1}(p_n - r) = c^{-1}p_n - \sum_{k=0}^{n-1}(c^{-1}d_k)p_k \in \operatorname{span}(\mathcal{P}_n),$$

using Lemma 1.3.9. For $k < n$, $x^k \in F[x]_{\le n-1} = \operatorname{span}(\mathcal{P}_{n-1}) \subseteq \operatorname{span}(\mathcal{P}_n)$, by the inductive hypothesis and Corollary 1.3.20(b). This completes the induction.

(b) Following the proof of (a) from the top degree down, $x^2 = (x^2 - 2x + 1) + (2x - 1)$ and $2x - 1 = 2(x - 1) + 1$. So

$$x^2 = 1 \cdot 1 + 2(x-1) + 1 \cdot (x^2 - 2x + 1).$$

Check: $1 + 2x - 2 + x^2 - 2x + 1 = x^2$.

Solution to Exercise 1.3.34

> *Uses.* Corollary 1.3.19 (Equal spans), Proposition 1.3.17 (A list lies in its span), Lemma 1.3.9 (Arithmetic of linear combinations)
> *Hint 1.* Write $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. What does the hypothesis $\mathbf{w} \notin \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$ say about a_k?
> *Hint 2.* Since $a_k \neq 0$, solve for $\mathbf{v}_k$. Then use Corollary 1.3.19.
> *Sketch.* Write $\mathbf{w} = \sum_i a_i\mathbf{v}_i$. If $a_k = 0$, then $\mathbf{w} \in \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$, so $a_k \neq 0$ and $\mathbf{v}_k = a_k^{-1}\mathbf{w} - \sum_{i<k} a_k^{-1}a_i\mathbf{v}_i$. So each list lies in the span of the other.

Since $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, we can write $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k$. If $a_k = 0$, then $\mathbf{w} = a_1\mathbf{v}_1 + \cdots + a_{k-1}\mathbf{v}_{k-1}$ (the term $0\mathbf{v}_k = \mathbf{0}$ contributes nothing), contradicting $\mathbf{w} \notin \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$. So $a_k \neq 0$. (In particular $k \geq 1$.) By Lemma 1.3.9 and Proposition 1.2.34,

$$\mathbf{v}_k = a_k^{-1}(\mathbf{w} - a_1\mathbf{v}_1 - \cdots - a_{k-1}\mathbf{v}_{k-1}) = a_k^{-1}\mathbf{w} + \sum_{i=1}^{k-1}(-a_k^{-1}a_i)\mathbf{v}_i.$$

Let $\mathcal{L}' = \mathbf{v}_1, \ldots, \mathbf{v}_{k-1}, \mathbf{w}$. The entries of $\mathcal{L}'$ lie in $\operatorname{span}(\mathcal{L})$: the $\mathbf{v}_i$ by Proposition 1.3.17, and $\mathbf{w}$ by assumption. The entries of $\mathcal{L}$ lie in $\operatorname{span}(\mathcal{L}')$: the $\mathbf{v}_i$ with $i < k$ by Proposition 1.3.17, and $\mathbf{v}_k$ by the display. By Corollary 1.3.19, $\operatorname{span}(\mathcal{L}') = \operatorname{span}(\mathcal{L})$.

This exchange is the step that drives the proof of Lemma 4.1.2.

Solution to Exercise 1.3.35

> *Uses.* Definition 1.3.10 (Span), Example 1.3.11 (Small spans), Exercise 1.3.34
> *Hint 1.* Test (a)–(d) in $\mathbb{R}^2$ with the vectors $\mathbf{e}_1 = (1, 0)$, $\mathbf{e}_2 = (0, 1)$, and $\mathbf{e}_1 + \mathbf{e}_2$.
> *Hint 2.* (e) is true. Write $\mathbf{u} = a\mathbf{v} + b\mathbf{w}$ and decide what $\mathbf{u} \notin \operatorname{span}(\mathbf{w})$ says about a.
> *Sketch.* (a) False: $\mathbf{e}_1 + \mathbf{e}_2 \in \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ lies on neither axis. (b) False: $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) \cap \operatorname{span}(\mathbf{e}_1 + \mathbf{e}_2)$ contains $\mathbf{e}_1 + \mathbf{e}_2$, but the lists share no entry, so $\mathcal{N} = ()$. (c) False: $()$ and $\mathbf{0}$. (d) False: $\mathbf{u} = \mathbf{v} = \mathbf{e}_1$, $\mathbf{w} = \mathbf{e}_2$. (e) True: $\mathbf{u} = a\mathbf{v} + b\mathbf{w}$ with $a \neq 0$, so $\mathbf{v} = a^{-1}\mathbf{u} - a^{-1}b\mathbf{w}$.

Write $\mathbf{e}_1 = (1, 0)$ and $\mathbf{e}_2 = (0, 1)$ in $\mathbb{R}^2$.

(a) False. Let $\mathcal{L} = \mathbf{e}_1$ and $\mathcal{M} = \mathbf{e}_2$. Then $(1, 1) = \mathbf{e}_1 + \mathbf{e}_2 \in \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$, but $\operatorname{span}(\mathbf{e}_1) = \{(a, 0) \mid a \in \mathbb{R}\}$ and $\operatorname{span}(\mathbf{e}_2) = \{(0, b) \mid b \in \mathbb{R}\}$, and $(1, 1)$ lies in neither.

(b) False. Let $\mathcal{L} = \mathbf{e}_1, \mathbf{e}_2$ and $\mathcal{M} = (1, 1)$. No vector is an entry of both lists, so $\mathcal{N} = ()$ and $\operatorname{span}(\mathcal{N}) = \{\mathbf{0}\}$. But $(1, 1) \in \operatorname{span}(\mathcal{M})$ and $(1, 1) \in \operatorname{span}(\mathcal{L}) = \mathbb{R}^2$, so the intersection contains $(1, 1) \neq \mathbf{0}$.

(c) False. $\operatorname{span}(()) = \{\mathbf{0}\} = \operatorname{span}(\mathbf{0})$ by Example 1.3.11, but the lists have lengths 0 and 1.

(d) False. Let $\mathbf{u} = \mathbf{v} = \mathbf{e}_1$ and $\mathbf{w} = \mathbf{e}_2$. Then $\mathbf{u} = 1\mathbf{v} + 0\mathbf{w}$ and $\mathbf{v} = 1\mathbf{u} + 0\mathbf{w}$, but $\operatorname{span}(\mathbf{u}, \mathbf{v}) = \operatorname{span}(\mathbf{e}_1)$ does not contain $\mathbf{e}_2$.

(e) True. Write $\mathbf{u} = a\mathbf{v} + b\mathbf{w}$. If $a = 0$, then $\mathbf{u} = b\mathbf{w} \in \operatorname{span}(\mathbf{w})$, contrary to assumption. So $a \neq 0$, and

$$\mathbf{v} = a^{-1}(\mathbf{u} - b\mathbf{w}) = a^{-1}\mathbf{u} + \big(-a^{-1}b\big)\mathbf{w} \in \operatorname{span}(\mathbf{u}, \mathbf{w}).$$

This is the case $k = 2$ of Exercise 1.3.34, applied to the list $\mathbf{w}, \mathbf{v}$.

Solution to Exercise 1.3.36

Uses. Definition 1.3.10 (Span), (1.3.1), Notation 1.3.3
Techniques. Double containment (Technique 1.3.14)
Hint 1. A linear combination of the concatenation $\mathcal{L}, \mathcal{M}$ has one coefficient for each entry of $\mathcal{L}$ and one for each entry of $\mathcal{M}$.
Hint 2. By (A2), the sum over the concatenation can be grouped as (the terms from $\mathcal{L}$) plus (the terms from $\mathcal{M}$).
Sketch. The combination of $\mathcal{L}, \mathcal{M}$ with coefficients $a_1, \ldots, a_k, b_1, \ldots, b_m$ represents $\sum a_i\mathbf{v}_i + \sum b_j\mathbf{w}_j$, by grouping the terms. So the vectors it represents are exactly the sums $\mathbf{u} + \mathbf{w}$, both containments included.

Let $\mathcal{L} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ and $\mathcal{M} = \mathbf{w}_1, \ldots, \mathbf{w}_m$, and let S be the set on the right. A linear combination of $\mathcal{L}, \mathcal{M}$ has coefficients $a_1, \ldots, a_k, b_1, \ldots, b_m$, and by (1.3.1) and (A2) the vector it represents is

$$a_1\mathbf{v}_1 + \cdots + a_k\mathbf{v}_k + b_1\mathbf{w}_1 + \cdots + b_m\mathbf{w}_m = \left(\sum_{i=1}^{k} a_i\mathbf{v}_i\right) + \left(\sum_{j=1}^{m} b_j\mathbf{w}_j\right).$$

(If $k = 0$ or $m = 0$, the corresponding sum is $\mathbf{0}$, and the identity holds by (A1) and (A3).) We use this identity for both containments.

$\operatorname{span}(\mathcal{L}, \mathcal{M}) \subseteq S$. An element of the left side is represented by some such combination, and the identity writes it as $\mathbf{u} + \mathbf{w}$ with $\mathbf{u} = \sum a_i\mathbf{v}_i \in \operatorname{span}(\mathcal{L})$ and $\mathbf{w} = \sum b_j\mathbf{w}_j \in \operatorname{span}(\mathcal{M})$.

$S \subseteq \operatorname{span}(\mathcal{L}, \mathcal{M})$. Let $\mathbf{u} \in \operatorname{span}(\mathcal{L})$ and $\mathbf{w} \in \operatorname{span}(\mathcal{M})$, say $\mathbf{u} = \sum a_i\mathbf{v}_i$ and $\mathbf{w} = \sum b_j\mathbf{w}_j$. By the identity, the combination of $\mathcal{L}, \mathcal{M}$ with coefficients $a_1, \ldots, a_k, b_1, \ldots, b_m$ represents $\mathbf{u} + \mathbf{w}$, so $\mathbf{u} + \mathbf{w} \in \operatorname{span}(\mathcal{L}, \mathcal{M})$.

In the language of Section 4.4, the span of a concatenation is the sum of the spans (Definition 4.4.1).

Solution to Exercise 1.3.37

Uses. Proposition 1.3.18 (Comparing spans), Example 1.3.11 (Small spans), Corollary 1.3.20 (Operations that preserve the span)
Hint 1. If $\delta = ad - bc \neq 0$, compute $d\mathbf{u} - b\mathbf{v}$ and $a\mathbf{v} - c\mathbf{u}$.
Hint 2. If $\delta = 0$, show that every vector (p, q) in the span satisfies $bp - aq = 0$ and $dp - cq = 0$. Then find a vector of F^2 that violates one of these equations.
Hint 3. For (b), compute δ when $\mathbf{v} = t\mathbf{u}$. Conversely, if $\delta = 0$ and $a \neq 0$, try $t = c/a$.
Sketch. (a) $d\mathbf{u} - b\mathbf{v} = (\delta, 0)$ and $a\mathbf{v} - c\mathbf{u} = (0, \delta)$, so if $\delta \neq 0$ then $\mathbf{e}_1, \mathbf{e}_2$ lie in the span. If $\delta = 0$, every $x\mathbf{u} + y\mathbf{v}$ satisfies $bp - aq = 0$ and $dp - cq = 0$; if $\mathbf{u} = \mathbf{v} = \mathbf{0}$ the span is $\{\mathbf{0}\}$, and otherwise one of $\mathbf{e}_1, \mathbf{e}_2$ violates an equation with a nonzero coefficient. (b) $\mathbf{v} = t\mathbf{u}$ gives $\delta = 0$; conversely, $\delta = 0$ with $a \neq 0$ gives $\mathbf{v} = (c/a)\mathbf{u}$, and with $a = 0$, $b \neq 0$ it gives $c = 0$ and $\mathbf{v} = (d/b)\mathbf{u}$.

Let $\delta = ad - bc$.

(a) Suppose $\delta \neq 0$. Then

$$d\mathbf{u} - b\mathbf{v} = (da - bc, db - bd) = (\delta, 0), \quad a\mathbf{v} - c\mathbf{u} = (ac - ca, ad - cb) = (0, \delta).$$

So $\mathbf{e}_1 = \delta^{-1}(d\mathbf{u} - b\mathbf{v})$ and $\mathbf{e}_2 = \delta^{-1}(a\mathbf{v} - c\mathbf{u})$ lie in $\operatorname{span}(\mathbf{u}, \mathbf{v})$, and by Proposition 1.3.18, $F^2 = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) \subseteq \operatorname{span}(\mathbf{u}, \mathbf{v})$.

Now suppose $\delta = 0$. A vector $(p, q) = x\mathbf{u} + y\mathbf{v} = (xa + yc, xb + yd)$ of the span satisfies

$$bp - aq = y(bc - ad) = 0 \quad \text{and} \quad dp - cq = x(ad - bc) = 0.$$

If $a = b = c = d = 0$, then $\operatorname{span}(\mathbf{u}, \mathbf{v}) = \{\mathbf{0}\} \neq F^2$. Otherwise one of these two equations has a nonzero coefficient. If $a \neq 0$ or $c \neq 0$, the vector $\mathbf{e}_2 = (0, 1)$ gives $b \cdot 0 - a \cdot 1 = -a$ and $d \cdot 0 - c \cdot 1 = -c$, one of which is nonzero, so $\mathbf{e}_2$ is not in the span. If $b \neq 0$ or $d \neq 0$, then similarly $\mathbf{e}_1 = (1, 0)$ gives b and d, and $\mathbf{e}_1$ is not in the span. Either way, $\mathbf{u}, \mathbf{v}$ does not span F^2.

(b) If $\mathbf{v} \in \operatorname{span}(\mathbf{u})$, say $\mathbf{v} = t\mathbf{u} = (ta, tb)$, then $\delta = atb - bta = 0$, so the list does not span by (a). Conversely, suppose the list does not span, so $\delta = 0$ by (a). If $a \neq 0$, then $bc = ad$ gives

$$\frac{c}{a}\mathbf{u} = \left(c, \frac{bc}{a}\right) = (c, d) = \mathbf{v}.$$

If $a = 0$, then $b \neq 0$ because $\mathbf{u} \neq \mathbf{0}$, and $\delta = -bc = 0$ forces $c = 0$; then $\mathbf{v} = (0, d) = (d/b)(0, b) = (d/b)\mathbf{u}$. Either way $\mathbf{v} \in \operatorname{span}(\mathbf{u})$.

The quantity $ad - bc$ is the determinant of the 2×2 matrix with columns $\mathbf{u}$ and $\mathbf{v}$ (Theorem 5.1.13).

Solution to Exercise 1.3.38

Uses. Exercise 1.3.37, Corollary 1.2.36 (Cancelling scalars and vectors), Example 1.3.11 (Small spans), Corollary 1.3.20 (Operations that preserve the span)
Hint 1. For (a), how many elements does $\operatorname{span}(\mathbf{v})$ have?
Hint 2. For (b), use Exercise 1.3.37(b). First show that a spanning list $\mathbf{u}, \mathbf{v}$ has $\mathbf{u} \neq \mathbf{0}$. Then count the choices of $\mathbf{v}$ outside $\operatorname{span}(\mathbf{u})$, which has exactly q elements.
Hint 3. For (c), a list in $\mathbb{F}_2^2$ spans exactly when it has two different nonzero entries. Count the complement.
Sketch. (a) $\operatorname{span}(\mathbf{v}) = \{a\mathbf{v}\}$ has at most $q < q^2$ elements. (b) If $\mathbf{u} = \mathbf{0}$, then $\operatorname{span}(\mathbf{0}, \mathbf{v}) = \operatorname{span}(\mathbf{v}) \neq F^2$. For each of the $q^2 - 1$ nonzero $\mathbf{u}$, the multiples of $\mathbf{u}$ are q distinct vectors, and $\mathbf{v}$ must avoid them: $q^2 - q$ choices. (c) A list of length 3 fails to span exactly when its nonzero entries are all equal: $1 + 3\left(2^3 - 1\right) = 22$ lists. So $64 - 22 = 42$ span.

(a) For $\mathbf{v} \in F^2$, $\operatorname{span}(\mathbf{v}) = \{a\mathbf{v} \mid a \in F\}$ has at most q elements, and F^2 has $q^2 > q$ elements.

(b) If $\mathbf{u} = \mathbf{0}$, then $\operatorname{span}(\mathbf{0}, \mathbf{v}) = \operatorname{span}(\mathbf{v})$ by Corollary 1.3.20(a) and (c), which is not F^2 by (a). So a spanning list $\mathbf{u}, \mathbf{v}$ has $\mathbf{u} \neq \mathbf{0}$, and there are $q^2 - 1$ such $\mathbf{u}$. For each of them, Exercise 1.3.37(b) says that $\mathbf{u}, \mathbf{v}$ spans F^2 exactly when $\mathbf{v} \notin \operatorname{span}(\mathbf{u})$. The vectors $a\mathbf{u}$, $a \in F$, are distinct by Corollary 1.2.36(b), so $\operatorname{span}(\mathbf{u})$ has exactly q elements, and there are $q^2 - q$ choices for $\mathbf{v}$. In total, $\left(q^2 - 1\right)\left(q^2 - q\right)$ lists of length 2 span F^2. For $q = 2$ this is $3 \cdot 2 = 6$.

(c) Let $\mathcal{L}$ be a list of length 3 in $\mathbb{F}_2^2$. If $\mathcal{L}$ has two different nonzero entries $\mathbf{u}, \mathbf{v}$, then $\mathbf{v} \notin \{\mathbf{0}, \mathbf{u}\} = \operatorname{span}(\mathbf{u})$, so $\mathbf{u}, \mathbf{v}$ spans $\mathbb{F}_2^2$ by Exercise 1.3.37(b), and so does $\mathcal{L}$, by Corollary 1.3.20(a) and (b). Otherwise all nonzero entries of $\mathcal{L}$ equal a single vector $\mathbf{w}$ (or there are none), and $\operatorname{span}(\mathcal{L}) \subseteq \operatorname{span}(\mathbf{w}) = \{\mathbf{0}, \mathbf{w}\}$, which is not $\mathbb{F}_2^2$. The lists of the second kind are the zero list $\mathbf{0}, \mathbf{0}, \mathbf{0}$, and, for each of the 3 nonzero vectors $\mathbf{w}$, the $2^3 - 1 = 7$ lists with entries in $\{\mathbf{0}, \mathbf{w}\}$ other than the zero list. That makes $1 + 3 \cdot 7 = 22$ lists. Since there are $4^3 = 64$ lists of length 3, exactly $64 - 22 = 42$ of them span $\mathbb{F}_2^2$.

Solution to Exercise 1.3.39

Uses. Definition 1.3.10 (Span), Definition 1.3.4 (Linear combination)
Hint 1. How many linear combinations does $\mathcal{L}$ have? Each element of the span is represented by at least one of them.
Hint 2. For (b), compare q^k with the number of elements of F^n.
Sketch. (a) A linear combination of $\mathcal{L}$ is determined by its k coefficients, so there are q^k of them, and $\operatorname{span}(\mathcal{L})$ is the set of vectors they represent. (b) F^n has $q^n > q^k$ elements when $k < n$.

(a) A linear combination of $\mathcal{L}$ is determined by its list of coefficients $a_1, \ldots, a_k$, so $\mathcal{L}$ has exactly q^k linear combinations (for $k = 0$, exactly one). The span is the set of vectors represented by them, and each linear combination represents exactly one vector. So $\operatorname{span}(\mathcal{L})$ has at most q^k elements.

(b) F^n has q^n elements. If $\mathcal{L}$ has length $k < n$, then $\operatorname{span}(\mathcal{L})$ has at most $q^k < q^n$ elements by (a), so $\operatorname{span}(\mathcal{L}) \neq F^n$.

The statement of (b) holds over every field, but over an infinite field counting is useless, and the proof needs the theory of dimension (Section 4.1).

Solution to Exercise 1.3.40

Uses. Lemma 1.3.9 (Arithmetic of linear combinations), Exercise 1.3.39, Proposition 1.2.30 (Additive arithmetic)
Hint 1. Fix one representation $b_1, \ldots, b_k$ of $\mathbf{w}$. If $a_1, \ldots, a_k$ represents $\mathbf{0}$, what does $a_1 + b_1, \ldots, a_k + b_k$ represent?
Hint 2. Show that $a \mapsto a + b$ is a bijection from the representations of $\mathbf{0}$ to the representations of $\mathbf{w}$. For (b), sort the q^k linear combinations by the vector they represent.

Sketch. (a) If $\sum b_i\mathbf{v}_i = \mathbf{w}$, then $a \mapsto a + b$ sends representations of $\mathbf{0}$ to representations of $\mathbf{w}$, with inverse $a' \mapsto a' - b$, by Lemma 1.3.9. (b) Each of the q^k linear combinations represents exactly one vector of the span, and each vector of the span is represented $N(\mathbf{0})$ times. (c) A divisor of p^k is a power of p.

(a) Let $\mathbf{w} \in \operatorname{span}(\mathcal{L})$, and fix coefficients $b_1, \ldots, b_k$ with $\sum b_i\mathbf{v}_i = \mathbf{w}$. If $a_1, \ldots, a_k$ represents $\mathbf{0}$, then by Lemma 1.3.9(a),

$$\sum_{i=1}^{k}(a_i + b_i)\mathbf{v}_i = \sum_{i=1}^{k} a_i\mathbf{v}_i + \sum_{i=1}^{k} b_i\mathbf{v}_i = \mathbf{0} + \mathbf{w} = \mathbf{w}.$$

Conversely, if $a'_1, \ldots, a'_k$ represents $\mathbf{w}$, then by Lemma 1.3.9(a) and (b) with $c = -1$, and Proposition 1.2.34,

$$\sum_{i=1}^{k}(a'_i - b_i)\mathbf{v}_i = \sum_{i=1}^{k} a'_i\mathbf{v}_i + (-1)\sum_{i=1}^{k} b_i\mathbf{v}_i = \mathbf{w} - \mathbf{w} = \mathbf{0}.$$

So $a \mapsto a + b$ maps the representations of $\mathbf{0}$ to the representations of $\mathbf{w}$, and $a' \mapsto a' - b$ maps back. These maps are inverse to each other, so both sets have the same number of elements: $N(\mathbf{w}) = N(\mathbf{0})$.

(b) As in Exercise 1.3.39, $\mathcal{L}$ has exactly q^k linear combinations, and each represents exactly one vector, which lies in $\operatorname{span}(\mathcal{L})$. Grouping them by the vector they represent and using (a),

$$q^k = \sum_{\mathbf{w} \in \operatorname{span}(\mathcal{L})} N(\mathbf{w}) = |\operatorname{span}(\mathcal{L})| \cdot N(\mathbf{0}).$$

(c) By (b), $|\operatorname{span}(\mathcal{L})|$ divides p^k. By unique factorization, the positive divisors of p^k are p^r with $0 \le r \le k$.

The bijection in (a) is the same idea as Proposition 3.1.19: all representations of $\mathbf{w}$ are one of them plus a representation of $\mathbf{0}$.

Solution to Exercise 1.3.41

Uses. Corollary 1.3.20 (Operations that preserve the span), Proposition 1.3.18 (Comparing spans), Proposition 1.3.17 (A list lies in its span)
Hint 1. For (a), express $\mathbf{w} - \mathbf{u}$ in terms of the other two differences.
Hint 2. For (b), try the standard vectors $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ in $\mathbb{R}^3$ and add up coordinates.
Hint 3. For (c), if $\mathbf{u} \in D$, recover $\mathbf{v}$ and $\mathbf{w}$ from $\mathbf{u}$ and the differences.
Sketch. (a) $\mathbf{w} - \mathbf{u} = -(\mathbf{u} - \mathbf{v}) - (\mathbf{v} - \mathbf{w})$, and each difference lies in $\operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w})$. (b) False: for $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ in $\mathbb{R}^3$, every difference has coordinate sum 0, hence so does every combination, but $\mathbf{e}_1$ does not. (c) If equality holds, $\mathbf{u} \in D$. If $\mathbf{u} \in D$, then $\mathbf{v} = \mathbf{u} - (\mathbf{u} - \mathbf{v}) \in D$ and $\mathbf{w} = \mathbf{v} - (\mathbf{v} - \mathbf{w}) \in D$, so $\operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w}) \subseteq D$.

(a) Since $\mathbf{w} - \mathbf{u} = -(\mathbf{u} - \mathbf{v}) - (\mathbf{v} - \mathbf{w}) \in D$, Corollary 1.3.20(c) gives $\operatorname{span}(\mathbf{u} - \mathbf{v}, \mathbf{v} - \mathbf{w}, \mathbf{w} - \mathbf{u}) = D$. Each difference is a linear combination of $\mathbf{u}, \mathbf{v}, \mathbf{w}$ (for instance $\mathbf{u} - \mathbf{v} = 1\mathbf{u} + (-1)\mathbf{v} + 0\mathbf{w}$), so $D \subseteq \operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w})$ by Proposition 1.3.18.

(b) False. In $\mathbb{R}^3$, take $\mathbf{u} = \mathbf{e}_1, \mathbf{v} = \mathbf{e}_2, \mathbf{w} = \mathbf{e}_3$. Then $\operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w}) = \mathbb{R}^3$. The differences $(1, -1, 0)$ and $(0, 1, -1)$ have coordinate sum 0, so every vector $a(1, -1, 0) + b(0, 1, -1) = (a, b - a, -b)$ of D has coordinate sum 0. Since $\mathbf{e}_1$ has coordinate sum 1, $\mathbf{e}_1 \notin D$.

(c) If $D = \operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w})$, then $\mathbf{u} \in D$ by Proposition 1.3.17. Conversely, suppose $\mathbf{u} \in D$. Then $\mathbf{v} = \mathbf{u} - (\mathbf{u} - \mathbf{v})$ and $\mathbf{w} = \mathbf{v} - (\mathbf{v} - \mathbf{w})$ lie in $\operatorname{span}(\mathbf{u}, \mathbf{u} - \mathbf{v}, \mathbf{v} - \mathbf{w})$, which equals D by Corollary 1.3.20(a) and (c), since $\mathbf{u} \in D$. So $\operatorname{span}(\mathbf{u}, \mathbf{v}, \mathbf{w}) \subseteq D$ by Proposition 1.3.18, and equality follows from (a).

Solution to Exercise 1.3.42

Uses. Proposition 1.3.18 (Comparing spans), Example 1.3.11 (Small spans), Exercise 1.2.45
Hint 1. Add up all the $\mathbf{u}_i$. Each coordinate of the sum is a sum of $n - 1$ ones.
Hint 2. If $(n-1) * 1 \neq 0$, get $\mathbf{s}$ and then each $\mathbf{e}_i = \mathbf{s} - \mathbf{u}_i$. If $(n-1) * 1 = 0$, compute the sum of the coordinates of an arbitrary combination $\sum a_i\mathbf{u}_i$.
Sketch. $\sum_i \mathbf{u}_i = ((n-1) * 1)\mathbf{s}$. If $m = (n-1) * 1 \neq 0$, then $\mathbf{s} = m^{-1}\sum \mathbf{u}_i$ and $\mathbf{e}_i = \mathbf{s} - \mathbf{u}_i$ lie in the span. If $m = 0$, the vector $\sum a_i\mathbf{u}_i$ has coordinates $S - a_j$ with $S = \sum a_i$, whose sum is $n * S - S = mS = 0$, while $\mathbf{e}_1$ has coordinate sum 1.

Let $m = (n-1) * 1 \in F$. Each coordinate of $\mathbf{u}_1 + \cdots + \mathbf{u}_n$ is a sum of $n-1$ ones and one zero, so $\mathbf{u}_1 + \cdots + \mathbf{u}_n = m\mathbf{s}$.

Suppose $m \neq 0$. Then $\mathbf{s} = m^{-1}(\mathbf{u}_1 + \cdots + \mathbf{u}_n) \in \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_n)$, and so $\mathbf{e}_i = \mathbf{s} - \mathbf{u}_i$ lies in the span for each i. By Proposition 1.3.18, $F^n = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_n) \subseteq \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_n)$.

Suppose $m = 0$. An element of the span is $\mathbf{x} = \sum_i a_i \mathbf{u}_i$ for some $a_1, \ldots, a_n \in F$; let $S = a_1 + \cdots + a_n$. The j-th coordinate of $\mathbf{x}$ is the sum of the a_i with $i \neq j$, which is $S - a_j$. So the sum of the coordinates of $\mathbf{x}$ is

$$\sum_{j=1}^{n} (S - a_j) = (n * 1)S - S = ((n-1) * 1)S = mS = 0.$$

The coordinates of $\mathbf{e}_1$ sum to $1 \neq 0$, so $\mathbf{e}_1$ is not in the span, and the list does not span F^n.

For example, over $\mathbb{R}$ the list always spans, while over $\mathbb{F}_2$ it spans exactly when n is even, and over $\mathbb{F}_3$ exactly when $n-1$ is not a multiple of 3.

Solution to Exercise 1.3.43

Uses. Proposition 1.3.18 (Comparing spans), Example 1.3.11 (Small spans), Corollary 1.3.20 (Operations that preserve the span)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. For (a), combine $\mathbf{e}_i + \mathbf{e}_j$, $\mathbf{e}_i + \mathbf{e}_k$, and $\mathbf{e}_j + \mathbf{e}_k$ to isolate a multiple of $\mathbf{e}_i$.
Hint 2. For (b), the sum of the coordinates of a sum of vectors is the sum of their coordinate sums. For the other containment, pair up the coordinates equal to 1.
Hint 3. For (c), the sum of two vectors of $\mathcal{W}_3$ that share two positions lies in $\mathcal{W}_2$. Then handle vectors with an odd number of ones by adding $(1, 1, 1, 0, \ldots, 0)$.
Sketch. (a) $(\mathbf{e}_i + \mathbf{e}_j) + (\mathbf{e}_i + \mathbf{e}_k) - (\mathbf{e}_j + \mathbf{e}_k) = (1+1)\mathbf{e}_i$. (b) Each entry of $\mathcal{W}_2$ has coordinate sum 0, so every combination does; a vector with $2r$ ones is a sum of r entries of $\mathcal{W}_2$. (c) For $n \geq 4$, $(\mathbf{e}_i + \mathbf{e}_k + \mathbf{e}_l) + (\mathbf{e}_j + \mathbf{e}_k + \mathbf{e}_l) = \mathbf{e}_i + \mathbf{e}_j$, so the span contains $\operatorname{span}(\mathcal{W}_2)$; a vector with coordinate sum 1 is $(\mathbf{x} + \mathbf{t}) + \mathbf{t}$ with $\mathbf{t} = \mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3$. For $n = 3$, $\mathcal{W}_3 = (1, 1, 1)$ and the span is $\{\mathbf{0}, (1, 1, 1)\}$.

The entries of $\mathcal{W}_2$ are the vectors $\mathbf{e}_i + \mathbf{e}_j$ with $i < j$, and those of $\mathcal{W}_3$ are $\mathbf{e}_i + \mathbf{e}_j + \mathbf{e}_k$ with $i < j < k$. By Corollary 1.3.20(a), the order in which they are listed does not affect the spans.

(a) Fix i, and choose j and k so that i, j, k are distinct, which is possible since $n \geq 3$. Then

$$(\mathbf{e}_i + \mathbf{e}_j) + (\mathbf{e}_i + \mathbf{e}_k) - (\mathbf{e}_j + \mathbf{e}_k) = (1+1)\mathbf{e}_i.$$

Since $1 + 1 \neq 0$, $\mathbf{e}_i = (1+1)^{-1}(1+1)\mathbf{e}_i \in \operatorname{span}(\mathcal{W}_2)$. By Proposition 1.3.18, $F^n = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_n) \subseteq \operatorname{span}(\mathcal{W}_2)$.

(b) For $\mathbf{x} \in \mathbb{F}_2^n$, write $\sigma(\mathbf{x}) = x_1 + \cdots + x_n \in \mathbb{F}_2$. Then $\sigma(\mathbf{x} + \mathbf{y}) = \sigma(\mathbf{x}) + \sigma(\mathbf{y})$ and $\sigma(a\mathbf{x}) = a\sigma(\mathbf{x})$, by the coordinatewise operations and the field axioms. Let $E = \{\mathbf{x} \mid \sigma(\mathbf{x}) = 0\}$. We proceed by double containment.

Each entry $\mathbf{e}_i + \mathbf{e}_j$ of $\mathcal{W}_2$ has $\sigma = 1 + 1 = 0$. So for a linear combination $\mathbf{x} = \sum c_{ij}(\mathbf{e}_i + \mathbf{e}_j)$, applying the two rules for σ term by term (by induction on the number of terms) gives $\sigma(\mathbf{x}) = \sum c_{ij} \cdot 0 = 0$. Hence $\operatorname{span}(\mathcal{W}_2) \subseteq E$.

Conversely, let $\mathbf{x} \in E$, and let $i_1 < i_2 < \cdots < i_t$ be the positions where $x_i = 1$. Then $\sigma(\mathbf{x})$ is the sum of t ones, which is 0 in $\mathbb{F}_2$ exactly when t is even, say $t = 2r$. Then

$$\mathbf{x} = (\mathbf{e}_{i_1} + \mathbf{e}_{i_2}) + (\mathbf{e}_{i_3} + \mathbf{e}_{i_4}) + \cdots + (\mathbf{e}_{i_{2r-1}} + \mathbf{e}_{i_{2r}})$$

is a sum of entries of $\mathcal{W}_2$ (and $\mathbf{x} = \mathbf{0}$ if $r = 0$), so $\mathbf{x} \in \operatorname{span}(\mathcal{W}_2)$.

(c) Let $n \geq 4$. For $i \neq j$, choose k and l so that i, j, k, l are distinct. In $\mathbb{F}_2^n$, $\mathbf{e}_k + \mathbf{e}_k = \mathbf{0}$, so

$$(\mathbf{e}_i + \mathbf{e}_k + \mathbf{e}_l) + (\mathbf{e}_j + \mathbf{e}_k + \mathbf{e}_l) = \mathbf{e}_i + \mathbf{e}_j.$$

So $\mathcal{W}_2 \subseteq \operatorname{span}(\mathcal{W}_3)$, and by Proposition 1.3.18 and (b), every $\mathbf{x}$ with $\sigma(\mathbf{x}) = 0$ lies in $\operatorname{span}(\mathcal{W}_3)$. Now let $\sigma(\mathbf{x}) = 1$, and let $\mathbf{t} = \mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3$, an entry of $\mathcal{W}_3$. Then $\sigma(\mathbf{x} + \mathbf{t}) = 1 + 1 = 0$, so $\mathbf{x} + \mathbf{t} \in \operatorname{span}(\mathcal{W}_3)$, and $\mathbf{x} = (\mathbf{x} + \mathbf{t}) + \mathbf{t}$ is a sum of two elements of $\operatorname{span}(\mathcal{W}_3)$, written as combinations of $\mathcal{W}_3$. By Lemma 1.3.9(a), $\mathbf{x} \in \operatorname{span}(\mathcal{W}_3)$. So $\mathcal{W}_3$ spans $\mathbb{F}_2^n$.

For $n = 3$, the only vector with three coordinates equal to 1 is $(1, 1, 1)$, so $\operatorname{span}(\mathcal{W}_3) = \operatorname{span}((1, 1, 1)) = \{\mathbf{0}, (1, 1, 1)\}$ by Example 1.3.11. The pairing trick needs a fourth position.

Solution to Exercise 1.3.44

Uses. Definition 1.3.10 (Span), Example 1.2.20 (Real and rational scalars)
Hint 1. Suppose $\sqrt{3} = a + b\sqrt{2}$ with $a, b \in \mathbb{Q}$, and square both sides.
Hint 2. The squared equation is $3 = a^2 + 2b^2 + 2ab\sqrt{2}$. If $ab \neq 0$, solve for $\sqrt{2}$. Otherwise treat $a = 0$ and $b = 0$ separately.
Sketch. If $\sqrt{3} = a + b\sqrt{2}$ with a, b rational, then $3 = a^2 + 2b^2 + 2ab\sqrt{2}$. If $ab \neq 0$, $\sqrt{2}$ is rational. If $b = 0$, $\sqrt{3} = a$ is rational. If $a = 0$, then $\sqrt{6} = \sqrt{2}\sqrt{3} = 2b$ is rational. Each case is impossible.

Over $\mathbb{Q}$, $\operatorname{span}\left(1, \sqrt{2}\right) = \left\{a + b\sqrt{2} \;\middle|\; a, b \in \mathbb{Q}\right\}$. Suppose that $\sqrt{3} = a + b\sqrt{2}$ with $a, b \in \mathbb{Q}$. Squaring gives

$$3 = a^2 + 2b^2 + 2ab\sqrt{2}.$$

If $ab \neq 0$, then $\sqrt{2} = \left(3 - a^2 - 2b^2\right)/(2ab)$ is rational, a contradiction. So $a = 0$ or $b = 0$. If $b = 0$, then $\sqrt{3} = a$ is rational, a contradiction. If $a = 0$, then $\sqrt{3} = b\sqrt{2}$, and multiplying by $\sqrt{2}$ gives $\sqrt{6} = 2b$, which is rational, a contradiction. Hence $\sqrt{3} \notin \operatorname{span}\left(1, \sqrt{2}\right)$.

Over $\mathbb{R}$ instead of $\mathbb{Q}$, $\operatorname{span}(1) = \mathbb{R}$ contains every real number. The span depends on the field of scalars, a theme of Section 1.5.

Solution to Exercise 1.3.45

Uses. Definition 1.3.10 (Span), Example 1.2.20 (Real and rational scalars), $\mathbb{Q}^k$ is countable, and $\mathbb{R}$ is uncountable
Hint 1. How many linear combinations with rational coefficients does a list of length k have?
Hint 2. The span is the image of the countable set $\mathbb{Q}^k$ under the map that sends coefficients to the vector they represent.
Sketch. The span of $v_1, \ldots, v_k$ over $\mathbb{Q}$ is the image of $\mathbb{Q}^k$ under $(a_1, \ldots, a_k) \mapsto \sum a_i v_i$. A finite product of countable sets is countable, and so is the image of a countable set, while $\mathbb{R}$ is uncountable.

Let $v_1, \ldots, v_k \in \mathbb{R}$. (Vectors here are real numbers, so we do not write them in bold.) The map $\mathbb{Q}^k \to \mathbb{R}$ sending $(a_1, \ldots, a_k)$ to $a_1 v_1 + \cdots + a_k v_k$ has image $\operatorname{span}(v_1, \ldots, v_k)$, by Definition 1.3.10. The set $\mathbb{Q}^k$ is countable, being a finite product of countable sets (for $k = 0$ it has one element), and the image of a countable set under any map is countable. So $\operatorname{span}(v_1, \ldots, v_k)$ is countable. Since $\mathbb{R}$ is uncountable, $\operatorname{span}(v_1, \ldots, v_k) \neq \mathbb{R}$.

The same argument shows that span over $\mathbb{Q}$ of any countable set is countable, so every spanning set of $\mathbb{R}$ over $\mathbb{Q}$ is uncountable (Aside (Spans of infinite sets)).

Solution to Exercise 1.3.46

Uses. Definition 1.3.10 (Span), Proposition 1.3.18 (Comparing spans), Example 1.3.11 (Small spans)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. For (a), pressing lamps in any order adds a sum of $\mathbf{t}_i$'s, and pressing a lamp twice does nothing. Over $\mathbb{F}_2$, what are the linear combinations of $\mathbf{t}_1, \ldots, \mathbf{t}_n$?
Hint 2. Work out $n = 1, 2, 3, 4, 5$ by hand. For $n = 2$ and $n = 5$, look for a set S of positions such that every $\mathbf{t}_i$ has an even number of ones in S.
Hint 3. For $n = 3m + 2$, take $S = \{i \mid 3 \nmid i\}$. For the other n, show $\mathbf{t}_{3j+1} + \mathbf{t}_{3j+2} = \mathbf{e}_{3j} + \mathbf{e}_{3j+3}$, walk along the row from the left end to get $\mathbf{e}_3, \mathbf{e}_6, \ldots$, then come back.
Sketch. (a) The reachable configurations from $\mathbf{x}$ are $\mathbf{x} + \sum_{i \in S} \mathbf{t}_i$, and over $\mathbb{F}_2$ these sums are exactly the linear combinations of the $\mathbf{t}_i$; $\mathbf{x} + \mathbf{y} = \mathbf{0}$ means $\mathbf{x} = \mathbf{y}$. (b) If $n = 3m + 2$, the parity of the lamps in positions not divisible by 3 is unchanged by every press, since each $\mathbf{t}_i$ meets those positions in 0 or 2 places, while $\mathbf{e}_1$ has parity 1. If $n = 3m$ or $3m + 1$, then $\mathbf{e}_3, \mathbf{e}_6, \ldots, \mathbf{e}_{3m}$ are in the span, $\mathbf{t}_n$ supplies whichever of $\mathbf{e}_{n-1}, \mathbf{e}_n$ is missing, and going back with $\mathbf{e}_{i-1} = \mathbf{t}_i + \mathbf{e}_i + \mathbf{e}_{i+1}$ gives all $\mathbf{e}_i$.

(a) Pressing lamps one after another adds the corresponding $\mathbf{t}_i$'s, and since addition in $\mathbb{F}_2^n$ is commutative and $\mathbf{t}_i + \mathbf{t}_i = \mathbf{0}$, the result of any sequence of presses from $\mathbf{x}$ is $\mathbf{x} + \sum_{i \in S} \mathbf{t}_i$, where S is the set of lamps pressed an odd number of times. Every subset S arises. Since the only scalars in $\mathbb{F}_2$ are 0 and 1, the linear

combinations of $\mathbf{t}_1, \ldots, \mathbf{t}_n$ represent exactly the sums $\sum_{i \in S} \mathbf{t}_i$. Finally, $\mathbf{x} + \mathbf{y} = \mathbf{0}$ in $\mathbb{F}_2^n$ if and only if $\mathbf{x} = -\mathbf{y} = \mathbf{y}$. So $\mathbf{x}$ can be switched off if and only if $\mathbf{x} \in \operatorname{span}(\mathbf{t}_1, \ldots, \mathbf{t}_n)$, and every configuration can be switched off if and only if the list spans $\mathbb{F}_2^n$.

(b) For $n = 1$, $\mathbf{t}_1 = \mathbf{e}_1$ spans $\mathbb{F}_2^1$. From now on let $n \geq 2$, so $\mathbf{t}_1 = \mathbf{e}_1 + \mathbf{e}_2$ and $\mathbf{t}_n = \mathbf{e}_{n-1} + \mathbf{e}_n$.

Case $n = 3m + 2$. For $\mathbf{x} \in \mathbb{F}_2^n$, let $f(\mathbf{x}) = \sum_{i \in S} x_i$, where S is the set of $i \in \{1, \ldots, n\}$ not divisible by 3. Then $f(\mathbf{x} + \mathbf{y}) = f(\mathbf{x}) + f(\mathbf{y})$. We claim $f(\mathbf{t}_i) = 0$ for every i. For $2 \leq i \leq n - 1$, the positions $i - 1, i, i + 1$ are three consecutive integers, exactly one of which is divisible by 3, so $f(\mathbf{t}_i) = 1 + 1 = 0$. For $i = 1$, positions 1 and 2 both lie in S. For $i = n = 3m + 2$, positions $3m + 1$ and $3m + 2$ both lie in S. So f vanishes on each $\mathbf{t}_i$, hence on every sum of them, hence on the span. Since $f(\mathbf{e}_1) = 1$, $\mathbf{e}_1$ is not in the span.

Case $n = 3m$ or $n = 3m + 1$, with $m \geq 1$. First, $\mathbf{t}_1 + \mathbf{t}_2 = (\mathbf{e}_1 + \mathbf{e}_2) + (\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) = \mathbf{e}_3$. Next, if $3j + 3 \leq n$, then $3j + 2 \leq n - 1$, so lamp $3j + 2$ has a right neighbor, and

$$\mathbf{t}_{3j+1} + \mathbf{t}_{3j+2} = \left(\mathbf{e}_{3j} + \mathbf{e}_{3j+1} + \mathbf{e}_{3j+2}\right) + \left(\mathbf{e}_{3j+1} + \mathbf{e}_{3j+2} + \mathbf{e}_{3j+3}\right) = \mathbf{e}_{3j} + \mathbf{e}_{3j+3}.$$

So $\mathbf{e}_{3j+3} = \mathbf{t}_{3j+1} + \mathbf{t}_{3j+2} + \mathbf{e}_{3j}$, and by induction on j, the vectors $\mathbf{e}_3, \mathbf{e}_6, \ldots, \mathbf{e}_{3m}$ lie in the span. If $n = 3m$, this gives $\mathbf{e}_n$, and then $\mathbf{e}_{n-1} = \mathbf{t}_n + \mathbf{e}_n$. If $n = 3m + 1$, it gives $\mathbf{e}_{n-1}$, and then $\mathbf{e}_n = \mathbf{t}_n + \mathbf{e}_{n-1}$. In both cases $\mathbf{e}_{n-1}$ and $\mathbf{e}_n$ lie in the span, and for $i = n - 1, n - 2, \ldots, 2$ in turn, $\mathbf{e}_{i-1} = \mathbf{t}_i + \mathbf{e}_i + \mathbf{e}_{i+1}$ does too. So every $\mathbf{e}_i$ lies in the span, and the list spans $\mathbb{F}_2^n$ by Proposition 1.3.18.

Since every $n \geq 1$ has exactly one of the forms $3m$, $3m + 1$, $3m + 2$, this proves (b). Small cases are how one finds S: for $n = 2$ the two presses are equal, $\mathbf{t}_1 = \mathbf{t}_2 = (1, 1)$, and the invariant is $x_1 + x_2$; for $n = 5$ it is $x_1 + x_2 + x_4 + x_5$.

Section 1.4

Solution to Exercise 1.4.6

> *Uses.* Theorem 1.4.3 (Subspace criterion)
> *Hint 1.* Compare with (II) and (III) of Theorem 1.4.3. The vector $a\mathbf{w} + \mathbf{w}'$ is a linear combination of length 2.
> *Hint 2.* For the converse, special values of a and $\mathbf{w}'$ recover the two closure conditions of (III).
> *Sketch.* If W is a subspace, then $\mathbf{0} \in W$ by (III), and $a\mathbf{w} + 1\mathbf{w}' \in W$ by (II). Conversely, $a = 1$ gives $\mathbf{w} + \mathbf{w}' \in W$, and $\mathbf{w}' = \mathbf{0}$ gives $a\mathbf{w} = a\mathbf{w} + \mathbf{0} \in W$, so (III) holds.

Suppose W is a subspace. Then $\mathbf{0} \in W$ by (III) of Theorem 1.4.3, and for $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$, the vector $a\mathbf{w} + \mathbf{w}' = a\mathbf{w} + 1\mathbf{w}'$ is a linear combination of elements of W, so it lies in W by (II).

Conversely, suppose the condition holds, and let $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$. Taking the scalar 1 gives $\mathbf{w} + \mathbf{w}' = 1\mathbf{w} + \mathbf{w}' \in W$, by (A5). Taking $\mathbf{0}$ as the second vector, which is allowed since $\mathbf{0} \in W$, gives $a\mathbf{w} = a\mathbf{w} + \mathbf{0} \in W$, by (A3). So W satisfies (III), and it is a subspace by Theorem 1.4.3.

Solution to Exercise 1.4.15

> *Uses.* Proposition 1.4.14 (The span is the smallest subspace containing a list), Theorem 1.4.3 (Subspace criterion), Example 1.3.11 (Small spans)
> *Hint 1.* One direction is Proposition 1.4.14(b).
> *Hint 2.* For the other, apply the condition to three kinds of list: the empty list, a list $\mathbf{w}, \mathbf{w}'$ of length 2, and a list $\mathbf{w}$ of length 1.
> *Sketch.* ($\Rightarrow$) is Proposition 1.4.14(b). ($\Leftarrow$) $\operatorname{span}(()) = \{\mathbf{0}\}$ gives $\mathbf{0} \in W$; $\mathbf{w} + \mathbf{w}' \in \operatorname{span}(\mathbf{w}, \mathbf{w}')$ and $a\mathbf{w} \in \operatorname{span}(\mathbf{w})$ give the closure conditions, so (III) of Theorem 1.4.3 holds.

If W is a subspace and $\mathcal{L}$ is a list in W, then $\operatorname{span}(\mathcal{L}) \subseteq W$ by Proposition 1.4.14(b).

Conversely, suppose $\operatorname{span}(\mathcal{L}) \subseteq W$ for every list $\mathcal{L}$ in W. For the empty list, $\operatorname{span}(()) = \{\mathbf{0}\}$ (Definition 1.3.10), so $\mathbf{0} \in W$. Let $\mathbf{w}, \mathbf{w}' \in W$ and $a \in F$. Then $\mathbf{w} + \mathbf{w}' = 1\mathbf{w} + 1\mathbf{w}' \in \operatorname{span}(\mathbf{w}, \mathbf{w}') \subseteq W$ and $a\mathbf{w} \in \operatorname{span}(\mathbf{w}) \subseteq W$. So W satisfies (III) of Theorem 1.4.3, and it is a subspace.

In this form the criterion needs no separate nonemptiness condition: the empty list supplies $\mathbf{0}$ (Remark 1.4.5).

Solution to Exercise 1.4.21

> *Uses.* Proposition 1.4.20 (Unions of two subspaces), Example 1.4.7 (Trivial subspaces)
> *Hint 1.* V is a subspace of itself, so $U \cup W$ is a subspace.
> *Hint 2.* Apply Proposition 1.4.20. If $U \subseteq W$, what is $U \cup W$?
> *Sketch.* $U \cup W = V$ is a subspace, so $U \subseteq W$ or $W \subseteq U$ by Proposition 1.4.20. In the first case $V = U \cup W = W$, in the second $V = U$.

Since $U \cup W = V$ is a subspace of V, Proposition 1.4.20 gives $U \subseteq W$ or $W \subseteq U$. If $U \subseteq W$, then $V = U \cup W = W$. If $W \subseteq U$, then $V = U \cup W = U$.

So a vector space is never the union of two proper subspaces. Three can suffice: $\mathbb{F}_2^2$ is the union of its three lines $\{\mathbf{0}, (1,0)\}$, $\{\mathbf{0}, (0,1)\}$, $\{\mathbf{0}, (1,1)\}$ (Example 1.4.12). Exercise 1.4.42 and Exercise 1.4.43 show how this depends on the size of the field.

Solution to Exercise 1.4.26

> *Uses.* Theorem 1.4.3 (Subspace criterion), Example 1.4.8 (One equation in F^n), Proposition 1.4.16 (Intersections of subspaces)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* Check whether $\mathbf{0}$ lies in the set first. When it does, test closure on simple vectors, such as standard vectors and their negatives.
> *Hint 2.* For (e), over $\mathbb{R}$ a sum of two squares vanishes only when both squares do. Over $\mathbb{C}$, look for a nonzero solution of $z^2 + w^2 = 0$.
> *Sketch.* (a) Yes, an equation as in Example 1.4.8. (b) No, $\mathbf{0}$ is missing. (c) No: $\mathbf{e}_1 + \mathbf{e}_2$. (d) No: $(-1)\mathbf{e}_2$. (e) Over $\mathbb{R}$ the set is $\{x_1 = x_2 = 0\}$, a subspace. Over $\mathbb{C}$ it contains $(1, i, 0)$ and $(1, -i, 0)$ but not their sum $(2, 0, 0)$.

(a) Yes. It is the solution set of $x_1 + 0x_2 - 2x_3 = 0$, a subspace by Example 1.4.8.

(b) No. The coordinates of $\mathbf{0}$ add up to $0 \neq 1$.

(c) No. The vectors $(1,0,0)$ and $(0,1,0)$ lie in the set, but their sum $(1,1,0)$ does not, since $1 \cdot 1 \neq 0$.

(d) No. The vector $(0,1,0)$ lies in the set, since $0 \leq 1$, but $(-1)(0,1,0) = (0,-1,0)$ does not, since $0 > -1$.

(e) For real numbers, $x_1^2 \geq 0$ and $x_2^2 \geq 0$, so $x_1^2 + x_2^2 = 0$ holds exactly when $x_1 = x_2 = 0$. So the subset of $\mathbb{R}^3$ is $\{\mathbf{x} \mid x_1 = 0\} \cap \{\mathbf{x} \mid x_2 = 0\}$, an intersection of two subspaces of the form in Example 1.4.8, hence a subspace by Proposition 1.4.16. In $\mathbb{C}^3$, the vectors $(1, i, 0)$ and $(1, -i, 0)$ satisfy the equation, since $1 + i^2 = 1 + (-i)^2 = 0$, but their sum $(2,0,0)$ gives $4 + 0 \neq 0$. So the subset of $\mathbb{C}^3$ is not a subspace. The same equation defines a subspace over one field and not over the other.

Solution to Exercise 1.4.27

> *Uses.* Theorem 1.4.3 (Subspace criterion), Definition 1.2.9 (Function spaces), Definition 1.2.13 (Polynomials), Definition 1.2.17 (Evaluation), Proposition 1.2.18 (Degree and evaluation versus the operations), Proposition 1.4.20 (Unions of two subspaces)
> *Techniques.* Finding counterexamples and minimal examples (Technique 1.4.18)
> *Hint 1.* The sets defined by linear conditions, such as an equation between values or coefficients, are subspaces. For the others, look for constants, simple polynomials, or diagonal matrices that break closure.
> *Hint 2.* For (b), try the constant function 1 and its double. For (d), try $x - 1$ and $x - 2$. For (f), try the two diagonal matrices with a single 1.
> *Sketch.* (a) Yes: the condition survives sums and multiples. (b) No: the constant 1 is in it, the constant 2 is not. (c) Yes: $|f + g| \leq M + N$ and $|af| \leq |a|M$. (d) No: $(x-1) + (x-2) = 2x - 3$ is nonzero at 1 and 2. (e) Yes: coefficientwise operations. (f) No: $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = I$.

(a) Yes. The zero function satisfies $0 = 0$. If $f(0) = f(1)$ and $g(0) = g(1)$, then $(f+g)(0) = f(1) + g(1) = (f+g)(1)$ and $(af)(0) = af(1) = (af)(1)$.

(b) No. The constant function 1 lies in the set, since $1 = 1^2$, but $2 \cdot 1$ is the constant function 2, and $2 \neq 2^2$.

(c) Yes. The zero function is bounded by $M = 0$. If $|f(t)| \le M$ and $|g(t)| \le N$ for all t, then $|f(t) + g(t)| \le M + N$ and $|af(t)| \le |a|M$ for all t, by the triangle inequality for real numbers.

(d) No. The polynomials $x - 1$ and $x - 2$ lie in the set, but their sum $p = 2x - 3$ has $p(1)p(2) = (-1) \cdot 1 = -1$. In fact, since $\mathbb{R}$ has no zero divisors, the set is the union of the subspaces $\{p(1) = 0\}$ and $\{p(2) = 0\}$ of Example 1.4.9, and neither contains the other ($x - 1$ is in the first only, $x - 2$ in the second only), so Proposition 1.4.20 also shows that it is not a subspace.

(e) Yes. The operations of $\mathbb{R}[x]$ are coefficientwise, so if $a_k = b_k = 0$ for every odd k, then $a_k + b_k = 0$ and $ca_k = 0$ for every odd k; and $\mathbf{0}$ has all coefficients 0.

(f) No, over every field. The matrices $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ satisfy the equation, since $1 \cdot 0 = 0 \cdot 0$, but their sum $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ gives $1 \cdot 1 \neq 0 \cdot 0$.

Solution to Exercise 1.4.28

Uses. Theorem 1.4.3 (Subspace criterion), Proposition 1.2.19 (Restriction of scalars)
Hint 1. The conditions $\mathbf{0} \in W$ and closure under addition do not depend on the field. Only closure under scalar multiplication does, and over $\mathbb{R}$ there are fewer scalars to test.
Hint 2. For (b), test multiplication by i. For D over $\mathbb{R}$, check that $\overline{z + w} = \overline{z} + \overline{w}$ and $\overline{rz} = r\overline{z}$ for real r.
Sketch. (a) A set closed under multiplication by all complex scalars is closed under multiplication by the real ones. (b) $\mathbb{R}^2$ is a real subspace but not a complex one: $i(1, 0) = (i, 0)$. D is a real subspace, since conjugation is additive and commutes with real scalars, but not a complex one: $(1, 1) \in D$ and $i(1, 1) = (i, i) \notin D$.

(a) Let W be a subspace of $\mathbb{C}^2$ over $\mathbb{C}$. Then $\mathbf{0} \in W$, W is closed under addition, and $c\mathbf{w} \in W$ for all $c \in \mathbb{C}$ and $\mathbf{w} \in W$, in particular for all real c. The real vector space $\mathbb{C}^2$ has the same addition, and its scalar multiplication is the complex one restricted to real scalars. So W satisfies (III) of Theorem 1.4.3 over $\mathbb{R}$.

(b) $\mathbb{R}^2$. It contains $\mathbf{0} = (0, 0)$, sums of pairs of real numbers are pairs of real numbers, and so are real multiples. So $\mathbb{R}^2$ is a subspace of $\mathbb{C}^2$ over $\mathbb{R}$. It is not a subspace over $\mathbb{C}$: $(1, 0) \in \mathbb{R}^2$ but $i(1, 0) = (i, 0) \notin \mathbb{R}^2$.

D. For $z = a + bi$ and $w = c + di$,

$$\overline{z} + \overline{w} = (a + c) - (b + d)i = \overline{z + w},$$

and for real r, $r\overline{z} = ra - rbi = \overline{rz}$. So D contains $\left(0, \overline{0}\right) = \mathbf{0}$, and

$$(z, \overline{z}) + (w, \overline{w}) = (z + w, \overline{z + w}), \quad r(z, \overline{z}) = (rz, \overline{rz})$$

lie in D. Hence D is a subspace over $\mathbb{R}$. It is not a subspace over $\mathbb{C}$: $(1, 1) = \left(1, \overline{1}\right) \in D$, but $i(1, 1) = (i, i)$, and $\overline{i} = -i \neq i$.

So the converse of (a) fails.

Solution to Exercise 1.4.29

Uses. Definition 1.4.1 (Subspace), Theorem 1.4.3 (Subspace criterion), Remark 1.4.4 (The zero vector of a subspace)
Hint 1. Reread Definition 1.4.1. Under which operations must a subspace be a vector space?
Hint 2. Test P against (III) of Theorem 1.4.3, with the usual operations of $\mathbb{R}$.
Sketch. A subspace must be a vector space under the operations of $\mathbb{R}$ itself, not under new ones. Under the usual operations, $0 \notin P$ and $(-1) \cdot 1 = -1 \notin P$. The claimed zero vector 1 is also a giveaway: a subspace's zero is the zero of $\mathbb{R}$ (Remark 1.4.4).

The argument shows that P is a vector space, but under operations that are not those of $\mathbb{R}$. Definition 1.4.1 requires P to be a vector space under the addition and scalar multiplication of $\mathbb{R}$, restricted to P. Under these, P fails (III) of Theorem 1.4.3: $0 \notin P$, and $1 \in P$ while $(-1) \cdot 1 = -1 \notin P$. So P is not a subspace of $\mathbb{R}$.

The zero vector 1 is a symptom of the error: by Remark 1.4.4, the zero vector of a subspace of $\mathbb{R}$ must be the real number 0.

Solution to Exercise 1.4.30

Uses. Proposition 1.4.20 (Unions of two subspaces), Lemma 1.4.19 (Adding a vector outside a subspace), Non-example 1.4.13 (Three ways to fail)
Hint 1. Two of the three steps are correct. Which one quietly assumes something about where $\mathbf{v}$ and $\mathbf{w}$ lie?
Hint 2. Closure of U under addition says something about two vectors of U. What if $\mathbf{v} \in U$ and $\mathbf{w} \in W$?
Sketch. The last step applies closure of U (or of W) to two vectors that need not both lie in U (or both in W). In the mixed case $\mathbf{v} \in U \setminus W$, $\mathbf{w} \in W \setminus U$, the sum lies in neither (Lemma 1.4.19); the axes of $\mathbb{R}^2$ are a counterexample to the claim.

The first two steps are correct: $U \cup W$ always contains $\mathbf{0}$ and is closed under scalar multiplication. The error is in the last step. Closure of U under addition applies when $\mathbf{v}$ and $\mathbf{w}$ *both* lie in U, and closure of W when both lie in W. The argument ignores the mixed case, $\mathbf{v} \in U$ and $\mathbf{w} \in W$ with $\mathbf{v} \notin W$ and $\mathbf{w} \notin U$, and in that case $\mathbf{v} + \mathbf{w}$ lies in neither subspace, by Lemma 1.4.19. The claim is false: for the two axes of $\mathbb{R}^2$, $(1,0) + (0,1) = (1,1)$ lies on neither axis (Non-example 1.4.13). By Proposition 1.4.20, it holds exactly when one subspace contains the other, which is exactly when the mixed case cannot occur.

Solution to Exercise 1.4.31

Uses. Theorem 1.4.3 (Subspace criterion), Definition 1.1.19 (Integers modulo n), Definition 1.2.1 (Vector space)
Hint 1. In $\mathbb{F}_p$, every scalar is a sum of 1's: $c = 1 + \cdots + 1$ (c terms) for $1 \le c \le p-1$, and 0 is the sum of p ones.
Hint 2. By (A8) and (A5), $(1 + \cdots + 1)\mathbf{w} = \mathbf{w} + \cdots + \mathbf{w}$. For (b), think of the integers inside $\mathbb{Q}$.
Sketch. (a) For $\mathbf{w} \in W$ and $m \ge 1$, $m * \mathbf{w} \in W$ by closure, and $(m*1)\mathbf{w} = m * \mathbf{w}$ by (A8) and (A5). Every $c \in \mathbb{F}_p$ equals $m * 1$ for some $1 \le m \le p$, so $c\mathbf{w} \in W$; with $c = 0$ this gives $\mathbf{0} \in W$. (b) $\mathbb{Z}^2$: closed under sums and negatives, but $\frac{1}{2}(1,0) \notin \mathbb{Z}^2$.

(a) For a positive integer m, write $m * \mathbf{w} = \mathbf{w} + \cdots + \mathbf{w}$ (m terms) and $m * 1 = 1 + \cdots + 1$ in $\mathbb{F}_p$. We claim that $(m*1)\mathbf{w} = m * \mathbf{w}$, by induction on m. For $m = 1$ this is (A5). For $m \ge 2$, by (A8), the inductive hypothesis, and (A5),

$$(m*1)\mathbf{w} = ((m-1)*1 + 1)\mathbf{w} = (m-1) * \mathbf{w} + 1\mathbf{w} = m * \mathbf{w}.$$

Now let $\mathbf{w} \in W$, which exists since $W \neq \emptyset$. By closure under addition and induction on m, $m * \mathbf{w} \in W$ for every $m \ge 1$. Every $c \in \mathbb{F}_p$ is of the form $m * 1$ with $1 \le m \le p$: for $c \in \{1, \ldots, p-1\}$, the sum of c ones in $\mathbb{F}_p$ is c, and the sum of p ones is $p \bmod p = 0$. So $c\mathbf{w} = m * \mathbf{w} \in W$ for every $c \in \mathbb{F}_p$. With $c = 0$ this gives $\mathbf{0} = 0\mathbf{w} \in W$. Hence W satisfies (III) of Theorem 1.4.3.

(b) Let $W = \mathbb{Z}^2 = \{(m,n) \mid m, n \in \mathbb{Z}\}$. It contains $(0,0)$, and sums and negatives of pairs of integers are pairs of integers. But $(1,0) \in W$ and $\frac{1}{2}(1,0) = \left(\frac{1}{2}, 0\right) \notin W$, so W is not a subspace. The proof of (a) fails because $\frac{1}{2}$ is not a sum of 1's in $\mathbb{Q}$.

Solution to Exercise 1.4.32

Uses. Exercise 1.1.40, Proposition 1.4.20 (Unions of two subspaces), Example 1.4.8 (One equation in F^n)
Techniques. Try small cases and small fields (Technique 1.2.38)
Hint 1. Factor: $x^2 = y^2$ if and only if $x = y$ or $x = -y$ (Exercise 1.1.40). So S_p is a union of two lines.
Hint 2. When are the two lines $x = y$ and $x = -y$ the same line? If they differ, apply Proposition 1.4.20.
Sketch. By Exercise 1.1.40, $S_p = D \cup D'$ with $D = \{x = y\}$ and $D' = \{x = -y\}$, both subspaces. For $p = 2$, $-1 = 1$, so $S_2 = D$ is a subspace. For odd p, $1 \neq -1$, so $(1,1) \in D \setminus D'$ and $(1,-1) \in D' \setminus D$, and S_p is not a subspace by Proposition 1.4.20; indeed $(1,1) + (1,-1) = (2,0) \notin S_p$. Answer: $p = 2$ only.

By Exercise 1.1.40, $x^2 = y^2$ holds if and only if $x = y$ or $x = -y$. So $S_p = D \cup D'$, where

$$D = \{(x,y) \mid x - y = 0\}, \quad D' = \{(x,y) \mid x + y = 0\}$$

are subspaces of $\mathbb{F}_p^2$ by Example 1.4.8.

If $p = 2$, then $-1 = 1$ in $\mathbb{F}_2$, so $D' = D$ and $S_2 = D$ is a subspace. (It is $\{\mathbf{0}, (1,1)\}$.)

If p is odd, then $1 + 1 = 2 \neq 0$ in $\mathbb{F}_p$, so $1 \neq -1$. Then $(1,1) \in D$ but $(1,1) \notin D'$, since $1 + 1 \neq 0$; and $(1,-1) \in D'$ but $(1,-1) \notin D$, since $1 - (-1) = 2 \neq 0$. So neither of D, D' contains the other, and $S_p = D \cup D'$ is not a subspace by Proposition 1.4.20. Concretely, $(1,1) + (1,-1) = (2,0)$, and $2^2 = 4 \neq 0 = 0^2$ in $\mathbb{F}_p$.

So S_p is a subspace exactly when $p = 2$.

Solution to Exercise 1.4.33

Uses. Theorem 1.4.25 (The subspaces of F^2), Exercise 1.3.28, Corollary 1.2.36 (Cancelling scalars and vectors)
Hint 1. By Theorem 1.4.25, it suffices to count lines. How many elements does a line $\operatorname{span}(\mathbf{v})$ have, and how many of them are nonzero?
Hint 2. Every nonzero vector lies on exactly one line. So the lines split the q^2-1 nonzero vectors into groups of equal size.
Sketch. (a) $\{\mathbf{0}\}$, four lines $\{\mathbf{0},(1,0),(2,0)\}$, $\{\mathbf{0},(0,1),(0,2)\}$, $\{\mathbf{0},(1,1),(2,2)\}$, $\{\mathbf{0},(1,2),(2,1)\}$, and $\mathbb{F}_3^2$. (b) A line has q elements, $q-1$ of them nonzero, and each nonzero $\mathbf{v}$ lies on exactly one line, $\operatorname{span}(\mathbf{v})$. So there are $(q^2-1)/(q-1)=q+1$ lines, plus $\{\mathbf{0}\}$ and F^2.

(b) By Theorem 1.4.25, the subspaces of F^2 are $\{\mathbf{0}\}$, the lines, and F^2, and these are different: $\{\mathbf{0}\}$ has 1 element, a line has q (see below), and F^2 has q^2, with $1<q<q^2$ as $q\geq 2$. So it suffices to count the lines.

Let $\mathbf{v}\neq\mathbf{0}$. By Corollary 1.2.36(b), the vectors $a\mathbf{v}$, $a\in F$, are distinct, so $\operatorname{span}(\mathbf{v})$ has exactly q elements, of which $q-1$ are nonzero. Every nonzero vector $\mathbf{w}$ lies on exactly one line. It lies on $\operatorname{span}(\mathbf{w})$. If it also lies on $\operatorname{span}(\mathbf{v})$, then $\mathbf{w}=c\mathbf{v}$ with $c\neq 0$ (as $\mathbf{w}\neq\mathbf{0}$), and $\operatorname{span}(\mathbf{w})=\operatorname{span}(\mathbf{v})$ by Exercise 1.3.28(b). So the lines partition the q^2-1 nonzero vectors of F^2 into blocks of $q-1$ vectors, and there are

$$\frac{q^2-1}{q-1}=q+1$$

lines. Together with $\{\mathbf{0}\}$ and F^2, this gives $q+3$ subspaces.

(a) For $q=3$ there are 4 lines. Listing the multiples $0\mathbf{v},1\mathbf{v},2\mathbf{v}$ of $\mathbf{v}=(1,0),(0,1),(1,1),(1,2)$ in $\mathbb{F}_3^2$, the six subspaces are

$$\{\mathbf{0}\},\quad \{\mathbf{0},(1,0),(2,0)\},\quad \{\mathbf{0},(0,1),(0,2)\},$$
$$\{\mathbf{0},(1,1),(2,2)\},\quad \{\mathbf{0},(1,2),(2,1)\},\quad \mathbb{F}_3^2.$$

The four lines contain $4\cdot 2=8$ nonzero vectors, which are all the nonzero vectors of $\mathbb{F}_3^2$, as (b) predicts.

Solution to Exercise 1.4.34

Uses. Theorem 1.4.25 (The subspaces of F^2), Exercise 1.1.40, Exercise 1.3.28
Hint 1. By Theorem 1.4.25, only the lines $\operatorname{span}(\mathbf{v})$ need thought. Show that such a line qualifies exactly when $\sigma(\mathbf{v})=c\mathbf{v}$ for some $c\in F$.
Hint 2. Write $\mathbf{v}=(a,b)$. From $b=ca$ and $a=cb$, deduce $c^2=1$, so $c=\pm 1$.
Sketch. $\{\mathbf{0}\}$ and F^2 qualify. A line $\operatorname{span}(\mathbf{v})$ qualifies iff $\sigma(\mathbf{v})\in\operatorname{span}(\mathbf{v})$, since $\sigma(t\mathbf{v})=t\sigma(\mathbf{v})$. With $\mathbf{v}=(a,b)$ and $\sigma(\mathbf{v})=c\mathbf{v}$: $a=c^2a$, $b=c^2b$, so $c^2=1$ and $c=\pm 1$, giving the lines $\operatorname{span}((1,1))$ and $\operatorname{span}((1,-1))$. These are different iff $1+1\neq 0$. So there are four such subspaces if $1+1\neq 0$, and three if $1+1=0$.

Call U *swap-closed* if $\sigma(\mathbf{u})\in U$ for all $\mathbf{u}\in U$. Clearly $\{\mathbf{0}\}$ and F^2 are swap-closed. By Theorem 1.4.25, every other subspace is a line $\operatorname{span}(\mathbf{v})$ with $\mathbf{v}=(a,b)\neq\mathbf{0}$. For $t\in F$, $\sigma(t\mathbf{v})=(tb,ta)=t\sigma(\mathbf{v})$. So if $\sigma(\mathbf{v})\in\operatorname{span}(\mathbf{v})$, then σ maps all of $\operatorname{span}(\mathbf{v})$ into $\operatorname{span}(\mathbf{v})$; and conversely a swap-closed line contains $\sigma(\mathbf{v})$. Hence $\operatorname{span}(\mathbf{v})$ is swap-closed if and only if $\sigma(\mathbf{v})=c\mathbf{v}$ for some $c\in F$, that is, $b=ca$ and $a=cb$.

Suppose $b=ca$ and $a=cb$. Then $a=c^2a$ and $b=c^2b$. Since a or b is nonzero, $c^2=1$, and by Exercise 1.1.40, $c=1$ or $c=-1$. If $c=1$, then $a=b$ and $\mathbf{v}=a(1,1)$. If $c=-1$, then $b=-a$ and $\mathbf{v}=a(1,-1)$. Either way $a\neq 0$, so $\operatorname{span}(\mathbf{v})$ is $\operatorname{span}((1,1))$ or $\operatorname{span}((1,-1))$ by Exercise 1.3.28(b). Conversely, both lines are swap-closed, since $\sigma(1,1)=(1,1)$ and $\sigma(1,-1)=(-1,1)=-(1,-1)$.

If $1+1\neq 0$, the two lines are different, because $(1,-1)=c(1,1)$ would force $c=1$ and $c=-1$. Then the swap-closed subspaces are the four subspaces $\{\mathbf{0}\}$, $\operatorname{span}((1,1))$, $\operatorname{span}((1,-1))$, and F^2. If $1+1=0$, then $-1=1$, the two lines coincide, and there are three: $\{\mathbf{0}\}$, $\operatorname{span}((1,1))$, and F^2. Over $\mathbb{R}$, the two lines are the diagonals, the mirror of σ and the line it reverses. Vectors $\mathbf{v}$ with $\sigma(\mathbf{v})=c\mathbf{v}$ are eigenvectors, the subject of Section 7.2.

Solution to Exercise 1.4.35

Uses. Proposition 1.4.24 (The sum of two subspaces), Example 1.4.10 (Functions)
Techniques. Double containment (Technique 1.3.14)
Hint 1. For $E\cap O$: if f is both even and odd, compare $f(-t)$ computed both ways.

Hint 2. For $E + O$, guess the even part of f by symmetrizing: average $f(t)$ and $f(-t)$. The odd part is what remains.
Sketch. (a) If $f \in E \cap O$, then $f(t) = f(-t) = -f(t)$, so $2f(t) = 0$. Every f is $f_e + f_o$ with $f_{e(t)} = (f(t) + f(-t))/2$ even and $f_{o(t)} = (f(t) - f(-t))/2$ odd. (b) In $\mathbb{F}_2$, $-t = t$ and $-f(t) = f(t)$, so both conditions read $f(t) = f(t)$. Then $E + O$ is still everything, but $E \cap O \neq \{\mathbf{0}\}$: the step $2f(t) = 0 \Rightarrow f(t) = 0$ divides by $2 = 0$.

(a) If $f \in E \cap O$, then for every t, $f(t) = f(-t) = -f(t)$, so $2f(t) = 0$ and $f(t) = 0$. Hence $E \cap O = \{\mathbf{0}\}$.

For the sum, $E + O \subseteq \mathbb{R}^{\mathbb{R}}$ holds trivially. Conversely, let $f \in \mathbb{R}^{\mathbb{R}}$, and define

$$f_e(t) = \frac{f(t) + f(-t)}{2}, \quad f_o(t) = \frac{f(t) - f(-t)}{2}.$$

Then $f_e(-t) = (f(-t) + f(t))/2 = f_e(t)$, so $f_e \in E$; $f_o(-t) = (f(-t) - f(t))/2 = -f_o(t)$, so $f_o \in O$; and $f_e(t) + f_o(t) = f(t)$ for every t. So $f = f_e + f_o \in E + O$, and $E + O = \mathbb{R}^{\mathbb{R}}$.

(b) In $\mathbb{F}_2$, $-a = a$ for every a, since $a + a = (1 + 1)a = 0$. So for every $f : \mathbb{F}_2 \to \mathbb{F}_2$ and every t, $f(-t) = f(t)$ and $-f(t) = f(t)$, and both conditions read $f(t) = f(t)$. Every function is even and odd: $E = O = \mathbb{F}_2^{\mathbb{F}_2}$. So $E + O = \mathbb{F}_2^{\mathbb{F}_2}$ still holds, trivially, but $E \cap O \neq \{\mathbf{0}\}$, and a function no longer has just one decomposition into an even and an odd part. The first argument in (a) fails because it passes from $2f(t) = 0$ to $f(t) = 0$, and the formulas for f_e and f_o in the second involve $1/2$. In $\mathbb{F}_2$, $2 = 0$ has no inverse.

Solution to Exercise 1.4.36

Uses. Proposition 1.4.24 (The sum of two subspaces), Example 1.4.11 (Matrices), Theorem 1.4.3 (Subspace criterion)
Techniques. Double containment (Technique 1.3.14)
Hint 1. N and K are cut out by entrywise equations, as in Example 1.4.11. For $S + N = F^{n\times n}$, build the symmetric part of A from the entries of A on and below the diagonal.
Hint 2. For (b) with $1 + 1 \neq 0$, use $\left(A + A^{\mathsf{T}}\right)/2$ and $\left(A - A^{\mathsf{T}}\right)/2$, written entrywise. If $1 + 1 = 0$, compare the conditions defining K and S.
Sketch. (a) A matrix in $S \cap N$ vanishes on and below the diagonal, and its entries above equal entries below. For A, let B copy A on and below the diagonal and be symmetric; then $A - B \in N$. (b) If $1 + 1 \neq 0$, $a_{ij} = h\big(a_{ij} + a_{ji}\big) + h\big(a_{ij} - a_{ji}\big)$ with $h = (1 + 1)^{-1}$. If $1 + 1 = 0$, then $-a = a$, so $K = S$ and $S + K = S$, which misses the matrix with a single 1 in position $(1, 2)$.

(a) The zero matrix satisfies the conditions defining N and K. If $A, B \in N$ and $c \in F$, then for $i \geq j$, $a_{ij} + b_{ij} = 0$ and $ca_{ij} = 0$, so $A + B, cA \in N$. If $A, B \in K$, then $a_{ij} + b_{ij} = -a_{ji} - b_{ji} = -\big(a_{ji} + b_{ji}\big)$ and $ca_{ij} = -\big(ca_{ji}\big)$, so $A + B, cA \in K$. So N and K are subspaces.

Let $A \in S \cap N$. For $i \geq j$, $a_{ij} = 0$ because $A \in N$. For $i < j$, $a_{ij} = a_{ji}$ because $A \in S$, and $a_{ji} = 0$ because $j > i$. So $A = \mathbf{0}$.

Let $A \in F^{n\times n}$, and define B by $b_{ij} = a_{ij}$ if $i \geq j$ and $b_{ij} = a_{ji}$ if $i < j$. Then B is symmetric: for $i > j$, $b_{ij} = a_{ij}$, and $b_{ji} = a_{ij}$ since $j < i$. Let $C = A - B$. For $i \geq j$, $c_{ij} = a_{ij} - a_{ij} = 0$, so $C \in N$. Hence $A = B + C \in S + N$, and $S + N = F^{n\times n}$.

(b) Suppose $1 + 1 \neq 0$, and let $h = (1 + 1)^{-1}$. For $A \in F^{n\times n}$, define B and C by

$$b_{ij} = h\big(a_{ij} + a_{ji}\big), \quad c_{ij} = h\big(a_{ij} - a_{ji}\big).$$

Then $b_{ji} = b_{ij}$ and $c_{ji} = -c_{ij}$, so $B \in S$ and $C \in K$, and $b_{ij} + c_{ij} = h(1 + 1)a_{ij} = a_{ij}$. So $A = B + C$, and $S + K = F^{n\times n}$.

Suppose $1 + 1 = 0$. Then $-a = a$ for all $a \in F$, so the condition $a_{ij} = -a_{ji}$ is the condition $a_{ij} = a_{ji}$, and $K = S$. Hence $S + K = S$ by Proposition 1.4.24. Since $n \geq 2$, the matrix E with 1 in position $(1, 2)$ and 0 elsewhere is not symmetric ($e_{12} = 1 \neq 0 = e_{21}$), so $S + K \neq F^{n\times n}$.

Solution to Exercise 1.4.37

Uses. Proposition 1.4.24 (The sum of two subspaces), Proposition 1.4.16 (Intersections of subspaces)
Techniques. Finding counterexamples and minimal examples (Technique 1.4.18), Double containment (Technique 1.3.14)
Hint 1. Look for counterexamples among $\{\mathbf{0}\}$, $\mathbb{R}^2$, and lines in $\mathbb{R}^2$. For (b), use three different lines.

Hint 2. For (c), one containment follows from Proposition 1.4.24(b). For the other, write $\mathbf{v} \in U \cap (W + X)$ as $\mathbf{w} + \mathbf{x}$ and show that $\mathbf{x} \in U$.
Sketch. (a) False: $U = \mathbb{R}^2$, $W = \{\mathbf{0}\}$, $X = \mathbb{R}^2$. (b) False: with the lines $U = \operatorname{span}((1,1))$, $W = \operatorname{span}(\mathbf{e}_1)$, $X = \operatorname{span}(\mathbf{e}_2)$, the left side is U and the right side is $\{\mathbf{0}\}$. (c) True. W and $U \cap X$ lie in $U \cap (W + X)$, which gives $\supseteq$. If $\mathbf{v} = \mathbf{w} + \mathbf{x} \in U$, then $\mathbf{x} = \mathbf{v} - \mathbf{w} \in U$ because $\mathbf{w} \in W \subseteq U$, so $\mathbf{v} \in W + (U \cap X)$.

(a) False. In $V = \mathbb{R}^2$, take $U = \mathbb{R}^2$, $W = \{\mathbf{0}\}$, and $X = \mathbb{R}^2$. Then $U + W = \mathbb{R}^2 = U + X$, but $W \neq X$.

(b) False. In $\mathbb{R}^2$, take $U = \operatorname{span}((1,1))$, $W = \operatorname{span}(\mathbf{e}_1)$, and $X = \operatorname{span}(\mathbf{e}_2)$. Then $W + X = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2) = \mathbb{R}^2$ (Exercise 1.3.36), so the left side is U. On the other hand, $U \cap W = \{\mathbf{0}\}$: if $(t,t) = (s,0)$ then $t = 0$. Likewise $U \cap X = \{\mathbf{0}\}$. So the right side is $\{\mathbf{0}\} + \{\mathbf{0}\} = \{\mathbf{0}\} \neq U$. (The containment $\supseteq$ always holds: $U \cap W$ lies in U and in $W \subseteq W + X$, likewise $U \cap X$, and Proposition 1.4.24(b) applies.)

(c) True. We proceed by double containment.

$\supseteq$. $W \subseteq U$ by hypothesis and $W \subseteq W + X$ by Proposition 1.4.24(a), so $W \subseteq U \cap (W + X)$. Also $U \cap X \subseteq U$, and $U \cap X \subseteq X \subseteq W + X$, so $U \cap X \subseteq U \cap (W + X)$. The set $U \cap (W + X)$ is a subspace by Proposition 1.4.24(a) and Proposition 1.4.16, so it contains $W + (U \cap X)$ by Proposition 1.4.24(b).

$\subseteq$. Let $\mathbf{v} \in U \cap (W + X)$, and write $\mathbf{v} = \mathbf{w} + \mathbf{x}$ with $\mathbf{w} \in W$ and $\mathbf{x} \in X$. Since $\mathbf{w} \in W \subseteq U$ and $\mathbf{v} \in U$, we get $\mathbf{x} = \mathbf{v} - \mathbf{w} \in U$. So $\mathbf{x} \in U \cap X$, and $\mathbf{v} = \mathbf{w} + \mathbf{x} \in W + (U \cap X)$.

Statement (c) is called the modular law. The counterexample in (b) shows that the hypothesis $W \subseteq U$ cannot simply be dropped.

Solution to Exercise 1.4.38

Uses. Lemma 1.4.19 (Adding a vector outside a subspace), Theorem 1.4.3 (Subspace criterion)
Hint 1. Let X be a subspace containing $V \setminus U$. You need to show that $U \subseteq X$ too. Fix a vector $\mathbf{v}$ outside U.
Hint 2. For $\mathbf{u} \in U$, where does $\mathbf{u} + \mathbf{v}$ lie? Then write $\mathbf{u}$ in terms of $\mathbf{u} + \mathbf{v}$ and $\mathbf{v}$.
Sketch. Let X contain $V \setminus U$, and fix $\mathbf{v} \notin U$. For $\mathbf{u} \in U$, $\mathbf{u} + \mathbf{v} \notin U$ by Lemma 1.4.19, so $\mathbf{u} + \mathbf{v} \in X$; also $\mathbf{v} \in X$, so $\mathbf{u} = (\mathbf{u} + \mathbf{v}) - \mathbf{v} \in X$. Hence $X \supseteq U \cup (V \setminus U) = V$.

Let X be a subspace of V that contains every vector of $V \setminus U$. Since $U \neq V$, we may fix $\mathbf{v} \in V$ with $\mathbf{v} \notin U$; then $\mathbf{v} \in X$. Let $\mathbf{u} \in U$. By Lemma 1.4.19, $\mathbf{u} + \mathbf{v} \notin U$, so $\mathbf{u} + \mathbf{v} \in X$. Hence

$$\mathbf{u} = (\mathbf{u} + \mathbf{v}) + (-1)\mathbf{v} \in X$$

by (II) of Theorem 1.4.3. So $U \subseteq X$, and with $V \setminus U \subseteq X$ this gives $X = V$.

In other words, the vectors outside a proper subspace generate everything: every $\mathbf{u} \in U$ is the difference of two vectors outside U.

Solution to Exercise 1.4.39

Uses. Exercise 1.3.33, Proposition 1.4.14 (The span is the smallest subspace containing a list), Example 1.4.23 ($F[x]$ as a union of a chain), Exercise 1.4.27
Hint 1. Choose $p_k \in U$ of degree k for each k. What is $\operatorname{span}(p_0, \ldots, p_n)$? See Exercise 1.3.33.
Hint 2. Every polynomial lies in some $F[x]_{\leq n}$. For (b), consider the even polynomials.
Sketch. (a) With $\deg p_k = k$, $F[x]_{\leq n} = \operatorname{span}(p_0, \ldots, p_n) \subseteq U$ for every n, and every polynomial lies in some $F[x]_{\leq n}$. (b) The polynomials with $a_k = 0$ for all odd k: a subspace containing x^{2k} for every k, but not x.

(a) For each $k \geq 0$, choose $p_k \in U$ with $\deg p_k = k$. Let $n \geq 0$. By Exercise 1.3.33(a), $\operatorname{span}(p_0, \ldots, p_n) = F[x]_{\leq n}$, and since $p_0, \ldots, p_n \in U$, Proposition 1.4.14(b) gives $F[x]_{\leq n} \subseteq U$. Every polynomial lies in $F[x]_{\leq n}$ for some n: take $n = \deg p$ if $p \neq \mathbf{0}$ and $n = 0$ if $p = \mathbf{0}$. Hence $F[x] = \bigcup_{n \geq 0} F[x]_{\leq n} \subseteq U$.

(b) Let U be the set of polynomials whose coefficients a_k vanish for every odd k. It is a subspace (the argument of Exercise 1.4.27(e) works over every field), it contains x^{2k} for every $k \geq 0$, and it does not contain x. So it is proper. Part (a) shows that it must miss some degree, and it misses all the odd ones.

Solution to Exercise 1.4.40

Uses. Theorem 1.4.3 (Subspace criterion), Definition 1.2.9 (Function spaces)

Techniques. Finding counterexamples and minimal examples (Technique 1.4.18)
Hint 1. For (b), the trouble is addition: two functions with periods that have no common multiple. You need a sum whose lack of a period you can actually prove.
Hint 2. Let g be 1 on $\mathbb{Q}$ and 0 elsewhere, and let h be 1 on $\sqrt{2}\mathbb{Q} = \{\sqrt{2}r \mid r \in \mathbb{Q}\}$ and 0 elsewhere. Find periods of g and h.
Hint 3. At which points does $g + h$ take the value 2? A period would move one such point to another.
Sketch. (a) The condition $f(t+1) = f(t)$ survives sums and multiples. (b) No. $g = 1$ on $\mathbb{Q}$ has period 1, and $h = 1$ on $\sqrt{2}\mathbb{Q}$ has period $\sqrt{2}$. Since $\mathbb{Q} \cap \sqrt{2}\mathbb{Q} = \{0\}$, the function $g + h$ equals 2 at 0 and at most 1 elsewhere. If $p > 0$ were a period, then $(g+h)(p) = (g+h)(0) = 2$, forcing $p = 0$.

(a) The zero function has period 1. If $f(t+1) = f(t)$ and $g(t+1) = g(t)$ for all t, then $(f+g)(t+1) = f(t) + g(t) = (f+g)(t)$ and $(af)(t+1) = af(t) = (af)(t)$.

(b) No: the periodic functions are not closed under addition. Let $g(t) = 1$ if $t \in \mathbb{Q}$ and $g(t) = 0$ otherwise, and let $h(t) = 1$ if $t \in \sqrt{2}\mathbb{Q}$ and $h(t) = 0$ otherwise, where $\sqrt{2}\mathbb{Q} = \{\sqrt{2}r \mid r \in \mathbb{Q}\}$.

The function g has period 1, since $t + 1 \in \mathbb{Q}$ if and only if $t \in \mathbb{Q}$. The function h has period $\sqrt{2}$, since $t + \sqrt{2} = \sqrt{2}r$ with $r \in \mathbb{Q}$ if and only if $t = \sqrt{2}(r-1)$. So g and h are periodic.

Next, $\mathbb{Q} \cap \sqrt{2}\mathbb{Q} = \{0\}$. Indeed, if $r = \sqrt{2}s$ with $r, s \in \mathbb{Q}$ and $s \neq 0$, then $\sqrt{2} = r/s$ would be rational; so $s = 0$ and $r = 0$. Hence $(g+h)(0) = 2$, while $(g+h)(t) \leq 1$ for every $t \neq 0$, because t lies in at most one of $\mathbb{Q}$ and $\sqrt{2}\mathbb{Q}$.

Suppose $g + h$ had a period $p > 0$. Then $(g+h)(p) = (g+h)(0+p) = (g+h)(0) = 2$, so $p = 0$, a contradiction. So $g + h$ is not periodic, although g and h are.

The same happens for many nicer functions, such as $\sin t + \sin\left(\sqrt{2}t\right)$, but proving that this one has no period takes more work. The indicator functions are chosen so that the proof is short.

Solution to Exercise 1.4.41

Uses. Proposition 1.4.14 (The span is the smallest subspace containing a list), Example 1.4.8 (One equation in F^n), Exercise 1.2.45
Hint 1. The four subspaces are symmetric. For the converse, split into two cases: every vector of U has all coordinates equal, or some vector $\mathbf{x} \in U$ has $x_i \neq x_j$.
